Tobacco crops have been very fair this season as regards quantity, but there is a great deal more broken leaf than usual. We were terribly bothered during the early part of the season by worms, which taxed alike the powers and patience of European superintendent and Chinese cooly; where they all came from will remain a mystery, since let them be picked off every tree ever so carefully today, they would just be as bad on the morrow.

THE CULTIVATION of the coconut palm is said to be the most remunerative branch of American farming. The trees do not produce much fruit until they are ten years old; but afterwards they continue prolific for nearly a century, and the yearly yield of each is worth, on the average, fifty shillings in New York. In the extreme south of Florida an enterprising native of New Jersey has planted 200,000 palms. Land, labour and trees have cost him only £20,000; and he expects, in two or three years' time, to be earning a clear £120,000 annually, or 650 per cent. interest upon his invested capital. The project is a seductive one; but lest British fathers with younger sons should dream of sending their hopefuls to grow coco-palms in Florida, we may as well add that in the northern hemisphere the valuable nut can only be cultivated near the sea, and south of lat. 27; and that the New Jersey speculator, with commendable prudence, has bought up the only tract of land in the United States that is exactly suitable for the purpose.—*St. James's Budget.*

CEYLON UP-COUNTRY PLANTING REPORT.

BLACK BUG ON COFFEE—"TEA REQUISITES"—THE BONUS SYSTEM IN TEA MANUFACTURE—THEFTS OF CINCHONA BARK—MR. L. G. HOLLAND—THE CACAO CROP—WHAT TO DO WITH COFFEE.

21st December, 1885.

Black bug and its doings have now but a limited circle to interest, a circle, too, which is ever lessening. Still, to those who belong to it, in other words those who are growing coffee, it will be a pleasure to them to know that the sealy abomination which has of late swept over some districts, with the destructiveness of fire, has from some cause or another got a very decided check, and that there is reason to hope that the pest is passing away.

A friend of mine who has taken considerable interest in the subject, and written in the *Observer* on the matter, has the honour as far as I know of being the first to notice this change in regard to the bug. On examining a branch they will be seen to be covered with a white substance like fungus, and to be quite dead. Even the young leaves of the coffee, which formerly only appeared to be immediately turned into favourite feeding grounds, are now mostly free from the presence of the pests, while on the older foliage the full-grown bug, which has wrought such havoc, and, like the much quoted "fierce light," has "blackened every spot," he is dead. If all were gone it would be well, but some of the young ones are still lively, from, let us charitably suppose, the thoughtfulness of youth.

A sample branch was sent to the Director of the Peradeniya Gardens, and his reply, which has been placed at my disposal, is as cautious as those which usually emanate from the true scientist. Dr. Trimen says: "I have examined the condition of the dead 'bugs' on your coffee. They are all as dead as mutton, but the cause of their departure is not evident. When I say *all* I should except many of the young ones which are still lively. I am not quite satisfied that the white substance is a fungus, and if it be it may have come on the *dead* bodies, and not have destroyed living ones, death having occurred from some other cause. But I will look further when I can get a little time."

It is but little comfort there is in these days in regard to coffee, and I chronicle the above as a probable cause of rejoicing.

Cacao seems to flourish in these showery days, and is full of promise for next crop. The one now being gathered is a fine quality, but in some estates which suffered from the drought in the early part of the year, it is a great deal less than it should be.

ON MAKING WREATHS.

A correspondent writes:—"I enclose a very good piece from the *Journal of Horticulture* on making wreaths, which I came across last night. I wish it had been a little earlier: it would have been useful to ladies for the Christmas decorations."—

The first step after having decided the required size of the wreath when completed will be to form a circle, which is most frequently used, and for which I have adopted the name of "skeleton." These skeletons are very deceptive, and it is one of the commonest errors with the uninitiated to make these much too large, and if the supply of flowers be somewhat scant the wreath in turn will present a very lean appearance. With a view of overcoming this I will briefly cite one or two examples. Presuming then that a wreath when complete is required to be about 12 inches in diameter, the size of the skeleton on which to build it should not exceed 6 inches in diameter when flowers such as Chrysanthemums and Camellias are in season,

but which may be increased to 7 or 8 inches when choice flowers, as double Primulas, Bonvardias, Roman Hyacinths, and Lily of the Valley, are employed. The diameter of the first-named may be a surprise to many; it is, however, fully justified by experience, and is more readily understood if the breadth of a very ordinary Chrysanthemum, Camellia, or Encharis be taken into account; with a moderate-sized flower of either of these, and some smaller sprays to furnish the sides, and with Fern fringing the inner and outer margins, it will be seen how easily the size may be increased twofold. My idea of a full-sized wreath when finished and ready for use is 15 or 16 inches in diameter (above that size I term them specials), and for this size a skeleton of 9 inches diameter will be ample. Having shown, then, something of how the size may be gauged, we must now construct the skeleton, and for this purpose galvanized iron wire will be found to answer well. Having got this into shape and of required size, next secure a hazel or willow to it and round the interior. This will prevent the wire revolving in the hands of the operator, and which frequently misplaces a flower or two, thereby causing inconvenience and annoyance. Having secured the hazel or willow to the wire, some fresh green moss should be bound tightly over it with small twine, which when finished should be slightly flattened. When this is done a firm surface about an inch wide will be the result, and all will be ready for placing the flowers. There are several other ways of preparing these skeletons, some binding them with cotton wool which I object to, on the ground of a green base for the flowers to rest upon being more suitable. Further, when the bulk of the flowers are arranged it frequently happens that by inserting small choice bits here and there a great improvement is made in the wreath. This may be done easily where moss is employed as a foundation, having a piece of stem wire to pierce the moss, and doubling it back as it emerges from the opposite side secures it in position. When cotton wool is used it will not allow of wire passing through it. For these reasons, and for the fact that moss retains the moisture considerably longer than cotton wool, which robs the flowers of the little moisture which is about them, I am strongly in favour of a moss foundation. Wreath skeletons made in various sizes are sold by horticultural sundriesmen, but all I have seen are anything but suitable for the purpose. They consist of two wires arranged in circles at about 1½ inch apart, and fixed by about four cross wires. This leaves a large cavity with which it is difficult to deal, and also uses an immense amount of binding wire in the work of arranging the flowers. One of the simplest contrivances I have seen is made of black tin cut in circles about three-quarters of an inch in width, or they may be made of scraps and soldered together. In the latter way, though a little more trouble in making, they are firmer than when cut out in one piece. Any tinman will make them. I have used these in quantity in sizes ranging from 5 to 12 inches in diameter. It may not be out of place for a moment to refer to the arrangement of a wreath, though, as I have remarked, much will depend on individual taste. Presuming, then, the flowers are cut, such as Bonvardias, Lily of the Valley, Roman Hyacinths, Gardenias, Primulas, Encharis, Azaleas, and Double Primulas, and wilding, and Camellias and Roses, and need pointing me to or on account of the custom to fasten off the flowers with no wood attached, hence stems, and to prevent them from falling; and the latter to keep them from becoming too gaping. If at hand some small sprays of Cypripediums, Lawesiana will be serviceable, and next in time of coming of M. de la Pen, which is generally a scarce article at this time of year. Begin the arrangement, then, by laying a spray of Cypress and upon which place a firm M. de la Pen, the latter somewhat cut and not too flat; then come a Camellia, Encharis, or Gardenia;—in fact, any of the larger and more prominent flowers to occupy the centre, filling in the sides with smaller flowers. Lily of the

well for fringing the sides. Continue the use of the Cypress, and insert here and there a small spray of Fern, firmly binding them as you proceed, and using a small pinch of moss on the stems of the flowers. This will keep the wire from cutting the stems, and will also supply moisture to them, always avoid a heavy arrangement and overcrowding, and allow as far as possible the flowers to assume their natural position. Use the flowers in as much variety as possible, and, if procurable, a few well-coloured sprays of Panicum variegatum will be found very pretty and effective jutting out here and there. It is productive, too, of lightness and elegance, which should characterise the arrangement throughout, and with it and Maidenhair Fern interspersed among the flowers a very pleasing and elegant wreath may be formed. In case of packing this is easily done by placing a stick across the skeleton, allowing it to rest on either side under the flowers, and attach a string to its centre; then make two holes in the bottom of the box, fast a string through and fasten securely underneath it will travel safely thus, and the person unpacking it will see at a glance how it is secured.—J. H. E.

INDIARUBBER IN THE DUTCH EAST-INDIES.—N. McNeill, Esq., the acting British Consul at Batavia, informs us that the exports of Indiarubber during the years 1881, 1882, and 1883 were, respectively, 511,765, and 1,217 piculs (a picul equals 140 lb). The trade in this article of produce has been very dull lately. The Indiarubber is obtained by the natives from the bark of the trees, and always contains more or less woody fibre intermingled with it. It is also occasionally adulterated with woody fibre to increase the weight. The island of Sumatra is richer than Java in the production of Indiarubber, the principal producing districts being Bencoeen and the Lampougs. The rubber obtained from the latter is generally considered the better of the two. The prices have varied during the past year from 120 to 80 florins for Bencoeen and from 160 to 110 florins for Lampoug per picul. (The Dutch East Indian florin is worth 1s. 8½d.) It is better to attach fixtures to a lathe spindle by means of the screw than to hold them by inserting a slank in the socket where the centre is put. The turning centre should run perfectly true, and where a practice is made of inserting drills, reamers, shanks, and other tools, the surface of the centre seat may be so marred and enlarged that the rotation of the centre will be out of line with the axial rotation of the spindle.—*Indiarubber and Gutta-percha Journal.*

SHOULD HORTICULTURE BE TAUGHT IN OUR PUBLIC SCHOOLS?—This question was ably handled by Professor Wickersham, late superintendent of Public Instruction of the State of Pennsylvania, at the late State Horticultural meeting. Objection was made that studies were now too numerous for the six hours a day, and six or eight months in the year of public schooling, but the Professor explained that he did not recommend the introduction of this and similar studies in addition to those already included, but in the place of others. He contended that, as the result of a careful study of public education, that a large portion of time spent in geography, grammar, composition, and so forth, was absolutely thrown away,—that the aim of public education should not be so much to educate as to place children on their own feet, educate themselves. Public school teaching should simply train children with the tools by which they could save their way as circumstances should arise, and to fit them for any particular way. Children should be taught to observe, to find an opportunity to plant a garden attached to every public school, and let the children see in geography or grammar, and vice versa, children in the garden, with the living plants before them, and a teacher capable of explaining things, do more good than the book studies of a whole week. The remarks of the Professor made a deep impression.—*Gardener's Monthly.*

Correspondence.

To the Editor of the "Ceylon Observer."

FISH-CURING IN CEYLON.

Burma Road 247, Penang, 7th Dec. 1885.

DEAR SIR,—I saw in your advertiser edition some over "fish-curing yards" but cannot find it back! It is possible you can be so kind to give me some informations over this trade? It is not so long ago. I read it perhaps Juli.

Very much is it for my interest what I saw in the *Tropical Agriculturist* over wood from Japan for the boxes imported now, prices etc., having plenty useful wood in Sumatra. "nosmell," it should be very agreeable to be in connection with a wood merchant of your country.

I be a Dutchman residing in Sumatra for short time here, to be informed and hope you have not to much troubles for it. I can only offer you my best thanks,

GUST. DIEMANT.

[All about the fish-curing experiment will be found in the *Tropical Agriculturist*, which is filed in Penang.—Ed.]

THE ANNUAL MIGRATION OF BUTTERFLIES.

DEAR SIR,—You have for many years drawn public attention to the singular migration of butterflies, so striking a spectacle each year, that all must feel some interest in it.

Despite your repeated record, nothing has yet been done towards compiling and editing a scientific and comprehensive record of annual observations, recorded and unrecorded, especially those which are exceptional.

Thus you recently noticed *brown* butterflies as joining in the migration, and many years ago, at Gampola, I witnessed a singular migration of one of our largest and most gorgeous butterflies, the great emerald green *Papilio Grino*.

I propose to all interested in such matters, that volunteers come forward to watch for migration of butterflies, and send a postcard bulletin to an editor of such records, noticing date, direction of flight, direction of wind, weather, and specie. All amateur observers to send a specimen folded flat in paper, of one fly of each species noticed to ensure scientific accuracy.

A most competent naturalist has offered to revise, assort and edit all such notices, once or twice a year, and, if your columns are open, I have no doubt will gladly send you a short periodical bulletin of progress, should the matter prove popular enough, to occupy your spare corner now.

Will ladies and gentlemen willing to join this "butterfly league" send me their names? No scientific knowledge is needed, and no apparatus beyond a net, a few pieces of paper, and a pen.

The naturalist who offers to edit these notes has kindly consented to publish his annual summary in my journal, and hence I propose to cooperate by arranging preliminaries.—Yours faithfully,
H. NEVILL. *Editor of Taprobanian*.

TEA ROLLING MACHINERY: GREAT SUCCESS OF BARBER'S NEW ROLLER.

Strathellie, Nawalapitiya, 20th Dec. 1885.

DEAR SIR:—I notice in yesterday's *Observer* reference made by Mr. Barber to the trial of his roller at Blackstone at which Messrs. G. A. Talbot, W. S. Thomas, A. Scovell, J. H. Barber and myself were present. As the matter of selection of tea machinery is one which is exercising the minds of so many, I venture to give further details of the trial.

As Mr. Barber states, 2 of the rolls were finished in 19 minutes each of actual rolling. The roller was not stopped until the 4th roll was finished.

and, including the time taken in filling and delivering, the following is a record of the exact figures of the consecutive rolls referred to:—

	Started at	Finished.
1st roll 80 lb. not sufficiently withered	12 noon	12-15
2nd " 85 " " " "	12-15	12-30
3rd " 85 " " " "	12-30	12-42
4th " 90 " " " "	12-42	12-56

Revolutions of the roller discs—30 per minute. Motor used, 12 ft. water-wheel with 3 ft. buckets.

The above results show 350 lb. of withered, or about 500 lb. of green, leaf rolled in the hour. The quality of the roll, too, left nothing to be desired, as was evidenced from the finished teas which I subsequently had the advantage of inspecting and tasting. Mr. Barber introduces an entirely novel device into the art of tea-rolling by machinery, in his movable oblate spheroid, or fluted globe, which in combination with his "Barber" battens alternating with other, raised and newly designed, battens on discs travelling in opposite directions (at about 30 revolutions per minute) gives to the leaf a true and complete centrifugal motion.

I am of opinion that the sooner and more generally this machine can be brought before the public the better; for the above results lead me to the conclusion that the roller is likely to command attention from many of those now introducing machinery into their factories, more especially those with deficient or expensive motive power.—Yours faithfully, ARTHUR SCOVELL.

SYLHET.—Tea production in Sylhet is rapidly increasing and the district will soon be one of the most prominent. The number of gardens is 111 against 46 in 1876, certainly a very rapid extension. The order of the Chief Commissioner prohibiting low lands being given to planters in the Pratabgarh tahlil is a little astonishing. The resolution says:—"This order naturally caused some dissatisfaction at the time, but already a large portion of the land thus protected has been occupied by ryots, who would otherwise have been excluded." By the lease granted to tea-planters for tea for a term of years one of the conditions is, that the same be sold by public auction in the Deputy Commissioners' office, after being duly notified in the *Assam Gazette*, and notices posted locally on the ground. It is difficult to see why Government should step in, and stop private enterprise. If the ryots want the land, let them attend the auction and bid for the lease. In addition to this, why did those ryots not take up this land before? Simply, either because they did not know of it, or else were quietly waiting by, till the tea-planter had drained the adjoining lands for tea, and thus rendered the portious lying higher, before unfit for rice cultivation, now sufficiently dry to permit of their being cropped. Who discovered that these low "bheel" lands were the finest of soils? No one but the tea-planter, and his reward is a prohibition by Government to go any further in his searches, as he must give way to his Aryan brethren! How comes it that Sylhet has been in existence for so many years without its being discovered that these lands were valuable? Was it before, or after the heavy influx of Europeans and capital that has poured into the district the last few years? Europeans discovered it, and are entitled to it, and this embargo placed upon taking up land, is simply a part and parcel of the wretched, short-sighted policy, which always has been the order of the day with the present Government. Not content with hampering the opening out of new gardens, with vexatious coolly regulations, the next step is taken, when foiled in this direction, in prohibiting the free acquisition of land, notwithstanding that planters may claim to have discovered its value.—*Indian Planters' Gazette*. Here we have a repetition of what was once a great grievance in Ceylon. Holders of patches of land near coffee estates gathered abnormal crops. But tea leaf is not so easily stolen and utilized as was the case with coffee berries.—Ed.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, December 3rd, 1885.)

INSECT PLAGUES.

The distinguished lady naturalist who presides so ably over one important department of teaching at the Royal Agricultural College at Cirencester has put forward an opinion to which we in Ceylon should do well to give the fullest consideration. There is, we apprehend, scarcely a country in the world which has suffered more than has Ceylon from the ravages of insect life. Hardly one of our agricultural industries has escaped unscathed from their attacks. Coffee, cinchona, cardamoms, coconut trees,—and probably, ere long tea—have their productiveness affected by these obnoxious visitants. If, as has been asserted by the lady in question, there exist means whereby, in a general way, such plagues may be guarded against in the future and eradicated in the present, our debt of gratitude to those who would show us how to accomplish such a result would indeed be great.

But it is acknowledged—and it must be evident to us all in Ceylon as the result of past experience—that individual effort can do little in such a direction. It is only, we suspect, by legislative enactment, and its full enforcement insuring co-operative working among all classes of our agricultural population, that the desirable end can be attained. There exist among us plenty of intelligent men who have already devoted much of time and money to the endeavour to rid themselves of those noxious enemies. But what can single effort avail upon a single estate or garden, or groups of estates and gardens, when on adjacent properties the evil is left to develop without any attempt to cope with it? We have recently had practical demonstration in another colony of the useful effect of Government interference in the direction referred to. In Cyprus, antecedent to British possession of that island, the constantly recurring plague of locusts prevented the hope that so long as it was allowed to continue the newly acquired colony could be made prosperous. Acting upon the advice sought and obtained from those best qualified to advise upon such a matter, the authorities in that island took vigorous measures to deal with the evil. Hundreds of miles—we do not think we exaggerate in saying so—of canvas screens were erected, over which the locusts in their wingless state were compelled to march in their steady migrations. On surmounting these screens they were compelled to drop into troughs of water prepared for their reception, and the result was that in one single season it was computed that a slaughter of these had been effected to the extent, we believe, of over 200 millions! What has been the result of the steady and continued application of this principle? We are under the strong impression that the plague will no longer visit the colony in any serious degree. It is at all events certain that for several seasons we have heard very little about the crops of the Cypriotes being destroyed by the agency of the locust.

Now it strikes us that what has been accomplished in one colony with such success could not entirely fail of accomplishment, though by a different method perhaps, in another. There must and—according to the *dictum* we have quoted—there do exist means for realizing a similar success with respect to the destruction of obnoxious insect life in other lands. It is true that in Ceylon our insect life is of a more diversified character than that dealt with in Cyprus; but nevertheless we should hold that the principle has been proved, and that it is to the application of it that our attention is desirable. Nearly all varieties of insect life pass through certain distinct phases. In the one or

other of these phases, the creatures possess but limited power of mobility, and are thus open to organized attack for their destruction. It is in the selection of the one particular stage to which effort should be directed that the chief duty of our naturalists consists. That point being determined, the further duty rests with them of pointing out the method to be pursued whereby attack may be most effectually made. To enable these two duties to be properly fulfilled, it is evident that opportunity must be afforded for the study locally by an expert in such matters of the habits and peculiarities of each form of insect plague to be dealt with. Such opportunity can only be afforded by Government aid, and it appears to us that we shall be—in view of the importance of the matter as regards its revenue—fully justified in calling upon our authorities to see that such aid is afforded, when next the necessity arises. When the ravages of leaf-disease upon our coffee trees first became strongly apparent, experts were called in to study the question. It is generally held that in that instance the course pursued was not productive of much practical result; but, although this may be true positively, it is far from being the case if we take the negative value of Mr. Ward's life-history of *Hemileia vastatrix* and his inferences into account, in showing in what directions outlay was useless, and so saving money, time and labour. The enemy was of a particularly insidious character in that case; but the same disability scarcely applies to the evils which may assail, and have assailed, our more modern industries. Science asserts that such evils generally can be coped with. We hold that such a *dictum*, so strongly expressed as it is and justified by the results already obtained as we have pointed out above in the case of Cyprus, deserves attention on the part of our rulers. When once experts have decided on a course best to be pursued in Ceylon, whether it be in respect of an enemy of tea, cacao, coconut palm or any other staple, let the most stringent measures be taken to ensure its adoption and pursuance. There should in such a matter be no half-measures. To be successful too there must be united action on the part of Europeans and natives alike, and the only way to ensure this is to make its avoidance liable to serious penalty. In any step towards this desirable end that our Government may have to take, it will have, we feel sure, the unanimous and steady support of all interested in the welfare of Ceylon.

THE MINCING LANE WHOLE-BERRY COMPANY (LIMITED),

with a capital of £10,000, in 20 shares of £500 each (the first issue of shares has been fully subscribed), is announced. The prospectus is of more than ordinary interest:—

This Company has been formed by Merchants, Growers and others interested in Coffee, to combat the adulteration that has been going on for years, and to supply the public with Coffee direct from the Colonial Market, *fresh roasted*, in small quantities suitable for families, clubs, hotels, restaurants, and other public institutions, thus avoiding all intermediate charges or profits. That no article of Colonial produce is subject to so much adulteration as Coffee is amply proved by the various analyses made from time to time: but we wish to draw particular attention to an analysis made in 1882 by the public analysts, Messrs. Wigner and Harland, of 37 samples purchased on the same day at 37 different shops in the Metropolis, and which gave the following results:—Two samples were genuine, one contained 68 per cent and 33 samples from 7 up to 57 per cent of Coffee, the whole averaging 32 per cent of pure Coffee and 68 per cent of chicory, dates, dandelion and other worthless veget-

able substances, with a certain quantity of finings, whilst a sample called Dandelion Coffee contained no Coffee at all, and one labelled, "*Specially prepared French Coffee*," contained 34 per cent of Coffee, the remainder being chicory and finings.

Every drinker of Coffee knows well the great difference there is between a cup made with *fresh roasted and ground berries*, and one made with Coffee which has been roasted or ground for weeks or perhaps for months, such as the public purchase in the majority of shops throughout the United Kingdom; the latter can only be compared to a glass of stale beer, or to the dregs of a decanter of Claret which has been opened for some days. The system which prevails in this country, of *roasting large quantities* at a time the bulk thus losing in a short period most of its aroma, is but a remnant of ignorance which this Company intends to do its utmost to remove. The worst treatment, however, reserved to Coffee, is that resulting from the wholesale adulteration practised under the sanction of Government.* Whoever buys *ground Coffee* in order to save himself a very little trouble, will be supplied in shops with tins or packets bearing such attractive names as "*delicious (?) french coffee*," or "*superior coffee with a little of the finest chicory*," etc., etc., and the stuff he gets will in most cases be made up of a little Coffee and a quantity of chicory or other vegetable compounds, which to say the least are as nasty to the taste, as they are devoid of any of the refreshing or invigorating qualities of real Coffee. The sellers and manufacturers of those mixtures derive enormous profits from their trade, for they sell what costs them perhaps 4d. or 5d. per lb at the price of the genuine article, say 10d. to 1s. per lb hence the persuasive efforts made everywhere to induce the public to buy their tins and canisters. The taste for good Coffee "has not" disappeared in this country, but the difficulty of procuring the genuine article is such, and the public is cheated so systematically or mislead so cleverly, when purchasing it in small quantities, that it is no wonder there has been a diminished demand here, whilst everywhere else the consumption of the fragrant bean is increasing, and nowhere more than amongst our transatlantic cousins, or the hardy populations of Northern Germany and the Scandinavian States. The following table shows the consumption per head of population in some of the Continental States:—Holland 21 lb.; Denmark, 11 lb.; Belgium, 13½ lb.; Sweden and Norway, 10 lb.; Switzerland, 7 lb.; Germany, 5 lb.; France, 2½ lb.; United States of America, 7½ lb.; and United Kingdom, 0 lb. 15 oz., against 22 oz. in 1854, notwithstanding an increase of population of more than 9 millions!! thus Great Britain, which does the greater part of the carrying trade of the world, whose Colonies grow Coffee in abundance, and whose opportunities for obtaining good Coffee are unequalled, consumes less per head of population than any other civilized country.

It is intended to sell four qualities only of roasted Coffee:—

No. 1 Whole-Berry at — 10d per lb., (a Good Strong Coffee) No. 2 Whole-Berry at 1s 0d per lb., (Strong and of Good Quality) No. 3 Whole-Berry at 1s 3d per lb., (Fine Quality and Highly Recommended). No. 4 Whole-Berry at 1s 6d per lb., (selections from the Finest Marks).

Canisters containing 1 lb. can be had at 1d per lb. extra which will be allowed when the tin is returned sound.

Every package will bear the Registered Trade Mark of the Company.

No. 1 will be quite equal to anything now retailed at 1s 2d, and the finer qualities will be selected from first class growths of Jamaica, Mocha, East India, Ceylon, Costa Rica, Guatemala, &c., possessing delightful fragrance and flavour. It can be pur-

chased in 1 lb. packets, or delivered free through the London and Suburban districts, in packages of 3, 5, 7, 10 lb. and upwards, and will be sent to any Town in the United Kingdom at a small charge for delivery. The first order of 3 lb. and upwards, will be packed in a good strong tin canister, which is to be retained by the purchaser for the storage of future parcels, and the Company will provide a strong mill, if required, at the trifling cost of 1s 9d to induce the buyer to *grind the Coffee only at the time of making*; the Company will likewise supply *simple Machines* for making Coffee at moderate prices. This is the only way of retaining the delicious aroma of Coffee, and it is universally practised on the Continent where good Coffee is always to be had, even in the humblest cottage. The Company will also sell unroasted Coffee of Nos. 2, 3 and 4 at 2d per lb. under the above roasted prices, its connections with growers and importers from every part of the world, placing it in an exceptional position for supplying the public with every kind and quality, at the most moderate rates. A simple Gas Roasting Machine, which every family can use, will be supplied by the Company, at a charge of 20s. As soon as practicable the Company intends to open a Central Depot in each district in London, as well as in the large Provincial Towns. If consumers will only buy their Coffee "fresh roasted" in small quantities, and grind it every day as they require it, taking advantage of the facilities which this Company offers to them, Coffee will soon be restored to its position as the most delicious, stimulating and healthy of the non-alcoholic beverages.

A local correspondent, in sending us a second copy of the prospectus, says:—

"I enclose prospectus of a Company which has been most successfully floated and all capital subscribed, the objects of which will be very pleasing to all coffee planters. A perusal of the document will, I am sure, be most pleasing to you, and whoever grows fine coffee will certainly share in the benefits which this Company is about to afford to Ceylon planters. The promoters of this enterprize deserve the thanks of all coffee producers here, and the names of Messrs. Patryk & Pasteur of Mincing Lane should not be forgotten so long as coffee lasts in the island."

TEA PACKAGES, WEIGHTS AND TARES. MARKING, &c.

Judging from sundry Ceylon Tea Invoices, and the Weights and Tares stencilled on each package, much time and money is lost in trying to weigh into a series of packages varying considerably in size and tare, an exact number of pounds of Tea, 50 lbs. nett, 80 lbs. nett, or 100 lbs. nett, as the case may be.

The chests are then carefully marked:—

Gross ..	111	115	120	lbs. (say)
Tare ..	31	35	40	" "
Nett ..	80	80	80	lbs.

all of which is really lost time and expense, for with such variations in the weight, it is impossible for the Customs or the Trade to strike an average gross and average tare, and bulking ensues with all its consequent expense and deterioration as a matter of course. It is understood we are writing chiefly for those who are newly turning their attention to Tea, and not for those shippers who have made these matters their study for some years, and can now arrange their packages as to escape bulking here. The difficulty of the varying Tare might, we think, be partly got over by weighing 100 or 200 empty packages, and carefully assorting them according to their sizes and weights; a chalk mark on each when assorting is all that will be necessary. It should in this way be possible to get at least 20 to 30 chests each weighing exactly 30 lbs., then 10 to 15 each weighing some other number of lbs. alike, and so on. If the packages measure the same, fill them full, and do not leave space for 5 lbs. in each package of say 20 half-

* According to the Customs and Inland Revenue Act, of 1883, the preparation and sale is allowed of chicory or any other vegetable substances, in imitation of, or for use as coffee or chicory, under an Excise Duty, levied by means of an adhesive Label Stamp of one half-penny for every 1 lb. packet of mixture, thus giving official sanction to the most reckless and unprincipled adulteration.

chests, in order that each may contain exactly 50 lbs., otherwise freight will be payable on equal to one "dunny" package in every 10. There should then not be a variation of a pound either way in a break of 20 or 30 packages, and if the Teas were carefully bulked before packing, there should not be any irregularity of quality, and the Teas should pass inspection without the necessity for a bulking order. We have seen 20 chests recently of which the Teas ranged all the way from 31 lbs. to 42 lbs. This difficulty can be surmounted, and is avoided on some estates, and our suggestions are made in the hope they may be practicable at any rate to some extent.

Marking should be as simple as possible. One objection to stenciling the Tare on the package is that a package may Tare 40 lbs. in Ceylon, and only 39 lbs. here. The Grocer who is allowed 39 lbs. Customs Tare immediately thinks he is being "done" out of a pound. Mr. Armstrong's suggestions on this head are well worth attention. Get rid of and avoid complicated marking. Print the name of the plantation, the Invoice number, and the kind of Tea. Every package will be weighed here, and if they run evenly, an average Tare will be allowed by the Customs, if not, they will be bulked and every package Tared.

Here are specimens of the Markings on two chests:—

MAC JONES & Co., COLOMBO.	INVOICE NO. 14.	MAGILLICUDDY ESTATE.
	GROSS 103 LBS.

PEKOE.

Packages.—Some packers adopt the plan of inserting and nailing a small batten in each corner of the chest. This gives great additional strength and rigidity. Packages which are not quite full are very easily damaged and broken—"like so many hand-boxes," as an ancient dock laborer said to us.

Small Breaks.—So much has been written on this head we may seem wearisome if we repeat that the Trade will not look at them, and Planters would do well to bulk unassorted the produce of their estates up to twenty or thirty packages. The price obtainable here, will, we venture to say, be fully equal to the average price obtained for assorted parcels consisting of from two to six chests of each kind, and much labour and anxiety be saved in the bargain. We have before us two Tea Catalogues printed for Sale by Auction in Minging Lane. The one contains 1,880 packages China Tea, represented by 11 samples. The other contains 180 packages Ceylon Tea, requiring the drawing, tasting and valuing of 21 samples. A few days ago there were sales of Indian Tea to the extent of 30,000 chests, and it was physically impossible properly to taste and value the 1,300 samples on which they were sold. We repeat, justice cannot and will not be done to Ceylon Teas printed in so many small lots.

L. A. RUCKER & BENCRIFT.

COFFEE ESTIMATES.

(Supplement to James Cook & Co.'s Weekly Despatch, December 11th, 1885.)

Crop Estimates as far as they have come before us:

	Estimate of present supply. Bags.	About last year's figures. Bags.
Rio.—1885-6—4 to 4,500,000 bags, giving a probable export of fully 4,000,000 bags. Very favorable accounts of flowering for the 1888-7 yield, reaching figures hitherto unknown, unless some calamity occurs	4,000,000	4,087,811
Santos.—The crop advances 1886-7 regarding Rio, apply also to Santos. 1885-6 crop estimated at 2,200,000 bags, including balance of old coffee, but exclusive of 150,000 bags in stock	2,200,000	2,164,470
Bahia.—No special information	120,000	115,185
Java.—Government crop 1885-6	529,879	1,019,000
Padang.—do	124,500	141,000
Java.—Private	225,000	256,000
Macassar, Timor, &c.	100,000	110,700
Ceylon.—Some estimates are as low as 150,000 cwt. Plantation, and it looks as if the yield would barely exceed 10 to 11,000 tons, say, with the "Ouvah" crop remaining over from last year, the export will be	Cwt. 230,000*	Cwt. 314,811
British East India.—Alleppey, Cochin, Beyrour, Calcutt, Badaghara, Tell-chery and Cannanore, Export 1st July, 1884, to 30th June, 1885, 10,374 tons, with Madras and Bombay probably in all	Tons. 18,000	Tons. 16,000
Costa Rica.—The 1886 crop was expected at one time to be 300,000 bags, but estimates are now being lowered, and at present stand at	Bags. 200,000	Bags. 150,000
Venezuela, La Guayra (a) and Puerto Cabello (b).—Coming crops do not promise well. In the low hands decidedly smaller than the last, probably 50 per cent is under the mark. In the high lands it is no worse than 1884-5, but fears are entertained that the drought may diminish production; quality has not improved, in fact, leaves much to be desired	Kilos. 21,000,000	Kilos. { a 12,326,050 b 13,752,813
Maracibo.—Political troubles in Colombia have prevented the coffee from being marketed in time to take advantage of the swollen rivers: exports, owing to drought, have been small during the past eight months, and the new crop, with about 30 per cent of the old, will be arriving together. Next crop say 240 to 250,000 bags	18,000,656	12,912,034
Porto Rico.—As with Domingo, a short crop is looked for; some accounts reduce to one half	18,000	25,000
Haiti.—It is generally expected that the crop will be about 500,000 bags. The quality will be above the average, as the weather during the spring has been dry, and the new coffees seem to be turning out of a very good description	Tons. 32,000	Tons. 37,000
Aricu.—A smaller crop is reckoned upon this season than last, probably not more than two-thirds of 1884-5	5,000	8,500
New Granada, Guatemala.—The exports have been hindered by revolutions, and a considerable quantity, it is thought, remains in the country to come forward with this year's coffee	15,000	14,000
Guatemala likely to be smaller; picking, according to October advices on the Coast, just beginning, while the crop in the higher districts had not reached maturity		
Manilla.—Exports January and December, 1884, 115,081 picols. Exports January and October, 1885, 75,597 picols, with probable shipments November and December, say	Picols. 80,500	Picols. 115,081
The coming crop of Batangas is reported on favorably, and the yield will probably be large.		

* T o high, we fear; we gave 200,000 cwt. as our outside expectation.—Ed.

PLANTING IN NETHERLANDS INDIA.

(Translated for the *Straits Times*.)

Coffee leaf-disease now so prevalent in Java is said by a planting expert in the *Bode* to be nothing new, from its having been known there during the last 50 years, but to be in fact so seldom met with that hardly any notice was taken of it. Formerly the stricken trees were simply dug out and their places taken by healthy ones. The causes assigned were various, the most general one being that the disease arose from deterioration brought on by coffee trees being forced by means of manure to bear when barely two years old. The planters were driven by necessity to take this course to avoid financial difficulties. Judging from the saying, "Soon ripe soon rotten" it stands to reason that trees so forced into bearing cannot in the long run yield sound and healthy berries, and that those reared from beans secured under such circumstances cannot fail to bear with them the germs of lingering disease sure to pass over into plants sprung from them.

THE BLACKSTONE TEA ROLLER.

Sembawatte, Nawalapitiya, 24th Dec. 1885.

Dear Sir.—I have had the pleasure of an inspection of the "Blackstone" Roller, and I consider it from the work I have seen it perform, greatly superior both in the quality of the roll and the quantity turned out to any roller yet introduced. At 12-23 we started with a roll of 90 lb of withered leaf and finding the machine had the capacity to hold more I added 10 lb which made the round 100 lb withered leaf, equal to 140 lb of green. Within the short space of 12 minutes the roll was discharged in a perfectly fresh and cool state, with a nice even twist: the Pekoe leaves were in a beautiful state of preservation, free from breakage, whilst the Sou-chong was all that could be desired. At 12-40 another charge of 100 lb withered leaf was put in, and at 12-53 (just 13 minutes) this was completed in as satisfactory a manner as the former.

The great rapidity with which the work is done is due to the novelty of carrying the leaf round a spheroid.

The invention is as successful as it is ingenious and appears to be based on a correct apprehension of the principle of rolling, which is gradual compression. This is done most satisfactorily by this new method employed, while the construction of the discs with alternately raised segments keeps the leaf Local "Times," from breaking while revolving round the spheroid. The arrangement of the battens too appears to be the result of careful experiments. This machine gets through 400 lb of withered, equal to about 550 lb of green leaf per hour, thus in a working day of 10 hours, 6,000 lb of leaf can be worked off.

I consider it quite capable of meeting the requirements of an estate turning out 100,000 lb tea per annum.—Yours faithfully,
D. FAIRWEATHER.
—Local Times."

"COLORED COFFEE."—Mr. T. Christy writes to us by this mail as follows in a semi-private note; but surely he has no reason to suppose that there is any falling-off in the preparation of Ceylon coffee? With so little crop to attend to, the work of preparing ought to be more carefully done than ever before:—"There is an enormous crop of coffee in Brazil, and great fears are expressed as to the price. I wish you could get someone to work up the question of fermentation of coffee berries; there is more in it than you think, for, if people wish to secure the extreme price, something must be done now when labour is cheap to put on more 'finish' so as to top the market. You would be surprised to find what a difference this makes."

THE CLIMATE OF THE HIGHER HILL-COUNTRY OF CEYLON.

The rain record of 1885 being now closed, I give the figures for the past three years, with the averages for the months and for the twelve months:—Rainfall for Abbotsford:—

	1885.	1884.	1883.	Averages 3 years.
January	... 1-57	61	4-17	2-12
February	... 2-11	72	8-44	3-76
March	... 2-00	6-34	3-78	4-04
April	... 2-72	1-12	6-29	3-37
May	... 5-20	5-80	11-61	7-54
June	... 28-54	9-00	7-93	15-15
July	... 14-12	11-19	16-77	14-03
August	... 6-58	14-39	15-00	12-00
September	... 4-84	7-85	5-71	6-13
October	... 9-19	12-86	7-04	9-70
November	... 5-86	8-45	7-36	3-22
December	... 6-97	6-80	6-00	6-59

Total... 89-70 85-13 100-10 91-64

For the abnormally wet and stormy year, 1882, the record is imperfect, but we have good reason for believing that the total deposit for that year was not much under 140 inches. But let us take the figure at 130, and the average rainfall will be raised from 91-64 inches to 101. As it is not likely that the low figures for the three past genial years, are all referable to a reaction from the excessive rainfall of 1882, it now seems certain that the figures we have been in the habit of taking as the average for this place, viz., 110, are too high and that 100 would be nearer the mark. The reason we fixed on 110 was that the late Mr. Heelis had obtained 106 as the average on Langdale at 1,600 feet. Our rain-gauge being placed 1,400 feet higher, and in a position facing the south-west monsoon, we naturally supposed our rainfall would be higher by at least 4 inches. But it is the fact that the rainfall increases in the Dimbulva valley, the farther away the position is from "the dividing range" behind which Uva lies and the nearer to that other dividing range which separates Dimbulva from Dikoya and Ambagamuwa and "the Peak" region. In the Kotagaloya Valley, the average rainfall is 1 believe, about 140 inches. Ours, it is now evident, is closely represented by 100 inches, as nearly as possible the figure for Nuwara Eliya. In this matter of rainfall only, however, does the comparison hold good. Our climate is much more genial, not only because of our lower elevation by 100 feet, but from the fact that this place has been opened entirely in woodland, while Nuwara Eliya, a damp, grass covered plain (the bed, doubtless, of an ancient lake), has its temperature lowered by the double effect of evaporation and radiation of heat on clear nights.* Although the results of three years are not sufficient to settle fully the averages of the months, and although June 1885 gave the excessive figure of 28-54 inches, as a reaction from deficiencies in the two previous years, yet the figures are sufficient to give a fair general idea of our rainfall, apart from mists and suspended moisture. It will be observed that while a large proportion of our rainfall—41 inches out of 91-64—falls in the three south-west monsoon months, June, July and August, only 20 falling in the three north-east monsoon months, October, November and December, yet there is no rainless month, although in the fine season, January to April inclusive, there is only just enough of rain to make the weather pleasant, about 13 inches for the four months, or an average of 3½

* This, however, has evidently been modified at one end of Nuwara Eliya by Lake Gregory which has helped to equalize the temperature.—ED.

inches for each of the four. With a mean temperature of about 61° for the whole year, the climate is about all that could be desired for health while good for luxuriant vegetation as green and golden flushed tea, up to 6,000 feet proves. We ought from the experience of 1885 to know the best time to prune tea, as the process has been going on over all the months of the last half of the year, the fields first pruned being in full bearing again before the prunings from those last dealt with have been buried. Here, as in India, it might be supposed that November would be the best month for using the knife. But the difficulty here, within 7° of the equator, is, that tea pruned early in November has a coating of tender flush on to endure the north-east winds of December. When the rubbing of moss off the stems, making good-sized longitudinal holes and burying prunings, weeds and rotten timber are added to pruning, a good deal of time is occupied. But, of course, the holing and burying next time will be lighter work. Apart from the winds of December having affected some of our young buds and flush on recently pruned tea, our only trouble at present is about very minute black bugs which appear on some of our flush, a dozen small specks or so on a young leaf, here and there. We are assured that there is little to fear from this minute insect, which seems to differ from the destructive coffee bug, and this is reassuring, for, under a powerful microscope, the creatures look in shape like turtles and in coat like flying foxes, while each has his proboscis inserted in the substance of the leaf. The affected leaves are, however, few and far between.—A couple days ago, I measured the stem of one of our fine seed-bearing tea trees. It was round and well formed—single and not a junction of stems—and a little above the ground its circumference was 26 inches. The tree, for such it is, is nine years old.

HYDRANGEAS AS LAWN SHRUBS.—The hydrangeas planted out may not be altogether a scarce plant in gardens, but it is scarcer than it should be, for few flowering shrubs last so long in bloom or are so effective when in, that condition. It may not perhaps be suitable for exposed positions in the northern counties, as it cannot be said to be quite hardy; but, seeing that it lives for many years in sheltered corners in the neighbourhood of London, it is clear that it is harder than many imagine. Here in Somerset it has endured 26° of frost in a position fully exposed to the north-east wind, and has not been seriously injured. We have plants of it struck from cuttings fifteen years ago, that are now 12 yds. in circumference, with more than two hundred heads of flowers upon them, and many of the heads are so large that they would not go into a gallon measure. I should add, however, that our soil seems to suit them better than some others may do. It is a sandy loam, and moderately deep, resting on the red sandstone. The plants to which I allude are standing on grass, and have plenty of room on all sides in which to develop themselves. They commence to flower in August, and invariably last in good condition until the end of November. In one part of the pleasure grounds the flowers come quite blue, while the others retain their normal pink colour. Our plants give us no trouble in the way of cultivation. The old flower heads are cut off as soon as they fade, which is all the attention they require. I may add that the flower heads are larger in a moderately damp summer than in a dry one, like the past. This shows that the roots like a fair amount of moisture while in active growth, and those who may wish to have specimens of hydrangeas in the best condition may make a note of this fact.—TAUNTON.—Field.

SILK COTTON-TREE.—From a mass of correspondence relating to white silk-cotton-tree (*Eriolobium anfractuosum*) commonly known as *Bilburgadamma* in Chinese, we learn that the tree is most abundant in certain Taluks of the Tanjore, Mysore, Shimoga, and Hassan Districts, and in the forests of Shimoga and Hassan. The reports of Messrs. Lowry and Graham Anderson are of special interest. In cultivation, the tree is extensively used as a support to the betel-vine, a purpose for which its rapid growth and naked under stems render it well suited. Mr. Dickinson, the conservator of forests in Coorg, is of opinion that the moister climate of South Canara is better adapted to its requirements than any part of Mysore. The tree can be readily propagated from pods or stakecuttings, which is an important matter in facilitating the quicker development of fruit-bearing plants. *Kapok* is ready for harvesting in the beginning of summer or in the mouths of February and March. After separating and well clearing, 22 lb. of *kapok* were divided for despatch to the valusters at London and Rotterdam. The reports submitted from the latter are favorable as regards quality and condition of the samples submitted for valuation; but the prices offered are so low that the expediency of taking any further steps to advance this industry is extremely doubtful. Where *kapok* is plentiful in the forests, it might pay to collect and export it, but certainly not in any limited area of cultivation. The London market does not require *kapok*, but they are anxious to obtain a few similar materials at low prices.—*India's Agricultural Gazette*.

CINCHONA CULTIVATION IN INDIA.—We regret to find that our friend Mr. Gammie of the Sikkim Gardens was unable to keep his promise to visit Ceylon on his way home or out, during a recent trip to the old country. Mr. Gammie however paid a visit to the Nilgiris, and we venture to extract the following interesting information from a letter he has sent to us:—

"On my way out I made a flying visit to the Nilgiri plantations. The Government plantations of Dodabeta and Neddivatam are very fine indeed. Better, indeed, could scarcely be desired. Ossington was also looking magnificent under Mr. Rowson's excellent management. The Madras Government made a great mistake, I think, in not retaining his services. He had collected over 100,000 lb. of dry bark by the stripping process, when I was there, and intended collecting over 20,000 lb. more by the same plan. The stripping plan is certainly a great success in that part of the world, and I can't understand anyone there preferring the shaving process to it. I also saw several most promising young *C. officinalis* plantations. I only wish cinchonas would grow in Sikkim half as well as they do in the Nilgiris. We go on in the usual way, and will do so, I suppose, to the end of the chapter. 'Uprooting' is the only plan we can make pay. We have a lot of very promising—i. e. for us—young hybrids and Ledgers. Our experience to date is that Ledgeriana follows as a second crop better than any other variety, but another year or two's experience is necessary before that point can be decided with any certainty. I am glad to hear that tea is doing so well with you. Having been away for the summer I don't know much about this tea season's working on our hills, but believe it will be about an average, and almost every tea garden of any age, in the hills, will show a fair profit on the season's outturn. I have not yet had time to read over the correspondence in the *T. A.* on the prospects of quinine manufacture in India, to which you directed my attention. But I may at once say that I have no faith in the success of any Company that is likely to be started for that purpose in Southern India."

WYNAED PLANTERS' ASSOCIATION, Dec. 2nd.—Colour of Coffee.—Mrs. Jowitz the Hon. Secretary of the special committee submitted the following report:—At a meeting held on the 11th November the correspondence on the subject of the colour of coffee was sifted and discussed. The statements therein contained are conflicting and the subject at the outset presents many problems difficult of solution. The committee have called for further figures which they hope may materially assist them in their investigations and have decided on certain experiments which they hope to carry out in the course of the next two months.

RUBBER IN WEST AFRICA.—According to a work by Mr. F. T. Valdez, formerly Arbitrator at Loanda, the process of extracting caoutchouc or Indiarubber takes place in June, July, and August, and is carried out by slaves. An incision is made in the tree, and a vessel placed under it, which, by means of a conductor, is filled in about twenty-four hours. From this the caoutchouc is poured into moulds of various forms, which have been well smoked with the massie, or palm-tree, from which the gum that gives the black colour, which they consider indispensable, is procured. When they think that the Indiarubber is of sufficient consistency they open the moulds.—*Indiarubber and Guttapercha Journal.*

THE INTRODUCTION OF THE POTATO IN GERMANY.—A correspondent in an American paper writes:—"While travelling in the upper Rhine countries, we found ourselves obliged to pass the night and part of the day in the little village of Offenbourg, on the borders of the Black Forest. While looking about in search for the marvellous that is always to be found in some form in these border villages, we came upon a huge monument, upon the pedestal of which was the figure of a man in the dress of the Elizabethan courtiers. Our wonders increased as we saw loosely piled upon the broad, projecting base, quantities of Potatoes carved in stone. It was a monument to Sir Francis Drake and the esculent tuber! The cavalier and discoverer bolts extended in one hand a Potato plant, and upon the four sides of the pedestal are inscriptions expressing the gratitude of a great people for the blessing that the Creator had been pleased to bestow upon them in time of famine."—*Gardener's Chronicle.*

FORESTS AND MOISTURE.—At the Boston (U. S. A.) Society of Natural History meeting recently, the subject of "The Influence of Forests upon the Atmosphere" was presented by Dr. G. L. Goodale. His conclusion, in brief, was that their influence is very slight. In regard to moisture their direct action in throwing off moisture is, he said, insignificant, but their indirect action in holding back the water which has saturated the soil in rainfall is very great. Droughts and excessively dry atmosphere are consequent upon an extensive cutting away of forest growths. In the debate which followed it was stated, without question or contradiction, that two broad conclusions have been drawn heretofore concerning the desert coasts of the south side of the Mediterranean Sea, and that other causes besides the cutting off of Forests must be recognised as having effected, in part or wholly, the result now seen. One speaker thought it to be a matter of conjecture whether there ever were any forests there.—*Gardener's Chronicle.*

PLANTING THE FORESHORES OF A LAKE.—I observe that your correspondent J. M. W. asks for advice in planting up the foreshore of a lake. Willows are not, perhaps, the best subjects to plant in any numbers; but a few trees of *Salix alba* might be put down here and there. Round the immediate edge I should give a preference to the common alder, planted close, more especially if cover for the purpose of approaching wildfowl, &c., is one of the objects in view. Among these, or at the back of them, *Taxodium distichum* will be found a valuable as well as an ornamental tree. Then, as the land recedes from the water's edge, *Pinus rigida* (pitch pine), *Abies* (*Tsuga*) *canadensis*, *Abies* (*Tsuga*) *Mertensiana* vel *Albertiana*, and *Quercus palustris*, are all excellent varieties for your correspondent's purpose,

and should, as they develop, yield profitable timber results. The common spruce adapts itself well to bog-lands, provided they are not of the worst class. If the ground is very full of stagnant wet. the system of planting known as "buttage"—i.e., in small artificial mounds—will materially aid the result. When thus protected during the first season, plants are enabled to set up a healthy root action, and are able to stand a much greater degree of wet than would otherwise be the case. In Germany the practice prevails to a very great extent. Open horizontal drains, cut at intervals of 20 yds. to 40 yds. apart, will, if there is any slope, contribute in a great measure to the success of the plantation, and, if practicable, should be made about twelve months previous to planting. With regard to the rabbits, wire netting is the only effectual protection that I am acquainted with. I should be only too glad to hear of some less costly substitute. Even with that, in the case of forest nurseries, constant attention is necessary to keep them completely out.—E. J. C. B.—*Field.*

THE BLACKSTONE TEA ROLLER.—Ambagamiwa, 24th Dec.—At the invitation of Mr. Barber, I visited this estate with some friends with a view to seeing the new "Spheroidal" Roller at work. Mr. Scovell and others have already noticed the excellence of this machine and have given details of the amount of work done, to which I can certify. This roller, I believe, will eclipse all the rollers at present in use, unless Frater's roller hold its own; but even here the Blackstone roller has a great advantage in Mr. Barber's special invention or spheroid which gives centrifugal motion to the tea and prevents the roll from "balling," making a more equal roll than any machine I have seen at work. The work is perfect, and when the roll is taken from the machine it requires almost no breaking but is ready for the sieve at once, the hard leaf, of which there will always be a little, rejected or rolled into little balls which can be pushed out at once: from the roller to the sieve is but 2 or 3 minutes. The sieve, though of the simplest construction, does its work equally well with the roller and takes out 30 per cent to 40 per cent of the pekeos. I have sampled the Blackstone against some of the best teas in the island, and their superiority in make is at once apparent. As to quality, when infused they hold an equally high position, as the sales will prove. I attribute the beautiful finish of these teas entirely to the machinery, and the quality of the tea is largely due to the perfect sifting, and separation of the fine leaf before fermentation and firing: in fact the two machines should be worked together. I would recommend every tea planter to visit Blackstone estate. There are no costly or expensive buildings to see, but apart from the intrinsic value of the machinery there are many small details in the manipulation of the tea from plucking to packing which will not fail to interest. Mr. Barber is adopting, what I recommended some time ago, a separate room with sirocco for final firing and packing. The advantages of Mr. Barber's roller may be briefly summed up thus:—Simplicity, small power required to drive the machine say 2 or 3 horse-power, easy adjustment of pressure, the spheroid speciality of the machine, ease with which the machine can be charged and discharged, and finally its great capacity for rapid and perfect work, the outturn being equal to not less than four rolls of 80 lb. each within the hour. The sieve is so perfectly simple that any good carpenter can make the whole in one day; it is the effective manner in which the roll is finished that makes the sieve so valuable.—JAMES IRVINE,

Correspondence.

To the Editor of the "Ceylon Observer."

PLANTING IN THE LOW COUNTRY IN
CEYLON: THE UDAGAMA PLANTING
DISTRICT: TEA AND OTHER
PRODUCTS.—IN ANSWER
TO CRITICISM.

Udagama, 15th Dec. 1885.

DEAR SIR,—I am quite certain it is as little their intention as yours, and I therefore would not wish to trouble you now were it not that forming the first subject of remark in your leader of the 10th inst. on an interview with two entitled tea authorities from India, what is said regarding our district may be likely to unfairly prejudice outside opinion against a neighbourhood, where planting has yet been attempted in it, only now passing through the universal transition era of tea for coffee, be it "Arabica" or "Liberian." This largely due to the fact (which alone, by the way, forms rather a sufficient argument against anything said) that the latter, though it be little to boast of, has proved, with us at least, a greater success than in most other districts. Were there an extensive acreage of tea here, as in the Kelani Valley, already in bearing, it would be quite immaterial: practical results, as in their case, would be amply sufficient to refute criticism; but meanwhile, and until the district has assumed its certain destiny, it is as well to be candid and speak the truth. We cannot afford to have capital undeservedly frightened away: on the contrary, what of all things we want is that investors should find their way here, nor could they do better. Having had the pleasure of a visit from Messrs. Logan and Teare, it is but polite and just, I should say, to believe that their opinion is fully as valuable as the opinion of any experienced Indian teaplanters on Ceylon as a tea country, and tea in Ceylon under the varied conditions, from those pertaining to the regions of natural ice, to a perennial humidity, but that Assam can boast of for six months only, and has practically to bemoan the absence for the rest of the year, despite the refuted argument for a period of hibernation as natural and necessary. As for drawing invidious comparisons between the various districts where all are so good, I have not a thought or wish, but it is only fair to remark as a point your friends seem to have overlooked entirely, that it is, as to the possession of this unvaried condition of heat and moisture—climate, in fact—that this district or rather, I should say, section of the island, extending over a large area, not strictly at the coast, but from some distance inland from Galle, can probably claim priority. As for soil: it has never been argued that the surface soil here can compare with much of the ground upcountry—only, that we generally possess a free and deep subsoil, strongly impregnated with iron. Ground, in fact, that, taken on an average, will compare favourably with that of any other lowcountry district, where the climate is also suitable for tea. And on this point, I think, you will accept the opinion of so good an authority as Mr. —, though I do not feel entitled to give his name publicly, as worth more than that of any passing visitor. He independently noticed, which I take to be one of the main points of consideration for tea, this depth of free soil, and it is fully borne out by the distance down to which tree roots can be found extending.

There is, in Udagama, but a small and scattered area of old bushes at present, that have most of them been allowed to run up for seed, but

which, taking them all in all, will, I think, compare well with any others similarly conditioned in the island, of a like age; and it was, in fact the absence of pruned bushes to judge from, that really disappointed your friends in their visit. With the growth of the only last year's clearing—opened under a certain order, and, most of it, not planted till December with plants from seed (partly Abbotsford) not sown till June—they expressed themselves especially pleased with. What they, or rather Mr. Logan, did not seem to like, as a new experience to him from the stoneless alluvial flats of Assam, was the steep ground, and especially rocky nature of this particular clearing. As for "quality of leaf": I have a favorable report by Messrs. Forbes & Walker on a few lb. made experimentally with a solitary No. 8 sieve, over an amateur oven. As with other lowcountry teas, it shows, you will notice, the pronounced strength and flavour, that—according to a gentleman (a planter of full experience) I happened to hear discuss the subject lately, largely and, I believe, equally interested in tea at both high and low elevations, and who, therefore, must be taken as an impartial authority—is likely in the long run to give the advantage in price and fixed demand to the latter. His verdict was, that, though a superior delicacy of flavor, though comparative lack of strength and body, in the high-grown teas may find them now, and, at first, slightly higher prices amongst connoisseurs who will pay, their number is not sufficiently legion to absorb more than a limited quantity, and, as a tea to satisfy a wholesale democracy it needs the strength and pungency the lowcountry leaf excels in. As for the opinions of Messrs. Logan and Teare, coming one from the Neigherries and the other from Assam, they can hardly be coupled as one—rather amusingly shown on an appeal by one to the other, after pruning a sample bush, as to whether his friend did not think "that about right?" in the reply that it was, except that for himself "he would cut a little lower, as his women would be hardly tall enough to do the plucking otherwise." On subsequent measure, though still a tall tree, it hardly argues well for the standard of labor procurable! and this brings in a point: whilst arguing comparative cost of labor in Ceylon and Assam Mr. Logan seems, in speaking to you, to have used a discreet silence on, or rather his lack of knowledge prevented a very material comparison being drawn. Though granting his figures as to their actual wages, his admission when here, as I gathered it, that 1s per lb. is their lowest rate of production, sets aside all argument of comparison under the headings collectively that go to make up our respective totals of cost. But on the one question only, however much there be, we may think, we have reason to complain of, it only needs but a few words on the subject, to gather the Government begotten paralysis under which, as a fact, they are prostrated in Assam as regards their labor. The hand of Government, in a manner no Ceylon Governor or Government would think of, in everything, adding supplementary items of cost under almost every heading in which labor forms a part, and its beneficent influence extended to save the coolies from killing themselves in any other employment than sleeping or eating their heads off. At least so, I confess, I concluded on being told that 6 plants, ball planted (take it at 60 as misheard, though I think not), was a day's task! this being elicited on looking over a nursery the fine plants in which attracted attention: and which, by the way, are now going in, largely as ball plants,

at the rate of 250 to 300 per diem. Apply the parallel generally as to the comparative amount of work done; add to this Government extras, loss on premiums by death, and the numerous other sub-charges we are exempt from; and as regards cheap labor, with whom really stands the advantage? As already said, the proof of the pudding is in the eating; facts are things that won't budge, and the comparison afforded by the published results of every Company, and the many private gardens in Assam and India generally, gives practical evidence, it seems to me, no planter from thence can attempt to qualify in their favor. They are out of the running in fact with Ceylon till they can see their way to reduce their expenses, say by 3d per lb. That is on a 400 lb. crop, a profit in our favor of £5 an acre, or say on a 200 acre estate an income £1,000 a year: in itself an interest on a capital outlay of £4,000, that might generally be considered sufficiently satisfactory?
A RESIDENT.

CHEMICAL DYES AND THEIR DANGEROUS CHARACTER: A WARNING.

DEAR SIR,—Not a few persons, even in Ceylon, have experienced in person the dangerous ill-effects of the many beautiful but deadly poisonous chemical dyes. The evil consequences to health are subtle and present themselves from the most unexpected quarters—from deadly colored papers, socks, sweetmeats, and even down to children's toys. The report of the Society of those interested in German chemical industry (Verein zur Wahrung der Interessender Chemisten Industrie Deutschlands) is a very serious blow to this branch of chemical enterprise, and many alluring pigments should cease to offer themselves to the public as the kiss of death.

The Commission defined poisonous coloring materials to be all those colors or color preparations which contain antimony, arsenic, lead, chromium, copper, mercury, cinnabar, gamboge, picric acid (which represents the many dangerous tar colors), barium, heavy spar, cadmium, zinc, tin. After reading the terrible list the wonder is we are not all dead men; for the use of these fascinating but deadly colors is not merely common at home, but they have also been largely introduced into India.

The sale of articles colored with these poisonous materials is to be made illegal by Act of the German Parliament. And the sooner this good example is followed by England, India, and every other country, the better will it be for the health of the people. Further, a fair field will then again be afforded for the many really beautiful and harmless Indian natural dyes, which, by the comparative cheapness of the chemical poisons, were being rapidly driven out of use. In this particular matter I am afraid "Judson" must be regarded as a dangerous character, while every tar color should be avoided as more than suspicious.

Surely this subject is not beneath even the attention of the Ceylon Government.

PUBLIC HEALTH.

RUBBER IN CEYLON: THE IMPROVED SYSTEM OF GATHERING MILK—SHOULD HARVESTING BEGIN?

London, E.C., Dec. 2nd, 1885.

DEAR SIR,—I have read the letter Messrs. Marval Irmãos have addressed to you. I am aware of the nature of their process and can fully confirm what they say. I cannot agree with your remarks when

you say that Ceylon has not sufficiently advanced in rubber culture, because you have the *Cryptostegia grandiflora* and other rubbers which yield milk and they are quite amenable to this process which is both simple and inexpensive. Dr. Trimen will confirm the fact of my having sent him some years since Mangabeira rubber seed, telling him at the same time that it produced a very fine rubber.—I am, dear sir, yours truly,
THOS. CHRISTY.

CARDAMOM PLANTING IN INDIA.

Mercara, 21st Dec. 1885.

DEAR SIR,—“Cardamom Planter” in your November's issue of the *T. A.* says, it would be highly interesting to know how India is standing the present crisis in cardamoms. I am glad to inform him that we can still manage to make both ends meet, even with the present low prices. The general opinion here is, cardamom prospects are done for. Some of our Wynaad friends, however, think differently, as they are going in extensively for them, and seem very hopeful for the future. I am afraid they will be rudely awakened from their fond dreams one of these days. The cultivation is being extensively increased all over Southern India, both by Europeans and natives, especially the latter, who are following the example of Europeans in planting up their jungles, and picking the fruit as it ripens, instead of stripping the racemes as they used to do. I know one native who got as much as 23 tons of cardamoms last season, and I hear he expects from 18 to 20 tons this season. He is still going in for more jungle, having bought about 3,000 or 4,000 acres more last year. Prices in the local market have declined in the last 3 years from R70 to R20 per maund of 28 lb. and there is no doubt the prices will fall still lower. We are having very wet weather here for December, the sky being overcast all day, and consequently great difficulty in drying our coffee crops.—Yours faithfully,
YELAKEE.

A HEALING PLANT.—In the *Archiv der Pharmacie* (November, p. 817) Dr. P. Zipperer describes and illustrates the structure of the root of *Parameria vulnearia*, Radl., which is used by the natives of the Philippine islands as well as by the residents there to furnish a kind of balsam that possesses remarkable healing properties. This is known by the name of Cebu or Tegulaway balsam. It is prepared by boiling the bark of the roots and twigs as well as the leaves of the plant in cocoa nut oil, and forms a yellowish-white oily liquid having a peculiar odour. Dr. Zipperer's examination of the plant shows that it contains 8.5 per cent caoutchouc in its tissues, and 3 per cent resin soluble in alcohol, and to these constituents its value appears to be due. Dr. Zipperer states that during two years' residence in the Philippines he had seen the balsam used by European doctors, as well as by the natives, with great success in various skin diseases and for healing wounds. It appears to promote an unusually rapid cicatrization. The plant is a climber growing in the mountainous declivities of the Island of Cebu, whence it is chiefly obtained. The fragments of leaves and twigs in the possession of Dr. Radlkofer were sufficient to enable this eminent histologist and botanist to assure himself by the microscopical structure alone that the plant differed from the only two other species of *Parameria* known, viz., *P. glandulifera*, Benth. (see Kew Report for 1881, p. 47), and *P. philippensis*, Benth., affording another example of the value of the microscope in pharmacognosy.—*Pharmaceutical Journal*.

NEW SPECIES OF PRIMULA FROM THE MOUNTAINS OF YUN-NAN, WESTERN CHINA.

The genus *Primula* is now in the ascendant, and the number and diversity of the species in certain regions, especially in the mountains of Asia, seems almost inexhaustible. When that part of Sir Joseph Hooker's *Flora of British India*, containing the Primulaceae, appeared some three years ago, it afforded a great surprize in the large number of new species of *Primula* described, chiefly from the Himalaya Mountains. After the reduction of a large number of forms that had previously been described as independent species to *P. obtusifolia*, *P. Stuartii*, *P. petiolaris*, and others, there still remained, including one in the addenda, forty-four admitted species. And every fresh district visited since has yielded something new, so that the publication of additional new species from the Himalayan region may be expected at any time. It is noteworthy that no species of *Primula* has hitherto been detected, either on the mountains of the western peninsula of India, or on those of Ceylon. One very fine and distinct species, *P. imperialis*, inhabits the mountains of Java, and the familiar *P. pinnatis* (siensis) and *P. japonica* are the most conspicuous of the few species inhabiting the extreme east of Asia. But lying between Eastern India and Western China is a vast tract of country, the interior of China, concerning the vegetation of which comparatively little is known. Various French missionaries, notably David and Delavay, have, however, made considerable collections in the western provinces of China, and M. A. Franchet has described a great many of their novelties in various publications.

His latest contribution* to Chinese botany is a synopsis of the species of *Primula* collected in the mountains of Yunnan by Delavay. The collection comprises twenty species, nearly all found around Lake Tali; and of these twenty species, sixteen are, according to Franchet, absolutely new; three are referred to Himalayan species, and one is treated as a remarkable variety of *P. auriculata*, a native of the Caucasus and Siberia. The greater number of the *Primulas* of the lofty mountains of Yunnan, Franchet says, are singularly remarkable for the beauty of their flowers, surpassing even the Himalayan species in brilliancy of colouring.—*Gardeners' Chronicle*.

REPORT ON THE HORTICULTURAL GARDENS, LUCKNOW.

Fruit Culture.—There appears, on the whole, to have been a fair crop of fruit. A number of English varieties of vine and an English variety of fig fruited in the gardens for the first time this year. It is expected that when thoroughly acclimatised these varieties will prove superior to those hitherto cultivated. Considerable advance has been made in the knowledge and cultivation of the Arabian date palm, and it is hoped to overcome the difficulty incident to the late ripening of the fruit by observation, selection, and hybridising with the native variety. The demands on the garden for fruit trees, especially of the orange tribe, has been in excess of the supply, and the area for nursery work has therefore been considerably enlarged.

Vegetable and Farm Culture.—It was in this province that the effects of the hail-storm were, perhaps, most severely felt, all the vegetable crops being much injured. The experiments with muskmelon and white Belgian carrot were thus checked. On the other hand, American table corns have succeeded better than in the previous year, and further success has been achieved with Dwarf French and Pole beans and "Queen" onions. Of the cottons, the China and Arabian seed of Nankin cotton failed here as elsewhere. The cross obtained between New Orleans cotton and acclimatised Nankin was so far encouraging, that the plants flourished in a season

* *Bulletin de la Societe Botanique de France* (1885), xxiii., p. 264.

when cotton of every description was elsewhere comparatively a failure, but in point of colour the results are not yet satisfactory. Further sowings will be tried. Prickly Confrey, introduced in 1883, will be a valuable addition to our fodder plants if it succeeds, of which there seems good hope. The hail-storm however has temporarily checked the record.

Withania coagulans and Salt bush (*Atriplex Nummularia*) continued to do well. The demand for acclimatised seeds continues to increase, and that for imported seeds to decrease, an evolution which is distinctly satisfactory.

Flower Culture.—There is little under this head to note beyond general progress. It was at one time hoped that Hippeastrum bulbs would find a sale with English Florists, but it now appears that Australian custom promises better appreciation.

Arboreal Culture.—Of the stock of seedling mangoes raised for gratis distribution, 7,680 were disposed of without effort, and the distribution of all kinds amounted to 12,400. There are 27,000 young trees now in the nursery.

Exotic Plantation.—The acre of *Divi-divi*, grown for the purpose of practically testing the commercial value of this tree, continues to flourish. A kharif crop grown between the lines paid for all charges on this acre during the year and left a small profit. This experiment, while testing the profit from *Divi-divi*, will secure a double purpose in exemplifying how inexpensively a grove may be formed. Of other trees in this plantation the table gives particulars, which, owing to the hail-storm, must this year be considered inoperative.

Date Plantation.—This appears to be making fair progress. The plants have done well. The plantation has been fenced in, two wells have been sunk, and a good deal of surface levelling accomplished. It is yet too early to discuss the prospect of the scheme.

Apprentices.—There are 15 boys on the roll, some of whom are qualified to take outside appointments. Ten applications for malis were received during the year.

TEA CULTURE IN NATAL.

TO THE EDITOR OF THE "COLONIES AND INDIA."

Sir,—I have great pleasure in handing you the enclosed slip from the Natal press, which I will thank you to publish at foot of this, for the information of the public desirous of finding an outlet for capital and labour.

Mr. Hulett writes us that the industry may be pursued with a commencing capital of 500*l.* upwards, the occupation being agreeable and interesting. In a condensed form I have furnished the *Field* with a general outline of this communication, and I shall be happy to afford your readers any further information in my power they may desire. Mr. Hulett is prepared to purchase the leaf as picked from the plant from beginners at an agreed price, thus obviating the need of machinery and want of knowledge in manufacture or preparing the tea for the market, and he will give every assistance possible, advice, &c., to those desirous of such.

From broker's report on samples I brought home last year, I quote the following values in the London market in bond:—No. 1, 1*s.* 3*d.* to 1*s.* 4*d.*; No. 2, 1*s.* 9*d.* to 1*s.* 10*d.*; No. 3, 2*s.* 3*d.* to 2*s.* 5*d.* per lb.; and would have been worth more if leaf had not been so broken. Samples were brought home in my portmanteau, and freely handled on the voyage.

I am, &c.,
MORTON GREEN.

Brixton Rise, S. W., Aug. 29, 1885.

TO THE EDITOR OF THE "NATAL WITNESS."

Sir,—For the benefit of all those who take any interest in productive development, allow me to give results of last season's yield of manufactured tea on

this estate—i.e., between September, 1884, and June, 1885, the manufacturing season:—

	lb.
$\frac{1}{2}$ an acre original (imported) planted Nov., 1877.	600
$\frac{1}{2}$ acres planted out Nov.; 1880, 70 lb. to acre.	3,850
2 $\frac{1}{2}$ acres planted out Nov., 1881, 500 lb. to acre.	13,000
18 acres planted out Nov., 1882, 250 lb. to acre.	4,500
50	21,950

It will be understood that the amounts per acre for the various ages can only be approximate, seeing that the variously aged trees are picked at one and the same time and leaf mixed. But seeing I have manufactured 22,000 lb. of tea, if we reduce the amount per acre for one age, we must increase the amount per acre for the other. I am aware that the yield will appear excessive, considering the age of the plants, but the total result is as above, and area picked over as stated. Surely this return, in a very dry season, will settle the question of sufficiency of rainfall in Natal for tea-growing.

It may be interesting to give a general view of the present position of the tea industry. The letters are placed in lieu of names of estates, as I have not applied to the owners for leave to publish the names.

LOWER TUGELA DIVISION, VICTORIA COUNTY.

A	Estate, 110 acres planted, 10 to 20 acres preparing for planting coming summer	
B	" 7 " 13 " "	"
C	" — " 7 " "	"

It may be safely assumed that 50,000 lb. weight of tea will be made in Natal during the coming season, with a very large increase each succeeding year.

In conclusion, I think I may fairly lay claim to have proved that tea-growing in Natal is a success—not merely that it will grow, but that it will grow to pay, and pay well, as an article of export. The initial difficulties have been overcome, and the future will doubtless show great improvement in the manufacture as experience is gained.—Yours, &c.,

J. LIEGE HULETT.

Kearsney Tea Estate, Nonoti, Natal.

TEA IN THE CAUCASUS.—One of our Russian correspondents informs us that under the auspices of a society the cultivation of Tea in the Caucasus is likely to be successful. Experience has shown that the shrub thrives at Souhoum-Kale, Batium, and various other places near the eastern shores of the Black Sea.—*Gardeners' Chronicle*.

SWOLEN MOUTH AFTER EATING PINEAPPLE.—A correspondent of the *British Medical Journal* states that "A gentleman about forty years of age received a Pine-apple as a present. The fruit had an unusually dark rind [Black Jamaica]. He ate several slices after dinner, carefully cutting off the rind, none of which touched his mouth. Within a few hours his lips began to swell. The swelling did not disappear for twenty-four hours. The tongue was not affected. The gentleman had no other uneasiness or pain." [We had a similar experience in some Pine-apples raised from suckers that came ashore from the "Tyne" Mail steamer, which came ashore off St. Albans Head in 1853.—Ed.]—*Gardeners' Chronicle*.

ANNUAL REPORT, BY DR. KING, OF THE ROYAL BOTANIC GARDEN, CALCUTTA FOR THE YEAR 1884-85.

The progress of the garden during the year has, I think, on the whole, been very satisfactory. Various plants of economic interest, and especially fibre-yielding species, have received attention during the year. At the request of the Government of India, a further attempt was made to introduce into the province of Bengal the kind of plantain (*Musa textilis*) from which Manilla hemp is derived. Plants of this species were accordingly distributed to the Magistrates of districts. As I anticipated, this attempt (like its predecessors) was a failure, and from the same cause. The low temperature of the cold weather, proved too much for the plants and they all died. A small patch of ricea continues to be kept up in the garden, from which quantities of green stems were made over during the year to persons interested in discovering an efficient cheap method of extracting the fibre. Quantities of roots were also distributed to several applicants. Bow-string hemp is a fibre which of late has attracted considerable attention. It is no doubt an admirable fibre, and is not difficult of extraction from the plant (*Sansevieria Zeylanica*) that produces it. The plant is not indigenous in this part of India, but it grows well here; and a good many plants of it have been distributed during the year. In several of my recent reports I have referred to the Japan paper mulberry as a hopeful source of paper fibre for Bengal. I am happy to say that the trees of this species in the garden continue to grow well. Although now only three years old, they are twenty-five feet high and have proportionately thick stems. The fibre contained in the bark is one of the best materials for paper known. It is easily separated, is strong, and requires little bleaching. As the tree grows thoroughly well and coppices freely, I think it quite possible that, in the course of time, natives may be induced to grow it on the odd corners of land which are so common near Bengali villages. It is gratifying to find that the bhabur or sabai, a native grass to which I first directed attention in my annual report for the year 1877-78, has now become a recognised raw material for paper, and that it is largely used in local manufacture. Mahogany and the various plants yielding India-rubber continue to be propagated and distributed as the resources of the garden permit. Much attention has of late been directed to the coca plant, the leaves of which contain an important alkaloid called cocaine, and efforts have been made during the year to propagate quantities of this plant for distribution.

In former reports I described the havoc committed in this garden by the grubs of a cockchafer which appeared in the soil of the garden in myriads and ate up almost every plant that it contained, sparing only the larger trees. During the year under review this pest gradually disappeared, and towards the end of the year Mr. Jaffrey had succeeded in re-stocking the garden with plants of sorts. But many of the rarer kinds, got at considerable expense from Europe and elsewhere, have disappeared, and their replacement must be a matter of time. The grub is, I hear, extending its ravages in the Darjeeling district. It is to be hoped that it will confine itself to the weeds in tea gardens, and that it will spare the tea bushes.* The sides of the sanitarium hill above the garden (by slips from which the garden suffered considerable damage in former years), appear at last to have become consolidated; and it is to be hoped no more damage will occur from that source. The vegetable garden owned by the municipality, but worked by Mr. Jaffrey for the Municipal Commissioners, having been greatly damaged by successive landslips, gradually became a losing concern, and was towards the end of the year resumed by the Commissioners.

* The cockchafer grubs, so destructive to the rootlets of coffee, have certainly, as yet abstained from attacking tea.—Ed.

who threaten to build either bazaar huts or washing tanks for dhobies on the site. The interposition between the grounds of the Eden Sanitarium and Botanic Garden of buildings of this sort would be a great blot on the amenity of the neighbourhood; and I trust the Commissioners may reconsider their decision and see their way towards restoring the ground to horticultural purposes. Sales of plants to the extent of Rs25 (against an estimated revenue of Rs300) were made at the garden during the year. Mr. Jaffrey has worked with much enthusiasm and energy under rather depressing circumstances.*

The thanks of the Lieut. Governor are again due to Mr. King and his subordinates for the excellent work done during the year.

EARTHING-UP.

The ridge, consisting of earth heaped round the base of the plant, exercises very diverse actions; often useful, it is sometimes without sensible action—occasionally the effect is even hurtful. The practice considerably modifies the physical constitution of the soil; it, moreover, exercises a very important influence on the manner of growth of plants. The temperature in the raised mound, as compared to the temperature of the level ground, has been found greater by 1° to 2.5°C. at mid-day at a depth of 10 centimetres during the day from June to August; this fact has been proved in various soils. At night, on the contrary, the temperature has been found to be 1° lower in the ridges. During winter it is generally the raised soil which is coldest. Generally when the sun is shining, the ridge aids the heating of the soil; when the sun has set, the ridge produces a cooling effect. These results are easy to explain; the ridged soil offers a greater surface to the sun, it receives the rays less obliquely, the soil there is very dry, and it takes a less quantity of heat to warm it; thus it is natural that it should be warmer during the day; during the night, on the contrary, the radiating surface is greater on the ridge, it is more mellow, more easily penetrated by the cold air; if there has been rain, the surface of evaporation is more extended, the temperature necessarily falls lower there than in the level soil. This increase in the temperature of the soil reacts on the plants by aiding the development of roots, by favouring the absorption of water, and generally by hastening their development. Experiments have shown that the more carbonic acid there is in the soil the colder it is; now the presence of carbonic acid proves the existence of inferior organisms whose work it is to elaborate the organic matter which forms the nourishment of plants: it is thus in the ridges that the plants find most food. But, it must not be forgotten that these inferior organisms only work when the soil contains exactly the proper amount of water which is indispensable to them; if the soil is too dry their work stops. If by earthing up we dry the soil too much we lessen or even destroy its fertility, and this explains to us why this practice may even become injurious. During one season the quantity of water existing in different sorts of soil, both in ridges and on the flat, was determined. One hundred parts of soil contained of water—

	Sand:		Sand:		Peat.
	Clay.	limestone.	limestone.	limestone.	
On ridges ...	16.35	10.33	1.22	43.99	17.74
On the flat ...	17.48	12.23	2.52	51.64	20.01

This table clearly shows that the soil of the ridge is always the drier; but it is in the siliceous sand that it loses the greatest proportion of water, so that it is in this kind of soil that the disadvantageous results are chiefly manifested. To sum up, the ridge will be useful on compact soils, rich in humus, holding water, and situate in moist climates; while in dry regions cultivation should be carried on on the flat.

We have said that the ridge exercises a very important action on the manner of development of

plants. On many species of plants, in addition to favouring the development of true roots, it promotes the development of adventitious or secondary roots; this may be seen in kidney Beans, broad Beans and in Turnips. Some species have not the power of making a "ventitious roots. Grasses, for example, as Wheat, Rye, Barley, Oats, Millet, Buckwheat, do not form new roots. [2] Such plants do not require the earth to be heaped up round their stem. There are even plants which are enfeebled by this treatment, because it causes an unnecessary lengthening of their stem, as in those plants in which the stem terminates at the surface of the soil in a rosette of leaves. If you put earth on such a stem you induce it to elongate so as to produce its leaves on the surface to a length equal to the depth of the soil over it, and this lengthening is effected at the expense of the materials which were destined to develop the other organs of the plant. Some very interesting comparisons have been made between Beetroots grown under identical conditions, with the exception that one lot was grown on ridges and the other was not. The average for one Beetroot is found to be:—

	Ridge.	Flat.
Weight of the leaves ...	359	391.6
" " " radicles ...	9.2	27.5
" " " root... ..	507.6	525
" " " whole plant ...	875.8	934.1

The ridge produces a diminution in the numbers of the leaves and in the development of radicles; it promotes lengthening above the ground, and with the lengthening of the stem there is a corresponding diminution of the underground and useful part of the plant. Evidently the ridge had lessened the total weight of the plant and the weight of the underground and utilisable parts.

In the case of Turnips, it may be noticed that the ridge prevents the crown from becoming green so that it remains tender and preserves the texture of the root; this latter is a great advantage in a plant used for food for cattle.

The ridge is greatly used in the culture of Potatoes; it produces such marked results that the tuber is planted almost on the surface; but if the Potatoes are planted deep the ridge is of no use, and is even often hurtful to the plant. In those kinds of soil where ridges produce bad results because they draw from the soil the humidity which is indispensable, the tubers must be planted deeply, and allowed to develop in level ground. Let us remark here that the culture on the flat will slightly favour the growth of weeds, on account of the maintenance of too great an amount of moisture in the soil; but these can easily be got rid of with the hoe. With the greater number of plants for which the ridge is useful, it is important to hoe the weeds as soon as possible; if we wait too long we risk touching and injuring the plants. In growing old they have partly lost their faculty of forming adventitious roots, and they profit much more from the work of new roots than from those which were formed earlier. With Potatoes the tubers which are developed on the new stolons have more time to ripen.

We have seen that the soil is drier in ridged land than in the plain ground, it would therefore be useful to sow, in certain lands, plants on the ridges, although these plants do not derive any direct advantage from it, for example, Beetroots. The ridges running north and south have a much more uniform temperature than those going from east to west; the south side is always drier than the north side. The ridges directed from north to south exhibit great uniformity in the evaporation of water from both their surfaces; it is evident that these are conditions favourable for the development of plants. Some Beetroots from ridges running north and south were ripe in September, those from ridges running east and west were only ready in October, the former contained 12.25 per cent of sugar, the latter 10.62 per cent.—Dr. WOLLEY in *Annales Agronomiques.—Gardeners' Chronicle.*

* His death has since been reported.—Ed.

ISSUE OF DUTY-FREE SALT IN INDIA.

The following is a Resolution of the Government of India, dated 23rd December, 1885.—

One of the chief objections taken to the salt duties is that, owing to the resulting high price, rattle are stinted in their supply of salt, while manufacturers and agriculturists are required to pay duty on salt employed in industry and agriculture. The attention of the Government of India has been given to the matter for some years in the hope that an unobjectionable method of freeing from duty salt required for the purposes above indicated might sooner or later be discovered.

No satisfactory way of affecting this object, and at the same time of protecting the State from risk of fraud, has as yet been found. The issue of duty-free salt on a simple guarantee that it will be used for certain purposes and for no others is, in the absence of special safeguards, out of the question, while the provision of such safeguards would entail the entertainment of establishments at inordinate expense, or the adoption of measures harassing to the section of the public concerned. The only plan which would fully meet the requirements of the case would be the denaturalisation of salt so as to render it unfit for human consumption, whilst it remained fit for use by cattle and as manure, or for industrial purposes, the salt not being easily restorable to an edible condition by any of the methods which could in ordinary circumstances be employed in India. If salt were thus prepared, it might be freely issued at little over cost price without danger to the revenue. So far, however, all attempts made to discover such a process have proved more or less unsatisfactory in their results.

2. The first experiment was made in 1876 by Mr. Wood, then Chemical Examiner to the Government of Bengal, consequent on an application from Messrs. Burn & Co., of Calcutta, for the remission of duty on salt used by them in the manufacture of glazed stoneware, pipes and similar articles. Mr. Wood reported that he was unable to find out a process which fully complied with the conditions laid down, namely, the discovery of an inexpensive method whereby salt may be rendered unfit for human consumption and can be again rendered edible only by a process, the cost of which would equal or exceed the duty levied on it. But he suggested an alternative method, namely, the admixture of salt with coal tar, the tarred salt being issued to manufacturers of glazed stoneware free of duty, upon a personal guarantee for its use exclusively in manufacture. This method was adopted and is still practised, the salt being issued subject to certain special rules framed by the Government of Bengal. The arrangement works satisfactorily on the limited scale on which it has been tried, but constant supervision is required, and tarred salt cannot be used except in pottery manufacture.

3. In 1877, Dr. H. Warth was directed to make experiments after the German method with some of the refuse salt of the Punjab mines. A mixture of salt with colocynth (*Citrullus colocynthis*) and another with lignite, oil-cake, and cotton seed were tried, but the result in both cases was unsatisfactory, pure salt being easily recovered from the mixtures, and the experiments were discontinued. On application to the Secretary of State for information showing precisely the process of denaturalisation employed in Germany, it appeared that salt was issued for agricultural purposes in two forms, (1) a coarse powder consisting of a mixture of oxide of iron and vermilion powder (*Artemisia absinthium*), and (2) blocks for beasts to lick, the salt being mixed with oxide of iron and charcoal powder. Salt for manure was mixed with charcoal dust, ashes, lamp-black or ordinary soot, in different proportions. These mixtures, though effective in Germany, would not be so in this country, where the salt duty is much heavier, and cheaper means of restoring the salt exist.

4. In 1879, the Government of Madras forwarded an application from Mr. Barter for permission to use duty-free salt in the manufacture of manure. The Commissioner of Salt Revenue, Madras, referred to

the various processes of medicating salt used in France, and recommended compliance with Mr. Barter's application, provided the salt was first mixed with poudrète in accordance with the French method. The Board supported the recommendation of the Salt Commissioner, but the Government of India considered that the issue of a mixture of the kind to the people of this country was obviously objectionable, as leading to serious misapprehension of motives. The proposal was therefore negatived.

5. The European methods of medicating salt having been found unsuitable, and the experiments made in Bengal and the Punjab having proved unsuccessful, the Government of India, in its Resolution of the 22nd August 1883, cited in the preamble, invited local governments and private individuals to make careful and systematic experiments for the discovery of a satisfactory process. Various attempts have been made in compliance with these instructions, but none of them can be considered completely satisfactory. The following is a brief summary of the suggestions received, and of the causes which render them ineffectual.

(1) Lieutenant J. F. Pogson, Dehra Dun.—A mixture of salt with slaked lime or chunam, carbonate of potash, powdered charcoal, rice flour and water. Experiment showed that the preparation was useless, pure salt being recovered from the mixture by solution in water and subsequent evaporation. A sample of cattle salt prepared by Lieutenant Pogson, of which he declined to name the ingredients, was tested by the Chemical Examiner, Punjab, and also found useless.

(2) Captain Davies, Barrack Master, Umballa, suggested a mixture of salt with green succulent grass in the proportion of 40 or more parts of the latter to one of the former. Edible salt can be easily recovered from the mixture.

(3) Mr. C. J. Simons, Mahmarra Tea Estate, Assam.—A mixture of edible salt with sulphate of soda (*khari nimab*) in the proportion of 4 to 8 and of sulphur vivum, black salt and mustard oil-cake in small proportions. The mixture was examined by the Chemical Examiner, North-Western Provinces and Oudh, who reported that edible salt could be recovered from it by an easy process.

(4) Dr. Warth.—A mixture of salt with *gur*, bran, oil-cake, and grass. Experiments made by the Superintendent, Experimental Farm, North-Western Provinces and Oudh, failed, edible salt being easily recoverable from the mixture.

(5) Surgeon-Major J. B. Gaffney, Civil Surgeon, Seoni, Central Provinces.—A mixture of salt with "mahwa" refuse from distilleries. Experiments made in accordance with this suggestion by the Assistant Commissioner of the Sambhar Lake Division failed, salt being separated from the mixture by the simple process of recrystallisation.

(6) Mr. H. Murray, of Lahore.—Mr. Murray suggested four alternative methods of preparing cattle fodder—(1) a mixture of hay, wheat, bran, grass, fodder, and gram with caramel, molasses (mixed with green fodder juice), and salt; (2) a mixture of bran, salt, and caramel; (3) a mixture of hay, bran, and various descriptions of fodder with cotton, mustard seed, caramel, molasses, and salt; (4) a mixture of wheat meal, gram, carauel, oil-cake, and salt. Every facility was afforded to Mr. Murray at the Mayo Salt mines, and salt supplied to him free of duty. He made a small quantity only of fodder by way of experiment, but, owing to the cost of conveyance by rail of an article so bulky as this preparation, it was found impossible to place the fodder in the market at a price which would be remunerative and attract purchasers. The experiments have been abandoned.

(7) Mr. R. Romanis, D. Sc., Chemical Examiner, British Burma.—A mixture of salt with sulphide of antimony, sulphur, and charcoal, or lime freshly slaked. This method fulfils the conditions laid down by the Government of India, but competent authorities, who were consulted as to its efficacy, report that fatal results may follow from continued consumption of a

mixture which contains antimony, a cumulative poison.

6. Various experiments were made by district medical officers in Bengal, but none proved successful, the difficulty being to prevent the easy restoration of pure salt from the mixture. The Chemical Examiner to the Government of Bengal is of opinion that a solution of the problem cannot be expected under the conditions laid down, which in their entirety are impracticable. This view is concurred in by the Chemical Examiner to the Government of the Punjab, and in Madras and Bombay it has been held that the problem is insoluble.

7. As already stated in the Resolution of 22nd August, 1883, the Government of India still hopes that a process may be discovered which, if not completely satisfying all the conditions hitherto prescribed, may yet be sufficient for practical purposes. In this view, the Governor-General in Council is prepared to grant a reward not exceeding Rs.5,000 to the inventor or discoverer of a process which will satisfy the main conditions, namely (a) that the cost of the process must be moderate, not exceeding about 4 annas a maund, and (b) the preparation must be such that edible salt cannot be easily extracted from it by any of the ordinary processes in use amongst native salt-workers. If several good processes are suggested the highest reward will be given to the inventor of the process which may appear to Government to be the most satisfactory in all respects, and a smaller proportionate reward will be granted for the next best process. The details of the attempts hitherto made to discover a suitable method of denaturalisation have been printed in the form of a pamphlet, copy of which may be obtained on application by persons who desire to make experiments.—*Madras Times*.

ECONOMIC NATURAL HISTORY OF BURMA.

The Burmese possess a strong liking for animal foods, but being prohibited by their religion from slaughtering domestic animals, they are reduced to seeking their supplies from among the lower orders of the beast world. Foremost in this respect come the various kinds of fish and shell-fish, not only from the sea and the rivers, but from inland pools and flooded low-lands, which become teeming fishponds during the annual inundations.

Commencing with shellfish, the "ladies' slipper" oyster, or jinjouk (*Ostrea cucullata*), is edible and pleasant when gathered in localities freely covered by the waves; but it is unwholesome, if not even poisonous, when taken from spots that are exposed for hours to the sun and air. The creek or rock oyster, or kama (*Ostrea talienwanbensis*), attains nearly a foot in length, and flourishes in compact clusters just below the level of spring tides, on solid ground, whence it is detached by the aid of an iron bar, and forms a wholesome article of food. A smaller kind, called kameh, sometimes promoted to the dignity of a separate species (*O. cirriformis*), is probably only a diminutive variety. A large, handsome mussel, of dark apple-green hue, highly esteemed as food, is apparently *Mytilus smaragdinus*. Similar use is made of several species of *Arca*, which move about in the mud of estuaries, and of some burrowing species of *Venus*.

In the backwaters along the coast, *Hatula diplos* is found in abundance. It is much sought after for food, its capture being effected by thrusting a stick into its hole in the sand. A species of razor shell (*Solen*) lives vertically buried in the sand, and repays the labour entailed in securing it by affording a succulent dish. The boat-spined chiton *nicobaricus* frequents surf-beaten rocks in company with limpets, and is gathered for eating. A like end is served by the snail-like *Phyllanthus embleka*, the "water hen" or yejet (*A. sp. n.*), and the "water monkey" or yemyouk (*Cistopus indicus*). The last-named is very common on the Aracan coast, and is sought for in the pools left by the tide. Its retreat is indicated by a small hole in the sand, surrounded by fragments of crab shell. The bait used is a crushed

crab, secured by a string held in the captor's left hand; when the animal is enticed out to seize the bait, the fisherman stabs him with a bamboo spike held in the right hand. Finally, a kind of squid or cuttlefish (*Argonauta oenoides*) is utilised for food, as some allied species are in the Levant.

Turning to fishes proper, and commencing with the bottom of the scale, the cockup or bekti (*Lates heptadactylus*) holds an important place. The young are distinguished as kakadi, and the adults as kathaboung. They are excellent eating when caught beyond the influence of fresh water, salting well, and contributing some of the best "tamarind fish" of India. The air vessel is thin, but affords good iuglass. The species of *Serranus* yield edible flesh, coarse when large. The name ngatouktu is given to *S. malabaricus* in Aracan. The species of *Ambassis* consist of little bony fishes generally much less than 6 in. long. The ngaziazat (*A. baculus*) and kyounghama (*A. nalu*) are eaten by the poor, and easily dried without salt. *A. Datiooides* (*D. polota*), called ngakya and ngawetna, inhabiting tidal rivers and estuaries, grows 1 ft. long, and is eaten by the poor. The species of *Gerres* are little esteemed, on account of want of flavour and bony character, but are dried and salted in quantity—notably the ngawetsat (*G. filamentosus*). The ngapathwon, or poradah (*Scatophagus argus*), is a foul feeder, but well flavoured when caught at sea. The ngawa, or black rock eel of Madras (*Chrysophrys berda*), grows 30 in. long, and is excellent eating. *Cirrhitus forsteri* is a firm-fleshed wholesome fish, 18 in. long. The ngapongna, or maugoe fish (*Polynemus paradiseus*) grows 10 in. long, and enters the rivers to spawn during the S.-W. monsoon and the cold months. It is highly esteemed as a delicacy, especially the roe. The ngatakhwonka (*Trichurus haumela*) is delicate eating when fresh.

Of the pomfrets, the black, or ngapamoung (*Stromateus niger*), grows 2 ft. long and is excellent food; the white, or ngamu (*S. sinensis*), is less admired; the grey (*S. ciencorus*) attains over 1 ft. in length, and is the most esteemed. A kind of seer fish, called kushat (*Cymbium guttatum*), and another *C. lineolatum* are eaten dried. Light and wholesome food is afforded by the ngarui (*Sillago sihama*) and *S. maculata*, which may be captured at all seasons. The ngathabok (*Gobius giurus*), though possessing an earthy flavour, much esteemed for food, and largely used for stocking ponds. A *Trypaena* (*T. vagina*) grows 9 in. long, and is eaten by the poor. Widely distributed and excellent eating is a kind of spined eel, the ngamywedo (*Rhynchobdella aculeata*). The ngamywedo (*Mastacembalus armatus*) grows 2 ft. long, and is an esteemed table fish; and the ngazyu (*Mugil corsula*), reaching a length of 1½ ft., is similarly admired. A small fish, seldom exceeding 8 in. long, is the ngabyima (*Auaha scandens*), highly esteemed as nourishing food. The ngayoung (*Arius burmaicus*) is inferior as food, but largely used in a salted condition; the same may be said of the ngayeh (*A. jaticus*). A kind of butter fish nganuthan (*Calliichthys macrophthalmus*), is well-flavoured. The ngabat (*Wallago attu*) attains a length of 6 ft., and is good eating. The flesh of the ngagoo (*Clarias magur*) is reckoned highly nourishing. Invigorating properties are ascribed to the flesh of the ngagy (*Saccobranchius fossilis*), and tanks are often stocked with it. The ngayiu (*Cirrhitina mirigala*) grows 3 ft. long, and is an excellent tank fish. The ngathing (*catla buchanani*) attains 6 ft. in length, and is a good fish for stocking tanks, but its flesh becomes coarse when the size exceeds 2 ft.

The ngakhong (*Barbus ebola*) attains a length of 5 in., but its flesh has a bitter flavour; the same remarks apply to the ngakhongma (*B. stigma*). *Chela clupeoides* grows to 6 in., and is good eating. A kind of shad, the ngatimouk, "sable fish" or "hilsa" (*Clupea ilisha*) ascends the rivers to spawn, and when taken full of roe is excellent eating, though rich, but after spawning it is unwholesome. *Monopterus javanicus*, found in fresh and brackish water, is esteemed for food.

Fishing as a recreative sport is, of course, unknown to the Burman; his object is to catch as many fish as possible with the least expenditure of trouble. Hence his methods possess some peculiarities. In the case of air-breathing fishes, of which there are many kinds in Burma, the local fishermen are in the habit of removing the water from a tank, and covering the mud with a cloth for two or three days. At the end of this period the fish have become half suffocated, and their capture at and near the surface of the mud is a matter of the greatest ease. Another favourite practice is the use of narcotic plants to stupefy the fish. With this object a *cul-de-sac* is formed, into which the fish pass, the mouth being closed by a netting of bamboo. When surrounded, the fish are narcotised. For this purpose a herb called *cinbizat* (*Splanthes paniculata*) is commonly used; also a bark named *guu* (unknown to botanists). When the fish within the inclosure have all been taken, the netting is removed, and a new supply allowed to enter. The process of stupefying is repeated at intervals of five or six days. Small fish caught in nets are thrown into boats and kept alive by frequent changes of water till the market is reached; large ones are strung by the gills or lips, and towed to market.

In the moist heat of the Burmese climate, fish becomes tainted very soon after removal from the water. The necessity for utilising the vast quantity of food which would otherwise be sacrificed from this cause has given rise to a peculiar method of preserving fish, for which the country is remarkable. The preparation is termed *ngapee*, and is alluded to in emphatic language by every traveller who has encountered it. There are several kinds, deserving of separate description.

1. *Ngapee-goung*, or "whole *ngapee*"—so called because the fish is prepared in the whole state—is eaten fried, roasted, or in curries. As a rule, little regard is paid to the kind of fish selected, but the *ngagoo* (*Clarias magur*) and *ngakye* (*Callichirus* sp.) are undoubtedly superior. The heads, fins, tails, and entrails are removed as well as the scales. The last-named process is effected by hand when the fish are large; when small, a number of them are tossed into a wooden mortar almost before they are dead, and a bamboo, frayed into a kind of brush at one end, is worked among them. Next they are all well rubbed with salt and packed in bamboo baskets, where they remain to drain under weights during a night. On the morrow they are released, again rubbed with salt, and spread on a mat exposed to the sun. After lying for a night, they are salted down in alternate layers (one of fish and one of salt) in jars, and stored away in a cool place. In course of time a saline liquor collects on the surface of the jars, and undergoes evaporation, by which a layer of salt is left covering the contents. This occupies about a month, by which time the article is ready for sale. Should the supernatant liquor become infested by maggots before desiccation is complete, it is drawn off, and more salt is applied. The brand made at and near *Blooragye*, in the *Angyee* township of the *Rangoon* district, is said to be esteemed all over Burma.

2. A modification of the foregoing kind is that termed *ngathalonkngapee*, from the fact that the *ngathalonk* or *hilsa* (*Clupea ilisha*) is exclusively used in its preparation. Each fish, having been disembowelled, but not deprived of scales, head, tail, or fins, is rubbed with salt, and exposed to the sun for a day; then a number of the salted fish are packed in a mat-floored shed, covered with matting, and pressed by adding weights during three days, when the curing is complete. Much care is taken in the handling.

3. Small fish, especially *Sturioids* (being scaleless), as well as shrimps, are chosen for the manufacture of *toungtha-ngapee* or *dhameg*. These, in an uncured state and without salt, are spread on mats in the sun for two days, by which time decomposition has made some progress. Next they are pounded with salt in wooden mortars, and finally placed in heaps under a roof. Hollow sections of bamboo are stuck into the heaps to afford means of escape for

a saline fishy liquor called *ngapyare*, which is collected in jars for sale as a flavouring for curries. The solid *ngapee* or fish paste is dug out when ripe, and forms a highly odiferous appetiser universally eaten with boiled rice.

4. Another kind, in which shrimps only are admitted, is an equivalent for the *balachong* of the Straits Settlements, termed *ngapee-kgyong* in Aracan, *gwai* in Tamou and *Mergui* and *tsientsa* or "raw-eaten" (because edible in an uncooked state), in Rangoon. Both brown and red shrimps are used in its composition. Small ones are exposed to the sun's rays immediately (usually) they are caught; when half dry, salt is added, and the mass is intimately kneaded by hand thrice daily for three days, with intervals of sunning, till it forms a paste, when it is potted for use. The treatment of large ones differs only in pounding being substituted for the kneading, and that taking place but once a day. More pronounced odour and flavour are secured by postponing the sun-drying process. If this is delayed a short time after the shrimps are caught, the product is termed *rekpyan-ngapee*; if a day elapses before the drying commences, the result will be *rekoopngapee*.

5. The variety known as *kek-ngapee*, made only for export to Rangoon and Maulmain, consists of large shrimps packed in baskets and subjected to pressure for twenty-four hours, then sun-dried for a day, finally pounded with salt, and repacked and pressed. These several forms of preserved fish are the most distinctive article of the Burmese dietary. The chief domestic animals are buffaloes and cattle, used for draught purposes; goats, preferred to sheep, as giving more milk; and poultry. The only mammal forming an object of the chase is an animal about the size of a small dog, called *samney*, or *thamney*, whose fur is very close and long, and highly esteemed. This creature lives in the mountains and is very difficult to capture. Several wild game birds are sought for diligently and esteemed on the table. These include jungle fowls and pheasants of more kinds than one, and a species of water-rail (*Rallus indicus*), called *yachik* or *kyakye*. The *Kakhyens* are expert at trapping forest fowl. One ingenious plan consists in building in a miniature fence with openings holding concealed snares, a dense clump of bamboo being selected for the purpose. The fence is composed of stems of tall jungle grass, and the snares take the form of a pliable bamboo firmly planted in the ground, with a running noose attached to the free end, which is bent down and secured only just tightly enough to prevent it springing up of itself. The birds seek to leave the cover by the openings, and thus ensnare themselves.

Another effective snare, adapted for small birds, is generally planted against the roadside edge of a patch of jungle. It consists of a wooden perch attached to a long bamboo and smeared with the juice of a local species of ivy, representing our own birdlime. Corals are stretched across the prongs of the perch, baited with winged ants, so fastened as not to impede the use of their wings, the continual flutter of which serves to attract the birds, who alight on the lined perches in order to feast on the insects, and are unable to escape.

The flesh of the python is much esteemed by the Karens for food, and the gall bladder for medicine. All lizards of the *Varanide* family are highly valued for food, and sought for in hollow trees by the aid of dogs. The Karens steal up the trees with a noose at the end of a bamboo, and snare them while leaping for the water, or catch them in a boat beneath the tree. The head is deemed venomous; but the flesh of the other parts is preferred to fowls. If not needed for immediate consumption, the captive is rendered helpless by breaking some of the toes, and knotting the sinews. The eggs are equally esteemed. The *padat* (*Liolepis guttatus*) is herbivorous, and in high favour as a viand. The flesh of the *miyoung* (*Urocodilus porosus*), which is very common and reaches 30 ft. in length, is in great request for food. A kind of turtle (*Morenia ocellata*) during the inundation

becomes scattered about the country, and on the subsidence of the floods, and during the grass-burning in April, many are either caught alive, or their scorched bodies are found afterwards, and greatly relished by the people. The flesh of the soft turtles is generally eaten by the Burmese, and may be good, though the animals are carnivorous. The *leikkyawon* (*Chelonia virgata*) is algivorous, and is the "edible turtle" of India. The boatmen on the rivers make it a practice, when mooring at a spot, to hunt in the neighbouring thickets for lizards, chameleons, snakes, and similar reptiles, with which they flavour the invariable dish of boiled rice. Even lizards found dead are esteemed a great delicacy when cooked.

The Burmese exhibit decided peculiarities in their choice of edibles. There is a small kind of beetle which fabricates balls of clay and dung as a nidus for its progeny, about the same size as tennis balls, and buries them in ground where cattle are stalled. These balls are eagerly sought after by the Burmese for the sake of the dainty grub contained within, which they devour with uncommon relish.

Another curiosity of the Burman larler is a species of ant, probably *Formica smaragdina*, which exist in large numbers, and constructs a nest of united leaves placed up in trees. The Karens regard these ants as quite a delicacy, and eat them in curries, to which their acid flavour gives a certain piquancy.

The domestication of bees receives its attention, but wild honey is gathered in large quantities by ascending trees to the nests at night, and smoking out the owners.

The consumption of thousands of salted hill rats every year by the Karens is, perhaps, due less to a natural taste for rat-flesh than the force of circumstances, for these rodents swarm in such multitudes at some seasons that the Karen must eat the rat, or the rat will eat him.—C. G. W. L.—*Field*.

A PLANT RICH IN TANNIN.

In the August number of the *Indian Agricultural Gazette* there is an article recommending the cultivation in India of the Australian Wattle, as it is said to yield "the best material in the world for the purpose of the tanner. There is on this side of India a plant which, in the estimation of the Indian tanner here, is superior in tanning properties to all plants used in India for the purpose. In districts where Marathi is the Vernacular, the native name for the plant is Tarwad. In districts where Canarese is spoken it is called Honawrigida or simply Awrigida. Its botanical name is *Cassia Auriculata*.*

Leather cured by the bark of this plant turns out softer, is preserved better and lasts longer than that cured by any other material, at any rate this has been the invariable reply to oft repeated enquiries I have made on this point. In the Bombay Presidency, the habitat of the plant is chiefly the open treeless districts. It grows there wild in every variety of soil, from the richest to the poorest, and in any situation, hill, dale or plain. It is a hardy shrub of quick growth, and if cultivated to the extent of simply giving up space to it, probably neither European planter nor Indian ryot need wait for the introduction into India of the Australian Wattles for a good investment in a tannin producing plant. Whether the cultivation of this plant would be a paying investment or not might be tried by the government, through the Forest Department. The cheapest way to do this would be to set apart a few acres in waste ground, in the open country for the growth of this shrub alone, all other shrubs in these areas being destroyed. Self-sowing would do the rest in multiplying the plants. After three years the shrubs would probably be in sufficient numbers and of growth sufficiently large to yield enough bark to place in the local markets for an

* It is pretty common in Ceylon, but has never, we believe, been cultivated. A trial should be made.—Eo.

experimental sale. The plants would not be killed in the cutting of the twigs for barking, such pruning would probably have the effect of increasing the number of shoots in each plant for the next season's crop.—W. S. PRICE, Asst. Settlement Officer, Revenue Survey, S. M. Country, Dharwar.—*Indian Agricultural Gazette*.

BURMESE RICE MEASURES AND RICE STATISTICS.

[There is much interesting information in this article, and amongst other items the rate of production in Burma, viz. 1,600 lb. of paddy per acre, say about 1,000 lb. of clean rice.—Ed.]

The necessity for compulsory action on the part of the executive for unifying the various standards used in Burma in connection with the Trade in Rice, will be acknowledged when the inconvenience occasioned by the great diversity that now prevails is fully explained. There are no legal weights and measures in the country other than those of India, which have not been adopted and are not recognized as current anywhere in the Province. Rice being the staple of Burma, the attention of the local authorities would appear to have been first directed towards regulating the capacity of the "basket" which here served the purposes of the English bushel in the grain market. Rules were prescribed fixing the size of this measure, which was expected to secure uniformity from Prome to Tavoy and Akayab to Shwegun. These regulations were, however, more honored in the breach than the observance, and the outcome is confusion worse confounded. The "basket" varies in different places, and different baskets obtain in the same place at the same time. The last state in this respect is, in fact, worse than the first. But so long as the inconvenience did not affect Government interests, the necessity for legislative action did not appear imperative. But now that the State Railways find the difficulty of the difference in standards in their Traffic working, inquiries are instituted with view of definite and final settlement. The importance of the vast interests involved may be inferred from the fact that there are now over 3½ millions of acres under rice in the Province, and that this paddy-land is more than 88 per cent of the cultivated revenue paying area, which is steadily increasing at the rate of 100,000 acres per annum. The total yield of these rice lands of British Burma is, according to the Administration Report for 1883-84, in an average year, about 2,615,930 tons of paddy, equal to 1,935,788 tons of cargo-rice. The total requirements of the Province for home consumption having been estimated at 947,000 tons leave a balance of 988,000 tons available for export. It may, therefore, be safely laid down as the rule for ordinary years, that, a-half of the whole crop is the exportable surplus. But, as under exceptional conditions, the export of rice has been known to reach nearly 1,100,000 tons in a single year—1882, the necessity of controlling such a large trade by a commercial basis or fixed unit of measure will be now obvious, particularly as there is a constant and preferential demand for Burman rice in the markets of the world. British Burma is practically able to export as much rice as all the other rice exporting countries in the East together, and it is worthy of note that Saigon and Bangkok rice fetches in Europe 25 per cent less than Burma rice. Furthermore, comparatively very little of the Bengal, Saigon, and Bangkok rice goes to Europe, while nearly all, certainly upwards of three-fourths, of the Burman rice is shipped to European markets. A surprising feature in these comparisons is the fact that the rice exports of Bengal show a tendency to decrease rather than increase. Saigon has only since 1881 commenced to export rice to Europe, which accounts for France

taking only 1,000 tons from Burma in that year. No Burman rice is exported to either Australia or New Zealand, possibly due to the unique import duty of 3*d.* per pound levied with the object of stopping Chinese immigration. It is satisfactory to learn that although the export duty of 4*d.* per maund is equal to 10½ per cent, add 6½ per cent to the price of milled cargo-rice, still the rice merchants of Burma are not pressing for the abolition of the duty. The average yield of rice in the husk (paddy) is computed at 32 baskets (1,600 lb.) per acre; and as the selling price of paddy in the villages last season averaged about 7s. per hundred baskets, while the Government demand for land-revenue was under 4s. per acre, the difference goes to show a rather handsome margin of profit to the cultivator. Hence, the people of Burma are, as a rule, much better off than those of India. The extent of these transactions in the chief staple of the Province coupled with the obvious disadvantages of having different rice measures in use, makes it desirable that the vexed question of the Burmese rice-basket should be disposed of at once and for all.—*Indian Agricultural Gazette.*

SWEET POTATO FLOUR.—The Americans assert that the flour made from sweet potatoes is sure to come largely into use, as it is most economical, requiring hardly any sugar to be mixed with it.—*Indian Agricultural Gazette.*

THE RICE TRADE of Bassein is expanding considerably. The exports for the current year already reach 170,000 tons, and are expected to reach 200,000 as paddy is still coming in large quantities. The season has been the best ever known there.—*Indian Agricultural Gazette.*

THE GOVERNMENT IRON WORKS near Bankur appear to have done a large trade in the year 1884-85, as the sales of iron rose from 122,000 to 498,000 tons. Both coal and iron ore are plentiful near the works, and a good supply of limestone has now been secured by paying a royalty to the owner of the land. On the other hand, the coal trade fell off considerably the exports from Raniganj being only 635,921 tons as compared with 796,937 tons in the previous year. Messrs. Burn and Company's pottery works at Raniganj continue to flourish, and they give employment to 700 men a day, whilst the value of the last year's output is estimated at £215,000.—*Indian Agricultural Gazette.* [Who will start superior pottery works in Ceylon? We have fine clays in great abundance.—Ed.]

INDIAN CATTLE AND SHEEP.—Messrs. Higginbotham & Co. of Madras send us a copy of the second edition of "A Manual of Indian Cattle and Sheep, their Breeds, Management, and Diseases," by Dr. John Shortt. The first edition of this work is so well-known that we need only quote the preface of the new edition to show what are its special features:—

A second edition of the Cattle Manual of India has been found necessary to follow the first edition which was published several years ago, and worked its way slowly but surely to public favour. Its success will I hope, with its faults, be more universally and rapidly extended to the present volume. As space forbids an exhaustive treatment of the subjects brought to notice in the work, it has been my endeavour to be not only accurate and useful, but as brief as possible, and to make it a trustworthy companion on the subject of which it treats. The whole work has been carefully revised, with a few statements here and there struck out, and some forty pages of fresh matter have been added. I have stated nothing that my own personal experience has not verified during a long series of years of cattle-practice in India. At the end of the book are a list of English and Tamil names of cattle diseases and a memo on fodder grasses, giving the Latin, English and Tamil names, and remarks on them. All owners of cattle in Ceylon should have a copy of this excellent work.

ATLAS OF PLANT DISEASES.—Dr. O. E. Zimmermann is publishing under the title of *Atlas der Pflanzenkrankheiten*, a series of photographic illustrations representing the microscopic appearances of the fungi affecting plants. An explanatory text accompanies the plates. The photographs are direct from the microscope, and are mostly very clear. It would be a convenience if the divisions of the micrometer scale were in future photographed with the objects. The work may be had of Messrs. Williams & Norgate.—*Gardener's Chronicle.*

CEYLON CINNAMON.—Herr Hilger reports (*Archiv*, Nov. 1, p. 826) that having received from Holland a large number of commercial varieties of Ceylon cinnamon, derived from different districts with different soils, he has had some of them estimated as to ash. Five samples of entire quills gave the following results: (1) 4.5 per cent of ash, of which 53 per cent was soluble; (2) 4.8 per cent, with 72.3 per cent soluble; (3) 3.9 per cent, with 88.1 per cent soluble; (4) 4.3 per cent with 61.7 per cent soluble; (5) 3.4 per cent of ash.—*Pharmaceutical Journal.*

LINNEAN SOCIETY, Dec. 3rd.—A paper was read "On *Castilleja elastica*, Cerv., and some Allied Plants," by Sir J. D. Hooker. The author states that under the name *Castilleja elastica* probably more than one species exist. The true plant first described by Cervantes has flowered and fruited in Ceylon; it is now fully described and figured with remarks on allied plants also yielding Panama india-rubber. Seeds collected by Mr. Cross in 1875 failed to germinate, but cuttings were also introduced, and from them plants were distributed to various colonies. Some difficulty is found in propagating by cuttings, as the side branches which are deciduous will not strike root, but seedlings have now been raised at Peradeniya, and the culture is, therefore, assured. An account of the introduction of the plant is appended.—*Athenaeum.*

MORE CINCHONA BUYERS ON THE COLOMBO MARKET.—The small number of buyers of cinchona bark on the local market has often been a matter for regret amongst sellers. We are therefore glad to inform our readers, most of whom are interested as planters of cinchona bark, that Mr. Christian Behringer, who recently arrived from Europe, has taken up his residence in Colombo, and will commence buying cinchona bark for direct dispatch to two or three quinine factories in America. This should help to strengthen the local market, and in any case is pretty sure to increase competition. Mr. Christian Behringer is, we believe, a younger brother of Mr. Alexander Behringer, the head of the Milan factory, and the prime mover in the once-powerful quinine Syndicate. On the failure of the Milan factory, both Messrs. Alex. and Christian Behringer, whose experiences of the intricacies of the cinchona bark market and the actual manufacture of quinine is not surpassed by that of anyone else, left for America and have since, it is believed, become connected with certain houses there glad to avail themselves of their services. The proprietors of the Mannheim factory in Baden, Messrs. Behringer & Co., are, we believe, cousins of Messrs. Alex. and Christian Behringer, whilst the firm in Stuttgart are also relations. The name is redolent of quinine, and we hope that the advent of Mr. Behringer in our midst and his purchases for the American market will be satisfactory alike to himself and to sellers of bark on the spot. We believe this is not his first visit to Ceylon. He was here some three years ago on behalf of the Milan firm, but made no stay. One result of his purchases will be that all bark purchased by him will most probably be shipped direct to America, relieving the home market by that amount. Last shipping season, from the 1st October 1884, to the 30th September, 1885, only 102,000 lb. were sent from this direct to America. We expect this will be much increased during the current season with mutual benefit to buyers and planters.—*Local "Times."*

THE PACKING OF CEYLON CINCHONA BARK.

4th January 1886.

I hear that much dissatisfaction has been expressed by the London bark buyers owing to the bad condition in which the cinchona bales have lately been arriving. A circular has been issued signed by all the manufacturers or their representatives, wherein they offer two suggestions to remedy the evil complained of:—

(a) That no bale of bark should weigh over 250 lb. nett.

(b) That stout gunny cloth, not thin Hessian canvas, should be used in packing.

The circular goes on to say that "the large and unwieldy bales so often shipped from Ceylon are in dock more or less unmanageable; to draw fair samples from such packages is most difficult and the wear and tear is naturally excessive. The thin Hessian canvas so often used by shippers gives way directly the goods are handled, and is often the direct cause of loss to the buyers."

PEPPERCORN.

AN ASSAM TEA PLANTER'S OPINION OF TEA IN CEYLON; AND A REPLY.

An Aberdonian wrote to an Assam planter asking his advice as to tea planting in Ceylon, and for some practical hints on the subject of what soil was most suitable for the plant. His answer was forwarded to me to reply to, which I did to the best of my ability, and the following I copy from his letter, as I think you might wish to print the remarks, and shall be glad to see what footnotes will be attached to them by the Editor. You will have no difficulty in discovering a dislike to the little island of Ceylon underlying the whole of the remarks, but I have got accustomed to that tone when Assam planters are questioned on the subject of Ceylon prospects.

EX K. C. B.

"Soil for tea must be porous, imbibing and parting with water freely. Stiff soils of every kind are to be avoided.

"No one believes in the permanence of stiff soil.

"Tea thrives best in light soils for the simple reason that the ends of the feeding roots are very tender and do not easily penetrate any other.

"Clay when dry is too hard for these root points, and when wet is too cold and too sodden for tea to thrive in it.

"In Assam we find that to grow tea thoroughly pays us better than to experiment with coffee and cinchona, but one conclusion I come to is, that either of them is a far more satisfactory plant to deal with than the tea plant.

"The tea plant has no tap-root. Tea hates wet feet, and as long as the roots are sodden will not yield any quantity of leaf.

"With reference to Ceylon the inference one is intended to draw is that tea will grow anywhere, and in any soil and will do anything so long as it is only planted in Ceylon. Come on boys! plant it in Ceylon! you're quite safe there!!! is the cry, and it is just the echo of the reckless trumpet-blowing that has already lured many an unwary one, and I am astonished to find a good many astute Aberdonians to boot.

"The *Indian Planter's Gazette* continually sounds a warning note concerning the rash way, in which all sorts of land and soils are being rushed into tea in Ceylon.

"The quantity made in Ceylon this year is nothing like up to the amount which we were jubilantly assured it would be in 1885.

"Ceylon crops are obtained artificially by manure, whereas in Assam good gardens give as large a

yield without any addition to the natural virtue of the soil. Climate, of course, also helps us. Already we hear of acres of tea being cut out and burnt owing to blight and disease, a disaster I never heard of in Assam.

"Mariawatte, the sweet Ceylon garden, about which such jubilant shouts were raised, is in no better a plight than its neighbours. The last number of the *Indian Planter's Gazette* tells how the yield of that garden has come down.

"This place has exceptional facilities for manure, being right beside a village. Its drop from 1,100 lb. per acre to 800 lb. has made the shouting gentlemen 'sit up.'

"This is only one notable case, and I hope, from all I have written, if you are thinking of investing in tea planting in Ceylon, that you will not do so: keep out of it, there's death in the pot."

But for the presumption that you know your correspondent and are satisfied of his *bona fides*, I should pronounce the letter attributed to an Assam planter a hoax; so crass is the ignorance displayed and so malevolent is the animus. Pitiful jealousy and petty spite breathe in every line, and that might pass as natural to the writer; but that any man should profess to be an authority on tea, who knows so little of the plant as deliberately to state that it "has no tap-root," indicates impudence in proportion to ignorance. If there is one cultivated plant more than another distinguished for its long and powerfully piercing tap root, it is the tea plant. On the side of the cart-road which passes through a portion of the estate whence I now write, an exposed tap-root of one of our seed-bearing tea bushes can be traced down to 8 feet from the surface, and on the sides of our paths, uncovered tap-roots measuring 5 feet and thereabouts are quite common. And not only so, but we have been much interested in watching the effects of the instinct which has led some of those partially exposed tap-roots to send out feeding rootlets at a depth of two and even three feet below the horizontal surface. I have repeatedly, in writing from this estate, mentioned the fact, that, in consequence of the piercing and opening up of stiff clayey subsoils by the stout, strong tap-roots of tea plants, cinchonas have flourished on localities where previously the fever plants had died out, when not associated with tea. In my notes, too, on the lowcountry tea districts of Ceylon, I mentioned the fact that a planter at Awisawella had sent to a mercantile house in Colombo a block of rocky caobok (laterite), with the tap-root of a tea plant which had managed to pierce a substance so intractable. The tendency of even tea seedlings to produce inordinately long tap-roots is so well-known to tea planters, and is a source of such inconvenience in "planting out," that great care is enjoined that in the formation of nursery beds for tea seed the ground should not be dug too deep. With every precaution taken, portions of the long tap-roots have generally to be cut away. That the man, who, professing to be a tea-planter, does not know, or pretends not to know that the tea plant has a tap-root, should be ignorant of the distinction between clay and clayey soil, or should pretend to confound things so different, is easily explicable. Who ever asserted that tea would grow in pure clay, or that tea, or any save aquatic and semi-aquatic plants, would grow in positions where they would have permanently "wet feet"? Much of the soil in the mountain parts of Ceylon is argillaceous, clayey; but that is a very different thing from saying that the soil is entirely or even preponderately clay, such as exists in swampy local-

ite; and from which excellent bricks and tiles can be made. There is just enough of clay in our Ceylon soils to render them so tenacious, that they are not washed away from steep hillsides, as the, no doubt, excellent but over-fine alluvial soils of Assam would be, if cultivated and exposed. This quality of tenacity or stiffness, in spite of the very original dictum of this wonderful Assam authority, gives a lasting quality to our soil. The conclusions established by the series of analyses and the careful observations made by the accomplished agricultural chemist, Mr. John Hughes, were that the soils of our young districts were very good in quality, although lime and forking were recommended to improve the mechanical condition of the ground, somewhat stiff for coffee and especially for cinchona. The proportions of alumina and iron, in a considerable number of cases, indicated a soil better for tea than coffee, and experience has proved that what with the piercing and opening-up power of the long stout tap-roots of the plant, tillage by means of the hoe and especially three-pronged, fork is amply sufficient to bring the soil into good mechanical condition, irrespective of lime, which, in any appreciable quantity, does not appear to be desiderated in tea cultivation. The truth is, that after the lapse of nearly half-a-century of experience with coffee and other products, we in Ceylon have made the discovery that our soil and climate are eminently suitable for the cultivation of tea, and our rapid success with the new culture, and the favorable verdict on the quality of our produce delivered by Mincing Lane and tea drinkers in Britain, account—of that there can be no doubt—for the miserable spirit of jealousy, spite and detraction which actuated the opinion from Assam sent to an Aberdonian. As to the yield of Mariawatte estate, no secret was ever made of the fact that, the exceptional yield from that estate was obtained by means of manure. Mr. Rutherford, too, who is, I believe, interested in that property, has estimated the average yield for Ceylon not at the exceptional figures of Mariawatte, but at the modest rate of 400 lb. per acre per annum. With so many very old and worn coffee estates converted into tea estates, and from which 300 lb. per acre will be a fair yield to expect, the average may possibly be lowered to Mr. Rutherford's rate; but there can be no question that for estates opened on virgin forest we may safely estimate 500 per acre on high estates and 700 on low, or a general average of 600 lb. per acre, without manure, against little more than half that figure on Assam estates all opened on virgin land. Then as to salubrity of climate, of which the Assam man carefully avoids mention, there is no possible comparison. Over the vast proportion of the Ceylon estates, the climate is all that could be desired. The very reverse is the case in Assam, many portions of which are pestiferous to such an extent that an Assam planter who visited Ceylon said to us that he would gladly exchange his well-salaried position in India, for half the money advantages in Ceylon. He stated, in order to illustrate the nature of the climate in Assam, that he had been compelled to send his wife and children to England, because it often happened that when he returned from a round of the property on which he resided he found his whole family prostrate with fever; his wife being the only survivor of four English ladies who a few years previously had come out to get married to Assam tea planters. Surely health and life are blessings worth preserving? It is quite news to us that tea blights are so bad in Ceylon. And then, as to labour supply, one of our late visitors to the contrary not-

withstanding, we are immensely better off than our Indian competitors, all of whom we should be glad to hail as friends, if they would only act and speak as such. In regard to communications, there can be no more comparison than in regard to climate. Besides excellent roads, grand lines of railway now run through our principal tea districts, while Assam is mainly dependent on very long river transit occupying weeks for our hours. But we have no wish to depreciate Assam, the premier Indian tea district, to the hard-won experience of whose planters we in Ceylon owe so much. Of them, we feel persuaded, the person who has compelled us to write so strongly on the defensive is no fair or worthy specimen; but a black sheep, such as is found in all large flocks. We wish our competitors in Assam and elsewhere in India well, and we trust the vast majority of them reciprocate this feeling. There is, and there will be for a long time to come, room for all of us and for all the tea, only differing in degrees of excellence, which we can supply for the benefit of the human race. Assam tea is distinguished for strength: ours for delicacy.

TEA MACHINERY IN CEYLON.

We urged on Mr. Jackson, as a tea planter and machinist of considerable and varied experience in Northern India before ever he saw Ceylon, that before leaving us this time he should prepare some useful hints for the Ceylon tea planters based on what he had seen of local circumstances and requirements. We are glad to find that Mr. Jackson has not gone away without writing the "few notes" required, and with the permission of his agents and publishers, Messrs. John Walker & Co., we now reprint from a handy little pamphlet which this firm is issuing to its constituents, "Mr. Jackson's Address to the Tea Planters of Ceylon." It will be read with interest and no doubt duly considered:—

TO THE TEA PLANTERS OF CEYLON.

GENTLEMEN,—I have been asked by many interested in tea if I could not make a few general suggestions that might be of use to them at this, practically the commencement of the great new Tea Industry of Ceylon, and having been made so welcome during my first visit amongst you, I have now compiled a few notes before leaving the island, and in doing so have confined myself to factory buildings and the manipulation of the leaf.

There is no doubt that the time is coming when there will be keen competition in the production of tea, and I daresay at this juncture you might readily take a wrinkle from the present state of matters in Great Britain, where sharp competition in nearly every manufacturing industry has of late years led to the pulling down of the old irregular buildings, these being replaced by well-thought out and commodious work-shops, adapted to receive every modern labor-saving machine procurable, the arrangement of which is so complete, that the article to be dealt with is received raw at one end of the factory, and leaves it ready for the market at the other, with the least possible handling during the manipulation, and everything is done at any time after it has entered the factory till it passes from it, and it is these well-arranged British establishments that now so successfully compete with, and keep their own against, all other nations.

The same thing in my opinion strongly applies to your now proposed factories in Ceylon for making tea. In scheming out these it should be clearly borne in mind that the arrangement be so complete that the tea leaves will not have to traverse the same space twice during the process of manipulation, for twice

over means twice the expense, leads to confusion, has a bad effect on the tea house staff, a deleterious effect on the tea, and in all probability a nasty effect on the profits at the end of the year.

The tea leaf should be received in the green state at the end of the factory, be weighed, passed on to the withering-room, then to the rollers, and thence to the driers, and so on till it is packed and ready for dispatch. This may seem a simple suggestion, but it is one that is often neglected till too late for remedy.

My opinion of a tea factory is that it should, if possible, be built in three wings:—One main building in which the machinery should be arranged; then one wing passing out at right angles to the main structure at one end for withering, and at the other end of the main structure another wing for packing and sorting.

By such an arrangement, a nice compound is formed, hemmed in on the three sides by the buildings, and on the fourth by a railing, and such compound will be found most useful for a variety of purposes, such as loading and unloading carts, spreading leaf in the sun, &c.

If the square cannot be formed, then one straight building is preferable to a number of detached small ones.

Verandahs to Tea factory buildings are a mistake. They exclude the light from the ground floor, and they are an expensive kind of roof for the space they cover.

Light is essential in a Tea factory, and I would advise, where practicable, the walls of the buildings should be entirely composed of glass between the columns.

A portion of the glass between each column should be fitted in sliding or hinged frames to provide openings when desired, particularly in the withering-rooms.

Buildings entirely composed of iron are in my opinion preferable to the composite ones of masonry and woodwork.

In selecting a site for the Tea factory, the planter will be guided by circumstances.

If water is to be used to give the motive power, then the most convenient position for the application of this should be sought for.

If steam power is to be employed then it will be desirable to have some forest land not far off.

The main building should be the first erected, and be large enough to contain sufficient machinery to eventually manufacture the whole crop of the estate when in full bearing, but in the meantime it would probably be sufficient to make all the Tea for the first few years, and as the yield increases, first one wing, and then another, could be added as required, thus completing the factory square.

I am of opinion that two-storied buildings throughout will be the best, and with iron columns, all fixings necessary for the line shaft, &c., will be easily attached.

A good many old coffee stores can be readily converted into good Tea factories by partially pulling down the walls, and introducing large windows in them, and where practicable the large masonry pillars usually found inside the coffee stores should be removed, and channel iron or old rails substituted as columns.

Where the woodwork of the coffee stores is materially decayed, the floors low, a lot of masonry to remove, and the position of the store not very central, or suitable, it should at once be abandoned, as nothing will be more disheartening than to find, after having spent a lot of money on the buildings, that they are at the best only second-rate, and probably incur a daily loss to the estate on account of not being central.

Old buildings like these might be used as withering-houses, or for cattle-liebs or other purposes, but unless they have special advantages for conversion into Tea stores, they had better be left alone.

It will be found a pleasure to manufacture Tea in a fine large commodious factory where no confusion can exist, but where the buildings are small, irregular, and the machinery crammed in hither and thither just where it can be got, a thoroughly effective and remunerative system can never be introduced, and the whole thing will remain a muddle to the end.

A good deal has been said for and against the use of Turbines as motors for driving Tea machinery.

I am decidedly of opinion, when properly made, they will be found superior to any description of water-wheel. Unfortunately, however, planters hitherto have but rarely thought of stating in their indentments to manufacturers, that the turbine they require must be made to run almost daily all the year round, and I have known of planters in India being supplied with a flimsy turbine made to drive a British farmers' barn thrashing machine, running perhaps once in three weeks, and for six months in the year. Could it be wonderful and, therefore, that such turbines come to grief when applied to drive heavy Tea machinery?

A Turbine, if constructed in a manner similar to what is now being made for driving dynamos for electric lighting, will undoubtedly give the best results.

When water is admitted to a Turbine, it at once develops a corresponding amount of power, and it can be just as quickly stopped, and being a quick-speed motor, any variation of the pressure applied to the leaf being rolled does not materially effect its speed.

This is not the case with the overshot water-wheel, which must have time to fill or empty its buckets before the speed is increased or diminished.

Where only one Roller is driven by the overshot wheel, the attendant can, by careful watching, get along fairly well with it, particularly if the lay shaft is fitted with a fly-wheel, but where two or more intermittent feeding and discharging Rollers are to be driven by such a wheel, there will be very serious risk of accident on account of such wheel not being under prompt control, but apart from this altogether comes the question of quantity of water, fall, and first cost, all of which will be found in favour of the Turbine.

The power can be conveyed from the Turbine to the machines entirely by belting, and the planter will at once see the great value of this, insofar that any coolie could mend a belt in a few minutes, whereas in the overshot wheel a coolie can neither tell when a tooth will break out of the segment spur-wheel or pinion, nor can he put such a tooth back again when it does break out.

Yet one more point in favour of the Turbine. A "governor" could be very readily applied to it to control the speed if deemed desirable.

I have been frequently asked whether the method of transmitting power for a considerable distance by steel wire rope is a good or desirable one.

What I advise is, if possible, get the Turbine in the factory, but if this is not possible, and a suitable fall or site for the Turbine within 500 yards, then use the steel wire rope rather than put down a steam engine.

A steel wire rope, say five-eighths of an inch diameter, will transmit about 30 horse-power if driven at the rate of one mile a minute, and such rope would probably wear out every second year. They, however, are not very expensive to replace.

With regard to the steam engine, I will only remark that I consider the horizontal fixed type, detached from the boiler, with the locomotive multi-tubular boiler, the best suited for Tea factories. The boiler should be two or three horse-power in excess of the engine, and have a special large fire-box for burning wood as fuel. Where a good efficient water heater is provided, compound engines effect very little saving under 16 horse-power.

These locomotive boilers can now be had in several pieces for easy transport to hilly estates.

There appears to be an erroneous impression abroad that a water-wheel and engine cannot be made to give off their power in unison with each other on to the same shaft.

Suppose, that I had a Tea estate on which I would be quite certain of sufficient water for three parts of the year to do all my work. I would at once put down a turbine and an engine as well (such engines being able for the work alone), and I would so arrange these by means of belting and pulleys, that they would be both connected to the main line shaft. Then, when water began to get short, I would light the fire in the boiler, then turn on all the available water on the turbine, and make up the balance of the power required with the steam engine.

I find a number of gardens will have to take this in consideration, and I advise, where fuel is scarce and expensive, even if there is sufficient water for half the year, that a combination of the turbine and engines to work together is desirable.

There are only one or two points I will touch on with regard to the management of Tea machinery, and the first is cleanliness.

I would suggest to those who have not done it, to try the effect of a little soft soap and water on the Tea Rollers and other machinery at the end of the day's work.

Every drop of waste oil, grease, dirt, and tea juice should be daily washed off the machines, and if this be insisted on, it will be found no task after a time. It will have a wonderful effect on the durability of the machine, and will stimulate a desire on the part of the Tea-house staff to keep everything else clean and tidy to be in keeping with the machinery.

It will also be found of considerable advantage to have the machines painted annually.

With regard to the lubricants that are now being used for the machines, there is perhaps nothing as a more important effect on their successful running and durability. Still it is one of those things very apt to be neglected, for, as a rule, if the coolie has any kind of oil to pour on the machines he is quite satisfied, and, if heated bearings result, of course construction of the machine is blamed. Castor oil, if it is properly filtered, and the oil-holes of the machine daily cleaned out, answers fairly well, but it is a dirty sticky lubricant for Tea machinery, is often mixed with sand and grit, and has frequently led to accidents and stoppages.

The best lubricant I know of at present is Englebert's, which is used most extensively in Great Britain, is not expensive, does not clog or get sticky, the waste oil is easily cleaned away, and it has given the greatest satisfaction in India, where it is now extensively used on our machinery.

Messrs. John Walker and Co. keep a stock of it in Ceylon, and any planter could readily satisfy himself of what I say by giving it a fair trial.

Filtering.—I hope, all being well, to carry out some experiments next summer, with a view of trying to bring this under control artificially, and I trust that sooner or later this difficult question will be solved, as it is the only thing wanted to enable the Tea grower to carry through the whole process of Tea manipulation independent of the elements.

Rolling.—I am very gratified to know that our Rollers have done, and are doing, such good work in Ceylon, and nothing will be wanting on my part to add little improvements to them from time to time as may seem desirable, the latest being the application of a granite cap, with a brass-faced lower rolling table, both of which give every satisfaction in working, and it can only be a question of time when they will be generally adopted.

Most planters know what a close-twisted leaf is, but I am not sure that all know what constitutes a properly rolled one, and I would ask those who have not done it, to take a large leaf from the cup after infusion, unfold it, and hold it up, so that it will be transparent in the light. If it has a cloudy appearance of green and dirty copper color, then the cells of the green portions have not been sufficiently

broken, and it is only the copper-colored portions of the leaf that have properly infused, consequently harder or more severe rolling is necessary, notwithstanding the leaf may have appeared closely twisted up when it left the roller, but on the other hand if the leaf has the dirty copper color transparency all over, then the rolling has been quite sufficient.

Fermenting is done in so many ways, and under conditions so widely different, that it is difficult to say which is the best.

I believe, however, that a very good plan would be to make a number of light wooden boxes about two feet six inches square, say two-and-a-half inches deep, each box being provided with two handles and a movable light wooden cover or lid.

Fill these boxes with the leaf to ferment, and place them in a rack 3 or 4 above each other, carrying them away to the Drier as the leaf is ready. Such a plan would save much space and handling on tables.

Drying.—In some recent comments under this head, I believe several important points have been overlooked.

In my opinion, when the fermented leaf is put in the machine to dry, it ought not to be taken from such machine again till it is dry, and the oftener it is removed from such machine, and exposed to the action of the cold atmosphere during the process of drying, so much less brisk will the tea be. I have proved that this is so beyond doubt, and I think the generality of planters will bear me out, that the No. 1 Sirocco gives a better liquoring tea than the Sirocco of later design, where the leaf is much more exposed to the cold air, showing clearly that my theory of having the leaf completely enclosed in the hot-air chamber for desiccation is the correct one.

It has been said there is some objection to our Victoria and Venetian Driers requiring motive power to work them, but if such motive power saves labor, produces automatic action in the machine, and a better liquoring tea, it will hold its own against all argument. The tea is not only turned over inside the machine, thus obviating exposure to the atmosphere, but a large number of coolies' work is saved, and there is absolute uniformity in drying, which cannot be obtained when the hands of a number of coolies have to deal with it.

Then it has been said that motive-power Driers are further objectionable, particularly where a steam engine is used, but here again I say the objection will be overruled when it is borne in mind that there will be enough sufficient steam left in the boiler when the rolling is done to complete the drying, as the power required for these machines is only fractional.

It has further been said that a number of small Driers are preferable to one large one for fear of breakdown.

This is, in my opinion, a myth, as the same argument would apply with more force to Rolling machines, and yet one large Roller is preferred to a lot of small ones. Our motive-power Driers are made in three sizes.

Sifting.—If Tea were only a granular substance like sand or grain this would not long remain a vexed question.

It has been stated that our continuous action Eureka sifter makes the tea grey during its passage through it. This is entirely under control by simply reducing the height of the lower end of the machine, so that the tea will travel over quicker, as it simply comes to the same thing whether the tea travels slowly over a limited distance or quickly over a longer. Tea will become quite grey in a hand sieve if shaken about long enough in it. I hope, however the day is not far distant when the bulk will be equalized before sorting, when a much less sifting surface will answer.

Belting.—I am of opinion that indiarubber bands are best suited for Ceylon.

I have lately seen several five-ply straps that were sent out with our first rollers some years ago, and they are practically as good as new, the reason in my opinion being due in a great measure to the use of Harris's patent clip for the joint.

In nearly all cases it is the jointing of the belts that gives trouble.

Coolies are often careless and punch holes in a very irregular way to form a joint, and it is this irregular cutting up of the straps that usually brings them to grief.

Another fruitful cause of the destruction of belts is too short centres between the pulleys over which they run.

In designing permanent factories it should be arranged that the driving pulleys of our Rollers shall be fifteen to twenty feet away from the line shaft, and for a main driving belt, twenty-five to thirty feet centres will be found about right.

Tools.—As Tea making depends much more on the efficient working of the machinery than coffee did, I would advise every estate to become possessor of a complete set of mechanic's tools, which will be found invaluable at times.

Fire.—I have been frequently asked what is the best precaution to be taken against the outbreak of fire, or rather, in event of it, what is the best extinguisher, and, having had some experience in this way just before leaving England, I am able to say that a firm there, having suffered considerably, made every enquiry into the use of Fire Engines as extinguishers, including manual pumps, and this eminent firm came to the conclusion, after full investigation, that almost all modern appliances were defective, insofar that by frequent long disuse they often got into an unworkable state, and were practically useless when required. They therefore decided on what I consider the best of all arrangements for a tea store, namely, to hang up sets of six buckets full of water on rack pins fastened to the walls about every thirty feet apart all over the establishment, several thousands being required to fully equip the factory, contending, and I think rightly so, that it is just when the fire is discovered that it is easiest put out, and instead of having to run about for men capable or acquainted with adjusting and working the fire pumps, all hands would know exactly what to do, and bucket after bucket of water would be dashed on the flames with the least possible delay; and this, I think, would apply well to tea stores, for if these buckets were fitted up all round full of water, the coolies, instead of running about and wondering where to go, would all make a dash for the buckets, and a volume of water would be poured on the flames quite sufficient to extinguish them if they had not got possession of the buildings, in which case, most likely, nothing on earth could save them.

Such buckets or the patent Harden Star Hand Grenade fire extinguishers are not expensive, would not take up any useful room in the store: and, although the suggestion appears a very simple one, I cannot too strongly impress on proprietors the desirability of weighing over its value and application.

WILLIAM JACKSON.

A correspondent of a mechanical turn and much practical shrewdness, after a perusal of the above, expressed his opinion as follows:—

"I have read the pamphlet carefully. I think Mr. Jackson is right, however, about the store and about the turbine and the engine maid. Also about belts and wire bands, &c. I am glad to find that his experience confirms a view I have always held, that the tea drying process should be a continuous one: on the score of saving in fuel, was my argument; his is on the score of better tea. A cheaper style of continuous drier than Jackson's Victorian, I think will be the drier. About the buckets of water, experience is only of value."

We have a favourable account of the small Hand Roller now advertised by Messrs. Walker & Co. from a practical tea planter who has given it a careful inspection: in a few days one of these is to be shown at the Colombo Iron Works driven by steam.

The title-page of Messrs. Walker & Co.'s pamphlet to which we refer is as follows:—

A Few Notes by William Jackson on Tea Machinery and Tea Stores.

And besides a full price list and catalogue of W. & J. Jackson's Tea Machinery together with a series of authenticated testimonials, it gives a list of Marshall & Sons' steam engines and boilers; an engraving and explanation to enable the correct measurement of water in a stream or mill-lead to be made, with a table for weirs; with a good deal of other information respecting road-tracers; hygrometers; fire-extinguishers; fireproof paint, &c. We quote the following passage in illustration:—

So much has been written in praise of Jackson's Tea Machines, that we have experienced some difficulty in deciding what to reprint in this pamphlet. Mr. Jackson's larger Rollers have been so long awarded the highest place by the Planters of India, Ceylon and Java, that it is not necessary to republish at this date any of the numerous testimonials received regarding them. The Hand Roller, though only brought out in 1884, has proved equally successful, and in 12 months nearly 100 of these machines have been sold. A few letters received regarding this Roller are printed further on, together with some extracts from Mr. Armstrong's paper on "The Manufacture of Tea."

"The Battle of the Driers" which has been waged so fiercely in Ceylon may now be considered settled, and the letters which follow, together with a few extracts from the Indian and Ceylon press, may be left to decide with whom the victory rests.

PLANTING IN JAMAICA.

A Jamaica proprietor who reads the *Tropical Agriculturist*, where he found Mr. Cottam's letters (or rather all that referred to practical tropical agriculture in them), writes to us as follows:—

I have read Mr. H. Cottam's letters from Jamaica with considerable interest. He seems to have made good use of his time so far as taking in the condition of the Eastern end of the island is concerned. I am afraid his remarks about the roads in our first clearing are more or less correct, they being after the style prevailing on Blue Mountain coffee estates before Mr. F. D. Marshall showed us the Ceylon style. I have taken Mr. C.'s advice and altered my ways. Since Mr. Cottam was in those parts, we have planted 10 acres on the north side of the main village in tea, which promises by its growth to do well. The great problem that remains to be solved is the cost of production. I am afraid we shall never be able to compete with your cheap rates of production in Ceylon. We shall have 95 acres planted in cinchona by the end of the year. We find that it grows far better on the north side of the main ridge than on the south side, the climate being more equable on the north side, and not so exposed to night winds. I shall be glad to know what you think about planting cinchona in new clearings among tea and coffee. There seems to be very different opinions held on the subject by your correspondents. I should hardly think if the cinchonas were kept well-topped and planted 8 ft. by 8 ft. or 10 ft. by 10 ft. they would do much harm to either tea or coffee, as they would be dug up and barked when about six years old before they could do much injury. The general feeling in Ceylon is now, we believe, adverse to planting cinchona in clearings with other products. Along boundaries, roads and pathways, however, there is a good deal of scope for cinchona. Etc. Notwithstanding the general depression and low rates ruling for all descriptions of tropical produce, the Blue Mountain coffee has kept up its reputation, as high as 135s per cwt. having been obtained in the Liverpool market for some of the best marks. The sugar planters

have had a trying year with short crops from drought, low prices for sugar, mortality among their working stock, and scarcity of labor from the exodus to Colon. The high prices obtained for flavored rums have helped many estates to pull through and a few must have made fair profits, as high as 7s per gallon having been obtained for some rums suitable for the German market. Penkeepers who depend chiefly on the planters to buy their stock have suffered equally with the planters; long and protracted drought in some districts with lessened demand through so many estates being thrown up, and the remaining estates supplying their needs from their herds of broken stock instead of buying young stock from pens have lowered prices. Pimento, which with logwood is the penkeepers' great stand-by, has been almost a complete failure through the drought, and logwood roots after making a great stir for a time on the south side have ceased to be remunerative to get out. The banana, orange and pineapple trade from Montego Bay has largely increased during the last two years, but the low prices obtained for fruit do not encourage any one to enter largely on the cultivation. The business is almost entirely in the hands of the negro settlers who supply Messrs. J. E. Kerr & Co. with fruit for their steamers which run between Montego Bay and New York. The bananas in this district are all grown by settlers around their houses, any attempt at extensive cultivation being checked by thieves, who gather one's bananas with the greatest regularity. The oranges are almost entirely grown on the pens; they thrive best in the rocky pastures, but they more often result in a loss through one's cattle getting choked, than in any profit that can be derived from selling them on the trees at 5s 6d to 5s a thousand. Coconuts have gone down in value lower than they have ever been, realizing only 40s per thousand instead of 70s to 80s, which they fetched two years ago. We greatly need a magazine like the *Tropical Agriculturist* in Jamaica, where we have no planting paper, and I have advised some of my sugar planting friends to become subscribers to your magazine."

PEARLS AND PEARL FISHERIES.

AN INTERVIEW WITH MR. STREETER.

A representation of a Pearling Station appeared in the Pall Mall Illustrated Supplement.

One or two curious facts came out in the recent correspondence in the papers respecting the pearling grounds in the Southern Seas—a subject surely of universal interest. Mr. Streeter, the famous pearl merchant, was himself one of the correspondents, and we are indebted to him for giving to our representative the following account of his fisheries in Southern waters:—

There are not many visible signs of jewels in Mr. Streeter's handsome rooms, which command a fine view of Holborn. The pearl merchant's first necessity, after the pearl, is light, for by nature's light only can a pearl be judged. The tapestry curtains ward off intruding draughts, and their heavy folds partition off the room when division is necessary. But the eye of the stranger falls first on the safe, with its doors thrown open, like an angel's wings. There the eye wanders to the tables clothed in black, to the burnished scales in their covers of glass, to the pearl pliers which lie in a tray on the table, to the cases ranged against the wall. At a table near the window sat Mr. Streeter, gazing with rapture on a lovely pink pearl. After we had had some conversation he said he would

show me some of the "riches of the earth." and bade me plunge my hands into bags full of rubies, bags full of sapphires and emeralds. He opened mysterious drawers, which shut with a sharp spring, and produced shabby cases holding gems of priceless value. Here are strings of iridescent pearls gleaming with prismatic hues. Here dazzling diamonds, shooting forth brilliant rays, there a ruby worth thousands, here a cat's-eye fit for a monarch's finger—diamonds, rubies, pearls, and emeralds, sapphires, and cat's-eyes, there they lay before me. But only for a minute. For these things are not exposed.

GEMS AND GEWGAW.

"The pearl is the most aristocratic jewel. No one but the rich aristocrat can afford to own it. To be inestimable in its value a pearl should be perfectly round like a marble, pure, and spotless. A black pearl is a rarity, and from a thousand shells you might obtain one. I suppose one of the Rothschild's has the finest collection of pearls in the world, Lord Tweedmouth comes second, and Lord Bristol is a close third. The fashion in jewels alters rapidly, though pearls always take the first rank. At present the emerald is the fashionable jewel, why, I cannot say; then come rubies and sapphires; the diamond is but a common gewgaw. Everyone can buy diamonds nowadays. I remember in 1870 diamonds cost £14 a carat. The price has fallen to £5, the result of too great a supply. But a really magnificent jewel, no matter whether pearl or diamond, always retains its value, and a collector, if he chooses to invest large sums in the purchase of the best article, can always sell at a profit. One of the greatest difficulties in dealing with diamonds is the operation of cutting, which needs an apprenticeship of a lifetime to make an expert. There are a few good cutters in the world, and there is actually only one man who can drill a diamond."

IN SOUTHERN SEAS.

Mr. Streeter and his son, Mr. George Streeter, who, although young, has himself been on the pearling grounds, visited New Guinea, and explored Cape York. He gave an account of the Streeter pearl fleet which is at present at work on the north-west coast of Australia. The fleet numbers thirteen decked boats, including a couple of 150 ton schooners. "Our boats have long been pearl prospecting in North Australian waters, and only recently they visited the deeply indented shores of southern New Guinea. There they discovered shells in abundance, but the unhealthiness of the climate wrought sad havoc among the men, who died of a disease peculiar to these Southern waters. The disease is a sort of heart complaint, known as beri-beri. So we withdrew the boats from such dangerous regions. I am most proud of the organization of my pearling fleet, but the expense has been enormous. Perhaps I have spent £10,000 up to now, and I am just beginning to secure a return. Do not imagine that pearl fishing is holiday work. It is like any other commercial enterprise, and needs steady application, great industry, untiring efforts, and readiness of invention to reap any substantial reward. Singapore is nominally our headquarters, and the operations are under the control of three Europeans, I call them 'my boys': one is my son, another is Mr. Haynes, and third is Mr. Clippendale. They are the white bosses, and my most trusted and devoted servants. They have under their command about a hundred and fifty Kanakas and Malays, of whom thirty or forty are divers. For each one of these I gave

a guarantee to their respective Governments, engaging to pay them a fixed wage. Each diver has £2 a month, and an allowance of £13 upon each ton of shells which he brings up. The shells run 2,400 to a ton."

HOW THE FISHERY IS WORKED.

Mr. Streeter then showed me some shells which had recently arrived, about ten inches in length by eight in width. "You will see," he said, "by these perforations in the back how many enemies the pearl oyster has," pointing to the back of the shell, which was much honeycombed. "If they succeed in boring clean to the flesh it is all up with the oyster. The theory of the pearl is that some foreign substance, a bit of grit or shell, finds its way within the harness, and the oyster, to avoid the irritating friction, begins the process of pearl manufacture by the peculiar secretion. The pearl is generally found in the beard. I need not tell you that the shells are highly valuable articles of commerce. When the opener has passed his hand in to feel for the pearl he throws it to the cleaner who does his work, the shells are packed up in hogsheads, and when they arrive in London they are sold by auction in Mincing-lane to go to the manufacturer, for the shell has taken the place of ivory. The pearling season lasts from March to the middle of December, for in the summer months the hurricanes render their fishing impossible. The plan of operations is something in this wise: the fleet is distributed over the fishing grounds, and one or two of them see to the supply of fresh water and stores. The mother ship generally lies at anchor in the bay, and the small boats leave her every morning to go to their various grounds close by. At night they return with their cargoes. The decked boats go further afield, and bring the results of their labor at longer intervals. At certain times the mail steamer which calls at Freemantle ships the cargo which comes home, the pearls themselves being sent through registered letters, and passing through post."

THE DIVER AND HIS DRESS.

"A year or two ago the divers suffered great hardships, always going in naked, when they could not stop beneath the water for a longer period than a minute and a half. The apparatus we use is made by Mr. Heincke, and of these we have about twenty, each costing £130. The dress is not like that we see used on our own shores, comprising only a headgear and a breastplate, the legs being free, but the natives like it very much, for they are able to stay under for longer, about two or three hours. I have never lost any men through sharks; they don't seem to like niggers; but the divers, by a trick which they have learned, when they see a shark approaching, squeeze out some air, which throws out a most vivid stream of air bubbles, effectually frightening the beast away." Each diver has a tender, that is the man who directs the rope, and four pumps, so that the working gangs are divided into quintets.

In one of Mr. Streeter's rooms hang a dozen imposing rolls, each of them worked by a string. Pulling the one marked Australia and South Pacific, the whole of that immense area was placed before my eyes by his son. Upon these trackless oceans, studded with a million isles, many of them laid down upon the chart without much pretence to accuracy—for the reefs and the sounds and the channels are always shifting—among these tropical wastes Mr. Streeter's brave little fleet has found its way, and the King of Pearls, although he has never visited foreign parts, is able to follow the various routes which they have adopted, and these are marked by

artuous lines on the map. Somerset I was informed was played out. Somerset lies to the north of Carpentaria, and sure enough there was the mark on the map.

THE LATEST NEWS FROM PEARLING GROUNDS.

"We are working," says Mr. Harry Streeter in his last letter from the fisheries, which was read to me, "with small open boats and two four-ton ketches, which are perfect in any weather, only coming every second day to give up their shells. The only flaw in our arrangements is that the open boats are too small for the work; in case bad weather sets in they get too leeward, and have to be out in a heavy sea and take their chance of swamping, while the ketches, being decked in, ride like ducks. Many a time after a hard day's work, and all hands thoroughly tired out, we have had to get up anchor and make sail after some poor beggar going out to sea, and not able to reach the ship. If a boat sinks the pump goes down with her, and there is a dress lost. One of the boats has sunk twice, but luckily close to the ship, and we have sent a diver down and got everything up without damage. At present we are under the lee of an island, and as the wind blows from south to south-west every night we lie as snug as possible; but when the first came down we were lying in the middle of the gulf—blowing a gale of wind every night, and dipping bows and stern ports under, though she had forty-five fathoms of chain out, and the anchorage was only eight fathoms. I would n't go pearling with Queensland niggers on any consideration. You have got to ride for a couple of months uncountry to catch your men, and after you have got them they must be watched night and day to prevent them 'putting.' Then every one on board literally pigs it out during the time they are on the grounds, having to sleep and eat on deck, no matter what weather. Fancy fifty niggers, six white men, and 50,000,000 cockroaches all chumming together, and all living on damper and tea. That's what it really amounts to. The men, who receive a handsome percentage, work like demons if we say nothing to them, letting them go out when they like and return when they like, and I assure you they are out at daybreak and not in till seven o'clock at night. Your experience of Torres Straits will tell you that if they go down there for three hours a day they think they have done well. Good eyesight and confidence are all that are wanted for apparatus-diving. All there is to do under the present system is to count the shells on arrival. This takes from an hour to an hour and a half each morning. Chips, myself, and the mate open them. This takes from two to four hours, depending on the number of the shell, and then they are washed and put in the sun to dry for twenty-four hours. The shell is broken into two pieces, the inside edges clipped, and then packed away in hogsheads. Though the shells run so small here, we have close on twelve tons in nine weeks, and if they had run the average of West Australian shells—1,200 to 1,500 to the ton—we should have close on twenty tons on board, as to make our present amount we have over 25,000 shells on board."

THE MYSTERIOUS PACKAGE AND THE FADED MANUSCRIPT.

Most of us have read Mr. Haggard's vivid account of the search for and discovery of King Solomon's mines, in which three adventurous spirits guided by a faded map done in human blood on a fragment of linen 300 years old set forth to discover the vast treasure which King Solomon

was supposed to have hidden in the bowels of a great range of mountains in mid-Africa. How they found it and what happened we leave our readers to find in the book itself, sufficient is to say that the story is one of the most fascinating pieces of fiction that have appeared for many a long day. I have said this because Mr. Streeter, who may certainly be considered the greatest expert living in diamonds and precious stones, mentioned the book to me, affirming that wherever Mr. Haggard got the foundation for his story, he would almost be inclined to accept some of it as sober facts. You would think me a Munchausen were I to tell you of the strange applications which are made to me to provide funds for such expeditions. If you have ever walked through some of the great picture galleries of Florence, you will notice that all the women are painted with most magnificent necklaces of pearl. What has become of them? Where have they gone to? People do not wantonly destroy such things. If you gave me an order today for a pearl necklace to cost £40,000, it would take me a year's careful inquiries to fulfil your demand. It might take even longer, for I do not know where such a one exists. Of course, I should have to collect the pearls singly from all quarters. "Every mail," said Mr. Streeter, "brings me strange documents from remote and forgotten towns of South America, from the east and from the west, from all quarters of the world. Now, here is one," handing me a small parcel bearing the Spanish postmark, wrapped in brown grass paper and carefully tied up at the ends. "You may open it and see for yourself what it contains." I carefully untied the mysterious package, wondering what riches it would disclose. The riches were but on paper. Nothing more than a tracing, showing a river, a few villages dotted about on each side, and a few sketches which showed the topographical features. Besides the thin tracing that cracked in my hand there were numerous writings on thin foreign note-paper. "That came to me a day or two ago from a correspondent of mine in remote Spain. The plan shows the route to a long forgotten mine which my correspondent has discovered. Here you see"—reading from the faded manuscript—"are accurate and minute directions for approaching it, with close and detailed description of the surrounding country, the rivers and the mountain passes, the character of the people, and the whole story of the mine. You need not trouble to read it, but the legend may amuse you."

A SAPPHIRE RIVER.

"I have projected many expeditions," said the King of Pearls; "some have been successful, others not. It is a great gamble, and one must take the good with the bad. Men come to see me here from all parts of the world with their schemes; some I take, many I reject. It is a hazardous business, for one has to trust to individuality. When a man comes to me with a proposition to work a mine, in Mexico say, I try to read his character in our talk, and if I like him and he produces details that seem to me credible, if he has character and decision—he is generally well travelled—we hit it off well enough. Sometimes they go, and for a time all is well, then they disappear for ever from view. In 1869 I sent out Professor John to the Diamond Fields in the first rush, and the party of three bought three claims for half a guinea a piece. For one reason and another they worked for awhile and then sold out. Since then these same claims have produced millions. That was a big slice of bad luck if you like. In Ceylon I have taken rivers for cats-eyes and sapphires. I once tried Cashmere, but could never get a concession, though the Rajah sent my wife the

handsomest shawl I ever saw. I have sent expeditions to the Salt Sea, and all round the coast of Australia. I have now a party working a Brazil river for gold and diamonds. Then, just before the Burmese war broke out, I was negotiating with Theebaw for a concession to work the famous ruby mines which lie above Mandalay. We have plotted out the road, for which we were to receive (paying £20,000 for the mine concession) eight miles on each side of the Irrawaddy, along which the road lies.—*P. M. Budget.*

FRUIT TREES ON SAXON HIGHWAYS.—The planting of the highway in Saxony with fruit trees is proving financially a very successful experiment. During the last three years the State received from this source—1882, 87,844 Marks; 1883, 110,161 Marks; 1884, 103,213 Marks; together 301,218 Marks. Wood sold also produced from 12,000 to 13,000 Marks. These amounts were received after the expenditure incurred in leasing and in auctions had been deducted.—*Kuhlor's German Trade Review.*

SULPHUR.—A deposit of sulphur was lately accidentally discovered in the Narsapur taluk in Godavari. In digging on a piece of waste land, some earth was turned up, the peculiar appearance of which attracted the attention of one of the passers-by, the village magistrate, who, having secured a small quantity of it forwarded it to the Civil Surgeon. A rough analysis of the earth disclosed that it was strongly impregnated with sulphur, and a further examination of the locality in which it was found resulted in the discovery that the deposit extended over a considerable area.—*Indian Agricultural Gazette.*

TEA IN THE PUNJAB.—The cultivation of tea in the Punjab or rather in the Kauga Valley is making considerable progress. During last year there were 1,925 plantations of which 34 were new. As many as 1,880 gardens are owned and worked by natives of India. The total area under tea during the year was 8,172 acres, of which 6,430 acres were under mature planting. Other 1,756 acres have been taken up for planting. The output for the year reached 1,334,002 lb., showing an increase of 34,000 lb.—*Indian Agricultural Gazette.*

BALING OF CINCHONA BARK IN CEYLON.—At the last public auctions dissatisfaction was expressed by the London bark buyers because bales of bark often arrive at their final destination in bad condition, heavy loss in weight frequently having to be borne by the manufacturers. In order to remedy this it is necessary, firstly as regards shippers—(a)—That no bale of bark should weigh over 250 lb. nett. (b)—That stout gunny cloth not thin hessian canvass, should be used for packing. The large and unwieldy bales, so often shipped from Ceylon, are in dock more or less unmanageable; to draw fair samples from such packages is most difficult, and the wear and tear is naturally excessive. The thin hessian canvas so often used by shippers gives way directly the goods are handled, and is often the direct cause of loss to the buyers. Secondly as regards docks and wharves—(a)—It is a *sine qua non* that samples should be absolutely unimpeachable. (b)—It is necessary that iron hoops, removed to facilitate sampling, or for the purpose of taring, be re-adjusted or replaced by stout cording. It is invidious to mention names, but two wharves undoubtedly deliver barks in a better condition for re-shipment than their competitors. The rates which importers pay to docks and wharves justify the trade in demanding that the work be done thoroughly and that barks be delivered to the buyers with every iron hoop adjusted or re-adjusted, or with a stout cord in lieu of any missinghoop. Kindly treat this matter as of importance, and we rely upon you to put this letter forward in the proper quarters.—We are, dear sirs, yours faithfully. (Signed) p. p. H. Buehler, P. Buehler, W. H. Cole & Co., Corbyn, Stacey & Co., Howards & Sons, François le Mail & Rivers Hicks, O. G. Meier & Co., J. C. Rohrweger, Fred. Thomas & Co., Thos. Whiffen, Widenmann Brocher & Co.—Local "Times."

THE PEARL OYSTER.

TO THE EDITOR OF THE "COLONIES AND INDIA."

Sir—An interesting article in the *Standard* of Moulay, Nov. 23, regarding the discovery of great pearl-oyster banks in King Sound, Western Australia, induces me to draw attention to the fact that oyster beds, which would seem to be inexhaustible, extend, as far as I heard when in the Colony, almost continuously along the eastern shores of Southern Africa. As early as 1829 Dr. Alexander Cowie, of Lower Albany, and his friend, Mr. Benjamin Green, who travelled through Kaffraria to Delagoa Bay, where they unfortunately both died of fever and exhaustion, left a record of the coast being abundantly supplied with oysters of two descriptions; and one place is mentioned, between Umzimvooboo and the Umzimulu, as being "twenty or thirty miles in extent, which was literally white" with these bivalves. I have two very fine specimens of the pearl oyster shells which were brought to me from Port Elizabeth last year, and which I understood were gathered not far north of that place. There are great quantities of the edible oyster everywhere along the coast, and, as mention is made of two kinds, the shells which I have doubtless belong to the second variety.

The Rev. Stephen Kay, an American missionary and explorer, travelled through Kaffirland in 1825-6, mentions in his visit to the Chief Daapa that he had seen numbers of oyster shells scattered about the door of the hut. The Kaffirs do not eat fish of any kind, but Daapa's mother, Quma, was a white woman, who had been wrecked on the coast and had been taken by the Chief Daapa's father as his principal wife. There are also, I have been told, great quantities of oysters in and around Delagoa Bay. Would it not be worth while to inquire whether these immense beds consist in a measure of pearl oysters, as if the industry pays so well in Australia, why should it not do the same in a country so much nearer the Home market, and where labour ought to be plentiful?—I am, &c., M. CAREY-HOBSON.

TUBEROUS BEGONIAS.

The time has arrived for again starting Tuberous Begonias into growth, and as their culture is not so generally known as it ought to be, a few plain practical remarks on this particular point might prove of service. The season of rest with the Begonia is practically at an end, and those tubers that have succumbed to injudicious management by either receiving too much water or not being sufficiently moist will be easily detected now. Though the Begonia can be wintered under conditions similar to the Gloxina, the former is injured more by extreme dryness than the latter; not that the Begonia prefers moisture when at rest, for such is not the case, as it is natural for them to lose most of their roots annually. A large percentage of annual losses may, however, readily be traced to insufficient care when drying them, which, in many instances is done far too rapidly; the more gradual the drying process the greater the chances of retaining the tubers sound and plump during their season of rest. Presuming the pots to still occupy the pots in which they flowered last summer, the first thing to be done is to clean off the surface soil so as to bare the tuber, after which carefully remove the soil so as to form a gradual slope from the apex of the tuber to the inside of the pot, leaving the tuber thus partially exposed in the centre. This is of great importance until growth has fairly commenced, when the danger is considerably lessened, and water must be given somewhat sparingly. For the first week or two it should be given round the side of the pot, and on no account be allowed to reach the summit of the tuber. Too much importance cannot be attached to this, for at the summit of the tuber, and in the position occupied by the main flowering stem of last year, will be found a large hollow crown or receptacle; if this water gains a lodgment there and is not detected failure must

instantly ensue. The same difficulty is experienced when drying them just as the stems are decaying; the water finds its way down the stems and settles in the top, doing the mischief without being discovered. In the event of the tubers having been shaken out of soil in the autumn and stored away they should be examined at once, and ascertain if they are sound and plump. If so shallow boxes will be found serviceable for starting them in. In this case either of the following ways or both may be adopted—*ie.*, place them on coconut fibre or soils and bury one-half their depth, or employing similar material place the tubers upside down, and just cover with soil. By adopting the last-named process there is no fear of water settling in the hollow crown at the top, and, what is more, the summit of the tuber is kept more uniformly moist than where they are partially exposed. A more uniform moisture might be maintained were the tubers kept dark till they began to start, when they may by degrees be gradually inured to full light. This is more readily accomplished where there are only a few dozens; where they are in large numbers special attention will be requisite, and special quarters also for them. Those placed in boxes with the crown downwards will need looking at in about a fortnight, when the majority will be found to be taking freely. These may then be reserved, for new roots soon will be emitted, potting them according to their requirements. Exercise forethought at all times in the management at starting, and especially so in watering, for by injudicious watering at this season many hundreds are annually lost. A temperature of 50° to 55° at night, with a rise to 65° by day, will suit them well, and if accompanied by slight bottom heat so much the better, keeping the atmosphere moist.—J.—*Journal of Horticulture*.

THE OFFICIAL RED CINCHONA BARK.

It may be useful as well as interesting to consider the present position with regard to cinchona bark for pharmaceutical preparations.

The British Pharmacopoeia, 1885, directs that all the official preparations shall be made from red cinchona bark, which it describes as occurring "in quills or more or less incurved pieces, coated with the periderm, and varying in length from usually a few inches to a foot or more." But for the restriction as to length this description might be held to include shavings of bark as well as what are generally known as quills. When it is considered that shavings, as recently stated by Mr. John Moss, constitute at least 95 per cent of the total imports of red bark into London, the question arises, Why is so large a proportion excluded? It would be interesting to know what form of bark, shavings or quill, was used by the operators whose results have recently enriched experimental pharmacy. Presuming that the experiments were made with a view of testing the official process for liquid extract of cinchona, we should conclude that quill-bark was operated upon. One operator, however, who removed only 56 per cent of the total alkaloids, admitted that he had used shavings. Mr. Moss, using quill-bark, succeeded in removing 88½ per cent of total alkaloids; and, during his remarks on this subject, in the course of the recent discussion of the Pharmacopoeia, the suggestion was accepted by Professor Redwood that the explanation of this difference in result was to be found in the difference in the form of bark.

A hope was indulged that Professor Redwood would have explained more fully the cause of the difference, and give the meeting the benefit of his large experience on this point. He did not, however, refer to it in his remarks, and the explanation has still to be found. Professor Redwood's view, when applied, we take to mean that red bark occurring in quills so constituted that when reduced to powder and treated with water containing free hydrochloric acid it yields up its alkaloids more easily and free than does red bark occurring in shavings when similarly treated. It is difficult to conceive why this should be so. Suppose a proper tree be selected, and the bark from half the trunk be

removed in strips, which, when dry, curl up and form quills, and the other half has the bark removed by shaving it off, is it meant that the former will behave differently from the latter to the same menstruum? We cannot think that this is the Professor's meaning, and yet are unable to perceive any other. It would be well if he would enlighten pharmacists on this point. Meanwhile, we trust that those who make the liquid extract of cinchona will experiment with shavings, and give the results for comparison with those obtained from quills; and if it be found that they do not very greatly differ, it may be possible to obtain official recognition for the former. This would be to the great advantage of pharmacy, which benefits in proportion to the removal of restrictions on the materials with which it works. Mr. Brady says that, with regard to Java, he believes there will be an increased quantity of scraped bark and a diminished quantity of the peeled. There can be little doubt that this will hold good of India, and if there be only 5 per cent or less of peeled bark now, what shall be used in pharmacy when there is none?—*Chemist and Druggist.*

THE ORIENTAL PLANE TREE.

Platanus orientalis [and its varieties], that ornamental introduction of 300 years ago, native to the Levant, Asia Minor, and Persia—not the American or Western Plane tree, *P. occidentalis*—has been largely planted in recent years in situations where, as on the Thames Embankment, the million can admire it, and where, as time passes, our Planes, like our Oaks, will inspire veneration, and elevate the thoughts.

Referring briefly to the Planes of history, among the many famous trees growing on the shores of the Mediterranean, one of the greatest antiquity, most justly venerated, grows in the pass of Thermopyle. None of the Planes of our own country have yet lived long enough to have attained old age, according to the period of their existence in the East. There are, for example, the so-called "Seven Sisters" growing on the shores of the Bosphorus whose age has never been discovered, and no remaining record is likely now to reveal it; but they are known as a matter of undoubted history to have sheltered a party of English Crusaders in the eleventh century. They are believed to be the oldest Planes in the world.

Such was the beauty of a large Plane tree standing in its prime on the soil of Greece, on land which was no doubt sheltered, watered, drained, and fertile, that Xerxes, on his invasion of that heroic little country, was fascinated by it, and remained chained to the spot for a whole day. A Napoleon or a Gladstone would have cut it down and marched on, but Xerxes remained quite entranced gazing upon the tree and sitting down beneath it. In war and gardening delay of this kind is fatal, and so it proved to the luxurious monarch, who passed on at last and was completely beaten by the Greeks. Among other famous and historic Planes Pliny mentions an aged tree which he himself had seen in Phrygia, and among whose boughs the vain musician Mersyas, as the story ran, had been suspended by Apollo when he slayed him alive after his defeat, the unhappy mortal having challenged Apollo to a trial of skill. Another Plane of romantic interest was that which Helen of Troy planted in Arecalia, and which Pausanias described as a tree of great beauty, as well as size, at the age of 1,300 years.

Interesting notices of another tree were successively published by the three travellers, Hobhouse, Buckingham, and Chandler, who each described a noble Plane growing on the banks of the Selinus, near Nostizza. To this tree has been assigned a diameter of 15 feet, a deceptive measurement, which must have included spurs at the base, and which conveys to the mind no idea of the size of the tree. In Persia this stately tree, called there the Chinari, is frequently met with in avenues, or in company with the Lombardy Poplar, affording shade and ornament to the dwellings of the peasants, or along the margins of the streams and watercourses.

Planes may readily be found in England 14 feet in circumference, measured fairly at 5 feet from the ground, and reaching a height of 80 feet. They require suitable soils and situations for their greatest growth. They are not perhaps fastidious, but there are two or three essentials to their most successful cultivation, which must not be overlooked in planting them.

Unlike the Sycamore, an Acer which was dubbed Pseudo-Platanus, and which runs over the hills of Europe, a native of Italy, Switzerland, and Germany, and doubtfully indigenous in Britain, a hardy tree, with stout twigs bearing storms well, the Plane loves shelter. It is a tree for valleys rather than hill-tops, and requires proper soils, while the Sycamore can accommodate itself to a variety of soils as well as sites. The Plane cannot endure a clay soil, and the shade of other trees proves obnoxious to it. It also requires good land, light rather than heavy, with natural drainage, but at the same time moisture at the roots, and a deep, free soil. In proper situations, in short—and, it may be added, wherever the Lime grows best, as single specimens or as groups upon the lawn, where it spreads itself wide and may be distinguished from the Maples at a glance by the scaling off of the bark and the round rough fruit—the Plane may be often observed. I noticed some very noble specimens last summer at Hursley in the shrubbery among other trees, all favourites of the late Sir William Heathcote. The Plane is a common ornament of English parks and gardens, as any observer of trees may know if he consults his memory (having travelled much), or Mr. Loudon, if he has read that delightful writer.

An enthusiastic admirer of the Plane has said of it that there is a mild majesty in its aspect and a grace in its form and in the disposal of its foliage, which admits light playing amongst its leaves and creates shade beneath the canopy of its branches, and renders it one of the best models of elegance which the vegetable kingdom can exhibit. Owing to its great beauty, therefore, as well as its tolerance of smoke, the Plane is obviously the best tree for the embellishment of great cities, the best for populous and conspicuous places for the improvement of public taste.—H. E.—*Gardeners' Chronicle.*

COLLECTION AND PREPARATION OF GUTTAPERCHA.

The collection of guttapercha generally takes place directly the rainy season is over, as in the dry season the gutta does not flow so readily, and during the rainy season the collectors are more liable to attacks of ague and jungle fever, and often after cutting down a tree a heavy rain will wash away the gutta as it flows out. At times the collectors go in companies, often receiving advances in money, clothes, food, and tools, to be afterwards deducted from the proceeds of their expedition, although cases are not unknown where the trader who makes the advances loses principal and interest from the non-success, death, or knavery of the collectors. Sometimes the natives who live in the vicinity of the trees collect the gutta and exchange it at the trading stations for goods of which they are in want. There is a curious belief amongst the natives that if a tree be cut down at the time of the full moon, the result is better than at any other time, as the juice flows more readily, although, on the other hand, other natives affirm that the seasons make little or no difference.

Yield.—The yield of a well-grown tree of the first or best variety is from 3 to 3 lb. of guttapercha, such a tree being about 30 years old, 30 to 40 feet high, and 30 inches to 3 feet in circumference. A full-grown tree sometimes measures 100 to 130 feet to its first branches, and with a girth of 20 feet at a distance of 14 feet from the base. Such a tree will sometimes yield 50 to 60 lb. of guttapercha, which quantity loses about 35 per cent of its weight in six months from drying. There is also

a great difference in the relative yield of different varieties, sometimes amounting to 20 per cent.

Method of Extracting.—Guttapercha is extracted in much the same way amongst Malays, Chinese and Dyaks. The trees are cut down just above the buttresses or lances, as they are called; and for this purpose a staging about 14 to 16 feet high is erected. The tools used in felling are either "belions" or "paraangs." A "belion" is a chisel-like axe, used by the Malays in cutting down trees, building houses, &c. The blade, as will be seen, is of a chisel-like form, and is secured to the handle by a lash of "rotan" or cane. The Chinese often use an axe perfectly wedge-shaped. The "paraang" with its short sword-like blade, is used to cut the rings round the trunk; it is a box of tools in itself in the hands of a good Malay, as with it he can cut up his food felling a tree, or building a house. They are made of various sizes, the one figured was given me as a keepsake by a Hadji from Palembang, on his way to Mecca, and is drawn quarter size. All these tools are forged by the natives themselves, and are used with considerable dexterity.

As soon as the tree is felled, the greatest haste is made to lop off all the branches, the natives asserting that if this is not done all the gutta would ascend to the leaves. Captain Lingard relates one instance where, it being late in the evening, one tree was left with the branches on, and the result was that in the morning, instead of obtaining 40 to 60 lb. of gutta only 10 lb. was obtained. The next operation is to cut and remove narrow strips of bark about 1 in. broad and about 6 in. apart. These cuts do not extend all round the tree, the under part of the tree being buried in the soft earth as it falls, and thus much gutta is wasted. Some natives also strike the bark with mallets, in order to accelerate the flow of milk. The milk or gutta flows slowly (changing colour as it flows) and rapidly concretes, and is of a different colour in different varieties, varying from a yellowish white to a reddish or even brownish tinge. The gutta, as it flows, is received in hollow bamboos, doubled-up leaves, spathes of palms, pieces of bark, coconut shells, or even in holes scraped in the ground. Only two-thirds of the gutta is thus extracted, as one-third is buried in the ground. (Captain Lingard told me that once he induced a native "pungulu," or head man, to roll over a tree which had been felled four years, and even then a large quantity was extracted. If the quantity collected is small, it is prepared on the spot by pressing it together in the hands into a mass, and making a hole in the one end of the mass and passing a rotan through to carry it by. Often it is sent into the market in this state, and is then known as "raw gutta" or "getah muntah," the latter word in Malay meaning "raw." If water gets into the juice, the gutta becomes stringy and is considered deteriorated, but after being boiled appears quite as good. Sometimes the gutta is kept in the raw state for a month or two, and then undergoes the next step in preparation, that is, of boiling, but this should, I believe, take place immediately after collection. The boiling is generally conducted in an iron pan or "kwali." These are cast or stamped pans, 15 inches in diameter and 6 inches deep, with two handles riveted on. Those made in Siam are generally preferred. The boiling is either made with simple water or with the addition of lime-fruit juice, salt, or coconut oil. Lime-fruit juice and salt are added to hasten coagulation. If one pint of the former be added to three gallons of gutta milk, the gutta coagulates or coagulates immediately on ebullition, and this addition expedites the preparation very materially. Coconut oil is added to give a better appearance to the product.

When the gutta arrives at the port of shipment, before it is exported it generally undergoes an examination with a view to classification in suitable classes. As it is found to present great diversities as to appearance, shape, size, and colour; from crumbling, hardly coherent, whitish or greyish "raw"

or getah muntah fragments, to reddish or brownish blocks as hard as wood. Sometimes it is made up into all manner of grotesque shapes, and rarely always adulterated with sago, flour, sawdust, bark, clay, stones, &c. The Chinese are great adepts in assorting and classifying gutta, and frequently "reboil" the guttapercha by making small parcels of different varieties up to a certain "standard sample." This is done by cutting or chopping the gutta into thin slices and boiling with water in large, shallow iron pans, keeping the contents constantly stirred with poles, and adding good gutta and even coconut oil to give gutta a better appearance. When sufficiently boiled, the gutta is taken out of the pans, pressed into large moulds, and packed for shipment.—*Indiarubber and Guttapercha Journal.*

THE SCIENTIFIC DRYING OF TEA.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL."

Sir,—It is amusing to see how old processes and patents are re-invented and announced with a grand flourish of trumpets as "Remarkable Discoveries."

A large mare's nest of this order was "discovered" about a week ago, by the *Daily Telegraph*, and the big egg that it contained has been handed "around" (as our American cousins say) for general wonder and admiration, until your talented correspondent, Artemus, cracked the shell and revealed, not a Phoenix rising from the flames, nor a Spread Eagle soaring to the skies, but a half-fledged ugly duckling, with no loftier note than an ominous "quack, quack."

The fact that air may be rendered chemically dry by being drawn or driven through many well-known simple and inexpensive chemical absorbents goes without telling; also that dry air will reabsorb more moisture than damp is not a very remarkable discovery; hence, if any of your numerous readers who already possess our drying cylinders will care to put this matter to the test of practical work, they can do so most easily and thoroughly at the cost of a few shillings. It would be merely necessary to adjust a box containing the absorbent in front of the fire and cause all the air required for combustion to pass through that box; they would thus have air supplied to the cylinder perfectly freed from moisture, however damp the atmosphere might be.

Dry, warm coke broken into pieces of about the size of a walnut is a very good absorbent and would cost really nothing, because as soon as it was saturated it could be changed for a fresh charge and put upon the top of the furnace to get dry and warm again, and thus serve the purpose *ad infinitum*.

I agree with Artemus that it would be very well worth trying this dried air for "withering;" for this purpose the fire should be reduced to a mere handful of hot fuel, and the cylinder lowered and rotated so slowly as only just to turn the leaves over from time to time to insure each leaf getting its fair share (and no more) of the withering action. The temperature of the air could be regulated to anything that practice proved best from 60° to 130° or any degree higher that it might bear. The same simple arrangement might be useful for drying also, because dry air at a lower temperature will do as good work as damp at a higher.

If the withering process were a success by this arrangement, I should advise either a modification of the cylinders, whereby they could be most economically constructed to do this special work or an arrangement that has been in successful operation for many years at the Royal Gunpowder Works. This machine was constructed from one of the models of my patent, after Sir Frederick Abel, Colonel Young, husband, and Mr. Anderson (of the firm Easton, Amos & Co.), had been up to my place to test the action of that model. It is simply the well-known arrangement of a series of endless bands, one above another, receiving the charge on the topmost band and carrying it to and fro from band to band until it arrives at the exact point of dryness required. My patent, therefore, is not for endless bands and heat,

ing arrangements *per se*, but merely for simplifications and economies of construction, and accuracy of performance. These economies could be carried still further where only moderate heat and dry air are required.

This machine has answered admirably for drying fibrous, light and porous products, such as cotton-waste, wool, &c., but the reason I did not recommend it to the planters was the finding, from carefully repeated experiments, that with wet and clotted leaves (like tea from the rolling mills), it was not so good in its action as the cylinders; the wet lumps were not so effectually separated and where a few leaves clung together, they did not get their fair share of the drying action and afterwards formed a spot of mould when the tea was stored. Moreover the element of first cost is always an important consideration, and machines on this principle to do as much work as a cylinder cost nearly twice as much to construct. This, however, would not be the case with a set of bands in a chamber for withering purposes only.

The whole philosophy of rapid economical and thorough drying may, I think, be summed up in these three points:—

1. That the tea should be kept in gentle but effectual movement, so as to separate every leaf from every other leaf and allow the dry air to get at both sides.

2. The application of as much air as can be introduced without blowing the charge out of the machine.

3. The skilful adjustment of the temperature of that air so as to obtain the highest drying power without injury to the product.

As an instance of the utility of attending to all these three points I may mention that 1 lb. of wool, when saturated with water until it weighs $3\frac{1}{2}$ lb. can have the whole of that water expelled in $5\frac{1}{2}$ minutes without the slightest injury to the fabric, whereas in the "Remarkable Discovery" of the *Daily Telegraph* it took twenty-eight minutes to perform that wonderful feat. In other words, by the scientific combination of movement, volume and temperature, the process can be accomplished in one-fourth of the time; or, what is still more important, four times the yield can be produced in the time needed by the marvelous plan of the "Remarkable Discovery." Of course where the product (like timber) cannot be moved there is nothing for it but to pile it up in a chamber and pump in 6000 cubic feet per minute of cool dry air for nine days (or ninety, as the case may be); but just consider what a few tons of rolled tea would look like if placed in drying-house of this kind for nine days or even for nine hours! No; "Divide and Rule" used to be the old motto, divide and dry is quite as good a cue in this case. You cannot break a whole quiverful whilst the arrows hold together, neither can you dry clotted lumps whilst they stick together; the surfaces get over-dry and their centres remain damp. "Movement" is the secret of success in this as in so many other things. The old system of kiln-drying is now universally admitted to be slow and imperfect, and you will see by the enclosures that my wheat-drying cylinders are gradually superseding them in all parts of the kingdom. Wherever a damp product is spread upon a floor or on shelves, if the dry power is from below, the lowest stratum gets scorchd and the upper gets scalded; if the hot air is diffused from the sides or from above, the upper stratum gets over-dry before the lower is dry enough; inequality of drying, or waste or heat, slowness of production, and a necessity for large buildings, and much manual labour in spreading, turning and collecting are inevitable, whilst *per contra*, with machinery, perfect uniformity, economy of fuel, rapid and regular delivery, compactness of building, and saving of labour are the proved and acknowledged advantages.

If your correspondent Artemus, or any of your readers, would care to pay me a visit to see illustrations of the two systems carried out in various models, or to arrange for experimental investigations

as to further practical improvements, it will give me great pleasure to make appointments with them, and thus to assist to the best of my ability in the "Scientific Manufacture of Tea."—Wm. A. GUNN.

DROUGHTS IN JAMAICA.

Mr J. Morris, formerly of Ceylon, in treating of this subject stated:—

The prevalence of comparative drought throughout the island during the last five years, the consequent arid condition of the country, the failure of springs and streams, the loss of cattle, and the diminution in the yield of crops, are factors in our local circumstances which certainly deserve thoughtful attention; and no subject could more worthily or more appropriately occupy the attention of a Society having the Agricultural interests of the country at heart than a careful consideration of circumstances which may directly or indirectly have contributed to the present state of things; and the means whereby they may be avoided in the future, or, at least, be greatly mitigated and relieved. It is generally admitted and indeed proved by reliable returns, that the rainfall in Jamaica since 1879, has been of a very partial and irregular character; and, on the whole, it has shown a marked falling-off as compared with returns of a similar period in former times. According to Returns published by Mr. Maxwell Hall, in the *Jamaica Gazette*, January 2nd, 1885, it would appear that, while the normal average rainfall for the whole Island—taking dry and wet districts together—is about 70 inches per annum, during the last five years, 1880-84 inclusive, the average rainfall has been only 56 inches per annum. This shows a falling-off in the rainfall at the rate of 14 inches per annum. The actual rainfall is as follows:—1880—55 inches; 1881—69 inches; 1882—58 inches; 1883—48 inches; 1884—50 inches. From this it would appear that during the last five years the rainfall has only once been near the average, while during four years it has been very much below the average. During the current year (1885) I regret to say there would appear to be no improvement. In January the rainfall was only one-fourth of the average; in February it was only one-half the average, and the effects of the drought were severely felt over the greater part of the island; in March the rainfall was only one-third of the average and reports from Trelawny and other parishes mention the drought as being the severest on record, the ponds being dry, and springs and wells failing. In April the rainfall was one inch above the average, caused by heavy rains in the West Central division; in other parts of the island, however, but little rain fell and in consequence of the preceding drought there was a great scarcity of water. In May the usual "seasons" entirely failed; the rainfall being only one-half the average.

A cubic foot of air heated to the normal temperature of the plains of Jamaica, viz., 80° Fah. and saturated with moisture holds 10.81 grains, Troy, in weight of vapour.* This is more than twice the quantity of vapour held by air heated to only 50° Fah. which may be taken as the normal temperature of a northern country like England. Hence we have, here, the key, not only to the more rapid evaporation and drying of the surface which takes place in a tropical country, but also to the larger and more copious precipitation which takes place, when the air by expansion in the higher strata, yields its moisture in the form of rain.

RECORD OF FLOODS AND DROUGHTS.

Besides those we have records of heavy rains, such for instance as in the storm of October 20th, 1711, when there fell according to Long, a "general quantity equal to that which falls in England in a whole

* I might here add that without vapour in the air there would be no clouds, no rain, no fog, no hail, no lightning or thunder, no blue-sky and no rosy twilight.

year." There are records also of heavy rains in 1785 and 1786; of floods in 1815 when nearly the whole aspect of the old parishes of St. David and St. Georges were changed and breakwaters and ravines formed which remain to the present day; of heavy rains in 1839 followed by severe drought in 1840 on the northside; of floods again in 1841 when they continued without intermission for nearly a week. In 1844 there were very heavy rains throughout the island which were repeated in 1848 and continued for nearly three weeks. The May rains of 1862 lasted for nearly two weeks. In 1867 there were floods in the North-eastern parishes. Heavy rains occurred from October to the end of December 1870. The rainfall for Manchester for these three months amounted to 82.5 inches and at Bath to 88.5 inches.

In 1876 there was a severe drought in the northern portion of the Island which retarded the growth of cane, succeeded soon after by heavy and continuous rains. The floods of October 1879, were the last of a general character which we have to record and these have been succeeded, as we are too painfully aware, by five years of comparative drought.

In spite of the present drought under which the country is suffering, it would be rash to assert that the rainfall is actually and systematically decreasing at a large rate over the whole Island. Mr Maxwell Hall, however, is forced to the conclusion that the rainfall in Jamaica must have been greater in former times than now, but attributes this "to a change probably systematic and periodic." If we could take periods of say twenty, fifty, one hundred or even two hundred years, and tabulate carefully the amount of rainfall deposited in each, we might then arrive at a fairly definite conclusion whether the rainfall is steadily decreasing or not. In the absence, however, of such returns, the wisest and most rational course, for the present at least, is to leave the question an open one. This, however, does not touch the inquiry whether the rains are as regular or as frequent as they previously were; or whether the influence of man in denuding the land of forest has not brought about a failure of the waters in our streams and rivers and produced such local changes in our climate as might lead to aridity and drought.

[And then Mr. Morris proceeds, in the usual style, to show the influence of forest on rainfall. In Ceylon denudation has not lessened rainfall, and we suspect the same may be said of Jamaica. Floods and droughts occur in all tropic lands, and rainfall depends on monsoons and mountains.—Ed.]

RETURN OF LAND IN THE HANDS OF GOVERNMENT, AS GIVEN IN THE HANDBOOK OF JAMAICA 1881-85, p. 122.

Government		Land under	
Unoccupied.	Land under lease to various persons.	Land.	Total.
67,482	12,908	26,980	107,536

In a note by General Mann, Director of Public Works and Surveyor-General, it is mentioned that "the lands held by Government are almost exclusively under the following three heads:—1st, Unpatented Lands; 2nd, Lands forfeited to the Government for non-payment of Quit Rents, and 3rd, Lands recovered from Squatters under the powers of the District Court Laws.

The last class of lands are only held by Government for seven years, after which they are sold, if not claimed before that by the rightful owner." The extent of land, both in private hands and in those of Government covered by forests is estimated at about one-fourth the total area of the Island. In other words three-fourths of the country has already been denuded of forests; and the work of denudation is being carried on at the rate of some 15,000 acres to 20,000 (30,000 according to the Crown Surveyor) per annum chiefly for the purpose of establishing negro provision grounds.

◆ DON'T DIE IN THE HOUSE.

"Rough on Rats" clears out rats, mice, beetles, roaches, bed-bugs, flies, ants, insects, moles, chipmunks, gophers.

W. E. Smith & Co., Madras, Sole Agents.

DECAY OF THE INDIAN SILK TRADE.

The *Pioneer* in a recent issue contained an article on this subject, the writer of which commences by showing, that, though there is a market in India for the cheap filatures produced by the native method, the large companies which work to supply the European market cannot compete with China. He explains the reason for this, as follows:—

The difference between Indian and Chinese silk admits of a very simple statement. Silk yarn loses much of its weight in the process of dyeing, and of course the foreign manufacturer will turn by preference to that kind of silk which loses least. Now if we take the produce of the worm that feeds on the mulberry—the species which created the old historic silk industry of Bengal—a pound of Indian yarn yields 10½ ounces after dyeing, but a pound of Chinese yarn yields 11½ ounces; the difference is therefore 6 per cent in favour of the latter, and in point of strength also the superiority rests with the Chinese product. If we leave the mulberry silkworm and take the multivoltine tussar, which is found wild in many parts of India, and used to be reared extensively on trees in the open air in Chota Nagpur and other hill tracts of Bengal, as it is still reared in the Central Provinces, which abound in the hill and jungle that it most affects, a comparison of Indian tussar and China tussar is again to the disadvantage of the former. The Indian yarn returns half an ounce less after dyeing, and is thus 3 per cent to the bad; but its deficiency in strength is a more serious matter. Every silk-weaver knows how much the lustre of his fabric—the quality which gives it attractiveness in the eyes of the customer and enhances its price in the trade—depends upon the natural strength of the fibre. The beautiful sheen of silk is altogether an effect of nature; it comes of the light glancing along the straight lines of the fibres which lie side by side and compose the thread. Twist the fibres, and you destroy their even straightness, and the lustre disappears. But if the fibres are weak they must be twisted, or the thread will not be strong enough for weaving. Now this is the case with Indian tussar, and hence a deficiency of lustre in the woven fabric, and a depreciation of 3 or 4 per cent in its value when compared with the more brilliant Chinese. Again, this same want of strength shunts Indian tussar out of one-half of its market. The thread is unfitted for setting in the loom lengthwise; it can only be used for weaving across the breadth of the piece, and thus the European weaver who works with Indian tussar has to choose some stronger silk for the groundwork of his web.

There are some of the reasons which account for the decline of the Bengal silk industry and the diminishing export of Indian silk generally. We are speaking now of what is technically known as *throwing* silk, that is, silk-yarn made by reeling the silk off the cocoon. It is a process in which machinery has no part, depending entirely upon the silkworm's work in the first instance, and next upon the dexterity of the human fingers that manipulate the fibres. A machine that could do this work would be worth a fortune, and indeed it is not likely that the problem of finding a substitute for young women's fingers will much longer continue to baffle the inventiveness of the age.

* * * * *

The fault of the Indian silk-worm is that in spinning his fibre he never puts in a sufficiency of "bone." "Bone" means, in the language of the trade, that hardness and firmness in the fibre which enables it to keep its even roundness through all the trials to which it is subjected in dyeing, combing, and weaving. If not duly fortified with "bone" the thread gets frayed at the edges, and becomes "flossy," and flossiness is a quality abhorred by the weaver. It is little differences like this which affect the prosperity of whole industries. The fortunes of the largest silk manufacturer in England have been built on a minute improvement in the process of combing, and the fortunes of Indian silk would revive if its fibre could by any means be harden-

ed a little. It is hoped that this end may be attained by greater care in the breeding of the worm. The Bengal silkworm, it is well known, has long been tediously degenerating under the neglect and carelessness habitual to the natives of the country, whose only object is to raise a crop as rapidly as possible, with the least expenditure of money and trouble. Unfortunately reform in this respect is a matter of extreme difficulty. In the Punjab and in Dehra Dun no pains have been spared to teach the ryots how to rear silkworms, good seed has been distributed, and competition has been stimulated by exhibitions where the best collection of cocoons finds a liberal reward; but it has all proved vain, except indeed as a demonstration of the impossibility of getting the ryot to give that methodical attention to his silkworms without which the goodness of the stock cannot be maintained. An experiment that has failed among the livelier and keener peasantry of Upper India has but a poor chance of success, we fear, in lazy, listless, Bengal. Then comes the question whether it might not pay to undertake the breeding of one's own silkworms: and this, too, has been tried in the Punjab, where those beautiful yaros were produced which attracted so much admiration at the Calcutta Exhibition. But the old defect of the Indian breed still cling to it, and all the care bestowed upon the selection and rearing of the silkworms has failed to develop the essential quality of bone in sufficient strength. The last resource is to make an entirely fresh start with new seed imported from Japan. But the history of these experiments suggests a doubt whether the new strain will long preserve its vigour. The hereditary weakness of the Indian silkworm may, of course, be traceable entirely to a long course of reckless breedings, but it is perhaps more probable that the cause is a climatic one, and in that case we shall see the Japan stock gradually yield to the fatal influences of its new habitat, and part with the firmness of its fibre just as the European stock of animals, or of men and women, parts with its stronger qualities of body and mind when condemned to reproduce itself in this country.

Look at it, then, as we will, the business of manufacturing thrown silk in India does not seem to have very bright prospects before it. The Indian product will hardly retrieve its price in the European market, and the question of successful manufacture for export seems to depend on whether some cheaper way of working can be devised, since it is yearly becoming plainer that the old-fashioned style of filature, with costly buildings and European management, cannot be made to pay. But if the whole situation has thus to be reconsidered, it is worth while to go a step further, and ask whether the fault does not lie deeper than any mere change of system. The grand secret of successful production is to have Nature as one's ally; but in seeking to produce thrown silk of European quality in India we seem to be constraining Nature against her will, or at any rate to be making the mistake of not setting her to work along the line of greatest efficiency. The special aptitude of the soil and climate of India is for the production of coarser kinds of silk; multivoltine varieties not adapted for reeling, but capable of a vast number of uses if properly spun. The demand for this waste silk, or wild silk as it is called, is rapidly growing in Europe, and at the present moment greatly exceeds the supply. A few years ago the product was valueless, but now we have improved machinery that can turn every particle of waste to account.

This sudden opening up of new prospects for waste or wild silk occurs most opportunely at a time when the cultivated silk industry, the manufacture of thrown silk, finds its outlook so miserably darkened. Silk firms might well consider whether they might not turn their capital to the development of this new trade, instead of sinking it in the attempt to rehabilitate a decaying business. India's place in the scale of production seems to be marked out by economic laws as that of a supplier of raw material. The tendency of modern improvements is to remove even the simple primary processes of manufacture from the first pro-

ducer, and get them done by the same sort of agency as the secondary processes; indeed, the simpler the process the more ingenious and elaborate, as a rule, is the machine. If this be true, the manufacture of silk in India is mere misdirection of energy; but in the growth and exportation of our waste and wild silks there lies an immense field all undeveloped. By wild silks we do not mean silk gathered from the jungle, but those species which, though cultivated, have never received any scientific attention: such, for instance, as the eri or castor-oil silkworm of Assam and North-Eastern Bengal, from whose cocoons the natives of those districts have for centuries spun thread which is wrought into fabrics of astonishing durability. Treated by the beautiful engines of the English spinner, these cocoons furnish the material for plushes with soft attractive handling, for rugs, and for other kinds of goods combining cheapness with beauty. The silkworm is an indigenous one; Nature co-operates with man in multiplying its production; and it seems reasonable to conclude that only capital and perseverance are wanted in order to lay the foundation of a new trade which may make the fortune of its discoverer and prove of immense benefit to the country.

EUCALYPTUS.

Memorandum comprising extracts from various sources relating to the Medicinal Uses and Virtues of the Eucalyptus.

Extract from *Burquoine, Burbigles & Co's Circular*.—The oil of *Eucalyptus globulus*, as a substitute for carbolic acid, has been much advocated of late. It is a most valuable anti-septic and has obtained the happiest results in bronchial catarrh. Professor Lister is of opinion that the *Eucalyptus globulus* should supersede carbolic acid as an antiseptic because of its harmless nature.

Extract from *Companion to the British Pharmacopoeia*.—Liquid extract of *Eucalyptus gum* 1 part, water 2 parts: dissolve and strain. An excellent remedy in arresting bleeding from the nose. Lint dipped in it checks bleeding from wounds. The gum is used in doses of 5 grains every four hours in diarrhoea and dysentery. The oil is obtained from the leaves by distillation.

Extract from *Medical Times and Gazette*, 1882.—The oil of *Eucalyptus globulus* is said to diminish the action of the heart and the blood pressure and to act as a stimulant, astringent and antiseptic on mucous membranes. Dr. Currier speaks highly of its use as a disinfectant and antiseptic in chronic ovaritis and tumours of the breast, in removing the factor of the discharges and relieving the pain and discomfort.

Extract from *Export Price Current and Trade Report*.—The leaves of several of the species of *Eucalyptus* when duly prepared and compounded into an ointment are found to possess healing properties, which, without exaggeration, may be termed remarkable. Josephson's ointment is the property of Messrs. E. Row & Co. of New South Wales. In the colonies it has achieved, we believe, considerable success in the treatment of wounds, &c.

Extract from *Australian Medical Gazette*.—[Being an article by John Murray Gibbs, M.A. and C.M., (Aberdeen), M.B.C.S.E., Doctor of New Zealand, with reference to a severe epidemic outbreak of diphtheria.] *First*.—After swabbing the throat with liq. fer. perchl. dil. and glycerine. *Second*.—Pour boiling water on blue-gum leaves and let the steam be inhaled day and night. Drawing steam through an inhaler, or holding the head over a jug, is a most wearisome process, and you find that patients, especially children, soon get tired of it; so I order the pou. jar or jug containing the infusion to be placed on a chair beside the bed, and a tent of the bed-clothes to be placed over it and the patient's head. This conveys the steam to the patient without exhausting him. Children soon feel the soothing effect, all uneasiness and pain in the throat leaving. Of course in mild cases the steam

does not require to be used so often. In several cases, after 5 or 6 hours' steaming, complete casts of the air-passage were coughed up, and the breathing became easy at once. One young lady, tapping the upper part of her sternum, said, "It is here." She could not swallow a tea-spoonful of water! Her lips were blue and her face of a dusky hue; but after hours of steaming the membrane was coughed up, and the breathing became at once easy. In one case, where steaming was not carried out, the little patient was semi-sphyxiated for three days before death put an end to her sufferings. It was the first case of this epidemic that I saw, and was not able to sufficiently impress the attendants with the importance of the constant use of this steam. In blue-gum steam we have a most perfect disinfectant, as in no single case, after the first twenty-four hours, was the breath unpleasant and the swelling in the neck quickly subsided. Towards eight o'clock the diphtheria patients generally became feverish, restless and unable to sleep, and it was wonderful to watch the soothing effects of the steam. A bucket was generally placed in the room containing the blue-gum water, and a red-hot poker placed in it, which at once filled the room with steam, and very shortly after one child after another would fall asleep. Twenty-four cases were treated as above, with the death of only one infant, aged eight months. There were six other children ill in the same family, and not one case of paralysis has occurred amongst them, although two treated with sulphur by their parents are badly affected. I think that I can claim for the above treatment.—1st.—Great simplicity; 2nd.—That it follows nature's own method of getting rid of the membrane, namely, by suppuration; 3rd.—That it prevents paralysis from following; 4th.—That it cures the severest cases.

Extract from the *Sydney Mail*.—[Substance of a letter from Dr. Ross, M.D.]—I am forced, from careful observation and long experience of hush life, to believe that the majority of our gum trees, no matter in what form used, whether in the shape of their leaves in their natural state, or dried, in ointment, powder, decoction, gum, extract, oil or alkaloid, all inherit virtues. Time alone is found to bring them into more general repute as an invaluable antiseptic and agent for counteracting lethal or poisonous exhalations; a cooling, healing application to wounds and ulcers, or rheumatism, and a salutary remedy in parasitic disorders in sheep. I shall now submit the following short extract of a remarkable *spina* wound case. On the 28th December 1861 I found the abdominal wound wide open and gaping and the bowels protruding, accompanied by a quantity of ichorous serum oozing from the large orifice. Had taken no medicine. His gin, sitting by his side, in the bush gonyah, attentively bathed the wound and swollen abdomen with a few of the most tender shoots and leaves of the red-gum tree, steeped from time to time in hot-water. In consequence of the natural appearance of the wound all chances of his recovery seemed now to have been quite taken out of my hands, for to attempt to close the wound, under the circumstances, would not only have been perfectly futile, but have added to the danger as the swelling was rapidly increasing, so much so that the case appeared quite hopeless and the pulse was sinking. On returning in the evening I found to my great surprise and astonishment that what I had considered to be a useless and cruel sort of application had not only lessened the size of the wound, but had positively had the effect of removing the swelling. Seeing such results, of course I could make no further objection to the use of this strange application in the shape of tender leaves, and the sixth day found the abdominal wound closed.

Extract from *Edin. Pharm. Journ.*, 1884. *Eucalyptus folia* (Eucalyptus) var. 1—Dose 5 grains, or more, in powder. The leaves of the *Eucalyptus globulus*, or blue-gum tree of Australia, have been employed medicinally in the treatment of ague and

bronchitis, and are now much used in Italy for Roman and malarious fevers; also, when coarsely powdered, are employed for smoking in cigarettes in cardiac and aneurismal asthma. The narrow leaves, mostly semitar-shaped, are more active medicinally than the broad leaves of herbaceous shoots.

Oilum Eucalypti.—Dose 1 to 5 minims emulsified with olive oil. Is distilled from the leaves of the *Eucalyptus amygdalina* and also from those of the *Eucalyptus globulus* and probably from other species. It is to this oil, and also especially to the great avidity for water which this tree has when growing, that it owes its antimalarial influence. The oil is a powerful antiseptic and has an ozonizing influence on the atmosphere while it oxidises. It has a pale yellow color, a penetrating, camphoraceous odour, sp. gr. about 0.900, and boils between 338° and 352° (Fahr.). It is not caustic like carbolic acid, nor does it produce much irritation, although it is very destructive to low organic growths. It is soluble in oils, fats, paraffins, and alcohol, but only a trace dissolves in water. The oil is useful (mixed with an equal quantity of olive oil) as a rubefacient for rheumatism. A large percentage of *Eucalyptus* oil consists of "*Eucalyptol*," which is also met with in commerce and is that part of the above oil which passes over between 338° and 352° F. It is obtained by treating the latter with caustic potash, then with chloride of calcium, and subsequent distillation.

Extract from the *Australasian*.—Baron Von Mueller has been at the pains of collecting and collating testimony from the scientific publications of many countries, and he cites recorded cases resting on the authority of practitioners of eminence to show that *Eucalyptus* oil possesses almost unique virtues as an antiseptic, as an agent for the reduction of the pulse in phthisis and typhus, for the diminution of bronchial catarrh, for combating incipient or threatened gangrene, and for healing certain ulcers. Dr. Wooster of San Francisco enumerates 129 cases of various diseases, 96 of which were cured by the administration of the fluid extract of *Eucalyptus* foliage. In 23 cases of remittent, intermittent and typhoid fever, every one yielded to the treatment. The American Faculty are using the extract largely in cases of diphtheria and scarlatina with the most gratifying results; and in severe cases of cystitis, it has effected cures when all ordinary remedies had failed. In the practice of a single physician in New York, 101 diphtheritic cases have been successfully treated by the fluid extract. *Eucalyptus* inhalations, it has been found, are capable of overcoming catarrhal asthma and whooping-cough and of arresting pulmonary consumption.

Extract from *Pharm. Zeitung*.—Rodolfo Rodolfi recommends, from personal experience, the chewing of two to three dried leaves of *Eucalyptus globulus* as a sovereign remedy for cold in the head and eryza, provided they are recent and not chronic. The effect generally makes itself felt in half an hour.

OTHER USES OF EUCALYPTUS OIL NOT MEDICAL.

Extract from the *Indian Agriculturist*.—A process has been invented in America for the manufacture of a preparation of the gum of the "*Eucalyptus globulus*." It has the effect of removing thoroughly the scales which form in engine-boilers, and thus prevents rust and pitting. The result of the introduction of this preparation has been so great as to create an immense demand for it both in America and Europe. The effect of this preparation in preventing the pitting and corrosion of boilers will, it is expected, extend the period of their usefulness 100 to 150 per cent, and at the same time effect a great saving in fuel, as scale is a non-conductor of heat, and therefore more fuel is required to generate steam in old boilers than in new clean boilers. We have seen an adverse opinion from an European Eng.

Extract from a *Letter from the Director, Government Victoria Plantations, Parks and Gardens*.—"The leaves of many of the *Eucalypti* yield very good

oils, and few are more valuable than that obtainable from the "*Eucalyptus globulus*." The way to extract the oil is as follows:—Fill a large still with the macerated crushed leaves, and water and distil at a low temperature. Shake up the product with a little salt (this causes the oil to separate more rapidly from the water which comes over with it from the still), decant the oil from the water and filter through the paper. The leaves should be macerated for twenty-four hours and then mashed up. This process facilitates the extraction of the oil by breaking down the cells which surround the glands that contain it.

FERN CULTURE.

Ferns are so universally popular, and are now used in such a variety of ways, that the demand for plants of all sizes has considerably increased during the last few years; and it requires some skill and management to keep up a supply throughout the year; especially of small plants suitable for the fancy pots which are now so much used. For this purpose the plants must be of a limited size, and to have nice healthy plants it is necessary to make successive sowings. Although the spores germinate most freely during the spring and summer, yet, under favourable circumstances, they may be induced to grow at any season of the year, even during the dull months of November and December.

To ensure success in raising Ferns from spores it is of the first importance that the fertile fronds should be collected at the proper time, and they should always be selected from plants grown in isolated positions as far as possible; as, where several sorts come in contact with one another the spores, which float about freely, will often settle on the fronds of different sorts, and it becomes difficult to ensure a crop of the particular sort that is desired. *Nephrodium molle*, *Pteris longifolia*, and some of the *Gymnogrammas*, are among the most troublesome Fern-weeds, and should never be allowed to come in contact with those that are required to be increased. The best time to collect the fertile fronds is just as the spore-cases begin to open; as soon as the fronds are taken off they should be folded up in paper, and if put in a warm dry place, in a few days there will be plenty of spores ready for sowing; or they will keep in good condition for a very long period. As good fertile fronds of many sorts are only to be had at certain seasons, it is necessary to be on the look-out so as to secure them when they are obtainable, bearing in mind that it is better to have a little extra stock, rather than to run short of any particular sort.

SOWING THE SPORES.

The plan we adopt is somewhat different to that which is usually advocated—viz., we usually use 48-size pots, which are filled firmly to within about an inch of the top with good loam, using no drainage whatever, and after the pots are filled they are thoroughly watered. Before sowing the spores, we sprinkle a little burnt ballast over the surface of the soil, or potsherds powdered fine and sifted through a fine sieve. As soon as the spores are sown, each pot is covered with a piece of glass and stood in a saucer of water; the saucers are not kept constantly filled with water, but sufficient is given to prevent the pots requiring any surface watering; the pots are placed under a stage near the hot-water pipes, where they remain until the spores begin to germinate, they are then removed to a lighter position, and the glasses are taken off every morning until the prothallia are well developed, when the glasses may be dispensed with altogether. As soon as they are sufficiently developed we prick them off into pots or boxes, the compost for which consists of equal parts of loam and peat, with a liberal alluvance of sand added; plenty of drainage is also used.

Ferns, when pricked off in a small state, must be lifted and replanted in patches, and these require dividing again when putted off into small pots,

though in some cases they are not divided singly, as when grown in tufts of three or four together they are more useful, and are useful much sooner; this especially applies to *Alantums* of different kinds, *Pteris serrulata* and its varieties, *P. hastata*, *P. cretica* and its varieties; while such sorts as *P. tricolor*, *P. argyrea*, *P. tremula*, *Cyrtomium falcatum*, or any of the *Gymnogrammas*, are better grown singly.—H.—*Gardener's Chronicle*.

THE COFFEE CROP IN COORG.—From a communication from the Press Commissioner which we have received regarding the prospects of the coffee crop in Coorg, we learn that the crop is expected to yield during the ensuing year an outturn of about 3,612 tons. With three or four small exceptions, this estimate embraces every estate in the province. The outturn is considered by the Chief Commissioner to be a favourable one, and represents about 1 cwt. per acre.—*Madras Times*.

VINE DISEASES.—The Italian Ministry of Agriculture has authorised the formation of an International Exhibition in the Royal School of Vine Culture and Enology (wine making) at Conegliano, near Venice, for the special purpose of getting together a collection of implements and machines destined for the application of lime and other remedies for mildew and Peronospora, in Vines. The implements, such as pumps, syringes, spray producers, will be tested practically, and prizes awarded as follows:—One Gold Medal and 500 lire (francs); three Silver Medals and 150 lire with each; five Bronze Medals. The Government will also purchase premiated instruments to the value of 1000 lire, for the purpose of distributing them in agricultural schools. Applications for permission to exhibit should be sent to the "Direzione della R. Senola di Viticoltura ed Enologia in Conegliano, Italy," before February 22, 1886, and all machines must be sent to the model farm of the School before March 1, 1886. The trials will commence on March 2.—*Gardener's Chronicle*.

HORTICULTURE AND FLORICULTURE IN SILESIA.—Court gardener Hoffmann has expressed the opinion that it is not possible to compete with Italy and France in horticulture and floriculture, since the countries require neither glass nor heating for their flowers. This has induced a large agriculturist in Lower Silesia to study the question whether the auxiliaries necessary with our climate to the production of the finer garden products cannot in that province be employed sufficiently cheaply. Possessing coal mines and glass and iron works he thinks conservatories of requisite size should be procurable at moderate cost, though for the establishment of these on a scale sufficiently large for the cultivation of tropical fruits of all kinds, but particularly oranges, lemons, and citrons, a Government advance of from 20 to 30 millions, free of interest, would be necessary, as well as adequate protective duties. We fear, however, that the scheme is chimerical. It is a hard matter to contend against the order of nature.—*Kuhlov's German Trade Review*.

AGRICULTURE IN GERMAN WEST AFRICA.—Lieutenant Siegm. Israel writes on this subject that his many years residence in West Africa convinces him that agriculture is quite possible there. He has either planted or seen planted in Africa potatoes, wheat, rashes, cabbages, cucumbers, oats, vines, and tomatoes, and if they are only grown properly they succeed splendidly. He also believes that it is possible to educate the blacks to field labour, and even to cultivate their own ground. Pea or ground nuts are very largely planted, and are sold to factors as 2s. per bushel of 28 kg. The negroes also plant kassava or yams, floury kinds of roots, and sweet potatoes are likewise successfully cultivated as food. Lieutenant Israel allows that the climate of West Africa is very trying for Europeans, but he maintains that in process of time it will be more tolerable, and he instances the vast improvement which has come over the sanitary state of the European population in Sierra Leone and Lagos since doctors settled there and hospitals were established.—*Kuhlov's German Trade Review*.

NOTES OF A VISIT TO THE DUTCH GOVERNMENT CINCHONA PLANTATIONS IN JAVA.*

BY HENRY B. BRADY, F. R. S.

On the 7th of May of the present year, the British Indian Mail steamer "Merkeru," bound from Brisbane to London, with a full complement of passengers, of whom I chanced to be one, entered from the southern side the narrow sea which separates Java from the neighbouring island of Bali. Six years previously I had passed almost within sight of the northern shores of Java, but with scanty time at my disposal; and it had been judged better to leave the country unseen than to invite the disappointment certain to result from a very hurried visit. This conclusion had in the interval been a frequent source of regret, but the omission was one which there was now the opportunity to repair.

It was early morning; and as we approached the narrower portion of the Strait the scenery of the coast to east and west became more and more striking and beautiful. To the right were the shores of Bali gently sloping to the sea, backed by a mountain-range, whose summits reached a height of 6,000 or 7,000 feet. But the chief interest lay on the western side, where Mount Rawon, Mount Idjen, and two or three other mighty volcanic cones, the highest of them towering to upwards of 10,000 feet, seemed close upon us. In the foreground little clusters of red-tiled bamboo cottages nestled amongst the palms at the water's edge, and the sun-lit rippling sea between, studded with gaily painted native fishing boats, of build and rigging strange to the European eye, served to complete an almost ideal tropical picture.

I had obtained leave to land at Banjocwangi, the easternmost point of Java; and the Captain, with his wonted kindness, had further offered to facilitate my movements by taking my heavier baggage forward to Batavia, my intention being to travel overland, in order to see as much as possible of the interior of the Island.

Intending to make some stay in the Capital on my return, I proceeded thence almost immediately to Buitenzorg, a little town among the mountains, forty miles south, the chief health resort of the Batavians and the usual residence of the Governor-General of the Dutch East Indies and his staff. My letters of introduction had been forwarded in advance, and I had hardly entered the Hotel before I received an intimation from the aide-de-camp on duty that I was to have the honour of a special audience at the Palace the same morning. I was received by his Excellency with great kindness, and the interview was in every way satisfactory. In the course of conversation, which happily for me was in English, I mentioned one or two objects I had at heart—foremost amongst them my desire to visit the Government Cinchona plantations in the Preanger; and, on leaving, his Excellency was good enough to furnish me with a private letter to his son-in-law, Mr. Van Gelderen Stort, the Secretary of the Preanger Regency, in addition to the usual formal papers. I had heard it said that the Cinchona plantations and the various experiments in culture carried on by the Colonial Government were guarded with a certain amount of jealousy, and I should not have been surprised had I experienced some difficulty in accomplishing what I wished. Nothing could be further from the fact; and I may here be allowed to express my grateful acknowledgment of the courtesy and consideration that the English traveller in Java experiences at the hands of the Dutch officials of every grade.

The Preanger, the district in which the Government Cinchona estates are situated, is a mountainous region in the south-west of Java, only separated from the Strait of Sonda by the little kingdom of Bantam.

* Read at an evening meeting of the Pharmaceutical Society, Wednesday, December 9, 1885.

Politically, it is a distinct Regency, the capital Bandung, being the seat of a Regent or native ruler and of a Dutch Resident. The people are Sundanese, one of the three Malay races of which the population of Java is made up; but with something more than the usual admixture of Arabs, and a considerable number of Chinese. The short line of railway originally connecting Batavia and Buitenzorg has been of late years extended almost through the Regency, and will, it is hoped, ere long form a junction with the eastern lines, and thus complete the inland railway system.

Buitenzorg itself is a fascinating place,—landscape and climate alike irresistible; and in addition to its natural attractions it possesses a far-famed Botanical Garden which is at once the most extensive and most instructively arranged, and perhaps on the whole the most beautiful, of any within the tropics. Once more I am tempted to diverge, unwilling to pass without notice the numberless plants interesting to us from their pharmaceutical or economic associations, whose acquaintance, living and growing, I either made there for the first time, or had the opportunity of renewing. But again I am reminded that this is not our present business.

The geography and character of the Island of Java seem to be very little known in this country, and I may therefore mention the following particulars. The island itself is about one-third larger than Ireland, and it is, I think, with the exception of Belgium, the most thickly populated country in the world, having a population in this small area of upwards of 20,000,000. Batavia is the largest and most populous town in the southern hemisphere, having a population of something like 500,000,* and spreading over an enormous area. The only city at all comparable with it is Melbourne, which with its suburbs has a population of 300,000 or 350,000. The island of Java is about 600 miles long and varies in breadth from 40 to 120 miles.

After one or two cursory visits to the Gardens in company with their indefatigable Director, Dr. Treub, I determined to take my departure for the Preanger at once, leaving their more detailed examination until my return. Accordingly, on the 1st of June, I took train for Bandung, where I found comfortable quarters at the little local hotel. Having made the needful calls and presented my letters, I accepted an appointment with Mr. Van den Berg, the Controleur of the Regency, for the evening of the same day, and was very kindly introduced by him to Mr. R. Van Romunde, the Director of the Cinchona Plantations—the successor in that office to the well-known quinologist, Dr. J. C. B. Moens. In the course of conversation (nearly all the Dutch officials speak excellent English) Mr. Van Romunde very kindly offered that, if I would stay in Bandung for a day or two, he would make the needful arrangements, and would himself accompany me to two of the establishments under his charge; whereupon the genial Controleur suggested that he also should be included in the party; and so it was settled, all trouble in the matter being taken out of my hands.

Bandung is situated in the midst of a wide plain about 2,000 feet above sea-level, bounded by mountain ranges to north and south. The localities selected for Cinchona cultivation are on the southern aspects of these opposing ridges. There are altogether eight Government plantations, four of about 200 acres each, two of 150 acres, one of 100, and one of 70 acres, total, say about 1,270 acres. One of the estates lies at an altitude of about 6,000 feet above the sea, and four at about 5,000 feet, the remainder are somewhat lower. Six out of the eight are on the southern group of mountains, that is to say, on the sides of Mount Malawar and the adjacent Wajang, Tileo, and Patoccha. Some, if not all of these were visited by Mr. H. O. Forbes in 1880; my own experience does not extend to that particular region. The expedition planned for me was to the two northern plantations, those

* We should say about 200,000.—Ed.

of Nagrak and Lembang, on the southern slopes of Tangkoeban Praoe.

Early on the morning of the day appointed our little party started in two cahars, each drawn by three smart ponies, on the road towards Lembang; and after about an hour's drive we reached a little village where saddle-horses were waiting for us. Thence, accompanied by a considerable escort of natives, riding and on foot, we commenced the steeper portion of the ascent by a devious mountain path. Though we had been gradually getting on to higher ground ever since leaving Bandung, there was at first but little perceptible change in the character of the vegetation, and one might still observe about the native cottages, bananas and betel-pepper, patches of cassava, the coconut palm and the areca palm, and clumps of tall bamboos. Somewhat higher these gave place more or less to the arenga or sugar palm and small plots of tea; whilst higher again coffee became the prominent object of cultivation, and this, together with fine crops of tobacco, were noticed up to an elevation of 4,000 feet.

Thanks to an early start we reached Nagrak about 9 a.m. On entering the plantations our attention was first attracted by a large patch of *Cinchona Josephianna*, well-grown trees eight or nine years old. The bark of this species has been found to be of low alkaloid value, seldom yielding more than 1 per cent of quinine, so that the tree is no longer regarded as worth growing, and the whole were being uprooted. Thou came a plot of *C. succirubra*, which, so far as quinine is concerned, is scarcely richer, and this ground was about to be cleared for the same reason. A similar fate has already befallen a large proportion of the plantings of *C. Calisaya*, *C. Pahudiana*, and *C. Hasskarliana*.

The homestead, if one may call it so, that is the buildings pertaining to the station, are situated about 13 pials from Bamlong, on a sort of platform 5,000 feet above the sea, the plantations extending to a further height of 400 feet or more on the mountain side. The area of the estate is about 200 acres. The buildings consist of the overseer's house—a commodious little wooden bungalow of the customary Dutch East India pattern, in a garden gay and fragrant with roses and heliotrope, and a number of rows of tidy cottages, built native fashion of bamboo wicker-work and thatched. Near at hand are the drying sheds and frames, stoves, and the like, as well as the nurseries stocked with young plants. The platform in front of the house commands a magnificent panorama of the plain of Bandung with the Tji Taroom meandering through it; and of the opposite range of Mount Malabar, thirty to forty miles distant, whose summits reach an elevation of 7,200 feet. A flag-staff with the Dutch colours is a conspicuous landmark from below; and close by is a tall handsome tree of *Cinchona Cortifolia*, which has been spared for its beauty in the general uprooting of that species.

Leaving our horses at the house, we proceeded to the work of inspection on foot, visiting first the drying-sheds. The bark is dried as far as possible without artificial heat. It is placed in trays 4 to 5 feet long by 3 wide, made of plaited strips of bamboo, the quills being arranged in orderly fashion side by side. The trays are slid on to long stages or tressles 3 or 4 feet in height. They are brought out early in the morning, and at sunset are all taken back into the adjoining sheds and piled in tiers. The frequent heavy tropical showers necessitate a large amount of care whilst the bark is thus exposed. For artificial drying there are houses with stoves and long flues, wood of course being employed as fuel; but those are comparatively little used, as, on the whole, spontaneous drying has been found to give the best results. At the time of my visit the trays were filled with *succirubra* bark in quills, and the root-bark of the same in small irregular shreds.

Passing from the drying-ground again into the plantations, which lie on a tolerably steep ascent, we found ourselves first in a tract laid out with *C. succirubra*.

As a tree *Cinchona succirubra* is one of the handsomest of the genus. The size of the leaves, especially those of the young plants, and the fine ruddy hue which they often exhibit, together with its vigorous habit of growth, serve to distinguish the species from most of its congeners. The plantation was undergoing the process of thinning, and to this end the surplus trees were being pulled up by the roots. The bark of the roots, which is thinner and much less easily separated than that of the stem, is carefully preserved; for it has been ascertained that in several species which are accounted of relatively low quinine value, notably *C. officinalis*, *C. anglica* and *C. succirubra*, the root-bark gives the better percentage of alkaloids.

Further on we came to a plot of what is termed by the Dutch botanists *Cinchona Calisaya*, var. *anglica*, which is supposed to be a hybrid between *calisaya* and *succirubra*, and possesses more or less the botanical features of both. The original stock is said to have been obtained from Ceylon. At a somewhat higher level, 5,200 feet or more, is a plantation of *C. lancifolia*, which is still regarded as a useful tree, the bark often yielding 4 or 5 per cent of quinine. At about the same elevation there is also a considerable planting of *C. officinalis*, but either the climate or soil are unfavourable to that species, for it grows slowly and the trees are long and spindling, though it is reported to thrive well in private plantations in the more easterly portions of the island.

Above these again was a large area devoted to *Cinchona Ledgeriana*. At present the whole interest of *Cinchona* planters is centred in this plant. The story of its introduction is probably known to many of you.* An Englishman, Charles Ledger, resident for the time in Bolivia, engaged in business chiefly in connection with the alpaca trade, but in constant communication with native bark-collectors, conceived the idea of obtaining the seed of the "famous white flower rojo escarilla" from the valley of the Yuogas. The difficulties were known to be almost insuperable. The Indians had a deep-rooted superstition that if their *Cinchona*s ever came to be successfully cultivated in other countries all their own trees would perish, and of course no precaution was left unheeded to prevent such a catastrophe. "More than half a dozen times," says Mr. Ledger, "I have had my luggage, bedding, etc., searched when coming out of the Yuogas;" and the strictest vigilance was exercised even by the local priests to prevent anyone talking seed or plants out of the country. This was as far back as 1856. A Bolivian Indian, Manuel Tacra Mamani, with his two sons accompanied Mr. Ledger in his travels, and one of the sons subsequently went with him to Australia. Previous to leaving Bolivia, Mr. Ledger had hinted to Manuel that he might require some of the seeds and flowers of the coveted species of *Cinchona* for the preparation of an important medicine, and the reputation which he enjoyed as a doctor was sufficient to give an air of probability to the story. On the return of the son from Australia in 1861, Mr. Ledger sent the sum of 200 dollars to Manuel by him, with a message that he looked to him to procure 10 or 50 lb. of seed from a certain specified batch of trees that they had visited together ten years before. Of the precise locality nothing is known to us except that it is in the Caupulicán district of the eastern Yuogas.

Ledger himself returned to South America in 1865, and Manuel met him at Tacna, in Peru, bringing with him the coveted seed. Under any other supposition than that it was required as a medicine, probably even the faithful Indian would have made no attempt to obtain it; and poor Manuel himself lost his life seven or eight years later in endeavouring to procure a further supply from the same source. Even after the seed was secured there was consider-

* An exceedingly interesting letter written by Mr. Ledger to his brother, giving a history of the steps by which the original seed was procured, appeared in the *Field* for February 5, 1883, p. 161.

able difficulty in disposing of it, but eventually a portion was bought for our own East Indian plantations, and the remainder was sold to the Netherlands Government for about £50.

So far as is known the seed sent to India was in every respect similar to that supplied to Java. At first Manuel had endeavoured to keep the produce of each tree separate, but the contents of his packets became accidentally mixed and no further attempt was made to preserve any distinction. But for some reason the results from British India have not, as a whole, been equal to those obtained in Java. Mr. David Howard tells me that at Naduwattam, where the seed was sown, the soil and climate did not suit the species and almost all the original trees died, whilst the neighbouring *succinbra* was allowed to hybridize the flowers of those that remained; so that there the strain was lost. Lower down in the Wynaad, however, on Captain Cox's plantation, the true *Ledgeriana* is now being grown, and produces bark quite equal to the average of the Java trees. There is also good promise of bark of the same sort from Ceylon; though the essential conditions, a rich deep soil with good drainage, are not there so common, and though at present much of their so-called *Ledgeriana* has no claim to the name beyond the fact that the seed was brought and paid for as such.

The Java consignment of seed was sown in 1866 at the Tjijirecan plantation, on the opposite side of the valley to Nagrak, and produced about seven thousand plants. These original trees were seen by Mr. Forbes on his visit in 1880, and are described by him as, at that time, "somewhat seraggy looking, about 2 feet in circumference, and between 20 and 30 feet in height." The story of the incredulity, astonishment, and delight of the Government chemists on their first analyses of the bark is also graphically recounted by the same author, who doubtless had the narrative from Dr. Moens himself; nevertheless these early results were not comparable with what have since been obtained.

To return now to the *Ledgeriana* plantations of Nagrak. The trees one sees collected there are supposed to be of the purest strain, yet I could not avoid being struck with the great diversity of their botanical characters; and I may confess that had some of them been shown to me separately as specimens I should probably have assigned them not only to distinct varieties but perhaps to different species. I can express no opinion as to the precise botanical position that *C. Ledgeriana* should occupy. I was assured by Mr. Van Romunde that the plant is always identifiable; and he agrees with his predecessor, Dr. Moens, in the opinion that it is a true species. The late Mr. John Eliot Howard, you are aware, regarded it as a variety of *C. Calisaya*, and this view is shared by many other botanists; whilst it has been treated by Dr. Otto Kunze as a hybrid between *C. officinalis* and *C. micrantha*. [An eccentric theory, in which no botanist of mark agrees.—Ed.] The present Director lays particular stress on the angle of the axil of the branches as a distinctive feature, the angle in *C. Ledgeriana* being always acute. The leaves, though of variable outline, are usually relatively long, narrow and pointed; and under all circumstances the upper side exhibits what, for want of a better term, one may call a velvety surface, that is to say, it has a soft deadish lustre, very different from the evergreen gloss of the typical *Calisaya*. The most valuable trees, from a quinine-yielding point of view, have small and pure white or creamy flowers; any red tinge is said to indicate the presence of quinidine rather than quinine in the bark. It is worth remembering that a few years ago the highest percentage of quinine was said to have been produced by one or two trees with a tinge of red in the flowers; but by the way in which the fact is stated it appears as though it was regarded as something exceptional, and in any case the proportion then attained has since been much exceeded.

The barks of the various trees of the *Calisaya* type, that is to say, of *C. Calisaya*, var. *Javanica*,

C. Ledgeriana, *C. Haskarlanni*, *C. Josephiana* and the Schuhrkraft hybrid, grown under the same conditions of locality and soil, cannot, I was assured, be distinguished one from another by any well-defined physical characters, the cracks and superficial markings being very much alike in all; though the epidermis of *Ledgeriana* sometimes exhibits a tendency to peel off, not noticeable in true *Calisaya*. The barks of *C. officinalis* and *C. succinbra* are of course much more easily identified.

All the *Ledgerianas* in this plantation had their tops lopped off to prevent further growth in the plant; a precaution dictated by practical convenience since the introduction of the process of scraping the bark, a process which I shall have something to say presently.

Having wandered about the grounds until we were tired and examined the plantings of all the more important species under culture, we returned to the nurseries in order to inspect the seedlings of various ages not yet ready to be planted out. These for the most part are kept in beds covered with roof-like shades made of split bamboo. The young plants are carefully protected in this way for two years before being transferred to the open ground. When planted out the young trees are placed at different distances apart according to the needs of each species—*C. Ledgeriana*, for example, being spaced 4 feet apart, *C. succinbra*, a much larger tree, about 7 feet apart and so on. The ground is at first kept carefully weeded; subsequently, as the trees grow up, the close shade of the foliage prevents any considerable undergrowth. Long narrow holes or trenches, a foot or more in depth and several feet in length, are dug between the rows, chiefly for the purpose of drainage, but they are useful also in collecting the soil which would otherwise be washed away during heavy rains.

The primary aim in Cinchona culture is to obtain the maximum quantity of bark containing the largest percentage of alkaloids, especially of quinine. With this object, various experiments have been made in connection with the propagation and cultivation of the trees, as well as in the manner of harvesting the bark.

A large number of plants are raised from seed. There is, however, an element of uncertainty in the result, arising from the cross-fertilization of the flowers by insect agency, and the consequent production of hybrids, the bark of which generally yields a smaller proportion of alkaloids than either of the parents. It has been stated, how far correctly I do not know, that in the case of *C. Ledgeriana* the first two or three crops of seed are most liable to yield hybrid plants, and that the subsequent produce comes much more uniformly true. The better species are also propagated to a considerable extent by means of cuttings.

But the process of cultivation most in favour at the present time is that of grafting. The different rate of growth of the different species of Cinchona, and their diversity of habit, are almost as remarkable as their difference in alkaloidal value. The quick-growing species however, are not those which yield the richest bark; and the object sought has been to endow the latter with the vigorous habit of growth of the stronger sorts. The most easily cultivated and in every way the most eligible of the rapid-growing species is *C. succinbra*, and this is used as the stock whereon are grafted shoots of *C. Ledgeriana*. The stock may either be a plant obtained from seed or one grown from a cutting. The graft is inserted whilst the foster plant is still very young; in the case of a seedling, as soon as it possesses a firm enough stem. The young plants after the insertion of the grafts require care and protection for several months before being placed in the open ground, but when once established they are as hardy as the rest. The grafts are always taken from trees of which the bark has given satisfactory results on analysis, and the plants produced retain the chemical characters of the parent. There are now large plantations of grafted *Ledgerianas*, the bark of which is known to contain 13 per cent of quinine.

Some years ago coppicing was tried as a means of increasing the yield of bark, but the results were not satisfactory and it is no longer practised.

The old method of harvesting the bark is by stripping the trees; to which end they are either cut down or pulled up by the roots when ten or twelve years old. A *Ledgeriana* tree of ten years should yield from 10 to 15 kilos. (24 to 35 lb.) of bark. Mr. McIvor's process, which consisted of removing long vertical strips of the bark and covering the exposed surface with moss, has been largely employed. I noticed a number of trees that had been so treated, the trunks of which had a very singular appearance, somewhat resembling fluted columns. This mode of collecting answers very well, provided sufficient care be exercised not to injure the cambium layer, a matter apt to be neglected by the native work-people; but it has a serious drawback in the shelter that the moss affords to all manner of noxious insects, and it has been relinquished in favour of scraping. It is well known that the exterior portions of the bark are richest in quinine, and the plan now preferred is to scrape off the outer layer with a long flat knife—a process that does not appear to interfere in the least with the normal growth of the tree. The stem and larger branches are scraped half round at one operation, the other half at the end of six months, and this may be repeated at the same intervals year by year. I observed some trees of *C. Ledgeriana* which had been scraped eight months before, with renewed bark fully a quarter of an inch in thickness.

Like all other cultivated plants *Cinchona* has its enemies. By far the most serious pest is a hemipterous insect, *Helopeltis antonii*, the so-called Assam tea-bug, specimens of which, collected at Nagrak, are on the table.

[Here follow two figures of the insects.]

Helopeltis antonii, Signoret.

a. Male; b. female.

c. side view of the scutellum.

Magnified about $\frac{3}{4}$ times linear.

The female insect is slightly larger than the male, and has a red thorax.

The insect punctures the leaf buds and very young leaves, and feeds upon the juices of the plant. The leaves shrivel and die, the growth of the shoots is stopped, and the tree, if not killed outright, becomes unhealthy and dwindles away. The plantations of *C. Calisaya*, *C. Ledgeriana* and *C. officinalis* have suffered most from the ravages of this pest, whilst those of *C. succirubra* have hitherto passed comparatively unscathed. Mr. Forbes states that the eggs of the insect "are laid and hatched on a species of *Datura* which is one of the plants most widely distributed over the district, thereby rendering all attempts to eradicate the evil rather hopeless." On some of the plantations the insects are collected daily in vast numbers and burned. I noticed also one or two clumps of trees, the leaves of which were completely riddled by a caterpillar, species unknown, but the damage in such cases is usually local and is not regarded in any serious light.

The permanent staff of the Nagrak plantation consists of about sixty natives, in addition to a variable number of coolies. The women and children of course do much of the lighter work. The pay of the natives depends more or less on the price of food; at the time of my visit, rice being cheap, it was twenty cents, or about 14. per day. The Nagrak establishment placed on the market last year about 165,000 lb. of bark, of one sort or other, fetching an average of 80 to 90 cents (says L. 4d. to 1s. 6d.) per lb. This year it was expected that the yield would be about 200,000 lb. of which the value was estimated at a guilder (1s. 8d.) per lb.

These, so far as I recollect, were the principal facts gathered on the day's ramble.

I was hospitably entertained for the night at the superintendent's house, and the following morning, whilst Mr. Van Romunde was otherwise engaged, the Controller and I mounted our horses, and accompanied by native guides took a bridle track to the summit of

the mountain, some 1,500 feet above the station. The path lay through uncleared forest and nothing could exceed the magnificence of the vegetation. Of the larger forest trees at this height a considerable proportion were new to me,—various species of oak and *Ficus*, *Lavrocoa* and *Meliacea*, *Myristica*, and *Podocarpus*, with great climbing aroids and parasites innumerable. There were thickets of tree-ferns, the fronds of which formed fairy arches overhead as we rode, and amongst lesser plants were raspberries of more than one species, with almost tasteless fruit, a little *Rhododendron* and one or two other *Ericaceae*, *Melastomas*, and *Begonias*, balsams, violets, orchids epiphytic and terrestrial, ferns and lycopods, in profusion. On attaining the summit we found that we had to descend a short distance on the opposite side to reach the crater. Tangkoeban Praoc has in fact two craters, one at somewhat lower level than the other. The upper is the older of the two, and is to all appearance extinct. As we saw it, the bottom, which was at no great depth, was nearly level, and covered with stones, gravel, and sand. There was a little water near the middle, the remains of what in the rainy season forms a small lake. The lower and larger crater, though not at present active in the ordinary sense, that is to say not eruptive, showed plenty of signs of subterranean energy. The bottom was partly occupied by a pool of boiling water or mud, which was often completely hidden by the cloud of sulphuretted steam issuing from it. The atmosphere of the whole place was strongly sulphurous, and the trees in the immediate neighbourhood, especially on the higher side, were blasted by the poisonous emanations; though shrubs and herbaceous plants of certain species appeared to flourish far down the precipitous sides of both craters.* From the platform above, one of those wonderful panoramas of hill and dale so often enjoyed by the traveller in Java, lay before us: a broad smiling fertile valley shut in by mountains—to the north-west the cone of Mount Boerangram; to the east the three peaks of Boekit Toengoei; their summits all reaching a height about equal to that on which we were standing.

We had not a great deal of time to spare, so after a general survey we retraced our steps by the same path to the Superintendent's house. On our arrival we found Mr. Van Romunde already waiting to accompany us to the plantations at Lembang, a village about 4,000 feet above the sea-level lower down on the mountain-side.

After leaving the forest the downward road lay through cleared ground chiefly occupied by coffee plantations, fenced in with hedges of a fine arborescent *Datura*, bearing large, white, trumpet-shaped flowers, or sometimes, as at lower elevations, with fences of *Lantana*, gay with bloom of every shade from delicate purple or pink to orange-brown. A pretty *Thunbergia*, with showy yellow blossom was common by the hedge-sides, and the curious little Rubiaceus tree, *Mussaenda froutosa*, with its conspicuous white bracts was observed at intervals all the way.

The establishment at Lembang is altogether on a smaller scale than that which we had previously seen, the total area under cultivation being only 70 acres; but it exhibits just the same completeness, and the same evidence of careful management in every detail. Near the house is a fine large tree of *Cinchona cordifolia*, spared like that at Nagrak, not for its value, but for its beauty. Here, also, is a magnificent example of *C. succirubra*, about thirty years old, said to be the finest *Cinchona* in the East Indies. As nearly as I could judge it was about 60 feet high, and the trunk 18 inches in diameter at 3 feet from the ground. The bark had an ugly appearance, being a good deal covered with the so-called "moss"—a sort of grey-beard lichen.

Amongst the points of interest on this estate is a plantation of *Cinchona Pitayensis*—fine young trees about 10 feet high, the leaves bright green with red

* There is a special fern, called "the volcano fern," which flourishes on the sides of the crater.—En.

midrib,—a variety yielding a tolerably rich bark. There is also a considerable plot of worthless *C. micrantha*, exhibiting the characteristic large panicles of small fragrant pure-white flowers, and the smooth longish-oval, strongly ribbed leaves. For the rest there was little but what we had seen before. In the sheds they were drying and packing "quill succirubra" of very rich colour.

Near the centre of the plantation, at the point where the main avenues meet, stands an obelisk, erected to the memory of the Dutch explorer, Jughuhn. It has, however, no inscription beyond some cabalistic numbers, apparently left by the officials of the triangulation survey.—sent homage to the memory of a great traveller! Having examined at our leisure the various sections of the plantation, we sauntered leisurely towards the village, whither the carriages had been sent before-hand; and, after resting awhile at the passing graban, we started on our return drive to Bandung, thus concluding an excursion, the pleasant memories of which will ever be associated in my mind with the kindness, and hospitality, and good-fellowship of my companions.

In these stray notes I have limited myself as far as possible to particulars brought under my notice whilst on the spot, avoiding such general statistical information as can be better gathered from the periodical official reports. I may, however, be allowed a single remark on the enormous importance which the East Indian Cinchona industries have almost suddenly assumed, both from an economic and a medical point of view. It is only about thirty years since the first introduction of the Cinchona into Java, and several years were lost by the want of practical success which attended the earlier experiments. It is less than twenty years since Mr. Ledger's seed was received in the East Indies; nevertheless, according to the latest report, there are now upwards of 700,000 trees derived from it in the Government plantations of Java alone, and nearly a million more young plants of the same in the nurseries. Not only has the effort been successful as an experiment in acclimatization, but even more gratifying has been the result of selection and cultivation on the chemical constituents of the bark produced; and it has now become an indubitable fact that trees can be raised on the plantations of Java, Ceylon, and the continent of India, furnishing bark richer beyond all comparison in alkaloids than any ever brought to us from their original home in South America.

The above paper gave rise to the following discussion:—

Mr. Baker said that whilst listening to this very interesting paper he had been thinking of the 200,000,000 of people whom England had to look after in Asia, whilst the Dutch had, as they had heard, about 20,000,000 to care for in Java alone; and he could not but reflect how important it was that the two nations should work hand in hand together for the benefit of these enormous masses of people. Whilst looking back to the history of the introduction of cinchona it was very satisfactory to think of the way in which the Dutch and English had helped one another, and of the liberal way particularly in which the Dutch had assisted the English, a matter which he feared was not sufficiently appreciated. For a long series of years Dr. Royle and other pharmacologists who knew how great was the danger of cinchona being annihilated in South America urged on the Government the duty of sending out an expedition to bring home seeds for cultivation, but for something like twenty years all these efforts were in vain. The Dutch, however, were more enlightened, they sent out Hasskarl, who, at great risk went to the native home of the cinchona in the year 1859 and brought back a great quantity of seeds which were taken to Java and there planted. Unfortunately a considerable quantity of seed which he brought belonged to kinds of cinchona which proved not to be valuable in respect

to quinine, such as the *C. Pahudiana*. This was the first occasion on which we reaped the benefit of what the Dutch had done. Some three or four years afterwards the English Government sent out an expedition under Mr. Clements Markham to Peru and Ecuador, and he introduced something like three distinct species. These were carried to the Neigherries and planted there; but our plantations near the Himalayas were founded with seeds obtained by Dr. Anderson from the Dutch. Coming to the present time the garden at Buitenzorg, as Mr. Brady had said, was very valuable, and most important work had been done there. It was presided over for many years by Dr. Schaeffer, whom he knew very well, and on his death he was succeeded by Dr. Treub and Dr. Burek, both of whom visited England before going there, and were, at the present time doing most valuable work. During the last four years they had published a periodical called *Annales de la Jardin de Buitenzorg*, which contained some very valuable papers. They had lately also founded a laboratory there, the use of which, with the gardens, was open to any students who might wish to spend some time there. All these things showed great liberality on the part of the Dutch; and to their experience our own success in cinchona cultivation in India was very largely due. Dr. Hasskarl, the veteran traveller, who laid the foundation of the whole enterprise, was still living, having retired for some twenty years; and Dr. Spruce, who introduced the seeds of the *Cinchona succirubra*, was also living, and in this country. His feeling with regard to both these men was that they had been very inadequately rewarded for the important work they had done. It would be very well for that Society, if it could do so in its corporate capacity, to make some recognition of their services in India he believed there were four species cultivated, *C. succirubra*, *C. officinalis*, *C. Calisaya* and *C. micrantha*, a very small number out of the whole genus, which included about thirty. Perhaps Professor Bentley or Mr. Holmes might be able to say whether there was any probability of other species being cultivated with advantage. With regard to the *C. Ledgeriana*, doctors disagreed. Dr. Treub considered it a distinct species, whilst Mr. Holmes believed it to be only a variety of the *Calisaya*. Cinchonas seemed something like brambles in England; it seemed almost impossible to segregate them into distinct specific types, and he believed some of the *Ledgeriana* almost shaded off by degrees into the *Calisaya*.

Professor Bentley said he did not profess to have any special knowledge of the cinchonas, which could, in fact, only be investigated properly by studying them in the countries where they were cultivated. The question Mr. Baker had put as to the likelihood of other species yielding a fair amount of alkaloid was one for practical chemists to decide. Mr. Baker had left him very little to say on the history of the introduction of these barks, but there was one point he wished particularly to lay stress upon, viz., that the Government did not pay sufficient attention to scientific men in this country. For a number of years Dr. Royle and others urged upon the Government the importance of sending out an expedition to explore the cinchona districts, but this was not done, and he could quite confirm what Mr. Baker had said as to the success of the cultivation being very much due to the indefatigable efforts of the Dutch. Whenever any application was made to the British Government for aid in exploring the colonies or anything of that character, the answer generally was that it was very doubtful whether any valuable results would be obtained, or whether the thing would be at all successful. That, of course, was not any answer, because a great Government like the English ought not to fear any expense in such matters. But in the case of the cinchonas the results had been most extraordinary, for instead of the product diminishing, the result of cultivation in India had been to largely increase the product of quinine. This was most important when the subject of introducing new plants was

brought forward. It did not at all follow that a plant would deteriorate by being taken from its native country, as under proper cultivation its value might be increased. In conclusion he begged to thank Mr. Brady very cordially for bringing forward the subject in so interesting a manner.

Mr. Holmes had listened with special pleasure to this paper, having long taken considerable interest in the *Ledgeriana* bark. Mr. Brady had had enviable opportunities of seeing these plants in their natural state, for those who had only seen dried specimens must be well aware that it was almost impossible to judge, from the small proportion of leaf which was attached to them what differences there really were between these trees as they grew. Mr. Brady had spoken of the gloss on the leaf of the *Ledgeriana* as being in some respects different from that on the *Calisaya*, and he should like to know if he had noticed a similar gloss on any other species. As far as he had observed, it only occurred on varieties of the *Calisaya*. He had also mentioned Dr. Romunde's opinion that the *Ledgeriana* might be distinguished by the way in which the upper portion of the bark peeled off; but he had placed on the table some specimens of *Calisaya*, which had been collected some thirty or forty years ago in South America, and others from Ceylon and Java, in all of which the same feature was observable. That therefore, could not be taken as a characteristic mark of the *Ledgeriana*. Mr. Brady also spoke of the *Ledgeriana* as being the true "rojo" of the Bolivians, but he should like to ask him whether he had noticed on the leaves the red tint by which that was supposed to be distinguished by the Indians. One interesting fact he had observed was the angle at which the branches started from the tree. Anyone who noticed the trees in the Square or in any part of the country would observe that each tree had its own distinctive angle of branching; and the same very much was the case with the veins on the leaf. The fact, therefore, that this variety or species had a distinct angle of branching seemed to point out that it must be either a well marked variety or a species, but so far as one could judge by the bark alone, he still held to the opinion that it was only a variety of the *Calisaya*. Mr. Brady also spoke of the *C. lancifolia* being cultivated in Java, and he should like to know if it was old enough to yield bark, as he had as yet met with none in commerce.

Mr. Baker said the *C. Hasskarliana* was not cultivated in India, and did not appear to be known. If Mr. Brady could give any information about it, it would be interesting.

Mr. Brady, in reply, said he had spoken of the garden at Buitenzorg as being the finest in the tropics; his experience only extended to Peradeniya, Singapore and Hong Kong, and he hoped he had not underestimated the charms of any of these. A large number of the questions put referred to the *C. Ledgeriana*, with regard to which he had not expressed any opinion of his own whether it was a species or only a variety. When it was debated by men like John Eliot Howard, Von Kuntz, Mr. Holmes, Dr. Romunde, Dr. Moens and others, he had no right to hold any opinion. His observations with regard to the want of distinctive characters in the barks referred to were also only a repetition of what he had been told by Dr. Romunde. He had, however, put the question to Mr. David Howard, whose opinion on the point was entirely in accord with what he had heard in Java, that he knew of no characteristics by which the barks of these so-called varieties of *Calisayas* could be distinguished one from another. It was held that the condition of the bark varied a good deal with the climate, and that the characteristics which appeared in one place did not necessarily hold good in another. He did not know whether *C. lancifolia* had yet appeared in commerce, but a certain amount had been harvested and analyses made of it. With regard to the gloss on the leaf and the texture of the surface of *Ledgeriana*, he could only say that a mass of it seen together in the sunshine had an

appearance very distinct from the true *Calisaya*. In the latter there was the evergreen sheen and bright surface. It was like the difference between the gloss of satin and that of velvet; the *Ledgeriana* had a soft, deadish lustre. As to *succirubra*, the foliage was altogether different both in form and texture.

Mr. Moss said he had made a statement not long ago in that room that the bark which came from Java to London—and of course the Java bark did not all come to London, for most of it went to Amsterdam—but 75 per cent of that which came here was not quilled, but in the form of spoke shavings. He had been making inquiries since then, and found that he spoke very well within the mark, and that at least 95 per cent was in these spoke shavings, and that only 5 per cent or even less was quilled bark. In fact it was quite exceptional to find any quilled bark coming here from Java. He should be glad to know if Mr. Brady could state the proportion of quilled bark actually produced in Java.

Mr. Brady said he could not say exactly. If a plantation was uprooted of course the bark was stripped, but with that exception he believed all the bark now was being scraped. In Java they did not use a spoke-shave, but a long flat knife. He believed there would be an increasing quantity of scraped bark, and a diminishing quantity of the peeled.

Mr. Moss remarked in that case there would soon be none for the Pharmacopœia.

Mr. Umney said it was very gratifying to him to find that in Java some importance was attached to the percentage of quinine which the bark contained. They had been informed lately that the quinine was of slight value in bark, for they had been told that because quinine and cinchonidine were alike in property there was no real advantage in using bark with quinine in it at all. It did seem, however, that the people in Java had come to the same conclusion as those in India and Mining Lane, and in fact he believed the same as most people entertained except the editors of the Pharmacopœia.

Dr. Paul had listened with great pleasure to Mr. Brady's account of his operations on the Java plantations, which were especially valuable in the lesson they taught as to the kind of plants which it was desirable to cultivate. The majority of the bark now coming from Java was poor, being derived chiefly from those plantations which Mr. Brady had referred to as in course of being uprooted. The original *Calisaya* varieties, taken there by Dr. Hasskarl and some of the earlier planters, were now giving place to the variety known as yielding Ledger bark. He was somewhat surprised to find that the *Cinchona officinalis* was so unsuccessful in Java. This was one of the most successful kind in the Neilgherry plantations, and though it did not yield bark containing anything like so much quinine as the *Ledgeriana*, it gave an amount of quinine varying from three to seven and even as much as ten per cent. The *Ledgeriana* were still more prolific in their yield in India, and also in Ceylon, but their tenderness and difficulty of culture almost counterbalanced the advantage obtained when they did grow well.

The President, in proposing a vote of thanks to Mr. Brady, said the lesson which Professor Bentley wished to enforce could not be too strongly impressed at the present day, viz., the importance of the economic and other sciences being encouraged by Governments and corporations. There was an enormous amount of original work in the various sciences which could only be done by systematic aid given either by governments or corporations. The fact of the introduction into India and Java of the cinchonas, and the interesting, wonderful and unique fact that the barks by careful cultivation actually produced in their new home a larger quantity of important alkaloids than they did in their native habitat was of the greatest importance. It would be obviously legitimate for any government or rich body to spend considerable sums in experiments, even though nineteen out of twenty should fail,

if the twentieth gave anything like the result which had been obtained in this instance. He recommended this observation especially to pharmacists, because there was a very common tendency with regard to the prosecution of research work to put the question *cuti bono*. The answer was, you must experiment, and if you search long enough you would be sure to get a good return.

The vote of thanks was carried unanimously.—*Pharmaceutical Journal*.

COCAINE.

Towards the end of last year the world of medicine was agreeably startled by the publication of a paper by Dr. Karl Koller, containing statements to the effect that a certain drug called cocaine could be employed with the best effects in surgery for the purpose of producing local anaesthesia. This drug is the alkaloid of the plant *Erythroxylon coca*, and has been known for more than twenty years. It was the subject of many experiments by Professor Schroff, who minutely described its peculiar properties in a lecture delivered in 1862 in Vienna; but, strange as it may seem, for many years the anaesthetic action of the drug was held to be of small practical value, and cocaine passed out of consideration. In 1880, however, there was another nibble, so to speak, at cocaine. Von Aurep became convinced of its usefulness, after elaborate research into its action. But it was not till four years afterwards that its virtues again attracted attention. Dr. Freud in August, 1884, published some interesting details concerning its action; as a result of which Dr. Koller commenced experimenting with the object of ascertaining its local effects upon the sensibility of mucous membranes. He first experimented upon guinea-pigs; and found that, by the use of a few drops of a five-per-cent solution, in the course of twenty seconds the front part of the eye—the cornea—could be touched with the head of a pin without the least show of distress on the part of the animal, provided the eyelashes were not irritated. Here was conclusive proof of the total absence of sensibility. But the question of the extent of the anaesthesia remained. Did it involve the deeper parts of the eye, or was it confined to the surface? To determine that point, certain experiments were made with complete success: the whole corneal substance could be made insensible.

This fact having been satisfactorily determined, Koller undertook in the next place to ascertain the effect of the drug in inflammatory conditions of the eye; and the result of the application of the drug was a most marked alleviation of the symptoms. These experiments were made upon animals. Attention was then directed to the effects of the drug upon the human eye: for here a large field for usefulness might be opened out. Experimenting first upon himself and then upon his colleagues, Koller obtained results identical in every respect with those supplied by experiments upon animals. He thus describes the sequence of symptoms following the use of the drug:—When a few drops of a two-per-cent solution are introduced into the conjunctival sac, or, better still, are allowed to run over the cornea, a slight burning sensation is felt, together with an increased secretion of tears. All this disappears after an interval of from thirty seconds to one minute, giving place to an obscure feeling of dryness. If now—that is, after the expiration of about one minute subsequently to the instillation of the solution—the head of a pin is brought in contact with the cornea, not only is there no pain, but the absence of sensation is so complete that the person is unconscious of the touch. Without any inconvenient sensation or the slightest reflex movement on the part of the patient, the conjunctiva can be grasped with a toothed forceps, or the cornea can be pressed upon. This complete anaesthesia lasts from seven to ten minutes; the normal condition of the eye returning after a variable time, during which the only thing to be noticed is the prevalence of some degree of sub-normal sensibility. A certain amount of dilatation of the pupil follows the use of the drug; but it is never very great.

To an outside observer cocaine is calculated to produce impressions somewhat akin to the marvellous. Here is a description. A camel-hair brush is dipped into a small bottle containing a fluid as transparent as water. With the brush so charged the part—let us say a portion of the tongue—is painted several times. After the interval of a minute, or a little longer, another brush is taken; but in this instance a glass one, and dipped into a bottle the fumes and colour and label of which establish its contents as fuming nitric acid. The tongue is anointed with the acid, great care being observed in so doing, and submits to the procedure without the slightest recoil indicative of pain. Such is cocaine, and such is its effect upon every mucous membrane. Almost every operation in the surgery of the eye has at one time or another been undertaken under the influence of the drug. Cataracts have been operated on, squinting eyes put straight, foreign bodies upon the cornea removed painlessly and with ease. But its utility is by no means confined to ophthalmic surgery. It can be employed whenever an operation upon any mucous membrane has to be performed. The tongue, to which reference has been made above, is an instance in point. The drug has even been used in the extraction and the stopping of teeth. More important are its benefits in the relief of sufferers from the agony of cancerous growths. So treated, cancerous wounds have become less irritable; and, unfortunately, false hopes of improvement have thus been excited. Another of its advantages is that it enables patients to whom a general anaesthetic would be unsafe or impossible to submit to surgical operations. For with a solution of cocaine at hand chloroform and ether may be dispensed with; and of course there is no troublesome nausea and vomiting, as there often is after the administration of those anaesthetics.—*St. James's Budget*.

THE NORTH-WEST OF NEW ZEALAND.

An interesting pamphlet on the North-west of New Zealand as a new field for emigration has recently been published by Messrs. Bean, Webley & Co., of Foster Lane, Chapside. The author, Mr. Alfred Cooke, Yarrowborough, says that he does not believe "there are fifty people in England who know anything whatever, definite or indefinite, of the present state of the extreme north-west of the colony." Regarding the culture of the Olive and Mulberry, both are said to be as yet only in their infancy, and it is to be regretted that the early settlers introduced wrong descriptions of both these trees, the result being that though the plants have grown well, and shot up into large trees, they are not adapted for the orchard, or for successfully rearing silkworms. On the subject of Orange culture the necessity of securing a site which can be readily drained, and which is not too much exposed to the westerly winds, is pointed out. "A thoroughly good site of land for an orangery is a fortune to a man, while an unsuitable locality may be the means of causing irreparable failure. With a suitable site, and other favourable circumstances, the Orange crop will pay four times better than any other crop; seventy trees should grow to the acre, and providing that the grower sells his crops at even 6d. per dozen (a very low estimate), a large sum per acre is obtained. A single tree in New Zealand has been known to yield 3,000 oranges. The Vine, Peach, and various other well known fruits, grow to perfection." The following account of Kauri gum from *Dammara australis* will be interesting.

The Kauri tree is described as the most valuable and finest trees in the Southern hemisphere, and from it exudes a soft gum, which hardens on contact with the atmosphere, and fossilises in the ground in the course of years. How long it may have been in the ground no one can say, but it is found on the sandhills where no trace of a tree remains, in the coal-beds in a district where the Kauri tree does not now exist, and in huge tracts of country from which evidently the forests have been in ages past

burned from off the face of the earth. The discoloured condition of some of the gum dug up from several feet below the surface of the ground indicates that the trees were at one time exposed to the action of fire. The gum-fields are partly in the hands of the natives and partly in those of Europeans, but they are mostly the property of the Government, who have hitherto been in the habit of putting up to auction the right to dig gum on these fields. It is out of the power of a working-man to bid a lump sum for the right to dig gum over an area of 20,000 acres of land for a term of two years, and the result is that the right of digging for gum falls into the hands of some merchant or storekeeper, to whom all who dig on the land are compelled to sell at a price fixed by the lessee. This method of leasing these lands is not by any means an equitable one. The first thing a gum-digger has to do is to purchase a spear—that is, a piece of round iron pointed at the end, about 3 feet 6 inches in length, fixed into a wooden handle; this he can get on credit from the storekeeper, as likewise a spade, knife, some flour, sugar, and necessaries, on the condition that he sells his gum to him. If the storekeeper is the lessee of the gum-land this is a matter of course. Thus provided the digger proceeds to the gum-field (a sort of moorland it would be called in England), builds a shanty of Raupo or Palm Fern, and commences to spear the country for gum. An experienced digger will know the likely spots for a good find, and can tell by the feel of his spear as it touches a hard substance underground whether it is gum, wood, or stone. If he thinks it is gum he digs it up, puts it in his kit or basket, and goes on. The gum as it comes from the ground is covered with dirt and rust, and every piece has to be scraped with a knife until the gum is fairly clean. A good deal of judgment has to be exercised in this matter, because if too much is scraped away the digger loses weight, and if not enough he receives a less price on account of bad scraping. Gum is also obtained in the forest from under the trees, and even from the tree itself. The best gum is very clear, like amber, and hard, but there are many sorts and varying prices. Though the average earnings per week of the gum-digger is from £3 to £4, a man has been known to earn as much as £20. He has to work very hard, exposed to all sorts of weather, digging all day, scraping his gum at night, and cooking his meals between while.

The trade in Kauri timber is also very important, and gives employment to a large number of hands. The Kauri forests in the district are of very large extent, and it is stated, at the present rate of supply, will last about another 200 years. The timber is of very great value, and is recognised in New Zealand and Australia as most useful for all sorts of purposes—house-building, ship-building, masts and spars, railway sleepers, furniture, &c. It is very durable, and easily worked. The tree grows to a height of 100 feet without a limb, and measures an average of 5 feet in diameter. Trees have been found measuring a chain in circumference, but such trees are of no value to the purchaser, as they are too unwieldy to handle and cut up. In all Kauri forests there are found at intervals trees of enormous size, which stand alone in their grandeur as parent trees to the less unwieldy generation around them. In the forest the young trees grow readily, but so soon as the parent trees are felled and removed a fire sooner or later clears the ground, and they perish. Altogether the Kauri is perhaps the most important tree in New Zealand.

The exportation of the fungus, *Himnochaete polychroma*, from New Zealand has frequently of late been commented upon. Mr. Yarborough speaks of it as a branch of industry only entered upon by children, who make a good deal of pocket-money by it. The fungus is bought from the collector, after being dried, at prices varying from 4s. to 5s. per pound, and is exported *via* San Francisco to China, to be used by

the Chinese as an ingredient for soup. In 1882 the export of fungus was 400 tons weight, valued close upon £19,000.—*Gardeners' Chronicle*.

THE ENSILAGE PROCESS IN INDIA.

TO THE EDITOR OF THE "FIELD."

Sir,—I have long watched with interest the growth of silos for the preservation of ensilage, and in 1883 my views as to the profitable adaptability of the system to India were ventilated through the press of that country. Most of the cattle fodder in that far-away dependency is luxuriantly grown and neglectfully wasted during the four monsoon or wet months, to be followed by something like a fodder famine throughout the eight remaining or dry months of the year. The inestimable advantages of the silo system were then pointed out, whereby great economy would be introduced into the commissariat and transport services, which constitute one of the chief money-consuming departments of the state, while the agricultural community would be immensely benefited by the improvement that would soon be effected in the half-starved, stunted village cattle by husbanding existing resources for consumption throughout the entire year.

On the occasion of a recent visit that I paid in India to Sir Herbert Macpherson, the distinguished and thoroughly practical commander-in-chief elect of Madras, I was greatly pleased to find the splendid success that had attended the efforts of that able and public-spirited officer in establishing a fodder farm in Allahabad, and in conserving the produce thereof by means of silos, which are neither more nor less than pits dug in the ground 30 ft. by 12 ft. by 6 ft., such as the natives have used from time immemorial for the storage of their grain. These pits are dug at a merely nominal cost, and the earth excavated from them, when heaped up upon the ensilage, supplies all the pressure required to keep the latter in good order throughout the year. No system of drainage has been found necessary.

I beg to inclose for your information a report of Gen. Macpherson's silo operations during the years 1884-5 from which the following results have been deduced:—

1. It does not appear necessary to go to the expense of building masonry silos, or to take any particular precautions in draining and pressing, as an earth silo seems to fulfil all the necessary conditions, and apparently drains itself if kept air and water tight.
2. The only pressure that seems to be necessary is that caused by the excavated earth being piled on the grass.
3. The best time to cut the grass is when it is mature—between Aug. 15 and Nov. 1 (in India). This will give a second crop of hay.
4. The fact of its raining while a silo is being filled, does not appear to do any harm.
5. The ensilage should be used green—*i.e.*, as it is taken out of the pit.
6. 35 lb. of ensilage would appear to be equal to 20 lb. of *bhoosa* (chopped straw)—the ration of a siege train bullock.
7. Ensilaged *karbi* (sorghum) forms good food for elephants.
8. The fact of cutting the grass for ensilage gives a finer and better second crop for haymaking.
9. Silos should, in my opinion, be made wedge-shaped—*i.e.*, rather wider at the top than the bottom, and with sloping sides, to preserve an even pressure. The floor and sides might be baked by burning rubbish in the pit.

These are the conclusions of Capt. Peile, who conducted the operations under Gen. Macpherson's orders.

PATRICK CARNEY, C.I.E.
Ellery Court, Norwood, Dec. 15.

COCAINE FACTORIES IN LIMA.—Meyer & Hafemann, wholesale druggists in Lima, Peru, are erecting works in that city for the purpose of manufacturing cocaine from the fresh leaves. A French pharmacist of Lima, Mr. Bignon, has likewise undertaken the manufacture of cocaine, and it is said with good results.—*Chemist and Druggist*.

THE WORLD'S MANUFACTURE OF QUININE.

We anticipated, in the *Weekly Observer* of November 18th last, the estimate we had framed for our "Handbook" of the total quantity of quinine prepared in the factories of the world. We based that estimate on the best information at our command, but we were not a little staggered by the quantity claimed for the Italian factories, namely, 123,200 lb. (55 tons) per annum, of which 110,000 lb. were said to be made by the great Milan factory alone. The statement was so explicitly put forward in print that we could only adopt it, and adapt it to the other portions of our estimate, as best we might. The result was a total reckoning as follows:—

United States	70,000 lb. per annum.
Germany	40,000
Italy	120,000
France	35,000
England	27,000
India	10,000

302,000 lb. per annum.

Last mail has brought us a letter from a most reliable quarter in London on the subject from which we quote as follows:—

The figures given as to the amount of *quinine manufactured*, in your paper folio 979, are certainly wrong and known to be so by all those who are behind the scenes. They are evidently derived from those published by the *Fabbrica Lombarda* before its failure to prop up its decaying reputation. It is of course impossible to give exact figures, but the annexed would be nearer the present state, of things; it must however be taken *cum grano salis*. This estimate which may be depended on as the most accurate as yet framed, and which ought to be substituted for our own, is as follows:—

Probable make of Quinine in 1885 in lb. per annum.

United States	70,000
Germany	70,000
England	50,000
France	40,000
Italy	30,000
India (febrifuge)	10,000

270,000 lb.

For the United States we had the best information collected during our recent visit, so that our London correspondents make no change. We are surprised, however, to see that the manufacture in Germany is quite as large, and we are pleased to find that Messrs. Howard & Whiffen turn out nearly double the quantity we ventured to credit them with. Italy only manufactures one-fourth the quantity claimed by the gentlemen who evidently wished to "magnify their office" or their country! Our estimate for France was very nearly correct, while for India we have the best possible information. Altogether we were 32,000 lb. above the mark; but this is a fault in the right direction; for with cinchona bark so cheap and abundantly supplied as at present, the manufacture is sure to increase, and we trust, the consumption to correspondingly improve. With quinine, one-half or one-third even its ordinary price of a few years ago, surely there is room for a great expansion of the consumption not only as a febrifuge for human beings, but in other ways, until not 270,000 lb., but 500,000 lb. of quinine will be required to meet the annual demand.

SKINNY MEN.

"Wells' Health Renewer" restores health and vigor, cures Dyspepsia, Impotence, Debility.

W. E. Smith & Co., Madras Sole Agents.

TEA ROLLERS.

(From the Hills.)

In re tea rollers and their performances,—varying from completion of roll in six minutes, by means of Thompson's Challenge machine, to twelve minutes in the case of Barber's, and from half-an-hour to fifty minutes with Jackson's Excelsior,—apart from finishing a large quantity of tea in a limited period of time, are there any other important advantages, and if so what, gained by speedy execution of the rolling process? I pause for a reply from experts. We might naturally conclude that quick rolling must mean more or less of heating, such as proved a strong objection to Kimmond's roller, but for the testimony of good authorities to the contrary,—at least in the case of the Blackstone roller. I have heard it said that the superiority of teas prepared on a certain well-known estate is due to rolling so *hard* that the distinction between tips and leaves is lost, all being of a uniform blackness. By some, again, the intense black colour is said to be due to iron with which the tea brought in contact in the process of being rolled. If hard rolling is the cause of the black colour and the superior quality, it would be desirable to know how long hard rolling is continued, and how heating, which I suppose I may assume to be injurious, is avoided. Then ought not moderate rolling, long-continued, to be equivalent to hard rolling for a shorter period? It must be largely a question of chemical effect on "the roll." Our period here, with a Jackson Excelsior, is so prolonged as fifty minutes, and I might have feared that this slow rolling process was injurious in some way to the tea, probably by permitting of a certain degree of "fermentation" taking place during rolling, but for the fact that in one of the leading factories of the country, from which high quality teas are turned out and where abundance of power to secure quick rolling is available, the time taken for the process is fully forty-five minutes: only five short of ours. Weather and withering, no doubt, influence the period of rolling; but I refer to leaf in average condition. Which is better for it and its return, a speedy roll or a prolonged; hard pressure or moderate?

Of 73,000 lb. of tea made on this estate in 1885, about 6,000 lb., it may be worth while to mention were sold locally. Apart from the inconvenience, of sales more or less of a retail nature, the chief reason for stopping local sales is the fact that the vast majority of orders were for our best quality—broken pekoe. The result has been seriously to reduce the average prices of Abbotsford teas sold in the London Market, and while we have no wish to acquire for our teas a better reputation than they deserve, by over fine plucking or similar expedients, we are, on the other hand, naturally anxious not to do ourselves and the reputation of our teas injustice. Hence the resolution to cease selling locally, save in a few exceptional cases, and to a very small extent, which has been arrived at and will be adhered to.

Since writing about the tap-root of tea, I have been told of a case where a tap root was followed down to 10 feet.

FRAGRANT FLOWERS.—The perfume manufacturers of Nice and Cannes crush 154,000 lb. of Orange blossoms, 13,200 lb. of Acacia flowers, 154,000 lb. of Rose petals, 35,200 lb. of Jasmine blossoms, 22,000 lb. of Violeta, 8,800 lb. of Tuberoses, and a relatively large amount of Spanish Lilacs, Rosemary, Mint, Lime and Lemon blossoms every year.—*Journal of Horticulture*.

CEYLON TEA AT THE EXHIBITION.

We have been indirectly pressing the local Executive Committee to let the world know a little more of what they have been doing about tea &c. Some correspondence with the Planters' Association is to be sent to us for publication we learn. Meantime we are indebted to the Chairman for a telegram just received, which stupidly has come by post from Bombay. This telegram ought to satisfy our planting friends and the Association. We shall now have a good Exhibition of products in the Ceylon "Court" in addition to the Exhibition and sale in the tea house—which tea house is close to our Court and quite distinct and separate from the Indian tea house—or that of any other Colony:—

From Secretary, Colonial Exhibition, London, to Chairman, Exhibition Committee, Colombo.

"On behalf of Mr. Birch no objection to tea being exhibited in specimen cases in Ceylon Court, but the arrangement of exhibiting tea in the special department as reported in King's letter must be adhered to. Ceylon Committee will therefore require you to send duplicate quantities of specimen tea for your Court and King's department. Send some cocoa beans at once to Commissioner for manufacture, which has been arranged for refreshment department."

The following has just reached us:—

Executive Committee, Colombo, 31st Dec. 1885.

To the Secretary, Planters' Association, Kandy.

SIR,—In acknowledging receipt of your letter of the 15th, 17th, and 18th instant, I am desired by this Committee to express its great concern at bearing that it is possible you may not be able to take any part in the local Exhibition to be held on the 18th, 19th, and 20th January. That Exhibition is intended to afford the public, who have provided the funds in which your Association has participated, some conception of the exhibits intended for despatch to London; and this Committee is still hopeful that your Association may be able to furnish by the 15th proximo some portion at least of the exhibits of estate products which will form so important a part of the Ceylon exhibits, and to which this Committee has made so large a vote of public funds.

With regard to the cases to which you refer, they have not yet been commenced, nor can they be until you have signified to the Director of Public Works your acceptance of the estimate (RS00 and odd) and furnished that officer with a cheque for the amount to meet expenses.

The resolutions accompanying your letter have received the approval of this Committee and copies of them will go forward to Mr. Birch by this mail. It is however, matter for regret that Mr. Christie did not attend the meeting yesterday, adjourned from the previous week, as that gentleman was informed, in order that he might be enabled to be present.

The Committee entirely coincide in the opinion expressed in the resolution received from you that exhibits of tea and coffee must be shown in the Ceylon Court; and for your information I annex copy of a resolution adopted by this Committee and forwarded to Mr. Birch; at the same time, in order to act up to the spirit of its previous acceptance of the arrangement with Messrs. Klug & Co., this Committee has signified to the Commissioner its intention to forward samples of tea for display by that firm in glass bottles in the Ceylon tea house separate from the teas of India.

With this Committee's letter before him, and assisted by the gentlemen whom you have recommended as members of the Tea Committee, and who have been approved by this Committee, Mr. Birch will, it is be-

lieved, be in a position to bring this matter to a satisfactory issue with the Secretary of the Royal Commissioner.—I am, sir, (Signed) J. CAPPER, Secretary.
(Resolution referred to.)

"That a copy of the resolution passed by the Planters' Association be forwarded to Mr. Birch, and that he be informed that the Executive Committee concurs in the view of the Planters' Association that apart from the display and sale of Ceylon tea by Messrs. King and Co., it is absolutely necessary that exhibits of tea, coffee, and cocoa be shown in the Ceylon Court with the other products of the colony."

Kandy, 7th January 1886.

To the Secretary, Executive Committee, Colonial and Indian Exhibition, Colombo.

Sir,—I am directed by the Sub-Committee of the Planters' Association to acknowledge the receipt of your letter dated 31st ultimo, and in reply to point out that it is not possible for the Planters' Association to exhibit the estate collections at the local Exhibition, chiefly for the reason that the main exhibits are only now at this season harvested; and that even if they were ready in time they could not in the case of such products as tea, cocoa, and cardamoms be exhibited without certain injury.

I am to express great regret that, owing to some misunderstanding, the construction of the special showcases for the Planters' Association at the Government Factory has been delayed, as they themselves would have formed an interesting exhibit before despatch to London.

Such articles as the models of cacao-pods, photographs, and any other exhibits that can be ready in time, the Sub-Committee of the Planters' Association would propose to send to the local Exhibition.—I am, sir, your obedient servant, (Signed) A. PHILIP.

TEA PREPARATION.

(From the Hills.)

It is difficult, sometimes, while observing the brevity necessitated by the cost of telegrams, to convey the meaning intended, and we fear that our telegram from Nawalapitiya may have produced the impression that we were contrasting the No. 1 Sirocco with the Victoria and Venetia Driers instead of, as we intended, classifying it with them, as desiccating tea without the substance being exposed to the outer atmospheric air. There is a wide-spread, but by no means universal, opinion, amongst tea manufacturers, that this exposure is a defect in the T Sirocco and in the No. 1 Drier to which the horizontal apparatus has been applied. It would seem that if raw, damp air is excluded from the tea-house, while the roasting process is proceeding, the effect of the internal atmosphere ought not to be injurious to any great extent. There is, however, a good deal of handling required, and we feel satisfied that the less tea is manipulated by coolies the better. The great merit of the Jackson, Victoria and Venetia Driers is, that not only is the tea not exposed to the outer atmosphere but that as the air in the interior absorbs moisture from the tea leaves, such air is incessantly drawn away by the fans. It was a surprise to us, however, to hear that only 100 lb. per hour was finished in the Victoria at Carolina Factory. Mr. Megginson does not believe in working machinery to its full capacity, and he remarked that a turbine equal to 40 horse-power would do better work when 10 horse-power only was exerted, than a 10 horse-power wheel worked to its full capacity would accomplish. Such an opinion, founded on experience, is worthy of respectful attention. Speaking of Jackson's Excelsior roller, the superintendent of Carolina Factory (where a third Excelsior is speedily to be added to the two already at work) remarked that where there was not power enough to

work the Excelsior up to 50 revolutions per minute, it had better not be employed. The inference clearly is that in Mr. Megginson's opinion, 50 revolutions per minute indicate the minimum of movement requisite for the proper rolling of tea leaf. But to show how experts differ, we may mention that before we could transfer to paper our mental note of Mr. Megginson's axiom, we received a letter from the superintendent of a factory whence teas of the highest quality, judging by prices obtained, have been recently issued, to the following effect:—

TEA ROLLING.

12th Jan. 1886.

Dear Sir,—In your issue of 9th instant I see an interesting letter "From the Hills" in which the writer asks for information *re* tea rolling. Ask him to try the following, with any ordinarily fine pluckings. I see he has a Jackson's Roller, which I consider actually necessary, to show following result.

Say that Roll is put into the "Excelsior" at 12 noon; fill up roller as hard as cooly can drive it home, set machinery agoing and keep going at rate of say 25 *re*volutions per minute for 10 minutes, gently stirring up by hand meantime. At end of 10 minutes request Ramasamy to get up on to the top, and roll thus for other 10 minutes. Ramasamy must now step down and "Kindyoodoo" roll: in fact he has to get down for this purpose at least every 10 minutes up to say 40 minutes after roll is put in. After it has been rolled from 35 to 40 minutes with Ramasamy swaying to and fro on top, Mgootsamny too must get up and lend his weight. A third cooly will be necessary for a short time before taking out Roll at 50 minutes just to give it final touch or squeeze. Take out of Roller and spread 3 inches thick on long table near window, break up thoroughly and sift through No. 3. Below No. 3 again spread 3 inches deep on table and cover with blanket till fermented. Above No. 3 also spread on table and keep there for one hour, after which again put back into Roller, turn on full water power and put *three* coolies on top of "Excelsior" rolling thus for 15 minutes at same rate as before *i.e.* about 25 revolutions per minute. If rolled as above I guarantee 85 PER CENT PEROES.

P.S.—If hard rolling be necessary for high return of Peroes—and I consider that it is—then Jackson's machinery *must* carry the day.

When doctors differ so widely what are poor laymen to do? Roll 60 to 80 revolutions per minute power being available, or restrict the application of power to sufficient to produce 35 revolutions per minute? It would seem that each must experiment and decide for himself. While slow rolling is recommended, here we have Mr. Barber turning out "rolls" from his Blackstone machine in 12 minutes, amidst the plaudits of experts. We telegraphed the result we witnessed with rather refractory leaf, and now we have the following letter from Mr. Barber, the gentleman who, beginning his career as a good lawyer, has, in the second phase of his existence, proved himself not only a good tea-maker but an ingenious and successful machinist:—

Blackstone, 14th Jan. 1886.

The leaf brought from Carolina by Mr. Megginson, in your presence and the leaf of Blackstone rolled afterwards by Mr. Megginson were fired and this day forwarded to Mr. Megginson, who writes his opinion as follows:—

"The appearance of all is superior; lignors are all satisfactory, but might have been improved by fuller fermentation. I am well satisfied with the work of the roller.

As regards fermentation I quite endorse the statement. The teas were fired when I was away at Carolina and they seem to have hurried the work through. But that does not bear on the issues.

Yours truly,
JAS. H. BARBER.

The amount of wood-fuel consumed by the Jackson motive power driers is a serious matter, in the

case of the Victoria 3½ lb. of firewood for every pound of dried tea. At 2,000 lb. of tea per diem, which the Carolina Factory is likely to reach, that means 7,000 lb. of firewood, if firewood alone continues to be used, per diem, or counting a year of 5 days per week at this rate, 1,820,000 lb. This result is astounding, and we cannot now wonder at the earnestness with which the gentlemen connected with the K. A. W. group of estates, dwell on the importance of forest reserves, for mere firewood purposes, apart from timber for buildings and boxes. The Abagammwa group of estates are, themselves, especially well off in this respect, and we hugged the belief that about 70 acres of jungle belts out of 549 acres, with 15 acres more of exotic trees, were more than ample, and that as our belts got clear of timber they might be profitably planted up with tea. We were, on the contrary, emphatically advised to cultivate timber trees in our belts. But what are old estates to do, where there is not firewood enough even to enable the coolies to cook their food? The remedy, no doubt, is two-fold:—

Machines ought to be improved in their construction, so as to economize fuel; and

Better kinds of fuel than firewood alone ought to be employed; such as coal or coke alone, or mixed with the firewood; or, better still, some artificial fuel, of compressed paraffin, for instance, embodying the maximum of caloric in the minimum of bulk.

Surely the time has arrived when coal at least, which costs about R20 per ton at Colombo, should be used with or in lieu of wood, the railway carrying large quantities at especially low rates? We hope our good friend Mr. Grinlinton, whose energy and faculty of organization have enabled him to confer so much benefit on the Colony already, will take up this question in earnest. If coal could be laid down at Nannuya, at about an advance of 30 per cent on Colombo prices, and at intermediate stations in proportion, we should think it would be useful and economical to use the black diamonds (crystallized firewood) in tea factories. Of course the extended employment of iron in buildings, and the receipt of tea boxes in shocks from Japan or elsewhere, will largely help; but the grand advantage of the supercession of firewood, by an imported or prepared fuel, better and cheaper, would be to obviate, not only the necessity of forest reserve on estates, but to set free the large areas of Government forest reserved for railway firewood purposes. If that result were gained, we should speedily have lines of flourishing tea estates along the 25 miles between the neighbourhoods of Nannuya and the Haputale Pass, the present unoccupied state of which has been most unfairly used as an argument against connecting by the iron road the large population of Uva (170,000) with the millions in the central and south-western portions of the island and with the harbour and shipping of the capital. We hope the problem of a cheap, artificial, compressed fuel for steamers, locomotives and tea furnaces may soon be successfully solved.

As to the supercession of coffee by tea, the process proceeds apace, and the new plant looks everywhere fresh and flourishing. That paragraph from India recognizing 1 cwt. per acre as a good return of coffee, was calculated to create a sensation. *contra* we heard of a planter in Dambala, who has paid special attention to the manuring of coffee, who is now rooting out plants which yield 3½ cwt. an acre, coffee at that rate and at present prices not paying. In Uva and in some other districts coffee may continue to do well, but the main hopes of most planters are, with ample justifi-

ation in what has been already accomplished, founded on the advancing success of the tea enterprise.

When we visited Blackstone pruning was in full swing, at which an experienced planter who was of the company shook his head. He said that pruning in the north-east monsoon in Upper Dimbula at over 5,000 feet was quite a different affair to pruning in Ambagamuwa at 2,500; and we were surprised to learn that rainy as Ambagamuwa valley is, 200 to 250 inches per annum, the drought and winds of the north-east monsoon are very trying, the heavy rains not being so well distributed as in many other places. But Mr. Barber, no doubt, knows what he is about, in this and in other matters. By a curious *fiasco*, teas from Blackstone will be about the *only* specimens shown at the local Exhibition. Had the Committee known in time that the Planters' Association specimens were not to be shown, they would, of course, have arranged for special exhibits of tea, so that the new product could compare favourably with the products of the cinnamon, coffee, cacao and coconut trees, which are richly represented. We found Mr. W. H. Davies this morning busily arranging six grades of tea made from the Carolina leaf which we saw rolled. There was a case of tea on the floor near by, and that seemed to be all. Amongst coloured pictures from Peradeniya, of coffee, cacao, nutmegs, cloves, &c., there was a beautiful and correct representation of Assam tea in blossom. We saw a model sirocco, which Mr. Davies said was to be shown in operation, the heating agent being gas. Twenty-eight photographs of scenes on Abbotsford, showing the cultivation on a mountain plantation of coffee, cinebona, tea and exotic trees, from the felling of the jungle to the beginnings of a tea-house, with descriptions are exhibited. That was all connected with tea, we think, for, on enquiry for photographs by Mr. Clerk, illustrative of the tea enterprise from field to shipping port, we were told they had not been sent. This is a pity for Mr. Clerk's sake as well as that of the public. If Mr. Clerk will send us a set of the photographs we shall gladly notice them.

THE FINE QUALITY OF AGAR'S LAND TEAS AND HOW IT IS SECURED.

A correspondent who has had good means of judging, tells us that no opinion we can express can be too favourable as regards the quality of Mr. Agar's teas, but the conclusive test is the opinion of Mincing Lane in the shape of an average price of 2s 2d per lb. for so large an invoice as 83 half-chests. How such teas are made by him and can be made by others, Mr. Agar has generously consented to let his brother-planters know through the *Observer*, as follows:—

AGAR'S LAND, BALANGODA: TEA-HOUSE NOTES.

PICKING.—Flush one week to 8 days old. Growth varied according to weather, therefore no hard and fast rule as to number of leaves plucked—rule is to be careful to leave on tree one full leaf and an eye above. This method answers well with us, growth being rapid.

WITHERING.—Weigh leaf twice a day, and if wet when brought to factory put out in sun two or three inches deep; keep turning over until dry, and put on withering trays as thinly as possible.

ROLLING.—(Jackson's "Universal").—Wither leaf well, without allowing to dry; fill up roller well without jamming, and roll gently, without any extra weight,

for 15 minutes. After this put on some extra weight, say 25 lb. and roll for other 15 minutes. Take out roll, spread on table, break up by hand, and sift through No. 4. Below No. 4 spread thinly on table and cover with blanket, and in about two hours this should be ready for firing. Above No. 4, roll off by hand quickly as sifting will be found to open the twist slightly; after which put this too on table, spreading out thinly—say three inches deep, and cover with blanket. Keep on table for one hour, until partly fermented, and put back into roller for 15 to 20 minutes of very hard rolling. Whilst rolling and fermenting, "roll" should be stirred up turned over every ten minutes, the former to give even roll and prevent heating, and latter to give even fermentation. To get strong liquor, juice must be squeezed well out of roll, but mopped up again of course, and it should be of a red colour and not too watery.

FIRING.—Should be done briskly, and not over-done. **SIFTING AND ASSORTING.**—Unassorted tea should be put away in tin immediately after firing. To sift, put unassorted into No. 8. Sift pretty hard, and teas above and below sieve treat as follows:—Above No. 8 put into No. 7—and sift and break this lightly with hand, which gives "pekoe souchong" below, "coagou" and "fannings" above. Below No. 8 put into No. 14 and sift out all that can be got to pass through; this leaves "pekoe" above and "broken pekoe" below.

TO SIZE ABOVE TEAS.—Sift pekoe souchong through No. 7 without handling it in any way. Sift and lightly break pekoe through a No. 10. Sift broken pekoe through No. 12, lightly of course. This leaves *small* quantities above each sieve. Above No. 7 mix with fannings &c., after breaking a little. Above No. 10 mix with pekoe souchong. Above No. 12 mix with pekoe. And "dust" to be separated with cloth fring *at only*.

CEYLON COCOA AND CHOCOLATE AT BRISTOL.

(Communicated.)

Finding myself during last autumn in the neighbourhood of Bristol I thought I would take the opportunity of paying a visit to the chocolate manufactory of J. S. Fry & Sons. To anyone interested in new products, there are few places which better repay a visit than this old town, which, though somewhat fallen from its former high estate, still retains much of its ancient connection with the colonies. Besides the large concern which is the subject of these notes, there are several tobacco manufactories, notably that of W. D. & H. O. Wills, breweries in which a considerable quantity of myrobalans and divi-divi is used, and several shops belonging to P. J. Lloyd & Co., who are doing a large and increasing business in Ceylon tea.

The chocolate manufactory, which now employs about 1,200 hands, is situated in the heart of the city. Founded about 1730; it has from time to time been very much enlarged; a Baptist meeting-house of date 1650 now being included in the premises.

The process of manufactory is a long one. The nibs or nuts as they call them previous to the removal of the shell are first roasted two-and-a-half hours, then passed through a machine which gently cracks them. They then go into a winnower, and, as the cracked nuts fall, the blast of the machine blows away the husk from the nuts which fall into a receptacle in the form of nibs. These are now crushed between millstones and pass from a coarse paste to a cream-like consistency. This liquid paste is next either stored for future treatment, or else taken to have the oil extracted. To store it, the liquid is gathered in tins which form moulds, as when cold the mass comes out in solid blocks.

If the oil is to be extracted the paste is put in canvas bags which are then subjected to hydraulic pressure. The oil is thus extracted, and the pure

cocoa remains in the bags. This is known as cocoa extract, and 100 lb. weight of liquid gives 70 lb. of powder. If prepared cocoa is required, the solid blocks abovementioned are broken up, thrown into a pug-mill, and mixed with powdered sugar and arrowroot. The solidified oil, or cocoa butter as it is called, is used by chemists, and I noticed the other day an advertisement of cocoa butter soap said to possess wonderful qualities. The process of making chocolate is also interesting, and all the various works connected with it are now done under the same roof. Thus I visited saw-mills, box-making rooms where very ingenious machinery was in use, tinsmiths' workshops, and a forge, as well as the rooms where the packets of cocoa are made up. This is done with great speed and neatness by the girls employed, each of whom fastens up about 1,000 packets a day.

I naturally made special inquiry about the produce of our island, which the manager told me was very highly thought of. It is lighter in colour, smaller, and more brittle than the Trinidad bean, but stronger in flavour. Mr. Machin, who showed me over, said he imagined the soil in Ceylon was lighter than that of Trinidad, which is no doubt the case. The Trinidad bean is, as he expressed it, more *matured*. One of the Messrs. Fry gave it as his opinion that the sweetmeat prepared from our produce was sickly in flavour, but I do not think the manager was of this opinion; indeed several people who have tried it, especially ladies, who are credited with a delicate taste in sweets, have told me it was the best chocolate they had ever tasted.

All were agreed that there was no room for improvement in the preparation of our produce, and, while there was a falling-off in quality some months before my visit, at the time, no doubt, when the drought and fly were at their worst, the later shipments, I was told, were quite up to the old standard. A bag from Isobel estate was being treated at the time of my visit, and in the books I saw entries of several well-known marks. From the light colour of our bean a good deal of Ceylon cocoa, it seems, is mixed with other varieties when a *light* chocolate is desired, and I noticed a large quantity of this kind being dispatched to the U. S. A.

Mr. Machin was of opinion that our produce is better suited for chocolate than cocoa, and as far as my experience of Ceylon prepared cocoa goes, I should be inclined to think he is right. The "Cobra Brand" of cocoa extract, though of delicate flavour, seems to me lacking in strength.

Besides the tablets of Ceylon chocolate which are now often to be seen in confectioners' shops, Messrs. Fry are making chocolate creams put up in tasteful boxes, with a couple of which I was presented. With the tablets are given directions for making chocolate in the cup.

I may mention that casual visitors are not shown over the factory, an introduction to one of the firm being necessary, but, that obtained, one is treated with the greatest courtesy by all connected with this thriving establishment. B.

CINCHONA CULTURE IN JAVA AND INDIA.

Amongst other interesting and important papers on agricultural and horticultural subjects in the *Tropical Agriculturist*, for which it is impossible to find room in our daily and weekly issues, is a long account of a visit to the cinchona plantations in the Preanger Regency of Java, to the correctness of which, having gone over the same ground, we can cordially testify. In the paper of Mr. Henry R. Brady, F.R.S., read before the Pharmaceutical Society, and the discussion which

followed, all the species of the fever-plant introduced into Java, India and Ceylon are described and their merits discussed, from the almost worthless *Pahudiana* (named after Mr. Charles Pahud, one of the best Governor's-General of Java) to the monarch of all the tribe, *Ledgeriana*, the quinine results of which when first tested by the Dutch analysts filled them first with incredulity and then with astonishment and delight. *Ledgeriana* is, unfortunately delicate, like so many other valuable plants, but, apart from some successful experiments in Wynaad and in Ceylon, the richest of the fever-destroying plants has found a congenial and permanent home in Java. The cinchona enterprise, in the face of all cankering and dying-off, has been unprofitable or profitable only in a limited degree, to individuals, from the very facility and rapidity with which the plants grew and produced bark so as to swamp the market. But the benefit conferred on humanity has been incalculable and the great cheapening of the product lately cannot but lead to a vastly increased use of the valuable alkaloid which is almost a panacea for malarious fever, besides its tonic effects.

COIR FIBRE DUST.—Mr. C. E. H. Symons, as Managing Director for the Horrekelly Estate Company, has called on us to say that he is quite prepared to justify the position he took up before the Railway Committee the other day as to the uselessness of great heaps of coir fibre dust now lying on the Horrekelly property. Mr. Symons will give full particulars to our correspondent "Agriculturist" if he calls on him; but meantime he has reminded us how the late Mr. David Wilson made a variety of experiments with a view to turning this dust to profitable use without result. It has been analyzed at home with the result that it is considered to be the equivalent very much of cork or saw-dust. The dust, however, is used on Horrekelly as far as needed for cattle-bedding purposes, and it is also occasionally ploughed in between the coconut trees, to keep the soil moist; but its value as a manurial application even when mixed with ammoniacal liquor is *nil* or nearly *nil*. Ammoniacal liquor is, however, freely used on Horrekelly otherwise. But there are large heaps of coir dust refuse on the estate which "Agriculturist" or anyone else can have for the carting away.

MAXIMUM YIELD OF TEA IN CEYLON.—We commend the following authentic report on the past year's results on the 100 acres' field on Mariawatte Tea Garden near Gampola to the attention of our Indian critics. It was not expected that 1885 would show so good a return as the former year; but as a matter of fact the yield is in excess:—

MARIAWATTE ESTATE.—Yield from 100 acres and rainfall:—

Year.	lb. tea per acre.	Rainfall.
1881	136	103.06
1882	312	113.60
1883	550	91.83
1884	1,092	82.72
1885	1,180	101.41

H. K. RUTHERFORD.

The fortunate proprietors of Mariawatte may well be congratulated on this result, and we suspect their experience is unequalled not only in Ceylon but in India, more especially if they go on for a third and a fourth year to crop at the same ratio on their magnificent hundred acres. On smaller areas even larger returns have been gathered:—for example 1,200 lb. per acre on 15 acres of which 200 lb. were gathered and made in one month is an experience on one place in Ambagamuwa.

ICELAND MOSS COCOA.—Attention should be directed to the excellent preparation of cocoa in combination with Iceland moss (*Lichen Islandicus*) manufactured by Messrs. Dunn & Hewitt, Pentonville, London, N. The moss acts not only as a mild tonic—being in itself an easily-digested and nutritious aliment—but also as a neutraliser of any excess of fatty matter which may be in the cocoa itself. It is contended by the makers on high authority that to eliminate the butyrateous matter of the coconut—commonly called cocoa butter—is to deprive it of the constituent upon which the chief value of cocoa as an article of food depends. The moss, in assisting the digestion and assimilation of these oily particles, renders cocoa prepared in combination with it a valuable article of diet to those suffering from pulmonary complaints.—*British Trade Journal*.

COPRA-CUTTING.—With reference to the machine inquired for from Fiji for cutting out the kernels of the coconut for copra-making, a firm of machinery manufacturers in England sends us the following:—"Coconut husks are stubborn and tough. They can, we believe, be cut down by a powerful lever, with three blades, to rip down three sides of the husk at one blow. Then, we think, a vertical saw, with from three to six parallel blades, would slice the coconut into regular rings, and the kernel can then be easily got out. This saw can be worked by foot. The coconuts would be held in a suitable holder, working in a groove, so it would not cut the man's hand. Or we would suggest a rapid-striking hammer, like a steam-hammer, but worked by foot power, giving, say, 1,500 blows per minute, just hard enough to loosen the outer shell, and then, of course, the kernel can be cut into any required shape, either by a lever-knife or with several blades on one lever, or in fancy shapes by a cutter-punch. Those who make any special tool have a considerable amount of experimenting to do, which is best done on the spot, to see if theory and practice agree. We should require some nuts in about the same condition as in Fiji before offering any machine for the purpose described."—*British Trade Journal*.

TAMBACHERRY ESTATES COMPANY (LIMITED).—Mr. William Abbott states that "the position and prospects of this undertaking have been steadily improving while the shares have fallen during the long period of depression, investors on the look-out for a neglected security being in ignorance of their real value. This Company was originally started as a coffee Company only, and extensive gold reefs are known to exist upon the property; but instead of expending all the capital upon experimental mining, attention has been mainly directed to the cultivation of coffee and cinchona (quinine). While both these important products were steadily growing into value the shares were declining. Until recently the whole capital of the Company, which had been reduced from 160,000 in £1 shares to £100,000 in fully paid and limited shares of 12s 6d each, was selling for £35,000. This Company owns an estate of 6,000 to 7,000 acres, about 2,000 of which are planted with coffee and cinchona, and to give some idea of the extent of the latter cultivation, the number of cinchona trees planted to date is over 8,000, and these plantings will be extended until they reach 1,000,000 trees. It is expected to realise from these at least 7s 6d to 10s per tree, or, at a moderate estimate, £350,000. Apart, however, from this large and valuable area under cultivation, there are the gold deposits in reserve to be utilised later on, should the value of the gold reefs in this district be more clearly demonstrated. This is a sound and honestly-managed Company. The Directors, being all largely interested as shareholders, take only half their fees, preferring to wait for their full remuneration until the Company is again paying dividends."—*Madras Mail*.

HOW TO SEND ORANGES FROM INDIA OR CEYLON TO EUROPE.—Do each up separately in paper if possible, thin white paper, then put three of them into straw bottle-envelopes, forcing the small ends out big enough to hold the smaller oranges, &c., fixing all tight in the wooden box.—S. BLIGH.

MUSTARD AND CRESS.—As other salad plants become scarce these will be more wanted, and weekly sowings should be made. Use shallow boxes, 15 inches wide and 3 feet in length, for sowing in at this season. Rich soil is put in to the depth of 2 inches or 3 inches, and the seed is simply put on the surface and the box placed in a warm house. By sowing one or two boxes a week a constant succession may be kept up, and as a box may be stood here and there in any odd corner the expense of culture is not great.—*Journal of Horticulture*.

FUMIGATION FOR INSECT PESTS is thus described in the proceedings of the A. and Horticultural Society of India:—Mr. Claude J. Dumaine lately suggested that fumigating with Mohwa Oil-cake, if done immediately on the first appearance of Insect Pests, while still affecting small areas, might be usefully tried by Tea Planters and others. He was asked to communicate his own experience and writes as follows:—"Koonri Oil-cake is made from the seed of the Mohwa (*Bassia latifolia*) from which the oil has been expressed. I was given to understand that the smoke from it when burned in a house was sure death to all kinds of insects. This gave me the idea of trying it in the open air. Some of my Paddy, Rabar, and Moong dal, having been attacked by blights, I gave it a fair trial, which proved a success. I got a number of ordinary *handies*, and filled them three-quarters full with dry cow-dung cake, and after firing filled up with Koonri Oil-cake. The *handies* were then distributed on the windward side of the affected fields. The wind that day was nominal and the smoke was very great, and I can certify that none of the blights outlived the operation. The plants were in no way affected. I fancy 20 seeds might be enough for a square Bengal beegah. The cost of the Oil-cake is R-4-8 a maund delivered at Howrah Station, exclusive of bags, and it is only procurable at a certain time of the year. I shall be glad to procure some for any person wishing to give it a trial."

PRUNING AND PLANTING FRUIT TREES.—Mr. G. H. Richards says in the middle of his article on this subject at p. 758 that "As to trees planted in good and deep, well-drained soil, and in favourable localities, very few remarks are necessary as to their ultimate management (either in respect to pruning root or branch. Fibrous roots and firm wood well set with flower-buds will develop simultaneously," adding, "and only after several years' barrenness will it be necessary to sever a few of the strongest roots in order to restore the balance of root and branch." But why allow an interval of "several years' barrenness" to elapse before taking steps to "restore the balance of root and branch, and the fertility of the trees"? By way of supplementing Mr. Richards' remarks, I would advise that corrective measures be taken as soon as possible after any tree or trees, indicate by scantiness of crop not attributable to meteorological influences, an unmistakable proof of wanting fruitfulness. And the earlier in the summer that these remedial measures are carried out the better chance will there be of securing a full crop of fruit from the trees operated on the following year. A trench should be opened on the depth of 3 or 4 feet, and a like distance from the trunk of the trees more or less, according to the size of the latter—working the soil partly out from underneath the ball of earth and roots, and cutting all the latter that the operator comes in contact with outside the prescribed space with a sharp knife, afterwards replacing the soil. The check thus given to the trees will prevent them from making an over-luxuriant growth, but on the contrary it will induce them to make short consolidated wood thickly set with fruit-buds.—H. W. WARD.—*Gardeners' Chronicle*.

CONCENTRATED EXTRACTS: USEFUL HINTS.

1.—It is not generally known that the juice of the *Jatropha Curcas*, the common fence plant of this country, is an excellent styptic. The fresh juice applied locally to a cut or wound at once stops all bleeding without a pain by simply coagulating the blood. It is said even to cure aneurism by subcutaneous injections.

2.—There is an excellent recipe for spiced beef. Pound up $\frac{1}{2}$ oz. saltpetre, $\frac{1}{2}$ oz. sugar, $\frac{1}{2}$ oz. cloves, $\frac{1}{2}$ oz. allspice, a tea spoonful of ground pepper, a tea spoonful of mace, half a nutmeg, and a pint of salt. Our local stores might supply this ready mixed. Take 10 lb. of beef without bone, and rub it all over with the mixture. Put some of the mixture at the bottom of a pan just large enough to hold the beef, put in the beef and stew the remainder over. Rub well every day for 10 days, then wash, tie into shape, cover over with lard or suet, put it into a pan with a pint of water, cover with paper, and stew gently for six hours.

3.—A putty of starch and chloride of zinc hardens quickly, and is good for stopping holes in metal. The following will remove freckles:—1 oz. of lime juice, $\frac{1}{2}$ dram of powdered borax, $\frac{1}{2}$ dram of sugar; mix in a bottle and let it stand a few days, then rub the liquor daily on the skin.

4.—The *Curum Adjacem*, known in India as *onum*, is largely cultivated all over that country. Its seed is regarded as the most powerful of all the umbelliferous carminative seed, containing the stimulant qualities of capsicum or mustard, with the bitter properties of chiretta or gentian, and the antispasmodic virtues of asafoetida. As a whole it is superior to the caraway.

5.—The French plan of giving castor oil to children is to pour the oil into a pan over a moderate fire, break an egg into it and stir up. When done flavor with a little salt.

6.—In putting up machinery for upcountry, to save carriage, a good plan is to cast fly-wheels hollow, and then at their destination fill them with melted lead. They afford the same centrifugal power as a larger wheel of iron, cost less, and take up less room.

7.—Corks can be made impervious by soaking them for several hours in a solution of $\frac{1}{2}$ oz. glue or gelatine in a mixture of $\frac{3}{4}$ oz. glycerine and 1 pint water at a temperature of about 120° F. Such corks can be made nearly acid proof by dipping when very dry for quarter of an hour into a melted mixture of 4 parts paraffine and 1 of vasoline.

8.—Water with lead in solution may cause paralysis, colic, gout, rheumatism, kidney disease, and other complaints. N. B.—Aerated waters sometimes contain lead. A simple test is to add a little tincture of cochineal, when the color will be blue not rose.

9.—Lactic acid and glycerine, mixed with water in the proportion of 1 lb. of each to 8 lb. of water, make a soldering mixture for tin cans of fruit, flesh or vegetables, which is imported harmless from a health point of view, having none of the poisonous properties of chloride of zinc.

10.—The forests of the United States are disappearing at the rate of 25 million acres a year. There are 450 millions of acres in the country.

11.—The use of nitro-glycerine, that is dynamite, is recommended instead of alcohol for stimulating the action of the heart. Only a minute quantity is required; it is practically free from taste and odour, it acts at once, and does not lead to the craving for alcoholic stimulants.

12.—Professor Vogel observes that the hemlock which yields its alkaloid in Bavaria gives none in Scotland, and he concludes that sunlight plays an important part in the generation of alkaloids. In confirmation of this, cinchonas cultivated in feebly-lighted hot-houses at home yield little if any quinine.

13.—To remove rust, cover the metal with sweet oil well rubbed in, let stand for 48 hours, smear again with oil applied freely by a feather, then rub with *very* finely powdered unslaked lime; or immerse the metal for a few minutes until all the dirt and rust is taken off in a solution of potassium cyanide,

say $\frac{1}{2}$ oz. to a wine glass of water, then take it out and clean it with a toothbrush and a little of some paste made of potassium cyanide, castile soap, whiting and water mixed to the consistency of a thick cream.

14.—A new cement for securing glass-stoppers has been recently recommended, made of finely-powdered oxide of lead and concentrated glycerine, which needs only to be smeared round the stopper. It dries quickly and becomes very hard, but can be readily scratched off with a knife.

15.—To remove ink stains from cloth: use oxalic acid or pyrophosphate of soda; grease, use turpentine or benzine; tar-pentine or candle stains, use Euxale Cologne.

16.—Floors. To stain, 1 lb. burnt amber ground in oil. Mix with boiled linseed oil till it becomes suitably colored without getting too thick. Rub in well with a woolen cloth, then rub off with another till it ceases to come off. To wax, 1 lb. wax shaved thin mixed with 1 gallon turpentine. Let the mixture work for 18 hours, then rub in with a woolen cloth.

17.—The beneficial effect of salicylic acid on exzema has now been well established.

THE SUPPLY OF CINCHONA BARK.

The anticipations of an improvement in the cinchona bark market, which prevailed some two months since, have not been realized, and instead of bark commencing a price of ninepence per unit, as it was predicted would be the case before Christmas, it was not much more than half as much at the last sale. The last shipments from Ceylon about the early part of this month have materially contributed to this result, as much as a million pounds of trunk bark having then been shipped in the course of a fortnight. Early in the month 32,000 ounces of quinine sulphate were put up at the drug sale and sold at low prices. The next bark sale will take place on the 12th of January, and it is expected that the quantity put up will be considerable, though the harvesting operations in Ceylon usually fall off towards the end of the year.

The changes that have taken place during the last few years in the supply of cinchona bark deserve some consideration from pharmacists, who have hitherto been in the habit of purchasing cinchona bark more according to external appearance than anything else. It has been pointed out that the characters which conventionally determine the market value of "druggists' quills" are very often fallacious, and have no real connection with the quality of the bark. Thus, for instance, quills of renewed bark, being destitute of the appearance that has come to be regarded traditionally as an indication of good quality, will not sell for druggists' purposes so well as quills of natural bark; though, being in reality richer than the latter, they are readily bought by quinine manufacturers. A silvery coating on the epidermis of the bark is one of the points to which a fictitious importance is attached, and not very long ago a parcel of fine quills, having an intrinsic value of about three shillings per pound as a quinine-yielding bark, realized at a public sale as much as four shillings and tenpence, simply on account of the fine silvery coating upon the quills. In another instance two parcels of Darjeeling quills, that were almost identical according to analysis, sold respectively for four shillings and a penny and two shillings and threepence.

The variability of succinbra bark, as regards the relative proportions of the several alkaloids it contains, is also a point of importance for the pharmacist to bear in mind, and although the Pharmacopoeia now only requires that cinchona bark used for pharmaceutical purposes shall contain between five and six per cent of total alkaloid, and that at least half the quantity shall consist of quinine and cinchonidine, many will appreciate the desirability of ascertaining with more precision the actual amount of quinine present in the bark to be used for pharmaceutical purposes. The Pharmacopoeia definition applying only to quill bark, shuts out from use the shavings, which

are so often much superior, as regards the amount of quinine, to any kind of quill bark; and since the established prejudices as to the appearance of bark would tend to favour the use of natural bark rather than renewed bark, the general effect of all these circumstances would be to promote the use of the least valuable kinds for pharmaceutical purposes. In the natural *succubra* bark it is almost an invariable rule that cinchonidine is present in larger relative proportion than quinine, so that, according to the present Pharmacopœia definition, the quinine standard of cinchona bark is reduced much below that of the previous Pharmacopœia, and the bark corresponding with that definition will not contain more than about 1 per cent of quinine.—*Pharmaceutical Journal*.

THE DIVI TREE AND SEASIDE GRAPE IN THE WEST INDIES.

Henaratgoda, 2nd January 1886.

Sir,—We beg to annex a cutting from *Leather* of 5th October 1885, respecting Divi Divi culture in the West Indies. Trusting it will be useful to intending planters of the said new product, yours obediently,
J. P. WILLIAM & BROS.

We are pleased to give the copy of a letter received from a correspondent who lives on one of the West India Islands, and has turned to the cultivation of divi-divi. Some four or five years since he forwarded for analysis some good samples of divi, acacias, and other tropical plants yielding tannin which were growing wild on his estate. Since that time he has planted some thousands of divi trees, and they are doing well; and from the tenour of his letter there seems to be plenty of scope for any who are disposed to go into the trade. We are not at liberty to publish our correspondent's name, but shall be glad to give it to any who are disposed to look at it as a commercial speculation.

West Indies, September 6, 1885.

Dear Sir,—Please accept my best thanks for your letter of 8th July, and also for the number of *Leather* accompanying it, which I have taken great interest in perusing.

I wish you every success in your conduct of the said trade journal, and shall be glad to give you any information in my possession as to tanning materials, etc.

My plantations of divi-divi are, so far, progressing favourably, but the tree is of slower growth than I anticipated. As none of the trees I planted over three years ago are bearing yet, it will, no doubt, take five or six years before I am able to obtain any crop from them.

Meanwhile, there is an abundance of divi pods going to waste every year on a property adjacent to mine, and where there are thousands of divi trees in full bearing. This estate could be had for £1,000 at most perhaps for less, and would easily give 100 tons of divi or more per annum at once. I have a great mind to buy it if I can find a partner to contribute half the capital. The property is situated on the sea-shore, so that the produce could be shipped without any further expense for transportation. If any of your leather acquaintances should feel disposed to make a good investment here is the opportunity.

The sea-grape (*coccoloba utrifera*) is most common on all our shores. I believe it is cultivated in Kew; at all events, they have dried specimens there in the herbarium. I enclose a slight sketch of the tree for your information. The leaves are very leathery and stiff, about eight to twelve inches across. The flowers are small, white, in a narrow spike, later on forming into a sort of dark blue grape, which can be eaten, but are rather astringent. The wood is dark red and a good timber. The tree grows on the sandy shore, and is quite common in most West India islands.

From the *Tropical Agriculturist* I learn that divi cultivation is now taken up in the East, both in Java, the Straits Settlements, and the East Indies. I

should very much like to know whether the future for divi is encouraging, and what prices are at present. I am determined to acquire the estate mentioned above. If you think you can find me a partner, or form a small company on shares, I shall be glad to learn your views. The land is about 600 acres, so there is plenty of room for further extensions.

INDIAN GOVERNMENT COMPETITION WITH CINCHONA CULTIVATION.

TO THE EDITOR OF THE "MADRAS MAIL."

Sir,—I trust you will also allow me to enter a protest against the Government planting any more cinchona. In these hard times, when most planters are living merely from hand to mouth, I consider it most disgraceful that government should continue to extend their plantations, which must be to the detriment of private enterprise. When the enormous number of cinchonas recently planted on the Government estates come into bearing, the crops yielded by them must affect the market. I submit the following figures, which speak for themselves—

No. of plants enumerated by Major Walker in 1878,	No. returned by the Directors as existing 31st March, 1885.
Wood 45,758	
Hooker 87,557	555,166
Neddivattum 208,780	432,691
Dodabetta 220,936	633,457

Thus Government has, in six years, extended its estates by over one million plants! Planters were led to believe that the Secretary of State had promised that no increase to the then present area should be made, except in the case of new or rare varieties (and a limit was placed to that); yet, under the present Directorship, upwards of a million of ordinary officialis and hybrid cinchona plants have been put out! I contend that these are neither new nor rare; therefore the Government is acting in direct opposition to its promise. The present object, as far as I can see, is to cover as much land as possible with anything bearing a resemblance to a cinchona. It is high time for the Planters' Associations to take action, and represent the matter, if need be, to the Secretary of State for India. That the plantations are being extended is proved by the Director's figures regarding the number of plants on the Hooker. Major Walker gives the area of this estate as 154 acres. Now, if the 555,166 plants said to be alive on 31st March 1885, were placed at four feet apart, they would cover 204 acres. But I am informed that many of the original trees are still in existence, and that they stand at from 7 to 8 feet apart, so this estate must have been considerably extended. Not only is the Government competing with the public in cinchona cultivation, but they, as landlords, charge a rent which is prohibitory. For land taken up under the new rules the annual rent is R.2-2-0 per acre, all forest being strictly reserved. My opinion is that Government should at once reduce the size of its properties. With a hundred acres at Dodabetta, and a similar area at Neddivattum there will be ample space to carry on any necessary experiments.

ANON.

SUNFLOWER CULTIVATION.—With reference to the inquiry from Mr. C. S. Smith, of Monbasa, in our October number, a correspondent sends us the following:—"The seeds of sunflowers can be sown in New Zealand during October; if the season is cold, towards the end of the month. The plants want plenty of room, and rows should not be less than 3 feet apart, and plants, say, 2 feet. For an acre it requires 6 lb. to 7 lb. of seed. To secure a good crop the land must be rich, and bone-meal or superphosphate may be used freely. Forty bushels of seed to the acre is the ordinary crop, and when it is remembered that a bushel of seed will yield a gallon of oil, the seeds containing 40 per cent of oil, it shows that from poor land, deficient in certain elements, very poor returns would be forthcoming."—*British Trade Journal*.

PLANTING IN CENTRAL AMERICA.

AN EX-OEYLLON PLANTER ON HIS TRAVELS ROUND THE
WORLD, ENDING WITH GUATEMALA.
LIFE AND CULTIVATION IN GUATEMALA.

REVOLUTIONS GALORE.

MY DEAR "OBSERVER,"—It is now a long time since I promised to write you, and many curious and exciting things have happened in the meantime. These events followed in such rapid succession that I always postponed writing, waited and wondered what would be the outcome, so that I would have something else to chronicle. Wars, revolutions, assassinated presidents, and earthquakes are now of almost daily occurrence, and cease to excite much interest. I shall accordingly wait no longer but proceed to tell you of this country and its cultivation, the city of Guatemala and its peculiar situation, coffee, cinchona, and my own adventures.

When I first arrived in Guatemala, March 1883, I was most kindly received by the English Consul, who introduced me to some of the leading planters. As the first East Indian planter who had visited Guatemala I was presented to General Rufino Barrios, President of the Republic. The President liked me very much, and offered to pay all my expenses through the Republic and furnish me with letters of introduction to the Governors of the different Departments. This of course I most readily accepted, and in a few days I was mounted and equipped for a journey up the Pacific slope. I visited all the coffee districts, skirted the Mexican boundary, and returned again to the city by way of the Atlas, or high plateaus. I was in the saddle 45 days, and averaged eight hours a day riding. I gave the Minister of Public Works a report. A few days after I cabled a proposition to introduce the cultivation of cinchona, which was accepted. I then left the city again for the Atlantic coast, crossing the continent. Thence by steamer up to the Mississippi to New Orleans, Chicago, Niagara Falls, New York, crossed the Atlantic to England, through France and Italy to Brindisi, and on to Ceylon again. I went thence to the Madras Presidency of Southern India to get cinchona seed. From the Government cinchona plantation, Dodabetta, I collected a large quantity of officialis seed. But I was mostly indebted to the superintendent of a large cinchona plantation of succirubra cinchona whose name quite slips my memory. The estate adjoins the Government plantation of Neddevattam about 18 miles beyond Ootacamund. This gentleman was extremely kind and I owe him lasting obligations. On my return to Colombo I procured from the Government Gardens 15 warden cases, containing a selection of plants which I knew were not in the Republic of Guatemala, cardamoms, tea, cloves, croton, cinnamon, etc.

I had 50 pounds of cinchona, I think the largest quantity that was ever shipped across the ocean. I packed it in a peculiar way all my own, and as it was a complete success I shall describe the method. I had 150 bags made of cotton cloth which were about a third filled with seed. My intention was to take the seed as baggage, which would enable me to take it out of the ship's hold at least every week, turn it over and handle it thoroughly to prevent it from caking together or getting musty; also to have fresh air circulating inside the box frequently would also be a good thing. The box was an iron one, which closed hermetically and fitted inside another box made of wath to protect it. Mr. Thomas A. Cockburn of Rathkelle estate, Badulla, an old New Zealand chum

of mine, obtained leave of absence and came down to Colombo to see me. Together we fixed all things up nicely. Cockburn had made some purchases of seed for me in Ceylon, which I had marked separately, and, am pleased to say, came up all right.

From Colombo to Singapore I opened my box of cinchona seed and placed the bags in the sun for a couple of hours in the middle of the day. This I did several times. By this exposure I expected to kill any moths or worms that might have been collected with the seed. After leaving Singapore I did not expose it longer to the sun, but handled it well, turning it over and over. I was strongly advised to pack in bottles. I am glad I did not, because I should have been obliged to ship as general cargo, which would have prevented me from handling or stirring the seed up from time to time. Bottles, too, are apt to break, and being corked the seed is always in its own atmosphere, which I don't think is good.

I see by my *Observers* that your Mr. John Ferguson has made a trip round the world. The articles which he wrote were extremely interesting to me, particularly so as I had preceded him only a few months on the same road. I shall dismiss the story of my trip therefore, as I can only repeat what he has already so ably communicated. I may mention I got remarkably good dispatch from Hongkong. We reached that port at 4 o'clock in the afternoon and by 10 next morning we were steaming away out of the harbour on the good ship "Arabic" for Yokohama, Japan. We stayed four days in Japan, and had a most gay and festive time. It happened to be the Mikado's birthday. Tokio was decorated in the most gorgeous array of banners and bright bunting, and the inhabitants rejoiced in their own peculiar way. After leaving Yokohama we had extremely bad weather for six days. A week before a cyclone had passed through the sea, which accounted for the extremely ugly waves. On the night of the fifth day out a lunatic who was on board had to distinguish himself by setting fire to the ship. He went very cunningly to work and nearly succeeded. At midnight he got up from his bed, noiselessly passed the berths of the other steerage passengers without disturbing them and entered the forehold, closed the door and shut himself in. He then struck a match and set fire to a number of bales of straw which were stored there. The material was very inflammable and the most disastrous consequences might have resulted; fortunately by chance a beathon Chinese happened to be standing on the upper deck opposite the gangway leading down to the steerage rooms and saw the man enter the forehold, and had the curiosity to follow and watch him. He at once flew on deck and rang the fire-bell. It was the first officer's watch; he leaped down from the bridge and entered the hold at a pace fitting the occasion, nearly brained the lunatic, and set to work to extinguish the flames. The crew were very well trained, and in a marvellously short time a flood of water was streaming into the fire. I arrived on deck at this time and saw the first officer enveloped and nearly choked in the smoke. I joined him, and when we and the other men came on deck after the danger was all over and the excitement subsided, it would have been difficult to recognize what kind of animals we were; a something more than monkey; but a very undignified man. Darwin I think would have claimed us as the long looked for "missing link."

We reached San Francisco in due course and thence to Guatemala. I completed the round of the world in eighty-four days deducting the

time I spent in India, which I think is only fair, as the steamer which dropped me at Colombo went direct to Hongkong. I had some trouble with my wardian cases of plants in San Francisco at the custom-house. I had them consigned there instead of through to Guatemala.

On reaching Guatemala city, I handed them over to the Minister of Public Works, and he in turn gave them to some planters. How the Guatemalians (natives) wondered. They are anything but a voyaging nation: quite the other way in fact. To go hence to a neighbouring city is thought an undertaking, but to go round the world was too stupendous for their undertaking.

The city of Guatemala is most peculiarly situated, perhaps none other like it in the world. It occupies the middle of what appears a high plateau of plain, but which in reality is split up by scores of barancas. The remarkable thing is that it is built fairly on the centre of the watershed between the two oceans, Pacific and Atlantic.

The rain which falls on the southern and western side of the city is drained off into barancas which form streams and are ultimately discharged into the Pacific Ocean. On the other half of the city the rain and drainage finds its way into barancas running in the opposite direction. These barancas converge and the water goes to swell the volume of mighty Matagua river, the largest in the Republic except the Usamasinta. The Matagua is a fine river capable of floating large steamers of light draught for fully 100 miles from the sea. Its outlet is on the Atlantic side. The river Usamasinta has an enormous volume of water; I think there is none other larger south of the Mississippi of the United States and north of Panama. Its tributaries drain the western boundaries of British Honduras and the whole north and centre of Guatemala. It flows through Yucatan and a section of Mexico, and is finally discharged into the Mexican Gulf. The city of Guatemala has something else very remarkable about it. It is a smokeless city. There is no smoke to be seen anywhere. The only thing which fumigates the atmosphere in the way of smoke is what issues from the mouths of the citizens in the shape of consumed tobacco. A Spanish American if he is not smoking it is because he has just finished a cigarette or is about to begin another. All the fuel used for household purposes is charcoal, which is brought in from long distances on packmules by the Indians and sold to householders. It is true there is a little firewood used, but very very little chiefly for kindling.

When I left Guatemala for India to collect my cinchona seed I left a gentleman in charge of the constructing seed nurseries. Don Louis Arrachea proved himself worthy of my trust and confidence. He erected seed nurseries all over the Pacific Coast, also made some in connection with the Municipalities of the Pueblos of the Alta Vera Pas. The nurseries on the Pacific slope were made in connection with the coffee plantations. Altogether I had built and nearly ready to receive seed some 19 nurseries. On my return to Guatemala I left as soon as possible for the Pacific slope with my seed, and after a most tiresome journey and surmounting innumerable difficulties and troubles, which to you would be almost incredible, I succeeded in getting my seed sown and sprouted. The form of the roof of the seed nurseries I had made after the manner which was found so successful in Ceylon. A simple thatched roof sloping towards the south and facing or open towards the north. This form I always found

secures the seedlings from the rays of the sun, at the same time gives them all the light of day, which is all that is required. I pricked out seedlings into extended nurseries beginning in July of last year, and redistributed them or scattered them further over the whole face of the land. The following are the names of the coffee districts and plantations on which cinchona is planted together with the number of plants planted out. In addition to this list there are a number of other plantations which have received plants but I have almost lost trace of them.

On the Pacific slope, district of El Tumbador.—Estate of the President, El Porvenir 600,000; Bola de Oro 100,000; El Peru 100,000; Nueva Granada 10,000; Siglo XIX 10,000; Nuevo Mundo 10,000; Monte Cristo 10,000; Canada 10,000; Las Lunas 6,000; Montevidéo 8,000; El Rosario 20,000; El Paro 5,000; Municipalidad 5,000.

District of Costa Cuca.—Los Mercedes 200,000; La Libertad 110,000; Desamparados 50,000; Santa Gertrudes 20,000; La Unidad 6,000; Las Delicias 8,000; San Benito 5,000; Las Marias 5,000; La Virgie 6,000; San Jose 7,000; San Augustina 6,000; San Isidro 7,000; La Violeta 7,000; Santa Elena 8,000; Palmira 7,000; Democracia 7,000.

District of Xolhuitz.—Helvetia 50,000; San Jose la Vina 63,000; La Suerta 20,000; Xolhuitz 20,000.

District of Pueblo Nuevo.—Pueñol 50,000; Santa Cecilia 9,000; La Cumbre 7,000; Casa Rojo 8,000; Nueva Francia 8,000; La Florida 5,000.

District of Antigua.—Capita 60,000; Portal 30,000; Philadelphia 10,000; San Andres 12,000; other smaller places 12,000.

Municipalities of Alta Vera Pas.—Municipality of Purhula 25,000; Tactic 30,000; Santa Christobal 10,000; Santa Cruz 60,000; Coben 5,000; S. Pedro 60,000; San Juan 1,000; some coffee estates 30,000.

Altogether I have about 1,500,000 fine plants two and three feet high planted out, making some allowances for vacancies. The method of planting out plants of all kinds differs somewhat from the way we do. In the nurseries the plants are pricked out much further apart than with us in Ceylon, so that a nursery with 100,000 plants covers a very large space, more than double the size of our Ceylon nurseries—particularly with coffee. The plants in a coffee nursery are fully a foot apart. When dug up they are taken with all the earth around them in a gigantic ball: one mozo or cooly cannot carry on his back more than three or four plants to the field. A coffee plant is a young tree with primary and often secondary branches. Holes are dug on the field of a size proportionate to the size of the plant. I often enquired what proportion of vacancies the planters had to a young clearing after the first planting. They did not seem to understand the question. It appears the planting out is done so thoroughly the first time, that there is no further need of supplies next year. The cost of the original planting is very much higher than with us, but then it is done and finished with. Planting out with a ball of earth as it is done in Ceylon, I am persuaded, is only a half measure. Here the plant is cut out of the nursery with a gigantic knife called a machete. In size the plant resembles, with its ball of earth, a large-sized flower-pot.

In planting a coffee estate the method of lining is also different. They run down one base line much the same as we do. They are then provided with a right-angled-shaped frame of light construction. The legs of the frame are put against the pegs placed in the base line, and in the apex of the right angle another peg is put and so on until the whole field is lined up. By this means the whole of the plants are exactly equi-distant, and whichever way one look are straight well defined coffee rows. The distance apart is usually 9x9. In some places this distance

is thought too close and they line 12x12. The tree is mostly allowed to grow just as it pleases. In some cases there are rude attempts at cultivation. For instance some few planters, those with advanced ideas (?), top the plant as soon as it is planted out within a foot of the ground, and two stems are allowed to grow for six feet; then these two stems are again cut and four stems are grown. After this the tree does just as it pleases. Picking is done with ladders, and a piece of one real (25 cents of your money) is paid for each measure. A measure is equal to one of your palm bushels. As soon as the cherry leaves the tree the method of curing is then entered on, and it is conducted in a most slovenly, careless manner. Now the great falling-off takes place. They have all Gordon's pulpers, cisterns for wet parchment, and drying patios for their coffee, peelers and the coffee is picked in the usual way. But strange, as it may seem, they don't seem to know rightly how to make use of them. The coffee bean is a very fine one, and I don't see any reason why it should not command the same price in the London market as the Ceylon coffee. But it does not by a long way. Now the question, I may say the very vexed question, which will occur to the mind of a Ceylon planter, is, how on earth is it that these people in Central America can make coffee plantations pay large returns, with labour at 50 cents a day and upwards, a longer sea voyage, and the very expensive isthmus of Panama to cross, with all the risks of transshipments and we cannot do so here? I think their wonder will almost amount to incredulity when I add that there is an export duty of 50 cents on every quintal of coffee. (A quintal is 100 lb.) The cost of taking the coffee from the districts nearest to the railway stations is from 160 cents to two rupees. The Railway Company has a monopoly by which they charge 80 cents for running about 50 miles. The Wharf Company has another monopoly by which they charge 60 cents for allowing the coffee to cross their wharf, which monopoly, is joined to another monopoly of transshipment of the coffee from the end of the wharf to the steamer, 60 cents more. Poor coffee, poor coffee planters! How would you in Ceylon stand that sort of thing? Don't you think every planter would before now have invested all his savings in dynamite and blown Ceylon into some other sphere rather than tolerate these monopolies one day? I think, they would. When in addition to all the above charges, I tell you that the coffee only fetches some 60 shillings (which is placing very high, 40 to 60 is nearer) in the London market, I shall not be at all surprised if my statements are received with a certain amount of incredulity.

But I hope to make you understand the reason thereof. The secret rests in the enormous production. A coffee estate in the best districts (I make this qualification because at one time people were so crazy for coffee that they planted it everywhere) when the trees are in full bearing yields about three quintals per querdá. There are eight querdás to an acre, so that the yield is from 1 ton to 1 ton 5 cwt. per acre. How is that? Does not the planter of Ceylon long for lands blest by nature in this way? I have seen of soil, a fine chocolate loam, rich and friable, 30 feet deep, and plenty of it intermixed with layers of volcanic ash a foot to three feet thick. The total amount of coffee shipped last year from Guatemala was about 400,000 quintals (pronounced kintals 100 lb.) which is very considerable. It is very difficult to arrive at correct statistics here.

The Indian population are a very industrious class, hard-working and law-abiding. There are

quite a number of different languages each quite distinct from the others. They are by far the largest portion of the population of the country: altogether I suppose there are about a million, and some 300,000 or 400,000 Ladinos, or mixed breeds, the descendants of the Spaniards intermixed with the Indians.

The Ladinos chiefly congregate in the towns and are employed in all the Government offices, post and telegraph, etc. The Indian occupy the altos and cultivate wheat, maize, potatoes,—oats, in fact all the wants of the people. They are great carriers of burdens, 100 to 150 pounds is not at all an unusual load for them to carry 150 to 200 miles. I like them very much indeed. They can be trusted implicitly except only with drink. Here lies their greatest weakness. They are born drunkards. It is customary in a family of Indians for the heads of the household to get drunk turn about. The husband is always accompanied by his wife, who keeps perfectly sober and sees that no harm comes to her spouse. Next feast day it is her turn to get drunk and he looks after her. A few weeks ago when returning from my last visit of inspection I passed a large village, which was simply crowded with Indians who had come to a fiesta. They were all under the influence of liquor and were becoming worse every minute. I passed through alright and for five to six leagues along the road I passed groups of twos, fours and sixes. The half were horribly drunk and the other half comparatively sober. They never attempt to molest anyone travelling when in this state. They all carried gourds which were filled with a kind of native beer brewed from sugarcane. I only saw one man alone; as I passed him he called: "Patrón, allow me to mount your spare mule. Take me along with you for God's sake. I am all alone. My wife is not here—left me," &c. Then he cried as though his heart would break and rolled in the dust. In travelling I always carry a revolver, but have seldom had occasion to draw it and never used it. They have a mortal dread of Englishmen. An Englishman could travel from the boundary of Texas through Mexico and Central America to the Argentine Republic, and I don't think he would be very much molested. They usually class our American cousins and the English as one, and call them Ingleses. "Los Ingleses estan muy bravos." On one occasion a Texan was travelling through the country and happened to be on the road on Holy Thursday. To travel on Holy Thursday is thought so bad, so outrageous and sacrilegious, that the culprit is in danger of being stoned in passing any Pueblo. The Texan, a muscular Southerner, quite innocent of harm, entered a village and was passing quietly through. He was greeted everywhere with all kinds of reproaches, and grown bold with talk and liquor they began stoning him. This was rather too much. He drew his shooting irons and in a very short time captured the town. The men mostly took refuge on the hill and the women closed their doors and prayed for the saints to relieve them of the fearful fiend. History records that he had a pair of horns and a tail; be that as it may, they all have a most wholesome fear of foreigners and especially los Ingleses ever since.

I think I shall now conclude this letter. So far I have had to crowd what I have to say very much. In my next I shall tell you of how we journey through this country. Also of my journey of exploration to the Atlantic coast, and my experience while commissioner to the New Orleans Exhibition.—Yours truly,

W. J. FOESYTH,

QUINOLOGICAL WORK IN THE MADRAS
CINCHONA PLANTATIONS.

By DAVID HOOPER, F. O. S.,

Government Quinologist.

Since the disappearance of Mr. John Broughton from the Madras Presidency in the year 1875 no systematic chemical work had been conducted in cinchona culture on the Nilgiris. The author, who had been appointed early last year, entered into his duties last October. The appointment was made with a view to advance the practice of cinchona culture at the Government plantations, "by analysing the bark of a very large number of their trees in different stages of their growth, when treated under different systems and when grown at different altitudes."

Mr. Hooper gave a table of analyses showing the quinine and the other alkaloidal value of a number of different kinds of bark. These results were the averages of numerous analyses. So far as they go it appears that in regard to *Cinchona Officialis* the younger trees are superior to the older ones, and the narrow-leaved variety to the broad-leaved. The following amounts of quinine were determined in three kinds of crown bark from trees of the same age:—

	Narrow-leaf.	Broad-leaf.
Natural ...	2.85	2.95
Mossed ...	4.03	3.47
Renewed ...	4.48	3.85

The variety of *officialis* named *angustifolia* some years ago created a widespread interest on account of the extraordinary amount of quinine found in it by Broughton and Howard. Mr. Hooper's samples were taken from tree twenty years old, 10 feet high, and with a circumference of 18 inches. Mossed gave 5.60, and renewed 4.91 per cent of quinine. The results show its superiority over ordinary crown barks, but in its present condition it appears to have no claim to be a prodigy in cinchona culture.

Barks from hybrids between *C. officialis* and *C. succirubra* have received of late a great deal of attention from planters. These, named respectively *C. magnifolia* and *C. pubescens*, yielded from 2.73 to 3.32 per cent of quinine, the *C. pubescens* yielding the largest amount of this alkaloid.

The *platensis* bark is characterised by yielding an unusual quantity of the alkaloid quinidine.

The analysis of the *Ledgeriana* tree at Naduvatom (quinine 5.58, cinchonidine 1.24, no quinidine, cinchonine .23, amorphous alkaloids .62) is fairly representative. Ledger bark from the South Wynnaid, yielding 8.41 of quinine, was an average sample of shavings taken from twenty-one trees of five and a half years old; the amount of quinine is equivalent to 11.31 per cent of the crystallised sulphate; this is one of the highest results obtained in South India.

In this paper was also reported the examination of a tree of *Cinchona succirubra* to discover the distribution of alkaloids in its various parts. The tree was twenty-three years old and 31 feet high; it had grown in an exposed situation, and had never been barked or mossed. The whole yielded of dry bark 27 lb. 14 oz.—Root, 2 lb. 8 oz.; stem, 20 lb. 14 oz.; branch, 3 lb. 2 oz.; twig, 1 lb. 6 oz.; dried leaves, 2 lb.

The root bark contained 5.30 per cent of total alkaloids, the bark of the stem below ground 4.21 per cent, while most other portions of the stem bark yielded under 4 per cent. The leaves only yielded .70 per cent.

Other experiments seemed to show that shade was very favourable to the development of quinine and cinchonidine.

From a short series of experiments on mossing old trees, Mr. Hooper thinks that generally old and original trees if of vigorous growth may still be improved by the mossing system.

[The President said he regretted that it had been necessary to merely read an abstract of the paper, for it was a most interesting one throughout, and would amply repay very careful study.]—*Chemist and Druggist*.

COFFEE AND CINCHONA.

During the past twenty-five years the coffee enterprise in Southern India has passed through some remarkable vicissitudes. In 1860 there were comparatively few estates opened in Malabar, Coimbatore, Coorg or Mysore, but several of the most fertile and profitable properties now in existence were developed prior to that date. This circumstance may be attributable to their possessing extraordinarily rich soil, to the coffee having been planted under natural shade, within sheltered belts, or on land where the forest had been felled, but unburned. A quarter of a century ago, "coffee planting," though restricted in area, had proved a lucrative venture, and despite the reputed unhealthiness of the climate, the paucity of roads, and the inexperience of the pioneers, a great deal of English capital was attracted to the coffee districts. The ensuing decade is memorable for a vast extension of the industry; large blocks of land were felled, cleared, and planted, inclusive of much land which was subsequently found to be unsuitable to the growth of the bean. Notwithstanding the ravages of "borer," which in 1866 and subsequently, created considerable alarm, particularly in Coorg, the proprietor of a coffee estate was generally regarded as an enviable individual, who was on the high road to making a fortune. Many properties changed hands at figures profitable to both vendors and purchasers, while handsome returns were the rule on all such as were prudently worked, even with "M. P." at £60 per ton. Such was the position of affairs, when, early in 1871, rumours reached India of the outbreak of a formidable disorder inimical to coffee, which, unlike "borer," primarily attracted attention in Ceylon, where its effects were speedily apparent over a rapidly increasing area. Towards the close of the year "leaf disease" had established itself on Indian plantations, showing at first most acutely on estates adjacent to the Ghats, whence it extended inland and assumed an epidemic type. It is still a moot point, whether a form of *Hemileia vastatrix* had not been prevalent in Wynnaid some years previously, it being surmised that it confined its attention to a particular variety of coffee, known as the "chick," which had been observed, so far back as 1867, to annually display a deciduous tendency about the month of September. Opinions differ as to the origin of "leaf disease," and the problem still awaits solution, but no divergence of views exists with regard to its disastrous effects. These embraced periodical destruction of the foliage and bearing branches; a falling off in the cropping capacity of the trees; the deterioration of the bean in substance and colour; and the stricken coffee, unless liberally manured, remaining paralyzed for months, until it languished below a point at which all cultivation became unprofitable. The inevitable consequence has been reduced production, with diminished exports; and though, during a spell of high prices, proprietors were enabled to carry on their properties, they were gradually confronted with the necessity to relinquish outlay on their least productive fields.

In 1878, the uncertainty attending the future of coffee induced a few planters to turn their attention to the introduction of cinchona on their estates, a project that received considerable stimulus from the marked success which had attended its cultivation by Captain Cox, in the Charambady District. The following years witnessed the gradual diminution of the area under coffee in Southern India, but they were coincident with the progress of cinchona planting, and at the commencement of the present lustre a vigorous effort had been made on the great majority of estates to establish the most approved and best known varieties of red and yellow bark trees. At the outset, it was impossible to forecast whether these cinchonas would flourish in Coorg and Wynnaid, whether they would (to quote a sporting term) "stay," or prove ephemeral, as has since been the case in Ceylon; whether abandoned coffee lands could be utilised with advantage, more especially for the growth of *Succirubras*, and the effect the later would produce if planted

at regular intervals on highly cultured fields of coffee. In the meantime, worthless estates had been abandoned; shade had been fostered over the more promising properties, and the most fertile portions of the latter were brought under the highest system of modern cultivation. Under shade, and with such improved treatment, coffee suffers less severely from the annually recurrent attacks of "leaf disease," and the yield from economically managed estates fortifies the owner against loss on working expenditure, while on some favored plantations in Coorg, Wynnaad, and the Nilgiris, bumper crops are still realized. Experience, though still immature, indicates that, where sheltered from the violence of the south-west monsoon, *C. Suciubras*, *C. Cal.* Ledgers flourish as a general rule on virgin soil in Coorg and Wynnaad, though the growth of the former is less rapid and vigorous upon abandoned coffee lands. Where the red bark is planted not less than 10 by 10 feet, in highly cultivated coffee, and when the branches are carefully lopped from the time they overshadow the coffee, the latter suffers no appreciable injury. In addition to the cinchona named, some other varieties have been successfully introduced which seem to find the soil and climate of the drier divisions of Coorg and Wynnaad thoroughly congenial. The success of cinchona in these districts may now be considered as assured; coffee planters who have survived a long period of misfortune may now be said to have two strings to their bow.—*Madras Mail*.

THE TUBEROSE IN NATAL.

So much progress has been made within the last few years in the cultivation of the double Tuberose in this colony, that no excuse is needed for bringing it under your readers' notice. I cannot exactly ascertain when the Tuberose was first brought to Natal, but it must have been about fifteen years ago. Mr. Justice Phillips, late of Natal and now of Cyprus, was a most ardent horticulturist, and the credit of importing the Tuberose is attributable to him. A short account of the fine estate planted by this gentleman near Maritzburg will be found in Mr. J. A. Froude's graceful little sketch, *Leaves of a South African Journal*.

For several years Tuberose bulbs, in number a few hundred, were simply cultivated, not propagated, their possibilities unthought of. About five years since, however, they were taken in hand, and a different culture began. Instead of the bulbs being allowed to occupy the same ground year after year without transplanting or division of any kind, they were regularly lifted about June, growth being then at a halt, the offsets taken off, and replanted the following spring (September).

I shall describe the method followed in a 10 acre field, which is daily under my notice. In October last year, the dry grass having been burnt off, the ground—perfectly virgin soil—was broken up with a large American plough drawn by twelve oxen; the few large boulders lying about were removed. For a first crop Mealies (Maize) were sown broadcast, and harrowed in. The next thing was to get the field enclosed with a good bank and ditch and barbed-wire fence. Owing to a press of work the Mealies grew up untouched by the hoe or cultivator of any kind, yet, thanks to the good season, an average crop of fair-sized cobs was gathered last April.

As is generally the custom here, during the winter, the cattle were turned in to feed off the cornstalks. In August last all was burnt that would burn, and the ground thoroughly ploughed, cross-ploughed, and harrowed twice, grass and Mealie roots gathered and burnt. The soil being in a fine friable condition, furrows were struck out 2 feet apart with a small iron plough and a couple of horses, a simple marking-machine drawn up and down the drills, and the sets planted 6 inches apart, and hoed in. Weeds are very carefully kept down, and with our heavy summer rains the growth of the plant is rapid. About midsummer (December) the splendid spikes of bloom expand, and continue till mid-winter (June); indeed

in this locality, 2,800 feet above the sea, I am convinced that, with a little management in planting successional batches, they could be had in flower in the open ground throughout the year. For so little frost have we, that Tomates generally continue to ripen fruit in the open through the winter; when in Maritzburg, about 200 feet below us, they are invariably killed by the cold. Cannot the Tuberose be flowered in the open—at least in the South of England? I venture to ask your readers to try. The climate of this colony is particularly well suited for the cultivation of bulbous-rooted plants—a hot, moist summer, followed by a dry, cool winter; and, I will add, this locality is favoured above many others for Tuberose culture. We miss the winter rains of the coast, and escape the up-country summer hailstorms. A rough estimate gives about 50 acres under Tuberoses in this colony, and the number of bulbs now in the ground nearly 3,000,000.—*R. W. ADLARD, Pieter Maritzburg, Natal.—Gardeners' Chronicle*.

TEA:

THE HOE, HANDWEEDING AND THE FORK.

Early in the year a leading planter from Ceylon paid a visit to Assam, and had a general look round the tea districts there, no doubt for the purpose of "picking up wrinkles." Considering the rapid strides made of late by our island rival in the home market, it is a question whether we may not have something to learn from Ceylon. Situated as Ceylon is, with a large and well distributed rainfall, and with a climate like a forcing house, it is, as has been said, a perfect paradise for leaf crops; and tea is likely to flourish where coffee, as a fruit crop, has failed. The marvellous increase of the tea exports from Ceylon, from practically nil ten years ago to nearly four millions of pounds in 1884-85, points to something more than mere advantages of climate and rainfall; it indicates very rapid extension of tea cultivation, and persevering and successful work. The prices realized by Ceylon teas show that they are by no means behind the best of our tea-houses in their manufacture. It is noted, moreover, that any quantity of land is available for the extension of tea cultivation, fresh-land—or "fee simple" as the Assam planter calls it,—at an upset price of 16 shillings an acre. Assam bids fair to become a formidable rival to Assam. One of the differences between Ceylon and Assam is in cultivation. The Ceylon visitor before alluded to introduced a subject which, in one or two districts, has since become a *questio, resata* among his hosts. He argued that the system of hand-weeding practised in Ceylon was one reason of their success; that the use of the old familiar hoe was very much against the tea bush, cutting its roots, turning over the soil in solid clods and not breaking it up or "fertilizing" it. "Hand-weeding" for a while became a regular bone of contention, to be discussed with more or less acrimony wherever two or three were gathered together. Some few Assamese swallowed the moose whole; others nibbled at it; others again would not look at it. In other words, one or two men went crazy on the subject of hand-weeding; some went in for cautiously trying experiments by not hoeing certain selected patches, but weeding them by hand a goodly number disdain the idea altogether, and stick to the hoe, pure and simple. No doubt handweeding is carried out in Ceylon on a large scale, most successfully. No doubt also it is true, as asserted, that where hoeing is done on hill slopes, the soil is thereby so much disturbed, that it is easily washed away from the roots of the bushes, leaving them exposed; and that it is necessary to carry soil and earth up such bushes again. Furthermore it may be acknowledged that the hoe does cut the laterals and must thereby do harm, more or less. Again, no sane planter, in these days of economy, would deny the advantage of being able to keep his garden clean at a fabulous *sirk* of about half an acre to a *cazira*, instead of hoeing it at 20 or 25 *nals*. Granting all these facts, the question remains,—will hand-weeding suit the soil and *jungle*—not weeds—of an Assam garden? The advantages of deep-hoeing

formerly considered of vital importance, are now very much questioned. Many successful planters have altogether given it up, as entirely unnecessary, if not injurious; but few go so far as to advocate leaving the soil entirely undisturbed, allowing the surface to harden and cake. If, therefore, the consensus of opinion is in favor of the theory that breaking the surface, and turning the soil, to admit some quantum of air and light, is necessary, hand-weeding will not do, evidently. But, argue the advocates of hand-weeding, tea in its natural indigenous state in the forest, has hard, caked, undisturbed soil around it, and thrives. This assertion, to begin with, is open to question. The soil in the forest, from various reasons, is not likely to become so hardened on the surface as in an uncultivated but trodden-over garden. Even if the assertion were true, it is of little weight. The tea tree in the forest has nothing taken out of it, as is garden descendant has. It is neither plucked nor pruned: naturally it thrives under different conditions. Further, is it possible to hand-weed everything that comes up in an Assam garden? Certain classes of jungle, such as what is known as the "cold weather weed," might be successfully coped with by hand. But how about the hands of the coolies deputed to weed out *udu* and *bortani* grasses, which cut like razors? It is to be feared that very little work could be done by hand in that class of jungle. On the whole, while we may have something to learn from Ceylon in other matters, we opine we can leave them their hand-weeding, unenvied and unadopted. As an accessory to forking it may be useful, but nothing further. The fork is apparently the cultivator of the future; indeed, we may say of the present, as it is rapidly superseding the hoe,—to our knowledge in Assam, the Deccan, and Darjeeling; and probably also in Sylhet and Cachar. The fork thoroughly breaks up and exposes the soil to the beneficial light and air. By it the roots of the obstinate *udu** grass are extracted and can be thrown away, while the hoe only cuts the grass near the root, turns that root over undisturbed in its own soil, and leaves it to take an immediate fresh start. The fork cannot cut the laterals of the tea bush, nor need it touch them, if used with anything like care. Indeed, the numerous advantages of the fork over the hoe hardly need to be dwelt on, and we look forward to the time when the hoe will be as obsolete on a tea garden as the pruning shears. Forking, aided perhaps by hand-weeding, is the cultivation of the future.—*Indian Tea Planter's Gazette*.

AGRICULTURE IN THE NORTH-WESTERN PROVINCES OF INDIA.

It is satisfactory to us, who have, since the first publication of the *Asian*, almost always endeavoured to encourage the work of the different Agricultural Departments throughout India, to see from the report of the operations of the Department of Agriculture and Commerce in the North-Western Provinces and Oudh for the year ended the 31st September last, that good work has continued to be done throughout the year. Arboriculture seems to have been well carried on during the year, no less a sum than Rs59,878 having been expended on it, whilst the sales from loppings and fellings of the different trees, as well as from the produce of the trees, realised altogether Rs38,285. In planting trees along the roads the same energy was shown, 1,768 miles having been planted out as against 1,226 miles in the previous year. But the cost was of course increased, amounting to Rs4,951 against Rs1,126. The nurseries at the end of the year amounted to 167, and they contained 286,519 young trees, the cost of their maintenance amounting to Rs7,831. A new invention has been made by Mr. Twigg, the Collector of Hanipur, for watering plants when enclosed within fences, which consists of a long tin tube sheathed with split bamboo carried

on a water cart, one end of which is put through the fence when the water is delivered from an earthen pot furnished with a nozzle fitting into a leather bag which is attached to the outer end of the tube. The agricultural experiments at the different farms do not seem to have been on the whole very successful as the season was very deficient in the rainfall, but this fact we have to bring into prominent notice—the advantage of deep over shallow ploughing, the crops on the deep ploughed ground when only one once ploughed, giving a produce of 18 per cent over those that had been twice ploughed with the ordinary native plough. Our native friends may thus be taught to understand that the first expense of buying a proper plough will soon be repaid, as compared with the work done by native ploughs, in an increased yield. So far as regards the manure question, the old native system of using cowdung was proved to be superior to that of any other system of manuring tried. Some experiments were tried with ensilage, and *juvar* forage was kept in good condition for eight months in simple pits dug in the soil. The cost of the ensilage when taken out and disposed of, showed that 8,000 lb. of this forage had cost only Rs15-14-8 at a time when the same quantity of dried and inferior forage could not be obtained under Rs25. There is nothing particular to notice in the proceedings of the Sabarapur and Lucknow Gardens beyond the fact that at the former Mr. Duthie, after a tour of three months in the Himalayas, brought back a large collection of new plants and seeds, and that the contributions from these gardens to the Amsterdam and Calcutta Exhibitions received three gold and one silver medal. Messrs. Lister & Co. are still extending their operations in sericulture, and have already 200 acres of mulberry planted and 200 additional acres of land cleared for planting, whilst they have in their nurseries a number of seedlings sufficient to plant over 1,000 acres. The company have hitherto felt the want of a sufficient number of rearing sheds, but these are now being rapidly constructed, as the prices realised for cocoons last year were quite high enough to justify them in extending their operations. Although prizes were offered for the best cocoons produced under cottage cultivation, as had been the case in the previous year, there appears to be little hope that the experiment will ever be successful so long as the cultivators are expected to rear worms at their own expense in all their stages. Some experiments were made in no less than seventeen districts with freshly imported American tobacco seed, but the result is said to have been good in only three districts—Pertabghar, Goudah, and Unao—where the plants flourished and yielded a good crop, and the cultivators were so satisfied with the result that they have kept a quantity of seed for future experiment.—*Asian*.

TEA CULTURE: HAND WEEDING.

I observe that the attention of some of our Managers has been drawn to this mode of cultivation, so successfully practised in Ceylon, with the object of having it tried at least experimentally in Assam. The advantages claimed for it by Ceylon planters are, that it costs less than our system and yields better results.

The chief objections urged against it from the Indian planters' standpoint are, first, that the greater abundance and more prolific growth of seed-bearing grasses and other weeds would either render the system impracticable, neutralize the economic advantages claimed for it, secondly, that even if practicable it would be undesirable on the ground of the exclusion in much greater degree of the beneficial influence of light and air to the soil.

With regard to the first objection it would be a great mistake to assume that similar conditions are non-existent in Ceylon with its moist forcing climate. It is their prevalence, in fact, which has led to the adoption of incessant rapid hand-weeding as the only effectual means of keeping the growth of weeds in subjection. The second objection has no doubt

* No doubt the *iluk* of the Singhaiese; *alang-alang* of the Malays. It is the main "jungle" of in any Indian tea districts and is fearfully prevalent in Java.—*En*.

a certain degree of abstract scientific validity, but in dealing with a question of this kind fine-drawn theoretical principles may be safely subordinated to the plain practical consideration—which of the two systems yields the more profitable results. Judged by this test in a comparison of the working of tea estates between the two countries, Ceylon would seem to have decidedly the best of it. Paying quite as much, if not more, for his labour, the Ceylon planter produces his teas at a lower cost per lb., of a quality at least equal to ours, and obtains a higher yield per acre from plant of the same age. If the climate tends to force the growth of tea, it should have the same effect on the growth of weeds, thereby enhancing the cost of production. In natural fertility of soil and surface configuration we should be at least on a footing of equality—a good deal more one would imagine in respect of the large tracts of old coffee land put under tea. We thus arrive at the fairly logical inference that the superiority possessed by Ceylon is derived mainly from its system of culture. Be that as it may, the Ceylon planter has this advantage in the argument, that while we have left his system untried, he has tried ours, and tried it to condemn it as little better than ruinous. It was found a very troublesome and costly process to restore to its former condition the land on which these hoeing experiments had been made, but it was held that there is no alternative between that course and absolute abandonment. This fact points to the most serious impediment to be encountered—though I believe not an insurmountable one—in the application of the system to our old gardens. In new clearances, however, carefully made, with the weed roots eradicated, there appears no valid reason why it should not be found to answer. In the case of a clearance made on grass land on a method tried by me, many years ago, with complete success in the objects than aimed at, it would have the best chance of success. The method is simply to dig or trench the ground to a depth of about 18 inches—starting with a clean cut trench by casting on one side the soil dug out of it, then carefully putting at the bottom of each successive trench first the grass roots, then the surface soil, and finally the sub-soil thoroughly pulverised at the time of digging. While the tea plant will readily establish itself and grow freely in such ground, finding nourishment for its tap root in the underlying surface soil and decaying grass roots, the subsoil now on the surface is so inimical to ordinary vegetation that no weeds will take root in it for many months after breaking up. Land treated in this manner will also be found to retain moisture in a much higher degree in dry weather, and to part with it more freely when in excess, especially where there is a stiff bottom—often a hard pan till thus broken up. This system would be inapplicable to ordinary forest land, nor could it be carried out in its entirety where a large extension on grass land had to be made in any one year. That it would be more costly than the ordinary method is obvious, but the extra cost would be largely recouped by the saving in cultivation in the first year, whilst the gain to be derived from the plant being established under conditions ensuring the minimum of vacancies and the maximum of healthy development, is not easily estimated. I may add that after the people got used to the work a three far nirk was got without difficulty. In the experiments made by me, the land was prepared early and the seed sown at stake with the least possible delay. This might not always be found practicable and safe, and where transplanting had to be resorted to, care would have to be taken in digging the holes to return the soil in the order I have described, so as to always have a pore subsoil on the surface.

While advocating this system of clearance of grass lands on its merits, one, and not the least of my objects in bringing it so prominently in view is my belief that it furnishes the key, so to say, to the introduction of "hand weeding" in our old gardens.

To attempt this before eradicating or destroying the tangled mass of weed-roots now in full possession of the soil of old gardens would be simply to court failure, and this object will be more effectually attained, I believe, by following in its main lines the plan I have described, than by any other. Precautions would have to be taken to preserve as far as possible the chief lateral roots of the plants from injury, but I think we may safely reckon that any partial damage in this way will be fully compensated for by the thorough breaking up of the soil and destruction of weeds, even if not followed up by hand weeding.

To those who may doubt the efficacy of this plan in destroying the vitality of grass roots by burying them at the depth indicated, an alternative procedure is open to them by digging to about the same depth, and carefully separating, collecting, and removing all weed roots. As an illustration of the beneficial effects of this mode of treatment, I can point to an experiment made on a patch of old tea purchased from Monyram Dewan more than 20 years ago, and which formed the nucleus of the Ginna-mara garden.

This piece of tea was in a sadly neglected condition, and with at least 25 per cent of blanks, but its response in the first year to this thorough treatment and malgré considerable apparent damage done to lateral roots, was a return of nearly 800 lb. of dry tea to the acre, followed by nearly 700 in the second year under ordinary treatment. Hand weeding was unthought of in those days, but it would have been an excellent opportunity for trying it, though I am inclined to think the first method described would be fully as effective and perhaps cost less. However, this is a point which can only be determined by practical experiments carefully conducted, and my primary object in throwing these observations together is the hope that some—a good many I trust—the managers of Indian Tea Gardens may be induced to make such experiments as may help to solve the problem of whether, and how far, the Ceylon system can be advantageously introduced on Indian Estates. The process must be a gradual one under any circumstances, but that is all the greater reason why no time should be lost in making a beginning.—G. WILLIAMSON.—*Indian Tea Gazette*.

TEA IN S. WYNAAD.—There is a prospect of considerable Tea extension taking place here, as Coffee prices are becoming most discouraging, and it is seen that tea is daily pressing closer and closer on the heels of Coffee.—*Indian Tea Gazette*.

CEYLON TEA SOLD IN ENGLAND.—A gentleman who was at home last year calls our attention to the quality of the teas being sold under the name of "Ceylon" to consumers in England in some cases by those who profess to have our best interests at heart. He has sent us a sample of the "Cobra Brand" tea sold at 2/8 per lb., which was taken from a packet in a grocer's shop in Devonshire, and adds:—"Though I am scarcely competent myself to give an opinion, it seems to me poor stuff and not worth the price asked, and several tea-planters to whom I have shown it concur in this view. I have heard several complaints in England of the quality of this 'Cobra Brand' which, however, is now very largely sold both in England and Scotland." The sample is certainly decidedly inferior, and is probably a "blend," while, we suppose, 2s 8d ought to secure a really good Ceylon tea. From an independent authority we learn that the tea is rubbishy: half of it broken red leaf and altogether not equal to Pekoe Fannings. This is certainly the way to damage Ceylon interests, by selling such tea as good average Ceylon at 2s 8d per lb.

WATERING VEGETABLES.—Peas pay for watering as much as any crop. When dry at the root they never fill the pods well, and the peas become hard, dry, and flavourless before they have ever attained perfection. The plan of growing summer Peas in trenches is a capital one. The soil must be loosened well down before the trench can be made, and when watering has to be done it is a simple matter to fill the trench with it. It has no means of running away and not reaching the roots, which is often the case on the level. Kidney Beans of all sorts should be thoroughly watered in dry weather. Cauliflowers should never be allowed to droop their leaves for want of it. Lettuces will take any quantity if they are to be cut large and crisp. Ridge Cucumbers, Vegetable Marrows, and Tomatoes enjoy abundance of water, and generally speaking dryness at the roots is a great drawback to all kitchen garden produce. Some plants may be small and far from maturing their crops, and by this it may be thought they do not require water, or that the absence of it will do them no harm at such an early stage of their growth, but this idea is wrong. If the plants are insufficiently supplied with moisture when young many of the roots will perish, they will become stunted, and no amount of after watering will bring back their usual or former vigour. Water should be applied to maintain their full strength, not to renew it after a great loss has occurred. Of liquid manure for vegetables we cannot speak too highly, and dissolved, artificial manures, as well as drainings from all kinds of manure heaps, may be used copiously. Spreading on the manure around the plants or along the sides of the rows, and then watering on the top of it to wash the fertilising properties down to the roots, is a practice which cannot be too strongly recommended.—A KITCHEN GARDENER.—*Journal of Horticulture.*

COIR FIBRE DUST.—As an Agriculturist, I cannot understand the position Mr. Symons, the Managing Director of the Horrekolly Company, has taken up as to the uselessness of fibre dust for application to the coconut tree. When analysed it may not have yielded encouraging results, but it has an intrinsic value as an application to the tree that yields or produces it. It has been publicly stated on the authority of Mr. Symons that owing to the moisture in it, it cannot be burnt, and that occasionally it is ploughed into the ground to keep it moist. No better testimony could be given as to its great value as an application to a dry, sandy soil, than its moisture-absorbing or moisture-retaining properties. The coconut palm luxuriates and revels in moisture, not stagnant; and any substance that gives body to a sandy, light soil and arrests the too rapid evaporation of moisture, ought to be readily availed of as an application to the tree, or to be ploughed into the ground. It is an admitted fact that moisture is a necessity for the absorption of manure by the roots of a tree; and if, as I believe, artificial manures are used on Horrekolly, fibre dust might advantageously be used as a "vehicle" for its application. All this apart from the manurial value the product of a tree bears to it. In the last *Tropical Agriculturist* I find Professor Caldwell says:—"That the most evident distinction between stable manure and commercial fertilisers * * * is its large proportion of vegetable matter (the italics are mine) or humus-forming material." So that a moisture loving product like fibre-dust can profitably be utilized as an absorbent of the ammonia to be had in a cattle-shed. Again: "That humus, through its decay in the soil, furnishes carbonic acid among other solvent agents; and this carbonic acid plays an important part, by bringing the native insoluble stock of plant food within easy reach." "That soluble plant food, added to the soil in commercial fertilisers, needs the help of humus, finally, for its solution." "That plant food in most animal and vegetable residues used as manures, costs much less than commercial manures." How pertinent all this is to the discussion recently raised in the columns of the *Observer*, as to the value of fibre-dust as an application to the coconut tree! It is to be hoped

that the directors and shareholders of the Horrekolly Company will see that not a lb. of the fibre dust will go to waste, but will be profitably applied to an estate where application and means of carriage are ridiculously easy. Perhaps this discussion will open their eyes to the, I thought, exploded belief, that one who controls the finances of an estate, is *per se* capable of directing its cultivation. If a practical planter, say Mr. W. Jardine, who is now in the neighbourhood, and who received his first lessons in coconut cultivation on Horrekolly be appointed to visit this estate, the shareholders will be gainers without doubt.—"Examiner."

APHIDE ON TEA LEAVES are thus noticed in the proceedings of the A. and Horticultural Society of India:—From Messrs. George Henderson & Co., forwarding an extract of a letter from Mr. Troup, of the Mollakattoor Tea Estate, Kumaon, with specimen of the affected leaves alluded to, asking for a report. As other planters may have been troubled with similar experience, Mr. Troup's description, with the report kindly furnished by Mr. Wood-Mason, are both given in full:—Extract from a letter, dated the 7th June 1885, from Norman F. T. Troup, Esq., of the Mollakattoor Tea Estate, Luckington, Baijnath, Kumaon. "By this day's post I am sending you a few sprigs of a Tea bush that presents a most curious appearance, and should feel very much obliged if you would kindly get some of your friends learned in such matters to explain what is amiss with them. The leaves of the bushes that are thus affected present a varnished appearance, and are coated with some sticky substance like honey which is also as sweet as honey, and the young shoots are covered with a small winged brown fly like the green fly that attacks some kinds of flowers in greenhouses. There are also some small six-legged insects like bugs on these bushes, of a slatish black colour dotted with white. I at first thought that these insects were accountable for both the brown fly and sticky substance on the leaves, but so far as observation has enabled me to ascertain they only prey on these flies. I observed the same sticky substance on the bushes during the winter, but then concluded it to be an abnormal supply of honey in the flowers, as at that time it was dripping out of them, but now there are no flowers for it to come from. This fly, other insect, and the stickiness do not seem to affect the health of the bushes, as those they are on, look as vigorous, and are flushing as freely as those free from them. Up to date, we in this district, have entirely free from all Tea pests, and hence my curiosity and ignorance regarding this one, if it is a 'pest.'"
Mr. Wood-Mason's report:—"The sweet and sticky substance on these leaves is no doubt 'honey-dew,' mixed with exuded sap. Many leaf-lice (*Aphide*) are provided on the dorsal surface of the ante-penultimate abdominal segment, with a pair of tubular prominences, the so-called 'honey-tubes,' each of which bears at its extremity a minute pore. From these pores there continually exudes a sweet fluid, secreted by special glands, and eagerly sought after by ant the so-called 'honey-dew,' which is frequently deposited upon the leaves frequented by the lice, there becoming mixed with the sap that exudes from the punctures made by these insects with the four stiletts of their sucking mouth in feeding. Hundreds of the lice [the 'brown bugs,' of your correspondent are females and young, and the 'brown flies' are males] are glued to the different parts of the sprig of tea-plant, as also are numbers of the fluffy white cast skins of larvae which are popularly termed 'Mildew,' though they have nothing whatever to do therewith. The matter is of no practical importance whatever."

DESTRUCTION OF RATS [AND GRUBS] WITHOUT INJURING TREES.

TO THE EDITOR OF THE "INDIAN AGRICULTURIST."
 Sir,—In a recent issue of the *Indian Daily News*, "A Florist" asks to know "how to get rid of rats without injuring the tree."

In reply, I would inform him, through the medium of your journal, of the method which my late father, Baboo Poran Chundra Dutta, the then principal flower merchant in British India, adopted successfully. He found in his Doltadanga and Soorah plantations in 1870 that rats did considerable damage to the young Australian and country seedlings; but he succeeded in keeping them off from plants by simply putting round the root one or two pods of the cowbage (*Mucuna pruriens*.) The cowbage is a pod covered with stiff bristles, which, should they touch the hand or skin, cause violent itching. The pod is generally known to Europeans in this country by the name of *cow-itch*, which is, I believe, a corruption of its proper name.

For worms, &c., my father found the following a very effectual remedy:—He took equal parts of fine, well ground *chunam* and salt, and mixing them well together, used to sprinkle the mixture on the ground round the roots of the plants. Having done this, he used to water the plants immediately, which caused the powder to sink into the ground, and killed the worms. This was done in all his Belgachia plantations, where he kept country seedlings. The worms used to eat the roots, but this remedy stopped their ravages at once. This may also prove effectual in the case of white-ants.

If "A Florist" wishes to know more about mauluring, I shall be glad to furnish him with further information.—HEM CHUNDRRA DUTTA, Rughoo Nath Chatterjee's Street, Malakar's Cottage.

PREPARING INSECTICIDES.

We take the following brief directions for mixing various insecticides from a recent pamphlet of the U. S. Bureau of Entomology:

LONDON PURPLE.—To 20 lb. flour from $\frac{1}{4}$ to $\frac{1}{2}$ lb. is added and well mixed. This is applied by a sifter or blower. With 40 gals. water $\frac{1}{4}$ to $\frac{1}{2}$ lb. is mixed for spraying.

PARIS GREEN.—With 20 lb. flour from $\frac{1}{4}$ to 1 lb. is mixed and applied by sifting or by a blower. The same amount of the insecticide to 40 gals. water is used as a spray.

BISULPHIDE OF CARBON.—For use in the ground a quantity is poured or injected among roots that are being injured. Against insects damaging stored grain or museum material a small quantity is used in an air-tight vessel.

CARBOLIC ACID.—A solution of one part in 100 of water is used against parasites on domestic animals and in their barns and sheds; also on the surfaces of plants and among roots in the ground.

HELLEBORE.—The powder is sifted on alone or mixed 1 part to 20 of flour. With 1 gal. of water $\frac{1}{2}$ lb. is mixed for spraying.

KEROSENE.—*Milk Emulsion*: To 1 part milk add 2 parts kerosene, and churn by force pump or other agitator. The butter-like emulsion is diluted *ad libitum* with water. [An easier method is to simply mix 1 part kerosene with 8 of milk.—Ed.]—*Soap Emulsion*: In 1 gal. hot water $\frac{1}{2}$ lb. whale oil soap is dissolved. This instead of milk is mixed to an emulsion with kerosene in the same manner and proportions as above.

PYRETHRUM. PERSIAN INSECT POWDER.—Is blown or sifted on dry; also applied in water, 1 gal. to a table-spoonful of the powder, well stirred and then sprayed.

TOBACCO DECOCTION.—This is made as strong as possible as a wash or spray to kill insect pests on animals and plants.—*North-Western Farmer and Dairyman*.

PREPARATION OF FIBRE.

It is interesting to know that the subject of our fibre industries is making considerable progress, and that the machinery now available is likely to work a revolution in this sphere of enterprise before long. Two chief obstacles seemed to stand in the way of any extensive utilisation of the Indian fibrous materials, namely:—(1) the want of a proper knowledge of the materials and of the means of their extraction; (2) the high rate of railway freight for the materials. Since the date of the Calcutta trials Mr. Death (the representative of the London Fibre Company, who have an interest in the machine) has been successful in bringing the matter under the notice of various firms and land-owners throughout India. To show what is being done, it may be mentioned that in one jute entre in Bengal twenty acres of land under jute will be set aside this year by some of the jute agents who are stationed there, for the purpose of a grand experiment. Half the produce of this land is to be tested by one of Death & Ellwood's machines, and the other half, by way of comparison, is to be extracted by the common native system of steeping. If the results obtained by the use of the machine are profitable, the following year will probably bring about an important change in the jute industry. Again, the machine was also tried with pine apple fibre and produced very good results. In a certain district in Bengal where the pine apple grows luxuriantly producing leaves from five to six feet long, the jute agent have made a plantation of 2,000 plants, and are about to try the machine commercially.

As to the second obstacle to the development of the fibre industries—the high railway freight for fibrous materials destined for paper-makers. The reduction in the railway freight was scarcely effected when the Lucknow and the Gwalior mills began to use this grass, as well as *munj*, which was also brought into commercial use by the change of rates. The Baley Mills used in 1883 (the first year of the reduction of the railway freight) 2,500 mannds of *babui*. That was a considerable quantity for the first year, and in the following year, 1884-85, the quantity used rose to 15,500 mannds. But there can be no doubt that *babui* will yet be used to a vastly greater extent than at present; indeed, the use of the grass may be said to have only been begun. As there seems to be some confusion on the subject, it may be well to state that the correct botanical name of this highly important grass is *Pooleia criopoda*. It grows over large tracts of country, and its extended use as a paper fibre ought to be a powerful stimulus to our paper-making industry. In Europe this branch of industry is threatened with serious loss, owing to the exhaustion of the supplies of esparto, and already the English paper-makers are beginning to turn to India in search of a substitute, but if the manufacture from the new fibres takes root on the spot, as there is every reason to expect, we may yet see a considerable portion of the trade transferred to this country.—*Englishman*.

ARBORICULTURAL EXPERIMENTS.

CASUARINA, DIVI-DIVI, AND EUCALYPTUS.

In the latest published report of the Agricultural Department a few interesting particulars are given of the experimental cultivation of casuarina, divi-divi, eucalyptus, and other productive trees. Although casuarina is known to be a hardy tree and grows on sterile soil, experiments continue to be made at the Sydapet farm, and the worst portions of it have been planted out with good results. Between eleven and twelve acres have been utilised and with little outlay, a hardy and valuable fuel producing plant is grown. In the newly formed plantations at Sydapet, guinea grass was successfully grown under shade, and it has been ascertained that the presence of grass is not only advantageous to the trees, but that it helps to improve the land and places a large supply of fodder at the disposal of the cultivator. On a plot

of 10½ acres of casuarina 40,236 lb. of fodder was obtained, and a second crop was ready to be cut. This will be welcome information to owners of plantations, especially in places not far from Madras, where expensive plots of land have been acquired and plantations are thriving. Guinea grass may not be a very remunerative fodder to grow, but with a large demand always for the fodder and with municipalities utilising every spare plot of ground for the growth of grass, there should be no difficulty in owners of casuarina plantations adopting the plan successfully introduced at the Government farm. Casuarina plantations were, a few years ago, all the rage among small capitalists, and in the Madras and Chingleput districts, some thousands of acres were taken up and planted under the darkest rules. Those who embarked in the venture with care and economy are reaping the fruits thereof. Casuarina is largely availed of for fuel purposes, and efforts still continue to be made in the formation of small plantations. As saad binding plants they have proved to be very useful, and that is one reason why almost over the whole coast line from Madras to Nellore, northwards, and as far as Oudaloro southwards, the cultivation of casuarina continues to receive attention. The trees at Sydapet are planted at the rate of 1,800 per acre, and the irrigation charges are returned at Rs8 per acre. The total expenditure per acre for establishing a casuarina plantation with guinea grass between the lines, is not more than Rs50.

A little time ago particular attention was given to the growth of *divi-divi*, a most useful plant, the fruit of which is extensively used for tanning purposes. The pods were said to possess many useful properties, and for a time large shipments of *divi-divi*, collected in the jungles not far from Madras, were made to England. The price of the seed was quoted at Rs12 per oz., and owners of private gardens paid particular attention to the cultivation of the tree and small plantations were formed in the outskirts of Madras. But the demand seems, for the present, to have ceased and we hardly hear of further experiments in this direction. At Sydapet three acres of land were planted with *divi-divi* and about 521 plants reared. An attempt made in this direction in 1879 produced a supply of 75 lb. of pods, and 22 lb. gave 2 lb. of seed. No particulars are given in the report of the marketable value of the pod, of the efforts made to extend the cultivation of *divi-divi*, or if any distribution of the seed took place. From the fact that at one time the pods were in great request and their usefulness for tanning proved, further experiments at Sydapet or under the auspices of the Agricultural Department, might have a good effect on the cultivation of this useful tree.

The cultivation of coconuts has also been undertaken in the farm, and a small plantation of eighty-five trees is maintained. Coconuts can, with little trouble, be grown on salish soil; the attempt made in the farm has proved successful. It has been planted alternately with casuarina, and the actual cost of laying out the field was Rs12 an acre. Some years ago the cultivation of the coconut was more extensively carried on than at present, and, according to some authorities this useful tree is not so productive as it once was: large gardens and topos were planted in connection with chaitrans, churches and other charitable institutions. This is more especially the case in all the Southern districts of the presidency—attached to every work of charity is a coconut tope the produce of which goes a great way to support it. Every part of the coconut tree, like the palmyra, is useful; the fruit, the fibre, the leaves are marketable, and though the oil of the coconut is not extensively used for domestic purposes at the present time, still we think that the formation of plantations should be encouraged. Small native capitalists preferred, up to a few years ago, to invest their surplus cash in coconut plantations. The returns from these investments were not large; people were then satisfied with small returns on outlay. But what satisfied them then is now insufficient. More remunerative speculations are sought after and a steady and sure source of income is being gradually neglected.—*Madras Standard*.

TOBACCO CULTURE:

SELECTION OF GROUND AND PLANTING OF TOBACCO.

The following advice as to selection of ground and planting tobacco is given by the same gentlemen to whom last week's article on plant beds and seeding was credited—Capt. R. B. Davis, of Hickory, N. C.—and will be found to contain much that will be of benefit both to the beginner and the experienced planter.

Selection and Preparation of the Soil.—As soft, deep, sandy soil is preferable, which before planting should be always put in the finest tilth, it being an adage with good farmers that a "crop properly planted is half worked." If the land is new ground, it should, after having been grubbed and chopped, be raked cleanly, and all leaves and litter burnt. It is then ready for the plow, and should be closely broken twice and cross-wise with the bull tongue, and as often harrowed. It should next be marked off by the bull-tongue in horizontal rows three feet apart, into which should be drilled three hundred pounds per acre, unless where the land is naturally rich, of a good and active fertilizer. It is then ready to be listed or bedded with a turning plow. I prefer the list, since it lightens the hoe work for hilling, and is at the same time a more economical use of the fertilizer—the balks between can be thrown out at the first weeding. With a broad weeding hoe these lists or beds should now be worked into conical hills, placing them three feet and three inches apart. I know that many recommend more crowded planting, giving the rows and hills a distance of only three feet. But in doing so nothing in my opinion is gained in weight, while something is lost in length, breadth and body of the leaf, which, with the manufacturer, are prime requisites. The hills can be laid off with great accuracy by stepping or otherwise measuring one row, and then placing the hills of the next between those of the first, and so on, or what is called dodging them. To prevent crowding or irregularity in hilling, this rule will be found of use where raw hands are employed. The hill culture, both in the preparations and the subsequent workings of the tobacco crop, should never be departed from, for the reason that that method of cultivation gives the land the best drainage of which it is capable. And in this crop drainage is one of the first things to be considered, for the reason that all the diseases to which the plant is liable—such as freching, firing, spotting, rusting and shedding—come from excessive rain, accompanied by excessive heat. The growth of the plant itself would suggest as much, for in time of drouth the leaves stand up to gather the rain, but so soon as it has enough of it they turn down and throw it off. I repeat, then, let no water stagnate upon the ground. For new ground the hilling can be done as early as April or May, and should be always when the soil is in good working order and neither too wet nor dry. In the one case it will bake and prevent the ready growth of the plant, and in the other it will require much rain to put it in the condition for planting. If the land is not new ground, either forest or pine field, it should be fresh, or at least long rested and in good heart, and upon which neither corn nor sorghum has been lately cropped. For such land the preparation is in all respects similar to that for new ground, except that a turning plow may take the place of the bull-tongue, and the hilling should not be done earlier than the first of May for fear that the hills may become grassy while waiting for plants or a season to plant them. To preserve such lands and to prevent damages to the growing crops from washing rains, water furrowing or gutting is recommended.

Fertilizers.—Tobacco land, more than almost any other, should be manured with a liberal hand. Stable or barn yard manure is every way the best, but when not to be had in sufficient quantity, must be substituted by some good commercial fertilizer, of which there are countless varieties upon the market possessing more or less merit.

Planting.—The tobacco plant requires usually one hundred days from the time it is transplanted to grow and ripen properly. To secure the best results, therefore, the planting should not be earlier than the 10th of May, and if possible no later than the 20th of June.

In the one case the plant is likely to be stunted in its early growth, as well as deprived of the dews of August and September, and in the other there is danger that it may not have time to mature fully before the frost. The plants are set very much as cabbage are, by inserting them to the bud and pressing the earth well to their roots and stems with a peg. A plant is said to be properly planted when the point of a leaf breaks off in the attempt to pull it up. The plant should never be suffered to wilt before they are set. If this cannot be done as fast as they are drawn from the bed, as many as can be planted in a single day should be drawn while the dew is on them, and kept until needed in a shaded place, with their roots on damp ground, their tops being occasionally sprinkled with water. If the hills have been put up with a good season in them, they can ordinarily at any time in May be planted without a rain, if done late in the afternoon. They should also be clapped with the back of the hoe, which clapping preserves the moisture and prevents crumbling of the earth after the planting peg, and should be lighter or harder, according to the dampness of the soil. But, with the abundance of plants, should the planter be blessed with a good season in May or June, ought else but planting is then to be thought of. It is a maxim with hay-makers that they should work while the sun shines. The reverse of this holds good with the tobacco planter, and he promises to be but a poor one who runs from a shower of rain. And yet for the convenience of housing it is not desirable that the entire crop should ripen at the same time; therefore it is not best that it should all be planted in a single day, or even in a single season. Instead, then, of hastening to get once over, it is better to look well to the replanting, in order to get a perfect stand in the portion which has been planted—to do so and as quickly as possible, shading or watering the replanted hills, when necessary, is recommended.—*Industrial South.*

ORCHARD INSECTICIDES.

(Written for the *American Cultivator*, by L. H. Bailey, Jr.)

The increasing numbers of insects, which are each year causing the production of crops to be more laborious and expensive, must be met with determination and by effective insecticides on the part of the farmer. The number of these insecticides which can be used to advantage in the orchard are numerous, and are each year increasing. Some of the best thought of our scientists is turned in the direction of economic entomology. The habits of many of our orchard insects are not yet perfectly known, and there is abundant opportunity for new and effective insecticides to be discovered or invented. Measures for lessening insect attacks may be divided into two classes—preventives and remedies. The preventives which are of most general use in the orchard are as follows:—

1. Good culture and tidiness. Good cultivation is the first and most rigorous demand made upon the orchardist for the prevention of insect ravages, as well as for inducing thrift in his trees. Tidiness in the prompt removal of all rubbish and litter, and clean cultivation, are direct and important preventives of insect depredations. It is almost useless to fight the codling moth, curculio, flat-headed borer, bark louse and numerous other insects in a slovenly orchard. Weak trees are special favorites of certain insects, especially the flat-headed borer and the bark louse. The frequent turning and stirring of the ground destroys the hiding places of insects, and exposes the larvae to birds and weather. The same turning and stirring are the means of adding fresh vigor to the trees, enabling them to withstand the attacks of insects. A continuous cropping of high grass is nearly always highly detrimental to an orchard, especially on poor land. The casual observer can easily demonstrate to himself the greater average abundance of insects in long-sodded orchards than in those which are always cultivated.

2. Washing the trunks and main branches of trees with soap and water and carbolic acid, as a preventive of egg-laying by borers and other insects. The carbolic soap wash, made by balling together one quart of soft soap and two gallons of water, and adding a pint of crude carbolic acid while the mixture is still hot, is probably the best wash to be had. The odor of the carbolic acid remains for a long time and it is very disagreeable to insects. A good wash is also made by adding to the above mixture a little sulphur. Washes for trees are chiefly of benefit in preventing the attacks of insects, or in destroying the eggs, or in killing such insects as bark lice, aphides, etc. The soap wash is all that is necessary for this purpose. I have never been able to ascertain any better results from whitewashing than from soapwashing trees, although I have seen it tried very often. There are good reasons for supposing that some injury results from whitewashing. It is certainly unsightly. Washing trees may be either a preventive or a remedy, although it is commonly used in the former capacity.

3. Encircling trees with freshly tarred cloth or some similar preparation to prevent the ascension of the canker worm and other insects.

4. Planting shrubs which will attract insects from fruit trees, and from which they may be easily captured. It has been found that some of the wild and cultivated spiræas attract the rose chaffer from grape vines and fruit trees.

5. Using odorants which will repel the insects. This might be included under No. 2. Ammonia diluted and syringed through the tops of trees will repel the codling moth. Putrid whale oil showered upon plum trees is said to protect from the curculio.

6. Protecting and encouraging insectivorous birds. Among remedies the following are the most general in their nature and the most important in their results:—

1. Syringing with Paris green and water. A scant tablespoonful of the poison, in four gallons of water is a common mixture for fruit trees. Some prefer a stronger mixture. The quality of the commercial drug is so variable that the positive proportions cannot be given. An ordinary syringe, which can be made by a tinsmith, is all that is commonly required. This syringe is filled with the poisonous water by drawing back the piston while the nozzle is immersed, and then by a steady push the liquid may be thrown over the highest tree. A nozzle with one circular opening throws the liquid in one unbroken stream, causing a great loss, while a broad nozzle with many minute holes does not allow the liquid to pass out with sufficient force to pass over a tree. The best cheap syringe which I have ever used was about 2½ feet long, with a barrel three inches in diameter, the upper end being made of copper and punctured with numerous holes an eighth of an inch in diameter. Some of the numerous fountain pumps which are now manufactured are much superior to the syringe. They throw a continuous stream with little effort. For throwing liquid over large orchard trees, Prof. Lintner finds a flat nozzle the best. This spreads the liquid, causing it to strike a large part of the tree at one time. Paris green is insoluble in water, and the liquid containing it must be often stirred to keep the particles in suspension. Paris green can be used to destroy nearly all leaf-eating insects which work upon the tree before the fruit is half ripe. It is the most effective of all remedies against the canker worm. It is also a good remedy for the first brood of the codling moth larvae or apple worms. When the apples are first formed they stand upright on their stems. The moth lays her eggs on the upper or "blow end" of the little apple. Paris green which is syringed over the trees lodges in this "blow end" and destroys the larvae when they begin to feed. Later the apples turn downwards and the rains wash away the poison. London purple is cheaper than Paris green, and is to be used in much the same manner.

2. Kerosene oil is attracting much attention as an insecticide. It is a deadly poison to nearly all insects while it is harmless to man. As it does

not mix with water, an emulsion should be made with milk. An emulsion composed of one-third oil and two-thirds milk, either sweet or sour, is found to be most serviceable. This emulsion may be applied in the same manner as Paris green.

3. Jarring off certain insects on to sheets spread upon the ground. This is the best method of destroying the plum and peach curculio, and it is effective in other cases.

4. Providing places where insects may hide. Tying bands of woollen cloth or felt paper about tree trunks is a means of catching the larvæ of the codling moth. The Ransom method of catching curculios provides pieces of bark or blocks about the base of the tree where the insects congregate at night. When we know more fully the habits of insect enemies, this principle may be greatly extended.

5. Applying the soap wash for the purpose of killing bark lice, scale insects, etc. The scale insects may be destroyed by a soap solution, which is injected on to the branches by means of a syringe.

6. Gathering by hand, as in the case of taint caterpillars, Fall web-worms, etc.

7. Killing borers with a twig or a wire, or cutting them out with a knife.

8. Burning infested twigs, as in the case of the twig borer, twig pruner, etc.

9. Attracting night-flying insects to fires or strong lights in the orchard.

According to Prof. Lintner, there are 176 different kinds of insects known to attack the apple tree in the United States. The greater number of these insects make the apple tree only an occasional food plant, however, but altered conditions made by cultivation may at any time cause any of them to attack the orchard. It is, therefore, highly necessary that the orchardist keeps in mind the leading preventives and remedies for insect depredations.—*American Cultivator*.

NEW GUINEA AS A FIELD FOR SUGAR AND COFFEE PLANTING.

The question of tropical agriculture in Queensland has of late years assumed such vital importance that any information concerning the neighboring island of New Guinea cannot fail to be of interest of everyone connected with sugar or coffee cultivation. The following remarks on the land laws under which the Papuans enjoy their holdings, their system of tillage, the nature of the soil and of the crops it produces, may prove interesting to your readers as well as to the sugar planter.

At Port Moresby all land is strictly private property, but the owner enjoys a life interest, and cannot sell in perpetuity. At his death it is divided equally among his children, or, failing issue, his nearest relatives profit by its distribution. This system has one great disadvantage in that its constant tendency is to cut up the land into infinitesimal patches; thus, for example, a man may hold twenty acres, but these will be cut up into perhaps fifty different lots, situated in as many separate localities. The difficulty of purchasing land under such conditions becomes self-evident, as a bargain has to be concluded for each plot, and the purchaser may be dispossessed at any moment by the demise of the seller. At Kahadi, a district seventy miles west of Port Moresby, the whole area is held by the head chief, and the tribe cultivate such portions as he may point out. His right is undoubted, and no one can burn grass or commence planting until his permission has been obtained. Here the purchase of land would not be attended with any very serious difficulties, but it would be necessary to renew the bargain with every successive chief. The inland tribes—Omae, Sogore, Mook, Havor, Favere, Dajour, and Sarsmins—seem to observe the same or very nearly the same laws as the Motu or Po-t Moresby tribe. Here, I believe, land will be procurable in time, as the people possess more than they require, and are anxious to see Europeans settled in their midst. This is accounted for by the fact

that, being constantly engaged in inter-tribal wars, they would enjoy an immunity from attack as long as the white man and his rifle remained among them. The system of cultivation in vogue throughout New Guinea is necessarily a primitive and faulty one; yet the fertility of the soil is so great that these people often produce tenfold more than they require, and are thus enabled to dispose of the surplus to less fortunate tribes on the coast. Whenever it has been decided to form a plantation, the people set about finding a suitable piece of land. This, as a rule, is situated on the steep slopes of some mountain side or on the crest of a leading spur. The jungle is cleared off and burnt, and land having been fenced in, preparations are made to break up the soil. This is no very difficult operation as practised by the Papuans. A number of men fall into line, and each being armed with a heavy stake or lever, they commence chanting some monotonous words; at proper intervals they raise their levers and drive them into the soil, breaking out a spit twelve inches wide. The boys and women pass over this roughly turned up soil and break it up with hoes and smaller stakes. This done, the plants are put in, and the whole operation is concluded by going through an incantation to Vata, as their evil spirit is called. A peculiarity of this system is worthy of record: it has taught the people the value and importance of co-operation. Thus they willingly assist each other in any undertaking requiring much labour, and this is done without payment. The crops grown are sugar cane—four varieties—the best being a rather light green one streaked with yellow. This I have seen six feet long after topping, and it grows admirably at an elevation of 2,500 feet above sea level. A purple cane also seems to do well, but of course faulty cultivation affects the joints, which are generally too short. I have often been obliged to wash the stickiness from my hands and beard after eating a few joints. I presume such cane must be good, and would strongly recommend its introduction into the Queensland cane fields. Bread fruit (*artocarpus incisa*) abounds everywhere in its indigenous state, but it is largely cultivated in the plantations. Taro (*colocasia sp.*), is largely cultivated, three distinct species being used. One of these has long leaves 6 ft. 20 in. wide. Yams of several species are cultivated everywhere, and form the staple food of the people. Immense quantities are housed and kept for winter use. In the Kahadi district a sweet yam is very largely cultivated and exported to Port Moresby, but it is very fibrous and its sweetness detracts from it as a vegetable. Bananas of several species flourish and yield large returns. One species I noticed had fruit 1½ long, very plump, and a bright golden yellow when ripe. This is a delicious little fruit, and well deserving cultivation in all tropical gardens. The bunches of fruit are carefully swathed in dead banana leaves, to the entire exclusion of light. This etiolates the fruit and ensures the production of the greatest possible amount of starch. Sugar, the Papuan does not seem to care for; starch, being more nourishing, is held in greater estimation, and the banana has consequently been degraded to the status of a vegetable. Tobacco is grown in every village, and I believe it is our common species (*nicotina tabacum*). The natives pluck a few leaves, dry them over the coals, and incontinently use them. Turmeric I found cultivated on the Kahadi country, where it is used for dyeing purposes. Ginger grows wild everywhere and is highly prized by the Otaisi. Coconuts thrive on the littoral. Betel nut (*areca ostechu*) is cultivated on the littoral and grows wild on the inland ranges. The natives of the latter clear the jungle from these, and gather prodigious quantities of the fruit. Pepper is grown in all the villages of Kaosili, and is used for chewing with betel. Nutmeg, as might have been expected, thrives in the warm and moist coast country of Kahadi. I here saw a large village surrounded with a belt of nutmeg trees, 80 ft. high, and loaded with fruit, but the Kahadians do not use it for any purpose that I could discover. Sago is manufactured from the sago-palm

on the south-west coast, and notably in the districts of Elema and Motu-Motu, whence it is exported in large quantities to Kabadi and Port Moresby and the districts on the south-east coast. This palm grows best on the swampy lands that border the coast line in the districts of Elema and Motu-Motu between Cape Possession and the Fly river. The above list comprehends all the plants I noticed as being cultivated, the outcrop being the only exception it affords. The country in the vicinity of Port Moresby is hilly, and owing to the dryness of the coast line, little adapted for agriculture.

But the immense area on the lower and upper Lubliki River is eminently adapted for scientific tillage on an extended scale. The river rises in the volcanic formation of the Astrolabe Range, and has for ages past been bringing down the rich volcanic and vegetable moulds of the jungle-covered mountains, and depositing them on the flat country which borders the river along nearly the whole extent of its lower course. These plains and open forest patches are admirably suited to the growth of sugar-cane, nutmeg, rice, in the swamps, tobacco, and a variety of tropical fruits of every description. The clove and cinnamon will thrive here in years to come, and assist in swelling the list of valuable products that must figure among the New Guinea exports.

Scaling the heights of the Astrolabe I found the whole country composed of a rich chocolate soil suited to sugar-cane, coffee, cinchona, cocoa. All these will amply repay capitalists who may invest their money in land in this portion of the island. Cotton I found growing luxuriantly in the village gardens throughout the upper valley. There is a constant, and I think reliable, rainfall which leaves nothing to be desired in this respect. The soil is everywhere of considerable depth, even on the open forest ridges, and can be easily tilled. By far the greater portion is covered with jungle, in which fine oak and other useful trees abound. Maize and arrowroot would, I am positive, yield prodigious crops anywhere on these rich alluvial lands, and their introduction would prove an incalculable boon to the natives.

The question of labor, that bug-bear of Queensland planters, would here be solved by the judicious employment of the native inhabitants, who, I do not hesitate to affirm so far as the inland tribes are concerned, will willingly labor in the field if kindly and justly treated. Any attempt at coercion, or the importation of foreign colored labor cannot but result in the most lamentable failure, and will give rise to serious complications. By dealing entirely with the native chiefs, their co-operation would be secured, and at the same time it would increase their influence and power over the tribes under their rule. These men are keenly alive to anything effecting their interests, and will greedily avail themselves of any pretext to ensure the one and enhance the other. Any attempt to deal with individuals will make these chiefs hostile and suspicious, and they will endeavour by every means in their power to defeat the objects such speculators may have in view. The above remarks refer to the dealings of Government with the chiefs, not to individual speculators. These must content to secure land through the Protectorate established by the English Government. This course must recommend itself to all right thinking men, who will readily understand the advantages accruing to them from a secure title and the friendship of the native chiefs and their subjects.

The importance of New Guinea as a coffee producing country cannot be over-estimated, now that Ceylon has been nearly ruined by the coffee leaf disease. Those who aver that it will be possible to obtain Papan labor for Queensland plantations know very little about the people. The presence of white men—*bona fide* planters—among the people will assuredly put a stop to the constant wars they carry on. Superior cultivation means more food, more leisure, and consequently more opportunity for mental improvement. In this manner we may confidently hope to pierce the veil of darkness in which these people are at present enveloped.—*Hongkong Daily Press.*

ROSE OIL, OR OTTO OF ROSES.

BY CHARLES G. WARNFORD LOCK.

This celebrated perfume is the volatile essential oil distilled from the flowers of some varieties of rose. The botany of roses appears to be in a transition and somewhat unsatisfactory state. Thus the otto-yielding rose is variously styled *Rosa damascena*, *R. s. superbiens*, *R. moschata*, *R. gallica*, *R. centifolia*, *R. provincialis*. It is pretty generally agreed that the kind grown for its otto in Bulgaria is the damask rose (*R. damascena*), a variety induced by long cultivation, as it is not to be found wild. It forms a bush usually 3 to 4 feet, but sometimes 6 feet high; its flowers are of moderate size, semi-double, and arranged several on a branch, though not in clusters or bunches. In colour, they are mostly light-red; some few are white, and said to be less productive of otto.

The utilisation of the delicious perfume of the rose was attempted with more or less success, long prior to the comparatively modern process of distilling its essential oil. The early methods chiefly in vogue were the distillation of rose-water, and the infusion of roses in olive oil, the latter flourishing in Europe generally down to the last century, and surviving at the present day in the South of France. The butyrateous oil produced by the distillation of roses for making rose-water in this country is valueless as a perfume; and the real otto was scarcely known in British commerce before the present century.

The profitable cultivation of roses for the preparation of otto is limited chiefly by climatic conditions. The odoriferous constituent of the otto is a liquid containing oxygen, the solid hydrocarbon or stearoptene, with which it is combined, being absolutely devoid of perfume. The proportion which this odorless solid constituent bears to the liquid perfume increases with the unsuitability of the climate, varying from about 18 per cent in Bulgarian oil, to 35 and even 68 per cent in rose oils distilled in France and England. This increase in the proportion of stearoptene is also shown by the progressively heightened fusing-point of rose oils from different sources: thus, while Bulgarian oil fuses at about 61° to 64° Fahr., an Indian sample required 68° Fahr.; one from the South of France, 70° to 73° Fahr.; one from Paris, 84° Fahr.; and one obtained in making rose-water in London, 86° to 89½° Fahr. Even in the Bulgarian oil, a notable difference is observed between that produced on the hills, and that from the lowlands.

It is, therefore, not surprising that the culture of roses, and extraction of their perfume, should have originated in the East. Persia produced rose-water at an early date, and the town of Nishin, north-west of Mosul, was famous for it in the 14th century. Shiraz, in the 17th century, prepared both rose-water and otto, for export to other parts of Persia, as well as all over India. The Perso-Indian trade in rose oil, which continued to possess considerable importance in the third quarter of the 18th century, is declining, and has nearly disappeared; but the shipments of rose-water still maintain a respectable figure. The value, in rupees, of the exports of rose-water from Bushire in 1870, were—1,000 to India, 1,500 to Java, 200 to Aden and the Red Sea, 1,000 to Muscat and Dependencies, 200 to Arab coast of Persian Gulf, and Bahrain, 200 to Persian coast and Mekran, and 1,000 to Zanzibar. Similar statistics relating to Lingeh, in the same year, show—Otto: 400 to Arab coast of Persian Gulf, and Bahrain; and 250 to Persian coast and Mekran. And Bahrain—Persian Otto: 2,200 to Koweit, Basrah, and Bagdad; rose-water: 200 to Arab coast of Persian Gulf, and 1,000 to Koweit, Basrah, and Bagdad.

India itself has a considerable area devoted to rose-gardens, as at Ghazipur, Lahore, Amritzur, and other places, the kind of rose being *R. damascena*, according to Brandis. Both rose-water and otto are produced. The flowers are distilled with double their weight of water in clay stills; the rose-water (*goobeh pani*) thus obtained is placed in shallow vessels, covered with moist muslin to keep out dust and flies, and

exposed all night to the cool air, or fanned. In the morning, the film of oil, which has collected on the top, is skimmed off by a feather, and transferred to a small phial. This is repeated for several nights, till almost the whole of the oil has separated. The quantity of the product varies much, and three different authorities give the following figures:—(a) 20,000 roses to make 1 rupee's weight (176 gr.) of otto; (b) 200,000 to make the same weight; (c) 1,000 roses afford less than 2 gr. of otto. The colour ranges from green to bright-amber, and reddish. The oil (otto) is most carefully bottled; the receptacles are hermetically sealed with wax, and exposed to the full glare of the sun for several days. Rose-water deprived of otto is esteemed much inferior to that which has not been so treated. When bottled, it is also exposed to the sun for a fortnight at least.

The Mediterranean countries of Africa enter but feebly into this industry, and it is a little remarkable that the French have not cultivated it in Algeria. Egypt's demand for rose-water and rose-vinegar is supplied from Medinet Fayum, south-west of Cairo. Tunis has also some local reputation for similar products. Von Maltzan says that the rose there grown for otto is the dog-rose (*R. canina*), and that it is extremely fragrant, 20 lb. of the flowers yielding about 1 dr. of otto. Genoa occasionally imports a little of this product, which is of excellent quality. In the south of France, rose gardens occupy a large share of attention, about Grasse, Cannes, and Nice; they chiefly produce rose-water, much of which is exported to England. The essence (otto) obtained by the distillation of the Provence rose (*R. provincialis*) has a characteristic perfume, arising, it is believed, from the bees transporting the pollen of the orange flowers into the petals of the roses. The French otto is richer in stearoptene than the Turkish, nine grammes crystallising in a litre (1½ pint) of alcohol at the same temperature as 18 grammes of the Turkish. The best preparations are made at Cannes and Grasse. The flowers are not there treated for the otto, but are submitted to a process of maceration in fat or oil, ten kilos of roses being required to impregnate one kilo. of fat. The price of the roses varies from 50 c. to 1 fr. 25 c. per kilo.

But the one commercially important source of otto of roses is a circumscribed patch of ancient Thrace or modern Bulgaria, stretching along the southern slopes of the central Balkans, and approximately included between the 25th and 28th degrees of east longitude, and the 42nd and 45rd degrees of north latitude. The chief rose-growing districts are Philippopoli, Ohirpan, Giopen, Karadshah-Dagh, Kojun-Tepe, Eski-Sara, Jeni-Sara, Bazardshik, and the centre and headquarters of the industry, Kazanik (Kisanlik), situated in a beautiful undulating plain, in the valley of the Tunja. The productiveness of the last-mentioned district may be judged from the fact that, of the 123 Thracian localities carrying on the preparation of otto in 1877—they numbered 140 in 1859—42 belong to it. The only place affording otto on the northern side of the Balkans is Travna. The geological formation throughout is syenite, the decomposition of which has provided a soil so fertile as to need but little manuring. The vegetation, according to Baur, indicates a climate differing but slightly from that of the Black Forest, the average summer temperatures being stated at 82° Fahr. at noon, and 68° Fahr. in the evening. The rose-bushes flourish best and live longest on sandy, sun-exposed (south and south-east aspect) slopes. The flowers produced by those growing on inclined ground are dearer and more esteemed than any raised on level land, being 50 per cent richer in oil, and that of a stronger quality. This proves the advantage of thorough drainage. On the other hand, plantations at high altitudes yield less oil, which is of a character that readily congeals, from an insufficiency of summer heat. The districts lying adjacent to and in the mountains are sometimes visited by hard frosts, which destroy or greatly reduce the crop. Floods also occasionally do considerable damage. The bushes are attacked at intervals and in patches by a blight similar to that which injures the vines of the country.

The bushes are planted in hedge-like rows in garden and fields, at convenient distances apart, for the gathering of the crop. They are seldom manured. The planting takes place in spring and autumn; the flowers attain perfection in April and May, and the harvest lasts from May till the beginning of June. The expanded flowers are gathered before sunrise, often with the calyx attached; such as are not required for immediate distillation are spread out in cellars, but all are treated within the day on which they are plucked. Baur states that, if the buds develop slowly, by reason of cool damp weather, and are not much exposed to sun-heat, when about to be collected, a rich yield of otto, having a low solidifying point, is the result, whereas, should the sky be clear and the temperature high at or shortly before the time of gathering, the product is diminished and is more easily congealable. Hanbury, on the contrary when distilling rose in London, noticed that when they had been collected on fine dry days the rose-water had most volatile oil floating upon it, and that, when gathered in cool rainy weather, little or no volatile oil separated.

The flowers are not salt-d, nor subjected to any other treatment, before being conveyed in baskets, to the heads of men and women, and backs of animals, to the distilling apparatus. This consists of a tinned-copper still, erected on a semicircle of bricks, and heated by a wood fire; from the top passes a straight tin pipe, which obliquely traverses a tub kept constantly filled with cold water, by a spout, from some convenient rivulet, and constitutes the condenser. Several such stills are usually placed together, often beneath the shade of a large tree. The still is charged with 25 to 50 lb. of roses, not previously deprived of their calyces, and double the volume of spring water. The distillation is carried on for about 1½ hour, the result being simply a very oily rose-water (*ghyul-suyyi*). The exhausted flowers are removed from the still, and the decoction is used for the next distillation, instead of fresh water. The first distillates from each apparatus are mixed and distilled by themselves, one-sixth being drawn off; the residue replaces spring water for subsequent operations. The distillate is received in long-necked bottles, holding about 1½ gallon. It is kept in them for a day or two, at a temperature exceeding 59° Fahr., by which time, most of the oil, fluid and bright, will have reached the surface. It is skimmed off by a small, long-handled, fine-orificed tin funnel, and is then ready for sale. The last-run rose-water is extremely fragrant, and is much prized locally for culinary and medicinal purposes. The quantity and quality of the otto are much influenced by the character of the water used in distilling. When hard spring water is employed, the otto is rich in stearoptene, but less transparent and fragrant. The average quantity of the product is estimated by Baur at 0.037 to 0.040 per cent; another authority says that 3,200 kilos. of roses give 1 kilo. of oil.

Pure otto, carefully distilled, is at first colourless, but speedily becomes yellowish; its specific gravity is 0.87 at 72.5° Fahr.; its boiling-point is 444° Fahr.; it solidifies at 51.8° to 60.8° Fahr., or still higher; it is soluble in absolute alcohol, and in acetic acid. The most usual and reliable tests of the quality of an otto are (1) its odour, (2) its congealing point, (3) its crystallisation. The odour can be judged only after long experience. A good oil should congeal well in five minutes at a temperature of 54.5° Fahr.; fraudulent additions lower the congealing point. The crystals of rose-stearoptene are light, feathery, shining plates, filling the whole liquid. Almost the only material used for artificially heightening the apparent proportion of stearoptene is said to be spermaceti, which is easily recognisable from its liability to settle down in a solid cake, and from its melting at 122° Fahr., whereas stearoptene fuses at 91.4° Fahr. Possibly paraffin wax would more easily escape detection.

The adulterations by means of other essential oils are much more difficult of discovery, and much more general; in fact, it is said that none of the Bulgarian

otto is completely free from this kind of sophistication. The oils employed for the purpose are certain of the grass oils (*Andropogon* and *Cymbopogon* spp.), notably that afforded by *Andropogon*, *Scheenanthus* called *chis-yaghi* by the Turks, and commonly known to Europeans as "geranium oil," though quite distinct from true geranium oil. The addition is generally made by sprinkling it upon the rose-leaves before distilling. It is largely produced in the neighbourhood of Delhi, and exported to Turkey by way of Arabia; it is sold by Arabs in Constantinople in large bladder-shaped tinned-copper vessels, holding about 120 lb. As it is usually itself adulterated with some fatty oil, it needs to undergo purification before use. This is effected in the following manner:—The crude oil is repeatedly shaken up with water acidulated with lemon-juice, from which it is poured off after standing for a day. The washed oil is placed in shallow saucers, well exposed to sun and air, by which it gradually loses its objectionable odour. Spring and early summer are the best seasons for the operation, which occupies two to four weeks, according to the state of the weather and the quality of the oil. The general characters of this oil are similar to those of otto of roses—even the odour bearing a distant resemblance—that their discrimination when mixed is a matter of practical impossibility. The ratio of the adulteration varies from a small figure up to 80 or 90 per cent. The only safeguard against deception is to pay a fair price, and to deal with firms of good repute, such as Messrs. Papanoglu, Manoglu and Son, Hmsen & Co., and Holstein & Co., in Constantinople.

The otto is put up in squat-shaped flasks of tinned copper, called *kankinas*, holding from 1 to 10 lb., and sewn up in white woollen cloths. Usually their contents are transferred at Constantinople into small gilded bottles of German manufacture for export. The Bulgarian otto harvest, during the five years 1867-71, was reckoned to average somewhat below 400,000 *meticals*, *miskals*, or *midkals* (of about 3 dw. troy), or 4,226 lb. av.; that of 1873, which was good, was estimated at 500,000, value about 700,000. The harvest of 1880 realised more than 1,000,000. though the roses themselves were not so valuable as in 1876. About 300,000 *meticals* of otto, valued at 932,077., were exported in 1876 from Philippopolis, chiefly to France, Australia, America, and Germany.—*Journal of the Society of Arts.*

THE EXPERIMENTS tried with the creeper known botanically as *Cryptostegia grandiflora*, which yields a juice capable of being worked into Indianrubber, proved that although it thrives well and is abundant in Poona and other places, yet it would not be profitable to make rubber from it.—*Indian Agriculturist.*

THE CHEAPEST ANTISEPTIC.—M. Pasteur anticipates that bisulphide of carbon will become the most efficacious of all antiseptics, as it is also the cheapest, costing but a fraction of a penny per pound in large quantity. It is also the best insecticide known, and for this purpose may, perhaps, be useful to preserve woodwork in tropical countries. Some idea of the use it is already put to may be gathered from the fact that over eight million pounds of the substance are used annually to check the ravages of phylloxera. Carbon bisulphide, as first produced, is about as foul smelling a compound as it is possible to find; but it is capable of purification till all offensive odour is removed, and it is sufficient pure in smell almost to mix with a perfume.—*Scientific American.*

MINOR INDUSTRIES.—The samples of locally prepared preserves Mr. Jayewardene has sent us include Pine Apple Jam, Orange Marmalade, Candied Orange Marmalade, Sour Orange (*Euhali dodan*) Marmalade, Sour Orange Candied Marmalade, country Olive (*Veralu*) Jelly, Citron Marmalade and Candied Orange preserved entire. He writes:—"Having learnt from a Frenchman the art of preparing jams, jellies, marmalade, pickle and various other such things, and spent much money in experimenting on Native fruits, &c., for nearly 6

years past, I was encouraged by your article on "Minor Industries" in your paper of the 20th November to take up the enterprise you opportunely suggested. I herewith send you a few samples of what I have prepared; but owing to the want of suitable vessels, I am prevented from sending you from all the kinds I have now in stock. I call your special attention to the jelly prepared of country olives (only a very little is sent, as it was made only for experiment) which we in Sinhalese call *Veralu*. It is one of the commonest fruits, as you well know, but not much used in any way. After preparing in various methods, I succeeded in making this delicious jelly of a beautiful colour. I am unable to send you some nice pickles till I get suitable vessels to send them in, and I am put to very great inconvenience and expense owing to want of suitable vessels. The preserves, jams, &c., prepared of some Native fruits, you will know, are very wholesome, even in cases of serious indisposition, for instance the bell-fruit, and sour orange, &c., are considered by Native Vedaralas as not only wholesome, but very efficacious in some diseases." We have great pleasure in testifying to the excellence of Mr. Jayewardene's preparations. They are clear, of fine flavour, and seem to justify his claim that they are pure and wholesome. He says that owing to the difficulty of securing suitable pots and jars, a supply of which he expects from England, he is unable to open a regular establishment for their sale, but he is prepared to execute orders and to send his preparations from house to house, at 40 to 50 cents per lb. according to the price of the fruit. There can be no doubt of the wholesomeness of preparations of the *Beli*-fruit, Sour Orange, *Yeli* and other fruits in certain disorders; and we hope it will not be long before Mr. Jayewardene reaps the reward of his enterprise. Why should not earthen pots, well burnt and glazed, like those in which Guava jelly is sent out from India, answer?—"Examiner."

GUTTA.—Messrs. Heckel and Schlagdenhauffen have already shown that the tree from which Shea butter is obtained (*Butyrospermum Parkii*, Kotschy) furnishes a guttaparcha which they compare to that of *Isaandra Gutta*, Hook. (*Comptes Rendus*, c., 1239). They have now made a chemical examination of this product, and in a note communicated to the Paris Academy of Sciences (*Comptes Rendus*, c., 1069) state that it compares well, in its fibrous structure and resistance, with the red gutta of Borneo. Its specific gravity is 0.976 as compared with 0.975 to 0.980, the standard given by Payen as that of commercial guttaparcha. In its solubility in carbon bisulphide, chloroform, benzine, cold or boiling alcohol, the two almost exactly agree. But petroleum ether, ethylic ether, oil of turpentine, and boiling acetic acid dissolve less of it than of ordinary guttaparcha, and these liquids when evaporated do not yield the same products; the residues from the butyrospermum gutta having a pitchy consistence, while those of commercial gutta from a dry adhesive varnish. For industrial purposes it seems to be equal to the best gutta percha of commerce, as it can be worked up in water quite as easily, and the moulds made with it are in no way inferior. This new guttaparcha has therefore a promising future before it, if it can be obtained in sufficient quantity for commercial purposes. In a recent paper by Dr. Treub on the guttaparcha yielding plants of the Dutch East Indies, that author states that the original guttaparcha plant, *Isaandra Gutta*, Hook., is almost extinct as a wild plant, and he recommends the cultivation of some of the most valuable species of *Palaquium*, especially *P. oblongifolium*, which are at present the source of the guttaparcha of commerce. The natives mix the products of various species, which differ greatly in quality and properties, and hence if the product of the species which yield the best gutta were obtained separately from cultivated trees, a far better quality than any yet seen in commerce might be obtained.—*Pharmaceutical Journal.*

COTTON SEED.—According to experiments by Sacc (*Journ. de Pharm. et Chem.*), cotton seed has the following composition:—Casein, 6 per cent.; dextrin, 2.0; sugar, 2.0; fibrin, 23.7; woody fibre, 32.1; starch, 9.6; greenish-yellow oil, 9.6; yellow wax, 0.8; water, 8.0; ash, 8.0. The seed affords by grinding 56.5 per cent of a yellow meal, which may be employed with milk in bread-making. This meal, or what is cheaper, the residue left after the seed has been passed through the oil-press, is available for clarifying syrups. —*Journal of the Society of Arts.*

SUCCESSFUL FRUIT GROWING.—All trees should be sprayed or washed two or three times a year, to destroy the numerous bugs and insects that prey upon them. The top of each limb and branch should have about one-third of the year's growth pruned away. Some cut merely the lower limbs, but this is not sufficient. When peach or apricot trees are eight or ten years old, they should have a severe cutting back, and all dead wood should be removed. Citrus trees need more thinning out and cutting back yearly, and loosening of the soil after each irrigation, than they generally get. These methods properly carried out will ensure good crops and better shaped trees; and the labour is lighter than when trees are neglected for two or three years, and an attempt is then made to put them in good condition. —*Rural Californian.*

TRAVELLING SEEDS.—Sometimes, seeds only, sometimes fruits, are thus transported by running streams and ocean currents. The fruits of Fennel are exactly like miniature boats; and Funchal or Fennel Bay in the island of Madaira owes its name to this plant, colonized there by seeds that have safely made the voyage from the main land. In like manner, Hazelnuts, Walnuts, and many other kinds of nuts, have been carried by currents to a new home beyond the seas. For a long time the source of the large Cocoanuts that drift about in the Indian Ocean, and are finally stranded on the east of Malabar, remained a mystery. These gigantic fruits, some of them more than 18 in. in diameter, and weighing from forty to fifty pounds, are not the produce of any neighbouring country, and the Hindoos called them "Sea Coeca," supposing that they are supplied by some unknown plant. It has since been discovered that they are the produce of the *Lodoicea*, a magnificent Palm, growing on the Seychelles Islands which lie on the eastern coast of Africa, more than twelve hundred miles from the nearest point of Indian territory. The currents of the Pacific Ocean carry out Cocoanuts and other fruits from the American continent to enormous distances in a similar manner. These find a resting-place on the coral ridges which are raised up from the bottom of the sea by the ceaseless labour of polyps; here they germinate, and soon cover with brilliant verdure what had formerly been a rock almost invisible to navigators. —*Indian Gardener.*

FERTILISERS.—We are decidedly in favour of using good fertilizers, and cannot fail to speak of nature's method of making soil, and creating fertility, i.e., green manuring. Nature's laws are immutable, and her teachings are infallible; but while we say this we are often painfully aware that we cannot satisfactorily fathom her philosophies. Nature creates soil by the process of green manuring, but we cannot explain exactly in what way she does it. Never mind! let the philosophy slide; we know it is so, and let this knowledge direct our movements and we shall be the better for it. Those who neglect this means of increasing the productiveness of their lands stand in their own light. We believe that the turning under of vegetable matter to decompose exerts an influence over the free fertilizers contained in the air and water and appropriates them; and on the well-known principle operative in many departments of nature that to "whosoever hath more shall be given," a soil abounding in humus accumulates power to increase its fertility in exact proportion to the organic matter it contains. If this is so, and who challenge contradiction, what shall be said of those who permissively consume with fire all the waste vegetable

matter produced on their land? Is it not unattractive, wasteful, injurious, in the long run fatal to the cherished wishes and expectations of the cultivator, and a sure way to ruin? We pause for a reply. —*Queenland Agriculturist.*

SOOT WATER.—As a cheap and easily made reliable fertilizer this is of great value. It may be used with much advantage wherever plants are grown in pots. There is no kind of plant it does not benefit, and it may be given to those which produce fruit, flowers, or fine foliage. It has the virtue better than any other fertilizer of clearing worms from from the soil in pots, and this is a great gain in itself. No kind of worm will remain in the soil which receives a supply of soot water occasionally, and it causes foliage, fruit, and flowers to assume a much darker colour than they do when it is not used. It imparts extra vigour, and may be used all the year round. Ferns are especially benefited by it, and the fronds assume a deep green colour under its influence. Strawberries in pots, Pines, Vines, Pelargoniums, Fuchsias, and indeed all plants improve in texture and appearance from its use. It may be used to expel worms before the pots are full of roots, but as a general fertilizer it should not be much employed until the roots have taken to soil freely. It is not wanted until then. Many have much difficulty in getting the soot to mix with the water, but this is easily enough managed. Any ordinary old bag should be taken; half fill it with soot, put a brick or large stone inside, tie up the mouth, and put it into the tank or barrel with the water. In a short time the water will have penetrated through every particle of the soot any covered it into a pulp. The water is then in excellent condition for use. It may, however, be too strong for giving to the plants as it is, but a quantity of it may be lifted and put into the pans with clear water, the strength to apply it being a matter which can only be determined by the cultivator. —*J. MITCHELL, Margam. — Journal of Horticulture.*

BARBADOS.—The island is like a garden; every scrap of cultivable land is turned to account, and in many cases the bare rock has been covered with a layer of artificial soil, thin, but sufficient for the canes, except in excessive drought. It is extraordinary to look at the country and see the industry which has been employed in utilizing every inch of it. Everywhere fields of thick waving canes, unfenced and undivided except by the white coral roads, thickly sprinkled with the shanties of the negroes, the white houses of the planters, the low buildings and tall chimneys of the manufactories, and the inevitable windmills; while here and there, but far too rarely, stand a few palm trees, their plumes bent over by the trade wind, and a dead branch or two hanging sorrowfully down the trunk like the helpless wing of a stricken pheasant. Everywhere sugar, sugar, sugar—before which all must fall. The trees were ruthlessly sacrificed to the saccharine Moloch till a diminished rainfall warned the planters that treelessness means rainlessness, and led them to place under the protection of the law such trees as were left. Thus it comes to pass that a drive over the country is most disagreeable owing to the absence of shade. There is no escape from the fierce sun overhead, or the frightful glare of the road beneath; the latter certainly the worse of the two evils, and often serious in its effects on the eyes both of blacks and whites. The only relief is a shower of rain, which is hardly a change for the better, as tropical rain is hard to keep out, and if the sun come after it the consequent damp heat is almost worse than anything. This high state of cultivation involves cheap labour, and Barbados, within an area of 160 square miles, contains a population of nearly 180,000. Of these less than 10 per cent are pure Whites. It is to this enormous population that Barbados owes its long-continued prosperity, and enabled it to stand successfully, the abolition of slavery and of the protective duties on sugar. —*Macmillan's Magazine.*

Correspondence.

To the Editor of the "Ceylon Observer."

TEA IN UVA: USEFUL INFORMATION. &c.

Badulla, 9th January 1886.

I suppose it is due to the fact that the cultivation of tea in Uva is as yet, comparatively speaking, in its infancy that we are up to the present time almost entirely exempt from criticism of any kind, but our turn is coming, and, when it does come, we are in hopes that we shall have so benefited by the experience of those who have preceded us in the cultivation that there will be very little to reflect upon. Let us lay to heart the lesson now being taught to others, and be not boastful, but await in patience what things the future may have in store for us.

A friend of mine, a tea planter (albeit he is a capital maker of tea as well), living within a hundred miles of Rookwood, whom I recently regaled with a short account of the progress we were making with tea in Uva, coupled with an invitation to come and see it, and winding up with a warning that the Kandy side folks had need to look to their laurels, good-naturedly retorted that they would take a deal of beating, that at best the running would be even; and that, as for the laurels, there were probably enough in the world to provide wreaths for the sunny brows of Uva for many years to come, without depriving Kandy of her share. So mote it be, for we owe a debt of deep gratitude to our friends on the other side.

We have not as yet amongst us any great authority on the plucking and manufacture of tea, but this will come in due course. A considerable amount of practical experience has however been gained on one or two important points. We have learned that tea can be planted and grown just as easily and inexpensively as almost anything else. We have learned that there are such things as good seed and bad seed, and this has proved a most painful experience to some of us. My own experience in this connection has been very trying, and I fear, judging from the large areas that have been planted with seed, I am not singular in this respect. We only know from hearsay what estates produce a good lot, but we have better experience to guide us as to the source of supply of rotten and light seeds which jeopardize the success of our nurseries and clearings and which will effectually prevent us from troubling the same people again. I have always been exceptionally successful with nurseries of all kinds, including tea, up to the present season. Last year 34 maunds of seed yielded me plants enough to plant and supply over 200 acres. This season I had over 50 maunds of seed, about half of which quantity was supplied by a Mr. Lomerinsky, while the balance was made up of 15 maunds imported from Calcutta, and 10 maunds from a well-known estate in Dolobage.

The two last lots of seed delivered in Badulla cost, roughly speaking, R1,600, while the former lot cost about R1,100. The outcome of plants has been as follows:—

From Dolobage	150,000 at R3	exclusive of nurs.
& imported seed	50 per 1,000	ery upkeep &c.
From Mr. Lome- rinsky's seed	150,000 at R7	exclusive of nurs- ing's seed
	per 1,000	ery upkeep &c.
and the plants at	R3.50 per thousand	are worth

more than twice as much as those which cost R7. These figures are somewhat startling, and it is hoped they will prove of some service to those of my brother-planters who contemplate making nurseries for the requirements of next year. The moral contained in them is obvious, and is of too important a nature to be lightly set aside. ICH DIEN.

THE BLACKSTONE ROLLER.

Tyspany, Kotmale, 25th Jan. 1886.

DEAR SIR,—Mr. Barber's roller is being much discussed on estates and in the papers, and, having seen the machine at work, I must speak as to the really "good" work it does. The question that seems most at issue is: "Will the roller roll anything but fine leaf?" I have heard it said that Mr. Barber only rolls very fine leaf, which is the secret of the good work and that the roller perhaps would not hold its own with other machines were it not for this fine plucking. I have seen the leaf brought in from the field and on the withering tats, and must say that the plucking was only "ordinary" plucking, such as one sees on most estates in Ceylon. I feel sure that Mr. Barber's roller will roll well any leaf that should be brought into a tea factory.—Yours faithfully, W. C. THOMAS.

COFFEE AND PEPPER EXPORTS FROM WESTERN INDIA.

Tellicherry, 4th Jan. 1886.

DEAR SIR,—We have the pleasure to hand you our usual statement of exports of coffee and pepper from this coast for the year ending 30th June last.

The figures cannot be taken to represent the exact yield of the districts in proximity to the different ports, for, as we have previously pointed out, some coffee finds its way to Madras, especially from the districts of Coorg and Mysore; and, as regards pepper, native dealers hold over from one season to another and no very accurate idea of each year's crop can be obtained.

Coffee.—The coffee crops in Coorg fell far short of anticipations, while in Mysore estimates were generally realized, the result being that Mangalore exported the largest quantity of coffee, heading Tellicherry, which, for some years previous, had maintained the first place. Judging from the exports of this produce from Calicut and Beypore, crops from Wynad, the Neigherries and the Ouchterlony Valley did not show any improvement. Cochin and Quilon have exceeded their last year's exports.

Peppers.—In Coorg crops will show an improvement on the past season, and, from all we have heard, planters who are now picking are generally satisfied that their estimates will be realized and in some cases exceeded, and we think the same can be said of Mysore. As regards the other districts, we have no any reliable information.

Pepper. Judging from exports, the yield this past season was a very good one, Tellicherry, as usual, exporting considerably more than all the rest of the ports put together, natives now cultivating to a very large extent in North Malabar. From what we can gather the coming crop, although not so good, will be as large as last year, a greater area of land having come into bearing.—We are, dear sir, yours faithfully,

p. pro, ALSTON, LOW & Co.
RALPH TATHAM.

TEA IN UVA: SPLENDID GROWTH OF YOUNG NURSERIES.

14th January 1886.
 DEAR SIR.—Nearly a whole year has elapsed since I had the pleasure of visiting one or two of the crack estates on the *Kandy side* of the country, as we Uvaites are wont to designate every acre of land after passing Nuwara Eliya Kandywards. The impression left on my mind with regard to the prospects of tea was deep, and it has proved lasting. What I then saw produced in me a mental breach of the tenth commandment, and I returned with serious misgivings as to our ever being able to compete with those whom I looked upon as more favored. These envious feelings have however declined in proportion corresponding to the progress made by our own young fields of tea during the past twelve months, and a state of mind which is far more comforting, has taken their place, so that at the present time we are calmly and deliberately coming to believe that Uva will grow as good tea, and yield as large returns as any other part of the country.

Now and again one of our member pays a visit to the other side, and brings back a report which is vastly flattering to us, but the strange part of it is, that, notwithstanding the fact that our young clearings now compare favorably with any in the country, there still exists a feeling of great incredulity as to our being able to produce the shrub at all. With the idea of bringing about a change of opinion in this respect, I have taken advantage of a coolly proceeding to the railway to send you a case containing a couple of tea plants taken from the clearings on Uva estate, Hewa Eliya. Both plants honestly represent the average growth in the fields from which they were taken. The larger of the two was grown from seed planted at stake on the 15th January 1884, so that it is now exactly two years old from the seed. The bushes were cut down to 20 inches three months ago. The shoots developed from the old wood will give you a good idea of the growth. The younger plant has seen 12 1/4 months of life in the field, and the land in which it was planted was *patana*.

I trust the plants will reach you in fairly fresh condition, and I hope you will not mind letting them remain in your office for a day or two in order that anyone in Colombo who takes an interest in the prospects of tea in Uva may have an opportunity of seeing what it is like. Your own opinion, I need scarcely add, will be greatly valued.

Yours faithfully,
 ICH DIEN.

[Our own opinion is, that finer bushes, for their age, could scarcely be seen anywhere. We have always believed in Uva as a good tea country.—En.]

CROPS OF NATIVE PRODUCE IN CEYLON IN 1885-6.

A correspondent supplies the following review:—
 "The crops of coconuts nearly every estate in the Western Province will be less than $\frac{1}{2}$ in the first six months as compared with the same period last year. I find that the crop already taken on many estates is about $\frac{1}{3}$ of what was taken in Jan. 1885, this it is said is owing to the drought that prevailed early last year, but it is expected that the crops during the closing months of the year will be nearly equal to that of last year. It is however positive that the total crops will be less than last year and this is the more to be regretted as prices are at present anything but favorable. [I regret to say that the same will be the case with cinnamon.] One coconut estate to my knowledge that gave 33,000 nuts last year in Jan. gave only 13,000 in Jan. this year, and another that gave 17,000 only gave 7,000. I am afraid from all enquiries that I have made that for some time to come prices will not improve."

PLUMBAGO USED AS A MORTAR AND AS A DYE IN CHINA.

Recently we have been able to collect a great deal of information regarding graphite in its various forms and the multitudinous uses to which it is applied, and now we have a very curious contribution to our knowledge from China. It will be seen that, by the celestials, a special form of graphite, associated with coal and bitumen, but confounded with neither by the astute Chinese, is used when mechanically united to lime as a plaster or mortar and with cloth fibres (also mechanically), so as to form a permanent dye. Here are two new uses for the extraordinary substance which aids in the manufacture of steel ordnance, is itself manufactured into pencils, and is good as a lubricant and a fire-proof paint. It was formerly valued as a medicine, and the writer of the very interesting account we quote has found the form of the ore he describes useful in surgery as a styptic and a substitute for substances usually employed as "dry dressings."

NOTES ON THE SO-CALLED "BLACK LIME" OF CHINA.

The following note on Black Lime, by Dr. A. P. Peak, Tientsin, appears in the Customs Medical Reports:—

This substance is made by Dr. Williams to be "a kind of bitumen," and as it has not been mentioned by any other writer with whose pages I am familiar, possibly the correction of this mistake and the noting of two uses to which it is put by the Chinese may prove of interest.

A suspicion of its bituminous origin might arise from the facts that at some places there are found traces of petroleum in connexion with the coal measures near which it is found, and that water in which it is macerated sometimes shows an iridescent film upon its surface. The substance in question is, however, *amorphous graphite*; and although it is mined in localities near the coal beds, the Chinese themselves insist that it has no connexion with them. The provinces of Chihli and Shantung are mainly supplied from mines in the foot-hills of the range bounding the great plain on the north-west, and much of this material is shipped from Liu-li-ho, whence large quantities of lime and coal are also forwarded, this city, situated at the head of one of the affluents of the Peiho, being the distributing point for a large mountain region. Near Liu-li-ho surface indications of petroleum seem to abound.

One of the uses before mentioned is its mixture with lime, to make a very hard and durable plaster, used in situations that are exposed to the weather. Because of this association, the Chinese call this "lime" like the other, although, as they say, it has not the fiery principle of the white lime.

A peculiarity of this graphite is its avidity for water, not from chemical affinity, as with lime, but from its great absorbent qualities. The crude graphite, in lumps as it comes from the mines, when exposed to contact with water, at once becomes permeated by it, and falls into powder. In this state the particles slide upon each other with the greatest ease, giving that lubricating quality which is characteristic of graphite. When mixed with freshly slaked lime, graphite in this state can be very thoroughly incorporated with it, each one of the finely divided particles becoming imbedded in a matrix of lime, and by laborious working and pressure, as the mortar sets the mass can be so consolidated as to make, when hardened, one of the best and finest grained mortars known, specimens

of which can be seen in the so-called "chunam" roofs.

The superiority of this mortar is due solely to the physical character of the little knife-edged, microscopic fragments of carbon; and yet, strange to say, the use of silicious sand in mortar does not seem to have commended itself to native builders. I have never been able to get one who was not familiar with foreign ways of building to acknowledge its utility. True, it is somewhat difficult to obtain on this great alluvial plain; still, where it can be had, so far as I know, loam is used in preference.

To pass to the second economic use of graphite; this is the curious one of dyeing cloth. The cotton garments universally worn by the middle classes are coloured with this substance. The cloth is soaked in a hot, aqueous mixture of graphite, in which there is a little glue; it is then placed on a stone and maulled with wooden beaters; again immersed and again beaten, the process being repeated many times with each piece, until the cloth assumes a deep and uniform tint attained by thus mechanically forcing the fine particles of carbon more and more deeply into the fibre of the cloth.

I have rarely seen a more beautiful object than fibres scraped from the cloth, loaded with brilliant, razor-like fragments of carbon, like diamond dust, especially when viewed in glycerine, under a $\frac{1}{2}$ immersion lens. It is difficult to believe that such beautiful transparent objects make up in mass the dull opaque plumbago.

This process of dyeing, if we may call it so, I believe to be unique in the art as practised at the present day. The colour is, of course, indestructible by the sun or chemical action, and can only be discharged by thorough and repeated washings. Hence it makes a very satisfactory and permanent colour for Chinese garments, and approves itself to the utilitarian native mind, as witness its universal use.

Graphite is abundant, and sells in the market here for 5 cash a catty; yet these are all the industrial uses of it, so far as I know.

Lead pencils, crucibles, stove blacking and lubricating are not yet achieved by means of it.

Oddly enough, the Chinese have not thought of using it in medicine. Yet the great hygroscopic qualities of the fine, soft, velvety powder, which may easily be obtained by levigation, indicate a direction in which it may advantageously be employed.

In such affections as require dry dressings, *e. g.*, moist eczemas and purulent otitis, it could not fail to be of service. As a styptic it is of considerable value. I have found that a combination of 3 parts of graphite, 2 parts of resin, and 1 part of acacia, by weight carefully triturated, possesses very marked hæmostatic properties.—*Hongkong Daily Press*, 12th Jan.

SPINEL-BEARING DOLOMITE.

Much of our crystallized mountain limestone, which occurs in beds amongst our other primitive rocks is so full of iron pyrites that by many it is believed that this source of sulphur would supply a local manufactory of sulphuric acid. Occasionally our dolomite exists with the gold-like iron pyrites replaced by sapphire-blue crystals of spinel. But this latter form is so rare that during our long residence in Ceylon we had not seen it until about three weeks ago Mr. A. J. Kellow brought us some very beautiful specimens from his estate, New Cornwall, in the Ambawella or New Galway Valley, below Nawara Eliya. He told us he had for many years been in the habit of burning the ordinary form of the rock into lime, but that it was only recently that the breaking-up of a fresh bed had revealed the blue crystals. A large and very beautiful sapphire-like crystal which Mr. Kellow showed us as having been found in the rock ought to have dissipated the idea of copper pyrites which

was suggested to us, and which we mentioned in sub titling a specimen to our ever-reliable geological referee, Mr. A. Murray, of the Public Works Department, a gentleman so strangely overlooked by the Exhibition Committee with reference to their collections of geological and mineralogical specimens, which he was perfectly competent to name and classify. Mr. Murray at once recognized the true nature of the crystals and wrote:—

"The geological specimens you sent me are very interesting—what you take to be copper pyrites is really *Blue Spinel*, an aluminate of magnesia, known to occur in crystalline limestone such as your specimen is."

Before the receipt of Mr. Murray's letter we had picked out some of the crystals with a pen-knife and finding them translucent we had dismissed the idea of copper pyrites and we got to reading about lapis lazuli kyanite and topaz. Had we thought of looking into Mr. A. C. Dixon's account of our mountain limestones, in the Journal of the local branch of the Asiatic Society for 1880, we should have found that the form bearing blue crystals was not so rare as we had deemed. Mr. Dixon reported:—"A dolomite occurring at Waripola, on the Matale railway, contains a large amount of blue spinel." In the collection of minerals which accompanied Mr. Dixon's paper, there were two specimens of spinel, one from Watagama, about half-way between Matale and Kandy, and the other from Ratnapura. Gygax had also supplied a specimen of spinel to the Asiatic Society's Museum, so long ago as 1848. In truth, Ceylon and Siam are recognized as the two great sources of spinel, one of the varieties from our island being named *Ceylanite*, and another *Candite* for the reason thus stated by Tennent:—"Spinel of extremely beautiful colours is found in the bed of the Mahaveliganga, at Kandy, and from the locality it has obtained the name of *Candite*." The origin of the name *Ceylanite* will be found further on. One of the authorities we consulted stated:—

Spinel, a mineral allied to corundum, consisting chiefly of alumina, with smaller proportions of magnesia, silica and protoxide of iron. It occurs in crystals, which are often octohedral and is chiefly found in Ceylon and Siam. Its colours are various: red, blue, green and black. It is much prized as a gem; red spinels are commonly called rubies; the Balas ruby is a red spinel and a violet coloured spinel is known as *Alexandrine* ruby.

From another we learned that spinel

Occurs in loose and embedded octohedral crystals. Hardness greater than that of quartz but less than that of corundum. Colours: red, blue, violet, green, yellow, brown and black. The first most common. transparent, translucent, opaque specific gravity 3.5 to 3.7. Infusible by the blowpipe; the red varieties are rendered black and become opaque by exposure to it, but on cooling at first of a fine green by transmitted light, then nearly colourless and at last become again red. Ceylon and Siam in isolated and rolled crystals in the beds of rivers. Embedded in carbonate of lime in North America and Sweden. RED:—84.47 alumina; 8.78 magnesia and 6.18 chromic acid.

BLUE:—Silica	5.48
Alumina	72.25
Magnesia	14.63
Protoxide of iron	4.26

It will be noticed that red spinel contains a good deal of chromic acid to which we suppose it owes its colour? The blue, it will be seen, has a good deal less alumina in its composition but more magnesia, with silica and protoxide of iron, against the chromic acid of the red variety which includes the spinel ruby. Of course, if fine rolled crystals of spinel are found in the rivers of Ceylon, the chances of finding large unworm crystals in the parent

rock are all the greater. Mr. Kellow will no doubt search for large, clear, flawless crystals, and we should say that where such crystals are not present, slabs of the rock for tables and mantelpieces, and pieces for paper weights, &c., would be likely to take a beautiful polish. Curiously enough, one of the traditions of Nuwara Eliya is that the late Mr. Wm. Kellow stated that while digging potatoes he had found a large mass of sapphire which he put aside, and which when he again looked for it, it could not be found. No doubt, the "sapphire" was a piece of limestone, blue and radiant with spinel crystals. Spinel occurs, of course, in other primary rocks besides the crystallized limestone, and we suppose it is Davy who is quoted by Pridham to the effect that "spinel is comparatively rare, though some small and most beautiful crystals of it are found in the interior, and it is found in specimens of clay iron ore in parts of the Central Province where gneiss prevails." No doubt, the red or ruby form was referred to. In the Manual of the Geology of India, we find it stated that

The spinel ruby differs from the true oriental (corundum) ruby in composition by containing a varying percentage of magnesia, and the magnesium is occasionally replaced by iron, calcium, manganese, or zinn. The mineral therefore includes many varieties, some of which are opaque and unsuitable for jewellery. The spinel ruby is distinguished from the corundum ruby by being of inferior hardness and, when crystalline, by its octohedral form.

There is little or no information as to the occurrence of the spinel in peninsular India. Its occurrence in Mysore has been asserted, but apparently requires authentic confirmation. There are several countries beyond the confines of peninsular India where the balas ruby has been regularly mined for.

And then a list of the extra-Indian countries is given, commencing with Afghanistan, where spinel is found in a matrix of crystalline micaceous limestone. Then comes a curious statement:—

Badakshan.—The balas ruby mines of Badakshan are situated on the banks of the Shighuan, a tributary of the Oxus. They have been known by reputation for very many centuries, and the name *balas* is derived from Badakshan, another form of writing the name of the country or from Balkh the capital town. This may possibly be the origin of the common mistake made in English works on precious stones, namely, that these mines are situated in Balochistan! Marco Polo states that in his time the mines were wholly in the hands of the King, who kept up the value of the stones by only permitting a limited number to be exported. Colonel Yule remarks upon this that the monopoly has been continued to the present day. When Murad Beg of Kunduz conquered Badakshan he was so disgusted with the poor output of the mines that he abandoned working them, and the population of the neighbourhood were sold as slaves. In 1806 the reigning Mir had one of the mines opened at the request of Pundit Mauphal, but without much result. Wood, in 1837, attempted to visit these mines but failed; however, he gives a short account of them. The matrix, he states, is a red sandstone, or a limestone largely impregnated with magnesia; most probably it is a liucstone, as such appears to be the usual matrix. The galleries were easily made and numerous, but the frequent influx of water caused much trouble.

Upper Burma.—It is stated that a large proportion of the rubies which are sold in Burma are really only spinel, this mineral apparently occurring also in the already described gem sands. When the crystalline form is obscure the two stones may be distinguished either by their hardness, specific gravity, or their refractory powers. Although of less value the spinel rubies are largely used in jewellery.

The Rev. F. Mason, who gives some interesting information on this subject, states that he had a stone, which every native who had seen it,—and

some of them are very good judges indeed,—supposed to be a true oriental ruby or red sapphire, but its crystalline form—a regular octohedron—showed it to be a spinel.

He states that the dark-blue or blackish variety of spinelle called ceylanite or pleonaste is offered for sale by the Shans under the same name as sapphire. Gem sand containing small fragments of garnet, beryl, and spinel, together with the more precious stones, is a regular article of merchandise with the Shans. Three-fourths of the mass consists of spinel. Purchasers may rest assured that the valuable stones have, as a rule, been all removed by the wily Shans.

Of course, the ruby, sapphire and spinel mines of Upper Burma belong now to the British Raj. Streeter, in his notice of "precious spinel," states:—

Under the generic name Spinel several minerals are included, as the Spinel Ruby, Balas Ruby, also Pleonaste, or Ceylonite, Candite, and other less valuable crystals.

The precious Spinel is found either detached, or embedded in granular limestone. It varies in colour, presenting carmine, blue, rose-red, reddish-brown, or some tinge of orange. It is found, loose in the sand in Mysore and Hindostan, but in Burmah, Pegu, Ceylon, Safragam, and Matura it occurs in well-formed, sharp-angled octahedra. In deep water-courses, subject to irregular inundation, it occurs accompanied with Zircon, Garnet, and magnetic iron ore; and in granite, accompanied with Apatite.

What is said of Mysore must be read in the light of the scepticism of Mr. Ball of the Indian Geological Survey, and as to "Ceylon," with "Safragam" and "Matura" added, as if they two latter were countries separate from Ceylon, we are reminded of the statement in all the books that graphite is found in "Travancore, Ceylon." We quote the further interesting information furnished by Streeter, which shows that good, large crystals of spinel are quite equal in value to sapphires. In view of what Mr. Ball writes in his Geological Manual, however, there can be little doubt that the specimens of blue spinel referred to below, owed their origin to either Burma or Ceylon:—

In North America, between Amity and Andover, some crystals of extraordinary magnitude have been found, measuring 16 inches in diameter, in company with granular limestone and Serpentine.

Although its form, which has the octahedra for its base, has caused it to be classed in the regular gem system, yet it can be readily distinguished from the Ruby, to which it has been allied, by its inferior hardness, and its specific gravity, which varies from 3.5 to 3.8, and is in this respect similar to the Topaz.

A peculiarity of Spinel is that the light which is reflected from the depth of the gem, no matter what the colour of the stone, is always of a pale yellow. The lustre is vitreous, and displays every degree of transparency. The refraction is simple, and in no stone is this more real and abiding than in this species. It is rendered electric by friction, but not by heat.

Spinel is a combination of alumina and magnesia. The varieties of color are due to the magnesia being replaced partially by iron oxide (Fe₂O₃), zinc oxide (ZnO), or manganese oxide (MgO), and lime (CaO); and the alumina, by ferric oxide (Fe₂O₃).

One of the finest specimens of Blue Spinel, a thickish oblong stone, was not long since in the possession of Messrs. Pittar, Liverson & Co. It was an Indian-cut stone, weighing 31½ carats. It was, on its arrival, re-cut by Mr. J. N. Forster, of London and weighed, after re-cutting, 25 carats. There is a strange history attached to this stone; it was considered from India as a Sapphire; subsequently it was found to be a Spinel, whereupon the purchaser returned it to the merchant, who at once wrote to the consignee in India, but the statement was not believed. The merchant determined to have it cut, and afterwards sold it for a much larger sum than it had been valued at as a Sapphire.

In the Exhibition of 1862 there were two very fine Spinels; one from India was cut *en cabochon*, forming an octagon-shaped stone, of perfect color and free from flaws. It weighed 197 carats. This was cut by Mr. J. N. Forster to an 81-carat "perfection stone." The other Spinel was also an octagon-shaped stone, of perfect color, very "spread," and free from flaws. It weighed 102½ carats, and was re-cut by Mr. Forster, and then weighed 72 carats. It is strange that both these stones arrived from India in the same year, viz., 1861. One specimen obtained by Dr. Heron is said to have weighed 49 lb. it is in three pieces, and contains cavities studded with crystals of Corundum.

In Merontz, in Bohemia, little rose-red crystals are found, in company with Pyrites; also in the Liebenburgen, in gold sand, At Aker, in Sweden, pale-blue and pale-grey varieties are found in limestone.

Crystals are found in the Owens River, in Victoria, and also in the pearl rivers of New South Wales, and in other part of Australasia.

The Blue Spinel is found in Sweden, Antwerp, and Ceylon both loose and as imbedded crystals. They are easily distinguished by their foliated fracture; the color generally is a faint-blue, violet indigo, or a seladine-green. It is translucent, and contains 3 to 4 per cent of iron.

Pleonaste was called Ceylonite, by Rome de l'Isle, who analyzed it with a number of other crystals brought from Ceylon. It was Haüy who, seeing its crystals resembled that of the Spinel, desired to give it a special position in the system of minerals and named it *Pleonaste*, which signifies superfluity. Further investigation showed that it was in reality a black variety of the Spinel. This has the best cleavage of the whole class; it is easy and parallel to the faces of the octahedron.

The specific gravity of this stone rises from 3.5 to 3.8. It consists principally of alumina, and about 10 per cent of protoxide of iron. Its infusibility before the blow-pipe, and its formation with borax into an iron-colored glass, are the surest indications of Pleonaste. Acids have but little influence upon it. It is found in Russia and other cold climates, but it is also found in Ceylon, as well as in the Dolomite region in Ratanas.

Spinel, in consequence of its lustre, color and hardness, is used for personal ornament, and for objects of luxury; but it is only when the crystals are fine and large that they are considered gems. In cutting it receives the same form as the Ruby.

Spinel Ruby, called Balas Ruby, varieties in value according to its cut and color.

In the inventory of the French Crown Jewels, in the year 1791, we find the following:—

One Spinel Ruby of 56½ carats	.. £2,000
One " " 12.5th "	.. 12
One " " 3½ "	.. 12
One Balas Ruby 20½ "	.. 400
One " " 12½ "	.. 120

At the present time small stones range from	.. 5s to 10s a carat.
Medium stones, of fair color	.. 20s to 40s "
Large stones	.. 60s to 100s "

Specimen stones attain even a higher value.

Balas, called Balais Ruby, are pale-red, or rose-red gems, with a tinge of blue appearing at the angles of the octahedron which gives them a milky kind of shimmer and depreciates their value. The color is due to chromic acid.

The Balas Ruby varies much in price; for example, a dark rose-red of 10 millimetres, square-cut and polished as a Brilliant, pure and lustrous, will sell for £12 while a pale-rose of like size will be worth sixteen shillings only in value depends entirely on the demand and the character of the stone, occasionally a fine specimen of five carats will realize £50.

From the article 'Burma,' in the new edition of the *Encyclopedia Britannica*, we quote the following paragraph:—

The precious stones which are produced in the Burmese territories are chiefly the sapphire and the ruby. They are found about 60 or 70 miles in a north-east direction from the capital, over an area of about 100 square miles, by sinking pits in the gem beds. The varieties of the sapphire found there are the blue or oriental sapphire, the red or oriental ruby, the purple or oriental amethyst, the yellow or oriental topaz, besides different varieties of chrysoberyl and spinelle. The Crown lays claim to the produce of these rivers; and all the stones that exceed the value of £10 are sent to the treasury. No stranger is ever permitted to approach the spots where these precious stones are found. The yu or jade mines are situated in the Mogoung district, about 25 miles south-west of Mein-koon. During certain seasons no fewer than 1,000 men—Shans, Chinese, Panthays, and Kakhys—are engaged in the excavation of the stone, which is found in the form of rounded boulders, sometimes of considerable size. Each digger pays so much a month for the right of search, and all he finds becomes his own. Momiin, in Yunnan, was formerly the chief seat of the manufacture of the jade, and still produces a considerable quantity of small articles.

Mr. Kellow and the proprietors of the blue limestone at Wariapola will see, from all that we have stated and quoted, that good spinel crystals are valuable as gems.

While on matters geological we may mention that amongst rock specimens sent to the Exhibition Committee, including quartz and clays of various colours decomposed from it in an upland valley, with rock of igneous origin, associated with those metamorphic formations, was a very fine piece of jasper, found by Mr. A. Murray near Bentota. This rock, if found in large masses, ought to be of value.

With the spinel-bearing limestone we sent to Mr. Murray some pieces of quartz, the finding of which in a peaty formation seems to have upset the mental faculties of a correspondent who wrote:—

"I fancy the specimens sent are merely quartz, at least heat and acid test, did not shew otherwise. But how the — did I find it (the stone) in a regular flat 'peat moss' as black as pitch and the character of the other stones, very few, were all different, common schist (is that proper spelling?) and other decayed common stone, all of which were few and thin on the whole swamp about 1 ton big—by itself?"

"I've followed Sir, Roderick Murchison and Geikie but I don't mind ever looking for this sort in a peat hole."

"Something new in my line for new year!! I've not a micro. to examine the cavities to tell the facets or I need not have troubled you, though I do scratch my head how the &c. it came there and 1 ton and more too of a piece."

Mr. Murray writes:—

"The fragments referred to by your somewhat erratic correspondent are quartz of varying quality—the cavities incrustated with perfect rhombohedral 'rock crystals' contained at one time some carbonaceous or other nucleus around which the crystals formed. The position of the fragments is accounted for by the simple fact that they have been—ages back—detached by disintegration from the parent mass and conveyed probably by aqueous agency to the so-called 'peatmoss.'"

BOTANICAL GARDENS IN NORTHERN INDIA.

The reports of the Government Botanical Gardens at Saharanpur and Mussoorie are always interesting, containing, as they do, the results of a large number of experiments of great practical importance; and the report for the year 1884-85 though it contains fewer records of successful experiments than some of its predecessors, is not at all inferior to them in interest. Perhaps the most important work done at these Gardens is that on the acclimatization and cultivation of fruit trees and vegetables. This is carried out on a tolerably large scale, and with considerable success,

new or more hardy varieties of useful fruit trees and vegetables being constantly obtained and propagated, so that plants and seeds can be distributed to private individuals throughout the province. During the year, more than 42,000 plants and cuttings, and 19,600 lb. of seeds were sold or given away, the greater part being sold to the general public, who evidently appreciate the opportunity given them of obtaining the seeds of plants which have been so acclimatized, that they can be counted upon to produce good crops if due care be taken with them. This is a point of considerable importance and one to which we think sufficient attention is not paid in Madras. Those who attempt to raise flowers or vegetables here during the cold weather are always more or less troubled by the difficulty of getting good seed; and even if they get the best seed from England, they find that in some they have very fair crops, while in other years almost everything is a failure. Now the experiments made at Saharanpur show conclusively that many vegetables improve greatly, both in yield and in hardness, when properly acclimatized.

Turning to the results of some of last year's experiments, we find that those in potatoes confirmed the results obtained in the previous year that the common country varieties give a greater yield than can be obtained from imported sorts. The "Scotch Champion," however, continues to improve, and seems likely to prove a valuable addition as its quality is first-rate. The largest yield per acre was got from the kind known as "Naini Tal," and amounted to 176 maunds. The "Scotch Champion" increased from 44 maunds in 1883 to 60 maunds in 1884, and to 71 maunds in 1885. Seeds of water melon, sweet melons, pumpkins, vegetable marrow (squashes) and Indian-corn were imported from America for trial, and some of them proved superior to any that had previously been grown in the gardens. Of the water melons the "Ice cream" and "Gipsy water" were small but of exquisite flavour, and well deserve to be introduced into this country. Of the melons only three varieties ripened sound fruit, but those were far superior to any of the country kinds. They are known by the somewhat peculiar names of "Netted outmeg," "Netted citron" and "White Japan citron." The only new vegetable introduced during the year seems to have been the komrah of New Zealand, a kind of sweet potato. It produced a capital crop. The tubers are smaller than those of the Indian variety, but not so excessively sweet, and they come into season at the beginning of the cold weather, when other vegetables are scarce. Amongst the new plants introduced into the gardens is one from Jamaica the *gouania dominicensis*, L., which is known by the not very elegant name of the "chaw-stick," on account of its "thin flexible stems being chewed as an agreeable stomachic." Tooth-brushes are also made from it by cutting pieces of a suitable length, and fraying out the ends, while tooth-powder is made from the dried stems. Febrifugal qualities are claimed for it, and it is used for flavouring cooling beverages. Another plant received from Jamaica is the "tree tomato, (*Cyphomandra betacea*). It is a native of South America, where it grows as a shrub some five or six feet high. Plants are easily raised from seed, and come into bearing in two years. The cultivation of the salt bush, on which we remarked last year, continues to meet with fair success, but the seeds hitherto produced have failed to germinate. The genus *Atriplex* to which this plant belongs, is represented in Sind by another bushy species *A. Stocksii*, Wright (bione) which closely resembles the Australian salt bush; experiments are now being made to determine whether or not this can be raised in the same way for planting on sterile saline soils. The "sheep bush" has proved quite unable to stand the damp heat of the rainy season, but perhaps it may be found able to grow in some of the drier parts of the Panjab where the climate more closely resembles that of its native Africa.

The report includes a very interesting account of experiments on spider silk. Attention was some time

ago called to a very strong form of cobweb, spun by an African species of spider, which yielded a fibre scarcely distinguishable from that made by the silkworm. This notice suggested to Mr. Duthie the idea of having some experiments made with spiders' webs which are found in great abundance at Bhim Tal. He accordingly obtained a quantity of these webs, and sent them on to Mr. Threlton Dyer, at Kew, to have them examined by an expert. The report received from this expert, Mr. T. Wardle, is most encouraging. The fibre can be freed from the gummy substance with which it is loaded by boiling it in a solution of soap, and is then found to have an average thickness of one three thousand one hundredth of an inch, which is considerably finer than that of Italian silk. The strength of the fibre is proportionally greater than that of silk, but its chief characteristic is its great elasticity. A piece 30 centimeters long will stretch to 36·6 centimetres without breaking, whilst China silk of the same length would stretch to only 31 centimetres. The spider silk has a round lustrous fibre like common silk, but the amount of gummy matter associated with it in the natural state is excessive, amounting to nearly fifty per cent. The fibre dyes readily, and Mr. Wardle believes that if it could be obtained in any quantity it would find a ready market. The specimen sent him was rather dirty, but still he thinks it would be worth at least 2 shillings per lb. Hitherto, we suppose, the only use to which spiders' webs have been put—except by the spiders themselves—has been that of forming the "cross wires" in telescopes and microscopes. For this purpose, where a fine and fairly strong fibre is absolutely required, nothing has been found to be so satisfactory as a rapidly spun spider's web. When a web is required a suitable spider is placed on one prong of a forked stick which is held in the hand of the operator. When the spider has been got into the proper position the stick is tapped sharply, so that the spider falls off spinning a fine thread as it goes, this thread is then wound across the forks, and is ready for use. When the operation is properly performed a beautifully fine thread is obtained which may be used under very high magnifying powers. Returning to the Bhim Tal spiders: the Rev. O. P. Cambridge reports that they belong to the Epeirids (*Viphielengys Malabarensis, Walck*). It is almost cosmopolitan, and is certainly met with in India, China, Australia, Borneo, and West Africa. He considers the silk very strong, and almost indestructible, but points out that since spiders devour each other it will be impossible to feed and cultivate them like silk worms without an unreasonable amount of trouble and expense.

The report contains, as an appendix, an account of a botanical tour made by Mr. Duthie to North-Eastern Kumaon. This journey involved the crossing of the Kalam Pass 18,700 feet above sea level. One night was spent in camp on the glacier at a height of 17,400 feet without fuel, and with a very scanty stock of provisions. The whole party suffered to a certain extent from the effects of the high elevation. One man thought himself so ill that he wished to be left behind to die when the party moved on next day, and Mr. Duthie remarks suggestively "a little more than coaxing had to be exercised in order to prevent his carrying out his wish." The inhabitants of the valley beyond the pass are mostly Bhutias. They have been hardly at all affected by Brahminism; have no family priests or purhbits; they worship the local deities, the presiding spirits of the mountain top and stream. Marriages result from the free choice of the young men and women, and are celebrated simply by a feast, seclusion of the women is unknown. They distil a liquor called "jan" from wheat, and take bouts of hard drinking. Their wealth consists of their flocks of sheep, goats, and yaks. They weave and sell woollen cloths, and act as merchants between Tibet and India, carrying borax from Tibet to Bamdeo, and bringing sugar, cloth, &c., from the Indian plains for sale in Tibet. A large number of plants of species which were either new or previously

unrecorded for Kumaon, were obtained, lists of which, with the elevations at which they were obtained, are appended to the report.

A feature of the Gardens, which seems worthy of imitation, is their use as a school for training gardeners. During the year, fifteen trained men left the Gardens for appointments in various parts of the country, on salaries of £10 to £15 per mensem. The distribution of men of this kind through the country cannot fail to have a considerable influence in improving the garden culture of the districts where they settle, by introducing the more scientific methods of horticulture which they themselves have learned at such thoroughly practical schools.—*Madras Mail*.

THE ENQUIRIES under crop diseases and blight show that nearly all our staples are affected by some kind of disease or other. Mr. Ozanne's remarks on the subject are thoroughly practical, and we have some hope that, in the not distant future, some remedies may be found to rid these crops of their pests.—*Indian Agriculturist*.

FRUIT TREES IN QUEENSLAND.—The following table of the growth of fruit-trees upon the selection of Mr. T. E. White (of Alfred Shaw & Co.), situated close to Cairns, is interesting as showing how fertile is the soil and genial the climate. None of the trees mentioned have been planted over two years. The cocoa-trees are growing without any shelter; the cinchona were not raised from seed, but were direct importations from Ceylon:—

	Ft. in.
Cinchona, up to	5 6
Mango, " "	11 6
Jack-fruit, " "	12 0
Cocoa, " "	3 6
Lemon, " "	9 0
Tamarind, " "	8 6
Gum copal, " "	7 0
Date plum, " "	9 6
Flacourtia, " "	11 0
Brazilian cherry, up to	5 0

—*Queenslander*.

INSECTICIDES.—Dr. Thomas Taylor, microscopist of the U. S. Department of Agriculture, read a paper in Washington in December, 1883, showing the value of naphthaline as an insecticide. The naphthaline experimented with was solid matter precipitated in barrels from the oil of tar, and was used in the form of a powder. Some of the powder sprinkled in a box was found sufficient to kill potato bugs, the winged phylloxera, the common house fly, ants, termites and beetles. Worms in flower-pots were driven out dead when brought in contact with the fumes of the gas given off by naphthaline. Frogs were killed by the same treatment, and animal life of all kinds was dealt with similarly, proving that naphthaline was an insecticide of great value. Other experiments showed that while it had this great power over insect and animal life it did not affect plant life injuriously. It could be placed in close quarters with the roots, the leaves, or the seeds of plants without destroying or materially affecting their vitality. Buried in the ground among the roots it would kill or drive away insect life or worms; shut in with plants it would effectually dispose of vermin, and perhaps cause a leaf or two to wilt, without doing any permanent injury; while put away with seeds for a year it would simply keep away all insect depredators and not in any way affect their germinating powers. This should be of great value in preserving seed, wheat maize—in fact, seeds of every description from the depredations of weevils. Dr. Bancroft has recently experimented in this direction with strong-smelling leaves, such as the leaves of the small-tri-tree to, at least, some purpose; but this naphthaline appears to be very strongly needed. It might do to preserve grain required as food for stock; still, it ought to be tried and a final conclusion reached—but for banishing weevils from seed of any description it should be invaluable.—*Queensland Agriculturist*.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Pen's London Price Current, December 17th, 1885.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.		QUALITY.	QUOTATIONS.	FROM BOMBAY AND ZANZIBAR.		QUALITY.	QUOTATIONS.

SPINEL AND GOLD AT WARRIAPOLLA.

From Mr. Fraser of Warriapolla, near Matale, we have received the following interesting letter:—

Warriapolla, Matale, 27th Jan. 1886.

Dear Sir,—It is curious how a coincidence takes place, and I now write to tell you that it was not until today, when I came in with a collection of some very peculiar and pretty coloured quartz lime rock (of which I had for long known the existence, but had only regarded as a mere freak of Nature, and had laid down as the foundation of some hundreds of yards of road) for the purpose of forwarding these stones to some friends, I happened to take up the *Observer*, and my eye rested on the article you give in your edition of the 26th January, mentioning Warriapolla as a spot where spinel had been found. It abounds here in large quantities, and until today I never knew it had any value. Once I found a piece of the size of a robin's egg and I asked a *jeweller* in Matale (if you can call these people by that term) what it was, and he told me that it was a ruby. My weak mind was unable to accept this statement, not having seen a blue ruby. I also found red crystals imbedded with the blue, but these I took to be the garnet—and so with no more thought on the matter the coolies continued building yards and yards of roadway with this sparkling stuff, and it has been all covered over with metal and gravel and lost to view. But the locality from which this bedding stone was gathered will still be found to abound in these bright blue crystals if they be searched for.

Mr. W. Tyder first noticed the peculiar crystal formation as of value when he was staying with me, and he showed me several other places where he thought precious stones must have been collected on the estate. A Sinhalese tells me now that I am reclaiming land which used in former days to be a rich source of precious stones to the natives who, after heavy rain, used to wash the sand of the river close to its banks, and they undoubtedly did obtain something, for otherwise I should not possess, as I do at the present time, a small packet of gold-dust, which years ago was washed out of the sands of the Warriapolla-oya, and sent to my father as a proof that gold existed in Ceylon, and on Warriapolla also. I am told by natives that this very portion of the river of which I now speak of was a continual scene of gem-hunters, and I myself have seen Moormen amusing themselves, as I thought catching fish. They may have found some other kind of fish, let us hope they did; for, at least, that, for a time, would keep them out of mischief.—Yours faithfully,

ROBERT H. FRASER.

It is no new experience, in mineralogical formations, that gems should be found associated with gold. So it was in Australia, and in that country roads were made and streets paved with rich gold-bearing quartz, a full generation before the Laird of Warriapolla indulged in the luxury of botoming his roads with spinel-bearing limestone, including probably, "full many a gem of purest ray serene." Mr. Fraser does not say how he ultimately disposed of that gem as big as a robin's egg. If perfectly transparent, uniformly blue and flawless, it would, probably, when properly cut, have been deemed as valuable as a red specimen of the same mineral, to which the name spinel ruby is given. Mr. Fraser, like Mr. Kellow, and probably a good many others, will now know what blue crystal, in

limestone mean and will keep a good look-out for large clear specimens of the gem, for gem it is, only second in value to the sapphire, when of equal purity and size. Of course, such gems are more easily got at in the beds of streams into which they have been washed than in the matrix, which must be mined and carefully broken up. On the other hand, regular mining may result in much larger and more regular finds of precious crystals, and, where the latter are not precious in the technical sense, their presence in quantity ought to give value to the stone as a marble. We mean to see how a hand specimen will polish, and we are sanguine that it will come out well. The result will be stated. Much of the country around Kandy, such as Haragama and the valleys of Dumbara and Matale, doubtless owe much of their fertility and probably a good deal of their insalubrity (for which Haragama and Rajawella were at one time notorious) to the large prevalence of crystalline limestone, and the soil and gases which result from its decomposition. Careful examination in the light of Mr. Kellow's recent discovery and Mr. Dixon's previous notice of the Warriapolla and Watagama formations, will probably establish the fact that a much larger proportion of our mountain limestones than any of us imagined are valuable as gem-bearers, apart from their varying, but in some cases rich, proportion of carbonate of lime. Of course, it is not gold which gives the beautiful golden colour to iron pyrites, but it is a fact that true gold is not unfrequently associated with iron pyrites. It is not our limestones alone which demand the careful examination of a mineralogist, such as is now employed by the neighbouring Government of Madras, but our quartz rock, some of which, especially on Mr. Blackett's property in Dolosbage, look very encouraging. Now that it would seem that gold in really paying quantities is being mined close by us, in Southern India, it would be well that the similar question in Ceylon should be settled once for all, even if in a sense the reverse of the existence of paying quantity. Our mountain limestones, which differ from and are economically less valuable than coral and shells, in consequence of the sometimes large amount of magnesia they contain, associated with carbonate of lime, are usually described as "beds overlying the gneiss" which is our principal primitive formation. But the truth seems to be that, very frequently, long veins of the limestone underlie the top ranges of gneiss, cropping out amidst the valleys and "foot hills." This will become apparent, on reference to Mr. A. C. Dixon's account of the principal dolomite beds or veins, which intersect the mountain system of the interior of the island:—

Dolomite beds. As far as I have been able to trace them during the time at my disposal, I find that these beds run through the gneiss in a somewhat parallel direction, striking generally N. W. by N. to N., and having various angles of dip from 10° to 40°.

I have indicated their position on the map. The first is one which outcrops a few miles this side of Balangoda, and runs N. N. W., occurring again at Hanuwala.

The second runs through Dolosbage and Maskeliya; probably the bed occurring at Billul-oya is continuous with this.

The third outcrops under the Great Western on the Great Western estate, and is continuous to the N. N. W. with the Wattegoda and Medakumbura dolomites, and probably also with the beds at Gampola and Kurunegala. A subsidiary bed—or it may be an outlier of this—occurs near the Passellawa rest-house.

The fourth bed outcrops largely at Wilson's Bungalow, Glen Devon, Dumbara and Matale.

The fifth occurs in the Badulla district. As in the gneiss we have a great many varieties, so also in the dolomites. They all contain carbonate of magnesia, which varies from 1 to over 40 per cent.

These limestones are very valuable for estate purposes as well as for building stone and building lime.

In colour they vary much, dependent on the numerous accidental minerals that occur along with them. Thus the specimens from Wilson's Bangalore are very dark; they contain pyrites, phlogopite, chlorite, epistote, &c.

A dolomite occurring at Wariapola on the Matale railway contains a large amount of blue spinel. Some of the crystals of these dolomites have large facets others small and of a granular texture. Many contain white translucent siliceous grains not easily distinguished.

A beautiful example of limestone of a somewhat peculiar tinge, due to the metal chromium, occurs beyond Kalaugoda, and often contains fine specimens of crystalline biotite—a magnesian mica. This limestone shews a very peculiar and characteristic weathered surface.

As we are writing, the following letter from Maskeliya reaches us with a small specimen of rock, similar to the Ambawella rock, but differing in the prevalence of small, white crystals contrasted with the blue:—

Theberton, Ambagamuwa,* Jan. 27th, 1886.

Dear Sir,—I send by this post a small sample of my limestone, as I see by the account you give in your issue of the 26th inst. of the stone found by Mr. Kellow, that mine is of the same description. I have it in my lime reef red, blue, green, violet and black, at least some of the limestone has black crystals the same description as the others in every way except colour. My children have found quite large pieces of red spinel which we have taken no care of, as Mr. Dixon told us they were only spinels and of no value. I have at times come across from the limestone really beautiful pieces full of these blue and violet crystals and other colours, but blue is the most abundant. Mr. Dixon did not think much of it and said they had something to do with copper and iron.

What an extraordinary Jan. rainfall so far in the month 7.32 against an average for the last 6 years for the whole month of 2.33 and a max. in 1882 of 4.64 and a min. in 1884 of 0.58 we had on the 20th inst. a shower at 4 p.m. in which 3.16 fell; the most we have ever had in 24 hours before closing the last 5 years, in Jan. was 1.50. The last wet Jan. was the year of excessive rain, 1882. Is 1886 also going to follow suit? Hope not. T. J. GRIGG.

P.S.—One of the boys smashed the other day a red spinel he found in $\frac{1}{2}$ inch square as he thought it was no use. I firmly believe if we had a good man to make a survey etc. in Ceylon, something would turn up of value to the island. T. J. G.

It is quite true that ordinary spinel is not of much value, but large, perfect crystals, especially if of ruby red colour, ought to be preserved and their value ascertained.

THE GOSPEL OF AGRICULTURE, NEW PRODUCTS, &c.

Not long ago I found a brother farmer in a very bad case. He said that it had actually come to it that a man could not make a living in this country, and if he could find anybody to give his land to he was going to hunt new ground. I was sorry for him for he did look powerfully long faced.

Says I: "Have you tried to make a living at farming?" "Have I tried?" he said with a look that indicated that I was a fool. "I have worked myself and folks nearly to death, and we have been getting poorer every year." "That is strange," says I, "some people do make a living right here in this country. I have not found it hard to do."

* Post town in Ambagamuwa, but dates in Maskeliya.—Ed.

After taking a long look at me, he said: "I carried my last cotton to market t'other day, and when I went to square up I was left in debt for meat and bread last year, and now I have got everything to buy this year. Them merchants just take all a poor farmer can make and then they ain't satisfied. We all work hard and have nothing, and we are always in debt. This is no country for a white man." As he said this his voice trembled and he shook. It made me real sorry; for he is a good, hard working man. Said I: "How do you manage, Zeke Pitkin; do you make a good garden and have plenty of vegetables in their season?" Looking down at his feet, he replied: "Do you reckon I have got nothing to do but work in a garden? I tell you it is all I can do to work my crop." "Well," says I, "you have been on the same place fifteen years—reckon you have got lots of fruit of different sorts to eat in the summer and fall and to put up for the winter." "I reckon I ain't. I need my land for my crop, and land with trees on it won't fetch a crop." "Do you raise plenty of Irish and sweet potatoes to do you?" "Plenty while they last; that ain't long?" "Do you keep cows to give you butter and milk?" "Sometimes." "Does your wife raise plenty of chickens and turkeys, and such like?" "How can she, when she has to help me with the crop?" "Do you make plenty of corn, oats and hay for your own use?" "Of course I don't, when I am obliged to put in a full crop of cotton to pay my debts and buy something to eat." Several fellows sitting round said: "That's what's the matter with Sallie." Says I: "Friends, I want to tell you what is the matter with Sallie, and Mary and Jane, and Tom and Bob and Zeke here, and all the rest of you. You say you can't make a living, and the truth is you are not trying to make a living. You are trying to make money by raising cotton to buy a living with, and there is no reason in that. Now, listen to me a little, for your own good: You and yours toil the year round to make cotton, and then you get your meat from 1,000 miles away; corn, flour, hay, and so on come the same way. The Yankees sell us their grass at a big price, and we work ourselves to death to kill grass. If you will do as I tell you, inside of three years every one of you will be easy." Several of them spoke right out and said: "Let us hear it." "Very well," I said, "go home, and tonight get your wives and children all round you, tell them just how you have been doing and how it has worked. Then say I propose to turn over a new leaf. First we will not spend one cent we can help—not a cent for tobacco, whiskey nor clothes more than is necessary. We will get cows enough to give us plenty of milk and butter, and we will attend to them, and we will get some cows and pigs and look after them. There will be a good garden and plenty of chickens raised. We will plant plenty of potatoes, corn and whatever is to five on. In short, we will go in to making a living first, and something to sell next. You will find all will agree to it. Then just stick to that for three years, and my word for it, you will never say again that a living can't be made in this country.

"Now if any of you doubt it come to see me, and I will show you that it can be done, and I will show you that it is done."

I saw that it took, so I followed up my ticks and said: "Now, friends, don't flinch, don't keep your trouble to yourself, and when it pinches you do not buy on credit, like your neighbours do and like you have done; don't give up. Just settle it with yourself and family, you will be free and you will come out right."

When I got through I thought the world was pretty good, so I shook hands all round me and said, "Good evening friends, I wish you success." As I walked off one fellow said, "I see it—his head is level;" and Zeke said, "you're correct for a fact."—*Baptist Record.*

TOON TREES NOT RESPONSIBLE FOR HELOPELTIS.

We are glad to see in the Transactions of the Horticultural Society of India the following commonsense reply to an ill-considered letter in which a tea planter traced "mosquito blight" to innocent toon trees:—

MOSQUITO BLIGHT.

The following letter from Mr. Johnson, of Jhakra Panighatta, was received in November too late to be read at the meeting for that month:—

"In a Report of the General Meeting of the Society held on the 25th October 1885, which I have only lately seen, I notice a letter from Messrs. Lloyd & Co. on the subject of Mosquito Blight on tea plantations, from which I gather that toon trees planted around or about the cultivation, are supposed to be the nurseries of the fly. From my experience of the blight (which is considerable), I don't think that any forest tree in particular can be said to be the breeding place of the pest.

In the first instance, I believe, the insects come in from the surrounding jungle, where the spear and other grass blades will be found to be punctured in a similar manner to the tea leaves.

When the insects invade the tea, they generally commence operations by some forest tree, but simply, I believe, for the shade these trees supply, as they appear to dislike the sun, and feed generally during the cool of the mornings and evenings, and I presume at night also.

In one of my plantations the blight generally begins in five places about the same time, two of these being shaded by Simul (Bombax Malabaricum), and the others by Palas (Butea Frondosa) trees, which do not seem in the least affected. It is a notable fact that the only division having a toon tree close to the cultivation has been hitherto the last to be attacked. The other plantation $\frac{1}{2}$ mile away has only four or five trees upon it, one of these being a toon, and the blight did not begin there this year till quite two months after it had appeared on the first-named cultivation, and then it affected the whole of the place, more or less, at once (not particularly by trees) as though the insects had simply waited in passing to lay their eggs, which, I may here state, are inserted by the parent flies in the succulent stems of the tender tea shoots.

The greatest damage to the tea bush, I believe, is caused by the young insect before it has wings, feeding upon the buds.

From the foregoing it would appear that forest trees of any kind in tea cultivation only do harm in that they give shelter to the insects during the heat of the day, and that plantations without forest trees are just as liable to be affected. We have yet to find out where the blight is bred in the first instance."

TAMARIND SEED OIL.

The following appears in the Proceedings of the Horticultural Society of India:—

Baboo Sosi Blushan Biswas, Editor of the Bharaj-Sraojivi, applied for information as to whether oil had been, to the knowledge of the Society, extracted from the tamarind seed. The Baboo was informed that the Society's *Journal* for 1856 seemed to contain the only recorded instance of oil being expressed from the seeds of the tamarind. A sample of this oil was sent in 1856 to the Society by Captain Thomas Davies from Boudana, who mentions that he discovered the seeds would yield an oil much to his own surprise and that of all the natives. He described the oil to be of a fine amber color, free of smell and sweet to the taste, and in his opinion suitable for culinary purposes. The Society's Sub-Committee reported favorably on the oil, and suggested that it might be found useful in the preparation

of varnishes and paints, as well as for burning in lamps. They considered about 110 a maund would be its market price, though this quotation would be no guide to us now.

A member of the Committee, Baboo Ran Gopaul Ghose, remarked that the tamarind seed (*Hyge beehchee* in Beogal) is mostly thrown away, in times of scarcity it is eaten fried to a limited extent by the poor, and a varnish for painting idols and finishing *Karpa* cloth, and *tatol* paper is also prepared from it, but the bulk of the seeds are thrown away. The Committee remarked that the oil had a smell similar to linseed oil, but Captain Davies subsequently explained that this was due to the mill in which it was expressed being one ordinarily used for making that oil. Babu Sosi Blushan Biswas has been asked to communicate further particulars as to the result of his own experiment.

INSECT PESTS OF INDIA are thus noticed in the Proceedings of the Horticultural Society of India:—An interesting correspondence under the above heading was recently published in the *Journal* of the Society of Arts, at the request of the Secretary of State for India. The correspondence is too long for a place in these proceedings but the following extract from Surgeon-General Edward Balfour's letter to the Secretary of State for India will convey an idea of the purport:—"Although every year, to some extent, and from time to time largely, losses occur there from the pests which attack agricultural produce, India has hitherto been remiss in this matter, contenting itself with references as to individual insects or blights to such persons as were thought likely to be able to give information. But the subject is of far too great importance to Agricultural India to be left to be treated in so casual a manner, and the special knowledge now available might be utilized to describe the insects which injure the agricultural, horticultural and forest produce of India, suggesting means of preventing, and remedies for the same." Miss Ormerod, who in England annually reports on the insects injurious to food crops, forest trees, and fruits, and the prevention of insect ravages, in writing to Surgeon-General Balfour, warmly approves of his suggestion, and remarks:—"The information that is needed could be given by plain and simple putting down by various persons of what they themselves have observed, and one man notices, perhaps, how deep the grubs go; another how long they live; and so by collating the facts, we get to know the whole history of habits, which is what is needed to work on. It may take a few years to get the whole life history of the insects, but we soon get in the way mentioned above (on which plan my own reports are formed) to learn the main points, and then all observers are requested to find the missing part of the history." The whole of the correspondence will be reprinted in the *Journal*. Members of the Society wishing to co-operate in the manner suggested in the above extract from Miss Ormerod's letter should send their names to the Secretary.

A CONTRIBUTION TO THE STUDY OF TRANSPARATION UNDER THE DIFFERENT RAYS OF THE SOLAR SPECTRUM.

A paper on the above subject by Rev. Professor Henslow was read at the Linnean Society on Thursday last, December 3rd. The experiments described were undertaken to test the results of Wiesner, who found (contrary to the opinion of others, who thought that the brightest rays of the spectrum were the chief cause of transpiration) that it was mainly due to the rays which are absorbed by chlorophyll. The spectrum of that substance reveals seven absorption bands, the most powerful of which are in the red, blue, and violet, and when plants were grown under coloured glasses Mr. Henslow, found just as Wiesner had done that transpiration attains to a maximum under the monochromatic red glass and under the blue and violet as well, while ordinary colourless glass gave another maximum. On the other hand yellow and green gave a minimum.

Wiesner's interpretation is that light thus absorbed by chlorophyll is converted into heat, and then it raises the temperature of the tissues, and so causes the formation of aqueous vapour. If this be true it would seem to account for Debrain's discovery that plants can transpire in a saturated atmosphere, and as a corroboration Wiesner found that light which had been first transmitted through a solution of chlorophyll was almost powerless to cause transpiration. A fact which Mr. Henslow could not account for was that while the red glass which admitted no other rays gave a maximum, the yellow glass which transmitted red and green rays besides yellow, gave a minimum. It would seem as if yellow had actually a retarding effect upon the other rays.

The method adopted by Mr. Henslow was to grow small Lettuces and other plants in miniature pots and by wrapping them up in a gutta-percha sheeting tied round the base of the stems all loss of moisture from the earth was prevented. Then he weighed the whole day by day after its having been under each coloured glass for twenty-four hours in succession. He thus ascertained the percentages of the losses, the means of which gave the results mentioned above.

Mr. Henslow also drew attention to the importance of distinguishing between transpiration and evaporation, the former being a vital action, the latter purely physical, and will take place from dead and living substances, but is modified or held in check to some extent by the latter. Thus if a leaf be cut in two, and one half suddenly killed by sealding it will be found that this one rapidly dries up, while the other loses water much more slowly. Again, thick leaves and older ones absorb more heat than thin ones and younger ones respectively, yet the transpiration is greater from young leaves and deciduous, contrary to what one would expect if transpiration depended solely upon heat.—*Journal of Horticulture*, 10th Dec. 1885.

NEW PRODUCTS.—Among the various samples of Borneo produce which Captain R. D. Beeston has sent to Melbourne per the barque "Ellen" is one of the vegetable tallow or vegetable wax (minyak tungkaw) which is stated on good authority to be the best lubricant for machinery that can be procured, and which combines economy with efficiency. There is no doubt but that this product if properly attended to will command a high price and be received with high favour in the Australian colonies, as while it is as good as palm oil, its price will never run to anything like so high as that commodity. Captain Beeston thinks very highly of it, and has particularly requested his Melbourne friends to have it thoroughly tested. We shall be happy to hear the result of the experiment.—*British North Borneo Herald*.

AMERICAN TEAS.—The Commissioner of Agriculture in his annual report states that the tea plants at the Government station near Summerville, is reported by the superintendent as being perfectly satisfactory. The plants are now large enough to afford during the early summer of this year leaves in sufficient quantities to warrant an effort at tea manufacture, if such an operation is necessary. That the Chinese tea plants can be grown over a large area of the United States, and that good teas can be produced of standard qualities from them is an established fact, but whether tea can be produced to suit the wants and requirements of the trade at a price that will be remunerative, is very doubtful. The Commissioner does not recommend any attempt to cultivate tea upon an extended scale until this fact has been demonstrated beyond doubt. Certainly the low prices which have been ruling for some time past gives very little hope that this country will be able to supply to any considerable extent the wants of the consumer.—*American Greener*.

NATAL PRODUCTS.—As to Natal coffee I have frequently drunk it, and about a month ago saw at the Queensbridge coffee works a couple of hundred bags of Natal-grown berries. It is not, however, very much cultivated, as experience has proved the climate is not altogether suitable, and, as Mr. Litton says, a disease attacked the trees a few years ago and played sad havoc with their growth. Coffee does not figure

among the exports, as what little is grown is consumed locally, in addition to large quantities imported from Brazil. Nothing can be said against the quality of Natal coffee. Cotton is not grown except in small quantities experimentally. Nutmegs, mace, cloves, and cinnamon are not grown here, the climate not being sufficiently tropical. Cayenne pepper to the value of over £500, and arrowroot to the value of £3,300, the produce of Natal, were exported during 1883. Wool (the produce chiefly of the neighbouring Dutch republics, the Orange Free State and Transvaal) to the value of £519,161 was exported from Natal during 1883, and other articles of colonial produce as follows:—Hides, £53,000; ostrich feathers, £14,900; maize, 19,000; ivory, £5,000; and Sugar (the chief industry on the coast lands) to the value of £122,000. Although the upland districts of the interior of Natal are well suited for dairy farming and for wheat-growing, it is a strange anomaly that nearly all the butter, milk, and cheese consumed in Natal are imported from foreign countries. Fresh milk retails at about 9d. per quart, and it is estimated that 2,000 one pound tins of condensed milk are used daily in Durban alone. All our flour is imported from South Australia. Our meat supplies in the form of beef and mutton are very poor as regards quality, and compare very unfavourably with that produced in Australia, and instead of Natal exporting preserved or salted meat, as stated by "P.L.," our butchers a couple of years ago were importing cattle from Madagascar. Fruit, such as pine-apples, oranges, bananas, mangoes, and grandillas, do well on the coast lands, and are grown largely. Pineapples last month were retailing in the streets here at 9d. per dozen. In the more elevated districts of the interior, apples, pears, peaches, and other English fruits do well, but the grape vine, which is cultivated so extensively in the Cape Colony, is not a success in Natal.—*Australasian*.

A REPORT ON CULTIVATION, MANURES, &c., at CAWNPORE has been sent to us by the Government of the N. W. Provinces of India, the main results being thus stated:—The manure experiments show that for kharif crops as for rabi cow-dung is perhaps after all the cheapest and most profitable fertilizer, as it is most certainly the manure most readily procurable by the Indian cultivators. In this kharif as in the last rabi a thorough inversion of the soil has proved decidedly advantageous compared with the mere piercing of the land with the native implement. It is in the end cheaper and gives a larger outturn for the labour worked. In the experiment Ridge-sowing versus Broadcast-sowing of cotton the country method comes off best. But a further test must be applied before a final verdict can safely be given. It appears plain that, under existing conditions of Indian cultivation, it is a distinct disadvantage to take two crops of cotton from the same plot. It is better to take the one crop and then plough up the land in the spring either for another kharif crop or a cereal in the following spring. New Orleans cotton failed. But there are other varieties which remain yet to be tried, and the successful introduction of an exotic cotton of a more marketable kind than the indigenous variety is not to be despised of. In regard to maize, which is a very important crop, it is proposed to attempt, in the coming kharif, the American method of sowing in "hills" or "squares." The secret of the success of this process lies in the free ventilation and sunlight secured to the plants. The success of the "hill" or "square" cultivation in America has been remarkable. The ensilage experiment is still on its trial. If the fodder proves really serviceable to working cattle, there seems every reason to hope that ensilage may yet become an institution in Indian farming. The whole cost of the silo up to packing and closing is less than the cost of digging and lining an ordinary kutcha well, so that on the score of expense the cultivator cannot well complain. The matter of ploughs is not an easy one. The same fashion of plough does not suit all soils and all sorts of cultivation. Experience, however, is being gained, and the Duplex plough will shortly be put to a practical test elsewhere.

CHINA SILK WORMS IN MADRAS.

The Director of Revenue Settlement and Agriculture, reports the results of the experiments made in 1883-84 with the 2½ ounce of silk seed obtained from Dehra Duh and distributed by his department as noted:—

	oz.
Eurasian and Anglo-Indian Association ...	5
Dr. Bidle for a Ceylon planter ...	½
Dr. Shortt ...	1
Collector of North Arcot ...	4
Major Pickance ...	2
Government Farm at Saidapet ...	8½
Total ...	21½

Large numbers of the worms reared at the Saidapet Farm died from starvation owing to the impossibility of obtaining a sufficient supply of mulberry leaves on the farm or from elsewhere; the deaths were chiefly among the big worms which were ready to spin. They refused to feed on anything but mulberry leaves. The experiment was, however, more successful than that of the preceding year, for the number of cocoons obtained relatively to the weight of the seed was 279 per cent more than in 1882-83. This is ascribed to the experiment having been made earlier in the season than was that of the preceding year. The worms thrive well during the cold season, but Mr. Benson remarks that unless a continuous supply of fertile eggs can be maintained locally, it will not be possible to engage in this industry with any prospect of success. The almost insuperable difficulties of providing in a climate like this a sufficient supply of mulberry leaves to feed the worms on—and mulberry leaves appear to be the only food that these varieties will touch here—make the enterprise of silk-breeding in Madras practically hopeless. The two ounces of seed supplied to Major Pickance yielded 5,921 cocoons, which gives a rate of 2,960 per ounce of seed against 2,884 at the farm. Three thousand four hundred and twenty-one of these cocoons, weighing 42 ounces, produced 5½ ounces of silk, or exactly one-eighth of the weight of the cocoons. The worms were fed on mulberry-leaves, and when the supply ran short lettuce leaves were substituted, but with what effect is not stated. Dr. Shortt's experiment with the one ounce of seed supplied to him was not very successful. The yield was only 410 cocoons, and only a very small quantity of silk was reeled off. The results of an experiment made by the Tahsildar of Palmanur, to whom some seed appears to have been supplied, were reported by Mr. Fawcett. One thousand five hundred and seventy cocoons were obtained, of which 1,460 were reeled, yielding 8½ tolas, i.e., about 3½ ounces of silk. The worms were very voracious and were fed on mulberry leaves.

A SUCCESSFUL DECORTICATOR.

Among the several decortiating machines on exhibition at the annex to the Main Building, or the Machinery Hall, is one entitled the Universal Fibre Decorticator, which is manufactured by the Remington Agricultural Company, and was invented by Mr. T. Albee Smith, of Missouri.

During the past month this decorticator has at times given displays of its qualities before numerous spectators, but on Thursday last it fairly astonished the seekers after fibre preparing machines who were so fortunate as to witness its performances.

The enterprising agent of the Remingtons, Major F. F. Hilder, anxious to test the capacity of the decorticator, had procured from British Honduras a quantity of *Bromelia sylvestris*, or silk grass leaves, banana and plantain stalks and henquin or sisal hemp leaves. It was generally known that the decorticator would be tested at 2 p.m., and quite a large crowd of experts was assembled, who were desirous of seeing it operate on green leaves. At length Mr. Smith placed several henquin leaves on the platform of the machine, which was set in motion,

and in a few seconds the fibre was perfectly cleaned, without any perceptible waste. The silk grass leaves and plantain and banana stalks were also operated with the same result. Kentucky hemp (both rotted and in an unrotted condition) was thoroughly divested of its woolly parts in one single and simple operation. The machine thus proved to the complete satisfaction of all who saw it work that it is, as it claims to be, a genuine universal decorticator.

Mr. Albee Smith, the inventor, expects to procure green ramie stalks before the Exposition closes, and will demonstrate to the public the ability of the machine to prepare ramie for market in one operation. Green jute stalks may not be obtained in time to enable the machine to show its ability to clean that fibre also. As the product of dried jute stalks is only fit for paper making, Mr. Smith does not care to bother with it.

The universal decorticator, therefore, claims to successfully operate all green fibre plants, whether leaves or stalks. As fibre extracted from stalks contains more or less resinous gum, it must go through another process after it is decorticated to secure complete disintegration. Mr. Smith asserts that the jute fibre decorticated by his machine, after being steeped in water for a week, becomes thoroughly disintegrated and is fit for market.

The display made on Thursday proves conclusively that Mr. Smith's machine can successfully decorticate green fibrous plants. It is the only machine on exhibition that has attempted to work green material. Persons desiring further information regarding this decorticator can obtain it by addressing to Major F. F. Hilder at the Remington exhibit in the Main Building, or at his office, 89, Poydras street, this city.—*Times-Democrat*. [We shall be glad to hear further about this machine, when it has successfully operated on Ramie or Rhea stalks.—Ed.]

SOAP AS AN INSECTICIDE.

Professor Riley, the State Entomologist of the Washington Department of Agriculture, has found, after a long series of experiments, that common soap is about the best and cheapest insecticide that can safely be used in gardens. Alcohol is too expensive, and volatile oils more or less injurious to plants; experiments with some of the latter, such as naphtha, turpentine, &c., having resulted in the total destruction of some orange-trees on which they were tried. Crude petrolcum, he says, destroys the bark; and even the refined oil in hot sunshine completely strips the tree of leaves. A mixture of kerosine with milk, which is subsequently diluted with water, was found to be apparently innocuous; but it requires trouble in the mixing, and care in using. The Professor makes the following remarks with regard to soap:—The value of soap as an insecticide has long been known; and the experiments which I tried which it were made chiefly for the sake of comparison with those made with other substances. The results, however, were so remarkable, that I feel warranted in saying that taking into consideration its efficiency as a means of destroying scale insects, its effect upon plants, and its cost, there is at this time no better remedy known than a strong solution of soap. In my experiments whale-oil soap was used, and the solution was applied by means of a fountain pump to orange trees infested with the red scale of California. In the strongest solution used the proportions were three-fourths of a pound of soap to one gallon of water. The mixture was heated in order to dissolve the soap thoroughly; and the solution was applied while yet heated to about 100° F. The tree upon which the experiment was made was very badly infested, the bark of the trunk being literally covered with scales. Four days after the application of the solution, I examined the tree very carefully, and could find no living insect on the trunk of the tree, and only a small proportion of the cocoons on the leaves appeared to be still alive. I was unable to examine the tree again

personally, but three months later Mr. Alexander Crow, of Los Angeles, made a careful examination of this and some other trees upon which we had experimented, and on this one he was unable to find any living scale insects. Taking into consideration the extent to which this tree was infested, and the fact that but a single application of the solution was made, the result is remarkable. In another experiment the solution was made as in the above, and then an equal amount of cold water added. The tree experimented upon was similar to the one used for the former experiment. Four days after the application no living insects could be found on the trunk of the tree and only a very few upon the leaves. In fact, the experiment was as successful as could be expected, it being very difficult to reach every insect on the leaves by a single application. When Mr. Crow examined this tree three months later he found but few living insects on it. As a result of all of my experiments with soap, I recommend the use of it in the proportion of one-fourth pound of soap to one gallon of water repeating the application after an interval of a few days. If a cheap soap be used which can be obtained for from four to six cents per pound, the cost of the remedy will not be great compared with what is to be gained.—*Indian Agriculturist*.

[Here in Ceylon, soap made from the coarsest coconut oil might be tried.—Ed.]

MORAWAK KORALE, RAKWANA AND KUKUL KORALE PLANTING DISTRICTS.

Rakwana is one of those districts that does not receive the attention it deserves, chiefly because it is neither near Colombo nor Kandy, and has not the advantages of railway communication. The climate is particularly healthy; so much so, that I do not remember ever hearing of a Rakwana planter dying in the district; he has usually left his salubrious hills for regions where his shadow has gradually grown less. This I would observe is a matter of no small importance to those who have to live many years in this island. Tea now is springing up on all sides: one favored estate expects 45,000 lb. of made tea for the current season and others expect considerable quantities. The soil of Rakwana appears to be particularly suited for tea; it is of almost any depth, and, if well selected, would equal in quality any district I know, being far in advance of most of those districts which are now the favorites. The difficulty here, as elsewhere, is the general one, insufficient capital; and not being upon any of the main routes, it never receives the attention it deserves, although its soil. I consider, superior to Ambegamva, and the probable cost of carriage to Colombo not more costly; yet the latter is more sought after. Its rainfall is about the same, and there is a good cart road right through it, from end to end, the extremity of which is only 96 miles from Colombo, the cost of transport now upon tea to Colombo being 1½ cent per lb. not weighed. Rice is at present sold at this spot by chetties at Rs-75 per bushel. The district is certainly somewhat difficult to reach from Colombo. A coach goes to Palmadulle, from whence the Rakwana bazaar is 16 miles by road. During the past few years, many acres of tea have been planted around this, one promising young estate being owned by an enterprising native. Like many other parts of Ceylon this never ranked very highly as a coffee district; although Palamcotta, Springwood, Deveronside, Caledonia and some other estates did well in olden days, and were above the average of coffee estates. These are now in a state of transition into tea, and will doubtless do as well, if not better, with this product, than will most of the old estates throughout the island. To the west of Rakwana is the Kukul Korale, where many thousands of acres of fine tea land lie; indeed, land suited for tea exists in thousands of acres from this on to Bentota. The blocks purchased 10 years ago for coffee lie at altitudes ranging from 1,500 to 3,500 feet, and are as a rule as healthy as Rakwana, and it is strange they do not draw more

attention. They have fair soil, good rainfall, and plenty of large streams for water power. Capital alone is wanted. Doubtless, when the tea enterprise receives more attention there will be a rush in this direction, but it will be at enhanced rates of purchase. Of these Southern districts, the Morowak Korale is the most advanced. Campden Hill is now a fine old property, and Hayes quite a picture, without its match in the island for a hill estate. I would strongly advise anyone wishing to invest in tea land to take a look round these Southern districts before he ventures into land elsewhere, for I am sure at present that he would obtain more for his money of good promising and lasting material to work upon than he could pick up elsewhere; whether he wants forest or an old estate with buildings complete to start upon.—(Cor. Local "Times.")

THE MASON COTTON HARVESTER.*

An interesting correspondence has just passed between her Britannic Majesty's Consul at Charleston, South Carolina, and the Secretary of State for Foreign Affairs, which has been communicated to the Government of India, relating to certain American inventions for the gathering of cotton, and the separation of foreign substances from rice and other grains. The first is a machine invented in South Carolina for gathering cotton from the plant on which it grows. It is called the "Mason Cotton Harvester," and it could be used in the cotton fields of India and Egypt. As the lateness of the season precluded the possibility of any exhibition of the actual working of the Harvester at the World's Fair at New Orleans, a committee of experts in cotton culture was appointed to test and report upon the practical efficiency of the machine at the home of its inventor, before the open cotton should have disappeared from the fields. This is what the committee say on the subject:—

"We devoted the whole day to the objects of our visit, and found Mr. Mason indefatigable in furnishing every facility for examination the most critical. He conducted us through every part of his workshop, not only explaining every part of his Harvester and Cylinder Gin, but the process of manufacturing the tools with which alone he could work.

"We are not called upon to report on the mechanical structure of the machine, but only upon its practical efficiency; and much curious information we derived from this investigation is uncalled for in this report.

"We were struck with the fact that every improvement made in the course of his experiments tended to simplify the machine, and its chief recommendation when now ready for work is its extreme simplicity, combined with strength and durability. The problem before him at the inception of his enterprise, and most pertinaciously adhered to through all his experiments, was to invent some substitute for the human fingers in picking the lint from the open bolls without damage to the stalk of the plant, its leaves, blooms, and immature bolls. This he has at last fully accomplished by means of rotating points or teeth—minute, but strong and durable—which will inevitably seize upon the fibres of the lint brought in contact with them, but so adjusted to the rotating surface as to pass harmlessly over every other form of matter. Fibres, and fibres alone, can reach these teeth, and once seized, the bolls to which they belong must follow.

"This we saw practically illustrated before our own eyes. The present cumbersome, box-shaped locomotive—joined, screwed, and bolted for any conflict with mules and negroes—in which the simple machinery was mounted and put in action by power derived from the rotation of the wheels of the locomotive, was hauled by a single mule over a long cotton row. Frost had more than once fallen on the upright stalks; the bolls were all open, with the cotton hanging to them loosely and limp. The limbs of the stalks

* Which, it is supposed, may be adapted as a tea-picker.—Ed.

and leaves were exceedingly brittle and crisp, yet as the machine advanced, we only missed the lint—stalks, limbs, and leaves remaining intact. Of course the lint, in being drawn from the bolls, came in contact with and adhered to parts of leaves almost pulverized. The shafts of the locomotive were attached to one side of the locomotive, so that the mule moved between the rows while the centre of the machine passed over the apex of the row.

"Of course the return trip threw the mule between the first and second row, and the machinery passed over the same row twice. After the return trip we noticed no change in the stalks, &c., but the lint was nearly all gone, safely stored in pendant bags. The result was wonderful—almost incredible to any but an eye-witness. It could have scarcely been subjected to trial under more unfavourable circumstances—those above mentioned and others that might be enumerated—and yet at each passage over the row about 50 per cent of the cotton there standing was bagged. Its almost intelligent selection of the open cotton, to the exclusion of almost everything else, was the most remarkable as well as gratifying feature. Those who have seen it work in a field with luxuriant weed, and on the first opening of the cotton, testify to this wonderful result. The seeded lint alone was gathered, while the blooms, leaves, and immature bolls were left uninjured. An intelligent planter from Mississippi, who witnessed its performance at this stage of the cotton plant, offered the highest prospective price for the machine for his own use in the present cotton crop. After close examination of the results, he gave it as his opinion that, with the machine then working and three good hands to follow and glean after it, he could do the work of forty hands a day.

"We take pleasure and pride in reporting that, in our opinion, this great South Carolina invention will prove a success. Mr. Mason himself, however, is not yet wholly satisfied. He believes that with better tools which he will soon have, all facilities for perfecting, he can render his machine still more effective. He is now aiming at gathering all the open cotton at a single passing over a row, and thinks he can do it. He is sure he can make all the parts adjustable, but doubts, from their present perfect state, whether he need improve the strength and durability of those already tested. He showed us several machines of various sizes already prepared for work, and pointed out several of his contemplated improvements, which none but a skilled machinist could appreciate. But the simplicity of true genius characterizes all its forms. The efficient parts are all made on the same model, and are all interchangeably adjustable. Any one part can promptly be replaced in the machine without derangement to the other parts. As it most necessarily fall into unskilful hands on the farm, this is vital to its success. The operator has only to retain his seat on the locomotive and drive his mule aright, and the machinery itself takes care of the cotton. The cotton gathered in this experimental trip of the machine was immediately transferred to the Mason Cylinder Gin, and promptly converted into lint ready for packing. Mr. Mason promises, as an adjunct to his machine, a cotton cleaner, which will remove all the light debris sometimes adhering to the cotton.—*Indian Agriculturist.*

METHODS OF POTTING.

Although the putting a plant in a pot appears at first sight a very simple process, and, indeed, is so with regard to plants of no very particular value, yet to many plants or families of plants it is doubtless of the first importance. Of what use would it be providing the best of garden structures, securing a sweet and wholesome atmosphere, &c., if our most delicate and choice plants were badly potted and their soils in consequence become sour and stagnant? And, to ask further, what was it in former days that caused garden pots in greenhouses to be so liable to a coating of green scum, and the plants so

particularly liable to the depredation of insects? Bad soils and bad pottings, doubtless, as predisposing causes.

One of the first improvements that took place in modern potting processes was the use of coarse and turfy materials instead of the finely riddled composts of former days. About the period of this advance people began to turn their attention to the make of garden pots also, and it was speedily discovered that the pots which had been so long in use were anything but faultless. Thorough drainage; as a principle in potting was speedily a growing question, and received the utmost consideration from practical men in all quarters who were well up in their profession. These great improvements doubtless received an extra impetus through the introduction of so many choice plants, many of which, especially some of the finer-rooted, commonly called New Holland plants, showed evident signs that they would not thrive under the old system. The commencement of the exhibition era also much facilitated progress of the kind, and now it may be said that British gardeners can grow, in the very highest perfection of which it is capable, almost every plant placed in their hands, from whatever climate or under whatever conditions in its own locality.

The first thing I would direct attention to is two modes of potting quite distinct. I do not say that there are but two ways, but, for the sake of simplicity in the affair, we may at once reduce them to two modes: all others are in the main modifications of them. One may be characterised as loose potting, the other as firm or close potting. The loose mode is applicable in the main to annuals and softwooded plants, and, I may add, to most plants of what may be called ephemeral character. The latter class are required to make their growth as speedily as possible, in conformity with their habits and the services they are qualified to render; the former class requires durability in the texture of the soil rather than rapid excitement.

Now, plants of these two classes ought to be potted very differently; and, in order to illustrate the matter, let us take two plants, a Balsam and a Heath. These two everybody is familiar with. In potting the former a compost is generally used, and this, in the ordinary language of gardeners, means a mixture. When such is used it becomes necessary that, in order to have it uniformly mixed, the soil be passed through a riddle or sieve. This compost is filled in lightly round the Balsam plant, and a shake or two, with a very slight pressure perhaps in filling, makes all right; but in shifting a Heath this process will not answer so well by any means. Here the skilful cultivator, after procuring his sandy and fibrous heath soil in a dryish condition, breaks it up into lumpy fragments, and these he places around the ball, packing them somewhat lightly, some even thrusting fragments of stones amongst the turfy material. As for the finer particles which fall out in the handling, he uses little of this but to coat the surface over.

As to watering newly potted or shifted plants, I may just show that this differs as much with these two classes as the potting or shifting process. The Balsam alluded to would in most cases benefit by a good watering with a fine-raised pot; but the Heath would require some extra caution. Most of our hard-wooded plants when repotted require that their ball of earth should be in a moist condition—not wet, but equally moist throughout. This secured, and the potting performed somewhat similarly to the Heath before alluded to, light waterings, not over-frequent, with the spout of the pot will prove most suitable. When I pot *Camellias* I always make a point of so dressing up and pressing the surface of the new soil in the pot as to leave the stem in a small concavity. This induces the water when applied to penetrate the old ball, a thing I hold to be of much importance until the new soil is filled with roots, when the surface may be made perfectly level. Many a valuable hard-wooded plant is ruined by loose potting, the water in such cases rushing through the loose soil to the

entire desertion of the old ball, the loose soil being speedily converted into a kind of mud.

I have before alluded to the use of very fibrous soil as one of the chief improvements in modern potting; let me here caution the young beginner against potting with wet soil. If soil in a wet state must be used, then all my advice about firm potting falls to the ground. My practice is this—Turf or fibrous loam, having lain about six months in the compost yard, is chopped down when very dry with a sharp spade, leaving lumps the size of a large potato in it. This being well handled a considerable proportion of the more loose soil falls away, and this is put aside for ordinary purposes. The turfy material is now housed, no riddle being used; and this will for months in the potting-bed if in a body, and prove always in excellent order for potting. Heath soil, peat, &c., are served in a similar way; and such materials in such a condition are qualified, either singly or in composts, to provide for every need in the plant way.

I must now recur to drainage matters. Here, again, practical men make a difference. Annuals, and many softwooded plants which soon come to perfection, require a very moderate amount of ceremony of this kind. A crock carefully placed over the hole, and over that a layer of the coarser materials of the compost, will generally suffice, although I usually throw a little charred material over the crock, or a piece of moss. When, however, we take the more delicate of the hardwooded class, specimens which have to remain a long time in their pots, and, indeed, plants of various kinds which are known to be somewhat shy rooters, the case is very different. Even in Camellia potting, for my part, I deem it expedient to be very particular; strange it is that some of our continental neighbours think and act so differently, for I have lately read that they are in the habit of simply thrusting a lump of turfy peat in the bottom of the pot, and also pot their Camellias almost entirely in peat. But it must be remembered that to grow young stock into a smart, saleable appearance, and to sustain large specimens in high blooming condition for many years, are two very different affairs. There can be little doubt that much of the failure so frequently complained of in Camellias, when in the hands of amateurs and small cultivators, arises in no small degree from the mode of potting them. Razors made to sell and razors made to cut are two very different things. I find also that where liquid manure is frequently used there is the greater need of sound drainage, as, under the best of circumstances, it has a tendency to close the interstices of the soil, especially if fine soil be used. I, however, bid utter defiance to this tendency by the use of very turfy and lumpy soil.

After all the care we can use in potting processes we may remember that it lies in the power of an ignorant and heedless waterer to nullify all our efforts in a very few weeks. This is a most serious consideration. The worst of it is that we scarcely know how to offer a rule to those who are careless or ignorant. A thoughtless person can never be relied on for watering; but the term "thoughtless" will scarcely express what I mean, for we have no cases of thorough mental inattention in those who labour with their hands. What I really mean is this—that no person can water plants well unless he actually cares for their welfare. Absence of mind is, therefore, here an unfortunate affair. One piece of advice may here be given to the uninformed. When plants are established in their pots, and require water, let them have a thorough watering, unless some special reason exists for dealing otherwise with them. Plants growing fast or blossoming heavily generally require more water than at other times; and plants sinking into a state of comparative rest, possibly shedding a portion of their foliage, bulbs, &c., require a very moderate amount of moisture; indeed, in many cases, none at all.

One other great feature in modern plant culture is the constant war that is sustained against the in-

sect enemies of plants. On this, however, it is no part of my present purpose to dwell; I merely point to it as dividing the honours attached to the high success of these times with good potting and watering. But I would observe that there is such a thing as predisposition in plants or families of plants to insects, and that one of the most fertile causes of this predisposition may be found in abuse of the root-action through bad soils, bad potting, and bad watering.

I would here beg the earnest attention of all inexperienced plant cultivators to a close consideration of the before-named principles, and suggest to them that the general health of plants is more dependent on the soil, and, in consequence, the root-action, than upon any precise amount of heat, or, indeed, any of those little collateral matters which are, as it were subsidiary to high culture, and recommend that a due attention be paid to the potting-shed and the conservation of soils.—R. E.—*Journal of Horticulture.*

FOR SPRAYING TREES.—There is no doubt whatever but that our citrus trees need occasional spraying to clean them of scale bugs of one kind or another, even if of no more dangerous sort than the soft scale, and a very good whale oil soap can be made for the purpose, of the following ingredients:—

Concentrated lye..... 2 pounds
Whale oil..... 1 gallon
Water..... 5 gallons

Boil until united, and you will have six gallons of soap, at a total cost of about 65 cents, or 1½ cents a pound. The regular price charged for this soap is from 5 to 10 cents per pound by dealers. The above recipe for making this soap is from Santa Clara County, and is largely used there. When applied, add from three to five gallons of water. With only three gallons of water added, the mixture will be too strong for foliage, but with five gallons of water the foliage will not be injured. If coal oil is used it should be added to the warm soap before reducing with water. There is very little additional labor to the fruit grower in making his own soap. In any case it must be warmed before application, and it is not much more trouble to make it than to warm it.—*Rural Californian.*

GOVERNMENT CINCHONA PLANTATION, MADRAS.—M. A. LAWSON, Esq., Director of Government Cinchona Plantations, Parks and Gardens, Nilgiris, explains to the Secretary to the Madras Government, the causes which have led to the so marked a fall off in the receipts. *First.*—In former years when the cinchona industry was in its infancy, and a large number of plantations were being opened out by private growers, there was necessarily a very large demand for cinchona seed and cinchona young plants; and, as the Government plantations were the oldest and most noted in the district, the growers naturally applied to Government to supply to their needs. This went on for several years, until the new plantations were able to supply their owners, with what Government before had only been able to produce. Again, these new plantations are now able to compete with the Government in the sale of seed and plants. *Secondly.*—Owing to the great depreciation which has recently occurred in the value of cinchona bark, the public have been deterred from increasing their plantations, or from opening new ones. The general result of these two above-mentioned circumstances has been a very small demand for Government seed and plants. The following table shows the miscellaneous receipts for the past eight years:—

	Year.	Amount.
		RS. A. P.
During	1877-78	2,321 2 3
"	1878-79	8,336 9 2
"	1879-80	12,300 6 7
"	1880-81	13,175 4 8
"	1881-82	6,048 1 5
"	1882-83	4,200 7 10
"	1883-84	4,352 6 8
"	1884-85	1,527 10 5
	Total	52,562 1 0

POLISHING WOOD WITH CHARCOAL.

The method of polishing wood with charcoal, now much employed by French cabinet-makers, is thus described in a Paris technical journal:—

All the world now knows of those articles of furniture of a beautiful dead black-colour, with sharp, clear-cut edges and a smooth surface, the wood of which seems to have the density of ebony. Viewing them side by side with furniture rendered black by paint and varnish, the difference is so sensible that the considerable margin of price separating the two kinds explains itself. The operations are much longer and much more minute in this mode of charcoal polishing, which respects every detail of the carving; while paint and varnish would clog up the holes and widen the ridges. In the first process they employ only carefully-selected woods, of a close and compact grain; they cover them with a coat of camphor dissolved in water [?] and almost immediately afterward with another coat, composed chiefly of sulphat- of iron and nutgall. The two compositions in blending penetrate the wood and give it an indehible tinge, and, at the same time, render it impervious to the attacks of insects.

When these two coats are sufficiently dry, they rub the surface of the wood at first with a very hard brush of couch-grass (*chiendent*), and then with charcoal of substances as light and friable as possible; because, if a single hard grain remained in the charcoal, this alone would scratch the surface, which they wish, on the contrary, to render perfectly smooth. The flat parts are rubbed with natural stick-charcoal; the indented portions and crevices with charcoal powder. Alternately with the charcoal, the workman also rubs his piece of furniture with flannel soaked in linseed-oil and oil of turpentine. These pouncings, repeated several times, cause the charcoal-powder and the oil to penetrate into the wood, giving the article of furniture a beautiful color and perfect polish, which has none of the flaws of ordinary varnish.—*Indian Mercury*.

RUSSIA AS A TEA GROWER.

According to information which has reached us from the Caucasus, Russia has decided to commence the new year with an effort to become her own provider of tea. For some time past the Government has been looking out for fresh industries to make up for the growing depression of the corn trade. Acting on the advice of experts, it has decided to start a tea plantation at Soukhum Kalé, and import a shipload of Chinese coolies to work it. That tea can be successfully grown in the Caucasus is a point which is already settled. Some years ago the British Consul at Tiflis grew a quantity of tea, and during the course of last summer a German succeeded with a number of shrubs imported from China. But although small experimental efforts have resulted in establishing the fact that tea can be cultivated in the Caucasus, it is yet to be demonstrated that it can be grown on a large scale at a price that will enable it to compete with the Indian and Chinese article. The home market is a large one. The Russians are notorious tea drinkers, and import yearly 72,000,000 pounds of tea, valued at £6,000,000. Of this quantity half is conveyed to Russia overland, across Siberia, and half borne by sea to Odessa and to Cronstadt. In either case the foreign article would be at a disadvantage in regard to the Caucasus tea, owing to Soukhum Kalé being only a couple of days' run from Odessa. On the other hand, labour is scarce and dear in the Caucasus, and the clumsy *monjil*, if imported, could never compete in the hot, moist valleys of Transcaucasia with the coolies of China or India. Further, for plantations to be established on a large scale, foreign capital would be needed, and that is precisely a commodity which refuses to patronise Russia just now. Altogether, therefore, the chances of Russia becoming a great tea grower in the immediate future do not seem very promising. Still the experiment is to be made, and India and China tea-growers will naturally watch the operations of the Russian Government at Soukhum Kalé with interest.—*Deal Chronicle*.

GOSSIP ABOUT COFFEE.

An enterprising American has taken out a patent for a process invented by himself for preparing a substitute for coffee, which is said to deceive even good connoisseurs. He uses for this purpose various sorts of grain, beans and others, besides an extract of willow bark. There is nothing new under the sun. The sharp American may have invented a mixture of his own, it is sufficiently known that coffee is imitated in all manner of ways, and there is no lack of inventiveness in the way of substitutes, adulterations, etc. Where lies the fault? If there is indeed reason to complain of over-production of coffee, then it is clear that the efforts of the pro-ducers ought to tend to the reduction of the cost-price. Genuine coffee will, of course, be always preferred to the best imitation, and only lower coffee-prices will be able to drive substitutes from the market. But ordinary sorts of coffee are at present low in price, and nevertheless the imitation industry flourishes here and there—only think of Date coffee, Lupine coffee, etc., and alas! of another industry that applies itself to adulteration and mixing. Did not a sly fellow at Paris some years since on being indicted on the charge of adulterating coffee, go so far as to defend himself on the plea that he defied any one to find a single grain of coffee in his product!

It is wanted absolutely to provide an article that approaches coffee as near as possible in taste, and by its cheapness be within reach of the humblest, then we come to the question whether the producers in Java could not provide this. It is known that here and there in Java, and in Sumatra too, coffee-leaves are also used. These will no doubt answer the purpose better than an extract of willow-bark, in which the *salicin* would have to do for the *caffein*, which is indeed present in the coffee-leaves. So also the tannic acid of the coffee-leaf will be opposed to the tannic acid of the willow-bark.

It would not do to strip fruit-bearing coffee-trees of their leaves to manufacture a substitute for coffee; but without damage green coffee-leaves might be collected from exhausted or barren-trees. If to these leaves the coffee-shells were added—the idea is not quite new—one might probably obtain a mixture that would at any rate be harmless, and remind you of coffee, though not to be sure of the finest quality: we should then have only to look about for the most fit and attractive form.

The Trade judges of the coffee by its external appearance, and colour is the chief criterion. This is a pity, because the colour does not exactly rule the flavour; one region prefers fair, yellow, or brown coffee, while another gives the preference to blue or green. There is no answering for tastes. But these various claims again give rise to all sorts of malpractices. There are some estates, where it is made an object to produce any colour that may be wanted. Is there any reason to blame them for seeking their own profit? None in the least. It is the fault of the consumers, who are ignorant of the intrinsic value of coffee, and stick to some particular colour, because it has a reputation. It is true, for a judge the colour has some value but the uninitiated knows it not; he only judges by usage, prejudice and so forth.

Yet not all the processes for colouring coffee are harmless, for colouring agencies are sometimes used that are anything but innocent. But the practice, also prevalent in Netherland, of exposing the coffee to a high moist temperature in rooms arranged for the purpose to secure a deeper colour of a flow or brown, is from a hygienic point of view, I believe, unimpeachable. It is even pretended, and it is very possible, that the coffee even improves intrinsically by this process.

The coffee-planter ought to make himself thoroughly acquainted with the claims of the consumers in different countries. It is then highly probable, may cert-ly, that he will discover the means of ways of enhancing the value of his products. From the Government stores, especially, coffee is sometimes brought to

market and sold at very low prices, which, in the hands of business men, fetches immediately a much higher value, because they know eminently how to speculate on what we might call "the fashion." Let the planters attend to this and derive the profit themselves. They know very well what an influence the preparation, the barning or storing, etc., have on the appearance of the coffee, and they are entitled to exercise this influence in their own interest, which can and will be done without any mystification. A good assortment is of great moment, when you once know what is desired. In this respect the brokers are the best instructors.—V. G.—*Indian Mercury*.

SILKWORMS OF ASSAM.

The following particulars are obtained from a Report on Silk in Assam by Mr. E. Stack, Director of Agriculture in Assam, which contains a complete description and account of the rearing of three domesticated silkworms, two of which have been erroneously considered by English silk-spinners as wild silkworms; these are the *Muga* and *Eri*, which, although they may, like other species, be found in a wild state, are not found in sufficient quantities to be called wild silkworms of Assam; they are cultivated worms.

The wild silkworms of Assam occur so sparingly, that no silk could be supplied in large quantities from the collecting of the cocoons. Silk in Assam are, therefore, obtained by the cultivation of three domesticated worms, and not from the wild silkworms. Mr. E. Stack says that in treating of the silks of Assam it is desirable to make it clear that, from the wild silkworms of Assam, as they now exist, nothing whatever is to be expected, and that it is very doubtful whether by the most strenuous efforts one hundredweight of wild cocoons of all sorts could be collected in the whole of the Assam valley.

Domesticated Silkworms of Assam.—There are three kinds of domesticated silkworms in Assam. These are the *Pât*, or mulberry worm (*Bombyx textor*); the *Muga*, or sun-feeding worm (*Antheraea assama*) whose cocoon, like that of the *Pât* can be reeled; and the castor-oil worm (*Attacus ricini*), yielding a silk which is spun by hand.

Pât, or mulberry silkworm.—Of this there are two species cultivated in Assam; the univoltine *Bombyx lector*, called *bor polu*, or large worm, and the multi-voltine *horn polu*, or small worm, *Bombyx crassi*. Both species are reared indoors on the leaves of the mulberry (*Morus indica*).

Attacus ricini.—*Eri* worm, or *Attacus ricini*. This is reared principally on the castor-oil plant (*Ricinus communis*), called *eri* in Assamese, but it feeds also on the *Kisera* (*Heteropanax fragrans*), and there are several other trees, as *antacha* (*Jatropha curcas*), the *gomiri* (*Gmelina arborea*), and even it is said, the common *bagri* or *ber tree* (*Ziziphus jujuba*), which the worm can thrive on in its later stages, if other food is not procurable in sufficient quantity. The *Eri* worm is multivoltine, and is reared entirely indoors, and as many as eight broods can be obtained in twelve months. Large numbers of worms are lost by disease during these indoor rearings, which is not to be wondered at, as the excreta and even the dead worms are not removed. The *Eri* worm is cultivated, to a greater or less extent, in every district of the province of Assam.

The number of moultings of the *Eri* worm is four, and the following description of it is given by Mr. Thomas Hutton in a paper which he contributed to the Proceedings of the Asiatic Society of Bengal for 1837:—"The caterpillar is first about a quarter of an inch long, and appears nearly black. The colour is, perhaps, more exactly described as a blackish-yellow. As it increases in size, it becomes of an orange colour, with six black spots on each of the twelve rings which form its body. The head, claws, and hollers are black; after the second moulting, they change to an orange colour; that of the body gradually becomes lighter. In some approaching to white, in others to green, and the black spots gradually become the colour of the

body. After the fourth or last moulting, the colour is a dirty white, or a dark green. On attaining its full size, the worm is about $\frac{3}{4}$ inches long." According to one series of observations, it would appear that in the hot months the first change of skin occurs three days after hatching, and the rest follow at intervals of three days, while the worm begins to spin on the fourth day after the final change, or the fifteenth day after hatching. In the cooler months, the period between each moulting is four or five days, making twenty to twenty-five days between hatching and beginning to spin; and in the winter season, the worm lives a whole month, or even longer.—*Journal of the Society of Arts*.

ADVANTAGES OF BEET SUGAR OVER CANE SUGAR.

- The great advantages that the continental agriculturist and manufacturer have over the Colonial are:—
- 1st.—A plentiful supply of willing *hauda* to labour at moderate wages.
 - 2nd.—Short time necessary for raw products to come to maturity.
 - 3rd.—Favourite crops to rotate with beet and a climate suitable for growth of cereals and potatoes, feeding of stock, &c., &c.
 - 4th.—The roots of such a texture that they can be easily manipulated, while the residue is of considerable importance as cattle food.
 - 5th.—Cheap fuel, with proximity to the best and largest market in the world and low freights.
 - 6th.—Climate of Europe more favourable for working saccharine solutions owing to absence of ferment germs, rendering the manufacture so much more simple.

- On the contrary the Colonists have to contend against:—
- 1st.—A sparse population who, in the absence of a winter and all inducement to lay by something for old age, cannot be depended upon for any continuous labour; hence necessity of importing strangers at a great cost to prosecute the sugar industry.
 - 2nd.—The sugar cane takes from 12 to 16 months to come to maturity, and is accompanied by a luxuriant growth of weeds. In a tropical climate much labour is required to keep these down, and also to promote the circulation of air and allow the sun to penetrate among the ripening canes.
 - 3rd.—Absence of any crops other than plantains to rotate with canes, and as the former are perishable, and the home wants limited, they could only be grown at a loss.
 - 4th.—The flinty texture of the sugar cane stalk and its being as yet only of value as fuel, militate against any process of manufacture that would destroy its value as such.
 - 5th.—The nearest market in which they can purchase coals is Great Britain, and freight and charges, raise their cost to 36s. and 37s. per ton before they can be delivered at furnaces. Freight home is also high.
 - 6th.—The necessity of manufacturing the cane into sugar immediately after being cut, as immediate deterioration sets in—all saccharine running into acidity and fermentation.

ADVANTAGES OF CANE SUGAR OVER BEET SUGAR.

- 1st.—A larger weight of cane can be grown on a given area of land, and at a cheaper rate than beet roots. 18 tons of sugar cane per morgen are grown with good tilage at 12s. 6d. per ton—best costs 12s. 11d. per ton, and produces 10 tons per morgen.
- 2nd.—The sugar contained in the sugar cane is of greater purity than is found in the beet, hence less loss in purification, and the finished cane sugar is on an average 6° higher in analysis, and brings in to the manufacturer at least 2s. 6d. per cwt. more, even after allowing for the extra cost of freight from Demerara, as compared with that from North Germany to this country.

3rd.—Beet sugar must be sold as made, and is often forced on the market at unfavourable times, because it suffers heavily from increase of glucose if stored, and a heavy penalty is exacted for delivery of any but fresh-manufactured beet-crystals. In Paris, at present, beet crystals of old crop are almost un-saleable.

Weighing all these pros. and cons., it is evident that the two industries are very evenly balanced, and that those of the sugar cane planters who are in a position to avail themselves of the very best appliances in manufacture might, under improved conditions of labour, look forward to times when they would hold their own against their formidable rival. One thing is evident, and that is, that strict economy must be practised in our colonies. The days when sugar at £25 to £30 could stand the enormous public expenditure which characterised some of our leading West Indian Colonies are past, and both governors and governed must be prepared to reduce taxa and expenses to the extent required for producing sugar at one-third less cost than hitherto.—*Sugar Cane.*

THE OLIVE AND ITS OIL.

BY THOS. WILSON, U. S. CONSUL AT NICE.

The olive tree is of the highest antiquity. It appears on the earliest page of written history in the leaf which the dove brought to Noah in the ark as evidence of the receding waters.

It held the highest rank in the ancient mythology. Minerva taught the Athenians its uses. The peoples of antiquity held it in great respect, and used its oil in their various religious ceremonies. It was at once the emblem of holiness and peace. The Romans refused to burn the wood, even on their altars.

The olive was brought from Egypt to Greece, and from thence spread over the countries where it is now grown.

It flourishes best in the basin of the Mediterranean Sea, between 35° and 45° north latitude, though this, as I have stated, will, owing to the difference of temperature on the same parallel, be but an uncertain guide in the United States. The oil produced on the African shore of the Mediterranean is inferior to that of the north shore.

Some of the islands of the Grecian Archipelago and the Adriatic produce fine oil, but the centre, both for quantity and quality, so far at least as concerns commerce, is at Nice and the surrounding country. From St. Tropez to Savone generally, but chiefly from the Var to the Roya, from Cannes to Vintemilli, the best oil is produced.

Here the trees have been indigenous since before the Christian era, and here they grow to the largest size and the greatest age. One at Beaulieu, in full vigor and bearing, twenty-two feet in circumference, and is supposed to be seven hundred or more years old.

The slower the fruit ripens the better oil it makes, but as it must be fully ripe and entirely free from blemish to make the choicest oil, and as it requires two years to come to perfection (the crop is only biennial), one can easily comprehend the dangers of climate, season, malady and accident which must be avoided, and the difficulties which must be overcome in order to obtain final success.

To accomplish this with a plant so tender requires a climate and situation of peculiar adaptation, and unless this is secured only attempt at its cultivation will be fruitless. The fruit freezes at 23° F. and the tree 16°. Once frozen, no remedy exists; the tree is destroyed, and must be cut down.

It speaks volumes for the climate of this region to say that the olive trees have grown successfully for the centuries I have indicated.

If the weather be too warm and the land too rich, the fruit ripens too fast, and its good taste is gone. If, on the other hand, it should become too cold, fruit and tree are both destroyed. Possibly I can do no better than answer the question propounded in the circular to which this is a response.

There are sixteen or seventeen different kinds, each with its botanical name, which have been grown in this region, but nearly all as exotics. The tree in common use is the European olive, and all the information given concerns this. It gives the best oil.

The tree begins to bear fruit at ten years of age, but it does not come to maturity until from thirty to fifty years.

For the olives of commerce—that is, to eat, either fresh or pickled—the young tree produces the best result; the mature trees produce the best oil.

The reproduction of the olive tree may be accomplished by all the modes known for trees. The best mode—planting the seed or pit—is practiced here at least. The people prefer planting the sprouts which come up from the roots of the tree, or which may be artificially made by bending a twig and covering it with earth until it has taken root. At the age of two years this stock may be grafted, or the operation is more like that of "budding." The graft is cut all on one side and introduced under the bark, then bound up in moist earth and allowed to grow. The stock above the graft is cut off.

The earth around and between the trees is tilled each year, and a crop, sometimes of wheat or beans alternately, planted in the spring and gathered in the autumn. The earth is manured every two years, and the trees are pruned every four years.

It is the same tree and the same fruit for oil as for commerce. But the best olives for commerce grow on the young trees; they are larger and plumper, and by selecting the fruit they obtain the finest quality, which are then preserved for commerce. There is a species grown at Nice for which is claimed a superiority of taste and fragrance. It is distinguished by a small black spot on the blossom end of the fruit. These olives are eaten in the country when ripe, are semi-dried and slightly seasoned with salt.

TIMES OF FRUIT GATHERING.—The trees begin to bear at ten years of age, but they do not reach their full capability or maturity until from thirty to fifty years. They continue fruitful for two and a half or three centuries. This is for grafted fruit. The wild olive lives and bears until twice that age. In Provence and other countries not so well adapted to them, they commence earlier and also die earlier. The trees are smaller, and the fruit can be picked by hand. There the crop is annual, the harvest being in November and December, while in Nice and surrounding country the harvest is biennial. Here the blossom or flower comes in April or May, and the first fruit, consisting of the smaller and inferior, is gathered in November and December, the better in January and February and March, while the best (for oil) is the last, in April and May. It produces the best oil when it ripens slowly, and, in some exceptionally good years, the harvest is continued into June and even July. The tree then recuperates until the following spring, when it flowers again. An olive tree, even here, would bear a crop each year if so permitted, but the "whipping" necessary to gather in the fruit destroys the blossoms, which do not come again until the next spring.

The trees are planted from each other at a distance varying from 10 to 15 yards each way. The larger trees require larger space, and the larger the trees produced. The trees need sun and air, and if crowded it will be to their detriment. This would permit, if I have figured aright, 40 to 50 trees to one acre. But they do not calculate by the acre, for the trees are planted on the hill-side, usually on made terraces impossible to plow, cultivated with the spade, and it is difficult to get an acre of olive trees together. In poorer soil and on the hillside the trees may be a lesser distance apart, even reducing it to six or eight yards.

The difference between olive trees in their product is as great as between apple trees. But the average production per tree, biennially, may be stated thus:—In fruit, from 60 to 120 liters; in oil, from 8 to 12 kilograms, or 12 to 15 liters.

no inducement, there is no economy in storing and using farmyard manure—it is a superfluous labour; but in all populous countries, and notably in our own, where the soil has been reduced by centuries of cropping, the basis of farming is the manure heap. Although in these days, importation of artificial manures has made farmers less dependent on farmyard manure than formerly, yet it is still, as of old, the central system of the farm, and its careful manufacture, preservation, and use are more than ever deserving of careful attention.

Farmyard manure consists of the solid and liquid excrement of animals, combined with the straw or other substance used as litter, and when fresh consists of about one part solid matter and three parts water. About one-half of the total dry matter contained in an animal's fodder is found again in the manure, so that it is easy to estimate approximately the amount of manure produced upon a holding in ordinary circumstances when the amount of dry matter contained in the fodder is known. For every 1,000 lb. live-weight of the animals fed upon a farm, the amount of dry fodder daily consumed is about 24 lb. and if we add to the half of that one-fourth for litter, *viz.*, 6 lb., we obtain the sum of 18 lb., which represents the total dry matter in the manure. To this has to be added three times as much water, *viz.*, 54 lb., and we obtain a total of 72 lb. wet manure per 1,000 lb. live-weight per day. This is only an average, for when animals are fed mostly on turnips, containing 92 per cent of water, the manure will be much wetter; if on hay, much drier.

The loss of dry matter which occurs in converting fodder into dung is mostly loss of carbon, which is partly burned in the animal's body in keeping up its temperature, and is partly stored up as fat and flesh. There is also a loss of nitrogen, which amounts on an average to about a fifth of the total nitrogen contained in the dry fodder, but which may be more or less, according to the kind and amount of fodder and the state of nutrition of the stock. There is very little loss of mineral matter. The potash contained in the fodder is mostly voided in the urine, while the phosphoric acid is almost entirely contained in the solid excrement.

The manure value of the animal dung is influenced by various circumstances. In the case of oxen in forward condition, the loss is very slight, while in the case of cows giving milk and in the case of calves or other young stock, more than half the nitrogen and about two-thirds of the phosphoric acid are lost to the manure.

The general character of the dung made by various kinds of stock is also very different owing to the different kinds of fodder, and the more or less perfect mastication and digestion to which it has been subjected. Milch cows fed on watery diet produce a dung containing only about one-sixth or a seventh of solid matter, while the dung of most oxen fed on a dry diet contains about one-fourth of solids. Owing to the perfect mastication which takes place in the ruminating process, the constituents of the dung are in a fine state of division, and the whole forms a mass through which air does not penetrate, so that the rotting process goes on very slowly, rendering it a very slow-acting manure. It is called a cold manure, since there is no apparent heat generated during its very slow fermentation. On that account it is necessary to mix it with a large amount of litter, in order to keep it free and permeable to air, so that the rotting process may be hastened. The dung of horses is a dry dung, and more open and porous, so that it ferments very easily and heats rapidly. When too concentrated, the heating is carried so far as to kill out the ferments in the heap, and cause a loss of manurial matter.

The urine of horses is also a more concentrated material than that of cows or oxen, and therefore it is very advantageous that the manure derived from oxen and horses, should not be collected separately, but mixed together in a careful, uniform manner. The dung of sheep resembles somewhat that of horses, but it is somewhat drier, and therefore well adapted

from counteracting the too fluid character of cow dung.

There are many questions that arise as to the making and using of farmyard manure. It may be asked whether fresh dung is not a better manure than that which has been preserved in heaps. It will usually happen that less loss of manurial matter occurs when manure is made directly on the field, inasmuch as the methods of preserving farmyard manure are usually imperfect. It cannot be said that the droppings left by cattle on a field are properly distributed; on the contrary, the manure is applied in about the worst conceivable manner. It remains for months protected by a hard resinous covering, and ferments with great slowness; it kills out the grass immediately beneath it, and renders that part of the pasture unfit for food for many months; the rank vegetation which grows on the spot next season is not acceptable to cattle, and the pasture becomes coarse and uneven. This might easily be avoided by a little attention, such as the employment of boys, or other unskilled labour, to scatter the dung and secure its more even distribution, or the removing of it altogether to the dung heap. The applying of fresh cow dung to the soil is not attended with any loss of substance, and in some cases is much to be preferred to any other method. This is especially the case when it is wanted to improve the mechanical condition of stiff clay soils; but, as a rule, some preparatory fermentation in the heap is very beneficial. The chief improvement that occurs to dung when heaped is the rapid rotting of the substance, whereby the hard straw or other litter is softened, and made more capable of yielding up its manurial substance to the roots of plants. The albuminoid matter in the heap is decomposed and converted into ammonia, and the ammonia is in turn converted into nitric acid, so that, from being a slow-acting manure, the dung becomes one of the strongest and most rapid manures on the farm. In cases where it is desired to prolong the action of the dung over a long period, it should be ploughed in fresh; but when it is wanted to expend itself chiefly on the crop to which it is applied, it should be as well rotted as possible. That the rotting process may be satisfactory, it is necessary that the manure heap be carefully made. It must be uniform throughout the whole mass, and this uniformity should be attained during the making of the heap rather than by turning it over at a later stage. When a heap is not uniform or equally fermented, the turning it over, although attended with some loss of ammonia, is to be recommended, as it is highly desirable to have the whole heap uniform; and the loss of the ammonia is not so great as is apt to be imagined from the pungent smell during the operation. When a manure heap is carefully mixed and layered in the making, and where there is a due proportion of litter and dung, the fermentation goes on equally through the heap, and there is no need of turning.

The preservation of farmyard manure is a subject which has been much neglected. There are now many covered courts and covered heaps, but as a rule the dung heap is exposed to the weather. In wet climates this is a great misfortune, as even with the greatest care, it is scarcely possible to prevent waste, and if there is no special care taken, as is usually the case, the loss of fertilising material is enormous. An uncovered manure heap in a wet district is the biggest hole in a farmer's pocket. In dry districts the loss need not be very great; and if care is taken in the making of the heap, it may be quite unimportant. While a dung heap is maturing there is a constant evaporation of moisture from the hot mass, so that it is apt to become too dry; and where the heap is under cover, it becomes necessary to run over the heap with water, or, better still, with urine. In a dry climate the amount of rain which falls upon the heap just about compensates for the loss of moisture during fermentation. In order that there may be no loss in such circumstances, the bottom of the heap requires attention. The water in the heap gradually drops down, and flows away as a constant brown stream highly charged with potash salts, and this may occur when the upper parts of the heap is too dry. It is therefore necessary to have the heap placed upon a

dry bed of earth or straw, or some absorbent material, and it should be surrounded with a gutter filled with this absorbent, and the earth or straw, or whatever it should be frequently renewed, the soaked matters being tossed up on to the top of the heap. When manure is exposed to the rain it had better not be quickly fermented, as in the process of fermentation the great change which occurs is the increase of soluble matter, and as this is liable to be washed away, it is well that manure which has to stand long should be very slowly fermented. In such cases it should be packed closely together, and exposed as little as possible to the direct force of wind.

There are some substances which are valuable in preserving manure and hastening its decomposition, but unless the heap is under cover or exposed to very little rain, they should not be used. Chief among these substances is *gypsum*. The effect of gypsum is to prevent loss of ammonia, and it may also hasten the nitrification process. It is a safe substance to employ, and it should be sprinkled over the heap as it rises, so that it may ultimately be fairly well distributed throughout the mass. Carbonate of lime or marl may also be added with advantage, and even fresh lime may be safely sprinkled through the heap in small quantity (about 1 per cent), and if put only on fresh dung, there need be no fear of loss of ammonia. Fresh dung does not contain ammonia; it is only after fermentation has set in that ammonia is formed. The action of lime and its salts is to hasten the conversion of ammonia into nitric acid, so that nitrate of lime is formed, and as that is a very soluble salt, it would plainly be a mistake to encourage its formation in a manure heap exposed to rain and liable to leakage.—*North British Agriculturist*.

BRAZIL COFFEE IN RUSSIA.

Our producers might follow with profit the example lately set by the Brazilian coffee-growers. The enormous increase of their product of late years has stimulated them to improve every opportunity for increasing its consumption in foreign countries. They took advantage of the international exposition held in St. Petersburg last summer and gained a most enthusiastic reception of their goods. Heretofore the consumption of coffee has been very small in Russia—only about 7,625,000 pounds in 1879, giving the small-est per capita consumption of any European country. Tea has been the national beverage.

It was known to Brazilian planters that their product had lost its identity in Russia by being mixed and sold under other names. They accordingly sent to the exposition a commission equipped with a complete exhibit of the various grades of coffee grown in Brazil. The commissioners took with them not only samples, but a complete outfit for having it prepared and served by their own cooks. The excellence of the beverage attracted marked attention, both at the exposition and throughout the country. It has become quite the rage, and newspapers have discussed its quality and merits and enlarged upon the extent of its growth in Brazil, recommending its direct importation into Russia as tending to increase and improve in many ways the commercial relations of the two countries. As a result of this enterprise it is said that the Russian government is considering the advisability of reducing the duty on coffee imported direct from Brazil, which will doubtless tend to increase its consumption.—*Indian Mercury*.

ON JAPANESE TEA AND TOBACCO.

BY J. TAKAYAMA.

The tea-leaves are gathered in May, and quickly dried by exposure to air, and carefully sifted so as to separate dust and fragments of leaves. They are then subjected to the steaming. This is done by introducing the leaves into a wooden tub, the bottom of which is formed of bamboo meshes, the tub being placed on an iron pan filled with water and heated from below. After thirty minutes, when the steam rises up, the wooden cover is taken off, and the contents are thoroughly mixed so as to steam uni-

formly all the leaves. This done, the tub is covered again with the lid. This process is repeated, and finally the contents are taken out and cooled. There is a tendency in leaves to adhere to the bamboo rod during mixing.

The leaves are now sufficiently softened to be rolled up between the hands by a gentle rubbing, after which the leaves are subjected to drying. This operation is a most difficult one, inasmuch as the quality of the product depends in a great measure on the treatment which the leaves undergo during the operation, since it is during drying that that fine colour becomes fixed, with simultaneous production of that delicate flavor and agreeable taste which are wanting in the original leaves; so that it requires excellent workmen, whose requisite skill is only attained after a long practice.

The drying is conducted in a shallow rectangular box, the bottom of which is made of a thick paper stiffened with starch. The box is placed over a copper-wire gauze supported by iron bars, which are provided across the furnace. The furnace is simply a rectangular box coated with clay, and has the depth of 2-5 shaku.

To begin the operation, first of all a charcoal fire is made in the furnace. The rectangular box is now placed over it, the leaves are next introduced into the box, and the workman continually rubs them between the hands, alternately tossing them up and letting them fall until they are nearly dried. Thus dried the leaves are further dried by keeping for a night in the same furnace after the charcoal fire is withdrawn. In large factories numbers of these furnaces are arranged in rows, and during the drying each furnace is attended by one workman.

The tea thus dried is, before it is sent to the market, subjected to sorting and sieving. The sorting simply consists in spreading out a certain quantity of tea upon a flat table, and in removing dust, stems, and other foreign matters by picking them up, which operation is usually done by women and girls. The sorted tea is then sieved.

The sieves of different meshes are distinguished from one another by the numbers 1, 2, 3, etc., and the number of sievings as well as the sieves used vary with the quality of the tea. Thus, in the case of coarse kinds, it is passed twice or thrice through each of 1 and 2, and in the best kinds only once through 2, 3, 4, and twice through 3, which has the meshes of nearly 3 millimeters. The tea thus prepared is preserved in earthenware or metallic pots, in order to preserve it from the moisture.

BLACK TEA.

Before intercourse with Western nations was opened this was scarcely known to us, but now at present it is manufactured, though to a very limited extent, for the purpose of exporting it to foreign countries. The writer states the following description of the process to be due to the report published by order of the board for promotion of industry, agriculture, and commerce. In preparing the black tea, the leaves from wild tea plants, or those which are cultivated without much care, are used, otherwise there will not be much profit. The leaves after gathering are scattered on a straw mat, and dried by exposure to air. They are then collected, and softened by tossing and clapping between the hands till they become adhesive. The leaves are then made into a number of balls, which are introduced into a large box, which is closed tightly and exposed to the sun for half an hour, when it is brought into the house, and allowed to lie in this state for one night. The balls are then taken out, and subjected to the rolling and drying in the same way as in the preparation of green tea. During the operation the workman turns the mass so as to prevent it from being burnt. This process is continued until the leaves break very easily by simply pressing between the fingers, when they are considered to be perfectly dry. The tea thus produced is freed from impurities and stalks, and separated into different kinds by passing through sieves having meshes of different sizes. The specimens he chemically examined are all those prepared in the celebrated tea-producing

no inducement, there is no economy in storing and using farmyard manure—it is a superfluous labour; but in all populous countries, and notably in our own, where the soil has been reduced by centuries of cropping, the basis of farming is the manure heap. Although in these days, importation of artificial manures has made farmers less dependent on farmyard manure than formerly, yet it is still, as of old, the central system of the farm, and its careful manufacture, preservation, and use are more than ever deserving of careful attention.

Farmyard manure consists of the solid and liquid excrement of animals, combined with the straw or other substance used as litter, and when fresh consists of about one part solid matter and three parts water. About one-half of the total dry matter contained in an animal's fodder is found again in the manure, so that it is easy to estimate approximately the amount of manure produced upon a holding in ordinary circumstances when the amount of dry matter contained in the fodder is known. For every 1,000 lb. live-weight of the animals fed upon a farm, the amount of dry fodder daily consumed is about 24 lb. and if we add to the half of that one-fourth for litter, *viz.*, 6 lb., we obtain the sum of 18 lb., which represents the total dry matter in the manure. To this has to be added three times as much water, *viz.*, 54 lb., and we obtain a total of 72 lb. wet manure per 1,000 lb. live-weight per day. This is only an average, for when animals are fed mostly on turnips, containing 92 per cent of water, the manure will be much wetter; if on hay, much drier.

The loss of dry matter which occurs in converting fodder into dung is mostly loss of carbon, which is partly burned in the animal's body in keeping up its temperature, and is partly stored up as fat and flesh. There is also a loss of nitrogen, which amounts on an average to about a fifth of the total nitrogen contained in the dry fodder, but which may be more or less, according to the kind and amount of fodder and the state of nutrition of the stock. There is very little loss of mineral matter. The potash contained in the fodder is mostly voided in the urine, while the phosphoric acid is almost entirely contained in the solid excrement.

The manure value of the solid dung is influenced by various circumstances. In the case of oxen in forward condition, the loss is very slight, while in the case of cows giving milk and in the case of calves or other young stock, more than half the nitrogen and about two-thirds of the phosphoric acid are lost to the manure.

The general character of the dung made by various kinds of stock is also very different owing to the different kinds of fodder, and the more or less perfect mastication and digestion to which it has been subjected. Milch cows fed on watery diet produce a dung containing only about one-sixth or a seventh of solid matter, while the dung of most oxen fed on a dry diet contains about one-fourth of solids. Owing to the perfect mastication which takes place in the ruminating process, the constituents of the dung are in a fine state of division, and the whole forms a mass through which air does not penetrate, so that the rotting process goes on very slowly, rendering it a very slow-acting manure. It is called a cold manure, since there is no apparent heat generated during its very slow fermentation. On that account it is necessary to mix it with a large amount of litter, in order to keep it free and permeable to air, so that the rotting process may be hastened. The dung of horses is a dry dung, and more open and porous, so that it ferments very easily and heats rapidly. When too concentrated, the heating is carried so far as to kill out the ferments in the heap, and cause a loss of manurial matter.

The urine of horses is also a more concentrated material than that of cows or oxen, and therefore it is very advantageous that the manure derived from oxen and horses, should not be collected separately, but mixed together in a careful, uniform manner. The dung of sheep resembles somewhat that of horses, but it is somewhat drier, and therefore well adapted

from counteracting the too fluid character of cow dung.

There are many questions that arise as to the making and using of farmyard manure. It may be asked whether fresh dung is not a better manure than that which has been preserved in heaps. It will usually happen that less loss of manurial matter occurs when manure is made directly on the field, inasmuch as the methods of preserving farmyard manure are usually imperfect. It cannot be said that the droppings left by cattle on a field are properly distributed; on the contrary, the manure is applied in about the worst conceivable manner. It remains for months protected by a hard resinous covering, and ferments with great slowness; it kills out the grass immediately beneath it, and renders that part of the pasture unfit for food for many months; the rank vegetation which grows on the spot next season is not acceptable to cattle, and the pasture becomes coarse and uneven. This might easily be avoided by a little attention, such as the employment of boys, or other unskilled labour, to scatter the dung and secure its more even distribution, or the removing of it altogether to the dung heap. The applying of fresh cow dung to the soil is not attended with any loss of substance, and in some cases is much to be preferred to any other method. This is especially the case when it is wanted to improve the mechanical condition of stiff clay soils; but, as a rule, some preparatory fermentation in the heap is very beneficial. The chief improvement that occurs to dung when heaped is the rapid rotting of the substance, whereby the hard straw or other litter is softened, and made more capable of yielding up its manurial substance to the roots of plants. The albuminoid matter in the heap is decomposed and converted into ammonia, and the ammonia is in turn converted into nitric acid, so that, from being a slow-acting manure, the dung becomes one of the strongest and most rapid manures on the farm. In cases where it is desired to prolong the action of the dung over a long period, it should be ploughed in fresh; but when it is wanted to expend itself chiefly on the crop to which it is applied, it should be as well rotted as possible. That the rotting process may be satisfactory, it is necessary that the manure heap be carefully made. It must be uniform throughout the whole mass, and this uniformity should be attained during the making of the heap rather than by turning it over at a later stage. When a heap is not uniform or equally fermented, the turning it over, although attended with some loss of ammonia, is to be recommended, as it is highly desirable to have the whole heap uniform; and the loss of the ammonia is not so great as is apt to be imagined from the pungent smell during the operation. When a manure heap is carefully mixed and layered in the making, and where there is a due proportion of litter and dung, the fermentation goes on equally through the heap, and there is no need of turning.

The preservation of farmyard manure is a subject which has been much neglected. There are now many covered courts and covered heaps, but as a rule the dung heap is exposed to the weather. In wet climates this is a great misfortune, as even with the greatest care, it is scarcely possible to prevent waste, and if there is no special care taken, as is usually the case, the loss of fertilising material is enormous. An uncovered manure heap in a wet district is the biggest hole in a farmer's pocket. In dry districts the loss need not be very great; and if care is taken in the making of the heap, it may be quite unimportant. While a dung heap is maturing there is a constant evaporation of moisture from the hot mass, so that it is apt to become too dry; and where the heap is under cover, it becomes necessary to run over the heap with water, or, better still, with urine. In a dry climate the amount of rain which falls upon the heap just about compensates for the loss of moisture during fermentation. In order that there may be no loss in such circumstances, the bottom of the heap requires attention. The water in the heap gradually drops down, and flows away as a constant brown steam highly charged with potash salts, and this may occur when the upper parts of the heap is too dry. It is therefore necessary to have the heap placed upon a

dry bed of earth or straw, or some absorbent material, and it should be surrounded with a gutter filled with this absorbent, and the earth or straw or whatever it should be frequently renewed, the soaked matters being tossed up on to the top of the heap. When manure is exposed to the rain it had better not be quickly fermented, as in the process of fermentation the great change which occurs is the increase of soluble matter, and as this is liable to be washed away, it is well that manure which has to stand long should be very slowly fermented. In such cases it should be packed closely together, and exposed as little as possible to the direct force of wind.

There are some substances which are valuable in preserving manure and hastening its decomposition, but unless the heap is under cover or exposed to very little rain, they should not be used. Chief among these substances is *gypsum*. The effect of gypsum is to prevent loss of ammonia, and it may also hasten the nitrification process. It is a safe substance to employ, and it should be sprinkled over the heap as it rises, so that it may ultimately be fairly well distributed throughout the mass. Carbonate of lime or marl may also be added with advantage, and even fresh lime may be safely sprinkled through the heap in small quantity (about 1 per cent), and if put only on fresh dung, there need be no fear of loss of ammonia. Fresh dung does not contain ammonia; it is only after fermentation has set in that ammonia is formed. The action of lime and its salts is to hasten the conversion of ammonia into nitric acid, so that nitrate of lime is formed, and as that is a very soluble salt, it would plainly be a mistake to encourage its formation in a manure heap exposed to rain and liable to leakage.—*North British Agriculturist*.

BRAZIL COFFEE IN RUSSIA.

Our producers might follow with profit the example lately set by the Brazilian coffee-growers. The enormous increase of their product of late years has stimulated them to improve every opportunity for increasing its consumption in foreign countries. They took advantage of the international exposition held in St. Petersburg last summer and gained a most enthusiastic reception of their goods. Heretofore the consumption of coffee has been very small in Russia—only about 7,625,000 pounds in 1879, giving the smallest per caput consumption of any European country. Tea has been the national beverage.

It was known to Brazilian planters that their product had lost its identity in Russia by being mixed and sold under other names. They accordingly sent to the exposition a commission equipped with a complete exhibit of the various grades of coffee grown in Brazil. The commissioners took with them not only samples, but a complete outfit for having it prepared and served by their own cooks. The excellence of the beverage attracted marked attention, both at the exposition and throughout the country. It has become quite the rage, and newspapers have discussed its quality and merits and enlarged upon the extent of its growth in Brazil, recommending its direct importation into Russia as tending to increase and improve in many ways the commercial relations of the two countries. As a result of this enterprise it is said that the Russian government is considering the advisability of reducing the duty on coffee imported direct from Brazil, which will doubtless tend to increase its consumption.—*Indian Mercury*.

ON JAPANESE TEA AND TOBACCO.

BY J. TAKAYAMA.

The tea-leaves are gathered in May, and quickly dried by exposure to air, and carefully sifted so as to separate dust and fragments of leaves. They are then subjected to the steaming. This is done by introducing the leaves into a wooden tub, the bottom of which is formed of bamboo meshes, the tub being placed on an iron pan filled with water and heated from below. After thirty minutes, when the steam rises up, the wooden cover is taken off, and the contents are thoroughly mixed so as to steam uni-

formly all the leaves. This done, the tub is covered again with the lid. This process is repeated, and finally the contents are taken out and cooled. There is a tendency in leaves to adhere to the bamboo rod during mixing.

The leaves are now sufficiently softened to be rolled up between the hands by a gentle rubbing, after which the leaves are subjected to drying. This operation is a most difficult one, inasmuch as the quality of the product depends in a great measure on the treatment which the leaves undergo during the operation, since it is during drying that that fine colour becomes fixed, with simultaneous production of that delicate flavor and agreeable taste which are wanting in the original leaves; so that it requires excellent workmen, whose requisite skill is only attained after a long practice.

The drying is conducted in a shallow rectangular box, the bottom of which is made of a thick paper stiffened with starch. The box is placed over a copper-wire gauze supported by iron bars, which are provided across the furnace. The furnace is simply a rectangular box coated with clay, and has the depth of 25 shaku.

To begin the operation, first of all a charcoal fire is made in the furnace. The rectangular box is now placed over it, the leaves are next introduced into the box, and the workman continually rubs them between the hands, alternately tossing them up and letting them fall until they are nearly dried. Thus dried the leaves are further dried by keeping for a night in the same furnace after the charcoal fire is withdrawn. In large factories numbers of these furnaces are arranged in rows, and during the drying each furnace is attended by one workman.

The tea thus dried is, before it is sent to the market, subjected to sorting and sieving. The sorting simply consists in spreading out a certain quantity of tea upon a flat table, and in removing dust, stems, and other foreign matters by picking them up, which operation is usually done by women and girls. The sorted tea is then sieved.

The sieves of different meshes are distinguished from one another by the numbers 1, 2, 3, etc., and the number of sievings as well as the sieves used vary with the quality of the tea. Thus, in the case of coarse kinds, it is passed twice or thrice through each of 1 and 2, and in the best kinds only once through 2, 3, 4, and twice through 3, which has the meshes of nearly 3 millimeters. The tea thus prepared is preserved in earthenware or metallic pots, in order to preserve it from the moisture.

BLACK TEA.

Before intercourse with Western nations was opened this was scarcely known to us, but now at present it is manufactured, though to a very limited extent, for the purpose of exporting it to foreign countries. The writer states the following description of the process to be due to the report published by order of the board for promotion of industry, agriculture, and commerce. In preparing the black tea, the leaves from wild tea plants, or those which are cultivated without much care, are used, otherwise there will not be much profit. The leaves after gathering are scattered on a straw mat, and dried by exposure to air. They are then collected, and softened by tugging and clapping between the hands till they become adhesive. The leaves are then made into a number of balls, which are introduced into a large box, which is closed tightly and exposed to the sun for half an hour, when it is brought into the house, and allowed to lie in this state for one night. The balls are then taken out, and subjected to the rolling and drying in the same way as in the preparation of green tea. During the operation the workman turns the mass so as to prevent it from being burnt. This process is continued until the leaves break very easily by simply pressing between the fingers, when they are considered to be perfectly dry. The tea thus produced is freed from impurities and stalks, and separated into different kinds by passing through sieves having meshes of different sizes. The specimens he chemically examined are all those prepared in the celebrated tea-producing

district Uji, and are supposed to be unadulterated. The accompanying table gives the result of the analyses. On examining the table there seems to be no connection between commercial quality and chemical composition, but it is very interesting to observe how nearly the same is the amount of the constituents in all specimens; so that, in any instance if we find some of the constituents, as ash, for instance, in quantity differing from those found in the table, we may consider such specimen being previously adulterated. Nitrogen in the table was determined by Dumas' method.

COCOA.—Accounts from Surinam are very favourable respecting the Cocoa-Culture; even the young trees, planted only five years ago in the Districts of Surinam and Commewyne on abandoned sugar-fields have surmounted the many difficulties, and promise a good crop. The one-year-old trees, on the contrary, are in a less favourable condition, owing mainly to insufficient sheltering against the heat of the sun, and are partially lost. Additional plantings of cocoa are constantly being continued. There is great scarcity of available manual labour, and this want is felt most severely in proportion, as the estates are father from the capital.—*Indian Mercury.*

ROSB MILDew.—GYRSTUM.—Some correspondence having appeared in your columns with reference to the above, it would be well perhaps to consider mildew which affects other plants in order to experiment in the hope of destroying it in Roses. Hops are likewise subject to a "mould" or mildew, which Mr. C. Whitehead remarks in his treatise on "Hops from the Set to the Skylight," "is due to an insidious parasitic fungus, known as *Sporotheca Castagnei*, of the group *Erysiphe*, allied to the fungus which causes the mildew in Vines." Sulphur is applied to Hops in the form of flowers of sulphur by means of a machine called a sulphurator, which dusts it over the plants, and it is generally considered to be a cure for the mildew, and a preventive if put on early. An agricultural chemist, in giving a lecture on the subject to a farmers' club in this neighbour-

hood, gave it as his opinion that if sulphur was applied in an available form to the roots he believed that it would prevent mildew. A Hop grower afterwards stated that he had found this theory corroborated by practice, and that having applied sulphur in the form of gypsum to his Hops they were very free from mould, while his neighbour's on the other side of the hedge were badly attacked. The above chemist stated that sulphur as applied by flowers of sulphur is not assimilable by the roots, while it is when supplied in gypsum. As an analogy the human frame needs phosphorus and potash, but they cannot be taken in the crude mineral form without doing as much harm as good, while if taken in an assimilable form in vegetables they are of great benefit. Hence those growers who have applied quantities of sulphur at a considerable expense to the leaves have only derived a temporary and incomplete benefit, and have not gone to the root of the matter.—Wm. Thompson, Tweed Vineyard.—*Journal of Horticulture.*

WYNAAD NOTES, 22nd Jan. 1886.—A longer period than usual has elapsed since I last sent you any news from our quiet corner of the world. Indeed there is seldom much to tell of Wynaad now-a-days, and that not generally of too exhilarating a nature. Our crop season is pretty nearly over, and carries with it, I fear many disappointments in the matter of unfulfilled estimates. Here and there the balance is to the good, but such good fortune is, unhappily, rather the exception than the rule. The prices, too, are terribly discouraging, and do not seem inclined to improve. We pin our faith, as a rule, upon cinchona, and here, if we dare to judge by appearance, we have good reason to anticipate a more hopeful future. Nearly all our plantings, especially of the *Ledgeriana* variety, are in splendid condition, and so encouraging is their appearance and growth that large openings in all directions are in preparation for the next planting season. There will probably be a great demand for first-class plants, which is met in anticipation by sundry extensive nurseries. South Wynaad is decidedly proving itself to be the home of the Ledger, although not so many years ago it was a subject of much speculation amongst those learned in such matters whether Ledger, or indeed any kind of cinchona, would live in our climate and elevation. Opinions still vary considerably concerning the best method of cultivation and preparation of the bark. Many devices are tried to discover the really best way of removing the bark, of drying it, and, above all, of encouraging a renewed growth upon the denuded stems, some being in favor of the old system of protection by moss and grass, and others believing in the better success of a hardening system produced by leaving the barked portions wholly exposed. It is a question to be answered by experience, and, no doubt, the results would depend greatly upon the situation of the trees and the weather at the time of harvesting. Another subject of very keen interest and discussion has been the colour of our coffee. Great complaints were made last year in the Home markets of the colour of Indian coffee, and strenuous efforts have resulted by our Association to discover the cause of so damaging an effect. Very many opinions are in favor of drying the produce under shade, and experiments are being tried to decide upon the best way of carrying out so entirely new a system. Unfortunately, the weather was exceptionally bad just at the time when most of us were in full pick. Indeed, such a season has hardly ever been known, and our climate seems to have altogether altered its usual routine. We have hardly any land-winds, and only a few of the cold nights and mornings to which we are accustomed in December. Instead of this, there was a considerable amount of rain about Christmas, and now we are having regular hot weather such as we usually expect in March and April. You may imagine the difficulties of drying under shade, with a warm rain dripping continually upon the seething heaps of coffee, which, positively, in some cases, commenced germinating before it could be removed to the Coast.—*Madras Times.*

REPORT ON THE PROGRESS AND CON-
DITION OF THE GOVERNMENT BOTAN-
ICAL GARDENS AND PARKS, NILGIRIS,
FOR THE OFFICIAL YEAR 1884-85.

SEASON.—The weather during the past year was, with the exception of the months of October and November, unusually dry, and little or no planting could be attempted till the end of the former month. In October no less than 22.84 inches of rain were registered. More than half of this fell in two days, and the wash, which this heavy fall occasioned, was very great. The winter was comparatively mild and little harm was done by frost.

All the lawns in the gardens have now been levelled and the grass upon them is being gradually brought into better order. Last year the grub of the cockchafer did a good deal of mischief to the grass, but this was remedied by top-dressing the injured portions with manure in the early spring. Now that the floor of the garden has been put to right, I hope next year to re-establish the flower beds and shrubs which, during the time that the alterations were going on, had to be removed. The bund of the tank below the band-stand gave way during the heavy storm which occurred in October last. The destruction of the bund was due partly to the tank having been dredged too deeply and partly to trees having been planted upon it. The depth of the tank has now been lessened and made uniform and the bund has been restored and strengthened. Provision has been made for putting up a fountain next winter in this tank opposite to the band-stand.

BARLIYAN.—(g) *Experimental Garden*.—This garden was of late years becoming overgrown with worthless coffee, oranges, pomeloes, &c., and which were cramping many of the more valuable trees. I have had all these cleared away, and I have also cleared of secondary jungle, about an acre of ground, which had hitherto been left uncultivated. This will give a sufficiency of room for planting out new introductions for some years to come. Most of the trees are flourishing; they have all been identified, and I have ordered that they shall have a zinc tally, with a number punched on it, attached to each. This, in the hot climate of Barliyan, will be more lasting than the usual painted label, and it will at the same time be much more economical.

KALHATTI.—(h) *Experimental Garden*.—Nothing of any importance has been carried out during the year in this garden. The *Cinchona morada* and *verde* seedlings which were put out last year have done very badly; the dry climate evidently did not suit them. In my last year's report I stated that I doubted if it was worth the while of Government to continue the cultivation of this garden, and I am now still more of the opinion that it is not.

PROPOSED MUSEUM OF NATURAL HISTORY IN OOTACAMUND.—In my report of last year, I asked if Government would be inclined to sanction the establishment of a small museum in Ootacamund, which should contain typical collections of objects of interest to those living on the Nilgiri plateau and in the Wynnad, and I further stated that I thought such a museum should take in all the chief branches of Natural Science—Botany, Zoology, Geology, Mineralogy and Ethnology. Government, in paragraph 12 of their G. O., dated 20th October 1884, No. 1,155, Revenue, reviewing my report approved of the suggestion, and they accordingly requested me to work out the details of the scheme in communication with the Superintendent of the Government Central Museum, Madras, the Conservator of Forests, Northern Circle, and the Collector of the Nilgiris.

Owing to the absence from the Hills of one or other of the above appointed Committee, no meeting was held until the 15th of last month. I then explained what I considered should be the scope of the museum, and I produced a plan of a building which I thought would be sufficiently large to contain all such collections as might be acquired during the first

few years of the museum's existence, and I pointed out that the building, which I proposed, would admit of being indefinitely extended. With respect to the scope of the museum, I urged upon my colleagues that it would be desirable that at first the collections should be confined to such objects only as would be of interest to the ordinary well-educated and intelligent resident, European or Native, and that complete collections of everything existing in the district which would be serviceable only to specialists should be allowed to stand over to a future day. These propositions, however, met with their most decided disapproval. They were unanimous in thinking that the scope which I proposed was far too narrow, and that instead of commencing with a small building and adding to it as occasion might require, a large museum should be built at once, which would accommodate a perfect collection of all natural history objects.

Seeing that we were of such very opposite views as to what ought to be done, I asked Doctor Bidie, Mr. Burrows and Mr. Gamble to put upon paper the views which they had advanced in the discussion. This they have kindly done, and I annex a copy of the report which they have drawn up on the subject.

Mr. Burrows, while agreeing in the opinions of Doctor Bidie and Mr. Gamble, considered that in order to make a museum in Ootacamund a useful and successful institution and to ensure its permanency, it should be so arranged and managed so as to prove an attraction to the public and a credit to the station. It should be accessible both to mere visitors and to learners and should be one of the public institutions of Ootacamund. In this we were all agreed. Ethnological collections, it was thought, in a district where there are several aboriginal races who might be likely to decrease in numbers rather than increase and to change perhaps their mode of life, would also be of real interest and require some space and some care in arrangement.

Then there would be a necessity for a series of specimens properly representative of the coffee, tea, cinchona, fibre and other industries of the district and Wynnad, and though Mr. Lawson thought that a small box of a few feet square would properly represent all that was useful to show as regards coffee, the rest of the meeting did not agree with him and thought that unless such subjects were thoroughly and well, perhaps even copiously, represented as regards the soil, growth, varieties, diseases and products of manufacture, the collection would be of but little interest and planters would not care for it.

Then the Gold-mining industry and the various though not very extensive mineral products including the building stones, &c., require to be shown, and though perhaps in themselves they would not take up much room, yet they would add to the sum total of the space required, and for this a wall space of 130 feet would be totally inadequate. And in Mr. Lawson's proposed room with three-foot cases, the spaces for the circulation of visitors would be reduced to merely 12 x 6 feet in each room. We were further agreed that if a museum be instituted in Ootacamund—as all were of opinion should be the case—it should be confined to the display of local products, and its aim should be that which in his address to the Biology section of the British Association at Swansea in 1880, Dr. Günther thus described.—

"The principal aim of a Provincial Museum ought, in my opinion, to be popular instruction. I do not mean that it should be merely a place for mild amusement and recreation, but that it should rank equal with all similar institutions destined to spread knowledge and cultivate taste among the people. To attain this aim it should contain an arranged series of well preserved specimens representing as many of the remarkable types of living forms as are obtainable; a series of useful as well as noxious plants and animals; of economic products derived from the animal and vegetable kingdoms; and last (but not least) a complete and accurately named series of the flora and fauna of the neighbourhood.

"The direct benefit of a complete collection of the flora and fauna of the district, in which the Provincial Museum is situated, is obvious and cannot be exaggerated. The pursuit of collecting and studying natural history objects gives to the persons who are inclined to devote their leisure hours to it, a beneficial training for whatever their real calling in life may be; they acquire a sense of order and method; they develop their gift of observation; they are stimulated to healthy exercise. Nothing encourages them in this pursuit more than a well-named and easily accessible collection in their own native town upon which they can fall back as a pattern and an aid for their own. This local collection ought to be always arranged and named according to the plan and nomenclature adopted in some monograph of the fauna and flora of the country; and I consider its formation in every Provincial Museum to be of higher importance than a collection of foreign objects."

No such small room as that which Mr. Lawson proposed would meet the circumstances of the cases as thus defined.

NOTES ON SOME OF THE MORE INTERESTING PLANTS WHICH HAVE BEEN INTRODUCED OF GROWN IN THE GARDENS DURING THE YEAR.

1. *Erythroxylon Coca*.—Two big bushes of this plant exist at Barliyar where they grow freely, but fruit sparingly. About 60 young plants have been raised from seed and a large number of cuttings were put down during the winter, but these have not done well. It may be taken as certain that *Erythroxylon coca* will thrive well in many parts of Southern India, and that it may be easily propagated from seed, but that it will be profitable for the European planter to grow it upon a large scale is a matter upon which I entertain much doubt. Vast tracts of country in South America are cultivated with this plant, and an almost unlimited quantity of leaves may be obtained from that country for the purpose of manufacturing the valuable alkaloid *Cocaine*. Last winter this alkaloid is said to have fetched 2s. 6d. per grain. At this price, could it have been maintained, its cultivation would have been productive of enormous profits, but the price has since declined to 7d. per grain, and it is very unlikely that even this sum will be realized much longer. In this opinion Mr. Thistleton Dyer concurs, and he moreover wrote a short time ago to caution me against being too sanguine that the cultivation of *Coca* would be a commercial success, or advising me at any rate to discount very largely the reports which had been spread abroad about it.

Mr. Hooper has analysed three samples of the leaves taken from the bushes at Barliyar. In his first attempt to isolate the alkaloid in a crystalline state he was unsuccessful; in his second attempt he succeeded in obtaining the alkaloid as crystalline, but with an admixture of some acrid principle which rendered it useless as an anæsthetic; his third attempt ended in complete success, and the alkaloid manufactured by him has been used and approved of by Dr. Broekman in his surgical ophthalmic operations. Surgeon-General Docter Furnell reports that the simple chewing of the leaves is productive of relief in cases of spasmodic bronchial coughs, and suggests that *Cocaine* should enter into the composition of cough lozenges. Mr. Hooper's analyses show that the leaves of the bushes grown at Barliyar are very rich in the alkaloid, as he extracted from them $\frac{1}{2}$ per cent.

2. *Erythroxylon monogyneum*.—The leaves of this plant are said to have been largely eaten during the famine by the natives of several districts where it grew wild in abundance, and it was thought probable that the leaves of this plant might be found to contain an alkaloid with properties similar to that which is obtained from the *Erythroxylon Coca*; and Dr. Cornish just before he left India wrote to ask me to have the subject investigated. As the plant does not grow upon these Hills, I applied to Mr. Gamble for his assistance, and he has sent me several small consignments of the leaves, which had been collected and dried by Mr. Higgins, Deputy Conservator of Forests in the Cuddaph District. These consignments

I handed over to Mr. Hooper, who, after his analyses of them, reports that they contain no anæsthetic property at all analogous to that which is found in *Erythroxylon Coca*; but that they do contain a bitter and a tonic principle which may have mitigated the pangs of starvation.

3. *Taraxacum officinale*.—Sir Joseph D. Hooker in the Flora of British India observes that—"It is remarkable that this common Himalayan plant should not be found in the Khasia or Nilgiri mountains even as a garden escape." This reproach to these Hills is now removed, and the aggressive dandelion may be found advancing in all directions about Ootacamund. It bids fair to cover our lawns with its yellow blossoms as in England, while in the deeply tilled soil of the cinchona estates such an abundance of it with roots 18 inches long could be collected as would supply the wants of all the Medical Departments in India.

4. *Medicinal Rhubarb*.—There are a few plants of this herb in the gardens at Ootacamund and in Sim's Park at Coonoor, but they have not thriven as well as could be wished. I shall try this plant under varying conditions during the next year in the hope of obtaining better results.

5. *Hyoscyamus*.—This valuable medicinal plant, which can be grown very well upon these Hills, has not been raised in any quantities on account of all demand for it having ceased.

6. *Eucalyptus Globulus and other Species*.—During the year 20 lb. of the oil of the leaves of the *Eucalyptus globulus* were sent to the Madras Medical Department. The last consignment was sold at the rate of R3-3-0—5 shillings per pound being the wholesale English quotation.

The processes required for the manufacture of the oil are very simple and inexpensive, and I think it is a pity that those who have large plantations of these trees should not endeavour to utilize them for this purpose as well as for fuel. The way to extract the oil is as follows:—

The young shoots, having perfectly matured but not old leaves, are passed through an ordinary chaff-cutter and cut into chips not exceeding one inch in length; the smaller the chips the more readily is the oil extracted from them. These chips are then macerated in water over night and put the next morning into a still, which is kept boiling, till the greater part of the fluid has past over as vapor. This is then shaken up with a little common salt to cause the complete separation of the oil from the water; the oil is then decanted from the water and passed through a sheet of filtering paper, when it is ready for sale.

Instead of passing the leaves through a chaff-cutter, it would be better to pass them through some crushing machine, as the object is to smash up the hard cells, which surround the cavities into which the oil is passed by the secreting cells. I do not know of such a machine, but I should think that some modification of the old-fashioned mangle would prove effective.

Eucalyptus obliqua, *E. sideroxyloides*, *E. piperita*, and other sweet-smelling varieties, all of which are said to yield valuable oils, grow freely on these Hills; they are much more beautiful in their general aspect, and their timber is greatly superior to that of the *E. globulus*.

7. *Rhus glabra*.—This is a febrifuge yielding plant, the seeds of which were sent from Kew. The seeds have germinated.

8. *Ipecacuanha*.—I regret to have to report that I lost a considerable number of *Ipecacuanha* plants during the last year. This was owing to my having forced the stock too rapidly during the winter. The number of plants, however, is being again increased as fast as possible and special care will be taken to prevent the recurrence of last year's catastrophe. I have been much disappointed with the growth these plants have made at Barliyar during the past year. That the *Ipecacuanha* will eventually prove a success I entertain no doubt, but I have to confess that I have still a good deal to learn about the best ways of cultivating it.

9. *Joannesia (Anda) Gomesii*.—This is a handsome tree, growing to the height of 50 or 60 feet and belongs to the natural order *Euphorbeaceae*. It is a native of Brazil where the bark is said to be used "as a certain remedy for diarrhoea brought on by cold," while the seeds are reported to possess powerful but safe purgative properties. I received seeds of this tree last autumn from Mr. Cameron, Curator of the Lal Bagh, Bangalore, who writes word that it flourishes well there. The seeds have germinated and young plants raised from them.

10. *Acacia homalophylla*.—This is the tree which produces the Australian violet wood. A small specimen fruited sparingly for the first time last year in the Government Gardens in Ootacamund. The climate here, however, seems to be rather too cold for its full development, but I should think that at elevations ranging from three to four thousand feet it would thrive well and might prove an important addition to our timber trees.

11. *Pa.*—This at an elevation from 5,000 to 7,000 grows more vigorously than I have ever seen it do in Europe, and I have planted a small plot of ground near the Jail on the Dodabetta estate with the view of finding out if it may not be profitably grown to supply the wood engraver's trade.

12. *Castilloa elastica*.—The few plants of this rubber yielding tree, which were put out two years ago at Barliyar, are growing grandly.

Last winter I went down at the request of Major Campbell Walker, Conservator of Forests, Southern Circle, to inspect the nursery of Castilleas which had been formed in Mr. Ferguson's garden and to advise how they might be best increased. I found the plants in beautiful condition and growing vigorously, and I was able to take from them about 150 excellent cuttings. These I planted myself in pots and plunged them in beds of soil which were also made under my direct supervision, and I gave minute instructions as to how they should be treated. Since that time it has been reported—vide G. O., No. 766, dated 25th June 1885, relating to a letter from Major Campbell-Walker—that although my instructions had been followed carefully, not a single cutting took root.

This is odd, for when the same instructions are carried out in the Government Gardens at Ootacamund the failures are less than 5 per cent of the cuttings planted. The failure at Calicut would appear to have been due to a want of judgment in watering the cuttings in their early stage, before the cut ends had calloused over.

When the side shoots are used as cuttings, difficulty has often been experienced in getting the plants raised from these to form a leader and grow upright; they generally sprawl along the ground. To obviate this it is only necessary to cut the young plants back to about a foot from the ground when side shoots will be formed, any of which will of themselves produce a leader.

13. *Ceara*.—This fruits freely at Barliyar and the seed appears to be eaten by birds and deposited in the neighbouring jungle, for young plants have been found growing where they never had been planted by man. If this is so, we may look forward to the Ceara rubber tree becoming a denizen of our ghât forests.

14. *Mangosteens*.—These fruited very well last year at Barliyar and are again this year promising to yield a large crop. The Mangosteen is an extremely beautiful tree and gives a very dense shade. It ought to be grown all over the Presidency.

15. *Litchi*.—This too fruited freely last year at Barliyar; it grows readily from seed and like the Mangosteen deserves to be better known than it is at present.

16. *Carob tree*.—This thrives well both at Barliyar and at Kalhatti, but in both places the trees bear staminate flowers only.

17. *Acacia decurrens*.—This tanning yielding acacia is being grown successfully at Coonoor by private persons, and, I believe, also by Mr. Gamble. It grows

fairly well at Ootacamund, but does not fruit. This is due probably to the wet gloomy weather coming at the time when it begins to flower, I have seen it growing magnificently on the Pahi hills where it flowers and fruits freely.

18. *Mahogany*.—Two casks of mahogany seed which had been received by the Kew authorities from Jamaica have just arrived in excellent order. I have distributed all but a few pounds of it; the greater amount going to the Forest Department and to the Agri-Horticultural Garden at Madras.

19. *Elilde Prickly-pear from Cyprus*.—Living specimens were sent to the Government Gardens at Ootacamund by the Director of Agriculture and Revenue Settlement last winter. The fruit had been highly recommended by Dr. Bonavia, Civil Surgeon, Etawah, North-Western Provinces, who thought it might be advantageously grafted upon the wild worthless prickly-pear of the plains. The plants arrived in fair condition and have been planted out at Kalhatti where they are doing so well that it does not seem at all likely that it will be ever necessary to have recourse to grafting them upon the wild plants.

20. The following plants mentioned in my last year's report are all doing well:—

Rhus vernicefera or the Japan Lacquer plant.

Rhus succedanea or the Japan wax plant.

Quitaja saponaria.—The latter was put out last year in the Government Gardens at Ootacamund. It was untouched by the winter frosts and is now more than six feet high.

The *Kanera Aracha* and *Cochin-China tuberous rooted vine* have also been planted out and are doing well.

21. *Waras*.—I was asked last year by Mr. Thiselton Dyer to obtain information for him about this dye. This I have done, and from specimens which I sent to Kew *waras* turns out to be the produce of *Flemingia Grahamiana* and *F. congesta*. With respect to the distinctive characters of these two species, I pointed out that after studying the plants in their living condition, I did not think them sufficiently constant to allow of the two species being kept separate, and in this opinion both Mr. Thiselton Dyer and Professor Oliver now concur. The *waras* yields a beautiful dye when applied to animal substances such as silk or wool, but it is inferior as a dye when used for the purpose of coloring vegetable products such as cotton or linen. Mr. Thiselton Dyer has kindly obtained for me a London expert's opinion upon the value of *waras*, and I regret to say that it is not such as is likely to lead one to believe that it will ever become an object of commercial interest. I may mention that when I was in Madras last winter, I was at the Agri-Horticultural Gardens a flower-show a specimen of *waras* in a native dyer's collection which was being exhibited, and from which it would appear that *waras* is not unknown as a dye in India.

22. Mr. T. Haubury has sent some three hundred packets of seeds from his garden in Italy. Most have germinated, and I shall hope to report upon the more interesting species next year.

Value of Nilgiri peat as fuel.—During the past year I have paid some attention to the manner in which peat is formed on these Hills and have experimented upon it, with the view of finding out what its value as a fuel may be. The peat on these Hills is formed entirely from plants belonging to the sub-kingdom *Phanerogamia* such as sedges and other marsh loving plants. There are no mosses which enter into its composition as is commonly the case in the northern and more temperate regions.

The value of the peat as a fuel is very inferior to that found in northern countries, and this is apparently due not to any inherent badness of the plants which go to form the peat, but to the great admixture of inorganic substances which are blended with it. The cause of this admixture is due to the amount of soil which every year is carried down from the Hills during floods and spread over the surface of the peat forming swamps. There is, however, some which is very good, notably that which is commonly sold as fuel in Ootacamund by General Baker. This is

little if at all inferior to the peat, which is obtained from the bogs of England, Scotland or Ireland. But of this good quality there is, so far as my investigations have gone, a very limited quantity.

HOW TO TEACH HORTICULTURE.

"What has he done?" was the criterion of the great Napoleon when the merits of a great unknown general were laid before him. When much theory is being talked and written about the higher forestry teaching, it may be interesting to know what Professor Lazenby, of the State University, Ohio, has done in the Horticultural Department of which he is in charge. Observation and practice are required to supplement and emphasize the instruction of the classroom.

The following is a brief summary of the means of illustration and instruction at the disposal of students:—

1. A museum, containing specimens of nearly every plant found in the State, and fairly representing the flora of the United States. A large collection of grasses, seeds of weeds and various economic products of the vegetable kingdom.

2. An orchard, containing numerous well-selected varieties of the apple, pear, cherry, plum, and quince.

3. A garden of small fruits, containing nearly all the good varieties of the strawberry, raspberry, blackberry, currant, and gooseberry.

4. A vegetable garden, with hot-beds, cold frames, experiment plots, conveniences for irrigation, etc.

5. Nursery and tree-plantation, with practice rows, budding, grafting, pruning, etc.

6. Ornamental grounds, planted with a large variety of ever-green and deciduous trees and shrubs.

7. A well-built and conveniently-arranged greenhouse, furnished with a good collection of native and exotic plants.

In America, compact teaching power seems preferred to that vague grasp after the unapproachably magnificent so well known in British Universities.—*Journal of Forestry.*

ORANGES IN PALESTINE.

Consul Merrill, of Jerusalem, states, in his last report on fruit cultivation in Palestine, that the orange groves in that country are confined chiefly to Jaffa and Gaza, and are situated near the sea coast. The trees appear to flourish best near the sea, the beach sand mingled with alluvial soil being best adapted to their growth. There are, in Jaffa alone, no less than 500 different gardens, containing, altogether, about 800,000 trees, both large and small. Of these gardens, 150 are ranked as first-class, while the others are ranked as second and third rate in size and production. The trees are planted about 15 feet apart, although there is no regularity or exactness on the part of the natives in planting them. In July or August, cuttings are made from the sweet lemon trees each about 18 inches long, and these are planted in beds and watered twice a day. They grow rapidly and in the second year they are budded. When the bud has taken, the lemon stalk is cut off, a few inches above the bud, and the new shoots begin to bear in the third or fourth year. The trees continue bearing for twenty or thirty years. During the summer every tree is watered once a week, and in some cultivations it is a rule to water the trees every fifth day. Water is brought to the surface from a depth of twenty-five or thirty feet, by means of horse power, the owner of the garden employing for this work horses, donkeys, or camels. The cost of irrigation, with which it is customary to reckon the other expenses that are necessary to keep the ground in order, is estimated at about one-fifth of the value of the crop in gardens of the first class, while in the inferior gardens it amounts to one-third, and sometimes one-half of the value of the crop. The orange trees in Palestine do not suffer from any noxious insects, fungus growth, or diseases of any kind, and both the climate and soil are admirably adapted to produce healthy trees. In planting, the ground between the trees is generally cultivated, small

fruits, or vegetables being grown where the branches of the trees do not touch each other. Interspersed among the orange trees are frequently seen palm trees, bananas, the apple, peach, plum, pear, apricot, or fig, and occasionally the mulberry and sycamore. The average cost to the producer of 1,000 oranges is estimated to be about 21s., and capital invested in orange gardens is expected to return between 12 and 15 per cent. For 1,000 oranges it is customary to reckon 1,500, so that after they are assorted, the purchaser will have, out of 1,500, 1,000 that are fit for exportation. They are consigned in large quantities to Europe, and among the different markets, that of Odessa is becoming the most important for Jaffa oranges. Thousands of boxes are also annually sent to London. Consul Merrill says that besides the Jaffa orange proper, which is the only description exported, and is of oval or lemon shape, and very large, there is another kind cultivated in Palestine. This grows upon trees that are grown directly from the seed of the orange, without budding or grafting. They are small, and of inferior quality, and are all consumed at home.—*Journal of the Society of Arts.*

EUCALYPTUS PRODUCTS.

The introduction of the oil of eucalyptus into the new British Pharmacopoeia will doubtless serve to direct attention to the products of this important genus of trees. The classical monograph of the genus by Sir F. von Mueller, of which ten decades are now before the public, contains a large amount of interesting and valuable information concerning both the oils of eucalyptus and the "kiao" or inspissated juice yielded by many of the species. This information is, however, scattered throughout the body of the work, and the absence of a general index renders it by no means an easy task to piece it together. It may therefore save some time and trouble if a brief summary of the more interesting facts concerning these pharmaceutical products are presented in a connected form in these pages.

Eucalyptus Oil.—In a genus, of which the members so closely resemble one another that it is no easy matter to identify any given species, it might be imagined that the products would not vary to any great extent. This, however, is not the case, for not only do the volatile oils differ in specific gravity, but in flavour, and in the yield afforded by different species. The oil of *E. piperita* and *E. haemastoma* have a peppermint odour, that of *E. citriodora* a citron odour, and that of *E. Staigeriana* exactly resembles oil of verbena.

The percentage of oil in the different species will be readily seen from the following table, as given by Mr. Bosisto and Mr. Nitschke, as obtained from 1,000 lb of about equal proportions of fresh leaves and twigs:—

	Bosisto.	Nitschke.
	Ounces.	Ounces.
<i>E. amygdalina</i>	500	—
<i>E. oleosa</i>	200	62½
<i>E. leucocydon</i>	160	—
<i>E. goniolepis</i>	150	—
<i>E. incrassata (dumosa)</i>	—	140
<i>E. globulus</i>	120	—
<i>E. odorata</i>	—	112
<i>E. obliqua</i>	80	—
<i>E. uncinata</i>	—	69
<i>E. gracilis</i>	—	54½
<i>E. rostrata</i>	15	—
<i>E. melioidora</i>	7	—
<i>E. viminalis</i>	7	—

The difference in yield of *E. oleosa* obtained by Mr. Nitschke probably depends upon the fact that the quantity obtainable varies according to the time of year at which the leaves are distilled. *E. oleosa* gives at one time only 2 pints and at others as much as 1 gallon of volatile oil per ton of leaves. In summer, when the soil is hard and dry, it yields but little oil; but in winter, when the moistened earth permits of more vigorous vegetation and development, the per-

centage of oil is much larger. The contrary is the case with *E. amygdalina*, which grows in upland districts, and which consequently has its vegetation checked by the greater cold in winter, and therefore yields oil most abundantly in the summer. The eucalyptus oil of commerce, as pointed out by Mr. MacEwan and others, has hitherto consisted chiefly of the oils of *E. amygdalina* and *E. dumosa*. The former lends itself well to the dilution of the more valuable essential oils such as neroli, rose, etc., for use in perfuming soaps, etc. The latter finds its principal use in the manufacture of varnishes, a comparatively small proportion being used in medicine. This will be readily understood from the fact that in Mr. Bosisto's manufactory alone at least six tons of leaves are operated on daily and the annual production is not less than 12,000 lb. of the oil.

The solvent powers of eucalyptus oil on resins, etc., have been given in the following order: mastic, sandarac, elemi, xanthorrhoea, resin, benzoic, copal, amber, anise, shalac, caoutchouc, and gutta-percha.

The oil added to methylated spirit, in the proportion 10 ounces of the former to 1 gallon of the latter, is used to dissolve kauri resin, which will dissolve in this mixture without the aid of heat to the extent of 2 lb. out of every 2½ lb. used; the addition of a little colophony or Venice turpentine rendering the kauri resin completely soluble. It is also used to dissolve asphaltum for photograph varnish. In veterinary practice it is used in Australia as an embrocation for swellings, bruises or stiff joints. In domestic practice it is employed for rheumatism, etc.

The necessity for manufacturing the oil cheaply as a commercial product has naturally led to the choice of the two species mentioned, which, as will be seen from the above table, yield a much larger quantity than *E. globulus*. The two other species which yield more oil than the latter, viz., *E. leucogydon* and *E. goniotalyx*, being probably more scattered in mode of growth, would be less easily procurable.

The oil which passes in commerce under the name of oil of *E. dumosa** is likely to vary considerably in specific gravity and in character since it is obtained from the mallee scrub, a dense shrubby growth covering desert land and consisting of a mixture of *E. oleosa*, *E. incrassata*, *E. gracilis* and *E. uncinata* in different proportions. Mr. Bosisto calculates that in Victoria alone the mallee scrub is capable of furnishing 4,843,872 gallons of oil, and the *E. amygdalina* 280,891,000 gallons.

Other species yielding abundance of oil, such as the *E. salubris* of W. Australia, will probably furnish volatile oil to commerce, when manufactories are established in the districts where they are abundant. The trees mentioned by Sir F. von Mueller as oil-yielding species are *E. salmonophloia* and *E. Raveritiana*, W. Australia; *E. acmenoides*, *E. microcorys*, and *E. eugenoides* in the Southern provinces. The volatile oil of *E. citriodora* will probably become an article of export as soon as it can be manufactured on a commercial scale, so as to compete in perfumery with oils of similar odour. This tree is regarded as a variety of *E. maculata*, bearing the same relation to it that *Thymus citriodora* does to *Thymus serpyllum*. The remark is made concerning it, in 'Eucalyptographia,' that the perfume seems only developed within the subtropical regions of the range of this species, but that it is nevertheless hereditary, i.e., when cultivated outside those regions.

Under the head of *E. crebra*, another species of eucalyptus, discovered by Mr. Sullheim, is alluded to as having lemon-scented foliage. This has since been described by Mr. T. M. Bailey, in the excellent synopsis of the 'Queensland Flora,' as a new species, under the name of "*E. Stigmeriana*, F. von Mueller, ined." This plant, according to Mr. M. Stieger, yields a large quantity of volatile oil, 21 per cent, which is exactly resins of oil of *Verbena* in odour, that it might easily pass for it. Its specific gravity is 0.901. The odour of the oils of *E. piperita* and *E. haemistoma* bears some resemblance to pepper-mint.—*Pharmaceutical Journal*.

* *E. dumosa* is considered to be a small form of *E. incrassata*.

TRACING PAPER may be prepared as follows:—Mix together with a gentle heat, one ounce of Canada balsam, and a pint of spirits of turpentine; spread it with a soft brush thinly over one side of good tissue paper. It dries quickly, is very transparent, and is not greasy, therefore leaves no stain on anything copied.—*Queensland Agriculturist*.

PRESERVING RAILROAD TIES.—It is at length found that it is profitable to creosote railroad ties in Europe, and large establishments for the purpose of so preserving them are getting common. In our country where we burn thousands of acres of timber annually, ties are yet too cheap to lead railroad men to think of it.—*Gardener's Monthly Horticulturist*.

PROSPECTS OF CINCHONA BARK.—A London authority, writing under date Jan. 8th, says:—"Quinine is active—and slightly higher. Some 70,000 to 80,000 oz. have been sold during the last 3 days. An improved demand from America is anticipated. The huge exports from Ceylon of cinchona bark have acted injuriously on the market."

INFLUENCE OF THE GRAFT ON THE STOCK.—Among the strongest arguments in favor of the idea that the graft has an influence on the stock is the experience of nurserymen with apple trees. It is well known that nurserymen can tell a variety by the root. A row of Maiden Blush apples when dug up presents a very different appearance to a row of Fallawater roots. It was supposed that the graft gave its own character to the root on which it was grafted, and this has been accepted as an undoubted fact. Now comes Mr. Eli Meech, of Shiloh, New Jersey, and tells the *Farmer and Gardener* that the reason for the difference in the roots is that the grafts send out roots of their own. Now we confess that this is much more reasonable than the older guess; and until we get more evidence are inclined to believe that Mr. Meech has the best of the argument.—*Gardener's Monthly Horticulturist*.

THE PRODUCTION OF SILK IN RUSSIA.—According to a Russian industrial journal, the production of silk in the Turkestan district is more important even than in the Caucasus; the yearly output averaging rather over 500,000 lb.; of which about two-thirds comes from the Sarawchansk district. Bokhara and Kashgar have, respectively, yearly crops of about 200,000 lb. and 300,000 lb. Silk cultivation has existed in Central Asia for seventeen centuries. In the first-half of the second century, the Chinese possessed nearly all that territory; to which fact the starting of the industry has been attributed. Its present development would seem, however, mainly due to its revival, in 1875, by the Governor of Bokhara. It is expected that the improved communications now being organised between Europe and Central Asia, will tend to open up direct trade in the raw material with the silk districts in question.—*Journal of the Society of Arts*.

SIR JOSEPH HOOKER, who has announced his intention of resigning his position as Director of Kew Gardens, has throughout his career manifested great interest in Indian botany. It is not generally known that he nearly acquired the crown of martyrdom as the reward of his scientific zeal when he was made a captive by the Raja of Sikkim. His researches have by no means restricted to the flora of India, although his Indian studies contributed in no small degree to his high reputation. According to a recent writer, "it is difficult to conceive that his 'Himalayan Journals' can ever be out of date either for instruction or entertainment." The work he has done as Director of Kew Gardens is of incalculable importance, alike in the interest of pure science and material progress. Although Sir Joseph proposes to give up his official salary and the official cares which entail upon him an enormous correspondence, his influence will not be lost to Kew, or to the scientific world, as we are told that he will continue his labours at the Kew herbarium.—*Indian Agriculturist*.

Correspondence.

To the Editor of the "Ceylon Observer."

THE AGRICULTURAL VALUE OF COIR DUST: ALLEGED BLIGHT ON COCONUT PALMS.

Colombo, 20th Jan. 1886.

DEAR SIR,—In *re* communications that appeared in the columns of your paper concerning what Mr. Symons is said to have stated before a Committee of the Legislative Council as regards the worthlessness of coir dust, and his subsequent explanation, I have only today seen one extract taken over from your contemporary the "Examiner" appearing in your last night's issue, and I have no hesitation in saying that I heartily endorse every word that correspondent has said, and would gladly abide by Mr. Jardine's decision whether coir dust is so utterly worthless as Mr. Symons tries to make out.

I have also recently heard that some large coconut estates in the Western Province appear to be afflicted with a kind of blight denuding the branches of all their leaves and making the appearance of the tree quite unlike its ordinary appearance. I don't want to raise any alarm, but a proprietor of a very large estate in the Negombo district stated that in his experience, counting over very many years, he has seen nothing similar to this. Have you heard anything of it? I trust now that Mr. Jardine is located in about the centre of a large and important district, he will, if he observes anything that betokens the approach of any blight, sound a note of warning in time.—Yours truly,

AGRICULTURIST.

[We have not heard of the specific attack mentioned, but the coconut palm has always been subjected to attacks from beetles and occasionally from locusts and leaf-eating moths. We should readily publish details of the new blight if sent to us.—Ed.]

TEA-SEED OIL?

Maskeliya, 25th Jan. 1886.

DEAR SIR,—Oil is made from tea-seed in China, and I hear that coolies are making it for their own use on estates.

The question is, would it pay estates to make oil from their tea-seed? Before long there will be a very large quantity of it on many places in Ceylon. Taking it from the trees would relieve them very much, as it could be done before the seed was quite ripe and long before it would drop naturally. If it would pay the expense of gathering and making, and give a moderate profit, surely it is worth while trying; another advantage would be, we should be relieved of the large quantity of seedlings there will be on many tea estates in the island.—Yours truly,

INQUIRER.

[Unfortunately it is the least valuable varieties of tea which seed earliest and most copiously. To get the maximum of oil the seeds ought to be left to ripen fully, and this would involve rapid exhaustion of the soil. As it is not likely that growing tea merely for oil will pay: the better course would be to get the weeder to remove the blossoms. Immature seed, smashed, is readily eaten by cattle. The author of the letter says in a private note:—"Enclosed a letter, *re* oil from tea-seed. I know it is a good oil, for we used it for our binnacle lights, on the voyage home from China, in preference to coconut oil. An oil mill on an estate would not take up much room, and if making it would pay, it would be another product or rather not quite all our eggs in one basket."—Ed.]

SALE OF CEYLON CROTON SEEDS.

Golconda, Haputale, 30th Jan. 1886.

DEAR SIR,—The undermined sales of croton-oil seeds may encourage some, and convince others that as yet croton cultivation is not to be despised:—

Date of Sale.	ewt. q. lb.	per cwt.	From Golcor.la.
10th Dec.	8 3 27	at 59s	"
"	6 2 0	" 57s	"
"	0 2 14	" 48s	"
1886.			
8th Jan.	9 3 17	" 67s	"
"	1 1 13	" 55s	"
"	25 2 11	" 70s & 71s	Wibaratene
"	5 2 14	" 55s	"

As T. A. quoted croton seeds at 36s and 40s as being the market rates on 3rd December, the above sales are sufficient proof that Ceylon can produce a good article even in crotons.

Messrs. Cumberbatch & Co. were the curing agents.—Yours faithfully,

JAMES WESTLAND.

THE BLACKSTONE ROLLER AND THOMPSON'S "CHALLENGE."

Dikoya, 3rd February 1886.

DEAR SIR,—Now that the Blackstone roller is claiming such notoriety, it would be as well for the purchasers and the public to know, if Mr. Barber is prepared to give a guarantee with each roller that there is no infringement of patents, and if in the event of Thompson or anyone else putting in a claim, he, Mr. Barber, is willing to take all responsibility on himself. Mr. Barber says, Thompson has not pretended that he has invaded his rights; if so, why not give to each purchaser a guarantee? Can you inform me what claim can be put in, should it be found that the machine is an infringement?—Yours faithfully,

TEA.

[Being asked for a legal opinion, we can only refer our correspondent to Mr. Barber, who being a lawyer as well as a machinist ought to know what he is about. Thompson, if he really believes that his patent rights have been invaded, will doubtless claim a royalty, but to ask us to specify the amount is what the engineer of the "Challenge" would characterize as "peculiar in the extreme."—Ed.]

TEA TREES WITHOUT TAP-ROOTS.—In the present unsettled state of knowledge in regard to what is best for the tea plant, here and there a bold soul steps out from "the ruck," and astonishes with the brilliancy of his ideas. One of these advanced thinkers has lately been promulgating the idea that a tea plant without a tap-root is a chamberer of the ground, no matter how well it may apparently be growing. He has not been afraid, either, to act upon his belief and put his theory into practice. Accordingly all plants with a peculiar habit, which he says is common to those whose tap-root have gone, a droop in the branches, I understand,—have been rooted out on those estates to which his influence extends. This may be right enough: and although few may have the courage necessary to follow such an example, still no one will mind the other fellow trying it for himself. A similar attitude of mind is evinced towards the much too particular man who has lately been uprooting good tea, because the lines are not quite straight! That is a refinement of planting which, like the proverbial straw on the surface, tells of the flowing of the tide of prosperity. It is neither a hard-up nor struggling man who could afford to do that.—*Cor.*

BLACK ANTS AND OTHER PESTS.

(To the Editor of the "Pioneer.")

Sir,—In the *Pioneer* of the 11th January is a graphic account of a householder's sufferings from black ants, so I may suggest a remedy which I have always found successful? The crude, dirty, commercial castor oil, as sold in the bazaars, is so disliked by black ants and they will not come near it. Meatsafes and admirals may be protected by letting the feet stand in little tin troughs of water, on the surface of which the oil floats. The oil may also be squirted down any openings from which black ants appear, either outside or inside the house. A lady whose store-room was infested with black ants to such a degree that the trampling swarms could be heard as well as seen expelled them with castor-oil of this sort. She steeped strips of flannel in the oil and nailed them on the edges of shelves, brushing them well once a week with the oil. The effect was marvellous. Kerosine, which your correspondent tried, has not been found effectual against black ants, but it is most efficacious against white ants, bugs and ticks in chicken-houses or pigeon-houses, if used persistently. Rooms or furniture infested with these pests should be emptied, and at first treated freely with kerosine every day for a week, applying the mineral oil everywhere to the roof, the floor, the walls, and the fixtures, like whitewash. Then it can be applied to the room in its ordinary state twice a week for three months at the edges of the room where the walls meet the floor. After that, if the edges are lightly brushed with the oil once a week, these pests will not return. To protect fowls from ticks not only must the fowl-house be painted with kerosine, but the perches also, and every fowl should have its feet lightly brushed with kerosine every night before it retires to rest until all ticks have disappeared, which will be in about a month. The floor of fowl-houses should be dug up occasionally and fresh dry earth put down instead of the old dirty soil. The ground near the fowl-house should be similarly treated, and clean, dry, sifted earth should be provided, in which the birds can take their "dust bath," which they seem to enjoy so thoroughly that it must be conducive to health.

R. TEMPLE WRIGHT, M.D.,
Surgeon Major.

Nagpore, C. P.

P.S.—Kerosine is equally useful to protest trees from lichen. First scrape all the lichen off the bark with coarse gunny of *tūt*. Then paint the parts thus exposed with kerosine.* At places where branches are cut or broken, or there is a serious crack in the bark or the wood, paint with kerosine, and then cover the part with tar, as a protection from the air. Can any one mention a good protective against mosquitoes other than mosquito curtains?

PRODUCT PER ACRE OF STRAWBERRIES IN WESTERN NEW YORK.—Mr. C. M. Hooker says that in 1884 strawberries produced a wonderful crop. Never before was so heavy a crop grown here—6,000 to 8,000 quarts per acre not being uncommon. The usual average in previous seasons not being over 2,000 quarts per acre. This great production arose doubtless from a very favourable growth of the plants in the fall of 1885, the plants coming through the past winter in good condition, and frequent rains during the growth and ripening of the fruit. Prices were very low.—*Gardener's Monthly Horticulturist*.

* Might be tried, cautiously, on lichen-infested tea trees.—ED.

REPORT OF THE CALCUTTA TEA SYNDICATE.

The Tea Syndicate held a meeting on Wednesday, the 9th instant, to receive a final report of its operations, which may now be said to have practically closed, though it is hoped that some fruit will yet be gathered from its labours. Mr. Cruickshank, the Chairman, gave an account of the operations of the Syndicate, recapitulating the steps that have been taken in the interests of Indian tea. The Syndicate was formed in 1880, with the object of extending the trade in Indian tea with Australia. £20,000 were raised by merchants, agents, and brokers in the city, and this was supplemented by grants from Government and contributions from others, and by shipments of tea, the commission on which helped to pay the cost of the operations. Mr. D. A. Sibthorp was sent to Australia, and by all likely methods sought to introduce Indian tea to the colonial market. His efforts were not very successful at first, but by degrees the tea got a footing and what we have noticed elsewhere seems to take place in Australia. The taste for Indian tea, thought not at first always appreciated as it deserves, gradually grows upon the consumer, with the inevitable demand in course of time. Agents in Australia were employed to push the sale of the tea, without any very encouraging success in some parts of the country. The returns of total shipments for five years have shown periods of activity and stagnation alternately, during which probably both the Syndicate and the consumers of tea were being "educated" as to the requirements of the market and the power of the growers to meet them. Though the extension of the trade with Australia has not been so great or rapid as might be desired, the Committee conclude that "Indian Tea has now acquired a secure footing in the Colonial markets, and it is not unreasonable to hope that as its merits become more widely known, the demand for it will steadily increase." In 1881, the Syndicate sought to place tea in the American market. But Cousin Jonathan does not appear to be a tea-drinker. Whether he prefers such nectar as "cock-tails" and "eye-openers," we are not prepared to say.* The American experiment was not even a modified success. The consumption of tea there in any case is small and the preference seems to be for the highly flavoured teas of China and Japan. We should have thought our American cousins had been more 'cute in their generation, but it seems not, as the total shipments to America, through all sources of Indian tea have scarcely exceeded one and-a-quarter million pounds, not much more than a teaspoonful per head per annum of the population. The Amsterdam Exhibition seemed to afford an opportunity of introducing Indian Tea on the Continent. Mr. T. Caritt visited several towns, and obtained some interesting information about the tea trade in those countries, but no practical result followed. The Committee had not the means to continue their efforts as had been done in Australia, and though some tea is now taken for mixing purposes, the business done is of a limited character.

The statement of account shows that the subscriptions amounted to £41,125; the disbursements on account of travelling, &c., to £18,671-11-3, in addition to which salaries, office expenses, &c., came to £25,720-12-6, and £19,597-12-8 were spent on other accounts. This extra expenditure has been met out of commissions realised on the sale of Teas, which has enabled the Syndicate

* Coffee is the favourite beverage in the United States, the relative positions of coffee and tea being there the reverse of what obtains in Britain.—ED.

to carry on its operations till now. There remained a balance of R7,422-3-3, to the end of July; and it is estimated that after all charges are met there will remain a balance of R6,000, which the committee recommend should be made over to the Indian Tea Association towards the expenses connected with the representation of Indian Tea at the Exhibition in London next year. The Committee regret that it has not yet been found practicable to secure an extensive use of tea in this country, as it is a drink well suited to the habits and requirements of the people. A proper distributing agency does not appear to be available. The Committee are not unmindful of the development of tea-planting in Ceylon, as cultivation is rapidly extending. There ought also to be a large increase in consumption. Tea is more extensively used than ever in the United Kingdom, and probably will increase in our English Colonies. Of the Continent we are not so hopeful. A Frenchman once hesitated to visit us in England lest we should "give him tea," which he regarded as a sort of medicine, "only procurable at the chemist's." This was in Paris during the Exhibition of 1878. We got a sample of Indian tea from the Exhibition, and so far overcame his prejudice as to induce him to have a cup, and—he wanted some more! No doubt the general prejudice may be broken down as the individual prejudice was in his case; but it will take time, and the world has yet an ample population to take the produce of the tea gardens.

The Committee direct attention to the possibility of trade with Central Asia and Tibet. It is hoped that something may be done in that direction. The Syndicate adopted the report of the Committee, and passed a resolution to wind up the Association, accepting the recommendation of the Committee to hand over the balance as suggested. It will be interesting to ladies who preside over tea tables, and pride themselves on their brew of the "cup that cheers but not inebriates."—*Indian Daily News.*

THE MARKET FOR COCA.

In the last number of the *Ephemeris* Dr. Squibb gives some particulars respecting the supply of coca leaves, which do not exactly coincide with the statements hitherto current. He does not unreservedly adopt "the holders story" that no fresh shipments could reach New York before May, especially considering that about the middle of February about 8 cwt. did arrive, not of very good quality, but much better than any there. This was offered at from 5s. to 10s., and by March 1 was still unsold. Dr. Squibb then gives the substance of letters he has received from authorities familiar with the West Coast of South America, whose information is, to some extent, new. Dr. Jones, of the United States Navy, and Mr. Daubelsberg, the United States Consular Agent at Arica, have sent Dr. Squibb letters and samples, from which it appears that the best coca is produced in Bolivia east of the mountain-range; that it is brought across the mountains for several hundred miles on the backs of pack-animals to Tacna, and thence by railroad about 40 miles to Arica; and that the rainy season from January to May renders the long transportation somewhat risky on account of damage by wetting. The original packages of 45 to 50 lbs. are called "tambores"; and these, after having crossed the mountains, are put two or more together into bales, and are thus exported. The leaves are, especially when compressed in large bales, very sensitive to damp and heat; and however green and good at the start, and whatever precaution be taken to secure cool dry transportation, they are always damaged somewhat, and often very much more than by the long trip across the mountains in small parcels. Bolivian coca of good quality is always dear, prob-

ably from the long and expensive journey to the seaports, and Dr. Jones says that in the shops along the coast it sells at 80c. to \$1 per lb.

Mr. Daubelsberg, the Consular Agent, who has dealt in Bolivian coca for many years, sends mail samples of good quality, and says that, lately, in order to secure the quality, the leaves are repacked in tins for transportation. The mail samples sent are so different in appearance from the coca commonly met with as to raise a doubt whether good Bolivian coca ever reaches this market. The leaves are much more uniform in shape and size than those ordinarily met with, and although not of a very bright green colour, are much more uniform in colour, and are less broken up. But the greatest difference noticeable is in the characteristic creases which mark the back of the leaf, extending on each side of the midrib in an elliptical curve from the point to the footstalk. In all the coca of the market these characteristic creases are wanting in a small proportion of the leaves; but, being of all degrees of faintness in other leaves, their absence cannot be considered as excluding the leaves from being the product of the coca plant, but that they vary under different conditions of climate, soil, &c. Bentley and Trimen, "Medicinal Plants," vol. I., article 40, say:—"It is scarcely possible to mistake the leaves of coca for those of any other plant—the two longitudinal arched lines on the under surface being characteristic. These, which are found in several other species of *Erythroxylon*, are not, as often described, veins or nerves, but folds or creases produced by the mode in which the leaves are packed in the bud."

In the small sample of Bolivian coca, however, not a single leaf could be found without this characteristic, and in very few leaves was it so faint as to require very close inspection. Another difference in this sample is that in some of the larger and older leaves the footstalk and midrib have the red colour, which in the wool of some species gives the generic name *Erythroxylon*, or red-wood.

Neither Dr. Jones nor Mr. Daubelsberg say a word about the new crop in May story, but leaves their readers to the inference that high prices have cleaned out the seaport towns along the coast, and that with the characteristic slowness of the people and their modes of transportation, it takes some time to re-supply them. As the reports of the high prices reach the interior, however, the probabilities are in favour of an over-supply.

The market supply of cocaine salt has, for some time past, been abundant, and it is highly probable that all the principal makers have a good stock on hand. The former high prices seem to have had the effect of rapidly diminishing the less rational uses of the agent, and of restricting it to the limited special uses to which it is applicable, and when thus limited the demand fell off—or, at least did not increase—while the amount manufactured continued to increase until the stock on hand became probably sufficient for several months' supply.

It is probable that the few makers soon found out by experience with their processes that even the leaves of poor quality gave larger yields than had been expected, and that the difficulties of extraction grew less and less with experience in the management of details, so that the supply became greater than the demand, and stocks thus accumulated. This, of course, led to a reduction in price and the abandonment of the very unreasonable prices caused by the first sensational demand. Under this improved condition of both demand and supply, the price of the hydrochlorate fell, in the wholesale market, from 50c. per grain, or \$7.50 per gramme, to about 30c. per grain, or \$4.50 per gramme. Dr. Squibb states that by his own process, with even moderately good coca at, say 90c. to \$1 per lb., it can be produced at this lower price, with a fair manufacturer's profit, but cannot be produced at a lower price until better coca at lower prices is accessible.—*Chemist and Druggist.*

NOTES ON 28 PHOTOGRAPHS, ILLUSTRATIVE
OF THE CULTURE OF COFFEE, CINCHONA,
TEA AND EXOTIC TIMBER AND ORNA-
MENTAL TREES, ON A MOUNTAIN
ESTATE IN CEYLON.

SENT TO THE INDIAN AND COLONIAL EXHIBITION OF
1886.

[With the belief that some of the information embodied in the notes may be useful to planters and generally interesting, they are now published.]

GENERAL DESCRIPTION.

The estate in question is at too high an altitude, 4,600 to 6,100 feet, for the cultivation of cacao and cardamoms. The so-called Arabian coffee would have succeeded well here, up to 5,000 feet, but for the effects of *Hemilea vastatrix* which appeared on Ceylon coffee in May 1869; cinchona, from first to last, has, with all its capriciousness, yielded very good returns; but on this estate as on the vast majority of Ceylon plantations, TEA is the culture to which almost exclusive attention is now devoted and on which justifiable hopes of success are founded. Calculations based on Indian experience led originally to scepticism as to the profitable growth of tea at so high an altitude, but experience on this estate, now reaching back to a decade of years, has proved that soil and climate are eminently suitable to the luxuriant growth of "the leaf which cheers but not inebriates," and an experienced Visiting Agent who has recently been on the estate has expressly reported that "tea flushes as well here as in the lowcountry." To account for this result, common to plantations in Ceylon of loftier altitudes than this by nearly 1,000 feet, it must be remembered that Ceylon is an island and that a large portion of the mountain zone is not more than 7° north of the equator. The estate is almost exactly on the seventh parallel, and the effects of the warm, moist insular climate is that a position at 5,000 feet here has a higher mean temperature than places little more than half that altitude 20° farther north, in Darjeeling. The much more equal distribution of the rainfall, and the absence of drought, frost and hail storms, also tell in favour of Ceylon. The mean temperatures of the estate (formed entirely out of woodland, so that radiation of heat and evaporation are much less than from the damp grass land of the Plain of Nuwara Eliya, 2 miles off in direct distance and 6,200 feet above sea-level) vary from 65° at the lowest limit to 60° at the highest. The mean temperature at the new bungalow, 5,800 feet high but sheltered by a grove of exotic trees, is between 61° and 62°. Fires are enjoyable, however, for a considerable portion of the year, the temperature going down to 50° at night, while the mid-day heat rarely exceeds 80°. The rainfall averages about 110 inches, of which 36 fall in the south-west monsoon months, June and July, but rarely has a rainless month been known and even when rain is not deposited a considerable quantity of moisture is suspended in the air. The difference of altitude on this estate is such (1,100 feet), that sometimes, half-an-hour's walk is sufficient to exchange dense mist on the upper portion for bright sunshine on the lower. The estate being situated on the western side of the great central table-land of Nuwara Eliya, the "dividing range" between the western and eastern sections of the mountain system is deluged with rain, as already stated, in the summer months, while about ten miles away in direct distance, estates on the Haputale range, in Uva, are, at the same period, basking in uninterrupted brightness. The most rainy season on the eastern side of the

mountain system is in the north-east monsoon months. Tea is a plant so cosmopolitan in its habits, that it promises to succeed equally well in the comparatively dry climate of Uva, as amidst the abounding moisture of "the young districts" and old Ambagamuwa with its 200 to 250 inches of rainfall. If we take the region over which estates are scattered as bounded by Nalanda on the north, Morawak Korale on the south, Monaragala on the east, and Awisawella on the west, this mountain plantation, with other estates around Nuwara Eliya, is as nearly central to the whole area as any locality possibly can be. What is wanted, not only in justice to Uva, but to make Nuwara Eliya the true centre of the plantation regions of Ceylon, is, that the railway should be extended across "summit level," (about 6,200 feet above the sea, or 900 feet higher than it has already attained) to Haputale. Other extensions will follow, embracing, ultimately, the "lowcountry" tea estates. The first coffee nursery was opened on the mountain estate in November 1871. The first coffee and cinchona were "put out" in 1872. The first ornamental plants, near the old bungalow, were planted in 1873. Scattered tea plants were placed along paths and drains in 1871-75, and in the former year the first tea nursery was formed. Large nurseries of cinchona and Australian trees followed, and planting was gradually carried on, until all but about 70 acres out of 549, stretching a longitudinal distance, over abrupt and swelling mountain features, of beyond two miles, were cleared and cultivated. The succeeding notes show how "the old bungalow," near the Coffee Store, gave place to the "new bungalow" and the Tea Factory.

At one time there were 300 acres of fine-looking and promising coffee on the estate, and still there is a large expanse of coffee which is nearly all that could be desired, as far as looks go, but this season we expect to get only 800 bushels of "parclment" instead of 8,000 which we should have had a right to look for had there been no outbreak of leaf-fungus. Besides a good deal of cinchona bark, the fair prospect is that in 1886 about 130,000 lb. of made tea will be harvested and dispatched. At an average of only 1s per lb. that would support expenditure, which the transition from coffee to tea renders heavy, and leave a fair balance to the good. To the end of 1885, the expenditure on the estate since the first purchase of land in December 1870 will have been about R1,200 per acre, including R13,500 contributions to grant-in-aid roads leading to the estate and R22,000 on between 40 and 50 miles of specially good estate paths. The difficulty and costliness of "weeding" in tropical agriculture may be estimated from the fact that R70,000 stand against this item in the accounts of this estate. When coffee culture was at its highest in Ceylon, it used to be calculated that the removal of one free-seeding weed, *ageratum*, cost the planters no less a sum than £300,000 per annum. Of course the conditions of soil and climate which favour the luxuriant growth of the cultivated plants are equally promotive of the growth of weeds amongst which "escapes" of flowering plants from gardens, form a considerable contingent. But there is reason to believe that land planted with tea can be weeded at considerably less expense than the constant hand-weeding of coffee necessitated. Of the total expenditure on the estate under notice, two-thirds or more have been returned in produce, notwithstanding the inadequate crops from coffee. For (the balance, besides an excellent bungalow, good coolly lines, coffee and tea stores and machinery, the tea store very large and the tea machinery

new, costly and practically complete), we have the well-roaded and drained estate of 549 acres (in an almost perfect climate) with cultivation approximately as follows:—

Coffee and cinchona	200	acres
Tea exclusively	220	"
Tea and coffee	50	"
Grass	4	"
Shelter trees	15	"

Total cultivated 479 acres
Reserve forest 70 "

Total extent, 549 acres

Calculating buildings, machinery and land, the present value of the property is about equal to the balance of expenditure, with added value accruing every day, as tea is extended and comes into bearing. In converting coffee into tea estates, of course the cost of clearing is very much lower than if forest had to be dealt with, and in the case of comparatively young estates at high altitudes, the soil has received all the benefits of tillage without being to any appreciable extent exhausted by the crops previously borne. In answer to the objection, so frequently made by strangers to the country, that the soil must be rapidly washed away from steep hillsides in Ceylon, because they are not terraced, after the fashion of Java and some parts of India; it may be stated that our Ceylon soils and subsoils contain a much larger proportion of clay than those of Java and India and that, while such soil is eminently suitable for tea, it is so tenacious that terracing can be dispensed with in favour of a good system of surface drains, such as prevails here, in addition to roads and paths of good gradients, which largely help the drainage.

NOTICES OF THE PHOTOGRAPHS.

FOREST BEING FELLED BY SINHALESE.—In this operation, the first in "opening" an estate, the natives of Ceylon excel. Cutting the trees half through from the base of a hill up the more or less steep incline, they ultimately take advantage of a specially large monarch of the forest which they cut right through, so that in its fall it produces an impetus before which all below goes down with a loud crash. This operation is generally performed so as to be completed in November, in order that the forest may be ready for "a good burn" in February and for holing and planting in April-August. Besides felling, burning and "clearing up" forest, the Sinhalese will engage in contracts for the carpenter and mason work of estate buildings, but it was rarely they could, (until the recent period of depression from the large failure of the coffee enterprise, when their poverty more than their will consented), be induced to take part in ordinary estate work; especially in association with their old enemies the Tamils of Southern India, whose necessities and desire to improve their condition have led them to migrate to Ceylon in very large numbers during the past forty-five years of the planting enterprise.

TEA, COFFEE AND CINCHONA NURSERIES.—These, our second set of nurseries (the first having been formed at the southern end of the estate in 1871), were opened in the sheltered valley behind the assistant's bungalow, the first consignment of hybrid tea seed from the Assam Company being received and sown here in December 1874. The reticulated objects in the foreground are branches of trees placed on platforms for purposes of shade, and from which all the leaves have disappeared. It was soon discovered in Ceylon, that, while shade is useful for coffee seedlings and indispensable for cinchona beds, it is,

at high elevations at least, superfluous in the case of the hardy and cosmopolitan tea plant, which grows well in regions where snow falls, 40° or further from the equator in China, while it flourishes with luxuriance in proportion to the heat and moisture of the climate, at 7° north in Ceylon. A waterfall, of which merely a glimpse can be obtained amidst the felled forest, tumbles down the steep hill behind, which is planted up to the limits of the forest belt with coffee, cinchona and tea.

GENERAL VIEW OF THE ESTATE, LOOKING SOUTHWARDS.—The view was taken from the rear of the assistant superintendent's bungalow, which lies in a sheltered valley, 4,900 feet above sea-level, and which was specially devoted to coffee, tea and cinchona nurseries. The effect of the felled and partially burnt forest in the foreground is, of course, enormously exaggerated by proximity to the camera, but the scene gives a vivid idea of the beginnings of hill forest cultivation in the tropics, and shews how utterly absent the conditions are which would afford scope for the plough and the harrow. The implements used instead are, a hoe called "manveti" (earth-cutter), an "alavanga" or crowbar, and three-pronged forks. In the more advanced cultivation in the background are seen the bungalow to the left, and the school-house and cooly-lines to the right, while behind the belt of forest separating the estate from "Cymru," lie the bold-featured "Railway Gorge" and the exquisitely beautiful Agra patanas, on which, and on the neighbouring Bopatalawa patanas, the Duke of Edinburgh hunted Ceylon elk (sambhur deer) in 1870.

GENERAL VIEW OF THE ESTATE, LOOKING NORTHWARDS.—In the near foreground are tea and cinchona nurseries with the original two sets of cooly lines, the school-house and bungalow with a glimpse of the coffee store, two more sets of cooly lines and the assistant's bungalow. The view is interesting as showing a plantation in varied stages of its early formation. Beyond the nurseries, opened in November 1871, are rows of coffee bushes, three and a quarter years old, extending to the right of the cooly lines in the foreground. These shade away to one and three quarter years old coffee above the assistant's bungalow, and end in alternations of felled and standing forest running up the sides of the range, which the Nanuoya (rising on Pidurutalagala, the highest mountain in Ceylon, altitude 8,295 feet,—and running into Dimbula) separates from the Nuwara Eliya mountains. All of the forest represented in the view, except reserve belts of about 70 acres out of 549, has since disappeared in favour of coffee, cinchona, tea and ornamental and useful trees, the latter chiefly natives of Australia and the Himalayas. To show how home names are reproduced in the case of Ceylon plantations, it may be mentioned that amongst estates immediately adjoining are: Abbotsford, Edinburgh, Inverness, Lorne, Glashangh, Andneven; Cymru; Avoca; Carlabeck and Langdale.

VIEW FROM "KNOCK FERROL," 5,200 FEET ABOVE SEA-LEVEL, I.—Cinchona plants and stumps of felled forest occupy the near foreground, then rows of coffee not sufficiently grown (only about 3½ years old) to hide the stumps and trunks of trees which escaped the fire and which are left on the ground to gradually decay, so fertilizing the soil. Coffee in its fifth or sixth year thoroughly conceals the charred and skeleton-like trees, so prominent on young estates. On old estates, where the fallen timber has been used up or has decayed, the absence of firewood for the coolies and now for the tea furnaces is a serious want, and the time seems imminent when a considerable quantity of coal,

coke, paraffin or other imported fuel substances will be in demand for consumption on the tea estates of Ceylon. The buildings on the right are the first sets of "cooly lines" or barracks. The young cultivation is bounded by forest reserves on "Lorne" and on "Avoca" hill (Dambagas-talawa; the glade of the Damba tree, 5,140 feet altitude) behind which lie the lovely Lindula "patanas,"—upland prairies. The mountain in the background stretch from, on the left, Kotiyagala (the Leopard Rock, 5,747 feet altitude, popularly known as "the Duke's Nose," near which the magnificent mountain railway to Uva crosses the ridge that separates the great planting district of Dikoya from the still grander district of Dimbula, which a few years ago showed the largest continuous expanse of cultivated coffee, interspersed freely with cinchonas, in the world and which is now rapidly attaining the same eminence as a scene of luxuriant tea culture) to Rilagala, which divides Ambagawana from Dimbula on the right.

VIEW FROM "KNOCK FERROL," 5,200 FEET ABOVE SEA-LEVEL, II.—The two species of the fever plants in the foreground can be easily distinguished: *C. succirubra* by its large and corrugated leaves, while the smaller and more acute-leaved *C. officinalis* is conspicuous in the right-hand corner. Both species grew well for from four to seven years, at the height indicated, although such an altitude is better suited for the shrubby *C. officinalis*, rich in quinine, than for the larger and tree like *C. succirubra*, which flourishes specially from 1,500 to 4,000 feet and gives abundance of "druggists' bark," rich in cinchonine and other alkaloids better for tonic decoctions than as febrifuges, although they are valuable remedies in fever cases also. In 1875, cinchona was just becoming important as a cultivated product in this island, which is now the chief source of the world's supply of the bark that, a generation ago, could only be obtained from the home of the cinchonas on the Andean ranges in America. Beyond the cinchonas in the pictures is an expanse of young coffee, amongst which and the fallen timber are seen a couple of estate paths and, to the right, a portion of what was intended to be a cart-road. Abundance of paths and surface drains, of gradients not worse, if possible, than 1 in 20 for the roads and 1 in 15 for the drains, are essential to the proper working of an estate, while a cart-road for manuring and other purposes is most valuable. Conspicuous in a gap between Elbeddanda on the left and the upturned-ship-like Talankanda, is the topmost portion of the pyramidal cone which renders the sacred "Adam's Peak" (Samanala Kanda of the Sinhalese so conspicuous. The height of the summit, on which, in laminated gneiss, is marked the so-called *sri-pada* (sacred footstep of Buddha) and to which thousands of pilgrims annually resort, is 7,352 feet. The sacred mountain is really in the planting district of Maskeliya, and its direct distance from the point of view is about twelve miles. Elbedda and Talankanda, which hide the base and flanking ranges of "the Peak" and which divide Bogawantalawa and Dikoya from Dimbula, are about 700 feet lower than the summit of "the Peak," the altitude of Elbedda being no less than 6,637 feet. The mountain estate indeed, commands varied and magnificent views of fully fifty mountains of 5,000 feet and upwards, including the highest elevations in the island, Pidurutalagala 8,295 feet; Kirigalpotta 7,832 feet; Totapala 7,746 feet; &c., with the valleys and grass-lands between.

VIEW OF THE GREAT WESTERN MOUNTAIN, 7,264 FEET ABOVE SEA-LEVEL.—This truly grand mountain mass, which is only slightly inferior to Adam's Peak in altitude and is, in some respects, perhaps superior

to it in scenic effect, is a prominent object, however its profiles and aspects may change, from every point in the vast district, or series of districts called Dimbula. The mountain, in its mass, is more isolated and therefore more calculated to convey the sense of magnitude than is the graceful pyramidal "Peak." The pride taken by all dwellers in Dimbula in their special mountain, which is about 5 miles west from Nuwara Eliya, separating the district in which it is situated from Pundalnoya and Ramboda, will be acknowledged to be natural and justifiable. But the last thought that occurred to us or any one else in Dimbula, in 1875, was that in 1885, the breast of the ancient mountain would be scored by the iron road, along which daily trains should run. These are now accomplished facts, happily for those who are engaged in the task of retrieving by the cultivation of tea, fortunes wrecked in the disaster which soon after 1875, began fatally to affect coffee. The view in this photograph was taken from a point above and behind the bungalow and the out offices, including stables, cow shed and poultry house at the foot of the grass-planted ravine, where now a lakelet exists. Paths radiating from "the old bungalow" (1,800 feet above sea-level) and portions of the cart road, break the monotony of the new cultivation, while ornamental trees in the neighbourhood of the bungalow give promise of the wonderful growth subsequently attained.

LOOKING UP THE RIVER AND THE MOUNTAIN-GORGE THROUGH WHICH IT RUNS.—This view, taken from a point below the bungalow, but about 300 feet above the bed of the stream, will give a vivid idea of the wild appearance of this portion of the estate, before the sides of the hills and the felled forest became clothed with coffee, cinchona, tea and ornamental trees. A great rock, "Melrose Abbey," is scarcely distinguishable in the dark shade of this picture. The path shown and which passed from the bungalow under the rock to the ford on the river, is now largely superseded by a splendid cart-road and a path starting from the fine iron lattice-bridge which spans the stream.

THE WATERFALL, "CORA LINN," IN "MAGGIE'S GROVE."—This is a most beautiful and romantic scene of which only glimpses are afforded in the photograph, in consequence of the density of the shade of a long belt of forest which was left projecting into the estate, to protect a fine mountain stream. This stream falls 200 feet or more from the point indicated, in successive leaps into the sheltered valley, the scene of the early nurseries described in Nos. 2, and 3. In the valley it is joined by several other streams, on which also cascades occur and the united body of water forms ultimately "The Falls of Corin" (whence water power is conveyed to the coffee store), before it enters our river, the Dimbuldanda-oya at 4,600 feet above sea-level, while the point at which it fell into the estate, about a quarter-of-a-mile up, was fully 5,300. So abundant are waterfalls on this mountain estate, that its Tamil name is *Aruri tottam*, the waterfall or cascade garden.

LOOKING UP THE RIVER TO THE LATTICE FOOT-BRIDGE.—The river is the Dimbuldanda Oya, (the Dimbul tree stream) which crosses the estate and which is now, at the upper limit of the property spanned by a fine carriage-road iron-bridge. The Dimbuldanda meets the Nannoya from Nuwara Eliya, face to face, a few miles below, at Radella, one of the very few spots in Dimbula flat enough to be used as a ground for cricket and other sports. The scene at our Dimbula "meeting of the waters," in all save poetical associations, transcends the famous meeting in the vale of Avoca.

NEAR VIEW OF CINCHONA SUCCIRUBRA.—The large leaved *C. succirubra*, here so faithfully represented, was, like the other species, growing luxuriantly on the top of "Knock Ferrol," in November 1875, but this larger and more robust form had not run to flower and seed at about 3½ years old as the more precocious smaller species had done. Before the splendid looking grove of cinchonas on this hill had commenced to "die off" from canker and the trees were cut down for the harvesting of the bark, it is no exaggeration to say that, besides the large quantities of seeds gathered, some millions of self sown seedlings were produced and either utilized on the estate or sold. There was a sale to one planter of three quarters of a million seedlings. Much seed was also sold from the older trees on other parts of the estate, so that from first to last Cinchonas, the culture of which was fortunately taken up at a very early period, gave far better returns than coffee did. Tea was also adopted as a subsidiary cultivation at an early period of the estate's existence, plants being put down, amongst other places on the top of "Knock Ferrol." As the cinchonas disappeared the tea bushes took their place, and there are now fine fields of tea where ten to five years ago groves of cinchonas flourished, here as well as on many other portions of the plantation.

NEAR VIEW OF CINCHONA OFFICINALIS IN FLOWER AND SEED.—The late Mr. McIvor of the Nilgiri Cinchona plantations, the real founder of the culture of the fever plants in India, was enthusiastic in his admiration of this picture, which was taken on the summit of "Knock Ferrol" at an altitude of 5,200 feet, on a day when the air was perfectly quiescent. The result is that even without the aid of a magnifying glass, nearly all, even the most minute botanical characteristics of the *C. officinalis* bushes in the foreground can be pretty well identified. The little lakelet on the top of the hill, (what, in the north of England would, I suppose, be called a *turn*), was the result of rain water collected in a depression on the summit. This depression bears some resemblance to the crater of an extinct volcano, only that the boulders on the shelving sides are composed of stratified gneiss. Similar pools, before the British planter invaded the Kandyan forests, were favourite resorts of the elephant, deer and buffalo. The reflected figures in the perfectly still and transparent water are so much more distinct than the originals, that the picture is frequently inverted by puzzled beholders.

THE "OLD BUNGALOW" and GARDEN.—This bungalow was run up rapidly from unseasoned timber sawn on the ground, in 1872. It was built on a site near the south end of the estate, conveniently near the coffee store and 4,800 feet above sea-level. Its life was eight years, not bad considering the circumstances, and even then it was only the posts in the ground which decayed,—doors windows, &c., being utilized for the "New Bungalow." As will be observed, the ornamental plants put down in 1873-74, had begun to show in November 1875, and by the time the site had to be abandoned in 1880, there was a dense grove of Eucalypts, Acacias, Pinus, Auracarias, Palms, Bambus, &c. Some of the blue gums (*Eucalyptus globulus*) planted in 1874 are in 1885 upwards of 100 feet high, while trees of *Grevillea robusta* though not so tall, show noble stems. If tea, which is rapidly superseding coffee on this estate of 549 acres and over 2 miles in length, becomes, as is sanguinely hoped, a decided permanent success, another bungalow will probably be built on this beautiful site for the second division of the estate. When the original building was erected, although four years had elapsed since the coffee leaf

fungus, *Hemileia vastatrix* had appeared, the prediction by the late Dr. G. H. K. Thwaites that it would prove fatal to what was than overwhelmingly the staple product of the colony, was regarded with incredulity by the vast majority of experienced planters. But the naturalist judged only too truly of the disastrous effect of the pest, new not only to coffee planters but to scientists. The spores entering the stomata of the leaves and the mycelium sucking the life blood from the cells, coffee became more and more enfeebled, from the process of elaborating successive crops of leaves only to become the prey of the fungus, until fine shows of sweet-odoured, jasmine-like blossoms either gave no fruit, or only berries most of which dropped prematurely. From 300 acres of coffee planted on this estate only a few normal crops were obtained, the returns latterly from fine looking bushes, being not sufficient to repay up, keep, an experience, unbaptly, only too general on young as well as old estates. But for the advent of the fatal fungus, however, there was abundant evidence that coffee, planted from 4,600 to 5,000 feet would have here done well. Happily for the proprietor, he resolved from the first not to have "all his eggs in one basket," and the principles on which he directed the estate to be planted were:—

Coffee up to 5,000 feet.

Tea from 5,000, to 5,500 feet.

Cinchona officinalis from 5,500 to 6,000 feet.

Cinchonas, of both species and tea bushes were also, from the first planted along paths and drains, and cinchonas interspersed with the coffee. By the time the new bungalow, at the northern end of the estate, and 5,800 feet above sea level (just 1,000 feet more elevated than the "old bungalow") was occupied, it had become fully apparent that coffee was doomed; that cinchona bark had become literally a drug in the market, and that hopes of retrieval and prosperity depended on the expanses of tea around the new bungalow. These began to yield, in 1878 and onwards, after a fashion that encouraged extensions on a large scale: indeed the prospect is that two years hence, the whole cultivated ground, except a few patches of exceptionally fine coffee and cinchonas, will be planted with tea. Of course it is impossible to predict what providential dispensation may lie in the future, but as yet, one of the great encouragements to the extension of the tea enterprise in Ceylon, has been the comparative exemption of the plant here, from the formidable attacks of *helopeltis*, red spider and other "blights" so prevalent and so injurious on many Indian plantations.

THE FIRST SCHOOL-HOUSE.—This building, (to the left) was erected shortly after the completion of the bungalow, a glimpse of the front of which appears over the knoll to the right. It is over this schoolhouse now superseded by one near the new bungalow, that eucalypt rise to a height of 100 feet and more. The coffee in the foreground was, when the photograph was taken, about 3½ years old and interspersed are cinchona and tea bushes, a year younger. Some of the tea bushes are now noble seed-bearers and close by is an English oak, which, after a good many years of bushy growth, was pruned and is now a very beautiful and promising tree of about 14 feet high. It seems to have latterly got rid of its tendency to deciduousness. A chestnut, which grew close by, was rooted out by the coolies as an undesirable "jungle tree." The superintendent and his wife have always taken a deep interest in the school, which for several years now has been conducted by an accomplished and enthusiastic Tamil teacher, "Apolow Daniel." Government give grants-in-aid to estate schools, but the conditions as to attendance, &c., limit those grants to small sums. The benefits to

the children of instruction are very great, and indirectly the parents benefit. It is inspiring to see and hear the children marching home from school, with the schoolmaster at their head, singing Tamil lyrics, (Christian poetry) as they go. Two Governors of Ceylon, Sir Wm. Gregory and Sir Arthur Gordon, visited this school and were much interested in what they witnessed.

NEAR VIEW OF COOLY LINES.—The building on the left, the walls and partitions of wattle and daub, roofed with shingles, is a fair sample of the ordinary abodes provided for the Tamil coolies who work the Ceylon estates. In some cases brick buildings, tiled, have been erected, but as a general rule the coolies prefer the more primitive structures which, at their worst, are greatly superior to the miserable hovels they have been accustomed to in India, and to the level of which, if permitted, they would speedily reduce their "lines." These, as originally built consist of ten rooms in a block, five on each side with a partition between, and a good airy verandah on each side. The process of closing up these verandahs, to which coolies are inveterately addicted, is indicated in this illustration, but instead of boarding, as here shown, earthen walls are generally thrown up. Fowls, and if this is permitted, pigs, are kept in the verandah compartments. The South-of-India Tamil has many good qualities as a labourer, but regard for the elements of sanitary science is not amongst his virtues. He does not appreciate ventilation and as for cleanliness, it may be enough to remark, that a cooly is told off on this estate for each of the three sets of lines, whose work it is to keep the paths clear of offensive matter and to prevent the stream or pond on the side of which lines are invariably built, from being contaminated with the one great cause of fever, dysentery, and cholera. The coolies will not even whitewash their own abodes: they must be paid for this work when performed. The round building in this picture is a shed for the cow of the head kangani (native overseer), and there are bits of garden ground in which plainstains and vegetables are cultivated by the coolies. But many owners of estates have ceased to grant such indulgences. Cattle are very expensive to keep and the coolies are such inveterate thieves, that if a man has any valuable fruits or vegetables in his plot, he must stay away from estate work to cultivate and protect them. These people so distrust one another that when a cooly man and his wife go to visit friends on a neighbouring estate, the husband carries away the cock and the wife the hen, to prevent the killing and eating of the poultry in their absence. Sometimes estate coolies do not scruple to appropriate fruits and vegetables grown in "the bungalow" garden, and a case is on record of their attacking a plot of potatoes during the night and carrying away the tubers, but carefully replacing the plants in the ground, to the great temporary mystification of the superintendent.

MORNING MEET AT THE COFFEE STORE.—It will be observed that the rays of the morning sun are lighting up the young coffee bushes and felled timber on the knoll behind the iron-roofed store. The labourers, with the Europeans and the kanganis in front, are mustered on the scarcely completed "barbecues" or platforms on which the "parclement" coffee, divested of the "chery" husk or pulp, and washed in cisterns, is partially dried before being despatched to the Colombo preparing and packing stores. The coolies are awakened between 4 and 5 a. m. by the beating of a tomtom or the blowing of a horn, bells being few and far between. Food is prepared, of which the labourers partake, carrying their midday meal to the field. Mustered at six, the force ought to be at work by half-past

6 or 7, and they then continue to labour until 4 p. m. The coolies themselves prefer this system to being allowed an interval of rest at mid-day and then working to a later hour in the evening. "Knocking off work" at 4 o'clock gives them a long evening for their amusements and the cooking of the evening meal. Each gang of coolies has its kangani and there is generally a head kangani, but frequent visits from the European superintendent are essential to securing good work. Indeed the main duty of a "sinna durai" or young master (assistant superintendent) is to remain with the working gangs in the field. Where the Tamil cooly excels the Chinese and negroes, is in his steady adherence to one scene of employment and his amenability to discipline and command. Turbulence and bloodshed in riots, and gang robberies are very rare occurrences amongst Tamil coolies, even after reckoning some exceptional cases since the bad times, produced by the collapse of the once prosperous coffee enterprise, set in.

PORCH AND VERANDAH OF THE "NEW BUNGALOW."—In building this bungalow in 1878-79, the error, if any, committed was in the opposite direction to that in regard to the temporary erection of 1872. For the new bungalow a hill top 5,800 feet above the sea, was levelled, and the whole structure is of solid stone and brick, with good, well-seasoned timber. The result, if somewhat costly, is excellent; the house being safe from every wind that blows, well fitted and furnished, standing amidst equisitely beautiful mountain scenery and with a climate which for a large portion of the year, is about perfect. The exceptions are for a couple of months in each of the monsoons, when rain and mist are somewhat copious. But such meteorological conditions, while not generally adverse to human health are most favourable for the luxuriant growth of tea. In Ceylon,—on this property up to 6,000 feet and on estates on the eastern side of the mountain zone to nearly 1,000 feet higher,—we have thoroughly disproved Colonel Money's rash dictum that a climate good for human health cannot be good for tea. We now know we can calculate on at least, 500 lb. of tea per acre, per annum; while the estate is one of the healthiest in the world for the Tamil laborers as well as for their European masters. "The new bungalow," like the old, is now surrounded by a fine grove of exotic trees, and the picture shews how the indigenous tree ferns flourish at this altitude. Roses, lillies, violets honeysuckle, Bougainvillea and furze seem equally at home here as is the tea plant.

THE BEGINNINGS OF A TEA FACTORY.—This building, with a portion of the massive Great Western mountain and the extensive Dimbula valley for a background, stands close to "the new bungalow" at 5,800 feet above sea-level, and distant less than two miles from the Nanuoya railway station which is 129 miles from Colombo and about five to the entrance to Nuwara Eliya Plain. This tea house, as yet one of the loftiest in situation in Ceylon, is, with a very large addition now approaching completion, conspicuous from the railway line which runs along the side of Great Western, and from the upper windows of the building magnificent views are commanded. A tea store, from the enormous horizontal space required for "withering" the green leaf, must be twice or more the size of a coffee store, and the machinery employed,—rollers, sifters, driers, cutters, &c.,—cast the modest coffee pulper into the shade, both as to complicated appliances and cost. Tea machinery unquestionably saves a great deal of human labour for field work, but the first cost of stores and machinery on a tea estate of any size, is, we can answer for it, very heavy, even

where water-wheels have not yet been superseded by turbines or steam engines. The duties of a tea estate superintendent, too, who, as is generally the case in Ceylon, has the responsibility of both field and factory, are far different and far more onerous than those which appertain to the superintendent of a coffee estate. Both must know something of machinery, but the manager of a tea estate must be not only a competent engineer but an intelligent and careful chemist, to boot. The coffee crop "came on with a rush" at one period of the year, and then came comparative rest,—such as even tea planters enjoy in Assam in the winter months, November to March. But in Ceylon, from its proximity to the equator and its damp warm climate, the tea flushes and the flush must be gathered and prepared practically all the year round, the chief agent in preparation being, not water, but the element which has been rightly described as a good servant but a bad master—fire. Tea is good, bad, or inferior, mainly in proportion to the care with which it is fired, and there is ever present a danger, the thought or the apprehension of which, rom lights occasionally employed at night, never, we suppose led to the insuring of a single coffee store. But insurance against fire and the use of fire-proof agents and precautions against fire, must be amongst the regular contingencies of tea-making. Going into and out of rooms at a high temperature and full of the malt-like fumes of "fermenting" and "roasting" tea leaves, must also be trying to human health. But great improvements have been effected, mainly by superseding the long lines of open furnaces called "chulas," each sending forth charcoal fumes,—wood or other fuel sufficing for such driers as are now used: the Sirocco, the Venetian, the Victoria, &c. Other improvements will, doubtless follow, and meantime tea planting and manufacturing are full of interest to men of intelligent apprehension. To give an idea of the horizontal space required for the proper "withering" of green tea leaves, it need merely be mentioned, that Mr. C. S. Armstrong, the great Ceylon authority on the tea enterprise, has calculated that six square feet of horizontal surface will be required for properly withering each lb. of green leaf, of which four lb. are required to make one lb. of dried tea, fit for use.

LOOKING SOUTHWARDS OVER THE CATTLE SHED AND NEW LINES.—The showery and misty weather largely spoiled what in clear weather is a magnificent view with the ranges of the grassy Bopatalawa patanas and the rocky heights of Kirigalpotta as a background. The foreground gives a good idea of some of our best and oldest tea, in full bearing again, after recovering from pruning, and also of broad-leaved cinchonas and ornamental exotic trees amongst the tea bushes. The little lakelet and small cattle shed also come out well, but it is a great disappointment that so little is seen of the new and extensive sets of lines beyond, which, when the coolies are at home in the evenings, convey the idea of a populous mountain village. Of upwards of 500 labourers:—men, women and children, on the estate, over 200 reside here, amidst the tea cultivation which, extending from the northern end of the estate, is rapidly superseding coffee in the middle and southern portions. In a commodious room amidst these lines, a congregation of about sixty to seventy Tamils, many of them Christians, assemble on Sundays for divine service.

THE "BEND VALLEY."—This picture, pretty as it is, (water and rock being always effective in photographs,) gives but a very imperfect idea of one of the most beautiful scenes in Ceylon. The anks which supply the water power that moves the tea machinery, are at the lower portion of a

valley (5,850 feet) each side of which is clothed with most luxuriant tea bushes, flourishing and bearing abundance of flush even up to 6,000 feet, on the right hand side. Had the weather been clear, (as it had been before the photographer arrived and as it was the day after he left,) the young tea fields on which the Superintendent must justly prides himself, would have excited admiration, equally with the expanses of mountain forest beyond, ending with the highest mountain range in Ceylon, that of Pidurutalagala, as a towering background. From the dark misty weather which prevailed, we get chaotic shade instead of interesting details of flourishing tea at 5,850 to 6,000 feet, in all save the foreground, where the leaf-yielding tea is seen covering the ground, while the bushes left for seed bearing purposes and a remarkable cinchona tree (with bare stem and unbragous crown) stand out picturesquely against the placid water. A good magnifying-glass will help to an idea of the tea cultivation, which can compete with any in Ceylon; but even the most glowing imagination can scarcely supply the beautiful and grand details of the forested-mountain background, which the envious masses of driving mist swallowed up. Nothing at all can be seen of the remains of the cinchonas that once covered in dense groves the valley sides and mountain knolls, which are now still more densely and we trust more permanently and profitably covered with a carpeting of first class tea.

GIANT TEA TREES: SEED-BEARING TEA TREE AND GROVE OF TEA TREES.—Our first giant tree (No. 21) which was planted in 1876 and photographed in 1881, when it was 8 years old and shortly before it succumbed to a storm, was remarkable, not so much for its height, 20 feet, as for the enormous area, 88 feet in circumference, over which its horizontal branches spread. Of a much handsomer habit (pyramidal) and considerably taller is another tree (No. 22) reserved for seed bearing purposes, which being of the same age was photographed at the same time. Its dense foliage forms a fine contrast to the stems of the blue gum trees to the right. A truly magnificent tree, is our second giant (No. 23) which was nearly 10 years old, when photographed October 1885, unfortunately in dark misty weather. It is only 7½ feet instead of 88 in circumference (one diameter being 27' 3" and another 25' 4") but its proportions are far better than those of its predecessor, its height being 26 feet, while the tendency of its wonderful wealth of stems and branches is not purely horizontal but inclining upwards. To the left some trees of *C. succirubra* are exceedingly well shown and the stem of an Australian eucalypt frames in the picture to the right. This giant tea bush growing down a bank, neither its root-stem nor its summit could be brought into the focus of the camera. Considering the very unfavorable weather, the photograph is a good and faithful portrait of a tea tree, such as planters from Assam have declared they never saw there. The indigenous tea tree of the Assam forests, is said, in books, to reach a height of 100 feet, but no authentic measurements to this effect are available. Our highest trees are 30 feet, a stem over 20 feet which was cut from the 1871 nursery being one of the objects to be exhibited with these pictures. A piece having been broken off, the present length is only 27 feet 1 inch. It formed one of many plants allowed to grow up thickly in the nursery, the remains of which, owing to the dark misty weather in which the photograph was taken, in October 1883, are indistinctly shown in No. 24. A magnifying-glass, however, will reveal a dense grove of tall tea bushes, over which rise Australian eucalypts. The tea bushes, about a cou-

ple of hundreds, left to grow in the nursery were nearly 11 years old when photographed. Economically, it was, of course, a great mistake, to allow trees, which, planted at good distances apart would have become excellent seed bearers (the jat being first-class) to grow crowded together, but the scenic effect of our tea grove is striking and much admired by visitors. The trees in the grove have, also, yielded a good deal of seed and judicious thinning will make them still more productive. The better the jat and the loftier the elevation, the longer do tea trees take in bearing fruit and from the many thousands of intended seed bearers scattered over this estate, including 1,000 plants of Assam hybrid, grown at Hakgala, for which R100 were paid some ten years ago, the amount of seed gathered as yet has not been so large as we could wish, last season having been especially disappointing. Still, many hundreds of thousands of the finest flush-yielding plants on the estate are from our own seed, borne by trees 8 to 10 years old. It seems probable that had we resorted more than we have done to judicious pruning of our first-class big tea trees, we should have had earlier and larger returns of seed. Almost all tea planters know the vexatious tendency to early and copious flowering and seeding of inferior kinds of tea, China or hybrids largely partaking of China characteristics. The lower the altitude at which tea is grown, the more is this tendency apparent and a source of annoyance. The lower the altitude of estates, therefore, the more important is it that the jat should be "indigenous," or hybrid closely approaching it. The best for all altitudes, however is first-class hybrid Assam, with a close affinity to indigenous. It may here be mentioned that, influenced by what was observed during a visit to Darjiling in March 1876, tea was originally planted 3×3 on this mountain estate. But the growth, so much more luxuriant than was anticipated, of the plants, speedily indicated 4×3 as a better distance to allow of careful culture and plucking. On "lowcountry" estates where the soil is much more liable to the destructive effects of solar combustion, closer planting than even 3×3 is frequently resorted to.

VIEW OF "KNOCK FERROL" FROM THE LAKELET NEAR THE OLD BUNGALOW.—But for the rainy and windy weather, this would have come out a fine picture. Not only are the trees swaying to the wind, after the fashion which vexes the soul of a photographer, but the very waters of the lakelet are so rippled, that it requires the application of a magnifying-glass to realize that water exists in the foreground, around which the graceful bambus, prominent in the picture, are grouped. On the very summit of "Knock Ferrol" (5,200 feet above sea level), the "Giant Bambu" of Burma (*Bambusa gigantea*, Wall.; *D. giganteus*, Munro) flourishes, and this noble plant seems to have found a second home in Ceylon. It flourishes not only on the banks of the Mahaweliganga, at Peradeniya, where there are magnificent groups at 1,600 feet above sea-level, but in our higher mountain regions at 5,000 feet and over. We have stems which are about 2 feet in girth. The beautiful yellow bambu, so common on lowcountry river-sides in Ceylon, also grows well here at 5,000 feet. But *Bambusa arundinacea*, which we found in full seed in South Wynaad in 1877, hangs fire at our elevation. On a lowcountry estate it flourishes exceedingly, and we were rejoicing in our splendid shelter belts, when we discovered that nothing could be so white as 20 to 30 feet on each side of the bambus. They were, therefore, cut down and destroyed. Bambus are among the most gracefully beautiful objects in the vegetable world, and they are useful economically, but beyond all other plants we

know, not excepting even aloes, they are deadly to other vegetation and they ought to be grown by themselves, or on isolated spots where they look well and do the minimum of harm. Up the hill side and on the summit, to the left of the giant bambus, are Australian *eucalypts* which also, it would be well to cultivate by themselves instead of interspersing them amidst the coffee and cinchonas. Tea is intolerant of the presence of any other plant, and as our tea culture advances, the Australian gums, casuarinas, acacias, &c. must be removed. They will afford timber and firewood (the blue gum giving good-sized railway sleepers and planks at 10 years old); but unless an Indian planter is right in tracing tea blight to *Toon* trees (a very improbable idea) we should prefer growing *Cedrela Toona* (the red-timbered variety) to any tree we know. As *Cryptomeria japonica* has succeeded well at Darjiling it will probably do well at high elevations in Ceylon; but the cheapness with which tea boxes can now be obtained from Japan, largely removes the necessity of cultivating timber plants. With good lead lining to the tea boxes, the idea of well seasoned and but faintly resinous pine wood tainting tea, seems chimerical. While on the subject of trees, we may mention that in Ceylon as in Assam there is a tree, a large-leaved *symplocos*, which must be ranked amongst the enemies of the tea tree. Either inherently, or evolved in the process of decay, the roots of this tree possess a principle fatally poisonous to tea-bushes growing in their vicinity. Unpleasant gaps occasionally occur in well-matured tea from this cause, while it is not yet certain that *Albizia stipulata* is so beneficial to tea cultivation as some Assam planters believe.

VIEW (DOWN AN ESTATE RAVINE) OF THE VALLEY OF DIMBULA, WITH THE GREAT WESTERN MOUNTAIN LOOMING IN THE MIST AND THE LINE OF RAILWAY SCORING ITS SIDE.—The application of a good magnifying-glass to this picture will shew what a splendid view was rendered imperfect by the dense mist, in an interval of which, less dark than usual, the photograph was taken by the instantaneous process. The morning train for Colombo, which had just started from Nanuya (129 miles from Colombo and nearly 5,300 feet higher in altitude) is shown on the line, one of the most remarkable mountain railways in the world. It was constructed for coffee traffic, especially that of Uva, but was opened, so far, in time to aid and receive the benefits of the rapidly advancing tea enterprise. The scenery viewed from this line, combines all that is beautiful and grand in nature, with the one exception of lakes, for which the mountain system through which the railway winds is too abrupt. One of the cascades over which the line passes rushes down to the right of the train. The part on which the train is shewn is less than 70 chains direct distance from the spot where the camera was placed. This was at the top of one of our finest and most characteristic tea ravines, through the centre of which the "bund" stream rushes rapidly down. Up the steep faces of the hills on each side rise rich fields of tea, which having, for from 15 to 18 months, yielded "flush" at the rate of not less than 500 lb. per acre per annum of made tea (2,000 lb. green leaf) were in October in the course of being pruned. To the left will be observed a few members of a gang of coolies engaged in the operation. The tea bushes in the right are as yet untouched but on the left hand side, had the weather been propitious, the various stages of pruning and burying would have been fully apparent, viz:—

1.—The ground strewed with the debris of pruned plants, decaying timber, weeds from the ravines, &c.; 2.—The prunings, decayed timber and weeds

heaped up ready for burying in the longitudinal holes which are being dug at near intervals in the rows of growing tea; 3.—Ground as clean as garden beds, in which the prunings, &c., have been buried, while the moss has been rubbed from the branches of the tea bushes, before the development, (with wonderful rapidity considering the elevation,) of the fresh buds and leaves.

In less than three months from a pretty heavy pruning the bushes get into full yield again, and can be plucked at intervals of from a week to ten days for twelve to eighteen months, before the sweeping application of the knife becomes further necessary. On the left side of the ravine, the system of paths and drains is well shewn. Rock except in the beds of streams being rare, the estate is exceptionally well roaded. In respect of rock fragments on the soil, the fine district of Haputale, in which road making must be difficult and expensive, is a striking contrast to Dimbula. So with most of the old Matale districts.

The soil at our highest elevations has been pronounced perfect for tea and the period seems distant when manure will be absolutely required, but the manner in which our "cattle shed field" has responded to the small quantities of fertilizing material available, shows how largely yield could be increased by manuring, if only the system could be made to pay. The difficulty in regard to the keeping of cattle on Ceylon plantations is the great cost of imported food (gingelly cake and grain) and imported labour in the shape of cattle-keepers, while guinea and swamp grasses require to be themselves carefully cultivated, or they will be exterminated by inferior grasses and weeds, on the principle of the survival of the fittest. A few milch cows must be kept on most estates, but probably instead of resorting again to those extensive cattle establishments, so common in the palmy days of coffee, tea planters will avail themselves of the ammoniacal white castor cake, with a small proportion of bone superphosphate; also potash and nitrates, all in moderate quantities. Meantime the effects of merely stirring the ground by forks and opening up the soil by the burying of prunings and other substances is most beneficial.

THE FALLS OF AHER.—The object for which this photograph was taken was defeated by the misty and windy weather which prevailed. Coffee, with a few cinchona trees, occupies the foreground, and a few scattered trees belonging to a belt of the original forest are seen on the ridge, 300 feet above (5,200 against 4,900 feet in the sheltered valley where the camera was placed), but a confused mass represents the really fine and exceptionally lasting groves of *Cinchona officinalis*, which it was wished to show, growing at heights above the coffee up to the edge of the ridge. Down "the falls of Aher" tumbles one of several streams which unite in the sheltered valley near the remains of the tea nursery of December 1874. Unlike the considerably larger stream in "Maggie's Grove," this rivulet has been bared of forest and the effect, especially in rainy weather, is very striking, the descent being exceedingly abrupt.

VIEW OF THE CINCHONA-CROWNED HILL, ABOVE "MAGGIE'S GROVE."—The dark, misty weather and the strong wind prevented this picture coming out well. A peep at one of the many waterfalls in the belt of natural forest which covers the stream, is obtained and a group of tall blue gums rises to the left; but, unfortunately, the fine cinchonas which cover the slope down from the ridge, can only be brought out by a good magnifying glass.

TEA TOPPING.—A correspondent writes:—"The Vade Mecum is to hand. I am very pleased with it; but I find that all young tea should be topped at 3 feet, both according to Armstrong and the V. M. How is it that we all top at 1 foot, 15" and 18"? and some men I have heard of doing it at 9". The two Indian men who were over the other day found fault on the score of all Ceylon tea being too low. Can you give information as to what is the right height for 1st topping? It seems to me that an amended Cameron system might be propagated with great advantage to all young tea, which, it seems to me, is not getting the right treatment." Tea planters, like others, must be largely guided by personal and local experience, but we have never heard of or seen topping at 9 inches.

PASSIFLORA EDULIS.—An excellent figure and an exhaustive account of this interesting species, which is in some places cultivated for its delicious fruits, is given by Sabine in vol. iii. of the *Transactions of the Horticultural Society*, under the name of the Purple-fruited Passion-flower. A short time ago, in a florist and seedsman's shop, in one of the leading London thoroughfares, we saw fine fruiting branches of the common hardy *P. cerulea*, labelled "the true fruiting Passion-flower, *Passiflora edulis*;" those who were induced to try the fruits of this would hardly be likely to give them a high place for desert purposes. According to Sabine, the North American, *P. incarnata*, was the first species introduced to this country, "and for more than a century, the only species cultivated, of one of the most beautiful genera of plants existing."—*Gardeners' Chronicle*.

CINNAMON PLANT.—Under this name, with the addition of "*Cinnamomum dulce*," graceful foliage and very fragrant, in company with the Passion-flower above mentioned, there was a nice batch of healthy seedlings of some Monocotyledonous plant, in all probability a species of *Elettaria*. On our calling the attention of the shopman to such a palpable blunder he assured us that the plant was correctly named, and, to prove his point, bruised a portion of a young leaf, when sure enough a certain aromatic odour, somewhat resembling that of the Cinnamon, manifested itself. Of course no one with the slightest knowledge of economic botany would be at all likely to mistake a Cardamom for the Cinnamon plant; still, in the interests of those who are guileless of any botanical knowledge, and who have a love for plants, it is as well to mention the facts already stated.—*Gardeners' Chronicle*.

EUCALYPTUS GUNNII.—In a recent number of *Forestry* an account is given of some notable trees at Whittinghame, East Lothian, the property of A. J. Balfour, Esq., M.P. Amongst others, particular mention is made of a *Eucalyptus*—*E. viminalis*. This plant does not belong to that species at all, but to *E. Gunnii*. In spite of the error in the name, *Forestry* is correct in looking upon the Whittinghame *Eucalypt* as perhaps the most remarkable tree of its kind in Britain. The tree in question was brought in as a seedling from Australia in 1846; it grew rapidly in its new home until the memorable winter of 1860-61, when it was cut down to the ground by the severe frosts which then prevailed. During the following summer it broke away into four limbs, which have now reached a height of about 60 feet, forming a tree of a novel and striking character. The girth of the stem below where the massive limbs project is nearly 12 feet, and the branches are laden with flowers and last year's seed-vessels.—*Gardeners' Chronicle*.

FLIES AND BUGS.

Beetles, insects, roaches, ants, bed-bugs, rats, micropogers, chipmunks, cleared out by "Rough on Rats," W. E. Smith & Co., Madras, Sole Agents.

"YUCCA DRACONIS" AS A PAPER MATERIAL.

An American paper says:—For a long time past the London *Telegraph* has, like a number of American daily newspapers, manufactured its own paper as a matter of economy. Unlike our own daily journals with paper mills of their own, it has secured a cheaper material than any of its American contemporaries, and, what is most surprising, the Englishmen came to America for their stock. After satisfactory experiments, the proprietors of the *Telegraph* bought a large tract of land in the Mojave Desert, of California, thickly overgrown with the yucca plant or "Spanish bayonets." The yucca is to be cut down, transported to a point on the Colorado River, and there ground into pulp, which is to be taken by rail to New Orleans, thence by sea to Liverpool. This certainly seems a very roundabout, expensive way for a London daily newspaper to obtain stock for its paper mill, yet it is in reality the cheapest method that could be devised. The yucca plant, though neglected on the Pacific Slope and throughout the West, is a vegetable growth admirably adapted to the requirements of the paper maker's wants for raw material, and is so useful that it pays to transport it from the desert wilds of California to London. The supply of yucca is practically inexhaustible, and the extensive experiment about being made by the great English daily is deserving of being closely observed by the owners of the largely circulated American newspapers, who consume enormous quantities of white paper, which must be procured at the cheapest possible rates. The yucca is a hairy plant found in Arizona, New Mexico, and Lower California; it is readily bleached and as a fibre, almost as strong as hemp. It can be manufactured at about the same cost as paper made from mixed cotton and linen rags. It may interest some readers to learn the particulars of an invention just introduced in America for the treatment of paper stock, of *Yucca draconis* or *Yucca puberula*, or *Yucca brevifolia*, or sotal tree, so as to produce a pulp or paper stock of a finer quality than heretofore, and the agents employed being native products drawn from the immediate locality (California), where the fibre is grown, with increased economy. The yucca wood or plant having been unbarked, shredded or torn up, so as to be in the condition resembling tow, by suitable machinery is brought into tanks provided with perforated double bottoms; water containing common salt or waste solutions, resulting from a subsequent part of the process, is run in so as to cover the mass, which is then weighted down and allowed to remain in contact with the solution for several days; but if the temperature is raised to about 100 Fahr. by means of steam, this part of the process will be accelerated. To facilitate the next operation, the longer portions of fibre may be passed through a strawchopper before the material is treated in these tanks, so that the main portion of the fibre under treatment should not exceed one inch in length. The material is next removed from the tanks and brought under a system of trituration, or further opening up of the fibre by means of a grinding or triturating contrivance. This may consist of a fibre opener (*défileur*) or a pan mill, consisting of broad grooved or ribbed granite runners working upon a grooved or ribbed bedplate of granite or horizontal stone working under a flow of water, with a discharge trough or spout provided with a sieve for preventing fibres of a coarser nature from passing through than desired; or the mass as it passes from under the stones may be run on to a "sorting machine," such as is used in wood-pulp mills, or a "knotter," which will separate the coarse from the fine fibre. The coarse part is, of course, put back into the mill or apparatus to be reworked. This method of opening up and disintegrating the fibre renders the subsequent chemical treatment more simple and effectual.

The fibre brought into this state is now subjected to a species of digestion with a strong solution of borax, prepared from the native borax mineral of earth occurring in the locality where the yucca is indigenous. This may be done simply in vats or tanks, provided with stirrers or agitators and steam coils with condensing contrivance, as is well known. The mass of fibre is

steamed in contact with the solution of borax, which should be about 12° Baumé, for two or three hours. The borax liquor is then drained off from the fibre, and sulphurous-acid gas or vapour is introduced by means of perforated inlet pipes or coils, the tanks or vessels being covered during this part of the process, and remaining covered for an hour (more or less), while the sulphurous gas is being thus introduced. The fumes from five parts (more or less) of sulphur to one hundred parts of dry fibre, by weight, will be sufficient. Water is now run in sufficient to float the fibre, and the stirrers are set in motion so as to wash out the combinations formed and left secreted in the fibre. This may be done in about half an hour. The waste liquor thus obtained is by preference used as a steeping liquor for the first part of the process, viz., the digestion in the tanks. The borax liquor run off is then treated for borax, the liquor being first filtered through a bed of animal charcoal to remove the coloring matter, and afterwards boiled down and crystallised in the ordinary way. By this means a cheap and valuable agent in the treatment of the fibre is said to be secured as the process refines the crude borax of the country at the same time the fibre is treated. In the production of sulphurous acid, the crude sulphur of the country is used either in the form of native sulphur or pyrites, in the ordinary manner, with the precaution of passing the gas or fumes through a washer containing water to which sulphite of soda has been added, or milk of lime, so as to neutralise or eliminate any sulphuric acid which may form. The sulphurous acid may also be made by fusing together the crude sulphur mentioned and sulphate of iron in a retort, when sulphide of iron will be formed and sulphurous acid given off. The sulphide of iron is used over again for the fresh formation of sulphate of iron, and so on continuously. Sulphurous acid is also formed by passing the fumes of burning sulphur or pyrites through a tower filled with vegetable charcoal, sawdust, pith from the yucca, or such like material arranged on the principle of the scrubber of gas works. The sulphurous acid thus absorbed in the before mentioned material may be easily driven off for use from a retort, and may be employed without washing, if required. For commoner descriptions of paper the borax solution may be dispensed with, and a simple digestion with sulphurous acid may be effected by allowing the moist fibre to absorb a larger quantity of the acid gas than previously stated, or about equal to the gas to be evolved from ten parts (more or less) of sulphur to one hundred parts, dry weight, of fibre under treatment, and steamed in the same for about four hours in a closed or covered vessel. The liquor forced is run off and used as a steeping solution. The fibre is then washed in a warm weak solution of carbonate of soda, to prepare it for bleaching and for softening the fibre. This liquor may also be used in the steeping operation. In either case the material is now ready for bleaching, which may be effected in the ordinary manner or by any known or convenient means; but for high-class paper it is preferred to bleach with hypochlorite of magnesia, instead of hypochlorite of lime, the former being less injurious to the fibre, and imparting a brighter color.—*Indian Agriculturist*.

ON POTTING PLANTS.

Among the first-learned operations in plant cultivation crocking pots and potting plants are to a young beginner two of the most important. As garden boys we were first taught how a pot intended to contain a plant should be drained, and in due time we were allowed to take our place at the potting bench, when in our own opinion we were fully fledged gardeners. To a man whose apprenticeship was spent under a good and careful master, by whom all that it was important for the beginner to know with regard to potting and such elementary work was carefully explained at the outset, a chapter on such a subject will be of little value, and he may justly remark on seeing this that he and all properly trained gardeners have learned long ago all there is to know about potting. But, unfortunately, there are not a

few men who from one cause or another have not been properly grounded in the operation of potting, and that it is so every gardener finds out often to his cost. Recently at a meeting of a gardeners' society, of which the writer is a member, the chapter in Lindley's "Theory of Horticulture," which treats on potting, was read and discussed; and although everyone seemed to think he knew how to pot a plant properly, much was said that showed how some at least did not rightly comprehend the operation, whilst one or two supported views which if acted upon could not but result in disastrous consequences. This, therefore, is the excuse for writing a chapter upon the subject.

Some useful advice was given by Mr. Muir at page 232 on how to drain flower pots; but one or two flaws occur in what he has said—notably where he suggests that an inverted pot should be placed over the hole in the bottom of large pots. Now we all know that the first object to be attained by drainage is a free and constant outlet for the water from the soil above, and thus it is that where crocks only are used we are always careful to place over the hole at the bottom of the pot a large one with the concave side downwards. But a small even-rimmed pot placed over the hole is practically the same as placing a flat crock or a piece of glass over it. This will be apparent to anyone who observes how closely the rim of a small pot when inverted over a flat surface will touch all round. By breaking a few niches in the rim of the small pot to be used as drainage the danger of blocking the hole of the pot drained is obviated. In Lindley's book an excellent plan is mentioned for preventing worms, &c., getting into the pot through the hole at the bottom when placed upon the ground. He says, "To remedy this I put at the bottom a piece of perforated zinc so as to completely cover the hole. Upon this a large crock is placed with the convex side upwards." For large plants which are stood out of doors during a portion of the year this zinc trap seems an excellent suggestion.

The depth of drainage used always varies with the requirements of the plant—Orchids and a few other plants, generally epiphytal ones, requiring a larger amount of drainage than others. Bearing in mind that for plants which are intended to remain in the same pot for several years the more drainage used the less soil room there is, it will be seen that a thin layer of crocks if properly placed will be better than a thick one. The roots of a plant when growing in a pot very soon reach the bottom, where they generally continue growing round, and seldom—with strong-rooted plants never—find their way back into the soil again. Where a thick layer of crocks is used it will be seen that the majority of the feeding roots have no food supplied them other than that contained in the water when passing through the soil and rocks. Where crushed bones are used as drainage the case is different, as the bones afford more nourishment to the roots than ordinary soil would. If a shallow layer of soil is preferred it is always advantageous to use shallow pots or pans instead of having a deep layer of drainage beneath the soil, which has the effect of allowing the water to escape from the soil quicker than is good for the plant. So long as stagnation is prevented it is better for all terrestrial plants that they be so situated as to have the soil about their roots kept moist without too frequent waterings, the effect of which is to completely decompose the soil or make it sour. For plants in very warm houses this precaution is of special importance.

Shifting plants into pots of larger size is an operation requiring some knowledge of the nature of the plants, and also depends not a little on the health and size of each. Considering first those plants which are slow growers, and therefore do not extend their roots very far in a year, such as *Ericas*, *Epacrises*, *Pimeleas*, and other hardwooded plants, the question arises, is it better to treat these plants on the one-shift system, as recommended by Dr. Lindley, or

to give them repeated shifts, such as would be no more than the roots would take complete possession of in a year? If it is admitted that soil deteriorates rapidly when frequently watered or when placed in heat, it must be apparent that to place a plant in a large body of soil which could not be occupied by the roots for several years is a system not to be recommended. There can be no question of the many advantages of the repeated or gradually increasing shift over that of the one-shift system—that is for plants which are being grown from small into large specimens, and which are slow growers. Many plants—such, for instance, as *Pelargoniums*, *Balsams*, *Fuchsias*, &c.—will under favourable treatment grow to a very large size in a single season. Some of the softwooded quick-growing *Heaths* also considerably increase in size in a year: for all such plants a much larger pot is advantageous. But we must remember that with very few exceptions the plants we grow are wanted to flower every year. Now, it is a well-known fact that under ordinary conditions a plant in a pot of proper size—*i.e.*, such as its roots would about fill in a year—flowers more freely than when planted out, or when grown in a larger pot than is required for one season's growth. The pot cramps the roots, causes the wood to mature quickly, and so induces the plant to flower. We know that the smaller the pot under ordinary conditions the greater the disposition to flower, so that by placing our plants in pots containing only enough soil to afford them the conditions required for the growth and maturation of the wood formed in one season, we are assured a supply of flowers which would probably otherwise have failed us. From this it will be seen that the safest and best system to adopt with regard to repotting and shifting is the annual and not the one-shift system, or, in other words, the placing of the plant at an early stage of its growth in a pot large enough to contain it for the following six or eight years.

Shifting plants is a different operation from that of shaking out and repotting, which is practised only for such plants as are deciduous or require a long season of complete rest. This operation is usually performed after the plants have been rested, cut back, or pruned, and started into growth again. As soon as the buds begin to show signs of activity is the time to shake out from the roots of the plants all the old soil and prune the roots somewhat, afterwards placing them in pots of a size only large enough to afford them support for a few weeks. Whatever may be said to the contrary, there can be no question as to the wisdom of this method as compared with that sometimes recommended, and which is to repot the plants during their rest and not before growth has recommenced. A little consideration of one of the simplest laws of plant physiology is sufficient to condemn the latter practice. (It must be borne in mind that we are now discussing plants cultivated in pots, which afford conditions very different from those to which plants growing naturally are exposed.)

The firmness of the soil is another point of some importance to the cultivator of plants in pots. Some growers, successful ones too, put the softest wood and quickest growing plants much firmer than many would advise. Some of the best *Pelargoniums* I have ever seen were grown in a stiff loam pressed down as hard as a brick. These plants were in rather small pots, but it was a revelation to one who had been taught to pot hardwooded plants very firmly and softwooded plants loosely. A prize *Mignonette* grower used to say his success was due to hard potting and bones, and his plants were in soil as hard almost as stone. They were bush and standard *Mignonettes*, such as we seldom see now. In this matter, however, much depends on the quality of the soil and the aim of the cultivator; still, the following general rules may be pointed to—*viz.*, all fine-rooted plants may be potted firmly (always excepting annuals), very fine-rooted plants with hard wood requiring the soil to be rammed hard. The harder

the soil is pressed about the roots the more sand or its equivalent should be mixed with the soil. For the production of flowers firm potting is an important factor; for foliage and quick growth loose potting is best.

In conclusion, a word of warning may be uttered against filling the pots too full of soil, so that insufficient room is left for watering. The more soil a pot contains the more water will be required to thoroughly moisten it when dry. This seems plain enough, but, as was said by one of those who took part in the discussion above referred to, "All these simple matters are plain enough, but many gardeners fail to see the importance of observing them. We all know how to pot a plant perhaps, but we do not all pot it properly."—W. N.—*Journal of Horticulture*.

WOOD.

BY JOHN WOODLAND, F. L. S., & C.

(Read before the Chemists' Assistants' Association.)

Wood is a hard, permanent, cellular, and vascular structure formed by plants. By them it is used, in a younger state, for mechanical support and to convey fluids; in an older condition, still as a support, and to contain secretions peculiar to the plants. The following woods are used when elasticity is required: ash, hazel, hickory, lancewood, and yew.

The following are in use when toughness is required, combined with elasticity: beech, elm, hornbeam, oak, and walnut.

For durability in dry situations, cedar, chestnut, oak, poplar, and yellow pine are chosen.

For colouring purposes, Brazil wood, camwood, logwood, and Nicaragua wood are used to furnish a red, green ebony a green, and larch a yellow colour.

For shipbuilding, elm, fir, fustic, pine, and teak are used.

For piles, as supports for piers or landing-stages, &c., alder, beech, elm, oak, and plane are in common use.

For housebuilding purposes, the ash, chestnut, fir, oak, pine, and sycamore are much used.

Where hard woods are required, box, lignum vitae, and mahogany are serviceable.

Timber is wood which has been prepared from trees or shrubs, so as to be fit and durable for the purpose for which it is selected. When soft or moderately soft wooded trees are to be felled, mid-winter is the best period of the year, on account of their containing the least amount of sap at that time; the next best period being the middle of summer, as, although at this latter period there is a large quantity of fluid in the stem, still there is not the same amount of nitrogenous fermentable principles as are found in spring and autumn. If the tree be a hard-wood one the period of the year at which it is felled does not matter to any great extent. In order to render the wood fit for timber it must be thoroughly seasoned by slow drying. In this process the sap is as well as possible evaporated, so that fermentation and decomposition are avoided, and the wood is shrunk to its furthest limit; the time usually required for this to be accomplished is from two to three years. If the wood is to be used in an exposed position the moisture with which it naturally comes into contact would be liable with the constituents of the sap to cause decomposition, hence water-seasoning is frequently resorted to. A running stream being chosen, the logs of wood are sunk in it for about two or three weeks, after which they are taken out and seasoned by slow drying; in this latter process all the constituents of the sap are washed away, and fermentation or decomposition is thus prevented. Other means employed to preserve wood which is exposed to moisture from the soil, such as gate-posts, telegraph-poles, hoop-poles, and railway-sleepers, are (1) charring the outer surface, by which the carbon set free, together with other products formed and remaining outside, help to preserve the interior from decay. (2) Painting, using with the paint fine sand, pumice, or finely-powdered glass which has been previously incorporated.

(3) Immersing and standing in bitumen, tar, or creosote; in either of which cases the wood is penetrated to the centre by the preservative material.

(4) The process termed "kyanising," which is now obsolete, and consisted of impregnating the wood with perchloride of mercury by means of a solution of the salt. (5) A process called "Burntetting," which has proved so successful at Woolwich, and consists of soaking wood in a solution of zinc chloride made in the proportions of 1 lb. of the chloride to 5 gallons of water. A splendid example of the preservative action of salt on wood is seen in the salt-mines of Poland and Hungary, the wooden supports in which have existed for ages.

Wood, when exposed to a damp surface and not well ventilated, is often attacked by fungi, commonly called dry-rot, *merulius lacrymans*, *merulius vestinator*, and polyporus destructor, &c., the mycelia of which rapidly spread, till in time the hard wood is replaced by a small powdery-looking substance. As the fungus only attacks wood when it is moist, the term "damp-rot" is obviously more correct. In spite of the substitution of iron for wood, as in making girders, in buildings, articles of furniture, tools, &c., the importation up to 1883 has steadily increased, the following being the returns for the past three years, in loads of 50 cubic feet each:—In 1882, 6,320,863 loads; in 1883 6,597,427 loads; in 1884, 6,132,925 loads.

I will now proceed to enumerate some ordinary woods, together with their sources and what peculiarities they may furnish.

Alder, obtained from *Alnus glutinosa*, Betulaceae.—This wood is especially adapted for withstanding the action of water, hence is used in connection with cog-wheels of millstones, pumps, drains, piles in water or mud, heels of wooden boots, &c. According to Virgil the first boats that were constructed were made of this wood. The best gunpowder is also made from the charcoal furnished by the alder.

Ash, obtained from *Faxinus excelsior*, Oleaceae.—This wood is lighter in weight and more elastic than that of the oak, and is less liable to be broken by a cross strain, hence its use for billiard-cues, poles, ladders, &c., but being fibrous it is more easily split than the oak. The ash-tree when growing is regarded as being a special attractor of lightning; also the yule logs of Christmas celebration were formerly furnished by this tree.

Aspen, from *Populus tremula*, Salicaceae.—The wood is not so good as that furnished by the white poplar, being porous, soft, and white; it is chiefly used for field-gates, milk-pails packing-cases, &c.

Beech, from *Fagus sylvatica*, Cupulifereae.—The wood is brittle and hard, but is apt to decay soon; carpenters' plane frames and other tool handles are made with it, and cabinet-makers use it for shelves, &c. Next to the oak this is the largest tree growing in England, its height varying up to 100 feet, and at Burnham Beeches some splendid specimens can be seen. Of this wood the Greek ship *Argo* was built, and in ancient times the wine-hovels were made of it, and hence the name of Bacchus, which we occasionally see in connection with the wood.

Birch, from *Betula alba*, Betulaceae.—This is one of the aboriginal trees of our island, as shown by the presence of twigs still retaining their silvery bark which are found in the lower strata of the peat bogs existing in the North of England and around Manchester. The wood known as Norway birch is much used in the Highlands and further south for making wicker hurdles, tying fagots of wood, and thatching straw-roofs, its advantages lying in its toughness, pliability, and durability. It is from the bark of this tree that an oil is yielded from which the peculiar odour of Russia leather is derived.

Brazil wood, obtained from *Casalpinia crista*, Leguminosae.—This wood is used for dyeing purposes, the colours obtained being red, rose colour, and yellow. *Brazilletto wood* is furnished by *Casalpinia brasiliensis*, and produces red and orange colours.

Box, from *Buxus sempervirens*, Euphorbiaceae.—The box-wood of commerce comes from Turkey, Asia Minor,

Circassia, Spain, and Portugal. This wood, being very close-grained and heavy, is largely used by turners, engravers, and carvers, also for the manufacture of mathematical instruments and articles that will take a high polish; the pure bitter it contains preserves it from the attacks of insects.

Cherry. *Prunus cerasus*, Rosaceae.—This wood is hard and tough, also light and porous; it is used by turners and engravers and for constructing pipes. These trees, when past fruit-bearing, were in olden times considered to be the habitats of demons.

Chestnut, from *Castanea vesca*, Cupuliferae.—The timber is chiefly used for beams and rafters of houses, heads and staves of casks, and as protecting gutters for gas-pipes, &c., underground. There is one plant growing at Tortworth in Gloucestershire more than 1,100 years old. The diameter at base is 15 feet, and by the last accorns received it still bears fruit.

Dogwood. *Cornus sanguinea*, Cornaceae.—The wood is used for preparing gunpowder charcoal, and, on account of its hardness, for skewers, cogs for wheels, &c.

Ebony, from *Diospyros ebenus*, or *Diospyros ebenaster*, Ebenaceae.—The heartwood only of this tree is black, and being very hard, durable, and wear-resisting, its uses are many and various; besides this wood, which is known as "Bastard Cayton Ebony," we have a black ebony yielded by *Diospyros melanoxylon*, also a fine variegated wood yielded by another species, namely *Diospyros guaiacina*, which makes handsome furniture. There are also red and green ebony woods.

Elder, from *Sambucus nigra*, Caprifoliaceae.—This plant whilst young grows with great rapidity, but when it attains the height of from 20 to 30 feet, its growth is arrested, and of these dimensions the tree remains for a great length of time. When young the wood is soft, but when old it becomes almost as hard as boxwood, and in a variety of cases can be substituted for it; butcher's skewers and tops of fishing-rods are commonly made of this wood. The Elder plant is reputed to have retaliative powers, and it is a custom at the present time in Lower Saxony for the woodcutters to ask permission (three times) of the tree to fell it, these requests being accompanied by an equal number of salivary ejections. Permission is takou for granted, as a matter of course; but should this form of ceremony be omitted, most dire results are stated to follow.

Elm, from *Ulmus campestris*, Ulmaceae, next to the oak, is the most common tree in England. The wood is hard, finely grained, and hence not apt to crack. It is used for the keels of vessels and wooden fittings of ships, also for cart-wheels and coffins; it attains its maturity at an age varying between seventy and eighty years.

The *Wych Elm*, from *Ulmus montana*, Ulmaceae, furnishes a wood that is both strong and elastic, hence is used for spade-handles, garden-forks, and rake-handles. The goarled wood is largely used by cabinetmakers for veneering. Both this and the preceding elms furnish woods which are tough and not readily acted upon by water.

Fir-trees belong to the genus *Abies* of the natural order Coniferae; they were formerly called "fire-trees" on account of the inflammability of their wood, due to the oleoresin it contains. These trees having a conical shape can thus be told from what are termed "Pine-trees"; one fir-tree (*Abies excelsa*) is the tallest in Europe, its average height being 150 feet. In obtaining the wood of these trees, the Russian peasant chops them down, but will not uproot them, as an elf of a revengeful disposition is supposed to take up his abode in the neck of the plant, and if disturbed will retaliate on the evictor of his tenancy.

Abies excelsa is the Norway spruce, and furnishes the white deal used so much for building purposes. *Abies pins* is the silver fir. The stems of each of these fir-trees are largely used for making masts of vessels, telegraph-poles, signal-poles, and building planks, and also for splitting up into mat-bes.

Fustic, obtained from *Machona tinctoria*, Moraceae.—The wood in chips is largely used as a dyeing agent, on account of the colour it contains.

Guaiacum, from *Guaiacum officinale*, Zygophyllaceae.—This wood (the heartwood of the plant) is commonly called "lignum vite" on account of its durability and hardness; it is peculiar, in that the fibres composing it cross each other diagonally, so that cleavage of the wood is difficult. It is much used for making rulers, skittle-balls, wheels and cogs of sugar-mills, pulleys, &c.; in parquet-flooring, by heating the flat pieces of lignum vite the natural resin exudes and aids in agglutinating it to its neighbouring pieces.

Hazel, from *Corylus avellana*, Cupuliferae.—The wood is very tough and flexible, hence it is used in making hurdles, crates, fishing-rods, hoops for casks, &c. A forked twig of hazel is stated to have the power, when held in the hand of a suitable person and pointing to the ground, of a divining-rod, by directing the holder to a place underneath which water exists.

Hickory, from *Carya alba*, Juglandaceae.—The wood is tough and elastic, and will stand prolonged strains; it is used for fishing-rods, walking-sticks, Canadian paddles, &c.

Hornbeam, from *Carpinus betulus*, Cupuliferae.—The wood is hard, tough, and white; it will burn like a candle, so with frayed ends will act as a temporary torch. It is chiefly used for the manufacture of agricultural implements and the cogs of mill-wheel.

Lancewood, obtained from *Duguetia quitarensis*, Anonaceae, or, according to another authority, *Guatteria virgata*.—This wood is tough and elastic to a very high degree, and being at the same time of light weight it is admirably adapted for making shafts of carriages, bows and arrows, fishing-rods, and lances.

Larch, obtained from *Larix Europea*, Coniferae.—The wood is fit to use for timber when the tree is forty years old; it has a reddish or reddish-brown tinge, but there is a great objection to its use on account of its warping, even after having been seasoned. The wood is apt to be attacked when growing, by the dry-rot, owing to the tree growing on badly-drained soils. It was formerly and superstitiously believed that the wood was impennetrable by fire. The American larch, called "hackmatack," is a heavy and cross-grained wood.

Lime, obtained from *Tilia Europea*, Tiliaceae.—This wood, called commonly "linden-wood," is used by carvers and turners owing to its being closed-grained and smooth.

Mahogany from *Livistonia Mahogoni*, Cedreliaceae.—This well-known wood is valuable for its hardness, fine colour, durability, and smoothness; it is sent from Central America and the West Indies. When a tree is discovered, a stage is erected about 12 feet high, the branches are removed, and then the stem cut down; great difficulty is often experienced in conveying the trunks to the river, down which they float until stopped by a cable drawn across the stream; rafts are then made of the pieces which are chosen, these being conveyed to their destination. Some trees have been known to produce as much as 1,000 each.

Maple (red), from *Acer rubrum*, Auraceae.—A variety of this produces curled maple, so called from the accidental undulation of the fibres; it is one of the most ornamental woods known, and exceeds in richness and lustre the finest Mahogany. It is used for furniture-making, and also for making stocks of rifles and fowling-pieces.

Maple (sugar), *Acer saccharinum*, Auraceae.—This furnishes the so-called "birds-eye maple," and is highly prized for furniture-making. Fair Rosamond is reputed to have taken her fatal draught from a bowl made of maple.

Mountain Ash, or *Roman-tree*, *Pyrus europæica*, Rosaceae.—The timber is much used for carriage and cart wheels.

Oak, from *Quercus robur*, Cupuliferae.—This tree in temperate climates is the largest in size, the longest lived, the hardest and most durable as regards its timber, and the most common of trees. In warmer climates the wood grows more quickly, and is consequently not so hard or durable. The ordinary height is 60 to 80 feet, its maximum age fifteen centuries.

When an oak fence is built up with iron nails the black streaks can be seen running down from the nails, owing to a kind of ink being formed from the iron and the tannic acid of the wood. The oak which has stalked acorns furnishes the best timber, which possesses great strength, tenacity, and durability. The white or American oak, *Quercus alba*, has a reddish timber, which, though more elastic than the English kind, is not so durable. Red oak, *Quercus rubra*, furnishes a deep-coloured timber, which, being coarser in texture, is not so useful.

Pear, from *Pyrus commutis*, Rosaceae.—The variety furnishing the hard or baking pears has a very hard wood, which is used chiefly for musical instruments, tool-handles &c.

Pine-trees belong to a genus called *Pinus*, Coniferae.—The trees can be told from fir-trees by being more or less flat at the top, where nearly all the branches congregate.

Needle Fir, *Pinus sylvestris*, yields the timber known as Dantzic or Riga fir, and Russian deal. It grows from 60 to 100 feet high, and is fit for timber at the age of fifty or sixty years. The best quality timber is from trees that have grown in cold situations, such timber equalling the oak in duration. *Pinus strobus* furnishes the white pine or deal of the United States; it is called the "Weymouth Pine." The wood is used for bowsprits and yards of men-of-war. *Pinus mitis* and *Pinus palustris* furnish yellow pine or deal. The latter pine will grow in very sterile soils, yet yields a wood which is more compact, stronger, and durable than that obtained from the other species. The least valuable of the pines is *Pinus bleda*, or "loblolly pine," the timber of which decays on exposure to air. The uses of pine-trees are similar to those of fir-trees.

Plane, from *Platanus occidentalis*, Platanaceae.—The wood is a fine-grained one, and becomes of a dull red colour in the seasoning; it is occasionally used by cabinet-makers, but quickly decays if exposed to the weather. The leaves of this plant are used by the Grecian lovers to ensure constancy; on their parting, a leaf is torn in halves, one half being retained by each; on meeting again the two halves are fitted together.

Poplar, from *Populus alba*, Salicaceae.—Wood is white, light in weight, and soft; it is not used for any purpose in particular, though that of the Canadian poplar, *Populus monilifera*, is largely used for flooring. One poplar, namely, the balsam poplar, *Populus balsamifera*, in the form of timber, is quickly rotted by water, like the wood of the horse-chestnut, hence, to protect the young buds of these trees from moisture, as rain, &c., we find a thick covering of resin present during winter and spring.

Santalwood, from *Santalum album*, Santalaceae.—This wood is sent from Malabar and the East Indian Islands. It is used for making small articles of cabinet-furniture, and its order prevents insects or worms attacking it.

Spindle-tree, from *Euonymus Europaeus*, Celastraceae.—This wood is hard, white, and finely-grained it is used for musical instruments, netting-needles, spindles (hence the name of the tree), and skewers. In France gunpowder-charcoal is obtained from it, and the young shoots when charred form a rough drawing-pencil.

Oak, or Indian oak, from *Tectona grandis*, Verbenaceae.—This wood is light and easily worked, being at the same time very strong and durable. It is largely used in ship-building.

Porcelain-wood, so called from the resemblance of the wood to tortoiseshell, is obtained from *Galettula speciosa*, Rubiaceae, and the same plant is by some authorities said to yield the striped or zebra wood used by cabinet-makers.

Walnut, from *Juglans regia*, Juglandaceae.—This is now largely in use for furniture, in which its rich deep brown and beautifully-marked wood can be seen to advantage. Before the introduction of mahogany this was almost exclusively used for furniture-making. It is also used for gun-stocks, as it is lighter in

proportion to its strength and elasticity than any other wood. Black walnut, from *Juglans nigra*, furnishes a strong and tenacious wood, and when well seasoned is not liable to warp or split; it is also secure from the attacks of insects. It is commonly believed in the country that high winds swaying the branches of the walnut or whipping the walnut-tree improves both the yield and the quality of the fruit hence the saying:—

A woman, a spaniel, and a walnut tree,
The more you whip them the better they be.

Willows.—The Goat Willow, or Sallow, *Salix caprea*, furnishes the best willow timber; when growing as a coppice-plant it furnishes hoops, poles, and rods for crates. The timber of the willow is white, soft, and light, the best-seasoned kinds being very durable. The dwarf-willows, *Salix viminalis* and *Salix rubra*, are propagated by cuttings for finishing osiers or willow-shoots, from which hampers, baskets, &c., are made.

Yew, from *Taxus baccata*, Taxaceae.—The wood is peculiarly hard, smooth, and tough, and was formerly used for making bows; it is beautifully veined and will take a high polish, hence is used by cabinet-makers for veneering purposes; being very hard and durable it is used for cogs for mill-wheels, axles, and also flood-gates of rivers, which scarcely ever decay. —*Chemist and Druggist*.

GORSE AS FOOD FOR CATTLE.

In reply to A. C. H. O., judging from the area for which we supply seed every year, we should say that gorse is still prized as food for cattle; indeed, there is no doubt that it is good for stock of all kinds. The time, too, when it can be used (from November to April) renders it additionally valuable. In feeding horses, Yonatt gives, as the equivalent of 20 lb. of gorse, 5 lb. of straw, the ordinary ration of beans, and 3 lb. of oats. It is excellent for milch cows, causing them to yield an abundance of rich milk, the butter being of superior flavour. As far as we can ascertain, the best machine for bruising it is the Gorse Masticator, by T. McKenzie & Sons, 212, Great Brunswick-street, Dublin.—JAMES CARTER & Co. (237 and 238, High Holborn, London, Jan. 4.)

In answer to A. C. H. O., I can say that I have found gorse first-class food for young cattle, calves of three months old doing well on it if mixed with pulped carrots, swedes, cabbages, or even turnip leaves, when they are to be had. The gorse must be grown on fair land and on soft shale rock; that on poor clay and certain sorts of rock is not worth gathering. I should be glad to hear of a good crusher or masticator; all I have seen are either too heavy or too tedious for a one-horse turning gear. Water and steam power I have not.—C. F. P.—*Field*.

[As gorse grows freely at Nuwara Eliya when milk in the season is in good demand, the above ought to afford a hint to the owners of milch cows.—Ed.]

ROOT FUNGI AND TREE ROOTS.

You have done well to give on p. 80 an abstract of the startling idea recently advocated by Dr. Frank and Dr. Woronin, and accepted as correct by Prof. De Bary. The idea is, as you point out, that certain fungi found on the roots of Oaks, Beeches, Sweet Chestnuts, Hornbeams, Hazels, and Willows, together with the root-fungi of Conifers, are the agents by which the tree obtains its "soil food," the fungi in turn being fed by the juices of the tree. Tree and fungus mutually help each other to live; so say the three Doctors. It is well that the *Gardeners' Chronicle* does not say the case has been "proved," but counsels "an attitude of intelligent expectancy, on the part of those who are not in a position to add either proof or disproof." It is not necessary to ask what the opinion of horticulturists, foresters, and gardeners is as regards this matter. Their opinion is perfectly well known and generally accepted as correct and reasonable, viz., that root fungi of all sorts cause the death of trees, that when young trees are planted in positions where root fungi abound the trees cannot live, and that

when trees are transplanted from fungus-infested positions to positions free from root-fungi they recover. Dr. Frank says he found the fungus present "in every root examined, belonging to the Cupulifere, also occasionally on Salicaceae and Coniferae, but not on woody plants belonging to other natural orders." It will be seen from this that the Cupuliferae are exceptional in the possession of root-fungi. The facts mentioned by the French and German botanists in reference to the vital cohesion of root fungi and the roots of trees are no doubt quite correct, but the idea of the tree-roots and their fungi deriving mutual support from each other I consider fallacious. That the roots of Cupuliferae show a partiality for a soil rich in humus, as stated by Dr. Frank, I also consider a fallacy. Do the roots of the Coniferae, too, show this partiality, or do they show the contrary? I have long kept up a MS. list of fungi as observed in Britain peculiar to certain natural orders of plants, and in this list the Cupuliferae is quite exceptional and phenomenal as regards the number of species of fungi by which the members are attacked. Next after the Cupuliferae, as regards large numbers of fungi, comes the Coniferae. Some natural orders of plants are not attacked at all, they have neither leaf-fungi nor root-fungi. The common number of fungi peculiar to any natural order is about twelve or twenty, some have only one or two, but when the Cupuliferae are studied there are more than 400 fungi found only on the members of this natural order. In the Coniferae I have 239 fungi on my list. Some live on the living leaves, others on the dead leaves, many on the living wood, others on the dead wood and roots. As the members of the Cupuliferae are plagued with more than 400 fungi peculiar to themselves it follows that the ground beneath the trees and the roots in the ground are liable to be infested with the innumerable spores and abundant fungus mycelium of 400 different fungi. The Coniferae, as I have said, have their complement of at least 239. If we turn to the Tiliaceae or Limes, we seldom find root-fungi, the trunks, branches, and leaves are also comparatively free, for, when all the fungi are told belonging to this natural order, they do not amount to twenty. When the spores of the 400 fungi peculiar to the Cupuliferae, and the spores of the 239 fungi peculiar to the Coniferae, fall to the ground and germinate, they in many instances necessarily attack the roots and rootlets, for the material of the tree, living or dead, is the natural *habitus* of the fungi. Many root-fungi are well known in their perfect condition as destructive parasites, and a printed list could easily be given of them. Dr. Woroin comes to the startling conclusion that the root-fungi probably belong to the genus *Boletus*, as if the mycelium of only one fungus attacked tree roots. His guess could not have been more unfortunate, for if there is any one genus of fungi more purely non-parasitic than another it is the genus *Boletus*. There is, however, as in this case, no rule (or genus) without an exception. There are several other astonishing delusions in the account as published in the *Berichte der Deutsch Bot. Gesellschaft*, as the idea that "root hairs are not formed" in trees affected with root-fungi. To "settle" the fact that the trees above mentioned do not form root hairs would be quite as difficult as, or even more difficult than, the task Mr. Jensen set himself when he set about counting the fungus spores in the dirty water which trickled out of the bottom of a flower pot. That the "discovery" "is comparable in all essential points to that of lichens" (referring, as the authors do, to the Schwendenerian hypothesis), the root-fungi "corresponding with the fungal element, the tree itself (!) to the algal gonidia (!)," I quite agree, for there is an equal amount of bad interpretation of facts in both "discoveries."—WORTHINGTON G. SMITH, Dunstable.—*Gardeners' Chronicle*.

CATARRH OF THE BLADDER.

STINGING irritation, inflammation, all Kidney and simi- lar Complaints, cured by "Bachu-paiba."

W. E. Smith & Co., Madras, Sole Agents.

GUTTAPERCHA: ITS HISTORY, COMMERCE AND SUPPLY.

Whilst in Singapore, my heart often ached when I have fallen across clearings for pepper, gambier, and the like, to see with what recklessness mighty monarchs of the forests are cut, or rather burnt down in all directions, unused and utilised trunks rotting on the ground. But this is not the worst, for as soon as such a spot has borne two or three crops, a fresh location is chosen and cleared in like manner. The neglected and abandoned spots are speedily covered with secondary jungle, often covered and choked with *alang* (*Andropogon carinatus*)* to the exclusion of all else, a plant whose roots are so stout as to defy a "chankol" or hoe, and prove a constant pest to planters from the rapidity with which it spreads. Thus it is that localities where products formerly were in plenty, now are altogether devoid of them, and the products have to be sought far away. With regard to guttapercha, the number of trees yielding it which have been destroyed is almost incredible.

Dr. Oxley calculated that to supply the 6,918 piculs (1 picul=133½ lb.) exported from Singapore, from the 1st of January, 1845, to 1847, the enormous number of 69,180 trees had to be destroyed, and the statement is by no means overdrawn. A writer in the *Sarawak Gazette* says, that from 1851 to 1875 over 90,000 piculs of guttapercha have been exported from that district alone, a quantity which means the death of at least 3,000,000 trees. And these are only two instances, the first showing the trade in its infancy, and the second that of a limited and comparatively small producing locality. In fact, the guttapercha tree has only been saved from utter annihilation because young trees do not yield a sufficiency of gutta to repay the cost of extraction. In some districts, indeed, the forests have been so denuded as to necessitate waiting for a period of ten or twelve years before any fresh gutta can be collected. It seems clear, however, that the growth of young trees of the best varieties has not been able to keep pace with the destruction, as they have and are still becoming scarcer, so that recourse now, more than ever, has to be had to the products of very inferior varieties.

At the present time there is a great difficulty in obtaining supplies of the best varieties, and manufacturers require them in much larger quantities than are now obtainable. Especially is this the fact with regard to guttapercha for telegraphic purposes, to meet the demand for the construction of new lines, and the maintenance of existing ones, and no substance has yet been found to be used as a complete substitute, or a supplementary one to fine guttapercha.

Now it will be granted, I trust, that the necessary supplies to meet this constant and increasing demand will not be forthcoming if speedy means be not taken to assure it, and this can only be met by having recourse sooner or later to conservation, acclimation, and cultivation of the trees yielding the best varieties.

In the Straits Settlements a splendid opportunity now presents itself to take this matter in hand. We are now in the possession of more power and influence in the Malayan States of the Peninsula than ever we were before, and by means of Her Britannic Majesty's Residents and other officials in these various states, can do much in taking charge of the forests, conserving them and introducing the cultivation of these trees for the benefit of the community at large. This would be far better than leaving such valuable state property to the tender mercies of rajahs and

* In one article I wrote, in a foot note I recommended this plant as a "sand binding plant." The War Office and the Suez Canal Company have taken notice of the matter; I trust they will try the experiment. Those who have been through the Canal know well the clouds of sand that greet them, and if the banks were well bound down the verdure would be a pleasant sight, save much dredging and many stoppages.

other native rulers, who, for the most part, for there are honourable exceptions, look only to immediate returns, and lose sight altogether of future benefit to the States. By letting or "farming" out these forests for the collection of gutta and other products, the working expenses of conservancy would be secured, and by a small royalty-charge on export an addition to the revenue obtained. A clause, to be stringently enforced, should be inserted in all such contracts, to the effect that for every tree cut down, four to six should be planted in the place thereof. I am the more anxious that the question of guttapercha, amongst other spontaneous forest products, should receive due attention, from the opinion I have formed that Singapore will not long retain in the face of so many direct shipments, her position as a great Eastern entrepot, unless new fields are opened up by commercial enterprise, and this can only be done by utilising the undeveloped resources of the great Malayan Peninsula.

THE CULTIVATION OF GUTTAPERCHA TREES AND IMPROVEMENT OF THEIR PRODUCTS.

Mode of Obtaining Guttapercha.—As is the case with a great number of other products, the trees are destroyed to obtain the Guttapercha. In my report on caoutchouc, to the Indian Government, I strongly recommended "tapping," and I think that it is now proved beyond all doubt that if the process is carried out as I there indicated, it is not only practicable, but all a vast saving, and a most economical method of working a forest of such trees.

With regard to guttapercha, I am, I must confess, somewhat in doubt as to whether "tapping" or only cutting through the bark to cut through the milk-bearing vessels as the tree is standing, is practicable; whether, indeed, it is possible to get a sufficiency of gutta to repay collection without cutting the tree down. A reference to the woodcuts will render this method more easily understood.

The native evidence is nearly overwhelming; still it may arise from indolence—a wish at one operation to obtain the greatest possible quantity without a thought to future supply, or from the absence of a sufficient aggregation of the trees within a reasonable distance to obtain a sufficient quantity to repay collection. Guttapercha does not flow so readily as caoutchouc does, but concretes more rapidly. The yield in the rainy season is nearly double that of the dry season, due, possibly, to two reasons: First, that nature has not yet been called upon to use up the guttapercha in the elaboration of new tissues; or, secondly, the greater amount of moisture causing greater fluidity in the milk. The Dutch Government tried to induce the natives to practice "Tapping," but without effect. "Boring," as practised in America, in procuring maple-sugar from the *Acer saccharinum*, and other species, has also been tried, but without success. However, "tapping" guttapercha trees can only be properly tried in a well-regulated plantation, and, if successful, will be a great saving, as the quantity obtained by successive tapping far exceeds in the aggregate, that of the single operation of cutting the tree down.

Impliments and Collecting Vessels.—If it be proved that nothing short of the death of the plant will do in order to extract the gutta, then at least a third more gutta can be obtained by providing wedges, rollers, or other simple mechanical contrivances, in order to allow of the extraction of the gutta on the side of the felled tree next the ground. The heliongs, prangs, and pans are well adapted for their purpose, and, being cheap, need not be superseded, as natives are as equally prejudiced against new tools as against new customs.

Preparation of the Guttapercha.—The utilisable products existing in plants suggest a most important question in phyto-chemistry. As to what their use and characteristics are whilst in the plant, we know little, and that little is almost entirely limited to, and inferred from the products after they are taken from the plant. Thus iodine does not exist, as such, in the plant itself, but is the result of fermentation after

the juice is extracted from the plant. Sugar-cane juice furnishes us with another illustration of the rapid change of a product after it leaves the plant. The juice, whilst in the cut cane even, does not change, but as soon as it is expressed it speedily ferments and changes into uncrystallizable sugar, and to retard this action lime is often added.

With milky juices the so-called milkiness is only brought about by exposure to atmospheric influences, and as soon as such exposure takes place, a new set of chemical combinations are inaugurated.

Guttapercha, as it flows from the tree, is a viscid fluid, acquiring milkiness and concreteness on exposure. As is well known, it splits up or is resolvable into two resins, viz., *albina* and *fluavile*, and is, like caoutchouc, a hydro-carbon, having a formula of carbon 87.80 and hydrogen 12.20

In commercial gutta-percha we have this hydro-carbon or pure gutta, plus a soft resin, a resultant from the oxidation of the hydro-carbon. M. Payen gives the following analysis of commercial guttapercha:—

	Per cent.
Pure gutta (milk white in colour and fusible)	78 to 82
Resins soluble in boiling alcohol, and consisting of two parts:—	
1. Crystalline or albina (C ₂₀ H ₃₂ O ₂), a white crystallized resin, crystallizing out of the alcohol as it cools ..	16 to 14
2. Fluavile (C ₂₂ H ₃₂ O), a yellow amorphous resin, falling as an amorphous powder on the cooling of the hot alcohol in which it is soluble ..	6 to 14

It is thus apparent that the change of pure gutta into a resinous-like mass takes place naturally if means be not taken to stop it. This resinification I have often witnessed and tested. If two bottles of equally pure and identical gutta milk be taken, and the one bottle be hermetically sealed and the other left exposed, the first will retain its goodness and the second will become resinified and as brittle as shellac. Again, in all sorts of raw gutta or "Getah Muntah" if these be kept for a certain period without being used up, they become resinous-looking masses, losing all the qualities of guttapercha—being, in fact, like so much kowie-gum, but lacking its utility.

This change I am sure can be lessened, retarded or altogether obviated, if the gutta be thoroughly well boiled immediately after collection. This should always be done, and through the non-attention to this, many an otherwise good parcel of gutta has deteriorated in quality or become useless.

There is also another fact to bear in mind with regard to this proneness to chemical activity of guttapercha. In cutting through the bark to arrive at the laticiferous vessels or tissues, many other vessels and cells become ruptured, containing tannic, gallic and other approximate principles, and the presence of these no doubt accelerate oxidation. In opening bottles of milky juices a turbidity and effervescence is often noticed, owing to the formation of a brownish liquid, the colour due, probably, to the presence of gallic acid, and gallic acid has been found to exist naturally in parenchymal cells and milk ducts. In blocks of gutta, which have not been properly prepared, these foreign substances induce the presence of a brown fermented and putrid liquid, which gradually decomposes the inert part, if not the whole mass. Many of these substances are soluble in water, and in the process of boiling would be removed.

Purity of Varieties.—As will have been seen there are many varieties of guttapercha, differing most materially from each other in character and value. These varieties are almost invariably mixed together by the natives, and great harm is done thereby. This is practised for two reasons, first that natives, when collecting, regard quantity more than quality; and a second, and worse reason is, that Chinese either acting on their own discretion, or possibly at times

on the orders of European merchants, mix different varieties, particularly if of low quality, adding in the operation a certain quantity of best or true gutta to impart a "tone" to the parcel, and thus allow it to pass muster. Sometimes this "tone" consists of a skin of good gutta over a core of bad. I speak the more strongly against this practice because I have seen it done in the East and have also seen its results in London; I speak, therefore, in both cases, from personal observation. Again, many of these so-called "low varieties" of guttapercha have no right to be classed under that substance at all, unless, indeed, we extend its significance and include under guttapercha such substances as kawrie-gum, gambier, cutch, &c.

This mixing, to a manufacturer, is a serious matter, and I firmly believe that in some cases where a "fault" has been found in a cable, often it has been caused by a fraudulent admixture of some such resinous substance, and its subsequent crystallising out. When it is borne in mind that the very smallest percentage of such an admixture may render a cable utterly useless at a most critical moment, I am sure that I shall not be charged with hypercriticism, or speaking too strongly on the subject. All the varieties of true guttapercha are valuable, but what I maintain most strongly is, that if any of these are to be mixed, that such mixing should be left to the discretion of the manufacturer at home; he, and he alone, should be best able to judge as to what varieties should be amalgamated to meet the various requirements in view.

Purity from Adulteration.—This I have already incidentally mentioned, and the necessity of freedom from adulteration will be admitted at once. A certain proportion of fragments of bark must always be looked for, but in many cases it is purposely added to increase bulk and weight; a sieve through which the gutta could easily run would obviate this. Stones, sometimes as large as one's head, clay, billets of wood, sawdust, and sago-flour, are the stock adulterants. The remedy for this may be seen in the following paragraph, and if a purer and less adulterated article were sent into the markets, traders would reap the benefit, as, at present, manufacturers have to include, in the valuation of a parcel, a certain margin for probable adulteration; frequently, buying gutta is like buying a "pig in a poke."

Preparation for the Market.—The very best form to prepare gutta in, for the market, is in thin dry well-pressed slabs. By having thin slabs, instead of the great irregular blocks now exported, gross adulteration by the introduction of stones, &c., would be reduced to a minimum, and also save to a considerable extent the wear and tear of machinery in the subsequent manipulation of the guttapercha. If the slabs are dry and well pressed a great saving in freight would be ensured, as at present examples are not unknown of parcels losing 25 per cent between the ports of export and import.

I have incidentally referred to the necessity of the cultivation under Government auspices; when this is done, and not till then, the manufacturer will have placed within his reach, what he really wants—A GOOD PURE AND UNADULTERATED GUTTAPERCHA. This subject, however, I trust to deal with shortly.—*Indian Rubber and Guttapercha Journal.*

COCONUT CULTIVATION; SALT FISH.

VEYANGODA, 4th February, 1886.

January closed with the weather usual at this season—fiere sun during the day, followed by chilly, dewy nights. The rainfall during the month was 9.09 inches as against 63 last year. This is the critical period on coconut plantations, and a time of great anxiety with those owning or managing them. All their energies are expended in saving, by propping up, the nuts they put on their trees by cultivation. A short period of such weather as we are now experiencing and our plantations wear a melancholy and jaded look, with bunches and branches drooping. If in addition to the

dry season we are entering on, we have to face the blight or insect plague, a correspondent in the *Observer* speaks of as being present in the Western Province, the look-out of the coconut planter will be black in the extreme. I have heard that in years gone by caterpillars denuded whole plantations of foliage. The late Mr. David Wilson, who had the reputation of adopting radical remedies, fumigated his trees with sulphur. The results exceeded his expectations. Caterpillars and coconut trees were both killed. Of course, this is possible only where trees had been overfurnished, for the fumes of sulphur in excess are known to be fatal to vegetable life. There was a spirited discussion on this subject in a local journal when Mr. George Wall put forward his cure for leaf disease by sulphur fumes. It is a question, however, whether it was possible to kill the hardy coconut tree with sulphur fumes, as most of the fumes generated under the trees would in a very little time have been dissipated into space. It is possible that the absence of foliage, the lungs of a tree, was answerable for the deaths. It is best for planters to be on the look-out and stamp out such visitations in the incipient stage.

In a former communication I gave expression to an opinion that the coconut tree is thankful for all the moisture it can get. Further observation shows that though the tree may benefit by much rain its owner does not. It is with coconut, as with all fruit bearing trees excessive rainfall produces leaf and not fruit. Cheeking of growth or wintering is as necessary for a coconut tree to bear as for any other fruit bearer. I was previously of opinion that the coconut was an exception to this rule, but recent observation shows that it is not. The flower spathes thrown out by the coconut palm during the last few months have with a few exceptions been abortive. If this is traceable to the wet weather we have just passed through, then it proves that the coconut is no exception to the rule I have just made reference to. I do not presume to speak beyond what I have observed or learnt from enquiries. These go to shew that in this district at least, coconut crops will be very short. A healthy tree in full bearing ought to have on it about twelve bunches in all stages of growth, from the incipient fruit in the newly opened spathe to the fully ripe nut. Hardly half this number of bunches, and very small bunches too they are, are now noticeable on the trees. A rise in the price of Copperah to something like R60 will compensate for small crops. There is no reason why this price should not be reached, if Merchants will only take the trouble to inspect the bulk of the copperah they export and not delagate this important duty to subordinates. A good article only will then be sent to meet continental demands, and with increased demand prices must rise. While on the subject of crops I notice the continued increase in the exports of cinnamon quills and chips. I do not think we can just yet expect increased prices, especially with the rise in the price of chips.

The thanks of the Island are due to Mr. Ravenscroft for not only starting a new industry, or at least increasing its scope, but for bringing within the reach of many a superior quality of dry fish. I noticed in the papers that Mr. Auward was able to sell only 3 cwts. out of the ton of dry fish he put up for competition. This cannot be construed into a want of demand for the article. People do not consume dry fish by the cwt., and loose dry fish is not a savoury article to be carried about. I think if he will only pick it in tins—kerosine tins ought to answer—of uniform weight, a demand for the fish is sure to spring up in up-country bungalow.—"Examiner."

PEA-NUT FLOUR.—The ingenious Americans have taken to manufacturing biscuits and pastry from the flour of pea-nuts, of which there is said to have been an enormous crop last year, Virginia and the two adjacent States having raised 2,500,000 bushels. As ground nuts grow in large quantities in this country, there can be no reason why a similar attempt should not be made here.—*Indian Gardener.*

RUBBER TREES IN OEARÁ.

The following information has been received from Mr. George Holdern, the Acting British Vice-Consul at Ceara, in reply to questions sent out by the authority of the British Government, with reference to cultivation of the Indiarubber tree in that province:—

Query.—What are the names and productive qualities of the different kinds of rubber trees grown within your district?

Answer.—There are two kinds of rubber trees known in this province, first the "Manicoba" plant from which the Sernambo rubber is extracted, and secondly the "Mangabeira" from which, with the application of alum, the "Mangabeira" rubber is produced.

Q.—What is the extent of land under cultivation by said trees?

A.—The Manicoba trees are only cultivated to a very small extent on the mountains of the "Serra Grande" and Serra da Uruburitama, the greater part of the trees growing wild are over the mountains, at an estimated area of 20 leagues. On the Seras of Marangupe and Pacatuba many trees are to be found, but in this district they have not been cultivated. The Mangabeira tree grows wild in nearly every wooded district where there is a sandy soil.

Q.—What is the nature of the soil most favourable for the cultivation of the Indiarubber tree?

A.—The soil most suitable for the cultivation of the "Manicoba" plant is the clay soil of the mountains. For the "Mangabeira" the sandy soil of the low lands, especially towards the coast. The planting of the "Manicoba" is very simple either from the seeds or from slips of trees. The cultivation of this plant has not been much extended in this province, the people limiting their efforts to substituting any tree that many die by another from seeds or slips. Most of the planting has been done by nature, every year when the Manicoba fruit or seed is ripe it drops off the tree, and falling into suitable ground springs up without any care whatever being given to it.—*Indiarubber and Gutta-percha Journal.*

THE ROTHAMSTED EXPERIMENTS ON SULPHATE OF AMMONIA AND OTHER ARTIFICIAL MANURES.

Many of our readers—especially those who are familiar with the proceedings of the British Association for the Advancement of Science, the Royal Agricultural Society, the Society of Arts, and some other scientific associations—will be aware of the fact that, for many years past, experiments on agricultural subjects have been conducted, on a working scale, by Sir John Bennett Lawes, at his estate at Rothamsted, in Hertfordshire. Through the courtesy of this gentleman, we have been furnished with some rather extensive printed memoranda as to the origin, plan, and results of the field and other experiments, conducted on the farm and in the laboratory at Rothamsted; comprising also a statement of the present and previous cropping of the arable land not under experiment. The report includes some interesting experiments (probably the most complete on record, as they extended over a period of more than 40 years) on sulphate of ammonia, in common with nitrate of soda and other nitrogenous as well as all the known kinds of manures. Sir J. B. Lawes states that he has found sulphate of ammonia to be "an exceedingly valuable manure." For some agricultural purposes, he considers that 1 lb. of nitrogen, in the form of nitric acid, is more valuable than 1 lb. of nitrogen in the form of ammonia, and therefore he would prefer to use nitrate of soda rather than sulphate of ammonia; as in the case of his experiments (published some years ago) upon the influence of nitrate and sulphate respectively on the production of sugar in the beet, which led to the employment of the former salt instead of sulphate of ammonia. The price of sulphate, he considers, will be regulated very much by the price of nitrate; and, with so great a fall in the price of grain, farmers cannot now afford

to pay so high a price for ammonia as they have done in the past. Every page of his printed report, he remarks, will be found to contain abundant evidence as to the immense importance of ammonia as a manure; and at Woburn, where experiments somewhat similar to his own have been carried on for several years, salts of ammonia have proved quite equal, and in some cases superior to nitrate of soda.

It seems that sulphate of ammonia has not always yielded such good results at Rothamsted, compared with other manures, as have been realized at Woburn and other experimental stations. There are two reasons which may or may not account for this, and in regard to which ammonia salts have been unfortunate. The first is that the uniform practice at Rothamsted has not been to use sulphate alone, but a mixture of equal parts of "sulphate and muriate of ammonia of commerce." At the present time, authorities appear to be fairly well agreed that, of the various salts of ammonia, the sulphate is the best for manurial purposes. Bearing this in mind, it is scarcely just to the latter to accept the results obtained from the mixture of sulphate and muriate as affording an accurate indication of those which would be obtained by the use of the sulphate alone. We do not find any explanation, in the memoranda, of the reason why this mixture is used in preference to pure sulphate. The second reason is one which especially bears upon the comparisons between sulphate of ammonia and nitrate of soda. As a general rule, the practice at Rothamsted has been to apply the former in the autumn and the latter in the spring. On this point, again, modern practice points to the spring time as the best season for the application of the sulphate as well as the nitrate; so, on this account, the sulphate is also at some disadvantage. We do not pretend to assign the extent of the effect of these two causes—the use of a mixture of sulphate and chloride, and the application in the autumn instead of in the spring—in regard to any calculations as to the value of sulphate, as ordinarily manufactured at gas-works, in comparison with other substances, but simply direct attention to them.

It is noticeable, although Sir J. B. Lawes considers "that the price of sulphate must be regulated very much by the price of nitrate," that to some extent these two sources of nitrogen are distinct from each other, as having special applications. It appears from his remarks that in some cases the nitrate is preferable, whilst in others the sulphate is the more appropriate salt to use; as for some purposes the former has been found to give the better results, whilst in others the latter has proved to be more advantageous. It follows that these salts are not to be regarded as competitors one with the other, except perhaps, to a limited extent, for certain purposes to which it is possible that they may be equally applicable; and that there is (we are not attempting a ponderous pun) a fair field for each salt. Here we have a striking agreement with the remarks already made in these columns on this subject by Mr. F. J. Lloyd, F.C.S., in his article on "The Value of Sulphate of Ammonia as a Manure."*

Apart from the value of the two salts respectively as manures, we would remind our readers that, as set forth in the article just referred to, sulphate possesses several practical advantages over nitrate. The latter is so deliquescent that, as a general rule, it cannot be used for mixtures; and, as we shall presently see, it is to the judicious use of mixed manures that the farmer must look for the best results. In addition to this, it is evident that they must follow the example of Sir J. B. Lawes, and learn to mix the manures for themselves, rather than depend upon the purchase of mixture from dealers. Sulphate of ammonia is efflorescent—it loses moisture by exposure to the air. In mentioning this property, it is important to notice that the loss is not due, as some have supposed, to the volatilization of a part of the ammonia. The alkali is in a fixed, non-volatile

* See Journal, Vol. xlv., p. 600.

from; and therefore there is no loss from storage. So, in buying sulphate that has been in stock for some time, the advantage is likely to be on the side of the buyer; but nitrate increases in weight by absorbing moisture, and is consequently reduced or attenuated in value to a corresponding extent. The advantage to a purchaser, in being able to go to the nearest gas-works, and examine and (if he desires it) analyze the sulphate before purchasing it, is evident.

In order to place the Rothamsted experiments in their proper light, it will be necessary to indicate the plan of operation, as described in the memoranda; and also to glance briefly at a few general principles respecting the use of manures. Sir, J. B. Lawes was the founder of the Rothamsted experimental station. Soon after entering into the possession of his hereditary property there, in 1834, he commenced a series of trials in different manuring substances, first with plants in pots, and afterwards in the field. Of all the experiments so made, those in which the neutral phosphate of lime—in bones, bone ash, and apatite—was rendered soluble by means of sulphuric acid, and the mixture applied for root crops, gave the most striking results. These results, obtained on the small scale, led to more extensive trials. A permanent laboratory was established in 1843; and from this date down to the present, a permanent staff of chemists, assistants, botanists, clerks, &c., has been maintained at the station, in addition to chemical assistance in London, Berlin, and elsewhere. The whole has been maintained entirely at the cost of the owner, who has further set apart a sum of £100,000, as well as certain areas of land, for the continuance of the investigations after his decease. The general scope and plan of the field experiments has been to grow some of the most important crops of rotation, each separately, year after year, for many years in succession, on the same land, without manure, with farmyard manure, and with a great variety of chemical manures; the same description of manures being, as a rule, applied year after year on the same plots. Experiments on an actual course of rotation, without manures and with different manures, have also been made. These experiments included wheat, barley, oats, beans, clover, turnips, sugar-beet, mangel-wurzel, potatoes, and grass. Samples of all the crops are taken and brought to the laboratory, where weighed portions, after being partly dried, are preserved for reference or further examination. The experiments upon them include examination for water and ash—sometimes the complete analysis of the latter—and the determination of nitrogen, whether as albuminoids, amides, or nitric acid. In the case of wheat, the experiments have extended to the flour obtained from it; the sugar from the beet, mangel-wurzel, and potatoes has been determined; and the botanical composition has also received careful attention. A large number of samples of soil, at various depths, have been taken and analyzed; also tested for absorptive capacity, as regards water and ammonia. Again, the rainfall and drainage have also been the subjects of many experiments; and the amount of water transpired by plants, the assimilation of nitrogen, and other topics, have also received attention. Some very exhaustive experiments on animals have been included; and, although many of the results of the investigations have been given to the world, as above mentioned, a large proportion remains unpublished.

A general glance at the operations comprised in the whole process of preparing land, for the purpose of growing crops of any kind, is necessary to enable us to appreciate the part played by the addition of manures to the soil. The mechanical conditions of the soil have a most important effect, and the laborious work incidental to digging, ploughing, or otherwise preparing the land is undertaken for the purpose of rendering the soil light and porous, and of reducing some portion of it at least to a state of division sufficiently fine to enable the various constituents contained in it to be assimilated by the plants. For the furtherance of this purpose, the farmer usually looks to the natural phenomena of rain or mist, as a source

of the necessary moisture; though sometimes this is supplied, wholly or in part, by artificial means. But the soil must not be so moist as to cake together; and therefore the drainage of the land, for the purpose of removing any excess of moisture, forms an important department in agriculture. Even after every care in the way of properly working up the land, much depends on the weather; so it is evident that only by means of such gigantic and long-continued experiments as those the records of which we are now considering, can any accurate information, suitable to form data for the formulation of rules for the guidance of the agriculturist, be obtained.

It is evident that manures may directly affect the soil only, and through this medium afford the desired benefit to the crop; or they may be fitted for direct assimilation by the roots of the plants, and inert as regards the soil. Three kinds of action are recognized by the agriculturist. These are, first, mechanical action, such as when sand is added to a heavy clay soil to render it lighter and capable of maintaining the desired condition of fine division; secondly, chemical action, as when a substance is added which induces actual changes in the constitution of the soil, as shown by analysis, which render it more suitable for the support of the desired crop; and, in addition to these, there are the rather obscure results known as "physiological action." Examples of all of these are afforded by the experiments before us. With regard to the latter, we may remark that the proverb "What is one man's meat is another man's poison" applies with equal force to the vegetable kingdom. Most remarkable experiences are on record as to the strange effect of certain substances on vegetation—results for which chemistry is quite unable to account.

Nitrate of soda appears to act directly upon the roots of the plants, without in any way affecting the soil. It is a very quick-acting manure, and but for this it would be almost useless; as, on account of its ready solubility in water, it passes away with the drainage. Indeed, it appears that a considerable proportion of it must always be wasted in this way. Sulphate of ammonia is entirely different in this respect. The soil has a sort of affinity for this substance; and consequently it does not pass off with the drainage water, like nitrate. The ammonia is gradually decomposed by the action of the soil; the nitrogen taking the form of nitrates, and the nitrates would be liable to pass off with the drainage-water, like nitrate of soda. In this manner, therefore, some of the nitrogen of the ammonia may be lost to the plants, if the salt has been applied any considerable time before it is required. Consequently, a certain amount of loss may result from applying the sulphate in the autumn instead of in the spring, as previously observed. The fact that the nitrogen must be converted into nitric acid before it is used by the plant has not been lost sight of by those interested in nitrate, who claimed that in this salt the nitrogen is provided in exactly the form in which it is required. But, as we have seen, this property is attended by rapid action, which is not permanent. Some go so far as to say that the nitrate leaves the soil rather worse than before it was used. We have heard of instances in which nitrate was applied to grain crops, and produced a splendid crop of green, but exhausted its powers before maturity was reached, leaving the crop in an unripe and immature condition; and it is easy to understand that heavy rains, coming late in the season, might have this effect. Sulphate, however, if it does not produce such immediate startling effects, is found to improve the condition of the land. No doubt the chemical actions between it and the soil, which result in the gradual liberation of nitric acid, also serve to assist the mechanical disintegration which is necessary to set free some of the constituents in such a form as to be absorbed by the plant.

While the advantages achieved by the application of nitrate are confined to the increase in crops obtained during the season in which it is applied, this rule cannot be adopted in the case of sulphate. The former is completely exhausted in a single season, and

does not leave any after-benefits; but the good effects of the latter are found to extend over some three or our seasons.

Passing on now to notice the various experiments in detail, we come first to those tried on permanent meadow land. Twenty different plots of grass land are under investigation; the present being the thirtieth season to which the experiments have extended. The operations comprise the use of a mixture of a small proportion of ammonia salts (the mixture of sulphate and muriate) with farmyard manure; of each singly; and of superphosphate of lime—made by mixing 200 lb. of bone ash with 150 lb. of sulphuric acid (sp. gr. 1.700) and water—with and without ammonia salts, also with the addition of sulphates of potash, soda, and magnesia. Silicate of soda and cut wheat-straw were also used in some of the mixtures; and some plots were left unmanured.

The art of manuring is sometimes defined as giving back to the soil that which is removed by the plants; but these experiments show that it is of a much more complex description. If this idea is correct, it should follow that land left unmanured would show a gradually decreasing yield. This appears to occur to some small extent; inasmuch that land to which manure was not applied yielded rather lower results in the second ten years than in the first. One plot left in this condition yielded an average annual production of 22½ cwt. of hay per acre during the first ten years, and 20 cwt. in the second ten years; another plot yielded 25 cwt. per acre for the first period, and 22½ for the second. But this variation between one period and another is not so great as that noticeable in some of the manured plots. One very instructive experiment bearing on this point is that tried on plot 18, which was treated with a mixture supplying the quantity of potash, soda, lime, magnesia, phosphoric acid, silica, and nitrogen contained in a ton of hay, as ascertained by analysis. It is very natural to suppose that this would be *ne plus ultra* of manuring; but, although an increased yield was obtained, the result—33½ cwt. as the average annual production per acre during a period of ten years—is very low in comparison with other results.

Turning to the advantages gained by the use of sulphate, it appears that although, when the ammonia salts are used singly, these results are not so good as those following the use of a corresponding quantity of nitrate, the former is superior to the latter when mixed with other substances. The best results obtained—63½ cwt. of hay per acre per annum—resulted from the use of a mixture of the sulphate of potash, soda, and magnesia, superphosphate, ammonia salts, and silicate of soda. The effect of leaving out the ammonia salts from this mixture was very marked; the yield being reduced to something like one-half. The ammonia salts also have a marked effect in increasing the value of farmyard manure. Using singly 14 tons per annum of this material gave a yield of 42½ cwt.; but the addition of the comparatively small quantity of 200 lb. of ammonia salts increased this to 49½ cwt.—some 12 or 13 per cent. Only in one case (No. 14) does the use of nitrate of soda in a mixed manure approach the results afforded by the ammonia salts. In this case a production of 60½ cwt. is obtained; but all the other nitrate mixtures fall very far short of this.

The experiments on barley show that farmyard manure gives the greatest production, and that the ammonia salts yield slightly lower results, when utilized as a source of nitrogen, than the nitrate of soda. When used for wheat, however, these salts occupy a better position, and compare fairly well with the nitrate. Some excellent results were obtained by employing a mixture of ammonia salts, superphosphate, and one or more of the sulphate of the fixed alkalies. With regard to oats, broadly the results are about the same as those obtained with wheat. Ammonia salts and nitrate, respectively used singly, are about on a par; and the former show a slight advantage when used in mixtures of the character above indicated. It is important to remember that 400 lb. of

ammonia salts are equal, in respect to nitrogen, to 550 lb. of nitrate; and these are the relative proportions maintained throughout the experiments. Taking the value of nitrate at £10, the ammonia salts are therefore worth £13 to £14 per ton. Value for value in the market, then, ammonia salts are superior to nitrate for grain crops. Generally speaking, the utility of a nitrogenous manure in respect to grain is very marked; the crops being frequently doubled by its use.

A set of experiments was tried with oats, using the mineral manure as before, but only half the quantity of nitrogenous manures. A considerable diminution in yield was the result; but it is remarkable that, under these circumstances, the ammonia salts secured better results than the nitrate. The unmanured land yielded an average of 13½ bushels of oats per acre per annum. The effect of using 200 lb. of ammonia salts per acre was to more than double this yield; the result being 28½ bushels. The use of a corresponding proportion of nitrate—viz., 275 lb.—secured a return of 26½ bushels. The results from the mixed manures are still more remarkable. When nitrate was used as the source of nitrogen, the results were no better than those secured by the use of ammonia salts singly—viz., 28½ bushels; but when ammonia salts were used, the yield was 38 bushels. The mixture which secured this result consisted of 200 lb. of sulphate of potash, 100 lb. each of the sulphate of soda and magnesia, 3½ cwt. of superphosphate, and 200 lb. of ammonia salts. The effect of leaving out the ammonia salts (all the other ingredients being used) was to render the manure perfectly valueless; the result obtained being only 13½ bushels, or rather less than the yield from the unmanured land.

A difficulty was experienced in the application of the nitrate on these plots, and possibly was the cause of the experiments noticed in the preceding paragraph. Where the nitrate had been applied, year after year, the land was so wet that it could not be brought into favourable condition for sowing, although more work was applied to the land; and the plants in consequence came up very irregularly. In one season a heavy fall of snow a week after sowing caused many of the plants on the nitrate plots to perish from standing surface water. These difficulties, due to the deliquescent character of the nitrate, to a large extent account for the low results obtained from this substance, as above noted. The use of nitrate is evidently under some difficulty in respect to drainage. If the land treated with the salt is insufficiently drained, it retains moisture so obstinately as in some cases to kill the young plant; and if ample drainage is provided, there is the risk of its running off to waste before it has done its work.

The results obtained with beans, peas, clover, &c., are rather difficult of explanation. The mineral constituents used as manures (more particularly potash) increased the produce very much during the early years, and to a certain extent afterwards, when the season was favourable. Ammonia salts produced but little effect, notwithstanding that a leguminous crop contains two, three, or more times as much nitrogen as a cereal one grown under similar conditions as to soil, &c. Nitrate of soda produced more marked effects. But when the same description of leguminous crop is grown too frequently on the same land, it seems peculiarly subject to disease. It appeared that ordinary garden soil yielded better results with these crops than arable land with every possible assistance in the way of manures.

Turning to the experiments on roots, it is noticeable that the ammonia salts were used with some advantage as a cross-dressing for turnip crops, when mixed with rape cake. When used in this way in conjunction with farmyard manure, superphosphate, and mineral manures, the ammonia salts secured much better results than either nitrate of soda or sawdust saturated with nitric acid. The greatest yield of the turnips—8 tons 16 cwt. of roots and 29 cwt. of seed was obtained by using farmyard manure, with

of the young
and required
of November

salts (mixed either with rape cake or sawdust) used as a cross-dressing. In the experiments on sugar beet, farmyard manure proved far superior to all others; and nitrate of soda was more successful, when used for cross-dressing, than ammonia salts. But although the actual produce was larger, the best grown from ammonia salts contained a large percentage of sugar than that from nitrate of soda. The experiments on uangel-wurzel agree mainly with those with beet, except that in some cases the ammonia salts show a marked advantage over nitrate. As in the case of turnips, the best results are obtained from farmyard manure, with ammonia salts and rape cake as a top-dressing. By these means, a yield of about three-fold, as compared with that from manured land, is obtained. In some other experiments excellent results were obtained by using superphosphate and sulphate of potash as a manure, with a cross-dressing of ammonia salts and rape cake. But a considerable amount of variation is noticeable in all these experiments even under similar conditions of manuring, &c., showing that, after all that can be done, the weather has a more potent effect upon the crop than any artificial conditions. A regards potatoes, it appears, from the average of ten years' experiments, that nitrate of soda is sometimes more suitable, both singly and in mixtures, than ammonia salts; whilst in other seasons the latter yield the best results. As with the other roots, the yield is increased sometimes more than threefold by the use of manures.

A series of experiments was commenced in 1848, and is still in progress, on a regular course of rotation of turnips, barely, leguminous crop, and wheat. In these, an extraordinary increase of yield has been obtained by the use of manures composed of pearlash, superphosphate, ammoniac salts, alkaline sulphates, and rape cake. The average for the first nine courses—1848 to 1853 on unmanured land is a production of 33½ cwt. of turnips, 3,988 lb. of barley, 37 cwt. of clover, 1,867 lb. of beans, and 4,516 lb. of wheat. By the use of the manures as just mentioned, on plots of equal extent, a yield of 336½ cwt. of turnips, 4,883 lb. of barley, 75 cwt. of clover, 3,230 cwt. of beans, and 5,308 cwt. of wheat was obtained. The turnips were increased about tenfold; the clover twofold; and the other crops to a considerable extent.

The most striking fact elicited by these experiments, is the importance of nitrogenous manures to the farmer. Used singly, they are as efficacious as much greater quantities of superphosphate and other alkaline salts. And when judiciously applied as mixtures, they not only make two, but three or four blades grow where only one grew before. If these extensive and costly experiments, which have been arranged and conducted with remarkable care, skill, and application, by Sir J. B. Lawes and his assistants, had done no more than to elucidate this fact, the benefit to agriculturists generally would be such as to entitle this gentleman to the proud position of a public benefactor. But, even from the imperfect outline of them which we have given, our readers will be able to judge that their value is incalculable to those directly interested in agriculture. It is most satisfactory to know that these experiments are to be continued; for it is only by taking the average of a large number of seasons that the effects of the variations due to climatic conditions can be eliminated.

In addition to setting forth the value of nitrogenous manures, these experiments conclusively show that sulphate of ammonia is by far the best of this class of manures in the market, at present prices. Sulphate is now quoted at but little more than nitrate; and 80 part of the former supply as much nitrogen as 100 part of the latter. With some kinds of crops the nitrate produces the more striking immediate results. But we have seen that, for securing these, a great deal of care in the matter of drainage is necessary; and, further, after every possible exercise of care and skill, a smart shower or two of rain, or early snow, may not only cause a considerable loss of nitrate to go to waste, but the mischief it does extend as far as the destruction of the

entire crop. So it is satisfactory to observe that these extensive and authoritative trials support the claims that have recently been made in our columns on behalf of sulphate of ammonia as a manure. Admitting the nitrate of soda to be theoretically the better—and this is by no means proved—it is evident that the mechanical properties of sulphate are such as to render it the best for general use, as recently urged in our "Correspondence" columns by "A Farm Bailiff and Valuer under the Agricultural Holdings Act," even if its price were considerably higher than at present. In saying this, we repeat that these two nitrogenous manures, if competitors at all, are only so in a limited sense, as there are special applications for each.

But, if this is true, why has sulphate lately fallen in value in the market nearly to the level of nitrate? One reason frequently set forth is that nitrate has proved to be the better for beet and root crops generally. These are the class of crops that appear to be least benefited by the use of nitrogenous manures, for the simple reason that they have plenty of leaf surface, and by this means take up nearly all the nitrogen they require in the form of ammonia, a minute proportion of which is always present in the atmosphere. The special advantages offered by the use of sulphate for grass and grain crops have been pointed out in these articles; and we can only accept one of two conclusions from the marked effect which the discarding of sulphate in connection with beet crops appears to have exercised upon its market price. These are, that the use of sulphate for grass, grain, or general purposes is not sufficiently understood (or, at any rate, not sufficiently acted upon); or that the market value of it is artificially kept down by the operations of speculators. Both are probably true to a great extent. Looking at the quantities of grass and grain grown in our own country, it would appear that the bulk of the sulphate made at an ordinary gas-works should be purchased at good prices by farmers in the vicinity. Under these circumstances, there is evidently room for the Sulphate of Ammonia Producers' Association which is now in course of formation. And if this body goes energetically to work in the direction of making known the value of sulphate for the various purposes, which have here been noticed, and also the establishment of direct communication between the producer and the consumer, results will be obtained that will prove beneficial to all parties concerned.—*Journal of Gas Lighting, Water Supply and Sanitary Improvement.*

SEED GERMINATION.

Sir,—Referring to Mr. Grierson's letter in last week's Journal, I would remark that it is a well-known fact that when fresh soil is exposed by deep railway cuttings, or otherwise, plants either quite fresh to a locality, or previously uncommon, frequently make their appearance in profusion.

A notable instance occurs in this neighbourhood. A few years since, having time on my hands at a country railway station not far off, I wandered on to the line, and was surprised to find not one, but several plants, which, although I had explored the neighbourhood fairly well, I had never previously seen. Since then, however, in collecting together and compiling all the information I could get at upon our local flora for the Essex Field Club, I have ascertained that all these plants had been found previously in small quantities within a few miles of the station. Now, as they were to be found only in special places and in small quantities, it is highly improbable that the seeds of all should have been carried to this one spot; nor was it likely that the seeds of all should in recent years have become spread over the whole country. I was therefore led to suspect that all these plants had, some time or the other, been more or less profuse, but had become rare through the soil becoming unseeded to them by exhaustion, cultivation, or some other cause; and that in making the railway cutting, both seeds and suitable soil had been exposed, and again the plant had become profuse.

This suggests a subject which I think might amply repay one who had the time to work it out thoroughly.

It is a remarkable fact that, with one or two exceptions, no plant or animal has been introduced into this country from our colonies. On the other hand, many of our plants and animals have been introduced into our colonies, and have in several cases become far worse nuisances than at home.

Hence it appears that our long cultivated country has become unsuited to the plants and animals from virgin soils; but that the comparatively recently cultivated soil of our colonies is frequently even more suited to the growth of our pests than their native land.

In the case of one of the exceptional plants which have established themselves in this country (*Anacharis Alismastrum*), the plant was for a long period a great pest, blocking up canals, and almost defying human skill to keep them open; but I believe the nuisance has of late years been less serious; possibly the waters have become less suitable for their growth, though the plant may have deteriorated through their having been no stamen-bearing plants introduced into this country.

These remarks might be extended into the domain of medicine. I believe instances are not wanting in which diseases, when first introduced into a country become a perfect scourge, but after a while apparently exhaust themselves; and there are several diseases which, whilst formerly defying medical skill, have now become more unobnoxious.

Some thirty years ago, in almost every third house in this neighbourhood, a case of ague would have been found at times; now the complaint has become comparatively uncommon, and there is some ground for suspecting that whilst our improved sanitary arrangements have in many cases mitigated disease, in some the mitigation may have been due to the pabulum, if I may use the term, having become exhausted by the virulence of the disease amongst our forefathers.—J. C. SHENSTONE, Colchester.—*Pharmaceutical Journal*.

PRODUCTS FROM KILIMA-NJARO, EAST AFRICA.

An important paper was read before the Society of Arts (Foreign and Colonial Section), on the 14th ult., by Mr. H. H. Johnston, entitled "British Interests in Eastern Equatorial Africa, more especially in the Kilima-njaro District, and on the Victoria Nyanza." In the course of his interesting communication, in which the country and its products were dealt with at length, Mr. Johnston thus referred to those articles in which our readers will be most directly interested:—"Gums are produced in the interior, both copal and a kind called false copal. Indiarubber can be procured from at least one creeper, the *Landolphia florida*, and I think also another, a species of fig. Coffee grows wild, especially on the northwards of the district, where it is the same species as the Abyssinian plant, which, it is supposed, being first introduced from the kingdom of Kaffa to the south of Abyssinia, thence derives its name. Coffee planting would succeed admirably in districts like Usambara, which may be regarded as the natural home of this shrub, which is, indeed, indigenous to the African continent. On the trees growing in the Kilima-njaro and Usambara forests, orchilla weed, in incredible quantities, is found growing. When delivered half clean, that is to say, mixed with sticks and rubbish, on the coast, it fetches from 3 to 3½ dollars per fresslab of 35 pounds. As regards minerals, iron ore is found in some abundance, and copper apparently also, since the natives possess rude rings and ornaments of this metal which have not come from the coast. Nitrate of soda covers vast plains to the south, west and north of Kilima-njaro. There is good building stone in many parts of the country. Limestone often appears. The vegetable productions of the natives' cultivation, are the banana, the sweet potato, the edible arum root, the sugar cane, Indian corn, *mtama*, or red millet, and many unnamed varieties of peas and beans. A little rice is grown in some districts, namely,

at Taveta and on the River Dana. Tobacco is everywhere abundant, and exceedingly cheap. I might mention my own, almost incredible, experience with the cultivation of European vegetables on Kilima-njaro. Immediately after my arrival I planted the eyes of a few potatoes, onion bulbs, and the seeds of mustard, cress, radishes, turnips, carrots, peas, beans, spinach, borage, sage, tomatoes, cucumbers, and melons. Everything came up, and flourished amazingly. In three months' time I had a dozen fine cucumbers from one plant, and so many potatoes that I was able to give them away to my men, as well as supplying my own table. I had everything else in abundance in a short space of time. Before leaving, I had planted my land at Taveta with wheat and coffee, limes, oranges, mangoes, and coconuts. I also distributed numbers of useful seeds among the natives. I should have mentioned in its proper place, before the vegetables, that there is a great quantity of delicious honey produced throughout this district. The wax is of very good quality, but the natives have no use for it, and merely throw it away." For the development of this marvellous country—a land literally "flowing with milk and honey"—where the climate is so exceptionally favourable, the great majority of the inhabitants eager to do a trade and desirous to be under British rule; which includes "vast plains" of nitrate of sodium, and where beeswax of "very good quality" is continuously thrown away, Mr. Johnston suggests that a company or association, with a few thousand pounds capital, be now formed, and that a thoroughly practical small expedition be sent out, before the Germans or French take the law into their own hands and *annex the lands*, and we trust no obstacle will arise to prevent this consummation from being accomplished. In the course of the discussion which followed the reading of the paper, one of the speakers confirmed Mr. Johnston upon one important point, and stated that a sample of the nitrate of sodium from the "Massai country" was found, on analysis, to be fully equal in point of quality to the best of that imported from South America.—*British and Colonial Druggist*.

COMMERCIAL AND MEDICINAL PLANTS OF MEXICO.

In a report issued by the United States Department of Agriculture, giving a review of the agricultural products and resources of Mexico, it is stated that in that country there are to be found 110 medicinal plants known to the physician, 12 varieties of well-known dye woods, many plants used for the same purposes, 8 varieties of important gum trees, and several of the resiniferous trees. Of the whole of the commercial plants, the vanilla, a parasite plant, is of the largest importance. This plant is of the orchid species, indigenous to Lower Mexico and Central America. It is planted from sprouts, and will become fruit-bearing at the end of three years, lasting from thirty to forty years. The capsule of the *Vanilla Planifolia* and *claviculata* is remarkable for its delicate and agreeable odour, and the volatile oil extracted from it. The several varieties of this plant are successfully cultivated in the States of Tamaulipas, Vera Cruz, Tabasco, Oajaca, Chiapa, Guerrero, Michoacan, Colima, Jalisco, and Hidalgo. Anil, the *Indigofera tinctoria* of the botanist, is extensively cultivated, and it is stated that indigo has long been one of the exports of Mexico. The following is a description of the manner in which it is cultivated. The old-fashioned crooked stick and oxen are used to plough the fields, and the soil has been raised into hillocks, the indigo seed is scattered broadcast over the same field, and this is all that is done. The rains beat down the seed sufficiently, and in about one week the young plant appears. The average quantity of seed required is about 100 lb. per acre. In the month of November

the corn crop is harvested, and the indigo plant is then three feet high, and very hardy. About September of the second year the plant is about eight or ten feet high, of proportionate thickness, and of a dark green colour, and it is then cut and pressed. To insure a large proportion of indigo pulp it is important that the plant be cut and placed in a tank at night, or at least before the sun has gained full force. The tanks should also be well shielded from the sun-light, as a strong light bearing on them during the operation materially lessens the quantity of pulp. The pressing tanks are three in number, built of stone and mortar, and are so arranged that the contents of one can be readily drawn into the other. The plant is laid in the first tank, filling it two thirds, and after being pressed with heavy stones, the tank is filled with clear water. After a fermentation of about ten hours the liquid is run off into the second tank, with wooden hand-paddles for from two to four hours. It is then allowed a certain time for settling, and is then drawn off into a third tank. The water, after three or four hours, is then drawn off, and at the bottom of the tank is left a blue pulp, which is taken out, dried in the sun, and packed for shipment. There are many well-known dye woods and plants indigenous to Mexico, which are mostly found in the Tierra Calientes, and embrace, among others, the Brazil tree, logwood, and the Campeche, so named after the State in which it grows. The dye trees of the Tierra Calientes include the *achiote* or heart-leaved lixa or anotta, the *tintaron*, which yields a beautiful sky blue dye, and the *genibillo*, yielding a strong bright yellow. Among the most numerous trees are several varieties of gum and Indian rubber trees, cork trees, and dragon root, which latter in Chiapa grows to a medium-sized tree. Palm trees are abundant in many districts, and a large industry exists in the manufacture of palm leaf hats, fine mats, and other articles of use and luxury. One variety of the palm tree, known as the *corozo*, yields an excellent oil. Other trees of the soap plant species furnish an excellent substitute for soap, and a root of the orchid plant, called *yate* in the aboriginal dialect, furnishes a very fine soap highly valued for cosmetic purposes. The castor bean is very largely grown, and the expenses of its cultivation are very small. It is estimated that an acre can be planted with 600 trees, yielding at once at least 3,000 pounds of beans, which if pressed as soon as gathered, will return 50 per cent or 1,800 pounds of oil. The castor plant thrives best under conditions similar to those of coffee growing. When a year old the plant reaches a height of 9 feet, with heavy foliage. The cultivation requires no more care than the corn crop, and its first yield, which subsequently increases yearly, is about six pounds. The production continues during five or even six months of the year, and it is stated that plants from two or three years old yield from five to six pounds every month, or an average of twenty-five pounds per annum for each plant. Another product which is used in Mexico and shipped to France for tanning purposes is the *Cascabel* bean. This tree grows wild, reaches a height of about 25 feet, and has branching foliage often 30 feet in diameter. It produces in large quantities a bean of a broad and crooked shape. The bean dropping to the ground when ripe is gathered, dried, and pulverised, and in this form makes one of the best of all tanning substances. The tree is found in the States of Michoacan, Colima, and Guerrero; it grows wild, and one laborer can pick as much as 250 lb. of beans a day. Among other useful and medicinal plants may be found the sarsaparilla, *toninoga*, a native cure for fever, the *barba de chihato*, or buck-beard the *quero*, the *paraguai*, and *chapi*, herbs used by the Indians to produce perspiration. The *jalisco*, a species of guava, or South American pear tree, is used for curing skin diseases. Sassafras is abundant, as also the soap wort, or *jaborera*. The dragon tree is valuable for its medicinal resin or gum. The saffron, cinchona, aloe, many varieties of the acacia, corianda, wild liquorice, and many other useful plants, shrubs, and herbs are found. The leguminous plants are numerous and valuable, and varieties

of the *Euphorbiace* family are found in abundance along the table lands of the lower Pacific States. It is stated that all the plants now cultivated in Mexico were known to both the Aztecs and their Spanish conquerors, and though the exportation of the plants and their products was at one time much larger than at present, there is every probability with the present and growing activity felt throughout Mexico, that a large increase in production will soon take place.—*Journal of the Society of Arts.*

NUTMEGS, BETEL-NUTS, TEAK AND FRUIT AT SINGAPORE.

There are now planted out in Singapore, as nearly as can be discovered and estimated, about twenty-five thousand nutmeg trees. In this number, there are about four or five hundred which have been bearing for considerable terms of years, including about two hundred or so from 18 to 21 years of age. The remainder consist of trees of all ages downwards, from about eight or ten years of age to one. The land occupied by these trees may be from about 550 to 600 acres. In the whole collective area there is only a very limited proportion of the best, but a large proportion of the worst soil.

It has become fashionable in these Eastern Isles where the imagination, like the jungle, is so apt to luxuriate, to pitch upon some trees of uncommon growth, and situated in the most favoured spots, as standards of comparison, and as sure indices of prospective wealth, in a species of cultivation which, beyond all others, demands the soberest exercise of the judgment, and the most liberal sacrifice of preconceived opinions and exaggerated expectations, before we can venture on a computation of the probable—certainly always more or less uncertain—results. Like most fruit trees, some nutmeg trees will bear large and others scanty crops. The annual rent will always vary considerably, for a full crop can hardly be expected beyond once in three years.

The betel-nut tree deserves consideration, for although it would not be worth the while for a capitalist to speculate upon it, still, as the nut is exportable, it is of more value than produce which must, from its perishable nature, be consumed on the spot. It is a hardy tree, and only requires to be kept free from thealang grass and jungle for two or three years, after which it will afford sufficient shade to prevent that grass growing strongly.

I have already noticed that Straits fruit trees promise well generally. The base of the hills, and gentle slopes, and undulations are well suited to them. The mangosteen seems to thrive on the flat clayey land, while orange trees, the pumelo, jacks, durais and others will be best planted on other sites. Some of these trees, the jack for instance, thrive well on the stony red iron soil. But it is obvious, with the acknowledged superior fruits of Malacca so close at hand, that the cultivation of unexportable fruits should be gauged by the number of local consumers.

The cinnamon tree may yet come to the aid of the planter. It has been introduced on the island, and thrives very well, but a very small number of trees only have as yet been planted out.

The cocoa, or tree yielding the chocolate bean, may be advantageously cultivated here. It has been long acclimatised in Penang, and chocolate of a fair quality is manufactured for the use of the Roman Catholic Mission by its padres. It is a hardy tree, and seems to grow wherever it has been planted there, both on the hills and plains.

The teak tree thrives at Singapore, and might be usefully employed along with the cocoa tree to line the boundaries of estates.

The pine-apples of Singapore and the islets in the vicinity, are of a superior quality. They are large, sweet and well-flavoured, and they are cultivated in such abundance up the steep sides of these hilly islands, that they are sold in the market for one-third of a cent of a dollar each, and are thus eagerly consumed by the lower classes. But it is not a

wholesome fruit, and, doubtless, it assisted the cholera in the ravages it made here last spring, when it is believed from six to seven hundred natives died of that dire disease. Several European seamen died on board the vessels in the harbour, but only one died on shore, and his habits were intemperate.

The pine-apple grows best on the arid rocky slopes, on the worst red soil, and it partakes outwardly of this red colour. If the pine-apple fibre comes into repute in England, which it is likely to do, then there will be a wide field here for its manufacture.

The Agricultural Society has not effected anything as yet in the horticultural department, which, I believe, it was intended that it should embrace. The Chinese and Malays raise in their own way all the vegetables which are brought to market. These are sweet potatoes, bad yams, kaladie, or the arum colosasia (of R) which is cultivated in swampy places. The root is single, oblong and bulbous, and it is eaten as a substitute for the potato. The stalks and leaves are sold as fodder for pigs. A few inferior cabbages are grown from sprouts by dint of stimulants which shall be nameless. Celery is also grown, but the root is not sold in the bazaars, the leaves only being so; and this absurd way of using this vegetable is patiently endured by the consumers, who will, it seems, consent to pay a high price for English preserved vegetables, which, for ought that has been proved to the contrary, might by the offer of premiums, and by a modicum of instruction have been cultivated at their own doors. It may be said that these will not grow here. So it was said long ago at Calcutta and Madras, yet perseverance has overcome every obstruction at these Settlements. The native vegetables are rather small, yet they are of good quality, and for a garden of a moderate extent, a soil can readily be made to suit every species which the climate will permit to grow. From all that has been stated, it would appear that the cultivation of this island is still in its probationary period. The Chinese have been shewn to be the chief cultivators, but then they have no attachment to the soil. Their sole object is to scourge the land for a given time, and when worn out to leave it a desert.

And what, we may inquire, what is to become of the thus impoverished land covered with the jungle they leave in the rear on their onward progress over the island. A fifty years fallow would barely return it to its pristine condition; and what agriculturist would be so rash as to embark on a large scale in the attempt to renovate it? In short, it seems clear, that if no general cultivation of a more permanent nature than pepper and gambier can be advantageously established, the forest must ultimately reassume its dominion. Unfortunately, there is no rice land worth mentioning which might induce a settled Malayau population. The only remaining chance therefore would seem to be the planting of coconut, areca, and other indigenous fruit trees and incorporating them gradually with sugar cane and trees yielding an exportable produce. As the case stands, it is clear that if there should be any considerable prolonged fall in the prices of pepper and gambier, the cultivation of these articles, and consequently of the greatest cultivated portion of the island would cease.

The area of the island has been stated at about 120,000 acres. But as far as the above two products are concerned, the quantity of land available for them might not be reckoned at above one-fourth of the whole, supposing that pepper and gambier must continue to be cultivated together and cannot prove profitable separately. Because the proportion of pepper land is much smaller than that suited to gambier. Then a very large deduction would be required for the jungle land which must be attached to each plantation for the supply of fuel. When the whole lands on the island and in cultivation shall have been measured and the nature of the remaining portion shall have been ascertained, a correct estimate may be made of the period after which pepper and gambier will cease to be cultivated. For it may be remarked

that these plants or trees cannot, until a long period of years has elapsed, be successfully raised a second time on the same soil.—*Singapore Free Press.*

RORAIMA.—Mr. im Thurn, an Oxford graduate, who wrote such an interesting book on British Guiana two or three years ago, has been engaged in exploring the most mysterious spot in South America. About seven or eight years ago Mr. Barrington, a geologist and naturalist, made known to science the existence of an inaccessible bit of table-land, called Roraima. It was surrounded by precipitous cliffs, and, it was believed, would only be explored by balloon agency. The top was covered with forests, and naturalists have ever since been on the tiptoe of expectancy with regard to this possible fragment or outlier of a former geological epoch. There we might possibly meet with a portion of the miocene or pliocene fauna and flora—fossilised elsewhere—which had become stranded, as it were, on this American Aarat! The secret was bound to be found out after this, and by an Englishman, too. Mr. im Thurn went back to Guiana determined to scale Roraima, and he writes to say that, after one or two failures, he has succeeded. He found the top covered with shrubs (no trees), and he found a large number of new species of plants, but no strange or new animals. The top of the plateau is 12 miles by four, and its weather-worn surface plainly reveals its geological antiquity.—*Australasian.*

IRONBARK.—This is one of the most valuable of Australian timber trees, and grows abundantly in New South Wales. Some kinds are said to be almost indestructible in any situation, impervious alike to the white ant and the Teredo navalis, and with all their defects, probably unequalled in the world for railway sleepers, piles for bridges, wharves, and jetties, fencing, or any kind of heavy carpentry, as well as ship-building, for beams, keelsons, stemposts, engine-beams, and other works below the line of flotation, where great strength is required and a heavy material is not objectionable. The "Ironbark" stands in the first class of Lloyd's list of shipbuilding timbers, and together with several other kinds is already extensively used by European ship-builders. There are several kinds of Ironbark in use, all, however, true Eucalypts. The two best species are said to be the white narrow-leaved Ironbark (*E. crebra*), and the white, pale, or she Ironbark (*E. paniculata*), both growing in the open forest, and on poor or indifferent soil in the northern coast districts. Three other species—the red-flowering Ironbark (*E. leucoxylo*), the silver-leaved Ironbark (*E. melanophloia*), and the large-leaved Ironbark (*E. siderophloia*)—also grow in the northern districts, and make valuable timber, though inferior to the two first-named. Ironbark is largely used for bridges and piles where there is no danger of the terrible Teredo, and for poles and shafts of carriages, wheel-spokes, and railway sleepers. Owing to the difficulty of obtaining it, Ironbark is the most expensive of all New South Wales hardwoods, and has maintained its price of 20s. per 100 superficial feet, quoted fifteen years ago, although almost every other hardwood has decreased in price since then, especially during the last two or three years, the average retail price in Sydney of most of the hardwood being about 15s. The whole seaboard of New South Wales, from Cape Howe to the Richmond River, contains ridges of this splendid wood. Large shipments of it are sent from the Clarence and Richmond districts to New Zealand and to Melbourne, for bridge-building, and more especially for wharves, jetties, piles and girlers. There is some fine Ironbark country, too, on the Clyde, from which district a great deal was formerly shipped to New Zealand direct. Considering the great demand for it, the long distance it has to be drawn to the water before it can be shipped, and, considering, too, its splendid properties, the price, large though it seems in comparison with that paid for other timber, can hardly be called extravagantly high.—*Australian Paper.*

THE GUANOO TREE.—An attempt is about to be made in Mauritius to grow the guano tree, which is said to be the finest and largest tree on the island of Jamaica. It has an abundant foliage, but its chief value consists in its pods, which are six or seven inches in length, and contain seeds or beans that make excellent food for men and animals. Oxen are said to be especially fond of them, and to get rapidly fat when fed upon them.—*Indian Gardener.*

HISTORY OF THE GOURDS.—De Candolle, in discussing the history and origin of cultivated plants, refers all the Squashes and Pumpkins to the Old World, but not to India, because they have no name for them in Sanscrit. Some American botanists believe that the Pumpkin and its varieties are indigenous to that continent, as the Indians declare Gourds had been a common food among them long before the Europeans discovered that country; and Champlain, who, in 1604, made a voyage along the coast of what is now the State of Maine, found the inhabitants cultivating Citrouilles (Gourds) along with Maize. Pickering, in his "Race of Men," says that specimens of a small variety of Gourd were exhumed from an ancient cemetery in Peru, like those which are still seen in the markets of Lima. Mr. Naudin, an indefatigable and distinguished botanist, has, during many years, observed and experimented upon all the known forms of Gourds, collected from all parts of the globe, and cultivated at the Jardin des Plantes. He reduces them to six species, only three of which, through their numerous varieties, are used as esculents, viz., *Cucurbita maxima*, the large yellow Gourd; *C. Pepo*, the Pumpkin, which he considers as probably the most variable plant in the world; and *C. moschata*, the Water Melon. An interesting paper on this subject will be found in the "American Journal of Science and Art," 2nd ser., vol. xxiv., and also in Darwin's "Variation of Animals and Plants under Domestication." The only plant among our English wild flowers that belongs to the Gourd tribe is *Bryonia (Brionia dioica)*, which may be seen climbing over our hedges and thickets in the summer, with its whitish flowers with green veins, and red berries in the autumn. This plant abounds with a fetid and acrid juice.—*Science Gossip.*

FIJI BANANAS.—Let us see how these very utilitarian, beautiful, and practical plants are cultivated. The easiest thing in the world is this same cultivation. The ground is broken up in circles of a few feet only with a long, pointed stick. Good-sized "suckers," or youthful offshoots from the root of an adult plant, called *sulina*, are taken up, the leaves are cut off, and the stem with its small root is inserted in the hole of the ground made for it; earth is filled in, and a covering of dry grass thrown around the base as a temporary protection from heat. That is all, and the plant takes care of itself. Miserable-looking objects these newly-planted stems are, and most unpicturesque where a number stand over a plot of ground. But ere long these dry things grow interesting, as the close-rolled rod of delicate greou leaf breaks through the paper-like envelope of the stem, and rises an exquisite object in the air. So leaf after leaf comes out, unrolls in beauty (sweet sixteen merging into womanhood), and soon you have a grove of polished yellow stems and waving green flags, shadowing purple cones and massive bunches of fruit. There is enough of the picturesque and the sightly now. When a stem has borne its one bunch of fruit, the owner cuts it down, and relegates it to "the portiou of weeds and outworn faces." But half-a-dozen lusty stalks are rising up round about its root and offer to take its place, so that for years the grove keeps itself and supplies its own vacancies, and I have been told, leaves the ground at the end of years richer than when it was first placed in possession. Nothing, I repeat, is so easy as banana-planting, nothing calls for less care than does banana culture, and in Fiji, at present, nothing is so profitable and rich in its returns. For this reason, what potatoes are to Irishmen bananas are to the aborigines of Polynesia.—*Australasian.*

PALMIRAH ROOTS.—Nature is considerate for the food of our townsmen. The yams of various kinds, are now succeeded by our palmirah roots—our cotta kilangos so that we are in our best food provisions. Boiled dried and chewing as beetle nuts, and other munching propensities we are all in clover long live the cotta killing the palmirah root.—*Cor.* At this fever season it is questionable whether the roots of the palmirah is not bilious and prone to help on fever.—*Ed. C. P.*—"Ceylon Patriot."

SEED SOWING.—We have to acknowledge the receipt of Messrs. H. Cannell & Sons' Floral Guide for 1885. This is something out of the ordinary run of Plant and Seed Catalogues, forming a handsome volume of upwards of 300 pages, and contains a vast amount of information and a host of wrinkles that will not only be found valuable to the amateur, but from which even the most experienced may learn something. The following extract on their system of germinating seeds will show the lucid style in which information is given:—"Sow your seeds in the usual way, only cover up and keep in total darkness until they begin to peep above the soil, then gently and gradually expose them to light. All this is so feasible that every sensible person will at once and for ever adopt it, and the success of all good seed will follow, and become a lasting practice and benefit. For years past excellent treatises have been written, practical men have adopted shading their seed-pans with paper, and others with a glass vessel of water, various coloured glass, &c., all of which but slightly approach this system, and why it has not become a general practice long since we are wholly at a loss to say. The advantage and success of this system is so apparent that it only requires to be once known to become universally adopted; first, when a frame, pot or pan is covered completely, it ensures one uniform moisture and temperature; consequently, every seed possessing the merest life will be sure to grow, and also save that continual watching—so necessary in the old style—and lessen to a minimum the anxiety of raising valuable seed."—*Indian Gardener.*

THE FRUITS OF CENTRAL ASIA.—Gardens constitute the beauty of all this land. The long rows of Poplar and Elm trees, the Vineyards, the dark foliage of the Pomegranate over the wall, transport one at once to the plains of Lombardy, or of Southern France. In the early spring the outskirts of the city, and indeed, the whole valley, are one mass of white and pink with the bloom of Almond and Peach, of Cherry and Apple, of Apricot and Plum, which perfume the air for miles around. These gardens are the favourite dwelling-places in summer, and well they may be; nowhere are fruits more abundant, and of some varieties it can be said that nowhere are they better. The Apricots and Nectarines I think it would be impossible to surpass anywhere. These ripen in June and from that time until winter, fruit and Melons are never lacking. Peaches, though smaller in size, are better in flavour than the best in England; but they are far surpassed by those of Delaware. The big blue Plums of Bokhara are celebrated through the whole of Asia. The Cherries are mostly small and sour. The best Apples come either from Khiva or from Susak, to the north of Turkistan; but the small white Pears of Tashkent are excellent in their way. The Quince, as with us, is cultivated only for jam, or marmalades, or for flavouring soup. Besides Water Melons, there are in common cultivation two varieties of early Melons and six varieties which ripen later any of which would be a good addition to our gardens. In that hot climate they are considered particularly wholesome, and form one of the principal articles of food during summer. When a man is warm and thirsty, he thinks nothing of sitting down and finishing a couple of them. An acre of land, if properly prepared, would produce in ordinary years from 2,000 to 3,000, and in very good years twice as many. Of Grapes I noticed thirteen varieties, and most of them remarkably good.—"Turkestan," by EUGENE SCHUYLER.—*Indian Gardener.*

Correspondence.

To the Editor of the "Ceylon Observer."

BLACK AND RED ANTS, TICKS ON FOWLS
(JIGGERS OF THE WEST INDIES).
BUGS AND MOSQUITOES.

SIR.—With reference to Dr. Wright's letter in Wednesday's *Observer* on some of these subjects, is there a householder of any standing in Colombo, who does not know the castor-oil and chalk cures for ants? and the fact also that after a time a film forms over the castor-oil on which the ants walk.

Chalk rubbed over the legs of tables and stands regularly is a cleaner and better preventive than the castor-oil cure for black and red ants. None of these insects can walk over chalk.

For vermin in fowls the best cure is, the pounded root of the sweet flag (the *wadakaha* of the bazaars) put with clean saw-dust into boxes of the fowl-house. For the flea-like insects that burrow into fowls' heads, and sometimes blind and even kill them, I do not know of any cure better than kerosene oil. Instead of the cure given in the letter before-mentioned, of the kerosene oil and the mode of its administration for the cure of vermin on fowls, and in rooms of houses, I think most people would prefer chopping the heads off the fowls and eating them, and leaving the rooms to the ants and vermin.

One of the best cures for mosquitoes in houses is, after all, Keating's Insect Powder, which is made of the flower-heads of *Pyrethrum cinerariifolium* and *Pyrethrum carneum* collected in large quantities in Dalmatia. If the freshness of this powder can be depended upon, shut your doors and windows, get a small flat chatty with some embers in it, sprinkle the powder steadily over this and fumigate the rooms and the sides of the bed, and all the mosquitoes will either escape, or swell and get black and die.

This is a temporary and expensive cure, some preferring the smell of clean kerosene oil on the hands and face, and this is pretty effectual. When Miss Gordon-Cumming was in Ceylon she used the oil of lavender, which is the most pleasant and effectual cure of all, but, seeing it was then sold at 14 an oz., it was rather an expensive cure. During those lulls between the two monsoons when the mosquitoes congregate in houses in Colombo, see that all the clothes-horses and dark corners where mosquitoes lodge are well dusted out several times a day.

Two firms in Colombo imported the mosquito powder from China, so much lauded by the late Mr. Fortune in several portions of his work on China, and as far as I recollect found utterly worthless.

No properly kept clean house in Colombo should have the domestic bug in it, excepting when they are brought in the "clean" clothes from the dhoby. If these loathsome insects by any means get a footing in bedsteads or other furniture, pour boiling water over all the joints, and when this is dry paint all these places and those likely to be occupied by these insects with a saturated solution corrosive sublimate either in water or spirits painted well into the joints. This is a most effectual cure, but care should be taken in using it, as the mixture is a most deadly poison.

W. F.

CROTON-OIL CULTIVATION.

Madras, 4th Feb. 1886.

DEAR SIR.—Several notices have appeared in your magazine (the *Tropical Agriculturist*) from time to time relative to the cultivation of *Croton tiglium* in Ceylon; will you kindly inform us whether it has been successful and has paid the cultivators? If it has, we shall be further obliged by your informing where we can get information regarding the most favorable elevation, soil, &c.—Yours faithfully,

GORDON, WOODROFFE & Co.

As to croton-oil cultivation paying, we have only to refer to Mr. Westland's letter published recently. A good deal of information on croton culture will be found in back volumes of the *T. A.*—Ed.]

IRON SPIKES IN COCONUT TREES.

Colombo, 8th February 1886.

SIR.—I shall feel greatly obliged to you, or any of your numerous correspondents, for a bit of information on a matter of very great importance to me. Is it likely that a coconut-tree would be damaged in regard either to its fruitfulness or durability by the insertion of say a dozen screws about half an-inch long in its trunk? The idea is to knock off the heads, flatten and sharpen the top ends, and drive them into gimlet bores, with the aid of a key; and thus if possible protect its fruit from thieves.

No doubt it will last longer than the bunch of thorns usually fastened half way up coconut trees to serve the same purpose; and in the longer run, perhaps, prove more economical too. After due notice has been given to the village headman that such a thing has been done, should a thief go up the tree so to tread and get injured, may I inquire whether the land-owner would be held responsible?—Yours obedient servant,

X. Y. Z.

[We should think the spikes would do more harm to the trees than to the thieves, but we doubt if the expedient is more legal than spring-guns are.—Ed.]

"A PLANT RICH IN TANNIN": *CASSIA*
AURICULATA; RANAWARA, SINH.

SIR.—In glancing over the *T. A.* for this month I noticed your footnote to Mr. Price's letter on the cultivation of this shrub. As you say, the plant is very common in Ceylon, being found all over the lowcountry and plentiful along the east coast. It is very easily cultivated and will grow in any soil. The tannin qualities of its bark are well-known in the English market, being largely exported from India and some from Ceylon. It is a shrub that springs up freely when coppiced and a profitable crop cut every second or third year. Round the Northern and Eastern coasts it is annually collected by the Moor traders, and I have seen gangs at work in the forests peeling the bark and carrying it off to Trincomalee. "This shows another of our forest products pilfered through the laxity and want of proper forest administration." The shrewd Moor trader of Coombo has his agents everywhere and gives from R4 to R7 per cwt. dry bark delivered in Colombo.

You will find Cassia bark quoted in the London market at R12 per cwt.

J. A.

TEA ROLLERS: THOMPSON OF THE
"CHALLENGE" VERSUS BARBER
OF THE "SPHEROID."

Colombo, 13th February 1886.

DEAR SIR.—In reply to "Tea's" letter in the *Ceylon Observer* of the 4th instant, as it would seem from this letter that Mr. Barber is in blissful ignorance of my views, intentions and notions

regarding this so-called improvement on my Patent Challenge Roller and more or less directly calls for an expression of opinion from me, I may here explain that anyone purchasing one of my Patent Challenge Rollers direct from me or my agent, Mr. E. B. Creasy, can alter the machine so bought, as Mr. Barber has done, or in any other way they may please, so far as I am concerned. But if any machines are sold or used other than those bought from me or my agent, of the design which, I understand, is in contemplation, it will be deemed an infringement of my patent in every sense. The only difference I hear of is that the projecting portions of my discs are detached from their discs and employed as passive in place of active rolling agents. If Mr. Barber will favor me with tracings of his own designing, through my agent Mr. E. B. Creasy, I shall be in a better position to judge how far, if at all, I will allow him to use the principle and detail of my patent. I may interest some to know that a Spherical Tea Leaf Roller was used by me some five years ago, and my patent for this with other Blue Books can I understand be seen at the Colonial Secretary's Office. Trusting Mr. Barber will be satisfied with the opinion given above, yours faithfully,

A. THOMPSON.

TEA ROLLERS: THOMPSON OF THE
"CHALLENGE" VERSUS BARBER'S
OF THE "SPHEROID."

Blackstone, 15th Feb. 1886.

SIR.—I have been very much instructed by Mr. A. Thompson's letter published in your paper headed "Messrs. Thompson's and Barber's Tea Rollers," and his remarks on my roller are entitled to special weight from the circumstance that he has not yet seen my roller. The only difference between mine and his, as he gathers, is that the "projecting portion of his discs (!) are detached from their discs and employed as passive in place of active agents." Mr. Thompson also adds: "A spherical tea-leaf roller was used by me some five years ago, and my patent for this with other Blue Books can, I understand, be seen at the Colonial Secretary's Office." How Mr. Andrew Thompson secured a patent "for this with other Blue Books" I cannot really understand, any more than I can see how he converted his patented cones into discs for the purposes of this letter. It is the surface of a cone or a flat disc or a concave disc, or a flat or grooved table, or a human hand, that can operate on a quantity of leaf, and bring about the desired result of a twist more or less perfect, according to the degree of efficiency respectively of these surfaces as agents employed for the purpose, and no one will care to enquire whether the table has four legs or five, or has drawers below this surface, or whether the other side of the cones be flat or round or smooth or rough. If Mr. Andrew Thompson means to maintain that every cone contains a disc at its base which is disclosed, on the conical projection being removed, then it is to be regretted that he did not remove this projection before he asked the Government to protect what he claimed then as a novelty in tea machinery, viz. the cones. But he was content to leave the flat disc and the cube and all the other geometrical figures into which his cones were capable of being cut, shaped and moulded behind or within his cones, and made the surface of the cones, for all practical purposes, the active part to operate upon the leaves so as to secure the end desired. The result is known to the few Ceylon

planters who purchased these "cones." For as far as the cylinder goes it is a casing—an envelope. It has been in use before in a number of machines, and notably in a tea machine of Kinmond's! So that it was not a novelty, could not be patented, and was not claimed as such for a patent. The head, body and tail of the machine therefore consisted merely of two cones suspended on shafts and revolved by coolies by means of handles like any "grindstone," or "hurdy-gurdy." The working or effective part of this roller, as with every other roller, is the surface presented to the leaf within the casing.

I am deeply indebted to Mr. Thompson for offering to look at my tracings and drawings with a view to ascertain "how far," as he says, "I will allow him to use the principle and details of my patent." But inasmuch as cones when they became "a passive agent" with me were relegated for the time being into the Sirocco room to become once more an active agent,—this time in the firing machine,—I cannot, I regret to say, avail myself of the co-descending offer to inspect and scrutinize my humble efforts to make a "roller while there was a challenge" in the world.

But I will refer Mr. Thompson to the distinguished machinist to whose inventive genius all tea planters will continue to remain debtors, for the best horizontal action roller and the first vertical action roller ever introduced, and that is Mr. Kinmond, who is now in Ceylon! He has taken the trouble to come all the way to Blackstone to see my bantling; and his opinion may perhaps startle Mr. Thompson. I shall send you if necessary a list of visitors to Blackstone who have seen the machine, and Messrs. W. H. Davies & Co. will give you a list of those who ordered the machine and confirmed their orders without a guarantee when they were told that on principle I declined to hold out a guarantee as an inducement to intending purchasers to take my machine in preference to others in the market. Mr. Thompson and all interested in the Blackstone roller may communicate with these gentlemen for their views as regards the surface features of "the active or rolling parts" of the respective machines; I use Mr. A. Thompson's own language with my endorsement that it is the only correct way of looking to ascertain the identity or non-identity of the two. I will now conclude by adding that I shall be glad to meet Mr. Thompson of the "Challenge" either in a friendly suit or in the ordinary way in the District Court of Colombo to have his claims tried, if he will only adopt the right and legitimate course, instead of endeavouring first to intimidate intending purchasers from taking my machines, and in the same letter magnanimously offering the use of his for the purpose of being converted into mine. This, we are told, is to be effected by employing his cones (gises!) as "passive agents"—outside the "rollers"!—I remain, yours faithfully,

JAS. H. BARBER.

P. S.—I have Mr. Thompson's specifications for the "Challenge" though not the "ustent" Blue-books; and this is what he has patented—he begins with: "*My invention consists in the employment of cones*":—not flat discs concealed behind cones to be disclosed and brought to light; and on the 13th day of Feb. 1886 or any date thereafter, for the first time. Verily he has hid his light under a bushel all this while. He finishes with: "*I claim the application of the cones*." I think the endeavour to square the circle and round the square should not be tried on an intelligent body such as the Ceylon planters are. I do not know how it may do in India.

THE NEW UVA PROVINCE.

COFFEE—TEA—CACAO AND CINCHONA—THE

MONARAGALA DISTRICT: ITS WANTS AND PROSPECTS.

(From Our Special Representative.)

15th February 1886.

I have never in the whole circle of the hill country of Ceylon seen cinchona fields so satisfactory in growth and appearance, so full of promise and so pleasing every way to the eye as those of the Messrs. Macfarlane on Cannavarella estate, about 5,000 feet high on the Namunakula range. Old Cannavarella estate I have known since the day when "Sandy Brown" engaged in my presence Mr. J. P. Ross ("long Ross") to go across from Dumbara to that out-of-the-way part of Uva to take charge of his interests. I saw it first over twenty years ago,* and I spent a couple of days on the place in 1872; it was a pleasure to me to see the old place in such good hands as those of the Messrs. Macfarlane, who, both in Maskeliya and Uva, are known as staunch reliable colonists and careful planters of the very best type. Some of the old coffee on Cannavarella—40 years old trees, I am afraid to say how many inches in girth—are still very "fit" for crop; but certainly the finest sight Mr. R. P. Macfarlane had to show me was his hundred acres of cinchona, in age from three up to seven years—planted in virgin forest-land, in clearings of from 20 to 40 acres (chiefly hybrid robustas), each field surrounded by jungle, unbroken expanses of healthy, vigorous growth, not excelled by anything I had seen even on "Lover's Leap," and far more striking to the eye, because on Cannavarella the cinchona fields are not interrupted by blue-gums or any other vegetation. Lower down on Oetumbe and Wayvelhena there are also fine cinchona clearings; but I should say that the zone about or above 4,000 feet in Uva must be perfection for cinchona.

I have already alluded to the fine cacao fields in the valley, and to the very promising tea clearings on both Glen Alpine and Spring Valley. On the latter property, if one has the patience for a three-mile ride through the estate, or a climb up steps so steep and prolonged as to remind one of those of Malta (which Byron apostrophized as "those cursed steps of stairs"), the reward will be found in the evidence of a splendid growth of tea at a high elevation, the bushes having stouter stems particularly, for their age than I have noticed anywhere else in the country. The bushes and promise of flush will be more evident by and bye, the clearings bring still very young. "Tea-seed planted at stake" seems to do exceptionally well in Uva; in one case, a clearing so grown, pointed out to me, rivalled one grown from plants put out at the same time. Nahavilla has a clearing of tea on a flat which was described to me as marvellous in growth; bushes 5 and 6 feet high in less than two years, I think. Cannavarella has also good tea. It was a real pleasure to look down from the Cannavarella ridge on the splendid expanse of luxuriant coffee visible on Nahavilla and Gowrakella.—nothing could be finer.—and later on to pass through Mausagala, a place which was being felled when I first saw it and which—thinks very much to the successive good management of Messrs. Crow and Deaker—has done as well for its owner in crops as perhaps any

coffee plantations of its size in the country and which is still in good heart.

On the left are the Passara group of estates, and right in front is the "isolated Monaragala mountain," which, though 30 to 40 miles distant by the riding path through the lowcountry, stands before us in clear weather so plainly as to enable each property and clearing to be distinguished. This is not wonderful, seeing that the view of the lowcountry to the sea from Cannavarella is so good that the Basses light is an object of nightly observation, being very distinctly seen. The outlook in other respects from these lofty Badulla ranges is extremely interesting; one never tires of the morning mist filling up hollows, or spread like a veil over the lowcountry or anon curling slowly up the mountain sides, assuming the most fantastic forms. But the cloud effects of an evening are even more entrancing, and one picture remains with me as "a thing of beauty and a joy for ever," the westering sun over the Totapala range lighting up a sea of cloud lying over Upper Uva and making it appear as the translucent crystal floor of Paradise.

Of MONARAGALA, and its nine or ten cultivated estates, I have only the usual record of trying pioneering difficulties to make. Difficulties with transport, absence of supplies, difficulties with climate, the heat at the foot of the hillside some 700 feet above sea level being described as simply unequalled in the experience of any planting district in Ceylon. There have been two if not three European victims already to climate—including the much-regretted E. P. Eastwood—and there is still much suffering from fever. A regular supply of good food would go far to enable planters and coolies to fight their enemy and as cultivation extends, no doubt the climate will be improved. At present out of 3,500 acres in private hands about 1,400 acres are under cultivation, half under coffee, and the rest chiefly cacao and cardamoms which promise exceedingly well. With a good road to Willaway, a medical dispensary in the heart of the district, and an improved bridle-path to Lunugala, there can be little doubt that the prospects of Monaragala will improve considerably. Already, there are few districts in the island which can show so satisfactory a growth of so many products as Monaragala. The Arabian coffee is as good as could be expected; the Liberian coffee equal to any in the island; the cacao is most promising; cardamoms bear heavily; now pepper and arecanuts are coming on nicely. I believe cinchona grows well on the upper part of the hill, and "crotons" (the croton-oil trees) grow like weeds. As regards tea, the growth leaves nothing to be desired. A planter who put in a few thousand plants in January 1885 last month found them averaging about 3 feet. These plants are a good hybrid, but some people think indigenous would do even better. However transport will have to be much improved before Monaragala planters will care to go in for tea on a large scale and there might be some difficulty in getting the Factory work well and carefully done owing to the climate. As regards labour the planters never have had any difficulty in getting coolies, and, except on one or two estates where water is bad, the coolies, I am told, do not suffer so much as their masters from fever. The climate however is undoubtedly a great drawback as regards Europeans, and, as I have said, we can only hope that it will improve with time. It is well known that the district was not well opened, and it is a matter of surprise that the older estates have come on as well as they have done. Some of the best cacao was "dibbled in"—a great tribute to the

* If you cut the boundaries round from Spring Valley, via Weyvelhena, Gowrakella, Nahavilla, &c. 45 years ago, and we remember Surveyor John Braybrooke blessing the steep features of Cannavarella. Little did we then dream of cinchona or tea, or cacao in Uva.
—Ed.

freshness and goodness of the soil. There is a lot of very fine forest still available in private hands, and of Crown jungle too, a great extent. The following notes from a planter interested in the district were made some months ago:—

ARABIAN COFFEE, looking well, about 10,000 bushels crop this year.

LIBERIAN COFFEE.—A fine cover on Sirigalla (which is also planted up with cacao) and bearing well.

CARDAMOMS.—These do very well and the clearing on Walton is giving a very good crop. They are all, I think, of the Malabar sort, and some sold in London in November 1885 fetched 1s 5d to 2s 3d per lb.

CACAO, I consider the most promising product. The 3 and 4 year old fields on Sirigalla and Maragalla leave nothing to be desired, and the young clearings on Monerakellie are A 1, while the old trees on Raxawa are splendid specimens. The Forastero sorts are now being planted to some extent and we came across a 24 year old tree with 30 fine pods, while an old tree on Kumaradola had given about 120 in the year. Shade—jak, rubber, dadap and croton—is being put in.

Helopeltis has done very little damage so far, and with the deep soil and good rainfall—about 90 in.—I do not think it will. *Aceas* are planted all round the clearings on Monerakellie and are coming on well, while a few *pepper vines* put in have made a start and we are going to plant a number this year at the base of jaks and forest trees and are going to give them a trial on the large boulders which are so abundant. A few *nutmegs* have also been put out on Sirigalla.

The recent sale of Monaragala cocoa reported by Mr. Mason is most encouraging, and although tea grows so well I think the Monaragala planters should continue for some time yet to give their attention to cacao and cardamoms. "Oh for a railway within Uva," the pioneers in this distant division may well cry. Planters on the Kandy side have been accustomed to regard the Namunakula estates as the *ultima Thule* of Uva, and it is difficult for them to understand that there are plantations and districts 30 to 40 miles beyond, farther out in the new province. I have been much struck with the evidences of an abundant labour supply during the present visit and also with the good relations existing between employers and employed. As Mr. Macfarlane told me on Cannavarella, such a thing as robberies of bungalows or outhouses, so common in the Dimbula, Dikoya, Maskeliya and Kandy districts, are almost unknown on this side, and planters take little or no trouble about locks and keys for their residences.

ANOTHER NEGLECTED INDUSTRY.

Dr. E. Bonavia writes to the *Pioneer*:—

In the *Pioneer* of 23rd November, 1885, page 5, I read that in 1841-82, out of total quantity of 993,175 tons of wheat exported from India, Italy took 17,966 tons. In 1882-83, out of 737,220 tons, she took 2,800 tons. In 1883-84, out of 1,017,824 tons, she took 22,270 tons, and in 1884-85, out of 792,711 tons, she took 35,045 tons, so that the exports of Indian wheats to Italy have nearly doubled in four years. There can hardly be a doubt that the Italians have found the hard Indian wheats—rich in gluten—eminently suited to the manufacture of macaroni and other Italian pastes. Just observe how low we in India obtain our macaroni an article of diet which is much prized by all who have eaten it, but which is now used only like "horbeas," on account of its prohibitive price. The Indian wheats first go to Italy, and some of them, either in Naples or Genoa, are then ground, sifted, and manufactured into macaroni. Then they are shipped as macaroni to England and France.

boxed in tins or wrapped in small paper parcels, and sent back to us as tins or packets of macaroni. The result of the Indian wheat's travels to the seaports, its voyage across the seas, its perambulation in Europe passing through three or four hands, and its return journey to India is that we get tinned macaroni—Fabbrica De Barbieri—expressly prepared for Crosse and Blackwell at R9 for a 2lb tin. That is the price I paid for it the other day in the shops. Other English firms also send us tinned macaroni at equally absurd prices. That which comes from France is made up in long blue paper packets, and bears the label of "Groult Jne, Paris—Macaroni gras de Naples." The latter, I think, is the best, but, if I mistake not, also the dearest. Last year I bought a tin of macaroni of another firm, also at an absurd price, and, in boiling the paste turned black. The difference between the superior and inferior kinds of Italian paste is that the more you boil the former the whiter they become, while the latter turn darker, the more they are cooked, probably in the same way that brown bread turns dark by baking. No one will probably deny that the Italians, rich and poor, live largely on macaroni; therefore the inference is that this article of diet can be manufactured and retailed at a comparatively low price, probably at a few pence per pound, while we are forced in pay for the imported article one rupee per lb. The new industry which I now suggest is a macaroni factory, which would work up our macaroni wheats on the spot where they are grown, either in Oudh or in the Punjab. The advantages are obvious. The carriage to the sea-ports, the voyage to Europe, the perambulation over Europe, and probably the cost of tin boxes and the return journey to the Indian shops with other expenses would be saved, and for the dear labour of Italy would be substituted the cheap labour of India. In addition the bran—a very nutritious cattle food—would remain in the country. Then we might hope to get our macaroni at about 4 annas or less per pound. At present a dish of macaroni is a luxury that only the rich can afford. If this article could be produced cheaply in India, all the European troops might be able to have it two or three times a week, instead of their monotonous and perpetual meat diet, winter and summer. All the Ang o-Indian and Eurasian population and the Christian population of South India would use it, and probably, if Mahomedan workmen were employed in the factories, the whole Mahomedan population of India would also eventually use it in the same way that many of them now use European fashioned bread (*double roti*, as they call it) made by Mahomedan bakers. It will thus be seen that the probable field of consumption is not at all small, if this article could be produced in India at a low price. There might, perhaps, be room for more than one factory.

This is not all. Macaroni and other Italian pastes, if properly dried, will keep a long time, and if sufficiently cheap would, no doubt, soon become an article of war provisions. For immediate use it does not appear that tin cases are necessary for macaroni. That imported from Paris is simply wrapped in thick blue paper. I kept macaroni in these papers all through last rains without their in the least spoiling. No doubt the Indian paper mills would be able to manufacture a cheap thick suitable wrapping paper. With macaroni might be associated the manufacture of "semolina," which is only a superior sort of "soojee"—an article highly nutritious, and suitable not only for making superior bread, but also as an article of war provisions for the thickening of soups and broths, and for making camp bread. Finally, in the same

factory might be set up the manufacture of biscuits, which are also now imported at ruinous prices; a good and cheap wafer biscuit, I should say, much needed in India for European troops. If a macaroni factory were started in India, where it is presumed the hard wheats are well-suited to its manufacture, Australia, the Cape, and all Eastern markets might get their supplies of this article from India. To sum up, the advantages would appear to be cheap macaroni for all Indian and Eastern consumers; cheap and plentiful semolina and bisuits—bran for cattle, sheep, and poultry; a profitable investment for capital; and a new industry for the labour of this country. All that would appear needful are capital, and a couple of Italian macaroni makers as foremen. Either Lucknow, Cawnpore, or Lahore, the centres of the wheat-growing districts, would be suitable places for factories. There the hot weather and winter are admirable seasons for drying the paste without artificial heat. Wireganza door and window fittings would be required to keep out the flies and to ensure general cleanliness.—*Madras Mail.*

PLANTING IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

For *Cinchona* Planters.—In a private letter it is stated that cinchona cultivation once so promising in Ceylon yields now nothing but disappointment. Seedlings and young plants generally fail to come up and many have died. The cause of this must be sought in degeneration of the cinchonas since growing them has been started in Ceylon from the fact being ascertained that each succeeding generation has less strength and vital energy than the preceding one. Perhaps also the true reasons for these unfavourable phenomena are to be sought for in unsuitableness of soil in connection with the climate of Ceylon.

Java Tea.—Great indignation has been aroused in Ceylon. It seems that while more than eighty prize medals were awarded during the Calcutta Exhibition to teas from Java and British India, those of Ceylon only secured two, neither of which was gold. In Ceylon this result is ascribed to jealousy on the side of India but, however it may be, the fact deserves mention anyhow.—*Surabaya Conrant.*

The animus of both the above paragraphs is obvious.—*Ed.*

THE POSITION OF CINCHONA BARK.

(From an Occasional Correspondent.)

London, 2nd Jan. 1886.

The recent heavy shipments of cinchona bark from Ceylon and the consequent heavy fall in the market in Mining Lane must have attracted the attention of all interested in the cultivation of cinchona. During the months of October and December, the shipments of bark from Colombo amounted to nearly 3,000,000 lb.

These shipments were caused no doubt by the high prices ruling in Mining Lane, as to which I read in Messrs. Lewis & Peat's circular for the year that "in October the improvement all round became very marked: large sales of all kinds were again effected and the unit rose to 54d and 6d in the early part of the month and to 64d and 7d in the latter." And the result is, that in December "the unit is down to 5d and 4d."

Very little of the bark shipped since 1st October can have participated in the good prices ruling at end of October here. And it may be safely stated that by rushing the bark in so fast at least 1d per unit was lost on the whole 3,000,000 lb. The question is, how will it be possible in event of

another similar rise in the bark market to prevent a similar deluge of bark?

Now, I am not one of those who scoff at the *laissez faire* system and who think that matters of supply and demand can, as a rule, be advantageously regulated from without. I have seen too much of the great results achieved by private individual enterprizes (and nowhere have I seen greater than in Ceylon) to be disposed to join in the constant modern cry for interference. But in applying the general rules of political economy it seems only reasonable to consider the special circumstances of each individual case. And, in looking at the very special position occupied by owners of growing bark, it does appear to be a case where with the minimum of combined arrangement as to shipments the maximum of advantage could be obtained. The time of harvest is at the will of the owner; and, so long as the trees are growing, the growth will give good interest till time of harvest.

Now I have a suggestion to make. While pondering on the loss recently caused to Ceylon growers by their disorganized rush into the market, I chanced to hear that for selection of exhibits for the coming Colonial and Indian Exhibition the various District Associations had been requested to choose the estates, each in its own district, which should send samples of produce. Whether or not the District Associations have succeeded in carrying out this duty efficiently and to the general satisfaction I do not know. But it has struck me that this same organization having been thus once brought into play might be without difficulty be further applied to the control of the cutting and shipment of bark. At present, probably, few know at all accurately what others may be doing in the matter. And the diffusion of accurate information would alone act greatly to the public advantage in preventing such wide and heavy simultaneous cutting as shall rob all of profits otherwise easily obtainable.

Having thus made my suggestion, I leave it to those immediately interested to judge it on its merits.

W. M. L.

TEA IN AMERICA.

(Special for "Ceylon Observer" by Col. E. Money.)

East India Club, London, Jan. 22nd, 1886.

I have not written in your paper for some months, but I have been wandering in the United States. I enquired as to Indian Tea while there, and possibly your readers may like to know the result.

Firstly, as to the possibility of the States, or indeed any part of America, providing tea. Before I went there, I heard and read much on this head, but what I saw during my travels convinced me that it never can be. There are climates in that vast region where tea would both grow and thrive, still those spots are not many or extensive. Suitable soil of course exists, I have never seen a country where it would not be found. But as we all know cheap labour is a *sine qua non* for successful tea cultivation, and it exists nowhere in America. I speak advisedly when I say "no where." In no part of Canada, or the huge British possessions, can it be found; and even were it there, the intense cold makes tea impossible. All over the States labour is both scarce and very expensive. One dollar 12 a day, with food added, is about the usual wage in the northern and western parts, and, though down south it is somewhat less, nowhere is it anything like the figure to justify tea cultivation.

We need not therefore fear a tea producing rival in America. Alas! there are too many already, but this at least is spared us.

Secondly, as to the prospects of America becoming a successful market (its capacity in that way beggars description,) for Indian and Ceylon tea. The said prospects are both bad and good: bad if no larger efforts to introduce it are not made in the future than the past has accomplished; good, immeasurably good, if the Tea Association set to work with a will, and really introduce it, which they have never done in the proper way.

The consumption of tea in the States is enormous,* partly due, of course, to the tremendous area, but also in a great measure to the habits of the Americans. They are, as a rule, a much soberer race than the English. They drink 't is true, but not in the same way as the English do. Sober for months, then three or four days of hard drinking. But to the point as it affects tea consumption. The Englishman drinks beer or wine with his dinner, sometimes with his lunch and supper. Not so the mass of the Americans: tea or coffee is their beverage, generally the former, and thus per head I doubt not they drink far more tea than we do.† I write without statistics, but except, perhaps, New Zealand, where the consumption is enormous per head, I imagine the Americans consume, individually, more tea than any other race in the world. [A great error.—Ed.]

Strange that it should be so, for it is the nastiest stuff I have ever tasted! It is principally Java green tea, fearfully weak, and the infusion is destitute of aroma, colour, or taste. No, I am partly wrong as to colour; sometimes it is a pinky green. But it is, without exception, the most woeful stuff I have ever drunk. It only shows how very acquired is the taste for tea, when the Americans consume such rubbish.‡

How can we alter their tastes, and get them to drink good tea? I think so, at least my experience out there showed me it would be difficult. I was stationary for some time in the State of Colorado, drank Indian tea, and gave it to the Americans who came to my house. They had never previously tasted any but their own vile compound. They all liked it, more the second or third time than the first, and some vowed they would never in future drink any other. But I had better proof. An Englishman in the capital of Colorado (Denver) by name "Cornforth" had started a large grocery store, and among other teas sold Indian. It was a very good high class Assam pekoe souchong, and he told me he sold a great deal and that it was highly appreciated. But finding it there was exceptional. It is to be had in New York, but, as a rule nowhere else in the States. At least enquiring in many places, I could find it nowhere except in one tea shop in San Francisco. There too they sold much.

But the fact is Indian tea is as unknown in the States as it was in Great Britain thirty years ago. We all know what enormous strides it has here (probably the figures for last year will give some 35 per cent of the whole consumption) and that in five years more, we shall equal if not exceed the imports from China. Can we not begin and pave the way for a like success in America? How are we to do it? Success is sure to come some day in any case, for it is absurd to suppose a good article will not eventually make its way there, but that day, if a real effort is not made, will be very long deferred. What then should we do?

* Surely not: only 1-18 lb. per capit against at least five times that amount of coffee.—Ed.
 † We drink nearly five times as much.—Ed.
 ‡ Japan Oologes are the teas chiefly drunk in America.—Ed.

Outside the futile efforts that have been made already, we can do literally nothing without co-operation. I can point out the road to success, but it must remain with the London and Calcutta Tea Association to achieve it. Were Indian tea sent in goodly quantities to America, forwarded to the principal cities of the States, and sold there by public auction to the highest bidders as done in Mincing Lane, it would thus be gradually introduced and made known to the masses. There would probably be losses on the first shipments, (a mere bagatelle did tea owners see the immense future advantages and subscribe for the purpose), but the ball would be set rolling, and the demand for Indian tea from America in a few years would be great.

It would run the same course in America it has done in England—not much would be drunk pure at first, by far the greater part would be mixed to give body to their tasteless decoctions, but the public would be educated to like the flavour, and would demand more and more of the mixture. When, as would certainly come to pass, and as is the case in England now, the tea sold had more than one-third of Indian in it, the cultivation in both India and Ceylon would be far from satisfying the demand that would then be created.

I will do what I can to urge this matter on the London Tea Association, but I would ask for your help to call attention to it in Calcutta.

Of course, both now and hereafter, when I speak of Indian tea I include Ceylon, and I may well do so, for she is running us a hard race.

EDWARD MONEY.

CEYLON UP-COUNTRY PLANTING REPORT.

DEMAND FOR TEA SEED—THE BOLD MAN WHO SCORES
 —PALMS IN NORTHERN INDIA—AN HONEST OPINION—
 PROFITS FROM SALES OF TEA SEED—RISE IN PRICE
 OF EBONY—COOLIES OUT OF WORK.

15th February 1886.

It has been very interesting to watch for some months past the excited demand that there has been for tea seed, and the leaps and bounds which it has taken in price.

That the local crop for some months was short was too manifest to all who had orders booked, for deliveries were put off in some cases, until the buyer was sickened with disgust, and threw up his bargain in despair. Nothing loath, however, was the seller to this style of protest, for there were plenty of others ready waiting to take the place of the disgusted man, and even to pay an advance of from fifty to a hundred per cent on the former prices.

The agents of the Indian tea gardens also helped to keep up the excitement, by booking orders from all corners, without any consideration as to the garden's capacity to execute them, and the result has been that Indian tea seed orders are being delivered short; proportionate shares only being handed out of the quantities ordered.

In times of undue excitement it is the bold man who scores, and it was surely a touch of genius which was manifest in the advertisement some time ago, which offered four maunds of tea seed at £100 a maund! cash to accompany the order!! and the advertisement to appear only once!!! Whether it was the price, or the immediate delivery, or the quality of the seed, or the vendor's confidence in the power of the single insertion, which fetched a portion of the public, I know not, but this I do know, that a man who wrote off whenever he read the advertisement had sorrowfully to confess that quick as he had been he was yet too late, for he had his cheque returned with the in-

timation that two men were in before him, and the first man had got the seed. How many more may have applied goodness only knows, but these three alone were triumph enough. Thus was genius rewarded.

There have been many imitators of this bold act since then, not exactly following in the same lines but rather animated with the same spirit. You know the story of the man sending home to one of the illustrated papers a sketch of a town in Northern India, and his chagrin to see it appear disfigured and rendered untruthful with clumps of palms. In answer to his artistic contributor's indignant protest that there were no such trees to be seen in that part of Hindustan, the London editor calmly replied that that might be so, but the British public demanded palms!

In these days there is an emphatic demand from the Ceylon planters for tea seed, and they are determined to get it and to get it where until now no good jät has ever before been got. As you value your seed so will excited buyers value it, and the way to turn a bad jät into a good one, is boldly to stick on the price.

It is only last year that I was with a friend who was after tea plants. Visiting a tea garden he was enquiring at the obliging manager if he knew of any nursery for sale, and was told that there was one there, raised from seed grown on the estate. "But," said the manager, "to be honest with you, I would not put them out myself." "Such confidence should beget confidence," laughingly replied my friend, "and if you would not plant them out, to be honest with you, no more will I." So vehemently, however, are the Ceylon planters demanding tea seed, that this despised jät, which less than a year ago had to be apologized for if a man were to keep an honest character, is today actually advertised at R60 a maund!

Is there any need for this hurry-scurry and scrambling for seed? The tea seed crop is not always to be short; nay, as far as my knowledge goes, there is at present a fairly good crop on the trees, and while no one would object to give a good price for a good jät, there is unfortunately much rubbish being offered at high prices, which would be dear at nothing.

Those who have seed-bearing trees of a good jät have since the present rise been doing remarkably well. From all such fortunate individuals there are purring expressions of thorough satisfaction, life is worth living, so complete is the reign of contentment within. When they descend to figures they can show many a good thing, and from among a crowd the best which I have heard of was the landing of 117,000 in the month of January from tea seed alone, and this from a place which is turning out large quantities of tea, at splendid prices. Is it to be wondered at that every here and there there is a sanguine man who scents at anything like a fall in prices either in the near or the distant future, who holds that the leaf and the seed will ever remain high, that the tea plant will do more for Ceylon than the coffee tree ever did, and that we are within touch of a prosperity which will rival the days of the past, if not indeed cause them to be forgotten?

The rise in the price of ebony, and the increased demand for it, are bringing out offers from dealers who are prepared to fell, and cut out the valuable timber from trees growing in your jungle if you are fortunate enough to have any. 110 a ton is offered for the wood, the cost of cutting and transport to be borne by the buyer. Considering that ebony is worth R85 a ton in Colombo, those who make contracts at R10 a ton are not likely to lose anything.

PETERCOCK.

PLANTERS' ASSOCIATION OF CEYLON.

The following are extracts from the 32nd annual report for 1885-6 of the Ceylon Planters' Association read at the annual meeting on 17th February, 1886:—

PLANTING PRODUCTS.

Coffee.—This staple claims precedence by reason of the value of its crop being still greater than that of any other product, but the exports of this old staple still continue to fall. In the Kandyan Provinces that most destructive of pests black-bug has continued its ravages, and ere long coffee will be practically extinct in the Northern Districts. In the young districts, too, the falling-off has been great, due in a measure to the continued attacks of leaf-disease, but more immediately to extended tea cultivation entailing the destruction of such coffee. In some favored localities—namely Udapussellawa and portions of Uva—good remunerative crops have been gathered and the coffee retains its vitality.—The exports for 1885 were 315,649 cwt., against 299,395 cwt., in 1884.

Tea.—The hopes which your Committee expressed during the last two years about this cultivation have so far been more than realized. The area under cultivation has during the past year been greatly increased, and in almost every district manufacture has commenced. The quality of the teas has been maintained, notwithstanding the large proportion gathered from young bushes, and satisfactory prices have been realized both in the London and Colombo markets. Your Committee has noted with satisfaction the establishment of a regular market in Colombo, and the strides which it has made—over half a million pounds having been exposed for sale there during the last seven months of the year. Improvements and economies in the modes of manufacture continue to be introduced. Your Committee trusts that by these means the quality of the teas will advance still further and the cost of production diminish. The exports for 1885 were 1,372,71 lb., against 2,392,972 lb. in 1884.

Cinchona.—Notwithstanding the growing feeling that in a few years' time this product will again become one of great value, there has been, practically, no further planting of cinchona. The need for money to plant tea, the slow growth of tea when covered by growing cinchonas, as well as the dying-off of the trees themselves, are causes which have led to the enormous export of 13,736,171½ lb. for the past year against 11,865,280 lb. for 1884. While a rise in price during the current year would lead to a considerable export, there can be no doubt that the maximum production has been reached, and that ere long there will be a great reduction in the quantity exported. It may be doubted whether the acreage under cinchona is now one-fourth of what it nominally was four years ago.

Cacao.—In drawing attention to this valuable product your Committee is glad to be able to point to the decided improvement observable in its condition during the year. Though the insect pest (*Helopeltis*), which seemed until recently seriously to threaten destruction or incalculable damage to large areas planted with cacao, cannot be said to have taken its departure, its ravages are comparatively mitigated. From whatever cause, whether a more favorable season and a more evenly distributed rainfall causing milder vigour and power to throw out leaf, the attacks of *Helopeltis* have been confined to patches now better understood to be naturally unsuited to the habits of the tree, owing to poor and shallow soil, exposed ridges and want of shade and shelter. It appears certain that the successful and profitable cultivation of cacao will be confined to certain localities and of such to only the best soil and lay of land. The improvement that has already taken place in shipment is matter for satisfaction while consumption steadily increases and prices are maintained beyond the expectation formed some years ago. The exports for 1885 were 7,192 cwt., against 7,255 cwt. in 1884.

Minor Products.—The production of cardamoms has increased greatly and as a consequence the price

continues to fall, checking further extension of the acreage under this valuable product, the exports of which during 1885 amounted to 184,142 lb., against 177,163 lb. in 1884. Your Committee regrets that there is no advance in rubber cultivation to chronicle. The trees grow well, but it is difficult to obtain from them at a moderate cost a sufficient quantity of rubber. Liberian coffee has in many districts been cut out to make way for tea. This year it shows a large increase of exports over 1884, but as the price obtainable for it is very low, and there is no likelihood of a better, it will probably shortly cease to be an important export. The exports for 1885 were 5,325 cwt., against 3,412 cwt. for 1884.

TEA STATISTICS.

Messrs. Gow, Wilson & Stanton send us their valuable Annual Report on the Tea Trade, illustrated by diagrams which at once appeal to the eye and show the exact position of India and China. In the second quarter of 1878, the average price of fair medium pekoe was 1s 9d per lb.; in the fourth quarter of 1885, the figure was down to 1s 0½d. But the average monthly deliveries, which were only 2,869,000 in the third quarter of 1878, went up to 6,940,000 in the first quarter of last year. It will be seen that, while the home consumption of China tea is lower now than it was in 1871, the consumption of Indian (including Ceylon) tea now exceeds by nearly 500 per cent the amount taken fourteen years ago. We should think that seldom or never has there been such an advance as this in any one article of commerce, but the advance of Ceylon tea alone in the next decade will probably leave even such a percentage behind.

The two kinds of Indian tea taken by the authors of the Circular are fair medium pekoe and useful pekoe souchong. In 1878 pekoe began at 1s 7d, rose to 1s 9d, went down to 1s 6d and closed at 1s 8d. In 1879 prices varied from 1s 3d to 1s 8d; in 1880 there was a descent to 1s, with a rise in 1881 to 1s 6d; in 1882 the price went down to 1s 0½d, rising to 1s 3d in 1883; rising from 1s 2d to 1s 3d in 1884 and going down below 1s; while 1885 began at 11½d, rose to 1s 2½d and closed at 1s 0½d. In round numbers fair medium pekoe was cheaper by 30 per cent last year than in 1878. Estates, therefore, which have not been able to reduce the cost of producing tea must have suffered severely. Much the same process has marked the history of useful pekoe souchong which began in 1878 at 1s 3d; sunk to 9½d in 1882-83, and closed in 1885 at 10½d. The deliveries in the period included rose from 1 million to 7 millions of pounds per month. In the duty scare period of last year deliveries went up to 8,654,000 in March and 8,703,000 in April, followed, of course, by a reaction. The deliveries calculated on for the first six months of 1886 are 5,750,000 per month, but we have little doubt the round 6 millions will be reached before the year is out. The percentage of Indian and Ceylon teas to the whole consumption rose from 3 per cent in 1861-65 to 17 in 1876 and 39 in 1885. The 50 per cent is not far off, and then China will rank No. 2 as a source of tea. China tea eliminated with a monthly delivery of 10 millions of pounds in 1879, but the deliveries have since receded to a fraction over 9 millions in 1885. From a mere medium in 1864 Indian tea has steadily advanced, until in 1865 the monthly delivery of Indian tea was 5½ millions of pounds, Ceylon adding another quarter of a million,

We only regret we cannot reproduce the very suggestive coloured diagrams, but the main facts are patent enough. Indian tea has risen rapidly in production and public favour, and the progress of Ceylon tea promises to be still swifter in every respect.

INDIAN TEA STATISTICS.

13, Rood Lane, London, E.C., January 27th.

Below we beg to submit a few facts bearing on the statistical position of Indian Tea, which may be of interest to you.

Gow, Wilson & Stanton, Tea Brokers.

Diagram showing the Monthly average Deliveries of Indian and Ceylon Tea in each Quarter, and the Comparative Course of Prices of Indian Teas (Pekoe and Pekoe Souchong), for eight years past. (Here follows the diagram.)

The prices of two descriptions named are given, as practically the useful Teas, from 10d to 1s 6d, cover about three-fourths of all the Indian Teas produced.

In the diagram above, the average monthly deliveries of Indian and Ceylon Tea for the past year show fluctuations which are more striking than those of any year depicted upon our chart.

These irregularities are to be accounted for by the abnormally high clearances which took place in March and April last in anticipation of the Budget; the market was then influenced by unusual excitement occasioned by the fear of an addition to the Tea duty. This happily proved to be unfounded, but nevertheless caused a substantial rise in prices, especially of the lower grades of Tea, as will be noticed by a reference to the Chart.

This disturbing influence coming so near the end of the season year naturally affected figures to such an extent as to cause the usual statistics taken at the end of May, to appear somewhat misleading. We therefore, for purposes of comparison give below, a table calculated from 1st January to 31st December—thus to avoid any erroneous conclusion.

	1883.	1884.	1885.
Import of Indian and Ceylon	61,667,000	67,152,000	66,863,000
Delivery	59,096,000	64,217,000	68,895,000

These extraordinary clearances appear to have unfavourably influenced deliveries for some months after the excitement—until the close of September, as shown by the following table, when we again find an excess over the corresponding period of 1881.

January 6,388,636; February 5,775,778; March 8,654,480; April 8,703,890; May 4,213,586; June 8,576,422; July 8,893,158; August 4,477,742; September 5,153,922; October 6,452,874; November 6,096,893; December 5,507,578, total 68,894,962 lbs.

For the whole period under review it is gratifying to notice an increase of 1,679,000 omndsp. It is also a significant fact—and one upon which we shall have occasion to comment later—that the deliveries for the past twelve months have exceeded the imports by 2,053,000 pounds—the first instance of any excess since 1881.

Turning our attention now to the total deliveries, including export, of all Tea for the past twelve months and comparing them with the two preceding years, we find a constant increase viz:—1885, 211,917,000; 1884, 219,633,000; 1885, 220,771,000.

The figures for home consumption in 1885 reach the enormous total of 178,655,000 lbs.—the largest ever recorded, as against 175,097,000 lb. in 1884, and 1,082,000 lb. in 1883—and the annual amount of Tea consumed per head of the population in the United Kingdom has now reached the unprecedented figure of 190 pounds. The entire increase in the home consumption has been made up of Tea from India and Ceylon, at the expense of China, and it is a curious fact that the home consumption of this latter description is lower than it has been since 1874—fourteen years ago—while the consumption of Indian Tea exceeds by nearly 500 per cent the amount taken in that year—so vastly has the popularity of Indian

and Ceylon Tea increased. The total home consumption in that year was only 123,529,000 lb. just over two-thirds of its present amount.

Taking all these points into consideration the present stock of Indian and Ceylon Tea appears none too much for our requirements, and this becomes even more significant when we observe that the present stock of all Tea (96,215,000 lb.) is lower than it has been at any corresponding period since 1879, when it stood at 95,348,000 lb. Our market, therefore, seems in no position to stand another strain of such severity as that to which it was subjected to during March and April last, without again undergoing considerable disturbance and inflation of prices in the event of there being any ground for alarm on account of duty.

On the other hand should there be no unusual disturbance in the ordinary deliveries we are likely to find the supply of tea from India and Ceylon during the next six months sufficient, but in no way too large for, the probable demand. Taking the Calcutta estimate of tea available for London as 65,000,000 lbs., and the total import for the same period from Ceylon as 6,000,000 lbs.,* this gives us 71,000,000 lbs. Of this, already 43,280,000 lbs. have arrived from India, and 2,642,000 lbs. from Ceylon, making together nearly 16,000,000 lb.—and thus leaving 25,000,000 to come forward. Adding the present stock of 26,000,000 lb. there will be a total of 51,000,000 lb. to deal with until the end of June. Assuming now that the deliveries during the next six months will be maintained at an average of 5,750,000 lb. per month, we arrive at 34,500,000 as the probable total of the outgoing, and this should leave us with a stock sufficient but not too large for our gradually increasing requirements.

An important feature of the present season, and one which planters would do well to remember, is the continued and steady demand which has set in for the lower grades of *good strong liquoring* teas. The British public have become accustomed to pay a certain price for their tea, and are every year trying to obtain a better article without additional cost. Retailers are compelled to meet this want by purchasing larger quantities of such teas as give the *strongest and most serviceable* liquors for the least appearance. This end is most easily attained by the substitution of Indian or Ceylon Pekoe Souchong or Souchong, and broken tea for the usually weaker liquoring (China variety). Retailers now are also meeting the public demand by introducing Indian or Ceylon tea into many of their lower priced mixtures.

EXPORT. We remarked upon a previous page that the deliveries for the past twelve months showed a substantial preponderance over the imports, and we now wish to offer some further remarks upon this subject. It is to be regretted that no official figures are recorded which show the amount of Indian Tea exported from this country, especially so as there appear to be strong grounds for believing that this branch of the trade is capable of most important extension, and indeed there is substantial reason for supposing that a marked expansion is even now in progress. At any rate, it is certain that large quantities of Indian Tea have been consumed during the past twelve months where but a short time since its use was confined to the smallest proportions. This subject of Export is one which merits close attention from the trade, but is too exhaustive to deal with in the limited space which yet remains to us, and we therefore hope to treat of it more fully at an early date in a circular bearing upon Ceylon Tea.

CEYLON TEA.—In the diagram upon the last page it will be noticed that the red blocks which show the average monthly consumption of Indian tea are tipped with black for the year 1880 and the following years, to represent as nearly as can be estimated the consumption of Ceylon tea, when no separate figures were

recorded to show the movements of this article. Small though these deliveries have been, averaging even in 1885, for which year actual statistics are published, only 62/8.16 lb. per month, there is no doubt they are the harbinger of an influx of tea so enormous that before many years are over, its influence upon our market will be of the weightiest description. Considering the great popularity of this article and its well merited reputation for high class quality, it must be gratifying to the British public to hear of the likelihood of so abundant a harvest.

EXHIBITION, 1886. There is no doubt that the coming Exhibition will do much to further the education of the public taste in the direction of both Indian and Ceylon tea, and we are glad that such steps have been taken as will secure to these articles a considerable amount of the attention they deserve; and let us hope that the benefits will extend to the encouragement of their use in other countries besides our own.

MANUFACTURE. The importance which attaches to the process of withering, upon which we have commented in previous reports, is becoming more and more fully recognised, and has recently been the subject of much able treatment both practically and scientifically in a well known periodical, so that there is a fair chance of the various new methods being thoroughly tested, and of the acquisition of more intimate knowledge of the chemical nature of the tea leaf.

SIZE OF BREAKS. The importance of making large breaks and avoiding the division of tea into too many varieties cannot be too strongly insisted upon; the public sales are now frequently so large that many buyers are compelled to pass over all the smaller lots, which thus meet with but little competition.

BUICKING UPON THE GARDENS must be effected with the greatest care that the tea in each chest may be *exactly* similar in character, otherwise all the expens is thrown away, and the gardens are subjected to the additional cost of rebulking in London.

GILRATH'S TEA PACKER.—We have received the following communications:—A trial of Mr. Gilrath's tea packer was made here (Kintyre Estate, Maskeliya) today (February 5th), which you will see by annexed description, by three other witnesses was satisfactory. Mr. Walter Agar and Doctor Berry White, the latter an Assam planter witnessed the packing of the first box and were pleased with the result. Had it not been for a defective screw a larger quantity of tea would have been operated on, but I am so pleased with the machine that I have ordered one to be made (for power or hand use) at once for this factory and when made fuller reports shall be given.

By the courtesy of Mr. H. D. Deane, Mr. Gilrath's Tea Packer underwent a trial at Kintyre Factory. The machine is very ingenious and compact, and, worked by hand on this occasion, packed four chests (3/8ths No. 2 Japan boxes) of broken pekoe 90 lb. each, in 22 minutes, a second trial of coarser tea resulted in two chests of 85 lb. each being packed in 6 minutes each chest, but a screw giving way further trial had to be suspended. The tea packed compared favorably with that packed by coolies in the ordinary way and showed no signs of being broken. With the few alterations which Mr. Gilrath will now carry out, the packer will prove of great value, in that it will pack tea in the *state it leaves the sives* unbroken and free of foreign matter. The machine operated with was constructed for power, but was worked by hand for this occasion, and under these conditions proved itself capable of packing 1,000 lb. per hour. We understand from Mr. Gilrath that the machines will in future be constructed by Messrs. John Walker & Co. and that the cost will not exceed £300.—(Signed) A. E. B. Stiven, Alfred Scovell, Thos. North Christie, H. D. Deane.

*The actual figure will be nearer 9,000,000 lb.—ED. 82

THE NEW PROVINCE OF UVA.

MADULSIMA AND HEWA ELIYA PLANTING DISTRICTS :

THE "ULTIMA THULE" OF UVA.

ALL ROUND THE ESTATES, WITH THE GROWTH OF CINCHONA, TEA, CACAO, RUBBER, &c. AS WELL AS THE CONDITION OF OLD KING COFFEE.

(From Our Special Correspondent.)

Unable as I was to visit the Madulsima and Hewa Eliya districts as intended, after the Governor had performed "the function" of proclaiming the new province, I am fortunate in being able to lay before you the following sketch of a trip round the districts. No one can say that "my cousin Ich Dien" does not form a competent guide, and although all he says about scenery and vegetation, coigns of vantage and groves of luxuriance, makes one inwardly resolve to "do" the twin districts on the first opportunity; yet, for the present, your readers are better served than if they had had to trust to the descriptive powers of your own correspondent:—

MADULSIMA, 8th Feb. 1886.

My dear X.,—I have just received your note, and am greatly pleased to learn, that at last there is a prospect of your being able to visit us in this veritable "ultima Thule" of planting districts, Madulsima to wit. I had almost prefixed the word *coffee* to "planting," so strong is the force of habit, but the old king's regal state is rapidly disappearing, and the boundaries of his once extensive and flourishing kingdom are as surely contracting in Madulsima, as they are elsewhere in the island. Whether we have done wisely in deposing the old monarch, and placing in his room and stead a sovereign whose name is Tea, supported by a cabinet, composed of cinchona, cacao, rubber, cardamoms, pepper, &c.—cinchona, of course being First Lord of the Treasury and Premier—you will be able to judge for yourself when you have seen the twin-sister districts of Madulsima and Hewa Eliya. It is a true saying, often repeated by our jealous neighbours in Badulla, and worthy of qualified acceptance, that Madulsima is not wont to hide her light under a bushel, and it is with "unconcealed but bashful satisfaction," that we congratulate ourselves on the fact that our district is the very hub of enlightenment, as regards the perfect cultivation of anything and everything which is warmed into life and usefulness, by the kindly light and heat of the sun.

More than a dozen years have gone by, since we last had the pleasure of seeing you amongst us, and you must be prepared for many changes.

The pioneers of the district have nearly all gone from us. Bailie, Adam, Mainwaring, Ballantyne and de Havilland have crossed the bourne from which no traveller returns. Arthur, Reid, Garioch and Edwards have gone to other districts. Channing Esdaile has just returned to his early love, and is, I fancy, the only remaining representative of our district in its youthful days. A new race has arisen, who display an intelligent interest and energetic action in the introduction and cultivation of "new products," of which latter you are anxious to see something. Come on then! and see for yourself, and be convinced that our districts have taken a new lease of life, which promises to be a more vigorous as well as a more profitable one than the old.

As many of the old landmarks have been removed, and you are anxious to see as much as possible, in the few days you have to spare, I would suggest your adoption of a route by which you may see nearly every estate in the district.

You had better try to make Passara on the same day as you leave Nuwara Eliya. You can easily reach Attampitiya to breakfast and come on pretty early in the afternoon to Badulla, where I will have a trap waiting for you, and you can then drive on quietly to Passara in the cool of the evening. Endeavour to start as early as possible next morning, in order that you may reach Lunugala early in the day.

The little town of Passara, which was only a few straggling caddies when you first knew it, will surprise you with the manner in which it has lengthened its stays and strengthened its stakes, and when you have passed through its long line (nearly a mile in length) of substantial brick-built bazaars, and emerged on the saddle, you will note that a bridle-path strikes off on the left hand side of the road, through Kitulkele and on to Madulsima, and by this route I propose bringing you back.

The path on the opposite side of the road, forms the only means of communication with Monaragala. If the morning is clear, you will have a fine view of the Peacock Hill as you drive along the road. It is a pity you could not have afforded to pay this rising young district a visit, for there is something well worth seeing in the shape of cacao and cardamoms, and rumours are not wanting that the brave and energetic band of planters whose lot is cast on its slopes are in a short time to astonish us with their tea. I hope this may be true, for the gallant little band who have transformed the "barren rock" into a flourishing garden deserve success.

But to return to your supposed immediate vicinity. The first estate you will come to is Letchamiwatte, now the property of E. C. Byers. Some good young cinchona in the fields adjoining the road will attract your attention. Next comes a small estate belonging to some chetties, who have not discovered the philosopher's stone in following the lead of the coffee planter. A few minutes' drive will bring you into Hanipha where liveth the genial "Godfrey," whose presence doeth one good like a medicine, and upon whom I shall ask you to call on your way back, as all his new products are on the other side of his big bold hill. A few miles more will bring you to Gallabodde, a full view of which you will obtain from your trap as you drive along. The little patch of coffee in the hollow at the bottom, seems still to be the best part of the property, which did more for Edwards and Watt, than it has ever done, or is ever likely to do for those who succeeded them. A few miles after passing Gallabodde will bring you into a group of young estates, known as Lower Madulsima, and from this point your interest in new products will be excited, and I venture to say, sustained until you have seen all that there is to be seen in Madulsima and Hewa Eliya. First of all then, let us take Kehelwatte, which, if it is not now in the van of progress with a large area of new products, certainly can lay claim to a very large share in their introduction into the district, for it was here that many hundreds of thousands of cinchona, cardamom and tea plants were successfully raised, which have since helped to maintain hundreds of acres in our district under cultivation, and pity 'tis that the spirited prime mover in these large nurseries did not meet with a reward more commensurate with the energy and enterprize displayed by him. May he still have it, in the little property close adjoining, but on the other side of the road, and named Hopton, which has some very fine young cinchonas, and a considerable area under

tea, just planted. Closely adjoining Kehelwatie, and on the same side of the road are two estates which have been opened within the past five years, and are almost entirely under cinchona. A few trees of Ceará rubber, planted throughout the fields immediately adjoining the road, show a rate of growth which would be satisfactory, did the return, even in depreciated rupees, correspond to it. You will by this time have reached Yapame store, where in the palmy days of long ago, large stores of all sorts of eatables and drinkables were wont to accumulate, pending their removal by coolies to their respective destinations in the district above. The beef-cooly carries all our oilmanstores nowadays; the transport of liquor has dwindled down to very insignificant dimensions; and the way into Madulima is no longer barricaded by stacks of empty beer bottles!

Four miles' drive from Yapame will land you in Lunugala. There is little to see by the way, beyond an upward peep at Shawlands, famous for the beauty of its tree-bordered little lake away up in the hills.

You will find a horse awaiting you at Lunugala, and a cooly to take your box on to Coccoawatte, where you will find much that will interest you. Two of the best new products the district has ever produced will be found in the Coccoawatte bungalow in the Philby's fine little boys. If you make good use of your time you will be able to see a good part of the estate before breakfast, and this course I would advise you to adopt, provided that it accords with the convenience of your host and hostess. The bungalow hill, which was formerly covered by a luxuriant growth of cinchona Ledger, is now under tea, which has evidently found something to feed upon, in the comparatively poor-looking soil, which forms this part of the estate. As you descend into the pretty sheltered basin below, you will find yourself wandering through lovely sylvan glades, where the richness of the vegetation is in striking contrast, to that which clothes the high-lands of the district. A clearing of flourishing cacao, which, at the date of my visit, showed a fine appearance of young and healthy fruit on the more advanced trees, with clusters of delicate little blossoms on those less fully developed, is planted under the shade of the old forest giants, and seems to be completely successful. Huge wide-spreading stocks of cardamoms border the different streams, and cover those patches of soil, which seem best suited to their successful culture, the ground being covered with a thick carpet of their far-ramifying rhizome-like runners, covered with little capsules full of the fragrant spice; all giving promise of handsome returns in the good time coming. The rubber trees, too, seem to have found something in the soil congenial to their well-being, and already admirably fulfil the shade purposes for which they were planted. Instead of the hour or two, to which your Coccoawatte visit must be limited, I feel confident that you will leave it with the regret that the hours were not days; but you must hurry on, for already you will have spent a great part of your first day in the district.

After breakfast, and half-an-hour's ride, in which your artist's eye will linger lovingly on many a ferny brake, and creeper-festooned clump of trees, on your return journey up the zigzags, you may depend on your "coo-ee-ee" being cheerfully returned by "the fan-hawe," from his prettily situated little bungalow. You will learn what wonderful results attended the uprooting of a clearing of cinchona Ledger on Parsloes, not only in the matter of analysis, and consequently in price, but

in quantity per acre as well, the bark proving exceptionally thick and heavy for the age of the trees.

Leaving Parsloes with "Figaro" or "Lucy Glitters" leading the way as usual, a smart cartier will bring you to the boundary of the Park, where you will see some of the finest succiruba trees for their age, that have been grown anywhere in the neighbourhood. *On dit* that this is the best unbroken cover of cinchona over five years old in the district. It certainly has strong claims to this distinction, but "comparisons are odious." The young tea shrubs, planted under the shade of the cinchona trees are healthy and well-grown, and their appearance denotes the suitability of soil, climate and rainfall for the extensions of the new king's domains. Before walking round the Park, you should give instructions that your saddle-horse be sent on to Yapame, to await your arrival. The other horse with the trap should be waiting you on the cart-road, at the point where you will strike it, after walking over the patanas from the Park. Drive as fast as you can to Yapame, whence you would do well to send the trap back to Passara; mount, and make straight for Mahadova. Karslake will, I have no doubt, be delighted to see you, and you will have an opportunity of talking over your old experiences on the Kandy side together.

You must be up betimes in the morning, that you may have a chance of seeing the sun rise dripping from his ocean bed, for there are not many spots on our fair earth, from which the advent of "God's crest upon His azure shield, the Heavens," can be viewed so advantageously. It is only on a clear day, and under certain lights, that the calm expanse of ocean is discernible at this great distance, but in the early morning, the incessant darting of long lances of light on the far horizon, constantly and as mysteriously changing as the forms in a kaleidoscope, tells us that the myriad rays of the new-risen orb, have buried themselves in the gleaming, moving surf, and are being reflected and refracted a thousand-fold.

A magnificent stretch of lowcountry lies between you and the coast-line, marked by features peculiar to itself. The low-lands of this tropical island of ours, seem always to be diversified more or less, by billowy heavings of the general surface; but here, we have an almost entirely flat land, dotted over with mountains of rock, which rise almost perpendicularly from the plain on which they stand. I do not know how those huge piles may be accounted for geologically, but to the imagination it would seem as if this plain had been the scene of that "battle of the gods," which finds a place in the traditions of so many nations, and as if some mountain or mountain system had been torn to pieces, in order to supply the ammunition of these rebellious giants. They have lain there for ages but subaerial denudation and disintegration, have been slowly and surely doing their work, and they are now broken up into serrated peaks, and pinnacle crowned heights, which give them a most picturesque appearance. One of these fantastic masses is the well-known landmark, euhemistically, but not inappropriately called "Westminster Abbey"; so that you see, we poor denizens of far-away Madulima do possess something to prevent our forgetting the world, even if we are by the world forgot. Far beyond Westminster Abbey stands the "Friar's Hood," and away to the left Trincomalee-wards you can just distinguish the "Gunner's Quoin." But I am digressing—an expression that some wise head has given utterance to be-

fore me—for you must take time by the forelock, and making an early start from Mahadova bungalow you should go as far as the northern boundary of the estate, and have a peep into Kudadova, where what was in former days a fine field of coffee, is now being crowded out of existence, by a vigorous growth of cinchona. Returning by way of the bridle-path in the direction of the tennis-court near the Amanadova boundary, your attention will be attracted by the luxuriant appearance of a belt of cinchona officialis, skirting the jungle which forms the top boundary of the estate. This is one of those exceptional fields, in which officialis has been an unqualified success, vacancies being few and far between, and the growth regular and good. The first harvesting operations carried out in this clearing, yielded a return of 300 lb. of dry bark per acre, at three years old, and the following year 500 lb. an acre were obtained, the crop of the two years realizing something over a shilling per lb. Mahadova can still boast of some good coffee, but I fancy it is bound to disappear either under the juggernaut wheels of cinchona, or the cheerful smiles of tea. An experimental patch near the little bungalow, and extending to some thirteen acres has just been planted with Assam indigenous. Seeing all that is likely to prove of interest to you on Mahadova, will not occupy more than an hour of your time, so that you should reach Amanadova boundary, before 8 o'clock. From this point half-an hour's ride should bring you to the other extremity of this property. A 25 acres clearing of newly planted tea near the top boundary will not fail to catch your eye. This was formerly under cinchona officialis which was uprooted at five years old to make room for tea. It yielded a crop of 1,000 lb. per acre of dry bark, which fetched a good price. Leaving the road here and crossing through the narrow belt of jungle to your left, will bring you within view of another of the Madulima Company's estates, Cabriabokka. The beautifully even cover and robust appearance of the young trees on this estate, furnish convincing proof of the fallacy of the oft-expressed opinion, that recently formed cinchona plantations are not so successful as of old. An analysis of the bark from the parents of these young trees revealed the existence of quinine sulphate to the extent of from 7 to 9 per cent, and the several analyses of bark taken from the progeny, indicate a proportionate richness of alkaloids. Remounting your horse, a few minutes' ride through Anamally, on which there is nothing deserving of special mention, will bring you into a 50 acres field of fine healthy looking coffee, which forms part of Verelpeattanic. Arrived at a little Roman Catholic shrine, always decked with fresh flowers, proceed by the road which branches off to the right, and you will find yourself traversing the tea clearings on Uvakellie. Here you will find that the growth does not compare very favourably with the tea in Lower Madulima, which fact may be in some measure due to the cinchona shade, under which they are growing. A considerable impetus to growth has, however, been observed within the past few months, and it is not at all improbable that though the growth of Uvakellie tea has been somewhat slow, in its infancy, the matured bush may be as fine as any in the district. You will see some more tea on this estate on the way to the Forest Hill gap which point you should reach about 9 o'clock. Wending your way downwards through Forest Hill you will see the finest field of coffee in the district, with perhaps the exception of Doomoo which is reserved for your return journey. Passing above the district hospital (about to be

abandoned in favour of a more suitable building to be erected somewhere near Lunnigala), you had better put spurs to your horse for there is nothing more worth looking at until you reach the boundary of Wewebedde estate, where what was known as the young coffee field—from which the late proprietor vainly expected so much—is now all planted with tea. A small patch in front of the bungalow promises well; and away towards the lower extremity of the estate, where the land spreads out in the form of a "terai" you will detect the ancient boundaries of the now-vanished "wewa," or lake, from which this property derives its name. You will obtain another good glimpse of lowcountry scenery from the Tavalampalassa gap, and in a few minutes more you will approach the confines of Dorapotha, and Quedjeley, now both abandoned, but still retaining interest from their being the scene of Mrs. Edwards' weird story, "The Mystery of the Pezazi." The steep patana ridge between these two is traversed by a long toilsome flight of steps, hollowed out by the weary feet of countless generations of credulous followers of Buddha in their vain endeavours to work out their own salvation.

A few minute's more tripping and stumbling along this rough bridle-path will bring you into Cocagalla, the original proprietor of which was either Sir John Lawrence or his brother Henry, of loved and revered memory. Whatever the coffee on Cocagalla may have been or done in times past, it is now in the serc and yellow leaf, but the great success which has attended the introduction and cultivation of cinchona here, leaves no room for regret that coffee has given way before it. On your way down towards the bungalow, you will pass through what, a year ago, was a dense forest of succubra trees, which had so often undergone the (barbarous!) operation of shaving, that it was deemed advisable to coppice them. The result has been highly satisfactory both in point of yield, and in subsequent growth of suckers from the coppices left in the ground. After breakfasting with Adolphus (affectionately contracted to Dolly), you will be shown round the famous clearing of cinchona Ledger, and if its appearance does not excite your admiration, the statistics of returns obtained from it certainly will. The clearing is small, being only seven acres in extent, and looks like a wedge hammered into the centre of an immense field of officialis. The trees were raised from seed supplied by Moens of Java, the two ounces yielding nearly 35,000 plants, almost all of which were planted here. At 2½ years old, a careful recount was made, which showed a total of 29,850 healthy, well-developed trees. At the same time branch bark was harvested, and yielded at the rate of over 350 lb. per acre, with an analysis of 1.75 of quinine sulphate. Six months later on, analysis of the stem bark indicated the existence of the chief alkaloid to the extent of 5.50 per cent, and when the trees were 3½ years old, sulphate of quinine had increased to 6.40 per cent. A system of thinning out trees of seemingly inferior type has been vigorously pursued, and thus, up to date, has resulted in a yield of dry bark equal to over 3,000 lb. per acre, exclusive of twigs; the average price obtained being something over 2s per lb. These figures speak for themselves, but, nevertheless, it seems to be pretty generally admitted that Ledger is very uncertain and short-lived; even the trees reserved as being the most true to type, in the clearing referred to, do not inspire one with a feeling of confidence. Far different is it in the case of the vast area of officialis and hybrid trees, young and old, which will burst upon your gaze, as you round the corner and enter

New Forest, also belonging to the Cocagalla group. The last three years' crops of bark from this group have been as follows:—

1882-1883 equal	36,000 lb.
1883-1884	" 92,000 "
1884-1885	" 128,500 "

Total .. 256,500 lb., or nearly 115 tons

Just before crossing the boundary line which divides this estate from old Hewa Eliya, you will see a long narrow belt of tea, a little over two years old, whose history furnishes incontestable evidence that a great part of this property and therefore a large area of land in the district is certain to yield excellent results under tea. This field has been regularly plucked, from the date of the bushes attaining their eighteenth month, and, although, so far as I am aware, no professional valuation of the manufactured tea has ever been obtained, I have seen a memorandum of the prices placed on a large batch of samples by a competent planting authority, and these ranged from 1s to 2s 1d per pound. A fact worth mentioning is, that the land on which this tea is growing, is very poor and occupies a most exposed situation, at an altitude of over 4,500 feet. There can be no reasonable doubt, that a very large area of Cocagalla might be planted up in tea with great gain to its proprietors, and it is to be hoped that Mr. G. E. Osborne, who is now in England, will return with full powers for the large extension of tea, on one and all of the Madulsima Company's properties.

Hewa Eliya is the next estate you pass through; the whole of which, with the exception of a small experimental field of tea, near the top boundary is uncultivated. The progress made by the young plants is however an indication that, wherever the soil is suitable, the other conditions of rainfall &c. are not absent, and it is to be hoped that the prospect will encourage the proprietor to extend the area under tea, next year. You should ride through this clearing on your return journey, as it is well worth seeing.

Instead of following the old tavalam road, which is now abandoned, walk on (for the paths are not very smooth just here) in the direction of the bungalow where poor old Ballantyne lived, keeping the lower road till you reach the stream near the boundary of what is now Elemane estate, where formerly lived that intrepid hunter and true-shot Barkley, now of tusker-slaying renown, who when here kept our tables so well supplied with venison, by the aid of his clever little pack. Here you may again resume your seat in the saddle and ride all the way to the top boundary. The fine big cinchona trees planted throughout Elemane will claim a glance in passing, but there is little more worthy of note until you reach Rathkeale, where although the roads are in beautiful order, the atmosphere, throughout the greater part of the year, is so deliciously crisp and bracing, that I feel sure you will prefer to walk, provided the weather is fine. A slight detour in the direction of the bungalow which nestles in a sheltered nook, behind the jungle forming the western boundary of the estate, will well recompense you for the little extra time required. You will find your way to the bungalow field, through a small clearing of cinchona officinalis planted under jungle shade, and thence through a patch of cardamoms, and half a mile of road gracefully winding through patana and trips of jungle (the scene of many an exciting chase) to the most recently planted fields of the estate. The growth here is all that could be desired, but the appearance of the whole is per-

haps a little marred by lines of straggling calisayas, alternating with rows of the more robust-looking succinbra and hybrid trees.

From Rathkeale you would do well to walk as far as the Roeberry stream, or if it is not too late in the afternoon, you might canter along the upper road which branches off near the wire fence, gain the Dehigalla ridge, and have a peep into the property beyond where the Blackwood Company have just planted some 40 acres with tea this season. Half an hour's ride through Roeberry, on which there is now a fine healthy cover of cinchona will bring you out on the patana near the Katukitukona trig.

You should reach this spot first about the hour of sunset, and a short time spent in contemplating the fair scene before you, with the wonderful cloud transformations, and the ever changing shades of light thrown over the wide valley beneath you, which separates you from the far away Kandy hills, will fix such a picture in your memory, as you will not easily forget, for,—

The heavens appear to love this vale:

Here clouds with unseen motion sail,

Or 'mid the silence lie!

By that blue arch this beauteous earth

'Mid evening's hour of dewy mirth

Seems bounded with the sky."

Yonder dark line of trees near the middle of the valley marks the course of the noble Mahaweliganga,

"Broad and deep and still as Time,

Seeming still—yet still in motion,

Tending onward to the ocean

Just like mortal prima."

Wending your way downward to the bungalow you will be surprised that such a luxuriant growth of vegetation could ever have been induced to cover with such profusion, so steep and rugged a piece of land as this part of Uva consists of. The growth and healthy appearance of the cinchona trees covering the steep slopes, would seem to point out that good natural drainage is of incalculable importance to its successful culture. Here, on Uva, as on Ceceowattie, you will find two of these wonderful products which arrest your attention, whether you will it or not, and you may criticise them when you see them, for, depend upon it, they will criticise you.

So much has been done in the way of tea planting on this property, that it will take you the whole day to see the different clearings, and please take special note of the fact, that these cannot be viewed from the saddle, as you will have done in the case of the different estates through which you will have passed, on the two preceding days. Fortify the inner man well at the early tea table, and put on the most comfortable, and strongest pair of boots you may have, for you will have a very stiff day's heel and toe work before you, good walker though you may be, and I think I have heard *à la* our old friend W. W. W. boast of his prowess in this respect.

You will enter the tea fields immediately after leaving the bungalow and with the exception of about half a mile of patana and forest, through which you must pass, you may continue to wander through them, from something like five miles, before you reach the northern extremity of the estate, where the oldest tea is to be found. The first field has been planted only quite recently, with sturdy-looking plants of Assam indigenous, and only extends to some 6 or 7 acres. Next follows a field of 30 acres of Assam hybrid, planted in land where the coffee had been cut out to make way for it. Then comes a small clearing on the ridge, which from the southern boundary of

the great central basin is planted with different kinds of acacias and wattles. From here you will obtain your first views of last year's clearings, on the northern side of the main basins, and the appearance of the well-grown bushes, in dead straight rows on the opposite slope, will compel you to confess that we are more than justified in entertaining the idea that we can grow tea, which, age for age, will bear favourable comparison with any in the country. Before reaching those fields, you will have to pass along the road, which now forms the boundary line of the 200 acres of the higher fields of this basin, still maintained under coffee cultivation. The trees are a very picture of health, and have, what in these degenerate days may be called a good crop on them, *i. e.* a fraction over a couple of hundredweights an acre. All the lower portions are planted with tea. Passing through these you will enter the large clearing you looked into from the southern side of the valley. Beyond this again, comes an unbroken field of 200 acres, backed by a large block of jungle, having walked through which, you will find yourself, in the first planted field of this estate, and, I feel confident, the appearance of this will surpass the most sanguine expectations you may have formed of the rapid growth on this side of Nuvara Eliya. If you have the time, and do not feel too tired, when you reach the top of this field, you should make a point of walking as far as the patana and trig.—distant only a hundred yards or so. Here, if you are at all subject to giddiness, you had better not approach within a couple of paces of the edge of the precipice, which descends almost sheer into the lowcountry, thousands of feet below. Were it not that I have already dwelt at some length on the wonderful grandeur of the scenery in these parts, I would fain linger lovingly on the magnificent expanse of bill and valley, and huge rock, "piled by the hands of giants for god-like kings of old," to be seen from this coign of vantage. I have often thought, that if we had any grounds for believing that the Mount of Temptation reared its noble head, in this island of ours, then this point might justly tender its claim to such distinction, for if all the kingdoms of the world may not be viewed from it, nearly the whole extent of the newly created Uva Province may be seen to great advantage, and surely no one will dare deny that this is the next best thing! The vast stretch of unbroken vegetation is diversified by tiny patches of paddy cultivation, glowing in all the fresh, green delicacy of youth, or bending calmly to the inevitable as they find themselves chameleon-like, changing to a golden yellow, or, here and there, shining like shields of burnished silver, and giving expression to this fair picture, as the eyes mark the light of intelligence on the human face; the bold lines of deep green vegetation, provoked by the waters of the great river, and its affluents; the jungle-clad slopes of the long ranges of hills which form the back ground away to the west, with their shapeless patches of another shade, telling where the destroying angel of chena cultivation (save the mark!) has been at his fell work—all forming a mosaic, a thousand fold more varied and pleasing to the eye than any that has ever come from the hand of the most skilled artificer.

The sun will have passed the zenith on the westward course ere you retrace your steps to the bungalow, but you will be able to ride more than three miles of the way, and a bath and breakfast will refresh you sufficiently to make you enjoy an hour's stroll in the cool of the evening, through the lower fields of tea in the neighbourhood of the bungalow.

Next morning you will commence the return journey to Passara making straight for Galloola to breakfast. Most of your way will be through estates already seen, until you reach Cocaqala, whence you should take the lower road, which will enable you to have a good look at Dunedin, where tea planted a year ago is flourishing, and gives every promise of a profitable career. A pretty large area, planted with seed at stake on this property in November last, shows by its satisfactory growth the forcing nature of the climate.

Passing through the lower portion of Forest Hill, planted a couple of years ago with *succirubra cinchona*, you will be struck with the splendid growth of what is, as well as what is not, intended to cover the ground. You will not fail to note also the fine cardamoms planted throughout the belt of forest, reserved near the stream.

Another half-hour's ride will bring you into a fine forest of cinchonas, in the bottom of Battawatte, which is of special interest as being planted on the much-despised (by a certain journalist) Uva patana. Extensive preparations in the shape of nurseries are, I understand, being made on this estate, against next planting season, and when the fine soil of Battawatte has had some of its richness extracted, to produce fine flushes of tea, I venture to suggest, that it will rank second to none in the district.

From this estate to Doomoo is but a few hundred yards, and you will enjoy the ride through this pretty little property, where the coffee seems in no way affected by the ravages of that fell pest *Hemileia vastatrix*. This promises to be one of those places where the plucky old monarch will make a last stand, and die game, if die he must,—and this would seem to be his fate. Poor King Coffee!

A few minutes more, and you will find yourself under the hospitable roof of Galloola bungalow, where your unannounced presence will prove a source of genuine satisfaction, to your *pro tem.* host. I am only one of the many, who have crossed the threshold of Galloola, in season and out of season, and have thereby taxed the good nature of J. H. B. C. to a point, which would have far exceeded the breaking strains of courtesy with most people, only to meet, time and again, with the cheeriest and most genuine of welcomes.

If you have a quarter of an hour to spare, the time would be well spent in having a look at the tea-house, not that there will be anything of much interest in it to you, who have already seen so many such buildings, but by reason of its being the first building in the district, which could advance any pretension to such a dignity, and further on account of its having a genuine leaf-rolling machine. A wonderfully ingenious piece of machinery it is too, as you will admit when you have seen it, and I hope its inventor, Mr. Frater, who is as popular as he is clever, will receive his reward in the shape of large orders from Madulisms, as soon as the large area of tea now planted, and to be planted, in the district, comes into bearing. That this machine is the genuine brain-fruit of him who has perfected the invention, and given it his name, there cannot be the doubt that is inseparably connected with the bringing out of other machines I could mention to you; for when it was in course of construction, and when its inventor was puzzling his brains about some of its minor details, I pressed upon him the advisability of visiting one or other of the tea gardens, where he would have an opportunity of witnessing other men's machines at work, and thus be able to form an opinion of what was wanted in his own, but he declined the

advice, preferring to work out his own idea. Had every man acted as honourably, we would not now be hearing so much of infringements. How this battle of the rival machines rages! Even in these far-away regions the din of the fray has reached us.

The really splendid field of two-years-old tea, within a stone's throw of the store, will attract your attention, and a walk through it will beget a confidence in the future of Madulsina, such as did not exist, even when coffee was at its best. The other fields of young tea on this estate all show a healthy and vigorous growth, betokening that soil and climate are exactly to their liking. The clearings here are amongst the most extensive in the district, and the extraordinary progress made by the young plants indicates that plucking and manufacture will be the order of the day at no distant date. What a strange comment it is on the perversity and blindness of human nature, that on this, the very spot where the old Dame wrote the doom of coffee on its own leaf, in what now seem to us such clearly defined characters, it should have taken us nearly twenty years to gather the import of her words of wisdom; but late though the response to her warning cry has been, it must rejoice her heart to behold these flourishing fields of tea as the result.

The next estate on your route is Verellapattina, and here you will miss the kindly welcome and warm hand-shake of dear old Garioch, who has just left us. Good luck to him! This is now the property of Mr. Channing Esdaile, whose is a safe lead to follow, judging from his past connection with our district. Verellapattina should make a fine tea garden, the lay of land being beautifully easy, and the soil generally of that deep ochreous colour, in which the shrub revels. There are some 30 acres planted this season, part of which is under the shade of coffee and cinchona. My own experience of such planting is, that, from six months old and onward, the plants compare very unfavourably with those planted in land which has been cleared of all other products to make way for them. A short walk along the boundary of Verellapattina towards Dagenham and Bolivia will enable you to gather some idea of the extensive scale on which the enterprising proprietor of these estates is planting tea. May all his undertakings end in complete success.

You will have to hurry on now as you must reach Hanipha before the shades of evening fall. The first few miles of your way will be over ground already traversed, until Anekland is reached, where you will see one of the finest fields of cinchona in the district, and which yields, year after year, large harvests of renewed bark, without any apparent effect on the health of the trees. Some of the cardamoms planted under the forest shade are very good.

Nidhanagalla is a promising young clearing extending to 80 acres, the whole of which is planted with the most valuable kinds of cinchona.

I do not think it is necessary for me to describe your route any further, as you are now in the neighbourhood of Mr. Godfrey Power, who will take charge of you, show you all round his own properties, and those of which he has charge; tell you all about his new products, both here and on Monaragala, a great deal better than I could possibly do, and finally will send you on your way rejoicing, while his hearty laugh will keep ringing in your ears for days after.

I must now conclude. I had no idea the outline of your route would have taken so much scribbling. My only fear now is, that you will con-

tent yourself with the delusion that you know the district well enough from the very imperfect and hurried sketch of it which I have given you, but no two people ever see a thing in the same light, and I therefore beg of you that even if you can find no stronger argument for your proposed trip than that of auld acquaintance, do come and see us for the sake of "auld lang syne." "Auf Wiedersehen."—I remain, your loving cousin,

ICH DIEN.

P.S.—At the last moment I find that Yapame estate has through inadvertence been omitted from your route. You will however see a good deal of it on your way from the cart-road to Mahadava bungalow, and should you wish to see more, you can take it on your return journey staying there for the night instead of at Hanipha as already suggested. I understand something has been done in the way of tea-planting during the rainy season now drawing to a close, but I have no idea of the extent of the clearings, Clifton, Daysbrook and Melrose you will get a good view of from the high way when driving from Passara to Lunugala on your way to the district.

UYA AND NUWARA ELIYA.

(From Our Special Correspondent.)

GIANT CINCHONA AND CACAO TREES—EXPERIMENTAL BOTANICAL GARDEN OPENED AT BADULLA—BOQUE ELEPHANT AND CHEETAHS READY FOR SPORTSMEN NEAR HARGALA GARDENS.

Who has, and where is, the biggest CINCHONA tree at this moment in Ceylon? In order to start the enquiry I have got the measurements of the big tree in Cannaverella as follows:—

	Feet.	In.
"Height	43	0
Circumference of stem 6 inches above ground	4	6
Circumference of stem 3 feet above ground	4	0

The tree is not a high one, but has a splendid bole as you will see from the measurement. It is a succirubra growing in poor soil.* Who can beat this? Some of the largest cinchonas ever grown in Ceylon, I think, were on the New Galway estates, as sections sent by Mr. Cotton to the *Observer* Office, and still used as footstools under some of the editorial tables, testify. These were grown from some of the first plants issued from Hargala Gardens, but the stems were cut down a good many years ago, and I rather think the largest section of stem, under my table, exceeds the 4½ feet circumference of Mr. Macfarlane's. The latter too must be an older tree. But without going back, it will be of interest to learn whether there is a larger standing tree at this time in New Galway, or elsewhere, than the Cannaverella "giant." I do not know if Abbotford has a rival,† but will be able to judge a few days hence.

I suppose some of the largest Cacao trees in the island are also to be found in Uya, on Keenakelle estate near the bungalow, and if the measurement

* Mr. H. B. Eady in his recent paper on the Java cinchona plantations writes:—"At Bentang is a magnificent example of *C. succirubra* about 30 years old said to be the finest cinchona in the East Indies. As nearly as I could judge it was about 60 feet high and the trunk 18 inches in diameter at 3 feet from the ground." The circumference at 3 feet high, therefore, is 6 inches ahead of the Uya tree. But the Java tree is probably ten years older.—Ed.

† Nothing approaching it. The oldest trees are not more than a dozen years old and the biggest were cut down or "died out."—Ed.

of the giant there were sent for publication, it might be worth comparing with the older one in other districts.

Of more importance, however, than big trees, whether of cinchona or cacao, to Uva, is the establishment of an EXPERIMENTAL BOTANICAL or rather ECONOMIC GARDEN. This has just been inaugurated at Badulla by Dr. Trimen (who was accompanied by Mr. Nock of Hakgala), at least so far as the selection of the ground and general plan of operations. Twelve acres of land have been secured adjoining the race-course in close proximity to the town, and, when laid out and planted, the Gardens will undoubtedly add a most pleasing feature to the beauty and attraction of the very charming capital of the new province. Dr. Trimen could not have a better lieutenant than Mr. Nock in carrying out his plans, and I have no doubt the usefulness of the Gardens in providing a supply of useful plants ("new products") to try on plantations, and especially near the native villages, will be widely appreciated. I trust the day is not far distant when every Provincial capital may be able to show its branch Gardens—ornamental as well as economic—instructing as well as delighting the people frequenting them. Annual Provincial Agri-Horticultural Shows with prizes and sports more especially for the people, will follow in due course. Meantime, Dr. Trimen has made a good start, for, besides his Hakgala and Henaratgoda branches, he has formally opened Gardens at Anuradhapura and Badulla, Batticaloa and Galle or Matara ought to be next favored. Jaffna, I believe, has a Public Garden under the Agent's care.

Returning to the Hills, I have to report that the story about the "rogue elephant" and Mr. Jordan's conveyance is a false alarm—an invention of the horsekeeper so far as the elephant is concerned, to endeavour to screen his own carelessness. It now appears that the horsekeeper, in bringing up the conveyance from Wilson's Bungalow, must have gone to sleep, with the result that the horse, in turning in to Hakgala Gardens as a resting-place to which it was accustomed, took the corner too sharply, and over the culvert went the whole concern—fortunately not on the precipitous side of the road.

There was just this justification for the horsekeeper in awaking from his sleep in supposing that the capsizement had been effected by an elephant, that a rogue tusker had been prowling in the neighbourhood some weeks before. The Hakgala Gardens have, it seems, been more than once visited by elephants during the past year, and the wonder is that so little damage has been done. On one occasion the herd broke down a small culvert and trampled everything in the neighbourhood of one of the outhouses. On that occasion their marks were observed along the jungle track and the evidence shewed that the herd was followed at a respectful distance by a single elephant—a big tusker—probably east out, but as yet unwilling to lead a solitary life, and turn rogue altogether. This same tusker, however, soon after paid another visit to the Gardens—this was in December last—and seemed to be especially attracted by the anemometer stand. He inspected the instrument and gave it a push, so as to turn the indicator round from N. W. to S. W.! But he did not do further damage save in rifting some trees of their foliage. Mr. Nock could scarcely reach with his arm outstretched and standing on tiptoe the part of the tree where the top of the elephant's shoulder had been rubbing off the bark, and the measurement of the footprint was 11½ inches inside. Mr. Nock accordingly judged that

his visitor was a big specimen, and this was confirmed by Mr. Spencer of Ambawella, who had a short time before spent a long day in following up the same animal, he thinks, a huge tusker, evidently a rogue, in the neighbourhood, and who would probably have secured him had not his native attendant bolted with his spare rifle at the critical moment. In December, Messrs. Kay-Shuttleworth and Bagot of Udapussellawa endeavoured to follow up the tracks of the visitor of Hakgala Gardens, but after going a considerable distance they found that he had evidently gone off to the Horton Plains. Later on, however, garden coolies, sent to the jungle for material wanted, returned on two occasions saying they had been driven back by an elephant. There is therefore evidently a good chance for a sportsman desirous of distinguishing himself by getting rid of a thorough rogue, in the neighbourhood of Hakgala.

Life in these Gardens in fact is varied by more than human and elephantine visitors. Only a few weeks ago, the cow of one of the employees which could not be found at nightfall, having wandered away on the patanas below the Gardens, was discovered next morning killed at the edge of the jungle. The owner suspected wandering Moorme, and appealed to Mr. Nock for redress; but the latter, on going to the spot, at once saw that the "Moorme butcher" was a cheetah, death having been caused in the way peculiar to that animal, by a spring on the shoulders and head, the neck of the cow being broken. A large part of the victim had been devoured; but the owner would not consent to sacrifice the rest in order to lay a trap for the cheetah, which no doubt returned to the spot, as is usual, the following night.

Mr. Nock's own adventure some time ago, when walking along a junglepath, a cheetah dropped from the bank above, some yards in front of him, and, after a look and a snarl, skulked into the jungle below, has already been recorded in your columns. It is parallel to Major Skinner's experience on the Adam's Peak range (as related in Mr. A. M. Ferguson's Reminiscences) when a cheetah sprang out and dropped at his feet during an early morning walk in a forest path. The brute just looked into the eyes of the startled Major, who stood stock still, and then bounded back into the jungle. No doubt the cheetah had sprung for a fourfooted animal, in which case he would have landed on the neck.

Talking of elephants, have you ever heard of Indian or African tuskers being imported and turned loose in our jungles? It was stated the other day that any big tusker now seen in Ceylon must be the progeny of the introductions referred to; but I certainly never read or heard of the African or any Indian breed being introduced into the island, and although "tuskers" are few and far between here as compared with Africa, still there can be no doubt of Ceylon having genuine tuskers of its own species of elephant. The idea of African elephants turned loose in Ceylon is, of course absurd. The enormous ears of the African elephant distinguish it markedly from the Ceylon animal.—*Ed.*

OIL SEEDS OF EGYPT.

Several plants are grown in Egypt for the sake of their oleaginous properties, the principal being as follows:—*Nesane*, or *Sesam* (*Sesamum indicum*), is cultivated in Central Egypt on a large scale, being sown in June and harvested in autumn. The stems are pulled up bodily, and conveyed in an upright position to suitable spots; as soon as the capsules are dry they open in the sun, and shaking them suffices to dislodge the seed. The oil obtained by pressing the seeds is thin and yellow, and serves largely in cooking, though liable to rancidity; when purified it is a good illuminant. The castor-oil plant, or *Kharôda almar* (*Ricinus communis*), attains the proportions of a small tree, and produces much oil, especially in Fayoum. An oil-yielding lettuce (*Klass*) is grown about Edfou, and in the southern part of the province of Thebes; when ripe, the plant is cut, dried, and threshed, the seed affording a pale yellow very sweet oil, used in cooking. An oil-yielding radish (*Synagah*) is grown for its seed, the oil finding application in the arts. The ground nut, or *Fil sennari* (*Arachis hypogæa*), requires a light soil into which it can thrust its seeds for maturation; the oil obtained from them may replace that of the almond, while the roasted nuts themselves are good eating, and serve instead of lard in pastries. Garden cress, or *Richâd* (*Lepidium sativum*), in Upper Egypt, affords a seed oil, while the young plants are used in salad. Mustard, or *Kharâd* is similarly utilised, and colza, or *Selgâm* (*Brassica campestris*), is grown solely for its seed oil. The seeds of the safflower, flax, and cotton, are all pressed for their oil in Lower Egypt; whilst the opium poppy (*Papaver somniferum*) and the heliotrope, turnsole, or *Ayn-el-chems* (*Heliotropium europæum*), are similarly utilised in upper Egypt.—*Journal of the Society of Arts.*

THE SUGAR INDUSTRY IN QUEENSLAND.

In this district (Mackay) the present season has proved itself to be one of the best on record for the growth of cane. No very heavy fall of rain has occurred—that is, nothing over four or five inches during the 24 hours—but rain has fallen at such timely intervals that the cane has grown as if it had hothouse treatment. And it has had such treatment, for the sun-heat has been intense, and the average temperature of the autumn above the usual figure. Similar favourable accounts are to hand from the Herbert River, Johnstone River, Cairns, and Cooktown districts. All the plantations at these places expect a heavy crop this ensuing season. On the Burdekin prospects are not so promising, the climate there being not near so wet a one as are the other localities both north and south of it. Here there has been an absence of that tropical growth so congenial to cane. Still, on one of the plantations the fields look splendid, and quite equal to those of Mackay. On the Burnett the cane also suffered from prolonged absence of rain, although this district is not a dry one; yet, through some cause or other, it did not receive its fair share of rain this season. The same remark applies, with not quite so much force, to the Mary River district. Everywhere the cane is healthy, no disease (new or old) having attacked it. In the Mackay district the *Standard*—the most authentic organ of the planters—after a careful estimate, puts down the area under cane there at 17,700 acres, a slight increase over that of last year, though by no means so great as would have undoubtedly taken place but for the various adverse circumstances with which the industry has been surrounded for the past 12 months. The number of acres that will actually be brought to the rollers is put at 14,000 by the same authority, and the yield of sugar at 23 cwt. per acre. This I consider too low, but the *Standard* justifies the estimate by pointing out the large area under rations, which will give only a low return, and the fact that among the plant-cane there are many misses. The estimate for the coming crop will therefore be 14,000 tons of sugar.—*Australian.*

THE LINSEED-OIL TRADE.

A few weeks ago the Managing Director of the North British Floor-Cloth Co., Limited, wrote to the Under Secretary of State for India, from Kirkcaldy, stating that "a very large amount of linseed-oil is used by the manufacturers of Floor-cloths (wax-cloth), Linoleums, &c., apart from the general painters' work, and that all these not merely prefer but pay a much higher price for Russian called Baltic linseed-oil, in preference to Indian or Calcutta linseed-oil, the reason being that the Indian seed-oil is considered to be too fat or rich and devoid of the more readily drying quality of the poorer oil obtained from the Baltic seed-oils. Presently Calcutta seed-oil is plentiful and cheap, whilst Baltic seed-oil is scarce and dear, and I think I pretty nearly give the respective value at £19 to £19 10s. per ton for Calcutta and £23 10s. to £24 per ton for Baltic linseed-oils. In this comparatively small town, but the seat of the Floor-cloth and Linoleum trade for Scotland, I think that not less than from 50 tons to 60 tons of linseed-oils are used weekly. Of course the (similar) manufacturers in London, Manchester, and Lancaster, &c., must use a very large quantity, and all doubtless preferring and paying a higher price for the poorer quality oil. No doubt, agriculturists prefer the richer quality of linseeds for cake for feeding purposes. Perhaps the Indian growers of linseed, were they fully aware of the higher prices obtained for the Baltic or poorer oils, could readily grow, and at smaller cost, linseed that would serve the purposes for which Russian seed is so much preferred and for which so much more money is obtained for the oils." In a letter sent by Mr. A. G. Murray, from Dolerie-Crief, to the Secretary of State, it is stated:—"I am told by Mr. Aytoun, Manager of a large Floor-cloth Works at Kirkcaldy, that they use fifty tons a week of linseed-oil, but that they find Russian oil best, the East Indian linseed is too rich and does not make a hard surface. I have told him how I found it possible to harden East Indian linseed-oil by adding rosin to it. This seems unknown here and keeps down the price of East Indian linseed, one of these apparently small details that turn trade. At the same time the cake made from East India seed is best for cattle feeding, but is not much used at present; the oil is the article that leads the market." This has been communicated to the Board of Revenue and the Director of Revenue Settlement and Agriculture. Inquiries will be instituted in view to determining—(1) the cause of the richer quality of the Indian article as compared with that supplied by Russia; and (2) how the Indian oil might be assimilated in quality to that which is in demand for the special trade indicated and for painters' work generally, for which a good drying oil is essential.—*Madras Times.*

WATERING PLANTS.

This is a subject which has been treated of frequently in the *Journal*, but not too often if the importance of the operation is taken into consideration. Good potting is essential to success, but carelessness in the application of water will quickly nullify the benefits of perfect potting. Too much and too little are the extremes to guard against. Supposing anyone to be growing four dozen plants; all may be watered rightly until growth is satisfactory, then there comes a day when one of them is so dry that the pot in which it is growing sounds like an empty one if struck with the knuckles. This plant is permanently injured, the young roots which were forming fast to support the plant are dead, and although the man in charge may determine that nothing of the kind shall happen again to that particular plant, his good resolution is too late. Once dry is once too much. If—ad-by another plant in the same batch may be subjected to the same ordeal, and so it goes on until nearly the whole of the plants are thrown into an unfavourable condition. There is no excuse for anyone who has the plants in charge, and can examine them twice daily. Staking and tying, and everything else connect-

ed with growing plants, are all of minor importance to watering. There is another side to the question which is equally important. Besides the possibility of giving too little there is also the chance of giving too much. Of the two evils it is difficult to say which is the greatest. Both are decidedly bad, and those who go to the one extreme generally practise the other; indeed a man who lets some of his plants become too dry generally makes up his mind, when reprimanded for it, to avoid the same thing again, and for a time he waters most assiduously—too much so in many cases, as giving large quantities of water when none is required, simply to make sure of the plant not becoming too dry, is a most improper way of watering. There is a happy medium, easily found and followed, of keeping plants in a growing state without going to extremes, and we would advise all men who have plants to water to adhere to it. Surface dribblings have often been decried, and must be so now and always. Sham watering of every description are delusions of the worst form which will soon become apparent. Watering pots full of soil before they contain many roots is a common practice, and a decidedly bad one, as it is at that time that the soil is most liable to become soar, and if it gets into this state before the roots have taken possession they cannot be expected to do much good in it afterwards. When plants have abundance of roots, and the pots, beds, and borders are well filled with them, it is more difficult to do harm with the watering pot than when few roots are there; but printed rules cannot be taken as invariable guides, but much can be accomplished by what one of your esteemed correspondents would call "thinking."—A. K. G.—*Journal of Horticulture.*

PLANTING IN NORTH BORNEO.

TO THE EDITOR "BRITISH NORTH BORNEO HERALD."

Dear Sir,—I visited the Sebugah estate the other day and was so much taken with it that I wish to say a few words in its favour in the hope that it may be saved from ruin.

The clearing seems to be about 100 acres in extent, of this about 50 acres are very well cleared and planted with Liberian coffee, cocoa, pepper, and lanut (abacca). It would be very difficult to say which of these is doing best; one in favour of pepper or coffee as the case might be would probably name his favourite plant, but as I have no preference I must in bare justice pronounce all doing uncommonly well. The coffee which appears in all stages from 18 months old to the young plants in the nurseries is fresh and vigorous. The Cocoa is very strong in the stem and shows promising signs of pods, the trees have suffered somewhat from wild cattle, but otherwise are all the owner could wish. The Pepper, even the plants only one foot high, are all covered with fruit. I think these want topping and clearing. The Lanut is waiting to be cut and made into rope, there is quite a small forest of these which is likely to be soon demolished by wild cattle and pigs.

If any one will look at the Sebugah estate and consider that it has been, and is still, under a 4 months drought, he will have some reason to praise the soil and congratulate the owner.

The low undulating surface soil of Sebugah has nothing in its appearance to recommend it in preference to that of many other districts in Sandakan, but I observed the sub-soil to be particularly well adapted to withstand droughts, being a stiff rich reddish clay which retains the moisture and keeps alive the plant. I noticed several acres cleared and holed for planting, and it is a matter of regret that they cannot be filled from the crowded nurseries; indeed I should strongly urge the owner to plant this up at once, and while the coolies are on the spot to clear away the second growth that has sprung up on the part that has been tilled but not cleared, and plant it up also, with coffee, cocoa or pepper, once thoroughly cleared and fully planted up, the place would require but little attention. I fancy, a few coolies sent once in three months would

keep it in order. The estate is well supplied with a manager's house and several houses for coolies, all well situated, water is good and plentiful, notwithstanding the drought. There is a nursery full of fine young plants; in short there seems nothing wanting to carry on a large estate. For some reason or other the owners of this fine estate have withdrawn their coolies, and it would seem, are going to abandon it, I fancy the reason is that insufficient capital was raised in the first instance. Let them ask Government who are always ready to help a good cause to help them in this—for their own credit as well as for the credit and good name of the country. Should there be any one who thinks an Experimental Garden is wanted in Sandakan district, let him visit Sebugah, and I am sure he will say, as far as coffee, cocoa, pepper and lanut are concerned, that no further experiment is necessary. I may add that we went to the Sebugah estate to shoot, and I am going back again next full moon.—A. C.

PAN AND ATR.

I fancy there is hardly a European out here who has not, at some time or other, come in contact with pan or atr, or both combined; and I venture to affirm that a very large majority of these know or care naught about the meaning attached to their use, while a great many of these ignorant ones regard their exhibition with disgust or aversion. These are not aware how insulting their behaviour is to those who desire to welcome and honour them, nor that their conduct has transformed a friendly ceremony into a hastily got over farce in which valuable atr is represented by various perfumed oils unworthy of the name. Nay, in some parts of the country, the call for pan is an accepted hint by the visitor to retire. Let us now examine the articles familiarly known as pan and atr, and then describe their real significance. Pan is the etiolated leaf of *Chavica Belle*, a climbing plant of the Pepper order, familiar in the Straits, where it grows in the open air. Out here it is very largely grown in pan gardens, great enclosures of straw or matting, in which the plants revel in shade and moisture, and thus become blanched. At the proper time the leaves are carefully picked, closely piled one another, packed into baskets, and then carried away for local sale or export. They have a hot, strongly aromatic, and grateful taste, but are not used in their plain state; they must become a pan-supari before they are edible. Strongly stimulant as they are, their virtue is to be assisted by the mild astringency of the betel-nut (supari), the fruit of that exquisitely graceful palm, so common about Calcutta, the *Areca catechu*; and the more powerful action of catechu or gambua; then an ant-acid is added in the shape of slaked lime. These drugs are enclosed in the betel-leaf, which is then folded into a flat cone, kept in position by a clove. For State occasions the cones are further wrapped in gold or silver leaf. Preparation of pan-supari generally falls to the woman-kind, who make as much fuss over their pan boxes, as our grandmothers used to do over their funny table workboxes. There is hardly a married man out here who has not heard the click of the ayah's betel-clipper, a small copy of the old loaf-sugar clipper.

The real complimentary use of pan is its supposed value in assisting the digestion of the rich food which properly follows the recipient to his home. Except in purely native society, and in some States where the practice is extended to European officials or visitors, the real use of pan has passed away, and the mere bestowal of the charged leaf survives.

And so it is with the highly interesting and poetical exhibition of atr. Christian recipients, while regarding it with an aversion equal to that of the pan, forget that they see before them the representative of a ceremony connected with their most cherished and sacred traditions; here they see what the sweet singer of Israel alludes to in his famous Pastoral; here they recall the touching devotion of her who expended perhaps her all on the "ointment of spike-

ward, "very precious" for at the sacred feet of her Lord. Let us first examine into the subject of atr, and then see how it ought to be exhibited and the anointing of the rite. Atr is the essential oil procured by distillation from the petals, leaves, or wood of certain plants; as it is yielded in small quantities, it is always added to a ground (zamin), which is almost invariably sandal oil (sandal), the essential oil of *Santalum album*.

The atrs in common use are rose (gulab), jasmine (chamel), pandanus (keorah), and henna (mehudi); the prices of these vary according to their dilution with sandal; if you chose to go in for real gulab-ki-atri (otto of roses) you will have to pay Rs120 per totah (rupee's weight) for it, so that it is vastly dearer than gold.

At the close of an ordinary durbar, bits of muslin soaked in rose-water and touched with an ardam spoon are the representatives of the sacred ceremony of atr, which is thus performed. Pan having been bestowed, host and guest rise; the former pours atr of roses into one hand, rubs both palms together, and commencing with his guest's head, passes them down his beard and body and down to his feet; then he salaams to his guest, who repeats exactly the same process with his host. The anointing being complete, raiment for the guest and, if necessary, a purse of money are provided, and the welcome is complete.

You cannot join in this solemn ceremony without thinking of "the precious ointment upon the head that ran down upon the beard, even Aaron's beard, that went down to the skirts of his garment." Nor can you forget David's share in a similar durbar. "Thou anointest my head with oil, my cup runneth over."

The ceremonial of pan and atr is only a portion of the welcome; food and raiment (khurish-poshis), or their equivalents in money, are also supplied ungrudgingly to the guest. When I joined as a griff in 1854 I recollect being welcomed at Bhopawar by a banker, who offered me as khurish-poshis a horse, a pair of shawls, a pagri, and a bag of Rs150; of these I was allowed to retain the shawls and pagri. I only mention this as one illustration of the kindly feeling in pre-Mutiny times.—R. F. H.—*Pioneer*.

INDIAN GRASSES.

All who have read Mr. Symonds' articles on the grasses of the Madras Presidency, and on Army Animal Management, which appeared in the *Quarterly Journal of Veterinary Science in India*, will be glad to have them in the more complete and convenient form in which they are now published. In the present work, the most important grasses of the whole Indian Peninsula are described, and figured with special reference to their use for fodder, and though, of course, a complete list of the Indian grasses cannot be expected, it will, we think, be found that all those known to be of value are included. Of course such a work must be in the main a compilation from other writers, but it needs a wide knowledge of the subject to make the compilation satisfactory, and we can congratulate Mr. Symonds on his success in this respect.

It appears that the most important of the fodder grasses of India is the *Cynodon Dactylon*, known in this part of India as hariali grass, and in the north as dhob. It is the same as the couch grass of Australia and America, and grows well in all parts of India. This grass is treated of at considerable length, and many useful details are given regarding its cultivation. Perhaps the most interesting part is a quot-

ation from a report made by Major General Ottley upon some experiments which he made at Vellore on its cultivation on a fairly large scale. The soil was first very carefully prepared and manured, care being taken to remove all the roots of the corra (*Cyperus Rotundus*), a most troublesome weed, which is often found growing along with the hariali, and which can hardly be eradicated after the latter grass has been planted. In the ground thus prepared the hariali roots were planted in furrows, and the whole was then laid out in beds, so as to allow of irrigation from wells in the compound. At the end of about a month the first crop was ready for cutting, and the judicious use of irrigation—once or twice a month—it was found that eight crops could be obtained in a year. Each crop yielded on an average two tons to the acre, so that it is well within the limits to say that 50 tons per annum can be obtained from 5 acres of ground properly attended to, and this yield is sufficient to render the crop a profitable one, even when we take into account the very heavy first cost of preparing the ground. On the produce of his five acres General Ottley was able to keep eight or nine horses and sheep, and to supply hay for the racing studs and livery stables at Madras; while during the last Burmese war, at a time when there was not a blade of grass in the country, he supplied all the hay needed for the Horse Artillery sent to Rangoon. Experiments made at the Sydapet Farm on a plot of 3 acres in 1868 showed, that a fair crop could be obtained even without irrigation, for from this plot 8 tons 13 cwt. of hay was obtained during the year. This hay sold for Rs300, while the cost of curing it was only Rs105. The hay made from hariali grass is of an excellent quality if care is taken to carry on the drying properly. The grass ought to be cut immediately after the flower appears and, according to Mr. Cameron, of Bangalore, the cutting should be done in the cool hours of the day, so that the newly mown grass may not be exposed to the intense heat of the mid-day sun and the drying should take place very slowly. But this is evidently a point on which "doctors differ" for Mr. Robertson, of Sydapet, gives advice which is very nearly the opposite of this as he advises that the grass should be cut in the morning after the dew is off it, that it should then be left lying for an hour or two, and finally be turned and tossed about till sunset, for "it cannot" he adds "be tossed too much during a hot sun." In dry weather two days of this treatment should fit the hay for being stacked. Our author does not attempt to decide between these diverse opinions, and neither will we, though we must admit that Mr. Robertson's advice seems to agree with the best practice at hand. A point which is not generally known with regard to hay is that it is decidedly advantageous that it should heat slightly after it is stacked, the fermentation that takes place in that case improving the quality of the hay as fodder, just as coarse grass is improved by fermentation in a silo. But of course care must be taken that this heating does not go too far. Mr. Robertson suggests the use of a single row of six inch drain pipes placed about the middle of the stack, and leading from the centre to the outside. But drain pipes are not things that are usually to be found in this country, and they can be replaced by hollow bamboos, or split palmyra stems, or the stacks may be built round a "centre," as is so often done at home. Hay which has been well made, attains its maximum value in from eight to twelve months, and after fifteen months begins to deteriorate, and by three years it is useless for fodder.

Another very valuable grass is the guinea grass (*Panicum Jumentorum*) a native of Guinea, but thoroughly acclimatized in this country. Not only does this grass yield a very large crop of a quality admirably suited for feeding horses and cattle, but it has the power of resisting the longest severest droughts. This was well shown on the Sydapet Farm during the last famine. A field of two acres was planted in September 1877, and in May 1877 it was perfectly brown,

* Spikenard is supposed by many to be the Roosa grass of the jungles of Central India; its fragrant essential oil, Roosa-ki-tel, is largely distilled about Indore. Others identify it with the incense root of Jata-masi, one of the Valerians, and essentially an Alpine plant. But Jata-masi atr is unknown, while Roosa-ki-tel is very familiar. Apart from its powerful and penetrating odour, the ... is a famous rubefacient.

and to all appearance lifeless, when the heavy rain which fell during the cyclone in that month led to its immediate revival. Before the third day of the rain was over, green shoots appeared all over the field, and in two months it yielded a crop weighing 5,566 lb. followed two months afterwards by a second cutting weighing about 12,000 lb. The popular idea that this grass requires to be irrigated, and that it should be taken up and replanted in fresh ground at the end of every two years or so, is situated to be quite erroneous. Of course irrigation will increase the yield, and any grass which grows so quickly requires an abundance of manure. The plants, too, soon become too large, and ought to be divided into four with a spade by two cuts at right angles through the centre, three of the parts may then be removed, and the fourth left where it is. A subject on which Mr. Symonds has a very decided opinion is the present most unsatisfactory state of the system of obtaining grass for horses by means of grass-cutters. In Bengal the grass-cutters are men who are regularly enlisted and serve for a pension, but in Madras and Bombay in the army as well as in private stables, the grass-cutters are women who are generally the horsekeepers' wives. All who keep horses know how difficult it is to have any real control over these women, and how badly they usually do their work, and that there is much need for an improved system. In connection with this we are glad to see that Mr. Symonds calls prominent attention to the very common error that the roots of grass are best for horses. If the roots are young and small they certainly possess a considerable amount of nourishment, but old roots are always mixed with the young, and these are not only un-nutritious, but are actually hurtful. The following directions regarding grass seem worth quoting for the benefit of private horse owners. "The grass should be brought in dry, laid on a trellis frame, beaten to remove dust and dirt, and it is then fit for use. Perfectly dry grass is not always possible, of course in the rains it is impossible, then they should bring in 20 lb. extra, take every advantage of getting it dry, keep it two or three days, then beat it and use it. In very wet weather, when there is continuous rain, to keep it would only induce fermentation, but as soon as there is a break in the weather, the drying should be assiduously attended to, and it cannot be laid out too thin." The practice of grubbing up the grass with a mamoty is strongly condemned not only on account of the number of roots which are thus mixed with the grass, but also on account of the destruction of the grass; but this latter objection can hardly be maintained in view of the experiments recently made at Lucknow, where it was found that by scraping the surface, as practised by the natives, an advantage of 10,320 lb. per acre per annum was obtained over the plan of allowing it to grow, and then cutting it with a sickle. These experiments were made on harial grass. In conclusion we may call attention to the sixty-two admirably executed lithographic plates of the various grasses described, which, taken along with the text facilitate the identification of each grass, and greatly add to the value of the book.—*Madras Mail*.

THE INDIARUBBER GATHERERS OF THE AMAZON.

For the most part the juice of the seringa has been hitherto collected on the islands and swampy portions of the mainland which lie within a distance of a hundred miles of the port of Para, and for that reason the produce is known as Para Indiarubber. In the great delta, away from the chauncis that have now become the highway for steamers between Para and the main Amazon, the explorer may paddle about in his palm-decked canoe through hundreds of miles of sequestered creeks, lakes, and streams, under the shade of huge overhanging trees of the richest variety and luxuriance, and for weeks together he will not find the slightest trace of man's existence in the dense solitudes, but here and there the hut of an Indiarubber gatherer. Although the industry is largely

confined to this limited district, the tree flourishes with equal vigour in all the swampy districts bordering the Amazon, and there are groves of untapped, seringas growing by the Tapajos, Madeira, and other vast tributaries of the central river. Indeed, the traveller by the steamboats (of English make, by the way) that ply on the Amazon from Tabatinga—the first fortress in Brazil on the Peruvian border—to Para, which is quite two thousand miles distant will observe that Indiarubber is an article of export from nearly all the places at which the vessel calls. At the remote Tabatinga itself, rubber and salt fish are taken on board, the contributions to the civilised world from the numerous Indians who dwell in the adjacent forest. Five hundred miles further down the river stands Ega, on the tributary Tefe, half-way across the continent. Bates, who lived there exploring in the interest of science for four years and a half (Agassiz fished there for six months), exclaims, "What a future is in store for the sleepy little village!" At present, that distant population of 1,200, composed of pure Indians, half-castes, negroes, mulattoes, and whites, exports Indiarubber along with cacao, sarsaparilla, Brazil nuts, copaiba balsam, salt fish, turtle oil, and other products of the district. At Manaos, a thousand miles from Para, there is "enough Indiarubber to coat the civilised world." The same article—although cacao is the favourite product from this point—is taken on board at the mud village of Villa Nova, and so also at the town of Santarem, to which it is brought down from the river Tapajos. Still, as we have said, the greatest portion of the supply is obtained in the swampy districts nearer Para and the mouth of the Amazon.

The caoutchouc-gatherer reaches the swampy regions on which alone the Para rubber tree grows towards the close of August, when the floods that have prevailed for four months and kept the tress under water to their crowns, have gone down. A spot is chosen where a good supply of rubber trees is at hand, and in selecting it the gatherer has to take care that too dense an undergrowth does not hinder a ready passage between the hut and the trees. The caution is highly necessary, for the juice is rapidly spoiled by contact with the air, and every one must be familiar with the difficulty of threading a Brazilian forest because of its marvellous mazes of creepers and shrubs.

A piece of ground, of a size proportioned to the number of the household or group, is cleared leisurely, about a yard of the stumps being left standing. At intervals the mestizo, with a genius for saving himself trouble, allows some of the harder trees to remain, in order to serve as supports for the roof. The floor of the projected dwelling must be raised above the reach of the water, and accordingly the felled trees are placed upon the stumps for that purpose. Small strips of the bark of the muruti palm are laid down as flooring. To form the framework of the roof thin trunks are fixed to the stems that have been left standing, and over this are placed immense palm leaves, sheltering a space probably sufficient to accommodate a company of twenty persons. To serve as walls—there is no need in the tropics of any protection against cold—bass-mats are hung all round the structure on a horizontal pole. Partition of the building into apartments is not regarded as an indispensable feature among these semi-savages, and the highest conception of refinement among them is satisfied by the construction of a ladies' chamber in the centre by hanging up a few mats. The staircase is not an invention that requires much toil or genius; some blocks are laid above each other, or a tree stem, with rough steps cut into it, is placed obliquely against the hut floor.

Look now at the pantry. A space at the foot of some neighbouring tree is cleared of earth to a depth of two or three feet and fenced round. The adjacent stream fills the pond with water, and to this reservoir are consigned the fish and turtles that are caught. Less care is bestowed on the food obtained by the Indian's gun; what remains over the necessity of the

day is simply dried in the sun, or salted and preserved in well-shaded spots.

The last few days before the caoutchouc harvest actually begins are spent assiduously in increasing the stock of shells and clay vessels necessary for collecting the juice, in gathering a store of tenacious clay for attaching these receiving vessels to the tapped trees, and also in laying in a supply of a certain kind of palm-nuts, which, as we shall see, play an important part in the preparation of the milky juice of the *Hevea Brasiliensis* into the Indiarubber of commerce.

The tree, which is the object of so determined an attack from September till January or February, cannot, indeed, be spoken of as at all remarkable in appearance in the giant forests of the Amazon, but it is certainly an imposing tree, often towering to a height of sixty or eighty feet; its round, straight, pale-grey trunk is devoid of branches till far up, as is the habit of all forest trees; the trunk has a circumference of two or three yards, and bears a stately but not widely spreading crown. The foliage is beautiful, the long thin leaves growing in clusters of three, the central one being more than a foot long. The fruit is of about the size of a large peach, and is divided into three lobes, each of which contains a small black nut, not only edible, but eagerly sought by the wild animals of the forest. In hue, the bark and foliage of the Para rubber tree have a strong resemblance to those of our own ash.

In the early morning, between the hours of five and six, the mestizo, in his light cotton vest and pantaloons, sets out from the rude hut, bearing with him a small axe, the edge of which is about an inch long. With this he makes twenty incisions or so into the bark of every third seringa at a convenient height, and with a little soft clay sticks one of his small shallow earthen cups just beneath the incision, to receive the milky sap that now oozes out drop by drop. In a few hours he has thus tapped thirty or forty trees, with the assistance of his wife and children.

It is now time that he should make a second round, in order to collect the juice; for, although the tiny cups are not yet filled, the wounds are already closed up with dried juice, and the sap itself now requires to be looked after if it is to be a good marketable article. Instead of the hatchet, the seringueiro this time takes with him a small wooden bucket, into which his wife and children empty the contents of the cups, each of these holding, perhaps, half a gill of juice. The emulsion, while still fresh, has an agreeable taste, not unlike that of sweetened cream. The skin of sap that has attached itself to the bark under the incisions, or to the edge of the cups, is also stripped off and stuck on the outside of the bucket. The husband clears the wound and sticks on another cup for the second crop of the day. The sap that has been obtained is immediately conveyed to the hut and subjected to the following important process.

A fire of brushwood is kindled, and on this a narrow funnel-shaped pot of clay is placed, in or underneath which the palm-nuts already referred to are heated. The seringueiro, with the bucket of juice by his side, seats himself before the fire, dips a club-shaped piece of wood with a flattened clay mould at one end into the milk, and turns the juicy end round and round in the white vapour issuing from the pot. In half a minute the milk is changed into a skin of a reddish tint. When this is firm the stick is again dipped into the milk; and so the process goes on, layer being added to layer, until a sufficient thickness has been obtained. Another stick is then taken up, and the work goes on until the juice has been exhausted. The benefit of the nut smoke is alleged to consist in its absorption of the oxidised resin of the juice, and it is the smallness of the quantity of this resinous body in Para rubber that gives it the highest value in the market of the world. A good hand will make five or six pounds in an hour. When the cakes are completed they are slit up with a sharp, wetted knife, and after being hung in the open air to dry for a few days, they are ready for sale. The flat, rounded Para rubber cakes, made in

the way we have described, are known in London as "bisuits," and command a higher price than any other kind of caoutchouc.

On the same day the trees are exhausted once more, and even twice, if they are rich in milk—a quality that reaches its maximum when they are about twenty-five years old. On the second day the second portion of the tree is attacked and dealt with; the third portion on the third day; and on the fourth the first portion may again be tapped with impunity.

How does the gatherer secure the sale of his caoutchouc? Boats ply up the rivers and creeks during the season with wine, trinkets of all sorts, and an endless variety of wares, and the rubber is exchanged for these articles. The chief delight of the half-savage Indian is in procuring fireworks, and days of toil are sacrificed for one evening of festive illumination.—(Abridged from *The Welcenc.*)—*Indiarubber and Guttapercha Journal.*

GARDEN ENEMIES.

Probably there is no country in the world in which the gardener has more difficulties to contend with in the way of insects and other vermin than in India. We have not only almost every pest that our brethren in Europe have to contend with, but a host of others that are even far more dangerous; and not only this, but we are further handicapped by the fact that those species which are most dreaded by English gardeners, such as Thrips, Mealy Bug, Red Spider, Aphid and Scale, which with them are only developed at a high artificial temperature, and consequently confine their depredations to plants grown under glass, where insects may always to a considerable extent be kept under control by fumigating, syringing, sponging, and the many other means employed for the purpose, in this country all these pests attack plants growing in the open air, where they are far more difficult to contend with, and which, if at all neglected, frequently get the upper hand and defy all efforts to exterminate them. An instance of this is given in our correspondence columns of April 28th, where the writer states that his entire collection of *Crotoms* had been most severely damaged through some cause to him unknown. We have since had an opportunity of seeing the plants in question, and found them fearfully infested with black thrips, certainly one of the worst insects with which we have to contend. Had our correspondent, however, taken proper measures as soon as this pest made its appearance, they could have been easily checked, but having once obtained a good foot-hold, they would not disappear till their work of destruction was complete. But have they really disappeared at all? we are inclined to believe this is hardly possible; in all probability millions of eggs or larvae are hidden in the soil or secreted on whatever leaves may be left, and will break forth again as soon as their incubation is complete. We have such a wholesome dread of this unpleasant visitor that, were our correspondent to offer us a present of his whole collection in its present state, we should hesitate to accept it, unless we were able to place the plants under quarantine for a month or two. Some writers maintain that insects are in every instance the effects of disease and not the cause, and although we cannot accept this as an invariable rule, still there is undoubtedly much truth in the assertion. One of the surest means of keeping plants clear of the ravages of insects is to maintain them in a vigorous state of health, for it is always found that it is the weak sickly plants that are first affected when insects of any kind make their appearance. As an illustration of the fact that insects follow disease and do not precede it, we may mention the general idea that prevails in this country regarding the ravages of the white ant on vegetation. We continually hear complaints, especially from residents in Mofussil districts, that *Roses* and other plants have succumbed to the attacks of this insect. But is this really the case? We believe not; in every instance that has come under our notice we have invariably found that

the plants were weak and sickly, and that they were suffering from root fungus or some other disease long before the ants commenced their depredations. This opinion coincides not only with the observations of Firminger and other Indian authorities, but also of Figuier, Smeathman and many eminent naturalists who have made the *Termites* their special study. It would be impossible for us to describe in detail the innumerable unwelcome visitors that are found in our gardens, but must content ourselves with briefly describing the most important of them—either insect, reptile, bird, or beast, and the most effective means that can be employed for their extirpation. We will commence with the insects, for these, though individually are generally so insignificant, collectively form some of the most powerful enemies that we have to encounter.

APHIDES.

In this family there are supposed to be upwards of one hundred and fifty species; many of these, it is stated, confine their attention to one plant or family of plants, such as *Aphis langera*, better known as the "American blight," which restricts its operations exclusively to the apple tree, and *Aphis fabae*, which is only found on the Broad Bean. Other species, however, are far more cosmopolitan in their ideas, and will attack almost anything that come within their reach. The most common of these is *Aphis rosea*, better known as green-fly or plant lice. These not only attack Roses, but almost any other plant on which they can effect a lodgement, and if neglected for a few days increase enormously. The young shoots of Roses and other trees all round their circumference for the length of upwards of a foot are often covered with this species; they remain crowded against each other, and sometimes there are two layers of them. If carefully observed, without moving the plants, they will, to all appearance, be tranquil and inactive, they are however gradually, but surely, absorbing the vital powers of the plants, piercing with the point of their trunk the epidermis of the leaves or stalks and drawing from them the sap they contain. Infinitely small as is the proboscis of the plant louse, when there are thousands of these creatures crowded on the stems or leaves of a plant it must evidently suffer. The enormous rate at which the aphid family increase under favourable circumstances seems almost incredible. Bonnet, a celebrated naturalist, gives the results of experiments made by him to prove how rapid is the multiplication of aphides; he says:—"A single female produces generally 90 young ones; at the second generation these 90 produces 8,100, these give a third generation which amounts to 729,000 insects; these in their turn become 65,610,000; the fifth generation consisting of 590,490,000 will yield a progeny of 53,142,100,000; at the seventh we shall thus have 4,782,789,000,000; and the eighth will give 411,461,010,600,000. This immense number increases immeasurably when there are eleven generations in the space of a year. Fortunately a great many carnivorous insects wage fierce war against the plant lice and destroy immense numbers of them. Thus they are held in check, and kept from multiplying inordinately."

Smee in his comprehensive work, *My Garden*, in discussing this subject, says:—"We are in the habit of looking to astronomy for numbers beyond the capacity of man to realize, but the multiplication of *Aphides* afford a more astounding illustration. To represent the number of the progeny of one of these creatures for the space of one year, thirty-six figures placed in a row would be required. As the distance in miles between the earth and the sun is represented by only eight figures, and as seventeen figures would represent the number of *Aphides* required to form a line between the same bodies, we may form a kind of indefinite vision of the immensity of the power of multiplication possessed by *Aphides*, and have a dim idea of the rapid manner in which they can cover vegetation when they appear."

In Europe there are several instances on record in which swarms of these insects, frequently miles in length and breadth and sufficiently dense to obscure daylight, have been observed. We are not aware if

any similar occurrence has been noted by daylight in this country, but in Calcutta and the surrounding districts each year, just at the setting in of the north-east monsoon, we have a very similar phenomena. At this period, for several nights in succession, the air is filled with a species of *Aphide*, these are particularly attracted by any artificial light, and in the vicinity of street gas lamps the crowd is frequently so dense as almost to obscure the light. This attraction leads them to their own destruction, for the heated air surrounding the lamps proves fatal to them, and in the mornings following these visitations they frequently cover the ground to a depth of two or three inches for several feet around each lamp. On one occasion, some two or three years since, they appeared in such numbers as to stop the performances in our local Theatres. Whether these myriads migrate at night only it is difficult to say. We can hardly think that such is the case: probably the stream is a continuous one, but in the daytime they fly at a height beyond the power of human vision. Where these immense shoals come from, and whither bound, seems clouded in obscurity. It is a strange fact, however, that in their migrations they have never been known to attack vegetation. It is very fortunate for us that such is the case, otherwise we should have as much cause to dread their visitations as that of a flight of locusts. Innumerable recipes have been recommended for the destruction of green-fly, some of them, unfortunately, proving just as effective in destroying the plants as the insects with which they are infected, in the hands of an inexperienced operator. In the use of insecticides we must always take into consideration the constitution and nature of the plants to be operated upon: with hard-wooded plants having well ripened growth we may use them much stronger than with those of a succulent nature, or where the wood is young and tender. With the former class of plants one application may thoroughly overcome our enemy, but with the latter it may be necessary to give three or four weak dressings at intervals of a week or ten days. The following are some of the most reliable remedies that can be employed for eradicating this pest.

I. *Soft Soap and Tobacco*.—Dissolve one pound of soft soap in three gallons of water, and when cool add one quart of strong tobacco water. Small plants in pots should be immersed in the mixture, bottom upwards, and held in it for a minute or two, taking care that the soil is not also submerged. When taken out allow them to stand about ten minutes, after which syringe with clear water till every insect has disappeared. Plants in the ground, or such as are too large to be dipped, should be thoroughly syringed with the mixture and afterwards with clean water.

II. *Sulphur Mixture*.—Four ounces sulphur, four ounces powdered tobacco, four ounces quicklime and eight ounces of soft soap in three gallons of water. This is only suited for hard-wooded plants, which should be well syringed with the mixture and then allowed to remain for twenty-four hours, after which they must be thoroughly cleansed with water.

III. *Soda and Aloe*.—An American horticultural journal gives the following preparation as a sure death to the green-fly, as well as many other insects that infest house plants:—Dissolve 2 lb. of wash-g soda and 1 oz. of bitter aloe, and when cold add one gallon of water. Dip the plants into this solution and lay them on their sides for a short time, and the insects will drop off. Syringe the plants with clean tepid water, and return them to the house. This mixture proves to be an effectual remedy for vermin on wall trees and hard-wooded plants of robust habit, but injures soft-wooded plants and tender newly-grown shoots of all plants.

IV. *Tobacco Powder*.—This is one of the most certain remedies that can be employed for the destruction of green-fly. Procure ordinary country grown tobacco, dry thoroughly and then pulverize as finely as possible procure a common powder puff or a cook's sifter; dredge, and after having first damped the plants,

dust the powder freely over the stems and leaves. The plants should be thoroughly syringed about twenty-four hours after the application of the powder.

V. Tobacco Water.—Take a pound of the strongest tobacco leaves, boil them for half an hour in a gallon of water, then strain and add half a pound of Gum Arabic and boil again till this is thoroughly dissolved; when cool add six gallons of clear water. This should be used in the same way as No. 1, but the plants must remain for about six hours before being syringed. The object in adding gum is to insure its adhering to the insects.

Nos. IV. and V. are recommended to the uninitiated in preference to the others; they are not only cheaper but are rarely injurious to plants even when used in excess.

AMERICAN BLIGHT.

The American Blight (*Aphis Langeri* or *Eriosoma Mali*) is, we believe, entirely unknown in this country.

ANTS.

We next come to one of the most troublesome of all insect families, and one of which this country has a vast number of species. Ants, black, red, brown, ash or yellow. Ants, omnivorous, carnivorous and granivorous, abounding in every district that is not actually a swamp. Fortunately for the gardener this is not one of those pests that seem to have been sent into the world exclusively for his edification, or rather we should say mortification. Ants distribute their favors equally amongst all classes of society, finding a congenial home either in a mud hovel or a mansion, although it must be admitted that the richer the food available the greater the attraction for them. The following methods of destroying ants are given in *Quin's Garden Receipts*:—

Bones.—An effectual way of destroying ants in places where boiling water cannot be used is to lay half-picked bones about. These will soon be covered with ants, and can then be thrown into a vessel of boiling water, after which they should be again laid down to attract a fresh batch of victims. By persisting in the use of this trap a house will be completely cleared of ants in a short time; the sooner, of course, in proportion to the number of bones employed.

Camphor.—If the ants have formed their nest at the root of a plant, pour upon them a quart or so of warm water, in which a piece of camphor, the size of a Hazel nut, has been steeped. This thoroughly destroys them, and is not the least injurious to the plant.

Chalk.—To prevent ants from climbing trees scrape the bark in a ring about 2 in. wide around the tree; then take a piece of chalk and rub it on the ring all round till no green bark can be seen. The moment the ants' feet touch the chalk it offers no solid footing, and they fall back, not one being able to ascend. A chalk mark, at least half an inch in breadth, around the upper edge of sugar barrels, boxes, &c., will not admit one ant into the interior. The same mark drawn on the edges of shelves will also prevent the approach of an ant. The chalk mark must, of course, be perfectly continuous.

Flower-pot Trap.—Suppose a colony of ants to be commencing operations on a lawn, it is an easy matter to trap them all by placing a large empty flower-pot with the hole stopped, over it. The ants will build up into the pot, and in a short time it may be lifted with a shovel and carried away and dropped into a vessel of water, which will make an end of them.

Flowers of Sulphur.—Flowers of sulphur are very useful in checking ants where boiling water cannot be used.

Gas Tar.—When ants make a run up the stem of a fruit tree, a line of gas tar all round will put a stop to their progress, and do no harm to the tree.

Guan.—It is not generally known that fresh Peruvian guano will drive ants from any spot, however firm a hold they may have obtained on it.

Mortar.—Mix a mortar bed of their nest, stirring the ants in with the mat until their nest becomes a mass of mortar, which may then be removed.

Petroleum.—Pouring of a little petroleum upon their nest every few days will effectually kill or banish ants.

Paraffin oil, benzoline, and kerosene are also very effective.

Quassia.—The following mixture has been found successful:—Four ounces of quassia chips, boiled for ten minutes in a gallon of water, dissolving in the liquid while cooling 4 oz. of soft soap.

Quicklime.—Perhaps as good a way as any of exterminating a nest of ants is to dig the nest open and flood it with a kettle of boiling water. If a bushel of quicklime be then thrown in and the earth replaced, the colony will be broken up, and the few ants left will seek other quarters.

Raw Meat.—A very effectual plan of getting rid of ants is to place raw meat in dishes or vessels of any kind about places which they infest, and as they prefer that kind of food to any other, they surround it in thousands. Boiling water is then poured upon them, and this, if persistently applied, with the bait above recommended, will in time effect a good riddance.

Soft Soap and Potash.—In the "Revue Horticole," September 1870, the following method of destroying or banishing ants is described as having proved quite successful:—Take 2 oz. of soft soap, 1 lb. of potash, and 2½ pints of water. Boil the whole together for some time, stirring the ingredients occasionally. The liquor may then be allowed to cool. With a pointed stick or dibble make holes here and there in the soil infested by the ants, at a safe distance from any plants which may be growing there, to avoid any chance of their roots being injured by the mixture (although this is doubtful), and fill the holes once or twice with the preparation. By this means M. de Forghet was completely successful in clearing his Melon beds of these troublesome insects.

Sweet Oil.—Fill small phials two-thirds with water, and add sweet or any other oil to float on the water to within ½ in. of the top. Plunge these upright in the ground, leaving only ½ in. standing out, near the nest or runs of the ants. The ants will come for a sip and go home to die. No insect can exist with oil stopping up its spiracles or breathing pores.

Treated Sponge.—In houses and other places where hot water cannot be poured on the soil without danger to the plants, pieces of coarse sponge dipped in diluted treacle will from a most effectual trap. The ants will crowd into the sponge, which should be taken up from time to time and thrown into a vessel of boiling water. Thick treacle spread on pieces of brown paper is also very effective; they get entangled in the mass when sucking it, and their bodies may be swept off the edges at different times till the nests are much thinned of them.

Turpentine.—Turpentine, gas-water, lime-water, a decoction of Elder leaves, chloride of lime, and chloralum, dissolved in water, soot; wood ashes, soap-suds, tar, paraffin oil, and benzoline, have also been recommended.

Water.—If the ants' nest should be in a pot amongst the roots of a plant, the best way is to immerse the pot and plant in cold water, and let it stand for five or six hours, by which time the ants will all be drowned and their eggs destroyed. One of the most simple and effectual ways to destroy ants is to pour boiling water on the nests at night, but in those cases where boiling water cannot be applied, recourse must be had to some other remedy.

Yellow Prussiate of Potash.—Yellow prussiate of potash (ferrocyanide), 1 drachm; raspings of quassia, 1 drachm; sugar in sufficient quantity to form a syrup. The ants are said to devour greedily and die almost immediately.

It must be borne in mind that in applying any of the above remedies, it may be necessary to repeat the dose several times. The ant is extremely tenacious of life, and is one of the "die-hards" of the insect world. Not only this, but during the breeding season as instinct leads it to carry off its eggs to a place of safety the moment that danger threatens, the immediate neighborhood of the nest must therefore be looked after, as well as the nest itself. When the ants are caught alive they must be at once carried away to a distant spot, and either burnt or drowned.—*Index, Gardener.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

SALT AS A MANURE: KAINIT.

Mr. John Hughes is an accomplished agricultural chemist, and any opinion from him is to be received with very great respect, but we fear he underrates the difficulty of so mixing salt with any substance, that pure inodorous crystals of chloride cannot be obtained by solution, filtration and evaporation. The question has frequently been discussed in Ceylon and always with the same result: salt can be recovered from the most complicated and the foulest mixture. As in India so in Ceylon, a considerable revenue is derived from the salt monopoly. All naturally formed salt here is collected on account of Government, and all that is manufactured is paid for by Government and stored to be issued to the public at a price about 500 per cent over cost. The revenue thus realized ranges close on R800,000 per annum, and such a sum cannot be lightly risked. For many years this consideration stood in the way of the issue of salt even for fish-curing operations, but, as this difficulty has been overcome, so we trust Government may yet see its way to the issue, under proper restrictions, of salt for agricultural purposes. There is an objection (too unqualified, we believe) to the application of lime to tea, and this product does not suffer from grubs as coffee did. Still it has its own enemies, and a mixture of salt and lime dusted over the bushes might be useful in preventing the growth of moss on the stems and in destroying moth, red-spider, fly and helopeltis, should the latter develop in any proportion. A Government officer might see the salt and lime mixed at central stores, whence it could be issued under penalty bonds, restricting the use of the mixture to purely agricultural purposes. But, with a good proportion of superphosphate of lime added, what can be better (white castor-cake not now in question) than the mixture (if it can be obtained cheaply enough) mentioned by Mr. Hughes? The kainit salts are described by him as composed, *one-half* of common salt, and the other half (with trifling quantities of foreign substances, probably) of sulphates of potash and magnesia. This substance and a proportion of superphosphate being mixed with the Norwegian salt-fish would come in free as a manure. So, no doubt, would pure kainit, if introduced by persons who did not care to use salt-fish, or who believed they could obtain that substance at a cheaper rate on the spot or from India. If Government did not interfere with the import of kainit, and we do not think there would be any such interference, except in the most improbable events of attempts being made to separate the chloride of sodium from the sulphates of potash and magnesia, kainit with its 50 per cent of common salt, in view of what Mr. Hughes says about the danger of too much salt, ought to suffice for mixing with farmyard dung to kill grubs, or for any other agricultural purpose. It being pretty evident, therefore, that apart from castor cake and salt-fish, kainit is likely to be a good application to tea: our readers will be interested in knowing the price at which kainit sells in the English market. We turn for the desiderated information to the circular of Messrs. S. Downes & Co. of Liverpool, dated Jan. 30th which reached us by last mail. We quote as follows:—

KAINIT OR SULPHATE OF POTASH.—Owing to the presence of ice in the Elbe, the imports of Kainit have this month been nominal. Recent advices report that the severe frost has completely interrupted water communication with the mines in the interior, and it is not expected that traffic can be resumed before March next. The effect of this stoppage of the supplies will be to materially enhance values on the spot. The demand so far is exclusively confined to chemical manufacturers by whom Kainit is extensively used in the preparation of compound or special fertilizers. Of recent years agriculturists have preferred to use it in a pure state, and by so doing have obtained most satisfactory results at a trivial outlay.

SUPERPHOSPHATE OF LIME.—The season has opened with a brisk demand for super from the outports, but the difficulty of securing suitable freight and tonnage for small cargoes has, in some instances, check business. Some heavy orders for home consumption have recently been placed, and, as the deliveries have far exceeded the production, stocks have rapidly diminished. The market generally exhibits considerable activity for this early period of the year, and prices are very firmly maintained. All indications point to a large turnover during the Spring months.

SULPHATE OF AMMONIA.—The market for Ammonia is firmer, and a slight advance has taken place in the value. Shipments continue on an extensive scale to the Continent. This article is now abnormally cheap, and as it is a superior and most reliable fertilizer, and is a satisfactory substitute for nitrate of soda, it merits the attention of intending consumers. Today, grey of the best quality, guaranteed 24 per cent, is quoted £10 10s to £11 per ton, on rails at the works.

In the Price Current, kainit is quoted, per ton, 23 per cent in bags £1 19s to £1 2s 6d. Superphosphate of lime per ton, 26 to 28 soluble £2 11s 3d to £2 13s 3d; 35 to 37 soluble £3 11s 3d to £3 13s 3d. We may add that immediately after kainit there is the quotation:—"Salt, suitable for agriculture at the works, per ton 5s to 7s." So that a ton of salt can be obtained in England at 5s, or nearly the Government price of a cwt. here!

We see in this circular that "cocoa cake" sells at the same rate as decorticated cotton seed cake.

We append Mr. Hughes' communication:—

Analytical Laboratory, 79, Mark Lane, London,
29th Jan. 1886.

My attention has been directed to a paragraph under the above heading which appeared in the *Weekly Observer* of January 5th and in which special attention was drawn to the case of a proprietor of an estate in Ayrpatana, who wished to purchase 50 tons of salt at the export price. R4 to R5 per ton, and offered to pay the expenses of a Government official who should visit the estate in order to see the salt actually applied to the land with a view of destroying grub. Why this reasonable request should have been refused it is not my purpose to enter into, but I merely wish to point out that there are means available for so mixing salt with certain manurial materials that the subsequent extraction of the salt in a condition at all likely to be used for food should be rendered extremely improbable. First of all I would say why not convert the crude salt as at first obtained into a *manure* by adding two or three cwt. of finely ground fish manure or dried blood or even *Peruvian guano* to every ton of crude salt? Any one of these materials would so strongly impregnate the mixture that the natives with their natural caste prejudice against handling any foul matter, much less of having the same brought in contact with their food, would certainly refuse to purchase salt

possessing any such peculiar odour as the above material would certainly produce.

Quite recently I examined a valuable mixture consisting entirely of Norwegian Fish Guano and Kainit salts, which, as a general manure, has lately been used in this country with marked success, and which is now being introduced by Messrs. Jansen & Co. of London as a fertilizer for sugarcane in the West Indies. The Kainit salts (which consist of sulphate of potash, sulphate of magnesia and quite one-half of common salt) had been added with the double object of preserving the dried fish powder from the attacks of ants, and at the same time of supplying potash salts to the canes. I have suggested that some superphosphate should be used in the place of a portion of these Kainit salts as being likely to be still more effective in rendering the dried fish unpalatable to grubs and similar insects and have in a former letter drawn the attention of Ceylon planters to this special advantage of superphosphate when mixed with ordinary manures.

There is no doubt that salt is a most useful and cheap source of manure, and it seems a distinct loss that any Government should throw difficulties in the way of its local use as manure or in the laudable attempts to destroy insect pests. My own view is that salt applied as an ingredient of a mixed manure is likely to be more effective in an agricultural sense than when applied in large quantity in the hope of destroying grubs.

Salt in anything like large quantities such as one or two tons per acre is likely to be injurious to vegetable life: indeed it is commonly used as a destroyer of weeds on gravel walks. I fear, therefore, that it cannot be applied in sufficient quantity to kill grubs without at the same time doing damage to the coffee or tea. At home a good dressing of caustic lime is usually found the best application for grubs and slugs, and, as I know very fair lime can be obtained in many coffee districts, I would recommend a trial of it rather than of salt. My object, however, is to urge that no unnecessary obstacles should be placed against the use of salt for agricultural purposes.

A mixture of 3 parts common salt and 1 part caustic lime would make a capital dressing, and the lime could be added to the salt under the direction of Government officials; and I don't think any fear of subsequent separation of the chloride of sodium need be anticipated.

JOHN HUGHES, F.C.S.

CINNAMON, LIBERIAN COFFEE, AND TEA.

VEYANGODA, 15th February 1886.

The rain we had on two days last week has been followed by bright, cloudless skies—very hot during the day and very cold at night. The rain will enable the peeling of Cinnamon to be carried on till about the end of this month; and but for the showers, I doubt if we could have been peeling at this date. Rain following dry hot weather has brought out a bud on the Cinnamon, which makes peeling rather difficult just now; but if we have a good soaking shower to harden the bud, the freshening up of the wood by the free circulation of sap will render the harvesting of the bark easy.

Alternate rain and sun during the last few months has helped Liberian Coffee to throw out and set a few good blossoms. Just now there is a blossom in spike. But the out-turn of this variety in parchment is disappointing in the extreme. Measuring with boxes, the Arabian variety gave an out-turn of from 60 to 70 per cent

according to measurement. Anyway, I think parchment was never less than 50 per cent of cherry with accurate measurement. The giant variety, which was belated to the skies on its introduction, gives only from 20 to 25 per cent parchment! Happily the prosperity of the Island does not depend on this product, but on tea which flushes freely here, except during the long drought. I look with great apprehension on the future of tea, owing to the recklessness with which all kinds of land are being planted up with any and every plant that will grow. The severe lesson taught with coffee—that vast unbroken expanses of any one product, if they do not induce, yet help in, the spread of insect and fungoid plagues, has already been forgotten. The ruin of coffee estate proprietors was not entirely due to leaf disease, but also to extravagance begotten of prosperity. We have a repetition of it in Tea. Each Estate vies with its neighbour in the erection of mammoth stores with expensive contrivances and every variety of machinery. What with Fairweather's and Gilruth's continuous withering tats where the freshly gathered leaf is laid, and with the Tea, after passing through the various stages of manufacture in as many different and patented machines, coming out at last ready packed for export in Gilruth's patented packers, the Ceylon Planter is only a step behind the ingenious Yankee, who putting a whole pig at one end of a machine receives it at the other in the form of cured ham or bacon. All this extravagance can be indulged in as long as Tea keeps up to present prices. What if to a lessened yield be added low prices? This is a contingency that must be honestly anticipated, for in the history of planting in this Island crises like these have been passed, out of which only the careful have emerged—I cannot say quite unscathed. All this may be denounced as the croaking of a pessimist, but I always err on the side of caution, and look with distrust at a rush to get rich. Two or three years ago when I first had an opportunity of seeing Tea planted largely and an Estate pruned, I expressed doubt publicly of the permanence of Tea, planted as it was on any soil without due consideration being given as to its suitability, and the only rest it had from picking, if rest it can be called, being when the bushes underwent the barbarous treatment called pruning, when it was not possible for them to make any root growth. I see that Mr. Logan, the Assam Tea Planter, who visited the Island recently, gives identically the same warning.—“Examiner.”

[It is easy to preach caution, but each hauds over the lesson to his neighbour. The adoption of good machinery is not extravagance, but true economy. Tea must be pruned or there will be abundant loss but no rush.—Ed.]

THE LANKA PLANTATIONS COMPANY, LIMITED.

REPORT.

To be presented at the Fifth Ordinary General Meeting of the Lanka Plantations Company Limited, to be held by adjournment at the offices of the Company on the 23rd January, 1886, at 12 o'clock at noon.

1. The Directors submit their report for the twelve months ending 30th June last, together with the balance sheet and accounts of the Company made up to that date.

2. They regret that adverse weather has again affected the coffee crop in Ceylon, whilst the continued depression in trade has so depreciated prices that the result of the year's operations, although better than for the year 1883-4, cannot be regarded as satisfactory.

3. The quantity of Coffee shipped home was 5,499 cwt. against an estimate of 6,530 cwt.; and the amounts realised and expected to be realised give a total of £16,366 10s. 2d. The average price of the Company's Coffee during the past year has been 60s. per cwt. while that of the previous year was 61s. 6d. per cwt.

4. The Cinchona Bark harvest has been about 125,011 lbs. (of which 25,637 lb. were sold in Ceylon); the greater part has been realised and the whole is expected to produce £4,873 3s. 10d.

5. In consequence of drought and from other causes the Cocoa has not produced the anticipated results.

6. The plantation of cardamoms has become productive, the first shipment has been received, and in future this article will form part of the annual produce of the Company.

7. The important results to be attained by the cultivation of tea had for a long time past the earnest attention of the Directors. The first plantings having fully answered expectations the acreage has been steadily increased and the Company now has upwards of 1,000 acres of tea planted, of which about 600 acres have become productive, and two shipments have recently been received from Fordyce. These teas are considered by the Company's Brokers to be of good quality and calculated to realize good prices. The Broken Pekoe has been sold at 1s 9d per lb. and the Pekoe at 1s 3d.

8. The following statement shows the present acreage planted with tea:—

Dikoya ..	Fordyce ..	300 acres
" ..	Gonagalla ..	150 "
" ..	Fruit Hill ..	225 "
Haputale ..	Ampittiakande ..	120 "
" ..	Arbhall ..	50 "
Maturata ..	Kilimalle ..	50 "
Uda Pusselawa ..	Rappahannock ..	50 "
Maatal ..	Yattawatte ..	60 "
		1,005 acres

9. The erection of a Tea Factory at Gonagalla and the purchase of the necessary machinery, has involved an outlay which your Directors considered should be made without any loss of time. A Jackson's Roller and a Davidson's Sirocco were purchased and shipped some time since, and it is believed that at this date the Factory has been completed and the machinery fixed and in working order.

10. From all sides evidence is accumulating that Ceylon will produce excellent teas both in quantity and quality. These teas are now sought for in the market immediately on arrival, and are sold at higher prices than those from India or China, and if the present average price is fairly maintained tea cultivation will prove largely remunerative.

11. A further selection of desirable situations for tea planting on the estates is being made and it is hoped that by the end of June there will be an additional 200 acres planted. Care is taken not to interfere with good coffee, but where coffee (as always happens on parts of estates) cannot be profitably cultivated, Tea will be planted, either amongst it or in its place, and it is probable that in this way and by planting up land not suitable for other products the land in Tea will gradually increase to 2,000 acres.

12. The quantity of tea produced per acre varies with situation and soil, on one Estate in Ceylon as high a return as 1,100 lb. per acre has been obtained, but if an average weight per acre of 400 to 500 lb. is obtained, the cultivation at present prices will leave a handsome profit. That Tea properties are highly remunerative is evidenced by the market value of the shares of the Assam, Jorehaut, Darjeering, Lebong and other Tea Companies.

13. Under date of 24th November the general manager writes that the "Tea is flushing grandly" at Fordyce and Fruit Hill (especially the latter) and that "about 800 lb. of green leaf is coming in daily." The completion of Factory and machinery will greatly facilitate the preparation of the Teas and regular shipments may reasonably be expected.

14. Although for some time past the operations of the Company have been constantly attended with more or less anxiety to your Directors, they have now every reason to believe that a great change for the better has taken place in the position and prospects of the Company, and that in the immediate future, it will resume the payment of dividends on its ordinary capital

15. The prospects of the Company are therefore certainly encouraging. The coffee crop for this season may not be large, but as only good coffee is now under cultivation a good return for outlay on upkeep may be expected; the greater part of the tea in Dikoya district will soon be productive; the cocoa on Yattawatte will be bearing more equally, the cinchonas will supply a larger quantity of bark than heretofore, and the cardamoms will add to the Company's revenue.

16. Your Directors deem it right to refer to the fact that of the 2,000 6 cent. £10 Preference Shares 1,100 have been applied for and allotted, and that 900 Shares still remain available for applicants.

17. The Dividends on the Preference Shares already issued have been duly paid out of the profits shown by the Accounts.

18. The Directors propose to deal with the amount remaining at the credit of the Profit and Loss Account by transferring £2,137 2s 4d to the credit of the Dividend Account, by which the sum distributed in 1883 (on an estimate of profit not realised by reason of falling markets, &c.) will be discharged, and to carry forward the balance to the Account 1885-6.

19. The following statement shows the names, acreages, products and cost of the Company's Estates, viz.,

Estates.	Districts.	Average of Coffee.		Average of Tea.		Average of Cardamoms.		Average of Cocoa.		Average of India Rubber.		Average of Patins & Cinchona & Forest.		Total.

The Cinchona on the several estates is estimated by the General Manager at about 1,400,000 trees of various descriptions and (in a recent letter) as covering an aggregate of 56 acres. This estimate is exclusive of Cinchonas planted amongst the coffee.

21. Referring to the notice given of an Extraordinary General Meeting to be on the same day as the adjourned Ordinary General Meeting, your Directors think it right to state, that it has been found that from time to time expenditure becomes necessary, which in their opinion from its nature ought not in fairness to be charged against the profits of the year in which such

outlay has been made, and they therefore recommend the addition to the Articles of Association of a clause, whereby they will be enabled to place such outlay to a special account and spread the payment over a period of years.

22. The proposed new clause has been formed upon and is in principle the same as clause 80 of the Regulations for the management of a Limited Company, given in the first Schedule (Table A) of the Companies' Act, 1862.

23. It is proposed to hold the extraordinary general meeting before the ordinary general meeting in order that the resolution suggested may be passed (if approved) before the accounts and balance sheet are submitted, as these have been framed on the assumption that such resolution will be passed and duly confirmed.

24. The two Directors who on this occasion retire, are Mr. R. P. Harding and Sir H. B. Sandford, and they both being eligible offer themselves for re-election.

25. Mr. John Smith (a Shareholder) the Auditor, also retires and offers himself for re-election.

By Order, Jan. 1886.

WILLIAM BOIS, Secretary.

No. 8, Old Jewry, E.C., 13t

JOHN SMITH, Auditor.

13th January 1886.

TEA GARDENS IN INDIA.

It may sound somewhat strange, but it is asserted as a fact by Mr. Luttmann Johnson in his last report on the Assam Valley districts, that there has never yet been any authoritative definition of a tea garden. In the Kamrup district rayats' patches consisting of only one or two acres, are reckoned as gardens; in other districts a concern worked by one manager with one set of books for accounts and one set of registers for emigration purposes, and only one place for manufacturing, is counted as three or four gardens, because the tea cultivation is not all comprised within one ring fence, but is situated in different patches. Under these circumstances doubts are thrown upon the figures showing the number of gardens worked in 1884, but these show a reduction from the previous year, due chiefly to the lists of gardens having been revised in all the districts except Sibsagar, and tea patches, which are not independent gardens, having been struck off. There were altogether in the district of Goalpara, Kamrup, Darrang, Nowgong, Sibsagar, and Luchhimpur, on the 31st of December 1884, 676 gardens, containing 93,235 acres under mature plants, and 3,432 acres under immature plants, the average area under tea in each garden being 157.7 acres. There were also 360,407 acres of land taken up, but not yet planted. The total outturn from the above districts was 32,987,107 lbs., giving an average of 354 lbs., per acre. This average, however, varies considerably, for many gardens in the Luchhimpur district produce nine and sometimes ten maunds per acre. The Panitola tea garden gave eight and-a-half maunds, and the Doon Doon Company reports eight maunds. In the Sibsagar district four maunds is considered a good outturn, and in Nowgong several gardens produce seven maunds, whilst over a large area the average does not exceed three maunds. The cost of producing a pound of tea up to the moment of its shipment on board the steamer for transport to Calcutta, has been reduced in some concerns to four and a-half and even four annas.—*Englishman*.

PLANTING IN CEYLON AND SOUTHERN INDIA.

TWO OPINIONS ON CEYLON TEA—LANTANA—ODIOUS COMPARISONS—RAIN IN CHOP TIME—CANNON'S MYSORE—HEMILEIA ON COFFEE FRUIT—THE CEYLON CRICKET—GOOD WISHES.

There is a letter by a Mr. J. O. Logan in the 19th of January issue of the *Indian Planters' Gazette* about which I should like to make a few remarks.

First, I must call attention to the great difference between this man's style and tone, and that of the Assam man who wrote in such execrable taste and with such small-pated prejudice to the inquiring citizen of Aberdeen. Of course the latter's remarks were not addressed to Ceylon, nor were they published by his wish; but such lamentable perversions of truth, such venomous acridity towards a struggling colony should be put down. We all know that it is that *esprit de corps*, that "cockiness," that has kept Ceylon through the dark and fiery trials of the past; and those who still have an interest in Ceylon enterprise should not be sorry that the smoking flax is not quenched, that the bruised reed is not entirely broken. One of the first hopeful symptoms of a convalescent is a certain assertiveness of temper and overbearingness of manner.

But over and beyond this view, those who love Ceylon are pained in their hearts at seeing anything like blind folly, or wilful repetition of acts the madness of which have been so apparent. Mr. Logan during his short visit has proved his shrewd

perceptive faculties, though he is rather "out" in many points.

He remarks on "the unnecessary jealousy" between Indian and Ceylon planters. Well I have seen a good deal of that even where tea is not concerned. The fault is not on the Indian side. It is a weakness begotten of insular prejudice. I had it myself, but I trust I have shaken it off. The same class of men engaged in the same pursuits can't be very diverse except through the course and influence of circumstances. Well, in Ceylon financiers had the thick end of the stick and all Ceylon dealings had a stock-broking smell about them. Mr. Logan hits one nail truly when he says "large estimates and expectations have been formed, and if any superintendent falls behind in his yield, someone else will be sent to bring it up, thus everything has been driven at high pressure," &c. This surely is strong confirmation of my remarks in former letters, remarks which were termed severe. Mr. Logan says: "In fact, the planters of Ceylon are hard at work killing their goose." Oh! it is clear to others; yet why will Ceylon shut her eyes to the truth? Drive those Colombo agents into the harbour; provide those Visiting Agents with pensions; burn all those estimate forms and paper logic; and lastly, dear planters, ask the editors of the *Ceylon Observer* to encourage prudence rather than criminal haste, to praise the quiet careful man and be less flattering to the man of statistics and enormous yields whose name is Rutherford.* Mr. Logan says: "Yet they are not without guides in the land," and goes on to refer to Mr. Sparman Armstrong's and Mr. C. A. Hay's cautious advice against forcing young bushes. I put the bulk of the blame on a set of pig-headed V. A.'s.† I heard more unseemly doctrine from the V. A.'s I met than from scores of young intelligent aspirants whose wings were singed by the quarterly contact with a peripatetic financier. The great weakness in Mr. Logan's argument is the very culpable omission he made, viz., to visit the Kelani Valley. Mr. Logan, of course, refers to the self-complacent contemplation of Ceylon figuratively in the looking-glass and literally in her literature when he says: "A remarkable tone of sanguine boastfulness runs through all the literature and much of the conversation about tea."

To sum up my idea of Mr. Logan's letter,—when an expert, trained in and accustomed to certain peculiar conditions of the country of his choice and certain peculiar requirements of the plant of his cultivation,—I say when this expert can visit a country where climatic conditions, vegetable requirements and pecuniary resources are all different, he cannot be a fair judge for or against. Now I have experienced the change I speak of, not as a temporary holiday, but a permanent change, and I have learned to respect both Mysore and Ceylon; and at the same time I have seen weakness on both sides. I have had time to weigh carefully the arguments, and I think anything like scorn or boastfulness betokens deficient knowledge or deficient brains.

I'll tell you a case of that. I had occasion to make a remark on the different view Ceylon usually took of lantana from the view entertained in India, namely, that the former thought it more of a blessing than a curse. This was at a planters' meeting and the remark was published, with the

* This is not fair to Mr. Rutherford, whose statistics, as given some time ago, erred, if at all, on the side of moderation.—Ed.

† What, or as they say in Aberdeen awa, "Fut ails ye at the V. A.'s, dauce bodies and, 'possible as they are?"—Ed.

result that men were so inflamed that they could not confine themselves to good manners, but attacked Ceylon, saying, that they were indebted to Ceylon for expensive cultivation and extravagant waste and they wanted to know what Ceylon could teach them with regard to an abominable pest that had scourged Coorg.

Thus you see, I can look down with calm benign equanimity and hush gently odious comparisons and proud boastings; and I have the pull of the argument as I know the weakness on both sides and can touch these weaknesses at will. It may be, and *is*, a benefit to see ourselves as others see us; but, on the other hand, those "others" know nothing of the inward conflicts and the hardships not visible to them, observe they never so closely. Therefore it is that though the scrutiny and criticism of others is wholesome, yet it is not altogether true and just.

We have had a very unusual experience in this country during crop, in the shape of heavy and prolonged rains. The awful effect of this must be explained to be understood. In the calm cloudless weather which is the normal state of crop-picking everything moves smoothly on. Crop ripens but slowly, and thus labour, machinery, &c., are all arranged accordingly. Also the blue vault of ether is so watertight that nothing is required, but covering from the silent forming dew. There are no palatial stores. Really those prize essays read very ludicrous after one has been in a country where money is not easily obtained and proverbially easily spent. A planter goes as far as his purse (his *own* purse, his pure and simple resources) allows him. Therefore as no rain is expected what's the good of buildings? A shed over the cherry and that is all the roofing. Everything else *al fresco*. A Ceylon man would be ashamed of this. The V. A. would indignantly demand the meaning of such shabbiness! Well, just think of the effect of heavy and prolonged rain. I shall leave it to your imagination stimulated by experience in days of old.

Crops are good, but it is the Coorg plant that is pulling men through, except on the Babu Boodan Hills where "Cannon's Mysore" is raised or on Santawarry; the old Mysore coffee, brought by Babu Boodan the ancient pilgrim, has been sapped by leaf-disease. Why? You see *berries* mottled and discoloured, unsweetened and blighted by the fungus. Mr. Marshal Ward said the spores entered the "wide open door" of the stomata and fed on the food-cells and thus caused damage. But where are the stomata or the cherry? * Mr. Ward went a good deal farther than Morris, but he only scratched the surface of a mystery, the importance of which Dr. Thwaites felt if he did not clearly see. Had it not been for cinchona and now tea, his prophecy of the coming "howling wilderness" came very near fulfilment. In Ceylon leaf-disease came just in time to spoil the blossom with a grand show of spores, not to speak of a chronic, prolific, sporific state of disease which your moist climate never checked. When cultivation in the open prevented the osmotic action painfully dwelt upon by that victim of a restless brain, Monsieur Montclair. His exosmosis and endosmosis sickened the reader, and the struggles with a foreign tongue finished him. Osmotic action is a great fact here, but you, in Ceylon, do not depend on it, as Nature is liberally supplied with moisture. Here during the comparatively rainless period between November and May, osmotic action (*i.e.* nocturnal and diurnal absorption of moisture

alternately) equalizes matters, and this is the great secret and reason in *shade*. If you want to realize that, step from a dusty road in Dumbara under an umbrageous *jak*. I wonder how the Dumbara men are liking their *rubber shade*. They will have to leave cacao for rubber and that will give fine scope to a man who likes new buildings, machinery, and novelty of all kinds.*

Strange to say you hardly see the fungus on Coorg coffee berries, and almost none of that discoloration. On an estate composed partly of Mysore coffee (like the old coffee near Oodoowelle store, Hantane, which I saw lately being rooted out), umbrella-like and irregular; and Coorg coffee, sappy, regular and vigorous like a Badulla new clearing in days gone by; on an estate composed of these the picking is ticklish owing to the quickness of ripening peculiar to the Mysore variety. The two kinds are very different but the old and weak kind produces plums that have made "Cannon's Mysore" famous. They advertise "Cannon's" in London. Some of you must have seen placards in London referring to that famous brand. Well, with cheap labour and fair crops average prices for all sorts of that brand are remunerative and something more at 100 shillings. It struck me as strange hearing planters young and old here talking about *colour*, comparing *prices*, as if their *treatment* of the coffee had much to do with it. I remember when a Ceylon paid manager was particular about his *parclement*; and after the carts moved stoutly off, he lost sight and sound of it unless he happened to see in the papers the familiar name of the estate and so many *tierces* of coffee. There was a delicious mystery about a "tierce." My idea was that local brokers and buyers knew what brands gave good coffee and what brands did not; but it is new to me to be told that *parclement* may be clean and yet the *colour* affected. One man tones his coffee and hope he likes the tunc. Then they never send a sample sealed bag down; nor do they think of sending samples by post, and yet they think they can adjust the tone and fix the colour on the estate. Then the rates by the curers are awful. There is room for that competitive energy so lately displayed in your advertisement columns by your enterprising coffee curers.

ABERDEENSHIRE.

CEYLON UPCOUNTRY PLANTING REPORT.

1st March 1886.

PROSPECTS OF CACAO—TROUBLES NEVER COME SINGLY—SHADE FOR CACAO—NEED OF NEW MARKETS FOR CEYLON TEAS—RUBBISH SOLD IN LONDON AS CEYLON TEA—AN OPENING IN RUSSIA WANTED—A PLANTER WITH THE TRADING TALENT.

Our skittish product cacao, which last year, owing to the drought, rendered many all but hopeless as to its ultimate success, has improved in behaviour and is promising still better. It is all owing to the rains, say the wise ones, and, given a normal season with a fairly distributed rainfall, there is, they maintain, a considerable quantity of "ile" for those who have the courage to persevere with its cultivation, and who have the suitable soil and surroundings for its growth. As far as I can learn, there is a fair crop being gathered now, and the promise for the next half-year is unusually good. The trees are vigorous; the pods are healthy; and as to the insect plagues which fret and worry the cacao, they are fewer in number and less destructive in their attacks. Those who know say, that the years when the

* We asked Dr. Trimen, and he said "The whole surface of the cherry is covered with stomata"—Ed.

* We do not pretend to know what is meant, but we do not like the tone of the remark.—Ed.

helopeltis and "thrips" are worst are always those seasons when things are out of joint.

On the principle that troubles never come singly, these entomological trials invariably follow in the wake of a parching season. When the trees can least stand it then they visit them in Hordes, and drive the planter almost to despair. As he looks upon his leafless trees the thoughtful cultivator may perchance discover—after a weary questioning of "Why?" and "Wherefore?"—that there is some hidden reason in it after all. For the sake of the puzzled I would humbly put forward one reason which has occurred to me, and which at least contains some truth. It is, that these plagues may have been sent for a refining purpose—to refine the dross, and purge away the "tin." No one will dispute their ability to do the latter, whatever else they may think.

Shade, which has been so much sought after for cacao, and for want of which much of the evil effects more truly traceable to drought was attributed, does not seem after all to be quite universally accepted as the one thing needful. No doubt the general idea is that without it you can do nothing, but still there are men of experience who object and say that even with it you will not do much better. Heavy crops are not to be had under shade, they maintain, and if you want to get this you must risk cultivating in the open. But I begin to fear that heavy crops in connection with cacao are, like many other things in Ceylon, a kind of delusion. Still a moderate crop of cacao pays well. I heard of one place which last year gave a cwt. and a half all round, and which, small as it may seem, nevertheless left a decent profit. We have a lot to learn yet about the cultivation of cacao. Mean while the numerous experiments which are being so generally made in regard to the tree most suitable for shade cannot but result in benefit of some kind.

The need of opening new markets for Ceylon teas has stimulated almost everyone who has anything to do with it to an effort of some kind or another. Those who in a humble way have tried to develop among their friends and acquaintances a taste for the pure unadulterated article have had pretty much the one experience. They have been told that it is just the thing for mixing with about three-quarters China, but unmixed the flavour somehow does not take at first. A friend of mine who had acquired the taste for the genuine article while staying in Ceylon has been amusing himself since his return to London in testing the stuff which is sold retail as pure Ceylon tea. A sorry compound it turns out in many cases, and no wonder when you can get pekoe for eighteenpence a pound! He has been speculating as to how it is done, and when he remembers that it is not a very high-class tea which can be bought retail here for a rupee a pound, he concludes that the drawing qualities which rendered the teas which he tasted regular nerve-setters must be got from mixing largely with cinchona twig! If it is not this it is something else more foreign to Ceylon.

I hear that an effort is about to be made to get an opening in the Russian markets for our teas, by means of the Black Sea ports. If it can be managed it will be well, for we all know how the "samovar" and the boiling cup of tea is a universal institution throughout all Russian territory. Russia used to be a good market for some of the produce of the Indian tea gardens, but of late the trade has been throttled through Moscovite jealousy and prohibitive duties. Whether Russia in Europe will act in the same

way toward our teas, as Russia in Asia has done towards the Indian, remains to be seen; but anyhow the offer of the Ceylon article is to be made, and under favourable auspices.

It is a universal belief among the planters of Ceylon that the storekeeper can always manage to hold his own. Merchant houses come to grief; banks stop payment; planters work hard, bury their coin in the hope of a glorious resurrection, are disappointed, and get gazetted; but the storekeeper is like the brook and goes on for ever. The exceptions to the rule are not worth mentioning and do not disturb anyone, least of all his successful brother. It is with pride therefore that I heard the other day of a planter who has developed in an eminent degree the trader's talent of holding his own. It seems he bought a pulper six or seven years ago, and during the last crop one of the bolts gave way which cost him Rs450 to replace. The bill for this he sends down to the maker of the pulper with the request that his account should be credited with the amount, as it is evident the bolt can't have been a good one at the first! To be able to found a claim upon so little, and hold on to it, deserves a reward, and although I believe he was unsuccessful in his application still his extraordinary talent for trying it on has so impressed his trading friends that they were thinking of offering him a partnership right off. They are sure he would be able to "run" a store with the best of them.

PEPPERCORN.

NEW ZEALAND FLAX.—Attention is directed in the *Therapeutic Gazette* (May, p. 321) to the vulnery properties of the New Zealand flax, *Phormium tenax*. It is used in the form of a strong decoction of the roots and bases of the leaves. The liquid is syringed into wounds and then applied on lint. The decoction requires to be made fresh every day.—*Pharmaceutical Journal*.

FIFTEEN SAMPLES OF BRAZILIAN COFFEE, from the International Horticultural Exhibition held in St. Petersburg last year, analysed by different students in the Pharmaceutische Institut, at Dorpat, working under the superintendence of Professor Drugendorff, appear to have yielded results varying within narrow limits. (*Pharm. Zeit. f. Russl.*, xxiv., 116). The caffeine ranged from 0.99 to 1.22 per cent; tannin, 5.16 to 7.6 per cent; albuminoids, 19.86 to 24.78 per cent; fixed oil, 13.5 to 16.48 per cent; and ash, 2.92 to 4.24 per cent, in which the phosphoric acid varied from 0.280 to 0.490 per cent. Professor Drugendorff considers that these results show that as food material Brazilian coffees do not fall behind other kinds; but there seems to be some doubt as to the aroma. The volatile oil observed was in too minute quantities to allow of investigation; but in some instances, and especially in the case of the inferior samples, it had an odour peculiar to Brazilian coffee.—*Pharmaceutical Journal*.

KOLA.—M. Heckel whose researches on the alkaloïds of the kola nut are so well known, has recently called the attention of the Academy of Sciences of Paris (*Comptes Rendus*, c., p. 1238) to the importance of the Shea butter tree (*Butyrospermum Parkii*) as a source of guttapercha. The milky juice of the trunk when solidified has, he states, all the appearance and properties of guttapercha. If this statement be correct, it must differ considerably from the "gutta shea" separated by English chemists from the Shea butter, this being friable and wanting in tenacity. A further communication is promised, giving the physical properties and chemical composition of this gutta. M. Heckel states that the tree can be tapped when four years old and that it grows readily in argillaceous-siliceous and ferruginous soils, and is found over a large extent of country. He also suggests that the *Bassia* trees of India should be examined with respect to the character of the milky juice they contain.—*Pharmaceutical Journal*.

CASTOR-OIL PLANTS.—It is singular that the oil expressed from the seeds of the castor-oil plant should have been used by the ancients, including the Jews, as one of their pleasantest oils for burning, and for several domestic uses, though its medicinal virtues were unknown. The modern Jews use this oil by the name of oil of kiki for their Sabbath lamps, it being one of the five kinds of oil their traditions allow them to burn on such occasions.—*Indian Gardener.*

ADULTERATED QUININE.—Some little excitement seems to have been aroused among the druggists of New York in consequence of three of their number having been charged by the public analyst with selling defective sulphate of quinine. It appears that the public analyst had reported that one of the impugned samples contained 86.14 per cent of anhydrous quinine sulphate; but as the United States Pharmacopœia only requires that the yield of anhydrous salt shall amount to 83.8 per cent, there was in this case an excess of anhydrous quinine sulphate amounting to 2.34 per cent. The other portion of the sample, however, instead of consisting entirely of water of crystallization was reported to have included between 4 and 5 per cent of other cinchona alkaloids, and on this account a prosecution of the seller was ordered by the Board of Health. Another druggist is reported to have had his name published as selling two grain pills which were deficient in quinine sulphate by one-hundredth of a grain, though in this case no other steps were taken.—*Pharmaceutical Journal.*

THE "YOPON" (*Ilex Cassine*, L.) is a shrub met with in the Southern States of America, where its leaves are occasionally used as a "tea." Formerly it was employed by the Indians in the preparation of a "black drink," and, according to Hale, at a certain time of the year they used to come down in droves from great distances to the coast south of Virginia for the purpose of drinking it. Large quantities of the leaves were thrown into a great kettle of water suspended over a fire, and the Indians sitting round helped themselves to large draughts, which after a short time induced free and easy vomiting. This treatment was continued during two or three days, until it was considered that a sufficient cleansing had been effected. Some of these leaves have been submitted to a chemical examination by Dr. Venable, who reports (*Journ. Amer. Chem. Soc.*, April, p. 100) that he obtained from them a small quantity of caffeine, equalling 27 per cent of the weight of leaves used. It will be remembered that caffeine has also been found in "mate" (*Ilex Paraguaysensis*), used in South America as a beverage.—*Pharmaceutical Journal.*

FIGS.—This is a favourite and generally distributed fruit in the Argentine Republic, and it is indigenous. It thrives everywhere, and gives the best results, especially in the regions bordering on the Parana River. The tree exhibits a wonderful development, reaching to a height of twenty to forty feet, with a massive trunk sometimes two feet in diameter. In the provinces of San Juan, Rioja, and Catamarca the crop attains to large proportions and considerable quantities are dried, producing the figs of commerce (*pasas de hijas*), which find a ready sale all through the interior of the country. While the provinces bordering on the Parana produce the fruit abundantly, no movement has ever been made to dry it, the people being content to consume the figs while fresh, though it is an industry which must sooner or later be developed. There are two kinds of figs grown in the Republic—the white, which are properly called *figs*; and the violet or purple coloured, which are called *brevas*. The first ripen in January, and are of a large size and better flavour than the latter. This second kind produces two crops per annum—one in December, and the other in March or April. Being thus much more prolific, they are more generally grown, though they are not so suitable for drying. The fig is not cultivated at all, but, in spite of the excellent climate, it is left entirely to nature. With so much in its favour the crop

might be made a most valuable one, and a most lucrative branch of foreign commerce, though at present, instead of being exported, nearly two-thirds of the dried figs used in the country are still imported from Europe.—*Indian Planters' Gazette.*

YAMS.—A correspondent wrote a few days ago:—"I am directed by Mr. Geo. Poulter, the lessee of Naivalla estate, Veyangoda (belonging to the late Mr. Jas. Alwis), to send you the accompanying parcel of yams which within the last 2 years he has commenced cultivating, finding same very easily grown and a profitable experiment if once introduced into the market. They are called 'cush-cush,' and his original stock of bulbs, bought at Whyte's store, Kandy, cost him Rs. He has a good many ewt. to spare for sale, this crop, I am given to understand, and if he could realize 6c per lb. weight, he tells me it will be a profitable speculation. I have eaten them myself, and have sent them to a few European acquaintances, and all who have tasted them have pronounced them really fine. Mr. Lamont has seen some (out of Veyangoda stock) grown close to Eilandhi at Henaratgoda and means to cultivate them himself; I have promised him some bulbs. I would suggest your steaming them and not boiling (after peeling) and will be glad to know what you think of them. I have tasted a good many varieties of Ceylon yams in my day but have never seen these excelled. I believe they are an importation from the West Indies, and I have heard it stated that Sir Jas. Longden was instrumental in getting them out. The specimen yams sent to us are about the size of potatoes and of the same purple colour as the large yams we remember as being so highly prized in Jaffna." We had some of them cooked as indicated, and we can bear cordial testimony to their excellence, as substitutes for potatoes. They are less glutinous than breadfruits and less saccharine than sweet potatoes, more farinaceous than either, very palatable eaten like potatoes, and delicious with a little butter added to them.

BRITISH BURMAH AND RICE.—The last Administration Report of British Burmah tells us that nearly ninety per cent (88) of the cultivated area in the province, is under paddy, the cultivation increasing steadily by more than 100,000 acres a year. Out of the 4,000,000 acres under tillage, 232,428 acres are fruit and vegetable gardens. "This kind of agriculture pays well, and that a ready market exists for all orchard and garden produce goes to support the view that the people of British Burmah are well off, and live comfortably." We have frequently pointed out that the calculations of our settlement officers are constantly vitiated by their uniform failure to take any account of the garden, fruit, and dairy produce of the ryot's holding. Whenever these holdings are in the neighbourhood of the cities which are growing up all over India, these items form a most valuable part of the produce, as we here read they do in Burmah. The report tells us that in most parts of the province, the land revenue amounts "to from one-twelfth to one-tenth of the value of the gross produce, and good markets are available directly the rice crop is harvested." The exports from the province are about £9,000,000 sterling a year, the chief items being:—

	£
Rice (paddy)	5,500,000
Cutch and Gambier	370,000
Hides	160,000
Timber	1,600,000
Cotton	200,000

The gross land revenue is about £670,000 a year, but the addition thereto of a capitation tax of £300,000 a year, brings the assessments up to nearly £1,000,000 sterling. The general result is that the land bears an assessment of about two rupees and a-half per acre, the State thus exacting a larger payment from the cultivator, than the so-called rack-rent levied by the zemindar in these provinces under the Permanent Settlement.—*Indian Agriculturist.*

Correspondence.

To the Editor of the "Ceylon Observer."

PROPORTIONS OF SORTS OF TEA.

19th February 1886.

DEAR SIR,—Your "overland" of 16th contains Colombo Brokers' reports of local tea sales; amongst others that of Messrs. Wilson & Co. with notes re "Blackstone" invoice, "which was sold privately, and realized many cents per lb. above any previous parcel sold locally by public auction, which contained the four grades with the same proportions." (The italics are mine.)

It would be interesting to know what price per lb. Mr. Wilson secured for overwhelming percentage of Pekoe Souchong and Broken Tea.—Yours faithfully,
TEA MARKER.

BLACKSTONE AND AGAR'S LAND TEAS.

Kandy, 19th Feb. 1886.

SIR,—Messrs. Wilson & Co. state in their "Tea Memorandum," February 16th, that "an excellent invoice from Blackstone estate withdrawn from public sale, was sold privately, and realised many cents per lb. above any previous parcel sold locally by public auction which contained all the four grades with the same proportion."

The last four words I have italicized, as therein evidently lies an awful lot for consideration. Will Messrs. W. & Co. favor the public with particulars a little more explicit? I ask the question, as it appears to me a pity that such a "crack" tea sale should be put under a bushel, as also that my own mind may be made easy on the score of top prices.

When in Colombo, I heard a great deal said about this wonderful break of "Blackstone" tea. That it had been bought in at R1-70 per lb. That it had been valued so low as 91 cents per lb. That it had eventually been sold to Messrs. W. M. Smith & Co. at R1-20 per lb.

If the latter story be true, I scarcely think Messrs. Wilson & Co. are justified in claiming first place for "Blackstone" locally; seeing that "Agar's Land" averaged R1-25 for 3,610 lb. of an "all round break," sold at public auction by the well-known firm of Messrs. Forbes & Walker.

I am of opinion that friendly competition and rivalry will do all tea producers good, and peradventure may be the means of attracting buyers from afar, thus giving an occasional "fillip" to the local trade.

I hope the next break "Blackstone" sends to our local market may find a bona fide purchaser in the public sale room; and it might interest and induce buyers to dip their hands more deeply into the orthodox breeches pocket, if the article put before them was knocked down at a reasonable figure, I shall probably put a break of "Agar's Land" tea on for sale in the course of a fortnight, 3,000 lb. or so, and it will give me pleasure to see "Blackstone" again in the field.—Yours faithfully,
SHELTON AGAR.

DANGER OF TEA PLANTING BEING OVERDONE.

DEAR SIR,—It is no news to you, I daresay, to say that people at home—in London as well as elsewhere—are now aware that tea is being grown in Ceylon. They are aware, too, that most of the tea is of very good quality, and that even Mincing Lane at length believes in Ceylon, and is disposed to pat it on the back in a most kindly and motherly way. Nobody outside of Mincing Lane needs now

to say a good word for it. That is what some of us had to do a few years ago and a few times over; but it is all changed now. Everybody drinks or wishes to drink Ceylon tea now; and everybody, or let us say nearly everybody, is ready to go shares with you in a tea estate, if you only will let him. Well, I for one am very glad and thankful that it is so and that we are all going to be so happy and jolly again. And yet one sometimes thinks. One sometimes thinks just for a moment perhaps, it makes no impression—that perhaps we in Ceylon, with our Scotch dourness and our English pluck, and our general combativeness and determination not to be beat by anybody or anything—that we may perhaps just a little overdo the thing once more.

Now I know, Mr. Editor, that you think you know the very words I'm going to say next, and that these words are: "My brethren, suffer a word of exhortation"; but it is n't so, I assure you. I'm not a licensed hand, and therefore cannot preach; and, though laymen are allowed to exhort, I have no idea even of exhorting.

I had some talk with an intelligent East India merchant, the other day, and I thought you might like to hear something of it. He is directly interested in Indian tea, and finds at present that his investment in that line pays him very well. But he questioned me about Ceylon tea, of which he said he had been hearing a good deal. I gave him the best and latest information I could give at the moment, and told him that the last estimate I had seen was that by this time there were about 100,000 acres under tea in all Ceylon. "One hundred thousand acres!" he said, and was amazed. And I confess that I was somewhat "scared by the sound myself had made." For I remembered that when in Ceylon in the early part of 1884, the answer that was given to my enquiry was that about 12,000 acres were then under tea; and to leap from 12,000 to 100,000 in some 18 or 20 months was rather a big jump. But what was I that I should gainsay the *Observer*? The chronicles of the tea bushes, are they not all written in that nice little pocket volume, the *CEYLON HANDBOOK AND DIRECTORY*? and don't I find in its very latest edition, which has not yet come to hand, that the "total approximate extent under tea" is set down at exactly 101,695 acres? But at any rate I was so "scared" by my friend's remarks (he reminded me that 100,000 acres meant 40 millions of pounds weight) that I promised to see the *Observer*, and verify my figures, and the result was that I wrote confirming my statement and giving the total as above—101,695 acres. Next day I had the following reply:—"I am much obliged to you for looking into the matter and writing to confirm the figures you had previously given me as to tea cultivation in Ceylon. If 101,695 acres be the area already under plant, however young, and not simply the aggregate area of the estates which are being devoted to tea of which only a portion (probably about a half, say) is already planted, I confess that I should take a very grave view of the *specie* that awaits the enterprize in all quarters say in 3 to 5 years. And yet I fancy the *planted* area is really meant."

I had more to say, but I write at the close of my mailday correspondence, and the time is just about up. But here is a cutting giving the greater part of an article from the *Statist*. You may have it otherwise; if not, you will like to see it.—With kind regards,
A CORRESPONDENT.

The new tea season, 1885-86, has opened, in the opinion of the *Statist*, under much more hopeful auspices than did last year—stocks are down one-half, consumption is on the increase, and the only element of disturbance to an immediate rise is the uncertainty

as to future supplies. It is becoming more evident every day that the capacities of tea-growing countries have not yet been adequately tested. Fresh capital, it appears, is being poured into Assam, where there is a practically unlimited field for its absorption. If we annex Upper Burma, and give free scope to Anglo-Indian enterprise in that direction, tea gardens may soon be heard of there which will press the Chinese harder even than those of Assam. Then Ceylon in the tea market of the future is going to be a very important factor. Growers of Ceylon tea say they can deliver it in London at 6d per lb., or little more than half the minimum cost of Assam tea. It grows indifferently over all the hillsides, and when the young gardens come into full bearing it may be supplied without stint. The crop of the current season is expected to reach 3,000,000 lb., or fully 10 per cent of the whole production of Indian tea, and the planters predict that they will be easily able to double the quantity next year, and three years hence they hope to have their export up to 20,000,000 lb. Then as respects the Indian tea companies their financial position is thus stated. With the best known appliances and the most careful management they can grow tea at a minimum of 10d per lb. In such a season as 1884-85 that would yield very little profit on medium crops, while on inferior sorts it might mean an actual loss. But on all teas commanding 1s per lb. or over it represents a substantial profit. Takiog Souchongs as a standard they have been selling during the past week at 9d to 10d for low grades and from 11d to 12d for fair to medium. As times go, this, though not a brilliant, is a sound, healthy market for the producer. All the indications point also to continued strength, if not to a further rise. There is certainly some temptation to bold operators to lay hold of the market and try to twist it up. Such an incident may develop almost any day, and the fact that it has not yet shown itself betokens risks lying below the surface and visible only to the initiated eye. One of these risks may be the vagueness of information as to the new sources of supply that threaten the market. Not only Ceylon, but Java, Brazil, Florida, and even Natal are all coming competitors to be prepared for. Should tea growing take firm root in all these places the marketable supply might in a very short time exhibit a startling increase, for it requires only three or four years to bring a tea-garden into bearing.

SPIKES IN COCONUT TREES.

Str.—My sympathies are with "X. Y. Z." who writes on "Iron Spikes in Coconut Trees" in your issue of the 18th inst. I am willing to allow that the spikes might do harm to the trees if put in too close and too deep, but like every other experiment, this must be proved by trying the effect upon one tree. I know nothing about the legality, or otherwise, of such action as a precaution against thieves, but it seems monstrous to suppose that it is illegal for a man to put spikes in his own trees if he wishes to. Every garden-wall in the old country has broken glass, or nails with the points upwards, stuck along the top in the mortar, and who has not seen iron spikes pointing upwards, and downwards too, along similar barriers? Whether you are right in stating that spring-guns are illegal I cannot say; but this I know, that, when a boy, I often turned away from a blackbird's nest with a sigh of regret and one last wistful glance at the spinnery in which I had seen the square board upon the tree with the terrifying announcement in capitals "Beware of man-traps and spring-guns." That the former were there a quarter of a century ago is undoubted, because I saw them. But thieves are not so kindly used in England as here; and I do not believe there is a country in the world where so much discouragement is given to honest thrift as in Ceylon. No sooner does a man by his industry possess a plot of coconut palms, of coffee, or of anything else, than he is assailed by thieves who steal the fruit of his labors, and by cattle which destroy and trample upon trees which he

has been at so much expense and trouble to raise. I say nothing about insect pests, or low market prices, after this; but I do say that severity instead of loving kindness should be shown to STEALERS OF PRODUCE.

KAINIT AND SALT IN AGRICULTURE.

27th February 1886.

DEAR SIR,—With reference to your article on Mr. Hughes' very valuable letter, and your supposition that kainit would be more largely used as a manure "if Government did not interfere with the import of kainit," owing to its containing 50 per cent of common salt, I beg to say that it has been imported into the island, and I believe without Government interference. I used it largely in compost heaps of ravine stuff and fish. I believe it was in the January number of the *Tropical Agriculturist* that a very interesting extract on kainit as a manure appeared. In Sabonadière's "Coffee Planter" an analysis of this "German Potash Salt" by Voelcker is given:—

Moisture	3.36
Water of combination	10.88
* Sulphate of potash	21.43
" lime	2.72
" magnesia	13.22
Chloride of magnesium	14.33
" sodium	30.35
Insoluble silicious matter	0.71
	100.00

I agree with Mr. Hughes, that, if salt is mixed with any substance offensive in smell, no one would go to the trouble of obtaining the pure salt from the mixture by solution and evaporation, and use it as an article of diet afterwards. Instead of Government going to the expense of destroying surplus salt, it will be true economy to sell it to agriculturists with a written guarantee that it will be used for agricultural purposes, after mixture with some offensive substance of course.—Truly yours, A. W. B.

CEYLON CACAO.—Messrs. J. P. William & Bros. of Henaragoda write:—"We send you by this post a sample of prepared cocoa for the market from Trinidad cocoa trees specially selected and sent by Mr. Morris (now Assistant Director, Kew Gardens) for your inspection. Messrs. Somerville & Co. have valued this cocoa for R52 to R55 per cwt. at Colombo remarking: 'It is very fine and there is a special demand for cocoa of this colour.' The beans are of a very fine color and delicate odour. They can be seen at our office.

PHYLLOXERA IN NEW SOUTH WALES.—Experts have given their opinion that the scourge of the grape vine, *phylloxera vastatrix*, is to be seen in the vineyards of Camden "beyond dispute." Its appearance is attributable to the loose administration of the Act relating to the importation of vine cuttings, and to the vines in Camden being sadly neglected. What will strike many of our readers with surprise is that this dread pest is said to be largely owing to the prevalence of the Isabella vine in that locality, and that the vine is "well-known to be a favourite with the insect referred to." The threatened rabbit invasion from the sister colony is an evil of no small magnitude, and now here is another evil not to be despised or neglected. So far as we know *phylloxera* has never been seen in Queensland; and it behoves our statesmen and every individual colonist to be up his arms against this insidious foe. A little, and a very little, negligence will suffice to land this curse to the vine-grower in our midst.—*Queensland Agriculturist*.

* Containing potash 13.20.

TEA PLANTING AS A CAREER.

(From the "Field.")

No doubt casual visitors to Assam during the winter months, seeing planting life under the most favourable auspices, are apt to take the optimistic view of matters; hence, on their return home, in relating what they have seen, they unwittingly mislead the younger members of their acquaintance by glowing accounts of the jovial life led by the planting community. Though I would not deter anyone from visiting Assam with the idea of engaging in commercial vocations therein, it is as well to place before those whose thoughts turn in that direction the evidence gained by a twenty years' residence, and subsequent visits to the scenes of one's early labours in search of a competency; for I presume that, now tea has found its level, none possessing the slightest acquaintance with the industry will dream of realising the large fortunes acquired by those early speculators who were first in the field some five and twenty years since. But I would earnestly counsel anyone who thinks of planting, before deciding finally, to spend one entire year among the plantations, to judge for himself as to his business capacity and physical capability. Planters are but only too glad of the chance of entertaining strangers, and willingly afford all information; while knocking about in the rains and hot weather will sufficiently test one's stamina, although the climate—if ordinary prudence and care in living be adhered to—is suitable to most Europeans of average health and constitution. The cost of a year's visit will be amply covered by £150, plus the expense of the journey and outfit; the latter had better be obtained in India, or from one of the firms in London accustomed to provide purely Indian requirements. Flannel should form the whole of the clothing both by day and night; boots, shoes, and saddlery being procured in Calcutta. The best time to reach the gardens is the beginning of November, as the rains are then over, the country easily traversable for ponies, and, as a rule, manufacture has ceased, and the most enjoyable weather for fully four months has set in.

An impression prevails that all the land suitable for tea in the southern province of Assam has been taken up; but nothing can be further from the truth. True, the most eligible sites as to communication with the main rivers have been secured, but there are still thousands of acres available, though such are situated veritably in the backwoods; but, from the rapidity with which the establishment of a tea plantation, even in the remotest corner of the district, tends to open it up by attracting settlers to the low lands suitable for rice in the vicinity, either on the grant or waste lands adjoining, Bengali or Manipoorie homesteads quickly spring up, and, before the plantation is in bearing, the approach to it lies through civilised cultivation.

The earliest tea plantations in the Surma Valley were formed on the amphitheatre of low hills that lie north of the station of Sylhet; and a visit to them will at once show the novice one of the greatest mistakes of the early planters. These hills, steep, and in places of conical formation, are mere heaps of soft sandstone, covered, very superficially, with a deposit of vegetable mould formed from the droppings, for ages, from the light forest with which they were originally covered. The pioneers looked more to site than soil, and, as the gardens here were opened for speculation, the operators had no need to trouble themselves as to the future. I suppose at least two thousand acres upon this particular range of hills, that for a couple of years presented a handsome vista of thriving tea plants, have had to be thrown up; the friable nature of the soil when disturbed by being causing wash to such an extent that the plants, what was left of them, soon retained the hold of the ground merely by the long tap roots, yielding less and less as years went on, until they ceased to give sufficient to pay for the upkeep. The more recent plantings have been properly terraced—the terrace sloping inward—and now the remaining portion of this land, even in the most

precipitous part of the range, can be brought under cultivation and profitably worked; moreover, the flat space occupied by the plant admits of deep cultivation by pick. Hence these once despised Sylhet "teelands" will yield a profitable return for many years to come, and mayhap, when the iron horse runs Lower through the Surma Valley, and throws sufficient more be labour into the country from over-populated Bengal, the abandoned bare slopes may once be replanted.

A well-terraced tea plantation, when the line has been properly kept, presents an exceedingly pretty sight, although just at this season of the year, when nearly every bush has been denuded of almost all its leaves in the process of severe pruning, the few that remain being scarcely visible from the dust deposited upon them in the course of the deep hoeing, the sight resembles long lines of well opened birch brooms than aught else. But as the visitor proceeds eastward the diversity of land brought under tea is most remarkable. Here, in the neighbourhood of the Lohak river, we have a profitable garden planted on hummocks of boulders, portions of which ground are so strong that cultivation by pickaxe has to be resorted to; and yet the yield of made tea averages upon such apparently unpromising soil nearly four maunds of 320 lb. per acre, that is 1,280 lb. of green leaf, of merely the first four to five leaves of the new shoots; the secret of this outturn lying in the fact that these hills are deeply impregnated with fine particles of lime stone. The Jaintia gardens, again, lie so low on flat land that half a dozen times during the year the bushes are for hours eaten and ten feet under water, which, coming down from the hills, flowing over miles of limestone formation in its progress, not only fertilises the soil, but eliminates for the time being those pests of the planter, blister blight and red spider, the bushes taking no harm from the prolonged submergence. The area of low-lying land brought under of late years has greatly increased, and, though errors of judgment have occasionally been made, and land planted that subsequently proved to be low altogether, and the suitable ground has been selected and efficiently drained, there is little doubt that low flats yield more prolifically than any other, and gardens have been formed upon ground that, previous to drainage, took one up to the knees, even after the moderate amount of rain that falls in a March storm. I have seen land so damp and spongy as to swim with land crabs, and a year after rendered so firm by drainage that it was rideable throughout the rainy season. To see the remarkable fertilising effect of lime impregnated water, it is merely necessary to visit the orange groves of Shella, near Chittag, in the Sylhet district. The trees here are twenty feet in height, and they disappear pretty often under water, yet the average yield is 200 fruit per tree per annum, and neither pruning or cultivation of any description is resorted to. But to resume. Some gardens are planted in soil that is little better than clayey slate (shale); others, again, notably the Coocheia plantation, in the open Hylakandy Valley, consists of a heap of lava which, ancient though it be, still affords sufficient nourishment to give a profitable return. Again, plantations have been established upon reefs of gravel drifts, and though the plants look, upon these latter sites, very unpromising for the first two years, after that period they develop in the most wonderful manner. It will thus be seen that the plant thrives, and profitably too, in all the diversified soil of the southern district of Assam, but the nearer the intending planter can get to the lime formation on the northern side of the country the better, as, even if his land itself does not contain the mineral, he can obtain the fertiliser if need be.

The duties of a planter in the cold weather are both manifold and onerous, although, from being carried on without the discomforts incident to the rainy season, his troubles and perplexities are not so much apparent. Presuming that his last batch of tea has been despatched, his first and most important consideration is the retention of his labour force for the ensuing season; and when one has to deal (as is the case on a moderately large factory)

with several hundred people, who about this time are smitten with nomadic tendencies—for coolies (unless imported at great expense from Calcutta) engaged in the district sign agreements only from year to year—the matter of re-engaging them requires much tact and judgment. The bounty, or *bonus* as it is called, varies from 10 to 20 rupees, and as this money has generally to be paid in advance, the risk is considerable. If the recipients are steady-going folk, and own, as most old coolies do, half a dozen cattle and as many children, the advance is pretty safe; but there is always a certain proportion of a roving disposition, unburdened with domestic care, and who are averse to saddling themselves with flocks and herds. Again, with a certain class of coolies, chiefly those from the N. W. provinces, marriage is merely an agreement between the parties for a year, terminable by mutual consent, so that the disruption of domestic ties leaves each at liberty to levant with the advance and exercise "bounty jumping" upon some other factory, so that, after paying away four or five thousand rupees in bonus, the planter, next day at muster, may find forty or fifty people missing, and though, when caught, the delinquents are punished and sent back to work out their agreement, the expense and anxiety of recovering the runaways is considerable, and, although all planters, for mutual benefit, behave as loyally as possible, it is extremely difficult, when a batch of people present themselves, to tell whether they are deserters or not. Occasionally a planter, eager to secure one of these nomadic gangs, binds them down and pays the bonus, to find out that they have already signed articles elsewhere, in which case both men and money are lost, for the cash is rapidly consigned to some safe quarter, and prosecution is time and money thrown away. An inexperienced individual, commencing planting on his own account, is particularly liable to suffer in this way, and start with a loss of perhaps £100 to commence with.

As soon as the plants show indications that the sap has run down, pruning has to be commenced; and when it is remembered that an acre of ground contains 2,722 plants, that the pruners have not the slightest horticultural knowledge, and that all has to be done with the knife, the supervision requisite to prevent mistakes must be both vigilant and incessant. True, much assistance is rendered by the native subordinates, many of whom are intelligent, and quickly pick up what is intended; but apathy and indifference are more the rule than the exception; and, though a man may be made to understand matters of detail himself, it is very seldom that one can be found either willing or able to take the trouble to impart such to each individual member of his gang. Plantation roads and bridges—the latter all formed either of wood or bamboo—need repairs and renewing, while any defects in drainage that have come to light during the rains, when operations in this line are well-nigh impossible, have to be rectified; while, if extension of the plantation is essayed, more risky outlay in the shape of advances to contractors has to be incurred, nothing being done in Assam, or, indeed, in any part of India, without advances. Machinery has to be overhauled, the supply of chests for the coming season arranged for, and all items of expenditure connected therewith carefully calculated, for in these days, when the profits on tea to the manufacturer are counted by pence per pound, the most rigid economy compatible with efficiency has to be exercised. Building, again, takes up a large portion of the planter's attention, and, from the perishable nature of the material of which most of the huts and houses are constructed, they need extensive repairs every cold weather. Most tea houses and some bungalows are, it is true, constructed of masonry, and the former provided with iron roofs—albeit bricks and mortar are not much in favour with those who have a lively recollection of the violent earthquake that took place on the 10th of January, 1869, when the Cachar gaul and bazar shot into the river; the church steeple came down in one solid block, and almost every *pucca* building either came down with the run or was

rendered unsafe. Hence wooden posts, mat walls, and thatched roofs form the bulk of the building material, and frequently, just as the factory is all in order at the beginning of the working season, in the dry parched months, a fire will lay the whole in ashes in the course of an hour. Coolies are proverbially careless with fire, and in the chilly nights of the cold weather get up a blaze within their huts in close proximity to the mat or reed walls, without the least regard to consequences, and, when an accident does occur, up goes the price of building material for miles around the scene of the disaster to 25, 50, and, if late in the season, 100 per cent, the dealers knowing full well that the people must be housed at whatever cost; and this contingency has always to be allowed for in the estimates. Many an unlucky planter has got on to the wrong side of his agent's books through an untoward fire in March or April.

A well-laid-out factory, if the site will admit, presents an appearance of thriving prosperity, despite small profits; situated generally on the banks of one or other of the numerous streams that intersect the tea districts of Sylhet and Cachar in all directions. As a rule, the coolie huts are built on either side of the main road, stretching up from the landing place to the tea house and bungalow, each hut standing in the plot of ground that the Government have decreed shall be allotted to each family; and where the coolies have stuck to the factory they were originally imported for, these small gardens are crowded with all sorts of fruit trees and vegetables while, as the adjacent stream teems with fish, the people can live both well and cheaply. The huts themselves can be made to assume a neat and trim appearance by an occasional small reward to the occupier who carries the palm in this respect. Raised upon about three feet of well beaten earth, which with the reed walls are neatly plastered with a mixture of cowdung and clay, and whitewashed, they look, at first sight, like masonry buildings. The tea house, of whatever material composed, is always a most imposing building from its size, the amount of space needed for manufacture being very great, the tall iron chimneys belonging to the roasting apparatus, projecting through the roof, giving the structure, at first sight, the appearance of a river steamer that somehow has travelled inland. The interior fittings consist of large withering floors, running the whole length of the building, many factories, however, having separate sheds for withering the leaf. The rolling machines, of which there are some half a dozen varieties, are all ingenious contrivances, but too costly for small factories. These have been designed to dispense with hand labour in rolling or twisting the leaf, and though most profess to complete the operation, it is generally found necessary to finish by hand; but the saving effected by them has been enormous, and the increasing competition among the numerous inventors will no doubt result in the production of a machine that will entirely dispense with hand-labour altogether. Equally worthy of notice is the patent roasting apparatus, looking like an immense cash safe. In this contrivance all risk of burning the tea, as was the case when, as formerly, it was dried in sieves over open charcoal fires, is avoided, the prepared leaf in these "siroccos" as they have been named, coming in contact merely with heated air; besides the immunity from over-firing thus secured, the planter has now no need of charcoal, formerly an expensive item in the cost of manufacture, as any fuel can be used in the furnaces.

The sifting machines are but modifications of the common winnowers, and, though they have likewise greatly economised hand labour in sorting the different grades of tea, final hand-picking is necessary. Chests are seldom made on the factory, but procured from contractors located on the banks of the main river; and throughout the year sawyers and carpenters are hard pushed to supply the over-increasing requirements. In fact, so brisk is the demand, that many planters have their chests sent up in shunks from Calcutta. At no distant date there is likely to be a dearth of timber, not but what there is

plenty in the districts, but that in accessible localities is rapidly becoming exhausted, and roads or tramways must in course of time be constructed to tap the supply in the more remote forests which cannot be reached by water-carriage. Whatever the bungalows may have been in the past, most planters are now fairly well housed, although, in first opening a garden, temporary places of residence, known as *bushas*, are generally run up, as when the ground is covered with heavy forest, it is well nigh impossible to select a suitable site for the permanent factory, and he who essays the opening of a plantation must be content to rough it until the surrounding jungle has been sufficiently cleared to enable him to look about him. Swamps in the immediate vicinity, unless such can be at once let out for rice cultivation, are a prolific source of sickness among the coolies, and should this amount to any considerable percentage, it leads to the intervention of the Inspector of Labourers, who has power to release one's coolies from their agreements, and declare the factory closed; the meaning of which is, that the planter is not allowed to bind anyone down, and must depend for labour upon those willing to run all risks incidental to residing in an unhealthy locality. It will be seen, therefore, how important an item is the pitching upon as salubrious a site as possible. Many planters conduct all business transactions in the bungalow—a practice that entirely destroys all privacy, as everyone who has anything to say considers he has a right to come prowling about the house at all times and seasons. In well-ordered establishments, however, the office is kept distinct from the dwelling-house, the advantages of which the intending planter will not fail to appreciate, especially if he is a married man.

In opening a new plantation, the chief consideration is first to get housed, and then to clear a site for your nurseries, for, though some sow the seed at the stakes, 4 ft. by 4 ft. apart, the practice is seldom attended with success. Seed reaches the planter in those days of steam communication so early, that it needs hard, untiring energy to get the nurseries ready for its reception on arrival, and, as the new comer has to depend on local labour for all preliminary operations, it is seldom that he can begin sowing until January, while the seed reaches early in December, and, as if kept in the boxes or bags for any length of time, it rapidly deteriorates, it is usual to sprout it out on the ground covered with just sufficient earth to preserve vitality, and at the same time to check premature germination. It is next to impossible to obtain labour in the month of December from the villages, as every one is engaged in the rice harvest, for which they receive no pay, but are remunerated by one bundle in every seven or ten, according to the strength of the crop, and all other avocations are thrown aside until the harvest is in. When labour becomes available, about the first week in January, no time is lost in getting the seed into nurseries, and the wider it is so sown the better. If the land to be hereafter planted is hilly, it has to be terraced and staked off, the plants being transplanted as soon as they have matured wood, and if a good stretch of dry weather intervenes between the early March rains and the setting in of the regular monsoon, about the middle of June, should labour be plentiful, good progress can be made. Transplanting can, of course, be continued throughout the rains, but it is by no means so satisfactory as planting in dry weather; the wet washes the soil from the roots, and the plant, being in full vitality, receives a check that it takes weeks to recover from. If the land is flat, and liable to submergence, the whole of the rainy season has to be devoted to perfecting the drainage and being out all outs; then, as soon as the rains are over and the plant at rest, transplanting can go on from November to May, though the sooner it is completed the better. Putting out plants that have been one year in the nurseries has many advantages that more than counterbalance the increased cost of labour; you have a plant to deal with possessing a good root system, enabled to resist the attacks of that abominably destructive insect, the paddie cricket, whose ravages among unmaturing plants, when once

placed out in the open, are something incredible. These insects work at night, and hundreds of plants disappear, cut short off above the matured wood. The creatures do not appear to eat the plant, but no doubt do derive some nourishment from it; or they would not destroy it. No precautions can guard against them, and the only method of keeping them under is to dig them out and destroy them; they are particularly active during the first four months of the year, just when the young plants need much protection, and seem quite unaffected by floods or the fierce heat the ground is subjected to during the firing of the felled jungle. Fortunately, Kokis, Mekies, Khassias, and Dhangers, are partial to them roasted, and they have many enemies, such as snakes, owls, frogs, and, lastly, the badger; but by June they begin to hibernate, and if the soil is moderately fertile, and labour sufficiently plentiful to keep the ground free from weed, the plant by the end of the rains in October is sufficiently robust, and will have attained a height to render the operations of the cricket abortive. But, to insure successful planting, constant attention and unremitting supervision are necessary; all plants injured in the process of cultivation, or any of sickly appearance or undesirable variety (for we have not quite got rid of the pure China seed), must be replaced as quickly as possible, to provide for which contingency, a reserve nursery should always be kept. Among imported coolies upon a newly-opened place there is usually a considerable amount of low fever, which, however, yields rapidly to mild doses of sulphate of quinine—personal experience compels me to assert that the cheap substitute, retailed by the Government, for the sulphate is of but little account. Though it is usual to entertain the services of a resident native doctor, it is always as well to employ, as a periodical visitor, the European medical man of the circle, as coolies are rather given to shirking and shaming if left entirely in the hands of one of their own countrymen, at least of that class the planter can afford to retain; and I must not be understood to imply that the properly qualified native practitioner is one whit behind his European *cofrère*, either in medical knowledge or becoming a party to what is known as "shamming Abraham."

On a plantation that has reached the bearing stage, the manager has little leisure from the middle of March, about which time manufacture usually commences, until the last chest is picked in November. The yield of leaf gradually increases from March, reaching its maximum about the first week in September, though no hard and fast rule can be laid down. Constant wet and absence of sun, with floods from the water of the cool hill streams in August, may chill the soil and retard the flushes, but heavy rain at night and a blazing sun during the day constitute a successful season, whatever the personal discomfort of living for three and a half months in a perpetual vapour bath may be. Each day's make, when sifted out into the various denominations, has to be tested and compared with the corresponding sample of the same date of the previous season, and hurried visits to the neighbouring gardens during the rains are in these days chiefly undertaken for comparisons of culture and interchange of ideas connected therewith. In fact, all through the manufacturing season the talk savours most decidedly of shop, and, though a casual visitor may be perhaps somewhat wearied by the theme, it has resulted in the pouring into the United Kingdom of the basis of a capital beverage, if one could but get the raw material pure in the first instance, and, secondly, induce those who profess to know how to brew the concoction to do so in a proper manner; but I fear that, except on the plantations, a few private houses and half a dozen offices within the shadow of the London Monument, a good cup of tea, properly made, is unattainable. It will be seen from the foregoing remarks that the planter's time, whether working on his own account or as a paid servant, is fully occupied; but, though success depends, as in all businesses, upon constant application, he need not be tied down day by day and every day. Two friends working a garden together can manage to look well after the property and yet obtain a

fair share of sport and pastime. In walking over the place, especially during the cold weather, a gun should invariably be carried, for, round the outskirts of the plantation, jungle fowl, pigeon, and such small game can be picked up without interfering with the work of supervision; and upon the weekly bazaar day, provided the coolies have been paid the previous evening, as they invariably should be, the planter can either visit his neighbours or join a shooting or polo party. The general method of paying coolies is by metal tokens, called tickets, every evening. All work being task work, these tickets can either be redeemed at the end of the week, or oftener, whenever small change is available for the purpose, and, as they are current in the neighbouring villages and the shops usually established on the factory, payment of the people is reduced to a very simple matter, only care should be taken that the device upon these tokens is sufficiently elaborate to prevent forgery. Anything crude and cheap may be imitated, giving rise to infinite confusion and causing considerable loss. Where two proprietors work together, they may either take a turn month and month about, or, if the concern is a prosperous one, one of the partners, as has been done, may take each alternate season in England or the hills, but these matters can be left to choice.

The purely commercial part of the business, to such as can afford to work with their own capital, needs but few words. A man with a capital of £6,000 can, if careful, and by limiting his area to 100 acres, work the same successfully for five years, allowing himself a fair salary, and keep on the right side of his agent's hooks. With less than that sum, or attempting more than the acreage mentioned with it, he is pretty certain to become involved, and from the day he borrows upon the coming crop—10 per cent. being the usual charge for the accommodation—he loses his independence, and jeopardises his property, sinking, as has been the case in many instances, into the position of the paid servant of the creditor firm, who can and have got rid of the original owner on numerous, though plausible pretences. The sum I have put down is far in excess of what many start with, but it will see a man through the five years, allowing him a decent amount monthly for his personal wants, and enable him to carry on his work without aid and in a proper manner. The returns from the fourth and fifth year should amount to about £500, clear of everything, and he can then gradually increase his area but not more than twenty or thirty acres, and, until this additional acreage is in bearing, not another rod should be added. The "lashing out" into big clearances with insufficient capital brought about the crisis in tea in 1866. The returns the second and third years induce many sanguine men to incur expenses that are not justifiable, and, in fact, the bushes will be more benefited by being left to mature than cropped to show a return; and, though instances are on record of plantations yielding three maunds per acre the third year (240 lb. of dried tea), such merciful cropping merely tends to stunt immature plants. Though many of the older plantations, exceptionally advantageously situated, turn out their tea at a total of every item of expenditure of 5 annas the pound, the average cost amounts to 8 or, say, a shilling, and the average price obtainable in Mincing-lane is a shilling; but then comes the gain in the exchange in remitting out to India, which, deducting banker's commission and other incidental charges, affords but a profit of 2d. per pound, or 3s. 4d. in the pound sterling, from which it will be seen that the profits upon tea depend at present solely on the depreciated value of the rupee. The exchange is not likely to improve; if, by some unforeseen circumstances it should do so, a pretty plight the Indian tea industry would be in.

Machinery has and is likely to do much in the future to bring down the cost of cut-turn, but the hopes of the planter lie in the rapid construction of the projected A-sam railway, which will throw an immense population into the district. As matters now stand, the planters are situated in precisely the same position that the early settlers in Australia were some forty years back, and must remain so until the labour

market finds its level. The pay of the coolie comes to £4.5s. per annum; but to this must be added the cost of his importation in the first instance, or the bonus, housing, medical charges, and sundry other items that nearly double this; so that, when all these items come to be carefully weighed, the man of moderate capital, ere embarking in a business that is at the best precarious, and will yield, when his garden of 100 acres is in full bearing, but 6 per cent., or thereabouts, upon his original capital, may well be cautious. It must be remembered that the bulk of the cut-turn hardly reaches London before November, and the remittances reach the factory some two months later: thus for three months the manufacturer, when solely dependent upon his year's crop for up-keep, has some three months to tide over with the comparatively meagre funds furnished by his first sales up to the end of July. In fact, tea-planting has become almost a hand-to-mouth enterprise, requiring mature consideration ere embarking in. The reverse side of the medal is, that a man who will be prudent, and not extend too rapidly, can, in the course of eight years, reasonably reckon upon having a compact property, returning a clear profit of £1,000 per annum, and allow himself at the same time three to four hundred a year for current expenses—a sum ample for all wants. The estate can well afford an assistant at the end of the fifth year, and the owner can then allow himself an occasional holiday, either in the country or at home; but until the plantation is paying, and fairly on its legs, gadding about the country, either for sport or other purposes, will simply invite failure.

As a rule, shooting and fishing can be had in the immediate vicinity, and eight years of work for the securing of a competency that can be bequeathed to one's family, is not a long period to sacrifice for the purpose. Of course, with a larger capital, one's operations can be extended, and the plantation made up to 200 acres at the outset; one hundred is, however, the handiest to commence with; but whatever area is decided upon, no addition should be made until the original plantation is in bearing. £6,000 for the first 100 acres, and £3,000 for each additional hundred up to four hundred; further extensions require additional European supervision, and necessitate out factories, which must be regarded, financially, as separate plantations; but ere such are established, the planter will, or should, have gained sufficient experience to calculate with certainty whether he can afford them.

Young men with from two to three thousand pounds at command may join others, but I cannot recommend this. Some years back a considerable number so situated came out, paying, in addition to investing their capital, heavy premiums, ranging from two to three hundred pounds, which latter was returned as salary during a three years' agreement; but disappointment almost invariably resulted. They became, in fact, partners in a company, lost entirely the control of their capital, and sank into the position of all other assistants, few remaining long enough to attain the position of managers, while the agency charges were so heavy that the interest upon their invested capital was hardly worth considering. Even four or five clubbing together to raise the £6,000 could draw but nominal salaries out of the common fund, and the annual income from the profits, after the five years, would but amount to £100 per annum, and, if divided, there would be no money left for extension. Two might succeed, but it would be eight years, as I have indicated, ere the returns were worth dividing. If two decided on starting the capital should certainly be not less than £9,000, and with that it would be prudent to confine operations to 150 acres for the first five years. Those that think otherwise can try, but will have themselves to blame if they find themselves mere caretakers, on sufferance, after a vain struggle to make bricks without straw. There can, however, be little doubt that, when labour becomes plentiful, the settlers in Assam will be enabled to turn their attention to other matters than tea, and, were space available, it could be pointed out that there are numerous articles, indigenous to the province, which would well repay development, and which private proprietors, once they have brought their tea plantings up to a

paying state, thus securing a steady income, could profitably turn their attention to; but such will strike the intelligent observer ere he has been many weeks in the district during his year of probation.

Hitherto I have dwelt upon tea from an investor's point of view, and have now to glance at the inducements it offers to the young man without capital, but who goes out as a paid assistant, depending entirely upon salary for a livelihood. In this case there can be no probation, but, unless one goes out either to a relation or friend who has established himself as manager, he takes, as it were, a leap in the dark. Formerly anyone was considered fit for a tea planter, and the country was flooded with young men unsuitable in many ways, lacking the remotest knowledge of agriculture, and from previous avocations totally unfitted for the business. A certain proportion certainly succeeded, and in time rose to the highest positions the industry affords, but not until mistakes culminating in the crash of 1866 brought nearly half the estates then opened to the verge of bankruptcy. In nearly all cases in the present day it is considered *sæpe qua non* that some knowledge of practical gardening should be possessed by the applicant, and a man who has passed through Kew or other large garden is preferred to any other. There are numbers of such now receiving pay upon our Assam tea plantations ranging from three thousand to seven thousand rupees per annum. All cannot of course hope to attain the higher salary, but a steady man who means business ought, in the course of three years, to be able to command £500 per annum; for, though he goes out maybe a thorough horticulturist, he must serve at least a couple of years ere he becomes *au fait* in tea manufacture, the management of coolies, and acquires the necessary knowledge of the language to fit him for the charge of an out factory. Being engaged chiefly in pure plantation work, his opportunities of learning the ins-and-outs of manufacture are by no means frequent; but the hazy day, when tea-making must go on to work up the leaf brought in the previous evening, will give him one day per week to devote to this branch, and close attention to all details will soon fit him for the higher position. The commencing salary is generally £150 the first year, £200 the second, and £250 the third, after which remuneration depends upon character and proficiency. To those who do not mind expatriation for some five-and-twenty years, the life affords a tolerably promising career, and, as furlough is usually granted, on half pay, every five or seven years, one need not break into his savings.

£150 a month should cover all expenses of living in Assam—I mean for a person of moderate aspirations—and, as safe interests can be had in India at 5 per cent., a moderate competency may be secured while one is yet in the prime of life, by the exercise of very little self denial. The paid assistant or manager has the same opportunities of relaxation as the working proprietor, and, moreover, can, if his cold weather duties are got through in good time, obtain some six weeks' leave of absence ere the manufacturing season sets in. If we come to compare the lot of a young man who takes to tea-planting as a career, with one of similar age and social standing who remains in England, and follow the comparison out for, say, five-and-twenty years, I am inclined to think the advantages preponderate in favour of the former. At the outset of his engagement he receives a salary that enables him to live in comfort, his avocations, being carried on in the open air, are healthy and invigorating, and, though there may be minor climatic discomforts in Assam to be encountered, that such are not inimical to health the death or invaliding rare proves; accidents have been few and far between, while, were the deaths attributed to climate even but very cursorily investigated, it would be seen that the majority were really due to imprudence in living, habits, or clothing. The very nature of the life tends to mitigate against any thing like dissipation, but there are temptations to imprudences, such as plunging into a mountain stream when heated, turning out of bed on a hot night and sitting in the open verandah to "cool down"—a pleasant indulgence at the time, but certain to be followed sooner

or later by unpleasant consequences—playing polo in racing caps, and many other apparently trifling indiscretions which, however, old residents never fail to warn the new comer against. But the climate of Assam has one advantage over that of the United Kingdom; in the former one knows what sort of weather to expect for weeks and months together, and so can adapt himself to meet what he knows is coming, and take all necessary precautions, while at home we are never certain for twelve hours together of what is to store for us. Servants, in remote corners of the tea districts, are difficult to procure, that is, really good ones, and much the best plan for a settler in the backwoods is to select one or two of his agreement coolies—Dhangers if possible—and train them for domestic duties; there are of course inconveniences attending this at first, but once the men learn what is required of them, they will be found far preferable to the general run of professional district domestics, very few of whom are to be relied on, either for proficiency in their duties, or honesty. The lower one goes in the social scale, judged from the native standpoint, in this matter, the better. With regard to other surroundings, a young man can make himself very comfortable at trifling outlay in the course of a very few months.

All kind of European vegetables come to perfection during the cold season, and from October to April there used be no dearth of such, while for the remaining portion of the year an innumerable variety of indigenous fruits and vegetables abound. Butchers' meat, in the warm months, is difficult to procure, unless one is in the immediate vicinity, either of the civil station or a cluster of gardens that will admit of the formation of a mutton club; but fish and poultry are both cheap and plentiful throughout the year, and the lighter food is certainly more conducive to health in hot weather. It is perhaps hardly necessary to mention fruit, and though some people are in the habit of considering aught but the most sparing use of it hurtful, I do not believe one single case of illness in an adult has ever been fairly traceable to the consumption of ripe fruit, either in Assam or any other part of India. Milk, either from cows or goats, is cheap and good, as also is that from the water buffalo, to those who like it, and butter, it made at the bungalow each morning, to ensure cleanliness, can be had in any quantity. Wine, as a rule, is not much used on the tea gardens, though good claret, at moderate cost, can be had from any of the French houses in Calcutta or Madras. Spirits, though procurable of decent quality, are priced excessively high, and as the consumption, to those who have any regard for their health, should be limited, it is far better to get one's requirements in this line direct from home, say once or twice a year. Beer is cheap, good, and wholesome, and to many men, who have been some years in the country, may be looked upon as a necessity, though exercise, especially when beer is used in the cold weather, is absolutely essential to health. It may here be mentioned that east and west of the plateau on the North Cachar Hills, that is to be traversed by the Assam Chittagong Railway, special facilities are afforded for the establishment of a brewery; the slopes on the north, from their comparative freedom from stone, being well adapted for the cultivation of barley; while on the higher ranges, the forests contain a vine that is nothing more or less than an indigenous hop, the special qualities of which for inducing sleep are well known to both Nagas and Meekies. Both private proprietors and *employes*—the latter when in the service of a substantial firm, and reasonably sure of being located upon the same plantation for a term of years—should lose no time in making themselves, as far as possible, independent of local bazaars (markets) in the food line, by erecting poultry and sheep houses—which building must, however, be pretty substantially built, to resist depredations from such midnight marauders as leopards, wild cats, snakes, kites, and, in the north, that bold plunderer, in the cold weather, the golden eagle—as it not infrequently happens during the dews that he may be cut off, for days together, from the source of supply. This precaution is absolutely necessary in remote districts.

The hill tribes being now reduced to order, there is but slight danger to be apprehended to life or property from them, and the inhabitants of the district, though not more remarkable for general honesty than other people, very rarely interfere with a European.—SYNTEG.

THE NATURE AND FUNCTIONS OF MANURE,

its value, and the various modes of its application, have been standing themes of disputation among horticulturists ever since the history of gardening has been recorded. All who have read with any degree of attention the various theories which have from time to time been published, must have been struck, and also considerably puzzled, by the great difference of opinion amongst those who profess to know something about the subject. A. thinks there is nothing like ashes or lime; B. pins his faith on bone-dust and superphosphate; C. has no doubt that there is nothing like muck—stable manure being worth all the new-fangled fertilisers that foolish experimentalists have invented. His father and his great-grandfather, and all his ancestors, were of the same opinion, and therefore he must be right. D., fortified by long experience, in which all his neighbours have participated, holds manfully to the practice that liquid manure is the one thing needful to successful gardening. E. tells us that he made no money until he used guano, which has converted his barren soil into miracles of fertility, and he therefore looks with pity on all those who do not follow in his footsteps, and as old fogies, who are tilling in the dark, ignorant of the true remedy for the infertility of their gardens. And thus these controversies have gone on from year to year—no one convinced by the arguments or the experience of others, but each adhering to his own theory and his own practice more strongly than ever.

Now, with the increased knowledge of the nineteenth century, it seems to us that all these various opinions and practices are equally right under certain circumstances, and wrong under other circumstances. No hard-and-fast rule can be laid down for the horticulturist any more than it can for the farmer; each case must be considered on its own merit, according to inherent soil-fertility, locality, and the climatal condition with which the gardener has to deal.

Since, then, every manure has its use and its value under given conditions, the great aim of the practical and thoughtful gardener should be to ascertain exactly what those conditions are, and the special circumstance under which their application can be made profitable.

Science has demonstrated very conclusively that every species of plant, whether growing wild or cultivated by the gardener, has its own peculiar chemical composition, consisting of a greater or lesser number of elementary substances united in well ascertained and definite proportions. It is also well understood by the horticultural chemist that plants have no power inherent in them of creating matter, but that their vitality only enables them to select and combine such materials as are presented to their feeding organs from without. The only sources of supply are the substances within reach of their absorbing or feeding organs, and these substances must therefore be contained in the soil or the atmosphere immediately contiguous to them.

The essential elements that are supplied by the atmosphere are carbon, which plants take from the carbonic acid of the air; oxygen and hydrogen, which come from the air to the soil and are absorbed by the roots of the plant, and a part of the nitrogen.

The essential ingredients that must come from the soil are potash, lime, magnesia, iron, phosphoric acid, sulphuric acid, a small amount of chlorine, perhaps a minute quantity of silica, and, finally, considerable nitrogen.

Consequently, in order that our plants may grow and thrive, they must have at the disposal of their roots in the soil a sufficient quantity of each of these ingredients of their food. If any one of the more important constituents—potash, lime, phosphoric acid, or nitrogen—be deficient, the whole plant suffers.

If we have a gardener especially eloquent on the virtues of any particular manure, to the exclusion of all others, we may be sure that he is the cultivator of soil rich in most of the elements of plants, but deficient in one or to of them; the addition of these missing substances will then produce truly astonishing results, and those who witness them can hardly be persuaded that what has proved so useful to themselves can be useful in the hands of others.

Every cultivable soil, however exhausted it may be, is capable of supplying more or less of these essential elements of plant-food, which it derives from the debris of pre-existing vegetation. This is called its inherent fertility, or natural strength. To this important point it is our intention to return shortly, putting before our readers the best ascertained means by which the fertility of our gardens and fields may be maintained.—*Gardeners' Chronicle.*

NORTH QUEENSLAND.—Reports are reaching us of something more than dulness and depression it that once flourishing sugar centre—Mackay. Hard working men and small land owners are, as usual, the first to feel and succumb thereto; and we learn with regret that some small farmers are already so pinched that they have to part with their holdings at great sacrifices to enable them to obtain the wherewithal to decamp and start something elsewhere. Everything is working into the hands of the monopolist, and the expressed policy with which the present Ministry started is being reserved. While the sugar industry was flourishing small farmers could live, either by cultivating sugar-cane or other needful crops to supply the wants of a thrifty population and their working animals and stock. Besides this, if necessary, they could formerly always get remunerative employment, and never needed to have any idle time. Now, however, labour is nowhere to be had, only the bare necessities of life will sell, and all that can clear out are doing so, being compelled to shift or starve. These are facts which speak for themselves, and we wonder whereunto it will grow; for at present there is no prospect of relief appearing within range of our political horizon.—*Queensland Agriculturist.*

AGES OF GERMAN FOREST TREES.—A writer in the *Forstlichen Blätter* expresses the opinion that the assumed age of 1000 years of German forest trees is a myth—that, even in the case of so-called historical trees, an age higher than between 700 and 800 years has not been proved, and that no German tree reaches that age in a healthy state. Trees of such antiquity are always hollow, and continue to exist only as ruins. As regards the limit of health of trees, it may be assumed that much depends, not only on the kind of wood, but also on the climate and the soil. The highest age which trees reach in a healthy condition is found in foliferous trees, not in coniferous trees. After that age has been reached, coniferous die off, whilst foliated may continue to vegetate for some time after having reached the limit of health. The highest age, found by counting the annual rings, is between 500 and 700 years, and this age is reached by the fir in the Böhmerwald and the pine in Finland and Sweden. The next highest age is reached by the silver fir, which, in the Böhmerwald, was found to be 429 years. The larch reaches the highest age of 271 years (in Bavaria). Of foliferous trees, the oak appears to resist the longest, the oldest known specimen (near Aschaffenburg), a holm oak, counting 410 years. In the case of the common oak, the oldest specimens, in which the heart was beginning to decay, being 315 and 320 years old. But the common oak grows much thicker than the holm oak. The oldest red beech trees have been found near Aschaffenburg (245 years) and Weisswasser (226 years). The maximum ages of the other kinds of German trees are as follows: Ash, 170 years; elm, 130; birch, 160-200; asp, 210; red alder, 145; mountain maple, 224 years. The tree most numerously represented amongst historical trees—the lime tree—is found the least in the collection to wood of old and oldest trees. This may be due of the fact that old and healthy lime are most scarce.—*Field.*

EXTRACTING VEGETABLE OILS.

Here where the castor oil tree grows like a weed and is perennial, and where the ground-nut grows freely, to say nothing of the olive and other producing fruits and plants, the following account from the *S. A. Advertiser* of a new machine for extracting oil invented by a South Australian citizen will be read with interest. Our contemporary says:—It has been found that the usual system of pressing the seeds to obtain the oil contained in them is much too expensive to be successfully carried out in a country where labour is so dear as it is in Australia; and Mr Birnbaum, who has studied the subject for many years, both practically and in the works of the best German authorities, has turned his attention to discovering a method which will minimise the attendant expenses. Very briefly described, his *modus operandi* is as follows:—The seed of the rape, linseed, or castor plants having been crushed, is passed through an apparatus which looks somewhat complicated to the unprofessional eye, consisting of a number of large zinc jars and tubes. In these the oil is extracted from the seeds by the use of bisulphide of gasoline, from the unpleasant odour of which the oil is afterwards freed by the action of heat. Still later the oil is separated from the water and filtered, and ultimately an article is produced which appears remarkably pure when examined under the microscope. The refuse which remains after the oil has been extracted is made into rape cake, linseed cake, and other articles. To manufacture sandal oil (which is well-known on account of its important medicinal properties, and is also used in making perfumes), the wood is crushed by machinery, and the result is treated in the same way as the seeds above-mentioned. The sandalwood which Mr. Birnbaum uses is imported from Western Australia, and the root gives the best oil, but it would be worth while finding out whether South Australian trees which bear the same name and are very odourless, would not answer. One advantage which the inventor claims for this system is that the seeds can be used just as they are clipped in bunches from the plant, without any trouble and consequent expense being incurred in cleaning them, a preliminary which is necessary when the oil is to be extracted by pressure. Mr. Birnbaum has secured a patent for this principle on which his apparatus is constructed.—*Planter and Farmer.*

STATISTICS OF PLANTS AS CLASSIFIED ACCORDING TO THEIR CULTURAL REQUIREMENTS.

If we classify plants according to the garden treatment they require they fall into four main groups. The intertropical zone includes a land area of 40,000,000 square miles, and the total number of characteristically tropical plants known to science may be roughly estimated at 40,000 or 50,000. These are found for at Kew in the Palm-house, the tropical Fern-house, the Aroid-house near the main gates, the central portion of the new range, and various small propagating houses which are not opened to the public. Of course the expense incurred in cultivating in the English climate any plant of this group is considerable, so that a careful selection from the 40,000 or 50,000 species has to be made. The second group of plants consists of those that can bear the English summer, but need protection during winter. These are provided for at Kew in the temperate-house, the succulent-house, the cool Fern-house, and the cooler parts of the new range. To this group belong the members of the three rich floras of the south temperate zone, where the height of summer corresponds with the depth of our north temperate winter. To this group belong about 20,000 species, or about a third of the known plants. Next come the hardy plants. The north temperate zone occupies about one-third of the earth's surface, and its plants number 20,000 species. Of these at Kew the classified collection of the herbaceous types is contained in what is called the herbaceous ground, which is situated north of the Cumberland Gate. Here are grown about 2,000 perennials and 1,000 annuals,

arranged under their natural orders. The classified collection of shrubs and trees is scattered over the different parts of what was formerly called the pleasure ground. For the special growth of alpine plants two rockeries have lately been laid out. The total flora of the arctic zone does not reach 1,000 species, and the plants which are confined to the higher levels of the mountains of the north temperate zone may possibly be twice as numerous, in all 3,000 species, of what gardeners call "alpines," i.e., plants specially adapted to a cold, damp climate, with a short summer. If we attempt to classify the plants of the British possessions under these four climate groups, the results will be something like this:—

Tropical plants	18,000	species.
Half-hardy	18,000	"
Hardy	8,000	"
Alpines	2,000	"
			46,000	"

—*Gardeners' Chronicle.*

FIELD EXPERIMENTS AT ROTHAMSTED.*

Perhaps the chief interest in the experiments upon crop cultivation will still centre around wheat. Broad-balk field, on the Rothamsted estate, is unique, so far as treatment and cropping goes. In 1839, this field carried a crop of turnips, manured with farm-yard dung; in 1840 it was barley; in 1841, peas; in 1842, wheat; in 1843, oats; all the four last crops being unmanured. The field was, therefore, according to all farming rules, in an exhausted state when the first experimental crop of wheat occupied it in 1844. Every year since 1843 has this field carried wheat, and with, some exceptions, nearly the same description of manure has been applied to each plot. In this field the visitor, during the present summer, will see the forty-second wheat-crop growing without manure of any description upon the unmanured portion of the field, still keeping up a wonderfully uniform yield of about thirteen bushels per acre, or about the average yield of wheat-lands in the United States of America. This is a striking fact for those who fear the eventual exhaustion of our soils. Equally startling is the result from the continued use of nitrate of soda year after year. This fertiliser is looked upon by many landowners and agents with suspicion as a stimulator and exhauster of the soil; and yet after forty-one years application of nitrate of soda, and nothing else, we have the astounding result of an average of 23½ bushels per acre, or double the yield of the unmanured plot. And, although it is true that the yield of the unmanured and nitrate of soda plots is less upon an average from 1868 to 1883 than it was from 1852 to 1867, yet it is equally true of the plot manured with 11 tons of farmyard manure annually; and this falling off is therefore probably due to a succession of bad seasons, more than to any actual exhaustion of the soil. Another striking fact brought out in these experiments is the excellent results achieved by applications of artificial fertilisers as contrasted with those obtained from farm-yard manure. In the latter case, where 11 tons of dung have been annually applied to the wheat-plot for forty years in succession, the very satisfactory yield of 34½ bushels per acre has been obtained over the entire period. When, however, a well-compounded mixture of artificial fertilisers has been applied, a larger yield has been obtained. For example, 200 lb. of sulphate of potash, 100 lb. of sulphate of soda, 100 lb. of sulphate of magnesia, 3½ cwt of superphosphate, and 600 lb. of ammonia salts, have given upon an average over the same long period 26 bushels per acre year by year. We must not draw these remarks to a conclusion without at least noting the interesting experiments

* Memoranda of the Field Experiments conducted on the Fern and in the Laboratory of Sir John Bennett Lawes, Bart., at Rothamsted, Herts., June, 1884.

upon barley, the leguminous crops, clover sickness, root crops, and potatoes. The memoranda close with a synopsis of a series of experiments upon rotations of crops commenced in 1845 in order to test the effect of growing crops in rotation, instead of continuously, and so to arrive at precise results when a system of mixed farming is pursued with and without manures, and in conjunction with sheep farming.—JOHN WRIGHTON.—*Nature*.

PRUNING.

The question is frequently asked, Do you approve or disapprove of pruning. The question thus put is unfair, and would therefore elicit an unfair answer. Principles for pruning may be laid down, but rules cannot be given without incurring the risk of doing more harm than good. That certain operations of pruning can be done with good effect there ought to be no doubt or hesitation, but that much mischievous and injurious pruning is done daily is equally certain, and to be lamented. It gladdens the eye and rejoices the heart of every good forester to see right and proper pruning done, and it correspondingly distresses him to see what he is doomed to witness every day in the malpractice of the art. Cutting off a branch is a very simple and unimportant act in itself, but it may be a grand and successful stroke or a deadly and disastrous one. The leading principle to be observed is never to cut off a branch from a tree unless absolutely necessary—necessary in a sense akin to that of the amputating of a limb from the human body. One of the causes of improper pruning being so common is on account of the fallacious belief that if one branch or limb is cut off, the sap which formerly flowed into it will, after the amputation is done simply change its current and flow into the adjoining branch, and thereby give to the one what was taken from the other. In the case of a tree growing up with a forked or double stem, one of them is cut away, for the simple reason that, if allowed to grow in that form, the future tree would be less than half the value it would otherwise be with a single stem or trunk.

This, however, is not generally regarded as the only object gained by cutting away the twin stem, for it is the popular belief, that if the twin stems are each annually gaining 2 inches in girth, if one of the two is cut away, the one left will not, as formerly, grow only at the rate of 4 inches annually. This theory, though not unlikely, is a false one, for it will be found by any one who may choose to examine the structure of the wood years after the operation has taken place, that the layers or zones in the stem had not increased as anticipated, but in all likelihood had rather decreased. Some sections of wood in our possession, cut for the purpose of examining their structures, show one general though not uniform result varying in certain particulars. Some of them show a considerable fall-off in the thickness of the layers, beginning with the first season's growth, in others the increase is not visible till the second year, but in all the sections the third year's layer is somewhat thinner than the one produced during the year in which the operation was made.

How and by what means, then, is the stem ever to be increased in thickness if it thus decreases as above described? It increases by a new and different process of growth altogether, in the following manner. Soon after the stems have been separated the bark of the remaining one begins to show little risings here and there which in due time produce buds, these again form small twigs, which ultimately form branches and limbs. It is from this new set of spray and branches that the stem growth begins to increase—from no other source and from no other cause. Now, if we thoroughly understand this principle of physiology, it will help us greatly in regard to pruning, and keep us out of many errors commonly fallen into. The result of pruning is to create rather than develop: to form a new series of growths rather than increase and extend the old ones. When any branch is cut off, the result is, that an embryo bud in its neighbourhood is thereby so far influenced by the operation

that it develops into a new and distinct branch, and starts growth, as it were, on its own account, rather than by contributing to the growth of the branch from which it takes its rise. I saw the other day an example of what I have been trying to describe. It was a Syamore shoot of underwood of about 1½ inch in diameter from which a branch had been lopped off in the ordinary work of heading back game covert. At the cut part a young shoot had started, and at four years' growth had become thicker than the original stem of ten or twelve years' growth from which it sprung.—C. Y. MICHIE, Culloden House, Banffshire.—*Gardeners' Chronicle*.

LIQUORICE ROOT IN SYRIA AND SPAIN.

The United States Government, having sent out a letter of instructions to Consuls to make inquiries as to the conditions under which liquorice root is grown, has received the following reports:—

Liquorice Root in Syria.—Mr. Consul Poche says:—"From all the information I could gather in the vicinity of Aleppo about the plant, it results that it is not cultivated in any part and grows wild in a large tract of this village.

"The root only is utilized. As to the plant itself, it is of no use. The plant that grows in the vicinity of towns is used for the heating of ovens. The cultivation of the root in this province, for exportation, dates from twenty years ago, and was inaugurated by a French manufacturer, Mr. Vidal, who established a factory in Antioch for the preparation of the root, which, after being dug out of the ground and dried, used to be scraped, made into faggot packages of three different sizes, and exported to France and Spain, where they used it for the preparation of the drink called "coco" (liquorice-water), and for pharmaceutical purposes. This enterprise, after some years of existence, failed, owing to bad management.

"For a long time this commerce was abandoned, when a few years since some firms of Smyrna, who deal in this article with the United States, sent their agents to Antioch, and began in the plains which surround this city to cultivate this root, which is exported in its wild state, either to Smyrna or direct to America. The exports have been simultaneously made at the ports of Suedich and Alexandretta. The cultivation of this root—which is considered to be the plague of the lands where it grows, as the latter cannot be used for any other culture, and to clear the same of it would require a long, assiduous, and very expensive work—has become an important resource for this province, which previously used but a very small quantity of it to make the beverage known under the name of "coco." The right to root up this plant from the lands where it grows is bought from the proprietors for a certain number of years, as the reproduction, notwithstanding the uprooting of the plant, is effected very rapidly. As soon as the first rains of November fall, and the plant becomes completely dry, and the sap is re-absorbed by the roots, workmen begin with spades to pull this root out. This article, in a damp condition, is heaped up in stacks on a bed of pebbles placed on sloping ground, which allows the rain-waters during the winter to run easily down. To prevent the overheating and the moulding of the root in question, these stacks, in the month of February, are turned upside down. This expensive operation is repeated at different times until the month of June, at which time, the drying being complete, the transport to the port of shipment is made on camels' backs. The firm of Alexander Sidi, of Smyrna, which has effected the most important purchases in this year, for the account of an American company, has just established at Alexandretta presses moved by steam, which will be used for the pressing of the liquorice root.

"The quantity which will be exported this year from the ports of Suedich and Alexandretta can be estimated at about 6,000 tons, at an approximate value of 102,000 dollars."

Liquorice Root in Spain.—Mr. Consul Marston says:—"The plant grows wild. It requires wild, low,

marshy ground, along the banks of rivers. The climate of Spain, say in the provinces of Murcia, Aragon and Toledo, is most suitable. It cannot be cultivated so as to increase yield.

"In Spain it requires, say, on an average, eight years to reach maturity.

"The plant or stalk is not utilized beyond the root.

"The exports of Licquorice from Malaga to the United States in 1882, 1883 and 1884, are as follows:—

	Quantity. Boxes.	Value. Dallars.
1882	1,348	32,841.45
1883	1,264	30,152.46
1884	200	4,770.96

Total 2,812

	Quantity. Boxes.	Value. Dollars.
1882	3,365	9,336.51
1888	8,285	24,371.50
1884	7,309	21,688.39

Total... .. 18,959

"There are several districts in Spain in which liquorice root is obtained, and large exports are made from Spanish seaports to the United States.

"The root is used in the United States principally for sweetening in the manufacture of plug tobacco; it is also used in the manufacture of drugs and in the preparation of medicines.

"It grows wild in the lower lands, in marshy grounds, and on the banks of rivers. Probably the best quality obtained in Spain is found in the provinces of Aragon, Murcia, and Toledo. The very best Spanish liquorice root is found near the margin of the Ebro, in Aragon. The next in point of quality is obtained near Cordova. Where it once takes root it is almost impossible to eradicate it. It grows in many counties, and varies in quality according to soil. Spanish liquorice differs quite materially in the several provinces, the principal variations being that in some parts the bark is red, brown, and light colour, the fuside varying from light-yellow to brown; the proportions of saccharine and starch vary also. Many kinds are fibrous, while others are almost as hard as wood. The ground is pulled at intervals of three, four, or five years, according to circumstances, by digging trenches, pulling everything visible as long as possible until it breaks.

"After a year or two it shows above the ground with a little stem; in the spring over this stem there are little flowers.

"From the time this stem appears until the flowers have all fallen, this root is not in condition to extract, for the sap does not return to the root till then.

"Each year, till the ground is culled, the quantity of roots and tops increases, until the ground is unfit for cultivation of any kind.

"It is from September till March that the root is gathered, and goes through a process of drying or curing before it is considered marketable, the time required for the drying or curing process being from four to five months, and requires a dry climate.

"Liquorice root is also found and gathered in Asiatic Turkey, Greece, Italy, in the Sicilies, &c. In the Sicilies and in Italy, very little, if any, is exported as root, it being used in the manufacture of roll or stick liquorice. There is a small section in England which produces a limited quantity. The United States also have liquorice root in several parts of the country, but the quality is not such as to give it value.

"The quality of root produced in the different countries is as follows, viz., Asiatic Turkey, decidedly bitter; Greece, bitter, but not so bitter as Asiatic Turkey; Sicily, sweet, but less so than Spanish; Spain, rich and sweet; Italy, richest and sweetest of all.

"Malaga has not up to the present time been considered an important shipping point for root; Seville,

Alicante, Barcelona, and Bilbao are nearer the producing districts, yet during the past three years a marked increase in shipments from Malaga has taken place, while the shipments of liquorice paste have materially decreased. The value of this root does not in Spain admit of its being increased in crop by cultivation, and the quantity gathered greatly depends upon the severity or mildness of the winter. If severe, it lessens the quantity gathered.

"Again, if other crops are good, labour being scarce, less root is gathered; consequently prices are higher.

"There are one or two large French establishments in Spain for making paste and stick liquorice, one in Seville and the other in Saragossa, besides a few small Spanish concerns also engaged in the manufacture of liquorice paste."—*Pharmaceutical Journal*.

NOTES ON THE VARIETIES OF GUTTA-PERCHA.

BY JAMES COLLINS.

In a previous article* I reserved a more complete enumeration of the varieties of guttapercha for a future occasion. In the present instance, I only give those which I have been able to examine personally; other lists which I have by me require yet further examination and comparison, and fuller materials than at present at my command. Many, too, of these names may prove synonymous, and the really valuable varieties may prove to be but few in number.

1. *Dichopsis gutta*.—Bentley and Trimen's "Medicinal Plants," plate 167. Synonym—*Isanandra gutta*, Hooker, "London Journal of Botany," vi. 463, t. 16, cc. Vernacular names—Gutta Tabai; Gutta Percha; Gutta Niato (Sarawak); Gutta Percha Durian (Sumatra); Nyatoc Balam; or Balam Timbaga (Bleekrode); Gutta Balam Durian (Borneo); Dudaug (Banka); Mazerwood tree (English). Geographical distribution—Formerly in Singapore in abundance, but only one or two preserved as curiosities; Malacca and Malay Peninsula, as far north as Perak; Sumatra; Borneo and other adjacent islands. In Helfer's collection of Andaman and Peninsular plants at Kew, there is a specimen of this plant. Remarks—Gutta, or as it is variously written, gutali, gatta, gitta, gatta, is the Malay term for gum or juice; percha (pronounced soft as in peach, not hard as perka; accentuated variously as parcha, percia, purcha, is the name of the tree, hence the term may be translated "gum of the percha tree." Recently, it has been suggested that percha means strips or fragments, so called from the way the gatta hangs from the incised trees, but this seems too far-fetched. The old name of Sumatra was Pulo or Pulau Percha, meaning "Island (Pulau) of the Percha Tree." Taban, tiaban, tabau is also the name of a tree, and according to Logan a new word has been added to the Malay language, viz.:—Menaban (Men[taban], signifying collected gutta tabau. The greater number of Malay nouns admit of conversion into verbs by the addition of a prefix. The tree is often compared to the Durian tree, *Durio zibethinus*, in its general appearance, and I have classed the Dutch varieties of Gutta Durian under it, as both specimens and accounts agree. Whilst in Singapore, I was fortunate enough to procure a fruiting branch, and also to prepare a little gutta from the same indigenous tree as the specimens from which Sir W. J. Hooker drew up his description were obtained. These specimens are now at Kew.

2. *Dichopsis gutta*, var. *oblongifolia*.—Synonym—*Isanandra gutta* var. *oblongifolia*, De Vriese, Pl. Ned. Bat. Orient; *ib.* De Haudel in Getah-Peria, Leyden, 1856, with colored figure. Remarks—This variety found in Borneo differs chiefly in having oblong instead of obovate-oblong leaves.

3. *Dichopsis macrophylla*.—Synonym—*Isanandra macrophylla*, De Vriese. Vernacular name—Ngiato puth (white gutta). Remarks—Mr. Motley, who collected a specimen of this at Bangernassing, Borneo, describes it as a large tree, with white and soft wood,

* Jan. 18th, 1881.

and with whitish green flowers. The flowers had so strong an alliaceous smell, that he could hardly suppose the smell without drawing the plant. It yielded a second-rate gutta-percha.

4. *Dichopsis Mottleyana*.—Synonym—*Isonandra mottleyana*, De Vriese. Vernacular name—Kotian. Remarks—Mostly, who found this tree also in Borneo, remarks, "A very tall and straight tree, with smooth reddish-grey bark, reddish within, yielding when wounded a copious flow of milky juice, which hardens to a white waxy resin, brittle when old, but readily softened by heat. Wood, reddish-white, woolly in texture, soon softening in the weather, but good for housework. The gum is said to be used to adulterate the inferior kinds of gutta-percha; it is certainly unsaleable alone. From the seed is expressed an oil used for lamps, and when fresh, for cooking. Grows in deep bogs, where its roots are under water for five months in the year."

5. *Dichopsis obovata*.—Synonym—*Bassia obovata*, Griffiths. Remarks—This gutta-percha yielding plant is found in the Tenasserim provinces, and in Borneo.

6. *Payena puberula*.—Synonym—*Isonandra puberula*, Miquel. Remarks—Is found in Sumatra, and attains a height of 60 ft. to 80 ft.

7. *Payena dasypphylla*.—Synonym—*Isonandra dasypphylla*, Miquel. Remarks—Known under the name of Gutta Benton, and is found in Borneo and Sumatra. According to Motley, it yields a second rate gutta, and is chiefly used for purposes of mixing with finer qualities. The tree grows in dry woods, having hard, white, and heavy timber, black, hard, and smooth bark, and abundant foliage.

8. *Payena Wrightii*.—Synonyms—*Ceratophorus Wrightii*, Hassk.; *Isonandra polyandra*, Wight. Remarks—A umatrua tree.

9. *Payena Leeri*.—Synonyms—*Ceratophorus Leeri*, Hassk.; *Azala Leeri*, T. & B. Vernacular names—alem-tjabel, Balem tandoek, Koelan, Getah Semdek, emarks—This tree, found in Palembang (Sumatra), wa, and Banka, is said to yield a very fair gutta.

10. ? *Payena macrophyllus*.—Synonym—*Cocosmanthus macrophyllus*, Hassk. Remarks—This tree, known under the names of Karel Muudieng and Getah Pertja, is found in Java, and grows to a height of 60 ft. to 70 ft.

11. *Chrysophyllum lanceolatum*, D. C. Synonyms—*Javanicum*, Stendel; *Nyctestition vincolatum*, Blume. Remarks—Known as the Klakakataag, in Java, and grows to a height of 60 to 80 ft.

12. *Chrysophyllum rhodoneuron*, Hassk.

13. *Sideroxylon utidum*, Blume, the Kinjatooef Banka and Njatooef Banka.

14. *Sideroxylon attenuatum*, D.C., known as the Tarcoutoong and Buasie, and found in Singapore, Java, Banka, and Philippines.

15. ? *Sideroxylon chrysophyllum*, De Vriese, found in Java.

16. *Bassia cuneata*, Blume, a tree of 60 to 80 ft. high, found in the Bantam district in Java.

17. *Bassia cricca*, Blume, known as Djengket in Java.

18. *Bassia argentea*, De Vriese, growing in Java.

19. *Bassia Junghuhiana*, De Vriese, growing in Java.

20. *Mimusops Manikara*, G. Don, the Manikara of Rheede, and the *Metrodidoros Macassariniensis* of Rumphius, growing in Java.

21. *Mimusops acuminata*, Blume, known as Genket; grows in Sumatra and Java to a height of 80 to 120 feet. Remarks—Nos. 12 to 21 are all said to yield a gutta-percha which is more or less utilized; frequently, however, for mixing with better sorts. There are numerous varieties of gutta-percha which have come under my notice, to which no botanical position has been assigned. A few of those need only be mentioned here.

22. *Gutta-percha Waringen*.—Under this name a Gutta-percha is collected on the Kapuas river in Borneo. The tree is described as being like the Waringen tree (*Ficus sp. varia*), with white wood, and grows in the hilly country, and generally in yellow clay soil.

23. *Vetiva*.—Found on the south coast of Borneo, and seen by Motley to yield a second-class gutta.

24. *Ploot* is found in Borneo, and yields a third-rate gutta. The tree grows in hilly districts, and its sap

is brownish. The leaves and bark resemble the Champaca (*Michelia Champaca*), but the leaves are redder on the under-side. The name Ploot, or P'loot, is a Dyak term, and the only one they seem to use for gutta-percha.

25. *Gutta-percha Papua*.—This is a fourth class gutta, and is in less demand than the two preceding ones. The tree is found on low ground in Borneo.

26. *Gutta-percha Bona*.—This variety, found also in Borneo, is in very little demand, as it is of low quality it is of a white colour when boiled.

27. *Katella*.—Borneo; used only for adulteration.

28. *Jankor*.—Same as 27.

30. *Gutta-percha Kladi*.—Same as 27.

31. *Gutta-percha Daging*.—This comes nearer in character to the Balata of commerce than any other Eastern product I have met with, and should most assuredly receive attention. "Daging" is the Malay term for "flesh," and aptly describes the toughness and gritty character of the generality of beef one meets with in the East.

32. *Gutta Muntah*.—This is unprepared gutta, "Muntah" being the Malay for "raw," or "uncooked." Hence the term is equally applicable, and, indeed, is applied to every variety of unprepared gutta-percha. Some years since, this name was known and used in the English market, but now is apparently supplanted by that of "White Borneo." It may be of the best quality of gutta-percha, or the very lowest; whichever it may be, if not boiled up quickly, it loses all its value, and becomes a mere resinous mass.

The following names and remarks on varieties of gutta-percha were kindly furnished me by Captain Lingard, who, as a trade and rajah, has had many years' experience of the question in the Brou and Boologan districts on the east coast of Borneo:—

33. *Getah Kalapeich Lanjut* (Brow).—Lola Lanjut, of Boologan, is the first and best quality, and is known in the English market as Lingard's "Nina" brand. "Lanjut" means "tough."

34. *Getah Kalapeich Mookas* (Brow).—Lola Mookas (Boologan), is a second quality. The tree yields about 10 per cent less than the first quality, and is more difficult to cut down. "Mookas" means "spongy."

35. *Getah Kalapeich Kapur* (Brow).—Lola Kapur (Boologan) is a third variety, and yields 10 per cent less than the preceding; in the wet season even 20 per cent less. The wood is much harder, and requires a stronger and heavier billing to cut the tree down.—*Journal of the Society of Arts.*

WEEDS.—Having been a hop grower, perhaps I may venture to point out the injury sustained from weeds. Since my own retirement I have for several years past observed the management of two large growers in the same parish. They both farm highly; but the one who expends the most on manures of various kinds, getting dung down from London, grows the smaller crops of the two, owing to his neglecting the cleaning of the ground. In May and June he invariably gets behind with the weeding, while his neighbour takes care to have the land kept scrupulously clean. Before the picking time his land becomes foul with great weeds, such as chickweed, groundsel, chenopodium, or "fat hen," which ought to have been cut as seedlings in spring and summer. It sometimes happens during one or two critical weeks in June and July, that the hop crop is seen to be hanging in the balance, owing to the bine having received a check from blight; and a timely dose of ammoniacal manure will probably push on the growth of the bine and fruiting runners, and rescue the crop which might otherwise be lost. The clean farmer ran thus save his crop, and, if the land is in high order, the hops will perhaps recover themselves without help. But if the land is foul at that particular period there is no chance for them, owing to the exhaustion of the soil by weeds. The Woburn and Rothamsted experiments prove, and Sir John Lawes has pointed out many times in his writings, what robs the weeds are. In competition with roots or cereals, the weed crop, when it happens to be abundant at the period of full growth in summer, will drain the resources of the land and do an immense amount of damage.—*Field.*

AMERICAN WOODS.—There are said to be 36 varieties of oak in the United States, 35 of pine, 9 of fir, 5 of spruce, 4 of hemlock, 12 of ash, 3 of hickory, 18 of willow, 3 of cherry, 9 of poplar, 4 of maple, 3 of persimmon, and 3 of cedar. The New York Museum of Natural History is to have a complete collection of the native woods of our entire country. The logs are being prepared for that purpose. They will be for the most part five feet long, a section, of half the thickness of the log at one end being removed. In this way both the longitudinal and transverse grainings are shown. There is also a diagonal cut on the section, which displays the grainings also. The remainder of the log remains in its natural condition, with the bark attached.—*American Grover.*

IMPROVED METHOD OF PRESERVING WOOD.—The improved French method of preserving wood by the application of lime is found to work well. The plan is to pile the planks in a tank, and to put over all a layer of bricklime, which is gradually slaked with water. Timber for mines requires about a week to be thoroughly impregnated, and other wood more or less time according to its thickness. The material acquires remarkable consistence and hardness, it is stated, on being subjected to this simple process, and the assertion is made that it will never rot. Beech-wood prepared in this way for hammers, and other tools for ironwork, is found to acquire the hardness of oak, without parting with any of its well-known elasticity or toughness, and it also lasts longer.—*Indian Gardener.*

THE CROTON OIL TREE.—With reference to your MATALE correspondent's remarks some weeks ago regarding the danger of planting this tree amongst tea bushes, and to which you added an editorially incredulous "oh!" I may state for your information, that native opinion goes much further, and no Sinhalese man will walk under this tree if he can help it! They say that the laxative power of this tree is such, that they dare not use the wood for cooking purposes, and that even a stick of it when carried on the shoulder has the same powerful effect! It is evident that this is a most dangerous tree to have in the proximity of tea bushes, and should be banished to the remotest regions of estates.—*Cor.* [That is because Sinhalese people say certain things. But where is the evidence that the wood of the tree has the slightest chemical effect?—*Ed.*]

THE RUBBER INDUSTRY OF THE UNITED STATES.—The rubber industry of the States has no rival in foreign countries. There is something like \$75,000,000 invested in the business of manufacturing rubber goods, \$30,000,000 of which is confined to the rubber boot and shoe industry. The total number of employes is placed at 15,000, and the total number of factories at one hundred and twenty. According to a recent consular bulletin the value of the annual product is \$250,000,000. Some 30,000 tons of raw rubber are imported every year, which, when combined with other materials in manufacturing, amount to 30,000 tons. The market price of the raw material has been forced up to \$1.25 per lb., while six years ago the price was scarcely fifty cents. In consequence of this advance in price, several substances have been prepared as substitutes for it, of which celluloid is the most important.—*Industrial South.*

NOTES ON ANIMAL PARASITES OF THE SUGAR CANE MADE AT MAUREAY, QUEENSLAND.—1. The Common Chaffer (*Hoplosternus* sp?)—the grub of this insect is one of the most destructive creatures we have to deal with. It attacks and destroys the roots of the cane, causing the leaves to become brown and dry up. The growth of the cane is arrested and the first high wind knocks it over. In this manner whole fields of cane are killed. When a stool of dying cane of this sort is drawn out of the ground it comes up without much tugging, an appears to have few roots. When drawn out of the ground in the earlier stages of the attack as many as seventeen fat larvae may be discovered here at their work of destruction. Towards the end of the year (Nov. and Dec.) the fully

developed chafers appear above ground in large swarms. They feed chiefly, and are most lively, at night: during the day they are to be seen thickly clustered, some feeding, but all more or less drowsy, on fig-trees (*Banyans*), cocoa-nut trees, *Poincianas*, and many scrub and forest trees. The egg is probably deposited at considerable depth, as the chaffer is provided with powerful fore legs with which to burrow into the ground. To me there appears an obstacle to any attempts to destroy the grub; it seems to dive deep into the ground before turning into chrysalis. In following the plough I have frequently picked up chrysalids, but from not one of them did this chaffer emerge. The great increase of this pest of late years is probably due to the wholesale annihilation of the native birds by means of the firearms of the Kanakas. The planters had on various occasions petitioned the Government to prohibit the indiscriminate use of guns by these labourers, but our request was only acceded to when the damage had already surpassed all remedy. Steeping the plants in milk of lime does not prevent grubs' attack. Miss Ormerod recommends the restoration of the average amount of, or the prevention of destruction of the insectivorous birds and bats as the only practical method of suppression.—*Planter and Farmer.*

PYRETHRUM.—The following notes concerning pyrethrum were communicated by Professor A. J. Cook, of the Michigan Agricultural College, to *Gleanings in Europe Culture*.—Pyrethrum is a generic term referring to the powdered flowers of one of three distinct plants—*Pyrethrum roseum*, *P. Cornutum* and *P. Cinerariaefolium*. The powder from the first-mentioned plants is known from the locality where the plants grow, as Persian insect-powder, and for like reason the latter is called Dalmatian insect-powder. Buhach is the Dalmatian insect-powder that is grown and manufactured in California. G. N. Milco, of Stockton, Cal., who, I believe, is a Dalmatian, has given the name of his product—buhach—to protect him against the adulteration which is quite sure to overtake so valuable an article. This powder owes its valuable properties to the presence of a volatile substance which, unless the powder is kept close, will escape, when the article is valueless. Buhach, which I have had a year, and have kept in a close tin vessel, is not so effective as last year, nor so effective as fresh powder obtained this year; yet it kills most insects to which it is applied. Another peculiar property of fresh pyrethrum is that it may be mixed with several parts of flour, and still be potent to destroy. This makes adulteration easy, and likely had its influence in causing Mr. Babach to adopt a peculiar name for his product. Babach—indeed, all pyrethrum—kills by contact and not by being eaten. Again it is entirely nonpoisonous to vertebrates. A friend told me that he ate a tablespoonful with no harm even to his digestion. I have found the powder every effective to kill many insects, when dusted on them by use of a dust-blower, or sprayed on them when mixed with water—one tablespoonful to two gallons of the liquid—by the use of a Whitman pump or when the alcoholic extract is applied as a spray. We kill our house flies by dusting on the powder. We do this as we retire at night, and can sweep up the dead or paralyzed flies the next morning. I prefer to kill cabbage worms, slugs, &c., by spraying with the liquid mixture. I consider pyrethrum a very valuable insecticide, especially the buhach, which is more apt to be pure and fresh. While many of our worst insect pests are quickly killed by use of this powder, I have found that some bugs and a few beetles are proof against it. In all our use of this substance, when dusted into close rooms like living-rooms or chicken-house, the dust comes in contact with flies, lice, &c., and quickly kills. We must put it immediately on the insects, as its virtue is soon gone." It is a common practice of dealers to keep this powder in open boxes or barrels, but it is evident from Prof. Cook's experience that pyrethrum so kept must soon lose its active properties.—*Form and Fireside.* [The base of all the "insecticides" and "insecticides" in use is *pyrethrum*.—*Ed. Queensland Agriculturist.*]

THE LOQUAT.—In the *Zeitschrift, allg. österrich. Apath.-Veines* (January 1, p. 13), Dr. Peckolt gives an account of the loquat (*Eriobotrya japonica*), which, although a native of Japan and China, flourishes freely in Brazil. In the flesh of the fruit he finds, as the more important ingredients, 5.034 per cent of fruit sugar, 1.674 of free organic acid, 0.455 of citric acid in combination, and 0.145 of a yellowish resinous colouring matter; in the seeds, a fat of the consistence of soft tallow 0.416 per cent, a brownish resin 0.160, amorphous amygdalin 0.150, and bitter extractive matter 1.300. He finds that the leaves taken in infusion, in the proportion of 30 grams to 240 grams of water, in the dose of a tablespoonful every two hours, produce a good effect in diarrhoea. The tincture of the leaves is employed in indigestion, and it is said with excellent results, but of this Dr. Peckolt has no personal knowledge.—*Pharmaceutical Journal*.

FLOWERS AND HEALTH.—Professor Mantogazza, of Pavia, has discovered that ozone is generated in immense quantities by all plants and flowers possessing green leaves and aromatic odours. Hyacinths, mignonette, heliotrope, lemon, mirt, lavender, narcissus, cherry laurel, and the like all throw off ozone largely on exposure to the sun's rays. So powerful is this great atmospheric purifier, that it is the belief of chemists that whole districts can be redeemed from the deadly malaria which infests them by simply covering them with aromatic vegetation. The bearing of this upon flower culture in our large cities is also very important. Experiments have proved that the air of cities contains less ozone than that of the surrounding country, and the thickly inhabited parts of cities less than the more sparsely built, or than the parks and open squares. Plants and flowers and green trees can alone restore the balance; so that every little flower-pot is not merely a thing of beauty while it lasts, but has a direct and beneficial influence upon the health of the neighbourhood in which it is found.—*Planter and Farmer*.

INDIAN TEA.—John Chinaman had better set to work at once to improve the quality of the tea he sells to the outer barbarians. They are no longer bound to resort to him for their supplies, and the instructive annual report of Messrs. Gow, Wilson, and Stanton shows that they are more and more availing themselves of this freedom of choice. In 1864 the average monthly consumption in this country was 7½ million pounds, India's share in the supply being only 3 per cent. of the total. But last year she furnished 39 per cent. of the total consumed—a surprising advance in such a comparatively short period. Nor is this all. Since 1879, when the importation of China tea reached its maximum it has steadily diminished, whereas that of its Indian rival has increased largely and almost uninterruptedly throughout the whole period of 22 years. It now has a dangerous competitor in the field in Ceylon tea, which, according to the circular, is destined to revolutionise the markets of the world. Although the industry is of quite recent origin in the sweet-scented island, the average monthly deliveries in England last year amounted to 268,000 lbs., or 3,216,000 per annum, while the quantity estimated as likely to be imported this year is 6,000,000 lbs. Fortunately for tea growers, there seems no limit to the increase of consumption in these isles. Last year's consumption—the highest on record—was 178,655,000 lb., being 4.91 lbs. per head of the population. It seems almost incredible that every man, woman, and child in the United Kingdom consumed, on the average, very nearly 5 lbs. of tea in the course of twelve months.—*Globe*. [With the gradual displacement of alcoholic drinks, the consumption per head will probably in the next quarter of a century be doubled, a large proportion of the 10 lb. per caput being Ceylon tea.—Ed.]

SUGAR PLANTATION PROPERTY IN THE SANDWICH ISLANDS.—The recent annual meeting of the Hawaiian Commercial and Sugar Company disclosed some interesting information relative to the largest sugar plantation on the Hawaiian Islands. The area of the property is 21,000 acres, only a portion of which is yet under cultivation. This, with the mill buildings and all other property of the company, is worth \$3,675,467.60. The liabilities amount to \$1,211,975.64,

thus leaving a surplus of assets of \$2,433,491.96—more than the amount of the capital paid up, which is \$2,250,000. The sugar crop of 1885 was 6,666 tons, which sold at \$102.18 per ton, yielding the sum of \$681,240. The price realised was \$14.22 more per ton, than for the 1884 crop. The 1886 crop, the cutting of which will be commenced in December, is safely estimated at 11,000 tons. At \$100 per ton this means the nice little sum of \$1,100,000, from which must be deducted \$60,000 per month, or \$220,000 for working expenses, leaving in the neighbourhood of \$400,000 as the year's profits. The crop of 1887 will be still larger, as the area under cultivation is being increased. It may be safe to assume that in three years from now the company will be out of debt and have an annual profit of half a million dollars for the declaration of dividends on a paid-up capital of \$225,000. The plantation property is the largest and best equipped on the Hawaiian Islands and it is generally conceded that it has no equal in any part of the world. It is fitted with the best and most improved labour and juice saving machinery. Japanese labour is now being utilized as much as possible in preference to Chinese. It has an excellent and complete system of irrigation; there are 43 miles of railroad, 4 engines and 498 cars for the hauling of cane. Of the whole crop of 1885, 80 per cent of the sugar, over 5,300 tons, was No. 1, the average polarisation of which was 96½ per cent of sugar. The remaining 20 per cent, second and third grades, averaged a polarisation of 85½ degrees. It would be interesting to learn where such a showing for so large a yield can be exceeded.—*Australasian Trade Review*.

THE NUTMEG.—Of immense commercial importance is the nutmeg tree, *Myristica moscata*, or *M. aromatica*. It is also ornamental by its clusters of berries or fruit. The plant is not commonly met with in this country, and it is seldom grown except in botanical or official collections. Its cultivation, however, is not difficult. It thrives in a sandy loam and brisk heat, and cuttings strike freely inserted in sand and placed in heat under a bell-glass. Of the Nutmeg tree Dr. Hogg has written as follows in his "Vegetable Kingdom":—"It is a native of the Moluccas and neighbouring islands, but it is now cultivated in Java, Sumatra, Penang, the Isle of Bourbon, Mauritius, and other parts of the East, and in Cayenne, Martinique, and some of the West Indian islands. It attains the height of thirty feet, with a straight stem and a branching head. The leaves are oblong-oval, glossy on the upper surface and whitish beneath, and with an aromatic taste. The flowers are male and female on different trees, insignificant, and of a yellowish colour. The fruit is round or oval, about the size of a small peach, with a smooth surface, green at first, but becoming yellow when ripe. The external covering, which may be called a husk, is thick and fleshy, containing an austere astringent juice; becoming dry by maturity, it opens in two valves, and discovers the nut covered with its aril, or mace, which is of a beautiful blood-red colour; beneath the mace is a brown shining shell containing the kernel or Nutmeg. A plantation of Nutmeg trees is always made from seed, and it not till the eighth or ninth year that the trees produce flowers. The sexes being on different trees, after the plants are two years old they are all headed down and grafted with scions taken from the female tree, reserving only one male stock for fecundation. The natives of the Moluccas gather the fruit by hand, strip off and reject the pulpy husk, detach the mace carefully, and expose it to the sun, which soon changes its beautiful blood-red colour to a light brown; it is then sprinkled with sea water to render it flexible and preserve it. The nuts are first sun-dried and then smoked, until the kernels rattle against the shell. This shell being removed, the kernels are dipped twice or thrice in lime water, laid in heaps for two or three days, wiped, and packed in hales or barrels. The unripe fruit of the Nutmeg is frequently preserved in sugar in the East; and before doing so it is necessary to deprive it of its acid properties by soaking it in spirits."—*Journal of Horticulture*.

THE COCONUT PALM AND ITS PRODUCTS IN TRINIDAD

form the subject of the following article in the *Demerara Royal Gazette*. No doubt labour is cheaper in Ceylon than in Trinidad, but by no means to the extent that Mr. Legge supposes:—

Persons interested in the development of the so-called minor industries of the colony may not think space and time wasted if we call attention to a phase of the coconut and coconut oil industry of Trinidad. Our export of coconuts last year was 517,920 nuts, and, as everyone knows, there is one coconut oil and fibre factory in the colony owned by a certain enterprising firm of this city. The Blue Book however does not discriminate in either its statement of imports or exports of oils and we cannot therefore give figures thereabout. However, the growth and export of coconuts is a minor industry to which no doubt increased attention will be given as time goes on. Ceylon, it appears, is the country that now holds the industry in its own hands. The anomaly that is always presenting itself to students of West Indian Trade was seen by Sir William Robinson, who wrote a minute to the Colonial Secretary of Trinidad that "with coconuts growing in the colony we are actually sending home for coconut oil. Where is the Agricultural Society?" The reply was that the imported price of the product was about 60 cents per gallon and the local price 75 cents to \$1.20. Thereupon Sir William wrote:—

This only proves that the supply of home grown coconuts is not large enough. There is no difficulty in expressing the oil. This is a matter that the Agricultural Society ought to look into. Ceylon exports over 2,500,000 gallons of coconut oil annually. Trinidad with any amount of land fitted for the growth of the tree cannot supply its own wants.

Out of the fibre, let alone the nut itself, a fortune is to be made.

The Agricultural Society took the matter up and letters were received—and are now published—from gentlemen actually concerned in the industry. They were not slow to point out why imported oil and fibre was cheaper than the local product; and their letters are a curious and instructive illustration of the causes that tend to retard the development of these colonies. We do not refer to causes originating in the economic policy of the several Governments; such as the absence of thorough and systematic protection and artificial stimulation of local industries, in which we have no faith, believing that it is to the interest of a country to produce whatever it can produce the cheapest and best and exchange for other products that are yielded cheaper and better by other countries more favourably circumstanced, but we refer rather to purely natural causes such as the absence of labour consequent upon a sparse population, the inferiority of such labour owing to the laziness or inaptitude of those who possess it, the distance from markets, cheap and rapid ocean transit and like causes. It is fundamental causes of this sort that militate against the progressiveness of these colonies, and only the slow workings of time will tend to their removal. And as we have said the correspondence to which we refer ament the coconut and coconut oil industries illustrates the working of these causes. It does seem strange to the superficial thinker that these colonies, which can grow coconuts with a profibleness equal to Ceylon, should be able to import coconut oil at 60 cents a gallon from Ceylon and yet unable to produce at a price from—as in the case of Trinidad—75 cents to \$1.20 per gallon. One of the causes is perspicuously laid bare by

Mr. Edwin Legge of Narival Coccol, a gentleman who states his views are the result of considerable experience:—

In the first place let us consider the question or rather statement in the Governor's letter,—“the fact that coconut oil can be imported cheaper than it can be purchased in the colony.” This is easily answered.

First, by the difference between the price of labour in Trinidad and that prevailing in such other coconut oil producing colonies as India and Ceylon. * * * I am not sufficiently acquainted with the labor markets of India and Ceylon to draw a comparison between them and that of this island as to the cost of converting, say 1,000 coconuts into oil, or as to the yield of their nuts compared with ours. I merely know what is generally known, that in those countries the cost of labour is nominal, being at the rate of 2 or 3 cents or a handful of rice per man, while my factory hands receive from 60c. to \$1.30 each. I know only too well what the cost of manufacturing coconut oil is to me and others on the East Coast, and will, further on, give you particulars of the cost and also of the yield of oil per 1,000 nuts. As I have been for some years engaged in the manufacture of coconut oil I am able to speak on the subject with a little authority. His Excellency is quite right when he says there is no difficulty in expressing the oil. None whatever, providing always that you have the necessary plant, as oil-making by hand is entirely out of the question, and to erect a suitable factory with all the appliances required would involve an outlay of at least 20,000 dollars. The profit of such a factory, in the present state of the coconut oil trade, would barely pay 8 per cent upon that sum.

There is at present but two oil factories in the island, this one, Nariva Coccol, which is by far the larger, and that belonging to Messrs. Ulrich & Sons at Mayaro, and there are only two other coconut estates whose crops would even warrant the erection of a factory on either of them. They are Mr. Ganteaume's at Mayaro and Mr. F. Agostini's at Icaacos, but neither of these gentlemen would, I think, build a factory unless driven to it by being unable to dispose of their nuts otherwise at a profitable rate. The whole of the East Coast furnishes a crop of eight and a half million nuts, 1,500,000 being grown and used on the Coast. Of the remaining 7,000,000 two proprietors have about 800,000 nuts each, while the rest is divided among a number of small proprietors, but ten of whom have a yearly crop ranging from 90,000 to 150,000, the others owning each a few trees with a yearly crop of 12,000 to 70,000 nuts. A central factory at Mayaro has been suggested, but no one has been found sufficiently courageous to embark in the enterprise.

Mr. F. A. Ganteaume lays bare another cause why coconut oil can be imported cheaper than it can be produced, notwithstanding the profuseness of coconuts in Trinidad and the presence of mills for expressing an untold quantity of the oil:—

The only cause of Ceylon being able to compete with us in our own market is simply a question of labour. Ceylon has a cheap and regular supply of this, whilst we are deprived of a similar advantage. The Suez Canal and steam communication has enabled the Ceylon growers to economically ship to European markets. Fibre will not pay unless made on a large scale and at great outlay for machineries. Then there is not a sufficient demand in the Colony or neighbouring Islands; exportation to Europe will not pay, it has been tried. In this article also Ceylon beats us, and for the same causes as mentioned before.

Nearly all the writers of the letters from which we have made the foregoing extracts advocate the protection of the industry by duties on the imported article. but that being a purely local question we need not go into it now. We have confined ourselves to the purely natural causes which militate against the success of the so-called minor industries. We believe it is so with many other articles than coconuts and their bye products, that they do not pay to produce either for local consumption or

export, for the simple reason that they can be imported cheaper from elsewhere. The particular article dealt with in this column affords an indirect confirmation of Mr. Jones' experiences in the minor industries. At all events, it is obvious that the so-called minor industries have an uphill struggle in the West Indies where the labour required for their production is so immensely disproportionate to the cost of labor in similar climes where such industries are firmly established and have a hold upon the world's market.

BLACK TEA.

In the Blue Book containing the report of Her Majesty's Consuls on China it is pointed out that the export of black tea has steadily fallen during the past four years. The demand for these teas in England, it is stated, continues to decline, and this, taken in connection with a large increase in popularity of Indian and Ceylon teas, leads Mr. Consul Sinclair and Mr. Alabaster to insist on the necessity for improvement in the production of China teas, if the latter are to keep the market at all. Mr. Jamieson, at Kiukiang, gives indirectly a further reason for the diminishing export of China tea. Speaking of the proposal to impose a *li-kan* tax on tea in Kiangsi, he says:—"The effect would be that a great deal of the common teas would not find their way to the foreign market at all, because they would be quickly replaced by the enhanced production in India." This Mr. Sinclair declares to even now hold true of the Foochow tea industry. Green tea has, however, been fairly remunerative. The export is considered a large one, being over 26,800,000 lb. Most of these teas come from Kiukiang, Ningpo, and Formosa, and large quantities are destined for the American market.

The following is taken from a report lately issued by the Land Mortgage Bank of India:—"Tea.—The Bank's crop of 1885 has reached 21,215 maunds, or 1,697,200 lb., against 20,616 maunds, or 1,651,712 lb in 1884, being an increase in quantity over the crops of 1884 of 599 maunds, or 45,488 lb. The manufactured tea of all grades has been generally good, and the quantity (1,128,358 lb.) sold up to date has realized an average price per pound of 1s 2½d., or close upon 1s 2½d per pound. The yields from the Bank's gardens in the Darjeeling district has been slightly in excess of the estimated quantity, but the managers of the Bank's gardens in Assam, Cachar, and Sylhet have been unsuccessful in reaching their estimates, a tributable, in the directors' opinion, to causes altogether beyond the manager's control—such as the prevalence of unfavourable weather for longer or shorter periods, at some of the Bank's gardens; the occurrence of a disastrous rainfall and consequential flood at Shabazpore (in Sylhet) in September last, which, according to the manager's estimate, destroyed fully 400 maunds of leaf, besides doing serious damage to the garden and plant, and a somewhat early closure of the season in some districts. Energetic measures were at once taken by the manager at Shabazpore to remedy the mischief done, and this work has continuously been, and still is, in active progress; whilst the latest reports from the Bank's various gardens are generally satisfactory, giving promise of increased yield in the ensuing year. Accurate data of the cost of production in 1885 has not yet reached London; but the directors believe that the cost of the crop 1885 laid down in London, and inclusive of freight, insurance, and London charges, will be about 10½d per pound, taking the rupee expenditure in India at 1s 7d. The area of extensions that will actually have been carried out during the year at various of the bank's gardens cannot be accurately ascertained until closed accounts for the year have reached London, but the directors believe that the debit to capital in respect of such extensions as have been carried out will be about 100 rupees per acre, equivalent at 1s 7d per rupee to £7 18s 4d, whilst the cost of the upkeep of tea under three years of age debited to capital will not exceed fifty rupees an

acre, equivalent at 1s 7d per rupee, to £3 19s 2d. If the estimated cost of the 1825 crop is approximately accurate and the remainder of the crop yet to be sold realizes the same average price as that which has been already sold, the profit on the season's tea crop (taking the rupee at 1s 7d) will amount to about £70,000, which with income derived from other sources, will not only cover the whole of the bank's expenditures 1885 for debenture interest and general charges, but will suffice to reduce the debit balance to profit and loss of £17,346 10s 9d brought forward from 1884 by about £8,000. The estimated yield from the bank's gardens in 1886 is 26,000 maunds, or 1,880,000, being an increase over actual yield of 1885 of 2,385 maunds or 190,800 lb, and under favourable circumstances the crop may perhaps be laid down at some reduction on this season's cost. The particulars of each garden's estimated crop, as well as the realized crop and the average sale price to latest dates during the current season, as compared with season 1884, are submitted in tabular form.—*H. & C. Mail.*

MATANG, SARAWAK, 15th Feb.—Cinchonas and Liberian coffee are thriving well here, and I hope to open 150 acres of the latter this year for a small company. The Chinamen are largely extending their pepper acreage owing to the present splendid prices. I fancy pepper is, just now, about the best paying product going. Hoping all connected with the old paper are flourishing.

COCONUT REFUSE.—We have heard a good deal lately about immense heaps of fibre refuse on estates, unsalable and useless, except as manure. Now that the question of fuel supply for our tea machinery is becoming so serious a one, it would be as well to see if this refuse fibre and dact could not be utilized as fuel upcountry, either in its present condition or saturated with some more inflammable substance, say petroline. With the help of hydraulic pressure, the refuse dust and fibre might be made into solid blocks of suitable size and shape for the furnaces. As the raw material costs little or nothing to commence with, these blocks should form a very inexpensive fuel for upcountry use, and should soon find a steady market. The coconut shells broken small, might be mixed with the refuse, and make it more valuable. We imagine that an almost unlimited demand would arise for this fibre fuel were it prepared in a handy form, and collected in quantity from the various estates along the sea-board. Local "Times." [While we doubt if the refuse would make a good enough fuel to pay for heavy cost of carriage, we believe it to be a valuable application to soil to keep it open and retain moisture.—En.]

ANOTHER NEW CLEARING FOR TEA.—We had a magnificent burn at noon today on the hill-range overlooking the Kandy lake, just a little below Mr. Pypers' new tea plantation, as it seemed to us looking on from the town. It was a grand sight to see the enormous clouds of dense smoke that darkened a portion of the atmosphere, driven along westward in large masses; while all along the burn, at least of so much of it as was seen from the town, lambent tongues of flame were seen shooting through the dark volumes of circling smoke that were being hurried along the brow of the hill. Of course all this means more of available ground for the cultivation of the plant whose leaves play so important a part in the preparation of "the cup that cheers but not inebriates." Perhaps the time is not far distant when the hills that bound the city of Kandy on the South, will be one beautiful tea garden, from Roseneth to Hantane, while from each extremity a staunch teetotaler would look with deepening interest across the vast expanse, and watch the successful cultivation of the new product, which is to restore to Ceylon a long epoch of agricultural prosperity and financial credit.—*Cor.*

"SALT FOR THE USE OF CATTLE AND FOR INDUSTRIAL AGRICULTURAL PURPOSES.

Government of India resolution offering a liberal reward for the discovery of a satisfactory process for rendering salt unfit for human consumption while leaving it fit for cattle, &c., communicated to the Board of Revenue and the Director of Revenue Settlement and Agriculture; and ordered to be published in the *Fort St. George Gazette* and laid on the Editor's table."

Such is the title of a paper we have received from the Government of Madras and in which a vast amount of correspondence is summarized.

We quote from the *Resolution* of the Government of India as follows:—

One of the chief objections taken to the salt duties is that, owing to the resulting high prices, cattle are stinted in their supply of salt, while manufacturers and agriculturists are required to pay duty on salt employed in industry and agriculture. The attention of the Government of India has been given to the matter for some years in the hope that an unobjectionable method of freeing from duty salt required for the purposes above indicated might sooner or later be discovered.

No satisfactory way of effecting this object and at the same time of protecting the State from risk of fraud has as yet been found. The issue of duty-free salt on a simple guarantee that it will be used for certain purposes and for no others is, in the absence of special safeguards, out of the question, while the provision of such safeguards would entail the entertainment of establishments at inordinate expense, or the adoption of measures harassing to the sections of the public concerned. The only plan which would fully meet the requirements of the case would be the denaturalisation of salt so as to render it unfit for human consumption, whilst it remained fit for use by cattle and as manure, or for industrial purposes, the salt not being easily restorable to an edible condition by any of the methods which could in ordinary circumstances be employed in India. If salt were thus prepared, it might be freely issued at little or no cost price without danger to the revenue. So far, however, all attempts made to discover such a process have proved more or less unsatisfactory in their results.

The first experiment was made in 1876 by Mr. Wood, then Chemical Examiner to the Government of Bengal, consequent on an application from Messrs. Burn & Co., of Calcutta, for the remission of duty on salt used by them in the manufacture of glazed stoneware pipes and similar articles. Mr. Wood reported that he was unable to find out a process which fully complied with the conditions laid down, namely, the discovery of an inexpensive method whereby salt may be rendered unfit for human consumption and can be again rendered edible only by a process the cost of which would equal or exceed the duty levied on it. But he suggested an alternative method, namely, the admixture of salt with coal tar, the tarred salt being issued to manufacturers of glazed stoneware free of duty, upon a personal guarantee for its use exclusively in manufacture. This method was adopted and is still practised, the salt being issued subject to certain special rules framed by the Government of Bengal. The arrangement works satisfactorily on the limited scale on which it has been tried, but constant supervision is required, and tarred salt cannot be used except in pottery manufacture.

In 1877 Dr. H. Warth was directed to make experiments after the German method with some of the refuse salt of the Punjab mines. A mixture of salt with colocynth (*Citrullus colocynthis*), was and another with lignite, oil-cake, and cotton seed were tried, but the result in both cases was unsatisfactory, pure salt being easily recovered from the mixtures, and the experiments were discontinued. On application to the Secretary of State for information showing precisely the process of denaturalisation employed in Germany it appeared that salt was issued for agricultural purposes in two forms, (1) a coarse powder consisting of a

mixture of oxide of iron and vermilion powder (*Artemisia absinthium*), and (2) blocks for beasts to lick, the salt being mixed with oxide of iron and charcoal powder. Salt for manure was mixed with charcoal dust, ashes, lamp-black, or ordinary soot, in different proportions. These mixtures, though effective in Germany, would not be so in this country where the salt duty is much heavier, and cheaper means of restoring the salt exist.

In 1879 the Government of Madras forwarded an application from Mr. Bator for permission to use duty-free salt in the manufacture of manure. The Commissioner of Salt Revenue, Madras, referred to the various processes of medicating salt used in France, and recommended compliance with Mr. Bator's application, provided the salt was first mixed with poufrette in accordance with the French method. The Board supported the recommendation of the Salt Commissioner, but the Government of India considered that the issue of a mixture of the kind to the people of this country was obviously objectionable as leading to serious misapprehension of motives. The proposal was therefore negatived.

This objection would not apply in Ceylon, but the objection of the easy recovery of this salt would, we suspect, remain.

The European methods of medicating salt having been found unsuitable, and the experiments made in Bengal and the Punjab having proved unsuccessful, the Government of India, in its resolution of the 22nd August 1883, cited in the preamble, invited Local Governments and private individuals to make careful and systematic experiments for the discovery of satisfactory process. Various attempts have been made in compliance with these instructions, but none of them can be considered completely satisfactory.

Then follow details of experiments.

We quote again:—

The Chemical Examiner to the Government of Bengal is of opinion that a solution of the problem cannot be expected under the conditions laid down, which in their entirety are impracticable. This view is concurred in by the Chemical Examiner to the Government of the Punjab, and in Madras and Bombay it has been held that the problem is insoluble.

As already stated in the resolution of 22nd August 1883, the Government of India still hopes that a process may be discovered which, if not completely satisfying all the conditions hitherto prescribed, may yet be sufficient for practical purposes. In this view, the Governor-General in Council is prepared to grant a reward not exceeding Rs.5,000 to the inventor or discoverer of a process which will satisfy the main conditions, namely, (a) that the cost of the process must be moderate, not exceeding about 4 annas a maund, and (b) the preparation must be such that edible salt cannot be easily extracted from it by any of the ordinary processes in use amongst native salt-workers. If several good processes are suggested, the highest reward will be given to the inventor of the process which may appear to Government to be the most satisfactory in all respects, and a smaller proportionate reward will be granted for the next best process.

The details of the attempts hitherto made to discover a suitable method of denaturalisation have been printed in the form of a pamphlet, copy of which may be obtained on application by persons who desire to make experiments.

Meantime it seems to us, that, if kainin can be obtained at the present moderate rates, it has for manurial purposes a great advantage over chloride of sodium in the considerable proportion of sulphate of potash it contains.

CEYLON PRODUCE IN THE LONDON MARKETS.

COFFEE—CINCHONA—TEA—COCOA.

Our recent home advices, by mail, inform us that the markets for nearly all Ceylon produce (tea only being a notable exception) still show the effects of the general depression, prominent throughout the past year in nearly every branch of business and trade. Excessive supplies check speculation and commercial enterprise, and so far it is impossible to guess how soon the general improvement so freely prophesied is to show itself. The COFFEE market, in spite of the Dutch sales having gone a shade above valuations, remains quiescent and inactive except for fine qualities of Ceylon plantation new crop, which being scarce command a good deal of attention. A steady market therefore for Ceylon coffee, the crop being so small, is most probable. Supplies from Brazil continue on a large scale, and the feeling in London is that the patience of the Ceylon coffee planter if he expects to see Brazil 'out' must be inexhaustible. They do say, however, that the old stocks in the interior of Brazil have now been mostly forwarded to Rio and Santos. On these points the following remarks from the latest Circular of Messrs. James, Cook & Co. (Feb. 12th) are of importance:—

The figures telegraphed last week from America were too late for our report; the stock 28,000 tons marked a reduction of over 5,000 tons for the month, and the deliveries for January, of all kinds, were 23,000 tons. The following remarks from Messrs. Minford & Co.'s Review of the American Coffee Trade, are of interest:—"The consumption of America is now about 9.31 pounds per capita, against 7.61 in 1879. While the United States as a whole is the largest consumer of Coffee in the world, its population is not so universally addicted to its use as in Holland, where the per capita consumption is about 21 lb., or in Denmark or Belgium, where it amounts to about 13½ lb." In Great Britain the use is less than one pound per head, but the London stock has fallen to an exceptionally low point—short of 9,000 tons, and the little good Coffee suitable for the use of this country is now so difficult to obtain, that the English market must be a strong attraction for highly valued qualities, especially as of the chief competing sorts, the blue Javas, less than 30,000 bags remain to be sold.

With the short export of Java still to be felt this season, somewhat less afloat from the Brazils, and late shipments of East India, a deficiency roughly estimated at about 15,000 tons, the statistical position must further improve. The imports into Holland were light in December, and during January are only 3,752 tons, against 19,238, and 11,990 in the same months of two former years. The stocks therefore will shew a substantial diminution, but the French official returns are not yet to hand.

There is nothing new as regards crop reports, for Rio the average seems to be 4½ million of bags and for Santos about 2½ million bags; under such circumstances an export of not more than 6½ to 6¼ million bags should be looked for from the Brazils.

CINCHONA has become dull, and the market will take some little time to recover the heavy exports recently made from this island. The trade base their calculations on comparisons made with previous years, and nothing will convince them that the prospective supplies are anything but enormous. It is hoped that by this time the depressing influences have been fully discounted and that the next movement will be an upward one. The statistical figures at the end of January are not so favourable as at the end of the previous month. The total landings for January amounted to 8,071 pack-

ages against 5,668 packages in 1885, whilst the deliveries fell to 3,365 packages against 6,647 in 1885, the stock thereby being raised to 66,400 packages against 62,247 packages at the end of 1885, and against 79,651 at end of January 1885.

We find from a general statistical survey of Tea up to the end of 1885 a sound position and one denoting substantial strength in itself. The total imports into the United Kingdom for 1885 amounted to 212,375,000 lb. against 215,212,000 lb. in 1884, and 222,006,000 lb. in 1883, a falling-off in the two years of 10,000,900 lb.

The deliveries for home consumption show a total of 182½ million lb., against nearly 171 million lb. two years ago, in fact, consumption per head of tea in the United Kingdom has increased to 4.98 lb. per head against 4½ lb. per head some four years ago. The export deliveries exceeded 42 million lb., which added to the home deliveries show a total of 224,498,000 lb. against 219,709,000 lb. in 1884 and 212,889,000 in 1883. The stocks, moreover, have fallen from 125 millions lb. in 1883 to 119 millions lb. in 1884 and to 104 millions lb. in 1885. The average price in bond, moreover, has increased from 6¼d in 1881, 1¼d in 1882, 4½d in 1883, 5½d in 1884 to 6½d in 1885, so that, on all sides, the close of 1885 shows a uniquely favourable position; for, whilst imports are less and the stocks greatly lower, the deliveries for home consumption have increased, and show a higher average per head of the population than formerly, which conclusively proves that tea is the special beverage of the British people. The price in bond, too, is higher than it has been for four years. These facts and figures in themselves would formerly have resulted in more active movements in the London market than has been recently witnessed; but the commercial public are no longer guided so much by the old method of stocks and deliveries as they are by prospective supplies, and areas under cultivation, information regarding which is more readily and accurately obtainable than it ever was before. The able article in the *Statist* on Indian Tea Companies, and referring especially to Ceylon tea (which we are at length enabled to republish in full under "Planting Intelligence"), will be read with interest by residents in this island. The commencement of the article deals with the sound statistical position tea has attained, and the hopeful view it is possible to take of its future. It dates this satisfactory turn in the tea trade from the threatened rise in the tea duties, which gave an impetus to the market never since wholly lost. It goes on to show how prospective supplies are the real guides in these days to the future of any market, and, until some reliable data is available, markets remain in a state of suspense. Whatever may be said about Assam and Burma, we do not think Ceylon has much to fear in the competition of Brazil, Florida and Natal, for even if these countries can grow tea of a sufficiently good quality, the absence of cheap labour is an impossible obstacle to any but a very limited output.

Our local public, and most of the friends of the colony at home, are now quite aware of the capabilities of Ceylon as regards the production of tea, but it will, perhaps, be yet some time before these are thoroughly understood by the world at large, although we must say that this article in the *Statist* demonstrates that people are beginning to understand that there is a "formidable residuum of hard fact" in the future of Ceylon tea, and in the cheapness of its production and manufacture.

In connection with our remarks and the consumption of our coming 'staples', (tea and cocoa) in the United Kingdom, the following table must afford encouragement, while it is a coincidence to

say the least that "poor coffee" should have fallen off in consumption in Britain by nearly 1-10th lb. per head since the time coffee leaf disease began to work mischief in Ceylon:—

The following figures, extracted from an annual table compiled by Messrs. Francis Reid & Co. of Liverpool, show the average quantities of the leading articles of food, &c., consumed in the United Kingdom by each head of the population during every few years since 1850, together with the net amounts of income-tax payable over the same period, viz:—

	1850	1855	1860	1865	1870	1875	1880	1883	1885
Sugar.	25.35	29.69	34.61	40.75	48.00	65.47	62.38	66.09	70.22
Tea.	1.87	2.25	2.66	3.26	3.78	4.36	4.66	4.74	4.98
Coffee.	1.11	1.24	1.23	1.02	0.99	1.01	0.96	0.91	0.91
Cocoa.	0.11	0.13	0.12	0.11	0.21	0.31	0.31	0.38	0.40
Rice.	1.63	5.65	5.94	2.04	6.72	11.66	14.31	12.35	7.43
Tobacco.	1.01	1.15	1.22	1.36	1.34	1.45	1.42	1.38	1.40
Wine.	0.23	0.25	0.25	0.40	0.50	0.54	0.47	0.39	0.38
Spirits.	1.04	1.00	0.94	0.90	1.02	1.31	1.05	1.02	0.89
Income Tax.	—	190.7	206.9	232.40	256.1	307.7	285.1	288.7	295.1

The "estimated" population was 27,123,000 in 1850; 28,154,000 in 1855; 28,941,000 in 1860; 30,000,000 in 1865; 31,100,000 in 1870 32,400,000 in 1875; 31,000,000 in 1880; 36,000,000 in 1883; and 36,600,000 last year.

THE MAKING OF BOXES BY MACHINERY.

A good good deal of opposition has lately been manifested to machine-made boxes, and the public has been invited to boycott goods put up in them. Mr. George Blair, socialist and box-maker, was lately interrogated on the subject by a New York reporter. The gist of his remarks is as follows:—

"About ten years ago there was no such thing as a machine-made box. Nowadays, in some trades, there is no such thing as a hand-made box. Formerly the knocking together of small boxes for soap, oil, &c., was a trade by itself, at which nearly 500 men in this city made fair wages. The wood was cut out by machinery, and the workmen nailed the pieces together. About 1874 some man improved considerably upon a machine which hammered in at one blow all the nails one side of a box. Since then improvement has followed improvement until now you pour a keg of nails in at the top of the machine and a boy feeds in the wood at the bottom. All that the boy does is to put in the right pieces and in the proper order, the machine doing all the rest. The machine works so well and so fast that the men have been driven out of the business by boys, the price of such work having dwindled until no man can make a living at it. In 1873 the Standard Oil Company paid \$3 for knocking together 100 boxes. Thanks to the machine, it now gets the same work done for eleven cents. The work of knocking the boxes together costs less than do the nails used. The boxes I speak of are used to put oil cans in, and may measure 20 inches in

length, 10 inches in height and 14 inches in width. The Standard Oil Company saves a fortune every year by the use of these machines, and so it is with soap boxes, some starch boxes, shoe boxes, &c., in fact every sort of box that is made in very large quantities and of one particular size.—*Industrial South*, Dec. 1885.

COLOMBO COMMERCIAL CO., LIMITED.

The annual Accounts are now presented to Shareholders, viz: Balance Sheet made up to 30th September 1885, Profit and Loss Account for year ending 30th September 1885. It will be seen from the Balance Sheet that £11,400 of Debentures have been paid off during the year, thus for the future effecting a considerable annual saving in Interest; the Company's Estates also now stand at a cost of some £1,500 less than by last account. The other items in the Balance Sheet do not call for special remark. The result of the year's working as shewn by Profit and loss Account, is a profit of £624 5s 6d and deducting from this the debit balance brought forward from last year of £223 0s 11d, there remains to the credit of the account £401 4s 7d. The Directors recommend that £376 of the above sum be now applied to the payment of a dividend of 2 per cent. on the Preference Shares for the year ending 30th September last. The above result is regarded as satisfactory by the Board, taking into account that on most of the Estates with which the Company is connected, and generally throughout the Island, a large proportion of the coffee is being supplanted by tea, the latter at present being in most cases too young to give returns, while the coffee crop continues steadily to decrease by reason of lessened area, leaf disease, and bad seasons. An important feature of the past year has been the fall in the price of Silver, which, while cheapening the cost of cultivating and working estates, emphasises the desirability of making additions to the Exchange Reserve Fund as soon as opportunity offers. The items in this year's Profit and Loss Account have been calculated at an Exchange of 1/6 per rupee. For the year now current the outlook as regards coffee is not good; the present price is the lowest; of recent years, and the crop will be the smallest ever received from Ceylon.

The following figures may be found of interest as shewing the falling off in the coffee enterprise of the Island.

	1875	1876	1877	1878	1879	1880	1881	1882	1883	1884	1885
Shipped for the year ending 30th Sept.	968,000	852,564,000	883,260,000	881,323,000	885,314,000	886,180,000					
Estimate											

The shrinkage of business which the above figures coupled with low prices denote is enormous, and could not have been faced by the Colony had not new products come to its aid. Amongst these cinchona has proved a most useful adjunct, but owing to large supplies the price of this product has fallen so low that its cultivation has ceased to be fairly remunerative, except under very favourable conditions. The above crop figures also shew that the volume of business lost through the failure of such a staple as coffee can only be replaced by an article of general consumption, and in this respect the product on which the future prosperity of the Island depends has even an advantage over coffee, the consumption of tea being almost universal and the demand for good tea practically unlimited. Passing from coffee to tea prospects are distinctly favorable. Large areas have been, and are being planted, and are thriving.

ing well, and the leaf realising satisfactory prices. The following figures shew the rapidity with which the growth of tea in Ceylon is being extended.

CEYLON TEA.		lb.
Shipped for the year ending 30th Sept. 1882		623,000
"	1883	1,523,000
"	1884	2,263,000
"	1885	3,797,000
Estimate	1886	6,500,000

and it is anticipated that the returns will continue to increase in about the same ratio until, at no distant date, shipments reach a minimum of 50,000,000 lbs. annually. Tea from the Company's property has already been received and sold, and there are now 1,000 acres under Tea on the Company's Estates, the bulk of which will be giving crop by the end of this year. The general business of the Company steadily increases, and your Directors look with every confidence to very satisfactory results so soon as a general revival in business is brought about by means of the Tea now in plant. Mr. Brown, Chairman of the Board, left for Ceylon at the beginning of December, and will inspect all the properties in which the Company is interested. Mr. L. Famin, a member of the Board, retires from office on this occasion, and being eligible, offers himself for re-election. Messrs. Deloitte, Dever, Griffiths & Co. the Auditors, also offered themselves for re-election.

By order, J. ALGER ROBERTS, *Secretary.*
London, 30th January 1886.

THE INDIAN TEA COMPANIES.

When the commercial horizon is being anxiously scanned at every point for indications of the much-needed trade revival, the tea trade has, of course, not escaped attention. In our issue of November 25th we showed that in that market everything pointed towards a decided recovery in prices. The deliveries for consumption have for some time back been steadily increasing, while the supply has been falling off and stocks have been shrinking materially. We might have gone a little farther, and admired

that the recovery had actually begun. An improvement has been going on for months, which cannot be adequately measured by mere rise in price. It may be more correctly judged by the altered tone of the market, and the much more hopeful view taken of its future. The new season is in these respects exhibiting a marked contrast to that of 1881-85. Then everything tended downward except stocks, which accumulated from week to week. Importers felt lugubrious, brokers were puzzled, and the retail trade was completely bewildered. No one could tell what was to happen next. The shrewdest operator could hardly make up his mind whether to buy or sell. Altogether, it was a most uncomfortable season, and but for a lucky accident which happened towards its close, it might have had even a worse ending than it did. In the early months of the current year, when prices were at almost the lowest level on record, the apprehension of a rise in the duty caused large deliveries, and gave a strength to the market which it has never since wholly lost. This was an interesting example of what the Americans distinguish as a "psychological boom." There was no substantial ground for it in the condition of the market as then known, but it changed the prevailing temper. It was an agreeable, though only imaginative break in the long-continued depression, and the current, once turned, has kept on pretty steadily in its new course till now it seems to have acquired a genuine impetus.

The new season 1885-86 has opened, therefore, under much more hopeful auspices than its predecessor did. As we demonstrated the other day by a very simple and convincing set of figures, the "statistical situation" has greatly improved. It seems anomalous that such an improvement as is implied in the diminution of stocks to the extent of one-half, should have had as yet so little effect on prices. Nothing is more common, however, than anomalies of this kind in speculative markets. When carefully investigated, explanations of them are not difficult to find. Markets, as a rule, follow very slowly the facts by which they are supposed to be regulated. Operators may see these facts clearly enough, and be taking note of them all the while, but they may be also taking note of other things no less important. In the case of the tea trade, the increase of consumption and the diminution of stocks, vital considerations as they may be, are only secondary in comparison with prospective supplies. These are the ruling questions of the future, and the Tea Market is at the present time in a very interesting state of suspense with regard to them. Rapid as the growth of the tea trade has been in the past ten years, it is still in its infancy. The capacity of tea-growing countries is far from having been adequately tested, while of late the industry has extended itself into new districts, where its development may be great beyond present anticipation. Fresh capital is being poured into Assam, where there is a practically unlimited field for its absorption. If we are going to annex Upper Burma, and give free scope to Anglo-Indian enterprise in that direction tea-gardens may soon be heard of there which will press the Chinese harder even than those of Assam. Then there is Ceylon. The history of tea-planting there is truly a romance of modern enterprise. Five years ago Ceylon was brought to the verge of bankruptcy through the ruin of its coffee planters. As a desperate resort, it took itself to tea, and the face of the island has already undergone a marvellous change. Plantations which were deserted and rapidly reverting to jungle have been transformed into tea-gardens, which promise to become as remunerative as coffee ever was in its best days.

In the Tea Market of the future, Ceylon is going to be a very important factor. Within the past year or two Ceylon tea has dawned upon the trade as a sudden revelation. All at once there dropped, as it were, from the clouds a strange tea with an aroma of its own, and a quality almost unrivalled. To produce this superior and unique article requires, apparently, not more labour or expense than the coarser kinds grown elsewhere. Its growers say they

can deliver it in London at 6d per lb., or little more than half the minimum cost of Assam tea. Nor is it, like Tokay or Johannisberger, limited to favoured spots. It grows indifferently over all the hillsides of Ceylon, and when the young gardens come into full bearing, it may be supplied without stint. The crop of the current season is expected to reach 6,000,000 lb., of fully 10 per cent of the whole production of Indian tea. The Ceylon planters predict that they will be easily able to double the quantity next year, and three years hence they hope to have their export up to 20,000,000 lb. There may be a little boasting in this, which those who indulge in it will be the first to regret when they find that it has drawn down on themselves a flood of competition. But a large margin may be written off for too optimistic anticipations, and a formidable residuum of hard fact be left. Until the capabilities of Ceylon have been definitely ascertained, both as regards cost and volume of production, there can be no very steady level of prices for tea. As regards Assam, importers have now a pretty clear idea of bottom values. The industry is to a large extent in the hands of London or Calcutta Companies, which give their shareholders the fullest and most exact information as to their speculations. Very few articles of Colonial produce have their history from year to year so carefully and reliably written as Indian tea. At the close of each season it is made known what every plantation has yielded, what the cost of growth has been, and how much per lb. has been realized.

The Indian Tea District Association, which has its headquarters in London, embraces nearly thirty different Companies, and every year it publishes an abstract of their Reports. This valuable document shows that the tea crop of the twenty-six Companies amounted in 1884 to nearly 14½ millions lb.; and that the average cost was 11½d per lb. The average price realized in Mincing Lane was 11d per lb.; consequently, the financial results of the season turned on the comparatively small margin of 2½d per lb. With some individual Companies it was considerably less than that, while with others it was a good deal more. The importance of quality as an element of success is very conclusively demonstrated by these averages. The range of prices realized over all the twenty-six Companies is very remarkable. It begins at 9½d per lb., and rises to 1s 8d. Equally wide and apparently erratic are the differences in the cost of production, their minimum being also 9½d per lb., and their maximum 1s 7d. One-half of the Companies pay more than 1s per lb. for their tea landed in London. Only two paid less than 10d per lb., which may, therefore, be taken as the minimum cost of production for Indian tea in 1884. Several of the oldest and best-managed Companies showed an average of from 10d to 1s per lb. The Assam Company, for instance, which heads the list in size of crop—its production last year having been nearly 23 million lb.—had a profit of only 1½d per lb. on its tea. Nevertheless, that narrow margin was sufficient for a dividend of 14 per cent on its capital. The average cost of growing was 10 1/5th d. per lb. and the price realized 11½d. As the Directors observe in their Report, such a price would a few years ago have been ruinous; but owing to the great reduction in working expenses, and the improved machinery in use, it is made to yield a fair return on the capital invested. Three other Companies paid last year even better dividends than the Assam—namely, the Jorehaut, the Brahmapotra, and the Brokat, which divided 15 per cent each. Their advantage was derived mainly from superior quality—the Jorehaut and the Brahmapotra having realized 1s 3d each, while the Brokat made the very high average of 1s 8d per lb.

Speaking in general terms, the financial position of the Indian Tea Companies amounts to this—that with the best known appliances and the most careful management, they can grow tea at a minimum of 10d per lb. In such a season as 1884-85 that would yield very little profit on medium crops, while on inferior sorts it might mean an actual

loss. But on all teas commanding 1s per lb. or over, it represents a substantial profit. Taking Sonchongs as a standard, they have been selling during the past week at 9d to 10d for low grades, and from 11½d to 12½d for fair to medium. As times go, this, though not a brilliant, is a sound, healthy market for the producer. All the indications point also to continued strength, if not to a further rise. There is certainly some temptation to bold operators to lay hold of the market and try to twist it up, as they have been doing with copper. Such an incident may develop almost any day; and the fact that it has not yet shown itself betokens risks lying below the surface, and visible only to the initiated eye. One of these risks may be the vagueness of our information as to the new sources of supply that threaten the market. Not only Ceylon, but Java, Brazil, Florida, and even Natal are all coming competitors to be prepared for. Should tea-growing take firm root in all these places, the marketable supply might in a very short time exhibit a startling increase, for it requires only three or four years to bring a tea-garden into bearing. Stocks and deliveries are no doubt very material data for the trade to be guided by, but there are other factors equally essential to a broad forecast of such an industry as tea-growing. The tea trade is evidently entering on a new period of expansion and development, all the possible results of which cannot be foreseen, either in Mincing Lane or out of it.—London *Statist*, Jan. 23rd.

REPORT ON THE GOVERNMENT CINCHONA PLANTATIONS IN JAVA FOR THE 4th QUARTER 1885.

(Translated for the "Ceylon Observer.")

The weather continued very dry during October. At the beginning of November the rains set in in force, whilst in December again some dry days were recorded. In the last month of the past quarter severe winds were experienced, which did some damage to the plantations, especially at Nagrak. Of the crop of 1885, at the end of the year 401,612 Amsterdam pounds had been sent to Batavia, whilst about 20,000 lb. remained in the packing-houses and on the estates. The production would have been considerably larger, had the large amount of rain and the scarcity of labor not interfered. The thorough working of the soil carried out during the east monsoon made its good effects felt, especially shortly after the setting in of the rains, and the plants exhibit a general vigorous growth. The production of 1886 ought therefore considerably to exceed that of the past year. About the middle of November a commencement was made with the upkeep of the young gardens, the replanting of the uprooted patches and the laying out of graft plantations at Tirtasari, which operations are being carried out uninterruptedly as far as possible. During November and December sales of cinchona seed were held, which together realized $\text{fl.} 688.75$. The 1,000 Ledgeriana grafts sold at the last auction fetched $\text{fl.} 730$. On 22nd Sept. 1885 at Amsterdam a second sale of cinchona bark of the crop of 1884 was held, with far better results than that of 4th November 1885. The highest price obtained at the last auction was $\text{fl.} 301$ per half kilogram for succirubra barks in long unbroken quills, whilst Ledgeriana shavings realized up to $\text{fl.} 2.94$ per half kilo. The total result of both sales was about $\text{fl.} 360,000$. By Government order of 30th Dec. 1885, No. 20, G. Toekamp Larimers, after having been for nearly four years actively employed in the Government enterprise as nurseryman, was appointed permanently to this post, whilst by the same order the fixed establishment was increased by two pupil overseers.

VAN ROMUNDE,

Director, Govt. Cinchona Enterprise.

Bandoeng, 5th Jan. 1886.

BEE-KEEPING IN INDIA.

A paper from the Madras Government recording the failure of experiments to breed indigenous bees in hives contains some curious information:—

Mr. Morris remarks that the English comb-foundation has five cells to the inch, whereas the worker comb made by the Indian bee has six cells to the inch, and he had, before he could get a swarm to settle at all, to remove the foundation and substitute for it comb taken from a wild swarm.

Mr. Nicholson observes that the English hive is much too large for the diminutive Indian bee, and thinks that no great profit can be derived from the indigenous insect, a swarm of which cannot, so he says, be expected to yield more than 10 lb. of honey in a season. He suggests the introduction of the English bee, and informs that he himself is attempting to obtain a few queen bees from Australia, whence he has previously tried to procure bees, which, however, died at Colombo, where they were detained for about a fortnight. These or the English may possibly thrive in the cool climate of the hill, but whether they will succeed in the plains seems rather doubtful. Still bees, wild and tame, are to be found all over Australia, and if they can, as they do, bear the climate of the northern part of that continent, they might possibly stand that of India.

Both Messrs. Morris and Nicholson remark that there is no difficulty in managing the indigenous bee in chatty-hives. Several hives of this description belonging to Mr. Morris are stated to contain strong and flourishing colonies.

Dr. Shortt and Mr. Morris promise further experiments with the English hives, but if, as may be inferred from the information given above, the hives are unsuited to Indian bees, ultimate success can hardly be looked for.

Resolution—It is satisfactory that Dr. Shortt and Mr. Morris propose to pursue their investigations. Results will be looked for with interest.

Mr. Morris remarks that the Indian hill-bee constructs six cells to the inch, while the English domestic bee constructs five, and in view of the former being diminutive and yielding comparatively so little honey. Mr. Nicholson suggests the introduction of the English domestic bee, but the board observe that one of the low-country bees of this Presidency, which not uncommonly builds combs from 1' or 1' 6" to 4' or 5' wide, and as deep in human dwellings and is not irascible like the larger rock bee, yields a very ample supply of excellent honey, and constructed a comb containing four cells to the inch, the cells being as much as 1½ inch in length, and the worker bee being larger than the English worker, and very nearly as large as the English drone.

The species would probably be easy of domestication, judging from their quiet occupation of human dwellings, and their domestication is very desirable, but unfortunately, there is a vulgar prejudice that they bring bad fortune to the house they settle in, and no efforts at domestication are likely to be made by the natives of this country, who only destroy them for their honey.

The bee referred to by the Board in their proceedings, dated 28th April 1885, No. 1,276, is *Apis dorsata*, variety *Testacea* (Smith).

Its natural habit is not to enter its hive by an aperture, but to construct a hanging comb. But it does not thence follow that it cannot be domesticated.

TEA DRINKERS will be interested to learn that over half a million pounds of willow-leaves, disguised as tea, were sent by America to Shanghai last year, to be shipped thence as Chinese tea.

KUMAON TEA DISTRICTS.—We are now in the midst of our cultivating season. It has so far been a very favourable one, both for pruning, manuring and hoeing. The temperature has ruled low this month, and after all the moisture we have had since the new year,—4 inches of rain and melted snow—we are now in want of some bright sunny weather.—*Planters' Gazette*.

FUNGI ON ROOTS OF TEA BUSHES.—We received a fungus-covered tea-bush-root, with the following letter, from Dikoya:—"By same tappal I send you a tea-bush-root covered with a red fungus, a parasite growth, and I shall feel much obliged by your sending it to your correspondent versed in such matters, as we are losing a considerable percentage of young tea bushes from this cause." The gentleman to whom we referred thus responds:—"I regret to say I can give no opinion." We would advise our correspondent to examine the soil in which the bushes are growing for the origin of the evil.

LIBERIAN COFFEE picking is the order of the day here, and in spite of the Kandyan coolies being scarcely *au fait* at estate work they manage to pick the "golden bean" fairly well. Their average picking per day is about sixty-four catties a head (about a bushel and a half) of ripe fruit, when considering the age of the trees, a little more than three and a half years, argues well for coffee in the future. The trees are laden with crop in every stage from the well set blossom to the matured cherry. While on the subject of picking it is to be regretted that the "giants of old," we have all heard of, did not in former days visit these shores, and leave a few of their "enbits of stature" behind, as among the coolies here, scarcely is there one that could not walk under a four foot six stand, and of course the higher branches are out of reach or are frequently dragged down and broken. Pepper is also doing well and in spite of the large orders for cuttings and seed it is believed the supply will equal the demand. Large nurseries for cuttings are in course of construction and with the rich soil here, this useful product is almost certain to turn out a success. The Ceylon cocoa is growing apace, full of crop and blossom and reminds one not a little, of its parent tree in the Dumbara valley of Ceylon.—*British North Borneo Herald*.

INDIAN TEA AND CEYLON TEA have for some years been running China teas very close in the race for popularity, and have attained a very high position for themselves in the English market; but it is something new to hear of South African teas "entering the lists" of dealers in this article. Tea cultivation on an experimental scale has been carried on for sometime in Natal, with such success that one of the planters is sending a "sample" of a ton of his produce to the forthcoming Colonial and Indian Exhibition. In fact, the rapid extension of tea-planting in that Colony has attracted the attention of Ceylon planters, several of whom have paid a visit there to judge for themselves of the prospects of the industry; and new enterprises are being started in different directions. Only the other day a share in a "tea garden" in Natal was advertised in the London papers as being for sale, and altogether the energetic Colonists do not intend to hide their light under a bushel. The example of Natal will probably be followed in other parts of South Africa; but a still better field for the industry exists in New Zealand, while there are, no doubt, several districts in Australia where as good tea could be grown as was ever produced in China. The Anstralian have a strong objection to John Chinaman himself, but there can be no sort of reason why they should hesitate to acclimatise, if possible, one of the chief vegetable products of the Celestial Land. Baron Ferdinand von Müller advocates the cultivation of the shrub in Victoria, where plants introduced by him and experimentally grown have been known to produce seeds. And if in Victoria, why not in Tasmania and New South Wales?—*Colonies and India*. [It is useless to anticipate a profitable tea culture in countries where cheap labor does not abound.—ED.]

DECORTICATED COTTON-SEED CAKE.

Sir,—My attention has been directed to the letter on the above, published in the *Field* of the 12th inst., and I can cordially agree with the writer in his suggestion that buyers should pay more regard to the actual composition of different lots of the abovenamed cake. Having had more than twenty years' experience in agricultural analyses, I can testify to the fact that badly prepared decorticated cotton-seed cake has over and over again been the source of serious loss of cattle and sheep, especially young animals, who are unable to digest the hard lumps, which being often associated with some cotton wool, render proper separation even impossible, much less digestion.

A great deal of stress has been laid by some chemists upon the reduction of the percentage of oil which has taken place of late years both in linseed and cotton cakes; and in another paper I have already pointed out that it is not so much the reduction of oil that is so objectionable, but the hard pressed character of the cake resulting from this extra pressure that is the real cause of so much mischief among stock.

We must remember that cotton-seed and linseed cakes are merely the residual products resulting from the extraction of oil, and that the manufacturer will use his judgment as to how far it pays him to employ improved machinery to extract a larger proportion of oil than was formerly the custom.

There will always be a good demand for cotton and linseed cakes, and though no doubt the price will be reduced, in consequence of the smaller amount of oil they may contain, still, I contend that the true remedy is for farmers to employ machines capable of reducing the hard-pressed cake to a fine meal, which can be sprinkled over cut roots and chaff with far greater advantage, in a feeding sense, than the present nut-like lumps, which is the condition now too common.

By all means let farmers and buyers generally avail themselves of the aid of chemical analysis to distinguish between the different qualities of cake, and let all cakes be sold by analysis, as manures are now sold; but it is quite useless to grumble about the reduction of oil; for as long as the manufacturer finds it pays him best to extract as much oil as possible, he will continue to do so.

As for selling meal instead of cake, every practical farmer knows very well that meal, in this changeable climate, will not keep sweet any length of time, and the best plan is to grind cake as required, from day to day.—JOHN HUGHES, F.C.S., 79, Mark Lane, E.C., Jan. 25.—*Field*.

THE SCIENTIFIC MANUFACTURE OF TEA.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL."

Sir,—I have read very carefully Mr. Main's suggestions and opinions as to the use of chemically dried air for drying and withering tea, and have also consulted scientific authorities and practical men on the subject. The general conclusion seems that for drying it is hardly likely to be of much use, because air at 212° (however damp the climate may be) is practically drier than it could be made by any absorbent. At that moderate heat it contains less than 1 per cent. of moisture, and no one seems to believe that 212° could by any possibility be injurious to tea, seeing that, in nearly all the drying processes now employed, air at from 250° to 500° has been used for many years. Still "the possible is immense," and, inasmuch as the system could be so easily put to the test by all who now use our drying cylinders, I will explain more clearly how this preliminary trial can be carried out.

Instead of lighting a fire in the furnace, fill it up with lumps of chloride of calcium or any other more convenient absorbent, and draw the air through this into the fan and drive it through the air-duct into the cylinder precisely as is now done with hot air. If this desiccated air is sufficiently powerful to dry the tea without any additional heat, so much the better; but if heat also is needed, a coil of steam-pipe in the air-duct will supply that want at a cost

of a few pounds. It will, perhaps, be admitted that the simple and regular movement of the cylinder is as good a plan as any for enabling air to act evenly and powerfully on the leaf, and hence would give the process a full chance of success. Chloride of calcium *per se* is a more powerful absorbent than charcoal, pumice, or other porous substances soaked in its solution and redried. As it dissolved it could be allowed to run off into a common boiling-pan to be re-evaporated; the lumps should be fed in regularly at the upper feed-hole so as to prevent any air getting into the pan without passing through the absorbent. Such a trial as this would disturb nothing and spoil nothing; would involve no heavy expenditure, and no discarding of a *tried* resource for an *untried* one, and no hazardous "Leap in the Dark." If the tea were not dried in once passing through, it could be sent through again and again, and its quality and market value ascertained.

Considering that all the air would have thus to pass through a large bulk of the absorbent, that the absorbent itself would be in its most powerful form, that such air could then be warmed to any desired temperature and kept perfectly pure, that the tea would be presented to it in the best form for being dried, and that both tea and air could be kept in or let out of the cylinder as quickly or as slowly as might be found best, I think it will be admitted that all the conditions for a full, fair, and completely convincing trial would be present. If successful planters would thereupon adopt more readily and widely Mr. Main's patent air-desiccators; if not, they could revert to their present processes without trouble or hindrance.

It is obvious that these same drying cylinders could be used to test the value of desiccated air at various temperatures for "withering" also, but for this process they should be rotated very slowly—say, once in a minute—so that the leaves should only just be lifted up sufficiently to separate one wet leaf from another and give the air free play amongst them. The volume and velocity of the air should be far less than in drying, and the ends of the cylinder closed up to any extent that practice proved to be best, so as to subject the leaf longer to the action of that air. A series of experiments should be carried out, carefully raising the temperature one or two degrees at each working—say from 85° the normal heat of the atmosphere, up to 100°, 110°, or any higher degree that the leaf would bear without deterioration. It may here be useful to record that the practical planters, who were present at my experiments last year, were perfectly satisfied with the withered condition of leaf when subjected to the action of ordinary air warmed to 110°; there was no indication of dried edges or "stewed" centres, the leaves being tough and supple, like a piece of very thin leather. I have no exact data, but probably desiccated air at 100° would be about equal in withering power to ordinary air at 110°. If I am right in this deduction, and 100° is the maximum heat of desiccated air that leaf will bear without getting scorched at the edges by the dryness, it would be an interesting comparative experiment to try one batch of leaves with desiccated air at 100°, and another with ordinary air at 110°, and note the ultimate result in the finished tea; personally, I believe that the result would be nearly the same, but there is nothing like a thorough practical trial for settling such questions at rest. It is a great pity that Mr. Main advises the retention of the clumsy old form of withering house, for, however much smaller their dimensions, they are absurdly wrong in principles and will lead to a wanton and woeful waste of his desiccated air. If he drives that air in at the bottom of the chamber the first tiers of trays will saturate it and the upper tiers will begin to retake the moisture from below. If at the top, the most valuable and lighter part of such air will cling to the roof, if at the sides the leaves nearest to the sides will get too dry and those further off be left out in the cold, and wherever and however it is passed into, or drawn out of, a roomful of trays the most exposed leaves will take more than their

share and the covered ones will cling closely together in their pristine and unmitigated wetness.

To rectify these difficulties I should construct (on the same principle as the dryers), very large and cheap octagons of wood and canvas with air-ducts of wood and canvas, and with shelves, louvers, air-vents and gear. With a coil of steam-pipe in the air-duct and a very slow rotation of the cylinder, these could be used in conjunction with Mr. Main's desiccator, or with a plain blast fan blowing through an absorbent or through pipes in a fire,—whichever was found best for the end in view. Such a construction as this could be fitted together in England, marked and taken to pieces, and folded up for shipment, like a tent, and put together again in a day or two. Quantity for quantity, it would be cheaper than any withering house, take up much less space, and enable planters to wither uniformly and thoroughly in all weathers. Nothing could be simpler and less costly than this, and as it would act automatically, like the dryers, it would, like them, save a great deal of time, labour, and anxiety. As an indication of how much labour may be saved by this form of machine, Mr. Robinson, of Mosaigre, advises us that one dryer enabled two men to do the work of forty or fifty. Hence, if in the withering process it only saved half that amount of labour, it would still soon pay for its first cost, besides contributing its share to the more "Scientific Manufacture of Tea."—Yours very truly, Wm. A. GIBBS, Gillwell Park, Chingford, Essex.

BRAZIL.—All the reports from the interior unite in describing the heat of the last two weeks of December as something almost beyond precedent. Considerable injury was done to the plantations.—*Rio News.*

WINE FROM ORANGES.—We learn from the *Queenslander*, some time ago, in the querists' column of that paper the subject of making wine from Oranges was mooted. "In response to our request for practical information a Vine grower and wine-maker, who has within the last few years visited many of the European continental vineyards, called upon us. He informs us, and wishes the fact to be made widely known, that a most excellent wine can be made from the juice of the Orange, and that since the troubles caused by the phylloxera a large proportion of the 'sherry' of commerce is Orange wine. Moreover, when properly prepared, he says, this Orange sherry is a most pleasant and healthful wine; indeed in his opinion it is only a matter of a few years and the greater part of the wine in the world will be made from Oranges, for the product is equal to that made from the juice of the Grape, and the yield per acre considerably more. His argument is, that in consequence of this discovery, the planting of Orange groves in suitable localities in Queensland cannot be overdone. As endorsing these conclusions in the *Melbourne Leader* we find the following paragraph:—It is stated the manufacture of Orange wine is developing into a very extensive business in Florida, where a magnificent American wine is being made in large quantities from the juice of the sweet Oranges, surpassing in purity any of the European wines. 'It is said to be the best tonic, medicinal or otherwise, that can be taken in the human system. It is nourishing, of agreeable flavour, and, what is more, a perfectly pure native wine.' No part of the fruit is used in the manufacture of the wine but the pulp of the perfectly ripe Oranges, and none of the wine bottled from the casks until it is at least three years old. In taste it is marvellously palatable, and contains but 8-64 per cent of absolute alcohol, and slightly over 5 per cent of sugar. Florida, filled with Orange presses, says the *Philadelphia Times*, will outrival the famous vineyards of France and Italy in time, for the manufacturers of this splendid wine are pushing ahead with new and improved machinery, are setting out countless orchards of the precious fruit, and investing thousands of dollars in the enterprise, which they are satisfied will soon become one of the greatest industries. The supply now is not at all equal to the demand."—*Gardeners' Chronicle.*

SUGAR IN BEETROOT.—Aimé Girard's experiments, reported in the *Comptes Rendus*, November 1881, show that the leaves of the Beet contain much more sugar in the evening than in the morning. It is hence concluded that the sugar is formed in the daytime in the leaf, and passes into the rootstock at night.—*Gardeners' Chronicle.*

UNHEALTHY TEA LEAVES.—A correspondent wrote some time ago:—"Can you kindly give me any explanation of the roughness of enclosed tea leaves? The back of the leaf is reddish, rusty-looking, and pitted as it were with smallpox. The front of the leaf is crinkly with a 'rhinoceros-hide' appearance. Such leaf is useless for tea-making, however young it is taken, as it is hard and will not wither. Some bushes are entirely like this. Others have the normal leaves with one or two of these hard shoots." The gentleman to whom we submitted the leaves writes:—"I have carefully examined the tea leaves under the microscope, but cannot say from what disease they have suffered. It may have been caused by drought, wind or sun scorch."

ACTION OF FROST ON LEAVES.—At the Scientific Committee, on Tuesday last, Mr. Bosevain showed some bunches of Camellias grown out-of-doors, the older of which were as if they had been parboiled, being of a brown colour, while the younger leaves were unburnt. Other examples of young foliage, uninjured by frost, were cited during the discussion. The question, for which no-one found more than a conjectural answer, was as to the reason for this difference. For our own parts, we are disposed to consider the injury as due to the influence of the sun on the wet surface of the older leaves, which, being of a darker colour, would be more injured than the lighter ones. Moreover, the older leaves are more horizontal in position than the younger ones.—*Gardeners' Chronicle.*

FORESTS IN FRANCE.—From a recently published report of the Administration of Forests, it appears that the area covered by woods and forests in France is 8,399,131 hectares; of which 1,012,688 hectares belong to the Government; 1,967,846 hectares are communal; and the remaining 5,415,567 hectares are private property; an hectare being equal to 2 acres, 1 rood, 35 poles. Between the years 1826 and 1881, 465,038 hectares were cut down, and 37,267 hectares replanted with trees. The value of the Government forests is estimated at 1,300,000,000 francs, and the annual revenue derived from them between 30,000,000 francs and 35,000,000 francs. For the present year the sum of 35,582,600 francs figures in the budget as the revenue from this source. The cost of administration and maintenance, however, is very great, and for the present year will be 17,772,000 francs, or nearly half the gross revenue, and leaves barely 19,000,000 francs of net revenue, which only represents about 1½ per cent on the capital, or 19 francs per hectare, whilst woods and forests belonging to private persons yield from 28 francs to 30 francs. It must be mentioned that these figures include the amounts paid for right of shooting, which in many cases is leased at high prices.—*Journal of the Society of Arts.*

MANGOES budded this month take very freely; the sap is well up, and the bark parts freely from the old wood. Previous to budding a lean, young shoot should be chosen from the variety to be budded; pinch out the top of the shoot while the young leaves are red, so as to throw all the strength into the wished-for buds. By the time the bark and the leaves of the young shoot begin to assume a green colour, plump buds have formed, which should then be inserted in the ordinary way of T budding upon the stock intended for them. In a month or five weeks the bud will begin to push; the tying should be slackened, to keep it from cutting through the bark and preventing the flow of the sap. A splendid lot of mangoes from this district were recently sent to the Diamond Fields, and reached their destination in good condition. The most pleasing part of the venture was the handsome prices realised for the fruit.—*Natal Mercury.*

TEA MANUFACTURE.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL."

Sir,—We, tea planters, are indebted to you for taking up the subject of tea manufacture in your columns, and note with satisfaction that the "big wigs" at home have under consideration the question how tea can be made to the best selling advantage on the gardens. The fact is, Sir, we planters who have not the good fortune to be proprietors have become rather tired of being preached to. Too much is expected of us. We are told to make economy our chief study, and in the pursuit of this we have not much time for speculative chemistry. I, for one, feel quite certain that the chemistry of tea manufacture is imperfectly understood; but just at present it is difficult to arrive at any reliable data, and we go on blindly as before. Each London and Calcutta broker has his theory as to the process of manufacture and our owners have theirs, which do not always coincide with the quasi chemical suggestion of brokers' circulars. Perhaps you can tell us what to do under these circumstances. Paraphrasing a well-known sentence in reference to the getting of money the advice given us by garden owners is "make tea that will fetch a high price, make it chemically if you can, but make it economically whatever you do." If we fail to please the remedy is that we receive notice to quit and have to commence life again. By all means let the subject of method of manufacture be threshed out by chemical experts, but so long as proprietors feel that there is a divergence of opinion as to the best means of making tea, let them have some consideration for those who are doing their best according to their lights. One of the curses of tea planting hitherto has been the reckless way in which "sopping" goes on for no other reason than an inability on the part of a manager to calculate the weather, or tell the condition of the London market six months ahead.—Yours, &c., AN ASSAM PLANTER.

CHINA GRASS.

Mr. Sansone, Director of the School of Dyeing at Manchester, writing on this subject, says:—In spite of all the efforts made by the Government of India, and of the many chemists, merchants, and manufacturers who have given attention to this question, the industry of China grass or ramie is far from having attained such development as many people imagine. In fact, this industry is still in its infancy, and much remains to be done before it is brought to a proper footing, or indeed before it can take its proper place among the other textile industries. Although many processes have been recommended, and although it is reported that the decorticating machines have proved a success and allow the bringing of the fibre into a marketable form, still I do not believe that the process of separation of the fibre from the woody part of the stalks has reached as yet the point of perfection required to make it capable of general application. Several years ago my attention was called to the fibrous material obtained from ramie, and I induced a relation in South Italy to undertake the experimental cultivation of this nettle. The results were thoroughly satisfactory as far as the facility of cultivation and the amount of the crop obtained were concerned. The planting was continued for two or three years, and it was established beyond any doubt that the cultivation could be made profitable. However, it was found impossible at the time to dispose of the product in the raw state, and as I knew at the time, no effectual method of extracting the fibre from the stalks the matter dropped for some time. Later on, in connection with my father, who tried experiments on the spot in the neighbourhood of Naples, we succeeded by a chemical process in extracting a beautifully silky and bright fibre which my father had spun by hand and then woven into a handkerchief; and even in this primitive way a first-class fabric was produced.

I have a certain prejudice against a thoroughly mechanical process for the extraction of the fibre from the ramie or reea plants, and in my opinion

a chemical process is a necessity either alone or in connection with the mechanical methods. I may perhaps be wrong, but still this is my opinion, based on the little experience I have had. That the fibre can be easily bleached and dyed there is also not the slightest doubt, as I proved to my satisfaction some years ago. I even dyed with the greatest ease mixtures of China grass and wool, which were afterwards spun into yarn and used for the manufacture of carpets, with very good results.

As I said before, the development of this industry is far from having reached the point that many people imagine. There is no doubt that a certain amount of reea and ramie is platted every year, and that the fibrous product is spun and made into fabrics alone or mixed with wool or silk. But still this business is carried on a limited scale, and even carried on with a certain amount of mystery. As it is, it seems to me—indeed I know for a fact—that there are abroad plenty of cultivators who would undertake the planting of the ramie or reea if they could be assured of being able to dispose of their product, while plenty of manufacturers would be willing to begin to spin the new fibre if they could be assured that a constant supply would be forthcoming. I think also that it would be desirable for Manchester enterprise to give more attention to this question, and I would suggest that all those gentlemen interested in this matter should form a kind of society with the object of studying the question thoroughly by holding meetings once or twice a month with the idea of collecting all reliable information and communicating mutual experience. Experiments might also be undertaken. As far as I am concerned I shall be glad to bleach, dye, or print any material that may be brought to me in our laboratory of the School of Dyeing, and I have no doubt that Mr. Reynolds, the Secretary of the Manchester Technical School, would be glad to put a room at the disposal of the proposed society for the development of the China grass industry in Manchester for holding its meetings.—*Home and Colonial Mail.*

GREEN OYSTERS.

An interesting paper is before us, which has been reprinted from the Quarterly Journal of Microscopical Science. It is by Dr. Ray Lankester, and has for subject the nature and origin of the green colouring matter found in the oysters of Marennes, a place situated on the coast of Normandy. These oysters have obtained on the Continent a reputation for excellence, and are consequently in demand, though, so far as the author's experience goes, they are not superior in flavour to those which are colourless. The green colour is confined to the gills and labial tentacles, and is only acquired in certain "parks" or reservoirs of salt water, in which the oysters are expressly placed for the purpose of fattening and "greening." The colour gradually disappears if the oysters are removed from these, so that in a month no trace of colour will be left. So long ago as 1820 a French naturalist named Gailion observed that the so-called "parks"—which are tanks about 4 ft. deep by 200 ft. long and 50 ft. wide—were swarming with minute diatoms, *Navicula ostreaaria*, which, when seen in mass, have also a green colour. It seemed to be a natural conclusion that it was from these *Naviculae* that the pigment had been obtained. The hypothesis that it was derived from the chlorophyll of green algae had to be rejected, for two reasons, the sufficient one being that the oyster does not feed upon coarse particles such as these green algae present. The difficulty was to account for the way in which the pigment of the diatoms was transferred to the gills of the oyster. The fact of its being found in the liver and intestine seemed to indicate that it was first introduced into the alimentary canal; but the muscles, nerve, heart, reproductive organs, and blood were quite free from colouring. In 1841 M. Valenciennes made a chemical examination of the colouring matter, and found that it was quite insoluble, except by means

of such strong acids as destroyed or fundamentally changed it. One thing Valenciennes conclusively proved, that the pigment contained no copper; and the view which he himself favoured—especially as no proof had been afforded of the oyster's swallowing the Navicula—was that the peculiar colouring matter was manufactured by the oyster itself in the intestine and liver, and was thence absorbed and deposited in the gills. The copper theory, however, was destined to be revived. It was undoubtedly true that a green colour had been fraudulently produced in oysters by the use of copper; but a still more remarkable fact was demonstrated by Professor Bizio, that a very minute quantity of copper is really normally contained in the blood of the oyster, as in that of other molluscs. Whether the oyster could take up enough of the metal to be really poisonous is still a matter to be determined by experiment; but Dr. Ray Lankester holds that the popular notions of oysters or mussels being poisonous when taken from the copper of a ship are mere fallacies. Anyhow, Bizio's theory in no way accounted for the green oyster of Marannes, and the Navicula does so account for it. It was proved, too, that the oyster feeds upon these Naviculae. Had Gaillon examined the alimentary canal under the microscope, he would have found not merely the dark blue-green colour, but the siliceous shells of the diatom in enormous numbers. The way in which the pigment is transferred to the gill filamenta is very remarkable. It does not permeate the gills as a whole, but is found localised in a set of peculiar sub-spherical cells, placed at intervals among the smaller columnar cells of the epithelium. These larger cells are "secretion cells," filled with granules, in which the pigment is concentrated. The granules are probably ultimately discharged as mucus. For the pigment itself the name Marenin is proposed; it is not really green, but blue, the green colour of the gills being most pronounced when the pigment is diminished in quantity, and deepening to blue as this increases. Finally, the "secretion cells" present some curious phenomena. They are often found separated from their attachments, and crawling like independent creatures, with slow amoeboid movements, on the surface of the epithelium, "probably," says the author, "on their way to disintegration, accompanied by production of a mucin-like substance." The singular appearance of these cells, with their long pseudopodia, is well shown in an illustrative plate, which also contains figures, largely magnified, of the diatoms and the gill structures, with a coloured drawing of the green oyster, natural size. There are sundry collateral matters dealt with by Dr. Ray Lankester, of considerable interest, for which we must refer to the paper itself.—*Field*.

MAHWA FLOWERS.

Attention has been publicly drawn of late to "Mahwa Flowers"—the corollas of *Bassia latifolia*—as a cheap source of cane-sugar. This species of *Bassia* is a tree attaining to a height of 40 to 60 feet, and common in many parts of India, especially in Central Hindustan. It has oblong leaves of firm texture, from 5 to 6 inches long; these fall in February, March, or April, and are succeeded in March or April by the flowers. These last for two or three weeks and then begin to fall. The fall takes place at night, and continue sometimes for a fortnight. The fruits, which resemble a small apple, ripen in three months; the seeds, one to four in number, yield an edible oil by pressure. It should be added that the trees are self-sown, and that they flourish in very poor and stony soil.

When the Mahwa tree is in bud, the ground beneath it is cleared of weeds, sometimes by burning. A single tree may yield as much as six to eight maunds* of flowers; even thirty maunds have been asserted to have been collected from one tree. These flowers have a luscious but peculiar taste when fresh; when dry they resemble in flavour inferior figs. They form a very important addition to the food of the poorer classes in those districts where the tree

abounds, particularly in the neighbourhood of woodlands and jungles. They are especially useful in economising cereals in seasons of famine and drought. They are sometimes eaten fresh, but more commonly sun-dried, and are usually consumed with rice and the lesser millets, or with seeds of various kinds, and leaves. It is said that a man, his wife, and three children may be supported for one month on two maunds of Mahwa flowers.*

It is not, however, as a direct article of food, nor as a material for the preparation of a rough spirit by fermentation (a very common use of these flowers) that Mahwa blossoms are now recommended. It has been affirmed that they may be employed as an abundant and very cheap source of cane-sugar. In the *Morning Post* of October 15, 1885, appeared an article on this subject, in which it was stated that, "If the Mahwa flowers be available in sufficient quantities for the sugar-makers of Europe, there can be no question that the days of the beetroot are over, and sugar-cane will go the way of all discarded products." This prediction depends, however, upon another condition besides that of the abundance of the flowers. If the sugar they contain be wholly or chiefly cane-sugar, that is, "sucrose," then the argument is not without weight. But the nature of the saccharine matter of the Mahwa does not appear to have been ascertained. MM. Riche and Rémond (*Journ. de Pharm. et Chimie*, 1880, p. 215) stated that the air-dried flowers contain 60 per cent of fermentable sugar, of which about one-seventh is crystallisable. The material available for analysis in Europe consists, of course, of the dried flowers. These may have suffered some change beyond the mere loss of water, but the evidence they afford on chemical examination is not favourable to the view that they are likely to compete with sugar-beet or sugar-cane as a source of cane-sugar. Here is the result of an analysis of a sample of Mahwa flowers (from the Kew Museum) in their air-dried condition:—

	In 100 parts
Cane-sugar	3.2
Invert-sugar	52.6
Other matters soluble in water	7.2
Cellulose	2.4
Albuminoids	2.2
Ash	4.8
Water lost at 100° C.	15.0
Undetermined	12.6

The flowers analysed had a slight smell of fermented saccharine matter and a distinct acid reaction. But it is not at all probable that they could have contained any large proportion of cane-sugar even when quite fresh, and that 15/10ths of that sugar had been inverted during the process of desiccation. We cannot argue from analogy in this case. For while the nectar of many flowers contains no sugar except sucrose, invert-sugar occurs in some blossoms, as well as in many other parts of plants. Even the urupie and growing stems of the sugar-cane and of many grasses contain much invert-sugar. It must, however, on the other hand, be remembered that cut sugar-canes imported into this country contain a large amount of invert-sugar, and that if they be kept a week only after the harvest the invert-sugar naturally present in the juice shows a marked increase and the cane-sugar a corresponding diminution. On the whole, then, so far as the materials at my disposal enable me to judge, I believe that the saccharine matter of fresh Mahwa flowers will be found to consist mainly of dextrose and levulose, and that consequently they will not be available as a material for the economic production of sucrose.

I have to thank Mr. W. T. Thiselton Dyer, C.M.G., Director of the Royal Gardens, Kew, for drawing my attention to this subject, and for a supply of the material on which I have worked.—A. H. SUDGEN.—*Nature*.

*For an interesting account of the Mahwa tree and its products, see a paper by E. Lockwood in the *Journal of the Linnean Society* ("Botany"), vol. xvii, pp. 87-90.

*A Bengal maund equals 82½ lb. avoirdupois,

SUGGESTIONS ON TEA PLANTING.

It is probable that tea-planters in future will be far more careful of the tea-seed they select for planting than they have been in the past; for although Indigenous is not firmly believed in, in Ceylon, except under very favorable conditions, the lower jats are unanimously condemned except for very high altitudes, and even this latter is a questionable conclusion. The two extremes, low Hybrid and Indigenous, do not, in this island, bear hard plucking so well as a good Hybrid of a type I might call something better than half-bred, and this gives a leaf easily manipulated; and, what is of equal importance shews a hardy disposition—what would be described in sporting circles as “standing punishment well.” The days of racing in tea plants are, I conclude, over. There is a form of Indigenous thought very highly of in India, but which, so far, has not become a universal favorite here, which is supposed to have come from Manipore, for it bears that name. It is different from the generality of so called Indian Indigenous, from being in appearance more like an Assam Hybrid. It is of rapid growth, but I have heard men who have it say that it resents anything like severe plucking almost as much as any other of the Indigenous kinds. It must not be presumed from what I have said that I am a general advocate for “hard plucking.” My use of this term applies more to the hard plucking which takes place on the most scrupulously plucked estate at that period of the year when flush succeeds flush in continuous order, when it is annoying to find many otherwise fine looking specimens which will not repeat their flushes. This, as I have said before, is a common habit of the two extremes, which the good Hybrid does not shew.

We have been accused by many Indian tea planters who have visited our shores of overplucking our bushes; also of plucking them when they are still too young. Possibly, we have been guilty of both these offences. The question, however, arises—what is the best age to begin, and, when begun, how should we go on? I think I could find in this island a few estates where overplucking is undoubtedly done, and where ninety-nine out of one hundred tea planters would go with me in this verdict. The early plucking of young tea has also been a failing of ours, which, happily, is not so common as a year or two ago, it being distinguishable afterwards by a small “collar” and weak and crooked wood in the frame of the tree. A large “collar” and curly top indicate overplucking, but not that the bushes were worked too early.

The question now arises how tea should be plucked. For my part, I am not in favour of going in for a large plucking surface on young tea, for it neither improves the bush or the crop. It induces the production of far too much “bangy,” for, as a rule, the larger the young bush is the greater in quantity will be the bangy. I prefer giving the young bush a large top of red wood. It is now the general custom in Ceylon to cut down tea, at eighteen months to two years respectively, whether grown in the lowcountry or on the hills to 18 inches in height; some equalize at an earlier age. After this there are various opinions as to how high it should grow before being “tipped.” Some leave 4, some 5, 6, 7, or 8 inches on the top; some count the leaves. For my part, upon young tea, I consider nothing comes up to the stick and to leaving a good liberal top. This I maintain for two reasons: first, you do not wish to work two-year old tea too hard; and, second, whatever looseness you shew them, will be more than recompensed by finer trees and a generous yield in later years. There are, however, spots where, from continuous winds and other causes, it may be best to shew less consideration. It is very often said that certain estates always look well but yield very little leaf. Upon those a 3 or 4 inch top should suffice, and, when the leaf is pluckable, it should not be lost; for, like certain kin, although in the best condition, they yield little milk. I could enumerate a few such tea properties in Ceylon.

In all ordinary localities I should cut my young tea down to 18 inches, and for the first six months afterwards use a stick of not less than 21 inches. My object for this is the following. The tea would fully recover the effect of pruning before plucking, and when plucked there would be a sufficient top upon the tree to induce the full development of the stem and permanent parts of the bush. Year by year I would carry out this principle until, when five years old, I should, as a rule, not leave more than 4 inches of a plucking top. I believe it has been found the best plan in Ceylon not to pluck bushes too heavy in the early part of the season, though towards its close, for the last few months, leaf may be taken very close. Most people leave a leaf, some a leaf and a half, though, in practice, I have rarely seen this system regularly carried out through a season. In Ceylon towards its close hard plucking is the rule. The system has not been long enough in vogue for me to speak conclusively upon this point, although I am inclined to think there is something in what our Indian friends say. Large yields are not necessarily the result of close plucking; it is the shortened periods between each round which improve the quality; this and plucking off everything which will roll gives a large return of leaf to the acre, and, when to it is added a stunted growth of young wood above the last pruning, a continual denudation of leaves results, and permanent injury must follow. Time will, however, teach us how far we may press our bushes. So far, Ceylon marks appear to have a theoretical and a practical value which do not accord. Possibly others might enlighten the public on this score, not on what they say, but on what they do; for my part, my mind is not quite made up. I am learning daily. The wonder to me is how bushes, which are kept nearly leafless, retain their vitality? Our Indian friends threaten a very sudden collapse. Speaking to an Indian planter upon this subject he said it might be necessary to throw tea out of cultivation for a few years to recover. This he had done over many acres which had been overworked. If this is sufficient, the remedy is not very terrible.—PEROE SOUTHERN.—Local “Times.”

OFF THE GENERAL TRACK IN CEYLON.

I noticed in my last the extensive tracts of forest and *makalana* lyiog between Balangoda and Pelmadulla. The high range of hills on the right has many unexplored hollows and nooks, where the soil is good, and all within easy reach from the Government trunk road at its foot. This will some day be a large centre of tea, independent in a measure of imported labor, with both wood for chests and fuel, merely requiring the energy and capital of the industrious to make it a centre of prosperity. The rainfall is somewhat heavy, but the country is accessible in a day from Colombo, and transport cheap—points of some importance. Madoola resthouse is well situated, possibly it has some wind during the south-west monsoon; but now it is very pleasant, with a grand view towards the west and south, and a large area of land around, with a soil presenting all the requirements of tea. It is everywhere populous and healthy. I noticed the natives with long bamboos sweeping the surfaces of their growing paddy—a method for removing the fly from the plant. The process appeared simple, but I thought capable of improvement, which education may supply, if it does not drive them away from their simple agricultural life altogether to one of ingenuity and thieving; for they all seem willing to relinquish work in the fields for anything entailing the respectability of clean clothes and silk umbrellas. Wherever a few houses were congregated together I noticed a gem-cutter, sometimes several working at their wheels. They usually possessed a number of very inferior stones they were only too anxious to dispose of: pale-colored sapphires and a great collection of non-descript stones, for which they wanted large sums. Pelmadulla is said to be one of those towns where it always rains, be it the north-east or south-west monsoon, and such is the impression it left on me. One evening, at 4 p.m., I could scarcely

see to read, so overcast was the sky, even in the verandah of the resthouse.

The road from Pelmadulla to Rakwana is, perhaps, the most uninteresting in Ceylon; one other is possibly its equal, that from Morawaka to Galle—chenas and paddy fields, and paddy fields and chenias; patauaa do not exist. The Weyganga is crossed four miles from Pelmadulla upon a well-constructed girder bridge. Near this is a toll-bar, where the usual 25 cents for a horse is paid; and, as I had nothing but a 10-rupee note, I had to get it changed. Now, my horsekeeper is a man of somewhat doubtful honesty—all horsekeeper are, I believe, the same. I have often wondered why men are so dishonest, since we have always been told that "honesty is the best policy." There must be some inherent taste for deceit or over-reaching in their natures, much as a boy feels when he goes a-poaching, a wilful delight in getting the better of another. I cannot believe it is merely the desire to possess the property of another: there must be some other impulse, except in cases where the annexed property is of great value. My reflections received some support when I said to my horsekeeper: "Here, take this 10-rupee note and pay the toll; and, if he cannot give you change, we shall get through for nothing. Don't part with the note without change." The unmistakable gleam shone in his eyes; the man who was usually silent, and somewhat morose in nature, seemed to rise above himself. He took the note with an intelligent and approving nod, and was soon at the toll-bar. I watched his face assume its natural expression as the change was handed out to him. He was disappointed. It is the want of excitement. The Police Court and theft are the chief centres of amusement, taking the place of theatres and field-sports at home.

Madampe is a solitary spot, at the foot of the pass before ascending to Rakwana, rather less than half way from Pelmadulla. The soil appears good. From this a bridle path goes off to Hambantota, and a new rest-house is being built on the site of the old one. It was a matter of wonder to me that it was not rebuilt on the top of the hill at its back instead of being buried again in the paddy field. I once spent a night here some years ago, and shall never do so again; the situation is altogether unlovely, and has nothing to recommend it. How many in Ceylon know nothing of Rakwana—how the badly traced cart-road eventually leads you to Barra store, and from thence zig-zag to the top of the Bulatotte Pass; how acres of abandoned land meet the eye at every turn. Yet there is a classic history attached. Many old planters wrought here for years; and, in spite of a not over-favorable soil and climate, with all the difficulties of labour, put their coffee as cheaply on boardship as their friends on the Kandy side. The remnants of their labor are still visible upon Palameotta, Barra, Springwood, Deveronside, Caledonia and many other estates. Tea is now luxuriating for miles along the road from Barra downwards; and when the Bulatotte Pass is once surmounted it begins again, and is present with the traveller almost to Morawaka.

From the Pass I looked down towards the hospitable abode of Maduanwella Banda, nestled among the lower ranges, with its pretty piece of ornamental water glistening in the morning sun, recalling old memories of the Government Agent—who wished to force him to give up a piece of land to one of the Government Agent's friends—approaching the old chieftain's house, and telling someone to say that the Government Agent wished to see Maduanwella. "Tell him that Maduanwella is inside his house," was the reply. This spirited gentleman certainly knew how to retain his dignity. He has the reputation of great hospitality to those who treat him rightly; and as he is well educated and well bred, he should not be curly horned with even by a Government official. His has always been a house where residents in the districts around have been hospitably treated.

Beyond, in the far south-east, the sea line is visible in fine weather. The cart-road, well made and metalled, continues almost to the boundary of Lauderdale, which is now quite an expanse of tea and cinchona, and at the back of the hill upon which these estates

are is the extensive Kukulu Korale, through which run down the rivers of Bentota and Baddegama. Morawak Korale is already a large and prosperous tea district where many estates are now paying well; indeed, it bids fair to be one of the best in the island. The large block of land once reputed to belong to Sir Hercules Robinson is now a magnificent show of young tea. Only had it been known in the past how much better the Southern Province is suited for tea than coffee, Morawak Korale would now be one of the most prosperous districts in Ceylon. It now presents the same appearance as most other places—a state of transition.

Anyone going from Morawak Korale to Galle can vary their route by a trip down the Nellawellaganga to Matara. The river journey is much the same as most river journeys in Ceylon. At first, when near the hills, the banks are steep, and the bed so low that nothing but the river banks and slopes upon either side are visible; lower down, as the large flats are reached, the view opens up; an old sugar estate is passed, one of the many spots in our island where the cultivation of sugar was attempted and failed. Those who are fond of birds would find much pleasure in watching the bold flight and wild cry of the speckled king-fisher, as it dashes into the water after its finny prey from a great height.

Matara is one of the most picturesque spots I know, close to Dondra Head, where coffee Arabica may be seen growing almost on the sea brink. The old town was founded by the Dutch, who fortified it against the Kandyans. I was much interested in the old star-fort upon the esplanade, the scene of many a stiff encounter with the highlanders of Ceylon, who came down to carry off the cattle, boys, or girls, or whatever came to their hands. Many a time have these now peaceful spots been dyed with the blood of both races, though I fancy full retribution was paid for all attacks when prisoners were taken by our Dutch friends. It is now a charming spot, with good buildings and a handsome bridge, though all around shews it to have been quite the little outlying fort where a stand, if necessary, could be successfully made. Matara to Galle is a repetition of the scenery lying between Galle and Kalutara, and can be undertaken in a similar mode of conveyance.—W. F. L.—Local "Times."

THANA SILK INDUSTRY.

Mr. B. A. Gupte, of the Sir Jamsetjee Jejeebhoy School of Art, Bombay, has an interesting article in the *Journal of Indian Art* on the Thana Silk Industry:—

In the sixteenth century the making of Thana silks is said to have employed as many as 4,000 weavers, and as late as the eighteenth century the English congratulated themselves on being able to induce some Thana weavers to settle in Bombay. For many years the industry has been depressed. There are now only seven families of weavers working fourteen looms, which in ordinary years do not turn out more than £500 (R5,000) worth of silks. Neither gold nor silver thread is worked into the silks. Plain silk cloth for Hindu waist-cloths or pitambaras is woven to a small extent. But the special Thana silks are of two classes, silk with checked patterns, generally black and white, and apparently of European origin, and silks with very graceful geometric, apparently saracenic, designs in a great variety of colors. The soft tints and free lines of many of the patterns are much admired, and would come into general use were it not that they cost from 40 to 50 per cent more than Chinese and French silks.

The weavers (Catholic or Portuguese native Christians) hold a higher social position than the ordinary Salsette Christian fishers and husbandmen. They have the special name of Khatris and marry among themselves, and sometimes, with such of the upper class of Christians as take service as clerks in Government offices. They seem to have no memory of

their original country or caste. They believe that they were Mussulmans before the Portuguese made them Christians, and though by intermarriage with other Christians they have lost much of their special appearance, it seems on the whole probable that before they were Mussulmans they were Hindus of the Khatri caste, and of Gujerati origin. Judging from their appearance, they have a larger strain of European blood than any other Sabette Christians. They speak Portuguese at home and Marathi out of doors. Their houses are neat, clean, and airy, generally of two storeys. The looms and the reeling and sorting gear fill part of the verandah and one end of the front room on the ground floor, the rest of the room, which is of considerable size, is filled with a round table, chairs, a cot, well-made wooden boxes and cases, and displays a row of colored prints round the wall, almost all religious, of Christ, the Blessed Virgin, and Pope. They eat animal food daily, fish, poultry, and mutton, and are regular though not excessive drinkers of palm juice and mowha spirits. The men dress in European fashion, and the women in the Maratha robe and either the Hindoo bodice or a European jacket. They are generally neat and clean in their dress, and on high days wear rich silk robes and much jewellery. Besides sorting, reeling, and spinning silk, the women of the weavers' families find time to sew their own, their husbands', and their children's clothes.

The Thana silk weavers keep Sunday as a day of rest. Besides Sundays, the chief holidays are Easter Day, Christmas Day, and New Year's Day. Their usual working hours are from seven to eleven, and from one to sunset. They never work by candle or lamp light. They have no trade guild. Boys do not in any way help their parents till they are fifteen years old. They are refined, gentle, and kindly, courteous and frank, seldom guilty of crime, and fairly frugal. They teach their girls as well as their boys to read and write in the Government Anglo-Portuguese School. Their girls remain at school till they are thirteen or fourteen years old. Though the competition of cheap machine-made European and hand-woven Chinese silks has gradually driven their silks out of the best markets, they have not sunk into poverty, or even fallen to the level of unskilled labourers. The earnings of those who cling to silk weaving are small, but most of them have well-to-do relations, and they are in no way a suffering or a depressed class. Their education and the nearness of Bombay have helped many of them to better themselves by taking employment as clerks. Several families have settled in Bombay and prospered, and of those who have remained at Thana, from fifty to a hundred go daily to Bombay by train.

All the silk woven in Thana is bought raw in Bombay. It is of four kinds—superior Chinese, Basra (Bussorah), inferior Chinese known as Ahmedabad, because Ahmedabad is its best market, and Persian. The superior Chinese is divided into three classes—*doem* or first, worth about £2 (R20) the pound; *doem* or second, worth about £1 18s. (R19); and *doem* or third, worth £1 16s. (R18). The Basra which is also arranged into first, second, and third quality, is worth from 12s. to £1 (R9 to R10), and the Ahmedabad or inferior Chinese and Persian from £1 2s. to £1 6s. (R11 to R13) the pound. Chinese *doem* or *doem* are used for the warp, Chinese *doem* and Basra are used for the weft of check silks, and Ahmedabad for weaving plain silk waist cloths and robes. The weaver has seldom any stock of made goods. When the head of the family gets an order he goes to Bombay, and in the Bhoivada near Boleswar, buys from four to twenty pounds of raw silk from a Multan silk dealer. These dealers have generally considerable stocks of silk of the four leading varieties, some of it from China, and a less quantity from Bengal and Bokhara. Bokhara silk is more costly than Basra or Ahmedabad silk, and is seldom used by the Thana weavers. The Ahmedabad silk, which comes from China, is generally coarse and dirty, and is also obtained by the Thana weavers from the Multan dealers.

The raw silk is handed to the women of the weaver's family who sort, reel, and twist it. It is then dyed by the weaver himself, and the part intended for the warp sent to the Mussalman warpers. When the warp is returned, the weaver arranges the loom and weaves. When the work is finished he hands the cloth to the customer from whom the order was received, or, when it was woven on his own account he sells it to local customers who come to his house to buy, or if there is no local demand he takes it to Bombay.

Bohoras and Parsis use the checked silks for women's garments. Some of the geometric patterns are much admired by Europeans for dresses, and by Parsis for trousers, and have a small but fairly steady sale. Except that the demand for Hindu waistcloths is brisker during the marriage season (November-May), the demand for Thana silks is fairly uniform all the year round.

The Thana silk weavers seldom employ hired labour at their own houses. When they do pay the weaver from 8s. to 10s. (R4 to 5) a piece of fifteen yards long by eighteen inches broad. This represents about twelve days' weaving, or a daily wage of from 7½d. to 1s. (5 annas to 8 annas). The Mussalman warper is paid 2s. (R1) for warping enough for a couple of *tunis* or one piece or *taya* of from fifteen to twenty-five yards.

To sort and reel the silk, a skein is moistened and thrown round the *pitara*, a rough circular bamboo cage about four feet across and two feet deep. In the centre of the cage is a rod about two and a half feet long. About three inches from each end of this rod, that is about two feet apart, are fastened six spoke-like pieces of narrow bamboo about a foot and a half long. The ends of the two sets of spokes are tied together with cords, and the skein of silk is thrown over the cords. In reeling and sorting the worker, who is generally a woman or a girl, sits to the left by one side of the cage on a stool. On the ground by her right side lie one or two reels with long handles and points. She sets the bottom of the central rod of the cage in a porcelain cup or in a smooth coconut shell, picks out the end of the hank, ties it to one of the reels and lays the reel at her right side, the handle lying on the stool and the point balanced between the great toe and the second toe of her right foot. She spins the cage by whirling the top of its central rod by her left hand, and as the silk is set free, winds it on the reel by giving the handle of the reel a sharp rolling motion with her right hand and letting the point whirl between her toes. As the silk winds it passes across her left leg just above the knee. A band of cloth is tied to the knee, and as the fibre passes over the band, the sorter is said to be able to tell by the feel when the quality of silk changes. One hank of silk generally contains two or three qualities of silk. Each quality is wound on a separate reel. When the quality changes, the sorter breaks the fibre, and picking up a fresh reel or the reels to which the new quality belongs, joins the ends with her tongue, and goes on reeling till another change in quality takes place. After it is sorted, with the help of a small wheel or *rota*, the silk is doubled by winding fibres from two reels on to a bobbin or *thal* of hollow reed about the size of a cigarette. These bobbins are next arranged on the frame of the *rohat* or throwing machine. The throwing machine or *rohat* is in three parts. In the centre is the bobbin-frame or *sarha* with a central and two side uprights: about two feet behind the bobbin-frame is the great wheel or *gural-rota*, about two and a half feet in diameter and with a broad hollow rim; and about three feet in front of the bobbin-frame stands an upright conical reel or *sokamba* about twenty-six inches high and eight inches in diameter. The central or bobbin-frame consists of a divided central upright and two side uprights, whose outer edges are cut into a row of eight notches. At right angles with the central upright, that is, parallel with the ground, a set of eight bobbin-holders are fastened about two inches apart. These bobbin-holders are

round tapering steel rods or pegs about the size of a packing needle, which stand out three or four inches on either side of the central upright. Over the end of each of these steel rods a bobbin is drawn in shape and size like a cigarette. Each pair of bobbins is connected with the wheel by a cord which encircles its hollow rim. From the inner end of the axle of the wheel, a coir rope runs forward and is passed round the central rod or the high conical reel or *sakumba*. In working the machine the thrower sits on a low stool, and, as he turns the wheel, the cords pass round its rim, the bobbins twisting the two fibres into one, while the coir rope from the further end of the axle turns the reel. As the bobbins set free the fibres, the reel draws them through the two sets of eight notches on the outer uprights in the bobbin-frame between two round rods, which are marked off by rings of cords into sixteen compartments, so that as the long reel revolves sixteen hanks are wound round it, eight from each side of the bobbin-frame. When full the large conical reel is taken away, and the silk is wound on a smaller reel of the same shape, called *sakumbi*, which measures eighteen inches long by seven in a diameter. This yarn, which is known as double of *dautar*, is used in making some checked fabrics. But most of the yarn is again wound on bobbins, and a second time put through the throwing machine, so as to make the regular or four-fold, *chartar* yarn.

These processes do not differ from those in use in Yeola in Nasick, except that in sorting the silk passes over the sorter's left knee instead of through her fingers. The throwing machine is much smaller than the Yeola machine, and the reel is conical and upright instead of round and flat.

When the silk is twisted, the warp threads are sent to Musalman cotton weavers to be arranged for the warp. This costs 2s. (11) for every thirty yards of warp. The next process is washing or bleaching. If the yarn is not to be dyed it is washed in country soap and water. If it is to be dyed, it is first bleached by boiling it in an alkaline ley, a mixture of slaked lime and carbonate of soda. The silk is steeped in the boiling ley from ten to fifteen minutes, and must be carefully watched, as it spoils if it is kept too long. After boiling the yarn is washed, left in a solution of alum for one night, and again washed. The silk is now ready to be dyed. The dyeing appliances are simple: an ordinary brick fire-place, a copper cistern, and a stone-grinding mill.

In dyeing silks red, cochineal, *coccus cacti*, and pistachio galls, *pistachia vera*, in the proportion of one of cochineal to four of pistachio galls are powdered together and boiled in the copper cistern or dye-beck, and the silk is steeped and stirred in the mixture till it takes the required tint. The boiling mixture is then allowed to cool, and the silk washed several times and dried. If the colour is dull, the tint is brightened by dipping in lemon juice mixed with water. In dyeing orange, the silk undergoes the same processes as for red, except that in addition to cochineal and pistachio galls, the dye-beck contains a variable quantity of *isparuk* or delphinium. To dye lemon-yellow, silk is steeped in a hot strained solution of *isparuk* and impure carbonate of soda, and is then squeezed and dried. Though not itself yellow, this solution gives the silk a yellow that does not fade by exposure to the sun. To dye green, yellow silk is steeped in indigo. For black, the silk is steeped in an infusion of myrobalans, and then, for three nights in *wachner*, *deusine cocuana*, and a paste containing pieces of steel, then squeezed, steeped either in coconut oil or coconut milk, and washed in plain water. To dye purple, red silk is steeped in an infusion of myrobalans and dried, without being washed. It is then steeped in a solution of sulphate of iron and washed. Another way of making a purple fabric is to use black silk for the warp and red silk for the weft. Silk is seldom dyed blue. When blue silk is wanted, the dye used is indigo, and the work is entrusted to Musalman indigo dyers, who are paid 2s. the pound. To dye tanny, yellow silk is boiled a

degree less in the alkaline ley than for other shades. It is then taken out, squeezed, kept moist, and, without being washed, is plunged into a solution of dyer's *rotleria*, *Rotleria tinctoria*, and powdered alum in the proportion of fourteen of the rotleria to three of the alum, mixed with carbonate of soda and boiling water, quickly stirred and left to stand till the effervescence passes off. In this mixture the silk is steeped, stirred, and left to soak for about four hours. This is the most lasting of yellow dyes, but the process requires close attention.

Nine chief dye-stuffs are used in colouring Thana silks: carbonate of soda, country soap, alum, coppers, pistachio galls, *isparuk* or *delphinium*, myrobalans, rotleria, and cochineal. Of these, pistachio galls, *isparuk*, rotleria, and cochineal are brought from Bombay, the rest are purchased in Thana. The carbonate of soda is of three kinds: *papad khos*, *kele khor* and *khari mali*. All of them come either from Sindh, where they are dug from the bottom of small ponds, or from Arabia. They are a mixture of the carbonate and sesqui-carbonate of soda and contain a variable quantity of silica, chlorides, and sulphates. According to the amount of impurity the price varies from above 1½d. to 3d. (1 to 2 annas) a pound. The soap or *sakon* is country soap, chiefly made at Kapadvanj in Kaira, from the oil of the *Bassia latifolia*, boiled with an alkaline ley of *Khori* and lime. It is sold in round pieces at about 2d. (1-1-3 annas) the pound. This soap is not suitable for fine work or for the toilet. The alum comes partly from Cutch or Sindh. The Cutch and Sindh alum has traces of iron, silica, and soda. The China alum is purer and better. Sindh and Cutch alum varies in prices from about 1½d. 2d. (1 to 1-3 annas) the pound, and China alum from about 1½d. to 2d. (1-1-16 to 1-1-3 annas) the pound. The pistachio galls, *buz-ganj*, are brought from Persia and Kabul. Thana silk weavers obtain it from Bombay at 1s. (8 annas) the pound. The *isparuk*, the flowers and stalks of a kind of delphinium, is brought from Persia and Kabul. It is used solely in dyeing yellow, and costs from 9d. to 1s. (6 to 8 annas) the pound. Of the two kinds of Indian myrobalans, the chebinia myrobalans is the one generally used. It is the product of the *hivad* (*Terminalia chebula*), which grows in all the Sahyadri forests. The cost varies from 6s. to 7s. (R3 to R3½) per manad. The *Kapila*, or powder on the capsules of the dyer's rotleria, comes from Malabar, the Himalayas, and Arabia. It cost from 1s. to 1s. 6d. (8 to 12 annas) the pound. After being washed or bleached and dyed, the warp silk is singed.

The next step is to make ready the loom. In this there are three processes, beddle filling, joining, and arranging. In filling the beddle according to the pattern, the weaver passes the silk between the teeth of the reed or *phain* and through the loops in the cords of the different beddles. When the threads are passed through the reed and the beddles, they are tied behind the beddle frames in small bunches or clusters. The end of the warp is then brought and laid beside these bunches of silk, and beginning with the right hand bunch, each thread is snapped and by a rapid twist knotted to one of the warp threads. When the joining is finished the threads are arranged through the whole length of the warp in accordance with their position at the beddles. The labour and cost of beddle-filling is generally avoided by leaving about six inches of the former warp behind the beddle, to which the new threads are attached.

The Thana silk loom differs in no appreciable respect from the ordinary hand loom in use all over India, and a fair idea of its construction may be gathered from the illustration showing a Thana silk weaver at work. The dyeing processes have been described at some length as examples of the intrinsic simplicity of Indian dyeing methods.

Thana silks are sold by the piece, at the rate of R35 for a piece of 12 yards long and 24 inches in width. The same price is charged for a piece 15 yards long and 18 inches in width. If 50 pieces and upward are purchased and allowance of R2 on each piece is made,—*Bombay Gazette*.

TEA AND CINCHONA IN CEYLON.

The weather throughout January was extremely wet, with a good deal of wind. Fine weather has now set in and February seems likely to be dry and warm, as it usually is. The dampness last month has been very beneficial to tea all round, and absolute salvation to those whose necessities obliged them to delay their planting until the end of the season. Great preparations for planting are being made for the coming season, and many millions of plants will be put out in due time. From time to time our local journals contain letters on what appear very simple details, but the deductions drawn from them do not strike everyone who has been accustomed, and possibly for many years, to make use of such details as a matter of course. The saving of labour shown in the enclosed extract is one of no little interest; and may be new to some of your readers.

"The original tea-fields in Ceylon were usually planted 5 feet by 4, or 5 by 5; then 4×4; while now 4×3 has become the most common, and, perhaps, in our present want of early returns, it is the best, though we are duly warned by our Indian friends that this distance is rather close. It should always, however, be remembered that a steep or rough piece of land may be planted much closer than a flat or clearing of somewhat even lay; though even on the steepest or roughest land the working lines should never be closer than 4 feet. Four by three permits, practically, the same number of plants per acre as 3½×3½ and with the vigorous action of the tea root gives the advantage in its favor, resulting really in one-eighth less travelling by the plucker, to pluck the same number of trees. For instance, in a clearing 200 yards wide, there would be 150 lines, if planted 4×3, and 171 if 3½×3½, showing an increase of labour necessary in the latter, as compared to the former. Considering the matter in this light, those who have planted 4×3 may ultimately benefit very largely, for there is no doubt of the power of the plant being able to fully occupy the land with its roots. It is merely a matter of time. Thus, in a clearing with lines 6 feet wide, 5 feet wide, and 4 feet wide, and 3½ feet, the number of lines respectively for 200 yards would be as follows:—

6×3	100 lines	plucking say	2,400 trees.
5×3	120 "	"	2,800 "
4×3	150 "	"	3,600 "
3½×3	171 "	"	3,600 "

"Considering the immense area travelled by pluckers throughout the season, it is very desirable that this work should be made as easy as possible, the aim being the largest quantity of leaf, for the least possible tramping. The writer remembers in the old days of coffee that coolies were told 'you must either bring in plenty of *palam*, or else finish a large stretch of land,' implying most emphatically that the two results could not be attained. It will certainly be the same with tea, and the less we trail our coolies over the hills, the more leaf they will, in consequence, bring us.

"While upon this subject, has it never struck tea-planters how excessively the labours of our pluckers are increased upon steep estates by always having to go up and down the lines on the face of the hill, when, by transverse or oblique lining, the feature could be skirted, Ramsamy then having no more downright shoulder work than his *anna* when he walks along his well-traced, almost horizontal roads. Also, if the lines were far apart and the trees close in the line, so as to almost form a hedge, would there not also be a saving of wash? Would not the closely planted trees help to protect the land from the rush of *debris* down its face?

"It has always been a vexed question whether plants are better than seed at stake; though, in my mind, I have no two opinions upon the subject. Plants are generally more certain than seeds, but, where the soil is good, the climate to be depended upon, and there are no injurious insects, I should much prefer seed at stake, as there are no turned roots, and no injury to them through exposure. The root of a tea-

plant is a very important organ, for all must have observed how carefully it is projected downward in the economy of the plant's growth, before there is much seen above ground."

"Since writing my last letter, I have heard but little more of Mr. Giruth's tea machinery, as there appears to be an insufficiency of competition amongst machinists in Ceylon. In the old coffee days there were two establishments in Kandy, and of late years only one. Monopoly of any kind is now an acknowledged evil, and I cannot help thinking there is a very good thing to be done in Kandy by an enterprising firm of machinists, who would supply and repair tea machinery, and do a general hardware business in that town. You have doubtless seen a description of Mr. Gow's system of withering tea-leaf, and I am rather curious to read the expression of the opinions of your planters on the principle of bruising the leaf during the process, so opposed as it is to all expressed ideas hitherto, and is the very thing Mr. Giruth claims to have avoided.

I see notices in our journals headed, "Another tea-taster from London;" "Another tea-broker has commenced business in Colombo." At this rate we shall have as many gentlemen as we can find work for, indeed how all the brokers manage to obtain a living is rather a puzzle. Just now there is a cessation in planting, but I hear of more than one instance where cinchona is being rooted up under the impression that it is doing damage to tea-plants put out amongst it. For sometime past flourishing coffee has been cut up for a similar reason. I observe a notice in one of your papers about the probable introduction of Japanese tea-boxes to your estates. I should myself imagine that similar boxes could be made cheaper on the spot, that is where there is available wood than they cost imported from Japan.

A notice has appeared of an insect infesting both cinchona and tea, which, until identified or named, by scientists, is known as the cinchona-bug. At it is of such interest to planters I do not hesitate to send it to you in full, and need only add that I personally took part in the investigation, and can fully bear out the assertions as to its abundance on cinchona, though I have not seen it on tea. The existence of the insect, as far as is visible to the unaided eye, cannot fail to have been observed by cinchona-planters, but its prolonged existence under the outer cuticle of the bark has hitherto apparently remained unknown; and the immense number of them extracting the life-juice given from the bark would seem to account for so many young plants failing to grow though they remain alive, a state of things which hitherto has not been accounted for. About a month ago we were informed that this insect, which we will for convenience designate the cinchona-bug, was found upon tea-plants as well as on cinchona. This statement we did not care to circulate until we had opportunity of verifying it, but we much regret to find it proved to be true. A correspondent writes in answer to our inquiry: "Yes! I have found the insect as thick on tea as it is on cinchona." Here, then, is another pest to contend against, and one of no small moment either; and we hope our correspondents will not fail to let us know the results of their investigations. The following is the paper referred to:—

"Upon many cinchona trees, even young plants of one year's growth, may often be observed small blisters, scarcely an eighth of an inch in diameter, of the same colour as, and in fact forming part of, the bark. They are grouped promiscuously round the stem and upon the under sides of the branches. Under this blister, which merely forms a thin covering to a shallow cell in the bark, lies a small insect, which at first sight would appear to be the *pupa* of some minute beetle; but a closer examination soon shows the mistake. They vary from white to chestnut upon the upper surface, according to age; the latter being the colour assumed by the adult female, the under side is pale purple. They are soft and fleshy, have no outward or visible members, and appear to be absolutely devoid of eyes. But from nearly the centre

of the under surface proceeds a long slender sucking-bristle: even this can only be discerned under a microscope.

"The insect is divided into the usual number of segments (of the cocoon), which are rather indistinct at the anterior, but deeply divided at the posterior extremity, and fringed at the sides with short tufts of hair. The eggs, which are laid within the cell, are oval, pale-red, and transparent; before the young insect emerges, its limbs and eyes are plainly visible through the thin covering. It is hatched within the parent cell, and is then almost identical in appearance to the young larva of the brown-bug (*Iecanium coffee*), being pale flesh-coloured with two short pointed antennae, six legs, two minute black eyes, and a pair of anal filaments which are almost as long as the entire insect. It soon wanders away in search of new pastures. When once it has fixed itself under the thin outer skin of the bark, it decides to stay there for the rest of its life, and accordingly dispenses with its legs, eyes, and antennae as being of no further use, developing instead a sucking-bristle. It is in this first stage, and in the adult form of the male, that the insect proves its close relationship to the scale-bugs.

"When the female insect dies, the covering of the cell falls off, leaving a small white scar. On many trees the bark is dotted all over with these white spots: in nearly every such case the tree has a hick-hound appearance and looks 'shuck in general.' In some districts it is difficult to find a single cinchona tree that is not more or less attacked.

"The male insects commence life in much the same way, but they congregate in larger colonies, though not so widely distributed. In the larval stage they keep quite apart from the females. I have seldom found the two sexes upon the same tree. To account for this, it would seem probable that periodically a complete batch of eggs develop into male insects alone. The male colonies are few and far between, but, where they do occur, they often cover the bark so thickly as entirely to alter its appearance. The male larva is very much smaller than the female, similar in shape, but of a pale-orange or yellow colour.

"But it is in the *pupa* stage that the male colonies are most apparent; for then each insect exudes a fibrous cottony substance from one extremity of its cells, which lies in oblong flakes acarily parallel to each other. I have seen a small cinchona (officialis) tree so thickly covered with these white flakes that the bark was completely hidden. Within this white substance lies the small red *pupa* which produces after a time the perfect male insect, a minute red fly, only just visible to the naked eye.

"Viewed under a microscope, it is seen to be provided with a single pair of delicate, faintly-hyaline wings, which, when the insect is at rest, are laid along the back overlapping each other. From the head proceed a pair of long, jointed antennae, fringed with short hairs. It has no anal filaments like the males of the black and mealy-bugs, but the tail ends in a long point, about a third of the length of the body of the insect. But the most curious fact concerning it is, that it possesses four large, black eyes, one pair situated on the top of the head and another pair on the under side. They are all true eyes, not the small 'ocelli' that are frequently present in other insects. This would seem as if it wished to make up for lost time, having been condemned to pass the greater part of its existence in complete blindness.

"The larva and pupa of the male insects are more destructive to the trees they attack than those of the female, though fortunately their colonies are limited. The female insects appear to live for a considerable time, as their cells are frequently covered with lichen; and during that time they have no doubt produced many broods of young ones, though they seem to lay only a few eggs at a time. They are preyed upon by several species of minute wasps, and a berry black mite helps to thin their numbers. A thick grey fungus generally follows the attacks of the male insect, enveloping the

truck branches of the tree in a complete airtight suit. I have found several allied species of this curious insect, living under the cuticle of the leaves of different jungle trees, and particularly in the leaves of the Australian 'Bottlebrush' tree (*Callistemon linearis*).

If this pest is known in India on the tea, and any remedies have been suggested, I shall be glad to hear about it, as well as to any damage done to the trees themselves.

Oil from tea seed forms the subject of another communication, and runs thus:—

"Very good oil to burn and for other uses is made from tea-seed in China (I believe it is a better oil to burn than coconut oil.) Coolies and others are now making it for their own use on estates. If it would pay the expense of gathering, making, &c., and give a profit, surely it would be worth while to make inquiries about. There is no doubt about it the trees would be relieved if the seed was gathered, as it would be taken off long before it would drop naturally; besides there would not be so large an amount of seedlings, which it is almost impossible for the weedeers quite to clear out. No doubt about it: trees seeding so early as they do in Ceylon is no light matter; and, if a way could be found to turn it to a profitable account, we should not be altogether losers. If it pays to make in China, why not in Ceylon?"

This is something new to me, and whatever the quality may be of oil expressed from ripe seed, I cannot think the product of unripe seed can be of much value.—*Indian Planter's Gazette*.

DR. BONAVIA, of the Lucknow Horticultural Gardens, has but little faith in the statements as to the suitability and value of the *Eucalyptus globulus* in swampy and marshy districts. The results of his experience with the tree confirm the unfavourable results that have also been obtained with it in Italy, and he is surprised that it should ever have been deemed fitted to discharge the efficacious and salutary functions that have been so universally claimed on its behalf.—*American Cultivator*, Dec. 1885.

INDIAN TEA AND COFFEE.—The coffee plantations throughout India (says the *Grocer*) are now threatened by external competition, chiefly from Brazil. In 1883-84, 185,839 acres were returned as being under coffee for all India. Their total yield was 30,750,000 lbs., or a slight advance on that of 1882-83 (an exceptionally bad year), but considerably below the average formerly attained. The cultivation of tea, on the contrary, received a decided impetus. There were 269,571 acres actually planted, or 12,000 more than in 1882-83 and considerably more than 100,000 additional acres were taken up for plantation. But perhaps the following comparison will give the best idea of the growth of tea-planting. During the last nine years the acreage under tea has increased by nearly 100 per cent, and the total output (65,906,699 lbs.) has increased 149 per cent during the same period. Assam still remains the most important province of India for tea, and alone produced more than 52,000,000 lbs. of the whole output. The area of the gardens increased from 178,851 acres to 189,153, and the approximate average yield of mature plants per acre is estimated at 323 lbs., against 290 lbs. in the previous season. In Bengal the number of plantations diminished, but the area under tea, especially in Darjeeling and Jalpigore, was nevertheless larger. In the Punjab the cultivation of the plant has been abandoned in Simla, and has now been restricted to some 8000 acres in Kangra. In Madras and Travancore the plantations were grown in much the same way as before. In Burmah tea was grown experimentally for the first time, with fair success.

* A small quantity of tea-seed-oil was made as an experiment some 20 years ago by the Superintendent of the Central Assam Tea Co. at Dillow. It burned very well, and the experiments would no doubt have been carried out on a larger scale, but for the death of the gentleman.—*Ed. I. P. G.*

PLANTING IN NETHERLANDS INDIA.

THE JAVA COFFEE CROP; CINCHONA; BREWERY.

(Translated for the *Straits Times*.)

The Government Coffee Crop in Java, this year, bids fair to be a short one, the estimate hardly amounting to half a million of piculs. This however would not much signify under ordinary circumstances. It is usual for the yield, every three or four years, to be for once far below the average outturn. But two very unsatisfactory crops one after the other as in the case now, bode ill for the future owing to its arising from the estates becoming worn out even in the best districts the worst of it is that these plantations can with difficulty be replaced by new ones.

The royal sanction has been given to the Articles of Association of a company started to work beer breweries in Netherlands India on a capital amounting to 125,000 guilders. The first brewery has been established at Batavia.

The official report on the Government cinchona cultivation in Java for the third quarter for 1885 show that, in that year, the crop of bark reached 421,612 Amsterdam pounds. The yield would have been larger had not cropping been hampered by heavy rain and want of labour. There was every prospect of the outturn in 1886 proving to be far above that secured last year.

"A VISIT TO THE CINCHONA PLANTATIONS IN JAVA."

Mr. J. C. B. Moens writes to the *Indische Mercur* as follows (we translate from the Dutch):—

Under the heading the *Ind. Mercur* of 9th January last contains a translation of a paper by Mr. H. B. Brady, which he read at an evening meeting of the Pharmaceutical Society on 9th December, and which was published in the *Pharmaceutical Journal and Transactions* of 12th December. This paper, which does full justice to the friendly reception of the traveller by the Director of Cinchona Cultivation, van Romunde, gives me an opportunity for the following remarks.

That no difficulty was placed in his way, either of travelling over Java or of seeing the cinchona gardens, apparently surprised Mr. Brady somewhat, as he had no doubt heard that it was not such an easy thing. It is indeed astonishing how such a strange and wholly unjust idea should still continue to exist, in spite of the numerous visits of Englishmen, not only to Java but also specially to the cinchona gardens. There was a time, particularly in 1878 and 1879, when the fame of *Cinchona Ledgeriana* was known throughout Ceylon also, that Englishmen came continually to see the cinchona gardens, often almost without an introduction, and only seldom provided with recommendations from the Government, and it has often been my very pleasant duty to give the travellers permission to see as much of the gardens as they wished, although my duties did not always permit of my accompanying them. Almost every week brought some of the pilgrims, and it was usual at Bandong to consider every stranger as an Englishman who had come to see the cinchona gardens. The report that we observed secrecy with regard to the cinchona cultivation we owe to the period when Junguhn was at the head of the enterprise. From that time also dates an order, by which everyone who was not provided with a written permit from Junguhn was refused entrance to the gardens, and it was even the case that Prof. de Vriese was refused admission to the nursery-houses, although he had the special permission of the Government. Junguhn did not trouble himself much about such a permission, and his will was law with the overseers, who were dependent on him. It is now seen how difficult it is to get rid of the bad reputation which we then acquired. It is unfortunate that

Mr. Brady had no opportunity of visiting the establishments to the south of Bandong also. He would then, after seeing the original trees, and the plantation of grafts at Tirtasari, have got a better and juster idea of the *C. Ledgeriana* than was possible at Nagrak, where there are only descendants of the original trees, and among those many which have deviated from the good type. The *C. Ledgeriana* is certainly very different from the description given by Weddell of *C. Calisaya*, and in my work, "De Kina-Cultuur in Azië," page 75, I regarded it as probable that the cinchona described by Was *Calisaya* was a more or less hybridized *C. Ledgeriana*. The special characteristic of the species *C. Ledgeriana* is that the clusters of blossoms are small and compact, the blossoms small, yellowish white and drooping, and the branches united to the stem at a very acute angle. Dr. Trimen, the able Director of the Botanic Garden at Peradeniya in Ceylon, who was able personally to observe the varieties in the cinchona gardens there, also regards the *C. Ledgeriana* as an undoubtedly distinct species. That Kunze should state that *C. Ledgeriana* is a bastard between *officialis* and *C. micrantha* is lest correct. Kunze calls *officialis* itself a bastard, and derives *Ledgeriana* from *Calisaya* and *micrantha*. Brady thinks that the climate or the soil was not suited for the *C. officialis*, which he saw at Nagrak, as this variety had formed such long spindly trees. Everyone falls into this mistake who sees this variety of cinchona for the first time, and especially when the acquaintance is made in a plantation where there are other varieties of cinchona. It is, however, the peculiar habit of *C. officialis*, and they look no worse at Nagrak than in Ceylon or on the Nilgiris. In fact the plantation at Nagrak is exceptionally excellent, on account of the high quinine yield of the trees, whose barks often give an average of 6 per cent of quinine sulphate.

NOTES ON POPULAR SCIENCE.

(By DR. J. E. TAYLOR, F. G. S., F. L. S. & C.,
Editor of *Science Gossip*.)

Glass-flooring is largely increasing in use in Paris. It is said to be cheaper than wood in the long run, and it has the advantage of admitting and allowing of the diffusion of light.

The sugar industry has been affected so often for the worse that any further change must be for the better. But this hardly seems likely yet—at any rate to the cane sugar industry. It is stated that the *synthesis*, or "putting together," of saccharose has been accomplished. Any lacerous matter obtained from potatoes, converted into glucose by the usual means, and then submitted to the action of an electric current, has done it all. The result showed 88-38 of saccharose, but even this does not make it cane sugar.—*Australasian*.

THE CINCHONA MARKET.

(From a Correspondent.)

There is trouble with the market, the analysis, the growth, and with the Government in regard to cinchona. Prices have fallen, and fallen below all anticipation, and no one in particular can be blamed for the present unsatisfactory state of the market. During the fortnight before the last mail left London there was good competition for all rich tests, at steady prices of 14d to 5d. the unit. The Stair estate sold a large pile of "Renewed Crown," of the mark R. D. E. over S. in a amonid, for 2s 1d. to 2s 2d. per lb. The Stair *officialis* is the true variety and well grown, the renewed bark having had sufficient time allowed to develop the alkaloids. The Ceylon shipments continue on a very full scale. We hear from Ceylon that large shipments will not be continued. Low prices have lessened extension, and planters are now giving their attention more to tea than cinchona. There is some prospect of a better market in the future, which

will lessen troubles regarding this particular department of the industry; but trouble number two is now with the analysis. Bark, which has been analysed by good authorities in India, and found to contain more than four units of quinine, has been sold in London on tests of less than two units of quinine, involving, to the unconscious and unfortunate owner, a loss of more than 50 per cent. The analysers have differed; who is to decide? The Pykara Falls Estate was very anxious to obtain a correct opinion of the value of their bark, and a sample was accordingly sent to the Government Quinologist, who replied as follows:—

"I have made an analysis of the sample of *Cinchona officinalis* from Pykara Falls Estate, and find it to contain:—

Quinine	2.61
Cinchonidine	1.63
Quinidine08
Cinchonine35
Amorphous alkaloids51

Crystallized Sulphate of Quinine ..	5.18
Moisture at 93 per cent ..	3.51
	11.67 p.c.

The following analysis was also obtained from sample sent to London:—

Crystallized Sulphate of Quinine ..	3.86
" " Cinchonidine ..	1.15
" " Quinidine
Alkaloid Cinchonine ..	0.60

And the bark was valued, on this analysis, at 5d per unit, to be worth 1s 9d per lb. Subsequently, the bulk of bark from which the samples referred to were taken, was submitted to auction sale at London in the usual manner. The test taken before the auction was reduced to 1.91 per cent sulphate quinine, and the bark was sold at one shilling a pound, notwithstanding that the price of the unit had risen to 6d. A stirring complaint was naturally sent to London, which brought the following reply:—"Nothing can be fairer than the whole transaction, and there can be no fairer test of the value of a product than by public auction. On arrival of a bulk of a bark in dock, it is carefully sampled by the dock experts, who then forward an average sample to the broker, a sample accurately representing the whole bulk. The broker then forwards a small sample, directly or indirectly, to every manufacturer in Europe and America, these samples going out three weeks to ten days before sale. The sooner they go out, the better naturally, they are worked, as each manufacturer analyses his own sample, and, as this requires time, late samples receive poor attention. We also forward to the analyst, if the bulk is valuable enough to admit of this, a sample to be tested for guidance only. On the Monday before the sale, all the above samples are exhibited, and the buyers come round and examine them, note whether the tests received from their clients are corroborated by the appearance, &c., &c. At the public sale the buyers and agents bid according to the instructions received. Not one of them, as a rule, ever asks if the broker has tested the bark." There is a question—What have private analyses to do with the result of dock samples and public auctions? There certainly should not be a difference of more than 50 per cent between the result of the private analysis and the dock samples; but such has been the case recently in so many cases, that we consider the question deserving of public notice. The sales of bark on account of Government have recently been stopped at Madras, and we have no doubt the great dissatisfaction experienced, on the one hand by the purchasers of bark at these sales, and on the part of Government on the other hand, in consequence of the greatly reduced prices realized, have contributed much to this result. The growth of cinchona on the Nilgiris is slow, and expensive in upkeep. Planters who have been out of their money for years in the cultivation of cinchona, are not only burdened with the difficulties referred to, but the great competition continued by Government, which is unrelenting in its demand for taxes, is most disastrous. What will Gov-

ernment do with its bark now, if it is not to be sold locally? It has tried London, it has tried Madras, and it has tried the alternative of selling nowhere, and sending their bark direct to manufacturers of quinine. Still they are dissatisfied, and the planters also. The faults and failings of this useful enterprise require fuller investigation, and we have no doubt the Government will see the advisability of giving as wide circulation as possible to all the information in its possession.—*Madras Mail*.

FROM THE HILLS OF CEYLON.

THE TOON TREE FOR TEA BOXES, &c.—ITS GROWTH IN INDIA, JAVA, QUEENSLAND, AND CEYLON.

UPPER LINDULA, 11th March.

Thanks for the tin of seed from Mr. Mundt, which is very welcome. As I anticipated, when I heard of it, the seed is that of the Toon tree (*Cedrela Toona*), which was all the rage in Java when I was there in 1881, and you may remember that I brought a large quantity of the flaky seed, collected for me by my good friend Mr. Kerckhoven, but which unfortunately lost its vitality *en route*. I first made acquaintance with this fine tree at Dehra Dun, where there are fine avenues of it along the roads. That was in February 1876, and in the following March I saw it at Darjeeling. At both those places and in Assam it grows well, and there are now a good many specimens yielding seed in Ceylon. My experience in India, Java and Ceylon seems to indicate that it does better at a high than a low elevation. A planter in Upper Hewahcta had his toon trees destroyed by beetles, but on Abbotsford they have grown beautifully, running up clean, branchless stems to 20 to 25 feet in four years. We mean to cultivate them largely, with *Grevillea robusta* and *Cryptomeria Japonica*. Seeds of the latter recently sent from Darjeeling by Mr. Gammie are doing well in our nurseries. The three trees I have mentioned are all valuable for timber purposes, and the toon is so much valued for house building and furniture purposes, that I suspect it will be found too valuable to be devoted to tea boxes. The inferior woods of Ceylon answer well, and now we are getting cheap boxes from Japan and elsewhere. Toon trees can be planted 6x6 and then thinned out. When I was in Brisbane the wharves were covered with magnificent logs of toon timber, known locally as "red cedar," cut in the Queensland forests; and in Java it was so much prized that all the roads in the Preanger Regency were being lined with it, young plants of the large-leaved cinchona succirubra being used to shade the planted out seedlings! Of all trees I know toon is the one for estates, if the beetles do not injure it. In our experience of somewhat over four years, no enemy has attacked our trees.

SCIENTIFIC TEA MANUFACTURE.—We call attention to a thoughtful article on this subject, by a subscriber to this Journal. There are several useful matters mooted in the paper, and others which will draw forth, doubtless, criticism; but this can only lead to useful and desirable discussion on a very important subject to all tea planters.—*Indian Tea Gazette*. [The paper will be given in full in the *Tropical Agriculturist*.—Ed.]

BRAZIL AND FLORIDA are mentioned by the *Grocer's Journal* as possible tea-growing countries. With its approaching slavery crisis, we do not think Brazil is likely, for very many years, to grow much tea, and as for Florida the expense of labour puts competition from that quarter out of the question. Upper Burma when pacified and populated may become a tea country, but we believe the period is far distant.

Correspondence.

To the Editor of the "Ceylon Observer."

PLANTING NEWS FROM BURMA.

Tavoy, Feb. 2nd.

DEAR SIR,—Planting nurseries in fine order and tea, coffee of kinds, arnatto, cardamoms and cacao and several other new products all doing remarkably well. Coffee in bud and a fine blossom will be out on coffee Arabian, and coffee Liberian in about other 10 days or so; I have got about 15 cwt. of produce to ship to London in store, the maiden crop of the Model Duke estate. I am to plant up other 40 acres this year with tea, cacao, coffee and cardamoms, also another for shade with croton oil trees and the sautree. Yours respectfully,

JAMES D. WATSON.

COBRA BRAND TEA.

DEAR SIR,—I enclose sample of Cobra Brand *Pekoe Souchong* labeled $\frac{1}{2}$ lb. packet 7d — 2s 1d per lb.!!! Exhibition &c. &c. Just lignor and taste it and say what it reminds you of; and whether it is likely to increase the liking for Ceylon *Pekoe Souchong* amongst those who buy it out of necessity to gain a new experience.—Yours
UNOWHEW!

Atrocious stuff: the Planters' Association ought to take action through their Commissioner and threaten the "Cobra Brand" people with a prosecution for injuring the good name of Ceylon teas.—Ed.

THE WORLD'S MANUFACTURE OF QUININE

Feb. 11th.

DEAR SIR,—In drawing up your original estimates of the manufacture of quinine in the world as published in the *Oceania Observer* of Nov. 18th, by some oversight you made use of figures which applied to the heavy manufacture of quinine in Italy prior to the failure of the *Fabbrica Lombarda* in August 1884. The excess of manufacture during the years that "Cuprean" held sway was far and away above the requirements of that period, and undoubtedly heavy stocks (perhaps from two to three million oz.—who can tell?) are still held by those who, as things have turned out, so rashly ventured into quinine speculation. Not until quinine goes above 4s the oz. again will these old stocks in any quantity be offered for sale, although their existence at all times, until they enter into consumption, will constitute an unfavourable element in the quinine market. The manufacture of quinine in Italy since the failure has not, I should imagine, exceeded 250,000 oz. per annum. Your figures for United States are surely too moderate.—I am yours faithfully,
J. HAMILTON,

c/o S. Rucker & Co., 12 Great Tower Street, E. C.

Mr. Hamilton will have found the needful corrections in the *Weekly Observer* of 19th January, based on information from a reliable quarter; the manufacture for Italy was given at 30,000 lb. and that for the United States increased to 70,000 lb. The consumption of the States we put at 86,000 lb., but Mr. Hamilton thinks there is capacity for consuming a much larger quantity. We put the world's consumption in our Directory at 302,000 lb.; and this we had to reduce under the information we received in January to 270,000 lb.; but Mr. Hamilton, one of the best authorities, assures us that he would put the present consumption of quinine in the world at 5,300,000 ounces at the least.

or 331,226 lb., at 16 ounces to the lb. or 441,606 lb. if 'apothecaries' measure is meant. We have no doubt, however, that the influence of cheap prices will be seen in a rapid increase in the consumption of quinine.—Ed.]

A BIG CINCHONA AND A DITTO TREE TOMATO.

New Cornwall 25th Feb. 1886.

DEAR SIR,—Your special correspondent will be interested in learning that New Galway can still show some decent cinchona succirubra trees. I measured one here yesterday with the following results:—

Total height	..	51 ft.
Circumference at foot	..	4 ft. 3 in.
.. at 10 ft. high	..	2 ft.

The stem is bare of branches up to 11 ft. A few years ago there were two stems, and the smaller was then cut away, or it would now have shown a girth of 5 or 6 feet. A gentleman who was here a few days ago took it to be a hybrid, the leaves appeared so small at such a height above him, "It is worth a £5 note to look at," was his verdict, but he forgot to leave that same note. We have been expecting Mr. John Ferguson down, as, when I met him the other day in Colombo, he said he would look us up. I hope he will come to verify above measurements and see some coffee worth looking at: tea too is going ahead, there are already somewhere about 300 acres under that product in this secluded valley.

Mr. Cotton can still show some fine succirubras on Warwick and will doubtless send you dimensions, but come and see for yourself. Who has the finest tree tomato in Ceylon? Mine at 2 years old is 13 ft. 3 in. high with a spread of branches 10 ft. in diameter and loaded with fruit.—Yours faithfully,
ARTHUR J. KELLOW.

TEA: NOTES AND COMMENTS.—Mr. J. C. Kinnmond has recently paid Ceylon a flying visit. He went to Avisawella to inspect his tea properties, over which he has already expended nearly a lac and a half of rupees, and so pleased is he with the prospects of tea in Ceylon that he is prepared to spend double that sum on our new product. An Assam planter travelling with Mr. Kinnmond described much of the land he saw tea growing on as "only suitable for railway ballast," and even after going through some of the most favored tea districts said he was disappointed in what he had seen, after all he had read about the Ceylon tea enterprise. Mr. Kinnmond has ceased to take any active interest in the machinery bearing his name, and has now, as he says become a pucca Ceylon Planter. It is said that Mariawatte will, this season, give 1,400 lb. tea per acre! What will Indian Planters say to this, we wonder? Bumper returns—much in excess of last season—are also expected from other well-known estates.—"Ceylon Advertiser."

* He, no doubt, forgot to "take a note on," and went away unconsciously humming:—

"The trembling notes ascend the sky,
And float upon the air."

—Ed.

† We suppose it is the effect of the climate of Assam which renders planters from the Valley of the Brahmaputra liable to the disease of disappointment when they visit the Valley of the Kelani. We have heard that the planter alluded to above gave the majority of Kelani Valley estates, formed as he said on gravelly soil, only seven years of existence. If he comes back at the end of the seven years, he will probably be surprised in an opposite direction.—Ed.

COCOA NIBS.—Instead of local cultivators of cacao trying to make chocolate, we advise some attention to be given to the preparation of cocoa-nibs for the local market; the beverage from them is most pleasant and nutritious. Here are the instructions furnished to us by one who knows:—"A tablespoonful boiled for two hours *vigorously* in a white-lined saucenpan with a tight fitting lid and say two cupfuls of water should make a breakfast-cup of cocoa drink. The aroma goes off if there is not a good lid. If boiled for four or five hours the drink becomes thicker, but the aroma goes. I think the nibs are simply well dried and husked; as the skin comes off and the nibs break into pieces of such as we boil. This is all I know."

FEBRIFUGES FROM CINCHONA BARK.—A paper sent to us by the Government of Madras gives full details of the cost of preparing a liquid extract of bark, which has been found very efficacious and which has the merit of being in a condition ready for use. The two chemicals employed in its preparation were acid hydrochloric and glycerine. Our readers will be interested in the figures showing comparative cost of various preparations:—

Comparative Cost.		R.	A.	P.
Cost of 175 oz. of the liquid	...	18	3	4
" of 1 dose of the "	...	0	0	2½
" of 1 lb of Darjeeling quinetum	...	17	0	0
" of 1 lb of English quinetum (as fixed by Government of India)	...	10	0	0
" per 5 grains of Darjeeling quinetum	...	0	0	2½
" " of English quinetum	...	0	0	1½

THE JOHORE AND STRAITS FIBRE COMPANY (LIMITED) has been registered with a capital of £25,000, in 45 shares. The company is formed to purchase for the sum of £12,000, £2,000 in cash, £10,000 in paid-up shares—certain leasehold estates in the Batu Pahat district, Johore also the right to use in Johore, the Straits Settlements, &c., the patent machinery of Mr. Ephraim Death for "scutching" fibrous stems, leaves, &c. The company proposes to plant, cultivate, and develop, rhea, also, moorva, pineapple, and other fibre-yielding plants, and to manufacture fibre therefrom, and also to cultivate tea, pepper and other articles. The consideration payable to Mr. Death is £1,500 in cash and 300 paid-up shares, also a royalty on the machinery used. Mr. E. A. Watson, of Johore, the vendor, is appointed manager of the company's property in Johore.—*L. & C. Express.*

FISH-CURING YARDS.—In reviewing the Report on the operations of Fish-curing yards for the half-year ending 30th September 1885, the Government remarks:—"His Excellency the Governor in Council concurs with the Board of Revenue in the opinion that the increase in the quantity of fish cured is, notwithstanding the unfavorable character of the season, very satisfactory. Government are glad to observe that the disinclination of the fishermen of Vizagapatam to resort to the yards has been overcome. In South Canara, however, the yards have been made but little use of, and the fishermen, apparently, still hold aloof. Malabar, as usual, takes the lead in the enterprise of fish-curing. The Tinnevely and Masulipatam divisions used the largest quantity of salt per maund weight of fish. The smallest figure was in the Nellore division. The average for all divisions was 12'64 lb., and not 12'67 lb., as quoted by the Commissioner. Though the variations in the quantities used at individual yards are generally becoming less marked, there are still some cases of striking disparity occurring in adjacent yards. The departmental experiments in fish-curing led to no decided results; but there can be doubt that they serve a useful purpose by way of example to the fishermen, and they should therefore be continued. The financial result of the operations for the half-year was a loss to Government of ₹1,956. The total number of yards at the beginning of the half-year is given as 136, but, according to the report for the preceding period, it should be 134.—*Madras Mail.*

ANNATTO SEED.—In reply to a correspondent we would say there is only a very limited market for this seed. At a recent London auction one barrel of 476 lb. sold at 6d per lb. Annatto paste, called by some people Bixa Dye, has also been shipped from Ceylon in small quantities, the last sale realizing 2 6 per lb. This requires great care in preparation to prevent its turning mouldy *en route*. This substance, we understand, is used for colouring butter and cheese, and it therefore requires to be sweet. The importance of this cannot be too strongly impressed upon manufacturers, as without this essential quality the product is simply worthless.—*Ceylon Advertiser.*

COCONUTS: VEYANGODA, 7th March.—If the crops I and my neighbours have picked are a criterion of the coconut crops of this district, they will be lamentably short this year. Speaking for myself, I have all the necessary conditions for an increase of crop annually for the next 10 to 15 years, and yet my crop this year has fallen short of that for last year, as far as we have gone. In reply to your footnote to that part of my letter treating of the relative prices of coconuts and copra, I may mention that I have worked on your figures. You give the average number of coconuts to a candy of copra as from 1,100 to 1,300. I accepted the latter figure. Even taking it at 1,200, it is plain that with fair dealing copra cannot be profitably sold at the present figures. I too, have heard of places where 900 nuts suffice for a candy of copra. I look upon such statements as apocryphal. Nine hundred picked nuts when dried may yield a candy of copra, but it is hard to believe that an estate of even limited extent can yield such splendid averages. All coconut planters will bear me out when I say that only very exceptional places, hardly one per cent of estates, give such a good average as 1,000 nuts a candy of copra. On a large estate that I know of, 1,400 nuts have gone to a candy of copra for several seasons running.—*Cro., "Examiner."*

THE JAVA TEA-BOX wood, of which Mr. Mundt has brought a specimen box (as well as the seed of the tree) is known to him as the "Surian" and from the name as well as the lid of the box sent us by Mr. Bois, Mr. Wm. Ferguson is able to identify the timber as that of the well-known or at any rate much-talked of *Cedrela Toona* already frequently referred to in our columns. "W. F." writes:—"Botanically the specimen of tea box wood is most closely allied to our Lunumidella, the *Melia dubia*, and the only Javan name like *Surian* is '*Suren*'—*Cedrela febrifuga*—a synonym of *Cedrela Toona*. I believe the wood is the produce of that famous timber tree of which the Flora Brit. Ind. 1, p. 569, says it is a native of 'Tropical Himalaya, from the Indus Eastward, ascending to 3,000 feet; and throughout the hilly districts of Central and Southern India, Burma (absent in Ceylon?). Distribution, Java, Australia.' Gamble, Manual of Indian Timbers, p. 78, says of *Cedrela Toona*:—"In Bengal and Assam, it is the chief wood for making tea-boxes, but is getting scarce on account of the heavy demand." The box-lid itself, if a fair specimen of the work done in Java, is not to be admired, for as "W. F." says:—"No man in or out of Ceylon is a better judge of the fact that the tea-box lid you send me is the produce of a blundering mechanic. It was put together unseasoned with wooden pins to draw the edges and keep them close, and then had two battens nailed on the *inside* instead of on the *outside*, and is altogether a coarse piece of work. The wood has shrunk in drying, and there is a wide opening between the boards. I feel sure it can't be cheap too: It screw nails in a lid of a tea-box for cheapness!" We do not suppose the box in question, being probably used for the purpose of carrying seed, is a fair sample of how a tea-box is turned out, at least in respect of the 14 screw nails.

WEEDS.

Sir,—I have been a little surprised that the various articles on agriculture in the daily papers have omitted to mention the change which the new American digger is working in the cultivation of farm lands. More especially have I been surprised, because at the present state of agriculture any alteration that can tend to decrease the cost of growing crops is obviously one of great importance.

If you will permit me, I will give some description of his implement and of its results on some lands which I have recently viewed. The American digger differs from the ordinary plough, which is in some districts almost entirely superseding, in that the former has a skimmer fixed midway between the coulter and the share and mould board, and that the two furrows from the skimmer and the mould board are more completely turned over than the single furrow from the mould-board of the old plough. The effect of the work is that the skimmer furrow (about 2-in. deep) with all the weeds and couch grass is first turned upside down, and then covered with the mould-board furrow (4-in. to 6-in. deep) and the weeds being completely secluded from the light, die, and rot in the ground.

The following may be given as some of the effects of using this implement: (1) Originally after ploughing up wheat stubble it was necessary to also cross plough, twice drag-harrow, twice chain-harrow, and finally burn or cart off the couch grass or twice. But now all these operations are avoided by the American digger. (2) The couch grass, after being completely killed and rotted, forms manure for the next crop sown on the land.

On one farm of 800 acres the use of this implement has saved £100 a year in labour, besides yielding to the soil a considerable manurial value, estimated by the tenant (the best and most practicable farmer in the midland counties, who had been doing battle with couch grass for over forty years), at £1 per acre.

In conclusion, I may mention that on another farm where considerable difficulty had always been experienced with couch grass, the result of the American digging the land after seeds, and again when it was in wheat stubble, was to completely, and I speak advisedly, free it from that and other weeds.—ARTHUR TAPP, 15, Great George-street, Westminster, Jan. 26.—*Field*.

ENGLISH HOPS.

HOW THEY ARE RAISED, CURED AND SOLD.

Mr. E. Mecker, of Washington Territory, who is reported the largest hop farmer in the United States, has recently paid a visit to the principal hop-growing districts of England, and reports some of his observations to an exchange, from which we make the following extracts. Successful hop growing depends upon two conditions, to produce the best and to produce them as cheaply as your neighbours. England now has nearly if not quite 70,000 acres in hops; Germany also, with a moderate crop produce a large surplus; Australia now sends her quota to swell the grand total, but, after all, the country that sends the best hops and the cheapest will command the market.

However barely it may grate upon the ears of our hop growers, it is a fact that our American qualities are not up to the standard of what they should be. In the London market the hop must stand its comparison with the product of the world. I have seen 10,000 samples of all kinds of hops grouped on the boards under the skylight. Hops for the market must be ripe, should be of a golden color, even in color, thoroughly dry, dried at a low temperature, and the samples which decay should be soft and springy—silky is the term used in England.

Ripeness usually brings the desired color, but the evenness of color is governed more by the management. For instance, if one fills a bin from the bottom up with early and late pickings, it is almost absolutely certain that some of his samples will show "streaky," and under the English rules can be thrown out as "false packed," and the grower is subject to punishment by law. In view of the fact that our Western States market wants our early-picked hops and will not buy our

ripe hops, a better method is to separate the first week's or ten days' picking from the later. Then we get the even color that is so desirable in any market. Hops must be thoroughly dried, and at a low heat.

In visiting the hop fields of Mid Kent I saw their stacks of poles, many of which did not look larger than good-sized bean poles with us; saw where great fields of hops had recently been "digged"; saw the laborers at work digging (spading with a pronged spade), and I really believe that the English actually cultivate their hops in the winter, and that, too, by hand. The whole of the 70,000 acres now in England are so "digged" by hand.

The English hop brings a better price than our hops, or at least has for this year. Were it not for this difference we could crowd the English hop growers to the wall, for their hops cost them more than with us. The rents, tithes and manure cost them not less than eleven cents per pound, and the sum total not less than twenty cents, and very often much above that, and yet the English growers say that they see no better opportunity in other crops.

All English hop growers bale their hops as fast as dried, some of them while hot. They never let them cool until in the bale. They have no stoves in their "vast houses" but use an open fire with charcoal and coal that does not smoke. I saw a vine-cutting machine to cut hop vines into short pieces, to be used for bedding for animals and for absorbents in manure piles.—*American Cultivator*.

EXPERIMENTS WITH SWEDISH PLOUGHS.

Hutugalle Ratemahatmaya reports to the Government Agent, North-Western Province, that he selected a tract of field of ten amunams' extent, and used the new ploughs in patch of two amunams, and cultivated the remainder under the usual system, by means of the native ploughs.

From the earliest stage he noticed the crop in the patch where he had used the new ploughs to be far healthier than that in the remaining eight amunams, both in growth and also in general appearance.

He realized 18 amunams during the previous Maha harvest in the strip wherein he had now used the new ploughs, which was equivalent to ninefold; and the present yield of the strip of eight amunams, in which he had used the native ploughs this harvest, was precisely the same, viz., nine-fold, whilst a few beds lying on the upper level of the tract yielded less, seven to eight-fold. But in the patch where he used the new ploughs he raised 32 amunams and 1 péla, which is a little above 16-fold, and about double the crop realized from the native ploughs.

It has been often remarked that these ploughs are rather too heavy. The Ratemahatmaya admits that they are heavier than the native ploughs, and unless cattle are used in a more spring manner than is generally the habit of the natives, who use one and the same pair of cattle from morning till evening, he has no doubt they will meet with this difficulty. He was aware of this at the time he took the experiment in hand, and adhered to the precaution, therefore, to have two sets of cattle, and had them changed, one set being used in the morning and the other in the evening.

The Teacher of the Panapitiya School reports that he has just gathered his crop of the field which he cultivated in accordance with the instructions given in the Director's Primer of Agriculture. The field is two acres in extent, in which he sowed 2½ bushels of paddy, which have yielded 70 bushels. He sowed paddy too early, and heavy rain set in when the plants were in blossom, otherwise he might have had a crop of 100 bushels.

The remaining portion of the same field is seven acres in extent, and was cultivated by his neighbours, who had only a crop of 68 bushels.

In this connection he states that he finds by experience that the better the ground is prepared, the less the paddy required to be sown; and the less the quantity sown, the better the yield of the crop.

In 1882 he sowed in the field in question 3½ bushels, which yielded 54 bushels; in 1883, 4½ bushels yielded 40

bushels; in 1884, 5 bushels yielded 23 bushels; in 1885, 2½ bushels yielded 70 bushels.

The Ratemahatmaya of Beligal Korale, in the Kegalla District, reports that he used the new iron plough for 15 lahass of a field, and only the native plough for another 15 lahass of the same field.

From the 15 lahass cultivated with the iron plough he obtained 8 amunams and 6 lahass, which was rather more than 21-fold, and from the 15 lahass cultivated with the native plough he only obtained 5 amunams, which was 13-fold. He had before only obtained 13-fold from the land which now yielded 21-fold with the iron plough.

The Schoolmaster of Wallala has also used the iron plough, and his crops are looking much better than those cultivated with only the native plough. They have since been reaped, and he got 52-fold against 20-fold.

It should be remembered that the proper way to cultivate with the iron plough is first to plough with the iron plough about six weeks before the usual ploughing time, and afterwards to mix up the land thus ploughed by ploughing again with the native plough across the furrows made by the iron plough.

With ordinary good luck a much better crop must be the result.—H. W. GREEN, Director of Public Instruction.

COMMERCIAL ASPECTS OF THE SILK INDUSTRY.

Our attention is almost compulsorily arrested by the fact of the decadence of this industry in our own country, a decadence threatened by extinction gradual but sure.

A few useful figures from the Board of Trade returns of the value of the imports into the United Kingdom, and of the exports of British and Irish produce from 1854 to 1880, ordered by the House of Commons to be printed in 1882, most seriously shows this. I will only give the totals of various kinds of silk goods manufactured by countries in Europe during two decades, and purchased by England.

Imports of silk manufactures from the continent of Europe, Decade 1854 to 1863.

Total.....	33,732,335
Decade 1874 to 1883.	
Total.....	118,310,572

In 1856, our total imports of manufactured silk from countries in Europe amounted to a value of £1,826,525.

In 1880, the total imports of manufactured silk from countries in Europe had grown gradually year by year in value to £13,055,983.

Thus in 25 years we had come to buy from countries in Europe of articles we ought to have manufactured for ourselves no less than £11,258,558, an almost incredible sum.

The breeding of silkworms has for a long time been a most important industry in Italy and the south of France. The total production of cocoons from these worms in Italy amounted, in 1881, to 39,300 tons, and in 1880, to 40,930 tons. In France, in 1881, the production of cocoons amounted to 20,362,179—9,000 tons, and were principally raised in the Departments Gard, Ardèche, Drome, Vaucluse, Var, and by the mouths of the Rhone. French statistics show that from this large quantity of French cocoons was produced, in 1881:—

	Raw silk.	
	lbs.	tons.
Total product in West Europe.	8,688,614	3,879
From the Levant	1,366,200	611

It will be seen from these figures what a very important matter it is that the greatest attention should be paid to the earlier operations in the manufacture of silk threads, and one cannot be surprised at the Lyons Chamber of Commerce starting anew to ascertain all the facts relative to the proper sizing, i.e., producing even threads of silk in a mere minute and exact manner than heretofore. For if the earlier stages and operations have not for their aim and effect the production of an even thread, no after

manipulation of winding, warping, dyeing, weaving, or finishing can effectually avail in turning out fabrics of the finest qualities, in all or any of the various purposes for which silk is used. Hitherto the sizing has been by rule of thumb, and dependent on skilled eyesight and fingers, in first sorting cocoons and afterwards reeling 4, 6, 8, or more together, according to the required thickness of thread, or what at this stage is termed raw silk, that is, the state in which it comes into the market before it is manufactured into organzine, traua singles, &c. An examination of the thickness of the ultimate fibre must then take first place, and this method has now commenced, and will be carried on in the new Lyons Laboratory, not only of all species and varieties, or, as the French call them, races, of cocoons, but of the thickness of these fibres throughout the entire length of the cocoons, which I have discovered to be very variable. Next come the important examinations, of strength and tension, or elasticity, when the foregoing tables illustrate in both the silks of domesticated and of wild worms. The necessity for examinations such as these is more apparent in the manufacture of these silks which, some years ago, I ventured to designate by the name wild. For some of the wild silks of India, for example, there is a great future, a prediction warranted by the successful employment of the principal wild silk, Tussur—or as it is termed in its vernacular, Tasar—during the last seven years. It would not be right to omit here the mention of the name of Sir George Birdwood, C.S.I., M.D. in connection with Tussur silk. In my South Kensington Museum "Handbook of the Wild Silks of India," I quoted a paper which he wrote in India, as long since as 1859, in which he advocates the desirability of an attempt being made in England to utilise Tussur silk, a suggestion which he has lived to see now abundantly realised. The extent to which the consumption of Tussur silk in Europe has reached is very large. France imported, from one port alone, last year, 2,000 bales of raw Tussur silk. Several English manufacturers have thrown during last year large quantities as high, in one instance, as 1,000 bales. The whole of these recently-increased imports may be said to be badly reeled from the cocoon, much of it very badly reeled indeed, causing the European manufacturers to cry out loudly for improved reeling in the Eastern centres of production. Already has the improvement begun, and to such an extent has it been proved practicable by one of my many correspondents and collaborators in the East, that raw Tussur is produced from a single bale only—that is, so delicate in the improved reeling, that the beautiful raw Tussur you see here is simply the double fibre from a single cocoon reeled into a single thread successfully, proving conclusively enough that in this, as in other species of silk, if the quality of the raw silk put in the market is defective in any way, it is not the fault of the silkworm, which always does its work with the precision that the honey bee builds her cell, but rather the hitherto inadequacy of preception of man to ascertain and adjust the natural variations and difference of the fibre of so wondrous a beauty, and so incomprehensible a product.

Mr. M. Blair (Glasgow) said he had recently had the opportunity of visiting India, and might say a few words about the wild silks of that country, to which he thought silk manufacturers in England had chiefly to look in the future. One of the first things which struck a visitor to India was the enormous resources of that great empire, the vegetable, animal and mineral, thoroughly explaining why it was that all the great nations which had held the East and West traffic had nourished so exceedingly—from the Babylo-nians and Phœnicians down to the English. The second thing, however, which struck him, was the unreliable character of the people; the apathy and indifference to an idea of improvement and advancement was something which an Englishman, and certainly which a Scotchman, could hardly comprehend. In India there was a large population living, and content to live, on the verge of starvation, and if you increased their income, one of two things took place. Either

they worked half-time, and so reduced their income to what it was before, or they added additional mouths to eat it up. Thus it was found that when rice was cheap, the work-people went away for half of the week and left the machinery standing idle. This had an important bearing on the silk question. A vast quantity of silk material could be procured from India, but it would always be of poor quality unless it were prepared under European supervision. The silk was good, but it was not well reeled, and the people were too indifferent to improve it. The one thing needed for the resuscitation of the English silk trade was a large supply of cheap and good material, and for that they might look to India, not only from the *Bombyx mori*, but from other and indigenous kinds which Mr. Wardle, had devoted so much time and study to; but it must be reeled better. He feared this would never be the case if they trusted only to the natives. Anything which required no very skilled labour, such as rice-growing, or perhaps cotton, they did very well, but where skill was required, they could not be depended on. If they had been trusted to grow tea, and prepare the leaves, there never would have been any Indian tea worth speaking of, but under European supervision, this trade had grown enormously. The same policy should be pursued with regard to silk, and the machinery should be, as far as possible, automatic.

Mr. Wailly said he knew very little about silk, though he had done something to introduce new species of silkworm into Europe. He had lately seen carded silk from various species, such as Indian Tussur, *Pernyi* from North China, and some from North America. He had sent specimens of these carded silks to the Paris Acclimatisation Society. His main work had been the introduction of the insects, and he had no doubt that, this year, the Indian Tussur *Mytila* would be acclimatised in Spain, and perhaps in some parts of Italy, though it would hardly suit the northern parts of that country, as it would take three months to rear.

Mr. Wardle, in reply after thanking the meeting for the compliment, said his principal feeling in this matter was one of anxiety and disappointment at the great loss which this country had sustained within the last thirty years, by the gradual decay of the silk industry. It behoved everyone who was anxious to regain it to set about the work at once. It was a melancholy fact, which could not be repeated too often, that for the last ten years the average value of manufactured silks imported into England from European countries had been twelve millions sterling, and he believed Mr. Birchenuagh would bear him out that if English manufacturers received orders for one-third that amount, it would make the silk centres of Coventry, Macclesfield, Congleton, Manchester, and Spitalfields, very busy indeed. In reply to Mr. Hart's question as to what he suggested, he would say study carefully the report of the Commissioners on Technical Education, for if he understood it aright it contained everything necessary to regain not only that, but any other artistic industry, either European or Eastern. It was a most valuable report, and he was sure it would do a great deal of good. It contained a vast amount of information, and the deductions which the Commissioners had drawn from their travels and observations were such as would enable any energetic person in time to overcome any difficulties. Mr. Wardle concluded by drawing attention to and describing the various specimens of silk exhibited.—*Journal of the Society of Arts.*

Tobacco Cultivation in Britain and Ireland.—A crop which could pay to its cultivator—over and above outgoings of rent, rates, taxes, wages, interest on capital and plant, &c.—£220 and upwards per acre, would seem fabulous in the eyes of the British farmer, if he were told that such produce had in comparatively modern times been raised on soil of the United Kingdom; and yet, if we may gather inferences from the Statute Book, the profits of cultivation of tobacco (irrespective of penalties to the revenue) appear to have been on something of the aforesaid scale in the

days of Charles II. The plant seems to have obtained a rapid and a firm footing in these islands within little more than a century from the discovery of the New World.—*Field.*

SAMPLES OF TEA.—From proceedings of Agri-Horticultural Society of Madras, January 1886. V.—Read the following letter from William C. Deane, Esq., the Manager Kodanad estates, dated Kotagiri, 5th December 1885:—"I have the honour to suggest that at the approaching Exhibition in Madras you make it a rule that samples that have been on show on previous occasions be debarred from competing for an award. In the case of teas it improves by keeping and a planter who keeps back the sample that has been awarded the gold medal and sends it down to you year after year, practically keeps out of the running all young estates, coming forward with his champion sample, whilst it is equally unfair to estates who manufacture fresh samples every year for show, as we have invariably done ourselves for many years past. The Exhibitor should in every case add to the declaration that it is the *bona fide* outturn of his plantation, that the sample has been specially manufactured for your Exhibition, 1886, and that it or no portion thereof has ever been on show or competed for a prize on any previous occasions." Read also letter from the Hon. Secretary, dated 10th December 1885, in reply, stating that it was too late this season to enact a new rule, but that Mr. Deane's letter should be laid before the committee and the result communicated in due course. Resolved that the following additions be made to the conditions of competition for next season:—"After the words 'that land' add 'and in the case of tea, that the whole sample has been actually manufactured within the year in which it is sent.' For 'tea must be sent not later than the 15th December,' read 'Tea will be received not later than the end of December.'"

SULPHUR AS AN INSECTICIDE.—In our last appeared a brief but interesting letter reporting a successful result from applications of sulphur to the soil in which orange trees affected with scale were growing. Sulphur being so generally employed as an insecticide, both alone and in combinations, such as Gishurst's compound, it is surprising that its value as a destroyer of the scale insect when applied in the manner described, has not been made known. The plan is sure to be tested very generally, for the scale is a pest of increasing magnitude, and if sulphur in the soil will keep orange trees free from its attacks, it should operate in like manner on all other trees and plants that are subject to scale. The whole order Myrtaceae has to struggle against this pest, and even vines, begonias, and other deciduous shrubs are hosts for different forms of scale. Our correspondent, "Amateur," has suggested that a trial should be made of sulphur as a cure for or preventive of phyloxera on the vine. He would institute inquiry whether phyloxera has attacked vines in country known to be naturally "saturated with sulphur." We are disposed to suggest that there can be no possibility of phyloxera living in soil "saturated" with sulphur, and that vines also would stand a very bad chance of living under such conditions. Vines certainly grow on the lower slopes of Vesuvius, whence sulphurous fumes are emitted at a great altitude. That the fumes do not reach the vines may be accepted as certain, because fatal results so frequently occur from the injudicious burning of sulphur in vinerias and greenhouses. The question whether the soil of Vesuvius contains sulphur in large quantity is quite another matter, and one on which information would be acceptable. The letter of "Selector" in another column opens up new views of the scale insect question. The writer appears to assume, in effect, that soil well drained at a sufficient depth to allow the trees ample feeding-ground, and thus to insure freedom of growth, is the condition essential to the absence of all such pests as those referred to by "Amateur." We shall doubtless hear results of the trials instituted by "Amateur's" friends, so that when sufficient time has elapsed the whole matter may be reviewed from a stand-point based on those results, and which does not at present exist.—*Australasian.*

TEA IN THE MADRAS PRESIDENCY.—The *Englishman*, commenting on this subject, says:—"The cultivation of tea appears to be gradually, if somewhat slowly, extending in the Madras Presidency, principally in the Vizagapatam, Madura, Neilgherries, and Malabar districts. The tea estates have an area of 7,553 acres, of which but little more than half is actually under cultivation. The outturn last season was 398,045 lb. There are also twenty-seven tea plantations in Travancore, which yielded 105,740 lb. last year." We do not think, however, that there is much to be feared from this competition, as home prices for these teas have not as yet proved encouraging.

KANDAPOLLA, NUWARA ELIYA, Feb. 1886.—Tea has proved the saviour of Ceylon, all Indian and other crokers to the contrary. New machinery is being erected in every direction, but we want cheap or moderately cheap machinery; we cannot afford to pay the prices for heavy machinery like Jackson's. Who will prove the good Samaritan and send us a cheap and effective withering machine? During her best flushing months we cannot wither our leaf under two days. A friend has just sent me sketch of his trade mark, a tea bush with the motto *Ceyloniensis Saluator*.—*Cor.* "Ceylon Advertiser."

NAILS.—It is predicted that in the course of the next five years, the steel nail will have as completely supplanted the iron nail as the steel rail has its iron predecessor. Already one of the nails manufactured in Wheeling are made of steel, and the machinery and plant necessary for their manufacture are being set up in every nail centre and at nearly every nail foundry. It is said that, under present conditions, steel nails can be made about ten cents per keg cheaper than those made of iron, even where the manufacturer has to purchase his ingots.—*American Cultivator*, Dec. 1885.

COFFEE.—With regard to coffee, Dominica was once one of the chief coffee-producing countries in the Western Hemisphere, and capital and enterprise alone are wanting to make its name known again in the home markets. Liberian coffee grows well in the low lands, and, in spite of the "white fly" blight, the so-called "creole" variety gives remunerative crops in lands situated over 1,000 feet above the sea. It is to be hoped, therefore, that there will be a good coffee exhibit at the forthcoming Exhibition.—*Colonies and India*.

CURE FOR MILDEW.—In support of his previous testimony with regard to the efficacy of sulphide of potassium in checking the ravages of mildew and allied forms of fungus growth on plants, Mr. Task, of Kewlee, Warwickshire, has exhibited a fine healthy specimen of a zonal *perlegenium* which a month previous was rapidly perishing from the disease. The plant had been totally immersed, soil and all, in the solution, to the complete cure of the malady. It need not be suggested that very bad culture must have caused so hardy a plant to be mildewed, and that clean roses and vines would have afforded testimony of a more encouraging character than the plant chosen for the purpose. Experiments should, however, and doubtless will be, tried with sulphide of potassium by many amateurs who are troubled with this very common pest, especially upon roses.—*Australasian*.

GREEN MANURES.—We notice that the question of green manure is assuming importance on the continent of Europe, especially in places where the soil is sandy. The procedure is to sow some crop that does not require manuring, and when full grown to have the field rolled over, with the plough following, by which the entire crop is ploughed in. By this means, every four or five years a very large percentage of the fertilising agents are spread over the ground, by which the farmer is enabled to get a fine crop of wheat with several crops of other cereals and grasses. Chemically, it is explained that it is the quantity of nitrogen in the succulent green plants that works the chief part of the benefit, while the decomposition of the fresh vegetable matter underground gives off carbonic acid gas which attacks the

inert silicates and turns them into assimilable sorts. When the decomposition is complete, a capital manure is the result. In Saxony this is usual method of manuring and fertilising the sandy soils in which the country abounds. Great efforts are being made in France to introduce this practice into the vast tracts of poor land. We would recommend this to the notice of our agricultural departments, as a means of fertilising and utilizing waste and poor tracts of land in this country.—*Gardener's Chronicle*.

MANGOES AND MANGOES.—The following list of twenty-two mangoes, which Dr. Short states are procurable in Salem, was read at a recent meeting of the local Agri-Horticultural Society:—Goondoo, nadechalai, kelmoohu, thil pasanthu, James pasanthu, bavutheen pasanthu, offic pasanthu, rungu-haria thil pasundu, seriam-kusarow, anbalatt, gathaimaru, mulgova, Yacob Romani, thuthpeida, sakkari kuttali, bathami, amercoola, banther gandi, apeem ani, thothapari, bengaluru, and gova bunder.—*Madras Mail*.

HOW TO MAKE GOOD TEA.—A correspondent to *The Grocer* writes, recommending the following system of making tea:—First, put the desired quantity of tea (one spoonful for each person, and one for the pot) into a small muslin bag, which drop into the teapot, after thoroughly warming and drying the latter; then pour sufficient boiling water into the teapot, and let it stand for about five minutes; after which, extract the muslin bag containing the tea leaves, and then the tea may be poured out, and drunk with real satisfaction. The advantages of this system are that the second and third cup will be found equal to the first; that the tannin and other properties of tea not considered beneficial are left in the muslin bag; and that the consumer gets a beverage which in this case may be described with perfect truth as "cheering, but not inebriating."

Java may be expected to run ahead rapidly now as a tea producer, seeing that its planters, who have hitherto been absorbed in sugar and coffee, have at length awakened to the need of a new string to their bow in tea. Tea has been regularly planted and prepared there for a generation back, but (as in Ceylon) no one cared to extend so long as other staples paid their way, and so Java exports annually no more than the 6 to 7 millions of lb. anticipated for Ceylon during the present season. But it did not require Mr. Mundt's visit to warn us of the serious competition which may shortly be anticipated. Mr. Mundt has come specially to learn all about our improved machinery, system of cultivation and preparation. He has already on his plantation two of Jackson's rollers (Excelsiors) at work to be followed by two of the Victoria Driers, and when we mention that Mr. Mundt has some 600 acres under Assam tea as well as an equal area under China, an idea may be formed of the large scale on which tea cultivation will now be undertaken in the rich volcanic island of Netherlands India. Nevertheless we abate not a jot of our belief in the ability of Ceylon to hold her own in the tea struggle: Assam and India generally, not to speak of China, must surely suffer first. Mr. Mundt has brought over a liberal supply of the seed of a tree which is universally used in Java for tea-boxes, being a rapid-grower giving good wood under favorable conditions at five to six years, and growing at any elevation while by no means inimical to the tea-bush. Messrs. Alstons, Scott & Co. are distributing the seed to try in different parts of the island and we are indebted to Mr. Percy Bois for a package to which a careful trial will be given at different elevations and the result reported.

DR. TRIMEN'S REPORT FOR 1885 ON THE CEYLON ROYAL BOTANIC GARDENS.

As usual there is much that is interesting and valuable to horticulturists, agriculturists, and botanists in Dr. Trimen's report, the whole, or the larger portion of which, we hope to reprint, in the *Tropical Agriculturist*. At the very outset in detailing improvements made in roads and paths, an incident is reported to show that Mr. Gladstone's favourite recreation of tree felling must in this tropical land be pursued with caution. There seem to be other trees besides the euphorbias which exude dangerously acrid juices. Amongst these is *Hura crepitans*, the Sandbox Tree, during the cutting of which some of the milky juice of the bark was squirted into the face of one of the workmen, with the result that the man completely lost the sight of one eye. We notice that along a new path have been planted seedlings of the elegant Australian palm, *Archontophoenix Alexandria*, so common in the dense "scrub" (tall forest) of tropical Queensland. Not only ought this palm to be more commonly used than it is in Ceylon, being as graceful as the areca, and considerably taller, but the example set at Peradeniya ought to be followed in utilizing the dwarf China bamboo for fences. In Singapore fences are almost universally made of this plant, which when pruned down and trimmed grows thickly and looks very neat. Subscribers to the Thwaites memorial in the Peradeniya Gardens, besides receiving a photograph of the building, will be glad to see the following account of it:—

This little building has been erected during the year, and now wants, to complete it, only some seats and a suitable inscription. The design is octagonal with a high-pitched, tapering "broken-backed" roof of the ordinary Kandyan style supported at the angles by thick-set pillars of brick and cement, and internally by eight slender, carved jakwood pilasters. The proportions in general and details of the pillars are in accordance with those of the octagon of the Maligawa Temple in Kandy; and I am much indebted to Mr. MacBride, Director of Public Works, for transforming my rough sketches into accurate working plans.

We regret to notice that of four black swans presented by Capt. Bayley of the P. & O. Company, and which added to the attractions of the enlarged garden pond, one fell a victim to a tiger-cat. Tea, as yet, seems happily exempt from serious damage by grubs, but those engaged in other cultivation will be interested in the information embodied in the following paragraph:—

The large lawn suffered during the wet weather of June from an attack of root-eating grubs. They were the larvae of apparently one of the same species of Meloidiid beetles that have been so destructive to coffee in some districts. The roots were eaten off below the ground, and the dried and withered grass could be stripped off the surface, with which it had no longer any connection. But the plague was short-lived, and the value of large insectivorous birds well shown. During the whole period of the visitation, the places affected were the bivouac of numerous crows who sought for and eagerly devoured the grubs (often so gorging themselves as to be scarcely able to rise off the ground), and eventually exterminated them. It is a matter for regret that this bird does not extend its range into the higher coffee districts, where "grub" has been so destructive.

A new edition of the Hand Guide is for sale in the Gardens at 25 cents a copy. Meteorological phenomena and their effects are thus recorded:—

The whole fall for the year was somewhat above the average, though January was absolutely rainless, and the fall for October—usually our wettest month—less than usual. The greatest fall recorded in any 24 hours was 3.21 inches on September 27-28

The river rose at the end of June to a great height than I have before seen and, threatened to cover a part of the drive, but subsided before any harm was done.

In March we suffered from a heavy north-east wind, and several trees were destroyed. The most serious loss was one of the Coco-le-mer palms (*Lodoicea*), nearly 35 years old, and an object of great beauty. Its fellow of the same age remains, but is not so well-grown a specimen.

The very tall and conspicuous Norfolk Island Pine (*Aracoria excelsa*) in front of the old Director's bungalow, died very suddenly in a few weeks from above downwards, and has been removed. We have many smaller specimens about the grounds, but none are healthy.

We suspect the magnificent Norfolk Island Pine will succeed better at loftier elevations than that of Peradeniya. The rainfall for 1885 was only 4 cents less than 93 inches, or 6 inches above the Colombo average. The rainiest months were June and July, aggregating 26.84 inches, and October-November, which gave 24.59. The number of rainy days was 146 out of the 365, a fact which will take some persons by surprise. The Hill Garden at Hakgala, which, as Dr. Trimen truly remarks, continues to increase in usefulness and beauty, received 10 inches less rain in 1885 than Peradeniya, but the smaller amount of 83.14 at Hakgala was far better distributed, the number of rainy days being 215, or 3 days fewer than the average established by the observations of four years. Of the weather Mr. Nock reported:—

The first few days of the year were very fine and bright, and the rest of the month was remarkable for wet, cold, foggy, and misty weather. The fog was very thick at times, but only on one day, the 15th, did we have any very heavy rain. On that day 1.14 inch fell. The other 23 days on which rain fell brought up the total for the month of January to 5.56 inches. The next three months were very dry; only 9.70 inches of rain fell during that time. May, June, and part of July, were very favourable months for garden operations, but from 15th July to 22nd September it was again very dry: 4.56 inches of rain were all that fell during these 68 days. The rest of the year was very reasonable, December, as usual, being a wet, foggy month. The total rainfall for the year was 33.14 inches which fell on 215 days, the heaviest fall in any registered 24 hours being 3.55 inches on 12th and 13th December, curiously on the same days and nearly to the same amount as in last year.

The highest temperature during the year in the sun's rays was 148.0 on 31st August, and the lowest on grass was 35.0 on 22nd February and 9th March. The mean amount of cloud for the year was 7.6 and that of ozone 2.8. The cloudiest month this year was June, with a mean amount of 9.5, and the brightest month was March with 6.1.

The mean temperatures of the months ranged from 58.5 in January to 66° in Sept. and the mean for the year was 62.9, or about 6° warmer than the mean of Nuwara Eliya. The extremes in the shade at Hakgala for 1885 were 79° on 31st August and 13.5 on 3rd Feb. The Henaragodda Garden (tropical) is reported to be in good order and to have supplied a large number of cacao pods for distribution. Of the Anuradhapura Garden Dr. Trimen reports:—

A further large supply of plants in five carts has been sent to this Garden from Peradeniya, comprising especially fruit trees, vegetables, and acaia, and ornamental shrubs. Large supplies of seed of the areca palm, jak mango, oranges, and limes were also forwarded for raising on the spot; and many have been distributed at a small charge to the owners of the newly-cleared paddy lands under the tanks. This work is capable of great further extension.

The past year was a favourable one for the garden the rainfall having been much above the average. The site of the garden is about 302 feet above

sea level, and the mean temperature, like that of Colombo, a little over 80°. The rainfall in 1885 was 79.73 inches against an average of 53.26, and the rainy days 113 against 102. The last figure shows that only on about 100 days can rain be expected to fall at Anuradhapura. Hence the necessity for irrigation works. Regarding the new garden at Badulla, in the new Province, Dr. Trimmen reports:—

I am gratified to find included in the Votes for 1886 a sum for an experimental garden at this town, the capital of the District of Uva, about to be created a new and independent Province. I have urged the desirability of this addition to the Botanical Department for some years in the interests of the inhabitants, native and European, of this large and important but somewhat isolated part of the Colony; and in March last, in company with the Government Agent, Mr. King, I selected a suitable piece of land somewhat over eleven acres in extent in a good position near the town. This has now been taken over by Government, and I shall at once proceed to fence it and lay it out. One object of this Branch specially kept in view will be the cultivation and improvement of tropical fruit-trees and vegetables, and I purpose to place it generally under the Superintendent of Hakgala and work it as a low-country extension of that Garden.

The interchange of seeds and plants with all parts of the world has gone on as usual, and it is stated that the

Customary *gratis* supplies of useful or ornamental plants have been made to the following public officials and institutions in this Island:—The Government Agents and their Assistants at Kandy, Badulla, Negombo, Kegalla, Kalutara, Matara, and Hambantota; the Queen's House Garden, Colombo; the Colombo Museum Grounds; the Ceylon Medical School, Colombo; the Local Board, Nuwara Eliya; and the Station Masters at Nawalapitiya, Mahabaiyawa, and Katgastota.

There is a long list of additions to the collections of plants at the various gardens, and then come interesting and important notes on economic plants and products. Dr. Trimmen does not believe in the extinction of coffee, but rather in the abatement of the evil which has afflicted it, and he is strong in advising planters to cultivate a variety of products. His tone about the cultivation of tea by the natives, in lieu of their lost coffee, surprises us. He hopes as we do, that the natives may benefit by working for wages, but he holds that tea cannot be cultivated profitably in small quantities, and that planters would give less for leaf sold to them than what it costs themselves to produce; but many of our readers know how those who have money invested in factories and machinery have been competing for leaf at high prices. Dr. Trimmen deprecates the growing of tea and cinchona together, as it is only in such cases that *helopeltis* has done any appreciable damage to tea. The "Verde" and "Morada" Calisayas receive honourable mention, the comparison with Ledgeriana, all the trees being 20 months old, being as follows:—

	Quinine.	Cinchon- idine.	Quinidine.	Cinchon- ine.	Amor- dilli- sabaloids.	Total.
C. Calisaya Morada..	1.53	1.13	—	1.16	.96	4.78
Do. Verde ..	1.92	.90	—	1.16	1.19	4.57
C. Ledgeriana ..	1.68	.66	—	1.03	1.74	5.11

Dr. Trimmen deprecates diminished attention to cacao from what he calls an unreasonable dread of *Helopeltis*. He adds:—

There appears now to be a general consensus of opinion among planters, that this bug attacks principally cacao grown in the open; and the planting of

shade-trees is becoming general. It may be expected that our export of this product, considerably decreased in the past year, will speedily recover; and if the *Helopeltis* panic led to a more appreciative selection of land, and more care in cultivation, it will not have been entirely injurious.

There are notices of the rubber and gutta yielding plants, and the opinion is expressed that coca leaves can be received in such plenty from America that there is no chance of the cultivation proving profitable in Ceylon. Dr. Trimmen is puzzled to know to what economic use croton oil is put seeing that its use in medicine is limited, and that Ceylon planters obtain 48s to 77s per cwt. for the seeds. A new vegetable, like but superior to vegetable marrow, has been successfully established at Hakgala; so with the tree tomato, the fruits of which are good for tarts. The mountain papaw is also mentioned by Mr. Nook as resembling apples. New Zealand sweet-potatoes promise to be a good introduction, as they grow at high elevations; and the Chinese ginger, which is said never to flower, is being watched with interest. Of 15 eucalypts at Hakgala, 3½ years old, the Jarrah (*E. marginata*) had attained 36 feet in height with 20 inches girth at base. The red gum (*E. robusta*) was 30 feet high, but 22 inches girth. *E. globulus*, the blue gum, is not mentioned. We quote the following paragraph:—

The publication in June of my new "Systematic Catalogue of Ceylon plants" involved the re-arrangement in accordance with it of the Ceylon Herbarium. This has been effected, and at the same time the series of drawings of our native flora has been similarly arranged in numbered genera-covers. The whole is thus now very easy for reference. This has occupied a good deal of time, but in connection with the work I was able to put together a series of notes on the flora of Ceylon, which have been published in the London "Journal of Botany" (May-September, 1885). In this paper about 180 additions to the flora of Ceylon are recorded, and 40 new species or varieties are described. Along with the new "Catalogue" this brings the record of the constituents of the Ceylon flora down to the end of 1884. That much yet remains to be done is obvious from the fact, that during the past year, 1885, fifty-two additional species have been discovered in the Island, some of which are striking plants.

I made a botanical tour through parts of the North-Central and Eastern Provinces during the year, and shorter excursions to Matwata, &c., and added many specimens to the Herbarium.

Museum.—I am still unable to initiate any exhibition of an adequate sort, but the approval of Government for the formation of such an addition to the Garden has been conveyed to me, and I trust that the small additional expenditure involved will also be allowed. After the successful Agri-Horticultural Show held in Kandy at the end of May, several of the exhibitors were so good as to present to the Gardens their exhibits. I have especially to record my thanks to C. E. Teenekoon, Ratamahatmaya of Kurunegala, for a fine series of paddy in 54 boxes, a collection of small grains, and other products; to A. Payne, Esq., of Handrokaanda, for collection of fibres; and to Ekneligoda Ratamahatmaya for specimens of work in "Ranabata" bamboo *Tectostachyum maculatum*. A great deal of my time during the latter part of the year has been taken up in selecting, preparing, and naming the rough logs of timber sent in by the Provincial Foresters and others, or collected by the Garden officers, to form a series for the Colonial and Indian Exhibition. Much labour would have been saved me had all the contributors complied with the suggestions sent out. As it is, a good deal of the material is undeterminable, and cannot be used. There will be numerous duplicate specimens, from which it is hoped a fairly full series can be made up for the Garden Museum, and perhaps also for that at Colombo.

CEYLON UP-COUNTRY PLANTING REPORT.

CHEAP TEA MACHINERY—PUTTING IT ON—SMALL PROFITS AND QUICK RETURNS NOT THE RULE IN CEYLON—YET ANOTHER AND CONTINUOUS ROLLER—THE PROSPECTS OF CACAO—NUTMEGS—A GOOD BLOSSOM ON COFFEE IN DUMBARA—&CO.

15th March 1886.

Is the appearance of Mr. C. Shand's cheap tea drier the beginning of an era when the prices for tea machinery will see a considerable reduction? That the machines required for the manufacture of tea cost a lot of money goes without saying, and that they could be made for very much less, and still show a handsome profit to the manufacturers, can hardly be disputed. There is, however, some delicacy of feeling among the rival makers in regard to lowering current quotations; no one desires to take precedence of the other in this good work: "After you," they keep repeating to each other, as they stand hat in hand: an exhibition of a high-toned refinement of which the planters would willingly see less.

I heard the other day of one machine which is high in favour, and has been well cracked up. It has turned out to be a regular milch cow to all who have to do with it—except the buyer. A planter remonstrating with the patentee on the big price he was asking, and pointing out—without any selfish motive of course—how much more satisfactory it would be for every one if a moderate price were demanded, instead of "sticking it on" as was being done, was told that the thing was impossible. How could he ask a moderate price when the makers of the article wanted £200 clear profit from every machine which left their shop, as their share of the spoil? Then there was the cost of manufacturing, the material, exchange, wages, &c., to be added. Last of all there was "something for my trouble." Altogether the patentee ran up a nice little hill, which, if passed, completely cut away the ground from the caviller, and what had seemed exorbitant turned out in the light of fuller knowledge to be cheapness itself.

And yet there is room and call for a cheap machine, only the engineers as yet don't see it to be to their advantage to respond to that call. The principle of "small profits and quick returns" which at home has done so much for those who have had the courage to embrace it as an article of business faith, is perfectly powerless here: it pays much better say they to sell fewer of the higher priced article, than more of the low priced one.

While on tea machinery, I may say that there is yet another roller about to appear. Unlike those now in the field, the new machine will be continuous in its working, the withered leaf coming in at the top, and a steady flow of rolled issuing from the bottom. The aim I understand is not to waste any power in continuing to roll what is already sufficiently rolled, nor to lose time in stopping the machine to take out the charge, and filling up again. If the new roller comes up to the expectation of its inventor, it will be a considerable advance on anything that is yet in the field, and will have before it a prosperous future.

The weather still keep very favourable for cacao, and those who see it as it is now, and contrast it, with what its appearance was this time last year can trace there in a fit emblem of the downs and ups of a planter's life. A Matale planter looking last season at the future of cacao, through the leafless boughs of his stricken trees, said in reply to a friend who had put in the cheery word that Matale was the very home of cacao, "yes, the last home"! And now

there is everywhere quite a change in tone, the croakers who formerly were legion have ceased their croaking, and the more hopeful have now their innings.

The season has also been a very favourable one for nutmegs, of which, however, there are very few in Ceylon who can boast of an acreage of any extent in bearing. It is such a difficult plant to rear, and so very slow to grow that it wears out the cultivator waiting for returns. I know of one planter who was so disgusted with this tardiness of growth that he pulled all he had up by the roots. For months he had agonized over every pair of fresh leaves, and when he came to calculate how much more he would have to go through ere they would attain to any kind of height at all he was appalled at the prospect, and cut the connection by condemning them to the happy dispatch. I once heard of a man who went in for growing teak in India, but backed out when his plants were still in the nursery, as he had come to learn that the teak tree took eighty years to reach its full height, and required fifty more years to mature!* Nutmegs are not quite so bad as that, still there is a vista of a decade in length ere bearing begins, and they go on improving for more than a quarter of a century.

I hear of a good coffee blossom appearing in Dumbara, and round about Kandy generally, where any with a fair heart is left: still it is a very "one horse" affair even at the best, and but for the old habit of expecting blossom at this season, the coffee in the lower districts might be dismissed with few words. Bug seems to have taken itself off to some extent, still it is about, and when it spreads its pall the end is near. PEPERCOIN.

TEA.

(Extract from the Report of the Indian Tea Association.)

FOR THE YEAR ENDING 28TH FEBRUARY 1886.

In last year's report there were some papers regarding a trade with Tibet in brick tea, and the Committee have since been favored by Mr. Alfred Simon, of Messrs. Schoone, Kilburn & Co., with a letter in which that gentleman drew attention to the fact elicited during Mr. Colman Macaulay's visit to Sikkim that the Tibetans are large consumers of leaf teas in addition to brick tea. The latter is only consumed by those who cannot afford to indulge in the luxury of the more expensive China varieties which, it appears, fetch very high prices, ranging from £2 to £3 per lb. As the principal difficulty in the way of a trade between India and Tibet in tea, wool, piece goods, hardware, &c., is the objection of the Chinese to allow traders to enter the latter territory, Mr. Simon suggested that the Chamber of Commerce should be urged to take immediate steps for bringing the subject to the notice of the Government of India. This was accordingly done, and an interesting letter was addressed to the Government of India by the Chamber of Commerce, in which the Committee said that, as Nepalese traders are now admitted into Tibet, the desire no further innovation upon Chinese exclusiveness than that the native traders of British India be similarly admitted, and they were of opinion that this could best be effected by sending a Commissioner to the Court of Peking from India specially charged to negotiate on the subject.

The result has been that Mr. Macaulay, an officer of the Bengal Government, was deputed to the Chinese Court, and it is understood that his mission has been so far successful that an arrangement is likely to be come to, which it is hoped may tend to the opening up of a trade with Tibet.

* Very different from Pat, who, hearing that a tortoise lived for 200 years, bought one to test the matter for himself!—*Fr.*

The attention of the General Committee was drawn to the increase in the importation of China tea into India, and from figures supplied by the Department of Finance and Commerce it was found that the total imports in the ten months, from 1st April 1884 to 31st January 1885, were 3,315,071 lb., of which nearly the whole, say 2,990,307 lb., was taken by Bombay. The export of foreign tea from India during the years 1883-84 and 1884-85 were 2,040,346 lb. and 2,072,187 lb. respectively, the bulk of which was sent to Kabul and Persia.

In their circular of the 4th May, the General Committee were able to publish an estimate of the output of the crop of 1885, say 68,735,458 lb. On the 12th November a revised estimate was published based upon actual results to the 31st August and reducing the figures to 66,087,646 lb.; but as some change in the prospects of the crop had taken place since these returns were sent in the Committee asked for fresh estimates based on results to the 31st October. From the returns then obtained, it appeared that the crop would be 66,410,807 lb. but it has actually turned out according to figures applied to the Association, 66,730,219 lb.

The attention of the General Committee has been drawn to certain figures in the annual report on the state of tea culture in Assam issued by the Chief Commissioner. The land under cultivation is divided into that under mature and immature plants, but the Committee have pointed out that it would be very much better if the distinction were made between yielding and non-yielding area, as the term "immature" may mean any plants from 1 to 5 years old, some of which would, of course, be yielding leaf. It is impossible, under the existing classification, to arrive at a correct calculation of the yield per acre, so it is satisfactory to know that the Chief Commissioner has adopted the suggestion of the Committee.

As regards the costs of cultivation and manufacture, it has been pointed out that in most cases this information can only be obtained from Calcutta agents, and the Committee have said that, if there should be any difficulty in collecting these particulars, the Association will be happy to render all the assistance in its power, but on the understanding that no details are published.

The General Committee were informed by the London Association that, at the request of the Trade, the Board of Customs had been petitioned to allow some slight alterations in the rules for weighing Indian tea. The result was a General Order from the Custom House, dated 9th November, copy of which was embodied in the Association's circular of the 19th December. Attention was therein called to the importance of careful bulking and weighing at the gardens and to the desirability of the rates of packages running as even as possible. It was also stated that information had been asked for as to the nature of the statement required to be given by importers of tea under clause 2 of the revised Regulations. The information in question has since been received and was embodied in the Committee's circular of the 8th February.

I am happy to say that the Association now represents a planted area of 143,125 $\frac{1}{2}$ acres, and that the accounts closed to the 28th instant, which are laid on the table, show a balance in hand of R1,694-2 after payment of contribution to the Chamber for the current month. Owing to the reduction of the amount of contribution this year from 1 anna to $\frac{1}{2}$ anna per acre, the receipts have only amounted to R4,509-10, including a small sum of R56 from the Francis Fund, while the expenditure has been R7,837-15-11.

COMING COFFEE, TEA AND COCOA SEASON IN CEYLON.

COFFEE BLOSSOMS.—The exceptionally dry hot season we are experiencing all over the island is having a beneficial effect on coffee, especially in the high and Uva districts. From Haputale we learn that the planters' hearts are gladdened by such blossoms, as they have not seen for many years back, and on the coffee retained in cultivation in the young districts we may also expect to find a really profitable return in crop for once in a way.

TEA is flushing in a wonderful way in many districts notwithstanding the dry weather, but the great rush in plucking will be after the first rains of the little monsoon, a few weeks hence. Mr. Bond, who leaves by this steamer, after a few years in Ceylon, can practically exemplify the great success of tea in Ceylon. He is the fortunate proprietor of Bitterne estate, Maskeliya, where tea has succeeded coffee in the most flourishing way, and has also a share in Kandaleya, a large and successful tea plantation.

COCOA is having a very favorable season, and good reports of crop prospects come from both Dumbura and Matale.

TEA AND SUGAR IN FIJI.

TEA culture is slowly extending, and confidence is maintained in its promise of remunerative returns. The Alpha crop finds a ready sale in the local market at 2s per lb., and the Levuka agent reports that the demand cannot be supplied. In the face of this advice received from Auckland read strangely. Though the Alpha yield is at present unequal to local demand, the balance would soon be changed by the larger area coming into bearing, and therefore the proprietor sensibly tried to find for his product a wider market. With this view he sent some to Auckland, having taken special care in the preparation and packing. After remaining there for some time the grower was advised that the highest offer made for it was 4d per lb. He has directed it to be returned to Fiji, where it will find immediate sale at therate first quoted. Tea cultivation is thriving very well on Messrs. Mackinnon and Barratt's Masusu plantation, Wainunu. It has not been more than two years under way from the time of preparing the nurseries, and the young trees now present so luxuriant and healthy an appearance that Mr. Barratt, an Indian tea-grower of considerable experience, asserts he never saw such remarkable growth. He is most sanguine as to the prospects. About a month ago, to test the properties of the leaf, he manufactured a few pounds of pekoe and pekoe souehong. The product was submitted to a number of competent judges, who, however, do not profess to be experts, and it was pronounced to be excellent in strength, flavour, and aroma.

Sugar shipments, principally to Sydney and Auckland, have been unusually heavy since the date of my last, and beside large consignments from the Mago, Tavuii, Denba and Ra mills, by regular steamers, sailing vessels have taken full freights from the Rewa Company's and the C. S. R. Company's mills. The latter mill stopped for the season early in December, and the output for the season is stated at 8,000 tons. The Rewa planters say the back season has been a splendid one, and the canes promise even better for next year than they did for that just past. To improve this chance, timely rains have fallen throughout the group. A week ago a heavy downfall on the Upper Rewa brought the river down with a high fresh, but fortunately no damage is reported. Work is going on steadily on the New

Zealand Sugar Company's estate at Ba. About 1,500 acres are planted, and the mill will begin crushing in June, by which time at least half the acreage will be fit for the rollers. The company can extend its cultivation to 3,000 acres on its own land.—*Australian*.

NORTHERN TERRITORY OF AUSTRALIA.

The Minister of Education has received from the Government Resident in the Northern Territory (Hon. J. L. Parsons) his report for the half-year ended December 31st, 1885. The Government Resident says that the liberal land regulations in the Territory have induced very heavy stocking, and the results throughout are highly satisfactory, large numbers coming over the Queensland border. On December 31st, 1885, the number of sheep depastured in the Territory was 40,000; of horned cattle, 136,000; and of horses, 6,000; this number is being increased weekly. It is believed that the efforts made by Messrs. Fisher & Lyons to open up a beef and dairy trade with Hongkong will be successful, as the movement is being taken up by various contractors in China for supplying the Commissariat Department of the army and navy. The Victoria River country is being cultivated with good results. Pending the opening-up of the country by the railway the mining industry is languishing. Agricultural prospects are improving, but Mr. Parsons says all advances must be greatly retarded till the railway works are started. With reference to Stuart's tree, Mr. Parsons mentions that in all probability there is very little hope of finding the tree which Stuart marked when crossing the continent or the tin box buried at its foot.

THE TEA MOVEMENT IN CEYLON

continues to make wonderful strides, and there is now computed to be under cultivation in that island a sufficient area to supply 50 millions of pounds in the year. Seeing that the present output of India is hardly more than 70 millions, it is clear that the competition is likely to be formidable. The present advantages which Ceylon possesses are not few. Coffee having failed, and cinchona not having turned out so successful as was hoped, owing to the under soil not suiting the adult tree, land and buildings have been selling very cheap, and the capitalists who have embarked in the new tea industry have been able to secure houses and plant of all kinds at a very low rate. Instances have occurred in which estates have sold for less than the value of the buildings upon them. On the other hand the land having been cultivated for coffee for several years is in excellent condition for tea, the coffee bush having in no way exhausted the soil of those ingredients required by tea; the roots of the two bushes tap different strata, and the new plant finds a well weathered till with abundant food. Then again the climate is such that the leaf can be gathered all the year round. A steady flow of tea of equal quality has set in, therefore, to the buying houses such as the soul of the London grocer loveth, for nothing does "the trade" appreciate so much as a steady and certain supply of the same class of tea all the year round, so that the customers may always be furnished with what they have learned to like, and may never accuse them of changing or adulterating the brand. Lastly, there is a plentiful supply of skilled plantation labour and a seaport close at hand. At present the tea is of excellent quality, and fetches higher prices in London markets than Indians of similar class, so that the fortunate Ceylon growers are making more per pound profit than perhaps did the Indian planters in their best day. Prosperity is showing signs of breaking out in races and sports, bungalow furniture, hospitality, and all the other healthy tokens of a surplus income. There is, however, fear that the day of decline may come for tea as it came for coffee, seeing that the Ceylon coffee planters took no pains to lay up a supply of good soil for future gener-

ations. The hill-side slopes were denuded of forest and in their hurry to be rich the earlier devastators would not incur the expense of banking up or terracing the vegetable soil which had been found under the forest trees, and there is, therefore, in most parts, only a veneer of good soil on which to work. How poor the soil is below is indicated by the decay of the coffee bush and the comparative failure of cinchona; and these precedents induce an apprehension that the life of the tea bush may not be long, especially as it is difficult for any plant in the world to withstand the continued robbery of leaves to which the Ceylon tea bush is subjected for eleven months out of twelve. Still the life will doubtless be of sufficient duration to influence very seriously the price of all other tea in the world within the next few years.—*Pioneer*.

PLANTING IN NETHERLANDS INDIA.

A WONDERFUL ORCHID—HEAVY FLOODS AND DESTRUCTION OF CROPS—BAD SUGARCANE DISEASE.

(Translated for the *Straits Times*.)

At the Government botanical gardens at Buitenzorg there is now flowering an orchid of gigantic size bearing the name *Grammatophyllum speciosum*, and displaying no less than twenty eight flower stalks. Each of them is on the average eight feet long. On one stalk alone, there are seventy flowers of which fifty were all open together at one time. The flower is generally $5\frac{1}{2}$ inches in diameter. Each flower leaf is 2 $\frac{1}{2}$ inches long and $1\frac{1}{2}$ broad. The colour of the flowers is yellow flecked with brown spots, while the curled edge which, taking the size of the flowers into account, is particularly small shows more of a copper colour with brown stripes. The flower stalks which, be it noted, are stiff mostly stand upright but the numerous heavy leaf stalks hang down, some of them being at least ten feet long. The flowers, like those of most orchids, remain long fresh. This plant grows on a tree about eight feet above ground and has completely encircled its trunk. One peculiarity in its mode of growth is that the numerous roots all grow upwards slantingly, a peculiarity which it has in common with very few plants. These roots, owing to their great number, form a kind of parasol turned upside down. This comparison may not be quite accurate, but no better is available. The leaves falling from above remain hanging between these roots and decay doubtless serving then as food for the plant. The latter requires, so to speak, very little care. The only looking after called for is indeed now and then to cut off decayed leaves or flower stalks. Even in the driest seasons, it has never any need of water. The *Grammatophyllum speciosum* grows in the jungles of West Java. It is the only one of the species to be found throughout the whole island. Mr. Hugh Low, the well known orchid grower and importer, who visited the Buitenzorg gardens a couple of years ago says that the *Grammatophyllum speciosum* is rarely found among collections in England.

Wide spread floods have caused such havoc and distress at Surakarta and elsewhere in Mid Java that relief committees have been formed for the benefit of the sufferers. At Samarang the floods recurring as they do every year have not been dangerous to life but have been as bad as they were years ago, when the situation proved so intolerable that a drainage canal had to be made at an outlay of about one million of guilders, with the result that, instead of making floods impossible, it has not even lessened the evil.

The *Locomotief*, from which the foregoing particulars are taken, says that at many villages the flood marks reached the height of seven feet and

large areas of rice fields were overflowed far and wide. The paddy which at the time had just begun to flower is looked upon as lost beyond recovery. The maize crop and other produce under cultivation shared the same fate. Besides loss of crops, damage to roads, bridges, &c., many persons perished in the flooded districts. The Sourabaya *Courant* calls attention to the circumstance that while too much rain fell in Mid Java there was too scanty a rainfall in East Java thereby bringing on heavy losses on native cultivators and European planters alike. Any change for the better will come too late to prevent the drought from taking disastrous effect on this year's sugar crop there being every prospect of a short yield. Many of the sugar planters have prepared themselves for the worst and the inevitable disappointment and, in other respects, are looking out gloomily upon the approaching future from the steadily lessening chances of remunerative prices for their produce, owing to the great fall in quotations of late. It is quite certain that 8 to 9 guilders per picul for No. 11, the price likely to rule next season, cannot but bring on heavy loss. A few estates, says that *Journal*, may drag out a lingering existence notwithstanding, but the great majority are doomed to ruin beyond recovery should these figures be the rule. Planters meanwhile, are doing their best to keep down the cost of production. There is no likelihood of the Government coming to their relief by doing away with the export duty on that article amounting as it does to nine per cent on the value, but the Netherlands India railway company has allowed a reduction of freight charges on sugar carried on its lines during the approaching crop season. There is yet no such lowering of freight on State Railways. Not only have planters to cope besides with difficulties in raising capital, but they are also now threatened with a disease among canes which withers them and dries up the juice. This disease has been making such rapid progress in West and mid Java that it will take the utmost exertion to make head. The Sourabaya Planters' Associations on hearing these ill boding tidings at once urged the branch associations elsewhere in the island to take combined action to check its spread by trying a change of plant cane as the only feasible remedy, likely to be of any avail.

The Director of State Railways has notified to the Sourabaya Sugar Planter Association that the Government will not hear of any reduction of the freight charges on sugar carried upon its railroads. The sugar planters have answered by intimating that they will not make use of the State line. The high rates of carriage on the latter are one cause of the difficulty in working estate in Java at a profit now that quotations are steadily falling.

The *Sourabaya Courant* reports business prospects there as gloomy in the extreme from continual failures among Chinese traders. Both retail and wholesale ones become daily insolvent, without there being any sign of improvement in the near future. Planting prospects are by no means encouraging. The rainfall has become heavier, but the wet season has set in too late to admit of recovery from the damage already done by the drought, the crop looked forward to being likely to be a scanty one. Not only the sugar field but also the rice outturn will in all likelihood prove short. Coffee prospects are more hopeful since the change in the weather though danger of its proving otherwise is by no means altogether warded off. A scheme has been set on foot to start coffee husking works at Pasuruan where there is every thing available to make the business a paying one Unless leaf disease checks

operations, success is looked forward to on the ground that it cannot fail to be advantageous to planters and capitalists alike to be relieved of the costly and slow cleaning of coffee on estates by having the operation conducted in central establishments at suitable places.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F. L. S., F. G. S. &c.,

EDITOR OF "SCIENCE GOSSIP."

I am pleased to notice that New Zealand flax (*Phormium tenax*) is coming to the front here as a therapeutic agent. A strong decoction, made from the root and butts of the leaves, and boiled for twelve hours, is employed in cases of severe lacerations and even amputations. It is said to produce a healthy granulation immediately. I believe the merit of first making the curative effects known is due to the *Australian Medical Gazette*.

The Americans have carried oyster culture to the degree of a fine art, thanks to the zeal and industry of Mr. J. A. Ryder, the distinguished zoologist. That gentleman has recently published a paper entitled "A New System of Oyster Culture," the principles of which are based on the knowledge that oyster embryos diffuse themselves throughout the three dimensions of a body of water, and will attach themselves to collecting surfaces similarly distributed therein, particularly if the latter are clean and fresh from organic growths. Mr. Ryder has discovered that artificial fertilisation of the eggs of oysters is not only feasible, but is an important adjunct to successful spat culture. Hitherto oyster cultivators have been content with obtaining spat from one dimension of the water only, viz., the vertical. A bushel of oysters yields one billion fry. Mr. Ryder rears his oysters in ponds 40ft. square, and the culch, or collecting material to which the spat attach themselves, is suspended in the water from horizontal cross pieces of wood.—*Australasian*.

CEYLON TEA.—A correspondent writes:—Mr. Gow, of the well-known firm of Messrs. Gow, Wilson & Co., was good enough to say that he thought there was little chance of Ceylon Tea, falling below a shilling for many years to come. It would, he remarked, always be a drinking tea, and go straight to the consumer instead of being used, as a large portion of Indian teas, for mixing purposes.—*Local Times*.

MATTARULIYA FARM.—This well known property said to belong to Messrs. Anthony Gibbs & Sons has been in the market for some time. It consists of 47 acres full planted with Mauritius and Guinea grass and coconuts, there being 12 acres of grass and 35 of coconuts. It is said that a well-known Sicilian millionaire made an offer of £47,000 which was refused, and yet I learn that two out of the three blocks, A and C have been sold for £13,000, and £10,000 each leaving only block B consisting of 15 acres for sale. This it is said is the least valuable of the three blocks so that the total realized by the 3 blocks (after 3rd is sold) will be less than what was offered for the whole as a lot sometime back.—*Cor.*

COFFEE.—The annual report of W. Schoffer & Co., Rotterdam, estimates the coffee production of 1885-86 at 11,801,000 ctr; the consumption at 13,545,000 ctr, thus showing a deficiency in the supply of 1,744,000 ctr, or nearly 15 per cent. more than the total crops. There must be some mistake in the estimate of consumption. That coffee should run low and tend downward under such conditions seems remarkable.—*American Grocer*. [So remarkable that we should certainly distrust the forecast and wonder whether it had an object in view. To show the great importance of the trade in Brazil coffee in the United States, we need merely quote the figures of 2,100,000 bags imported at New York alone in 1885.—Ed.]

NEGLECTED INDUSTRIES IN INDIA.

TO THE EDITOR OF THE "PIONEER."

Sir,—I venture to send you the following lines, with the hope that some good may come of them. For want of a variety of openings for the employment of capital, one has often seen tea companies started and competing with other companies, with the result of lowering, and perhaps ruining, the profits of all. Coffee and cinchona plantations have been started in numbers, and are destroying each other's profits. The same occurs with cotton and other mills, cotton screws, &c. No sooner is an industry set up and is found to give a fair profit to the shareholders, than capitalists rush in and spoil, not only the profits of the pioneers, but also their own; while other and new industries, which might give a profit to capital, are neglected. I shall here mention a few industries which I think might use up the capital of one or more companies with profit. There are now in India two imported plants, which I introduced many years ago. Both of these grow like weeds in almost any part of India, except where severe frost occurs. These are (1) the Malta lemon tree, *Citrus Limonium vulgaris* of Risso; and (2) the Seville orange, *Citrus Bigaradia* of Risso; Both can be propagated to any extent by budding on the common *khatta* stock, by layering, and by seed. Both could be easily attended to by women, children, and the cheapest labour. In any temperate part of India, where the *kayshi nimboo* grows, these will grow, requiring only irrigation during the hot, dry months. For the actual cultivation little skill is necessary beyond that of a common *mali*. For working up the produce one or two skilled foremen from Europe would at first be necessary. The industries resulting from these two delightful plants are the following:—From the Malta lemon: The rind is made into candied lemon-peel, or is pressed for its essential oil, called "essential oil of lemon-peel." The latter is used in pharmacy, confectionery, perfumery, and for flavouring effervescent lemonades. The rind, pulp and juice all together, boiled with sugar, make a first class lemon jelly, superior to marmalade: the juice alone of course is turned into citric acid. This is used in pharmacy, confectionery and for making acidulated effervescent drinks. But its great future in India would, I think, be for the preparation of citrate of iron and quinine, the one tonic needed for picking up the fever stricken population after being weakened by malarious fevers. From the Seville orange: The rind, pulp and juice are made into marmalade of the first quality. The flowers, the finest scented of all the orange tribe, are distilled for their essential oil, called oil "neroli." It is also extracted by "enfleurage." This oil is used in pharmacy, perfumery, &c. The distilled water, after the oil is removed, is the "orange flower water" of commerce, used in pharmacy and confectionery. From the leaves, which are highly scented, another essential oil called "petit grain," is distilled, and is used principally for scenting ordinary soaps. The Indian lime, or *kayshi nimboo*, might also be utilised for its acid, and it can also be made into lime-jelly! The reader may perhaps think that these are trifling notions, but considering that Moir & Co. alone have three steam factories in different parts of Europe making marmalade from Seville oranges I need hardly say, that these notions are not, after all, so trifling as they would at first appear. Cheap sugar and cheap fuel would of course be important items in these industries. It might be said that it would be cheaper to get all these products from Europe. So it was said, years ago, that it would be cheaper to carry cotton to England from India, and bring it back as manufactured articles, than it would be to work it up in India. Nevertheless there are several mills in Cawnpore, and many on the Bombay side and other places, which, if worked at all, can only be worked at a profit. It might be also said that the demand for such products in India would not be enough to support these industries. Let us see. All Europeans in India, including soldiers, are fond of cakes, as also the whole of the Eurasian population; and cheap candied lemon and orange peel

would find a sale among them. This, however, is one of the minor products. All Europeans and Eurasians are fond of effervescent lemonades. These ought to be made with citric acid flavoured with "lemon oil." Now, however, as imported tartaric acid is cheaper than citric acid, so-called lemonades are really tartarades. And the flavoring, with few exceptions, is probably nowhere. As teetotals increase, the consumption of effervescent lemonades, if nicely made, will also increase. Marmalades are now perhaps only used by Europeans who can pay for them. But, if sufficiently cheap, both marmalade and lemon jelly would be used by most Europeans, including soldiers, and also by most Eurasians. Cheap scented soap would be used by all Europeans and Eurasians. As to citrate of iron and quinine, who in this country would not be glad to have it cheap? It is one of the best tonics to renovate the blood after malarial fevers. The above is as far as India alone is concerned, but then there are other markets to which these products might have access. Of this I am certain, that beyond the necessary land and facilities for watering the trees, growing them would present no difficulty whatever. They can both be made to grow like any indigenous tree, and with proper cultivation they will flower and fruit abundantly. These two trees give their main crop of flowers in spring, and ripen their main crop of fruit in December. But at odd times they flower and produce what natives call "dumrez" fruit, which ripens at intermediate times, so that practically they bear fruit all the year round, but produce their main crop in winter. Bangalore has a Mediterranean climate and would probably suit these trees well. His Highness the Nizam's territories have remarkably rich soil, and these plants are almost certain to thrive there. It would appear that orange and lemon trees like lime in the soil, the orange tree wood giving in its ashes no less than 45 per cent of lime, according to Liebig. In the *Pioneer* of the 5th February last, the now famous Pundit is made to say that in Tibet, in the valley of the *Zayul*, at an elevation of 4,500 feet, he saw the lemon and the plautain growing. This, however, I know, that in Rome the lemon tree is often killed by frost, and in Florence they grow it in big *nands*, and house it in winter. In Naples and Sicily it grows abundantly. The history of the introduction of the orange and lemon in Europe points to their having been taken there by the Arabs, and that they came from India, or from some place beyond the Ganges, so that their home is either in, or somewhere near, India. I have little doubt that on the southern slopes of many a Himalayan valley the orange and lemon trees would find many places, with a quasi-Mediterranean climate, excluding, of course, the sea. In or near Sylhet the orange is probably indigenous, or has been grown there from time immemorial. Calcutta is supplied with oranges from Sylhet. Why could not the Sylhet orange be grown for its fine fruit in the same plantation with the Seville orange and the Malta lemon, for their own special products, so that the planter would have "several strings to his bow?" In Lucknow the Sylhet orange grows remarkably well. In Delhi the Giotra orange grows famously. In Nagpore a fine orange is grown which supplies Bombay with this fruit. Wherever any orange or lime will grow, the Seville orange and the Malta lemon will grow equally well. Finally, I need not say much about Kashmir, which is *par excellence* the land of fruit. As to the occupation, what could be more charming than growing oranges and lemons; making jams and jellies; and distilling essential oils? The planter has a choice of the plains or the hills for his operations; nor is it necessary that the manufacturer should be also the grower of the raw materials. Mill-owners do not grow their own cotton, wool or fibre; sugar refiners don't grow their own sugarcane; and rarely do *oil* planters grow their own plant. Recently Lord Wolsley has been chaffed in many papers for ordering marmalade for the Sudan Expedition. It is understood that lemon juice or citric acid is one of the best anti-scorbutics known. Both in the Army and Navy it is largely used, and I believe the way it is usually administered is to have a parade of the

men, two or three times a week, when fresh vegetables cannot be obtained, and each man is made to swallow a measure of acid juice. To observe the faces of the men as the bottle moves down the line, would be enough to show that it is not a very pleasant draught. To tell the truth, if I had to take citric acid, I would prefer taking it in the shape of marmalade or lemon jelly, at breakfast time, with either bread or biscuit, and without making faces. I doubt not that both soldiers and sailors would prefer them also, to the orthodox lime-juice. As to bulk, there would not be much difference, as a large portion of the lime-juice is nothing but water. Instead of the latter, the marmalade and jelly have sugar, flavoured with the rind of the fruit. But in the event of soldiers preferring lime-juice, pure and simple, there would be no difficulty in manufacturing that also. Possibly these hints may not be without result to some Anglo-Indians who "do not know what to do with their sons." It is no longer a question of making fortunes either in India or anywhere else. The urgent question is how to earn a *decent comfortable living*. When we find gentlemen's sons either enlisting or accepting the posts of railway guards with the hope of future promotion, the road to fortune-making must be well blocked up. These who have read what the Americans are doing with the orange in Florida will understand how much there is left undone in India with regard to these wonderful trees. There are not perhaps many persons who may have tasted Seville orange marmalade pure and simple, as the demand is larger than Seville and other places can supply; and therefore the commercial marmalade is not likely to be "pure and simple." Marmalade made at home from pure Seville oranges, and simply boiled with sugar, is truly delicious. Hitherto the orange and lemon trees in India have been left in the hands of natives only, and a few horticultural gardens. There are few trees that repay the cultivator in fruits and other products so well as the orange and lemon trees. They do not merely give a moderate crop every second year or so, like the mango tree, but are laden with fruit year after year, and sometimes all the year round. In order to get this, however, they must be regularly fed and watered at the proper season.—E. BONAVIA, M.D.

TEA BOXES.

[Mr. H. DRUMMOND DEANE writes to the editor of the *Indian Tea Gazette*.—]

Dear Sir,—I have been reading your interesting work on the "*Tea-Planters' Guide-Book*." I would add on page 249:

"*Tea Lead* 84 x 22 is the best for full chests, and 72 x 22 for half chests; these sizes are easily procurable, and save time and expense in soldering; 4½ oz. lead is more economical than 5 oz. lead, which latter is mostly used in India, the former in China and Japan."

Solder.—It is far cheaper to make your own, using for this your waste tea lead which you melt down and mix with *Black Tin*, in proportion of 2 of lead to 1 of tin; when properly mixed run into a wooden mould. A good mould is made of a block of a hard wood, say 18 x 12 x 4 inches, with grooves into which you run the solder.

Woods of Tea Boxes.—On page 216 you are good enough to mention the boxes I have been the means of importing from Japan into Ceylon and India.

Cryptomeria Japonica is a wood resembling Cedar wood; it has a slight smell, but I have had reports from Messrs. Wilson & Smithett and from Messrs. Rathbone Brothers, both of London, which both say that it in no way taints the tea. I am to have the honor of exhibiting a set of these boxes at the Colonial and Indian Exhibition next year, with the consent of the Planters' Association of Ceylon. I claim for these boxes the following advantages to Tea Planters.—1st, *Cheapness*. I understand from Messrs. Williamson, Magor & Co., who are my sole Calcutta Agents, that they hope to place the largest chest *f. o. b.* the Assam Steamer at a trade under 16 annas.—2nd, *Strength*, the new system

of dovetailing every half-inch has been proved by experience of my Yokohama friends (Messrs. Fraser, Farby, and Varuum) who export close on 8 million lbs. Japan Teas yearly, to be an improvement in every way on the old system of 5 or 6 dove-tails, to a chest-side, for the reason that each nail acts as a wedge, and makes itself felt as such. If a little glue is used before putting the box together, the result is a package simply unbreakable, and by the use of a few extra nails, hoop iron is unnecessary, thereby saving freight.—3rd, *Simplicity*. The boxes are so accurately made that no carpenter is required, an ordinary cooly being able to put them together. To prevent all possible chance of warping or swelling, all the planks are passed through a *kiln dryer*, and all the moisture taken out, thus ensuring an equal and uniform weight to each package. Care of course must be taken not to *always* put the two first pieces that come from the shooks together, as it sometimes might then happen that *two joints* would come together, which would weaken the box. 4th. My friends in Japan have a tract of 25 square miles of this timber, and are in treaty for as much again with the Japanese Government, so there is no fear of supplies failing for some years. My sole Agents are Messrs. Williamson, Magor & Co., Calcutta, and we hope and intend to cheapen if possible rather than extend the prices as soon as the cost of these first few trial shipments have been proved. I have no doubt my friends will advertise in the leading planters' papers, and I shall write to them on this subject at once.

There are two other woods in Japan of a nearly pure white color and absolutely free of smell: these are called "Mome" and "Matsuo." Some planters here seem to prefer them, though heavier in weight than *Cryptomeria*. The latter weighs about 16 lb. a 100 lb chest, the two former 21 and 24 lb. respectively, all in half inch wood. Meanwhile, dear sir, I must apologize for troubling you at such length, but it is in the interest of brother planters I have done so, as the advertisements must of necessity be meagre in information. I hope early in the new year to visit Calcutta, and by then I hope a business will have sprung up which shall be of benefit to both Ceylon and Indian planters.

COFFEE EXPORTS FROM RIO.—The total export of coffee for the year was 3,975,798 bags, against 3,753,625 bags in 1884,* of which two thirds were exported to the United States. The coffee trade, it is considered, was not entirely satisfactory during the past year. As, however, our trade has become very much modified through the establishment of direct representatives of consumers in our market, it is extremely difficult to form an opinion as to the result of business. One would think it impossible for important firms to ship, as they do, were the business an unprofitable one; yet quotations from consuming markets, as a rule, are considerably under our current quotations.—*Rio News*.

THE EFFLUVIA from decomposing paste and glue is as unwholesome as it is offensive. If, when making the paste or glue, a small quantity of carbolic acid is added, it will keep sweet and free from offensive smells. A few drops added to mucilage or ink prevents mould. In whitewashing the cellar and dairy, if an ounce of carbolic acid is added to each gallon of wash it will prevent mould and also the disagreeable taints often perceived in meats and milk from damp apartments. Another great advantage in the use of carbolic acid in paste for wall-paper and in whitewash is that it will drive away cockroaches and other insect pests. The cheapest and best form of carbolic acid is the crystals, which dissolve in water or kieficy at an excess of temperature.—*American Cultivator*.

*The figures do not include Santos and other ports.—Ed.

INDIAN TEA IN AUSTRALIA AND AMERICA.

The total shipments of Tea to Australia and New Zealand from the time the Syndicate commenced its operations up to the end of last season have been as follows:—

Season	Through the Syndicate.		Through Other Sources.	Total.
	lb.	lb.	lb.	lb.
1880-81...	287,193	801,722	1,088,915	1,376,108
1881-82...	472,904	367,904	840,808	1,310,712
1882-83...	1,051,941	1,671,327	2,723,268	3,775,211
1883-84...	68,901	271,712	340,613	409,514
1884-85...	31,165	1,308,517	1,339,682	1,370,847

The shipments of Tea from Calcutta to America during the past four Seasons have been:—

Season	Through the Syndicate.		Through Other Sources.	Total.
	lb.	lb.	lb.	lb.
1881-82...	195,850	2,740	198,590	198,590
1882-83...	523,012	159,806	682,818	682,818
1883-84...	128,730	123,265	251,995	251,995
1884-85...	41,894	85,284	127,178	127,178

Samples of Indian Tea were also sent to Moscow and Amsterdam. In the former case, no encouragement followed, but as much as 48,610 lb. were forwarded to Amsterdam, and free samples were largely distributed, with, it is believed, good effect, as heretofore Indian Tea was quite unknown there. It may be safely concluded that through the efforts made, thus, by the Syndicate in the various Colonial markets, Indian Tea has acquired a footing which it only needs careful fostering to develop into a large trade, for on its merits alone Indian Tea is bound to succeed.—*Indian Tea Gazette.*

ROYAL SOCIETY OF QUEENSLAND.

The President brought forward a sample of the roots of *Cyperus esculentus*, the edible tubers of which are known in the south of Europe as *Amané de terre*. He had introduced this into Queensland some years since, and had observed that in its habit of growth it was scarcely to be distinguished from that pest of gardeners, the "nut grass," *Cyperus rotundus*, Linn. Dr. Bancroft also remarked that the small bulbs, which he had previously brought before the society as forming an article of diet amongst the blacks of the interior, and which were known as *Yora*, had proved on cultivation to belong to a *Cyperus* allied to this *C. esculentus*. As a further example of a Cyperaceous plant of economic value affording an esculent, Dr. Bancroft directed attention to an *Heloccharis*, an aquatic sedge which had lately been introduced into the gardens of the Brisbane Acclimatisation Society through his agency. He also exhibited the fruit of the candle-nut-tree, *Aleurites moluccana*, found in the gardens of the colony, and remarked that beyond the value of its kernel as a prolific oil-producer, and its use as an extempore illuminator amongst the Polynesian Islanders, there resided in this kernel comestible properties which were not to be despised.

Amongst other plant products of economic value exhibited were the fruit of the *Liog* of the Chinese *Trapa bicoloris*, the seeds of which are farinaceous in a marked degree, and, like those of other species of the genus, largely used on this account as an article of food. Also, the so-called fruit of *Horenia dulcis*—i.e., the fleshy peduncles of the true fruits, and which contain a sweet edible pulp. As illustrating the importance of a consideration of the sexuality of plants, Dr. Bancroft drew attention to the male and female inflorescence of the Carob tree, of the Mediterranean *Ceratonia siliqua*, Linn., the source of "Oramel." The flowers of a particular tree being restricted to those of one sex, and remarked that this fruit tree was more adapted to the climate of the Darling Downs than to that of Brisbane, and that it was necessary to have plants of both sexes, or in the event of possessing a female plant or potential fruit bearer only, to have access to the pollen derived from flowers of a tree of the opposite sex. The Papaw was not a persistent monoecious plant, but the fruit which

sometimes appeared, as in an example exhibited, on a plant styled a "male plant," was generally distinguished by the presence of a peduncle, from that derived from an undoubtedly "female plant."—*Queenslander.*

THE SUGAR INDUSTRY IN INDIA.

Some attention has lately been given to the sugar industry, to the manufacture of jaggery, to the introduction of new description of mills, and to the general progress of this important enterprise. Many years ago the sugar trade of some of the sea port towns on the Coromandel Coast was an important one: factories were established both by European and native merchants, and in the inland districts too much attention was devoted to this industry. A German missionary acquired large plots of land in the North Arcot district and planted sugarcane with the object of manufacturing sugar of different qualities, and, if possible, the description known as loaf sugar now obtained from England. His efforts were to some extent successful, and for a few years the enterprise turned out well. But with his return to Europe owing to failing health, the whole concern, which was placed in the hands of natives, went to the wall, and to this day may be seen the ruins of the factory, the sheds and other buildings once devoted to carrying out a really paying industry. The manufacture and exportation of sugar for about two decades hardly received any attention. European and native merchants preferred to embark in cotton, coffee and other enterprises, but now that there is a fall in these directions, sugar is beginning to look up again, and with new and improved machinery a decided improvement has taken place in this industry and still further development is apparent.

A recent report submitted to Government by the Director of Agriculture shows that Messrs. Thomson and Mylne of Beheea, in Bengal, have succeeded in introducing a large number of their mills into the Madras presidency. A mill was first sent to North Arcot and thence to Coimbatore, but the results were not satisfactory as no enquiries were made by growers of cane. Since then the introduction of the cane mills in the Bellary district has been most satisfactory, for we learn that the local representatives of Messrs. Thomson and Mylne sold eighty-one mills in the first eight months of last year, and of these seventy-five were bought in the Hospett taluk, Bellary district. The extension of sugar-cane cultivation in the Ceded districts, is chiefly due to the enterprise of a well-known merchant of Bellary who has not only introduced improved ploughs and other machinery, but who has been instrumental in starting cotton mills and other industries which must, in time, prove remunerative and materially improve the condition of the ryot classes who have for years reared no other crops than the cheap cereals that are the staple food of the poorer classes. We have not particulars of the extent to which the sugar industry has been of recent years pushed on in Bellary and Hospett, but the following information of the working of the new descriptions of mills in the Godavery district may be of interest.

The Godavery and Vizagapatam districts are important centres of the jaggery trade of the presidency. In certain favorable seasons, the supplies shipped to Europe have been very large and not long ago the quality of the jaggery put on board ships leaving the roads was of the worst possible description. With the introduction of new mills there may be some improvement in the quality of the article prepared for shipment. A native firm in Coconada writing to the Agricultural Reporter to the local Government states in a letter, dated 2nd March last, that since 1831 they endeavoured to obtain machinery for crushing sugar-cane, and after much difficulty they obtained a mill from Beheea which crushed all the cane grown on a field to acres in extent. The repairs to the mill were carried out by the country smiths, and by inducing other ryots to view the mills, they procured a few, and during the first year of the introduction of the Beheea mills, forty-eight found their way into the Godavery district. A depot was

opened at Coconada for the sale of these mills, and between December 1883 and March 1884, the total sales increased to 169. Since then the sales had risen by about 100 mills, and the agents expressed the hope that they would be able to place about 100 in the hands of owners of sugar plantations in the present season. These results must be very gratifying to manufacturers as well as to merchants in general, as with the new and improved mill, the quality of sugar available for shipment will not only improve, but the return to the growers more encouraging. The success with which the mills of Messrs. Thompson and Mylee have been introduced shows that, if growers obtain a fair article at a fair price they will readily purchase it. The Beheca mills from their simple construction, moderate price and the facility with which they can be repaired, are likely to become very popular, and as they are largely used in the Godavery and Bellary districts, the time is not distant when they will be introduced into other parts of the presidency. With cheap mills, sugar-cane cultivation, which is now confined to a few districts, may gradually extend.—*Madras Standard.*

OUR NATURAL COURSE OF AGRICULTURAL ADVANCEMENT IN CEYLON.

(Contributed.)

In a country so exclusively agricultural as Ceylon, I have always maintained that every inducement should be given to whatsoever will advance the cultivation of the large areas of waste land throughout the island. Cobbet maintained that the greatest benefactor of his country was he "who could make two ears of corn grow where only one grew before." The Ceylon Government has spasmodically taken up the question and shewn an interest in the restoration of a tank, or in some high-sounding scheme. Whatever the aim of our rulers, the result has been that large sums of money have been spent, and, with one exception, we hear of no great advantage being gained. Even were these numerous projects so often mooted carried out, there would practically be insufficient resident population to take full advantage of the benefits resulting from the outlay of these large sums of money, and it would be found, as it has been already, that, with the restoration of the tanks, there would be no extension of the cultivation of land. This of course might be met by offering inducements to Indian immigrants to settle. This, in these days of experiments, at first sight appears feasible enough. I am told that water alone is necessary to make the large wastes of the northern half of our island expanses of growing rice. In the Western, Southern, and Central Provinces there already exists a population of varying stages of industry, a people who are willing to roam a reasonable distance from their homes, and who will, if sufficient inducement offers, invest their earnings in cocoons at Ohilaw or Puttalam, or work a mine of plumbago at Karuuegala. A study of their habits shows a willingness to enter any district subject to two conditions, and these, it will be observed, are those held universally by most wealthy natives—first, that the locality chosen be accessible without any extreme labour; and, second, that it must have a resident population, or such must be close at hand. I need hardly add the industry chosen must bear the test—Will it pay? No unbiased person could visit either Puttalam or Ohilaw, or any of the large plumbago pits, and assert that with healthy inducement the natives of Ceylon are absolutely idle or indifferent. The wealthy natives amongst us, such as the Soysas, the Rajaipakes, the Perieses, and many others prove that capital and industry are to be found; and it astonishes us that this class has not been more largely consulted in all matters upon the development of the island's resources.

In the Central Province, the European element has with varied success grown coffee, cinchona and tea, resulting in a perfect system of communication between it and the sea-board, which again has been the chief cause of the large areas of extended cultivation now existing in the tract of land forming the triangle be-

tween Colombo, Kandy, and Puttalam. Europeans have not shewn the same necessity for population and accessibility in the lands they have chosen; for they have entered wildernesses wholly uncultivated, and, in a few years, illustrated what Western enterprise and industry may produce in converting them into prosperous estates. In time, roads have brought these into the network of civilization.

It will, from the above, be observed that the natural advancement of industry, especially where the natives are concerned, is progressive from the chief centres of industry and population. The native capitalist is not likely to invest his money at the Giant's Tank, nor in the heart of the Wane; yet he is willing to go as far as he can to look after his venture without excessive exertion; neither does he appear to consider property of value or desirable unless there be a resident population. The extensive repairing of tanks by our Government would appear to have been undertaken without a due consideration of the ways and means for their maintenance after restoration; for, when once repaired, the village soon reverts to its old somnolent condition.

I would urge that greater attention be paid to those localities within the range of general enterprise, whether European or native, and in this way gradually extend the radius of operations; instead of rushing to spots beyond the reach of capital, industry, or intelligence. It would then benefit a larger number without bringing capital beyond the reach of the most industrious and enterprising, and would by the progressive extension of communication bring the consumer and the producer into close connection with each other. There appears, at first sight, a great advantage in Ceylon becoming a large rice-producing country, and supplying itself with that which it now imports in such prodigious quantities, but a very casual study shews that the cost of transport must always prevent the wide use of locally-grown rice, until at least the population of the already populous portions of the island has extended towards those localities where rice can be advantageously grown. At present, it can be more cheaply imported from rice-producing countries and delivered, say, at Matale, by rail, than it can be cleaned and brought up by road from Anuradhapura. It doubtless is a very great temptation to an ambitious Governor to restore a buried city, to make a railway, or to repair a giant tank, with which in all time his name will be associated, far more than to urge forward the natural progress of industry and enterprise in its natural channels. The Western mind does not choose to follow that of the Eastern; yet it is manifest that the progress this island has made, apart from that of Europeans, has been almost wholly within the vicinity of the three most populous provinces of the island, and, judging from this, it is manifest that, by fostering and leading on in this direction, more solid and permanent benefit must result than by restoring and unearthing old cities and tanks beyond the reach of capital and enterprise. The immense extra expense entailed in working in these out-of-the-way spots can only be compared to that of a military force in the field in an unhealthy locality, to which, at any price, every necessary of life has to be conveyed; the cost of which must be three-fold, both in the outlay of money and human life, to what it would be near at hand.—Local "Times."

CORROSION OF THE LEAD LINING OF INDIAN TEA CHESTS.

It will be remembered that some time ago a correspondence took place between Dr. Voelcker and Dr. Watt on the above subject, but their opinions so widely differed, that the discussion left matters in a more unsatisfactory state than before. The INDIAN TEA ASSOCIATION, then, very judiciously took the matter up, and referred the whole case to Mr. Pedler, the professor of chemistry to the Presidency College. That gentleman has since issued a lengthy Report on the subject, which we will here refer to. Mr. Pedler is of opinion, and we think very reasonably so, that the proper preliminary step should

have been to accumulate and collate the mass of evidence which must be available from the experience of planters and agents themselves. It is only by a comparison of such experience that a true solution of this vexed question can be safely arrived at.

In 1883 Dr. Wigner published a Paper on the packing of substances of delicate odour, such as Tea, and he refers therein to experiments which he had made during the previous five years regarding the alleged effect of certain Indian woods on tea-lead. He came to the distinct conclusion that the corrosion of the tea-lead was due to the generation of acetic or other volatile acid, which, in the presence of carbonic acid and moist air, would account for the corrosion complained of. Mr. Pedler is in agreement with this opinion, and he says that in almost all respects the experiments he has himself made confirm the theory put forth. To test the matter efficiently, certain boxes of tea were specially prepared, and the wood, the lining, and the contents, subjected to separate tests.

The first experiment made was on a box made of damp unseasoned wild mango-wood. After being kept for several weeks unopened, it was found that the surface of the lead next the wood was almost entirely covered with a white powder, principally "white lead." In some places the lining was entirely eaten through, and all over the whole external surface corrosion had set in, but the side of the lead next the tea was found bright and free from corrosion, although slightly tarnished,—the latter probably due to imperfect drying, and consequent insufficient check of fermentation. Further, the surface of the wood next to the lead was found to be distinctly acid to test-paper.

A second experiment was made by distilling some of the wood of the box in a current of steam, and the distillate was then tested by placing it at the bottom of a bottle. A piece of tea-lead was then hung in the bottle so that it did not touch the liquid, and the bottle was repeatedly filled with air charged with moist carbonic acid; with the result that distinct corrosion took place. Various other experiments were made, and care taken to use *seasoned* wood as well as wood damp, or partly seasoned only. The result was the same, although the effect was more rapid in the case of unseasoned wood. Boxes made of other kinds of wood were then experimented with, and in five out of six cases no corrosion took place, and there was no perforation. The conclusion arrived at by Mr. Pedler is, that the experiments prove that the active agent in the corrosion of the lead linings in the examples taken was not produced from the tea contained in the chests, but from the wood of which they were formed.

We have not space to follow seriatim the many and various experiments made, but the result arrived at has been to prove—1. That unseasoned mango-wood attacks lead, in a moist atmosphere, violently. 2. That seasoned mango-wood kept dry has no action on it. 3. That seasoned mango-wood subsequently saturated with water becomes again in a condition to attack lead in the presence of a moist atmosphere, although not so violently as unseasoned wood. 4. That unseasoned and damp wood of any description corrodes the lead more or less. 5. That the corroding substance, whatever it be, must be formed gradually in the wood, and that the formation is connected with the continued presence of moisture.

The latter conclusion should be taken to heart by those who, unthinkingly, use woods, of whatever kind in anything like a green state. In the Terai we have seen boxes made from almost green wood, and we well recollect remarking that they would split to pieces in anything like a rough journey; but it did not occur to us, then, that far more serious consequences might follow, in the corrosion of the lead itself. Now that this has, however, been conclusively proved, it is to be hoped that the use of unseasoned wood may be rigidly interfered with, for, given heat and moisture to set up putrefactive fermentation therein, the presence of all the sub-

stances necessary to corrode tea-lead will, says Mr. Pedler, at once follow; and few, we think, will be inclined to dispute such self-apparent logic, although, hitherto we have not sufficiently regarded the fact.

Most men, even though knowing little of chemistry, would incline to the belief that tea, properly manufactured, could hardly have any chemical action on its lead covering, any more than that lead free from contact with decomposing influences could effect the tea, but it is satisfactory to have the matter authoritatively set at rest; and we now know for certain as the results of much painstaking scientific observation by an eminent expert, that if damp and unseasoned, wood is used for the manufacture of Tea boxes, corrosion of the lead is, under favorable circumstances, almost certain, although some varieties of wood may act more violently and rapidly than others. We learn, also, that even seasoned wood allowed to become saturated, may produce, under circumstances of high temperature, putrefaction, or corrosion of the lead lining. The necessity, therefore, for protecting chests from moisture, in transit, is impressed upon us; for it has been further demonstrated that Tea can easily take up the disagreeable odour which damp wood may emit.

It is most satisfactory to find that this much-vexed question of the deterioration of Tea from the use of unsuitable woods for packing, or from the use even of *suitable* woods unseasoned, has been authoritatively disposed of.—*Indian Tea Gazette*.

THE CULTIVATION OF COCA.*

BY HENRY H. RUSHY, M.D.

For more than two months the writer has been continuously engaged in the study of the coca-plant and its products in the districts of Bolivia which produce the best quality of leaves. The results, which are likely to greatly increase the recently-created interest in the plant, will be published shortly, when his studies shall have been concluded. At the present time I will only discuss a question concerning which speculation is rife, namely, the adaptability of the plant to culture in countries where it is now unknown.

For the details concerning cultivation here presented I am chiefly indebted to Mr. Oscar Lohse, one of the most intelligent cultivators in this country, and proprietor of the Finca of San Antonio, two leagues from the town of Carocia, Yungas.

The district of Carocia may be considered as fitly representing the remainder of Yungas, and Yungas as representing the principal coca districts of this republic. The conditions of soil and climate may be briefly stated. Proceeding eastward from La Paz, its somewhat more than ten thousand feet † above the sea, for a distance of four or five leagues, we reach the summit of the pass over the easternmost cordillera of the Andes, this cordillera having an average elevation in this immediate district of perhaps sixteen thousand feet. This ridge, always more or less snow-covered, cuts off a large portion of the westward-bound clouds, which are thus either precipitated in the form of rain before reaching the summit, or, arriving there, are deposited in the form of snow, and then returned by means of rivulets to the valleys, chiefly of the eastern slope. It should be noted that in Northern Peru and Ecuador this cordillera is higher than here, so that the eastern slope in those regions is more profusely and regularly watered than here. From this pass, had we a direct road, we could travel in half a day, so steep is the descent, to the banks of the Carocia River, having an altitude of only two thousand four hundred feet. When we have descended to six thousand four hundred feet we should meet with our first coca plantations, and after passing two thousand feet level we should have left them principally or entirely be-

* From the *Therapeutic Gazette*, January.

† I have given altitudes and measurements approximately in English feet. By the Spanish measurements the altitudes are much greater.

hind. Within this four or five thousand feet, then, lie the coales of Bolivia. No description can convey a perfect idea of the steepness of this luxuriant slope. Travel, entirely by riding-animals, is extremely difficult. There are only occasional places where we can readily leave the road, and here plantations are established. The hedge of coffee-plants at the roadside proves on examination to be the uppermost row of a plantation; and as we peer down among the shrubs we marvel that anyone can preserve his footing while cultivating or collecting the coffee. The scenery is of course magnificent, and of a different type, I should think, from that of any other part of the world. The mountains are too young to have lost to a great extent their ragged outline, yet softness is imparted by the richness of the vegetation. We stand among the coca-plants and distinctly see another cocal nearly four thousand feet below us.

As there is no better guide to the agricultural capacities of a country than its native plants, I will mention the characteristic classes. At the pass, with an altitude of about thirteen thousand feet, we have but little vegetation,—this low and mat-like, to escape the cold and the winds. Crossing, soon after, a spur having an elevation of one or two thousand feet less, we meet with several Gentianaceæ, notably a *Helonia*, believed to be *H. Rothrockii*, Gray, of New Mexico. Here, also are some shrubs in Acanthaceæ and Bigoniaceæ. At nine thousand feet we begin to find orchids and calceolarias, with some small trees in Melastomaceæ. At eight thousand feet we meet with our first tree-ferns; the timber-trees become quite large, and Begonias begin to make their appearance. From this point the vegetation begins to assume a really tropical aspect. We find many species of calceolaria, fuchsia, and Amaryllidaceæ, while the variety of orchids and ferns is quite bewildering. At six thousand five hundred feet we see the first palms, and the forest-trees become buttressed giants, staggering under their loads of vines and climbing aroids and ferns, and their branches covered with Bromeliaceæ, orchids, and other parasites. Seventy parasites have been counted upon a single fallen tree.

The cultivated plants of the coca district are coffee, rice, cacao, sugar cane, tobacco, maize, cotton (the arboreal species), sweet potatoes, yuccas, and the ordinary garden vegetables. The principal fruits are oranges, bananas, coconuts, lemons (sweet and sour), citrons, grapes, chirimoyas, alligator pears, tumbas, pomegranates, grenadillas, figs, papayas, lukmaas, melons, and pineapples, the last just introduced.

The soil in such a broken country is of course very diversified, ranging from a very light decomposed shale or sandstone to a heavy blue or chiefly yellow clay.

The rainy season begins in October, and continues until May or June. During this time the rains are copious and almost constant. During the succeeding two months there is scarcely a drop of rain, and during the next two there are only occasional showers.

Such are the conditions under which the coca grows in this section.

When we come now to consider the methods of cultivation here adopted, we must be cautious about accepting them as the best, merely because they are generally followed here. It is to be remembered that the Bolivian system of agriculture has not received the attention that it should have had, and that it is very probable that reforms might be introduced in present methods.

Nor is it proper to proceed concerning coca-culture without a few words concerning what is meant by the "best quality" of coca-leaves. To a manufacturing chemist the best quality would mean the quality that would yield the largest percentage of crystallizable cocaine, obtainable in the easiest manner, while the same coca might be considered for domestic consumption as representing one of the lower grades. It is highly probable that the amount of cocaine forms no element in the Indian's estimate of the quality of coca, no more than the percentage of nicotine establishes the quality of a particular grade of tobacco. Coca-

leaves are classed in general by the Indians as "hajas dulces" (sweet leaves) and "hajas amargas" (bitter leaves). The former are made sweet by the abundance of alkaloids other than cocaine. While it is true that a greater abundance of those alkaloids is usually accompanied by a larger percentage of cocaine also, yet the variation in the amount of the latter is not so great as in the former; so that while in the sweet leaves the bitter taste of the cocaine is masked by the presence of the other alkaloids, in the bitter leaves its flavour is the predominant one. The presence, then, of these sweet alkaloids, as we may call them, translating the simple and expressive term of the Indians, determines the domestic value of the coca, and all that is known of the best methods of cultivation is based on the production of the highest percentage of these alkaloids.* Experience may determine that for manufacturing purposes a very different line of principles of culture should be followed.

I have made a large number of assays tending towards elevations, soils, exposures, seasons, ages of plants, and of leaves, different varieties, wild and domestic, different parts of the plant, and various modes of drying and packing. The results will be embodied in a future monograph, mere passing references being made to them for the present. I have about concluded that the percentage of the sweet alkaloids varies inversely as the amount and continuance of moisture that the plant receives. Thus, the Peruvian, Ecuadorian, and Brazilian coca, which, as I have stated, is much more copiously and regularly watered than the Bolivian, is markedly inferior, so that Bolivia regularly exports about one-eighth of her crop to those countries. I am inclined to think that the greater breadth and thinness of the northern leaf may be partly due to the greater water supply and the consequent greater degree of evaporation. Again, the Indian always seeks the coca grown at the higher elevations, where the humidity is much less and more irregular than in the districts along the rivers. We are thus obliged, for reasons to be elaborated in the future, to regard these alkaloids as preserving a sort of a balance of moisture, by which the plant stores up during the wet weather a concentrated supply of water, which may be very slowly yielded up during a time of need.

Having thus chosen a high altitude, the next thing is to select a soil. A rivalry exists between a yellow clay and a hill-side soil rich in vegetable matter. My assays have yielded the best results (as to total alkaloids) from soils of the latter class, and I am inclined to think that those who prefer the former soil do so because it yields a somewhat larger crop.

The ground for the nursery-bed is prepared during the latter part of the dry season by breaking it up very thoroughly to the depth of a foot or more. The fruits mature during the early part of the rainy season, December and January. They are red, and consist of a fleshy outer portion and a shell-like inner portion, which encloses the single seed. These people suppose that the germ cannot escape from the shell if planted in its natural condition, and they have continued for hundreds of years to deposit the seeds as soon as gathered in a shaded place, in layers an inch or more deep, and covered with a thin layer of decaying leaves or similar substance. The heat generated by the decomposition of the fleshy pericarp serves to induce germination, and the embryo bursts from its bony covering. This growth unites them in from eight to fourteen days into a solid mass, which is broken up into small pieces and planted in furrows in the nursery. In this process very many of the sprouts are broken off and the plants destroyed. Mr. Lobse has adopted the plan of sowing the seeds broadcast as soon as gathered, and covering with a little earth, or, better, a layer of banana leaves or decaying vegetable matter. Germination requires from eight to twelve days longer, but all the plants are saved. In either case a covering of brush or straw must be placed over the nursery.

* It is desirable that there should be a more precise definition of the peculiarities here referred to.—ED. *Ph. J.*

at first only three or four inches above the surface, and elevated to six or seven inches as the plants grow. Usually this elevation is repeated once more.

All this taking place during the rainy season, the plants have reached a good size before the advent of the dry weather, and so do not call for any artificial water supply. Advantage is taken of the ensuing dry season to clear the land and prepare the ground for the new coeal. On the manner in which this is done depends much of the future well-being of the plants. The ground should be thoroughly powdered to the depth of two, and, if possible, three feet, all roots and large stones being removed. On these steep slopes it is necessary to terrace, the terraces being supported by stone walls, the stone laid dry. The width of the terraces, according to the slope, varies from several feet, with a number of rows of plants, to much less than the height of the wall, only a single row of plants being admissible. It is here generally believed that shade tends to the production of the best quality of leaves; so the coeales are planted thickly with a small broad-topped leguminous tree related to the St. John's bread, but whose name I cannot at this moment recall. There is no doubt that this is a mistake. I have made repeated comparative assays of shade-grown and sun-grown leaves from adjoining plants, and invariably found the latter much richer in total alkaloids. I judge the custom to have arisen from two considerations. There is, as I have stated, a period of two or three months when the plants receive no rain, and then these trees afford a protection from the fierce heat. Secondly, shade conduces to the production of a large, smooth, beautiful leaf, of elegant colour, and thus adds to the appearance of the product. The terraces being thus prepared, on the advent of the permanent rainy season the plants, now from 8 to 12 inches high, are transplanted, being set from one-half to six inches apart, according to ideas of the hacienlero. From this time until the first leaves are picked the greatest care must be taken to keep the soil thoroughly stirred and free from weeds. The plants having been transferred in October or November of one year, the first picking is made in March or April of the second following year, one year and a half from the time of transplanting, or two and one-half from the seeds. In case an insufficient space has been prepared, the remaining plants are often left until the following year, and then transplanted, the operation being much more dangerous to the life of the plants.

The chief danger of picking the leaves earlier than the period indicated above is not the strain upon the vitality of the young plant, as many of the leaves drop off themselves, but because it is almost impossible to avoid breaking off the very tender tips of the twigs, the result being fatal to many plants. Immediately after this first picking, fresh leaves develop with great rapidity, and in July or August of the same year the plant flowers for the first time. The lovely white flowers, if undisturbed, remain from three to six days; but from the very first they are dislodged by the slightest jar, the corolla falling entire, although it is morphologically polypetalous. The fruit ripens in December and January.

During the first few years the percentage of alkaloid increases rapidly, reaching its maximum at or before the age of ten years. At the age of twenty it begins to diminish, but with extreme slowness, so that the plants are practically in their prime up to the age of thirty-five or forty. It is probable that the decline is then due rather to the exhaustion of the soil than of the vitality of the plant. Fertilization of the soil has never been resorted to. It is probable, as suggested by Mr. Lohse, that as much can be done for the coca in this way as has been done for other plants.

A coca harvest is called a *mita*, an Indian word meaning a division or drawing of lots, and there are from three to five in a year, according to the season. The time of picking is determined solely by the condition of the leaves. When they have become mature they turn yellow if in the dry season, and brown if in the rainy, and within eight days at the outside will

fall to the ground and be lost. As soon as the *mita* is over, the ground is cleared from weeds, and, under an ignorant notion that further cleaning is injurious, is left undisturbed until after the next *mita*. But Mr. Lohse has tried the plan of keeping the ground clean, with the result, thus far, of receiving the next crop in little more than one-half the time required by his neighbours. No irrigation is resorted to during the dry season. Although it is possible that good might result, at least to the welfare of the plant and the size of the crop, I suspect that after a long time an abundant and steady supply of water would result in a decrease in the amount of alkaloids. Mr. Lohse has tried the experiment of mulching at the end of the wet season with a few inches of banana-leaves or other refuse, with excellent effect upon the plants during the succeeding dry season.

This plant is subject to only two diseases of any importance. The first is *taja*, which I suppose to be the result of a fungus which attacks the undeveloped leaves and tender twigs. It is said by some to be caused by careless picking, in which the twigs are broken. By others it is said to result from the planting of seeds taken from young plants. The only remedy is to remove and burn the diseased portions. The second disease, if such it can be called, is the ravages of a caterpillar called "ulo," which makes its appearance in December, and destroys the crop so quickly that it admits of no remedy.

The method of picking and drying the coca has been so often and so well described of late that it is not necessary to dwell upon it. Coca-picking is a profession to which the children are trained from a tender age. The leaves are picked singly, both hands being employed with a rapid alternating motion, which strips a twig in an instant. Great care is taken to avoid breaking the twigs, and the young leaves are not picked. Little sacks are tied about the waist, or the women's aprons are pinned or sewn into the required form. They are then transferred to larger sacks, which must be filled and emptied with great promptness, or the leaves will become heated and turn black.

The price here paid for picking is a Bolivian dollar, equal to about seventy-one cents United States currency, for each thirty pounds, which, when dry, will weigh about twelve pounds.

The leaves are exposed to a hot sun upon a pavement of nicely-fitted flat stones, and stirred occasionally until dry. Under the most favourable conditions the drying is accomplished in about three hours. About the coca place are built the storage and packing sheds. These are furnished with very broad doors, and men are in constant attendance to sweep the coca with brush-brooms through these broad portals at the slightest indication of rain. A very few drops of rain are sufficient to decolorize and ruin the sale of the coca, though it is my impression that such decolorization, if produced by but little rain, is no indication of loss of cocaine. During the first few days that the dry coca lies within the storage-sheds it undergoes a slight sweating process.

When I come now to speak of the best methods of packing the coca for export, it is fair to say that nothing definite is known. Such coca as has reached Europe or the United States in good condition has done so purely by accident; for perhaps the very next lot, dried, packed and shipped as nearly as possible in the same manner, has arrived entirely ruined. I have tried many methods, and as often as I had thought that the secret was discovered my hopes have resulted in disappointment.

As regards the exportation of the culture of coca, the experiment has been tried, I believe, but once. Several years since, Mr. F. L. Steiart, of La Paz, shipped a small quantity of seeds *via* London to Ceylon, and during the past season the first products were shipped to London and sold at a high price. Seeds for export should be exposed for several days to a hot sun, so as to rapidly dry the fleshy exterior, which thus forms a protection to the germ within.

It is my opinion that the coca plant is adapted for culture in many countries where it is now unknown

Among the countries where it would be well to experiment with it are Guatemala, Mexico, the East and West India, India, Southern China, portions of Africa, and possibly of Italy. It is doubtful if it would grow in any portion of the United States. Requiring an average temperature of at least 70°, the only districts at all suited would be Florida and Southern Texas; and it is highly probable that proximity to the sea-coast at so low an altitude would prove fatal. Nor would irrigation prove adequate in those countries possessing a long dry season. The plants must not only have an abundant supply of water at the roots; they must be bathed in a humid atmosphere for the greater portion of the year. But from what I have read of some of the countries above named, I am confident that the plant would there find a congenial home. Jamaica offers especially hopeful conditions.—*Pharmaceutical Journal*.

ON RAMIE (OR CHINA GRASS).

A LECTURE AT TULANE HALL.

Views of Mr. Jules Juvenal about Ramie, its Value as a Crop, its Uses in the Industries, and its Place in Commerce and Agriculture.

At Tulane Hall, on Saturday night last, there was a large gathering of those interested in the cultivation of ramie and other fibrous plants. Judge Wm. M. Burwell presided.

Mr. Jules Juvenal, the lecturer of the evening, thus addressed his listeners:—

INDUSTRY OF TEXTILES.

The industry of textiles is the foremost of all industries. It is that which all over the world gives employment to the greatest number of labourers, brokers, merchants and manufacturers. The consumption of its products is diurnal and without limit. The world has ever been looking for new textiles, but particularly so since the past fifty years, which have brought about a general increase of population and modern improvements in the fabrication tissue. The attention of the manufacturing world has during the last few years principally been called to the ramie, or China grass.

RAMIE.

What is ramie?

It was formerly placed by botanists in the class of urtica, or ortia, but it is now called boehmeria, or spearless nettle.

I will call it by no scientific name. I will simply name it the richest of all plants, for it possesses wealth of growth, wealth of development and wealth of fibre.

In ordinary light ground, with a little watering now and then, no plant will grow as rapidly, no root will multiply quicker and produce more stalks, no vegetable fibre is handsomer, richer or more silky than ramie.

Notwithstanding all these elements of success the Chinese alone have for a thousand years past extensively cultivated the ramie plants. How comes the civilized world to be thus backward in introducing a plant of such excellent return and known in Europe since the beginning of the present century? For my lecture to-day I will endeavour to inform you concerning:

1. The causes which have delayed the cultivation of ramie in Europe and America.
2. The best methods for its cultivation and production.
3. American machinery applicable thereto, and a description of the machines at your Exposition.
4. The chemical treatment of ramie and of all textile plants.

The chemical treatment is the complement of all decorticating machinery, for it takes away by dissolution all gummy and resinous matters adherent to the fibre, which no machinery can completely eradicate. I will tell you how this can be accomplished chemically, not only with no injury to the fibre, but with the result on the contrary of adding to its silky qualities. This perfected chemical process is the property of our firm, the Ramie Fibre Manufacturing

Company, of New York, of which I have the honor of being director. It is by applying this disintegrating process to the Ramie fibre, which offers the most resistance of all, and witnessing its excellent results that, pushing forward our researches and experiments, we have succeeded in applying to all textile plants the same process at modified degrees, according to the resisting force of their various fibres. Many of these grow in abundance under your own latitudes, the pita and silk grass of Honduras (remarkably fine fibre), the common bagasse of your sugar cane, the typha or common cattail, which grows abundantly in New York, New Jersey and Sandy Hook, the bowstring hemp for Florida lily, the yucca of the gulf coasts, the banana, the plantain, the ixle, the bear grass, the Spanish dagger, the lichegulla, the Mexican naguayo, etc. With the exception of the cattail or typha, which may be monopolized by New York, all the plants which I have named can be imported in leaves—that is to say, in the crude state, free of duty to New Orleans, which is naturally destined to become first their natural depot, and then their place of transformation into textile fibres by the establishment of factories along your lake coast. By this means New Orleans would become the chief market of the world for textiles, and it will have been one of the results of your Exposition. I will show you later on how this is to be effected. But let us for the present go back to ramie.

CAUSES OF THE DELAY TO THE INTRODUCTION OF RAMIE IN EUROPE AND AMERICA.

The first shipment of ramie from India to England was a lot of three bales, shipped in 1810. Experiments then showed that a ramie rope could support a weight of 252 pounds, while a Russian hemp rope of the same size would break on the weight of over eighty-four pounds.

The ramie question remained at a stand-still during the time of the wars of the empire and the political questions which disturbed Europe during the first half of this century.

It is only in 1862 and during your great war, in which the bravery, gallantry and death-daring qualities of the Southern people attracted the admiration of Europe, that the subject of ramie industry was resumed. Experiments were made in London and in Rouen to mix cotton with ramie. Messrs. Cardier & Co., of Rouen, successfully wove a lot of Egyptian and Indian cotton, mixed half and half with cut China grass. The warps thus obtained proved much superior to those woven out of pure cotton, but the difficulties presented by the irregularity of the Chinese market, which failed to supply a sufficient quantity of China grass, and the necessity of special looms, caused the abandonment of the fabricators of that special tissue, and cotton having resumed its normal prices was taken back as the sole agent of fabrication.

In 1869 the English government of India, believing in the future of ramie, and with the intention of introducing it into the public domain, instituted a prize of £5,000 for the best machine for decorticating in the green state.

Innumerable pamphlets and lectures on ramie mention this circumstance as being the cause of the progress made by that textile. I am of an entirely different opinion. I think that the allurements of that prize of £5,000, though made with the best intentions, but to which were attached impracticable conditions, helped greatly to retard, by the rejection of the machines presented, the development of ramie culture. European mechanics were asked in Europe to make machinery for use in India, to work a product scarcely to be found in Europe even for purposes of study, experiment, and consequently appropriate modifications of mechanical appliances.

The English Government would have done better in applying to the culture of ramie in Europe the amount of the premiums offered for the Calcutta machines.

A few acres of ramie in the Island of Jersey, where a retired French Colonel cultivated it with success,

would have furnished French and English mechanics all experimental material necessary to obtain a practical solution of the problem, which could have been demonstrated by competition in London.

Jute, notwithstanding its low price and easy decortication by retting, and though imported in England since 1796, remained fifty years without being utilized to any considerable extent.

It is only in 1849 that a merchant of Dundee persuaded the Holland home Government to use jute bags, instead of those made out of flax for shipments of coffee by the Government in India. A vast field was thereby opened and jute since then has made considerable headway. The same will happen with ramie, whose fibre being so much more valuable, has been envied by nature with more obstacles to its decortication, and it is not surprising that some time and money have been lost in attempting to solve the problem.

Like all great schemes, the ramie question is liable to the accusation of having enthused, crazed and ruined a large number of its devotees. An extensive field of ramie is a beautiful thing to look at, and when at the same time one considers that the simplest kind of study demonstrates that the bark of each stalk presents an extraordinary wealth of fibre, astonishment ceases at the fervor of the adepts of this plant.

As I have said before, the competition at Calcutta, made under impossible conditions, retarded the invention of a practical machine; for, besides the difficulties presented by distance and the absence of material for experiment, the European mechanics were asked to produce machine; which could accomplish the delicate and tedious hand labour of the Chinese workmen, who made a pound of ramie a day by scraping with a wooden knife a part of the gummy and resinous matters.

If experiments had been made in London instead of Calcutta on green stalks coming from Jersey, the absurdity would have been quickly ascertained of asking of practical machinery more than the mere separation of the fibre, which in the green state is easily accomplished, leaving for chemical agents the task of eliminating the gummy and resinous matter adhering to the bark.

There lies the whole secret.

If all inventors of decortivating machines, some of which are very clever, have heretofore failed, it is because they have aimed at filling the conditions imposed for the Calcutta competition; that is, to make a machine capable of producing directly the China grass. This, nevertheless came near being accomplished last year at Calcutta; but with what paltry results! The Smith machine, of London, which obtained a prize of 2,000 rupees, or £1,000, produces, with two men and a three horse-power, sixty pounds a day.

Under such conditions ramie would be twice as high as silk. What is needed is a combination by which production, cleaning and fabrication will give a silky fibre ready for the loom at a cost from twenty to twenty-five cents about the price of first-rate flax.

CULTURE OF RAMIE.

We have shown by public experiments at the Exposition, what our machine can do. We will continue our experiments on green ramie during the last days of the Exposition.

Our machine is simple and within the means of all cultivators to produce the crude material. Near it is our small apparatus for the cleaning of ramie and all textile plants. We will lay no stress upon facts which have been made patent to all. The samples coming from our machine and from our apparatus speak for themselves, and have obtained first premiums for ramie and jute.

Speaking about jute, I must say that I have received many inquiries about that plant. It would seem that the American planter believes in jute without knowing exactly what it can give. Let me advise him to abandon jute. There is nothing in American jute. It cannot compete with Indian jute, which is

brought to New York at four or five cents a pound, ready for manufacture.

I will describe other machines than ours which are now on exhibition. For example, the partisans of work on the dry material will find in Mr. Gibson's machine an excellent one.

The question of machinery is now solved, and we will have as many machines as we want so long as they are asked only to work the crude bark either green or dry.

Production should now be our only pre-occupation. Planting should be done at once—May or June—so as to raise a crop in autumn, and I will demonstrate that a net profit of \$100 per acre can be made during the year following the first plantation.

But, what climate is adapted to ramie culture?

What quality of soil? How shall we plant? Where are the plants and roots?

How shall we cultivate and reap? How will the crop be sold, and what certainty is there in the future of ramie?

TO WHAT CLIMATE IS RAMIE ADAPTED?

The State of New Jersey, whose Legislature had offered a premium to ramie planters, has cultivated this plant with success by protecting its roots with straw during winter. I would, nevertheless, advise planters in the Northern States to cultivate it only on a small scale.

This is not the case in Southern States, from California to the Carolinas, where by planting in a light soil, somewhat moist and easy of irrigation, success is certain, however extended may be the enterprise, this particularly in Louisiana, Mississippi, Alabama, Florida, Texas, New Mexico and California. The banks of the Mississippi, from New Orleans to Cairo, will soon, I am confident, be green with ramie, and if your levees are not absolutely secure, it seems as if ramie had been made for such a contingency, as a sojourn of even a whole month under water does not destroy this plant.

In support of this I will mention a circumstance which happened in Louisiana:

Mr. Laforest, or Bayou Heron, who had a half arpent of ramie that remained two months under water after withdrawal of the waters found the plants in good condition. Evidently there is a limit to all things, but it is well established that complete immersion for two or three weeks will not injure the ramie.

HOW TO PLANT.

Ramie is a perennial plant, and has to be planted but once for every thirty years. The planting is to be done exactly the same as with Irish potatoes. Work the soil well by plowing. Trace rows three feet apart and plant the ramie root in the rows at one foot distance; then cover with two or three inches of well pulverized earth. At a distance of three feet each, we will have seventy rows to the acre, and planting the roots one foot apart will give us 120 roots per row, or 14,000 roots per acre. In order to obtain a plantation of straight and well-formed stalks, the plantation must be made closed and uniform.

The present high price and scarcity of ramie roots would scarcely admit of the average planter investing at once in 14,000 roots per acre; but in order to push forward the propagation of ramie, I would suggest to planters the following scheme:—

Leave a distance in planting of three feet between the roots, which, instead of 14,000 will make 5,000 roots to the acre.

In three months, when the stalks will be about two or three feet high, spread them down in the rows without breaking. This will furnish for the autumn new stalks, which will complete the plantation up to 14,000 roots. Besides this, the planter can take from each mother-root two or three cuttings to plant another acre, and so on.

As I have told you at the beginning, ramie is the most prolific of all plants, and Mr. E. Darby, of New Iberis, La., was right when he said to his son a few years ago:

"I have planted a good acre of ramie in our garden. When I will be no more do not disturb it; take good care of it. If its utility is not appreciated to-day, the time will surely come when the true value of this plant will be universally recognized and you have in these roots the beginning of a fortune."

WHERE TO FIND RAMIE PLANTS OR ROOTS.

Various Louisiana planters have in their fields some thousands of ramie plants which they could afford to divide. For my part, I have a large stock of the species *Tenacissima*, the best of all, which I hold at the disposal of any planter wishing to plant an acre or more of 5,000 roots, payable half cash, half in crude bark from the crop of 1887.

HOW TO CULTIVATE.

Planting being over, if the summer season is accompanied by a prolonged drought it will be necessary, during the hot weather, if the soil where the ramie is planted is not naturally moist, facilitate growth and vegetation by irrigation, which should be more or less frequent according to the permeability of the soil. Irrigation, however, must be stopped fifteen days before gathering, to permit the stalks to fortify and lose their excess of moisture.

The land should be disposed as to permit easy watering. The best disposition consists in placing the plants on small ridges, separated by furrows which serve at the same time the purpose of irrigation and drainage. Like all plants whose leafage is strongly developed, ramie absorbs from the atmosphere a large portion of the elements necessary to its nutrition, consequently it does not exhaust the soil, and will prosper in ordinary ground whilst hemp and flax need a very rich soil, which they speedily exhaust. It is good at each crop to abandon on the ground the leaves of the ramie plant, which thus return to the soil a part of the elements taken from it.

It should not be inferred that ramie is indifferent to the action of fertilizers.* Its vegetation is always proportionate to the elements furnished for its sustenance, provided always that they possess an assimilating nature. Therefore, as is the case with plants of rapid development, liquid fertilizers are the best. These should be used, mitigated with water, in the spring and at every cutting. Farm manure should be employed only as a covering before winter, so as to permit the snow and rain to saturate the soil with its elements.

During the first year the culture of ramie requires weeding around the young plants so as to rid them of noxious grasses. When, however, the plant has taken possession of all its allotted space, weeding becomes unnecessary, and the labor is reduced to giving in the spring one smoke of the plow to clean the draining ditches, and another one in autumn to cover the feet of the plant for the winter.

HOW TO HARVEST.

According to the Imperial Treatise on Chinese Agriculture the ramie stalks should be cut before the budding season, when their lower portion begins to assume a brown tint.

The harvesting of stalks should be made with a very sharp scythe, to avoid tearing, which would interfere with eicatrization. If the stalks are to be used in the green state, they should be made up in bundles of about 200 and carried to the machine. If they are to be used dry, they must be left to dry in the sun as rapidly as possible. This process offers some difficulties, as the stalks contain a great deal of water and are hydrometric by themselves. It will be necessary to use natural labor to turn over the stalks on the ground until they are dry. It is important not to gather them in until perfectly desiccated, for they would then rapidly become moulded, which would also be the case if they were kept in a moist place. When it is wished to utilize the ramie leaves for the feed of animals or paper-making, they should be stripped from the stalks at the time of harvesting.

* One of the great obstacles to successful cultivation is the exhaustive nature of the crop.—Ed.

HOW TO SELL THE CROP AND WHAT IS THE PRODUCTION PER ACRE.

It is important to bear in mind that ramie, like cotton, hemp and flax, presents varying qualities, according to soil, mode of culture and harvesting.

In China, for weaving the finer tissues a difference is made even between the fibrous strata on the same stalk. The exterior fibre is coarser and stronger than the interior fibre nearest the wood, which is employed in weaving silk goods.

The first crop is shorter, branches off more than the second and third, and produces inferior fibre.

Treatment in the green state not requiring that the plant should be fully matured produces a finer quality of fibre and allows cutting when the stalks are about five feet high. This gives also an advance of fifteen days on the crop, which in Louisiana would permit making three crops.

Practica will teach with more exactness what will be best to do, for though the above information is derived from positive experience, yet it is an experience made in countries different from your own.

The average value of the crude ramie bark has been estimated at five cents per pound. At that price there is a great European demand. In addition to this let me tell you that it is by 100,000 roots that the villages in the south of France are now planting ramie, and since two months the prices of roots have risen 30 per cent. American consumption will, I think, enhance the price of five cents per pound of crude bark, for manufacturers here are at this very moment waiting for a regular and sure production to rear up their fabrics.

However this may be, we are ready now to pay five cents cash per pound for the crude bark of ramie, dried and baled, landed in New Orleans, where we establish a branch office.

One acre planted now with 5,000 roots will have 14,000 plants at the fall, and will produce in 1887 at least fifteen stalks per plant, and a total in round numbers of 200,000 stalks, giving one-eighth of an ounce of bark, or a pound by 125 or 130 stalks, or 1,600 pounds an acre per crop, or for two crops 3,200 pounds per acre, at five cents a pound, \$160. Putting down at 80 the annual expenses, harvesting and pro rata of first cost of the roots, we arrive at the splendid result of \$100 net profit per acre for two crops, and in Louisiana, with its lengthy fall, joined to the treatment in the green state, which requires less maturity in the plant and therefore less time, three crops are almost a certainty.

WHAT ASSURANCES ARE THERE IN THE FUTURE OF RAMIE?

A certain proportion of the ramie crop will be applied to the fabrication of finer tissues. There will, of course, be a choice of qualities, but the true commerce of ramie will extend upon condition that the average quality of ramie will be produced at a price which will permit its advantageous use in the manufacture of tissues of general consumption. The price of five cents a pound for the crude bark corresponds with the good tissues which are now being manufactured from first quality of flax or wool. Under these conditions I would say to every intelligent American farmer: "Hasten to plant one, two or three acres of ramie, enlarge your production each succeeding year, and, however large it might grow, there is no possible danger of too much ramie in the United States before twenty years to come. When that moment arrives American genius will meet the emergency."

MACHINES.

The machine or decorticator of our company working only on material in the green state, I am naturally a partisan of that system. But I do not for that reason condemn the work on the dry material. The future will show who is right! There are five machines at your Exposition, three working on the green and two on the dry material.

MACHINES FOR TREATMENT IN THE DRY STATE.

The Sandfort Machine.—This decorticator is composed of two machines or parts of machines. The first comprises two or three pairs of deeply fluted rollers, having a forward and backward motion, which breaks the woolly part of the stalks. It is used mostly for breaking flax, for which it is well adapted. The second machine, or second part of the decorticator, is composed of a big fluted revolving drum, working by friction, and is intended to soften the material, if necessary, after it has passed through the first machine. The International Fibre and Juice Extracting Company, of New York, to whom belongs the Sandfort machine, has made several public experiments of ramie, jute, hemp and flax, which have spoken for themselves.

THE GIBSON MACHINE.

This machine is a pretty little model, made on the principle of the hand-peddling method practised by the natives of India on jute stalks. The peddling is done by two steel cylinders, in which sharp grooves blend into a spiral, the cutting part not overreaching the diameter of the steel cylinders, so that it cannot cut any part of the wood, but only lifts the fibrous bark. The cylinders are placed one above the other in such a manner that they exercise a certain pressure on the stalk, and thereby seize the fibrous bark and throw it between two rollers covered with gum cloth, which delivers the fibre in two parts, the upper cylinder seizing the upper part of the stalk and the lower cylinder the lower part of it; the stalk once free from the bark slides between the two cylinders; is seized by two rollers and thrown on the floor in front of the machine.

Mr. Gibson is showing daily the good work of his machine.

MACHINES FOR TREATMENT IN THE GREEN STALK.

The Routledge or Jamaica Machine.—This machine, which is of large dimensions, divides the stalks into two parts by means of a sharp knife; each part after having been divided is beaten by two revolving bats, which break the wood; the fibrous bark then passes between a drum having revolving knives and plates fitting exactly the diameter of the drum and moving in the same direction; the bark then falls upon a revolving table.

UNIVERSAL FIBRE DECORTICATOR.

Manufactured by Remington Agricultural Company, P. Albee Smith, patentee. Consists essentially of three pairs of rolls and a pair of endless apron. The machines are of two styles. One is designed so as to enable the feeder to deliver the stalks. The other requires a workman at the rear end of the machine to take the cleaned fibre, the feeder being constantly employed in supplying the machine with material. In the first style the front rolls are smooth; the second are fluted, running about seventeen revolutions per minute. The third pair are armed with scraping blades, rigidly fixed to their periphery and winding spirally around the rolls. These rolls are also hollow, with perforations through their shell, through which water is allowed to flow for the purpose of keeping the blades clean from gum; also to wash the fibre, running 300 revolutions per minute. The material is placed on the table, and is passed half way or more into the machine, then run back on the table, reversed, and the other end cleaned in the same manner. The second style of machine has scraping rolls in place of the smooth rolls, as in the first style. These rolls perform the office of feeding rolls, and also of cleaning the passing ends of the material by reversing the pairs of rolls, instead of the material being operated on.

THE LEFRANC DECORTICATOR.

Our company's machine, known as the Lefranc Decorticator, is made simply of two grooved rollers and two endless chains working inversely with scrapers. The ramie stalks are introduced in packages of about twenty stalks well spread out, under the rollers, which, after having mashed them, conduct them to drive out the wool between the scrapers of the endless

chains. During the operation a pair of pincers seizes inversely the crude bark, which, thereupon, are taken up in double action by the scrapers that completely eliminate all ligneous parts. The forepart of the machine then takes up the fibrous bark, which is then perfectly cleaned. This machine turns out about 500 pounds in a working day of ten hours, and its price is from \$400 to \$550, according to size.

OTHER MACHINES.

Besides the five machines above described, three others, not on exhibition, have been pointed out to us in New Orleans:—

1. Mr. Luff's machine, made by a very skillful mechanic of your city, Mr. Lewis Johnston.

2. The Vogel machine, whose inventor has been for a long time studying the ramie question.

3. The Delavigne machine, constructed by a veteran in the art. We are not acquainted with these machines, but they are all patented, and their inventors speak very highly of them.

At all events, now that the farmer is only asked to produce the rough bark for the market, the problem of machinery is solved in every way, either to work the green or the dry material. It is only a matter of choice. Practical working will determine which is the best method, and, as the machines mentioned above can scarcely find work to any extent before the crop of 1887 is taken in, there will in the meantime probably be made improvements which will make them perfect. Nevertheless, taking the decorticators now on exhibition at the Exposition as they stand at present, I would suggest, in the face of a question of such importance to Louisiana and the United States, that the official jury of the Exposition make a special test of the matter by giving each decorticator an equal number of ramie stalks to work, the clean product to be placed on exhibition, with a report on the work done by each.

CHEMICAL TREATMENT.

The great difficulty to overcome in making vegetable fibres useful as textiles, comes from the cement that attaches the fibres together and the colored pelticle which covers them. The substances to be eliminated for the utilization of these fibres are called, "vasculose, cutose and pectose," and our chemical process produces the effect of dissolving these substances, not only without weakening the fibre but making it stronger and more silky. Other processes have obtained a certain result by the use of caustic alkali with pressure, or such oxidizers as permanganate of potassium, hyperchlorate, chlorine and bromine, but these come high and consume more time than ours. We began first by applying our dissolving agent to ramie with modifications according to the quality of the plants treated. For example, American ramie required 3° Beaume of our dissolvent, while the China grass, already somewhat cleansed, required only a bath of 2° with the same time in boiling, three hours. It is particularly the washing and departhing with plenty of water after our chemical bath which should be done with great care. By this means a perfectly distinct fibre is obtained which we bleach and brighten up with our two other products—azotozone and chlorozone. The results obtained have won for us two first premiums at your Exposition.

ALL TEXTILE PLANTS AND PROSPECT OF THEIR TREATMENT IN NEW ORLEANS.

It is in studying how to dissolve the guany and resinous matters of the ramie that we have been led to treat almost in the same manner all the textile plants which grow, so to speak, at the very gates of New Orleans: the bananas and silk grass of Honduras, the pita and maguey of Mexico, Guatemala, Cuba, Jamaica, the flax of Florida, and the yucca of the Gulf Coast. I will not insist upon what I have previously said of the certain future of New Orleans as the first market in the world for all textiles. All I ask from this assembly is that a committee be appointed this very evening from among you to study the question specifically and technically with me, and to make a public report of all that can be imported in the way

of fibrous product, free of duty, from Mexico, Cuba, Jamaica, Central America, Venezuela, Brazil, etc., and made into commercial textile fibre in New Orleans. Every innovation, as also every new culture, however useful it may be and bounteous its promises, must wrestle against routine and old established precedents, and must have the help of a high patronage.

The Irish potato, without which people could scarcely exist at present, had a hard fight against routine and ancient customs, and the help of the court of Louis XVI became necessary for the assertion of the claims of that useful plant to the patronage of Europe. The noblest ladies of that age wore the pretty little violet flower of the potatoe as an ornament, and in that way gave to flower and fruit the desired popularity.

CONCLUSION.

I therefore place the ramie plant under the protection of the ladies of Louisiana. Unfortunately it has no button-hole for a "dude" or a bouton for a lady, but every Louisiana or Creole lady should make it a point to have at least some of these plants in her garden, and I hereby make a tender of the precious roots to all who will call for them, and I beg them to take under their special care the future of the ramie culture, which then cannot fail to prosper. Thus will the ladies of Louisiana, the fairest flowers of the sunny South, help their native land to retrieve its pristine prosperity and splendor.

I thank you, ladies and gentlemen, for the extreme kindness with which you have listened to me, and if any more information about ramie is wanted, please call or address at our company's stand, Machinery Hall, F 5, Exposition Grounds. I will gladly respond to any inquiries.—*Times-Democrat*.

Mr. D. MORRIS.—We understand it is the intention of Mr. Morris, on leaving Jamaica, to take up his appointment at the Royal Gardens, Kew, to make a tour of the West India Islands, for the purpose of becoming personally acquainted with their circumstances and resources, and with the view of being able afterwards to give them advice and assistance in the development of new industries. Several of the islands have already been visited by him; but it is, we believe, his intention to make now a careful study of their circumstances, to be afterwards embodied in a special report, or utilised in directing the wonderful resources of Kew to the amelioration and improvement of West Indian industries.—*Colonies and India*.

ASPHALT WALKS.—Take two parts of very dry lime rubbish and one part coal ashes, also very dry, and both sifted fine. In a dry place, on a dry day, mix them, and leave a hole in the middle of the heap, as bricklayers do when making mortar. Into this pour boiling hot coal tar; mix, and when as stiff as mortar put it down 3 inches thick to form the walk. The ground should be dry and beaten smooth. Sprinkle over it coarse sand; when cold pass a light roller over it, and in a few days the walk will be solid and waterproof. An old path will only require to be swept clean; a new made one to be well beaten and rolled. Choose a warm day, the warmer the better; let the tar be boiling hot; use the common, long-handled, iron-bound tar brush, and iron tangle holding about a gallon, for the purpose of taking only so much tar from the boiler at one time as can be used in about a quarter of an hour, and paint over with a good coat. Let a lad follow with dry sifted sand, throwing over enough to prevent the tar sticking to his feet, and then go over with the roller. Two men tarring will employ a lad to follow with the sand, and another to attend the fire and supply the tar as fast as used. This repeated every three years the surface will become quite hard, and the paths will always be perfectly dry and pleasant to walk upon even in the worst of weather. The walks are made soft by the sun if the tar has not been made quite hot when used.—*Indian Gardener*.

IN SOUTHERN LOUISIANA, 200 or 300 feet below the surface are strata of solid, pure crystalline sulphur, 100 feet in thickness and of unknown extent.—*Amer. Grocer*.

AMONG the curiosities of Brazil is the POTTERY TREE. The trunk does not exceed a foot in diameter, but it grows to the height of one hundred feet. The chief peculiarity, however, is in the nature of the wood and bark, which contain so much silica that they are used in the making of earthenware. The fresh bark cuts like soft sandstone.—*Indian Gardener*.

THE QUEENSLAND SUGAR INDUSTRY: Mackay Jan. 13th. —December rains were very heavy in Christmas week, and reached the respectable total of 11 in. for that month. Under the influence of the hot weather which has followed, the young plants are growing with a tropical speed that requires to be seen to be credited, and should present prospects continue next season's output is likely to rival that of 1885, high though it has been. Matured canes do not benefit by summer rains, as on account of the growth of new shoots from the stool the density of the piece becomes lowered, and this it is that renders January grinding to some extent unprofitable. Land bearing ratoon crop must be cleared in order to preserve a regularity of area under crop each twelvemonth. Thus as the required space for 1887 crop becomes available on each estate, the busy period will close in the factories, results will be analysed, and a future course of extension or retrenchment considered accordingly. The district has already exported some 78,000 tons of the staple product, so the season's total yield is likely to exceed 21,000 tons, or an average return per acre of about 30 cwt. of sugar. The outturns from all centres within the tropics, excepting the Burdekin River, will exceed considerably figures of previous years, the Johnstone River, in particular, having made astonishing progress. From there and Herbert River gratifying results are reported, and at both places plenty of cane will be left to stand over until next season.—*Australasian*.

THE "REVUE FRANÇAISE DE L'ÉTRANGER ET DES COLONIES" is the title of a monthly review, commenced last year and published in Paris, the editor being M. Edouard Marbeau. The number for November last contained, among other interesting matter, a paper by the veteran planter M. Es-Chassériau on Liberian coffee cultivation in Singapore and Johore, in which he gives a most glowing account of his own success with this product and holds out encouraging prospects of its success in Singapore and on the peninsula. The writer says that *Hemilea casta* is identical with the *oilum* of the vine, which it certainly is not. From what he says of himself one would almost think he was a Scotchman in disguise, for he evidently has a "guid conceit o' himsel." He estimates the outlay on an acre at \$300 for six years, while the return he puts at \$520, leaving a profit of \$220, but he says that this is a very moderate estimate. He also recommends the planting of Assam tea in conjunction with with the Liberian coffee, and proposes the formation of a company for this purpose. The January number of the *Revue* contains a paper on the Malayan Peninsula, accompanied by a map, the writer being M. J. de Morgan (a French Welshman?). This paper gives a succinct history of the Peninsula and an account of its resources. There is also a timely paper on Burma, by M. H. de la Martinière. The February number contains articles on a variety of subjects, all of interest. We wish the *Revue* every success and a long and useful career.

SIMULTANEOUS DECADENCE AND PROGRESS OF COFFEE IN BRAZIL.

Our readers will be glad again to see a letter from our valued correspondent, Mr. A. Scott Blacklaw. He gives an interesting glimpse of the home life of the descendants of Portuguese colonists who own so much of the soil of Brazil. But the important portion of the letter is that which deals with the gradual decay of coffee on old cultivations, the large exports of the berry being due to railway extension and the opening of new lands, of which there is still a superabundance in the great South American Empire:—

Province of Rio de Janeiro,
Brazil, 20th Jan. 1886.

Active outdoor pursuits and a continual spell of "roughing it" have prevented me giving you a letter occasionally. You know the subject which I used to please your readers was "coffee"; well, I have been for a long time out of coffee, and, therefore, could say little about it. Besides, it seemed to be a thing everybody was disgusted with. You, in Ceylon, were annoyed that it would not shake itself clear of the leaf-disease; and here, in Brazil, we got uneasy about it, because of its low price, and all who used to derive profit from it looked with alarm at the production having outgrown the consumption. But you reply: "Could you not have given us something on *new products*?" "New products!" yes, but what is new to me is old to Ceylon. I could give you a deal of information about sugarcane, but that you have tried years ago and found it would not pay. Let us not forget our old friend *coffee*. The hill-sides of Ceylon are not the only places which he has forsaken after luxuriating for a number of years. In former times, the lower parts of the Province of Rio de Janeiro were the principal coffee-producing district in Brazil. Even not much more than ten years ago it exported as much coffee as Ceylon did ever in her palmy days. Now, in these same districts, it is scarcely looked on as a pursuit. The trees have gradually dried up as one would say—gone all to dry branches and green points, and gradually died out.

One does here and there meet with a green patch under shade beside a roadside hut, reminding one of your native coffee gardens—but even these refuse to give fruit, and are not considered worth keeping clean. For some time the planters thought it was only change of seasons, and they thought the trees would come round, but they gradually got worse. I did not know the Province of Rio then, so could not say anything of the nature of the disease. Since I have come to know it, I cannot find accurate accounts as to the principal cause. Some blame an insect which destroyed the roots; others said it was a leaf-disease which, according to some, was a fungus; while others would insist that it was an insect, and a great many intelligent planters believed it was all these things combined: that the plant got weakened through growing from seed produced in the country, said seed being the produce of the plants of other seed grown in the country and so on without any importation of fresh seed. As usual in all cases affecting agriculture Government was implored to do something, and Government offered a reward of £5,000 (50,000 milreis) to any one who could find out the real cause and discover a remedy. Up till now not one has come forward. Meanwhile the estates have suffered and the trees have died. The farmers in these circumstances have been reduced in means. Some had to sell half their slaves, a great many went and bought land in the "far west" and opened flourishing plantations in districts where

railways were being made, and where there was no leaf nor root disease, where they had only to fell the forest, plant the coffee, planting Indian corn and beans at the same time, keep the ground clean, let the coffee only grow and pick the crop and live at ease as before.

No more fretting with the planter, now the corn and beans give him as much as enable him to feed and clothe his negroes, and the transport of his coffee is paid in Santos, he receiving accounts and money for the nett proceeds.

Many on whom the blight had first fallen were unable from reduced circumstances to buy new land, and their old was now unsaleable. As you are aware, the condition of life and the connection of the planters with the soil are different here from what they are in your country. Your Ceylon coffee planter looks at his occupation as in no way fixing him to the locality. He expects to spend a certain number of years in Ceylon, and retire to Europe with as much as will enable him to live comfortably the rest of his days, another planter succeeding him. The *Fazenda* in Brazil is the Brazilian planter's home; on this land he was born and here he would spend his days, although he may be occupying but a twentieth part of the great block of land which was granted to his first colonist ancestor by the Portuguese Government during the time of the South American gold-hunting expeditions, still the other nineteen parts are occupied by his relations. Perhaps for the last four generations there has not been a single marriage amongst the descendants of the old colonists contracted outside of the family group. It is thus a hard thing for these people to be compelled to remove, and many have stayed on the old estates, to try to make a living by a change of *lavoura* (agriculture).

But what was there to fall back on since coffee now gave them nothing? At first they tried Indian corn and beans, and planted up many of the coffee plantations with *mandioca*,—*Mait-hot utilisissima*. The first and second of these were prepared for the market at little expense and there was a market close at hand for them at the capital, to which there was cheap transport. *Mandioca* however required manipulation to be turned into *farinha de mandioca* or into tapioca. In the days of successful coffee planting, these three were grown extensively on all the estates, the rule being that the cost of the upkeep of the estates, which included the feeding, clothing and medical expenses of all the field hands, and the large retinue of washerwomen and servants about the house, must be borne by the cultivation of these three articles. It was not considered particularly good management if the superintendent could not also keep up the town establishment as well. Every *fazendeiro* of any pretensions to importance must have his house in the nearest town or village, and some of them lived there constantly, seldom going out to see the estate; there were others who would only visit the town at the times of the church feasts of which there are a great many during the year. We must not forget that the very large land owner had also his *palacete* in Rio de Janeiro. Coffee planting then occupied an important part in agricultural life. If the *fazendeiro* had to pay interest on borrowed money, the collapse of coffee planting was his complete downfall.

As I mentioned before there was no remedy, nor has there yet been any found to check in other districts beyond the Serra do Mar—where the canker is now spreading and causing gradual decay, nor is there any likelihood of any one coming forward to claim the *fifty thousand milreis*.

A correspondent in the *Jornal de Commercio* as late as 27th November last shows how difficult it is

to discover a remedy, owing to the cause being different "in various districts"—he says, "it appears impossible to discover a cure for the disease of the coffee trees, its organism is subject to so many different alterations. Different means might have been discovered to combat the various diseases. The deficiency of certain mineral salts in the soil causing serious perturbations in the vegetation of the coffee trees could not be vanquished by the same means employed for the destruction of animal or vegetable parasites." "This study relative to the diseases of plants, requires a long continuation of experiments to verify what is the cause of the disease. Sugarcane for example in the Northern (Provinces of Brazil) is attacked by a disease, attributed by some persons to the want of mineral salts in the soil, by others to the action of a cryptogamic parasite and sometimes to oxalic acid the product of elimination" (that is the burning of the trash after cutting and clear the ground which so many sugar planters all over the world believe in.—A. S. B.) "Therefore to achieve the end, desired by the provincial assembly of Rio de Janeiro (who have offered the reward of £5,000—or 50,000\$000.—A.S.B.) it is necessary to establish a laboratory where these studies of agriculture can be made with perfection, and only in this way can a true remedy be discovered."

This is not the first time the leaf-disease of Brazil has been introduced into your columns. I have not any of the papers by me at present, but I think that in any former writings to your paper I mentioned that the disease or a debility amongst the coffee trees was first noticed in 1861, the season 1860-61 was a dry one, and there was also a heavy crop picked, indeed the largest Brazil had given previous to that and the same quantity was not reached again until season 1874-75. These were for 1860-61 bags 3,185,091, and for 1874-75 3,205,567 from the Port of Rio de Janeiro alone. I am safe in saying that in the latter mentioned season 1874-75, not one-tenth of the quantity mentioned was got from the same locality as that of 1860-61 but nine-tenths of that large crop of 1874-75 was got from plantations opened beyond the *Serra do Mar* to which the disease or debility had not reached. Let us remember that the Province of Rio de Janeiro which used to be the great producer of coffee, occupies a stretch along the coast about 200 miles long by running nearer East and West than North-East and South-West. About one half of the land is on the sea side of the range of high mountains called the *Serra do Mar*, of which the peculiar looking Organ Mountains near Rio de Janeiro form part, and the other half is beyond that range. The breadth of the province from the sea to the inland range is from 60 to 90 miles. Before 1860-61 nearly all the coffee was produced on the sea side of the *Serra do Mar*. There the disease appeared just about 1861-62, and precisely there at the present day coffee will not thrive under any conditions. *Cemistoma coffeellum*, an insect of which I gave you account some years ago, was believed at first to be the cause, but this insect propagated by a small moth ceased to be so destructive as to cause much loss and ceased to be noticed, but still the coffee trees dwindled, then many believed in the various causes I have mentioned above; but there was no stoppage of the gradual decay of coffee trees all along the sea side of the *Serra do Mar*. Now for the last few years it has been making such havoc in those districts beyond the *Serra do Mar*, the same that supplied that large crops I mention of 1874-75, that the Government have offered the reward I mention, £5,000, to anyone who can discover a cure. You ask what is my

own opinion on all this? Well, I will say shortly that all these fungi, all the insects, and the various assertions about the climate having changed are not the cause at all. The parasites, fungi, &c., are an effect, not a cause. A nearly debilitated bullock will get covered with insects such as ticks while the healthy ones of the herd will have none, a few more weaker bullocks will also get covered with ticks—and by and by the insects will breed so fast as to cover the healthy ones too. Coffee gets debilitated through long continuous cropping in the same soil without manure, or there may be something in the soil which coffee requires as necessary to its healthy growth, and which the manures hitherto applied do not contain. The tree gets weakly and becomes a prey to disease of various kinds, and has not strength to rally against attacks of fungi and insects. There may be exceptions as in your Ceylon leaf disease which if I remember right broke out first in Ceylon, in one of your youngest districts at that time, Madulsima, in the Uva or Badulla District.

But here in Brazil all the old coffee estates have ceased to yield coffee, not only in the Province of Rio de Janeiro but São Paulo as well. I do not mean that in São Paulo disease has been at work beyond what I described to you some years ago in regard to the coffee leaf miner—(*Cemistoma coffeellum* - Stainton)—which still exists all over Brazil, and is not confined to coffee trees, but is found on forest trees, and small shrubs as well—and at present does healthy coffee trees little harm—but a gradual decay has taken place on all old estates from some cause not clearly discernable, the result being apparent exhaustion.

In South Africa the same decay in coffee trees has taken place. Natal which at one time exported 30,000 cwts. a year, and supplied home consumption—which amongst the Boers is no small quantity, has to be supplied with coffee, and that supply comes mostly from Brazil. When in that country (South Africa) in 1882, I saw whole plantations of coffee reduced to dry sticks, and green points the same as one sees so much of in the old districts in this country. One could witness no direct cause, and every other Planter gave a different reason for it. In that colony a Commission was appointed by the late General Sir George Pomeroy-Colley in 1881. I think they reported in 1882, for the copy of the Report I saw had no date—and no particular cause could be assigned by the Commissioners to the decay of the coffee trees. The Commission recommended that fresh seed should be got from other countries, to manure plants from the commencement of planting, to stop pruning, and to watch the results which were being tried by some—particularly the Natal Land and Colonization Company—of allowing the trees to bear three to four crops and then replanting. The fresh seed recommendation is no doubt highly to be approved. It has been tried in the districts where the decay first commenced in this country, but by the time the plants came into bearing the old cause was at work.

In the new districts far to the west in the Province of São Paulo and Minas Geraes, fresh Bourbon seed has been extensively used, and notably on the estates in São Paulo, owned by the present Minister of Agriculture, and those of members of his family, and who knows but that a persistence in this system of putting in fresh seed from other countries in the opening up of new districts where the disease or cause of decay has never reached, may have the effect of giving a longer span of life than has been customary here and in other countries where coffee planting has been successfully carried on, until all at once a change came over it.

As a proof of how the disease spreads, here are the totals from a Parliamentary paper published in October last year, only it is not stated in which years these maximum crops were picked.

Detailed list of forty-one estates in one small district of S. José de Leonissa in Province of Rio beyond the Serra do Mar:—

The name of the owners and names of estates are given, which I do not copy.

Maximum picking in one year, 128,847 arrobas: Probable crop might have been picked now include from clearings, 252,800 arrobas; Crop picked in 1885, 26,580 arrobas.

N. B.—A sack of coffee of 60 kilograms is counted 4 arrobas. In the districts besides the above-mentioned, namely, S. Fedelis, Madalena and Cantagalla the yearly loss is in the same papers calculated at 1,000,000 arrobas.

"It is added this 1,000,000 arrobas valued at \$5,000 (say 10s) the araba on the average will give the enormous quantity of 5,000,000\$000 (£500,000) annually, and this result it is easily calculated takes from the Provincial Government 1 per cent export duty, this is Provincial only; there is 9 per cent of Imperial export tax besides, —the sum of 200,000\$000."

Now you will think after hearing all this that the coffee enterprise of Brazil is ruined, or you will say: "Well really it cannot be so bad! you see what large crops she has been giving, and see how her excessive production has brought down the price of coffee!"

Let me explain how she has been able to keep up her exports. Before 1860—when the largest crop up till then was picked—there were very few railways open.

With the falling-off of the production of the estates on the sea-side of the *Serra do Mar* commenced the transport by railway leading in to the Province of Minas, the Don Pedro II. Government Railway had forced its way through the mountains, at the cost of 13 tunnels through the solid gneiss. Gradually different branches struck off from it, while every year a slice was being added to the main line. The length of the main line now is 875 kilometres—and the branches leading off is 843 kilometres, and still extension are being continued. The coffee that is carried by these lines has all to come to be shipped at Rio. The bulk of the Rio shipments now is from coffee grown on plantations in districts where there was very little coffee grown in 1860-61—With all this improvement in transport and the opening of plantations far beyond the reach of infection from the diseased districts. Still the export of coffee from the port of Rio is very little if any more that it was in 1860-61 . . . 3,183,091 sacks
1883-84 . . . 3,138,721 . . . 1st July to 30th June

This goes to prove what I have observed above.

The great increase in the export of coffee from Brazil is from the S. Paulo plantations. The produce is shipped at Santos direct for the European or North American markets.

In 1877 she shipped 800,000 sacks
now she ships 4,000,000 . . .
and goes on increasing. All owing to railway enterprise. The Paulista planters are an energetic, patriotic set of men; with the exception of the short stretch of railway from Santos to Jundiaby—140 kilos—which was made by an English company; all the other lines have been made from capital supplied by themselves. The total extension open is 1,815 kilos and there are extensions being proceeded with on all the lines and branches. Low as the price is and costly as the transport must be from the far west of the Province to the port of Santos, clearings are still being opened.

As regards labour supply they are availing largely of European colonists. There has lately been more care taken in the selection of these, and the planters are getting to understand the way to treat them. On the whole while, this railway extension spirit exists, I see very little prospect of a smaller production of coffee in Brazil, and further, I look for a still larger export than the annual 4,000,000 sacks from Santos. We may calculate that Rio will remain at about the average of, for last 20 years, 3,200,000.

A. SCOTT BLACKLAW.

P.S.—I have spun this out so long I have not left room to say what I intended about the cultivation in the districts where coffee has ceased to grow (I do not like to make promises but I may return to these), nor to notice the coffee returns for last year which are just out. You, however, will receive these from other sources. A. S. B.

SIR ROBERT HART AND THE DE-TERIORATION IN TEA.

The following notification addressed to the Tea Guild by Taotai Shau, with Sir Robert Hart's letter to the Tsung-li Yamèn, was published in the *Shenpao* of 25th ult. :—

On the 23rd day of the 10th moon of the current year, I received a communication from H. E. Tseng, the Superintendent of Southern Trade, informing me that he received on the 14th day of the 10th moon of the 11th year of Kwang-su, through the Board of War, a despatch from the Tsung-li Yamèn, covering abstract of a letter from the Inspector General of Customs, Hart, which the Yamèn received on the 28th day of the 9th moon, on the Tea Trade, saying as follows:—

"Tea is one of the most important articles of commerce of China, and lately the tea sold for the foreign markets has become worse and worse in quality. The Chinese merchants, thinking that the foreigners must have their tea, and for the sake of making extra profits, have been supplying an inferior article, not knowing that other places are also producing tea. Besides Japan, the new tea planted in India is increasing day by day in yield and is daily meeting with favour everywhere, and its export this year has been much larger than the last. If the Chinese merchants continue to neglect this branch of business, continuing to add spurious things to the weight of the Tea and not taking care to have the article properly made and dried, I am afraid the Tea business will be completely ruined."

The Yamèn finding that the increase and falling off in the trade affects both the Government and the people, and considering that since the establishment of commerce with foreigners the amount of silver that has flowed into foreign countries is very considerable, we having Tea and Silk only to balance and recover our loss; and now that the Inspector General's letter points out the fault of the tea merchants in making small profits at present without thinking of the trade in future, the Yamèn has to ask the Superintendent of Southern Trade to inform all the district authorities where Tea is produced, to advise the Tea makers and merchants to take care, and not spoil the business for the sake of profit only. The Yamèn encloses a copy of Hart's letter for the Superintendent's perusal.

The Superintendent, having on receipt of the above written to all the Officials and Taotais to inform the tea merchants to act accordingly, I have on receipt of the above written to the Shanghai Magistrate, and now make this present communic-

ation for the information of the Directors (of the tea Guild), to immediately inform the tea-merchants who deal with foreigners to improve by all means their article, so that the trade may be mutually protected. Do not disobey this.

Dated 2nd day of 11th moon 11th year Kwang-su.

The following is the full text of Sir Robert Hart's letter to the Tsung-li Yamen as translated from the *Shen-pao*:—

The teas sold by Chinese merchants to foreign countries during the last four or five years have become very inferior in quality day by day. The Chinese merchants, thinking that tea is an article much wanted in foreign countries, and seeing that notwithstanding its inferiority it is being taken all the same, have been making in this way larger profits than before, forgetting that by this manner of making profit they are running to certain ruin. These merchants ought to know that there are other places which can make tea. Besides Japanese tea, which is being exported to all countries, the new tea planted in India is increasing in yield, its make is also becoming better every day, and its demand is also increasing day by day. If the Chinese merchants don't seek to improve, I really fear that the consumption will be greatly diminished within a few years. By reckoning in cattie I find the Chinese tea sold to foreign countries last year amounted to 200,000,000 cattie, the Indian tea exported to several countries amounted to 16,000,000 cattie, and the export of Ceylon tea amounted to 2,000,000 cattie. This year the export of Indian tea has increased to 19,000,000* cattie, and Ceylon tea to 4,000,000 cattie. Considering that a few years ago not a single catty of tea was produced in those two places, and so many having been produced now, we don't know to what quantity it might be increased a few years hence. Tea is very important for China; if the Chinese merchants think of reducing labour and squeezing the necessary materials for the sake of making profits only, the tea trade of China cannot fail to be ruined. If the noble Ya-men does not communicate this state of things to the Southern Superintendent of Trade, so that he may direct the proper authorities to clearly inform the tea dealers by proclamation of the importance of adding spurious things to the teas, also not to make the teas heavy by keeping them wet, and not to economise the labour of manipulation, when this branch of business has been ruined, do not say that it had not been previously advised. Tea is one of the largest articles of commerce in China; it contributes to the revenue of the government and supports the people. The state of things having reached such a degree, I cannot be silent; therefore I respectfully make this for the Ya-men's information.—*Mercury.*

TEA MOVEMENT.

From the statistical tables below it will be noted that the popularity of tea as a beverage does not increase, being just the same per capita as it was in 1879. In consideration of an increase of over eight millions in population, the decline in the total imports from 1880 to 1883 inclusive is remarkable. It is customary for the Government to consider all tea withdrawn from warehouse as having passed into consumption. If the stock held at the close of each year was close to an average, such a basis would show actual results. As, however, the stock held at a fixed date has differed greatly, we attribute the variation in

* Either the figures for India are far too low or those for Ceylon too high: we do not crop 10 per cent yet o what India produces.—Ed.

consumption, reported below, as being due more to that cause than to any change on the part of consumers regarding tea as a beverage. Waiving that, however, the figures show conclusively that during the past ten years the article has not grown in favor with the people.

The Government Bureau of Statistics reports the quantity of tea entered for consumption since it was made duty free and the consumption per capita for twelve years past, as follows:—

Year ending June 30th.	Quantity. Pounds.	Consumption per capita. Pounds.
1874	54,410,055	1.27
1875	64,708,079	1.47
1876	62,744,429	1.38
1877	58,941,178	1.26
1878	65,366,449	1.36
1879	60,182,463	1.22
1880	72,159,266	1.44
1881	81,940,796	1.59
1882	79,030,854	1.50
1883	79,071,225	1.31
1884	65,774,234	1.18
1885	69,820,172	1.22

The total imports for the last two fiscal years the total value of the same as declared at Custom House, and average cost of importations per pound compare as follows:—

	Pounds.	Value.	Average per lb. Cents.
Imports, 1885	72,104,956	\$14,047,583	19.48
Imports, 1884	67,665,910	13,636,053	20.15

Of the quantity received last year China furnished 35,895,835 pounds, or 49.78 per cent; Japan, 32,156,032 pounds, or 44.59 per cent; England, 3,540,148 pounds, or 4.9 per cent, the balance of the imports coming from fifteen different countries.

We are firmly convinced that there will be no increase in the popularity of tea as a beverage until the average quality of the imports from China and Japan is raised. In Japan the Government has endeavored to raise the standard by legalizing the formation of guilds, the object of which is to prevent the adulteration of the leaf. A central association is to control the local guilds. It is to be hoped that good results will be the outcome. The average quality of last year's imports was below that of previous seasons, especially the China greas. Finest Formosans have not been equal in character to the same grade received in 1881, and that was below the quality of the 1883 crop. Cargo grades were about the same as received in 1881, but some claim they were below. The demand for colored Japans is maintained; basket-fired tea, owing to the rapidity with which the flavor is dissipated, does not grow in popularity with consumers.

In England there has been a marked decline in the importation of China black tea, due probably to competition with India and Ceylon teas. This shows a necessity for improving the character and quality of China tea.—*American Grocer.*

[The unpopularity of tea in the United States is attributed to the poor quality of China and Japan sorts, and yet the fine teas of India and Ceylon can scarcely find a sale. Only a little over 1 lb. of tea per capita in America against nearly 5 in Britain shows a curious difference of taste. But the Americans are mainly coffee drinkers, getting their supplies cheaply from Brazil.—Ed.]

COFFEE TRADE SUB-SECTION OF THE LONDON CHAMBER OF COMMERCE.

REPLY TO THE QUESTIONS OF THE ROYAL COMMISSION ON DEPRESSION OF TRADE.

Question 3.—Of the total quantity of coffee sold in one year, from 1s 5d to 1s 4d is retained for home consumption, the remainder is exported to almost every country in Europe, mostly to Germany. The figures have been:—

For	Exported.	Retained for Home Consumption.
	lb.	lb.
1881 ..	107,728,000	.. 33,016,000
1883 ..	109,089,000	.. 32,148,000
1882 ..	111,611,000	.. 31,362,000
Average for 10 years.		
1872 to 1881	132,000,000	.. 32,700,000
And from		
1862 to 1872	101,600,000	.. 31,300,000

Question 6.—The home trade in coffee has been, undoubtedly, shrinking.

Question 7.—The shrinking which has lasted for a great number of years, really began in 1853, became worse in 1863, and continues much the same to this day.

Question 10.—The diminished consumption is to a great extent to be traced to the legislation of 1853 and 1863 on the subject of mixtures, the Treasury having, in 1853, allowed the sale of *mixed coffee and chicory* if labelled "mixture," and in 1863 permitted the sale of *mixed coffee and chicory without any labelling*. The result was that consumption fell from an average of 1 lb. 6 oz. per head of population in 1854 to 1 lb. 2 oz. in 1863, and to about 15 oz. per head in 1880. This shows, on the population of the last census of 1881, a diminished consumption of coffee of over 11,000,000 lb. annually.

Question 13.—The home consumption of coffee could be improved by legislation. *The Customs and Inland Revenue Bill of 1882* allows the preparation and sale of any vegetable substance made in imitation of, or for use as coffee or chicory on payment of an excise duty (stamp), giving thus almost unlimited scope for the adulteration of coffee; either coffee ought not to be allowed to be sold mixed with other ingredients in the same package, or, if the sale of a mixture is permitted the *proportions* and names of the ingredients contained in it should be stated on the package.

Question 14.—(c) The increase of direct steam communication between several of the producing countries and Continental ports has diverted to foreign ports direct some of the supplies which used to come to this country to be re-exported afterwards.

Question 14.—(d.) The fall in prices during the last few years would tend to stimulate consumption in this country and elsewhere.

Question 14.—(h.) Foreign competition is, no doubt, stimulated by the lower charges ruling in such markets as Hamburg, Havre, Antwerp, &c., as compared with the charges of the docks and wharves in London; this tends to restrict the export from this country, consumers abroad finding, in these times of keen competition, that they can buy the same quality of coffee cheaper in Hamburg, Havre, or Antwerp, than in London.

Question 14.—(i.) The differential duties and bounties in France and Spain in favour of importation direct from producing countries as against importation from this country, have almost entirely stopped the export trade in coffee from England to those countries, except for some particular kinds of coffee which French buyers can only find in this market.

Question 14.—(j.) The duty on coffee yields a very small net revenue, and its abolition, with the removal of the restrictions which it entails would be a very great boon to the trade.

Signed on behalf of the Coffee and Cocoa Trade Section. H. PASTEUR, Chairman.

The Chamber of Commerce Journal, Dec. 5th.
—*Riv. News.*

STEALING COCOA IN GRENADA.—Complaints are heard in Grenada of thefts of cocoa, and it is said that the practice is due to the readiness with which small parcels can be disposed of to ready purchasers. This looks very much like offering a premium for theft, and some people might be disposed to say that the buyer was as bad as the thief. It is hoped the Government will take the earliest opportunity of legislating on the matter, since, during the frequent visits of His Excellency the Governor to the country, he must have become cognisant of the great evil complained of.—*Colonies and India.*

A TEA PLANTER who has just visited the Straits Settlements, &c., says:—"We saw some of the plantations in Johore, where there was a grand flush ready for picking, in Christmas week. They grow tea, coffee, pepper, indigo and—everything. The Sultan's people are most attentive to visitors, as he wishes to encourage settlers. There are thousands of miles of good tea land available. A good many Ceylon planters have already gone there, and have either got or purchased grants. The climate is fair, neither very hot nor very wet, but never cold."—*Madras, Mail.*

The Wonderful stories told of grain which had been made to grow after having lain dormant for thousands of years in the hands of mummies, do not seem to have any foundation in fact. Mr. H. K. Parks states in the *Journal of Science* that he has investigated all the cases he can find, and shows that there is not a single authenticated instance of corn found in a mummy having been grown. Some of the seeds found in mummies have germinated, but as they produced plants—oats, for instance—not known to the Arabs of three thousand years ago, it seems evident that they were systematically put in the hands of the mummies by the avaricious Arabs of modern days.—*American Grocer.* [This seems to be the truth of the matter as regards mummy wheat. But there seems no doubt that seeds buried in the earth retain their vitality for ages.—*Ed.*]

SUGAR IN FIJI is not the thing of promise it was a short while back. A correspondent says:—"Planters still say they cannot make the cultivation pay with present rates ruling. The largest mill on the Navua and the plantations connected with it have lately come to grief and were sold. The labourers, over 500, were all removed. This is bad for the Navua in particular and sugar planting in general, as such a collapse will frighten other capitalists. On the other hand, two or three new mills have been erected: one on Mango, an island to windward, owned by a Melbourne Co., and managed by a brother of Mr. Borron in Ceylon; another on an island to the north of Vitu Levu, owned by the new New Zealand Sugar Refining Co. The sugar made is of first-rate quality, and it is to be hoped all these mills have a prosperous future before them. If sugar cultivation turns out unprofitable, it will almost be a deathblow to Fiji.—*Planter and Farmer.*

TEA-PLANTING ON OLD COFFEE ESTATES.—A planter from a district north of Kandy writes:—"———— is flourishing, and I hope it will turn out well, but it's a fearful uphill game planting abandoned estates. We put some 200 acres under seed at stake; but what with black grub and other insects eating the young plants down, it is disheartening work, and I lost a large percentage in this way, all is not plain sailing! I am glad to say, however, that they are shooting up again and again above ground; really the young tea plant is wonderful in its tenacity considering all it stands. Here I allowed weeds to grow, after spending a lot of money in getting the place clean. I found that where plenty of weeds, were, the plants were safe and growing well; grub does not confine himself to the young tea plant, but will take to eating weeds as much as tea. I employed boys with very great success catching them, and everyone they caught was a plant saved, so therefore it paid us well. I would not plant seed at stake again in abandoned coffee land. I burnt off another 75 acres yesterday, and this will give me close on 300 acres. As much as any man can well look after when our troubles of pests are over. Come along up and see this fine old district."

MARKET RATES FOR OLD AND NEW PRODUCTS.

TEA IN CEYLON AND JAVA.

Messrs. Gow, Wilson & Stanton have issued two valuable and very suggestive circulars illustrated by eye-speaking diagrams, one referring to the progress of tea in Ceylon and Java respectively. The comparison or rather contrast is wonderful; for, while the exports from Java have been nearly stationary for 10 years, beginning with 4,808,000 lb. in 1875, rising to 6,159,000 in 1878 and sinking again to 5,590,000 in 1884; the exports from Ceylon have risen in half the time, from a little over 114,000 lb. in 1880 to 4,352,895 in 1884. With some variations the price of Ceylon tea has also risen during the six years, from 11d to 1s 3½d per lb. Well may Messrs. Gow, Stanton & Co. write:—

It is indeed a rarity to find any commodity increasing so rapidly in production and showing a rise in price so constant and sustained. We feel sure that these encouraging results will tend towards even more strenuous efforts on the part of planters to excel in quality the produce of other Tea growing countries, while they continue to increase the quantity of their exports. We would strongly urge them to remember that the future prosperity of the Ceylon Tea trade must depend mainly upon the excellence of quality to which the article attains.

Looking at the astonishing rapidity of production in Ceylon and the certainty of progress at a much accelerated rate, figures are produced to help to a solution of the questions,—what new markets for tea can be opened? and what room for expansion is there in existing markets? The British race are the great consumers of tea, although in the United States the national taste has gone off in favor of coffee. In Britain the consumption per head is now 4.90 lb. per head, while the three millions of the Australian colonies, New Zealand and Tasmania, taken together, use over 7½ lb. per head. The more Australia is peopled, therefore, the better for tea-growers, and as better times come in Britain, no doubt, the consumption of tea there will more and more assimilate to that in Australia. Even in Canada and Newfoundland, the consumption is equal to 4½ lb. per head, against only 1.30 in the United States. The truth is that the people of the United States have never had good tea presented to them, and their taste has been formed or their prejudice strengthened by burnt and adulterated stuff from Japan. Of Continental countries Holland alone consumes over 1 lb. of tea per head, the figure being 1.05, while Russia, with all that we have heard of her constant tea drinking, uses only 0.61 per head. In the Cape Colony and Natal they are not yet much ahead of Russia, and as for other countries of any importance in the world, the figures go down from 0.76 lb. per head in Denmark to 1-100th of a pound per head in chocolate-loving Spain! Here, we suppose, as in other parts of the Continent, tea can only be obtained in the shop of the apothecary, and then the stuff obtained is "medicine" with a vengeance. We look for much effect from the distribution of really good tea at the forthcoming Exhibition, to be followed up on similar occasions, as also from the operations of syndicates and individuals. Even in South America where maté is so largely used, good tea is gradually making way. But of about 350 millions of lb. of tea exported from producing countries,

over two-thirds is drunk by persons of British origin, a fact which (in the face of the still great consumption of alcohol) largely accounts, without doubt, for our position in the world. Tea grown by Englishmen in India and Ceylon is rapidly displacing the inferior China stuff, the proportion in Britain now being 10 per cent of the former, a proportion which will rapidly increase, Ceylon keeping, we doubt not, the foremost place in quality she has already obtained.

But the teas of Java have also greatly improved from their once low standard and with the decadence of coffee, we have no doubt that very largely increased attention will be paid in Netherlands India to this new product, more and more seed being introduced from India. During 1885 there was a marked improvement in price and for two years deliveries had largely exceeded imports, so that supplies, owing to this fact and to recent drought in Java, were short of demand. The imports into Britain had risen from 1,216,000 lb. in 1881 to 3,343,000 in 1885. This was considerably more than half the total exports from Java. With 20 millions of population the local consumption must be appreciable, and we suppose we shall not be much out in estimating the present total production of tea in Java at 8,000,000 lb. of which over a million are locally consumed*? There will now be a race between the Dutch and the British Islands, but we shall soon be far ahead, for we believe that practically all the tea produced in Java is grown on 39 properties enumerated by Messrs. Gow, Wilson & Stanton of which that of our good friend Mr. Kerkhoven, Sinagar, seems to be the chief. It sent away 6,218 chests and 20 boxes last year, while 3,155 chests are against Bagelen, and (curious exception) 5,258 boxes against only 1,000 chests in the case of Nangoeng. What are 39 estates, however, large their respective acreages, to our 500 to 600 plantations, with over 100,000 acres already in tea; but then Java is now fast going ahead planting more land with tea. With all the improvement which has taken place, the average for Java tea sold in 1885 was only 9.84d per lb. against 1/3½ for Ceylon. Having heard in 1880-81 that the Melbourne market had been tried with Java tea in vain, we suggested that there might be some excess or some deficiency in the volcanic soil, the probability in our mind being a deficiency of iron. But Mr. Moens, who had analyzed the soils, did not favour this view; so we suppose the real inferiority of those really nice-looking teas was due to defective fermentation. Messrs. Gow, Wilson & Stanton are right in urging the adoption of the best jats, but the case of Darjiling and the Kangra Valley would seem to prove that there is no inferiority of quality in the leaf of China tea, if properly treated. Our business, however, is to turn out teas of the best quality in Ceylon, while our quantity goes on increasing, so as soon to overtake and rapidly pass our competitors in Java. As the figures for total consumption and quantity used per head of population in various countries of the world, are of great and permanent importance, enabling us to see what the chances against a glut of production are, we quote them as they are so carefully compiled and so cautiously submitted by Messrs. Gow, Wilson & Stanton:—

The figures in the subjoined list, which are chiefly based upon an average of five preceding years, give the amount of tea taken for home consumption in various

* Our "Handbook and Directory" shows a total production for Java of 8 million lbs. and up to 7 millions for export: the Batavia Exchange showed 6,600,000 lbs. of export in season 1884-5.

countries, together with the average quantity annually consumed per head of the population:—

1879	5,724,689	1884	5,590,069

A JAVA PLANTER'S IMPRESSIONS ON PLANTING IN CEYLON.

As we mentioned some days ago, there is at present in Ceylon a visitor from Java who is making a tour of Ceylon and India to compare notes on planting matters—Mr. G. Mundt of Paranalak estate, Preanger Regencies, Java—and a few of his impressions on planting in Ceylon gathered from him in the course of conversation, may be of interest to Ceylon planters.

Mr. Mundt is President of the Java Planters' Association and a large proprietor owning some 2,400 acres, 600 acres of which are planted with China tea and 300 acres with Assam, the bulk of the remainder of his estate being cinchona and cacao. As he has had 22 years' experience of planting and occupies so leading a position, his views may be taken as carrying considerable weight. Mr. Mundt has nothing but praise to bestow on what he terms the marvellous energy which in a few years has transformed the coffee plantations of Ceylon into flourishing tea estates, producing an article unrivalled by any country in the world. Our roads especially are objects of admiration, no such highways existing in the planting districts of Java. "Your magnificent roads were the salvation of the country when the coffee enterprise failed, for without them you could never have opened up the country and planted it up with tea as you have done," says Mr. Mundt. "More 's the pity," will probably be replied "that

they should now be in danger of being ruined by that wretched MacBride system."

Mr. Mundt severely condemns the system of planting on steep hillsides, and says that when he left the train at Nannoya, after a journey from Kandy, his mental observation was that Java need not fear any rivalry from Ceylon in a few years for tea could not last long planted on such slopes as everywhere met his view from the railway carriage. This opinion has been somewhat modified by closer and more minute inspection, but he still holds to the view that planting on such steep hillsides is a mistake which Ceylon planters will in time to come have occasion to regret. In Java, no one would dream of cultivating a slope of more than 35 degrees. In the process of cultivation, he says, it is inevitable that the little fine soil there is left on those hillsides will be washed away and your tea will die out as coffee has done. There seems to be no steps taken to prevent the washing away of good soil; on the contrary the system of drainage adopted here is calculated to assist in carrying off the soil into the ravines. Here, he says, the drains are continuous, emptying themselves into the waste land, and soil must be washed away and lost.* Questioned as to the method adopted in Java, Mr. Mundt drew a sketch of their drains which we roughly reproduce:—

It will be seen from the above that the Java drains are mere oblong holes with no outlet and the soil when washed into them remains there till taken out, as is done after heavy rains, and replaced round the tea bushes. In this way really no soil is lost and Mr. Mundt says that since this method was adopted some fifteen years ago, there has not been a handful of soil washed away.† Mr. Mundt expresses considerable surprise that so little of the comparatively flat land in valleys is cultivated. In Java, he says, they would care nothing for the steep hillsides, but would devote their attention to the flat land lying at the foot of the hills. There are very few estates there at a greater elevation than 3,000 ft. and they are nearly all of them 2,000 ft. and lower.‡ There is a good deal of such land to be found in the hill country of Ceylon, the soil of which our Java visitor thinks is well suited to tea planting. Having visited some of the estates in the neighbourhood of Nuwara Ebbiya, Kandapola and Dimbula, Mr. Mundt is of opinion that generally speaking the jät of tea grown thereon is not superior, though in places he saw some very fine hybrid tea. The soil, too, he considers poor, and thinks that it is possibly owing to this and to the elevation that the tea compared with his own growth looks poor. But though the tea bush does not grow to what he considers perfection, Mr.

* The soil in Java is loose decomposed volcanic matter. Ours is generally clayey enough to be tenacious. We do not, therefore, fear steep hill sides, or helping the natural drainage with a good system of channels which carry off the maximum of water and the minimum of soil.—Ed.

† It is really the system of manuring which we saw in perfection on Sinagar. It is good for manuring purposes, but certainly not for drainage. We believe in abundant drainage and in our steep estates lasting nearly as long as the level or undulating lands of Java.—Ed.

‡ Quite true, but we believe that much better results would be obtained at twice the altitude.—Ed.

Mundt is envious of the magnificent flavour and aroma of the tea produced. This he accounts for by the elevation and the fine plucking adopted here. In Java they pluck coarser in consequence of their richer soil and more forcing climate. In Java the usual planting distance is $3 \times 4\frac{1}{2}$ in horizontal rows. When the plants are taken from the nursery they are topped, and at nine months the mother-stem, as it is termed in Java, is cut out. Plucking commences about 18 months after planting out. Mr. Mundt thinks that even higher prices would be realized by Ceylon tea planters if they paid more attention to manufacture, and had better tea houses and machinery, but it must be remarked that at the time he spoke he had not seen the best factories. From what he had seen of the manufacture, it was his opinion that our teas are over-fermented. In Java they do not "ferment" but merely "colour" the leaf. He thinks also that our tea is rolled too much; they never roll longer than twenty minutes, and Java tea is remarkable for its good twist.* In Mr. Mundt's opinion it would be better that small estates instead of putting up a small factory and manufacturing in a small way with imperfect machinery should combine and erect one large central factory with the best machinery and conveniences. The result of this, he thinks, would be the out-turn of better made tea with the natural consequence of better prices. With such excellent road and railway communication he thinks no difficulty should arise in conveying the green leaf to the central factory; if the estate was some hours distant from the factory he would wither the leaf and then send it in.

Coffee. Mr. Mundt believes, will never again amount to much in Ceylon, though the little he had seen struck him as being healthy and free from disease. In Java it is dying out and crops are decreasing year by year.

As to *Cinchona*, Mr. Mundt thinks Ceylon planters have not mastered the requirements and habits of this product. He has seen very little that is really planted well, it is all planted with the idea of getting returns as quickly as possible rather than with the intention of permanently cultivating it. It is planted far too closely and on land where it cannot get sufficient depth of soil to grow properly. Though the elevation of most Ceylon estates is too great for *Ledgeriana*, he thinks a bastard ledger, a hybrid between ledger and *succubra*, should do well on good land, but not on the steep slopes now planted with *officialis* and *succubra*. It is his opinion that in the course of a few years a very large proportion of the *cinchona* planted on the higher estates will die out as the ground is too steep and the soil not sufficiently deep. In Java a very large extent of ground is planted with really good *cinchona*, giving an analysis of 10 and 11 per cent of sulphate of quinine, and when this bark is thrown on the market Mr. Mundt fears Ceylon *cinchona* planters will suffer. In Java they never touch a *cinchona* tree until it is seven years old. A method they find very successful is to make grafts of the true ledger on *succubra* stems. This grafting was formerly done entirely in the nurseries but they have now hit on a means of making the graft after the trees have been planted out. There are very few estates there that have begun to shave their trees, nearly all the bark that has been sent away is from coppiced trees. When Java planters begin to shave they will put on the market millions of pounds of bark far richer in quinine than can be produced in Ceylon.

* True: to the eye Java tea is perfection; to the palate it is considerably short of perfection.—Ed.

Mr. Mundt regrets the absence of roads and railways in Java which prevents millions of acres of good tea and *cinchona* land being planted up.* They have a railway through some of their districts, but the rates charged are so exorbitant that very few planters make use of it. Java can take a lesson from Ceylon in this respect. The Ceylon railway system Mr. Mundt regards as a magnificent triumph of engineering skill and the scenery of the mountain region he says is very beautiful.

Mr. Mundt goes to India in a few days after visiting the Nawalapatiya and Dumbara districts but expects to return to Ceylon in about a month.

WYNAAD PLANTERS' ASSOCIATION.

A general meeting was held at the Pookote Club on the 3rd instant. *Present*.—Messrs. Abhott, Achard, Atzenwiler, Batty, Gooding, Jowitt, Lamb, Taucuary, Vaukeesema, Walker and G. Romilly, Honorary Secretary. Mr. Tanqueray in the chair.

Royal Commission.—Read letter from Mr. Pasteur accepting the task of representing this Association on the proposed Committee to be held in London. With regard to the competition of Government in *cinchona* cultivation, Mr. Pasteur wrote as follows:—"I understand that, some years ago, in reply to remonstrances from *cinchona* planters, the Indian Government stated their unwillingness to give up then the cultivation, for fear of the industry being abandoned by private growers in case of a serious fall in prices occurring; but they gave at the time a kind of promise, or pledge, that they would not complete permanently with private industry. It would be interesting to get at the actual reply of the India authorities, which, perhaps, might, strengthen our case against them."

Madras Forest Act.—The subject of cattle trespass was discussed, and a draft of a petition to Government on the subject read and approved.

Cinchona.—Read letter from the Government Director of *Cinchona* Plantations on the subject of the early flowering and seeding of *cinchonas* as compared with former years. Resolved that the thanks of the Association be forwarded to the Director. With regard to a private circular sent out last month on the subject of analyses, members are informed that the matter is in abeyance, and are requested not to send samples till they hear further on the subject. Read letter from Mr. Winterbotham regarding the shaving of *Ledgerianas* and offering samples for experimental analyses. Mr. Lamb also offered to keep a hundred *Ledgerianas* for experiment. Resolved that the Association will really accept both offers and will bear the cost of analyses.—*Malaya Mail.*

PLANTING IN NETHERLANDS INDIA.

(Translated for the Straits Times.)

The advertisement of the North Borneo Company announcing facilities for opening out tobacco estates there has caused attention to be drawn, at Batavia, to the advantages of Cotie for growing that article, from that country resembling Deli in climate. The Sultan is willing to lease out land. Navigation in the river there is easy and its mouth is regularly visited by mail steamers. The considerations lead the Batavia *Dagblad* to the conclusion that tobacco growers seeking fresh fields will do better in Cotie than in less developed North Borneo.

Three enterprising Europeans have just started tobacco growing near Padang on the West coast of Sumatra upon land about 3,000 feet above sea-level. Throughout last year, their operations proved unsuccessful from planting being set about in the wrong season. The samples of tobacco they have turned out so far, show that the land chosen is suitable. The future only will show whether the irregularity of the rainfall in that quarter may not bar success completely.

* Half a million of each would swamp the world and ruin the enterprise.—Ed.

TEA MANURING EXPERIMENTS.

CONTINUATION OF EXPERIMENTS WITH CASTOR-POONAC AND CASTOR-CAKE AND BONE-DUST IN COMBINATION, IN SEASON 1885, ON "CHANDPORE TEA ESTATE," CHITTAGONG.

Having copied Mr. McL. Carter's paper describing the results in the first year after manuring his tea with castor-cake alone and castor-cake and bone-dust, we are now glad to be able to lay before our readers as copied from the *Tea Gazette* the figures showing the continued effect in the second year. Mr. Carter looks for further increased yield and profit in the third year:—

On a reference to the *Indian Tea Gazette* of 6th October 1885, page 257, para. 2, I assumed the cost of manuring with castor-cake alone 1 lb. per bush=24 cwt. per acre, as on plot 3, to amount to R70 per acre, and also that the increased yield of tea in second season and without any further application of the manure would be 30 per cent., and that in all probability it will be actually 32 per cent. But the results at end of season have not borne out either of these anticipations; nevertheless the registered increase is still fairly satisfactory, as the following returns testify:—

2ND SEASON.

Plot No. 1 of ¼ acre—no manure	lb.	tea per acre
Plot No. 2 of ¼ acre, manured with 6 cwt. Bone dust and 12 cwt. Castor-cake to the 18 cwt. of combination per acre	do. 899	do 899
Plot No. 3 of ¼ acre, manured with 24 cwt. of Castor-poonac alone per acre	960	do 961

Comparing one plot with another, No. 2 shows an increase (due to manure) of lb. 103 tea per acre equal to 3 per cent over plot No. 1.

And No. 3 an increase of lb. 165 tea per acre equal to 20½ per cent in excess of No. 1, whereas between Nos. 2 and 3 the latter gives an increase of lb. 65 tea per acre equal to 7 per cent only.

The profits per acre therefore are on Plot No. 2:

	as.	R. A. P.
Plot No. 1 of lb. 796 tea per acre at say	8	equal to 5398 0 0
Plot No. 2 of lb. 899 tea per acre at say	8	do. 449 8 0
In favour of latter, lb. 103 tea per acre at say 8 as. equal to	51 8 0	
Less cost of manure	do	nil
Net profits per acre in 2nd Season	do	51 8 0 or 81·6 percent
Add profits per acre in 1st Season	do	34 13 6 or 53·3 „
Total nett profits per acre in two Seasons do	86 0 6	or 130·9 „

cost per acre 1 should have said of combined manure on plot 2 was R63-1-6 in 1884.

Results from Plot No. 3.

	lb.	R. A. P.
Plot No. 1 of 796 tea per acre at say 8 as.	398	0 0
Plot No. 3 of 961 tea per acre at say 8 as.	480	3 0
In favour of latter by lb. 165 8 as.	82 8 0	
Less cost of manure	do	nil
Nett profits per acre in 2nd Season	82 8 0	or 117·8 per cent.
Add profits per acre in 1st Season	72 8 0	or 103·5 per cent.
Total nett profits per acre in two Seasons	155 0 0	or 221·3 per cent.

The cost of manuring per acre in 1884 on plot No 3 being R70.

I have merely to add further, that the bushes on above plots were pruned down to 18 inches on 25th January, and that at end of Season 1885 their average growth was on—

Plot No. 1.	25 inches.
Plot No. 2.	28 inches.
Plot No. 3.	27 inches.

The areas were deep dug once on 21st December 1884, and light hoed and ridged combined four times subsequently in Season 1885.

The first flush was taken on 29th March, and the last on 29th December, making 26 flushes in Season at average interval of 10½ days. The rainfall in the year was close up 119·99—and average temperature 69° to 70° at 6 A. M. daily.

These trials will be carried on in 1886 also, which makes the third Season; and I expect the manured plots will still show an increase of crop over the non-manured adjacent area, and such a result will be eminently satisfactory.

“CHANDPORE,” } F. McL. CARTER,
6th March 1886. } Manager.

SUCCESSFUL TREATMENT OF RHEA FIBRE.

The *Colonies and India* states:—

The praiseworthy efforts made by the Government of India to stimulate inventors to the discovery of a means of economically preparing the fibre of the Rhea or “China Grass” for manufacturing purposes have at last met with success. For many years past the strength and beauty of the fibre yielded by various species of *Urtica* have been fully recognised as superior in every respect to all known fibres, either for textile or other manufactures. The fibre of the variety known as Rhea or *Ramie*, more popularly as “China Grass,” and in France as “Vegetable Silk,” has long been the admiration and despair of experts and inventors, who have striven to discover some means of separating it from the bark and the wood of the plant, to which it closely adheres, and to free it from the resinous or gummy matter in which it is enveloped; and only the proved value of the product could justify the efforts which have been so persistently made to overcome the difficulties attending the reduction of the raw material to a marketable state. The honour of the discovery of a perfect method of accomplishing this is divided between two French inventors—one, M. Favier, who has invented a machine for the production of “ribbons” by decorticating the stems of fibrous plants by steam, and M. Frémy, who, in conjunction with M. Urbain, Director of the *Encyclopédie Chimique*, Paris, has perfected a system of converting such ribbons into *filasse*, ready for spinning. The beauty and tensile strength contained in the *filasse* produced by these joint processes from the fibre of the *Ramie* is unequalled. It rivals silk in softness and glossiness, and excels even the celebrated *etipa tenuissima*, or New Zealand flax, for strength and durability, while it is superior to both in the almost unlimited fields which exist for its cultivation. The trial of a piece of “belting” for driving machinery, made of China grass, as compared with a similar belt of leather, showed that the former could sustain a stress of 8,326 lbs. per square inch, as against 4,239 lbs. per square inch borne by the latter; while a water-hose of China grass containing water at a pressure of 600 lbs. per square inch only “sweated” as much as ordinary hose under a pressure of 100 lbs. The great difficulty in the way of the economical utilisation of this fibre has been the large quantity of resin or gum with which the fibres are coated, and which it is most difficult to separate, especially when the grass is in a

dry state. The Favier-Frémey process entirely surmounts this difficulty at slight expense, and the uses to which the fibre produced thereby can be put are so numerous that its consumption will only be limited by its production. The natural field for the growth of this plant is in India, where large tracts of land are being specially planted with it; but it will probably grow in almost any tropical country, and the West Indies, Northern Australia, and South and West Africa will no doubt be found suitable for its production. Some experimental areas have been planted with success in Egypt and on the shores of the Mediterranean, and its cultivation is being taken up in Burma and the Straits Settlements. In fact, its area of cultivation is no less unlimited than the field for its industrial use.

At intervals for years back we have seen statements like this, but they have never been confirmed. Rhea or ramie produces a strong and beautiful fibre, but it is an exhaustive crop, and it is most difficult and expensive to clear away the wood and gummy portions of the stalks.

NORTH BORNEO: GOLD AND PRODUCTS.

(British North Borneo Gazette, March 1st.)

Captain Beeston, whose services we informed our readers in our last number had been secured by this Government for the purpose of making a Mineralogical and Geographical Survey of the country, was to have left for Segama at midnight on the 16th ultimo, but a few hours previously a gale sprang up and has only just moderated; as we write (February 28th), everything being in readiness the expedition will probably start tomorrow or next day. It will be accompanied by Mr. Henry Walker and a Chinese merchant interested in the gold discovery. Mr. Walker proceeds to point out the localities where he had previously discovered gold.

Gutta Percha has been discovered in the Mankaladom district, one day's journey from Putatan "tamu," on the route to Tambunan, and a party are shortly going up to work it. The Mankaladom people are gatta, up to now, to be ignorant of its value and gatta trees cut down by them in making "pudi" clearings, are left to rot where they lie. Cinnamon is also reported in Ulu Putatan and Ulu Tawaran considerable quantities of this spice used formerly to be exported from Putatan, and Kimanis.

Liwan tobacco continues to come down to Putatan "tamu." A Javanese planter who recently saw a sample of it, pronounced it to be superior to any tobacco grown in Java. It seems a pity that public attention is not drawn more to these tobacco districts; where a planter would only require to direct his attention to the question of transport, the question of soil capability having been solved for the last two hundred years probably. The native "tamu" at Ulu Papar and Ulu Tawaran, as also that at Ulu Sungai Damit, Tawaran, are all rapidly developing.

Two experienced assistants, Messrs. Groenert and Thijs, from Deli, Sumatra, have joined the estate at Limbuak, Bangney, also a batch of 50 Chinese coolies. The site of the late crop has been planted up with native paddy, which is doing well, while all round felling and burning goes on merrily for this year's crop. There is very little sickness among the coolies. A substantial cart-road in the direction of Mitford has been commenced.

THE BULKING OF INDIAN TEA.

To the Editor of the HOME AND COLONIAL MAIL.

SIR,—We have seen some correspondence in your last issue on the subject of tea bulking; and whilst we should not go so far as to say that half the Indian tea now sold in the public sales is of uneven quality, we are quite of opinion that reasonable grounds of complaint do exist in regard to the system on which the bulking is done. Irregularities in quality are too frequent, even with some of the largest and oldest gardens. Buyers naturally ask how it is that the Chinese can bulk 500 chests of one break so accurately that rebulking in London has never to be resorted to whilst Indian planters are so careless about it that frequently in breaks of tea said to be bulked at the factory, and even many of those which have been bulked in London some chests will be more dusty than the rest, some more staly, and others almost out of condition. We have no desire to make unnecessary complaint but we beg to remind planters and importers that the Indian tea business has now reached such magnitude that the time of brokers and buyers is so fully occupied with work necessary to the carrying on of the regular business that every hour taken up in making and settling claims which, if the bulking were accurate, should never arise is an utterly unprofitable and needless waste of energy. It is but fair to say that some of the selling brokers are always ready to adjust a reasonable claim; whilst others invariably profess themselves unable to discover irregularities which must be apparent to the merest tyro.—We are, &c.,

TAYLOR, COLMAN AND SUDLOW.

INDIAN TEA ASSOCIATION.—Regarding the forthcoming Colonial and Indian Exhibition, the Association state they have failed to induce the Government to give a grant-in-aid. This illiberality of the Indian Government contrasts badly with the handsome generosity shown by the Ceylon authorities, who have awarded the Planters' Association there a handsome sum for the purpose of aiding a complete representation of Ceylon teas. The Syndicate itself, however, intends to devote the balance of its own funds, some £6,200, for the purposes of the exhibition of Indian tea, and the money could hardly be better spent.—*Indian Tea Gazette*.

VITALITY OF PALM TREES.—In his German Garden Journal (*Deutsche Garten-Zeitung*) Dr. Wittmack, Professor of Botany at Berlin, gives a most striking instance of the longevity inherent in trunks of palm trees of the genus "Cycas." He says:—"In the large palmery of the renowned seed and nursery establishment of Mr. J. C. Schmidt at Erfurt (Germany), there have existed for the last eight years two trunks of *Cycas media*, having a height of thirteen and sixteen feet respectively, and being, consequently, specimens of such dimensions as were never before brought to Europe. These two trunks, forming a portion of a large cargo brought from Queensland, were on their arrival in 1878, considered to quite dead, but, for the sake of curiosity, they were, nevertheless, planted in the ground. Imagine the astonishment of everybody concerned at finding that these 'mummies' had suddenly returned to life, their crowns ornamented with wreaths of thick foliage, which is now completely grown and affords a most imposing sight! It is to be hoped that these two scions of the primeval vegetation of an epoch far remote will continue to thrive, with 'stature unbent by age,' and not again relinquish the youthful activity so suddenly displayed, and that a chance may be afforded them for making up for the loss they sustained during the enjoyment of eight years of somnolent beatitudes."

THE PLANTING REVIVAL OF CEYLON.

Some two years ago we called attention in rather a forcible manner to the state of distress in Ceylon, consequent on the decadence of the coffee planting industry. But Ceylon has since then taken a new lease of life. Coffee has gone from bad to worse, but its place in the island has with almost magical rapidity been occupied by tea. For the first time the editors of that really wonderful volume, Ferguson's *Ceylon Handbook*, say that they cannot any longer look upon coffee as the most important branch of the agriculture of Ceylon. The tale they have to tell about the history of coffee planting in Ceylon is both interesting and instructive. The first upland plantation was formed in 1825 by Sir Edward Barnes. Between 1833 and 1844 the mountain ranges on all sides of Kandy became rapidly covered with plantations, and in 1844-1845 the coffee mania was at its height. Five millions sterling were sunk in less than as many years. The rush for land was only paralleled by the rush towards the Australian gold mines. "The Governor in Council," says Sir Emerson Tennent, "the military, the judges, the clergy, and one-half the civil servants penetrated the hills, and became purchasers of Crown lands. The East India Company's officers crowded to Ceylon to invest their savings, and capitalists from England arrived by every packet. As a class, the body of emigrants was more than ordinarily aristocratic, and if not already opulent, were in haste to be rich. So dazzling was the prospect that expenditure was unlimited; and its profusion was only equalled by the ignorance and inexperience of those to whom it was entrusted." Then in 1845-1846 came the crash, partly dependent on the financial explosion of 1845 in England, partly on the withdrawal of the protective duties, and partly on over-production:—"The consternation thus produced in Ceylon was proportionate to the extravagance of the hopes that were blasted; estates were forced into the market, and madly sold off for a twentieth part of the outlay incurred in forming them, others that could not even be sacrificed were deserted and allowed to return to jungle." For nearly three years the enterprise appeared paralysed: the ruined disappeared, and the timid retreated. But the enterprise slowly and surely recovered until in 1869 leaf disease made its first appearance, and this fatal disease combined with the enormous outturn of coffee from the Brazils and other new fields rendered a Ceylon coffee planter's life uncertain in the present and perilous in the future. But troubles as is their wont came not "as single spies but in battalions." The failure of the City of Glasgow Bank reacted disastrously through the Oriental Bank on the Ceylon planting enterprise, and led to a great withdrawal of capital, until in the season 1882-83 with 200,000 acres in cultivation the export, say the Messrs. Ferguson, "was only 260,000 cwt. or less than was shipped forty years earlier from less than one-fourth the area!" This terrible falling-off in coffee crops reacted on nearly every branch of local trade and industry. To make matters worse the Oriental Bank itself failed, and the colony would, it is generally believed, have been irretrievably ruined had not Governor Gordon taken on his own responsibility the courageous step of guaranteeing the Oriental Bank currency notes. It was at this trying period that we printed the article to which we have already referred. We showed that coffee was doomed in Ceylon, and that Ceylon would be doomed too, unless the planters realized this fact and turned their attention to other products suited to the climate of their marvellously fruitful island.

Our remarks were as was natural, warmly discussed and criticised at the time.

To critics either in or out of Ceylon, the future seemed almost gloomier than the past. The planters were either leaving the island as rats leave a sinking ship, or living in sorry circumstances on the produce of their estates. Colombo was crowded with starving assistants out of employ, some of whom actually shipped themselves as coolies to Queensland. But the story of the twelve years decadence may best be told with a few figures, and we give the returns for every pair of years since 1871-75 when a maximum may be said to have been attained:—

Seasons.	Coffee Exports Owt.
1871-76...	1,676,762
1876-78...	1,554,339
1878-80...	1,478,275
1880-82...	1,015,530
1882-84...	574,272
1884-86 (estimated)	510,922

But owing to competition in the Brazil and other coffee fields not yet affected by leaf disease, the price of Ceylon coffee had fallen too. The highest price touched was 135 shillings per cwt. in 1873; the lowest 61 shillings in 1885. As the first result of this extraordinary depression the total number of superintendents of coffee estates has fallen off from 1,389 in February 1881 and 1,108 at the end of 1883 to 1,081 in December 1885, the latter corresponding to 1,448 estates now in cultivation out of a total 1,923 properties. "It is probable, indeed," say Messrs. Ferguson, "that more than 300 European planters have left Ceylon in the four years, because their places in some cases may be filled by Ceylonese, whose names would swell the present number of superintendents. Perhaps we may fairly say that our planting community diminished at the rate of a hundred superintendents or proprietor-superintendents a year, between 1880 and 1885. A serious loss, now we trust gradually to be made up as tea-planting extends." Here we have the key to the revival of Ceylon. For those planters who had pluck enough to stay on, looked to tea and almost solely to tea to recoup them for their losses in coffee. Many other things were tried, Liberian coffee (which has on the whole proved a failure), cinchona, cacao, cardamoms, rubber, and so on. But tea has succeeded beyond all expectation. Messrs. Ferguson are bold enough to think that before Sir Arthur Gordon hands over the reins of Government, Ceylon will have gained most of that planting prosperity which has been lost through the dire effects of the coffee leaf. "And," they add, "we further see the promise in our tea, cacao and other new industries, together with the continued extension of palm as well as grain cultivation, of a degree of stable comfort and even wealth for the people such as could not be imagined when Ceylon was at the very height of its ancient glory in the days of the great King Parakrama, the creator of 'the Inland Sea.'"

We have looked at one picture. We will look at the other; and seldom has English pluck been better illustrated than in this sudden substitution of tea for coffee. Tea and coffee are greatly intermixed on the different estates with each other, and with cinchona and cacao and rubber. But after a great deal of trouble Messrs. Ferguson have succeeded in approximately dividing the acreage devoted to each. The total area of the 1,923 plantations in Ceylon embraces 652,355 acres, and 1,446 of these with an acreage of 308,018 are still in cultivation under 1,081 superintendents. The

area under each crop is given as follows in acres:—

Coffee (Arabica)	124,707
Coffee (Liberica)	2,387
Tea	101,695
Cinchona	48,246
Cacao	12,325
Cardamoms	4,682
Rubber	629

It will be a surprise to most of our readers to find that in extent of area the tea in Ceylon already almost rivals the coffee. There are 50,000 fewer acres of coffee under cultivation than in 1883, while tea has increased by 70,000 acres. The mixed estates of coffee and tea will soon be all tea, and by the end of the year it is expected that coffee which in 1877 occupied 270,000 acres will be reduced to 100,000 acres or less. This is one of the most extraordinary changes that has ever been effected in an English colony. Tea planting in the high districts was only really commenced in 1833, and not much was done until 1884-85. Already as we have shown more than 100,000 acres are covered with the tea shrub. The progress of tea cultivation in Ceylon is shown in the following figures:—

Years.	Acres.	Years.	Acres.
1879	6,500	1883	32,000
1880	9,271	1884	67,000
1881	13,500	1885	102,000
1882	22,000		

Here we have something like the proverbial leaps and bounds. But the returns of the exports of tea for the last six years will show more eloquently than we can the extraordinary development of this new industry:—

Year.	lb.	Value: R.
1879	95,969	85,229
1880	162,575	150,641
1881	348,157	322,993
1882	697,268	591,866
1883	1,665,768	916,172
1884	2,392,973	1,355,784

The returns for 1884-85 are given by the Chamber of Commerce at 3,796,581 lb. With the present rate of increase more than 20,000 acres per annum will probably be put under tea for some years to come until some 200,000 acres are planted with this staple. But the area now covered is sufficient to guarantee an export of tea in the season 1888-89 of very nearly 30,000,000 lb. Messrs. Ferguson give the following table as the approximate output of the intermediate seasons:—

1885-6	6,750,000 lb.
1886-7	12,000,000 lb.
1887-8	20,000,000 lb.
1888-9	30,000,000 lb.

They, however, go further than that. They say that ten or twelve years hence Ceylon will export 60,000,000 lb. of tea. Tea is produced more cheaply in Ceylon than in Northern India. The London brokers have for some time past been loud in praise of its fine qualities, and it commands a ready sale at home. Ceylon seems to have weathered the storm; and leaf disease, which at one time very nearly ruined the planters, has, by forcing their attention to tea instead of coffee, proved a blessing rather than a curse.—*Times of India.*

THE MILAN QUININE WORKS:—It is reported that the "Fabbrica Lombarda di Prodotti Chimici," in Milan, the failure of which created a considerable sensation at the time, will again resume manufacture, backed up by a syndicate of bankers. The creditors who appealed against the arrangement accepted by the majority have lost their case and had to pay the costs of the action. There is, however, still some talk of a further appeal.—*Chemist & Druggist.*

PLANTING REPORT FROM PANWILA DISTRICT.

COFFEE—CACAO—CROTON—TEA, ETC.

Franklands, Watagama, 24th March 1886.

COFFEE.—It is a pleasure to read of our old friend King Coffee still promising good crops on some estates, which are no doubt favoured with a good climate, soil, and shelter, have been properly cultivated and not planted thickly with cinchona, in spite of leaf-disease. On the Kandy and Malale side we had a worse enemy than leaf-disease to contend with, namely, black-bug which finished off most of our trees in no time, though there are still patches of good coffee here and there doing well, and there is some fine young coffee in Dunbara said to promise well this year. There can be no doubt that planters with good coffee in the high districts will do well to cultivate the same thoroughly, as Brazil cannot give as fine quality of coffee as some of our high estates do, and good high grown coffee will keep a price of its own and be in great demand. Leaf-disease is gradually disappearing.

CACAO.—Everyone will remember the great scare about our cacao in 1884-1885. I remember at the Planters' Meeting in Kandy on the 28th June 1884, there were some planters who thought all cacao was lying out, notably our present Chairman, who had been to the low-country cacao estates, would not allow any excuse to be made on account of want of shade, poor soil or exposed land, for had he not seen a nursery of cacao plants in good soil even lying out? Some planters urged shelter to protect the cacao from the wind was all that was required; some thought shade the best. I strongly recommended shade and the croton oil tree as a quick grower and a profitable tree. In my letter "Advice to Young Cacao planters," published in *Observer* on 8th October 1884, I urged shade as necessary for cacao mentioning many varieties of trees as suitable, &c. There being still some croakers going about the country, I wrote my next letter published in *Observer* on 15th November 1881 ending as follows:—"The scare about helopeltis, fly and borer I treat with contempt as they can be well checked." Times have changed at last; we have again good accounts of cacao promising good crops and looking well with very little helopeltis, fly or borer about. The requirements of cacao are now better known; cacao planted in sandy soil and on poor exposed ridges have been abandoned, shade is being planted as quickly as possible, in old soil manure is given, and in dry climates water trenches are made. It is a mistake to think that because cacao plants taken up with a small quantity of good nursery soil (even some nurseries are made in poor soil) planted out on an old estate or in poor though deep soil without shade does not come on quickly, that it cannot be grown profitably—it is here where the owner must have confidence and allow some extra expenditure the first two years, to dig up soil around plants, give some manure, get up shade and cut trenches. Once the plants are well established there is no fear and expenditure then will be as low as on any estate though beginning with better soil. Especially is this the case when you can get old coffee land, good chena or even patana with a good climate near a high road or railway station; lands of this description I value more than even forest land, the value of which we have still to find out as regards soil, wind and climate, say nothing of distance from a high road, &c. I have proved this with coffee, tea, cinchona and cacao and can safely recommend a trial by anyone who has land so situated. If, however, the owner of such lands thinks all he needs to do is to have his place planted up as cheaply as he can and not to give the necessary assistance to his plants in the proper way, and when needed, I would advise him not to plant any but first class jungle land and wait until he can get such in Ceylon, which however he will find a great difficulty at present, and sell his own land to others who will perhaps prove to him in a few years what a charmer he lost.

CROTON.—I am glad to hear from several planters

to whom I supplied croton-oil seed that it is answering well as shade and shelter and gives a quick return which helps to pay expenditure until cacao comes into bearing. Anyone who wishes to see how croton-oil trees shade well answer with cacao should come to Watagana, visit Maria, Goonambil and this estate. On the latter cacao is planted 10×10 and a line of croton 5 feet apart up between each line of cacao; so croton lines are 10 feet apart or about 800 trees to the acre; from plants 6 inches high planted in September 1884 I got this year 2 cwt. per acre—as soon as the croton trees get larger I shall by degrees take out trees until I have a distance of 20 feet apart or 15×20 .

As regards your correspondent who writes that it makes coolies sick to work among croton and that natives do not even use the wood for cooking—this I can by personal experience contradict. I as well as coolies on this estate work daily among the crotons and we are all in good health. In January last I cut off lower branches for 3 to 4 feet from the ground and I can assure your correspondents both Tamil and Siuhalese come daily and carry off the wood for their cooking and with my permission.

TEA.—I am glad to say tea is a great success in our district and there is some fine tea now on nearly all our estates; from our old tea we can get our 600 lb. per acre—6 inch plants planted in December 1884 are now from 3 to 4½ ft. high; one on this estate I measured 4 ft. 11 inches. On some estates the tea is topped as soon as there is red wood 84 inches above ground.

CINCHONA.—We have some very fine cinchona in our district giving good returns, especially so on Raxawa estate.

ANNATTO.—One estate has planted a good deal of this product, which is doing well.

Cardamoms, Pepper and Ginger are doing well here. —Yours truly, J. HOLLOWAY.

TEA IN MASKELIYA.—The Maskeliya "flats," which at one time promised to make the fortune of their proprietors in coffee, now look even more promising under tea and afford a better assurance of permanency. Peria Maskeliya in this way is likely to give its 600 or 700 lb. of tea leaf per acre, while from Biterne or a comparatively small acreage in bearing, the fortunate proprietor hopes to gather as much as 30,000 lb. this season and double that next year. But even higher up, in Dimbula, we hear of estimates of a return of 600 to 700 lb. per acre. It is strange how entirely free of grub is the same land under tea that seemed alive while coffee was available to be attacked. White-ants bear the same relation to tea—that is at a low elevation—that grub did to coffee, and during the present dry season, a good deal of mischief from white-ants has been experienced, especially on weak plants or trees, in the Kelani valley. It is probable that the Assam plan of clearing out and burning off all timber, so as to leave no receptacle for ants on the land, may have to be followed in our lower districts.

PLUMBAGO.—We noticed a short time back the deputation of Dr. King, of the Geological Department, to report on the probability of obtaining water by means of artesian wells in the neighbourhood of Vizagapatam. We now learn that he has expressed an opinion that there is very little chance of this ever being successful in that district. But Dr. King has made an excursion to Gallikona, where he is said to have made some important discoveries as to the mineral wealth of the district, and a report on the subject is to be published after his return to Calcutta. The existence of plumbago in large quantities is pretty well established, as it is commonly used by the local potters for glazing earthenware. Some traces of gold are also said to have been discovered within a mile of the cantonment; but Dr. King's report

must be awaited for full particulars.—*Indian Agriculturist*. [If plumbago in quantity, unmixed with rocky particles, is discovered, it will be a new departure in India. The existence of plumbago and its use as a glaze for pottery are nothing new. Ceylon is, as yet, the only country where large masses of perfectly pure plumbago are found.—Ed.]

GOVERNMENT WHITEWASH.—Clean looking buildings around a farm add very much to its appearance, and for cheapness nothing equals whitewash. We give below the recipe for making what is known as "Government Whitewash," because the White House is annually washed with it: To make five gallons of brilliant stucco whitewash for buildings, inside and out, takes six quarts of clean lumps of well-burnt stone lime; slack with hot water a covered tub to keep in the steam. It should then be passed through a fine sieve to obtain the flower of lime; add one-fourth of a pound of burnt alum pulverized, one pound of sugar, three pints of rice flour, made into a thin, well boiled starch or jelly, and one pound of glue, dissolved in hot water. This may be applied cold on inside work, but for outside work it should be applied warm. A whitewash thus made is said to be more brilliant than that of Paris, and to retain its brilliancy many years.—It should be put on with a common painter's brush, a second coat being applied after the first is well dried.—*Rural Californian*, Jan. 1886.

SALT UNFIT FOR FOOD.—The following advertisement is said to have recently emanated from the India Office:—"Notice is hereby given, that the Government of India are prepared to grant a reward not exceeding 5,000rs. to the inventor or discoverer of a satisfactory process for rendering salt unfit for human consumption, whilst still leaving it fit for use by cattle and as manure, or for industrial purposes. The main conditions are: (a) that the cost of the process must be moderate, not exceeding about four annas a maund; and (b) that the preparation must be such that edible salt cannot be easily extracted from it by any of the ordinary processes in use amongst native saltworkers. If several good processes be suggested, the highest award will be given to the inventor of the process which may appear to Government to be the most satisfactory in all respects, and a smaller proportionate reward will be granted for the next best process. A collection of papers bearing on the subject will be supplied on application at the Revenue Department of the India Office." Can it be true that the policy of retaining the salt duty has forced the Government of India into such a false position as this? What an opportunity for the preachers of sedition in India! "Here is the paternal English Government seeking to provide means whereby the beasts that perish may have their necessary medium of salt free of duty, while we human beings, if we should attempt to satisfy our craving by sharing the salt which our cattle are not denied, are doomed to run the risk of poisoning, or at the least, to find that the salt is rendered worthless, in order that we may be compelled to pay a tax on an article so essential to health." Here is a text for the anti-English Babu! Of course there is the argument that the salt tax is an essential source of revenue, with which the Government cannot dispense. But if the Government is reduced to such a dilemma that the retention of the tax hampers agriculture, and its abolition threatens bankruptcy, what shall we say of the authorities who voluntarily gave up a source of revenue in the cotton duties to humour a "free trade" whim, and so did no good to any body, while retaining a salt tax which is productive of so much harm—physical, moral and political?—*Colonies and India*.

KANDALOTA is plucking in from 3,000 to 4,000 lb of tea leaf a day and is likely to make the largest quantity of tea this month, ever made on any single estate in Ceylon.—*Visitor*.

FLORIDA.—The recent cold snap in the South is said to have benefited rather than injured the orange trees in Rochelle, Fla. The insects have been killed, the trees have thrown off all the old leaves, and are now putting out a vigorous growth.—*American Grocer*.

PRICE OF RICE.—The exportable surplus of rice from the present crop in Burmah is unprecedented, and the early shipments have been sold at the lowest prices ever known to the trade. Quotations to arrive are 6s 9d per cwt., or less than 1½c. a pound. At this figure rice is the cheapest food in the market.—*Bradstreet*, Feb. 1886.

COCA FOR CHEWING.—One of the latest novelties in the specialty line is a compound of coca, tea, coffee and cinchona, which is put up in the form of pressed cakes, like tobacco. Portions of the "plug" are to be chewed, the saliva being swallowed, and the exhausted quid rejected. The compound is styled, ridiculously enough, "Coca-bola."—*National Druggist*.

The Bank of Brazil has recently sold a good coffee plantation in the municipality of Piracicaba, São Paulo, containing 80,000 coffee trees, half of them young, for the sum of \$36,000. The plantation was well mounted with machinery for clearing coffee, and had 12 slaves besides.—*Rio News*. [In Brazil coffee trees are planted about 240 to an acre.—*Ed.*]

FLORIDA.—The surprising statement is made that only one acre of land to each three thousand acres of territory comprising the State of Florida is fit for habitation or adapted to agricultural purposes. Nearly all the good land has been secured and is held at high prices. More than half the area of the seventeen orange counties is under water or consists of inhospitable swamps and pine barrens.—*American Grocer*.

TEA IN UVA.—After all that has been written about tea in the Principality, no one now doubts that is an assured success. A friend from the Kandy side told me the other day that after seeing tea eighteen months and two years old in Uva, he was not only convinced of the suitability of the Uva climate for tea, but he said the "make" of the tree was stronger than any tea he had seen on the Kandy side at the same age.—*Cor.* "*Ceylon Advertiser*."

MR. SHAND'S TEA-DRIER had a good trial as arranged yesterday afternoon when a number of gentlemen including Messrs. John Brown, Ballardie, Horsfall and others, expressed themselves well pleased. It took about 2 hours previous firing to get the heat up to 350° on the plates and 250° on the trays. With the furnace and chimney outside the tea-house everything is very clean and convenient by Mr. Shand's arrangements and he holds that his plan is by no means wasteful of fuel, indeed that it will probably save on the Sirocco. On one point there is complete agreement of opinion, namely, that there can be no cheaper tea-drier than that of Mr. Shand.

TEA PLUCKING IN DARJEELING.—We had most seasonal falls of rain last Tuesday and Wednesday which have had the effect of freshening everything, and the bill sides are beginning to assume their summer coating of green. These showers have of course improved the prospects of all kinds of crops very considerably, and as the rain has been followed by bright, warm sunshine, good, vigorous first flushes on the tea bushes ought to be the result. Under the old, and had, system of tea plucking this would be an unusually early tea manufacturing season, but the hill men, at all events, having profited by dearly bought experience, now let the first flush run to a length varying from eight inches upwards according to circumstances, and the natural result is that, as compared with the older

ays, but little tea is made off the first flush. The result of the new departure has been that many gardens which used to pay an almost nominal dividend, and sometimes none at all, while the goose that laid the golden eggs was being slowly murdered, are now paying steady dividends of from 7 to 14 per cent year in and year out, and the bushes come up smiling to the fingers of the pluckers. This change in the system of plucking is certainly due in a very great measure to some of the Assam men who came here between 1873 and 1876, and notably, I think, to Mr. James Riddell, an old and experienced Superintendent of the Jorchaat Company, who was sent out specially to pull the Darjeeling Company round when it was really in a bad way.—*Indian Planters' Gazette*.

TURKVA TEA Co., LD.—The Secretaries have issued their report and audited accounts for 1885. The total output has been considerably under the estimate, owing to the red spider blight, which made its appearance in the beginning of May and spread all over the garden by the beginning of June. The rainfall (13.50 inches) during this month was too light to check it, and there was not much improvement until the end of July. The estimate was for a crop of 283,000 lb. of tea, but only 240,040 lb. were made, of which 235,640 lb. were invoiced and 1,320 lb. have been retained for sale at the factory. Of this quantity 140,225 lb. were shipped to London and 98,415 lb. have been sold in Calcutta. The gross average price realized inclusive of amount recovered from the Insurance Co. for 13,350 lb. lost on board the *City of Manchester* is annas 12 pies 10½ as against annas 9 pies 5 per lb. in 1884. The balance retained at the factory is valued at annas 15 per lb. The total expenditure amounted to R125,602-8-9 and the working of the season resulted in a net profit of R63,416-10-6. After adjustment of the Profit and Loss Account, and providing for payment of the *ad-interim* dividend at the rate of 5 per cent, declared on 11th November last, there remains a balance at credit of R29,692-2-8 from which the Secretaries recommend the payment of a final dividend of 4 per cent., making 9 per cent in all, at the season's working. This will absorb R29,372 and leave a small balance of R320-2-8 to carry forward. The estimates for the current season are R124,000 for a crop of 3,300 maunds, or 264,000 lb. of tea.—*Planters' Gazette*.

CINCHONA DISEASE IN JAVA.—To the *Straits Times* translation we are indebted for the following paragraph showing how the cinchona planters in Western Java are suffering from canker:—"The Sourabaya *Courant* has received gloomy reports of a disease among the roots of cinchona trees in West Java, that calamity proving to be wider spread than many persons would have thought. The trees are dying out altogether throughout whole plantations not at first but just when they were getting valuable and into bearing. Capital to large amounts invested in hopeful estates have thereby been lost beyond recovery and many leased tracts of land will lapse to Government. Judging from appearances no kind of plantation enterprise will thrive in Java with any promise of a bright future to industrious Europeans. Planters in Java, so says the Samarang *Locomotief*, far from being discouraged by disease among canes and cinchonas threatening ruin to these kinds of cultivation are jointly striving to make head against them by establishing experimental stations where trials may be carried on to find out the best methods of growing produce articles, warding off disease among them and securing higher yields. To aid sugar growers, measures have been taken by the Planters Association to send supplies of sound and healthy plant cane from East Java to stricken districts in the Western portion of the island. The Planters' Association at Sukabumie has taken steps to induce growers to take joint action to bring about an increase in the consumption of quinine thereby to prevent a further fall in the price of that article or at least to check its decline."

DIMBULA AND DIRÓYA, March 1886.—We are now having very dry weather during the day, the heat being excessive. This for coffee is splendid weather, and already a blossom has been forced out with more in spike, but it is only after all a feeble effort as compared with what a coffee blossom should be. For the last three weeks the air has been thick with smoke from the burning coffee. Every one who has planted tea is anxious to get the coffee out as quickly as possible. Tea does not make much progress this weather, but the acreage planted must be enormous.—*Cor.* "Ceylon Advertiser."

FUEL has on many tea estates become a serious matter for consideration, more especially where there is no water-power, and steam-power will have to be used. There is no doubt that fuel will have to be imported. Coke will most undoubtedly be the best fuel for the tea dryer, but it is both costly and bulky. Ordinary bituminous coal makes too much smoke, will soon choke the flues of the Sirocco, which will need constant cleaning, and create dirt in the tea house. Welsh coal will most probably be used, but surely we should be able to get a compressed fuel specially adapted for use in the Sirocco, and I will call the attention of Messrs. Davidson, manufacturers of the Sirocco to this. They must provide us with fuel specially adapted for use in the Sirocco, and at a price laid down in Colombo which will not be prohibitory.—*Cor. Ibid.*

COCA.—We understand that the next meeting of the Linnean Society will be shown a very fine specimen of the coca-plant, bearing a quantity of red berries. This coca-plant shows a remarkable likeness to the cacao-plant (*Theobroma cacao*), which accounts for the peculiar smell of cocoa sometimes adhering to parcels of coca-leaves, and which on some occasions has led to their refusal by buyers, who were under the impression that this smell had its origin in some form of sophistication. A firm of London druggists have received a consignment of coca seeds, which are intended for shipment to the colonies, where there is some talk of raising coca plantations. Hopes are entertained that a successful cultivation in Ceylon or other parts would drive the South American coca out of the European market, as in that case the American growers would be able to obtain a comparatively better price for it from the natives than they could realise here.—*Chemist and Druggist*, Feb. 1886

TEA.—South African and other Colonists are turning their attention to tea planting. Tea cultivation on an experimental scale has been carried on for some time in Natal, with such success that one of the planters is sending a "sample" of a ton of his produce to the forthcoming Colonial and Indian Exhibition. In fact, the rapid extension of tea-planting in that Colony has attracted the attention of Ceylon planters, several of whom have paid a visit there to judge for themselves of the prospects of the industry. Only the other day a share in a tea "garden" in Natal was advertised in the London papers as being for sale. The example of Natal will very probably be followed in other parts of South Africa, while several districts in Australia and New Zealand claim to be able to grow good tea. Baron Ferdinand von Muller advocates the cultivation of the shrub in Victoria, where plants introduced by him and experimentally grown have been known to produce seeds.—*Home and Colonial Mail*.

TEREBENE is the popular medicine of the moment. Dr. Murrell published an article in the *British Medical Journal* of December 12th, in which he stated that he had obtained excellent results in cases of winter cough by the use of pure terebene. The dose he advises is from 5 to 20 minims on sugar. He also administers it as a spray, from one to two ounces to be diffused and inhaled every week. Terebene, he finds, also relieves flatulence and acidity, and combined with equal parts each of oil of cubebs and oil of santal wood, mixed with liquid vaseline and used in an atomising apparatus, he has found to yield excellent results, not only in winter cough but also in post-nasal catarrh, as well as in improving the tone of the voice. Terebene is a molecular

modification of the spirit of turpentine, and is usually obtained by acting on turpentine by 5 per cent. of concentrated sulphuric acid and distilling repeatedly. It is a product very similar to sanitas.—*Chemist and Druggists*, Feb. 1886.

MADULSIMA TEA.—We received samples the other day of the first tea made well-known on a Madulsima plantation where a large area has been planted with tea. Messrs. Willson & Co. have been good enough to give the following report on the same—a report that ought to encourage tea planters in that *ultima thule* of the Uva districts:—

"No. 1: Broken Pekoe 1s 8d to 1s 9d—blackish greyish, little mixed leaf, little flaky, some pekoe ends; good strength, but dull flavor.

"No. 2: Pekoe 1s 3d up—blackish, greyish, mixed, choppy leaf, few pekoe tips; dull flavor, fair strength.

"No. 3: Pekoe souchong 1s 0d; fairly twisted, blackish, greyish uneven leaf, few pekoe tips; dull flavor, rather thick.

"The above samples, having been kept in paper, have been rendered dull and flat." The samples did not get fair play, having been sent forward in paper and they lay some days exposed before examination.

TEA IN UVA.—An Uva planter writes:—Mr.— was as pleased as he was surprised with the wonderful growth of tea here, said he hadn't seen anything to approach it on the other side. This was very high praise, seeing that he had seen tea in so many districts before he came this length. I have been the greater part of today with coolies cutting down my oldest tea which will thus be ready for plucking towards end of April, and will afford a capital opportunity of testing its flushing capacity throughout the dry months of June, July and August. I hope, and really think that the result will be such as to put an effectual and everlasting stop to that grave shake of the head and inconcomitant expression "Will it flush?" which some of our as yet unbelieving Kandy-side friends are wont to assume whenever the subject of tea cultivation in Uva is brought forward. A good many thousands of pounds of tea will go forward from Uva this year, and next year we shall be in the thick of it. Oh, for the Railway!

SCIENTIFIC TEA MAKING.—It must be kept in mind that during the *rainy season* the process of artificial withering becomes naturally divided into two parts. When the leaf is brought from the garden *outwardly dripping with rain*, it seems to us useless to begin withering till the leaf is rendered *outwardly* dry. In wet weather, therefore, our first operation is to place the wet leaf into our drier where the rain is quickly evaporated, and in this part of the process a temperature of 110° may be used with impunity. This we fancy is the source of the misconception we are rectifying. It will be fully understood, however, that this temperature applies only to the evaporation of the rain-water on the leaf, and even in this operation we would advocate a somewhat more moderate temperature—say 100° F. So soon as the leaf is thus rendered outwardly dry, the second part of the withering process is begun, and in it we use no artificial heat. It will thus be seen that we are in exact accord with the writer in your columns: and as he is doubtless a practical planter, it is gratifying to us to find that while unintentionally misrepresenting us, he so fully confirms the principle, as regards temperature, upon which we proceed. We will only further add that notwithstanding the opposition to our process of "experts" at home, we are arranging to have it practically tested in India and in Ceylon during the approaching season.

JAMES A. R. MAIN.

JNO. DICK.

Glasgow, Feb. 10th.—*Planters' Gazette*. [Those trials will be the true test of the merits of the invention, but we believe Mr. Armstrong and a great many others would object to warm air even in the removal of moisture from the leaves.—ED.]

PHYLOXERA AT THE CAPE.

We have received from a correspondent in South Africa some details of the long-dreaded appearance of the Phylloxera in the vineyards of the Cape Colony. As long ago as 1880 the importation of living plants in any form or shape was forbidden by the Cape Government. This measure was so strictly enforced that consignments of young beech-trees from England and of tree-ferns from New Zealand were not allowed to be landed. In 1884 the prohibition was for a short time relaxed. But it was speedily revived, under a penalty of 500*l.* or two years' imprisonment with or without hard labour in the case of any infringing it. The insect has now, notwithstanding, actually appeared in a few vineyards near Cape Town, and in two others about twenty-four miles off.

Fortunately the Cape Government has competent scientific advice at hand. Mr. Roland Trimen, F.R.S., the Director of the South African Museum, and a well-known entomologist, attended the Phylloxera Congress at Bordeaux in 1881 as the representative of the Cape Colony. A Commission to examine and report on the outbreak has been appointed, consisting of Mr. Trimen, of M. Peringuey his assistant, and of Prof. Macowan, F.L.S., Director of the Botanic Garden. M. Peringuey is a Bordeaux man and a good entomologist; he first drew Mr. Trimen's attention to some suspicious-looking mites on a slide which had been taken from a Cape vineyard by the doctor of a French ship, about Christmas.

Two or three of the vineyards are simply swarming with Phylloxera. But in others it appears to have only recent centres. Unfortunately sulpho-carbonates and carbon bisulphide are little more than names in the colony, and it has been necessary to telegraph for a supply. Pending the arrival of the insecticide, the vines are being uprooted and burnt. The result so far is encouraging, and the small range of the insect leads to the hope that it may be well kept under if not stamped out.—*Nature*.

COCONUT PLANTATIONS AT BATTICALOA.

20th February.—The demand for Coconuts is great. They sell at R33.34 per thousand, and Copperah at R36.37 per candy.* The scarcity of nuts may be attributed to the short produce. I do not quite agree with the common opinion that this is traceable to the long dry season we experienced last year. The flower spathe thrown out after the flood of last year by the Coconut palm has, with a few exceptions, been abortive, and I presume that this is attributable to the heavy floods of 1885. A healthy, well-bearing Coconut tree ought to have 12 bunches on it in all stages of growth, from the newly opened spathe to the fully ripe nut. Although there are 12 spathe on the tree, most of them are denuded of nuts. I am afraid that the price of Coconuts will rise extremely high this year.

Plantations have commenced to wear a dejected look already, and Coconut bunches and branches are fast dropping to the ground. While on the subject of Coconuts, I may say in reply to your footnote to my letter that it is true that the price of Oil regulates the price of Copperah, but how is it that the price of Oil remains stationary or recedes? Is it that demand for it is slack, or that the enormous stocks said to have accumulated in England, have not been appreciably reduced? I beg leave to question your figures as to the relative price of a thousand Coconuts and a candy of Copperah. You give the difference as only R6. That is true only of exceptional places where nuts are so large that the Copperah of 1,100 or 1,200 nuts go to a candy.

In exceptional places we have heard of 900 to 1,000 nuts subsiding for a candy. Ours is a safe average for average places in average seasons.—Ed. "Ex."

* In the Western Province, the difference in price between a thousand nuts and a candy of Copperah is about R6—as from 1,100 to 1,300 nuts go to a candy, and the cost of drying is R1.25 a thousand. How many Batticaloa nuts go to a candy?—Ed. "Ex."

During a season of drought or large crops, on average properties from 1,300 to 1,400 nuts go to a candy. Taking the former figure as the average, and the price now ruling for Coconuts R30, let us see what Copperah ought to fetch. 1,300 nuts at R30 = R39 plus R1.02 $\frac{1}{2}$ for drying 1,300 nuts at R1.25 = R40.02 $\frac{1}{2}$ per candy of Copperah in the villages. Add to this transport to Colombo, and the price reaches something like R41.50, and yet traders who pay R30 for Coconuts here, sell a candy of Copperah in Colombo at from R36 to 38, and get a profit too! The Merchants who buy Copperah can possibly say how the trader manages this. The uninitiated in these mysteries simply feel bewildered when attempting to solve them.—"Examiner."

THE MANUFACTURE OF SALT.

It will be remembered that Government recently deputed Dr. J. J. L. Ratton, to investigate and report upon the quality of salt manufactured in the Madras Presidency. We hear that that officer has informed Government that he can do nothing personally to improve the quality of salt at present manufactured. The excise system prevails now at so many manufacturing stations, that the new system treated of in his "Handbook of Common Salt" could only be forced upon the salt ryots at a few places, and it would not affect the bulk of the salt made in this Presidency. But there is still a stronger reason for delaying any action that might be taken at the pans, and that is, the system of selling salt by measure prevalent in this Presidency is entirely opposed to the manufacture, that it would be impossible to maintain an improved method of manufacture without constant and extended supervision, which would require a very large increase in the staff of the Salt Department. It was pointed out that pure salt, as compared with bad salt, is remarkable for its weight and solidity, and as we pass from pure rock salt through the different grades of manufactured salt, physical qualities deteriorate *pari passu* with chemical, until we meet with the worst chemical descriptions, which are very light and hollow. The salt trader will always purchase the lightest, *i.e.*, the worst salt chemically, because it pays out and out the best, bought by weight and sold by measure, and the effect of this on the salt manufactures is, that where there is any choice of pans there is a run on those which make bad salt, and the good salt stores are neglected. The yearly demand for salt increases the bad pans. Fresh pans are opened, and the place develops and prospers, whereas the good salt remains long unsold, the yearly demand falls off, pans are thrown out of cultivation, and the ryots abandon the manufacture in disgust, or outbid their rivals in the manufacture of bad salt. There is no chance of getting the manufacturers to make good salt, so long as the present system of purchase by weight and sale by measure is allowed to continue. But if it is essential to maintain the *status quo* as regards purchase and sale, Dr. Ratton suggests the removal, as far as possible, of local rivalry by limiting the number of salt manufactories to a few points on the coast, far apart and well supplied with means of communication by rail or canal, as Tuticorin, Vedarman, Madras, Beypore, &c. At each of these places, an increased staff could be concentrated for the supervision of manufacture, and the increased cost would be more than met by the savings of the closed manufactories. As a standard of quality to be obtained by the salt manufacturers, he would suggest the Vedarman swamp salt as it contains nearly 99 per cent of sodium chloride, and is the product of purely natural forces. Government, in passing orders, observes, that under the existing administration, the quality of salt produced at most of the works has been subordinated to the development of the salt revenue, in consequence of which salt has been for some time past deteriorating. This is admitted by the Commissioner of Salt and Abkari Revenue, but the only remedy which that officer has been able to suggest, is a legal enactment prohibiting the sale of

salt by measure—a proposal which the Government have after a careful consideration, already negatived, and see no reason for departing from their decision on the point. The true remedy for the unsatisfactory state of things which exists with regard to the quality of the salt non-sold lies in taking steps as will ensure nothing but good salt being excised or passed out of monopoly factories or depots. For this purpose a Committee composed of Messrs. J. H. Garstin, C. S. I., and J. F. Price, C. S., Deputy Surgeon General Bidie, C. I. E., and Surgeon Major J. J. L. Ratton, has been appointed by Government, and it will consider (1) The standard of quality to be fixed, (2) The test of qualities to be applied, the officer by whom it should be carried out, and the method of application, and (3) the question how salt rejected should be disposed of, and to such other points as may occur, or be suggested to them in the course of their enquiry.—*Madras Mail*.

FISH MANURES.

It was little more than forty years ago that the first importation of Peruvian guano occurred in Scotland. About twenty years ago the imports of Peruvian guano attained their maximum, and they have since gradually dwindled away—the rich deposits of guano are now exhausted, and there remain only poor deposits, which in a great measure will not repay the cost of importing.

To find something that will take the place of a high-class Peruvian guano is of course a great desideratum, and it has been claimed for fish and flesh manures that they are the modern representatives of Peruvian guano, and the name "guano" has, therefore, been applied to them. Their composition, so far as total phosphates and nitrogenous matters are concerned, lends some support to that opinion, but the resemblance is only a superficial one.

The composition of Peruvian guano was a very complicated one, and the constituents were of a delicately-balanced kind, capable of easy decomposition in the soil, and the effect of these upon the crop was very rapid and precise. A large proportion of the phosphates were alkaline, and therefore immediately soluble, while the nitrogenous matter consisted chiefly of ammonia salts or complex soluble substances, which were rapidly converted into ammonia salts or nitrates, and were thus made immediately available for the nourishment of plants. "Fish guano," on the other hand, and flesh manures, such as "Frey-Bentos guano," consist of phosphates which are insoluble in water, and of nitrogenous matters of an albuminoid kind, which are only slowly decomposed in the soil. Before these constituents can be used by the plant, they must first be dissolved or decomposed, and that is a process which takes some time. The insolubility of these manures renders them unsuitable for application in circumstances where Peruvian guano exerted a powerful influence, such as in the starting away of cereals or young grass when applied as a top-dressing.

These substances are chiefly valuable for broadcast manuring with the view of raising the general fertility of the soil, or for application to root-crops which have a prolonged period of growth. The utility of fish guano in these respects has been very clearly demonstrated at the experimental stations of the Highland and Agricultural Society. The fish guano plot has gone on steadily improving since the beginning of the experiments, and it has been noticed that the Turnip crops have looked fresh and continued their growth far on in the season. The only year in which a marked deficiency in that plot was manifest was in 1884, at the Pumpherson station, when a crop of Beans was grown. The very backward state of that plot on that occasion pointed out very clearly wherein lies the chief deficiency of fish manure. The results obtained with the Bean crop exceeded in interest any that had occurred before upon the station, and the one overruling constituent in a Bean manure was shown to be potash. All the plots that had potash applied to them did well, and those that had the largest dose of

potash did best, while those that had no potash applied to them were a failure. The most notable failure was seen in two plots which had been manured with fish guano and fish meal.

It is characteristic of fish manures that while they contain much phosphate and abundance of nitrogenous matter, they contain scarcely any potash. But it is well known that the abundance of some fertilising constituents in a manure counts for nothing in the raising of a crop if one of the essential constituents of plant food is absent, or if the one which the crop requires most is present in insufficient amount. We therefore found that the plots manured with fish manures produced a smaller crop than any other plot save one, and that was the plot to which no potash had been applied since the beginning of the experiments.

We thus see that there have been two causes at work to lower the value of fish manures in the estimation of the farmer; in the first place he has been led to expect, from the misleading name under which it has been sold, that it would be a manure resembling in its efficacy Peruvian guano, with whose extraordinary fertilising power he had been familiar; and secondly, the nearly total want of potash, which, though not abundant in Peruvian guano, was nevertheless present in that manure to the extent of about 3 per cent.

What, then, is needed in order to make fish manures once more attractive to the farmer? They should be sold under a name that does not raise false expectations, and they should have potash salts added to them. They would be still further improved if there were added to them some high-class superphosphate and a little sulphate of ammonia. For general purposes I would recommend a fish manure so mixed as to show from 5 to 10 per cent soluble phosphate, 15 to 20 per cent insoluble phosphate 10 per cent of ammonia partly soluble, and $\frac{1}{2}$ per cent of potash, and I feel sure that if manufacturers can produce such a manure it will rapidly become popular with farmers, and produce a good market for a substance of which there is truly an inexhaustible supply, and the result will not only be a gain to agriculture, but also a means of giving greater stability and security to our fisheries, which have lost much in the past from the wholesale destruction of valuable fish material.—Extract from a paper by Dr. A. P. Aitken, in the *North British Agriculturist*, Jan. 27, 1886.—*Gardeners' Chronicle*.

TEA PLUCKING.

Plucking has been receiving much more attention during the last few years, and deductions made go to prove that with even greater care, better results could be obtained. We are glad to learn that agents are having their eyes opened to the damage done by writing reprimands for short outturn when the manager has been adopting a wise policy in sparing his bushes, so as to get as large a surface upon them as possible. Some planters we know aver that the tea bush should be kept down to a certain height, and that if allowed to grow beyond this, the flushes cease to be as vigorous, or as frequent. We are prepared to admit that there is some truth in this, but we think that the height the bushes should be allowed to grow to, as well as the breadth are easily determined by the vigour which they display. According, then, to the vigor of the bush should the style of plucking be suited. It is of course impossible to apply such a system to every individual bush; but there is no reason why it should not be applied to sections of a garden. If bushes are large and vigorous it stands to reason that they can support a larger number of suckers, and feed a larger number of eyes; therefore at the beginning of the season it would be advisable to allow the first flushes to grow out longer and leave more axils than would be the case with less vigorous bushes. No planter of course desires to have weak bushes, but at the same time in nearly every garden a certain proportion of poor bushes are to be found; and generally some sections are more to liable

suffer from blight of different kinds than others. It can hardly be questioned that blight shows either weakness in the bush, or that there is some extraneous, hostile, substance in that particular part of a garden in which blight appears most severely.

The vexed question is, however, whether fine or coarse plucking pays the best? Whilst weighing the *pros* and *cons* one must not lose sight of what is most beneficial to the bushes, and which course can be pursued the longest with impunity to them. A great many haphazard statements have been made on the subject; but within the last few years a good deal of valuable, reliable, information has been accumulating. So far as we can learn, the consensus of opinion leans towards coarse plucking, as not only giving the best pecuniary result, but as lasting longer, doing the bushes little or no harm. In fact we have heard it asserted that gardens have improved in appearance from this treatment. We are not prepared, however, to accept this altogether; but would lay before our readers the system we have heard recommended as the most efficient, leaving to themselves to judge whether it should be followed or not. In former years the rule observed as closely as practicable was to commence upon a six-leaf flush, taking three leaves, and leaving three, from the axils of which hitherto the second flush came; when the second flush attained five leaves, to take three, and leave two; the third flush proceeding from these in turn, was often taken in the same way; and in the fourth flush, as soon as it attained four leaves, it was usual to leave only one leaf on the bush. After the fifth and sixth flushes, it was generally a clean sweep of everything that came out. The wood thus attained would probably, at an average of twainches, give a height, for six flushes, of twelve inches, which was considered sufficient to prune upon, or rather to prune off, for it was as a rule cut off say three inches above the former year's proung; so that so much was wasted that might have been made into tea.

The system we have heard recommended recently and which to an outsider seems to carry some weight is quite the reverse of this. At the beginning of the season instead of plucking upon a six-leaf flush, the flush is allowed to grow out to eight or nine leaves, when three leaves are taken off, and the other five or six leaves left on the bush are allowed to remain and ripen into material for next season's pruning; after this first flush is thoroughly established, the garden is regularly visited by the plucking women once a week, and the bush is completely stripped of all new leaf which has shown during that time. At the beginning of the season if the growth is vigorous, leaving six leaves on a bush means at least nine inches in height from the place where the shoot strikes out to the top of it; as the distance between the leaves is always great early in the season. So that if we allow, say, three or four inches above the former year's pruning, there still remains six inches of wood to be cut away. Another contention we have heard in favor of this system is, that allowing the flush to run this way in the beginning of the season gives much cleaner wood, and that although on the very surface there is before the end of the season a lot of brushwood. Another argument is that both young and old leaf being taken together, the quality of the tea made is much better than if only medium leaf were plucked; that the quantity is largely increased; and that towards the end of the season the harder the bushes are pinched, the harder they throw out. Our tea-planter friends would do well to consider the subject. We have put the ideas we have heard before them.

We could point to a good number of gardens in which this system is followed and which seem to go on increasing in yield, year by year. With regard to fine plucking, we believe there is the great drawback that the bushes never get the same foundation as in leaving the first flush as recommended above, and in consequence the constitution of the bush is, to a certain extent, injured. It might be worth the while of some of our friends to experiment with two plots, alongside of one another, in both instances allowing the first flush to get a start, but after that plucking fine in the one case, and plucking coarse, in the other. We have heard it stated, but we do not know how true it is, that the loss in

quantity in fine plucking is about 20 to 25 per cent., whereas the difference in value is nothing like compensatory. It is a subject of much interest to all connected with tea, and well worthy of the best consideration; even one maund per acre extra yield makes a wonderful difference in the cost of production. In the tabulated list in the *Home and Colonial Mail* the best paying garden certainly plucks fine, but this is quite eclipsed by the number of good paying gardens that pluck coarse. Assam teas have taken a strong lead in quality last year, but shareholders have had to pay for it; which tends to prove that, for profit, quantity and not quality is the thing.—*Indian Planters' Gazette.*

TEA CULTIVATION IN FIJI.

is thus noticed in the *Fiji Times* of Jan'y, 23rd.—As mentioned in the former Wainunu article, Masusa, the plantation where Messrs. Mackinnon and Barratt are now engaged in the systematic, and what is confidently expected to prove the thoroughly successful cultivation of the plant, lies on the left bank of the Wainunu River, some mile and a half from its mouth. The plantation was originally opened by Mr. A. Peters for Mr. Alfred Sharpe, and all preparations were made to prosecute coffee cultivation on an extensive scale. But the prospects of the industry declined. The proprietor entered very largely into the sugar enterprise on the Navua River, the minor undertaking was abandoned, and the plantation was subsequently acquired by its present owners as a property specially suitable for tea cultivation. In arriving at this conclusion, Mr. Barratt, who is an Indian tea-grower of very considerable experience, was guided, not only by the apparent suitability of the soil, situation, and aspect; but also by the result of his enquiries and research as to the important matter of rainfall and general climatic conditions. As these appeared favorable the enterprise was entered upon with hopeful confidence.

The plantation, which has a splendid river frontage, affording every facility for the loading and discharging of small craft, embraces about 500 acres, well situated, easily worked, and with a practically inexhaustible strength of soil. This is indeed the distinguishing feature of the Wainunu district. Miles on miles back from the coast-line, whether the foot is turned toward Yanawai on the east or Nadi on the west, magnificent stretches of comparatively flat land are met with, carrying a wonderful depth of rich loose soil, formed by the vegetable deposit of ages, and possessing forcing qualities that are attested by the luxuriant growth which everywhere springs up in rankest profusion. The timber supply on these prolific but particularly waste lands, and particularly that lying toward Yanawai is admitted to be unsurpassed in any part of Fiji, and it is a planter's axiom that light clearing makes poor crops, and *vice versa*.

It is now about two years since its proprietors commenced operations, and up to the present, results have fully realised expectations. The greater portion of this time has of necessity been devoted to the business of getting into order, to the establishment and cultivation of the nurseries, the preparation of the soil, and the setting out of the young plants. But now, while this work still goes on, there is beside a large area of land planted up, in which the young trees look so luxuriantly healthy that in reviewing his experience, Mr. Barratt asserts that he has never before seen such remarkable growth. To bring the properties of the leaf to practical test, he recently prepared a few pounds of tea from these trees. The qualities manufactured were those known to the grower and trader as pekoe and pekoe souehong, being the respective product of the young leaf and of the intermediate class between the first quality and the coarser description manufactured from the largest leaf and known as souehong. Samples of this, the first product of the estate, were recently forwarded to Levaka and duly tested by competent judges, with the result that the tea was pronounced excellent, its characteristics being strength, a pure flavor, and a rich yet delicate aroma. This would seem to indicate that Messrs. Mackinnon and Barratt have not

mishjudged the capabilities of Masusu for tea production, and that there is every prospect before them of a successful future.

In working this out it is their intention to avail themselves of the latest improvements in mechanical appliances, one of which promises to effect a very considerable saving in the all important matter of labor. Hitherto it has been the practise to carefully pick the flushes, as the output of leaves to be harvested is called, by hand; but a machine has been patented which works on the principle of a wheat-header, and travelling along the tops of trees, gathers the leaves rapidly and reduces the work of picking to a minimum.* The rolling, sorting, drying, &c., is also done by machinery, so that with the plantation once in full yield the number of laborers required should not constitute a heavy working charge.

At present there are about 40 Polynesian laborers on the estate, and work goes on with them with the very smallest amount of friction. They are well treated and they have the sense to know it. That they are well fed their appearance testifies; that they are well and comfortably housed a visit to their snugly-built and trimly-ordered "lines" will prove, while that proper provisions has been made for them in the event of sickness, appears in the spacious and cleanly hospital, which, however, was empty at the time of my visit.

Besides these mentioned, the buildings on Masusu are the homestead, a comfortable wooden structure with native houses as adjuncts, and a large iron erection, built in the year one of the coffee era, but found to be of the great service in the present, and promising to be of even greater service in the future tea time. I will not intrude upon the privacy of the homestead further than to say that there is a lady hostess whose presence and surroundings contribute a softer and higher tone than is generally characteristic of plantation life.

I have already casually said that the soil is of superior quality, strong, yet easily worked, and need not be artificial fertilization during the natural life of its proprietors. From the river banks to the hill tops it is a deep, rich friable loam in which all vegetable products, indigenous and imported, attain a most satisfactory development. This was particularly noticeable in the healthy look and flourishing growth of the food crops after the drought of the late season. With such advantages, as may be supposed, all necessary supplies, fruit and vegetable, are obtainable in profusion, and with fish and wild fowl from the river, and an abundance of fresh milk, butter, eggs, &c., from a well-stocked farm and poultry yard, the occupants of the Masusu homestead should find their lives cast in very pleasant places. If they do not, they are within an easy day's run of Levuka, and a short change will soon reconcile them to their country life.

DROUGHTS AND WHAT KIND OF RETURNS WOULD BE OF SERVICE TO TROPICAL AGRICULTURISTS.

People living in a tropical country, especially when that country is almost exclusively dependent upon agriculture as a means of livelihood, must be continually struck with the indispensable value of rain. It is therefore with more than usual interest we are inclined to look upon the returns showing the longest periods of drought at various rainfall stations in Ceylon, recently supplied by our courteous Surveyor-General, though we must say we have always considered the word "drought" has with us a wider meaning than simply freedom from rain. For instance, the most droughty year we can remember, after almost thirty years' residence in Ceylon, was decidedly 1884. We do not say that rain was necessarily less frequent then, but that, when it came, for a long time

* Such a machine has been reported from America, but no sane person, we suppose, believe in a leaf-picking machine.—Ed.

the fall was in insufficient quantities to do any appreciable good. Coconut holes, after inches of rain had fallen, remained dry a foot below the surface. The dry months of February and March were followed by a south-west monsoon, with an exceptionally low rainfall; consequently in many districts it was not until the north-east monsoon set in that the drought of the land actually ceased.

After a continuance of dry weather, it is very frequently the case that a light shower falls, at least light in comparison to what one would then require; consequently the drought is far from being at an end. Rain is wanted for two chief purposes—first, to maintain vegetation, and second, in a lesser degree to supply drinking water in the wells and streams; so it is the effect it has in these two ways that it benefits humanity; and in a hot climate, where evaporation is more sudden, there is naturally a greater necessity for ample moisture. Thus it will be seen that the practical effect of a so-called draught, as shewn by the Surveyor-General's tables, may be quite different from what we should in a purely agricultural sense denominate it.

The moisture requisite for plants will always be influenced favorably or otherwise by sunshine and wind, they being the chief producers of rapid evaporation, so that a larger supply of moisture will be necessary under the influence of sun and wind than in a cloudy or quiet atmosphere. In looking through the Surveyor-General's list and comparing it with our experience of those droughts which for a long time affected agriculture and wells, we do not find any very marked similarity of results, and we can only ascertain that by reference to the full returns, as usually published. Simply as shewn, they merely indicate the longest period without rain, which may after all be neither injurious to moist vegetation, nor to mankind. It often happens that for long periods only a few inches fall, say, something under three inches a month, which where unaided by irrigation, is synonymous with a failure of crop upon those cultivated plants of most value to cultivators, except, as sometimes is the case, near streams where the land absorbs sufficient moisture to retain the fertility of coconut and other perennial plants.

A table showing the continuance of droughts, where the aggregate rainfall did not exceed 3 inches a month, would be very interesting; especially in those provinces the climate is such as to permit the growth of our most valuable products, such as tea, coffee, cocoa, and coconuts. Cocoa is a plant requiring, in addition to a rich soil, a fairly regular rainfall never falling short, for two months consecutively, of the three inches aggregate in a month. Coconuts bear drought much longer, and would, in deep, rich land stand the same test for three or four months without much injury. In a locality near the sea, or upon alluvial flats where water can be reached within eight to ten feet from the surface, it is very difficult to say how long they would thrive without rain—perhaps six or seven months—but this would altogether depend upon the degree of suitability of the land upon which they were growing. Tea is not, truly speaking, a tropical plant. Many on that account consider that its period of life will not be long in Ceylon; others again assert that the only way it can be maintained is by a yearly drought necessitating a rest; yet we believe a continuance of the less-than-three inches a month test, for longer than three months, would cause it great injury. In most parts of India tea undergoes yearly fully three months' dry weather, where probably a smaller rainfall than we consider the minimum we can stand in Ceylon is experienced; but it must be remembered that it is in a latitude fully 10 degrees further north than Ceylon, and also where it is indigenous. Even in our island we should doubt if a larger rainfall than 120 inches over the nine months, and, say, six inches over the three dry months—in all 126 inches—would be any advantage to tea. It seems to be the condition of most plants in nature to have a period of dry weather in each year, lasting from one to six months;

not necessarily rainless, but a period during which the ground never becomes absolutely wet, when we have no doubt the ailing of the soil contributes much to many of its particles becoming food for plants, and the moisture being driven deeper, it extends the limits at which roots can descend, remain healthy, and fulfil their functions; yet we know there is a limit even to this.

As a means to a practical end, we consider returns showing the longest periods when the rainfall has been confined to three inches a month would be of great use and interest to the public, showing as they would the effect of rainfall upon perennial cultivations, they being the only ones retaining any real permanent value in the island. It would at once indicate the adaptability of lands for special cultivations more than any other test. Where droughts continue over many months, the grazing of cattle or chena cultivation is the only use to which land can be applied unless within the reach of irrigation. A mapping-out of the country on a more elaborate plan than that adopted by Mr. Vincent in the map accompanying his report would be very useful, especially if there were various colors for droughts of less than three inches in the month, for, say, period extending over one two, three and four, months respectively. It is strange that the list supplied should contain no returns from such an important place as the chief town of the North-Western Province. The public are under an obligation to the Surveyor-General for the information supplied, and hope that he will continue publishing returns likely to help forward the largely extending and important interests upon which alone, it may be said, the permanent welfare of Ceylon is dependent.—Com. local "Times."

TEA WITHERING BY MACHINERY.

It has long been disputed that, however possible it may be to invent Machinery, suitable for Tea Manufactory, which shall adequately perform the various processes through which the leaf has to pass under the system of hand manufacture, the elemental phase of "withering" must be left to Nature, and could not be performed in an equally efficient manner by Art. We have, ourselves, never been able to understand this contention, since there is no special external atmospheric condition necessary for perfect withering except "heat," accurately applied,—or rather perhaps, as it may be more correctly designated, *warmth*: such a character of temperature, in other words, which, while absorbing moisture, should, without any approach to "steaming" the leaf, render it soft and flaccid for rolling, and for generating that fermentation which should ensue on the bruising of the leaf cells. Mere applied "heat," alone, will not effect this, as, in the latest introduction for Machine-withering patented by Mr. Main, "baking" rather than "withering" is found to be the result. What is wanted is heat *in motion*, in imitation of ordinary atmospheric heat, and such an exposure of the leaf to an equal temperature, over all its parts, as is obtained by leaf thinly spread and turned on *changs* over the floor of the room above the factory, by which the warm air from below percolates, as it were, equally through the whole of the leaf on the tray. This is in imitation of the China system, where a thorough draught of warm air passes through all the leaf; and not only so, but the leaf is subjected to a process of tossing and beating (so to speak) by which that equal distribution of warmth so essential, is obtained. In the attempts hitherto made at withering by machinery, it has been found difficult to keep the leaf sufficiently separated. The tendency has been for the leaf to fall in "heaps" round the revolving cylinder, and thus equal withering of each leaf has been impossible. Thus, as we say, the idea of adequate withering by machinery has been almost abandoned. A new invention, however, is now about to be put before the public by Mr. W. Gow, of Messrs. Gow, Wilson, and Stanton, Rood Lane, London, Tea Brokers, which seems to fulfil the conditions required; and it is claimed for it that while taking away the extra

moisture from wet leaf by artificial heat, none of those chemical constituent parts upon which good Tea depends are carried off; and further, that the process so separates and exposes the leaf to the operation of dry warm air, that the withering is even, and the tip brought out more fully than by the ordinary process; with the result of good infused color, briskness, flavour, and tippy appearance.

Withering being, in fact, incipient fermentation, it follows that an extension of the principles of correct withering is followed, on the bruising of the leaf, by natural fermentation, and this Mr. W. Gow's Invention claims to produce in one and the same machine. A series of trials made recently by Mr. Gow himself before an assemblage of practical planters in the Darjeeling and Terai districts, resulted in an expression of opinion by those gentlemen that exceptionally good infused color, briskness, flavour, and tippy appearance, had been secured by the exhibit made before them; and that oxydization and fermentation were, by Mr. Gow's machine, fully and chemically perfected; and that tea made even from coarse leaf (which was the kind experimented on,—it being then the end of the season), gave a good black appearance, and was generally favourably affected. The Meeting further found that a good twist in rolling was given to the leaf, and, all superfluous moisture having been removed, the process of "firing" was much more speedily carried out.

Mr. Gow asserts that tea subjected to his process will possess better keeping qualities than tea made in the ordinary manner, and, as a special tea expert, his opinion on this subject is of high value.

We were shown by Mr. Gow some tea made towards the end of the present season by his process, and the out-turn was a bright copper colour, while the infused leaf unfolded itself, showing that all the surface had been fully and equally operated on by the water, and the greatest nutriment extracted.

The Chinese do not push the withering of leaves to excess, but only so as to obtain the necessary fermentation, keeping the leaves moist during the whole time, and thus preventing any approach to desiccation, which would result in a poor weak liquor. Mr. Gow follows the Chinese system, and can, certainly, to be the first to apply Machinery to its practice, for in his Invention warm air softens the leaf, and fermentation follows on the cells of the leaf being broken by a process of "beating," after the manner adopted by the Chinese, which exposes each leaf to the action of the oxygenic air-current passing continuously through the machine. Means are provided for regulating the temperature of the air by induction, thus following the natural principle of equality of temperature.

It is not a small merit to have overcome the difficulties which have hitherto presented themselves in regard to mechanical withering, and we congratulate Mr. Gow on having been so successful where others have failed.

The following Summary will explain the chief points and advantages of this unique Invention:—

- (1) That the management of the leaf is under perfect control.
- (2) Leaf, after being "withered" and "fermented," can be kept for some time without deteriorating.
- (3) During the last few minutes the leaf is in the machine, by shutting off the induction of cold air (necessary for regulating the temperature) the temperature can be raised to 250°, 300°, or 350° Fahr. which would set up an action analogous to that obtained by the Chinese in "panning."
- (4) By the peculiar working of the machine, the leaf-cells are gently broken or bruised, so that the fermentation is quickly set up.
- (5) When the leaf leaves the "Witherer" it has become colored, and the bloom or down is seen on the leaf. The pekoe ends are multiplied by the convoluted leaf-buds opening out, and though still soft are covered with a light yellowish bloom or down. In the ordinary process of rolling, a coating of tannin is

taken on, and the "ends," when dry, present a bright orange color.

(6) In the rolling, all that is expressed is the moist gum containing the tannin and other chemical elements. If the withering and fermentation is properly carried out (taking into consideration the time of year and the contingent condition of the leaf), the leaf is ready, after the rolling, to go straight to the firing apparatus, thus doing away with the separate fermentation now necessary after rolling. The time occupied is stated at about 50 minutes or an hour. Of course, leaf which has previously become partially withered before being placed in the machine, would require a much shorter period of time to finish. The present machine, which is 8 ft. by 8 ft., is capable of preparing 6 to 7 maunds of fresh green unwithered leaf at a fill.—*Indian Tea Gazette.*

EUCALYPTI THE TALLEST TREES IN THE WORLD.—The tallest accurately measured *Sequoia* (*Wellingtonia*) standing in the Calaveras Grove, California, measures 325 ft., and there is no positive evidence that any trees of this genus ever exceeded that height. Of late years, explorations in Gippsland, Victoria, have brought to light some marvellous specimens of *Eucalyptus*, and the State Surveyor of Forests measured a fall-on tree on the banks of the Watts River, and found it to be 475 ft. from the roots to the top of the trunk. The crest of this tree was broken off, but the trunk at the fracture was 9 ft. in circumference, and the height of the tree when growing was estimated to have been more than 500 ft. The tree, however, was dead, though there is no doubt that it was far loftier than the tallest *Sequoia*. Near Ferushaw, in the Dauleong district, Victoria, there has recently been discovered a specimen of the Almond Leaf Gum (*Eucalyptus amygdalina*) measuring 380 ft. from the ground to the first branch, and 450 ft. to the topmost twig. This tree would overtop the tallest living *Sequoia* by 125 ft. Its girth is 80 ft., which is less than that of many *Sequoias*, but, as far as height is concerned, it must be considered the tallest living tree in the world.—*Scientific America.*

NEW EDIBLE FUNGUS.—Mr. Colenso call attention to the rapidly-increasing value as an article of export from New Zealand of *Hiruela polytricha*. This mushroom, first described from the East Indies and Java by Montagne, is of various sizes and shapes, some specimens measuring even a few inches. It is found in New Zealand growing on the trunks of trees, both on living and on decaying ones, especially on the latter while standing, particularly on the stems of *Corynocarpus levigata* and on *Melicope ramiflorus*. Both of these are endemic. The former is mostly confined to the sea-shore, where it often forms dense and continuous thickets. The latter tree is scattered plentifully throughout the country. When dry, the mushroom becomes shrivelled up, and is as hard as horn; when wet, it is soft and elastic, almost subgelatinous. It grows in compact gregarious masses. The market for this fungus is China, where it is largely used by the Chinese in soups. It appears that another species of the same genus indigenous in North China has long been an article of commerce. Mr. Berkeley notes of our British species, *H. auriculata*, that it was once a popular remedy for sore throats, and adds that it is still occasionally sold at Covent Garden Market. The New Zealand species is plentiful, and obtained at little cost, the drying of it being an easy matter. Originally the price paid to collectors was a penny per pound; now it is nominally twopence halfpenny, while its retail price in China is five times this. The declared value per ton at the Customs ranges from 33l. to 35l. a ton, and is doubtless much below its real value. During the last twelve years some 1,858 tons of this fungus were exported, chiefly from the ports of Auckland and Wellington, and of a declared value of almost 80,000l.—(*Trans. Penzance Nat. Hist. and Antiq. Soc.*, 1881-85.)—*Nature.*

SWINBURNE (TEA LEAF) CROPPER.—The latest addition of machinery to the production of tea is one which has

often been projected by planters, but which, as far as we know, has never till now been carried to completion. The "Swinburne Cropper," which is simple in construction, though an ingenious and not inelegant machine, is designed to supersede hand plucking altogether on Indian tea gardens, and there can be no doubt that if it fulfils its purpose it will be by far the most important invention which has yet been applied to tea production. The *prima facie* objection to machine plucking is the possible injury which the plants may suffer from the somewhat drastic treatment; but the inventor, who has tried the system on his own gardens in Assam for two seasons, asserts that so far from this danger being a real one the bushes are actually strengthened by systematic pruning. The machine is calculated to do the work of about ten coolies, being worked by one, and as very little skill or practice is required in its manipulation there should be no difficulty in its general introduction. The blades of the cutter are so arranged as to be incapable of taking off more of the flush than is necessary to make good tea, and as the surface is reduced by the process to a perfect level, it follows that on the second pruning all the leaves must be of the same age. The leaf is therefore more homogeneous, and the quality consequently improved, while the quantity, according to Mr. Swinburne's experiments is not diminished.—*Planters' Gazette.* [Our feeling is that the machine may be useful in reducing tea bushes to an even surface, but not that it can supersede the discriminating human hand in plucking.—Ed.]

A MACHINE FOR WITHERING AND FIRING TEA LEAVES was thus recently described by the London correspondent of the *Indian Tea Gazette*:—Were I not bound by promise—owing to the exigencies of the Patent Laws—not to anticipate, by prematurely disclosing them, certain startling inventions, it would interest your readers to learn of a new departure in tea-drying and withering, which will shortly be announced. I am not permitted, however, to do more at present than merely hint at the facts, and most reserve for a riper occasion any statements in detail. Suffice it, that the prospect is that of almost a revolution in the present system of drying, and the appliances will commend themselves to large concerns, the expense being very great in the first instance. It is asserted that leaf can be withered in from one and a half to two hours, and fired in 15 minutes at a temperature of only 200°. In wet weather the rain water is driven off in 15 minutes preparatory to the withering process. The dryers are made in two sizes, and these turn out four maunds and ten maunds of tea per hour, respectively. Neither in the driving off of the rain-water or in the withering, is there any sign of the slightest laceration of leaf, "stewing," "scorching," discolouration, or other injury or deleterious effects, as tested already in a number of experiments with private leaves. The dryer has the power to "fire" at any desired temperature, at the option and under the control of the operator, and whilst "it will effectually fire its charge of tea at 200° F. in 15 minutes, it is equally effective at a lower temperature, provided, of course, longer time is allowed; or if a higher temperature is adopted, it will dry proportionately quicker." You will remember that some months back I informed you of a new withering appliance containing a Blackman Air-propeller in its construction. The appliances I am now alluding to also make use of these propellers both in firing and withering, but the process is not the same as that I then referred to. The principle I hinted at so far back as my letter to you of the 27th March last, since which date a vast amount of scientific acumen has been brought to bear upon this new method, both from the chemical and mechanical sides of the subject; and the scientific data collected and made use of in the construction, whilst bringing theory to ripe perfection in practice, deserves to be rewarded with success. It will soon be before the world to be judged upon its merits, and as withering in rainy weather is a terrible business at present, there is every reason to hope that this new appliance will prove in practice upon the gardens all that its inventors expect from their trials with private.

RICE PEST—GILLA—ACACIA AND DOBIS.

(Notes from proceedings of the Agricultural and Horticultural Society of India.)

RICE PEST.—At the ordinary general meeting of the Society last week, Mr. Wood-Mason, in view of the wide interest in the subject, read a report he had prepared for the Chief Commissioner of Burma on an insect pest which effects paddy. The "Palao Byoo" or "Teindung Lo" (*Paraponya Oryzae*?) a lepidopterous insect, which in the caterpillar stage breathes air dissolved in water by means of tracheal gills. This paper is illustrated by drawings of the creature in different stages as caterpillar, pupa and cocoon, and as the subject of rice pests is so highly important, it will, with the sanction of the Chief Commissioner, be reproduced in the Society's Journal.

THE "GILLA."—A communication was then read from Dr. Bonavia, Etawah, asking for information regarding the "gilla." He writes:—"Dhobis up here and probably also down in Bengal use a curious kind of nut for crimping linen, without using any crimping irons. This nut they call in Ouddh 'gelha' and here 'chain' the latter means a seed. They say it is brought from Bengal and sold in Cawnpore. The pods are long and many seeded, and each is of the size of a small and fat pocket-watch, of a horse-chestnut colour, and with highly polished sides. Dhobies cut one side, and scoop out the kernel; then they introduce two fingers into the cavity, and quickly stroke the damp linen forwards with its polished surface. This crimps it beautifully *erosacaya*. "I believe you have in the hills east of Bengal some kind of acacia which produces a long broad pod with this seed in it. Can you kindly give me the botanical and local name of it from the above description? A new interest attaches to this 'ge'na. A lady took one with her to England to crimp her child's linen 'dhobi-fashion,' and showed it to Mr. Ruskin. He has undertaken, I am told, to set up a village with workpeople, using nothing but primitive implements. He was so interested in this primitive Indian crimping machine, the 'gelha,' that I fancy he has some idea of adopting it in his primitive village. The upshot is that I have been given the task of finding out the botanical name of the tree which bears this interesting crimping implement. It is very efficient, I know the seed, and have seen it used, but have not its botanical name. If you can kindly help me in this matter, you will oblige me and will confer a favour on Mr. Ruskin."

The Deputy Secretary stated that the seed to which Dr. Bonavia referred was that of the *Entala scandens* (Benthau), *E. puresathus* (DC), the *Mimosa scandens* of Linn. and Roxb., a large climber common to many parts of the tropics, and found in Sylhet, Nepal, Ceylon, Java, the West Indies, &c. The Hindustani name *gilla* appears to be commonly used, but it has many other names: *Uriya* Geredi, *Nipalese* Pangra, *Bombay* Gardal, *Ceylon* Mahapuswela, *Tel.* Guilatiga. According to Royle (Illus. of Botany of the Himalayas, Vol. I, p. 183) the seeds are used by the natives for washing the hair, and *Poir.* (p. 256) says it is used by the ghaut people as an anti-bile. Drury mentions that it is employed as an emetic in Java. The seed is made into snuff-boxes in the West Indies, and according to Dr. Birdwood (Cat. of Vegetable Products of Bombay Presidency) "the pods are used by the police here." Although the pods are of great size, sometimes six feet and more long and 4 feet 5 inches broad, it seems a strange article for the police to use. Gamble says "the seeds are eaten after roasting and steeping in water, the kernels are used by the Nipalese for washing the hair, and in Bengal by washermen for crimping linen." The seed is sold in the bazaar for medicinal purposes, and is used in a powdered form; it is administered as a stimulant; but this use is not mentioned by Oshlagnessy or others. Dr. Watt, in his Economic Products of India, says that "an oil is made from the seed, the properties of which are unknown." But the use made of it by the dhobis seems the most general.—*Pioneer*.

BABUL TREE PODS.

Messrs. Arbutnot and Co. forward a report from their Home correspondents on the probable value of seed-pods of the babul tree (*Acacia Arabica*), samples of which they had sent to England at the instance of this department. It will be seen that the pods are not valued at more than from £8 to £10 per ton. At this rate it is hardly likely that it would pay to export the seed-pods. Mr. Wardle does not regard the babul seed-pods as of many value for dyeing. For tanning they are not as valuable as several cheaper substances. Mr. Wardle, however, suggests "that the best way of making this product useful would be to extract the tannin from it where it grows, and as probably the bark and even the branches of this acacia may contain more tannin than the seed-pods, all could be boiled down together and a better average yield of tannin obtained." The attention of the Forest Department may perhaps be drawn to this suggestion. I have to add that, at the request of this department, Messrs. Wilson & Co. of Madras are about to send a consignment of the babul bark and pods to Australia to see if a market can be found for them in that colony.

TO THE UNDER-SECRETARY OF STATE FOR INDIA.

I have now the honor of reporting on the sample of crushed seed-pods of the babul tree (*Acacia Arabica*) which accompanied your letter of December 27th, 1881, requesting me to give my opinion respecting the commercial and tinctorial value of this substance.

I have carefully examined the seed-pods, both chemically and tinctorially, and I beg to submit the following report:—

"Theoretically I do not regard this substance as of any value. The coloring-matter contained in it is very small, and is only sufficient to dye silk or cotton a fawn color. It is not possible to obtain from it directly either violet or black as stated in your letter, but it has other properties which are those of a mordant.

"Its value in my opinion consists only in the amount of tannic acid contained in it, and it is only on account of this that I believe it to be used in dyeing. Its tannic acid both helps to form a black with iron salts and also helps to brighten and fix some other dyes, both vegetable and mineral colors.

"The following laboratory notes will explain themselves:—

"I estimated the amount of tannic acid by Löwenthal's permanganate process and found the quantity to be 10.26 per cent of tannic acid or tannin, calculated in the same way as in estimating the tannin in sumac, galls or myrabolans, but which mode of estimation would be equivalent to 15.39 per cent of tannin, similar to that contained in oak bark, valonia or extract of chestnut.

"Comparing the seed-pods, then, with these substances, they contain only a very low percentage, because good qualities of sumac contain 15 to 20 per cent of tannin, of galls 65 to 77 per cent, of myrabolans 20 to 40 per cent, of oak bark 8 to 13 per cent, of valonia 25 to 35 per cent, and of chestnut extract 20 to 25 per cent.

"Like other tannin substances these seed-pods impart weight to silk, the tannic acid uniting with the fibre, probably much in the same way as it does with hide or skin forming leather. The amount of weighting matter in these seed-pods absorbed by silk is equal to 17.2 per cent of the weight of the pure boiled-off silk or 16 oz. of silk in gum when boiled off and weighted with the extract from the seed-pods becomes 14.07 oz. as against 15 oz. in the case of sumac.

"I send with this report the following illustrations:—

One skein of silk dyed blue-black.

Do.	do.	black.	
Do.	do.	green.	
Two skeins of	do.	red.	
One skein of	do.	mauve.	
Do.	of	do.	violet.
Two skeins of	do.	do.	brown.
Do.	of	do.	drab.

"The blacks have been dyed with iron salt, the colors each various tinctorial matters, chiefly aniline colors, with having received a base of tannic acid by the silk

having been immersed in a strong solution of the tannin extracted from the seed-pods.

"As to the commercial or money-value of this substance, the price of sumac being to-day £16 per ton, it would be worth not more than £9 per ton. It will be sufficient to compare its market-value with sumac only.—THOMAS WARDLE.

"N.B.—On further consideration I would suggest that the best way of making this product useful would be to extract the tannin from it where it grows, and as probably the bark and even the branches of this acacia may contain more tannin than the seed-pods, all could be boiled down together, and a better average yield of tannin obtained.

TO W. T. THISELTON DYER, ESQ.

"You will observe the amount of tannin is considerable, being more than that given by balonia, which is generally 25 per cent. The color is also very good; it would not give the same weight as balonia, but I imagine would make a leather more like oak bark. The pods must be gathered ripe so that the seeds may be taken out, as they are 60 per cent of the weight of the pod and contain no tannin. The bark of the babul is also good, about 20 per cent, but it is not so clean, and has a good deal of roughness, which adds to the cost of freight. Now, as to the probable value, that is another matter: balonia is worth now (good) £17 per ton. But tanners know the value of that, and there is no difficulty in disposing of it. But every new material has to run the risk of the market; it may be at the wharf for months without being looked at, until some prominent man tries it. It should certainly be worth at least £10 per ton, but I could not guarantee that price.—W. N. EVANS.

KEW AND ITS WORK.

(From the *Gardener's Chronicle*.)

VALUE OF VEGETABLE PRODUCTS.—Just consider for awhile what a large proportion of the food and clothing of mankind has to be derived from the vegetable kingdom. Last year the value of the agricultural crops grown in Great Britain alone amounted to £136,000,000 sterling. The value of the grain and flour imported amounted to £67,000,000 sterling. These two added together amount to over £200,000,000, or £6 per head for each person in the country. The exports of the United States, mainly grain and flour, amounted last year to 740,000,000 dollars, or nearly £150,000,000 sterling. The total exports and imports of India last year amounted to £131,000,000 sterling, and of these materially over £100,000,000 belonged directly to the vegetable kingdom in one form or another.

THE FUTURE OF THE ANGLO-SAXON RACE.

And consider, also, to what a large extent the future fortunes of the British Empire depend upon a proper development of the capabilities of our colonial possessions to produce the vegetable crops that are useful to the human race for food, clothing, medicine, and other economic uses. Our population is now 350,000,000. What will it be in a hundred years' time? Notwithstanding emigration, the population of Great Britain has doubled in the last half century, whilst that of France, that in the seventeenth century amounted to 38 per cent of the whole population of Europe, now hardly attains 13 per cent. To 350,000,000 add 50,000,000 for the population of the United States, which has increased above 20 per cent during the last ten years. The estimate recently put forward by Mr. Gladstone does not seem at all an extravagant one, that in a hundred years' time it is not improbable that the English-speaking race and its subjects will mount up to a population of 1,000,000,000. How all these men and women and children are to be supplied with needful food and clothing is a problem that will try to the very utmost the knowledge and the foresight and the energy and the enterprise of the generations that are to follow our own.

And think of these things, too, from a social and political point of view, side by side with this growth in population and this wonderful revolution that has been brought about by railways and steamships and tele-

graphs, how we have been growing gradually more and more luxurious in our habits of daily life, and how the spread of education and the popularisation of art and the enormous increase which has taken place during the last generation in the number of those who possess incomes of moderate competence have increased the quantity and quality of the things which as a nation we consider that we need to enable us to live our daily lives in contentment and comfort, and how that now, more than ever, the mass of the nation will have an influence in making the laws and controlling the great issues of our foreign and colonial policy.

THE POWER MAN HAS OF SPOILING THE WORLD.

And reflect also upon the melancholy testimony borne by the historic record how through man's greediness, improvidence, and quarrelsomeness many of the countries that supported the great nations of antiquity have been robbed of their natural beauty and fertility. Pass round the basin of the Mediterranean and compare the state of things now with what it once was in Persia, in the valleys of the Euphrates and Tigris, in Syria, Palestine, Asia Minor and Greece, in Northern Africa, in Cyprus and Sicily, and in a lesser degree in Spain and Italy. Everywhere we find the same sad contrast of wide tracts of country that were once fertile corn-land now changed to sandy deserts and pestilential marshes, aqueducts, and roads ruined by neglect and violence, vineyards and Olive gardens, and groves of Date Palma ruthlessly destroyed, and mountains that were once sheltered by groves of Oak, and Pine, and Chestnut, changed to bare stony ridges, of which the water springs have been dried up, and the grassy sward parched away, and the coating of alluvial soil which the roots of the trees kept in its place carried away by the rain to silt up the rivers and harbours of the lowlands. Contrast the Carthage of Regulus and Scipio Africanus with the Tunis of to-day; or the Cyprus that was ruled by the Venetians, when the island maintained a population of 1,000,000, with the Cyprus which was handed over a few years ago by the Turks to the English, when the population had sunk to 140,000; or the Lebanon of to-day with the Lebanon of Hiram and Solomon; or the Assyria of to-day with the Nineveh of Jonah, Sennacherib, and Asurbanipal; or the Babylonian plain as it is now with what it was in the days of Nebuchadnezzar and Belshazzar. We are told by Herodotus, who visited the city seventy years after it was taken by the Medes and Persians under Darius, that the walls of Babylon formed a square 50 miles in circumference, and that the Bablylonian territory supported, not only its own resident population, but also the whole retinue and army of the Persian king for four months in the year, that one of the satraps owned 16,800 horses, and that his dogs were so numerous that four large villages were excused from all other taxes on condition of supplying them with food. He says that the soil of the Bablylonian plain was so fertile, that of Wheat it yielded a return of two or three hundred-fold; that Millet and Sesamum grew to a great size; and that over the whole plain the Date Palm flourished, bearing fruit abundantly. Now for centuries the plain has been a sandy desert, without any regularly settled inhabitants, and the visitor sees only a few Arab tents and frail reed huts, furnishing an impressive contrast to the ruins of the great walls and temples, the only trees now a few Willows and Tamarisks along the river, and here and there a spiny Acacia scattered over the sand.

RECENT CHANGES.

About the plants that have been cultivated for many centuries, such as the Vine and the Hop, the cereal grasses and the common fruits and timber trees of the north temperate zone, the farmers, gardeners, and foresters who have been working at them for generation upon every phase of growth and every modification of soil and climate know far more about their different varieties and the situations they need in order to be grown successfully, than botanists, whose attention is not concentrated upon the plants which are specially valuable from an economic point of view,

which do not number more than perhaps a hundred species out of the 100,000 with which the botanist has to deal. But even of most of these during the last generation, as population has increased and the carrying trade has been completely revolutionised by steam and electricity, the countries in which they are grown have been changed very materially. The total amount of foreign food imported into Great Britain in 1864 was an average of 28s. per head. In 1883 it amounted to 69s per head, the difference representing a lump sum of £77,000,000 per annum. In 1864 the total amount of foreign grain and flour imported into the country was worth £20,000,000 sterling; in 1883 it cost £70,000,000—an increase of £50,000,000 in twenty years. Before the war of secession in the United States the Southern States had almost a monopoly of the trade in raw Cotton; last year the value of the raw Cotton exported from India was between £14,000,000 and £15,000,000 sterling. In 1840 China had a monopoly of the Tea trade. In 1883-4 the value of the Tea exported from India was 408 lakhs of rupees, or over £4,000,000 sterling. In 1850 the area under cultivation of Tea in India was not more than 1,000 acres, yielding an annual crop of £250,000. In 1880 the area under cultivation was 206,700 acres, yielding an annual crop of 40,000,000 lb., representing an invested capital of £15,000,000 sterling; an annual expenditure of £2,000,000 in wages, and, at the rate of five to an acre, yielding means of subsistence to over 1,000,000 natives. The annual export of Coffee from Ceylon, instead of being now as it was in the years between 1865 and 1878, £5,000,000 sterling a year, has dropped to £1,500,000.—J. C. BAKER.

GIBBS'S TEA WITHERER AND JACKSON'S AND DAVIDSON'S DIRERS

have been thus noticed in the London letter of the *Indian Tea Gazette*—

I think I told you that lately I went out to Mr. Gibbs's quaint old place Gillwell Park in Essex, to inspect a model of his proposed withering machine. Since then a laudatory notice of some length upon Mr. Gibbs and his inventions has appeared in the *Times*, but as very little is said about his drier for tea, and that much is already well known, it is hardly of special interest to your readers. His model is an adaptation of the principle of his drier, only the witherer is to be probably constructed of tanned canvas stretched upon a wooden frame, thus reducing the cost enormously, as also the weight. It is to work at a much reduced temperature, of course. I saw privet leaves, dripping wet as taken from a bucket of water thoroughly dried of all surface moisture, without the slightest apparent injury to the leaves, after having been passed *once* through the cylinder of the model, the initial temperature being about 200° Fahr. The same leaves were passed through a second time, but at an initial temperature of only about 150°, and on falling out the leaves were to all appearance and touch perfectly withered. The cylinder was revolved *very* slowly by hand. The hot blast was filtered through asbestos, a thickish pad. Of course, the working temperature was much below the initial temperature, as cold-air below 60° Fahr. was drawn in at the open end of the cylinder from the room, which cool air, of course, mixed itself with the hot-air, as soon as the latter left the air-duet. The fan was turned at much less speed than when used for *drying*. So far all promises well, as the machines being cheap, a sufficient number could be used, requiring less than a donkey-power each to do the largest quantities of leaf. And I saw quite sufficient to satisfy me that in "intelligent" hands very little practice would be required to produce, to all appearance and test of touch, perfectly withered leaf in the most rainy of rainy weather. But! and there is always a *but*—it has seemed to me that, in the discussion going on about withering, and in the minds of inventors, too, one point is kept too much out of view. We all agree that nature has a stage at which the best possible conditions rule for effecting given changes, and that withering comes

under this—may I call it, Law. We can, doubtless, by experiments, find out the best conditions, and bring about those conditions *artificially*, for so withering tea leaves as to turn them out perfect to all appearance and test of touch. But this is not all that is necessary by any means. The leaves may be of a lovely uninjured appearance and soft as down, but, if this effect has been produced *too rapidly* to the detriment of certain invisible, intangible, yet important conditions, the leaf so withered, will be found very disappointing when the time for its "fermentation," after the rolling, has come, and gone, and the leaf is found to be still "unfermented!" This drawback I think might be overcome by steaming the leaf after rolling, to add the moisture necessary to "fermentation" which may have been unwittingly driven off *in excess*; the worst of it all is, however, that this vital point, upon which success will hinge, is just the one the inventor cannot detect, or even experiment upon *in his country*.

Mr. W. Jackson has returned for a time, and at dinner two nights ago, on his passing through Town gave me a most satisfactory account of the success his driers have met with in Ceylon. We first met at the installation of his first completed rolling-machine in the Sibsagar district, in 1875. I think it was, and time seems to have treated him very kindly since then, to judge by his appearance and active gait, the latter full of characteristic energy and "go." His driers have evidently now fulfilled his anticipations, and he is fully armed with those latter-day weapons, reliable testimonials, with which to demolish all hesitation on the part of cautious Directors. The machines are costly, he allows, *but*—there it is gain—they are automatic and so require the minimum of attendance; they are durable and simple in construction, and will not entail frequent repairing; the tea is never handled or submitted to friction or any motion likely to injure its bloom; and the outturn is considerable, whilst the space occupied is very trifling.

Mr. Davidson the other day, whilst over on a visit from Belfast, showed me a large model of his new "T-Sirocco," and explained its various advantages over the earlier "T-Siroccos" first sent out. The amount of detailed experiment personally conducted by himself to arrive at the present improvements must have entailed months of close application, and constant labour and thought. The improvements chiefly related to the construction of the stove which has been enlarged and rendered more durable, and capable of supplying a vastly increased volume of heat; to the insertion of dampers above the stove to retain and thereby prevent loss of heat, whilst getting up the temperature previous to commencing drying; and last, but by no means least, to the very perfect equalization of temperature at all points under the trays. To obtain the latter object, nothing but actual experiment could be relied upon, and hundreds of trials in arranging the new draught-guides, their shapes and positions, were necessary before the present satisfactory result was obtained. The temperature is now so equalized as to show no greater variation than 50 Fahr. at any two points.

Mr. Davidson has good cause to anticipate a vastly increased working-capacity for these new T-Siroccos, and a much longer life for the stoves. It was found that the excellent quality of the fire-bricks employed in last year's stoves concentrated the heat too intensely upon the iron portions, getting up the temperature at these latter points to almost smelting heat, by compelling these to receive not only their own share of the heat, but that of the surface of fire-brick too, which latter radiated its share of heat, and bestowed it so to speak upon the respective iron portions. The fire-bricks have in consequence been done away with the temperature thereby being now evenly distributed over the whole interior surface of the stove, should not be found too severe, and the stove being increased in size, its heating capacity has been increased.

Mr. Davidson, I might mention in passing, has been lately induced, in consequence of repeated requests, to start selling tea in pound packets from his "Sirocco

Works." He complied very reluctantly after considerable persuasion, his faith in the venture not being great. He is known, however, as the maker of Tea Drying Machinery over there in Belfast, and the public seem to argue, that as he has so much to do with the manufacture of tea he must know where to obtain it good, for without any push on his part, this retail business has suddenly attained a huge success, much to Mr. Davidson's surprise, and he has already the second largest business in Belfast, within a few mouths of starting! He deserves to succeed in all he does, his friends think.

A MARKET PRODUCE SAMPLE DEPÔT.—Amongst the most practical of the market arrangements in Berlin is that recently inaugurated by the market authorities in that city. A permanent exhibition is now established of samples of all articles of daily consumption, and includes those sold by grocers, dealers in colonial wares, luxuries, drugs, country and garden produce of every kind. The purpose of the sample depôt is to facilitate the sale of such goods by means of the permanent exhibition, and by the publication of future sales and offers; and, further, the object will be attained—1. By means of a show of samples, sample books; by exhibiting price currents, telegraphic announcements, address cards, prospectuses, &c., which will be open to public inspection without charge. 2. By undertaking the business of a commission agency and acting as representatives of merchants, importers and exporters. 3. By advertising in the public prints free of charge to those showing samples. 4. And by undertaking to carry out sales by auction on the behalf of inland or foreign traders. The exhibitors will subscribe for the services of the sample depôt authorities the sum of 20 marks yearly, and the legal tariff fixed for commission agents. The space required by the exhibitor for the due exhibition of his wares will be allotted without charge. These arrangements would seem to be well suited to both buyer and seller alike, as the former can inspect, free of cost, any article he is desirous of buying either wholesale or retail, and the latter is certain of finding a market for his goods without any further charges than those mentioned. Measures will be taken to prevent any abuse by dishonest persons of the information at the disposal of the depôt by the fees afforded only to buyers of known probity.—*Gardeners' Chronicle.*

SHAND'S NEW TEA DRIER, CEYLON.—On the afternoon of Wednesday last Mr. C. Shand's New Flue Tea Drier was open to public inspection at the St. Sebastian's Store, Colombo. In the absence of any green leaf on which to experiment, nothing in the way of a conclusive trial was attempted, nor could any information be afforded as to the comparative advantage of the invention in regard to the degree of heat attained from any given quantity of fuel. The construction of the drier is very simple. The one on view is a brickwork chamber, 34 feet long, 3 feet wide, and about as much in height; two rows of iron plates are built horizontally into the brickwork, 8 inches apart. The lower are a foot or so from the floor of the chamber, and the upper ones some 3 inches below the top of the outside walls. A furnace at one end furnishes the heat, the smoke passing under the lower row of plates, which are made absolutely smoke-tight, and escapes at the other end of the chamber. The space between the plates constitutes the air flue; air is admitted on one side above the furnace, and heated in the flue, and like the smoke escapes at the other end. The upper surface of the top row of planting of the flue forms the drying platform, on which the tea trays are placed, as in the ordinary system of chula firing, or moved along after the manner of a "Sirocco." A new idea was under experiment at St. Sebastian's. A wooden staging had been erected over the flue, in which three rows of trays could be placed, divided from each other by thin metal sheets, something in the way of the fret Siroccos that came to Ceylon. The thermometer registered 300° at the time of the experiment, and

the air in the flue was apparently of an even temperature throughout or nearly so. In our opinion, as well as that of several present, there is room for considerable economy in heat and fuel, to which no doubt Mr. Shand will give his early attention. The great advantage offered to planters in the Flue Tea Drier is that the furnace can be made to consume anything that can be used as fuel, whereas the old chula system necessitated the use and manufacture of charcoal, which, on many estates, is expensive, and on others impossible, to obtain. A modification and adaptation of Mr. Shand's invention will doubtless supply a desideratum on small estates, where the larger and more expensive machines are beyond the means of the proprietor; but we doubt much any great adoption of the Flue Drier as it now stands. We understand Mr. Shand asks for a royalty of R100 on each Flue Drier erected for use, and is prepared to supply the iron plates at some 50 per cent below the current prices in the Island.—Local "Times."

DAMAGED TEA AND CHESTS.—Our readers will no doubt recollect the discussion which arose some short time ago in reference to certain packages of Ceylon tea arriving in the home market in a damaged condition; and various propositions were put forward as to the cause of this injury to the contents of the packages. It was by some supposed to arise from the unseasoned or unsuitable wood of which the tea boxes were constructed; this had tended to corrode the lead, and damage the contents of the case. Again, it was suggested it was the action of the insufficiently or improperly cured tea itself, which acted on the lead. In any case the tea was damaged, and in one instance gave occasion to legal action between the parties through whose hands the damaged tea had passed. A new light has now been thrown upon the subject by Messrs. Geo. White & Co., of London, who, in their "Ceylon Tea Memoranda", just to hand, state as follows:—"It is important that shippers should be careful to prevent teas acquiring a druggy flavour, as the sale of several parcels has been prejudiced on account of this lately. Tea, as is well known, easily becomes impregnated with any strong scented article, so that it should not be placed near deleterious substances, either in the tea-house, godowns, or on board ship. We believe this is, more often than not, contracted while on the voyage home; so that it would be advisable to ship in steamers used to the trade, the bills of lading for which have a special Tea clause." We need hardly point out that similar contamination with other articles of produce has been a common complaint in all courses of shipment in every part of the world, though we are not aware of any serious instance of it in regard to tea. We should have thought that the lead-lining to tea boxes would have acted as a sufficient guard to exclude the scent attaching itself to the tea, but probably it impregnates the boxes first, and when the lead is opened the scent gains admittance. A large number of cases impregnated with a powerful scent might for a time contaminate a whole store, and so affect the tea in course of bulking. There can be no doubt that in course of time the import or manufacture of tea boxes will constitute a very large and important industry in Ceylon, and it would be well to collect all information and details bearing on the suitability or otherwise of the wood employed for the cases, not omitting that of its susceptibility to contamination from extraneous odors. Protection from contamination on shipboard on the voyage home will, we suppose, be afforded when exports largely increase, and exporters will have it more in their power to dictate terms to the carrying steamers. A ship load of tea is at present unheared of, but the time will come when such a thing will be quite as likely from Ceylon as it has been from the tea ports of China, and in such case a special tea clause in the Bills of Lading will be no novelty in Colombo. Rough country-made packages would, we imagine, be more likely to be damaged by contact with powerfully scented articles, than the neat close-fitting machine-made or imported boxes such as those brought to our notice by Mr. Deane.—*Ibid.*

DISEASES OF PLANTS CAUSED BY THREAD WORMS.—M. Prillieux has recently published a paper on this subject referring to the nematoid worms which (1) penetrate the interior of leaves and cause their decomposition; (2) which produce galls on the flowers of grasses; (3) which produce galls on roots; and (4) those which attack Beetroot. The two first worms belong to the genus *Tylenchus*. The two last are species of *Heterodera*.—*Gardeners' Chronicle*.

THE GIANT CATERPILLAR.—It may interest some of your readers to hear that the caterpillar figured in your issue of the 20th is very commonly met with in the hill country of Ceylon. Owing to its resembling in colour so closely the bark of the trees on the leaves of which it feeds, it is not readily noticeable, and I usually discovered it whereabouts from the ground beneath the tree being strewn with droppings. It is necessary to handle it with great caution, as the sharp bristles on its back become at once detached on coming in contact with the naked hand, causing intense irritation. When about to turn into the chrysalis state, the larva spins itself a cocoon—or, rather, half a cocoon—firmly attached to the stem, or one of the branches, of the tree on which it has been feeding. From the chrysalis, in course of time, emerges a large dark-coloured moth, the sole mission of which appears to be to lay eggs, since whereas it is endowed with an enormous body, its wings are quite out of proportion, being ridiculously small and quite unequal to the task of raising it from the ground; indeed, it was commonly known to us as the "wingless moth." The male moth is totally different, being less than half the size of the female, with fully developed wings, shaped like those of the privet hawk moth, and a tapering body. I think the larva of the male must also differ from that of the female, since of several specimens which I kept in captivity from the caterpillar to the moth stage, all proved to be females.—W. F. LAURIE, Charlton, Staines, Feb. 25.—*Field*.

DR. BUCHNER ON THE CAMEROONS.—Dr. Max Buchner gave a lecture on Wednesday in the Architektemhaus, Berlin, in connection with the German Colonial Association, on the value and the future of the Cameroons. Dr. Buchner said that the value of this possession was at present small, but the elements of great prosperity were unmistakable. The present exports came from a zone of production of not over 100 kilometres reckoned from the coast inland. What lay beyond was as yet completely unknown. The Cameroons possessed a rich volcanic soil, which extended from Fernando Po in a north-easterly direction, and the country had also an abundance of rain, which was a point of great importance. It could not be said that there was any great mineral wealth; at least, no signs of it had thus far been detected. As a plantation and trading colony the Cameroons were of undoubted value, but to encourage emigration thither on any great scale would be criminal. The products of the land included the oil palm, the cocoa palm, coffee and cocoa, quinine, indigo, caoutchouc, rice, and sugar. The oil palm only grew wild at present, but it could be cultivated. The cultivation of the cocoa-nut palm had also been neglected. As to coffee the question of sale had to be considered, and the market was now overrun. Cocoa would pay better, and this could be easily cultivated. The Cameroonian mountains offered an excellent ground for cultivating quinine, while rich and sugar were to be grown in the lowlands. Dr. Buchner spoke of the necessity of opening up the inland region, and hinted at the possibility of a railway proving in time remunerative. Meanwhile beasts of burden would have to be used—especially oxen, as they thrive better and were capable of more work than horses or asses. As elephants were very abundant there—more so than in any other part of Africa—an attempt should be made to tame them. The ultimate opinion expressed by Dr. Buchner was that the Cameroons would pay the costs of keeping and administering it. Africa as a whole was regarded as a poor country, but the Cameroons belonged to the richest parts.—*Kohl's German Trade Review*.

THE MADRAS TEA INDUSTRY.—The Madras tea industry is doing well. There are 84 plantations, all in the Vizagapatnam, Madura, Nilgiris, and Malabar districts. These have a total area of 7,553 acres, of which little more than half is actually under cultivation. Last year the outturn reached 398,045 lb. In Travancore there are 27 plantations, occupying a cultivated area of 1,487 acres. The total outturn was 105,740 lbs, of which the whole was black tea.—*Indian Tea Gazette*.

THE PHILOSOPHY OF TEA DRYING.—Mr. Gibbs (Gibbs and Barry) writing to a contemporary, remarks as follows:—"The whole philosophy of rapid economical and thorough drying may, I think, be summed up in these three points.—1. That the tea should be kept in gentle but effectual movement, so as to separate every leaf, from every other leaf and allow the dry air to get at both sides. 2. The application of as much air as can be introduced without blowing the charge out of the machine. 3. The skilful adjustment of the temperature of that air so as to obtain the highest drying power without injury to the product."—*Indian Tea Gazette*.

ASCENT OF THE SAP.—The precise course followed in its upward course by the water absorbed by the root has been a matter of controversy. Sachs, and many with him, contend that the sap rises through the walls of the vessels and ducts by a process of imbibition. Others, again, such as Böhm, Hartig, and Vesque assert that the fluid does not pass up the sides of the vessels by imbibition as water would pass up a lump of sugar or a piece of sponge, but that it passes upward through the central cavity of the vessel. The matter might be settled if it were possible to seal up all the vessels of a branch without in any other way obstructing the process of transpiration. Thus either the branches would wither when the vessels were all sealed up, showing that their cavities are the conduits, or they would remain fresh, even though the vessels were obstructed, when, of course, the inference would be that the water passed up the side walls, and that the obstruction of the central cavity was unimportant. Professor Errera, of Brussels, and his pupil, M. Laurent, have lately put the matter to the test. They made a mixture of twenty parts of gelatine to 100 of water, and added to it a quantity of Indian ink, previously ascertained to have no ill effect on the plant. The gelatine melts at 33°C. (92°F.), and remains fluid till the temperature falls to 28°C. (83°F.). A branch of a Vine (*Vitis vulpina*) attached to the trunk, was bent so that the base of the curve was plunged into the melted gelatine at a temperature of 30°–33°C. (say 86°–90°F.). This done, the branch was severed from the trunk, care being taken to keep the branch, while the cut is made, beneath the gelatine. Under these circumstances it is easy to trace the ascent of the gelatine to a height of from 4 to 8 inches. When the branch is cut in the manner indicated it is immediately placed in cold water, when a small thickness is again cut from the end of the branch, so as to secure contact with the water of a clean surface in which the gelatine occupies the cavity of the vessels, alone without covering the cut ends of the walls of the vessel. All branches in which the cavity of the vessels is thus blocked, wither within a few hours, while test branches, cut like the others, under water or in air, and treated exactly in the same way except as regards immersion in gelatine, remain unwithered. If the portion of the branch infiltrated and obstructed with gelatine, be cut away, and the freshly cut surface be now immersed in water, it preserves its freshness. From these experiments, M. Errera concludes that the "water of transpiration" ascends through the cavities of the vessels, and explains in this manner the fact that the upward current passes through the portion of the wood formed in spring, and which is marked by vessels of large diameter, rather than through the autumn-formed wood where the vessels are narrower and thicker walled—the latter condition favourable, as it would seem, to imbibition.—*Gardeners' Chronicle*.

TEA CULTIVATION BY NATIVES IN CEYLON.

For several years back, we have regarded tea cultivation as an industry peculiarly adapted to the Sinhalese villagers and Tamil squatters or colonists in the Western, Central and a great part of the Southern provinces of Ceylon. We felt quite sure that as soon as the Ceylonese people saw what the European planters were doing with tea on all sides of them, their ambition to own tea bushes and gardens of their own would be stirred up. In 1837, when the exports of coffee from European plantations practically commenced from this island, the total shipments were 34,000 cwt., of which probably more than half came from native holdings; and thirty years later, in 1868, the native exports were equal to 218,000 cwt. against 780,000 of plantation coffee.

Similarly and even in a larger ratio may we expect the development of a native tea-growing industry, and, unlike our morning contemporary and Dr. Trimen, we do not see why the villager with his little garden of bushes should not get the full reward of his labour. Factories are certain to be so multiplied that the purchase of the native cultivator's leaf at remunerative rates can always be secured within easy distance. Of course, there will be some native gardens of considerable extent. Indeed, they are likely to range from a few bushes or a few acres to clearings of 20 to 50 acres; while other native proprietors will compete with their European neighbours in planting up old coffee estates, which have had a rest under lantana or ehena, with tea. Eventually, we do not think the estimate is at all exaggerated that world give 109,000 acres as the area to be planted with tea by Sinhalese and Tamils on their own account in Ceylon, giving in crops, when in bearing, some 20 to 30 million lb., to add to the 45 to 50 million lb. which the regular plantations are expected to yield. The process of planting native tea gardens has already begun and we may depend upon it that it will henceforward go on at an accelerated rate.

TEA AND TEA COMPANIES.

CALCUTTA, March 21st.

TEA.—The report of the agents of the Good Hope Tea Company shows that the output was 1,646½ maunds, which sold at an average of As. 12.6 per lb., against 1,301 maunds at As. 9.9 per lb. in 1881 and 868½ maunds at As. 9.6 per lb. in 1883. The gross revenue for the year was Rs. 1,03,040 and the charges Rs. 57,9, leaving a profit of Rs. 46,601, which includes Rs. 160 brought forward. Dividends aggregating 40 per cent. have been declared, and a balance of Rs. 6,601 is carried forward. The estimate for 1886 is 1,800 maunds at an outlay of Rs. 17,540. The capital of the Company is one lakh, and the area of the garden 880 acres.

The report of the agents of the Lower Darjeeling Tea Company shows that the output was 579½ maunds, or 46,360 lb., against an estimate of 700 maunds, the average price realized being As. 9.5. The output for 1884 was 51,140 lb., realizing As. 7.9, and that of 1883 was 32,872 lb., realizing As. 10 per lb. average. The gross revenue was Rs. 29,479 and the expenditure Rs. 24,421, leaving a profit of Rs. 5,057. Interest paid amounts to Rs. 1,783, and the debit balance from last year is Rs. 21,27, so that the year 1885 closed with a sum of Rs. 5,943 at debit of profit and loss, which the managing agents hope will be cleared off at the end of this season. The estimate provides for 680 maunds of tea at an expenditure of Rs. 21,400.

The report of the agents of the Phoolbaree Tea Company shows that the output was 247,774 lb. against an estimate of 290,000 lb.—the deficiency is laid to mosquito blight. The average price realized was As. 10.8 against As. 9 last year. The gross receipts were Rs. 1,66,337 and the expenditure Rs. 1,01,388, leaving a profit of Rs. 64,949 interest on debentures, commissions, and one-fourth of the new buildings and preliminary expenses reduce the amount available to Rs. 16,185. Dividends aggregating 9 per cent. have been paid, and a balance of Rs. 105 carried forward. The estimate for 1886 is 3,400 maunds, with about the same expenditure as 1885.

The report of the directors of the Luckadoorah Tea Company shows that the output was 9914 maunds against an estimate of 1,000 maunds. The average price realized for the tea was As. 10.41 per lb. The gross revenue was Rs. 53,232 and the expenditure, including some new cultivation, was Rs. 45,111, leaving a profit of Rs. 8,121; and adding the balance brought over from last season the amount at credit of profit and loss is Rs. 16,231. Dividends aggregating 7 per cent. have been paid and Rs. 31 carried forward. The estimates for 1886 provide for an output of 1,050 maunds of tea and 40 maunds teaed at an expenditure *locally* of Rs. 31,000. The area under tea is 326 acres, of which 229 are in full bearing.

The report of the agents of the Washbarie tea garden shows that the output was 1,686 maunds against an estimate of 2,100 maunds. Mosquito blight accounts for the difference. The average price realized was As. 11.2 as compared with As. 9.3 last season. The gross revenue was Rs. 62,624 and the expenditure Rs. 57,557 leaving a net profit of Rs. 5,067, and with the balance brought forward from last season, the amount available is Rs. 81,804. A dividend of 10 per cent. has been declared, Rs. 4,451 written off Factory and Machinery accounts, and a balance of Rs. 3,353 carried forward. The estimate for next year is 2,000 maunds, and the expenditure on this basis works out 6½ annas per lb. laid down in Calcutta.

The report of the directors of the Eastern Cachar Tea Company shows that the output was 4,504 maunds against an estimate of 4,750 maunds. Heavy hailstorms account for the difference. The receipts were Rs. 1,89,592 and the expenditure, including debenture interest and Rs. 1,900 totalled up Rs. 69,164, leaving a profit of Rs. 29,431, which the balance from last year swells to Rs. 25,569, or a little over 3½ per cent. on the capital. The estimates of the coming season are 5,000 maunds at an expenditure of Rs. 69,158.

The report of the directors of the Loubah Tea Company shows that the output was 5,293 maunds against an estimate of 5,265 maunds, the average price realized being 11 annas. The gross revenue was Rs. 28,754 and the expenditure Rs. 11,613, leaving a profit of Rs. 17,139, which the balance brought over from last season increases to Rs. 33,021. Dividends aggregating Rs. 12½ per cent. have been declared; Rs. 10,000 written off extension account, and a balance of Rs. 10,521 carried forward. The estimates for the coming season are for 5,500 maunds at an expenditure of Rs. 20,111. The area under tea is 1,567 acres.

The report of the Directors of the Grob Tea Company shows that the output was 2,875 maunds against an estimate of 3,370. Season unusually wet and cold. The total expenditure, including interest on outlay, was Rs. 122,654, and the gross receipts Rs. 152,740, showing a profit on the working of the gardens of Rs. 30,086; and after paying interest on the mortgage, manager's commission, &c., there is a balance at credit of profit and loss of Rs. 17,347 to go in reduction of the mortgage debt of Rs. 1,31,698. The estimates for the coming season are for 3,050 maunds at an expenditure of Rs. 1,18,302. The area under tea is 798 acres, and the gardens stands at Rs. 58,606, the capital being 5 lakhs.—*Pioneer*.

SALT WORKS IN COLOGNE.

Kainit, as a substitute for salt and far more than a substitute, in consequence of the large proportion of potash, having been recently noticed in our columns, the following account of the German mines whence this and other valuable salts are derived will be interesting to our readers:—

REPORT BY CONSUL WARNER IN STASSFURT.

For many years the saline beds in Northern Germany have been yielding immense supplies of rock salt, and as large quantities of the products of this salt are annually imported into the United States for agricultural purposes, some statistical information on their production may not fail to be of interest, especially to that class of American agriculturists who use the quality called kainite (the hydrated chloride of potassium and sulphate of magnesium.)

The raw potash salt contains on an average the following ingredients; Chloride of potassium, 16.8 per cent; chloride of magnesium, 26.5 per cent; chloride of sodium, sulphate of magnesium, 11.6 per cent; chloride of calcium, 0.4 per cent; insoluble matter, 0.8 per cent; and water, 30.8 per cent.

The importance of these beds has been constantly increasing during the last twenty-five years by discoveries of other almost inexhaustible supplies of potash salts in and around the cities of Stassfurt and Aschersleben. These two places are within a few miles of Magdeburg, the capital city of the rich province of Saxony, in the Kingdom of Prussia.

Besides the great value of these salts for manuring purposes, kainite taking the lead on account of its being in a condition directly applicable to the soil and its cheapness in comparison with any other artificially prepared fertilizers, they are largely used in the various chemical industries for the manufacture of chloride of potassium, sulphates of potash and soda, preparations of magnesium, potash, &c.

The following statistics, published by the German Imperial Government, will convey some idea of the growing importance of these beds. The Stassfurt and Aschersleben saline beds produced, in the following years.

Year.	Rock salt.	Potash Salt.
	ewt.	ewt.
1864	1,620,094	2,330,791
1870	2,258,581	5,837,857
1874	3,237,411	8,591,219
1880	5,415,103	13,361,841
1884	6,895,900	19,383,820

The figures show that while the production of rock salt within the period of twenty years has quadrupled the increase of potash salts has been ninefold. The salt works now in the immense basin are, Stassfurt, opened in 1857, the Leopoldhall, opened in 1862, the Consolidated Alkaline Salt Works, in Westeregeln, opened in 1873, the Saltröck mines, New Stassfurt in Loderberg near Stassfurt, opened in 1877, the Potash mines, Aschersleben, opened in 1883, and the Salt mine, Ludwig II. opened in 1884. The official statement of their product in five years, prepared by Dr. Frank and Mr. R. Besser, the director of the salt mines in New Stassfurt is as follows:—

Year.	Karnallite.	Kainite.	Kieserite.	Boracite.
	ewt.	ewt.	ewt.	ewt.
1880	10,561,239.0	2,755,915.0	17,857.0	2,073.0
1881	11,811,521.0	3,106,031.0	11,638.0	2,256.5
1882	12,185,995.5	3,895,154.0	93,162.0	2,513.5
1883	19,001,061.0	4,532,005.0	97,004.0	4,102.5
1884	11,799,179.6	4,090,087.0	274,777.0	3,182.3

These figures show that the greatest yield of kainite was in 1882, and the largest yield of kieserite was in the year 1884.

Karnallite, which is produced in such enormous quantity, is described by Johnston and Cameron as a compound of magnesium and potassium chlorides and water. Of kainite they say that its composition is variable. Good specimens contain chloride and sulphate of potassium equal to about 11 per cent of potash. Nearly one fourth of kainite consists of magnesium chloride and sulphate, the rest is made up chiefly of common salt.

SEED-PEARL SHELLING AT BATU BATU.

The following, from the *North Borneo Herald* will be interesting to our readers. The pearl shell referred to is the species found in Tumbalang Bay, near Trincomalee, the large thin shells of which are said to be used by the Chinese as substitutes for window glass, and which are put to artistic use, small pictures being painted on them, having all the effect of transparencies:—

The prominent point of land called Batu Batu jutting out into Padas Bay is now the centre of much activity, and many refugees from the dismembered kingdom of Brunei have made it their home. Constant feuds, intrigues and misgovernment have rendered life and property insecure in Brunei and gladly have our immigrants exchanged the red banner of Brunei for the protection afforded by the aegis of the Royal Chartered Company.

Most of the immigrants come from Brunei, others hail from Labuan, Lawas and neighbouring rivers. The roving adventurers who trade from port to port along these coasts do a good business with the Muruts who bring down jungle produce, for which hitherto there was no market, and the newly-arrived "horny-handed sons of toil" immediately find employment in seed-pearl fishing, boat-building, cutting plank and spars for boats, planting paddy on the Linkongan, Lukutan and Sipitong rivers or working sago on the Padas or other rivers that debouch into Padas Bay. The garden woods of Batu Batu and surrounding country have for many years past been well known in Labuan, and within the last month the Labuan Government has been supplied from Batu Batu with spars of the famous "Bintangor" wood for their new flagstaff. The deposits of coal at Bukit Nalayan are as yet quite undeveloped, and samples have been sent to the Indian and Colonial Exhibition, London.

But the principal occupation of the immigrants is in gathering the seed-pearl shells (*placuna placenta*), called by the natives "selesip," which abound in Padas Bay. A flotilla of twenty or thirty boats roams about the bay, generally together as in herring fishing, in search of the oldest shells and when these are found to be too young the boats move on to another bank. It is a rule with the fishermen always to throw back the young shells into the sea, but if a shell has been opened and the oyster destroyed it is not thrown back, as it is said that the dead shells kill the live ones. These shells pay the fishermen in a threefold manner. First, the shells divested of the oysters fetch in Singapore from \$1.80 to \$2 a picul, then the oysters dried in the sun only (not salted) sell for about \$4 to \$6 a picul in Labuan and thirdly the seed-pearls are sold in Labuan at one Mayam \$1.80, one Basing=10 Mayams \$80. When a boat comes in, the load of shells is turned out on the beach. Then each fisherman gets two buckets, these are made of the sheath of the nipa palm, and with a sharp knife manufactured for the purpose, the shell is opened and the oyster is cut off within $\frac{1}{2}$ of an inch from the hinge of the shell. The oyster falls into one bucket, and the part clinging near the hinge is scraped off and falls into the other bucket. It is this little bit that contains the seed-pearls, if any, and they are carefully extracted. The oysters are laid out on mats to dry in the sun and sold in Labuan.

A great number of the seed-pearls are disposed of in the village at Batu Batu. When the fisherman buys his few necessaries at the Chinaman's

shop he pulls out his little bundle of seed-pearls and pays in that currency, the Chinaman making a good thing out of this transaction. These seed-pearls are not much valued in Europe, but in China they are used as ornaments or pounded into medicine and the shells being thin and transparent are also a substitute for window glass.

There are four principal banks of seed-pearl shells in the shallow part of Padas Bay, in a ripe state for working operations, and there are some more where the shells are still growing; these are forbidden ground until such time, say another six or nine months, when they shall have attained maturity.

The scene on the sand or mud banks in the bay is lively, men, women and children up to their knees in water gathering the shells that are imbedded. They seem very busy withal cheerful and chattering and seem glad to see the Government boat, with the British North Borneo Revenue flag flying aft, picking its way among their boats. As we pass the women playfully throw a few shells into our boat for luck; further on may be seen, on sticks fixed on the bank, some white flags to keep "evil spirits" away.

The collection of the Royalty on the seed-pearls exported was a somewhat difficult nut to crack. The Regulations said that 5 per centum *ad valorem* was to be collected.

Mr. C. A. Francis, the energetic officer in charge of Batu Batu found that the seed-pearls were so easily hidden away that the revenue therefore amounted to very little. A tide-waiter was sent to his assistance, his duty being to go about among the people, find out what pearls had been procured, and to search them. The first month only brought in some \$6 revenue, and as his pay was \$12 a month the result was disappointing. He searched the fishermen but found little or nothing, all the while knowing well that they had extracted many seed-pearls from the bivalves. Little boys showing their bright teeth looked up with their laughing eyes, the picture of innocence, and all the time concealed little packets of seed-pearls between their toes, but native boys can do anything with their toes from holding a nail straight with them while hammering it into a plank to combing their hair. Of course the natural bashfulness of Province Dent officials forbade a close examination of the ladies, and the result was that this mode of collecting the Revenue was a dead failure.

It was now suggested that \$2 should be charged on every boat, but this plan was found to be impracticable as fifteen or twenty persons would crowd into a large boat so as to evade the tax. At last the fishermen themselves were consulted in the matter and they voluntarily proposed that a head tax should be levied on every man woman and child who were employed in fishing on the banks. The old men said the young people gathered the most shells as they could stand longer in the water than they could, as it gave them cramp to be too long in the water, and that it was quite fair that the young ones should be taxed.

The payment of \$1 per head per mensum was agreed to by all, and the first month *i.e.* December 1885 brought in a head tax of \$81, whilst the month of January 1886 yielded a revenue of \$95, and the people pay this mode of taxation cheerfully and rapidly.

In the Inland Sea at Kwala Penyu, in Province Dent there are shells of the same description, the only difference being that they do not breed seed-pearls, and it is said that in former years they did not produce any. The Assistant Resident has now sent away several hundred

weight of Padas Bay shells for deposit on these banks, believing that the admixture of the breeds may remedy the defect in these barren oysters.

The seed-pearls shelling is as yet in its infancy, and it is expected that a large population will settle at Batu Batu to this and other lucrative occupations. As Julius Cesar is said to have conquered England for the sake of her pearls, so let us venture to hope that a similar but less demoralising and more profitable invasion will take place in Province Dent.

PISCICULTURE.

To the Japanese, who add pisciculture to the polite accomplishments, the following account of carp culture in China will prove interesting. We take it from the columns of *Nature*:—"A report on carp-culture in China has been made by Dr. Macgowan to the Carp-culture Association of the United States. Pisciculture, it appears, was cultivated at a very early period, being regarded as a branch of agriculture. The carp is, of all fish, the most frequently reared by artificial means in China, but nearly every species of *Cyprinus*, bream, tench, roach, goldfish, &c., is so raised. A treatise on fish-rearing has been attributed to a Minister of the fifth century before our era, but it appears to have been really written eight centuries later. The work says that of the five modes of rearing animals by far the most productive and valuable is fish-breeding. The pond used for this purpose (it goes on) should be an acre in extent (the depth is usually less than eight feet), and nine stone islets, each having eight inlets or bays, a yard below the surface of the water, should be constructed in it; then twenty gravid carp and four males, each three feet long, are to be deposited in it noiselessly in the month of March. Two months later a turtle should be placed in the pond, two months later a couple, and after a like period three more. By this time there will be 360 carp. The turtles are to prevent their being transformed into dragons and flying away. The object of the islets and bays is to afford greater space for the fish in their sinuous voyages, for the more a fish travels the fatter and bigger he becomes. The Chinese author then makes the following calculation: in the following year the pond will be found to contain 150,000 carp 1 foot in length, 450,000 3 feet, 10,000 2 feet. In the third year 100,000 1 foot, 50,000 2 feet, 50,000 3 feet, and 10,000 4 feet. A thousand of those that are 2 feet in length should be retained for replenishment, and all the rest be sent to market. In another year their number will exceed all calculation, and they require no feeding, hence the value of carp culture. All the varieties, we are told, come from the black species. Those destined to become white change to silver or yellow, while the others turn first red and then golden. Some of the white sort are so nearly transparent that their viscera are visible. Much of the art of rearing them consists in affording due amounts of shade and sunshine in the course of their growth, and in changing their water, not more than half of which is to be removed every fourth day. In the earliest times the practice, which continues today, was introduced of planting mulberries on the margins, on which apiaries were placed, the droppings from which fed the fish, while the leaves of the trees first nourished silkworms and then goats. These droppings are said to impart a peculiar flavour to the fish."

Apart from some nonsense, this account is valuably suggestive. Fish ponds well stocked would be valuable institutions on estates and elsewhere in Ceylon. Proper fish could be procured from China, Java, India and other places.

MANITOBA AND ITS PRODUCTS.

Owing to the great reduction in the value of farming produce, many of the agriculturists of Great Britain have been endeavouring to break their leases and to remove their Lares and Penates, along with the little hard cash which they still possess to some other scene of labor, and naturally the question of which colony would be the best suited for them has been the one uppermost in their thoughts of late. Pamphlets have been published and are to be had *gratis* from the agents-general of the various colonies, and it is amusing to note how each colony is pointed out, in the pages of the pamphlet specially referring to it, as the most desirable one for any person to go to, and, taking the first of these that comes to my hand, I find the Province of Manitoba thus referred to by one William Howey of Birtle Mass, who says:—"I consider there is no better place under the sun, for men with a small capital." Now I have never been in Manitoba myself, but I have known many who have been there,—men who bore the hardships of early settlement in New Zealand and Australia, who had 'roughed it' in the good old colonial way, and had never shirked hardwork or hard fare, men also who had helped to open up the jungles of India and Ceylon, and had planted coffee on the clearings, who had lived often on nothing but curry and rice from one week's end to another, and who were in no way afraid of hard work or rough living, and strange to say these have all got the same thing to say about the Paradise of Manitoba, viz., that they would rather be hanged in Anstralia or eaten by a tiger in India, than die a natural death in Manitoba. Now something must be wrong; either my informants have been ill to please or the pamphlet has been written by one whose imagination is stronger than his veracity, and as I am not easily induced to accept of any tale as gospel, I always try to find out as much as possible for myself as to which story is the true one. With regard to Manitoba an opportunity was offered me lately of inspecting some of the produce grown there, which was being exhibited in Aberdeen, and I took advantage thereof of going to see them and of endeavouring to clear up the doubt which had become inherent in one on the subject of the suitability of Canada as a field for emigration, and its assumption to rank first as a grower of farming produce. The exhibition was crowded, but I made two visits to it and took careful note of everything that I saw. The specimens of grain—wheat, maize, oats, barley, &c.—were very poor, the wheat being exceedingly small, and the oats so 'shelly' that the weight per bushel could not have been more than 36 lb.; indeed it was a poorer specimen than the average of the 'light oats' in this part of Scotland—that is the grain which is separated from the good oats in the process of winnowing. The barley also was very small. According to the pamphlet above referred to, the average yield per acre in Manitoba in 1883 was wheat 21 bushels oats 36 and barley 26, and all these are much behind the British averages.—The samples of peas and beans were very good, although small, but there was no doubt that they had been through a sizer, similar to those employed in coffee mills, as the exactness of the size of all the peas was too remarkable. But the strong point of the exhibition undoubtedly was the potato department; the specimens of these esculents left nothing to be desired. I have seen perfect potatoes in New Zealand, and, in the

same country, I have seen 30 tons to the acre grown; but I never saw anything better than the specimens of ashleaf kidney and magnum bonum potatoes exhibited as grown in Manitoba. The onions also were very good, and so were the carrots; but the collection of turnips and mangolds were as poor as any I ever saw. They were large, coarse and hollow, covered with warts and hideous excrescences, and, although several of those looking at the specimens expressed surprize at the magnitude thereof, I observed that any practical farmer who referred to them at all, did so in far from complimentary terms, styling them rough, 'fusionless,' finger-and-toed and worthless. On the whole the specimens were in no way equal to those to be seen at any country show, with the exception of the potatoes, and so I am inclined to give credit to the somewhat sneering remarks of those who have told me about their trips to Manitoba, and their determination not to throw their lot in with the struggling settlers there. It is not my purpose to refer to the photographs of the fine scenery of Canada and the stuffed heads of buffalo and mouse-deer hanging round the hall—these were fine indeed—but emigrants cannot live on scenery, even although they may occasionally have their larders full of buffalo 'junk,' and I only intended, when writing this, to give you my idea of the products of the Canadian farms, as compared with those of other colonies or even of the mother-country. I have no doubt the specimens which I saw were fair samples—at least the Canada North-West Land Company, under whose auspices the exhibition was held, would surely not have put themselves to inconvenience to collect inferior specimens to send so far as to Aberdeen Awa. COSMOPOLITE.

REPORT FOR 1885 OF THE ROYAL BOTANIC GARDENS, CEYLON.

Besides what we have already quoted, we add a few further extracts from Mr. Nock's report on that now favourite resort of visitors to Nuwara Eliya and tourists, the Hakgala Gardens:—

The Hill Garden continues to increase in usefulness and beauty, as the improvements planned out five years ago, and steadily continued since, approach their full development, and the many newly-introduced plants begin to exhibit themselves more prominently. The Carriage Drive extension was continued (by labour from Peradeniya as in previous years), and sufficiently finished to enable it to be used by carriages for its whole length. About 150 yards, however, are still un-metalled and very rough, but I hope that the whole road will be properly finished off during the coming year. The damage by flood recorded in my last report was repaired and a larger culvert, (40 feet long, 2 feet deep, and 22 inches-wide) was made under the drive to carry off the overflow water; but again in June a heavy fall of 2.98 inches rain in two hours washed away a considerable portion of the road and embankment. This was at once thoroughly repaired, and the embankment strengthened with brickwork and cement. It now appears to withstand the floods, and it is hoped will give no further trouble.

The Superintendent's bungalow has been increased by the addition of two more rooms, and the enlargement of a third, and by an extension of the verandah. This gives him an office for garden work—a want hitherto much felt at Hakgala. The work was carried out by the Public Works Department, under the superintendence of Mr. Nock. The small reservoir built last year has answered its purpose very well, and proved very useful indeed during the droughts of February-April, and August-September. Though at times very low, there was always enough water for the nurseries, plant-houses, and flower-gardens.

It still leaks a little. The erection of a cattle-shed on the high road below the Garden, for the sake of obtaining the manure, has been carried out. It has been strongly built (by the Garden coolies) and should last many years. It is already frequented by cartmen, and the Garden deriving the benefit contemplated. A site for new cooly lines was selected, and the framework and roof of the building has been put up and thatched. But it has not been found impossible to spare from the necessary work of the Garden labour sufficient to finish it. I have selected the following extracts from Mr. Nock's comprehensive report on the Gardens:—

"*Roads and Paths.*—The Carriage Drive from the bungalow to the entrance gate was thoroughly repaired in January, and the grass verges made complete throughout the whole distance. Near the lower end of the fernery, the old drive made a very sharp and ugly bend to avoid a bank, some 4 ft. high. This bank has been cut away for about 12 ft., and the road made of a better curve and an easier gradient for a distance of 84 feet. New paths, 4 feet wide, have been made in various parts of all garden,—in 165 yards,—as well as 272 yards of narrow 3-foot ones in the herbaceous ground; and 637 yards of turf-edging has been laid down along the sides of paths. 108 square yards of turf have also been laid down to form a lawn near the rose garden and on the bank below the new pond.

"*Fernery.*—I am glad to be able to report that the plants in the fernery have done well all through the year. Some of the foreign species have made remarkable growth, and are now quite established. The New Zealand "Silver tree-fern," *Cyathea dealbata* has already begun to form a stem, and has now 25 fronds. The Australian tree-ferns, *Dicksonia antarctica* mentioned in last year's report, have also continued to thrive; and the groups of the lovely indigenous tree-fern, *Alsophila crotata*, have made excellent growth during the year, and have been much admired by Australian and European visitors.

"*Plant-sheds and Nurseries.*—In the plant-sheds and nurseries, a large and varied stock of plants has been kept up for distribution, and for the supply of the Garden. The greater part of the nursery has been liberally dressed with manure and though some parts of it are still very poor, the soil generally is in much better heart and the plants have in consequence grown more freely, and have given greater satisfaction; 35,300 seedling plants were pricked out during the year and 55,400 cuttings put in. The propagating-house continues to be most useful for striking cuttings of the more delicate sort of plants, and for raising seeds, &c. Without it, I feel sure, I could not have saved the one straggling germinating shoot of the new and valuable West Indian vegetable, *Sechium edule*, which has, I am glad to state, now been successfully established.

"*Borders and Shrubberies.*—A great amount of work has been done to the borders and shrubberies in the way of manuring, planting, and re-planting, and thinning out and pruning. Altogether 38,500 plants and seedlings of various trees, shrub, and garden plants have been planted out during the year, the greater part, of course, being showy herbaceous garden plants and annuals. Three new borders have been made near the lower entrance to the fernery,—one will be devoted entirely to Fuchsias, and the others planted with mixed plants. Two more borders were also made between the edge of the new pond and the carriage drive. A belt of six rows of different conifers and one row of *Acacia melanoxylon* has been planted on the path leading near entrance gate, at the back of the juniper planted there last year. In July and August the upper portion of the old *Cinchona ledgeriana* plantation was cleaned up and planted with *Pinus striata*, and on the lower side enough ground was cleared for and planted with two rows of *Pinus lumpinata*, and one of *Pinus Khaya*. The first two named are doing well, but a good many of the last, besides dying out in the hot dry weather, were destroyed by elephants; and I regret to say we have no more plants of this kind to fill up the vacancies.

"*Flower Garden.*—The beds here have for most part of the year been filled with showy temperate plants, which, on the whole, have done well, though both here and in the borders in the other parts of the Garden it has been impossible to obtain that uniform appearance so much desired, on account of an unusually large number of grubs and slugs which have attacked almost everything put out this year.

"*Rose Garden.*—White gravel has been laid on the paths in this garden; and the ground on the upper side of it has been made level and planted with English grass, which has now covered the whole surface, and forms a nice fresh-looking turf. A few new roses have been added by exchanges, and nearly all have grown well. Considering the plants have been set out only just over a year, some remarkably fine blooms have been produced. I may mention that one bloom of "Paul Neron" measured 7½ inches in diameter, and was as richly-scented as any I have ever grown. September produced the greatest number of blooms, and the size and colouring of the flowers were very satisfactory.

"*Herbaceous Garden.*—It has been found that the herbaceous garden made three years ago is far too small for the number of species we now have, and as it is not practicable to extend the garden there, it was decided to form an entirely new one on a site adjoining the rose garden. This site has been cleared of jungle, roots and stones removed, the ground made even, and laid out in sixteen beds 4 feet wide, with a path between each bed 3 feet wide and a grass verge on each side 1 foot wide. The average length of the beds is 50 feet. The monocotyledons will be placed in the beds nearest the rose garden, and already 100 species of them have been planted out.

"*Visitors.*—The increase of visitors is remarkable, being 475 more than in 1884, when there were 539, against 1,014 during this year. April gave the largest number (192), and June the smallest (23).

We quote also what Dr. Trimmen says about tea and cocoa:—

"*Tea.*—Ceylon has exported over 3½ millions (3,796,584 lb.) of tea during the year, a rise of 1½ million, but yet somewhat less than was anticipated. The area under this cultivation (roughly estimated last year as 65,000 acres) is now calculated, with as much accuracy as can be attained, at 101,695 acres. This is a very large extent, but it must be remembered that fully half is not yet in bearing, and much more still very young. It has been estimated that this existing acreage should yield in four years' time an export of not far off 30 millions lb., and to that will have to be added the yield of the bushes of the next two years' planting. Such predictions, which take into account no accidents, have not any great value; but allowing this to pass, I must confess, that, however encouraging in one aspect these figures may appear, they have to my mind a serious aspect also. For the present, however, prices are well maintained and our trees are free from any serious blights or insect ravages.* But it cannot be too strongly urged upon planters to endeavour to occupy such a strong position by the cultivation of other products, that they may be able to bear the changes in these respects which are but too likely to occur.

It has been suggested—and the question is likely to be more discussed—that the cultivation of tea by the small native landholders in the villages might well be encouraged by Government; and during the year official applications for plants and seed have been referred to me. It is certainly very much to be desired that some cultivation could be found for the villager to take the place of his coffee now almost totally destroyed by leaf-disease; a little consideration will however, I think, show that this cannot be done by tea at least under present circumstances. What has been

* *Helopeltis* has done some slight damage in a few estates, the fully-developed insect sucking the young leaves. This has been, so far as I have seen, where cacao is grown along with tea, a combination perhaps better avoided.

proposed is that the native cultivator should sell his green leaf at the factories of the neighbouring planters. He would thus be entirely at the mercy of the buyer, who, it is but reasonable to expect, would not care to pay more (it would be probably less) per pound than what it costs him on his own, perhaps large, highly-cultivated, and well-worked estate. Such a price would be a miserable return to the native grower for a crop which he has secured at the expense of, for him, much time, care and trouble, and would be far inferior to that he could obtain by other easier cultivations. Tea is not a profitable product to grow in small quantity; and I cannot recommend that its cultivation in the villages should be encouraged, when there are many other more suitable and more profitable products available. If, however, it were possible for the villagers to make tea for their own use, its growth by them might be recommended.

But the direction in which one may hope to see tea-cultivation benefit the Sinhalese villager, is by inducing him to work for wages on the estates. It is satisfactory to know that this is already commencing in some districts: if generally followed by the natives, habits of industry will be formed, and the helpless indolence and apathy, and consequent semi-starvation, so often to be seen among the Sinhalese, be gradually abolished in proportion.

Cacao.—It is with regret that one observes a decided check in the cultivation of this plant, especially as this appears to be principally due to an unreasonable dread of *Helopeltis*.* For the ravages of that insect do not seem to be on the increase and though it has become somewhat more widely diffused, it is not in most localities a very serious pest, such as would justify the abandonment of a promising industry. There appears now to be a general consensus of opinion among planters, that this bug attacks principally cacao grown in the open; and the planting of shade-trees is becoming general. It may be expected that our export of this product, considerably decreased in the past year, will speedily recover; and if the *Helopeltis* panic lead to a more appreciative selection of land, and more care in cultivation, it will not have been cutely injurious.

There has been some demand during the year for seed of the Trinidad varieties at Peradeniya, and the belief is general that these larger-growing kinds are harder than the old Ceylon sort. Since the date of my last report, I have arrived at the conclusion that the various "pale-fruited" kinds (see report for 1882) springily cultivated in Ceylon, as well as all the strains of these new Trinidad plants, are to be referred to the "Forastero" class of cacao. All of them, whatever the colour of the pods—purple, dark-red, pink, yellow, or pale-green—have seeds ("beans") which are flatish in form, and purple or violet internally, and become very dark after curing. Our old cacao, on the contrary, has the pod nearly always red (occasionally bright-yellow), and the seeds are more rounded in shape, and always white or yellowish on section when fresh, becoming red after preparation for the market. As to the proper name of this latter sort, I may quote a portion of a letter which I addressed to the *Observer's* newspaper in November last, upon the subject:—

"The fruiting of the selected and named varieties sent from Trinidad in 1880 and 1881 has since shown that all those names (Candeamar, Cayenne, Virilico, &c.) are applied to terms of what is known there as 'Forastero,' cacao, and that none of the purple-seeded kinds are of the 'Criollo' or 'Caracas' variety. It will therefore be well to use for the future the name 'Forastero' for them here also.

"This being the case, the question naturally arises as to the ordinary red cacao of Ceylon. What variety is it; and is there anything like it grown elsewhere? For some time I have been becoming more convinced

* There is a fair woodcut illustration of this adult *Helopeltis*, from Java specimens, in "Practical Entomology" for December 12, p. 189, and of the earlier stages also in "Gardener's Chronicle" for January 16th, 1886, (p. 34).

that it is *this*, that is the 'Caracas' or 'Criollo' cacao and I might have taken stronger ground on the matter than I did in my last report. Mr. Morris, of Jamaica, who has had good opportunity of investigating the cacao, both in a wild and cultivated state, tells me that he knows of 'only one kind with the cotyledons white or whitish, and that is what is known as 'Caracas cacao.' This, it is well-known, is now a rare kind in the West Indies, and scarcely to be found on Trinidad estates, having died out, though formerly largely grown here. Evidently Ceylon obtained its plants before this change had occurred. The high quality of 'Ceylon cacao' is thus explained, as well as its delicate tempera-

We add a few further extracts:—

Seschion edule.—The "Cho-cho" or "Chayote" has been successfully established at Hakgala from the single surviving seed of those sent from Jamaica in January. Mr. Nock reports:—"After being nursed up in the propagating house for a few weeks, the plant was put out at the end of February into the nursery. It commenced to bear in May, and has continued to do so ever since, affording an excellent crop. The vegetable (fruit) it produces is pear-shaped, and the average weight is about 2½ lb. The largest one we have grown here yet weighed 3½ lb. The plant being perennial, adds greatly to its value. As it is the first time it has been grown in this country, it may be useful if I state the best way of cultivating it. It thrives best in a rich, deep, well-drained soil, but may be made to grow anywhere by preparing the site for each plant in the following manner:—Make a hole 4 or 5 feet in diameter, and 18 inches to 3 feet deep, according to the sub-soil. If the sub-soil is good and free, you may go to the depth of 3 feet; but if it is clayey or likely to hold water, 18 inches will be quite deep enough. Place a layer of rough stones at the bottom of the hole to a depth of 6 to 9 inches for drainage, and over this a few inches deep of small twigs or half-rotted leaves to prevent the fine soil from getting between the stones and choking the drainage. The hole may be filled up with the following compost:—One-third ordinary garden soil, one-third half-rotted cattle or stable manure (cattle manure preferred for hot, sandy soils, and stable manure for cold, clayey soils), and the remaining third may be formed of leaf-mould, sand, washashes, lime, and the sweepings of the poultry-yard, in about equal portions. When the hole has only been taken out 18 inches deep, it will be necessary to raise the soil about 18 inches above ground; and in every case, except in very dry districts, it is best to raise it. The whole fruit, which is sent out in a germinated state, must be planted about 3 inches deep in the centre of the hole. It begins to grow at once, and in a week or ten days it will have made a good start. It is a creeper, and each plant will require a space of about 20 feet square."

The cho-cho also does very well at Peradeniya, but the fruit does not there attain quite so large a size. I think it will be less suitable for the lower elevations. I consider it to be a very valuable introduction, and a real addition to the vegetables of Ceylon. I most resembles the vegetable marrow, but is, in my opinion, superior in flavour to the best varieties of that vegetable.

CYPHOMANDRA BATAVA.—The "Tree Tomato" has become well-established in Hakgala Garden, and is now bearing good crops of fruit. Mr. Nock says:—

"Some of the plants are now 11 feet high, and the fruits produced are very fine. They are egg-shaped, about 5 inches long and 2 inches in diameter, and when fully ripe are of a bright yellowish-red colour. They make excellent tarts, are very good stewed, and are much relished by most people when quite ripe and eaten raw, like gooseberries. The plant is very robust and easy to grow here, and I believe it will thrive, and be very

* Not a very apt name. Neither in foliage, flower, nor form of the fruit is there much resemblance to the Tomato; in all these respects the plant is nearer to the brinjal or egg-plant.

profitable from an elevation of from 2,000 to 6,000 feet. Under favourable conditions, the plant remains in bearing for many (ten or more) years."

Carica esculenta ("Mountain Papaw").—Mr. Nock reports from Hakgala:—

"Both as a fruit and ornamental plant this is a very valuable introduction. It grows freely in the mountains, and produces an abundance of very useful fruit. Stewed or cooked in tarts and puddings it has very much the flavour of apple, and for mincecatt it is quite equal to them. It is also very good when fully ripe, eaten raw with a little sugar."

ARRACACHA ESCULENTA.—The few seedling plants of this vegetable, which were raised during the latter part of 1884 at Hakgala (see last report, p. 13) were planted out in February, and have matured a fair crop of the edible roots. A good quantity of young plants have been propagated from crown cuttings, and these are now available for distribution. This vegetable has a peculiar flavour, and a cheesy consistence, and is not relished by everyone. It might be called the "South American Parsnip."

Ipomoea chrysorrhiza.—The "Kumara" or New Zealand sweet-potato has turned out very suitable for Ceylon culture, and possesses several advantages over the ordinary sorts. The tubers, though smaller, come more quickly to maturity, and thus afford more crops during the year. In taste they are much less sweet, and more like the true potato; but the great advantage is that they can be grown in the hills at the highest elevations. This was received from Kew in 1883 (see my report for that year, p. 9). Botanically it can be regarded only as a race, adapted to a temperate climate, of the ordinary *I. Batatas*.

Chinese Ginger.—Of this plant—the source of the preserved ginger of commerce—nothing is certainly known. In China, where it is grown, it is said never to flower. I have received from Kew a box of roots, which are growing well at Peradeniya. The plant is clearly quite distinct from ordinary ginger, and I await its flowering with interest.

Eucalyptus Plantation.—Mr. Nock reports:—

"The trees—now 3½ years old—suffered a good deal from the high winds in the South-West monsoon, and most of them, which are now too big for stakes, show a decided lean from that point.

For comparison of growth I give below the measurements of fifteen kinds for the last three years:—

	Jan. 1884.		Jan. 1885.		Jan. 1886.	
	Height ft.	Girth at base. in.	Height. ft.	Girth at base. in.	Height. ft.	Girth at base. in.
<i>E. robusta</i>	140	8	24	15	300	22
<i>longifolia</i>	110	6	24	14	350	19
<i>marginata</i>	139	6	25	13	360	20
<i>Gunnii</i>	136	5	26	10	330	16
<i>cornuta</i>	134	5	22	10	320	15
<i>colossea</i>	120	7	21	15	306	18
<i>viminialis</i>	109	6	18	14	256	19
<i>botryoides</i>	100	7	22	14	291	20
<i>microcarpa</i>	97	5	22	12	250	18
<i>Siberiana</i>	80	6	16	13	266	17
<i>amygdaliua</i>	710	7	15	12	226	19
<i>piperita</i>	79	6	17	13	250	19
<i>hemastoma</i>	72	5	15	12	230	18
<i>Lehimanniana</i>	65	4	12	9	216	13
<i>alpina</i>	28	3	5	5	126	9

KHEDAH OPERATIONS.—The *Englishman* states that the Government kheddahs in the Garo Hills are yearly becoming more productive under the superintendence of Mr. Sanderson, and the present season is by far the most successful on record. For ten years before Mr. Sanderson's appointment the average capture did not exceed 58 elephants, and since then the number has run up to 252. This year, however, during the eighty days from 20th December to 10th March, the capture of no fewer than 402 elephants was effected.

SYLHET TEA PROSPECTS.—As was stated in the *Pioneer* yesterday South Sylhet is suffering from drought, hardly any rain having fallen since early in October. A correspondent informs the *Englishman* that the districts south of Maulvi Bazaar are in a very bad way indeed. On the tea gardens both old and young plants are dying, and an early leaf season is now out of the question. The writer adds that, owing to the exceptional dryness of the weather jungle fires are greatly on the increase in the district of Sylhet. On many tea estates portions of the coolie lines and other buildings have been burned to the ground, together with one of the manager's hungalows in the South Sylhet Tea Company.—*Pioneer*.

A STATUE TO COFFEE.—A good deal of literature has been inspired by coffee, but few men of letters have sung its praises, and it seems to have been reserved to a Viennese coffee-house keeper to erect the first statue in its honor. Toward the end of the seventeenth century one Kolschitzky, who had rendered good service to the besieged during the league of Vienna, opened the first coffee-house ever seen in the Austrian capital, and now one of his own cloth has put up a statue to commemorate Kolschitzky's two great services to his fellow citizens. The statue, which is said to be "a fine work of art," represents Kolschitzky in a Turkish uniform (the disguise he adopted when carrying through the Turkish lines intelligence from the besieged to the Duke of Lorraine), holding a cafetiere in his right hand and a cup in his left. At his feet lies a bag of coffee. This realistic piece of sculpture has just been unveiled at the corner of the Kolschitzkystrasse and the Favoritenstrasse, and has been formally made over to the city; and, as the Viennese loves his *café noir* with a perfect affection, there is much fitness in the gift.—*St. James's Gazette*.

FLYING-FOXES IN QUEENSLAND.—The curse of this colony and the bane of the fruit-grower is the flying-fox. How to checkmate them is thought to be a puzzle. The following from the *Leader* is stated to be a certain method of destroying these animals. "Select a tree to which they appear to give the preference, and on that tree hang from one to five oranges prepared as follows:—Scop a cylindrical hole in the orange, then introduce a piece of brass wire bent in the shape of a corkscrew, so that it will securely hold the orange hanging from the limb of the tree where you shall place it. All this being done, just before dark, when the flying foxes begin to make their appearance, force into the orange a quantity of cyanide of potassium the more you can put in the better—but be careful not to keep your nose over the fruit while doing so. The citric acid contained in the orange will immediately attack the cyanide of potassium, and produce cyanhydric (prussic) acid; this action will be considerably helped by the small electrical current generated between the copper wire and the cyanide, and the gaseous product of the chemical reaction will escape from the hole at the top, the flying-fox coming near it dropping dead instantaneously. The fruit will be besides poisoned by the double citrate of copper and potash manufactured inside, so that when the discharge of cyanhydric acid becomes insufficient to poison the flying fox, the animal being able to bite the fruit will be killed, but not instantaneously. The emanations of the cyanhydric acid will attract the flying foxes from a considerable distance. The poisoned fruits should be removed and buried in the morning, or else they may destroy valuable birds. In the long nights a second hanging of fruit at about midnight should be done."—*Planter & Farmer*.

Correspondence.

To the Editor of the "Ceylon Observer."

TEA DRIERS.

15th March 1886.

DEAR SIR,—I am glad to see Mr. Shand coming out with an efficient yet reasonably priced tea-drier. To push back as long as possible the necessity for the purchase of those expensive home-made driers will be a boon to many even if they are not rendered altogether unnecessary. More than a year ago now I built a set of chulas on a plan of my own, with the fireplace only for several chulas (as many as you like) and over each of these I am now erecting (enclosed) slides for four trays. A row of two or three of such converted chulas may have a fire at each end—under control without disturbing the trays.

Patentees are fond of calling their inventions after the hot winds of the earth: so I would suggest that the common chula be henceforth called the Simoom (as I once saw it blowing at Suez, covering deck and cabins with fine dust). The arrangement above described may be erected for a few rupees, and be called the Monsoon.

I may take this opportunity of adding, that, in order to make the converted chulas a success, much attention must be paid to draughts and air-currents—inside and outside of them—which are difficult to control.

Yours,
R. W. J.

NEW TEA DRIERS.

Dikoya, 18th March 1886.

DEAR SIR,—It may interest "R. W. J." your correspondent in yesterday's issue, to learn that his suggestion of the name "Simoom" for a tea drier was anticipated several months ago by a building inventor, residing not a thousand miles from Hatton, the off-spring of whose creative faculty will, I learn, be shortly put before the public, and which I am told will, of course, eclipse anything of the kind that has yet been introduced.—Yours truly,

"THE MORE THE MERRIER."

TEA ROLLERS.

Blackstone, Nawalapitiya, 22nd March 1886.

DEAR SIR,—It will be gratifying to your planting readers to learn from Messrs. Wm. J. & H. Thompson's report just received that they confirm the testimony of experts in Ceylon who have favored the public with their remarks, as to the quality and appearance of the tea rolled by the Centrifugal Spheroid Roller. I have seldom rolled a fill for more than 12 minutes at an average, and often filled the machine with its maximum capacity of 110 lb. although, as a rule, I keep to 100 lb.: most of these rolls were done in presence of visitors, day after day. So that you may now fairly congratulate your readers in having an efficient machine in all respects for their factories.—Yours faithfully,

JAS. H. BARBER.

P. S.—100 lb. of "wither" per hour at least, equal to 500 green leaf.

Extract referred to:—

"The highest quotation has been made by Blackstone, for an invoice of much excellence in make of leaf, quality, and strength—but even such teas as these have suffered from the depression already referred to. It may be of interest to state that Mr. Barber's new rolling machinery was used in the manufacture of this parcel."—Wm. J. & H. Thompson, Feb. 25th.

THE PLANTING AND PROSPECTS OF CINCHONA MARKET.

DEAR SIR,—Having had occasion to travel in several districts in search of a snug piece of land for tea and cinchona, I was very much struck while on the beat at the small area in cinchona chiefly in the older districts—of course, I mean, compared to what it used to be two years ago. Most certainly Ceylon is not likely to export the quantity of bark that has lately overflowed the market. The unusual quantity was the result of clearing land for tea as well as from the abandoning of coffee estates. The majority of which had fields of cinchona varying from 5 to 50 acres. I noticed that the planting of cinchonas on *new* land is still going on in middling elevations. The variety chosen is Ledger. In the upper districts officialis is still the favorite, but no much of it is being planted. The hybrids, ordinary calisayas, &c., seem to be out of the catalogue. On many estates that were abandoned the cinchona has been coppiced with the hope, that, even if the land is not kept clear, in time there will be a forest of cinchona. This is *very unlikely*. On places with coppiced cinchonas over a year old, the weeds and jungle stuff are obtaining the mastery, and it is pretty clear that these lands must be kept clear for at least three years. On some of the estates roots and all have been taken up, but the majority of owners find it too troublesome and expensive to collect the root bark and sell the stumps to tambies at some low figure; for, besides the fact that the cinchonas coppiced *do not* come on unless attended to, the villagers quietly dig and remove them from time to time, the high weeds and jungle screening them from detection. I am pretty certain that proprietors of cinchona estates, planted of course with only Ledgers or officialis, will in a couple of years reap a good harvest, for the price is bound to *treble* so long as the American supplies do not show an improvement in quantity.* There is one thing drawing the attention of growers, viz., the advisability of not cutting a single branch or twig at any time or age. The practice of doing so does not improve the thickness of the trunks; rather the contrary effect is produced. As for the facility of shaving such trees the advantage is not much,—peculiarly hardly appreciable. A small percentage of twig might be annually removed if the price for such bark exceeds 12 cents a lb. As for branch bark, its collection without cutting branches is not so expensive or tedious as people would fancy. Only

TRY.

PREPARATION OF COCOA (FROM THE CACAO-PLANT) IN CEYLON.

Watterantene No. 2, Kandy, 29th March 1886.

DEAR SIR,—I beg to annex a letter for publication which I received from Messrs. Volkart Brothers. The subject is of value to the planting and commercial community. I need not enter into detail, explanatory of the method in which cocoa produced by me is prepared nor flatter myself that the method of my preparation is far superior to that of others.

I find an article published in the Planters', "Vade Mecum" speaking very highly of Mr. Jeffries' cocoa. True the external appearance is fascinating but the fermentation is defective. All that the manufacturing bodies require from the planting community is goodly fermented cocoa and *not* the bright appearance of the skin (or outer covering of the bean). I am only sorry that mine is of a different variety, or I should use all my effort

* Our correspondent forgets the Java and Indian supplies which are expected to increase.—Ed.

to compete with Mr. Jeffries in the outward appearance maintaining my superior method of fermentation.—I am, dear sir, yours faithfully,

J. P. COTTON.

(Copy of letter from Messrs. Volkart Brothers.)

Colombo, 18th February 1886.

J. P. Cotton, Esq., Watterantenne.

DEAR SIR,—In reply to our letter of the 15th instant, we are glad to inform you that the quality of the last lot of Watterantenne cocoa, in fact all the cocoa we brought from you, with the exception of the small lot delivered in December last, is all that could be expected, as far as preparation and fermentation of the actual cocoa is concerned. The only improvement that could be wished for, regards outward appearance and color. We send you today a sample of Gangaruwa cocoa which produce has hitherto stood foremost with regard to colour and appearance of skin, though your cocoa is no doubt superior, so far as thorough fermentation and real quality of the beans goes. In spite of the latter advantages, the Gangaruwa cocoa will, through its better appearance, perhaps fetch three to four rupees more with some buyers than your cocoa.

If you could manage to combine the same fermentation, which your cocoa had so far, with the appearance of Gangaruwa cocoa, Watterantenne would be almost perfection and fetch fancy prices. From all what we have heard, however, thorough fermentation and good color do not go hand in hand, but the one must be always partly sacrificed to the other, and we are of opinion that Mr. Jeffries of Gangaruwa has, as a rule, done a little too much for color and appearance.

The lot, from which we are sending you the sample, has, we understand, been dried by an American fruit-drier tried for the first time on Gangaruwa with the result that the inside of the bean presents a better look, and is better fermented than former lots from that estate. It is of course always desirable to give the cocoa a light color, as appearance is for many buyers of more importance than thorough fermentation, but unless you are sure not to impair the fermentation, in attempting to arrive at the outward appearance of the Gangaruwa produce, we would advise you to continue curing on your present method.

It is very risky to go in for color only, as really deficient fermentation much more seriously affects the price than a dark appearance, and your cocoa is really very little off in this respect. There is now and then a parcel (chiefly native produce) brought to this market which has a strikingly bright red color—tiled it might be called. This is a sure sign of bad, i.e., deficient fermentation and such stuff is of very little value and almost useless for the manufacturer.

We believe Mr. Jeffries' trees are of another variety than yours, i.e., Cabello which is naturally of lighter color. It has certainly a rounder bean than yours.—Yours faithfully,

(Signed.) VOLKART BROTHERS.

This is all very interesting so far as it goes, but cacao planters would of course like to have Mr. Cotton describe his process of fermentation and Mr. Jeffries his process with the fruit-drier.—Ed.]

FISH MANURE FOR TEA GARDENS.—Under this heading, a native correspondent of the *Indian Agriculturist* advises an application of a handful to each bush and states:—"In a garden in Assam, also in one at Madras situated on the Hills (I omit names here) fish manure was used to renovate the soil, as the out-turn of these two tea gardens had fallen off in flavour and quantity, though they had been well manipulated. The fish-manure proved effectual.

JAVA CINCHONA planters too, are beginning to find out that it is more to their interest for them to ship bark to London than to Amsterdam, owing to brokers at the former city paying greater attention to sorting operations for the fortnightly sales, dealing with their customers in a more businesslike manner, and remitting proceeds forthwith by telegraph. At Amsterdam, on the contrary, brokers take their own time in transacting, so that planters often have to wait two months after the close of the sales for remittances of the amounts due them. In London Java bark fetches higher prices than at Amsterdam, from greater competition among bidders.—*Straits Times*.

COFFEE AND CINCHONA IN CEYLON AND JAVA.—Talawakele, 1st April.—We are having perfect weather for blossoms, and wherever there is coffee worthy of the name, there will be a good crop. I see red-spider flourishing in all directions. My young tea is sorely stricken, but I suppose the coming rains will wash it off. I suspect that is to be our pest on the new product in a not very distant future. I hear Belgravia is for the second time one white sheet of blossom. May it all "set" and come into store, for it is a precarious crop nowadays. Could you not procure for us reliable information re cinchona in Java? If the large acreage of high percentage bark one hears of, is really under cultivation, and within a couple of years of being fit to operate upon, the sooner we get rid of our inferior stuff the better, for there will be no market for it. Then what about Bolivia with its extensive plantations of high-class cinchona? Whether the extended areas one hears of in other countries will turn out as deceptive as that said to be under the cultivation in Ceylon in 1881, ought not to be difficult to arrive at. It would not be a bad idea for those interested here to subscribe to send a reliable expert to find out all about it. I should be glad to give my mite. Fancy the blue looks of many of us two years hence, if we found that our cinchona would not pay for harvesting!

THE IMPORTATION OF JAVA TEA in London rose from 1,808,827 pounds in 1875 to 5,590,069 in 1885. That article has gained a firm foothold in England from its soundness and good quality. The imported quantity is not likely to increase very largely within the next few years owing to there being no prospect of any speedy growth of production in the near future, as the exports from Java to different ports show but little variation of any moment within the last ten years. In quality Java tea is said to be open to great improvement by Indian varieties coming more generally under cultivation. Seeds of these have been increasingly imported into Java of late, from planters there having become more convinced of the need for laying hold of every available means to ensure their produce approaching more nearly the standard quality of first class Indian and Ceylon teas. Java planters now prefer to ship their produce rather to London than to Amsterdam, with the result that they have been charged with lack of patriotism in seeking a market among foreigners instead of among their own countrymen. Their reason for disregarding the Home market is that, at London, business is more quickly transacted, all the quantities shipped are sooner accounted for at remunerative rates; whereas, at Amsterdam there is less certainty of high profits, greater loss of time, and lower quotations ruling. Ten years ago, says the *Java Bode* tea growing in that island had apparently reached its highest point and the yield had actually begun to fall off, whereas, now, owing to the article finding ready sale in Britain, its cultivation is steadily increasing and planters look forward to a brighter future.—*Straits Times*.

THE AFRICAN RUBBER TREES.

In the West of Africa Indiarubber is collected from several species of *Landolphia*, of which the best known are *L. Ovarienensis* and *L. florida*. According to Spöck and Grant *L. florida* is stated by the natives to yield the best rubber of any of the species. This plant is a woody climber, growing well in places where little else could be profitably grown, i.e., in damp rocky ravines. Its trunk often travels along the ground, looking like a large box constrictor, until it meets with a trunk to climb up. The stem attains a diameter from six to eight inches at a few feet from the ground, and then soon divides into more slender branches, which ascend to the top of the tree, and throw down long pendulous branches and clusters of large snowy-white flowers, ascended like Jessamine. The fruit has a sweet acidulous pulp, which is eaten by the natives. The leaves are opposite, and their colourless midribs are sharply angular underneath. The young shoots are deep green and spotted, jointed every ten inches, and about one-third of an inch in diameter; they are brittle, and a cord of pith may be pulled out of them. The plant climbs by means of tendrils which arise from the joints, and which consist, in some species—as in *L. Ovarienensis*—of the hardened flower-stalks after the ripe fruit has fallen off.

The natives make playing balls of the juice of the *L. florida*, and consider its rubber to be the most adhesive kind. The milk if rubbed upon the skin adheres like birdlime, and can scarcely be rubbed off.

According to Mr. J. Collins' statement, in the Government Report on the Cautchouc of Commerce, African rubber is collected and prepared in a very slovenly and wretched manner. The natives cut off a piece of the bark, and the milky juice is allowed to run into holes made in the ground, or on leaves. In some districts the natives simply allow the juice to trickle down their arm, going from tree to tree until the arm is covered, when beginning at the elbow, they roll the cautchouc back towards the hand, till it comes off in the form of a ring. In other districts the juice is collected and allowed to coalesce in wooden vessels. The wood of the plant contains a gum, so that if the cut penetrates beyond the bark, the gum becomes mixed with the cautchouc and spoils it. Recently, however, the collection has improved in some districts, and the price risen in consequence.

From the above statements it will be seen that the *Landolphia florida* possesses many advantages. Its flower might be used for the extraction of a perfume; its stems, from their character, permit the easy extraction of the juice; the plant could be grown on land otherwise useless, while the rubber, if carefully collected, promises to be of considerable value. From its climbing habit and rapid growth it would more speedily attain maturity, and yield a quicker return than the Pará and other rubbers, which are trees, and which could not be safely or profitably tapped under twenty five years; whereas the *Landolphia* could be tapped when three years old. By the system of growing them in plantations, and cutting down the young shoots almost to the ground every year, the stems and leaves could be taken to the rolling mill, and the crushed mass digested with bisulphide of carbon, in which the rubber is soluble, but which does not dissolve the gum and resinous matters contained in the plant, these if left in the rubber would injure its quality.

The plants could be grown around existing trees, and thus trouble, time, and expense might be saved. They are easily cultivated, and, with proper care, are susceptible of much improvement. In cultivating these plants it must be remembered that their chief requirements are a tropical temperature, and a thoroughly moist atmosphere. There is no reason why the *Landolphia florida* should not become a favourite ornament of hot-houses in the country, for which its soft green laurel-like leaves and delightfully fragrant handsome flowers especially fit it. In preparing rubber for commerce it should be remembered that large masses of cautchouc never fetch so high a price in the market as small pieces, for the simple reason that it is much more easy to detect admixtures of dirt and bark in the small pieces. The more free from foreign substances the rubber is, the higher price it will realise in commerce.

Mr. Collins recommends the preparation of rubber in the form either of separate sheets or cakes, not more than one or two inches thick; and if moulds are used, wooden ones, of the shape of a child's battledore, are preferable. Dryness is another important point; if the rubber be prepared by a wet process, such as the addition of alum or salt to the juice, &c., it is necessary to prepare very thin sheets of it, as thick pieces cannot be dried thoroughly. The gradual and cautious application of heat appears to produce the best rubber. Iron or stone vessels are much better for collecting the juice than vessels made of clay, which contaminate the milk and make the rubber of less value. In most of the plants yielding Indiarubber the milk goes to the flowers when the flowering season commences; hence, in gathering the flowers for perfume, there would be the further advantage of increasing the amount of rubber in the leaves by removing the flowers.

Vogel's African Rubber tree, or *Urostigma Vogelii*, is stated by Mr. Neyle to yield one of the best kinds of Indiarubber in West Africa; it was first collected by Vogel, at Grand Bassa, but was afterwards discovered in Liberia, from whence the first specimens of living plants were sent to Messrs. Christy by Mr. D. J. Dennis.

The tree grows from 20 to 30 feet high, and has large leathery stalked leaves, from 6 to 8 inches long by 3 to 5 inches broad, furnished with four or five lateral veins on either half of the leaf. The small fruits, which are about the size of beans, are found on the terminal leafy branches, usually in pairs, on the stem near the base of the leaf-stalks.

The trees are tapped when about five years old by making slashes or incisions in the trunk, the juice is collected in vessels and the gum is separated from the sap by the use of acids; it is then made up into balls about the size of a large orange. Although the quality is at present remarkably good, it could be greatly improved by care in the collection and preparation for the market. If the trees are tapped before they are five years old the juice is watery, and does not yield such good or strong rubber. The natives, in order to get as large a yield of juice as possible, pollard the trees at a height of 10 to 12 feet and cut back the branches to prevent the strength of the plant being used up in growth, this causes a free and regular flow of sap. The cuttings which are removed are easily propagated and will grow vigorously.

The tree will grow near the sea at an elevation of 50 to 60 feet above sea level, but does not flourish well in marshy ground. The ease with which the plant is propagated, its hardness in sea air, with the excellent quality of the rubber which it yields, renders this a desirable species for cultivation in the lowlands of Southern India and Ceylon; also in Java, Sumatra, Penang and Siam.

Amongst other African sources of supply are the *Laba* species, found chiefly in Madagascar and the Mauritius. M. Coignet mentions that on the north-east coast of Madagascar cautchouc is obtained from three varieties of climbing plants, and a shrub sixteen to nineteen feet high. Of the climbers one variety gives the best product, though the natives use all together. The cautchouc is prepared either with salt water or artificial heat. Madagascar rubber, formerly called Mauritius rubber, has long been largely used in France, and is now highly appreciated in England. It ranks next to Pará in price.

The *Willughberia edulis*, also found in Madagascar, is a climbing plant, which when wounded yields a pure viscid juice, that soon changes to cautchouc on exposure. This is also an Asiatic plant, and is cultivated in Java. —*Indiarubber and Gutta-percha Journal*.

TEA IN UVA—UVA TEA HAS COME TO THE FRONT.

Uva, though late in the field as a Tea district, is now rapidly coming to the front, and at this date there are upwards of 9,000 acres of Tea planted in Uva, which acreage will probably be doubled during the coming planting season. If the proprietors of Uva have such confidence in the soil and climate, surely outsiders may leave the matter to those most

interested, and be assured that they will carry to a successful issue the work so well begun. Already Uva Tea has been well received in the market, and the first planted clearing, not yet 3 years old at an elevation of 4,000 feet, is said to have produced its 100 lbs. made Tea per acre. Surely this should convince every one that Uva is a district well suited for Tea. Uva, however, is a very extensive district, and its climate is as varied as the district is large. Lower Uva in many places is dry and arid; towards Katarama and Hambantota, the country is arid and covered with a growth of thorny Cactus, and water during the dry season is nowhere to be found. The hill districts, on the other hand, have abundance of rain, varying from 70° to 120°, and this rainfall is as a rule well distributed. The whole of the Naminacooley range has an abundant rainfall, and rarely suffers from drought, even during the dry season. The range starting from Hapatule Pass to Hakgala under Totapella has a more constant rainfall than Naminacooley, and although the rain may not fall in very heavy showers, it is perhaps better distributed than in any Uva district, as the South-west monsoon rains, attracted by Totapella and other high mountains, are blown over the range and fall in mild showers along the face of the hills, whilst a little lower down the patanas on the plain are parched with drought. The whole of the Hapatule range has plenty of rain from Uva to Kandapola, and from the top of the Pass to the Sabaragsmuwa boundary at Halpe of landslip notoriety, and the Madulsima range from Passara to furthest Uva has one of the best climates in Uva. Monaragala also attracts rain freely. The districts or portions of the Uva district most likely to suffer from drought are low lying valleys like Passara, Bulatwatte, the Angodde Valley, the base of the Madulsima hills below Lanugala, the valley of the Ooma Oya, the country below Halammulle and below Lenastota and between Lenastota and Wellawaya and about the bottom of the Ella Pass; also the base of the Hewa Eliya range facing the low country on both sides. All these places mentioned suffer during the months of June, July and August from drought and from intense heat radiated from the plains below; and if Tea fail anywhere it will be in localities like these; but I am not prepared to say that Tea will fail there, for I am aware that in India the Tea plant will endure not only a three months' drought, but a dry heat even more intense than we have in any of the places mentioned; and it is generally, I may say always, in places where drought is most severe, that the growth is correspondingly great on all plants strong enough to withstand the drought. Now Tea is a plant peculiarly adapted to withstand drought, inasmuch as it has two distinct systems of roots. The top roots I have seen 6 and 8 feet down in a stiff clay, whilst the surface soil to a depth of 18 inches, if well forked, is literally matted with fine rootlets. I am not prepared to say that the lower valleys will not grow Tea remuneratively under these conditions, but there is no doubt that the high districts which have been so remunerative in Coffee will prove equally so in Tea. The seasons in Uva are more distinctly marked than in the Kandy districts, and there are two distinct seasons of growth corresponding with the change of monsoon. The South-west monsoon is comparatively mild, but during the months of April, May and June, we have what are called the spring rains, corresponding with the breaking of the little monsoon on the Kandy side and the regular South-west monsoon. The rains are not continuous, but fall in refreshing showers, and the growth of all vegetation is most rapid, far more so than in a continuous-wet climate. During the months of June, July and August vegetation ceases. These are the months when Nature seems to rest. The heat is great, and the drought often severe, though heavy dews fall at night, and occasional thunder showers keep plants from suffering excessively. About the 15th or 20th of August a few heavy thunder showers generally fall, which bring out our heaviest Coffee blossoms, and in September the rains are frequent and heavy enough to thoroughly saturate the soil, and vegetation

takes another start and in a week the whole country is green. November and December are the wettest months of the year, and the growth on Tea or Coffee continues till about the end of December, when vegetation again ceases from cold and wet during January. February is usually a dry, cold month with little growth on anything, but with the month of March a few thunder showers usually fall, the air is not so dry and cold, and vegetation again starts and continues till again checked by the dry months of July and August. It will, therefore, be seen that in Uva there are two distinct seasons of growth, and two seasons of rest caused by drought or cold. These seasons of rest will not only enable the Tea Planter to time his pruning with judgment, but will really benefit the Tea plant. The season for plucking will be fully eight months, viz. from March to the end of June, and again from the first of September to the end of December. Many planters, however, will be found to pluck well into the dry months. Tea plucked during dry weather being the strongest and the finest, if a flush is plucked no matter how dry the weather, unless the plant is absolutely withered up. Nature will always make an effort to renew itself, and it is these short fine flushes which give the most exquisite Teas. The sap is inspissated, and the flow sluggish, but the whole essence of the plant seems to be concentrated into a small space. In wet weather with a strong growth, especially after pruning, the sap is weak and watery, and the "liquor" is poor and has little strength. I do not propose here to go into the matter of cultivation or preparation of Tea in Uva, but the planter will soon find out what is the best system to adopt; but Uva has every thing necessary in soil and climate to produce the very finest Tea the world can produce.

I have frequently been asked, Will the Uva Patanas grow Tea? My answer is double: Yes and no. It must be understood that there are two perfectly different kinds, of patana in Uva; the one is natural patana, as to the origin or cause of which there is great diversity of opinion; the other is cultivated land allowed to go to grass. To me there seems to have been two causes at work. In one case, such as the Nuwara Eliya patanas, the Horton Plains and other similar patana, there can be no doubt as to their origin—they are simply the bottom of a lake upheaved at some remote period. You have the black mould with a fine strata of water worn gravel underlying it on a bed of impervious clay. Trees will not naturally grow on soil like this till treated with lime. These patanas are almost identical with the great American Prairies. We have other patana, frequently small patches surrounded by forest and covered with short grass and ground orchids. These patanas are either caused by absolute poverty of soil, or may be from some deleterious substance in the soil. I attribute it in some cases to a mineral oxide. I am not geologist enough to enter into this question further than to say that I have seen a most deleterious oxide and in great abundance in the patana soils of Uva said to be a black oxide of manganese. By far the largest portion of the Uva patanas have at one time been forest and have been under cultivation. The whole of the interior basin from Wilson's Bangalore to Hapatule, and from Wellmade to Bandarawella and round Fort Macdonald has all been cultivated, and where not too much wind blown is capable of cultivation now or of being re-forested. The Elephant Plains in Uda Pussellawa have been cultivated every inch of them. Old Rambokpotte Ratemahatmaya once told me that he recollected when the whole of the Redapane Pass from Taldeniya to Badulla was all forest, and the Koshelle patanas and the hills round Badulla were to a great extent covered with forest. There is an immense acreage of patana in Uva capable of profitable Tea cultivation—and a still larger acreage capable of being re-forested at a comparatively small cost. Re-foresting the country would probably greatly improve the climate, apart from the value of the timber, and the value of successful Tea cultivation on the waste patana cannot be over-estimated. Each Tea estate might re-forest enough patana to supply fuel.—JAMES IRVINE.—Local "Advertiser."

A TEA QUERY.

TO THE EDITOR OF THE "PHARMACEUTICAL JOURNAL."

Sir,—I shall be glad if any of your readers can tell me if any attempt has been made to introduce the leaves of *Melastoma Theezans* as a substitute for tea. I find mention made of it in an old number of the *Edinburgh Journal of Natural History*. M. Bonpland says: "We have often drunk with pleasure the infusion of the *Melastoma Theezans*. It has the colour of tea, and is much less astringent, but more aromatic. Many persons would doubtless prefer this drink to tea, and I think it will be found as useful in most cases." The *Melastomaceæ* are not so far removed from the *Tristemonaceæ* and *Cinchonaceæ* as to render it improbable that some of the species might yield some principle resembling theine or caffeine. It is called the Guianan tea-plant.—J. A. WHELDON, A. P. S., Burgess Hill, Sussex.

ALLEGED IMPURITY OF COMMERCIAL SULPHATE OF QUININE.

Some months ago Dr. de Vrij drew attention to the optical method of distinguishing the alkaloids of cinchona bark and to certain results he had obtained by applying this method to the examination of quinine sulphate of commerce. The inference drawn from those results was that commercial quinine sulphate always contains from 5.47 to 18.46 per cent of cinchonidine sulphate.

Dr. de Vrij has extended his criticism of quinine sulphate, and in the *Nieuw Tijdschrift* of this month publishes the results of his examination of the make of the two principal English manufacturers of this article, reporting the amounts of cinchonidine sulphate to be as follows:—

	Howard's.	Whiffen's.
Quinine sulphate	84.769	82.208
Cinchonidine	9.508	6.942
Water of crystallization ...	5.723	10.850

100. 100.

The makes of quinine sulphate which are now impugned as containing large amounts of cinchonidine sulphate are among those which bear the highest reputation for purity, and it may be expected, therefore, that the publication of these results will lead to further inquiry into the value of the optical method of analysis by which they were arrived at. Though Dr. de Vrij attaches much importance to it, other authorities are of opinion that it cannot be relied upon. Dr. Hesse, who has given great attention to this optical method, considers that it is even capable of indicating the presence of cinchonidine where it does not exist at all, or from three to four times as much as there really is present, and the inferences drawn from results obtained by this method do not appear to have any greater value than that by which Dr. de Vrij was led to state that total alkaloids of succirubra bark always possess a particular rotatory power by which their origin may be recognized, an inference that has now been completely exploded and ascertained to be necessarily erroneous.—*Pharmaceutical Journal*.

THE RED SPIDER, SO CALLED.

This creature is not a spider, but an acarus or mite, and lives exclusively upon vegetable products. In zoological classification they both belong to the class Arachnida, but the mite is in the order Trachearia, the spider in that of Pulmonaria. The function of breathing in the two orders is different. In the mite it is performed by air tubes distributed through the body, whilst in the spider the air is admitted by spiracles situated on the abdomen, and which are lined by a membrane plated into numerous folds, which resemble gills. On these characters is founded the sub-division of the class into pulmonary and tracheary Arachnida.

But apart from all technicalities any one with a good pocket lens might satisfy himself that the pests of gardeners differ in important particulars from the

spider. The head and breast, or thorax, of the spider is connected with the abdomen by a slender cord, as in insects. It has eight eyes, and the same number of legs, besides two short arm-like projections, or palpi, with which to catch and to hold its prey. The body of the mite is not so divided; is somewhat oval in form and tapering to the head, which is terminated by a syphon or sucker, with which to extract the juices of plants. It has six legs, but by undergoing a transformation similar to insects an extra pair is not unfrequently acquired. The body is transparent, with dark vein-like ramifications along the back, which we take to be the tracheæ. The aged females only are red, which may have given rise to the popular name by which they are known. They spin webs, but not artistically as spiders do, as they seem chiefly designed for nests, or, when the workers are unmolested, convenient residences for large communities; whereas the web of the spider is not only a snug retreat in times of danger, but a base from which to operate against enemies as well as a sure to entrap unwary flies or other creatures upon which it feeds.—*Gardeners' Monthly*.

FRUITS IN NEW BRITAIN ISLAND.

The fruit of Duke of York island consists of the banana, cocconut, tan, mummy apple, and a description of wild mango. Yams and taro also grow on the island, but sweet potatoes are the chief product, and serve as one of the main articles of trade between this and the other islands.

The bananas also are in some parts of the island very fine, but the yams and taro are not to be compared with those of New Britain, or the yams of New Ireland, which are noted for their large size. The taro of New Britain is also considered the finest in the South Seas. Taro is a large bulbous tuber, with leaves much of the shape of the *Caladium*. I have never seen the flower. There are two different kinds, one of which grows in swampy ground, and the other on the hill-sides; the latter is the largest and best, the swamp taro being waxy to eat. Taro is planted in rows, about one pace apart, and is kept clear of weeds by the women; the hill taro grows to the size of fifteen inches long, by one foot circumference. When cooked in a small quantity of water, the starch that exudes from it makes the water into a thick paste, therefore it requires more water added continually, and when cooked, is soft and mealy, and is one of the very best vegetables I have ever eaten. The native way of cooking it is even better than boiling; the outside rough brown coating is scraped off with a sharp shell, and after cutting the taro in halves lengthways, it is wrapped up in banana leaves, and placed in a fire where it is not too hot; when cooked, it is much like good new bread, and is excessively nutritious. After taking the taro out of the ground, the tuber is cut off, leaving about an inch still adhering to the stalks and leaves; this is again placed in the ground, and in about three months has another large tuber ready for cutting. The leaves are terribly astringent, and, if eaten raw, will take the skin off the mouth, and render it very sore for some days, but the young leaves, cooked, are very delicious.

There is also a fruit called the "tan," which I don't suppose many European know much about. It grows on very high trees, whose wood, by the way, is beautifully grained and very hard, though nice to work. The fruit is shaped much like an apple, and also grows in bunches as some apples do, but if you take one in your hand and press it, when ripe, the skin will come clean off, and the inside is then found to be beautifully clear jelly-like substance, which, when placed in the mouth melts into water. This jelly surrounds a brown stone, of which the natives make a sort of cake, after it has been soaked for some days. The "pappo," or mummy apple, has also some curious facts connected with it that are useful to know. The very young apples, when boiled, make a most delicate substitute for vegetable marrow; the stalks and leaves, if boiled with clothes, will render them beautifully clean and white; they come out of the boiler a bright gamboge yellow, but when hung up to dry in the air, they turn

perfectly white again; a small piece of the leaf or stalk, boiled with an old fowl or tough piece of meat, makes it quite tender.—*Journal of the Society of Arts.*

THE INFLUENCE OF FORESTS ON CLIMATE.

The third number of *Petermann's Mittheilungen* for this year contains an article by Herr A. Woeikof on the influence of forests on climate. The commencement of a scientific investigation of this subject was made when the Bavarian forest meteorological stations were established, and when Prussia, Alsace-Lorraine, France, Switzerland, and Italy followed the example. As a general rule it may be laid down that in the warm seasons, as between forests and places close at hand which are treeless (1) the temperatures of the earth and air are lower in the former, (2) their variations are less, (3) the relative humidity is greater. After examining observations as to evaporations, Herr Woeikof states that the influence of forests in diminishing evaporation from water and the soil is so great that it cannot be accounted for alone by the lower temperature of the hot months, the greater humidity, or even by the shade. An important influence, which has hitherto been but little appreciated, is the protection from the wind afforded by the trees, and this the writer regards as more important than all the others together in reducing the degree of evaporation. With regard to the influence of forests on rain and snowfall, there is as yet only a single series of observations supplying comparative statistics, and extending over a sufficiently long period. These were taken in the neighbourhood of Nancy, and they show an important influence of forests in increasing the rainfall. It might appear that the effect of forests on rain in the climate of Central Europe in winter would be small, for the difference between the temperature and humidity of the forest and the open is very little, and the quantity of moisture in the atmosphere is small. But the observations show that it is at this time of the year that forests get much more rain. This the writer attributes to the clouds being lower, the resistance which the forest offers to the movement of the air, and to the moist west wind. Forests retain rain by undergrowths of grass, moss, &c., much better than open ground, and let water off superficially only after a heavy rainfall; the remainder filters upwards slowly, and much of it is used for the evaporation of the trees. Although forests, especially thick, luxuriant forests, cannot exist without certain supplies of moisture, yet it is the same to them when the supplies come, for they retain what they get and use it over a long period. One example of this is the Lenkoran forest on the west coast of the Caspian, where the vegetation is more luxuriant than in any other part of Europe, yet very little rain falls in summer, but the rainfall in autumn and winter is great. The water is stored up by the forest, and is used in evaporation during the heat of summer. Humidity of the atmosphere, however, is not inconsistent with a high temperature, as the Red Sea shows; but in forests the humidity is due to the evaporation of the leaves—in other words, to a process by which heat is converted into work, and hence the coolness. Herr Woeikof then endeavours to ascertain the influence of forests on the climatic conditions of their neighbourhoods in the western parts of the Old World, between the 38th and 52nd degree N. latitude, the places selected being in all cases in the open. Thus for the 52nd degree eight stations are taken between Valencia in Ireland on the west and the Kirghiz steppes on the east; for the 50th, Guernsey on the west, Semipalatinsk on the east, and thirteen stations, and so on for each two degrees of latitude to 38°. The general result of the observations in fifty stations in six different degrees of latitude is that in Western Europe and Asia large forests have a great influence on the temperature of places near them, and that by their influence the normal increase of temperature as we travel eastward from the Atlantic Ocean to the interior of the continent is not merely interrupted,

but they give places far removed from the coast a cooler summer than those actually on the sea. A striking example of this is Bosnia. An examination of the statistics shows (1) that in Bosnia the summer is 2°·5 to 4°·5 cooler than in Herzegovina; (2) even on the island of Lissa, in the full influence of the Adriatic Sea, the summer temperature is more than a degree higher than that of Bosnia, which is separated by lofty mountain ranges from the sea. Bosnia owes this comparatively cool summer to its great forests, while Herzegovina is almost disafforested. To sum up: forests exercise an influence on climate which does not cease on their borders, but extends over a large or smaller adjacent region according to the size, kind, and position of forest. Hence man by afforestation and disafforestation can modify the climate around him; but it is an extreme position to hold that by afforestation the waste places of the earth can be made fertile. There are places incapable of being afforested, which would not give the necessary nourishment to trees.—*Nature.*

TIMBERS OF UPPER ASSAM.

It will be easily understood that in a country where the temperature of the plains and low hills never falls below 45 degrees F., and never rises above 100 degrees F., with an average rainfall of 120 inches a year, vegetation cannot but be of the most luxuriant character and extreme variation. In fact, one of the characteristics of Upper Assam is its interminable jungles constituted in places by thick forests of colossal trees, and in others by impenetrable cane or bamboo groves. As a rule, cane jungle will grow in swampy ground where water lodges for several months, and sometimes all the year round. Bamboo jungle will grow in low lands flooded occasionally, but where the water does not remain for any length of time. Forest jungle generally grows in dry soil, and one or other of any special trees seems to prevail according to the different altitude of the ground, or perhaps it would be better to say according to the different degrees of moisture retained by the soil. The prevalence, however, of any special tree is by no means strikingly apparent. In spite of favourable ground, and the gregarious tendency of nearly all forest trees, it seems that a great variety will grow and flourish side by side in a way which would seem quite incongruous in our country. The only clear fact in these forests is the total absence of certain species of trees under peculiar circumstances. Thus Nahor and Makahi, as will be seen hereafter, are never found in low lands, especially if subject to occasional floods, while Uriam and Hollock are never found in high, well-drained lands. However, as a rule, one may stand in one of these forests surrounded by trees growing as thickly as possible, and he will find it difficult to detect half-a-dozen trees of one species. This fact considerably enhances the wild beauty of the Assam jungles, but it has been up to the present time a great drawback, from a mercantile point of view, to the proper utilization of the timber. For the purpose of collecting one kind of timber it necessitates going a great distance through untrodden jungle, and after having found and cut it to the smallest size, elephants are required for the purpose of dragging it off. This process, of course, causes a large portion to be wasted, which under other circumstances would be very valuable. The Assam Railways and Trading Company, amongst other concessions, obtained from the Government of India, have the monopoly of the timber trade for 1½ miles along each side of their line, which runs from Makum Junction to Margherita (a distance of 23 miles), and the specimens on view at the Health Exhibition came from these forests, which extend, practically, uninterruptedly from end to end of the above-mentioned portion of the line. When the Company first commenced work in opening out the country, little or nothing was known as to the real value of many of the timbers, and as the Company's works depended so much on them, they had to start at the beginning, and thus acquired an amount of information which will prove very valuable for the future of the timber trade of that country. The follow-

ing is a description of the various specimens exhibited.—

Mesua ferrea.—Assamese name, Nahor; English, Iron-wood; specific gravity, 1.23; co-efficient of rupture in cwt. and decimals, 27.9; loss of weight when chemically dried 25 per cent; maximum shrinkage due to above operation, 8 per cent.

There are some good patches of almost exclusively Nahor trees to be found here and there, growing on high, well-drained ground, but they are not extensive. The stem is generally straight, and the average size is from 25 feet from the foot to the first branch by 5 feet girth, maximum height found 45 feet from foot to first branch, maximum girth 12 feet 6 inches. The branches are generally thin and of no use as timber, but they produce excellent charcoal and make first-class firewood.

The timber is of a deep red colour, with very close undulating fibre, rather brittle, warps and splits when cut into planks or small scantlings, heartwood not attacked by insects of any kind, and stands almost indefinitely, both exposed and under cover, without deteriorating. Before being used it should be stripped of all its sapwood, and thus prepared, forms an invaluable material for bridge piles, beams and thick scantling generally; in fact, it serves almost as a substitute for cast-iron.

Artocarpus Chaplasha.—Assamese name, Sam; English, Moukey Jack; specific gravity, 0.63; co-efficient of rupture as above, 12.3; loss of weight in chemical drying, 32 per cent; maximum shrinkage due to above process, 5 per cent.

This tree does not seem to have a preference for any particular ground; it grows in low land with as much vigour as upon the hills. It is never found in patches, but is liberally scattered all through the jungles. The stem is seldom very straight and branches off soon, sometimes at a few feet from the ground, but the branches often produce good timber. It is of a bright yellow colour when cut, and deepens into a brown walnut colour in the course of time. The fibre grows pretty straight, not very close, breaks short, and receives easily a clean polish. It warps and splits very little. It stands well either exposed or under shelter, and insects will not attack it. It is a very useful timber for any purpose where great strength is not required, being specially adapted for household furniture, as it is equal or superior to teak for this purpose.

Bischofia Javanica.—Assamese name, Uriam; English, none; specific gravity, 1.04; co-efficient of rupture as above, 15.2; loss of weight in chemical drying, 24 per cent; maximum shrinkage due to above process, 10 per cent.—*Indian Tea Gazette*.

THE MANAGEMENT OF COFFEE SOILS.

At the time of the Madras Agricultural Exhibition of 1883 there were prizes offered for the best essays on certain subjects connected with the objects of the promoters. The two first articles in the volume, by Mr. Clarke and General Morgan respectively, are on the question of the best way of treating land that has been planted with coffee. The former of these writers chiefly devotes himself to proving the tremendous loss that is sustained by what he terms "waste," or causes not connected with the exhaustion of the tree from producing crop; while General Morgan lays before planters the evils that arise from the use of inert manures, and badly selected seed. Assuming Mr. Clarke's figures to be correct (and as they are based on those in the report presented by Mr. Hughes to the Ceylon Planters' Association we may safely do so), we imagine that most planters will be startled to find how large the proportion, of this, presumably, preventable waste is.

Coffee is not in itself an exhausting crop; compared with wheat, or turnips, the actual formation of the bean takes very little nutriment from the soil. The comparison is of course not a fair one, though so often made, for in these analyses the existence of the tree which bears the bean, and has to maintain itself in vigour, is always neglected. If, however, the waste could have been avoided, or at least minimised, many estates which are now abandoned would still be giving good crops. Of the four most

important elements of the soil, namely, nitrogen, potash, lime, and phosphoric acid, an average crop is calculated on one acre to use up but 21 lb., while a moderate estimate of the amount of loss by wash on the same surface is no less than 322 lb., or in other words enough to produce sixteen crops of coffee. Mr. Clarke adds to this a loss of 169 lb. for leaf; but as this is, in the nature of things, unavoidable, it may be left out of our present calculations. Of the wastefulness of a mode of cultivation such as this, there can be no doubt, and the only question is, how can it be remedied. Mr. Clarke strongly advocates draining, by cutting catch drains at short intervals across the face of a new clearing, by making wash-holes between the trees, and by forking. As to the first of these cures, there are estates on which drains answer well enough; but there is, for some reason, a strong prejudice against them amongst planters in Southern India. General Morgan, for instance, utterly condemns them as worse than useless in the essay that is printed immediately after Mr. Clarke's; and yet in Ceylon no planter who could possibly afford it would leave his estate undrained. Whether it is from some difference in the soil, or from the heavier rainfall which causes them to become choked, drains do not appear to answer in our planting districts. Besides this, they add enormously to the "opening charges." Mr. Clarke estimates the cost of drains and wash holes on his system to be £100 per acre. Now a proprietor who thinks £50 per acre a liberal estimate for felling, pitting, roading and planting, would neither consent, nor could afford to treble this expenditure to carry out a work that all his neighbours would assure him was useless. The expenditure on manure, too, which Mr. Clarke points out would be saved by conserving the soil, need not be incurred till at least after one crop has given the planter some return for his capital. The plan of making wash-holes is, however, recommended by both these essayists, and as it has been tried on many estates, is worthy of some attention from those interested in the matter. These pits are to be cut in the intervals between the trees; they are 5 feet long by 2 feet broad, and 1½ feet in depth; they are useful for preventing a great rush of rain in the monsoon storms, and the leaves, weeds, and prunings should be collected in them, removed from time to time, and forked in over the surface of the field. Mr. Clarke gives some remarkable instances of the efficacy of the prunings when returned to the soil of vineyards. A great deal of a planter's success depends, however, on the careful selection of laod. Twenty years ago it was supposed that any land in a coffee district was sure to do well, and a large number of estates were opened, only to be abandoned after dragging out a hopeless existence for a few years, and ruining their owners. Very steep land should certainly be avoided. General Morgan gives an instance in opposition to this, but in the Ouchterlony Valley, and the behaviour of coffee in that favored locality cannot be accepted as a guide in other districts.

Neither writer has a word to say about shade, and this is a serious omission in writing of the treatment of soils, for the shade trees not only protect the coffee from the sun, but enormously fertilize the soil by shedding their leaves. General Morgan strongly insists on the necessity of procuring good seed for coffee nurseries, and instances several estates in Wynaad where the neglect of this precaution has had disastrous results. Wynaad, indeed, has recently been a fruitful theme for the agricultural moralist from other districts: it has been somewhat in the position of the drunken man at the temperance meeting, "the frightful example" of the vengeance of outraged Nature on the planter who disbelieves in George Ville. Be this as it may, there is no doubt a great deal of truth in General Morgan's warning, and the fact that planters in one district now endeavour always to procure seed from another, or even from Java, Jamaica or Brazil, shows that they have appreciated the fact. There is one suggestion of Mr. Clarke's which we will notice in conclusion, namely

that there should be set apart in each coffee centre an experimental field, worked under the direction of a central authority by which all results should be carefully collected and circulated. . . The initiation and direction of such a scheme must be undertaken by the Government, also probably the scientific advice and analyses required; the cost of working should be borne by the planters, but there is no reason why the experimental fields once started should not be self-supporting." The idea appears to be a good one, and with an organisation such as the Ceylon Association would no doubt soon be taken up. Planters in India, however, are fond of working for their own hands, and outside their District Associations show little aptitude for combination, except when threatened by some act of the authorities, involving a common danger. There can be no doubt that with the present low prices for coffee any scheme that would show planters how to increase the yield of their trees, and save them from deterioration ought to be welcome.—*Madras Mail*.

MANURING FRUIT TREES.

A series of investigations has lately taken place relative to the manuring of fruit trees. It is asserted that the generality of fruit trees take away from mother earth large amounts of mineral and other manures known as fertilising salts, and that either non-productiveness or smallness of the fruit is chiefly attributable to the exhaustion of these soluble salts. Experiments made on two sections of a vine plantation—one part left to nature and the other manured with soluble phosphates—proved that the grapes contained a greater quantity of sugar and a considerable rise in the percentage of potash over the unmanured portion; also, that the plants, far more healthy in appearance, retained their leaves longer in the autumn, and were less liable to the attacks or oidium. If these statements are correct, it is evident that the application of bonedust, nitrate of soda, guano, and other similar manures would have a very beneficial effect on our vines, whether they are grown for wine or dessert purposes. Experiments go to prove also that strawberries show a wonderfully marked improvement when treated with the manures above mentioned. It has also been well proved that peach trees gain a valuable advantage by the application of such manures, as the fact has been proved that the fruit of trees manured is both larger and better flavoured. If the plan is of advantage to the above-mentioned trees, it must be evident that it would be of advantage to all other kinds of fruit trees, and entirely throws to the wind the dictum of an orange-grower that disease only appeared to the colony after such manures were administered to the trees. Dr. Goemann's writings and experiences conclusively show that it is the want and not the application that causes the diseases complained of. Again, growers cling to the old-fashioned stable manure as being the most suitable; but, while we are not prepared to dispute its value, it is not the thing that nature requires, especially as in it cannot be found the mineral salts requisite to establish the deficiency caused by the absorption of the original elements by the trees. Our fruit tree growers have at command, weather being favourable, manures, easily handled and easily applied, that will render fruitgrowing a more payable affair than hitherto, and result in good healthy growth and the keeping away of all manner of insect pests. To do any good wet weather is necessary, and this much can be said in its favour—that no kind of manure is of the least value when applied during dry weather, or when the soil itself is dry. Fruit tree growers need not be told that towards the end of winter is the best time to dress vines and fruit trees. Again, by burning the prunings and dressing the soil with the ashes, the grower will give in an indirect manner to his fruit trees valuable nitrates, and in these days of troublesome insect pests the most sensible method is always to burn the prunings in place of continuing the old practice of throwing them into a heap, from which in some form

or other the enemy may escape and continue its damages. The value of these chemical or mineral manures is but yet imperfectly understood, and it is only owing to the scarcity of old-fashioned manures that growers have become conversant with their importance, and from older countries than this we can glean valuable information of their utility. Again, in this colony, stable manure is for the most part nearly valueless, consisting of sawdust and droppings, so that it is far cheaper in the end to use the manures advocated in this article. By-the-way, experimentalists advise that these manures should always be applied well away from the bole of the trees, a very sensible advice, considering that the root feeders are well away from the trunk, so that the application near the trunk must simply be a waste of money. While on the subject of chemical manures, our American cousins have been experimenting on their valuelessness in potatoe cultivation. The old theory is that there is no better manure known for potatoes than good stable compost. Yet, strange to state, comparisons prove that the balance of crop is in favour of the soluble salts in the ratio of eight to six, thus fairly proving that ground requires to be renewed with these salts even to grow fair crops of potatoes. The conclusion is simply this: that all crops exhaust the soil more or less of mineral manures, and if the cultivator's object is to keep up fertility he must in addition to ordinary manuring freely apply to the land in some shape or other chemical soluble salts known as fertilisers. To the vigneron the hints herein contained, that by applying these fertilisers the fruit will contain a greater percentage of potash, should be valuable, as by their application the general acidity so noticeable in our colonial wines may in a measure be overcome, and even when used for dessert purposes their lusciousness will be greatly enhanced. Those who grow gooseberries in the interior of the colony should not fail to well manure their bushes. It is a well-known fact that gooseberries are gross feeders, and quickly exhaust the ground of any goodness that may be in it. Therefore, if good food is required, manuring of some sort should be given annually during the winter months. The same rule applies to currants, which, in regard to size of fruit, would be materially improved by the application of nitrates or good stable manure.—*Sydney Mail*.

PLANTING IN CEYLON AND IN FIJI.

Under the head of "Planting in Ceylon," we recently published a valuable contribution from Mr. R. L. Holmes. The range of subjects therein brought under notice cannot fail to possess a deep interest for all those engaged in developing the agricultural resources of the colony. Indeed, as the progress of the colony and the prosperity or all who are associated with it is entirely dependent upon this development, the interest should become general as each recognises the direct or indirect bearing of the matter upon his individual welfare. The community has already received a sufficiently severe lesson upon the folly of carrying all the eggs in one basket. When the cotton failed, planters had literally nothing to fall back upon. The time that should have been devoted to experimental culture had been wasted. It had then to be dispensed with as a guide, and to be prosecuted at hap-hazard, in the face of conditions which made failure assume the most serious proportions. The planters were literally at their wits' end in "pottering" before the sugar industry gathered sufficient strength to constitute it a mainstay.

It cannot be altogether unprofitable to reflect upon the probable amount this has cost the planters individually, and the colony generally. How many thousands, for instance, might have been saved if a course of experiment, conducted in various parts of the group, had first demonstrated the most favorable conditions under which coffee could be cultivated, and had indicated under what circumstances it was impossible to make it a success? How many thousands might have been added to the aggregate value of estates if such a course

had pointed out the superior suitability of the tea plant for cultivation in Fiji, and had induced the laying down of the abandoned coffee plantations in this or some other crop which had given fair promise of a remunerative character as the result of actual experience. Of course it may be objected that this is all speculation, deriving its quasi-philosophic appearance from the light of the after event. Granted. But directed on a reasonable course speculation becomes a very profitable mental exercise. Upon practical men its effect is to induce experiment, and as this is the special object now in view, so valuable a factor may well be employed in working out the desired result.

Considering former experience it might have been fairly expected that the breathing time following upon the establishment of the sugar industry would have been utilised for the purpose of ascertaining by what products, offering a fair chance of remunerative cultivation, it could be supplemented. But the person who would ask—What has been done?—must be answered, practically, nothing. Once again we have seen ruin impending over the colony. Again we have seen its staple industry checked and brought perilously near to the verge of suspension. There is now every prospect that the cloud is rolling by. But if such were not the case, is it not evident that for the sheer want of a substitute industry to turn to, the outlook would be even more gloomy than it was after the cotton failure.

In the face of this poverty of available resource, notwithstanding the wonderful capability of our soil and the advantages of our climate, it is suggestive to turn to the long list of articles enumerated by Mr. Holmes as forming certain of the various sources whence Ceylon derives its wealth. It has not two, but rather two dozen strings to its bow; and as Mr. Holmes correctly observes of the catalogue he has furnished:—"It would be easy from it to fill in a very long list of plants we ought to have, and have not, in Fiji." But to secure their introduction and to test their suitability for the climate it is first of all necessary that some effort shall be made toward the establishment of an experimental garden. The proposal is no new one, but has been ventilated and urged in these columns over and over again. At one time there even seemed a prospect that this insistence would not be barren of practical result. The attention of the old Agricultural Society was aroused. The matter was forcibly represented to Sir Arthur Gordon. Its importance was by him freely admitted. Promises of some definite action in the desired direction were as freely given. But, as though satisfied with this measure of success, the spasmodic interest then subsided. No sustained effort followed to obtain the fulfilment of the promise, and therefore nothing resulted.

Perhaps, though, it is incorrect to say that nothing resulted, since some time afterward reference was officially made to the "Botanical Gardens," as to a something actually existing. Enquiry then elicited the fact that there was a plot of ground in rear of Draiba dignified by this pretentious title. There are indeed a few who could even now go to the place "where once the garden smiled," and who yet preserve traditions of the magnificent *Crotons*, *Draenas*, etc., there cultivated. Is it not a thousand pities that so bold an attempt to improve our list of remunerative products should have been prematurely abandoned.

Mr. Holmes conceives that with respect to the prospect of obtaining the establishment of this experimental garden the Government is "past praying for." Strictly construed this may be accepted as a general characteristic of governments. But in the sense intended and coming from one who has himself done much in the direction of improving our product list, the remark is indicative of the pernicious and disheartening effect of official apathy. Nevertheless he pertinently propounds for authoritative answer the question—"Is it right, honest or wise to shirk this matter any longer?" An admission has lately been made by the Administrator that in consequence of the decline in sugar values the revenue has so suffered that works of importance must be postponed. What then would have been the result had the depression continued? And in the face of the

probabilities which the reflection must suggest, is there not a peculiar significance attaching to the question above quoted. In every interest subject a strenuous effort should be made to force the subject on the attention of the Government. It is one of vital importance and its consideration should be compelled, at least to the extent of eliciting an answer to the question above formulated.

This is a matter which specially comes within the province of the Planters' Association. Further, as several of its members are also members of the Legislative Council, and as the subject is one which warmly commends itself to their support, the Association should be in a position to obtain something more than a mere formal reply. It must be expected that the first response will be a full admission of the importance attaching to the subject, a declaration that it has at all times very largely occupied official attention, and pathetic regrets that the present state of the revenue does not warrant, etc. This should not be accepted as concluding the subject, although the force attaching to the last clause cannot be gainsaid. But some guarantee for the future should be obtained by the setting aside of land for the purpose, say on the Rewa; and the placing of it under the temporary charge of some officer, say Mr. Robert Wilson; with instructions to do something in the way of inauguration. Many are the instances that can be mentioned in which the seed or products likely to add to our export list has been introduced for gratuitous distribution, has been distributed, and has been heard of no more because of the desultory manner in which the experimental culture has been attempted. This would hardly be the case if the seed could be forwarded to any public establishment for trial by a public officer who would feel that a special weight attached to his report. However humble and unpretentious the beginning, the development of the institution would rapidly follow as its value became appreciated, and even now no question is entertained that it would soon repay the expenditure it would involve. The object can be secured if the effort made is commensurate with its importance, and this simply depends upon the Planters' Association and the unofficial members of Council.—*Fiji Times*.

THE CULTIVATION OF INSECT WAX.

It is within comparatively recent years that insect wax has become an article of export from China, and even now comparatively little is known among the general public of this article. Insect wax consists principally of cerotic acid in combination with oxide of ceretyl, and has been used lately in England for manufacturing purposes in making a superior kind of wax candles, though the article is at present far too costly for general use. Considering, however, that nearly 500 tons of beeswax are annually imported into England alone, and that Chinese insect wax is adapted in a superior degree to all the purposes for which beeswax is used at present, it stands to reason that Chinese insect wax has a great future before it if its production can be increased and cheapened. Strange to say, insect wax has hitherto not been discovered anywhere in the world except in the one Chinese province of Szechuen and in South America. But South American insect wax is hardly known yet, nor has it so far become an article of commerce. Some years ago the insect wax of China attracted the attention of the French Government, and an attempt has been made in Algeria to rear the Chinese wax insect on imported insect trees and wax trees there, but with what results we cannot tell. From a Parliamentary Blue Book lately published it appears that the Director of Kew Gardens also had his attention directed to the matter and applied to the late Sir Harry Parkes for information on the subject of insect white wax, for specimens of the insect trees and wax trees, and for forms of the wax product. Sir Harry Parkes instructed Mr. Hosie to visit the wax producing districts of Szechuen and to supply all that the Director of Kew Gardens required. Mr. Hosie accordingly journeyed in June and July, 1884, through central Szechuen, studying the subject in loco, and his official report has been presented, by

command of Her Majesty, to both Houses of Parliament, as the second China Blue Book of 1885.

Mr. Hosié's report does not by any means clear up all the obscurities which have hitherto surrounded the mode of producing insect wax, but it is the first reliable and at the same time well nigh complete account, entering into most of the details of this intricate subject. His report is, however, presented in a somewhat disjointed manner, which makes it difficult, without careful study, to piece together, into a connected outline, the dislocated pieces of information which he distributes under the heads of (1) the insect tree, (2) the insect, (3) the wax tree, (4) the wax. But the sum total of his report is not only of interest for Chinese commerce in general, but for Hongkong in particular, if, as we are inclined to believe, it may be possible to introduce in Hongkong the rearing of wax insects and the cultivation of the insect tree and wax tree. It is with a view to encourage enterprising spirits in the Colony to make the experiment of transplanting from Szechuen to Hongkong this valuable industry of the production of insect wax that we attempt briefly to put together, from Mr. Hosié's report and from other sources of information at our command, a connected statement of the principal facts connected with the production of Chinese insect wax.

It appears, then, that there are many districts, all over the province of Szechuen notably, however, the Chien-ch'ang valley, the Chien-wei district, and the neighbourhood of Ch'ung-ch'ing, where a certain tree, which is at present supposed to be the *Ligustrum lucidum*, grows wild. Mr. Hosié omits to state the exact position of these places, but we find from Playfair's "Cities and Towns of China," that all the regions where this tree is found in abundance and where the industry connected with it flourishes, are situated between lat. 29 and 30 N., and long. 103 and 104 E. Now, in the above mentioned places a considerable business is done, simply in detaching from the boughs of this so-called insect tree numbers of pea-shaped excrescences or galls and exporting them to different places in Szechuen and other provinces of China, especially Huanan and Kweichow. There is, so far as we can see, nothing to hinder the export of these galls, in sound condition, even to Hongkong. Each of the galls contains a small colony of tiny brown insects, resembling minute lice, each with six legs and a pair of club antennae, and (in many cases) also a small white cocoon containing a beetle (known as the buffalo beetle) which has also six legs and a long proboscis armed with a pair of pincers. These galls are, about the end of April each year, detached from the boughs of the insect trees, wrapped in parcels of 20 or 30 galls each, in leaves of the wood-ool tree, whose edges are fastened together with rice straw, or done up in paper packets, each weighing about 12 Chinese ounces, and sold at a price ranging from half a tael to one tael a packet.

The purchasers of these galls, whether in Szechuen or in other provinces of China, being owners of wax trees, now take the packets of galls, and, after making a few rough holes in the leaves enveloping the galls, suspend the packets close to the branches of the so-called wax tree. Mr. Hosié gives no name to this tree, leaving it to the Director of Kwé Gardens to identify the specimens forwarded to him. But we may add that hitherto this wax tree has been considered to be a species of *Fracinus*, and named *Fracinus Chinensis*. Mr. Hosié supposes that, when the packets of galls have been suspended underneath the boughs, the following process takes place: The buffalo beetle above mentioned living within each gall, having previously done part of his duty in boring a hole through the rind of the gall, escapes through the holes made, and being at first unable to fly, remains, with crowds of other buffalo beetles, of both sexes, for some time on the branches of the wax tree, leaving behind eventually, when taking flight, deposits of minute eggs, destined to cause some mischief. Meanwhile, however, the wax insects also escape through the holes made by the buffalo beetle, creep rapidly up the branches of the wax tree, and,

after remaining for 13 days on the leaves of the older branches and having moulted there, descend finally to the tender branches, fix themselves on the under sides to the bark by their mouths, to commence to produce, by some as yet unexplained process, a liquid which gradually encrusts the branches with a thick coating of wax. But during this period these emerge also from the eggs, deposited on the branches by the buffalo beetles, certain insects, called wax-dogs, which prey upon the wax insects and are to be shaken off by the cultivators by beating the trunk of the tree with clubs. After a period of some three months, the crust of wax encasing the branches is about a quarter of an inch thick. The branches are then lopped off, the wax is removed by hand, thrown into boiling water and thence it is skimmed off and run into moulds as the white wax of commerce. The branches are then boiled also and the remainder of the wax extracted, yielding an inferior kind of insect wax. The insects, which, during the boiling process, sink to the bottom, are pressed to squeeze out the last vestiges of wax, and they are then used as food for pigs. The owners of the wax trees have but few expenses, and do on the whole a profitable business. It is estimated that in good years a packet of Chien-ch'ang galls costing about half a tael, will produce from 3 to 4 catties of wax, the present price of which is about 40 taels a picul. But as in bad years not more than a catty of wax can be expected to be produced by a packet of galls, the trade has a considerable element of risk in it, unless the owners of wax trees raise also insect trees and propagate the insects themselves.

We think it highly desirable that an attempt should be made to acclimatize both insect trees and wax trees at different levels of our hills, with a view to ascertain to possibility of domesticating in Hongkong the production of insect wax. As the Superintendent of the Botanical and Afforestation Department is now going home on a well-earned leave of absence, it is hardly possible that anything can be done in this direction until his return. When this takes place, we believe that if Mr. Ford were to make an excursion in Szechuen to investigate the habits of the wax tree and insect, and to procure specimens, it would be attended with results as valuable from a scientific point of view as his excursion up the West River to make investigations respecting the cassia lignea, and possibly more valuable as regards the material interests of the colony.—*Hongkong Daily Press.*

A CHEAP FEBRIFUGE.—Government seems now to be fully alive to the importance of obtaining cheap febrifuge which would be easily placed within the reach of even the poorest. The importance of this question can hardly be overestimated for the deaths from fever in the Madras Presidency in the last 18 years amounted to 3,884,482, the mortality from fever being about three times as great as that from any other cause. A liquid extract of the cinchona alkaloids, which can be prepared very cheaply, has recently been tried in several of the most feverish districts. It was prepared by Mr. Hooper, the Government Quinologist, and contained 24 grains of the alkaloids to the fluid ounce. Dr. Cornish now reports that the experiments have been very successful, and recommends that this extract should be prepared in large quantities. He suggests that the strength should be increased to 40 grains to the ounce, and we believe that Mr. Hooper has found it possible to prepare an extract of this strength. The cheap febrifuge prepared in Bengal is unsatisfactory, inasmuch as it causes nausea and disorders the digestive functions, but this is not the case with the extract prepared by Mr. Hooper, even when it is taken in large doses. Probably this is due to the circumstance that the alkaloids are in the form of tannates, and that the astringency of the tannin counteracts the tendency to cause nausea. It is now proposed to manufacture this extract in large quantities. We wish that private enterprise would step in, and make it unnecessary for Government to do this itself.—*Indian Agriculturist.*

THE COLD IN FLORIDA.—We have already mentioned the very unusual degree of cold experienced in Florida. We now learn that it is expected that the Orange trees will lose their leaves, and that the young trees will be wholly destroyed. It is calculated that 500,000 boxes of Oranges, worth 1,000,000 dol., have been destroyed by the frost.—*Gardeners' Chronicle*.

TAPE-WORM CURE.—The administration of one drop of croton oil and a drachm of chloroform in an ounce of glycerine having been recommended as useful in obstinate cases of tape-worm, Mr. McCullum, of Ontario, writes to say (*Brit. Med. Journ.*, June 13, p. 1231) that the vehicle only is necessary for the purpose, since the glycerine will kill the tape-worm quite as effectually without anæsthetising it with chloroform, or purging it with croton oil. This property of glycerine, he states, he first observed one day when removing a worm from the stomach of a fish and putting it into a drop of glycerine upon a microscope slide, where it died almost immediately. He was therefore led to dry the experiment of substituting glycerine for the nauseous male-feru dose with good results. Sometimes he has found it necessary to follow the glycerine with a gentle purgative, but not always.—*Pharmaceutical Journal*.

PAPER BEDCLOTHING.—A paper-making firm in New Jersey has for several weeks been turning out counterpanes and pillows of paper. No. 1 manila paper is used, two large sheets being held together by a slender twine at intervals of three or four inches. The twine is gummed, so as to hold the sheets firmly together where it lies. A hem is placed on the counterpane to keep it from tearing; the safety edge is composed of twine. Ornamental designs are stamped on the outer surfaces of the covers and cases, giving them a neat, attractive appearance. When these counterpanes and pillow-cases become wrinkled from use they can easily be smoothed out with a hot flatiron. The counterpanes can be left on the bed when it is occupied, and in cold weather will be found a warm covering, paper preventing the escape of heat. The new paper bedclothing is 75 cents per set, and will probably become popular.—*The Paper Maker*.

WINDS sometimes prove fertilisers, though the South Indian planter finds that, as a rule, his coffee and cinchona will not flourish in exposed positions. The district of Limagne, in Auvergne, is one of the most fertile in all France. It lies east and north-east of the Domes mountain chain, and is swept by the prevailing winds of that region, which, according to M. Alluard, transport the fertilising dusts of the volcanic hills and shed them, by means of rain or snow, upon the soil below, thus, as it were, supplying the latter with fertilising chemicals. Phosphoric acid had been found in the volcanic dust of the Domes; so also have potash and lime. From an examination of dust brought down by rain on the Puy de Dome, M. Alluard estimates that nearly 400 grammes of dust descend on a square metre in a year.—*Madras Mail*.

THE DETERIORATION OF INDIAN TEA.—Every now and then, when prices at home show an appearance of decline, alarmists are found to come forward with the consolation: "I told you so! Your teas have deteriorated, and people are not now so eager to buy them." And not finding any other sufficiently apparent reason for explaining why this supposed deterioration has taken place, these alarmists fall upon *Machinery* as the cause,—the head and front,—of the stated decadence of quality. A home Paper, rejoicing in a so-called "Planters' Supplement," thus sapiently expresses itself:—"The consumption of Indian Tea has immensely increased the price has largely decreased, and the quality steadily deteriorated." As if the very fact of increased consumption was not of itself a direct answer to the last charge, while the reduction of price shows no more than the success of the endeavour made to compel large absorption by more moderate rates than prevailed heretofore. So long as our supply was limited in extent, we could afford to hold out for high prices, but when that supply became largely increased, the necessity followed of more nearly assimilating our rates to those of China teas than previously we could afford to do; and by the aid of machinery the reduction in the cost of

manufacture has enabled us to sell at lower prices with almost equal profit. As to the quality of machine-made Teas presenting a fatal contrast to Teas made by hand, we do not believe the assertion. Carelessness in manufacture will produce equally bad results whether you hand-make or machine-make your Teas; but it has been undeniably proved that well-made machine Teas are fully equal to hand-made Teas.—*Indian Tea Gazette*.

PHYLOXERA IN FRANCE.—The *Times* correspondent says:—"The *Journal Officiel* publishes the annual report by the Director of the Agricultural Department on the proceedings of the Phylloxera Commission. It has been decided that none of the processes made known during the year 1885 entitle the inventors to the prize offered by the Government, and accordingly the old remedies continue to be recommended. These are—(1) submersion, (2) sulphuret of carbon, and (3) sulpo-carbonate of potassium. The surface under Vine cultivation attacked, and still resisting, amounted to 642,000 hectares in 1885, against 664,000 in 1884. This apparent diminution is, however, due to the complete abandonment of numerous plantations. In-fore the appearance of the disease there were in France 2,503,000 hectares planted with Vines. Vines now cover 1,990,586 hectares, which fact shows that the Vine growers have to a great extent remedied the evil by planting during the last fifteen years, so that the deficit only amounts to 500,000 hectares, but at the same time the amount of loss remains enormous. In 1885 submersion was applied to 24,339 hectares, sulphuret of carbon to 40,585, and sulpo-carbonate to 5,227. American Vines which have been planted now replace those destroyed over a surface of 72,262 hectares. Thus the surface which has resisted the attacks of the insect amounts in all to little more than 145,000 hectares, that is, about 22 per cent of the whole surface suffering from the disease. These efforts, which have been continued uninterruptedly for eight years, should, in the opinion of the reporter, inspire full confidence in the future."—*Gardeners' Chronicle*.

INFLUENCE OF LIGHT ON THE DEVELOPMENT OF ASSIMILATING TISSUE.—We learn from the *Bulletin de la Société Botanique de France*, that M. S. Groszlik, who has been conducting experiments on this subject, selected the primary horizontal leaves of *Eucalyptus globulus*, as on their upper surface when fully developed they have palisade cells, and on their lower surface loose spongy tissue, while the adult leaves directed vertically have palisade cells on both sides. Three principal phases are discernible in the development of these leaves.—1. The very young leaf has between its two surfaces, besides the bundles in course of formation, only one homogenous tissue, formed of cells equal in diameter in each direction, and which the author calls primitive mesophyl. 2. The leaves still remaining vertical develop at the expense of the mesophyl, and in contact with the epidermis on each side a layer of palisade cells. According to Mr. Groszlik these leaves have then the definite structure of the adult leaves. 3. The leaf becoming horizontal the upper surface receives more light than the lower, and the structure appears unsymmetrical. The palisade tissue of the inferior surface is gradually transformed into spongy tissue, and thus the definite structure is arrived at. The author cites some experiences confirming his ideas on the influence of light.—1. He maintained in the horizontal position a leaf taken at the first stage of development. Under these conditions it only develops palisade cells on one face, and not on both, as it does normally. 2. On operating on a leaf arrived at the second stage, and in which, as has just been seen, palisade parenchyma is developed on the two faces, and on keeping this leaf vertical and equally exposed to light on both sides, Mr. Groszlik demonstrated that the development is stopped, and the spongy tissue does not appear on the lower surface. The conclusion arrived at is, that there exists in the leaves a tissue which is not yet differentiated, the primitive mesophyl, and that it is at the expense of this tissue that is developed either palisade tissue or spongy tissue, according to the conditions of illumination. Light favours the formation of palisade tissue, shade that of the spongy tissue.—*Gardeners' Chronicle*.

PROGRESS OF INDIAN TEA.—The trade in tea with China, the Straits Settlements, and other countries, has fallen off 67½ per cent which is attributed by the Collector of Customs to the low prices of the common kinds of Indian tea, which enabled the buyers of cheap tea to supply their wants from the local market.—*Indian Tea Gazette.*

LINNEAN SOCIETY, February 4.—Brigade-Surgeon E. Bonavio, in a paper read, asserts that the wild *Citrus hystrix*, D. C., is the grandparent of *Luna tuberosa*, *L. agrestis*, *Limonis Feri*, *Limonellus aviariensis*, and others, while also more distantly the grandparent of the cultivated true limes of India, Ceylon, &c. The reason why the lime has so persistently a winged petiole, according to him, is that this is derivative from the immense winged petiole of its progenitor *Citrus hystrix*.—*Nature.*

THE CUSCUS YAM.—Through an oversight we omitted to refer earlier to Mr. G. E. Poulier's successful cultivation of this delicious yam in the lowcountry. Mr. A. Whyte of Kandy, now of Nuwara Eliya, first introduced it into the Island from the West Indies some years ago, and it soon became a favourite owing to its flavour and mealiness when boiled. Many, we know, prefer it to potatoes, and those who wish to try it may not be too late if they apply to Mr. G. E. Poulier, Nal Valla Estate, Veyangoda.—Local "Examinauer."

TEA IN THE ANDAMANS.—The extent of land under tea in the Andaman Islands under charge of Mr. A. J. King, now amounts to 186 acres under plant, all of which is Assam hybrid. Forty-two acres of new land have also been pitted ready for planting on this year. The outturn last year was 9,501 lb. which realized R5,330; 1,988 lb. of the tea was sold locally, 3,537 lb. to the Commissariat, 3,827 lb. by auction in Calcutta, and the balance is in hand. The tea which was sold in Calcutta does not appear to have been of a very good description, as it only realized R1,412. Exclusive of the charge for convict labor, the expenditure came to R2,920, the receipts thus exceeding it by upwards of R2,400. The manager estimates that in 1886-87 at least 20,000 lb. of tea will be produced, and he purposes to undertake the contract of the supply of tea to the troops in Burmah for that year.—*Pioneer.*

BRAZILIAN ROSEWOOD has formed the subject of an interesting communication by Mr. A. Galletly, the Curator of the Edinburgh Museum of Science and Art, read before the Edinburgh Botanical Society at the meeting on February 11. This rosewood has probably been used in Europe for three hundred years, yet its botanical source is still unknown, although generally referred to one or more species of *Dalbergia*; nevertheless the trees are said to be abundant in all the eastern provinces from Pernambuco to Rio de Janeiro and the exports from Brazil have reached the value of £100,000 per annum. An attempt has been made to throw some light on its origin by examining the resins and resinous colouring matters contained in the Brazilian and Honduras rosewoods, as well as those of the Indian woods of the genus *Dalbergia*, which resemble rosewood, viz., *D. latifolia* and *D. Sissoc*. From the experiments made, it appears that the extracts obtained by means of ether, naphtha and alcohol are nearly the same in all, both in character and quantity, naphtha extracting about 1½ per cent of matter from the wood, ether about 4 and alcohol about 14 per cent. The alcoholic extract has a strong tinctorial power, one part in 100,000 showing a distinct colour in a test-tube. Other woods gave different results, ebony yielding hardly any colour to alcohol or ether, and mahogany a tincture of far less colorific power. (*Gard. Chron.*, Feb. 20, p. 297).—*Pharmaceutical Journal.*

PEAT MOSS AS A MANURE.—Having had some experience in using peat as a manure after it had been employed as bedding for horses, the particulars respecting it may be of service to "W. M. B." (See "Enquiry," p. 216.) For three seasons it took the place of straw in the hunters' stables here, and we made use of it during that time for various kitchen garden crops, such as Peas, Beans, Onions, those belonging to the Brassica family, &c. For Peas, Beans,

and such crops, for which the ground was trenched in the autumn, it was used very liberally, and was incorporated with the soil as the work proceeded, and of course lost its rankness before the crops were sown; in other cases it was dug in and the ground cropped while it was in a raw state, and the results were in each case similar to those derived from the use of straw manure. We had misgivings as to its value as a fertiliser, and closely observed its effects, and the Celery crop was the only one that appeared to suffer from its use; but as we used it for one year for this crop, and then under rather unfavourable circumstances, I should not be justified in attributing the deficiency wholly to the manure. The Potato was the only vegetable that we considered was improved from its use. I ought to mention our soil is a retentive clay, naturally cold and wet, upon which the peat wrought some improvement in the way of lightening and causing it to break more freely when subsequently worked. A light soil would not be improved in the same way by its use. We discontinued it here in the stables because straw was preferred on account of cleanliness.—THOS. COOMBER.—*Gardeners' Chronicle.*

HOW TO DRY PLANTS.—The materials recommended for this purpose by the Rev. George Henslow are common cartridge-paper, thick white blotting paper, cotton wadding, and mill-board, all cut to the same size. The plants should be gathered in dry weather, and soon after the flowers open, when their colours are brightest. Succulent plants (such as Daffodils, Orchids, or Stonecrops) should be put into scalding water, with the exception of the flowers, for a minute or two, then laid on a cloth to dry. Arrange the specimens and papers in the following order:—Mill-board, cartridge-paper, wadding (split open, and the glazed side laid next to the cartridge-paper), blotting paper; the specimens having small pieces of wadding placed within and around flowers, to draw off all the moisture as quickly as possible, blotting-paper, wadding as before, cartridge-paper, mill-board. When the specimens, &c., are thus arranged, heavy weights should be put on them: about 30 lb. the first day, 60 lb. afterwards. Remove them from under pressure in a day or two; carefully take away the papers, &c., except the blotting-papers between which the specimens are placed; put these in a warm air to dry, whilst the removed papers, &c., are dried in the sun or by the fire. When dry (but not warm) place them in the same order as before; put all under the heavier pressure for a few days, when (if not succulent) they will be dry. Flowers of different colours require different treatment to preserve their colours. Blue flowers must be dried with heat either under a case of hot sand before a fire, with a hot iron, or in a cool oven. Red flowers are injured by heat; they require to be washed with muriatic acid, diluted in spirits of wine, to fix the colour. One part of acid to three parts of spirits is about the proportion. The best brush with which to apply this mixture is the head of a thistle when in seed, as the acid destroys a hair pencil, and injures wherever it touches, except glass or china; therefore it should be used with great care. Many yellow flowers turn green even after they have remained some weeks; they must, therefore, be dried repeatedly before the fire, and again after they are mounted on paper, and kept in a dry place. Purple flowers require as much care, or they soon turn a light brown. White flowers will turn brown if handled or bruised before they are dried. Daisies, Pansies, and some other flowers must not be removed from under pressure for two or three days, or the petals will curl up. As all dried plants (Ferns excepted) are liable to be infested by minute insects, a small quantity of the poison, corrosive sublimate, dissolved in spirits of wine, should be added to the paste, which it will also preserve from mould. The best cement for fixing the specimens on to the paper or cardboard is gum paste. It is composed of thick gum-water and flour mixed in warm water, by adding the two together warm, and of a consistency that will run off the hair brush.—*Indian Gardener.*

TRIAL SHIPMENT OF LIBERIAN CHERRY COFFEE FROM CEYLON TO THE AMERICAN MARKET.

Some time ago we mentioned that we thought there was a good market in the United States for parcels of Liberian coffee in the cherry and one or two sales quoted by us compared very favourably with the prices obtained for the pulped and cleaned coffee in the London market; but a later experience is, we regret to say, not so favourable. The particulars we now give, may be of interest to owners of Liberian coffee gardens. The following is an extract from a report from a Philadelphia merchant, of the result of an experiment made last year in shipping Liberian cherry dried in the shell or "unhulled" as the Americans say:—

When business began to open in September I sent small samples of the bags of coffee cleaned, not only to coffee brokers, but grocers, resulting in only a few offers of 8, 8½ and 9 cents per lb. which I did not feel free to accept, hoping all the time that the coffee market would soon have a better and brighter outlook, but, instead of that right the reverse, the best price possible being at 10 cents per lb. net cash, as per account herewith enclosed. If these bags had been my own, I would not have sold until next month, when I could have sold for 11½ or 12 cents. Coffee market points that way now.

At no time within the past 30 years has the U. S. coffee market been so upside down and irregular. At any time within the past six months I could, and today could buy Rio coffee at 6, 7 and 8 cents per lb. Six millions of bags of coffee reached this country within the past year—two millions more than in the previous year. No wonder the market has been upset, and coffee never so low in price. If I could have waited for the market I would have received a higher figure for this parcel. In hulling coffee and making it perfectly clean, so as to sell, some of the hulls are ground too fine to sell. It is utterly impossible to hull and brush away the fine dirt from the coffee, and not experience the loss in gross weight. Out of the 9,876 lb. gross weight, I got all the coffee, if not more than if pulped in the old way on the coffee plantation, where there ever is a loss of actual coffee and the hulls or pulp thrown away. The planter in selling has to allow for the freight on his clean coffee, whereas, I have sold as you see enough hulls to pay the freight on both hulls and coffee. The freight was \$53.92; hulls sold for \$50.00. Suppose you had pulped and cleaned these 94 bags on the plantation, you would have received no more actual coffee than I have done—then the time and cost of hulling, &c. Could you have obtained 10 cents per lb. for the coffee at the place of export?

All we know is that the net result for 88½ cwt. gross weight of cherry shipped from Ceylon is £18 12s equal to R249 or about 1 rupee per bushel for the cherry which measured some 250 bushels. At the time it was shipped we believe more than this,—perhaps, as much as R14 per bushel—could be got for it from native dealers in Colombo. The charges in the American invoice are a caution! True, the "hullings" paid for the freight, and the local estimate of about 10 to 12 bushels of dried cherry to the cwt. of clean coffee, was singularly close to the actual result, namely 2,527 lb. or 2¼ cwt. which realized about 45s per cwt. But the charges, especially for "hulling and cleaning" (nearly £20 sterling in order to get 22 cwt. clean coffee) were stupendous, and as a curiosity as well as a matter of instruction to Liberian coffee planters we append the

Philadelphia invoice referred to:—		Dollars.	
Cr.			
By Unhulled Liberia coffee

From the net 91.06 dollars or the R249 we must deduct R7 "Consular fee for invoice" in Colombo and R69.70 charges between the garden and the vessel, so that for the 250 bushels of dried cherry, the planter gets the magnificent sum of R172.30! Selling to "Tambies" on the estate or at any rate in Colombo, he could have netted not less than R300, so that no more cherry coffee is likely to be sent in this way to America as an experiment.

WHY TEA CANNOT EVERYWHERE SUCCEED IN CEYLON:

HOW IT IS BEING "RUSHED" IN SOME CASES. THE NUMBER OF ENEMIES. (By an Old Coffee Planter.)

The young Goliath (tea) stands and will stand Ceylon in good stead, but there is many a false David slinging at him with stones in the shape of rubbishy land, bad seed, bad plants and bad planting, so that some blooming capitalists seeing their champion in a sick condition in a year or two after this may feel as did the Philistines of old.

We have the gentleman who proposes to sell seed of a good hybrid jät and a very hybrid jät it is, principally China.

We have the gentleman selling tea seed off 3 years bushes, off which he is plucking leaf freely at same time.

Then we have the gentleman who tells his cooly to crack off the outer skin of the tea seed in the field and then soaks the seed in his cisterns to keep it up to weight.

Then there is the gentleman who orders his coolies to dig 300 holes and plant 500 plants.

Then there is the patana and thin scrub planting gentleman who will palm off his acres on the confiding Assistant two years hence.

TEA PLANTING IN SOUTH AFRICA

is exciting a good deal of attention and the Natal papers are devoting space to information for the planters. A description of a visit to the most extensive and successful garden yet planted—some ten to fifteen acres—shows the dimensions of the enterprise. Here is what the proprietor says of the results attained:—

Mr. Brickhill's great object and chief desire is to encourage colonists of limited means to go in for the cultivation of tea, for the simple reason that little expense is incurred as compared to the propagation of the coffee plant; only the cultivator must exercise a considerable amount of patience and attention to the plants at first as it is three years before they fully matured and begin to show a return for the capital invested. The returns are good; and when asked for some idea, Mr. Brickhill said that last year, with only the assistance of his coolies, he erected some buildings on his estate effected large improvements, and was able to pay all the expenses incurred out of the profits of the tea. This season he says he shall have better returns, and by the introduction of patent machinery he will be able to do very well. Mr. Brickhill's concluding words sum up all that can be said in favour of tea cultivation. On the question being put, he said "If I had my days to live over again I would start in Natal as a tea planter."

Some facts about the garden are of interest:—

Across the gully, through which a stream runs, on the gentle slopes, is found in good bearing condition the original China tea plant, which has been in the ground for 22 years. Some of them measure across 10 ft. by 7ft. and it is said they will live for 100 years yet. In the hack ground we entered another enclosure where a batch of coolies were busily engaged picking some China tea. This process is a very delicate one, but the coolies soon get into the way. The season for picking, we were told, generally commences in September and finishes in the latter end of April; and Mr. Brickhill informs us that whilst last season he had to pick every fortnight on the same plant, this year he had to pick every week, except with the last two pickings which have been at intervals of ten days; and he expects now as the season is approaching an end that there will always be ten days or more of an interval. We were next taken to the tea house where the manufacture goes on, and this appears to be as simple as the cultivation. After being picked it is laid outside in the sun on the "barbecue" or brick cemented floors where it is allowed to wither. It is then taken inside by the coolies and rolled for a time, which expels the juice, and eventually the whole mass is formed into good sized balls, and allowed to remain on a shelf for about three hours in that state. After this process it is laid out in the sun on zinc plates to get warm, and then it goes through a second process of rolling, and is again brought outside to undergo what is termed "sunning," and remains in the sun for two hours or so. After the sunning the "cooking" in the hot chamber commences. Here there is a furnace which is the entire length of the building, and is fired from the outside, so that no smoke or anything obnoxious can contaminate the tea. On the brickwork which forms the walls is laid plate iron the length of the furnace. On the top of this plate is laid on each side a row of single bricks which leaves a vacuum in the centre, through which the heated air passes and which is covered with sheet iron. On the top of this gently heated plate the tea is cooked, and is moved about until it is finished. This process lasts about half-an-hour, after which the tea is ready for packing in boxes. From the *Mercury's* "Planter's column" we extract a few paragraphs to show what the Natalians are thinking about:—

The following important questions have been sent to me for the purpose of answering; but before doing so I publish them in the hope that I may receive practical assistance from men who are engaged in the industry. The following are the queries:—

What class of tea is best suited for cultivation in Natal?

To what elevation above the sea can tea be grown with safety?

Will home-grown seed do, or will it be better to get it from India or Ceylon?

What distance apart should tea be planted?

What is the best way of planting in land cleared for the purpose?

What do you think will be the cost of planting old coffee land and bringing it into bearing?

How would you plant the seed—in nursery beds, or how?

Should nursery beds be shaded; if so, in what way? In transplanting from the nursery, is it best to prune the tap root or not?

What size of plants are best for planting?

How many plants would 100 lb. of seed give?

What will be the yield per acre of tea planted in good coffee land?

What rainfall is requisite for successful tea cultivation?

What do you recommend with regard to plucking?

Will soil with limestone grow tea, and give a good return?

What tea roller would you recommend?

What is your opinion about withering?

What tea drier would you recommend?

Have you seen Greig's tea drying and withering machine at work; if so, what is your opinion about it?

Can any of my readers inform me at what price per ton coke can be landed at from England? Later on coke or coal must be used for manufacturing tea on some estates. Coke of course would be the cleanest and brightest, and give out more heat than coal. I heard the other day that a tea planter had ordered a quantity of coal as an experiment, and hope that it is colonial coal he has ordered.

Is there any demand for croton seed in small quantities (down to 10 lb. or so)? What is the present market price? Is it necessary to cure the seeds in any way, or is it marketable in the husk, merely dried in the sun? Any information on the above points will be esteemed.

INDIAN TEA COMPANIES.

CALCUTTA, 27th March.

TEA.—The report of the Directors of the Chandypore Tea Company for the past season show that the outturn was 207,200 lb., which is 6,740 lb below the estimate, the average price realised being As. 8-9 per lb against As 8-4 last season. The gross revenue was R1,13,767 and the ordinary expenses R1,01,420, leaving a profit on the season's operations of R12,347, and the net balance brought forward from last year swells this amount to R13,095, out of which a dividend of 5 per cent is to be declared, which will exhaust R12,500, and the balance carried forward. The estimates for the current season provide for an outturn of 204,000 lb at an expenditure of R1,01,000.

The report of the Directors of the Cochelea Tea Company shows that the outturn was 85,858 lb. which realised an average of As. 9-6, against 79,665 lb average in As. 9 for 1884. The gross revenue was R51,607 and the expenditure R44,662, leaving a profit of R6945; and deducting the debit balance from last year, the amount available is R6,282, out of which a dividend of 2 per cent is recommended. The estimates for the current season provide for an outturn of 90,000 lb at an outlay of about R47,000.

The report of the Directors of Dehing Tea Company shows that the outturn was 4,348½ maunds against 4,550 maunds last year, and 152 maunds less than the estimate. The average price realised and to be realised is put down at As. 9-5½ per lb against As. 7-9½ per lb last season. The estimated gross revenue is 2,03,361 and the expenditure R1,71,076, leaving a profit of R32,288, and deducting the debit balance brought forward from last year, the amount at credit of profit 2nd loss is R26,859. The Directors recommend a dividend of 3 per cent and that a balance of R50 be carried forward. The estimates for the current season provide for an outturn of 4,700 maunds, but the probable expenditure is not stated.—*Pioneer*,

MATURATTA: KADBRAGALLA, 4th April.—Glorious weather up here. Tea now flushing freely and very fair blossoms out on the remaining patches of good coffee but they are getting, as in other districts, few and far between. There has been a good deal of sickness about of late, chiefly fever, influenza, a few cases of measles and smallpox which keep our energetic medico pretty well on the move. Petty thefts, are, I hear, greatly on the increase in the villages as they find having no coffee to steal and not yet learned the art of tea manufacture they are keeping their hands in by stealing from each other. Rahatungoda post office was opened on the 1st, which is doubtless a boon to those over in that neighbourhood, but not so to us as we do not now get our Colombo and Kandy letters till 10-30 instead of 6 a.m.

NATIVE ENTERPRISE.—The natives of the country are not far back in following their European brethren in planting new products and believing in same. Mr. Lewis Mendis, the well-known plumbago dealer of Kurunegala, has successfully opened out as fine a tea estate as one could wish to see at Balapitimidara within a mile or two of properties belonging to Messrs. Wiggin and Boustead. "Kirimetia," as it is called, consists of 170 acres and has all but 40 acres opened and fully planted out with tea, 25 acres are being planted now and 40 acres will be fit for plucking in June. The proprietor and manager, Mr. Mendis, is just now in treaty for a Jackson's Roller and Venetian Drier, both of which he hopes to remove to the spot ere many days are over. Mr. Mendis's example may well be followed by others of his countrymen.—*Cor.*

THE VALUE OF HOMING PIGEONS in Country medical practice has lately been described by an English doctor. He starts upon his daily rounds with a basket of the birds. Upon leaving the house of a patient who needed immediate attention, he would start off a pigeon with the required prescription, and the assistant in the doctor's surgery would forward the medicines to the patient long before the doctor's arrival home. A case is lately cited in which pigeons regularly carried a morning newspaper to their owner. The statement about the letters may be correct, although pigeons sometimes delay entering the room in which the messages must be detached, not from the wing but from the leg. But as even $\frac{1}{2}$ oz. would be a heavy load for a pigeon, the story about the carriage of a newspaper is manifestly incorrect. Parts of a newspaper printed on thin paper containing the despatches describing the fall of Sebastopol, were brought by the *Observer* pigeons from Galle, but as a rule the messages they carried were written on very thin tissue paper.—*Ed.]*

OIL and GRAPHITE LUBRICANTS.—The following paragraph is interesting as the latest and most conclusive testimony in favour of plumbago as a lubricant. It will be noticed that the foliated form of the mineral is mentioned:—

Experiments lately made with graphite and the best sperm oil, respectively as lubricants, are reported, with all the results in favour of graphite, each test being stopped the moment the bearing "squeaked." Eleven minutes used up the sperm oil, while the graphite lasted thirty-eight. The bearings lubricated with the best sperm oil cut, while those with dry graphite or graphite oil did not. The tests were on close bearings, and very high pressure. One-third the quantity of dry graphite did nearly three times the lubricating of the best quality of sperm oil, and for a long time after the sperm oil was exhausted—it squeaked at eleven minutes—the graphite oil continued to lubricate without a cut. The average coefficient of friction was, on oil '0555; on foliated graphite, mixed with enough of

water to distribute it over the bearings, '0596; and on graphite cylinder oil, '0366. The use of plumbago pure and simple is much safer than when mixed with other substances.—*Mechanical Engineer.*

THE "RAIN TREE."—The *Gardener's Magazine* contains an article by the Rev. L. J. Templin on "interesting vegetable forms" from which we quote a specimen:—"A tree known as the Rain tree, *Pithecolobium Saman*, is found in the dryer parts of South America. This tree grows to the height of sixty feet, and its leaves have the property of condensing the moisture from the atmosphere. So copious is this condensation that a continual shower falls from the leaves and the branches, until the surrounding soil is converted into a veritable marsh. Places that would otherwise be barren deserts, are by this means, covered with the most luxurious forests. It is said that the British Government is introducing this tree into India, to counteract the aridity of portions of that country." This tree is now pretty common in Ceylon. It grows rapidly and makes a magnificent shade tree. At night the leaves hang down, so that condensed moisture, might if present, easily reach the ground. But is there the slightest evidence that the leaves actively condense moisture after the fashion described, or to any appreciable extent? The rain tree and the electric tree may be classed together.

THE WESTERN NEW GUINEA CEDAR COMPANY with a capital of £2,250, in 45 shares of £50 each, has not only been formed, but it would appear from a recent newspaper paragraph that a couple of millions of feet of timber had been already cut! The prospectus states that

"This Company is being formed for the purpose of working the Cedar Forests discovered by Mr. Charles Stewart, Naturalist and Geologist, during his recent explorations in British New Guinea. Mr. Stewart reports that on the River Cosu he found a practically inexhaustible supply of Cedar, which on being examined by experts has been pronounced by them to be of first-class quality. The river upon which the discovery was made is navigable for large vessels, which can be loaded from the bank alongside the timber. The local native labor can be utilized at a very small cost in trade, and has been found manageable. An order has been obtained by Mr. Stewart, from His Excellency the High Commissioner for New Guinea, protecting the discovery of Cedar on this river to himself, and practically granting him a monopoly of the trade of the river. Mr. Stewart and his partners reserve to themselves thirteen fully paid-up shares in the proposed Company to recompense their outlay in the preliminary expedition, and the whole proceeds of the sale of the thirty-two shares offered to the public will be used towards obtaining cargoes of Cedar and forwarding to the Melbourne or other Colonial Markets. The amount required will be amply sufficient to cover the whole cost of cutting and shipping the first cargo, and henceforward there will be not only no necessity for further contributions, but large dividends may be at once confidently reckoned upon."

The "Cedar" referred to is, no doubt, the ubiquitous and valuable red Toon, so well-known and highly prized in India and Australia. A degree of local interest attaches to the enterprise from the fact that the Company was formed by a gentleman formerly in Ceylon, Mr. H. W. Kellow, cousin of Mr. Arthur Kellow of New Cornwall, Nuwara Eliya. The latter suggests that New Guinea cedar may be a possible source of supply of timber for Ceylon tea chests, but we fear Red Cedar is too valuable to be used for such a purpose.

SEED OF RHEA GRASS.—The Horticultural Society of India state in their recent proceedings that a communication had been received from Messrs. Sutton and Son, Reading, England, stating that "as Rhea Seed is likely to be in considerable demand in India, they are prepared to supply finest quality seed of *Urtica nivea* and *Urtica candicans*." As yet there is little or no demand for this seed, but as it is seldom saved in India should any of the different processes now known for extracting the fibre prove commercially successful, the demand is likely to prove great. The Indian seed has long been thought infertile, but the Society has recently raised a considerable quantity of plants from seed gathered from plants in its own garden.

FRUIT GROWING.—Some short time ago Suav boasted of its strawberries. Thereupon Rewa at once claimed credit for its apples; and now Levuka, not to be behind-hand, can speak with pride of its grapes. Many attempts have been made to acclimatise the vine here, and not without partial success. The plant grows luxuriantly and forms a most graceful ornament for training on the verandah trellis or elsewhere; but as a fruit bearer it has not been a marked triumph. The difficulty has been to give it a winter, so as to check the continual flow of sap and prepare it for a fresh fruit-bearing start. Both Mr. Dufty and Mr. Harman have managed this by digging the vine up and exposing the roots for a while, but though bunches of grapes have been so obtained, they have been rarities, neither full-grown or well-flavored. More recently Mr. W. I. Thomas have adopted a different plan, and with a marked improvement in result. He has at his house a vine which is about five years old, but which still lately only bore occasional acidulated curiosities. But on the advice of a friend, who recommended the practice as one he had seen adopted with success in other tropical countries, he last year laid the roots thoroughly bare, and afterwards filled in with sea sand and manure; and he is now rewarded with a very fair crop of full-grown and very fine-flavored fruit. Already he has cut about 15 pounds weight of grapes from his vine, and as he has distributed them widely very many can testify that they are of excellent quality and most luscious appearance.—*Fiji Argus*.—[With some such treatment of the roots and severe pruning of the branches, fairly good grapes could, we should think, be grown in Colombo.—Ed.]

MATALE EAST, RATTOTA.—(A Model Planting Report from an enthusiastic Ceylonese).—This district is coming to the fore in the development of the tea industry, if I may judge of the large area of land now under cultivation with this product, though at first some were sceptical as to the sufficiency of rainfall for a remunerative flush. Though it cannot be categorized as a beau ideal for tea cultivation inasmuch as climate is concerned, yet it possesses many desirable advantages in respect to altitude and suitability of soil. Some few of the estates that initiated this staple here in the early days of its introduction have by their produce and its quotations proved conclusively that it is not behind hand on the score of remuneration. As its cultivation advances I hope the district will compete with the far-famed districts of Ambagamuwa, Kelany Valley, Deltota, &c., as it so successfully did in the good days of yore in regard to King Coffee. Happening to pass Oo—and Ni—estates—at one time the enchanting scene of luxuriant coffee fields—on my way up to Madulakele, I observed a large acreage under and in process of cultivation with the selfsame product that characterizes "a cup that refreshes but not inebriates." I hope you are aware that these properties changed hands recently to the Colombo Commercial Company, Limited, and considering the short time

that has elapsed since the purchase, it is a matter of congratulation to witness the works so far progressed. With the advancement of the enterprise it is devoutly to be wished that the time will not be far distant when this once world-famed district would recuperate its long lost prosperity. In conclusion I must not omit to mention the *very* creditable manner that the estates have been so far worked in all their divergent works by the present superintendent who no doubt deserves his meed of praise.—April 2nd.—I regret you have not yet given insertion in your inestimable journal to my letter sent from Rattota on the 28th ult. *in re* the tea industry there. I beg you will give same publicity in one of your early issues, so that it may have the beneficial effect of drawing more capital thither, since there is a pretty good acreage of private lands that can be cultivated with this staple. I read your editorial on tea cultivation by natives with pleasure.

ORIENTAL BANK ESTATES COMPANY, LIMITED.—The *Investor's Guardian* of 13th March has the following notice of the new Company for which everybody has been waiting so long. Although however the Company has at length been registered, there has been no transfer as yet to it of the estates vested in the O. B. C.; but there can be little doubt in which direction the decision of the Court will go. The floating of the Company is evidence of increased confidence, in Ceylon estates especially.—This company was registered on the 5th inst., with a capital of £566,700, divided into 60,000 preferred shares of £5 each, and 266,700 shares of £1 each, to acquire any of the tea, sugar, coffee, or other estates of the Oriental Bank Corporation (in liquidation), situate in Ceylon and Mauritius, and any of its lands, buildings and other real property in India, Ceylon, China, Japan, and elsewhere, and to carry on business as tea, sugar, cocoa, cinchona, and coffee planters, wine and brandy merchants, fruit growers and preservers, brewers, and manufacturers of all kinds of vegetable products. Although but little over a year had elapsed since the New Oriental Bank Corporation was formed to take over the banking business of the original Corporation, it is now regarded as one of the most successful of recent financial enterprises, a result due to the assiduous attention given to the affairs of the bank by the members of the executive. As several of these gentlemen are interested in the present Company, and will, no doubt, assist in its management, a successful future may be reasonably anticipated. The holders of the preference shares will be entitled to be paid out of the profits, and as a first charge thereon, a fixed cumulative preferential dividend at the rate of seven per cent. annum. The subscribers are:—

	Preferred Shares.
Edward F. Harrison, South Norwood Hill, Indian Civil Service (retired) ...	1
A. J. Macdonald, 40, Threadneedle Street, banker ...	1
R. M. MacLean, Elliot Hill, Blackheath, banker ...	1
W. W. Cargill, Lancaster Lodge, Campdenhill, barrister.. ...	1
John S. Scrymgeour, 10, Altenburg-gardens, Clapham Common, bank manager ...	1
G. W. Thomson, Newstead, Forest-hill, banker ...	1
Robert Turner Robie, 40, Threadneedle- street, Secretary to a Company ...	1

The number of directors is not to be less than four, nor more than eight; qualification, shares or stock of the nominal value of £500. The subscribers are to appoint the first directors, and may act *ad interim*; remuneration £1,000 per annum.

PRICE'S PATENT CANDLE COMPANY, on the suggestion of Mr. G. May, Reading, are preparing a biiodide of mercury soap, to be used as a disinfectant after surgical and other operations. The biiodide, of which there is 0.5 per cent. in the soap, is rendered soluble by the addition of potassium iodide.—*Chemist and Druggist.*

GRAPHITE LEAD.—Says the *Rio News*: in a short time will be commenced the exploitation of mines of graphite lead, *tierras refractarias*, on the property of Sr. German P. Ronquand situated on the Oriental coast near the San Juan Hills. A company of shareholders with a strong capital has been formed in this city for the exploitation of the various minerals these mines contain and in the opinion of well-informed persons flattering results are assured.—Graphite lead is, of course, nonsense. Plumbago, popularly but incorrectly "black lead," is meant.—ED.

THE ROTARY PUNKAH.—Messrs. W. H. Davies & Co. have on view at their offices one of Blackman's air-propellers arranged as a rotary punkah for ventilating and cooling a room. The revolving disc is fixed on a stand and has a crank attached to which is fitted an accelerating movement by which one turn of the handle gives two turns of the disc. It runs very lightly and can be easily turned by a cooly and the ventilation of the room is perfect. It possesses many advantages over the ordinary punkah, not the least of which is that, not being directly over the desk of the person using it it does not fan all papers &c. off the table, and its influence is felt throughout the room and not only in its immediate vicinity.

TALPOT PALM LABELS.—The editors of the *Tropical Agriculturist* are sure to be diligent readers of the *Gardeners' Chronicle*, and the following extract from the latter journal will not readily escape their notice. But it may be as well to give it insertion here, as it shows the success Dr. Ondaatje is securing for an adaptation which, it is believed, will do much to stimulate their small local industries in Ceylon, the prosecution of which is very desirable in the domestic interests and general wellbeing of the people:—Since writing to you in September last on the above subject I have been carrying on the following experiments with a view of obviating the difficulty of writing on the label with a style or sharp pointed instrument, and of testing its capabilities generally. Experiment 1: Labels were easily written on with black Japan varnish and vermilion with a quill pen and paint brush; they were then allowed to dry for a few hours and when well dried exposed to the open air in a garden. After they had been thus exposed to the weather, and even to the heavy snowfall lately experienced, no damage ensued, and the writing remained intact; in fact the labels looked better. No curling up followed in any one. Experiment 2: A number of labels hung over the kitchen stove were unaffected by the heat. Experiment 3: A sponge dipped in turpentine or methylated spirit and rubbed over the labels effaced the writing perfectly, thus rendering labels fit for use over and over again. Experiment 4: Dilute acids or alkalis applied to remove any writing did no injury, the surface being protected by a silicious cuticle. Any soiled label may be cleaned by washing with soap and water. Experiment 5: Labels written on with sulphuric acid by means of a quill pen and held near the fire until dry, and then quickly plunged in water produced a permanent and indestructible writing, the acid acting on the tissue. Conclusion. From the foregoing experiments I think it is clearly established that the Talpot Palm label possesses qualities which render it more useful than those ordinarily used for plants, &c. I may add that in this climate the label stands exposure better than in the tropics, and is likely to be more enduring. W. F. Ondaatje F. L. S. The labels are cheap, durable, and easily written on. Dipped in varnish after writing on them would make them almost imperishable.—ED.]

A DIMBULA PLANTER of the early days is now on a visit to Colombo in Mr. James A. R. Clark of Tinnevely (son of the late Mr. Robt. Colvin Clark of Colombo), who first learned planting under Mr. John Martin on Mount Vernon in 1865-7, and has not been back to the district since he left it for India. What a change there has been in the 20 years! Mr. John Martin is almost the only one left in Dimbula of the few who were at work there in the sixties! Mr. Elphinstone had begun his Logie clearings, but resided in Kotmale, and Mr. Wm. Smith (now of Pussellawa) was busy in Craigie Lea. Beyond Talawakele all was forest, unbroken save by the patanas; roads and bridges there were none and it was a journey of difficulty even to pass from Craigie Lea across to the New Valley of Dikoya where Messrs. Kelly, Fetherstonbangh and a few more, mostly dead or gone, had begun pioneering. Mr. Clark means to visit the old hunting as well as planting grounds on his return from Australia in August. He has not been successful in finding a purchaser for his Tinnevely coffee, cacao and tea properties. They are situated in a deep valley between two hill ranges, get the sun from 8 till 1 p. m. and have exceptionally fine soil, and although the leaf fungus is by no means absent, it has not prevented fair crops being continuously gathered; while on the other, the Travancore side, the disease has literally swept coffee out of existence. Some idea of the luxuriance of the soil may be formed from the enormous size of the trunks of the older trees—some of them 40 years old, have been cut down to the ground by Mr. Clark and suckers allowed to grow up, so that after two or three years the clearing looked as of that age only and is giving good returns. Even young plants from the nursery grow and crop fairly well. But Mr. Clark has not neglected new products—cacao and tea especially. Squirrels from the large reserves of forest are the chief trouble with the former, and as they, if left alone, select the ripe pods and after enjoying the mucilaginous portion leave the crop on the ground, Mr. Clark is inclined to regard them as harvesters! A new product which is found to do and pay well on both sides of the Tinnevely-Travancore range up to 2,000 feet is Zanzibar chillies. They have been planted on some hundreds of acres—so good is the price got in London and seed has been got direct from the East Coast of Africa. Has any one tried these chillies in Ceylon and for what can the specially good demand in London be? We quote as follows from Smith's "Dictionary of Economic plants":—

Capsicum, a genus of the Nightshade family (Solanaceae). *C. annuum*, is supposed originally to have been a native of some part of South America, but is now cultivated in all tropical regions. It is an annual plant, attaining a height of about 12 or 18 inches. It is too tender for successful outdoor cultivation in this country but succeeds well and produces fine fruit under glass. There are several varieties, their fruit varying in shape and colour, being either long or short podded, red or yellow, all of which are known under the name of Pod Pepper. There are some very distinct varieties considered by some authors as species, such as Cherry Pepper (*Capsicum cerasiforme*); Bird Pepper (*C. baccatum*); Bell Pepper (*C. grossum*); Spur Pepper (*C. frutescens*), which are all more or less grown in different countries, and extensively used in cookery in hot climates, being considered beneficial in exciting the appetite. The dried fruits when ground constitute Cayenne Pepper. In this country they are generally used as pickles, and in sauces. The small fruits known by the names of Chillies, are mostly produced by *C. fastigiatum*. Capsicums are extensively cultivated in Hungary, giving employment to 2,500 families.

THE TRADE IN FEATHERS.

BY P. L. SIMMONDS.

The fashion for wearing feathers has had a much longer reign than most other fashions with ladies, and hence the trade in feathers and birds' skins has now attained enormous proportions. When we find the annual value of the imports into this country alone of feathers exceeding two millions sterling, the application, preparation, and subsequent retail sales must necessarily be very profitable to those concerned. The largest quantities come from India, Asia, and Africa, but subsidiary supplies also reach us from America. In the present remarks I shall confine myself to the land birds, leaving the aquatic ones possibly for a future notice.

The average annual importation into this country and France of small foreign birds of bright plumage is no less than a million and a half. They come mainly to England for distribution. We import about a quarter of a million humming birds yearly. At a public sale in the autumn of last year, besides the loose feathers, 147,386 bird skins were disposed of during the two days' sale, among which were no less than 44,381 green or Amazon parrot (*Chrysotis amazonica*) and other species.

The following figures show the importance of the trade in feathers in this country—specifying the annual imports for nine years:—

	For Birds.	Ornamental Feathers.
1875	£ 126,177	£ 713,199
1876	109,045	778,477
1877	109,041	873,192
1878	91,679	1,002,902
1879	80,238	1,146,211
1880	107,554	1,367,128
1881	127,374	1,322,255
1882	144,694	1,957,840
1883	155,240	2,011,926

We re-export about half of the ornamental feathers as follows:—

	£
1879	491,140
1880	660,931
1881	723,187
1882	1,003,273
1883	1,009,123

France and the United States take half of these exports.

In a paper which I read before the Society in February, 1876, on "The Trade in Ostrich Feathers" (*Journal*, vol. xxiv. p. 225), I brought down the statistics of our imports to 1874, and it is interesting to trace the subsequent rapid augmentation which has resulted from ostrich farming, and the domestication of the ostrich in South Africa since that period. The direct imports of these feathers from South Africa are specified in the returns. In contrast with these, I may place the imports from Northern Africa, which I collect from the countries of import, viz., Malta, Egypt, Tripoli, and Morocco.

	South Africa.	North Africa.
1875	£ 293,866	£ 94,164
1876	360,572	67,481
1877	400,926	61,180
1878	590,372	33,162
1879	717,056	45,949
1880	959,079	47,651
1881	973,774	28,183
1882	1,421,337	49,268
1883	1,425,681	86,943

Aden is an *entrepôt* for ostrich feathers, from 7,000 lb. to 8,000 lb. being exported annually; half of these are received from Berbera.

Mr. R. H. Elliott, in a paper read not long ago before the East Indian Association, called attention to the large exports from the port of Madras, which are chiefly sent to Hong Kong and Singapore, and argued that the bright plumaged birds would soon be exterminated.

The following were the shipments thence in the last three years:—

	FEATHERS.	Value.
1881	122,175	£ 1,662
1882	105,515	1,908
1883	167,750	2,666

	BIRD SKINS.	Value.
1881	82,400	£ 91,998
1882	98,300	2,098
1883	11,275	166

But if we take the whole of our imports from India, they form a much larger aggregate:—

	£	£
1871	21,840	25,175
1872	29,149	19,482
1873	38,836	22,164
1874	38,481	24,082
1875	37,197	33,058
1876	23,587	66,453
1877	18,563	

The following figures, showing the total exports of feathers from British India, prove the importance of the trade. They are for the years ending March in each year:—

Year.	lb.	Value.
1879	55,000	£ 21,933
1880	41,279	18,618
1881	65,133	26,944
1882	67,164	28,966
1883	89,639	30,425
1884	104,621	47,639
1884	46,487	41,352

(Six months to Sept. 30.)

From India we receive chiefly the blue jay, jungle cocks, orioles, trayloads, kingfishers (*Alcedo Bengalenis* and other species), peacocks' feathers, and pelicans' feathers. Of the last named there is a terrific slaughter carried on during the moulting season in Cambodia. They are taken in enclosures, and one to two thousand killed nightly for about a week. The greyish feathers from each wing, and the black feathers at the extremities are plucked and tied up in bundles, and they are in the East chiefly made into fans. These feathers are in request in Europe, as they take dyes readily.

The feathers of the little egret heron, and of the *Ardea alba*, are much esteemed for ornament. To show the large employment of these feathers, I may state that at a feather sale in January, 1876, the feathers sold, on a moderate calculation of twenty to each bird, involved the slaughter of 9,700 herons, all from India. Then we have the feathers of the marabou and adjutant storks from India. The former has a long range of latitude in Western Africa, extending from Senegal to Aegola. The feathers of the greater and lesser adjutant are scarcely equal to those of the marabou. The gigantic stork or adjutant is extremely common in Northern India, more especially in Bengal, being well known in the larger towns as an efficient scavenger bird.

Peacock feathers, both from the body and the tail, seem in great request for feather trimmings. At a public sale in August, no less than 75 cases were sold, containing not only complete skins of the bird, but brilliant blue neck skins, wings, and body feathers, tail feathers, classified into eyes, swords, which are the brilliant metallic green feathers which border the tail at each side, and fish tails, the ordinary feather with the eye cut out. Peacock feathers are much employed in India as fans, brooms, picture cleaners, &c., which sell locally at 6d. to 1s. each.

Of the eighteen species of birds of paradise known, fourteen inhabit New Guinea and the adjacent islands, three Australia, and one only the Moluccas. The four true birds of paradise which form a well characterised group, belong solely to New Guinea and the adjacent islands. The other species are more rare. The best known are the great bird (*Paradisæa apoda*, Liu.) known since the middle of the 16th century.

found in the Aru islands, and the small emerald (*P. papuana*, Bechst), the plumage of the latter being used to decorate alike the head gear of eastern rajabs and western dames of fashion. The redbird has flowing side plumes of rich crimson instead of yellow. The king-bird is a little gem of exquisite plumage, having two slender wire-like shafts, nearly 6 inches long, protruding from the tail, each terminating in a broad emerald green spiral fish.

Birds of paradise must have been found by the Portuguese on their conquest of Malacca in 1511, brought to that emporium by the Malay and Javaese merchants for the markets of China. At all events they must have seen them on their arrival in the Moluccas in the same year or the beginning of the following. But the earliest account we have of them is that given by Pigafetta, who was at the Moluccas ten years after the Portuguese had reached them. His description, taken from the original manuscript published in 1800, is as follows:—

"They gave us also for the King of Spain two most beautiful dead birds. These birds are about the size of thrushes. They have a small head and a long bill; legs fine as a writing quill, a palm long. They have no wings, but in their stead long feathers of various colours like great plumes. The tail resembles that of the thrush. All the feathers except those of the wings are of a dark colour. They never fly except when the wind blows. They told us that these birds came from the terrestrial paradise and they called them *burung diwata*, that is 'bird of God.'"

It is probable from this account that the birds of paradise sent by the King of Tidor, one of the five Moluccas, to Charles V., was not the great emerald bird with which we are most familiar, but one of those which are natives of the Moluccas. At present the principal emporium for these birds in the East is the Aru Islands, and to the west, Batavia and Singapore; they are brought to the two last ports by the prahms of the Lugis of Celebes. We obtain our supply by way of Holland, and they cost from 20s. to 25s. each at first hand, according to quality. In 1872, 3,000 of these bird skins were shipped from the port of Dobblo in the Aru Islands.

The delicate feather sprays of the osprey or fish hawk (*Pandion halioetus*), of a light yellowish-brown or snowy white, are largely used in making cigarettes.

Prodigious quantities of the feathers of the Impeyan, argus, and other Indian pheasants are also received. Even in Lendenhall market the plumassier will purchase the freshest common pheasants for their plumage; they are skinned and dressed for ladies' hats, and the carcasses of the birds sold cheap.

If we turn to South America, we find that there is a demand for the feathers of the American ostrich, as it is called, the *Rhea Americana*, which are known in commerce as "vulture feathers." In 1865, there was shipped from Buenos Ayres 153,330 lb. of these feathers, valued at £38,408. The quantity shipped later from Buenos Ayres was in—

	Kilos of 2½ lb.	
1871	...	31,177
1872	...	73,132
1873	...	69,202
1874	...	59,454

Most of these go to France, but our imports were to the value of £8,422 in 1875, £10,735 in 1876, £4,520 in 1877, and the imports have now dropped to about half this quantity.

The feathers of the male bird realise more than that of the female.

The tail feathers of the golden eagle (*Aquila canadensis*) are used by the North American Indians for head ornaments. The yellow flicker (*Colaptes auratus*) and other gaudily arrayed summer birds yield their plumage for ornamenting dresses. The feathers of the Australian emeu are of a brown colour, fine but brittle. The plumage near the tail, however, is long and graceful. The feathers are dyed almost every shade, and are now much used for trimming and ornament. From Victoria these feathers, to the value of £3,187, were shipped in 1883, chiefly to the United Kingdom.

The quantity of these feathers obtained in Uruguay, in 1875, was 92,400 lb.; but this fell, in 1877, to 44,000 lb., valued at £20,000. This decrease arose from several causes. First, the indiscriminate slaughter by the hunters; not only of the birds, but of their eggs and young; second, the extension of the cattle; and, lastly, a Government decree, in 1877, forbidding the chase of the bird under heavy penalties, and encouraging production by offering a premium to the first person who should produce a certain number of birds in a domesticated state. This decree had the effect of reducing the total production of the feathers from the chase by two-thirds.

A great many farmers have now seriously undertaken the work of domesticating and raising the birds so as to obtain the feathers at certain times. It is thought that, in a few years, this will lead to increased quantity and improved quality, the feathers plucked by the hand, being said to be finer and more downy. Fine feathers, in packets, fitted for the European market, are valued at about 12s. per pound; and they fetch, in France, 16s to 18s. a pound. They are nearly all sent to Havre; a few stray cases may occasionally be shipped to New York.

About £500 worth of feathers and bird skins are annually brought to Cayenne, including tufts of the heron, skius of the rapapa, the turkey sultan, and varieties of the humming birds. From South America also came the red cardinals, the blue crupus, and many other birds of lustrous plumage.

From the feathers of *T. resplendens* and other trogons, the mosaic pictures of the Mexicans were made. One of these, most delicately and beautifully executed, containing many figures, is now in the Ashmolean Museum, at Oxford, and is there said to be made of humming birds' feathers. The subject is "Christ fainting under the Cross." The whole picture is about the size of the palm of the hand, and the figures are barely half an inch in height.

The above cited facts and figures will convey some idea of the importance of the commerce in feathers and bird skins chiefly for personal adornment.—*Journal of the Society of Arts.*

THE LAST QUARTERLY REPORT on the Dutch Government Cinchona Plantations in Java quotes some remarkable results obtained in the examination of bark from "succirubra hybrids raised from Ledgeriana seed." The total alkaloids in ten samples ranged from 9.66 to 14.46 per cent., and in most cases the quinine was relatively high. In one instance out of 12.26 per cent. of total alkaloid the quinine is given as 10.67 per cent.—*Pharmaceutical Journal.*

EFFECT OF FROST ON ORANGE TREES IN FLORIDA.—A correspondent of the *San Francisco Chronicle*, says:—"I have travelled away from my theme, which was in the beginning the cold wave. Some friends, with myself, were talking about it to a gentleman, long a resident of the State, and its effect upon young orange trees. Some rather remarkable incidents bearing upon this subject were related. Among other things, he stated that it was not the cold or the frost by which the trees were killed, but the heat of the sun closely following it. 'If,' said he, 'any one will take the pains to get up before sunrise and make an incision in every tree, two or three inches long, with a sharp knife, there will be no danger of harm from the heaviest frosts. I had a neighbor, who, going through his grove before sunrise, found his young trees all killed, as he supposed. In a sort of rage he took out his knife and scored the bark of about a dozen or two, to make the destruction sure, but in a few days—lo! and behold!—those he had cut came out in renewed life and beauty and were the most vigorous trees in the grove. Acting upon this hint, he always afterward saved his choice trees by an application of the knife before the sun had a chance to get at them after a frost.' I give this for what it is worth, being assured of it as a fact. It is the newest thing out, and I leave it for gardeners and philosophers to give the reason why."—*Gardeners' Monthly Horticulturist.*

GUM TREES.—I noticed in the *Field* of Feb. 13 an inquiry as to the height of Australian gum trees planted out in this country. I have one—*Eucalyptus globulus*, I believe—which was given me in a pot in 1880. I planted it in a clear space in a wood in the autumn of 1881; so that this is its fifth winter out, though it is the first in which there has been any severe weather. After reading your correspondent's letter, I measured the tree, and found it to be 30 ft. from the ground to the topmost shoot. The stem is slight in proportion to the height, and there are no branches of any size. I have had to stake the tree several times to keep it upright; it seems to grow too quickly for its strength. It is on sandy soil in Kent.—W.—*Field*.

TREE-CLIMBING PLANTS, like the human parasites who hover round successful men, usually excite suspicion and dislike. But there may be uses other than their apparent ones for even such. Professor T. R. Fraser, at the May meeting of the Botanical Society, described the admirable properties in heart disease of *Strophanthus hispidus*, the source of the arrow poison of the natives of Eastern Africa. Professor Fraser's experiments with this new drug, very many times more powerful than *Digitalis*, or the common foxglove, appear to inaugurate a new era of hope to many new sufferers from a class of diseases apparently increasing with the march of modern progress. He gave great credit to Mr. John Buchanan, of Zomba, Eastern Africa, for his exertions in furnishing the necessary material.—*Journal of Forestry*.

NEW CALEDONIA.—Coconut trees exist in the colony in different varieties, nearly all having been planted by the Kavaikas. Most of the groves are on the eastern side, where the majority of the tribes are to be found. This precious tree produces yearly from 50 to 80 nuts. The kernels, dried in the sun, are readily sold under the name of *coprah*, at from 300 to 350 francs (£12 to £14) per ton. This is the chief means by which the natives obtain the goods and luxuries of civilization. A few important groves are, however, held by Europeans. The other principal fruit trees are the orange, lemon, banana, canella apple, mango, guava and Shanghai peach. In spite of indigenous valuable timber, no important felling of trees exists in New Caledonia. The quantity cut is not even sufficient for the use of the colony since New Zealand and Californian imported timber amounts to the yearly value of 500,000 francs (£20,000).—*Journal of Forestry*.

THE INDIAN FOREST SCHOOL.—An impartial study of the recent report of this institution at Dehra Dun leads us to conclude that it cannot replace a similar school in Britain for the advancement of home and colonial forestry, as hinted by Mr. Glaston in the recent debate. Founded on continental models, British common sense is modifying the curriculum for the specific needs of Indian pupils. Thus Sylviculture has been separated from the theoretical instruction of the lecture-room in Morphological and Physiological Botany, and is now taught practically in the forests; while Mr. Clifford's course of lectures on Entomology has been expanded so as to admit the study of all injuries and diseases incident to forest plants, whether by animals, insects, or other plants, such as climbers, epiphytes, parasites or fungi, as well as the decay and preservation of timber. This is now termed Forest Etiology.—*Journal of Forestry*.

KILL THE POULTRY LICE.—Almost all poultry are lousy, more or less. I think good arrangements for dusting will always keep the lice in check. The small hen louse moves along the roosts and sides of the building several feet, and sometimes annoys cattle and horses, but the trouble to them is quite temporary. If the fowls are freed from them, they will leave other stock at once. Roosts might always be removable, so that they can be scraped and washed with kerosene. I find kerosene or crude petroleum an excellent addition to white-wash. This treatment, with a good dusting box for the fowls, in which there may be occasionally thrown a handful of wood ashes and a pound of flowers of sulphur, will keep lice effectually in check. Horses and cattle in adjoining apartments, with only loose board partitions

separating them from the poultry house, will not be seriously troubled by the vermin.—Col. WELD, in *American Agriculturist*.

LEAF ROLLERS supply many destructive agents to the Rose, including the following: *Tortrix heparana*, *Tortrix ribeana*, *Lozotonia rosana*, *Pardix tripunctata*, and *Spilonota roborana*. The grubs of the above make their appearance with the first opening of the leaves, of whose structure they take advantage to construct their summer abode, banqueting, in the meantime, on the leaves that shelter them, and, if unmolested, after working havoc among the foliage, make for juicy buds, which they soon disfigure and render entirely useless. The larvæ have the peculiarity, when disturbed, of lowering themselves with a web-like thread. The only remedy for their destruction, and also those of the winter moth and swallow-tail moth, is assiduous handpicking.—*Indian Gardener*.

RED SPIDER (*Tetranychus telarius*).—These little creatures are unquestionably very injurious to Roses, either when trained to walls, or grown under glass. They increase most rapidly, and though so minute in size, they have extraordinary powers of extracting the juices from the leaves; and to further aggravate the deadly mischief thus caused, they spin tiny webs over the leaves and points of the young shoots, so as to completely clog up the pores of the leaves, thereby stopping their powers of transpiration and absorption and giving them a parched or burnt appearance. As these little nuisances abhor damp, the best remedy is the constant use of the syringe. We have found a wash, composed of a large wineglassful of petroleum in two gallons of soft water, most effectual. Before playing on the plants, draw up a syringe full and force it back again into the vessel two or three times, so as to mix the petroleum as much as possible with the water. The wash may be used every day, or as long as is found necessary.—*Indian Gardener*.

GALL NUTS.—It will be remembered that the only speaker in favour of the Extension of the Railway to Uva, at the now famous meeting of the Ceylon Agricultural Association, referred to an industry in Gall Nuts as likely to be fostered if facilities for transport were afforded. The nuts, he said, could be had for the mere picking. We read in a Commercial exchange that "South European gall nuts dried and analysed by competent men have yielded an average of 25 to 30 per cent of tannin. The oak forests near Neusaltz, on the river Oder, yielded in the autumn of 1883 a large quantity of gall nuts, all of which decreased in size considerably after drying in the air. An average sample of these gave 32.21 parts of tannin to 100 parts of the dried substance. This tends to show that the German gall nuts are as good as those from Southern Europe, as far as their tannin percentage is concerned, but their tanning solution is slightly yellow. For all that they are of little use on account of the large amount of water they contain when fresh, and their small size, and are therefore hardly worth gathering. Another form of gall nuts comes to us in a pulverized form from Smyrna, under the name of Smyrna rove. In a sample received from Hamburg, 18.92 per cent was found, while 100 parts of substance, dried at 100° C., yielded 21.78 per cent of tannin. Although its percentage of tannin is smaller than that found in the German nut gall, the rove finds extensive employment in tanning. This is due to the fact that this is of larger size, and therefore more worth gathering. There is, however, one drawback to the exclusive use of nut galls for tanning purposes; the leather it produces is of a good colour, but not nearly as durable as that produced by the oak bark process." It would be interesting to know what quantity of nuts was collected altogether by Mr. Milson—that is the gentleman whom the speaker above referred to mentioned as having collected some nuts—at what season they could be picked; whether the nuts have in any way been analysed, and with what result; what use the nuts were put to; and, above all, whether collecting them will satisfactorily answer the test which is applied to the undertaking, towards the success of which they are predicated to be accessory—"Will it pay?"—"*Ceylon Advertiser*."

LETTERS FROM JAMAICA--NO. 10.

Blue Mountain District, Jamaica, 28th Dec. 1885.

DEAR SIR,—The much needed "seasons" equivalent to our Ceylon monsoon have at length come. The rains are very late as they are due in October or November, but for the last two or three weeks we have had very good showers. This last week has been the heaviest of all, so that we have had no work. It cleared sufficiently on Christmasday to enable us to get to church, but came on again heavily in the afternoon; it has since cleared up, and the temperature in the mornings and evenings reminds me of Nuwara Eliya. Mr. Morris has telegraphed to the papers, that 11 (eleven) inches of rain fell in 24 hours at Cinchona; then I have heard the gauge overflowed. There have not been such rains since the flood of 1879, and it is to be hoped that the other parts of the island which had suffered so much from drought have had sufficient to last for some months. To us up here, it has almost been too much, as we get frequent light showers and mists which keep the ground moist and cool, so that planting, especially of stumps, may be done every month except June, July and August.

According to statistics previous to 1880 there seems to have been much more rain, the mean average at Cinchona being given in the Jamaica Hand Book for 1885-6 at 121.62 inches; so that estates lying on the same range, must get nearly as much, and it must have been much worse in the "old days" before so much land was opened up. This state of things surprises me all the more that the coffee was never sent to Kingston to be cured, thus saving the planter an immense deal of time and anxiety, and I believe of expense also. I cannot take for granted that the quality could be spoiled because the coffee was cured at Kingston any more than the bold coffee from Haputale, Ramboda, and other favored districts of Ceylon. It can only have been lack of cart roads, and the consequent expense of carriage on mule-back of parchment coffee: a mule now carries 200 lb. of clean coffee, which is a pretty tidy weight for one animal. If a curing firm were to set up at Kingston I should be very much inclined to send my coffee. I believe a mule could take 5 bushels dry parchment to Gordon Town, when it could be carted to Kingston. With "property" mules one could thus send 10 bushels to Gordon Town for 1s 6d. I only wish such another firm as John Walker & Co. would set up a business in Kingston, I will enumerate what paying work they might undertake. First the making and repairing of all sugar and coffee estate machinery, making small hand-pulpers to enable the settlers, as in Ceylon, to turn their coffee into good parchment coffee instead of the wretched stuff they now bring to Kingston, and which only fetches 38s to 40s in the London market. With suitable hand-pulpers, they would turn out a good sample and if they dried it properly would get a much better price than they now obtain for the badly cured stuff they bring to market. The firm could by the above named coffee, set up a set of mills, cure and ship it to England and realize, good profits. Then if some venturesome planter like myself sent his coffee to them to be cured and it still fetched high and paying prices, I have no doubt others would soon follow suit. In addition the firm would have open to them the repair of ships, and ships' machinery, building contracts and all kinds of carpenters' and blacksmiths' work in repairs, etc. They might also keep a general "store" for the sale of estate tools, and all requisites in the ironmongery line required by planters and the general public. I am confident

that with such a business well managed by some "canny" Scot, and if they were satisfied with 'modest profits, they would soon do an excellent business. Most of the business in Jamaica is in the hands of Jewish firms who are very enterprising and have managed to keep out the Gentiles to a great extent. There are only one or two engineering shops in Kingston, so they have it all their own way and charge absurdly high prices: fancy having to pay 5s each for iron spade bars, one inch thick and three feet long, steeled at both ends, one flat, one pointed! I cannot imagine why the Blue Mountain district was never opened up by good cart-roads; the difficulties are not much greater than in many parts of Ceylon, and in the old days when planters had plenty of slaves, they could have done it cheap and fast, but of course sugar was king and coffee planters in the minority, and I also fancy they were so well satisfied with things as they were, and their enormous prices and profits, and not needing to be as hardworking and energetic as the modern coffee planter and emigrant: they were content to "let well alone."

I am glad to say prices keep up for our Blue Mountain coffee, I was so fortunate as to obtain 111s, 122s and 130s for a small shipment of my coffee; it netted 108s. Would I had more of it, but I must have patience till the new fields come into bearing. The neighbouring estate, Sherwood Forest, is giving a very fine crop, and Radnor and the other estates are also doing well. Amongst the curiosities of Negro-English, I may mention the words "as much." If you ask a man if he has any stumps left, he will reply "Yes, as much," meaning there are still plenty. In the field the other day, I told the people to save the good sticks, as I wanted to build a shelter-hut; the answer was "You have as much," meaning that they were plentiful. The other day I got a letter from an educated man, a schoolmaster, whose pen I had detained for breaking into my guineagrass, informing me it was "illegal to impound stocks" on a Sunday. Amongst other peculiarities, they will talk of "one, one coffee being ripe," meaning a few berries here and there just worth the picking. The absurdity also of saying the "rivers have come down," when they are in flood, instead of saying the rivers are *up*, or have risen. The fact is, so many of the Jamaica rivers are dry beds during a portion of the year, that it does not seem out of the way to say the water has come *down*; as if it were stored up in the mountains for sundry times and "seasons," when it does come down with a vengeance, people being frequently drowned. One of the most onerous things the dwellers in Jamaica have to bear is the heavy import duty of 12½ per cent on most goods, besides the export duties on sugar, rum and coffee; this is even carried out to levying duty on articles by the parcel post, thus causing great inconvenience and delay to country residents who have to send all the way to Kingston to clear their goods. An other anomaly is that there is not a uniform rate of postage: some places near Kingston and those towns to which the railway extends are favoured with a penny postage, whilst we outsiders have to pay 2d for the half-ounce.

11th February. The above was written about six weeks ago, but was somehow mislaid, the writer supposing, it was about this time appearing in the *Observer*; for this accident he now apologizes. Crop has commenced, and is of very good quality, the promise of good crops expressed in the former part of this letter is likely to be realized; and no doubt some very fine specimens will be shown at the Colonial exhibition. Our very popular Director

of Public Gardens and Plantations, Mr. D. Morris, has been deservedly promoted to be Sub-Director at Kew; and his departure will be universally regretted, and be moreover a real loss to the colony.

W. S.

NATURAL HISTORY IN NUWARA ELIYA.

AN OLD VISITOR FINDING OUT SOMETHING NEW.

13th April 1886.

When writing you from Nuwara Eliya as to past reminiscences in Ceylon and Nuwara Eliya and the great changes which time and the railway, the great maker of modern civilization, have produced, I had little thought at the time of the hidden wealth of *life*, animal and vegetable, contained in the high jungles of this beautiful island. It is often and is generally supposed that the high forest lands and bare grassy hills or patanas of Ceylon are almost destitute of animal or bird life and that elk (the sambar deer) with their natural enemy the cheeta and a few herds of elephants are the sole inhabitants of the tangled thickets of dwarf bamboo, nillu and brambles; but the forest swarms with life, and bird life is most numerous. Few of the birds are of brilliant or gaudy plumage, though the common jay and the spotted woodpecker are bright and beautiful enough in plumage though discordant in their harsh notes. To see bird life in all its beauty you must select the early morning after a shower, and just as the sun's first rays light up the plain seat yourself quietly in a half-open, half-thorny thicket and watch the birds as they come to sun themselves and feed. Nearly all are insect-feeders; many of them are nesting, and the song of the male bird though low is sweet and musical. The black-bird, the roker, the tom-tit, the bulbull (Kelaart's) have low sweet notes and the brambles and thorny thickets are literally alive with these beautiful little birds; would that they were more numerous, for the black grub larvæ of the common grey moth is so destructive to plant life that the gardener in his kitchen and flower garden is often driven to despair, the labor of weeks will be destroyed in a night by the ever-present black grub which destroys the young and tender plants as fast as they are put out. Were it not for insectivorous birds, so prolific is insect life, that it would be impossible to grow anything. Mr. Whyte, the well-known naturalist of Kandy now at the Grand Hotel cottage, Nuwara Eliya, has in the grounds attached to the Hotel obtained one or two rare specimens of birds, notably the whistling thrush or "Aringa Blyghii" first found by Mr. Blygh which is said to be exceedingly rare; also Palliser's ant-thrush and a very beautiful Night Jar. These birds are almost unknown to ornithologists though I am doubtful if they are really so rare as is generally supposed, but they must be sought for in the quiet half-open glades of the forest in the early morning. Mr. Whyte is not only a naturalist but a horticulturist and botanist, and is most enthusiastic in his love of birds and plant life and his great desire at present is to introduce into the country insectivorous birds and to protect and encourage such as we have. A strict and stringent law should be passed to prevent the destruction of small birds: the benefit derived from them is incalculable. Mr. Whyte's favourite of all Ceylon birds is the robin, and I feel very sympathy with him in this. Like our "robin redbreast" of the story books he is a domestic pet and will breakfast with you at the table and as an insect-destroying bird is equal to the home starling. When in Nuwara Eliya I was greatly instructed by Mr. Whyte's conversation on matters relating

to bird and insect life, I suggested that a most useful bird might be naturalized or domesticated here, the Australian magpie or piping crow; these birds are most amusing, the natural call of the male is a beautiful clear piping call like the note of a flageolet; they can be taught to talk and will sing any common or simple air, and like the mocking bird will imitate the call or song of any domestic animal or bird, but as insectivorous birds I know none so valuable. I have seen a piping crow watch a tuft of grass and in an instant dart like a flash of lightning on a snake 14 or 16 inches long, seize it at the back of the head and break its neck. If Mr. Whyte can induce the people of Ceylon not only to care for and preserve their own beautiful birds but introduce others he will do good service to his country.

My steamer is due and time is short but I will write more of the beauties of Nuwara Eliya did time permit. What a wealth of vegetable life is there! There a botanist might spend a month on the lichens of the Nuwara Eliya plains alone.

[We can from personal observation confirm every word said in praise of the great shrike called the Australian magpie, both as insectivorous bird, songster and mimic. When we were in Australia many of the so-called magpies were dying from inability to digest the thousands of grasshoppers they were preying upon. We have seen a tame "magpie" stretch his neck in order to crow like a cock, while next moment his head was down and he was gobbling like a turkey. An accomplished specimen at Echuca began with an orthodox coo-ee! asked "Who are you?" and after several other observations whistled a tune. We tried to obtain specimens for Ceylon, but we failed as the bird is strictly protected. But our Government could get a dozen pairs by applying to the Government of Victoria. The shrikes could be let loose in Nuwara Eliya and surrounding districts to feed on the cockchafer beetles and other insects.—Ed.]

IN SEARCH OF A HOME IN TASMANIA.

(By an Old Colonist.)

BY THE BANKS OF THE DEVERON—AND DERWENT—FIRST IMPRESSIONS—A CHARMING SPOT ON THE BANKS OF THE DERWENT—HOUSE-HUNTING AND DISAPPOINTMENT—NO FREE LAND ORANTS IN TASMANIA NOW—LIKE THE PERPLEXED HUSBAND IN "CALLED BACK."

It was years ago, while fishing from the banks of the Deveron, that dear old Tytler and I resolved to seek a home in Tasmania. We knew all about it, for had we not read the best authorities on the subject? The climate of course, all agreed, was the very acme of perfection for old Indians. The soil, if somewhat patchy, we knew how to select. "Here" said R. B. T. with a wave of his hand, "all is musty, bug and witherage; there vigorous youth with a glorious future, a grand home for the bairns. Here we are cramped; there abundance of elbow-room. Why, man, an island as large as Ceylon or Ireland or 18,000,000 acres occupied as yet by a population only equal to that of the granite city. And oh, man, the glorious rivers now stocked with salmon and trout! Mind you a river frontage is a *sine qua non*; and while the boys look after the sheep or orchard and the girls the poultry or dairy, we, my boy, will do the fishing and talking!" Meanwhile dear old R. B. T. has been called home to a better paradise, while I alone am left to realize or otherwise the dreams of Deveronside. At present my notes must be brief, for the time for dreams and sentiment is past and the time for work arrived. Moreover it will be borne in mind that these are simply *first impressions* liable to b

modified by a more extended experience as far as possible; however the motto "brevity and facts" shall be adhered to.

My first impressions of Hobart were anything but disappointing; its spacious streets, handsome freestone buildings, beautiful vegetation and delightful temperature more than fulfilled anticipations.

To find temporary shelter for my family was my first duty. This I had not very much difficulty in arranging in a good hotel at two guineas per head per week for board and lodging. This accomplished, I walked out to the Botanical Gardens to see what this celebrated climate and soil can produce—a charming spot on the banks of the Derwent—and for a few hours I simply revolved amongst the numerous old European friends which here seem to have found so congenial a home. Giant geraniums, brilliant verbenas and a perfect jungle of Heliotrope, greet me as I enter the gate. The gardeners though civil are not very communicative but when I enquired if such plants as I have named require any protection in winter, the answer was a very emphatic: "Oh, no." This, to my mind sufficiently settled the question of temperature though people do persist in saying "the winters are very cold here." I cannot here enumerate all the familiar trees, shrubs and flowers which re-awakened memories of bygone days. From the noble Scotch Fir down to the Bourtrie bush and bonnie yellow broom, all seem to rejoice in the change of climate, while not a few of my tropical acquaintances, notably the Lantana, the trumpet-flower (*Datura*), Balsams, Vincas, Veronicas, Yuccas and sundry palms, find a home sufficiently congenial. Many of the shrubs so common at home here grow almost beyond our ken. The Bay and Portugal laurel, so like a coffee bush in England, here more resembles a sturdy oak laden with a marvellous profusion of bright berries. The holly, too, becomes a large tree with such lusters of berries as it never bears in its native clime; indeed, I have seen no country for a moment to be compared with Tasmania for fruit and seed. Ceylon may have a monopoly of tender green leaves, and England for green fields, but for profusion of fruit you must see Tasmania. The "hawthorn-glade" can never under any conceivable circumstances in England look so resplendent with fruit as it does here; while the *sweet-briar* we must never mention it here—what the *Ageratum* and *Lantana* are to the planter in Ceylon, Couch grass to the English farmer, *sweet-briar* is to the Tasmanian husbandman.

I could willingly spend days in these lovely gardens; but I am reminded that a more pressing if less agreeable duty awaits me, viz., *house-hunting* which here as at home I find to be the most worrying, wearying work I ever engaged in. My requirements were simple and definite enough: "To rent with option of purchase, a good house with orchard or small farm, river frontage, &c." "No need to advertise," said agents in London, "you'll find at once abundance of what you want." In vain however I scanned the papers on arrival and those terrible impostors the house agents by their most exaggerated descriptions gave me many a vain journey. At length something like the thing wanted made its appearance in the morning paper, an advertisement in more than ordinarily intelligible English. "Highly desirable investment, 10 acres of the richest land in the valley of Glenorchy with river frontage and good stone building thereon" &c., &c. "Here now is a nucleus to work from," I said; and off I went by the first coach to the fifth mile-post from Hobart. My chagrin may be imagined on finding the "rich land" to be an exhausted and abandoned field by the side of a lagoon, without the ghost of a tree or shrub; here a thistle

and there a sweet-briar tried to find their way through the baked clay, but both seemed inclined to give up the struggle in despair. The stone edifice consisted of the remains of four walls about 15 x 12 feet. Years ago there evidently had been a roof of some sort, but this portion had entirely disappeared. I strongly expressed my disappointment to the first man I met. "Ah," said he, "I know of the very thing to suit you, about two miles from here. Beautiful little estate on the bank of the Derwent, though now much out of order, the proprietor having lived for the last few years in Victoria; splendid garden and 100 acres of riverside land capable of growing anything; excellent family house." "That's the thing!" I exclaimed, "and I'll go and see it. Did you say there was good fishing?" "I don't know what you call good fishing," said my new friend, "but I caught 87 dozen mullet and salmon" last night in that ere water." I do not know where all these wonderful fishermen expect to go, but I suspect there are others besides Mr. Fawcett's friend up the water who can tell a good big thumper. However if the description be only half true the place will suit me, and off I struck through the fields—demolishing as I went the top of many a stalwart Scotch thistle. The sun was now high in the heavens, and the day altogether proved one of the hottest of the season, the thermometer recording 100·2 in the shade. Yet to an old Ceylon man this did not seem very oppressive. What disturbs me more is that as 100 is to 90 so is 60 to 54. I was glad, however, when I got into the shade of some trees which half hid a bungalow similar in many respects to Fairyland, and as I wiped the perspiration from my brow with one hand I instinctively picked a twig from the branch above with the other. Interested I was to find an old favourite *Aloysia Citriodora* the scented verberna, with stems like my thigh and growing to the mature height of 20 feet. The flower garden was certainly wild enough but the geraniums held their own against all comers, proudly raising their brilliant scarlet trusses above the heads of the tallest thistles. The house was deserted but in fair order and offered ample accommodation. The orchard of about 2 acres was fully stocked with apples, apricots, plums and peaches, and, though quite abandoned, bearing really astonishing crops. The gooseberries had dried on the bushes and the luscious greengages were likely to soon do the same, save on the lower branches which some stray pigs seemed to reach. I followed their example and proved the plums which so pleased the pigs to be of excellent quality. I now sauntered on the lawn gently undulating towards the Derwent. "This," thought I "is exactly what I dreamed of and the sooner I secure it the better. With what pleasure I shall mow down these weeds! I renovate the flower-garden and see the orchard put in order! and then should some old Ceylon friend come and see me (shades of R. B. T.) only think of the fishing!"

With these pleasant thoughts I hurried back to Hobart in order to find out the agent of this desirable property, with as little delay as possible. This I had little difficulty in doing, but, alas! only to be again disappointed. The owner of — is a very wealthy man and does not care to let or sell. Though living in Victoria he is one of the largest proprietors of Tasmania owning

* Native "salmon" and a very inferior fish to our Scotch salmon, to naturalize which £10,000 has been spent and it is doubtful if ever a single fish has been caught by rod or net. "I never see'd one," said the Risdon ferryman to me the other day, "and I have been here for 30 years. There," he said, pointing to a shoal of porpoises, "there is where your salmon fry go."

93,000 acres chiefly along the principal river valleys, many of the blocks shaped fan-like so as to take in as much of the river frontage as possible. In short, Mr. — is a species of land-grabber, the bane of this and every country they exist in, and the pitiable Government of this colony, while enforcing strict laws upon the poor little immigrant as to the timely improving of his lot, wink at the great *squatocrat* who may hold 100,000 acres and not employ a dozen men or spend £100 in the colony, but, by George, their day's coming! 6d an acre tax on all uncultivated land would work a cure. Out of the 6,000,000 acres alienated I do not believe there are really 100,000 acres in cultivation in this colony.

My next move was to try and secure if possible a block of virgin forest, out of which, I feared not, I would in time, carve an estate for myself. The official, however, in the Lands Department smiled when I hinted at a water frontage; no such land seems available, and yet 12,000,000 out of the 18,000,000 acres are still in the hands of the Government. I note a correspondent writing to a Madras paper gives details regarding free grants of land. To prevent disappointment it would be well to note that this is a thing of the past: the immigration agent has informed me that no more will be given.

There is evidently nothing gained by being in a hurry in this country, the residents of which take life about as easy as any people I ever came across, and I now resolved to take a house *pro tem* in Hobart and look leisurely around me for something more suitable. One morning on this errand I went out armed with sundry letters from house agents, it was past 6 o'clock and the sun high enough to have quite dried up the rain of the previous night. The temperature such as to make me forget I had a body subject to any pains or ailments, the trees so green and glossy, the flowers so pure and lovely, while the deathlike stillness of all around made me feel like an intruder in some spiritual or unearthly sphere. My own footsteps were the only sounds that reached my ears for the first hour. By-and-bye servant-girls began to look out, rub their eyes and wonder at the strange man on the street. At length I reach address No. 1, and as the personage I sought was a "builder" I without any compunction proceeded to knock him up. This, however, was a more difficult matter than I had calculated upon and had I not enlisted the services of a passing gardener I doubt if I would have succeeded.

Very much in dishabille and only half-awake the builder appears, grants a few monosyllables and then arranges to overtake me if I would walk down towards the house to let. He has not yet overtaken me, but I examined the premises and decided they would not suit.

The next house on my list I visited with some little interest. The late occupant having been an old Ceylon friend who retired here some 20 years ago, was lately seized with a longing to see his friends in England etc he died; but only reached Melbourne when he suddenly passed away.

It was now about 9 o'clock, but there was no appearance of the present occupant's moving. I stood for a few minutes admiring the Laurustinus in the front garden, and then proceeded to ring the bell; in about 10 minutes the door opened, and I just saw a nose from under which came a voice, saying: "Could you call again between 10 and 11?" I said, I could, but didn't say, I would, for I had already made up my mind that the square little box was not value enough for the rent asked (£110 per annum),

and so I returned to my hotel inwardly resolving to indent for some Sinhalese carpenters and build a bungalow for £500 better than any offered here at £100 per annum.

Strange people the residents of Hobart! Like their surroundings fair enough to look upon, but strangely apathetic and uncommunicative. Readers of "Called Back" will remember how the poor, perplexed husband looked upon his lovely Pauline during the first evening of their married life, how he eagerly listened for some intelligent remarks from her beautiful lips, and at length in despair he bade her good-night and strolled out to take a walk. In a somewhat similar frame of mind I now start on an extended tour, or series of tours throughout this really beautiful island, and my next duty will be to communicate my impressions of the interior.

EXPORTS OF TEA FROM CHINA AND JAPAN.

The season being now closed, we quote the figures for exports of tea from the "Hongkong Chamber of Commerce Price Current":—

Export of Tea from China and Japan to United Kingdom.		lb.
Total from 1st June 1885, to 29th March 1886...	...	150,251,138
Total from 1st June 1884, to 29th March 1885...	...	144,405,926
Total from 1st June 1883, to 29th March 1884...	...	150,742,895
To Continent of Europe.		
Total export to date...	...	8,660,926
Against same time last year...	...	10,093,683
" " 1884...	...	8,960,668
To Australian Colonies (including New Zealand.)		
Total from 1st June, 1885, to 29th March 1886...	...	21,769,305
Total from 1st June, 1884, to 29th March 1885...	...	19,078,816
Total from 1st June, 1883, to 29th March 1884...	...	14,432,537
To United States.		
Total from 1st June, 1885, to 29th March 1886...	...	64,582,520
Total from 1st June, 1884, to 29th March 1885...	...	54,768,567
Total from 1st June, 1883, to 29th March 1884...	...	58,463,824

It will be seen that the exports to Britain after having gone down from 150½ millions in season 1883-84 to less than 11½ millions rose to 150¼ millions of pounds in the season just closed. In the case of the Continent of Europe, the process has been quite different: from less than 9 millions in the first season, the export rose to over 10 millions, sinking in the season just closed to 8,660,000 lb. In the exports to the Australian colonies and New Zealand, the increase has been continuous and very large, from 14,432,000 to 19 millions, and last season no less than 21½ millions of pounds. To the United States, too, there has been a very large increase of exports, the excess in last season over the previous one being nearly 10 millions of pounds. It is now clear that neither the French war, heavy export duties nor low prices have permanently lowered the capacity of China to send tea into the world. We suppose the total export from China and Japan this last season, is one of the largest ever made up. The

figures are:—

United Kingdom ..	150,251,000 lb.
United States ..	64,552,000 ..
Australia and New Zealand	21,749,000 ..
Continent of Europe ..	8,661,000 ..

Total .. 215,233,000 lb.

It will be seen that more than 3-5ths of the whole went direct to Britain, while Britain's Australian colonists took a quantity, which made over 172 millions lb. for the British race, exclusive of Canada which is lumped up with the United States.

In our "Handbook and Directory" we find our calculation for the maximum export from China and Japan is 275,000,000 lb.

PLANTING IN NETHERLANDS INDIA.

(Translated for the Straits Times.)

In Cote on the East Coast of Borneo, a Dutch-owned tobacco estate, the first one ever started there, has been opened. Simultaneously another plantation of the same kind has been established by a Netherlander within British territory in North Borneo. In that land of promise a German tobacco estate which has just entered its second year, on an island, is still the only outcome of planting enterprise.

A company with capital amounting to 2,400,000 guilders has just been started at Amsterdam under the style of "the Palembang, Company." A Pamphlet has been circulated among persons interested in the scheme giving particulars about Palembang, which is described as being an extensive Province of the size of Java and Madura, but peopled only by 600,000 inhabitants found mainly on the high tablelands, and on the rivers flowing therefrom. The country abounds with widespread forests, on land never yet brought under cultivation and full of the varied produce usually met with in the Sumatra woods such as rattans, rubber, *gutta serena*, dammar, gum benjamin &c., besides an abundance of splendid timber. The land along the rivers is covered with a thick layer of humus and is highly fertile. A concession has been secured from Government which comprises the leasing to the company of a portion of this land, 15 miles long by 4 broad which will be turned to account partly for growing gutta and tobacco, and partly for collecting jungle produce. Broad, deep, and gently flowing rivers in the neighbourhood ensure effective means of communication both inland and with the seaboard, close at hand. The climate is as healthy as in Deli and is said to be very suitable for tobacco growing. Coolies are procurable from the chief town and Java. That tobacco of good quality can be raised there is proved by the fact that the native grown article, known by the name of Rano tobacco, bears a high reputation for aroma throughout Netherlands India. Experience only will show whether it will be equal to Deli tobacco. Easy and cheap communication by water naturally will prove highly advantageous to the enterprise. Indiarubber and gutta percha both of which it is intended to grow are articles getting more and more into demand for industrial purposes. These gums are now mostly obtained from gigantic trees the collection being carried on by natives in a very reckless and rough fashion. By their thoughtlessly cutting down the trees before gathering the product, the latter begins to get scarcer. There is even danger of supplies failing, the only means of prevention being cultivation and judicious collection. Besides these trees, where cultivation is attended by difficulties, there are in the Palembang

forests, others from which by tapping, gums can be obtained which, when purified, equal in quality the best kinds known. These gums by means of approved and inexpensive appliances can be brought to market in thoroughly transparent condition. These gum-yielding trees grow very abundantly in the forests of Palembang, the article being known generally by the name of *getahantun*. Plantations of these trees may be expected to bear within seven years with every prospect of handsome returns regularly afterwards. The starting of the Company is a good sign showing, as it does, that people in Holland are beginning to take an interest in hitherto neglected colonial possessions.

Another coffee estate in Mid Java, so says the *Sourabaya Courant*, assessed at a quarter of a million of guilders has been sold for a few thousands only. Within the last few weeks several estates have gone the same way, one of them bringing only 8,000 guilders. Such cases bid fair to be on the increase with the unavoidable result that the mountain districts will for the most part relapse into jungle. In Surakarta, two coffee estates formerly yielding thousands of piculs have reverted to Government from their having become utterly worthless and unsalable owing to disease and low quotations.—*Batavia Dagblad*.

CINCHONA ANALYSIS AND VALUE: THE DIFFERENCE.—A planter has shown us correspondence referring to a batch of over 1,000 lb. of cinchona bark. The local analysis gave 52 per cent quinine, and the local valuation was 11 to 13 cents per lb. The bark on being sent to London was analyzed 1.33 and sold at 6½d per lb., or say three times 11 cents!

CEYLON TEA.—The *Colonies and India* for this week has the following paragraph relating to Ceylon tea. While agreeing in the main with what is therein stated, we cannot but observe that a great mistake has been made in the assumption that "the first samples made such a favourable impression on the consumers here, that the market was, so to speak, taken by storm." Quite the reverse, it is well-known, was the case. Some years elapsed before the brokers would look at the "black and nasty stuff" which was sent home, although, as was recently pointed out in these letters, there was one man, Mr. Roberts, who saw in it great possibilities in the future. It is as well to bear this in mind in order that no relapse may ever be permitted:—

We have frequently drawn attention to the rapid growth of tea cultivation in Ceylon and to the high place which the produce of the island has taken in the English market. When we look back but a few years, to find the whole of Ceylon practically one immense coffee plantation, the quantity of tea which it now exports is marvellous. The principal cause of this rapid growth of a new industry is to be found in the uniformly high quality which Ceylon teas have maintained. The first samples made such a favourable impression on the consumer here that the market was, so to speak, taken by storm. Having achieved so much, it is to be hoped that the Ceylon planters will not sacrifice the quality of their produce for the sake of quantity, as has been done in China, for if they do they will inevitably lose the market they have so firmly established. It is a well-known fact that each year shows a greater falling off in the quality of China teas, and to this fact is to be attributed a large share of the increase in the consumption of Indian and Ceylon growths. Ceylon teas combine the best qualities of both Chinese and Indian varieties, possessing both the delicacy of flavour of the former and the strength of the latter, without the astringency which sometimes prevails to so unpleasant a degree. Let Indian and Ceylon planters all make "Quality" their watchword, and they need not fear competition elsewhere.

NO HEN should be kept beyond her second laying season as a rule. Because many pay no heed to this point but keep hens three, five, or more years, they wonder why they lay so badly.—*Queenslander*.

A RECENT find in the Subra silver mine, Australia, consists of a very high quality of stephanite, containing as much as twelve thousand ounces of silver per ton. The bunch is estimated to contain twenty tons.—*Madras Mail*.

PROFESSOR BUDD says fresh fruits may be preserved during long shipment by wrapping each specimen in tissue paper that has been soaked in salicylic acid. If the journey is very long, use double folds, and fill the interspaces with material similarly prepared.—*Ibid*.

MAURITIUS LAND CREDIT AND AGENCY COMPANY.—The twenty-third annual report of the directors of the Mauritius Land Credit and Agency Company (Limited) shows a credit balance of 9,217. The directors propose a further dividend of 2s per share, making a total dividend for the year at the rate of 12½ per cent., adding to the reserve fund 1,500l., and carrying forward 217l.—*Overland Mail*.

THE EXPRESSION of the eyes of persons killed by violence is considered an important matter in criminal jurisprudence, but its value has been greatly lessened by reason of its evanescent nature. A French scientist has found a means of restoring the life-like expression. It consists, simply, in applying a few drops of glycerine and water to the cornea.—*Burgoyne and Burbidges*, Feb. 1886 P.L.

COCA LEAVES.—Cable advices from Peru report an advance of 15 per cent., consequently, and in spite of the bear operations going on here, holders of good dark green Huanuco leaves have raised their price to 40c (1s 9d), and if sales begin at anything near this figure, much higher rates will be sure to prevail. With the present demand for cocaine, there is not three months' supply of leaves in this market.—*The Chemist and Druggist*, March 1886.

CARDAMOMS.—Private advices state that the cultivation of cardamoms is being extensively increased all over Southern India, both by Europeans and natives, especially the latter, who are following the example of Europeans in planting up their jungles and picking the fruit as it ripens, instead of stripping the racemes as they used to do. As a result, prices in the local market have declined in the last three years from 70 rupees to 20 rupees per maund of 28 lbs. (4s. 7d. to 1s. 4d. per lb.), and it is thought they will fall still lower.—*Ibid*.

MR. J. WARE EDGAR, C.S.I., of the Bengal Civil Service, who reported his departure on furlough on the 1st instant, is scarcely likely to return to India; he was in many respects an able officer and was one of the best judges of a good dinner in the service. [So writes the *Indian Planters' Gazette*. Nearly ten years ago Mr. Edgar very ably summed up the history of the tea enterprise in India.—Ed.]

TREATMENT OF SICK HEADACHE.—A novel remedy has been put into practice with very good results, for the cure of this unpleasant malady, by Dr. W. Gill Wylie, who says *New York Medical Journal*, "So soon as the first symptoms are felt, the patient should take a pill, or capsule, containing one grain of inspissated ox-gall, and one drop of oil of gaultheria, every hour until relieved, or until six have been taken." The doctor adds that sick headache is almost always cut short by this means.—*Burgoyne and Burbidges* Feb. 1886 Price List.

A PEACH ORCHARD.—The largest Peach orchard in the world, according to the *Illustration Horticole*, is the property of Mr. J. H. Parnell, in Georgia. Mr. Parnell is the brother, we believe, of Mr. S. C. Parnell.

of Home Rule notoriety. The Peach orchard in question comprises 840 hectares, containing about 150,000 trees, planted at a distance of 4 metres one from the other, and grown as bushes or low standards, to facilitate the picking of the fruit. Seventy thousand of these trees belong to the "Parnell" variety. The land was bought at a cost of 12,000 dollars, and at present the annual revenue is more than two-thirds of this sum. Mr. Parnell sent as many as 900 boxes of Peaches in a single day to New York.—*Gardeners Chronicle*.

ARTIFICIAL SODA.—Very few people are aware of how much the modern world owes to Nicholas Leblanc, the inventor of artificial soda. By combining six salts he produced very cheaply the soda used in commerce, and the result has been a revolution in manufacturing processes of enormous value to the industrial world. Indeed, some writers claim that the manufacture of this soda was as fruitful of good as the invention and application of steam. Baron Liebig said that without this process modern chemistry could hardly be called a science. It seems that with this artificial soda, sulphuric acid and hydrochloric acid can be made in immense quantities and at a very small cost. A statue is about to be erected in Paris to commemorate the fame of Nicholas Leblanc. This memorial was first proposed in 1855, and it has taken thirty years to raise sufficient means from the manufacturers who have profited so greatly by Leblanc's process of making soda.—*Inventor's Mart*.

POULTRY.—The secret of successful poultry-farming although perfectly intelligible and clear, has not by the many been apprehended in this colony. It is mostly done by the rule-of-thumb in a come-lucky-go-lucky style, and as might be expected under such circumstances, Nature's laws are frequently violated and great disappointment and loss ensues. There are well defined laws of nature which govern matters in every sphere of life and industry. When these laws are apprehended and intelligently applied success follows as certainly as the night the day; when ignorance of these laws is conspicuous and operative failure accrues. The following from the *Marysville Appeal* is clearly given upon natural lines and we heartily commend it to the attention of our readers. Poultry-farming will pay only as it is properly understood, and energetically and economically carried out. Our authority says:—Vegetables of some kind and green feed are necessary to egg production, and should be given quite often, cooked vegetables being the best in all cases, mixed with meal, bran or shorts. Some meat should be given them about once each week, where the hens have no access to worms, or something as a substitute for these, their natural diet. Cooked meat is the best, or if given raw should be cut up fine, like mince meat, and fed from some clean dish or board, not thrown on the ground in the dirt. In the absence of worms or meat, milk is the best substitute, and possesses the requisite parts to assist in egg production. Hens are fond of milk in any form, it is good for them sour or sweet, or in the form of buttermilk; for laying hens do not need much corn in warm weather, say twice each week, and have it cracked or ground. It is too heating and fattening for summer feed, but may be fed oftener in the cold weather. Give cooked feed as often as you can, such as boiled vegetables, potato peelings, and such other kinds as you have, mixed up with bran, shorts, and meal. Feed wheat or some other grain for the evening meal, as they have the whole night to digest it. Change the grain feed often, and give fresh water daily and your hens will repay you for the extra trouble and expense by a liberal "shelling out."

WINTERING AND LATE PRUNING.

TO THE EDITOR OF THE "MADRAS MAIL."

Sir,—My attention has just been called to a leader in your paper of the 1st of April last. I think your review of my essay in the 'Tropical Agriculturist' is a very fair one. 'En passant' I may remark, that planters are proving my 'modus operandi' by small experiments. I feel sure that the system I advocate will gradually steadily supersede the present utterly indefensible and pernicious method adopted, inasmuch as my mode aids nature by acting in consonance with the seasons, which continue unaltered, as evidenced by the statistics (covering a period of twenty-two years) which I embodied in my essay. I take this opportunity of pointing out a few mistakes made in your reference to it. First; I do not condemn 'handling,' but I do deprecate the present method of pulling off with the fingers. I use a knife, for reasons explained, and the advantages of it must be obvious 'prima facie.' Second: Gauling—here I think you have slightly misjudged my mode, to explain which I subjoin extracts from my leader and my essay.

From Leader.

"Gauling—This is adopted in steep lands with a view to prevent wash. It consists of cutting trenches 2 feet in width by 2 feet in depth * * * Mr. Quarm says that a coolie can do 12 trees, and that the work costs R10 per acre. Since, however, a coolie's pay is four annas, and that coffee is planted with about one thousand eight hundred trees to the acre, a simple calculation will show that he is considerably mistaken in his estimates."

This computation of cost was made with reference to the planting on the Shevarois, which is usually 7x7 feet apart; coolie hire under 3 annas per day. So gauling, on this data, costs considerably under R10 per acre.

Third.—Digging.—Though this operation on the Shevarois has cost R50 per acre, I since ascertained from experienced planters in Wynnad, that such digging would cost about R20 per acre in that locality.

Fourth.—You doubtless have data for pointing out what appears to you the "great blot" of system. In 1861-62 we could arrange to get alternate gangs both of Malals and Churnas, as well as Moplahs, to come up regularly from March to the middle of June, and I venture to state that if on Mr. Reilly's estate, Canarese and Tamil women are taught pruning, Moplahs, Malals and Churnas men, who in timber work I knew to be singularly intelligent, are not less fitted to pick up a very simple process. The facts that tea estates on these hills are worked practically all the year round, and that coffee estates, to wit Glenavans, with good management, can keep over 150 coolies during these months, March, April, May and June, tend conclusively to prove that labour can be made available whenever wanted, especially now when, owing to the depressed state of labour, and the money markets, labour is abundant. I contend, with instances to prove my allegations, that no earnest planter has ever lacked labour. My further allusion is to the late Mr. James Gordon, who in the midst of much bolder settlers in Vytheira was told he could not the year round keep 300 acres clean-band weeded. He kept 700 acres so, by energy and determination. Permit me to close this letter by pointing out the immense advantages derivable from the system I advocate, whereby succeeding crops of coffee can be obtained for six years, without the applica-

tion of manure:—

Wintering without manure	...	2 crops
Gauling do do	...	2 do
Digging 15 inches deep puca	...	2 do *

Cost: wintering in Shevarois 30 trees at 3 annas, 900 to acre, Gauling R8 per acre, and digging (on Shevarois costs R32 and Wynnad R20).

I am, with other planters, indebted to you for bringing planting interests powerfully forward as I see by your issue of the 13th instant.—(AGAR) A. QUARM.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.)

To counteract the extensive frauds in the sale of commercial fertilizers, engrosses more and more the attention of the agricultural community. The restoration to the soil of the fertilizing materials carried off by the harvests since many centuries of culture, is the *sine qua non*, not of all progress, but of augmentation in yields. Farmers now form clubs to purchase chemical manures direct from standard factories, and the banks discount their joint paper, for eight or ten months, at low rates. A co-operative society, generally limits its action to a radius of eight miles. Many extend their operations to the purchase of seeds, acclimated live stock, machinery, and cattle foods. In the case of new machinery, an instructor is employed to explain and superintend working. One club has nominated ambulatory book-keepers, to post up members' accounts. The "union" principle is working so admirably, that it is in contemplation to extend its sphere of action to the erection of out-offices.

In the iron-smelting districts of Germany, an extensive industry exists, for the extraction of the phosphorus from the ore, so as to enable steel of greater tenacity to be prepared. The scoria or slag is thus rich in residual phosphorus; also in lime, as the latter is employed to de-phosphorize the iron-ore. The slag crumbles to a coarse powder when exposed to the air; but when it contains less lime and more waste iron, it has to be crushed like mineral phosphates. On peaty soils requiring to be sweetened, or meadows rich in humus, this granulated dross is invaluable; the same happy results must follow, on lands deficient in phosphoric acid and lime. The new fertilizer—for such it really is, has told with marked effect on barley, oats, and marigolds. From 5 to 13 cwt. of the powdered scoria, along with a proportion of potash and nitrogenous fertilizers, suffice for an acre. According to M. Fleisher, the phosphate slag, contains 17½ per cent of phosphoric acid.

A MOUNTAIN RIDE IN JAMAICA COFFEE AND CHINCHONA PLANTATIONS.

A bright January morning in Jamaica—and it is difficult to imagine anything more invigorating than such a morning in these latitudes at an elevation of 4,000 ft. above the sea—tempted me to forego the cares of official life for a season, and to start on a visit to the Chinchona Government estate, situate on the great Blue Mountain range. Leaving the cantonment of New Castle, our road first leads by a steep zigzag ascent to Woodcutters Gap, the eye being charmed with the view of strange crumpled hills melting into the Liguanea plains, with their brilliant gleams of sugar cane, and beyond that the sea of a deep blue. It was an exceptionally promising day for a mountain ride, as the sea view ended in a clearly defined horizon, which is unusual here, and an horizon cutting the outline of hills over 2,000 ft. in height. Woodcutters Gap is some 500 ft. higher than New Castle, and lies in the line of least width of the island, and consequently affords a beautiful prospect of the sea on the north side and that on the south of the island. To the north, over Cedar Valley, and slopes and hills beyond description, is seen Annotta Bay, and to the southward the town of Kingston, the long rib of the Palisades fringed with cocoa palms and mangrove swamps, ending in Port Royal in the blazing

* Extract from Essay.

sunshine. Beyond that lies Old Harbour, and the view is closed by the quiet landmark of the Round Hill in Vere, hazy in the western distance. It was difficult to believe, in the almost keen mountain air, that, even as we looked, the yellow fever was doing its deadly work in Port Royal far below. On one memorable occasion (last New Year's Eve) I saw Cuba from this gap, floating like St. Brandon's blessed isle in the distance.

The road here descends round the north slope, if slope it can be called, of Catherine's Peak. Let me for a moment explain that the "road" is a bridle path cut in the face of the hill, with a sheer descent on one hand, and a steep ascent on the other. Frequently the outer slope is precipitous, but is in most cases so covered with bush that the real steepness is obscured, and the danger of falling "down the gully," as it is called, is not brought too prominently before one. The heavy rains cause the roads to need constant repair; it is a most common occurrence to find a landslip of loose earth covering the road, or occasionally a large boulder blocking the path; and, on the other hand, the road will become caved by rain on the inferior slope, and leave but a narrow thread of foothold overhanging a scooped-out recess. The way is rarely level, and it is absolutely necessary to wear a crupper, or a back girth, which is simply one girth brought back in rear of the pony's belly, and pulled so tight as not to slip forward over the stoutest part of the animal.

They are mostly deficient in shoulders, but are wonderfully sure-footed game little beasts, up to any weight. They are too sensible, as a rule, to play the fool on these narrow roads, as a catastrophe must be the inevitable result. A pony that will be troublesome in a roomy road in the plains, will often, in his own interest, behave with the greatest care and decorum on these narrow bridle roads.

To return to my journey, the road descends along the northern slope, past stately and graceful groups of tree ferns, and masses of climbing fern on either side, and affording views of hill, dale, and sea that would delight the artist at every step. We then reach Silver Hill Gap, which unites Catherine's Peak with the main ridge, and here, leaving the road to Buff Bay on our left, we turn down to the Yallahs river by a blossoming hedge of Cherokee rose. At our feet lies the Silver Hill Coffee Works, distinguished by an enormous cabbage palm, with the Yallahs brawling below the barbecue; while on the further bank climbs a long stretch of exquisite feathery bamboos of a grace not to be expressed.

We ford the Yallahs up to our girths in water, and a nasty crossing it must be when the rivers are down (i.e. in spate), and ascend a steep slope over a shaly landslip, with broken cliff on the left, and on the right a sheer drop of 30 ft. into a gloomy pool. Here the road, to our delight, displays stretches of level, and as we put our ponies into a canter, we glance at a curiously striated bluff of rock on the farther bank of the river, which appears to have been burnt to a cinder by volcanic action and then weather worn into a rotten state by rain and stream. Winding along the hill side at a brisk pace, here and there a mongoose sentries under the pony's hoofs as we pass along. These little animals were introduced to exterminate rats, but having done that, bid fair to exterminate all other animal life. Eggs and young birds are their favourite food, and consequently quail, partridges, and pigeons have vanished in the hills, and save in the unwholesome swamps there is no sport to be had. The poultry, too, suffer grievously from their foraging. Now we come to a coffee estate known as Clydesdale, where the negroes are sitting at their mid-day meal, and have enough of old time courtesy left to salute "massa," and the women to bob an ungraceful curtsy with a smile of welcome. Now we wind upwards, up steep clayey zigzags, past the ruined coffee works known by the inappropriate name of "Industry," with its barbecue grass grown, and one tall spectral palm high against the sky. Upward still through bush, with wild tangle of roses, the remnant of some dead-and-gone garden, and, turning sharp to the right, we round the hill and arrive at the Cinchona. The Cinchona I can only describe as a little earthly paradise, 6,000 ft. above the sea, beautifully kept, and, in a layman's opinion, of immense scientific value. To see a well-kept homelike

tennis lawn was indeed a treat in the midst of the tropical luxuriance in the valley below, and the wild mountain ranges above. The director was not there that day, but the lady of the house with the utmost kindness did the honours, of the place and showed us the nurseries, the fern houses, and the orchid houses. We saw the careful manner of rearing the cinchona; we saw the tea plants flourishing, and the collection of ferns to a botanist must have been unmixing joy. A grand yellow hibiscus stood out with prominent grace among the infant plants of the nursery, those quaint orchids taking apparently their outfit from a bit of rotten wood, and smiling out in strange, almost grotesque, beauty, not easily be forgotten. The temperature was 60° by the thermometer, and our courteous hostess informed us that there had been two degrees of frost on the grass that morning. The view is beyond my poor powers to describe. Above slept peacefully Blue Mountain Peak, giving an impression of calm repose, though at times he looks sullen enough. Through a great river gorge to the north flows the Green River (arm of Yallahs), and away on the east we see Yallahs flowing through a snail muddy delta into the sea by the Albion Sugar Estate, which he nourishes. Then, again, a gorge to the east, on the far side of which rises the ridge of Newton, culminating in Catherine's Peak, with a most striking feature of two great red rifts in the clayey hill-side, and the smiling Port Royal visible, belying by its appearance the curse of disease that seems now to brood over it.

The director, I understand, is about to leave Cinchona for an important and honourable post at Kew. I, as a newcomer to these tropic scenes, could hardly think of Kew and its District Railway, connecting it with London, as a favourable change from this mountain garden of beauty.

Suddenly there whirls up a mass of cloud and vapour beyond Catherine's Peak, and we see that Wood-leather's Gap must be in its normal state of cloud. In this strange climate we tremble for the dryness of our homeward ride. What if these clouds dissolve, and the Yallahs shows his force? But the alarm proves groundless, and the mists vanish as they came.

The beauty of Jamaica, and the charm of its hill climate, are beyond realisation till experienced. Your readers may care to know that to anyone with an eye for scenery the country is a constant delight, and, living being cheap, the ordinary individual can afford what the negro would call "plenty ponies" to carry him about to enjoy it.

We had to tear ourselves away, and bid adieu with many expressions of gratitude to our kind and courteous hostess, and start for the homeward ride. We returned by like route to that by which we came, save that we passed out from Cinchona by another road leading through St. Helen's Gap—a mere saddle or rib, with sheer descent on either side into a steep gully, and connecting the hill of Cinchona with the main ridge peak. These gaps are naturally the place of passage for the roads, and afford the most striking views of the two valleys which they divide. It is impressive, after toiling up a long ascent to a gap, to find not only the view in rear, which has been gradually developing as the height increases, spread out to its full extent, but a new view opened out in one moment on the farther side. On the return journey, the whole sea to the north was obscured by cloud, so rapid are the changes here. We reached (strange for Jamaica!) the cluster of white huts straggling up the mountain, without a drop of rain, having thoroughly enjoyed our little expedition.

New Castle, I may add, is five miles from the limit which any wheeled vehicle can reach, hence we live much to the saddle, and our health gains in consequence.—DUPPE.—Field.

ANTS (*Formica sanguinea*) are occasionally very troublesome pests, being very determined and incessant in their attacks, generally eating into the flower buds, and thereby rendering them perfectly useless. A little arsenic mixed with moist sugar, and placed in their runs, will soon destroy them.—*Indian Gardener*.

INSECT FLOWERS.

These are attracting more than usual attention in Victoria at the present time, owing to the suggestion made by Mr. C. Watt, of Brunswick, to the Minister of Agriculture, that if planted in the Geelong vineyards the pyrethrum might destroy the phylloxera, with which they were infested. Baron Von Mueller thought that the experiment ought to be tried, but did not prophesy success. The department immediately sent to England for a supply of seed, which was received about the middle of December. It was announced that some of the seed would be raised at the Dookie experimental farm, and that any person wishing to test the plan in vineyards still infested could obtain a supply of seed from the department.

Numerous applications were made in response to this offer. The seed will be distributed also amongst persons who wish to see if the plant can be profitably grown for commercial purposes. It is understood that a very large trade in the pyrethrum seed is done in California, where it is extensively grown for the manufacture of insect powder. The imports of the seed to this colony for the purpose are also large.

For the information of our readers we print some extracts from a paper on the "Comparative value of various species of Pyrethrum," published in the *Canadian Entomologist* for 1879. "The *Pyrethrons* are hardy plants which bloom abundantly the second year from seed. The powder is prepared from the half-opened flowers gathered during dry weather, and dried in the shade, under cover; but the process of gathering, drying, and preparing involves so much time that their culture can only be made profitable where labor is cheap. Single flowers are much more powerful than double flowers." We may further remark that the herb is worthless as an insecticide.

It is not the vapour from the flowers that is poisonous but some non-volatile resinous constituent. It is not sufficient to enclose an insect in a limited space with a number of the flowers. They must be finely powdered, and the powder must be distributed in such a way that some of it enters the mouth or breathing pores of the insect. It then produces a kind of paralysis, the insect showing signs of life for many hours after it has lost the power of movement.—*Chemist and Druggist*.

TEA IN CEYLON: THE KELANI VALLEY: TEA STORES.

Locking forward to the time when I shall have to jog along with a factory of the "Old Saving's" type—wooden flooring, weather-boards, and shingles—or become the owner of a "Crystal Palace" like my neighbour on the left, I am longing for the day when there may be a consensus of opinion as to the merits of each class of store. Situated as I am, I have had opportunities of noticing the work done in stores of the cheaper kind, and it has been quite evident during the last twelve months that the best priced teas from this Valley have been made in them. I have also been able to form an idea of the labor, and expense attending the erection of "Crystal Palace"; and what has struck me is the elaborate and costly means adopted to support what, after all, is merely a roof. I say merely a roof, because the upper storey is not meant to have any heavy weight upon it—it is only intended for the withering of green leaf. Of this, three tons would be a very unusual quantity, whereas our old coffee stores, with stone pillars and wooden posts, often had thousands of bushels of coffee on their upper floors. All a tea factory requires is strong base-floor to support machinery and withstand white-ants (for this concrete and cement are the best materials), plenty of withering space, and protection from rain and sun. Now, to support a building of this sort in a column costing Rs9 to Rs100 each against wood or stone, or stone alone, costing from Rs10 to Rs25 each, are surely unnecessary, and have nothing to recommend them to make up for their very great extra cost. I cannot help regarding the run upon such iron structures as a "rage" with which the planting, like other communities, is often seized.

It may be said that they are easy of erection, coming out from home complete in every detail. Let any man laboring under such a delusion consult a brother planter who has had to put together one of those stores, or has had to transport its material for two or three miles where neither water nor wheel transport is available; I venture to say our enquiring friend will stick to the old-fashioned stone or timber? In many parts of the low-country good timber is very scarce, but enough can generally be got to support the roof of a factory and, where it cannot, then get teak from Colombo; my advice. Let me of the "Old Saving's" type not be led astray by being told that the "best is the cheapest in the end"; or be chaffed into iron by such twaddle as "penny-wise and pound-foolish"; or (if North countrymen) "loved hawkes not wisely, but too well." That tea estates will not last for ever, or all events that their owners will not, may, I think, be taken for a fact, not as we say in this valley, for a *dolka*,—Local "Times."

MANGOES IN INDIA AND CEYLON.

"*Reis and Kayyet*" makes the following observations on the respective merits of the mango as grown in India and Ceylon:—"While the people of the Indian continent, especially in the north, have been complaining of dearth of mangoes this year, nature has been bountiful to the neighbouring islanders of the south. 'There has,' says the *Ceylon Patriot*, 'been a large crop of this fruit; which means that the poorer people will make an extra meal a day.' This in Jaffna, abundance indeed, has had the usual effect of making the Jaffna fastidious. The complaint now is that the fruit is not good enough—not half so good as that in the Western province. The Jaffna mango is said to be somewhat of an acrid taste. Indeed, this is said to be the case with most fruits in that part of the island, which are large but not delicious. 'Our soil,' says the writer, 'perhaps contains too much of saline matter; and our fruit-trees, instead of being left to grow as well as they can, require a lot of cattle-manure. But this is just what is not done. The fact is, the working people do not care for the exquisite delicacy of garden cultivations, but only seek something to satisfy hunger if only the article be not absolutely nauseating.' We suspect, however, these Ceylon eaters to be inefficient *connoisseurs*. We speak from no continental affection or northern assumption of superiority. In regard to fruits and farinacea, we are not disposed to make any assumption. On the subject of the mango in special, we are always prepared to defer to Ceylon. That, in our northern tradition, is the original *habitat* of the mango pilfered by the great Ravana from the orchard of the Olympian Jove, India. We ourselves, sixteen years ago, routed an Indian Prince in durbar assembled, who prated of the perfection of his mangoes and insisted upon, his country being the heaven-ordained home of the fruit, by relating circumstantially the origin of the mango among us, as handed down from father to son from time immemorial, thus, by changing the *venue* from the continent to the island, cutting away the ground under the proud chief's pretension. The tradition, however, is not necessarily conclusive of the fact, and it is still open to the learned to determine the first *habitat* of the mango. To all intents and purposes, India—the main land—is now the mango country. On the hypothesis of its Ceylon origin, there seems to have come a degeneracy over the plant in the island, by the confession of our Jaffna friends, the fruit on the coast nearest to India is a most vicious one. Although preference is given to the outcome of the orchards in the interior, we suppose the best Ceylon fruit will not compare with the mango in Southern India or in Bombay, to say nothing of the perfection attained in Bengal Presidency. The insular taste appears to us to be gross. *Ceylon Patriot* is absolutely in raptures over the coarse sweetness of the pak. Our contemporary writes—"The jack in size will beat out any in the Sinhalese country, but those nice bags of honey, when the fruit is ripe, combining all the

delicacies of the honey-comb, and the essence of the sugarcane, you do not taste in Jaffna." The exquisite delicacy of the *langra*, for instance, or of the Mozufferepore leeches, must be lost upon those who can be pootical over the heavy jak.—*Indian Agriculturist*.

[Until the *Ceylon Patriot* condemned the mangoes grown in the calcareous soil and dry climate of the Jaffna Peninsula they were considered the best in Ceylon. We hold to that belief still where the kinds grown are good and receive attention, for only recently we ate some from the north which quite composed with "Bombay mangoes."—En.

EXPERIMENTS WITH FERTILIZERS AT THE CAWNPORE EXPERIMENTAL FARM.

Are thus recorded in an official report sent to us:—In the series of duplicate plots saltpetre gave the largest yield of all the single manures. The results of applying this fertilizer appear to be always, or nearly always, certain: and for cereals it would appear undoubtedly the best. The increase which it has given, compared with ordinary cowdung during the last four years, is as follows:—

	Increase per cent. over unmanured land.	
	Saltpetre.	Cowdung.
1881-82	83	7
1882-83	101	61
1883-84	22	34
1884-85	84	42

Among the combined manures bone superphosphate yielded fair results when applied in combination with saltpetre. It is doubtful, however, whether this manure can ever at present prices come into ordinary use by the Indian cultivator. In the *18th Series* the results of the present season confirm those of previous years, *viz.*, that for a cereal crop a soluble nitro-nitrogenous manure is essential. This fact is now completely established. The series will therefore be dropped. *Application of excrement of different kinds.*—The series appears for the first time. *Poudrette* heads the list. Sheep-dung comes last. *Green Soiling.*—Indigo ploughed in green yielded a net increase of ₹27.8 per acre, against ₹19 obtained last year. This difference in favour of the present season is chiefly due to the heavy late rains, which thoroughly rotted the green plants and allowed of rapid and easy assimilation of the fertilizing ingredients. Usar soil* in the vicinity of Cawnpore was treated *in situ* with calcic sulphate in the rains of 1884. Barley, gram, and peas were sown, but the land evidently had not time to be pulverized, and the plants, after coming up a few inches above the ground, withered and died. Samples of soil from the usar plain where these experiments were tried have been analyzed, at my request, by Dr. Romains, Chemical Examiner British Burma. He is of opinion that the fault lies more in the mechanical texture than in the chemical nature of the soil. The report which Dr. Romains very kindly prepared is appended.

We add further extracts: *Deep Ploughing.*—Taking the average of all the experiments, deep ploughing gave an increase over the ordinary shallow country ploughing of 43.5 per cent when the land was ploughed 9 inches deep and 43.5 per cent when ploughed 5 inches deep, although the number of shallow ploughings was twice as many as of the deep ploughing. In order to give practical proof of the wisdom of deep ploughing, ploughmen from this experimental station, under the charge of apprentices, have been sent out to five selected districts with the new (duplex) plough, and are now touring about in those districts, ploughing for cultivators wherever they get a chance. It is no use exhibiting a new plough when ploughing operations are ever. The important matter is to catch the people while ploughing is going on and drive the new plough in the fields side by side with common country implement. The work done thus in ordinary course naturally draws the attention of the

* Soil rendered in fertile by a saline in fluorescence, often the result of irrigator.—En.

cultivator. If we are ever to get deep ploughing into the heads of the people, this, it seems to me, is the only way. The district officers of the five selected districts and some of the selected zamindars and talukdars have cordially co-operated. The reports of progress received up to date are encouraging.

The addition of gram as well as peas to wheat and barley crops seems to result in a large aggregate yield. This explains why the Indian farmer is so fond of mixtures.

RESOURCES OF UPPER BURMA*

Note by Dr. Romains, Chemical Examiner, on his return from the Upper Burma expedition.—AGRICULTURE.—There is little cultivation from Thayetmyo to Nyaungu, near Pagan, except near Sibuygyum at the mouth of the Salen river; and the country is dry and barren. From Pagan to Ava the west bank, including the delta and valley of the Chandwin, is fertile. Myingyan, which may be considered the commercial capital of Upper Burma, is the centre of this district. The staples are maize, millet, sesamum, pulse, and cotton, the latter exported to China. The east bank round about Mandalay ad towards the south-east along the valley—the Myitjue—is a rice-growing district, about 30 miles in length by 15 in breadth. Between Myadaung and Bamaw, both on the Irrawady and north of Mandalay, is a sparsely inhabited district which seems fertile, but is reported to be very unhealthy.

MINERALS.—Coal occurs at three localities on the west bank near Thingadaw and at Kabang nearly opposite on the East bank, and is reported to be found near Sagaing opposite Ava. Good coal is reported to occur at Kale on the Chinwin far to the north-west. The Thiogadaw coal was worked by the Burmese for some time.

PETROLEUM.—The best known locality is Yenangyaung about 70 miles south of Pagan on the Irrawady. The oil here is very viscid, flowing slowly into the wells. It contains much paraffin. At Pagan on the west bank of the river, and a short distance from it, there was a well flowing some time ago rather more limpid, also containing paraffin. There is said to be petroleum in the Yaw country west of the Tangyi hills opposite Pagan; it is described as flowing from springs at the surface of the ground. It is said to be more limpid than the Yenangyaung oil, resembling the Boronga oil. It is only used locally as there are no roads in that district. The yield from Yenangyaung is estimated at 600,000 viss, or 1,000 tons per mensem. There are two groups of wells there, about three miles from the river, with about 200 wells producing oil, many others exhausted. The oil occurs in little basins like the Baku oil and unlike the American, which seems to form subterranean lakes.

IRON.—Iron was once worked at Pupadaw, 30 miles from Pagan. The manufacture is now discontinued.

SILVER.—Silver and lead are brought from the Shan States lying to the east of Upper Burma. The great silver mine at Bawdingyi is now flooded and not worked.

GOLD.—Gold is said to occur at Bamaw, but, it is believed it comes really from Yuan lying to the further north of Shan States.

PLATINUM.—Platinum is said to occur in the sand of the chinwin near Kanni. A large quantity of what was supposed to be platinum ore has lately been collected and sent to England from this locality. I

* From Rangoon, the capital town of Lower Burma, to Mandalay the seat of Government of the late king of Upper Burma, the river Irrawady stretches almost due north. Thayetmyo lies at a distance of nearly 200 miles; north of Thayetmyo is the town of Pagan. Ava lies to the north-east of the latter place at a distance of nearly 100 miles in direct line. Half way between Ava and Pagan is the town of Myingyan, the commercial capital of Upper Burma. From Ava to Mandalay the distance is about 20 miles. All these towns are situated on the east bank of the Irrawady,

hope to have an opportunity of examining this district in the hot weather holidays.

RUBIES.—The Burmese are very proud of their ruby mines: "Lord of the Ruby Mines" is one of the official titles of the King of Ava. The rubies, or more probably spinels, are found in the crystalline limestone of Sagaing, 16 miles north of Mandalay, and at Mogaung and Kryptin near the Shwen mountain. They were described as occurring in three ways: 1st, in quartz rock? (limestone); 2nd, in the soil on the mountain side; 3rd and chiefly, in a bed of gravel below the surface called hma-sa. This gravel is full of water and the rubies are obtained by sinking a well till this stratum is reached. Then a man descends and going beneath the water fills a bucket and sends it up. At the surface the rubies are separated by washing from clay and sand. The large ones are carefully picked out and the remainder crushed to powder and used for polishing. It is composed mainly of octahedral crystals of spioel. It is extremely improbable that alumina should crystallize in quartz. What they call quartz is probably crystalline limestone as at Madaya, or some other metamorphic rock. The present holder of the mines had contracted to pay 2½ lakhs of rupees to the King, but he is unable to do it.*

JADE.—This stone is much valued by the Chinese. They obtain it in the river-bed at Mogaung in water-worn boulders. These find their way to China *via* Rangoon, the waterway down the Irrawaddy being easier than the caravan route over the mountains between Bamaw and China.

MARBLE.—Marble is quarried at Sagyin, 16 miles north of Mandalay.

GEOLOGY.—The general geological structure of the country is very simple, the principal formations run north and south in great mountain ranges. The tertiary formations of Pegu extend to Kyontalang in the great bend of the river below Ava. The metamorphic rocks of the Martaban hills are continued in the Shau hills east of Mandalay. The limestone of the Salween in the second defile in Kachin hills east of Bamaw represent the Dawana range east of Moulmein. The country west of Irrawady is almost unknown. As far as Pagan it is obviously the same formation as the east bank. Then we have alluvial plains between the Chindwin and Irrawaddy. The Irrawaddy valley between Sagaing and Male at the head of the defile has been described by the late Dr. Oldham. The hills to the westward are alternately metamorphic and tertiary rocks. The same condition exists along the west bank as far as Thigyaing, where the river turns to the eastward.

The country generally has a great resemblance to the North-West Provinces and bears the same relation to Pegu which they do to Bengal.—*Indian Agricultural Gazette.*

COCOA AND COCA.—A lengthy article in the current number of the *Medical Press and Circular*, by an Lecturer on Anatomy and Forensic Medicine, on "Cocoo and Cocaine," certainly deserves a place in any future series of "The Curiosities of Literature." It in references to cocoo, chocolate, and *Erythroxylon Cocoo* leaves are inextricably interwoven. As instances of the confusion in the writer's mind may be quoted three statements occurring within twenty lines: (1) that to Mr. Dunn we are indebted for popularizing the use of cocoo in this country; (2) that it is calculated that 10,000,000 of human beings indulge in cocoo chewing, and (3) that cocoo contains two alkaloids, theobromine and cocaine. After this we are not surprised at being told that in the preparation of cocaine, after the removal of that alkaloid, "hygrin" remains in the mother-liquor.—*Pharmaceutical Journal.*

WILLOW.—A correspondent of the *American Druggist* describes a visit to a "willow farm" in Georgia where 400,000 willows are growing and 800,000 slips have been recently set. The willow switches are allowed to grow for years, during which they attain a length of from four to seven feet. They are then cut and after

being steeped in water the bark is stripped off by machinery and the withes are wiped and done up in bundles. The bark and the leaves are dried and baled, and command a price of twenty-five cents a pound for medicinal purposes.—*Pharmaceutical Journal.*

DISSOLVED BONES.

By DR. A. P. AITKEN.

Chemist to the Highland and Agricultural Society.

Bones coarsely crushed had not long been in use as a manure; before it was found that their efficacy was greatly enhanced by dissolving them to some extent in sulphuric acid. That was a very important discovery, which not only marked an epoch in agriculture, but gave rise to a new industry, which has now assumed large proportions, and indirectly had a beneficial influence on the whole manufacturing trade of the country. Its immediate effect as regards the use of bones was to transform them from a slow into a quick-acting manure, capable of being applied with advantage to crops whose period of growth was of short duration. It enabled farmers very considerably to reduce their expenditure in the purchase of bones, for it was found that one bushel of bones when dissolved with acid produced a far more immediate and powerful effect upon the crop than two or three bushels of crushed bones; and as the price of bones rapidly rose in proportion as their use became more general, this discovery was a great boon to agriculture. Farmers bought sulphuric acid and dissolved the bones themselves, but as this was a troublesome operation, and not unattended with danger, a class of men arose who made it their business to dissolve bones and supply farmers with the finished article. This was the beginning of the manure manufacture, and it was not long before it was found that eoprolites and all other phosphates were capable of being dissolved in a similar manner so that superphosphates and other dissolved manures came rapidly into existence. The great promoter of this new industry was Sir John Bennett Lawes, who not only led the way in the manufacture of manures, but also studied their effects upon his experimental farm at Rothamsted, and instructed farmers regarding their properties and the method of their application. This new industry gave a great impulse to the manufacture of sulphuric acid, and as that is a substance which forms the chief basis of our chemical manufactures, the effect of this discovery influenced the manufactures of the country in their most remote ramifications.

We have seen that bones contain about half their weight of phosphate of lime—the other half consists chiefly of organic matter. The phosphate of lime in bones is what is called insoluble phosphate, that is to say, a combination of phosphoric acid with as much lime as it can unite with. But one-third or two-thirds of the lime can be taken away and still leave definite compounds. When two-thirds of the lime have been taken away, the compound formed is soluble in water, and is called soluble phosphate of lime. The object of adding sulphuric acid to bone phosphate is to remove two-thirds of the lime by converting it into sulphate of lime, just as in the case of superphosphate, which is a mixture of soluble phosphate of lime and sulphate of lime. But in dissolving bones it is found that if enough of acid is added to convert all the phosphates into the soluble form, the whole is converted into a liquid mass, which refuses to dry up, and is unfit for use as a manure. This is owing to the organic matter in the bones. There is therefore a practical limit set to the proportion of soluble phosphate which dissolved bones can contain. It varies a little, according to the amount of organic matter and moisture contained in the bones, but as a rule, in the case of pure dissolved bones, not much more than half the phosphate is present in the soluble form. The usual practice of manufacturers of pure dissolved bones is to add more acid than is necessary, and to dry up the product with fine bone meal, and by careful mixing and somewhat laborious treatment produce a soluble manure.

* The neighbourhood of our spinel-bearing limestones, especially beds of streams ought to be searched for spinel supplies and rubies.—Ed.

Other things besides fine bone meal are frequently used as a drier. Steamed bone flour dries more effectively than bone meal, but if it is used to any great extent the product will be somewhat high in phosphate and somewhat low in ammonia. Bone ash is found to be a still more absorbent substance, and it is much used to dry up dissolved bones; but bone ash contains no nitrogenous matter, and is very rich in phosphate, and therefore when it is used the product is high in phosphate and correspondingly low in ammonia, and, moreover, it is no longer pure dissolved bones, though that name is always given to it. Bone ash is not bones; it is simply impure phosphate of lime derived from bones, and is no better, except as a drier, than any other finely-ground phosphate. The same may be said of bone char, which is frequently used as a drier, and which gives the black colour to many manures sold as pure dissolved bones. If manufacturers think that in using these forms of bone phosphate they are making pure dissolved bones, they are simply deceiving themselves. Any other phosphate would be about as near the mark, and some manufacturers, knowing that, do not hesitate to employ any convenient phosphate as a drier, and find it makes very good "dissolved bones." Some of the ground phosphate is dissolved in the process, of course, and the product is practically a mixture of dissolved bones and superphosphate. Having gone so far, the next step is to quite ease—the proportion of superphosphate may be much increased, and it does not need to be bone-ash superphosphate, as that is no better than any other kind, so that by-and-by a manure may be sold as dissolved bones which consists largely of superphosphate, and there are to be found samples of dissolved bones, which are just superphosphate, in which some bone meal has been used as a drier, or probably as a blind, to give the stuff an appearance of dissolved bones. In such cases there will be a very great deficiency of ammonia, but having gone so far, there need be no difficulty in supplying that by means of some highly nitrogenous substance, such as flesh meal, which after all is not very far removed from the nitrogenous matter of bone; and if that is not to be had, there is always horn dust, ground leather, shoddy, or some similar material to fall back upon to make up the analysis of dissolved bones.

The result of all this is that by a process of *facile decensu*, there is scarcely to be found a manure sold under the name of dissolved bones which is a genuine article. A great proportion of them contain no bone material at all so that the term 'dissolved bones' has become in these days what is correctly described in the instructions of the Chemical Department (Highland and Agricultural Society's *Transactions*, appendix B) as a conventional name applied to compound manures, consisting of any kind of mixture of phosphatic and nitrogenous materials, which can be dissolved with (or without) an admixture of bone, so as to produce a manure containing from 15 to 20 per cent soluble phosphates, and from 1 to 3 per cent of ammonia.

Many of these manures are excellent preparation—just as good as pure dissolved bones, perhaps better—and they have the merit of being formed from material, which would otherwise be allowed to go to wastes. There is no reason why agriculture should not get the benefit of them, and the more of such waste materials that can be turned to good account the better; but it is now time that the abuse of selling them under the name of dissolved bones should be abandoned. Manure manufacturers make no secret of the spurious character of the manures called dissolved bones, and it has become quite recognised in the trade that purity is not expected in them, and that it is impossible to adulterate them; but although the trade know that, and most intelligent buyers know it, and are accustomed to buy these manures at prices at which genuine bone manures could not be made, yet there can be no doubt that the great majority of buyers are deceived by the name; and as there is a prejudice in favour of dissolved bones rather than any dissolved compounds, a higher price is paid for them on the understanding that they are what they pretend to be. This is like getting money under false pretences, and is a reproach which the manure trade should get rid of as soon as possible.

If genuine dissolved bones are desired they should be bought under a guarantee of purity. Pure dissolved bones cannot contain much more than 20 per cent soluble phosphate and from 2½ to 3 per cent of ammonia. When well made, it is, of course, a good manure, but not a whit better than many of its imitations.

The dissolving of bones in sulphuric acid is a wasteful process not to be recommended, for by so doing the bones are degraded to the level of mineral phosphates, which supply soluble phosphate more cheaply and more efficiently than bones. If soluble is wanted for a crop, then the cheapest form of superphosphate is the best thing to apply. If bones are wanted for the crop or the land, then the natural bone, finely ground, is the cheapest form of application. If both are wanted, both should be applied separately, but to attempt to combine these advantages by dissolving bones is to effect a compromise that is not economical—it is to spoil good bones, and make poor superphosphate.—*North British Agriculturist*.

KEW AND ITS WORK.

THE RECENT HISTORY OF A TROPICAL COLONY.—Take a tropical colony like Ceylon, and study how all the conditions of life there are revolutionised by the entrance of the irrepressible Anglo-Saxon:—In 1837, when Coffee planting was started, Ceylon was a mere military dependency, with an annual revenue amounting to £372,000, or less than the expenditure, costing the mother country a good round sum every year, the total population not exceeding 1,500,000, but requiring nearly 6,000 British and native troops to keep the peace. Now we have the population increased to 2,750,000 with only 1,200 troops, all paid for out of an annual revenue which exceeded £1,300,000; a people far better fed, educated, and cared for in every way. The total export and import trade since planting began has expanded from £500,000 to £8,000,000 or £10,000,000, according to the harvest. During the forty-five years referred to some £30,000,000 or £40,000,000 have been paid away in wages earned in connection with the plantations to Kandyan axemen, Tamil coolies, Sinhalese carpenters and domestic servants. More than 200,000 Tamil coolies were saved from starvation in Ceylon in the Madras famine of 1877-8. According to official papers there are more than 16,000,000 of people in Southern India whose annual earnings, taking grain and Rice at its full value, do not average per family of five more than £3 12s. a year, or about ½d. a head per day. In Ceylon each family can earn from 9s. to 12s. a week, and save half or three-quarters of that amount. Our calculation is, that from each acre of Coffee or Tea land kept in full cultivation five natives (men, women and children) derive their means of subsistence. It is no wonder that, with a population nearly doubled during the planting era four or five times the quantity of cotton-cloth is consumed, and ten times the former quantity of food is imported into the island.*

HOW A BOTANIC GARDEN CAN HELP THE COLONIES.—It is in selecting the plants for new colonies or old ones that have been ruined by neglect, or in helping to bring into cultivation plants valuable economically that run the risk of being exterminated in their native localities, that the help and advice of a botanic garden is required, particularly for the correct identification of the best species. Take, for instance, Cinchona, India-rubber, and Gutta-percha.

CINCHONA.—In temperate climates quinine is one of the most useful of drugs, and in tropical climates it is now used universally in curing and warding off fever. Quinine and its allied alkaloids are the product of the bark of trees of the genus *Cinchona*, which is restricted in a wild state to a narrow belt of the Andes of South America, at an elevation of between 2,000 and 8,000 feet above the sea-level, principally along their eastern declivities, from latitude 10° S in Bolivia to latitude 10° N. in Venezuela. Here, of

* Ceylon, by W. Ferguson, F. L. S. Pp. 83-84. [No. by J. Ferguson, co-Editor of *Tropical Agriculturist*.]

course, they are very difficult of access, and they are getting destroyed rapidly. *C. succirubra*, for instance, which was found formerly in all the valleys that open to the plain of Guyaquil, is now almost confined to the western slopes of Mount Chimborazo. In 1860 an expedition was sent out under Mr. Clements Markham to the Andes to procure living plants with seeds, for conveyance to India, and after many adventures and disappointments its efforts were crowned with success. There are in the genus about thirty-six species, differing from one another in their climatic constitution, and still more in economic value, but they are very difficult of botanical discrimination, because the primary types are linked to one another by puzzling intermediate forms. The Dutch sent out an expedition to the Andes under Hasskarl in 1854, but unfortunately a large proportion of the plants which they obtained proved to belong to *C. Pahudiana*, a species of very small medicinal value. In the Indian plantations four distinct species have been planted extensively—1. *C. succirubra*, which yields the red bark of commerce, yielding about 5 per cent of alkaloids, quinine and cinchonine in almost equal proportions. It thrives at a lower elevation than the three others, but is specially sensitive to frost and long-continued drought. 2. *C. micrantha*, which yields the grey or silver bark, also poor in quinine, but rich in cinchonine. 3. *C. Calisaya*, and its variety *Ledgeriana*, which yields the royal, called also the yellow or *Calisaya* bark—the richest of all in alkaloids, of which quinine forms half or three-quarters (not less than two, and, in exceptional cases, as much as ten per cent of quinine). 4. *C. officinalis*, which yields the pale or *Loxa* or crown bark, containing half or 1 per cent of alkaloids, of which more than half is quinine.

In India the product of the bark is used mainly in the form of a mixed febrifuge, in which the different alkaloids are not separated from each other. This is prepared from the finely powdered bark by mixing it with milk of lime and spirits of wine. At the close of 1882 there were in the Bengal plantations a stock of nearly 5,000,000 trees, of which three-quarters were *C. succirubra*, yielding an annual crop of 400,000 lb. of dry bark. The amount of capital altogether expended in Bengal in the plantations and manufactory was £100,000, and on this the receipts for 1878-9 yielded 41 per cent on the capital outlay, exclusive of 5,500 lb. of the alkaloid taken for the Government hospitals, replacing an equal amount of quinine, which if purchased would have cost the Government £44,000. Dr. King estimates that by the end of 1878-9 the total amount saved to Government was £80,000; and Mr. Wood, the Government quinologist, estimates that the cost of the mixed febrifuge will ultimately be brought down to 1s. per ounce. The price of the sulphate of quinine in England has been reduced during the last few years from 13s. to 5s. per ounce. As before explained only four out of the thirty-six species have been extensively planted in India, and of the economic value of many of the others very little is known clearly.

INDIARUBBER.—The substance sold under the name of indiarubber is the stiffened milky juice of at least six different genera of trees, belonging to three widely different natural orders—*Landolphia* and *Willughbeia* in Apocynaceæ, *Castilleja* and *Ficus* in Artocarpaceæ, and *Hevea* and *Manihot* in Euphorbiaceæ. Part of it comes from South America (shipped principally from Para and Carthagena), part of it from Sierra Leone, Mozambique, and Madagascar, and the remainder from tropical Asia. Besides these two genera of Apocynaceæ there are at least six others which yield a similar milky juice not at present utilized to any considerable extent. In the United States in 1883 there were 120 indiarubber factories, employing 15,000 hands. The total importation of raw material into the States in that year was 30,000 tons, worth about £5,000,000 sterling. The value of the manufactured goods made in a single year is estimated at £30,000,000. The quantity of unwashed rubber imported into the

United Kingdom in 1883 was more than 10,000 tons, worth about £3,500,000, but in 1885 it had sunk to less than £2,000,000. None of the trees which yield indiarubber have yet been brought into cultivation on a large scale, and the time will soon come when either this will have to be done or the supply will gradually lessen. There are about sixty distinct species of these rubber-yielding genera, and the botanists and foresters will have to settle between them which of these are best worth cultivating and where it will pay to grow them. Unfortunately, at the present time the price of indiarubber of all kinds is exceptionally low, the best Para rubber being now only worth about 2s. 6d. per pound in London against 4s. in 1884, and the best of the African and Asiatic kinds about 2s. per pound.

List of the Indiarubber-producing Genera, their Native Countries, with the Number of Species in each and Annual import:—

Order.	Genus.	Number of species.	Native country.	Tons imported into England in 1880.
Apocynaceæ.	Willughbeia	9	Tropical Asia	530
"	Landolphia	16	Africa and Madagascar	2200
"	Hancornia	1	Brazil	
"	Urceola	7	Malay Peninsula and Archipelago	
"	Dyera	3	Malaya Peninsula	
"	Couma	4	Guiana and Brazil	
"	Alstonia	3	Malay and Fiji	
"	Cameraria	2	West Indies	
Artocarpaceæ.	Castilleja	3	Central America and Cuba	100
"	Ficus	2	Africa and Tropical Asia	370
Euphorbiaceæ.	Hevea	9	Amazon region	5768
"	Manihot	1	Brazil	35

GUTTA-PERCHA.—Gutta-percha of the best quality is the product of *Dichopsis* Gutta, a tree belonging to the natural order Sapotaceæ, inhabiting the Malayan peninsula. In order to obtain it the Malays follow the wasteful plan of cutting down the tree. The bark is first stripped off, and the milky juice which then exudes is collected in the shell of a Coconut, or the spathe of a Palm. The juice quickly stiffens on exposure to the air and forms gutta-percha. The average quantity obtained from one tree is 20 lb. In 1875, 10,000,000 lb. in weight were imported into this country from Singapore, and this would involve the destruction of, perhaps, 50,000 trees. It was first brought into notice in 1842, and at that time the tree was plentiful in the forest of the island of Singapore; but during the next five or six years it was totally destroyed in the island except a few trees that were kept as curiosities. In 1847 it was plentiful in the forests of Peiangu, but a similar fate soon befell it there, and now the time has come when, unless it be systematically cultivated somewhere, the supply will decrease. According to the latest authority there are six distinct species of *Dichopsis* growing wild in the Malayan peninsula, and in Java and Sumatra, and several species of the neighbouring genera, *Chrysophyllum*, *Sideroxylon*, *Bassia*, *Mimusops*, *Payaena*, and *Imbricaria*, yield a similar milky juice; but it still remains to be settled which species are best worth cultivating, and where they can be most profitably grown. The annual value of the gutta-percha imported into England is between £300,000 and £500,000 per annum. *J. G. Baker.—Gardener's Chronicle.*

A CORRECT ESTIMATE OF CHINESE AGRICULTURE.

The skill of the Chinese in agriculture has very commonly been asserted in this country to be greatly superior to that of the natives of Hindustan. In justice to the latter, we now direct the attention of our readers to the following extract from *The River of Golden Sand*, by Captain Gille, R. E., page 76:—

Notwithstanding the industry of the Chinese and their admirable system of irrigation and terrace cultivation, there can be very little doubt that the exceedingly high estimate in which their agriculture is held, is very far from being deceived. This appears to have been derived from the French missionaries, for as early as 1804, Barrow speaks of the way in which it had been over-rated. Nearly all moderns who have been in China make the same observation, and yet there remains amongst Europeans out of China, the conviction that the Chinese possess secrets unknown to, or unguessed at, by Europeans. The real point in which the Chinese excel is in industry. It is industry that leads them to take such care never to waste the smallest trifle; and it is industry that makes it worth their while to gather up the last fragments. Industry again enables them to dispense with any other manure than the sewage of the towns. For a peasant will walk into the town, fetch his manure, and take it to his field himself. It is by industry that in the large plains, the Chinese are enabled to keep their rice fields properly watered; for it is not possible to conduct the water by canals to every part and every level of a wide plain; it must therefore be lifted artificially, and all day long coolies are to be seen in the extensive plains, raising water by the means of little tread-mills. But beyond this industry, the Chinese can hardly lay claim to any superiority over other nations. They plough about as well as the natives of India, doing little more than scratch the ground. It is true that they can raise two crops on the same field, as, for instance, when they plant opium under rape, or yams beneath millet. But this is a system not altogether unknown to European farmers, and in the East Indies it is customary to grow yams underneath the sugar-cane. Some of Barrow's remarks appear to be worth quoting:—"They have no knowledge of the modes of improvement practised in the various breeds of cattle; no instruments, for breaking up and preparing waste lands; no system for draining and reclaiming swamps and morasses. . . .

Leveling the sides of mountains into a succession of terraces, is a mode of cultivation frequently taken notice of by the missionaries, as unexampled in Europe and peculiar to the Chinese, whereas it is common in many parts of Europe, and in the hill tracts of India. . . . Of the modes practised in Europe of improving the quality of fruit, they seem to have no just notion. . . . Apples, pears, plums, peaches, and apricots are of indifferent quality. . . . They have no method of forcing vegetables by artificial heat, or by excluding the cold air and admitting at the same time the rays of the sun through glass. Their chief merit consists in preparing the soil, working it incessantly, and keeping it free from weeds." Thus wrote Barrow, three quarters-of-a-century ago. The Chinese are no further advanced than they were in his time; and it is hardly necessary to add anything to his remarks, except to observe that not only have the Chinese "no just notion" of improving the quality of fruit, but that to this day, they remain in complete ignorance of the science of grafting.—*Indian Agriculturist*.

ASBESTOS.—When on a visit to Rockhamton recently, we were shown some splendid specimens of asbestos, and we were informed that if there was any demand for the article, it could be unearthed in almost untold quantities. Our Yankee cousins are setting us an example in this matter which we would do well to follow. They are making hats with an asbestos-lining to the crown, on the well-known fact that asbestos is a non-conductor of heat.—*Planter and Farmer*.

MANILLA HEMP.—The plant so well known as the Abaca (*Musa textilis*), from the stem of which Manilla Hemp is prepared, is described as doing remarkably well at Sandakan, in Borneo. The smallness of the population, the well-to-do character of the people, as well as their disinclination to hard work, is said to prevent anything like an industry in the preparation of the fibre being established similar to that in the Philippines. Should a machine, he discovered adapted to its production, at however small a profit, there is no limit to the quantity that can be produced.—*Gardeners' Chronicle*.

FROGS.—Some short time since a French gentleman waited on us and stated his intention of starting the cultivation of frogs for this market. This business appears to answer in America. We learn that during the summer months from 1,000 lb. to 2,000 lb. of frog's meat are eaten daily in New York. They are shipped fresh to that market from Canada, principally in large half-barrels. The love for frog meat is on the increase. Epicures and men of extreme wealth give exorbitant prices for them. The large green frog is the chief kind sold. In Chicago they are called water chickens, because their flesh is as white as that of a chicken when dressed properly. We have the great advantage over Canada for this branch of stock raising that our waters do not freeze. In a drought it might be necessary to dry the frogs to the next lagoon.—*Planter and Farmer*.

CHARCOAL.—It really would appear as if the common and despised charcoal were far more valuable than any of us think. We all know its value as a manure for fruit trees—at least if we do not weigh too. Some of us have the secret of growing the most beautiful flowers, as all may by a liberal application. Six months since we had a correspondent who thought he could fatten pigs on charcoal, and many are in the habit of giving it regularly to their pigs and poultry; while here and there a housewife keeps a few lumps in her dairy, and places pieces on the butcher's meat to keep away danger of taint. It is excellent in all these cases, and now the *American Cultivator* tells us of an experiment of fattening turkeys with its assistance. It appears that four turkeys were confined in a pen and fed on meal, boiled potatoes, and oats. Four others of the same breed were also at the same time confined in another pen, and fed daily on the same articles, but with a pint of very finely pulverised charcoal mixed with their food, mixed meal and boiled potatoes. They had also a plentiful supply of broken charcoal in their pen. The eight were killed on the same day; and there was a difference of a pound and a half each in favour of the fowls which had been supplied with charcoal, they being much the fattest, and the meat greatly superior in point of tenderness and flavour. As charcoal can be so readily obtained it is well worth while giving it a trial in the above way.—*Planter and Farmer*.

TRAMWAYS.—Are fast becoming a necessity on our plantations, more especially since the labour difficulty has confronted the proprietors, as it is found that by means of trams and cars plantation work can be done much more satisfactorily and economically than with horses and carts. An advertisement in another column states that the demand for the Decauville Portable Tramways has become regular, and that they are always kept in stock in Sydney for prompt transshipment where necessary. In our excursions from time to time among the plantations we have heard willing testimony as to the thorough efficiency of this particular description of tram appliances, for in the estimation of experienced men they are truly "ahead of all competition," and are winning for themselves a good name wherever tried. So far they have been mostly limited to plantations, but anywhere that large industries are conducted, and heavy portage is an item, they can be turned to good account, as for instance in vineyards, arrowroot plantations, olive yards, manufactories, brickyards, mines, quarries, forests, or earthworks. The cost of good labour-saving appliances is a mere trifle when compared with their efficiency and reliability, and a true economist will not lose sight of this.—*Planter and Farmer*. [We should think those tramways might be useful on at least the low country tea plantations in Ceylon.—Ed.]

OUR American cousins are still exercising their genius in the way of creating butter and cheese. An importation of the latter article from New York State was recently analyzed in London and found to contain no product of the dairy whatever. Its principal components were lard and colouring matter. These cheeses ought to make good cart grease.—*Planter and Farmer.*

IMMENSE AMOUNT OF WATER GIVEN TO THE ATMOSPHERE BY TREES.—The amount of moisture given out by trees is immense. In some trees the upward rush of moisture from the roots is very powerful. The workmen in ship-yards frequently find in the centre of teak log a core of sawd 50 or 60 feet long, an inch in diameter, and hardened to a marble-like consistency, which has been carried and deposited there by the sap in its upward course. A few years ago a number of scientists of New England made a calculation as to the amount of water given to the atmosphere by the "Washington Elm," Cambridge, Mass. They calculated that the leaves of that tree would cover over 200,000 square feet of surface, and that they gave out every fair day during the growing season 15,500 lb or 7½ tons of moisture.—*L. B. PEASELEE.—Indian Gardener.*

It is not at all reassuring to Queensland vineyardists to find it stated as a matter of fact that that terrible scourge of the vine, the phylloxera vastatrix, has really reached so near as the Camden district in New South Wales. A very striking fact this, and one that suggests a mode of defending ourselves from this terrible scourge. It was at Camden that the first Australian vineyard was planted, and we learn that close planting has always been the fashion there. This leads great weight to the opinion that the phylloxera always appears first in old and thickly planted vineyards. It is said by the best authorities that the system of planting *en chaine*, on which we gave one article last issue and another in this, presents an almost complete defence against the ravages of this insect, which increases most in those vineyards where in consequence of close planting the roots of the vines form a network underground and are more or less interlocked. If we really would escape the phylloxera then let us plant on this system in rows twenty yards apart, or even more for the Isabella, and with a space of six feet between the plants in the row.—*Planter and Farmer.*

VALUABLE ECONOMIC PLANTS.—Among the collection of valuable economic plants furnished from the Public Gardens, we may especially mention the grafted East Indian mango; the Manila hemp, plants which belong to the banana, but produce seed and not edible fruit; the silk grass; Ramie, two varieties, green and white; the Kola nut; bay rum tree; vanilla with pods; jujube tree; tea tree; Sicily lemon; cassia, cinnamon, nutmeg, clove, liquorice, &c., so celebrated for its anæsthetic properties, and which was introduced about four years since; the citron, cocoa, Liberian coffee, Brazil nut, carlamom, olive, ginep, sweet oranges, Tang-rine orange, sweet lemon, cashew, shaddock, &c. Thousands of valuable plants like those on exhibition are obtainable from the public gardens, and Mr. Morris wisely avails himself of these shows to place before the public in an attractive and interesting form these and other plants, and thereby impart general information. It stands to reason that Mr. Morris cannot meet the people at the public gardens, and therefore he moved the gardens in miniature to Winchester Park to meet the people and, while giving them every information, show what the Government is doing. In the fern and orchid tent two large tables are filled with specimens from the Gardens, which, while not competing for prizes, add materially to the attraction and bring out the specimens sent by private exhibitors.—*Gleaner.*

BERMSESE PALM PRODUCTS.—A farinaceous substance, resembling sago, is obtained from the pith of several palms. Such are the talipot or *pape* (*Corypha umbellifera*), another species (*C. Gebanga*), the *milho* (*Caryota veans*), the *tanung* (*Arecia saccharifera*), and the *midang* (*Lycea rumphii*). The coco-nut or *ong* (*Cocos nucifera*) is cultivated on all parts of the seaboard. The leaves of the talipot or *pape* are used as fans, and for writing on, in the latter case being pegged or sewn together, gilded sometimes in patterns

on a vermilion ground, and rubbed with petroleum to keep away insects and damp. The leaves of the *milho* afford fibre, and the stem of the *midang* exudes a resin used in sores. The juice of the *tan* affords toddy, and, therefore, by boiling down, sugar; and the trunk is applied to many uses. The leaves of the *tanung* yield fibre, the hollowed stem serves for pipes, and the juice drawn at flowering-time gives toddy and sugar. These two last-named products are also derived from the juice of the *theaboug* (*Phœnix paludosa*). The *dani* or water palm (*Nipa fruticans*) fulfils many duties; its roots bind the soil of the river banks; the leaf is universally employed in thatching; the juice is converted into toddy, sugar, and vinegar; the fruit is eaten when ripe; the flowers are made into a preserve, and the branches are used as fuel. The prevalent habit of betel-chewing renders the areca nut palm (*Læca catechu*) one of the most important of this very useful family.—*Journal of the Society of Arts.*

CONVERSION OF WEEDS INTO MANURE.—A correspondent of the *Indian Agriculturist*, writes as follows on this subject.—Spread thinly a layer of gas lime over the ground, as a "top dressing." If gas lime fresh from the purifiers be applied to soil, the salts which it contains will destroy vegetation. It is, therefore, necessary to expose it to the atmosphere in order to transform the injurious sulphur compounds into fertilizing agents. The sulphur and ammonia which render fresh gas lime fertilizing agents, and become destructive to vegetation, are the ingredients so valuable in decomposing compost heaps; it therefore follows that the fresher the gas lime can be applied to compost heaps, the sooner the results required will be obtained, as the salts which *go off* with exposure to the air, have a powerful effect in decomposing the vegetable substances in compost heaps. Such composts when applied as manure, after three or four months, contain sufficient salts and tarry essences to make the substance uncongential to insect life, so that by the application of such manures a double object is obtained.—1st, the fertilization of the soil, thereby rendering it more sharp, porous, and friable, and 2nd, the destruction of insect life. It must be remembered that the apparent crystallization of gas lime is due to its exposure to the atmosphere. It will thus be seen that it is unwise to look upon weeds as of no value, as they can easily be converted into manure, in a most inexpensive manner, and made to become, practically, insecticides as well as fertilizers.—*Indian Tea Gazette.*

THE KINGSTON (JAMAICA) FLORAL AND HORTICULTURAL SHOW, which closed on Thursday evening, was a pronounced success from every point of view, and the fact that about fifteen hundred visitors were on the grounds the first afternoon, and nearly a thousand on the second day, shows conclusively that the residents of Kingston and vicinity are ready to support warmly, both by their presence and contributions, any effort having for its object the welfare and refinement of the people. This result is in a great measure due to the indifragible exertions of D. Morris, Esq., the Superintendent of the Public Gardens and Plantations, and the readiness with which he has afforded information and advice to those who have evinced an interest in the cultivation of plants. Nor have his efforts been confined by any means to that alone, for he has introduced and distributed extensively many new varieties, and, by exhibiting specimens of hundreds of plants carefully cultivated at the public gardens, and personally explaining the course there pursued, he has rendered very valuable service to the public, as well as contributed in a large measure to the success of the exhibition. A novelty at the show was a tent, in which Mr. D. Morris had provided some delicious tea prepared from the leaves of the tea plant grown at Omeleona, and which was pronounced by all equal to the good grades of foreign tea imported to this country. A very thriving business was done in this tent, judging by the large number of persons who partook of Mr. Morris's hospitality, and as he has designated the new tea "No-he," we presume he knows where the euphonious title originated.—*Gleaner.*

THE USES OF HORTICULTURAL SOCIETIES.—We take the following extract from a paper of Mr. L. B. PIERCE, of Ohio, on the means of extending the usefulness of local horticultural societies contained in the *Transaction of the American Pomological Society*:—"If you can persuade or teach an Irish washerwoman that Grape Vine will grow beside her shanty (in the United States) as readily as a Morning Glory (Convolvulus), that a garden that grows Cabbages and Potatoes will also grow Cauldflowers and Strawberries, you have taken one step towards the millennium—you have got her and her family a step out of the beaten track, and this single step may lead her sons into lines of life that will crave neither the short-stemmed pipe nor the whisky bottle."—*Gardeners' Chronicle*.

THE Cultivation of the Wattle-tree is quite an industry in Victoria and South Australia. There are several species of these trees, all belonging to a class pre-eminently suited to the Australian climate, being equally able to withstand wet and dry seasons, and a bush fire, instead of destroying the dormant seed lying on in the ground as would naturally be supposed, causes it to germinate and grow. The large amount of tannin in the bark was early discovered by the Australian settler, and as settlement became closer, and tanneries increased, fear was often expressed that the supply of wattle-bark would soon be exhausted. However, observation showed that light loamy or sandy lands would grow a crop of wattles provided only it was fenced off from cattle; this led to a large area of land being so treated in Victoria, but in South Australia the actual ploughing of the land and sowing the wattle-seed was extensively carried out, and the results are said to have been very remunerative. The trees are ready to strip in about five years from time of sowing, but the process of stripping is always looked upon as wasteful, as only the bark upon the trunk and main branches can be peeled off, and much waste is left upon the smaller branches. It is therefore satisfactory to learn that an Adelaide firm have succeeded in inventing a process for extracting the tannin principle from the tree, a process in which the whole of the tree, leaves, bark, and wood, is used. The extract so prepared is of a sticky semi-liquid consistency, not unlike thick molasses in appearance. It has stood the test of practicability for the tanner, and now several of the local tanners use it in preference to the crude bark, for it saves them a great deal of labour and expense, and renders unnecessary the storage of a large quantity of bark. Several casks of the "extract" have been shipped to England, and it seems not unlikely that new industry has been created. To the farmer it opens out a market for a product which can be grown in the poorest soil, and with the least amount of cultivation possible.—*The Queensland*.

FUNGI, FOOD AND DISEASE.—Mr. W. J. Simmons, Secretary to the Public Health Society of this city, delivered a very interesting and instructive lecture on the night of the 15th instant, choosing as his subject, "Decay, and the Germ Theory of Disease." After a short preamble on the economy of the vegetable kingdom, the lecturer entered upon a very exhaustive analysis of the family of fungi. He said that an intimate study of it would lead to the discovery that that it touched human life at every point. "It was to fungi that we were indebted for both bread and wine, and but for it, we would have neither vinegar nor beer. The fungi touched us, too, when they blighted our crops and desolated our vineyards; when they paralysed the silk industry of France and Italy, and swept, like a destroying angel, over the teeming herds of Russia. Fungi were a terror to the agriculturist, the farmer, and the cattle-breeder; the physician had learned to recognize in them the certain cause of anthrax, and the probable cause of consumption, and a host of other diseases; the surgeon taxed his skill to prevent them from invading his hospitals, and showing themselves with deadly effect in his patients' wounds. Their seeds, germs, or spores were mingled with the air we breathed, and the food and

drink we consumed. True to the laws of their vegetable life, those spores persistently produced fungi of the parent type. And this constancy of re-production ran through the whole class. As Tyndall strikingly says: "Sow any of the fungi in a state of purity in any appropriate fluid, you get it, and it alone in the subsequent crop. In like manner, sow small-pox in the human body, your crop is small-pox; sow there scarlatina, your crop is scarlatina; sow typhoid virus, your crop is typhoid; cholera, your crop is cholera. This disease bears a constant a relation to its contagium as the microscopic organisms just enumerated do to their germs; or as a thistle does to its seed. No wonder, then (he goes on) with analogies so obvious and so striking that the conviction is spreading and growing daily in strength, that reproductive parasitic life is at the root of endemic disease."—*Indian Agriculturist*.

COCKCHAFFERS.—Mr. Booth, the well-known nurseryman of Hamburg, says:—"About ten years ago we suffered terribly from Cockchafers, whole plantations of Rhododendrons and Conifers being completely destroyed by them. Against such devastation all artificial remedies were more or less powerless. We then adopted the starling plan. We caused 100 breeding cages to be made of the very simplest construction, and in the spring they were all occupied. As soon as the Cockchafer comes or is coming out of the earth the starling is there; it picks the Chafer clean out, tapping about on the ground with its beak until it finds it. Beside almost every hole from which a Cockchafer has escaped one might find the wings and whatever is uneatable, proof enough that the Chafers' enjoyment of life had not been of long duration. We increased the number of cages, and have now from 175 to 200. We have since then had plenty of Cockchafer years, but have not again experienced such injury from them, and in working the ground to a greater depth for them the number of grubs found is comparatively few." Another remedy adopted by French gardeners is to thicken sow the affected ground in autumn with Colza, which is ploughed in as soon as the first frosts begin to make their appearance. Half-decayed Cabbage leaves, or indeed the refuse of any Cruciferous plant, should be ploughed in at the same time. It seems that the Cockchafer grub cannot stand the leaves of any of the Cruciferous plants in a state of fermentation, the sulphurous emanations given off by them being poisonous to the insect. Planting Cabbages or Turnips in ground infested by the Cockchafer grub is said to be effectual in driving them away. Another method, which is only applicable in woods and plantations, is described in the "Merseburger Official Journal" as having been successfully tried in a nursery belonging to the Royal Forestry at Bischoffsrode, comprising 1½ acres of land, and surrounded by high trees, especially by Oaks, completely ravaged by Cockchafers. Just before the flying time seventeen different spots were artificially prepared as breeding places in the following manner:—Alongside the paths, and near the fences, from 3 ft. to 4 ft. square of ground were covered with fresh manure from 5 in. to 6 in. high, without mixture of straw or any other material; upon this was laid 2 in. or 3 in. of fresh earth, nicely smoothed down and raked. These spots were carefully watched during the flying season, but, owing to the absence of any bored holes, were left undisturbed until the middle of July, when it was discovered that in those spots exposed to the sun, the manure was a living mass of grubs ½ in. in length, whilst in those places more in the shade the number of eggs was inconceivable. These heaps were brought together, and collectively burnt outside the nursery."—*Indian Gardener*.

ROUGH ON RATS.

Clears out rats, mice, roaches, flies, ants, bed-bugs, beetles, insects, skuunks, chipmunks, gophers. Druggists.

THE STOCK OF CINCHONA BARK IN LONDON.

London, 12th March 1886.

DEAR SIR,—In a paragraph of your Overland issue dated 16th Feb. I notice some remarks regarding the stocks of bark in London at the end of Jan. which are undoubtedly erroneous. A very large proportion of the stock of 67,000 packages mentioned is composed of the old importations of Cuprean bark, which have not yet entered into consumption, and for which at present there is no demand. This bark is packed in serons, each weighing about 150 lb.—some packages are even smaller. If an average of 200 lb. per package is allowed, in my opinion, the whole stock of bark in London at that date would be easily included; so that, instead of 25,000,000 lb., we have 13,400,000 lb. Several of the packages too are cases of druggist quills, which do not average as a rule so much as 100 lb. The Java bark that sold yesterday (some of its Ledger root by the way at 2s 7d) arrived in bales of various weights from 110 to 150 lb. I should be inclined to estimate the stock of bark in London at rather under 13,000,000 lb. than over, and much of it of poor quality. Apologizing for trespassing on your space, I am, yours faithfully,
JOHN HAMILTON.

CEYLON TEA IN LONDON.

213, Havelock Street, Mayfair, London, W.
1st April 1886.

DEAR SIR,—I read with considerable interest the letter which you printed a short time since upon the subject of Ceylon Tea (so-called) as sold in England: and would ask you to allow me to add my voice to the complaint by giving a few facts, which are within my own personal knowledge.

I prefer to drink *pure Ceylon tea*, but have great difficulty in getting it, even from the most respectable shops in London, not, mark you, because they do not profess to sell the article: but from the undoubted fact, that a great many *tea* merchants and grocers sell a mixture of cheap China and Ceylon, as genuine Ceylon tea.

Why we naturally ask, should they do so? I will endeavour to show why, at least, some of them find it pays to practice this deception, (I might say "fraud") upon the public. The principal part of the tea sold by these packet dealers is at 2s per lb., and for that price, the public expect a very good tea, both in liquor and leaf.

The dealer buys his tea on the Mincing Lane market, say at 1s per lb. (you can't buy any Ceylon tea worth drinking under) which, with duty makes 1s 6d per lb. prime cost. He then puts the tea into packets, (lead), which with labels, time, &c., cost at least 2d per lb. more, thus 1s 8d per lb.: the dealer wants 3d per lb. profit, his agent, who retails it to the consumer another 1d, and adding 1d per lb. for rail carriage to agent, we get a grand total of 2s 3d per lb., in other words 9d per lb. more than it cost the dealers. From whence comes then the 2s *pure Ceylon tea*, which a dozen different brands are selling in the manner I have described? It is perfectly plain to us that it pays the dealers better to buy cheap

China tea at 7¹/₂d or 8d per lb. put a dash of Ceylon with it to give character, and, labelling it *pure Ceylon tea*, in original packets as imported, sell it as such, and ruin our trade, for that, I am sure, will be the result in a few years. It is not of course, impossible to get genuine Ceylon tea, but you must get recommended to the right quarter for it, otherwise you are bound to be imposed upon, especially in the 2s tea. I enclose a sample from some I bought at 2s 4d per lb. I recommend my friends to do the same, it is very nice. Apologising for the length of this letter.—I am dear sir, yours truly,

GEORGE ALEXANDER.

CEYLON HIDES IN THE EASTERN PROVINCE.

Batticaloa, 3rd April 1886.

DEAR SIR,—In your editorial of the 6th March, under the head, "Ceylon Leather," you allude to the difficulty which a London correspondent finds satisfactorily to account for the low prices obtained for Ceylon "buffalo hides," and ask if "any of your readers can give you information on the subject?" I think some reason may be found for the inferiority of the hides exported from the Eastern Province of Ceylon. Buffaloes being reared here solely for purposes of cultivation, they are not slaughtered for food. Wild ones are occasionally shot by some of the Mgors who eat beef, but the hides thus obtained having bullet holes in them are valued less; and such hides form about one-ninth of the quantity exported. Nine-tenths are from animals which die of murrain or from overwork, and the skinning process of these carcasses seldom begins before decomposition sets in. These, I think, are the causes of depreciation in the value of buffalo hides exported from this province.

I cannot speak positively about hides from other provinces in the island. I know that a large number of buffaloes are slaughtered for food in the other provinces, but I have reason to think that the skins of diseased animals form no small portion of the quantity exported from those provinces. The trade in skins and bones has been taken up by some Moorish traders and Sinhalese settlers. In former times one could hardly see a Sinhalese except in those parts inhabited by them, but now almost every village has two or three lowcountry Sinhalese settled for good. Several of these, I believe, are much wanted by the police of the Western and Southern Provinces. The villagers either know nothing about them or are unwilling to give information against them as they have come here as to a "city of refuge." I think if the rewards for the apprehension of these gentry be raised, and the period extended to a year, and some detectives be sent from time to time, we may hope to get rid of them.
S.

TEA LEAF PLUCKING GALORE!

Kandaloya, Nawalapitiya, 4th April 1886.

DEAR SIR,—As Kandaloya expected crop for March has been brought before the public, it may possibly interest some of your readers to know that the amount actually secured was 22,433 lb. in March.

The three highest daily deliveries of leaf were 4,720 lb., 5,200 lb. and 6,500 lb.

The largest "cannack" of leaf brought in by any single plucker on one day was 63 lb.—Yours faithfully,
W. TURING MACKENZIE.

* "Cannack," task or quantity.—Ed.

CUBEBES AND IPECACUANHA: INFORMATION
WANTED.

6th April 1886.

SIR,—Would you or perhaps any of your numerous readers furnish me with some data for the cultivation of the above products? e.g., conditions under which best grown, yield per plant, mode of cultivation, &c., and market value. Reliable information would be most acceptable to, yours faithfully,

PIONEER.

[Has "Pioneer" the volumes of the *Tropical Agriculturist*? If not let him get them. We could fill one-fourth column with references to the pages where the above products are noticed.—Ed.]

THE PREPARATION OF COCOA (CACAO).

Wattarantenne No. 2, Kandy, 12th April 1886.

DEAR SIR,—I believe that there are few (if any) in this island who are better able to judge of the marketable quality of Cocoa than Messrs. Volkart Brothers, who are extensive traders in the commodity. From the correspondence in your issue of the 1st instant, you will see that they draw a wide line of demarcation between *quality* and *superficial appearance*; the latter is very easily obtained, and if my object had been to attract notice by a mere golden appearance of the "Wattarantenne" Cocoa, I might have left Mr. Jefferies and Gangaroola in the shade very long ago, but my object has always been to gain a good name, not only for Wattarantenne, but for the Ceylon product in general. The letter of Messrs. Volkart Brothers amply shows the commercial world that although the Cocoa prepared by me may be deficient on the minor point of a rich and glowing appearance, yet that, as far as regards quality obtained by successful fermentation, it is far superior to the Gangaroola produce however excellent the latter may be as a catch in the European markets. I believe that you will agree with me that the essential quality of all good Cocoa must be successful fermentation—a process which must be obtained by unusual skill and patience, and I do say that you are guilty of a very small act of exaction in calling on me just at present to give publicity to the method by which I have obtained the much desired fermentation, but when your numerous experienced and scientific correspondents have disclosed in your columns the methods by which they have attained the much desired end, I too might be induced to come forward and explain the process I have adopted, and I have no doubt that Mr. Jefferies too will come out with his secret of color, if secret it be. I beg to enclose for publication a letter of Messrs. Volkart Bros. of date the 5th April 1886, which speaks for itself.

Thanking you for so generously opening your columns to the ventilation of a topic of public and commercial interest, I am, sir, yours faithfully,

J. P. COLTON.

Colombo, 5th April 1886.

J. P. COLTON, Esq.,—Dear Sir,—In reply to your letter of the 29th ultimo, we beg to inform you that the lot of cocoa you inquire about, shows in our opinion an improvement over former parcels with regard to outward appearance; as to color, however, we should say more evenness is still required.—Yours faithfully,

(Signed) VOLKART BROTHERS.

P.S.—On the whole the parcel is very satisfactory.

NATIVE AGRICULTURE AND THE D. P. I.

DEAR SIR,—I believe few are aware that the students of the Agricultural School under the leadership of Mr. Jayawardana are carrying on paddy cultivation on lands belonging to Mr. W. Abeyaratne of Kirillapane. I admire Mr. Green's energy in endeavouring to teach

the natives how to grow two ears of paddy where one is only now grown, but Mr. Green must know well that many native cultivators can ill-afford to spend R22 for a Swedish plough, when native ploughs are available for R2.50 each. It is to be hoped that Mr. Green will get our mechanics here to make a much lighter and cheaper plough having nearly all the deep-ploughing qualities of the Swedish plough. Mr. Abeyaratne has further shown his public spirit by furnishing the Agricultural students with seed-paddy free of cost, besides ploughing and sowing at his own expense some of the adjoining portions of his fields in the orthodox native fashion. It was very unfortunate that last season's crop was destroyed by large numbers of corn-fly and unpropitious weather.—Yours truly,

M.

CEYLON TEAS.—Only 400 packages were offered in sale this week, and a few of the higher grades not reaching their reserve prices were withdrawn. The same remarks as to the relative value Indian pekoe souchongas and pekoes apply to these teas. The marks "Highlands" and "Middleton" showed desirable qualities and commanded fair prices. Most of the other marks comprised small breaks which always receive less attention.—N. McNair & Co., 26th March.

"COAL TAR SUGAR."—The Manchester Society of Chemical Industry has had reported to it "a new substance" named saccharine, "extracted from coal tar," and possessing "sweetening properties far stronger than the best cane or beet-root sugar." The chemical name of saccharine is "anhydro ortho sulphanine benzoic acid," and "one part will give a very sweet taste to 1,000 parts of water." It has no injurious effect on the human system, and patients suffering with diabetes are said to have been treated with it without inconvenience. Its use as a substitute for sugar, and for medicinal purposes where sugar is not permitted, is considered probable. Dr. Fahlberg, a German chemist, is "the inventor." He combined it with glucose or starch sugar, obtaining dextro-saccharine? scarcely distinguishable from the best sugar.—Bradstreet, Feb. 1886.

TEA SEASON 1886-87.—Say Messrs. Stenning, Inslipp & Co. in their Indian Tea Report of 25th March:—"A word of caution to planters at this time may not be out of place, and we would urge, as we have often done before, the advisability of adhering to a moderately fine system of plucking. The comparatively high prices that have ruled for the commoner classes throughout the past season have been mainly due to better quality, the result of a careful method of plucking, and not so much to short supply, moreover, it is probable that the improved position of Common China Congou will lead to a large export from that quarter next season, in which case common grades of Indian, if of poor quality resulting from coarse plucking, will only realize low prices."

MYSORE GOLD.—The yield of gold from the mine of the Mysore Company at Colar last month was considerably less than in the immediately preceding month, though there were three more working days in March than in February. The shipments of Mysore gold from Madras for the twelve months April 1885 to April 1886 (exclusive of May 1885 when there were no shipments), were 8,788 oz. worth R1,49,200. In the five months December 1885 to April 1886, the shipments were 5,772 ozs. worth R3,00,000, or at the rate of 13-852 oz. worth R7,20,000 per annum, from only one shaft. The Company has two square miles of land, strongly accentuated by auriferous indication. It might sink and equip a dozen shafts with the £60,000 additional capital just placed at its disposal for the special purpose of developments. The industry is still in its infancy—its robust infancy.—M. Mail.

TEA AMONG THE BHUTIAS.

Mr. Darrah, the officiating Director of Agriculture in Assam, in his report for 1884-85, gives a curious account of the process of infusing tea pursued among the Bhutias at Dewangiri. Two pots, one of brass and filled with water, the other an earthen one and empty, were put over a fire. A piece was broken off a brick of tea and crumpled up in the hand to separate the adhering leaves and twigs. The handful so obtained was put into the dry earthen pot, and stirred up for a few seconds till hot. Then about a couple of wine-glasses full of potash-water (made by straining water through ashes) was poured on the dry tea, and when the heat had almost evaporated the moisture, another spoonful of water (now hot) was added from the brass pot. The tea meanwhile was kept stirred to prevent its burning, and when nearly dry, a second, and then after an interval, a third spoonful of water was added. When this, too, was almost dry, all the water from the brass pot was poured in, and a teaspoonful of salt having been added, the mixture was boiled. As soon as the bubbles showed that the liquid was boiling, it was ladled out with a spoon formed from a gourd into a sort of churn made from a thick piece of bamboo about two feet long. The churn was provided with a wooden cover, through a hole in which a piston-rod worked, the piston being simply a round piece of wood roughly fitting the interior of the churn. The boiling liquid having been poured in, the churn was worked for a few seconds, and then about a table-spoonful of *ghi* was added to the mixture. The churn upon this was worked vigorously for a few minutes, considerable pressure being evidently required to force the piston up and down. The Bhutia next poured back the liquid into the earthen pot, which meanwhile had remained on the fire, and tasted the tea. He stated that more salt was wanted, and added accordingly about an egg-spoonful. The whole was boiled again for about a minute, and then tasted and pronounced right. The amount was equal to the contents of two ordinary quart bottles.—*Pioneer*.

DECAYING INDIAN INDUSTRIES.

Among the remarks made by Mr. Grant Duff which require expansion or elucidation to make them truly valuable, or to show their lack of value, was one about the decaying trades and industries of India. He said he did not care for the encouragement of manufactures in this country which England or Europe could supply cheaper and better. Here there are two questions to be asked: first, if Europe can supply them better and cheaper, does she do so? and next, if Europe can now supply them cheaper and better, is it impossible, is not rather very possible, for India, by improving her methods of manufacture, to produce many kinds of goods both cheaper and better than Europe can supply them? And if this be possible and practicable, ought not the country to set about accomplishing it as a fact? Apply Mr. Grant Duff's remark to the production of hand-made Arnee muslin at 1 Rs. a yard; and we quite agree with him: it would be cheaper and better to get English or Scotch lawn at 11-8 or 21-8 a yard, even though it might not be quite so utterly too fine. But much of the cheapest cotton fabric that England sends to this country, if cheap, is abominably nasty, being overloaded with chalk and packed damp, because it is bought by weight; and therefore the longer it remains unpacked, the more the fabric rots, till, at last, when the rustic buys cheap a thick,

closely woven cloth, which has every appearance of being strong, he soon finds that it would have been better for him to have purchased a hand-made product of the village loom. Of all those manufactures and trades for which India supplies the raw material, she ought to strive to learn cheap and rapid modes of production, by importing and employing the most modern machinery used in the manufacture. Even if the price at which she could thus produce the fabric were not lower than it could be produced in foreign countries, India would be benefited by the expenditure of capital and the employment of labour in the country itself. But even with well paid European superintendence, the manufacture of Indian products in India is likely to lead to a much cheaper fabric or manufacture than what can be produced in England; for there is freight in and out to pay, and there are the profits of many middlemen. This is provided by the manufactures of cotton mills set up in India the fabric is less injured by chalk and damp; it is cheaper and stronger than most English manufactures of the same class that reach India; and yet the manufacture yields a handsome profit. We would like to see the same process of producing and manufacturing according to European methods applied to iron in India. The quality of Indian iron ore is excellent and the supply is unlimited; and yet the produce of iron mines in India is declining, because of the vast quantity of iron imported from England and America. In 1884-85, the produce of iron by natives in Southern India amounted to only Rs. 117 against Rs. 1,357 in the previous year. Doubtless this arises from the vast quantity of iron imported by the railway companies. There were no less than 16 lakhs' worth of iron and steel, wrought and unwrought, imported into the presidency in 1884-85; besides six and-a-half lakhs of rupees' worth of machinery and mill work; and nearly six lakhs' worth of rolling stock, in which, we presume, there must be much iron. The sale of old iron rails and other worn-out railway materials of iron at a cheap rate, helps to reduce yearly the amount of Indian iron produced. Where ore is so abundant and pure, is it not a pity that so much of foreign iron should be imported? Might not forests be planted near the rocky regions where the best Indian iron ore is to be found; so that the next generation at least may begin to utilize the abundant excellent Indian ore? But this would require either that Englishmen take up the industry and work it according to European methods; or that natives study and learn European methods of smelting the ore and make it up. Here is an immense work awaiting commencement in the Salem district, which may change the aspect of industry and life in a large portion of the presidency. Will no wealthy native give his mind to the matter, and prepare the way for his son's vulcanizing the country?—*Madras Times*.

REPORT ON CHINA, INDIAN, CEYLON
AND JAVA TEAS.(From *Geo. White & Co's Annual Report*.)

LONDON, March 20th 1886.

The season now fast drawing to a close has been chiefly remarkable for the sterling quality of most of the crop, and for the run since September on teas for price as retailers found the lower grades were of such useful description that they could afford to purchase them in large quantities, even at higher prices than usual. This diversion in the demand seriously affected due to finest kinds, and these being neglected, prices rapidly declined until a fall of 11 to 61 per lb. was established, which has never been recovered. The results will nevertheless be satisfactory to garden owners, as in consequence of the enhanced prices obtained for the lower grades the average has been well sustained.

After the few first shipments, which lost heavily, importers of Calcutta-bought teas did well for a time, but later on the business proved unsatisfactory. The uncertainty again prevailing as to the probable outturn has been misleading, and made it extremely difficult to forecast the future of our market, as the estimates available for Great Britain have varied from about sixty-three to sixty-six millions during the season.

Importers have shown more discrimination in bringing their teas forward, especially since the commencement of 1886, and therefore the market has not been so heavily weighted at one time as in former years. The effect of this has proved salutary, for had excessive quantities been forced on the market during the first two months of this year there is little doubt that, owing to the depressed state of trade throughout the country, especially in Ireland, a serious collapse in price would have occurred.

The statistical position of China tea is exceptionally good so far as stocks are concerned, but that of Indian is, at first sight, less favourable, the deliveries for the past eight months being behind those of the corresponding period of the previous season, in consequence of the excessive clearances last spring in anticipation of the Budget.

Prospects for the coming season appear to be fairly good, though there is a great danger of managers being tempted to go in for quantity owing to the high prices which have been for some time ruling for the lower grades. If similar quality be maintained we can absorb a large quantity, but should, this, however, not be the case prices will rule very high. The Congress and the season 1884-5 the tendency being to a lower standard than 8s. say from 1s 8d to 1s 3d. The way in which some really choice teas (especially the Assams received last August) have been competed for by the trade should encourage the manufacture of fine full flavoured parcels with a bright copper coloured infused leaf, and a rich dark liquor, which creams over when shaken, given this with a fairly well made leaf free from dust, and good prices are almost always ensured.

With an increasing yield every year, especially from Ceylon, it becomes a serious question whether the consumption will keep pace with the supply. It is, therefore, satisfactory to note that, though America has not responded well at present, the Colonies now take about two million pounds; while a demand seems to be springing up on the Continent for flavoured teas, especially Ceylon. Should this develop it will be a great help to our market, as it will relieve our stock and induce more competition.

As, however, China will not be ousted from the Continental trade without a severe struggle, we think it not unlikely that the average price obtained here may decline and would, therefore, advise Managers of Gardens to strain every nerve to keep up the quality of their productions, while lessening the cost of manufacture, if possible. Ceylon teas appear to be still much appreciated for the home trade, as the average is 3s 3d against about 1s 1/2 for Indian, and say 10d for China.

Fewer complaints have been made about undesirable quality, partly owing no doubt to the weather and greater attention to manufacture, together with more experience having been gained in the use of drying machines.

To obtain a good name for the produce of a garden should be one of the chief aims of the manager, as many retail houses will give several pence per pound above the ordinary market rates, if necessary, to secure a brand of which they can be depended upon obtaining a certain supply, and at the same time can rely on the quality being good. For this reason, entire consignees shipped direct invariably sell best in London, as they attract the attention of the regular buyers, but when sold in Calcutta the breaks lose their individuality and on arrival here are often passed over amongst a lot of mixed marks.

As regards sorting it is to be hoped, as the trade is so rapidly expanding, that it will be made more practicable to minimise the number of breaks by making them larger, so that by having fewer samples to be gone through daily, buyers may be able to taste all the sales carefully. The dividing up of parcels of the same tea in Calcutta has not been so noticeable during the past season, but there has been a very large proportion of duplicate breaks of similar tea in the same garden invoices, where they have been sent to Factory Bulk, and often did this occur whilst the sales were heavy. That the leading buyers refused to bid for such duplicate lots unless they were re-bulked together here into larger parcels. This is an important matter, and every endeavour should be made to avoid the recurrence of this during the present year.

Ceylon teas have been unusually noticeable on account of the number of sorts, as nearly every new garden has been represented in its first shipments by five or six different prescriptions, and in two or three of the most wonderful manner. In fact, now that teas of a moderate price are sought after, we are of opinion that it would answer, especially on small gardens, to pass all the unsorted tea through an equalizer, and obtain a small even leaf Pekoe Sonchong or Peke, free from dust, and chips it as "one" large break, instead of sitting into four or five non-sampling ones, which are not seen by the leading buyers and have to be offered by themselves after the sales.

Fewer instances of the use of improper wood for chests have occurred. We understand that a new metal package has been patented, which, if successful, will supply a want in districts where timber is scarce.

A larger proportion of "factory bulked" invoices has been sent home, and in many cases the teas have passed inspection, but on the other hand the appearance of some has been so irregular that it was necessary to re-bulk them. We cannot too strongly impress upon Managers the necessity of greater care being taken to obtain evenness of quality, and appearance, not only by careful blending prior to putting the tea into the chests, but also by using every precaution in pressing it into the packages so that the leaf should be uniform. It has been proved by experience in packing breaks of 50 to 100 chests that the end of the pile or heap becomes more or less broken and dusty, and if placed in the last few packages, renders their appearance sufficiently different to destroy the regularity of the whole parcel, as the colour of the leaf is altered when crushed. It would be better to reserve the balance of the pile for the next packing.

It is, however, to be hoped that bulking in London will soon be done away with, for, as we have several times pointed out, many fine Pekoes and Broken Pekoes are deteriorated several degrees, and by the treatment they receive here, especially if they are hurried out for sale, as is often the case when heavy arrivals are taking place and the warehousemen are fully engaged. Take a Calcutta purchase for instance which may have been bought on a sample drawn out of one of the best chests in a break, and compare it after bulking on this side, and its unfortunate position will be fairly recognizable, especially if often accompanied for much of the discrepancy between the Calcutta cost and London value. We hear that one of the leading firms of London Agents is sending out printed bulking instructions, to be posted up in each tea house, being cognizant of the necessity that this branch of the industry should be carefully and efficiently carried out, partly to save expense and also to ensure the teas going into the hands of the retailers, without being turned but, just as they left the gardens.

Many shipments have shown a decided improvement in quality, no doubt traceable to some extent to the use of seed from India and the greater familiarity obtained with the machinery employed. The teas are in good demand for export as well as for home consumption, as they can now be used much more freely than when they nearly all possessed the peculiarity attaching to them a few years since. Moreover, they have one great advantage, particularly where it is desired to sell immediately on arrival, viz., they rarely require re-bulking, and the packages have an even tarr. In that respect the island of Java has set a good example for India to follow, and we hope for the interests of all concerned she will do so.

COMPARATIVE QUALITY OF THE OUTPUT OF THE DIFFERENT DISTRICTS FOR THE PAST THREE SEASONS.
CEYLON,—105,000 acres, greater portion not yet in bearing.

Estimate of tea made during 1885.—Season 1885-6, *4,500,000 lb

1885 Crop.—Still in favour with consumers, and whenever supplies have fallen off, there has been a strong demand and full rates obtained. These teas have made a great name for themselves which will probably be maintained if the quality is kept up.

1884 Crop.—Still in favour owing to their useful qualities. Some undesirable shipments, however, have realized low averages. Demand likely to continue for all parcels with full flavour.

1883 Crop.—In considerable request at steadily improving rates throughout the season, the demand for these growths having become general from all parts of the United Kingdom.

PLANTING IN WESTERN DOLOSSBAGE, CEYLON.

18th April.

I have been thinking for some time back to send you a few planting notes, but the cares of this world and the deceitfulness of riches have so far checked the good intention—like the pavement to a certain place which shall be nameless.

Tea.—In all directions one sees signs of renewed activity in preparing for, and planting this deservedly popular product on both new and old land. There are some places which one would think hardly justifying the expense, and, interior profits may be doubtful, but tea is a wonderful shrub, and it is difficult to say where to draw the line. I am working at a small "toonda" which well illustrates the vicissitudes of the past planting years. First of all it was planted up with coffee, then it was laid down with guinea grass at a time when palatial cattle-

* Likely to be much nearer 5,000,000.—Ed.

sheds and manuring were thought to be a cure for leaf-disease: then came the craze for cardamoms, and as there was some shade and prices something more than a shadow, Hey presto! and behold a cardamom grove. The scene changes. Cinchona raises its superior head, and the lowly tea will soon fill up all vacancies and do more towards the appearance and prosperity of the "totam" than all its predecessors. After that, I think, we need not fear. If tea goes we'll just be up and doing and take to something else!

Cocoa.—We are having splendid weather for this product—sunshine and shower—and it is looking its very best. Well, it is nice to have breathing time after what has been suffered from *Helopeltis*, for it is a sad enemy from what I have seen and heard. Being an insect plague I have hopes that we may be able to keep it under subjection. The season being favourable, there is a goodly display of early fruit and blossom. The afternoons are very sultry, and out of doors the heat is pretty nearly unbearable. This is the cultivation for villagers round about their houses and gardens; but local history proves that they are fonder of reaping where others have planted.

Cinchona does very well and several estates have a good show of trees. An idea was broached the other day which should be acted upon, and that is to ascertain through the best means what Java is likely to do in this line, and also as regards tea. The necessary expenses, I'm sure, could be made up.

Coffee, Arabian and Liberian, is a thing of the past. Like poor old Jeff—"disturb him not, he's gone to rest"—I've waited on him—coffee, not uncle Jeff—many a weary year—whiles in pleasure, whiles in pain, listening on bed to the everlasting rain pattering on shingles and wondering about the morrow's muster and the "palam" at the 'dropsy' stage.

THE YEAR BOOK OF NEW ZEALAND 1885-6.*

This is a book most necessary to be consulted by all intending settlers in that colony, and affording valuable and minute information of a kind such as a traveller would be thankful to have ready to his hand. The topics dealt with are varied as the life and activities of the colony. The Universities and the price of meat, the manner of acquiring Crown lands and the wages demanded by a house-maid, how the country is governed and how the people are taxed, the operations of a Missionary Society and the cost of a bottle of beer—all these and many other matters of interest, domestic, educational, legal, governmental, geological, geographical and historical are comprised within the brilliant red covers of this large and carefully compiled Hand-book. The compilers let off the steam of patriotic ardour in the opening pages devoted to a "General Description." There we read that "all the productions of the

* The Year-book of New Zealand, 1885. Compiled for the use of intending Settlers, Tourists, Merchants and Manufacturers, from information furnished by the works of the Agent-General and the Government of the Colony. By George Vesey Stewart and Thos. Simpson Jones. "A good land, a land of brooks of water, of fountains and depths that spring out of valleys and hills; a land of wheat, and barley, and vines, and fig trees, and pomegranates; a land of olive, and honey; a land wherein thou shalt eat bread without scarceness, thou shalt not lack any thing in it: a land whose stones are iron, and out of whose hills thou mayest dig brass."—Deut. viii. 7-9. Published at the Offices: New Zealand Chambers, 31, Leadenhall Street, London, E.C.; and Tauranga, Bay of Plenty, New Zealand.—1885.

British Islands flourish luxuriantly in New Zealand—wheat, barley, oats, potatoes, flax, beans, peas, marigold, turnips, apples, pears, plums, cherries, gooseberries, currants, raspberries, strawberries, &c. peaches grow wild and luscious in the forests; apricots, quinces, loquats, figs, grapes, melons, ripen in the open air. Manure is unnecessary for the rich virgin soils of New Zealand: and potatoes, unblighted, are floury as they were in Britain before the failure of '47. There is not a venomous reptile in New Zealand, nor are the crops ever withered by drought as in Australia and South Africa, or devastated by locusts or grasshoppers." We do not remember the exact appearance and flavour of the British potatoe previous to 1847, and our usual referee on matters of Ancient History is gone up-country, but the recollection of the yet undegenerate tuber has evidently survived through forty years save one in some minds at any rate, and this shows its goodness and the goodness of its rival and equal, the New Zealand potato. In reading the above quoted paragraph we were more than ever struck with the utter perversity of some men we have known who have actually gone to look upon that scene of abundance and paradisaical freedom from reptiles and have returned to settle down contentedly in this country of no potatoes, many snakes, occasional droughts and chronic visitations of worse enemies than locusts and grasshoppers. However, it is only in the first half-dozen pages we get this style of writing. Afterwards the compilers settle down to details and we get nearly 900 pages of information highly creditable to those who have so well and ably brought it together and to the country which it describes.

THE DENATURALIZATION OF SALT.

THE REWARD OFFERED BY THE GOVERNMENT OF INDIA.

Not the least of the many objections which may be urged against the imposition of a tax on salt is, that it prevents, or greatly curtails the use of that article in agriculture, the arts, and manufactures. The value of salt in agriculture was known in very early times, and there are references to it in Chinese, Greek, Latin, and Hebrew literature. Its value as a manure must have been established long before the beginning of the Christian era, for it is mentioned, by way of illustration, in the following verse of St. Luke: "Salt is good; but if the salt have lost his savour wherewith shall it be seasoned? it is neither fit for the land, nor yet for the dunghill, but men cast it out." Modern science has confirmed the soundness of the empirical methods of the ancients, and the manurial value of salt is now fully established. Salt has also long been used as an ingredient in the food of domestic animals, and is very necessary to their health. This is borne out by the partiality for salt shown by some wild animals, a fact which is taken advantage of in Chittagong, where the villagers induce the semi-wild *gayals* to come in, and allow themselves to be milked, by giving them a small quantity of salt on each occasion. Sportsmen, too, well know that a "salt-lick" is generally a sure find for bison and other big game. In arts and manufactures salt is not so extensively used in India as in European countries, where it plays an important part in many chemical works. In India, however, the fish-curer, the glass-worker, and the tanner all require salt for their trades, and it is possible that if the article could be issued free of duty several new industries might spring up.

But neither in agriculture nor in manufactures can salt be profitably used to any considerable extent unless the duty is removed. To do this, so as to leave the salt revenue unaffected—and India can ill-afford to lose it at the present juncture—it is necessary to discover some method of rendering salt unfit for human consumption without affecting its suitability for employment in other directions. In those European countries in which salt is still taxed, this problem has been satisfactorily solved. In Germany, salt is denaturalized by the mixture of oxide of iron, and vermouth powder, or charcoal, when it is intended for cattle, and by the addition of charcoal, ashes, lamp-black, or ordinary soot in the case of salt required for manure. In France, the denaturalizing agents used are very numerous, but salt intended for manure is, as a rule, mixed with poudrrette. None of these processes are, however, suitable to the conditions obtaining in India, where the duty is much heavier, and where the powerful tropical sun renders the process of lixiviation extremely easy. It would indeed be possible to use the poudrrette process, but the Government of India considers that the issue of a mixture of the kind to the people of this country is obviously objectionable as leading to serious misapprehension of motives. The suggestion was made by the Commissioner of Salt Revenue in Madras, and supported by the Madras Board of Revenue, and we doubt whether, so far as the Southern Presidency is concerned, the objection taken by the Government of India is well-founded. There could, in any case, be no misapprehension of motives by coffee-planters, and Mr. Bliss's proposal referred to salt required for a patent manure, which was primarily intended for coffee gardens, and was not likely to be patronized by the ryot. The Government of India, however, rejected the Madras suggestion, and since then the chemists of Bengal, Assam, and Burmah have been endeavouring, but without success, to discover a process which will fulfil the conditions laid down by the Supreme Government. The latter has accordingly just published a resolution on the subject, and has offered a reward not exceeding Rs.5,000 to the inventor, or discoverer of a process which will satisfy the main conditions. These are that the cost of the process must not exceed four annas a maund, and the preparation must be such that edible salt cannot be profitably extracted from it by any of the ordinary processes in use amongst native salt-workers. The conditions are extremely difficult. All the organic, and many of the inorganic substances suggested as denaturalizing agents are liable to be destroyed by a degree of heat too low to affect salt. To be really effective, the substance added to the salt must be chemically similar to it, and must, at the same time, be of low price. None of the substances detailed in the Resolution now before us fulfil these conditions, though that advocated by Dr. Romanis goes near to doing so. He proposes a mixture of salt and the sulph-antimuriate of sodium (Schlippe's salt) the solubility of which is nearly the same as that of common salt. Salts of antimony act as emetics on human beings, but have no such effect on cattle and horses, so that the preparation would not compete with edible salt. This process was rejected on the ground that antimony acts as a cumulative poison, and that fatal effects would follow its continued use. Dr. Romanis has, however, in the columns of the *Indian Agriculturist*, denied this, and states that he presumes the idea was suggested by the analogy of arsenic. This is a question, however, which we must leave the chemists to decide.

The Government of India seems to us to be nuduly nervous regarding its revenue. Salt can

easily be so discoloured that any attempt to publicly sell the denaturalized article would be discovered without difficulty. In this Presidency it is only on the coast that any extensive attempt would be made to recover common salt from it, and surely a Department of which the subordinate agents are so vigilant that they recently obtained the conviction of an old woman for being in the possession of illicit salt when she was in reality only taking home her husband's ashes, is sufficiently powerful to prevent the success of any endeavour on a large scale to evade the Salt Laws. The question is of such importance that an experiment might well be made to see whether the issue of prepared salt, free of duty, would have any appreciable effect on the revenue, and we would suggest that it should be undertaken by the Madras Salt Department, the organisation of which is inferior to none in India.—*Madras Mail*.

TEA CHESTS: CORROSION OF LEAD LININGS.

The "Journal of the Asiatic Society of Bengal," issued on 29th December last, contains a "Memorandum on the Corrosion of the Lead Linings of Indian Tea Chests, by Alex. Pedler, F.R.S., Professor of Chemistry in the Presidency College, Calcutta," which shows that very careful and intelligent experiments were made. The result is summed up as follows:—

The conclusions that my experiments have led me to form are as follows:—

1. That tea properly manufactured in the ordinary way has no power to corrode lead.
2. That if unseasoned and damp wood is used for the manufacture of the tea boxes, corrosion of the tea lead is, under favourable circumstances, almost certain, but that some varieties of wood act more violently than others.
3. That even if seasoned wood be used to make the tea boxes, and if it be allowed to become saturated with water, and then placed in favourable circumstances of heat and moisture, corrosion of the tea lead may occur, though not to so great an extent as if unseasoned wood had been used.
4. That the active agent does not exist ready formed in unseasoned wood, but is produced by a secondary action from the constituents of the wood.
5. That the corrosion is not usually due to contact action between the lead and the wood, but that a volatile substance is gradually produced from the unseasoned wood.
6. That the corroding agent is usually acetic acid in the presence of moist air and carbonic acid, but that other acids of the same series are sometimes produced and also act on the lead, and in the case of butyric and valeric acids a greenish yellow incrustation is formed differing entirely from the whitish or yellowish incrustation produced from acetic acid.
7. That the acetic acid and other acids are produced by the decomposition (probably by a kind of fermentation under the influence of heat and moisture, and perhaps started by decomposing nitrogenous matters) of certain substances which are known to be present in woods. Such bodies are fermentable sugars, starchy matters, malic acid, etc.
8. That the lead linings of the tea chests having been corroded and perforated by the corroding action of these acids in the presence of moist air, and carbonic acid, the tea can easily take up the disagreeable odour which the wood itself will possess, after it has undergone the change in which acetic acid and butyric acid, etc., are formed, and thus the quality of the tea will be deteriorated.

As a matter of fact, very little, if anything has recently been heard of damage to tea by unseasoned or damp woods in tea boxes.

AN ALLITERATIVE TEA CIRCULAR.—We have received by the mail a handbill issued by a tea firm in London of a very ingenious design. The virtues of the tea sold by this firm are set forth in a paragraph every word of which commences with the letter T. The following is a specimen:—"T will turn the mercantile trade to tractable tacit tenderness, 't is transcendental to the trashy Teas (time-serving tradesmen tender; thoughtful theorists tell tales that 't will turn the Tea trade "topsy-turvy."

FINE INDIAN COFFEES.—Says Messrs. Patry & Pasteur on March 25th:—"The bulk of the cargo ex 'Clyde' has now passed the hammer; the quality, we have no hesitation in saying, is the finest we have seen for some years, the color being bright and the bean large, plump and well made. Should the cargo per 'Straits of Gibraltar,' which is shortly due, turn out of equal quality, we are inclined to think a new and profitable era is dawning for growers of Indian coffees, especially as the supply of Ceylon will be very limited on account of the extension of tea cultivation in that land."

TOBACCO.—The late Under-Secretary for India has won perhaps rather a precarious boon for English agriculturists in securing the abolition of the restrictions on tobacco cultivation. It is always an uncertain crop, and probably in the English climate would never be otherwise than speculative. At the same time it exhausts the soil severely, and requires much greater heat than an ordinary summer will give for developing a tolerable flavour. Still, in these times of depression it is quite fair that the chance of trying it should be opened to the English agriculturist, and possibly remedies may be found for some of the more obvious difficulties. Regulations will have, however, to be issued for its cultivation and taxation, as if it were grown free while imported tobacco is heavily taxed, the result would be a bounty in favour of its home production. The first experiments will probably be made in Lord Harris's own county, Kent.

BRICK TEA.—In noticing a Government Report on Agriculture in Assam, the *Indian Planter's Gazette* states:—

Clause 11 ends with an interesting note about "Brick" tea. We look upon this as an excellent outlet at some future day for our coarser class of leaf if we could establish a trade with Thibet and the Bhotas for it; the subject is well worth the attention of our planters. Roughly speaking, the method of manufacture is, to mix the tea leaves with rose-water, and allow them to ferment for a day or two. Decomposition having then set in, the whole mass can be worked up like clay for brick-making; it is then put into moulds, made into bricks, and dried. The Thibetans put a small portion of this into an earthen vessel, churn it up mixed with water and sometimes a little ghee, until the whole mass becomes a frothy, milky liquid, when they consider it fit to drink. So far as we can gather, no art is required in the manufacture of brick tea, and it is supposed that the Chinese use all the leaves gathered from prunings for its manufacture.

OUR TRADE WITH CEYLON.—The direct trade between the United States and Ceylon during the year 1881, the latest for which there are returns, is given by Consul Morey as follows: Import from the United States direct was \$39,108 worth of kerosene oil; and the exports to our country were 11,039 tons, valued at \$912,537. The only marked feature in this return is the increase in coconut oil of \$42,543; the total quantity being \$450,000, and largely in excess of any previous year's showing. There was also an

increase of nearly \$70,000 with respect to plumbago, though the quantity shipped was below that of the previous year by 3,000 tons; a circumstance probably indicative of a renewed demand in America for a superior quality of that article. Of the exports to the United States, coconut oil and plumbago amounted to \$825,000, leaving only about \$118,000 for all other articles, the chiefest of which were citronella oil, Arabian coffee and coir yarn. The total trade of Ceylon was as follows: Imports, \$17,391,000; exports, \$13,407,000. Among the imports the following were the principal articles: Cottons, \$2,200,000; rice, \$7,100,000; coal, \$1,622,000; iron and steel goods, glassware, liquors, kerosene, and a variety of general manufactures. While Ceylonese produce reaches this country direct to the value of nearly \$1,000,000 per annum, only American kerosene finds its way to that colony. The fault is undoubtedly largely our own.—*American Exporter*.

CINCHONA CULTIVATION IN BOLIVIA.—The following article from the latest *Chemist and Druggist*, showing what German Colonists are doing in Bolivia in plantations of cinchona, is of interest to Ceylon planters:—

The ruthless destruction of the cinchona forests in Bolivia by the Indians and half-castes, who monopolised the collection and felled the trees, or striped them in so careless a fashion as to well-nigh destroy them, has lately caused the Bolivian Government to resort to the formation of plantations or *quintas*, which are mostly worked by German colonists. During the seven years which have elapsed since the first commencement was made, these plantations have been extended over large tracts of ground in the districts of Guanay, Longa, Yungas, and Mapue, particularly in the latter. The greater part of the plantations are found in the broken and undulating region of the Andes, where they are situated on the mountain sides and along the valleys, at an altitude of 3,300 to 3,900 feet above sea-level, which is found to be as high as it is desirable to cultivate. A single tree yields from 15 to 20 lb. of seed, which is collected in the beginning of the Bolivian summer (November and December). The seed is thickly sown in boxes or in beds of 13 by 3 feet, well watered, and when the young plants have grown to a height of 6 inches, and have developed a few leaves, they are transplanted into pits of 8 to 10 inches depth, and about 6 feet apart. They are lightly covered with twigs and leaves to protect them during the next three months against the sun's rays, the soil around is carefully hoed, and this careful nursing is continued for two years, when they may be considered out of danger; the loss meanwhile averaging frequently as much as 25 per cent. After six years the tree should be about 13 feet high, with a diameter half-way up the trunk of 6 inches. If the bark is of the choicest quality the trunk is straight and resembles that of an orange tree. If the tree is left undisturbed until its eleventh or thirteenth year, it will have attained a diameter of over 12 inches, but its bark, although more close-grained and heavier, is less rich in quinine. The best results are obtained by gathering the bark about the seventh year. The bark is collected by making a transverse incision in the trunk a few inches from the ground, and a second incision 24 inches higher; two vertical incisions, diametrically opposite one another, are then made, and the bark peeled off. When the tree is stripped it is cut down one foot above the ground, and from its base, which has the bark upon it preserved, about twenty fresh shoots sprout up; these are after a while cut off, with the exception of the two or three most vigorous ones, which are allowed to remain. A tree yields on an average about 5 lb. of bark. This bark, spread out in a paved court, dries rapidly in the dry season, but during the rainy season it takes nearly three weeks. As said above it is only a few years since the systematic culture of cinchona bark has become a factor in the resources of Bolivia, and it will be some years more before this cultivated bark will take its position among commercial products.

MARKET RATES FOR OLD AND NEW PRODUCTS.

CEYLON TEAS FROM OLD & YOUNG ESTATES; AND ALLEGED DETERIORATION.

It is news to us that there has been any marked deterioration in the quality of teas from the older estates in Ceylon, well-established marks, so far as we have noticed, fully maintain their position and reputation in the home markets, and the criticisms of London Brokers during the late months have been rather directed to the generality of Ceylon tea and principally under comparatively new marks. In proof of this, we have only to refer to the fact that such teas as those of Looecondura, Blackstone and Galboda have continued to be held up in the Brokers' reports as models of what ought to be followed in the preparation of Ceylon teas. In some cases too of extensive cultivation we know of estates or marks which have rather bettered their average and position—making allowance for the slaker market and fall in prices. A striking instance of this is afforded in the wellknown "K. A. W." teas, because apart from the extensive area of cultivation directly attached to this, the largest Tea Factory in the Island, nowhere else is the leaf of outside plantations so freely purchased, and yet the result so far has been no deterioration, but rather an improvement and strengthening of the good position of the K. A. W. mark. Kadawella Factory, it will be understood, is fully supplied with machinery, with ample withering room, and with an adequate staff in all departments carefully supervised. All this would certainly point to the fact that any falling-off in the quality of teas from other quarters is due to the want of one or other of the requisites we specify: needful machinery, superintendence or care. In one or two cases of known marks where a slight deterioration has been reported, the remark has sometimes been made to us, "Oh, Mr. — is too busy with extraneous and very profitable work to give that attention to the preparation of his own teas which he did in the early days."

But the complaints preferred to us and which we made known about a fortnight ago, arising out of the condition and quality of teas offered at local sales, referred almost entirely to young gardens and new marks. It is possible that the want of a sufficient staff of trained natives for the tea-houses may be the cause of the inadequate preparation which was condemned. To deny superintendents, the help of "tea-men"—coolies who have learned and know something of the work of preparation—would indeed be a penny-wise and pound-foolish policy. In other instances, shortness of labour and the want of machinery (a roller especially) may account for the disappointingly deficient quality of the teas. But making allowance for all the supposed causes, we fear that in some instances at least, nothing but ignorance or downright carelessness can afford a sufficient explanation.

It is suggested that the Planters' Association should enquire into the subject of the "Deterioration of Ceylon Teas;" but apart from the fact that the industry is in too incipient a stage—taking the country as a whole—for any such inquiry, and that the matter is one of peculiar delicacy for any corporate body to deal with (e.g. by circular, "We notice your teas selling below, and your neighbours' above, par: why is this thus?") the business is really one calling for the attention of proprietors, agents of visiting agents and individual

superintendents. A discussion cannot fail to do good by turning attention to the deficiencies—in superintendence, machinery, labour or care—in each case and by promoting a determination to do better and a spirit of emulation among our tea-makers. The way in which Ceylon planters learn from each other and ever cease striving after improvement in their work, is the admiration of all our Indian visitors. Let instruction be made available where required, and do not let us have grasping proprietors neglect the fact that the reputation of their gardens may be ruined at the very outset, through a false economy, or a desire to push their superintendents into tea-making before they have had the requisite training or experience and needful assistance. It is nonsense to suppose that a ring of Colombo buyers and brokers can account for alleged deterioration. As a matter of fact, the testing of teas for the last Colombo sales showed a decided improvement on that for the penultimate series, and the prices at once rose in correspondence therewith. If Ceylon Teas are to maintain their good position and reputation, each proprietor or responsible agent must see to it that his estate superintendent has the qualifications and appliances and labour which are absolutely necessary to enable him to turn out satisfactory parcels of the product to which attention is now almost everywhere so exclusively directed among the Ceylon planters.

THE TEA MARKETS IN BELFAST AND THE NORTH OF IRELAND.

It is wellknown that the Irish in Ulster consume a large quantity of high priced teas, the linen-weavers there especially being credited with living chiefly on strong green teas (up to 1s and 5s a lb.) and potatoes. This adds to the interest felt in a correspondence which has taken place between Mr. Davidson of Sirocco fame and a Belfast tea merchant. Messrs. Davidson & Co., wrote to us as follows by last mail:—

"We enclose a page from *H. & C. Mail* of 12th instant from which you will see that a newspaper war has been waged here between our Mr. Davidson and a local tea retailer, and, as the matter is likely to be very interesting to planters generally, we trust you will see your way to reproduce the correspondence in the *Observer* and *Tropical Agriculturist* as it appears in the *Mail*."

Pressure on our space forbids republication in full but we give such extracts as will enable the controversy to be understood:—

Mr. Davidson, the well-known Sirocco Manufacturer, has done much to popularise Indian tea in Belfast. He commenced by supplying his friends and neighbours with small quantities in a quiet way, and his reputation as a wise man about tea having rapidly spread, he has developed a large business in Indian and Ceylon teas. This seems to have occasioned displeasure to some members of the tea trade in Belfast, one of whom (Mr. Anderson, of North Street) has entered into correspondence with Mr. Davidson in the "Belfast News Letter." In this correspondence Mr. Davidson has decidedly the best of it, as will be seen from the following extract of which we give a first instalment this week and propose to continue as the letters will interest Indian tea planters.

The controversy opened by a manifesto by Mr. Anderson, enlivened with italics, in which he says:—"China, at one time, was the only country from which tea could be obtained; now, tea forms one of the staple products of India, while Japan, Java, and Ceylon furnish their quota of the world's supply. "Tea cul-

tivation has grown prodigiously in India during the last twenty years. A quarter of a century ago the tea plant was almost unknown there; whereas now there are "many hundreds of tea gardens" covering very extensive areas of the richest land in the Northern Provinces of India. These yield about seventy million pounds of tea per annum, nearly all of which finds its way to the London market. First-class tea dealers who have access to the "extensive variety" embraced in this "enormous quantity" are manifestly in a much better position to supply the public than parties confined to the produce of any one particular garden. The soil and climate of India produce very different tea to that of China. China teas possess a sameness and uniformity which strikingly resembles a similar trait in the character of the Chinese people.

"India, on the other hand, produces teas 'bristling with peculiarities,' and wide as the poles assunder in flavour and strength. And, though Indian teas are vastly superior in intrinsic merit to those of China, yet lengthened experience and a critical taste in selecting and blending are indispensably required to produce a 'thoroughly drinkable Indian Tea.'" "To acquire this experience, and to become fully acquainted with the immense variety of teas grown in so many different countries, long years of training and study are requisite. These qualifications are brought to bear on the selection of tea in Belfast in a 'greater degree' than any other place in the United Kingdom. Hence it is that Belfast has obtained a reputation for 'high-class tea' such as is not possessed by any other town or city in the kingdom.

It is well to bear in mind that the vast proportion of tea on the market is of medium to common quality. The "very finest descriptions" form an exceedingly "small portion" of the total supply, and the consequence is that they are eagerly sought after, and "fetch very long prices." It is not an uncommon occurrence for the choice breaks of the best Indian gardens to bring 3s "per pound in public sale" in London. Add to this figure duty, freight, and charges, and the cost to the dealer is raised to 3s 8d. It is quite evident, therefore, that if the "choicest teas are wanted full values" must be paid. The public may rest assured that, no matter what inflated description is given of low priced tea, "none of it" is worth more, to say the least of it, than the price asked. Many of these common teas are "badly cured," the result of "imperfect knowledge" on the part of amateur tea planters of the chemical changes involved in the curing process. Such teas have been largely sold in England and Scotland, and in a lesser degree in Ireland too, "misleading descriptions" and "meaningless terms" being employed by unscrupulous vendors to deceive the public. At a time like the present, when a great deal of worthless trash is offered for sale in Belfast, it is necessary to emphasise the fact that high-class tea is more enjoyable, more wholesome, and more economical than "inferior tea."

To this Mr. Davidson replied with a letter, in which he says:—

"The seventy million pounds of Indian teas imported during the past season brought an average price of about fourteen pence per lb. at the public sales in London, whereas the China teas, of which about 150 million lb. were imported during the same time brought an average of only about tenpence per lb. These prices are, of course, 'in bond,' and subject to the duty of sixpence per lb. extra. Indian teas, therefore, show an intrinsic superiority equal to fourpence per lb. over China teas, and although even the Indian average of fourteen pence seems very low, when considered alongside of the thirty-six pence quotation which Mr. Anderson refers to as a proper price (in bond) for 'high class' tea, nevertheless, Indian planters have to be contented with it for their average in the meantime, and like the farmers in this country here just do their best to hold their concerns together, hoping for better times to come, or for some method of reaching the consumers more directly with their teas. My own experience as a tea planter dates back

to the year 1861. The annual out-turn of tea from India was then only about a tenth of what it now is, and prices were much better. In my own estate I managed to realise an average price for my entire tea crops up to the year 1870 of over 2s per lb in bond in London. Since then the rapidly increasing production of Indian tea has brought down prices tremendously, as shown by the average prices realised for last season's total crop; but the consumer nevertheless has been paying very much the same price as formerly. Perhaps Mr. Anderson would attribute this decrease in price to what he describes in his advertisement as the "imperfect knowledge on the part of amateur tea planters of the chemical changes involved in the curing process."

"The Indian tea planters, as an entire community, are responsible for the manufacture of the seventy million pounds tea crop above referred to, and if 'they' are amateurs, where shall we find the professionals?" "Tea planters, as a rule, are always most anxious to improve their manufacture and increase the quality of their teas, and any light which Mr. Anderson can give of a practical nature concerning 'the chemical changes' involved in the curing process' would be interesting to them, as well as to myself, considering that out of the 70,000,000 lbs. Indian tea last imported into the United Kingdom, about 50,000,000 were dried and cured in the 'Sirocco' drying machines, of which I am the inventor, patentee, and maker. These machines are manufactured at my 'Sirocco' Works here in Belfast, and there are over 1,000 of them already in use, and a very large number on order with me at the present moment. "If Mr. Anderson can impart any special information as regards an improved system of curing tea, whereby his ideal 'high-class' quality at 3s per lb. in bond might be obtained, I have no doubt it would be as gratefully received by my planter friends as by myself."

The following letters are in continuation of the correspondence in the *Belfast News-Letter* and *Ulster Echo* between Mr. Davidson and Mr. Anderson relating to Indian tea. Mr. Davidson writes, March 2nd:—

"My last letter on the above subject appeared in your issue of the 27th ult., in reply to a letter by Mr. Joseph Anderson, of North Street, which he published in the *Belfast News-Letter* of 24th ult.

In the concluding paragraph of my letter I challenged Mr. Anderson to a fair relative comparison and valuation by a London expert of his teas at 3s 8d. and 2s 8d with mine at 2s. per lb. and I have since then been waiting for him to take up the glove; but as no letter or intimation has appeared from him in response (though he has now had more than ample time to reply), nor any attempt been made to disprove my statements or statistics, he evidently declines the challenge. I certainly did observe that the original advertisement, with Mr. Anderson's name attached, and to which my letters referred, appeared again in the *Belfast News-Letter* on the day following the publication of my last letter to that paper; but, in the light, which has been thrown on it by the statistics quoted in my letters, no sane person could accept that advertisement as either a reply to my challenge or a refutation of my statements. "The gist of the entire correspondence, so far as the general public is concerned, might be summed up in the single question 'Can good tea be obtained by the consumer at 2s per lb?' The statistics which I quoted indicated that it can, and I backed up these statistics by selling my own tea at 2s per lb. Whether my tea is good or otherwise, is a matter which the public can easily ascertain, as 'the proof of the pudding is in the eating.' I know it is supposed that sugar is sold at a loss, in order to draw customers for tea, but what is this more than an admission that excessive profits were being levied on tea? Possibly, when compared with the large profits hitherto looked for on tea, the small margin available on sugar may have been reckoned almost as a loss, but any system of business which deliberately contemplates, and arranges for the goods of one of its important departments to be sold at a steady loss, is unsound in principle, and must sooner or later be abandoned."

This drew the following from Mr. Anderson—
 "Now, having found by careful comparison that Mr. Davidson's 2s tea is considerably inferior in liquor to the tea I have been, and am, selling at 2s., I have no hesitation in placing before the public a Tea at 1s 9d which I guarantee fully equal, if not superior, in the cup to Mr. Davidson's 2s tea. I leave the merits of the case with the public who are hereby invited to compare and judge for themselves, and they will thus be in a position to decide whether Mr. Davidson, who is only one of four owners in a small tea garden, can supply the public as well as a tea merchant who has access to the produce of 150,000 acres in India, some 15,000 in Ceylon, in addition to the practically limitless area under tea in the Celestial Empire."

Whereupon Mr. Davidson replies with the subjoined:—

I presume we may accept the letter which Mr. Joseph Anderson publishes in your columns this morning, as his 'statement' that he declines my challenge to have a fair comparative report and valuation by an independent London expert of his teas at 3s 8d and 2s 8d. side by side with my tea at 2s. per lb. I should have been very sorry to think, had my challenge been accepted, that there would have been any probability of the London expert putting both of Mr. Anderson's qualities below mine at 2s. per lb. seeing that I only claim for my 2s tea, that it is value on the London market for 1s 3d. to 1s 4d. plus 6d duty whereas the 'statement' which Mr. Anderson wanted me to 'frankly admit' was that he (Mr. Anderson, of North Street) pays 3s per lb. plus 6d duty and freight for the tea he sells at 3s 8d. In my letter to you, dated February 25th, I stated that the total quantity of Indian and Ceylon teas sold in the public sales in London between July 1st and December 31st, 1885, amounted to about 39,500,000 lb., of which only about 14,000 lb., or 403 per cent., sold at 3s and upwards, and about 30,000 lb. sold at between 2s 9d, and 3s per lb.; and it may possibly be of further interest to the public to know how the Indian and Ceylon teas sold during the past month.

"The average price for the whole 6,000,000 lbs. sold in February is rather under 1s 2d per lb., and, therefore, much the same as the average price of the 39,500,000 lb. sold in the latter half of 1885. Seeing that the February sales show no transactions at over 2s 7d per lb. Where, does Mr. Anderson obtain his supplies at 3s per lb. plus 6d duty? He did not get them at the public sales in London lately, at any rate! and if, in the face of the above facts, he likes to pay 3s plus 6d duty for his 3s 8d quantities to dealers who buy their teas in the London public sales, it merely shows that he is not reaping a proper reward for those 'long years of training and study,' and for the 'lengthened experience and critical taste' to which he so modestly referred in his original advertisement. It also indicates how equally liable to error he is in the opinion he expresses in his letter today concerning my 2s tea, and it justifies the stipulation which accompanied my challenge, to the effect, that the opinion sought concerning the relative values of his 3s 8d and 2s 8d teas and my 2s tea, should be that of 'an independent London expert'—the trial in such case being sure to be conducted in a fair, open, and above-board manner.

Mr. Anderson's reference to myself as being 'only one of four owners in a small tea garden,' will, like his other statements, be nothing the worse of further elucidation by facts and figures. The name of the garden referred to is 'Subong.' It is in Cachar, in the province of Assam, and consists of about 2,000 acres, held from the Government of India. One-half of the estate belongs to me, and the other half to my three partners. There are 100 acres under plant, the variety of which is so superior that the seed from it has been largely purchased, at the very highest market prices, by the Ceylon, as well as the Assam planters, for extending their estates. The total yield of tea from the estate for past season was 121,000 lb., which by arrangement between my partners and myself, all comes forward to me here. Six months ago I did not count on being able to

sell this entire crop direct to consumers, but the demand has increased so rapidly that not only can I now easily dispose of it all, but I have to supplement it by the purchase of teas from other estates, the majority of which I have personally visited. I hope Mr. Anderson, will excuse my thus trespassing for my extra requirements into part of 'the produce of 150,000 acres in India,' and some 15,000 in Ceylon,' to which he seems to claim an exclusive 'access.'

Mr. Anderson, under date March 6th, says:—
 "Referring further to my letter of yesterday, I desire to emphasise the fact that the issue now lies between Mr. Davidson's 2s tea and the teas I offer at 1s 9d and 2s. The public who are interested are invited to compare and judge for themselves."

Upon which Mr. Davidson writes:—"Referring further to my letter of yesterday, I desire to emphasise the fact that the issue now lies between Mr. Davidson's 2s tea and my teas at 1s 9d and 2s." "From this it is evident that Mr. Anderson now thoroughly appreciates how utterly vain it is for him to attempt any longer to pose as the *disinterested champion* of the whole retail tea trade for maintaining 3s 8d prices for tea to consumers in face of the reduced prices at which, as shown by the statistics quoted in my letters, 'high-class teas can now be obtained from the growers.' I had scarcely expected him to 'throw up the sponge so completely in respect of both 3s 8d and 2s 8d qualities as this last letter of his indicates. Mr. Anderson must be very careful not let himself be too easily beguiled by the allurements of low prices offered from 'the *practically limitless* area under tea in the Celestial Empire,' to which he, in his letter of the 4th instant, claims to have such exceptional 'Access,' for I fear a good deal of 'worthless' trash comes forward, from that Flowery Land. I have never visited China, nor do I profess to know much personally about China tea, but Mr. W. H. Chalmers, of 37, Mincing Lane, London, is considered an authority, and in a letter which he addressed to the editor of the *Statist* on January 29th last, in reference to China tea, says—"To the trade who bought common China congo in 1882 and 1883 4d to 5d the present quotation of 6d may seem dear;" and referring to the stocks of China tea held in London, he mentions that on June 30th, 1885, there was a stock in London of 21,350,000 lb. of China congo, valued at from 5d to 6d per lb. He was then remarking, he said, upon 'common to fair' congo; but I understand that the very flavoured and high-class qualities of China cost about 1s 4d to 1s 6d per lb.

It is to be hoped that in Mr. Anderson's 'access' to the produce of the Celestial Empire he will totally avoid the 'common to fair' congo."

Mr. Davidson deserves the thanks of the Tea planters of India and Ceylon.

PLANTING IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

Mr. J. P. Carst, a planter who intends to be the pioneer in growing tobacco in Cotie, left Java for that State about the middle of last month. He is reputed to know all about the country and its Sultan. He is besides fully aware that the soil there is highly suitable for tobacco cultivation in particular, and that the Sultan is greatly in favour of European planting enterprise being started in his dominions. Land for the purpose has already been promised to Mr. C. who feels confident of securing labourers without any difficulty. Life and property there are in his opinion as safe as could be desired, safer no doubt than in Deli or at some places in Java. The Sultan is held to be an enlightened person, friendly to progress, and partial to Europeans. He is not only a member of the order of the Netherlands Lion but is also a freemason. There is every prospect of his taking care that his European friends shall suffer no harm from the natives unless they wilfully bring it on themselves.

The *Surabaya Courant* has received less discouraging advices regarding the root diseases among the cinchona plantations in the Preanger Regencies. It seems to be chiefly confined within limited area comprising estates fewer in number than in other localities to the West and North West. Hence the extent of the evil is not so great as was at first anticipated. The disease has, however manifested itself on isolated spots in other plantations wherever the subsoil is bad and hard or but slightly porous. On such spots, cinchona plants naturally cease to grow up as soon as their roots reach the subsoil, upon which they drag on a lingering existence until at length they succumb for good. Elsewhere in that quarter the estates are thriving notwithstanding the want of rain for many months. The bark exported from Java is increasing in quantity yearly, but is yet barely one-eighth of that shipped from Ceylon. Prices continue falling owing to the supply exceeding the demand without any chance of recovery. The moment any rise does take place, cinchona trees are rooted up in Ceylon and their bark thrown upon the market thereby again bringing quotations down. In that island, confidence in cinchona cultivation is gone owing to the prevalence of canker, and tea growing is rapidly taking its place. So long as there are trees to be uprooted for this purpose over wide areas so long will prices continue low from the market being liable to be overstocked at any moment in consequence. The only encouraging sign is the steady increase in the consumption of quinine, and the discredit into which the substitutes for it have fallen from their inability to ward off fever.

CEYLON UPCOUNTRY PLANTING REPORT.

APPROACHING PLANTING SEASON—TEA PLANTS AND PRICES—TEA SEED—ORABITUDE.

26th April 1886.

As the planting season approaches the interest in tea nurseries becomes intensified. 'How much should we ask a thousand?' is the uppermost thought in the minds of those who are fortunate in having for sale good, strong, well-grown plants. As for the buyers, there are the ardent souls who book early and pay high; but then they are neither disappointed nor worried once they have plunged. Others, however, hang back content to let the over-anxious get satisfied, as they are ever an element to keep a market unsteady, disturbing it always in an upward direction.

For the early S.-W. there are not, I believe, a very large stock of plants to draw from, and prices are at present firm, at high rates. Should the season be a favourable one for planting, it is more than likely that buyers will easily be obtained for all, but the extensive nurseries which have been put in everywhere since December last, are being run up with all expedition, and it does not require one to be a prophet, nor the son of a prophet to foretell that by and bye there will be cheap enough plants to be had, and this more especially for the N. E. Should therefore the rains be delayed, the earlier results of these late sowings will be in the market to compete with those which in the meantime are "masters of the situation." As to present prices, I have heard of one nursery which has been sold at R7-50 per 1,000; another at R8-50; and as for what is asked, R12 per 1,000 is as yet the most sublime point which my information makes me to register. A local firm lately advertising lamps in your columns drew the public attention to the "absurd prices" it was charging. It is on the same principle that I chronicle R12 a thousand for tea plants!

Orders for tea-seed, which were booked at the end of last year or the beginning of this are fast being executed; but new orders are slow in appearing. The crop of seed is good on the whole and the advance of price which obtained when it was scarce, is not now being sustained. The appearance in the advertisement columns of some of the favourite estates having seed for sale, is evidence enough that in the meantime the demand has been satisfied. The feverish haste for seed which was so visible a few months ago, is now transferred to the tea plant, around it are all the heat and excitement, whereas the other is neglected, and has to woo a market, instead of having to be won.

Those who buy Indian seed run a very considerable risk, and this you come to realize the longer you have to do with it. The mixed jät which can be seen in some properties where the seed has been imported is a warning. Such stuff. Plants with leaves like "curly kail" while others are about hard enough for shoe-leather. Of course it is not all like this, but the presence of the better kinds scattered throughout a new clearing is an added sting, as showing what might have been. I should say that those who buy imported Indian seed, except with a guaranteed pedigree, when there is so much of really high-class local seed to be obtained, invite a catastrophe, and merit their fate. I am told that so very particular are some of the Indian tea planters regarding the seed they buy that they will not trust others to gather it for them, but stipulate to be permitted to harvest it themselves, and yet, trusting Ceylon has tons of anything and everything sent into its market, and it is all sold somehow, and gets planted somewhere.

There are some nations said to be utterly devoid of gratitude, but ours is not among the number. There was a canny Scot who had ventured into tea, in whose heart there was a remembrance of favours past, and who had made up his mind to show his sense thereof by sending, as a token, a box of tea. He had a hardworking superintendent whose estimate for expenditure he had pared to the bone, whereas the estimate for crop was inflated far beyond anything reasonable. It was all but hopeless to expect to get it, and yet he proposed to send on the tea in question, as soon as the estimate was realized! His manager got his instructions to do this; meanwhile on the strength of this the proprietor had that pleasurable sense of having done what he could to acknowledge a favour of some moment, and this too at little cost. It was the manager who stopped the current of his gratitude, for the estimate was never obtained.

PEPPERCORN.

"THE TEA GARDEN OF THE WORLD."

MR. JOHN HAMILTON ON THE PROSPECTS FOR YOUNG TEA PLANTERS IN CEYLON.

Mr. John Hamilton of Newton, Dikoya, and lately and at present of a well-known firm of London Produce Brokers, is full of interest in all that appertains to the planting enterprise of Ceylon. The full title of the seasonable brochure which he has just published is as follows:—

The Ceylon tea Industry, an opening for men of moderate Capital. By John Hamilton (*Late of Ceylon*). Price one shilling, March 1886.

And he introduces his 17 pages of closely packed information and advice by the following preface:— I have endeavoured in the following short notice of the Ceylon Tea Industry to convey to people's minds a few of the most material facts connected with the new enterprise, and to explain the opening that exists, and the career that is possible, for men

of moderate capital now going out to Ceylon. It is very difficult to make people, unacquainted with the island and all that is taking place there, understand the great transition necessarily involved in the operation of exchanging one staple for another as the permanent product of the land. Over a very large area in Ceylon, coffee trees are being replaced by tea plants, and as far as human experience can judge, tea promises to be a most brilliant success. The deep depression consequent on the failure of coffee, culminating in the crash of the Oriental Bank seems now to be passing away, renewed hope and confidence engendered by tea prospects is gradually returning and every month the position becomes stronger and stronger. If anything I may have written should clear up doubts remaining in people's minds regarding the future prosperity of the Ceylon Tea Industry, this pamphlet will not have been written in vain.

There is, of course, very little which is not familiar to our local readers, but as indicating the scope of the essay we quote the introductory paragraph with its sensible warning to young men "seeking" employment in Ceylon, adding thereto the headings of the succeeding paragraphs:—

After a prolonged period of intense depression, owing to the partial collapse of its chief staple, the attention of capitalists is again being directed to the island of Ceylon, which now offers an opening to men of capital, energy, and enterprise, such as is seldom met with in a tropical colony. The change which has quite recently come over the fortunes of the island, owing to the development of an industry which promises to be not only a remunerative but a permanent one, is almost unique in the annals of Colonies. No sooner was it proved that tea of excellent quality could be produced in large quantities per acre, anywhere almost where the rainfall was sufficient, from sea level to 6,000 feet altitude, and at a cost which left a handsome profit on the undertaking, than planters and merchants, whose hopes and prospects in many instances had been reduced to the lowest ebb by a succession of heavy losses, commenced to buy seed and plant up their land with tea. Tea, unlike coffee, does not require virgin soil* although it is possible that tea planted in land not previously cleared and cultivated will yield heavily for a longer period without manure than that planted in land previously taken up with coffee and cinchona. There are new districts being opened entirely with tea, yet it is on the estates previously opened with coffee that the greatest and most important development has taken place, and these estates will gradually be replanted entirely with tea. Coffee estates, even in favoured localities, formerly exceedingly profitable, have ceased to pay owing to wet seasons unsuitable for a fruit crop, coupled with an insidious disease in the leaf of the plant, which gradually spread over the whole island. These causes, followed by a heavy fall in the value of the commodity, had rendered whole districts comparatively infertile and unremunerative; yet on these estates a considerable income has been derived during these years of depression from the bark of cinchona trees, thousands of which had been planted about, or in separate clearings, and by their means a period of uncertainty and gloom was tided over, and planters were enabled to cover the expense of planting up their land with tea, portions of which where first planted are now giving good returns from the latter product. I have found it necessary to give these details in order to explain to those unacquainted with the position of affairs in Ceylon my reasons for stating that a good opening once again offers in Ceylon. In these days of keen competition it is a most difficult thing to find any desirable

openings for younger sons—every profession is more than overstocked. Business just now is had everywhere, and it is imperative in many cases for men to seek an outlet for their capital and energy in some colony. In Australia, apparently, to ensure success a man must have not less than £10,000 as a minimum. A man with this amount of capital would probably be enabled to find an opening for himself in the mother land, and would be disinclined, unless of an exceptionally enterprising turn of mind, to expatriate himself to the Antipodes without first trying some occupation requiring such a capital in his own country.

I may as well state, once for all, that there is no opening in a tropical colony for a man without capital. Everyone who goes out to such a colony must go with the intention of investing on his own account sooner or later. He should have not less than £2,500 behind him, and it will be even better if he has from £4,000 to £5,000 of his own. It is by no means necessary that he should have his money in his hand at starting. It were better by far that he should go out and live in the country and look about him for a year or so and learn his work and his way about, and then decide as to what part of the island he intends to invest in. Arrangements could doubtless be made for intending settlers to have a place to go to on arrival, where they may learn their work, and have every opportunity of acquiring a thorough insight into tea planting and the management of coolies. A man going out without capital, although it is possible he might push himself into employment, and may seemingly be getting on and drawing a fair salary, exposes himself to enormous risks such as falling health, without adequate means to supply his needs, loss of employment through no fault of his own, and no possibility of making a future of any use to himself without extraneous aid in the shape of funds.

Then follow sections headed as follows:—
Climate. Government. Tenure of property. Communications. Labour Supply. Soil. Lay of the land. Leaf disease in the coffee plant. Nature of investments. Forest lands. Partially opened forest land. Opened land yielding produce. Uncultivated estates. Mariawattie. Loans on mortgage. Cost of production. Present acreage under cultivation. Yield per acre. Production in the next two years. The future market for Ceylon tea.

Finally Mr. Hamilton winds up:—
There are doubtless many parts of the world where tea could be successfully grown as far as the actual cultivation of the plant and manufacture of the tea is to be considered, yet it is only in countries where a combination of circumstances, amongst which a cheap and ample supply of labour is the first essential, makes it possible. Ceylon, just now, holds a peculiarly favourable position in this respect, as in addition to the combination aforesaid, the materials for a great tea enterprise are to be found ready at hand, owing to the collapse, or rather partial collapse, of its great staple, coffee. People unacquainted with the expense and tedious delay in developing a forest-grown tropical colony, can scarcely realise the important position Ceylon holds for intending colonists, in having its communications fully opened out, and a large supply of trained labour. Moreover, in Ceylon there already exists a highly enlightened, intelligent, enterprising body of industrious men, ready to avail themselves to the utmost of the new industry so fortunately come to their rescue. There are several books, directories, &c., on Ceylon, which the intending settler will be sure to hear of, and which will fill in the outlines. I have roughly drawn in as concise a form as possible, in endeavouring to give a short account of the rising tea industry in Ceylon, possibly destined, ere long, to make this island the tea garden of the world.

BUCHU-PAIBA,

Quick, complete cure, all annoying Kidney, Bladder and Urinary Diseases, Druggists.

W. E. Smith & Co., Madras, Sole Agents.

* This is rather too bare and sweeping an assertion: although undoubtedly a leaf crop is more easily produced in our Ceylon climate from poor soil than one of fruit: still, in the higher districts especially, it will be remembered that most of the land opened for coffee never got the chance owing to the effect of the leaf disease of being exhausted its virgin properties.—ED.

THE ALLEGED FALLING-OFF IN THE QUALITY OF CEYLON TEAS.

There is another way of accounting for the falling-off in quality of some of the Ceylon teas, especially in those cases where quality was preferred to quantity in order to obtain a name for producing high-classed tea.

It is now found, since the heavy decline in the prices of broken pekoes and pekoes, that plucking fine, say, only 300 lb. per acre instead of 500 or 600 lb. does not answer. 600 lb. at an average of 1s 3d. per lb. is better than 300 lb. at an average of 2s per lb. if that was obtained. It appears possible that Ceylon planters will shortly see the wisdom of sorting only into two qualities. Pekoe, in which the broken and orange tips are left, and pekoe something to include all the remainder except dust and red leaf.

CAPT. DONNAN'S INSPECTION OF THE CEYLON PEARL BANKS.

Capt. Donnan, Master Attendant and Inspector of Pearl Fisheries, has just concluded his annual inspection of the pearl banks of the island, —or rather of those which are inspected annually, here being some few banks for which an inspection every two or three years suffices. We are glad to say the results of this year's inspection are eminently satisfactory, and Capt. Donnan is happy to be in a position to report that never before in his experience have the prospects of a large and lucrative pearl fishery been so good. The banks just inspected are those lying off the coast of Arippu and Mannar, extending a distance of about 20 miles at from 1 to 15 miles from the shore. These comprise the Cheval paar, the Motarakam paar, the Periya paar, the Kallatidel paar, the Periya paar kerai, the Kondachchi paar, the Vankali paar, the Nadakkanda paar, and the Anairiluntan paar. It is on the first two of these paars that the oysters are found which usually constitute the fishery, the others as a rule being barren. Two others, however, were this year found to contain very fair quantities of oysters, namely the Periya paar and the Periya paar kerai. Capt. Donnan estimates that on the Cheval and Motarakam paars they are at present no less than three hundred millions of oysters, about 2½ years old. These will be ready for fishing in a couple of years, but the quantity is too great to be all fished in one season—indeed there are as many oysters there as are usually brought up in four fisheries. The only months during which fishing operations can be carried on are March and April, when the wind comes alternately off the land and sea. In the south-west monsoon it is impossible to get the boats out, and so entirely dependent are the divers on the wind and the weather that a change of wind and a breeze from the south-west, even during the calm weather of the north-east monsoon, interrupts all work till it ceases. Capt. Donnan also inspected six banks off the island of Karadover, on three of which young oysters were found. He estimates that there were 30 millions of about 18 months old. As no oysters have been found here before, the fact of there being a large a quantity now there is important. On another bank, which was last fished in the year 1832, about one-and-a-half million of oysters were found of three years old.

These banks will probably provide a profitable fishery for the year 1890. It is anticipated by Capt. Donnan that about half of the quantity of oysters now on the banks may be fished and this will bring a large and welcome addition to the revenues of the colony for the years 1888, 1889 and 1890. There is, however, a difficulty ahead which may seriously affect the success of these fisheries. It unfortunately happens that the Indian Government fishery on the Tuticorin banks will take place at precisely the same time as the Ceylon fishery. Now there are not sufficient divers to successfully carry on two fisheries together and the obvious consequence is that both must suffer. In Ceylon there are no divers, they all come over from Southern India whenever there is a fishery and it is a question whether they will not rather remain at home and take part in the fishery on their own coasts than come over to Ceylon—though it is extremely probable that the better reputation of Ceylon pearls and the good treatment the divers experience under Captain Donnan may induce them to forsake India for Ceylon. In addition to this there is the certainty that if the two fisheries take place together the prices realized for the oysters will be lower than they otherwise would. We understand that Captain Donnan has been in communication with Captain Phipps, Inspector of Pearl Fisheries to the Indian Government, with a view to arrange for the fisheries taking place at different dates. Captain Phipps, however, does not think it can be avoided as he also is dependent on the same conditions of wind and weather as control operations on the Ceylon coast, and his fishing can only be done in the months of March and April. A suggestion was made that the Arabs from the Persian Gulf should be engaged to do the work if sufficient local divers could not be got, and we believe correspondence passed between the Government of Ceylon and the British Resident at the Persian Gulf on the subject, as a result of which it was ascertained that any number of Arabs would be willing to come. But the grave objection to the adoption of this course is the wild and lawless nature of the Arabs of that region. Capt. Donnan sees that great difficulty would arise in the control of them, indeed it would probably require a British gunboat to keep them in order! However as the fishery cannot take place for two years, there is time to satisfactorily grapple with the difficulties which present themselves, and we confidently look forward to valuable fisheries in the three last years of this decade.

FUEL FOR TEA ESTATES.

(From the "Ceylon Advertiser.")

The difficulty of obtaining fuel for the manufacture of Tea, though perhaps exaggerated by some, is not a question of the future only. It is already of serious importance to many, and will increase yearly as Tea comes into bearing. Neither in the Kalutara district, nor in the Kelani Valley is there likely to be any difficulty in obtaining fuel for a long time to come, and where there is abundance of wood, no better fuel can be got either prepared as Charcoal or in billets, being less likely to burn out the fire bars or plates of the Sirocco than either Coke or Coal, and where wood can be procured at say 1l per cubic yard weighing 5 cwt., it is cheaper than any fuel which can be used in Ceylon. The Tea Planter's difficulty, however, will be the uncertainty of the supply and difficulty of transfer. At present the Ceylon Government Railway pay to the Forestry Department 11-37 cents per cubic yard for selected wood. This wood, I believe, weighs about 600 lb. to the cubic

yard. Selected lowcountry timber, however, is much heavier than the ordinary forest growth of the hills. An acre of ordinary hill forest will not probably turn out more than from 200 to 250, say 225, cubic yards to the acre, of wood fit for fuel, or 126,000 lb. Allowing 2 lb. of wood for every lb. of Tea cured, it will take an acre of forest annually for every 63,000 lb. made Tea. Given an estate of 300 acres, yielding 400 lb. Tea per acre, it will take practically 2 acres of forest every year to cure the Tea. To supply an ordinary estate of 300 acres yielding what is now the recognised average yield of Ceylon Tea, viz., 400 lb., it will be necessary to keep replanting quick-growing trees every year. The value or heating power of the fuel will vary much, and differ much in weight, according to the timber planted or growing naturally on the land, and the cost of cutting and carriage will also vary with the conditions of each estate, but on no estate where timber is available should fuel cost more than R1 per cubic yard of say 600 lb., which should cure half its weight in Tea, giving one-third of a cent of a Rupee per lb. as the cost of fuel, but to this must be added the value of the land held in reserve. Fifty acres of forest held in reserve means the loss of a crop of 20,000 lb. tea were it in cultivation. Coal is at present the only substitute for wood, and at the current price of coal in Colombo, a ton of coal will cost from R30 to R40 per ton on the estate, according to the station at which it is delivered, and the carriage to estate added, the value of coal compared to wood is as three of wood to one of coal, which will give the following results:—

4 Yds. wood = 1 Ton weight.
12 " " = 1 Ton of coal as is 3 to 1.

A ton of coal will cost R35 to R40, or in other words three times as much as wood, or practically the cost of coal is one cent per lb. of tea against one-third of a cent for wood. Railway rates for transport of fuel must be lowered for coal, and patent compressed fuel will doubtless be delivered in Colombo at greatly reduced rates; but the great difficulty still remains—how are we to get fuel to stores situated in inaccessible* places? Coal is costly and difficult of transport; coke is much more costly and the most destructive to fire bars and heating plates of the dryer of any fuel which can be used. Wood, where it can be got in abundance, is the cheapest of all fuel, and the easiest managed by an ordinary cooly, but the cost of reserve forest lying idle, especially on small estates, is a very serious matter. There are few large estates, however, where quick-growing timber may not be planted in ravines, on ridges or on broken land or poor patana. Planted timber will give at 5 or 6 years old nearly as much fuel from the thinnings as an acre of ordinary natural forest. Planted timber is regular and close, and having no trash or soft stuff or "Mousa" in it, all is available. A natural forest, when the underwood is taken out, is often little better than a scrub with hardly a dozen trees to the acre. The first thing for a tea planter to do is to plant every piece of waste land with quick-growing trees. The cleaning up of old timber on the estate will probably last till the planted trees are fit to utilize. These trees, if not used for fuel, can be used for tea chests made on the estate, far superior to any imported boxes we have had yet.

"But to the point"—the fuel of the future is undoubtedly petroleum, crude petroleum from Upper Burma, or from the Black Sea should Burma not settle down as soon as we should wish. Petroleum is a natural product of the earth, the origin of which is not yet fully understood, but it is found to be much more abundant and more generally distributed than supposed. Fresh discoveries are constantly being made, and the uses to which petroleum is now applied are every day increasing. At the works in connection with the new bridge over the River Forth the most wonderful development of modern Engineering, crude petro-

leum is used for heating huge masses of iron,* with the result that there is not only a large saving in cost of fuel, but the heat is thoroughly under control, and so equally diffused over the entire surface of the steel, that there is no burning of the plates or unequal heating of the surface. Now, this is exactly what we want in our tea drying machinery. All our tea dryers in use rapidly wear out, and are not only costly to repair, but as in the T Sirocco the whole machine has to be taken to pieces to replace the burned plates. This is troublesome and involves stoppage of work in the factory. Messrs. Davies & Co. have the model of a T Sirocco on their premises fitted for burning gas. This, of course, is useless on our estates, but a similar arrangement adapted for the use of petroleum is what is wanted. Petroleum in drums or casks is cheap and easy of transport. Place the oil in tanks some distance from the factory, so that there would be no danger from fire or explosion. The great advantages to be gained by using petroleum are a saving in first cost of fuel; the petroleum being in light drums or packages is easy of transport; heat under perfect control; lighted or extinguished in a moment; and great saving in the wear or burning out of the plates of the machine; perfect cleanliness; and if properly arranged, no smoke, and almost entire immunity from risk or fire.†

I would ask that the manufacturers of the T Sirocco, Messrs. Davidson & Co of Belfast, give special attention to this matter of fuel. It is a serious one in many districts. The writer of this article has seen in America not only crude petroleum used in the boiler of an engine, but the natural gas given off from the wells. We must in Ceylon at once utilise the natural resources of Upper Burma, and assist in the development of that great country.

In connection with the question of fuel on a tea estate, as important almost is the question of "power" for machinery. No tea planter can produce cheap and good tea unless he has good machinery and "power" to drive. The estates which have the best machinery will lead the way. No machinery will do its work efficiently unless under "control" and any tea roller, no matter whose roller it be to do good and fast work must be driven at a good rate of speed; and that speed to do good work must be continuous and equal, but under perfect control. All rollers, like Frater's, Barber's and Thomson's, should be driven at a high rate of speed, and I would warn every tea planter to be most careful in the selection of the site for his buildings. Get water power if possible—carry your leaf any distance to get water power. A steam engine is unquestionably and undoubtedly the most perfect machine power we have, and far preferable to the most modern invention in turbines; but a ten horse-power engine will consume five cwt. coal in a working day of eight or nine hours, which means an annual expenditure of R3,000 for coal, or its equivalent in wood if it be got on the estate R1000. Every Tea Planter must take seriously into consideration the question of fuel in connection with the certain fall in prices of Tea. On many estates, it will simply mean the difference between a profit and a serious loss.

JAMES IRVINE.

THE BULKING OF INDIAN TEA.—It is claimed for Ceylon, and is admitted by the London brokers, that sorting in Ceylon is much more even than in India.—*Indian Tea Gazette*.

CEYLON TEAS.—The Trade Organ, the *Product Market Review*, speaking of Ceylon teas, says that the active demand for them is proof of their increasing popularity; that they are largely characterized by great strength and fine flavour, without the astringency of most Indian teas; and can thus not only be used for mixing with other kinds, but can be consumed unmixed.—*Indian Tea Gazette*.

* We inserted a full account of the experiment.—Ed.

† Surely this is too sanguine a statement?—Ed.

* Mr. Irvine must have come closely in contact with the Irish who have made their way to the "inaccessible" portions of Canada.—Ed.

TEA DETERIORATION.—I am at present inclined to think coarse plucking and insufficient supervision are the chief causes. Tea making can't be done by coolies the same as coffee curing was: it must be personally supervised.—*Planter.*

POTATOES.—The market is quiet stocked with potatoes. They are from Bombay and cannot be kept long. I wish some enterprising person would think of getting potatoes from Nuwara Eliya. Even at a little extra cost the mealy fresh potatoe is better than the leather-like stuff which our cooks serve a table as English potatoes.—*Cor. "Ceylon Patriot."*

DR. FORSTER, of Amsterdam, contributes an article on "How shall Physicians Cleanse their Hands," to the *Central für Klin. Medicin*, and has, after a series of careful experiments, come to a conclusion that a solution of carbolic acid of the strength of two and a-half per cent, was not capable of "sterilising" the fingers after visiting infectious patients, but that a solution of corrosive sublimate of the strength one in two thousand formed a reliable antiseptic wash.—*Burgoyne Burdidge's*, Feb. 1886 Price List.

CINCHONA CULTIVATION IN CEYLON.—Perhaps the most successful piece of Cinchona cultivation in Ceylon of its age and extent is found in a well-known plantation in the neighbourhood of Nuwara Eliya, and some particulars we have learned of the same may be of interest. The area under cinchona is about 90 acres, trees 5 to 7 years of age about 3,000 trees to the acre. Since 1878 there has been gathered about 105,000 lb. of good bark and 72,000 lb. of branch and dust. The total outlay is probably not over 70,000 rupees, so with much of the good bark selling up to 2s. a lb. and the branch and inferior for a good few cents locally, it may be judged that the investment is a very profitable one, more particularly since the estate still looks with perhaps 250,000 trees, as if it had never been cropped, and it cannot be worth less as it stands than £10,000 sterling. The great success of this plantation is, however, specially exceptional, standing out in bold relief to many disappointments.

CASTOR OIL.—A correspondent writes:—"Per today's post I forward to your address a small bottle of castor oil made by myself on this estate. I shall feel it kind if you would inform me at your convenience as to its qualities and if there would be a market for it." The packet reached us before the letter, the bottle broken as it was packed only in a paper box. We could not make out what the clear odourless oil was until we read the letter. Such oil would be valuable as a medicine; the cake is one of the best manures; and in India castor oil is the great lighting material, the railways in Northern India having factories of their own. Castor oil and castor pounce will always find a market, but oil-yielding seeds try a soil very much, and we fear Ceylon could not compete with India in the cultivation of the castor oil plant. Our correspondent might send a specimen of the oil, properly packed in a wooden box to one of the Colombo Chemists, in order to ascertain the real value.

DETERIORATION OF OUR TEAS.—We fear there cannot be much further doubt as to the recent falling-off in our teas, in face of the continued complaints of the London brokers—and it is now a question of finding out the real cause of the mischief, and a remedy for its removal. A well-known tea planter in the course of a private letter to us, says:—"This all humming about old soil being worn out. I have tea in its twelfth year giving more per acre than ever it did, and tea of a better quality. All through this season I have had better prices for my teas than last year, but when a Broken Pekoe, which is finer than last year at the same time,

fetches only 1s 2d as against 1s 11d, what can be done—put it down to falling off in manufacture? If the broker values these lower than what they sold at, it shows he goes by the *rating rates*; if he values near what they sold at, then he will fairly give an opinion, and it will show that such a price can be got even at the present time. I have a doubt as to whether the tea-taster is in the habit of giving an unbiased opinion, and not merely judging a tea by what it is selling for at home. That is, supposing 1s 2d to 1s 3d be the price being paid for Pekoes in London and he gets a tea worth 1s 8d whether he will judge it worth that or only go 1d to 1d on what is being paid at home? I see a man now writes to say that the assistant is sent to look after the plucking, hence the falling-off. As tea is pruned from July to November on some gardens, the teas, being made between September and December, in fact until the end of January, will always drop down in price, unless the estate is a small one and the pruning done in a month. Now, it takes me from July till December to prune my estate, so I must always keep throwing a poor tea on the market for some months, mixed with the strongest tea of unpruned bushes."—*Local "Times."*

CITRON.—In recent consular reports appear interesting accounts of this well-known ingredient of plum puddings and wedding cakes. Leghorn citron is what it is usually termed, but little or none of the article is grown there, Sicily and Corsica furnishing the supply of the new fruit. The citron tree is of the citrus variety, and is as near like lemon as it can well be. It is propagated principally from cuttings, and flourishes near the sea in sheltered positions and in warm and sandy soil. The tree resembles somewhat an overgrown bush, and as the citrons often weigh from six to eight pounds each, the branches of the tree must be supported by props. The trees are subject to peculiar constitutional diseases which kill without mercy. As the profit of the grower depends largely upon his favorable situation, etc., it is hard to make even a rough estimate of the business. Supposing the trees to be planted three yards apart, and allowing fourteen citrons to each shrub, the average weight of the fruit per acre would be 9,345 pounds. The price of this fruit in Leghorn is about six cents per pound, but from this must be deducted cost of casks in which fruit is shipped, \$3; cost of cutting and packing the fruit, \$2 per cask; general expenses of citron farm estimated at \$68 per acre. The Corsican or Sicilian grower packs the fruit cut in halves, in casks with brine and ships to Leghorn, where are nine factories for candying citron, employing three hundred men. On arrival there in these casks the fruit looks like huge lemons with tremendously thick rinds and little substance inside. They remain in pickle some thirty days, and are tough and bitter. They are then boiled in fresh water till soft, cut into quarters, and all seeds carefully removed. They are then placed in jars with hot syrup, and for about three weeks the proportion of syrup is constantly increased until no more sugar can be absorbed. The proportion is 80 per cent of sugar to 100 per cent of fruit. The quarters are then placed on wire netting to dry, and when ready are packed in the small wooden boxes so familiar to us. Citron in shorb may be described roughly as the thick peel of a species of lemon, pickled to extract its bitter flavor and absorb the oil, boiled to make it tender, and saturated with sugar to make it palatable. As with other articles of commerce, so it is claimed that the prices of citron are largely regulated by speculation, varying from nineteen cents to twelve cents per pound at Leghorn. A curious fact is that more citron is imported into Italy than exported from it, the proportion for the last three years being as ten to one. The soil of Cuba is eminently adapted for the citron shrub, but few trees are, however, grown there, everything being abandoned for the staple crop—sugar cane. It seems so hard for communities to learn the lesson of diversified crops; all sugar cane, all cotton, or all wheat apparently must be expected. Cuba, Mexico and California offer advantages in the culture of citrus fruits, and are only awaiting enterprise to develop these profitable pursuits.—*Grocer American.*

AMERICAN OIL OF PEPPERMINT AND MENTHOL.*

At a recent meeting of the Philadelphia College of Pharmacy, Mr. A. M. Todd, who is largely engaged in the manufacture of oil of peppermint and menthol in Michigan, mentioned, in response to an invitation, some of the results of his experience.

Mr. Todd said that the process for the distillation of oil of peppermint in use in the United States, and which has entirely superseded the old process, was introduced about twenty-five years ago, and consists of using wooden vessels, steam being driven through the herb placed on false bottoms. The vessels are of such capacity that fifty tons of herb per diem of twenty-four hours can be worked off.

When the fresh herb is distilled, it requires generally an hour to obtain all the oil; but if it has been partially dried, thirty minutes will suffice to accomplish the purpose. Formerly it was the common practice, to allow the water of the distillate to run to waste, and this occasioned an enormous loss of oil; now, after the oil has been collected from the distillate, this is again used to steam through the herb, and as it is already charged with all the oil it will hold in solution, it effects a great saving in the process. The condensation is effected by passing the distillate which is drawn off from the body of the still through a five inch pipe into a number of copper pipes, tinned inside, and these are connected with block tin worms, 2 inches in diameter and 100 feet long, connected with the receivers. The first portions of the distillate are more limpid than those which are drawn off afterward, and the last portion is more resinous and bitter.

To obtain the menthol, the vessel, which Mr. Todd calls the container, has an inner vessel for the purpose of refrigerating the oil, and is surrounded also with a wooden refrigerating vessel. In the container is a valve above the bottom from which to draw off the uncoagulated oil. The oil will, in rare instances, furnish crystals without artificial cold, but generally a mixture of ice and salt is used for refrigeration, by which a temperature of -8° F. is obtained. However, some specimens of oil from certain localities congeal at 24° F. this being about the highest temperature at which the natural oil from true peppermint has been observed to crystallize. The mass of crystals at first more resemble paraffin than regular crystals but if care is taken to remove the fluid portion while a low temperature is maintained, the crystalline formation is more distinct, and will remain solid at about 110° F. The crystals formed toward the close of the process are harder and firmer. The commercial crystals are finer and still have some of the oil adherent, but the pure and perfect crystals are more free from oily matter. When the oil is reduced to zero, the yield of menthol crystals is about 20 per cent. of the oil subjected to the process, but varies, and, strange as it may seem, the specific gravity of the oil has changed but one one-thousandth from its original density. So far as observation has gone no difference in therapeutic value or power has been noticed between the crystals and the liquid portion of the oil, when a pure oil is compared with it. As a rule, the oils produced in Michigan are of good quality, the farmer being careful of the character of the crop; some lots of oil have been observed containing as much as 40 per cent. of alcohol. The first portion of the distillate obtained in rectification is odorous, and at -5° F. yields no menthol, while the last portion is extremely odorous and is also destitute of menthol, but the temperature at which the separate fractions boil has not been tabulated. In fractionating 400 lb of pure, natural oil of 915° specific gravity in twenty pound fractions, extremely interesting results were obtained as to the variations in specific gravity, but not having his memoranda at hand, Mr. Todd could not state the changes with sufficient exactness. The first fraction was obtained in about thirty minutes, the last required six hours.

Professor Maisch inquired whether the first or inodorous portion was as useful as the middle or aromatic portion, which one would seem to regard as more desirable.

Mr. Todd replied that he had never investigated the therapeutic action of the first or light portion separately, yet he did not consider it as valuable by itself for all the purposes for which the united fractions were useful, though it might contain some distinct and valuable properties peculiar to itself. He had recently undertaken the study of these fractions in their physical aspect, and it would also be interesting to determine their therapeutic relations. The true characteristics of pure essential oils seem not to have been determined and laid down in the books with sufficient exactness, and their study affords a field for the most fruitful research.

Pharmaceutical Journal.

SANDAL WOOD.*

BY WILLIAM KIRKBY, F.R.M.S.,

The true sandal wood tree is a native of the mountainous parts of India; but is found more especially in the Mysore and Coimbatore, extending northwards into Cauara. It likewise grows on the Coromandel Coast, in Madura, Assam, and Cochin China (?). As a garden plant it appears as far north as Saharunpore. The same tree (or a variety) is met with in several islands of the Eastern Archipelago, namely eastern Java, Sumba, Timor, and probably others. In India the natural habitat of the tree is said to have been reduced by cultivation,† and it is now raised, principally from seed, in Government plantations in the Madras presidency and the Mysore.

Sandal wood is yielded by other plants of the *Santalaceae*. In the Fiji Islands it is obtained from *S. Tasi*, Seem. *S. Sppularium*, A. Gray, and *S. Freycinetianum*, Gaud., furnish a supply in the Sandwich Islands; in New Caledonia *S. Austro-Caledonicum*, Vieill.; in Western Australia *Fusanus speciosus*, Br. (*S. spicatum*, DC., and *S. cygnorum*, Miq.); in Tahiti *S. insulare*, Betero. An inferior kind has been met with in the Percy Isles, Repulse Bay, Cape Upstart, and the Palm Islands; it is the wood of *Erocrisus latifolia*, R. Br.‡ The wood of *Plumeria alba*, belonging to the *Apocynaceae*, is sometimes substituted for sandal wood. Balfour also states that a white sandal wood, called Lava or Lawa, is imported from Zanzibar into Bombay.§

When the sandal wood trees have reached perfection, which they do in from twenty to thirty years, having then a diameter of from 9 to 12 inches just above the root, at the end of the year they are either cut down or dug up, if the former the roots are generally dug up afterwards. Worthless branches are removed, as is also the bark if the work is done properly, and the trunk is buried for six or eight weeks, sometimes left lying on the ground, in order that the white ants may eat off the inodorous sap-wood. It is then taken up and sent to the depots where it is sorted into three kinds. Concerning the sorting, Buchanan¶ says:—"The deeper the colour the higher the perfume, hence the merchants sometimes divide sandal wood into red, yellow and white; but these are only different shades of the same colour, and do not arise from any difference of species." He distinctly implies that the three kinds are derived from the heart wood. To the same effect is the following statement by Udoy Chand Dutt,|| when writing of white and yellow sandal wood:—"These varieties are founded on the difference in depth of colour of the heart wood." From this it appears that the statement which has been made by some writers, that white sandal wood is the sap wood of *S. album*, is, to say the least,

* Paper read before the Sheffield Pharmaceutical and Chemical Society, February 16.

* From the *American Journal of Pharmacy*, March.

somewhat misleading. The sap wood is, nevertheless, found in commerce, for Balfour* describes it as "coated with thick compact bark, has a grey and brownish epidermis, it is nearly odorous, and has a slightly bitter taste." As the white is doubtless a lighter shade of the yellow, so is the red (apart from that obtained from *Pterocarpus santalinus*, which is truly red) a deeper shade. The red kind was not recognized in Sanskrit medical works, the only kinds mentioned being *srikhandā*, or white sandal wood, and *pitachandana* or yellow sandal wood. When the wood has reached the depôts it is cut into billets from 2 to 4 feet long. In cutting down the trees the earth is removed from about the root so that the collectors may cut as low as possible. The billet taken from the trunk immediately above the root is called the root-billet and is of superior quality.

The tree grows freely in hedges and gardens, and in a rich soil attains its full size; but in such localities the timber is of little value and has scarcely any smell. Soil and elevation have great influence on the amount of oil produced. It thrives up to an elevation of 4,000 feet, and yields the largest quantity of oil when grown in dry, sunny, rocky, mountainous districts, although it does not reach its full height. It is rarely found in forests. As has been previously stated it is now grown in Government plantations from seed; but it also springs from roots which have been left in the ground.

Sandal wood.—Sanskrit, *chandana*, *srikhandā*. Vernacular—Bengali, *chandān*; Hindi, *safed chandan*. The wood and essential oil have been esteemed for the last 2000 years by the Hindus. The straight pieces of heart wood are much valued for carving boxes, desks, and other useful and ornamental articles. Rich natives use the wood for burning their dead relatives, and all classes add at least one piece to the funeral pile. In powder the Brahmins mix it with the pigments they use for making their caste marks. As a medicine it is considered by them as bitter, cooling and astringent. Reduced to powder it is taken in cocoa-nut water, and an emulsion is used to anoint the body with after bathing. It is also burned to perfume temples and dwellings.

Sandal wood is imported into this country in logs from 3 to 4 feet long, and, from 3 to 8 (rarely 14) inches in diameter. That the alburnum is imported is very doubtful, as I have not found any mention of its presence here. The duramen is very heavy, somewhat hard to cut transversely, but easily cleft. In colour it is yellow, fawn-coloured, or reddish-brown. It has a very strong, persistent, agreeable odour. The taste is aromatic. "Three sorts are recognized in the commercial houses of China, namely, *South Sea Island*, *Timor* and *Malabar*"; the last fetches from three to four times as high a price as either of the others."†—*Pharmaceutical Journal*.

POTATO CULTURE.

SELECTION OF GROUND.

Success in potato culture is attainable not only in different climes, but also in a very great variety of soils. Under otherwise favourable conditions, the tuber will grow as well in clear sand as in stiff clay. The happy medium is generally the best.

A thin layer of fertile surface-soil, resting upon a clay sub-soil, which is impervious to water, should never be used for potatoes, not even if thoroughly underdrained. The tubers are more apt to rot in heavy, sticky soils, particularly in a wet season, than on light sandy or gravelly ones.

It is a very common practice with farmers to plant potatoes on clover sod, plowed in the spring. This selection is a good one, provided, however, that as in the case of young and rank-growing clover, the sod is such as to admit of thorough pulverization, or that the field can be plowed early enough during the summer or fall previous to give ample time for the sward to rot

and thus make cross-plowing practicable. Otherwise, when the clover-field is old and the roots of grasses and weeds are woven into a tough, thick sward, which cannot be easily broken and pulverized, it would be advisable to have a crop of wheat, rye, oats, or corn precede the potato crop.

An admirable selection.—For early sorts—clay loam, very rich. For late sorts—Sandy or gravelly loam, of medium fertility. Naturally drained, loose and mellow clover-sod, or stubble after stiff sod is the best imaginable condition or state of cultivation in either case.

MANURE AND ITS APPLICATION—FEED THE LAND AND THE LAND WILL FEED YOU.

Coarse, unfermented stable dung is nearly worthless for the potato crop, unless as a much on very porous and dry soil. Thoroughly rotted compost in moderate quantities is a good fertilizer for tall-growing varieties, while low-growing (early) sorts are greatly benefited by more liberal applications.

The clover on the pasture lot or meadow selected for a potato field should not be grazed or cut very late in the fall. We could hardly wish for a better fertilizer than a good growth of clover, covered during the fall with a coat of fine old manure or barn-yard scrapings lighter or heavier—according to variety to be planted—and, if possible, applied with a Kemp manure-spreader or, at least, evenly and finely distributed by means of harrow or otherwise.

For stubble ground, fall manuring can be recommended only on condition that the manure is harrowed or cultivated into the soil and thus left until spring.

On land manured the year previous, potatoes will do well without additional fertilizing, still the application of wood ashes or lime often increase the yield. Newly applied stable manure seems to attract the wire-worms, and therefore has the tendency to produce scab in the tubers. Coarse manure is a frequent cause of prongs, protuberances, "fingers and toes."

Commercial fertilizers meet with no objections of this kind. The fairest, smoothest and best shaped tubers are generally grown on well pulverized soils which were fertilized with chemical manures, or not at all the same season. In recommending such fertilizers, we enter debatable ground. While we have never failed to see good results from the application of phosphates, etc., whenever we tried them on potatoes or other crops, there are many cases on record, as reported by different farmers, where even complete fertilizers—those containing ammonia, phosphoric acid and potash—utterly refused to respond. Still we believe that the fault is with the man often rather than with the material. Commercial manures and chemicals give us one great advantage. Of the three most important elements, ammonia, phosphoric acid and potash, the soil may contain a sufficiency of one or two. If we know, from previous experiments, which these elements are, it will be only necessary to supply the one that is lacking. Thus, our own soils were always deficient in phosphoric acid, and therefore greatly benefited by its application, next by that of potash, but not noticeably by ammonia. On other soils ashes, or some other forms of potash, either alone or in combination with phosphoric acid, or ammonia, will greatly increase the yield.

If previous experiments have not been made to determine the relative proportion of these elements in the soil, complete manure like Mapes' or Stockbridge (Bowker) special potato fertilizers, Powell's potato producer, etc., which contain the three ingredients in about the right proportion for the crop, can be relied on with safety. From 600 to 800 pounds to an acre should be applied broadcast, just before planting, and deeply harrowed into the soil, or in drills, about an inch or two above the seed and covered by a few inches of soil. The well-known English experimenter, Sir J. B. Lawes, of Rothamstead, used 300 pounds of sulphate of potash (130 pounds actual potash), 350 pounds superphosphate of lime, 550 pounds of nitrate of soda, to produce a crop of 400 bushels. This means almost a mere manufacturing of the crop out of chemicals, without ceasing on the soil for assistance (as to the supply of raw material); and such manufacturing might be carried on year after year on the same land.

* *Op. cit.*

† Emeric and Hanbury, 'Pharmacographia' (1874), 543.

The cost of raw material would be about as follows:

300 pounds of sulphate of potash at 2½ cents, ..	\$7.50
350 pounds superphosphate at 3½ cents, ..	12.25
540 pounds nitrate of soda at 3 cents, ..	16.20

Total \$35.95

Expensive as this manuring appears to be, we could well afford it, if thereby we make sure of a crop of 400 bushels.

Where unleached wood-ashes are obtainable at little cost, they may take place of sulphate of potash, and perhaps show better results at less expense. The cheapest source of phosphoric acid for potatoes, probably, is dissolved South Carolina Rock, containing about 27 to 30 per cent. of bone phosphate, and costing \$16 per ton.

Nitrate of soda is an awkward thing to handle, on account of its great solubility, and dear also. However, it has this one great advantage; that there is no need of applying it sooner than the growing vines show the lack of it. Never apply it in the fall.

A rank growth of clover or of clover roots, turned under, supplies all the ammonia needed, and is generally the cheapest form in which ammonia can be obtained. This manurial substance plays a very important part in giving thrift and luxuriance to the foliage, and while large tops, *in themselves*, are not our object, we can hardly hope to reap a large crop of tubers without their assistance.

The supply of ammonia, especially if scarce, should be supplemented, reinforced, as it were, by the application of potato pulp represented in a *sufficiency* of seed.—*Southern Planter*.

TEA: PAST AND PRESENT.

The ancient Chinese legend relating to the origin of the tea plant tells us that the first tea-bush sprang up from the spot where Confucius has thrown his eyelids, which he had cut off in anger because sleep had overtaken him when he had vowed to keep awake. Humanity owes an enormous, an incalculable, debt of gratitude to those eyelids, and one which is acknowledged by young and old, rich and poor, statesman and pauper, duchess and dairymaid. Many of us would be but poor creatures without our tea. Were we deprived of that wonderful little leaf what could we fall back upon as a substitute? Coffee is the next best beverage, but coffee in some temperaments induces sleep. Without tea the weary watcher by the sick-bed would find her task a doubly heavy one. Without it, the brainworker would be still more heavily handicapped than he already is in a "world of dreary noises." How many examinations would have been "missed" but for the refreshing and stimulating properties of the fragrant evergreen; how many chances lost; how much work ill-done! Have not the poets sung of tea, in lines too often quoted to bear repetition? Could we but trace the inspiration to its source, we should probably find that their happiest phrases, their most neatly turned couplets, are due to the magic infusion. Do we not all, thinkers, toilers, idlers, fly to a cup of tea when we want to make any unusual exertion, intellectual, physical, or merely frivolous? And yet the curious point is that out of the millions who use this valuable beverage and acknowledge its mighty influence, but a small proportion understand how to prepare it, while many abuse the gift by indulging in it too freely, or by drinking it under conditions that not only deprive it of its value, but render it absolutely harmful. The toughest constitution in the world cannot fail to be eventually injured by constantly imbibing tea that has been overdrawn. Yet this latter is the usual condition in which it is partaken. The water in which the leaf is infused should not be allowed to boil for more than a minute before being poured upon the tea. With every moment beyond that time the peculiar property of boiling water that acts upon the fragrant leaf evaporates more and more, and eventually disappears. It seems a simple thing enough to "make the tea," and there are

many who even allow children and servants to perform that important office for them. The true disciple of the teapot treats the art with more respect. He has studied it from every point of view, and in every stage of the process. The idiosyncrasy of kettle and teapot is to him a matter of importance. Both must be immaculately clean and of a shining radiance. He knows that the little brown earthenware teapot, despised of the aesthetic of the earth because comfortably easy to live up to, is the very flower of teapots for his purpose. It becomes thoroughly impregnated with the flavour and redolent of the aroma of the plant. A silver teapot is next best, but there is a natural hesitation about exposing the precious metal to the fire, which militates against its usefulness in this regard. For heat is one of the great essentials in making a "good cup." It is more important than the novice might imagine to have the teapot made thoroughly hot before the tea is put into it. The connoisseur will half fill it with hot water, put on the lid, and set it by the fire until only the handle can be touched with impunity from heat. After this has been carefully attended to, good tea can be produced from a less quantity of the leaf than if the thorough heating of the receptacle had been neglected. Opinion is divided as to the precise number of minutes which should be devoted to the process of "drawing." Some authorities say five minutes, others seven. A few even go so far as to recommend ten. It is, however, a matter that depends in great measure on the quality of the tea, and even more upon that of the water. Only experience can afford a safe guide. The slightest taste of bitterness may be accepted as a sure indication of over-drawing, a condition that renders tea alike hurtful to the nerves and to the digestive organs. Cosies are dangerous, if occasionally ornamental, articles. Their mission is misunderstood. Originally intended to keep the teapot hot during the process of drawing, they have been utilized for maintaining the temperature during the greater part of an afternoon. The facilities they offer are but temptations to avoid the trouble of making fresh tea for every fresh set of callers, and the wise man and prudent woman will do well to beware of the tea that comes from under a cosy. It is almost certain to be overdrawn.

Indian tea is being imported in larger quantities every year. In 1871 the average monthly consumption of Chinese tea in England was a little under ten millions of pounds; and that of Indian tea about a million and a half. In 1884, the consumption of the former had sunk to a little over nine millions, while that of the latter had risen to nearly six million pounds. Indian tea is both fuller and purer in flavour than Chinese. Two spoonfuls of the former make a stronger infusion than three of China. An unanswerable proof of the superiority of that which comes from Hindustan is found in the fact that it sells at a much higher price than Chinese at the London tea auctions. It is nearly all bought up by tea dealers to mix with the inferior kinds of China tea. Until quite lately the public has had no means of buying Indian tea, save the coarse pungent Assam kinds, which is used to mix with varieties that need some stronger flavouring. This very fact has created an impression that all Indian teas are too strong to be used without mixing them with Chinese; but those who have tasted the delicious Kangra Valley or Darjeeling varieties are speedily disabused of an idea so erroneous. The flavour is eminently delicate, as behoves the leaves of plants grown in one of the finest climates in the world, on the lower slopes of the Himalayas, midway between the eternal snows that crown their summits, and the intense heat of the plains of the North-West Provinces. With those who are unaccustomed to the use of Indian tea, it is a common error to use too much leaf in infusing it. To do so is to produce a bitter taste, which is at once set down to the fault of the tea—not of the tea-maker. The latter has probably been accustomed to ladle out the ordinary, low-priced teas, sold at 2- or under. When it is remembered that the duty upon all tea imported into this country is sixpence per pound, and that this with freight charges and retailers' profit have to be added to the cost of culture and manufacture, it is not difficult to draw the conclusion that really fine tea cannot be obtained at such a price.

Regarded in its social aspect, tea is a valuable actor. The five-o'clock gatherings which have of late played so important and refreshing a part in the whirl of the fashionable day owe their origin wholly to the beguiling qualities of the fragrant cup. Some years ago it was regarded as a beverage only fit for women, but its fascinations now hold in thrall the warrior, the politician, the man of law, and even him of physic, who sternly forbids it to his patients. The hostess who makes it strong, but never lets its strength deteriorate into bitterness under the sinister influence of cosey or charpotkri; who gives her guests a "brew" of the leaf of rarest flavour and finest growth; is always sure of that pleasant sprinkling of the nascaline element at her "five o'clocks," which serves to make them popular and to prevent the conversation from becoming absorbed in such wholly famiame topics as distinguished the German "kaffee-klatsch" or other functions which are attended solely by the ornamental sex.—*Lewis & Co's Tea Trade Circular.*

OIL OF SANDAL WOOD.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

In the early part of the present year my attention was directed to the subject of sandal wood by the fact that there appeared in the druggists' wholesale price lists an oil of sandal wood marked "W. I.," and offered at about one-third of the price of the genuine oil. As the genus *Santalum* is not represented on the American continent it was evident that the "West Indian" oil must be obtained from some other plant. The results of inquiries made since then appear to me to possess sufficient interest to be placed on record in the columns of this Journal, and may perhaps be prefaced with advantage by a short account of the species which have hitherto furnished sandal wood.

The genus *Santalum* comprises about twenty species, distributed over Asia, Australia and Polynesia, although others may probably yet be discovered in New Caledonia and New Guinea.

In aspect the trees of this genus bear some resemblance to the Myrtaceae, in having opposite, mostly entire leaves, furnished with oil glands, and flowers similarly arranged. Like the Eucalypti they have no petals, but differ in the small number of stamens (four or five) to each flower, and in having only three to five seeds attached to a central pectate.

All the species delight in dry, rocky localities, particularly those of volcanic origin, degenerating in their yield of oil when grown in moist situations.

The most westerly species in *Santalum album*, L., a native of India and the islands of Sumba and Timor and other islands in the Eastern Archipelago. The most easterly is *S. insulare*, found in the Marquesas Islands and Tahiti. The most northern species, *S. Freycinetianum*, Gaud., is found in the Sandwich Islands, and the most southerly, *S. Cunninghamii*, in New Zealand.

The species which have at different times furnished the sandal wood of commerce are as follows:—

S. album, L.—This species furnishes East Indian sandal wood and probably also that known as Macassar sandal wood. A variety of *S. album*, the *S. myrtifolium* DC., which differs in its more lanceolate leaves, and occurs on the mountains in the east of Madras, is also a source of a sandal wood oil, which possesses comparatively little fragrance.

The interesting account given of sandal wood in 'Pharmacographia' may be supplemented here by some particulars given by Dr. Bidie concerning the distillation of the oil in India, and published in the Pharmacopoeia of India (p. 461), from which the following quotation is taken:—

"It (the tree) is carefully protected by Government, and only the trees that have reached maturity, which they do in from eighteen to twenty-five years, are cut down. The felling takes place in the end of the year, and the trees are then stripped of their bark and conveyed to various depôts where they are cut into

billets, which are carefully dressed and sorted according to the quality of the wood. These billets form the sandal wood of commerce, and are sold by weight at an annual auction, native merchants congregating from all parts of India to make purchases. The pieces that are straight and have most heart wood, fetch the highest price, as the fragrance for which they are so much prized depends on the presence of an essential oil, which is chiefly situated in the dark central wood of the tree. The Mysore Government has long had establishments for extracting the oil, which is sold at the annual auctions along with the wood and chiefly bought up for exportation to China and Arabia. It is procured from the wood by distillation, the roots yielding the largest quantity and the finest quality of oil. The body of the still is a large globular clay pot, with a circular mouth, and is about 2½ feet deep by about 6 feet circumference at the bilge. No capital is used, but the mouth of the still, when used, is closed with a clay lid, having a small hole in its centre, through which a bent copper tube about 5½ feet long is passed for the escape of the vapour. The lower end of the tube is conveyed inside a copper receiver, placed in a large porous vessel containing cold water. When preparing the sandal for distillation the white or sap wood is rejected, and the heart wood is cut into small chips, of which about 2 maunds or 50 lb. are put into the still. As much water is then added as will just cover the chips, and distillation is carried on slowly for ten days and nights, by which time the whole of the oil is extracted. As the water from time to time gets low in the still, fresh supplies are added from the heated contents of the refrigerator. The quantity of oil yielded by wood of good quality is at the rate of 10 oz. per maund, or 2½ per cent. It is transparent and of a pale yellow colour, and has a resinous taste and sweet peculiar smell, which is best appreciated by rubbing a few drops of the oil on the warm hand. The specific gravity is about 0.980."

Santalum insulare.—A native of the Marquesas and Society Islands. The wood of this species was observed by Captain Cook, in his voyage round the world, to be used by the natives of Tahiti under the name of *Eai* or *Eahai*, for perfuming coconut oil.

Santalum Freycinetianum, Gaud.—A native of the Sandwich Islands. Together with its varieties, *ellipticum* and *paniculatum*, and *Santalum pyrdarium*, A. Gray, it furnished, for a number of years, the sandal wood of these islands. The natives distinguished only two kinds of the wood, which they called *Laa keeko*, or white, and *Lanulohala*, or red. From 1790 to 1820 numerous vessels called at the Sandwich Islands for sandal wood, and as much as 400,000 dollars were realized from this trade in one year by King Kamehaeha. The destruction of the trees was carried on in such a reckless manner that when Dr. Seemann visited Oahu in 1849, he saw only a few bushes not exceeding three feet high, at a place called Kuaohi, and only a few isolated specimens were left of the magnificent groves that formerly covered parts of the islands of Hawaii, Maui, Oahu and Kauai. An attempt was subsequently made to sell the scented wood of *Myoporum Sandwicense*, A. Gray, in order to revive the trade, but it did not succeed.

S. Humei, Seem.—The discovery of this sandal wood tree in the island of Eromanga in 1820 diverted the sandal trade to that island. The violent treatment received by the natives from sandal wood collectors led to difficulties which resulted in the death of the celebrated missionary, John Williams, in 1839. This source also became gradually worked out, although in 1859, the wood was still so plentiful that one firm employed sixty men to cut it in the bush. On a specimen of *S. Humei* in the British Museum there is a note in McGillivray's hand-writing to the following effect:— "Produces the greater part of the sandal wood shipped from Eromanga, and formerly also from the New Hebrides. Nearly extinct. May, 1859." Another specimen dated February, 1860, bears the remark, "Now done." From this it would appear that this source of sandal wood was exhausted about 1860. Specimens of *S.*

Homei also occur in the same herbarium from the Isle of Pines and New Caledonia.

Santalum Yasi, Seem.—The wood of this tree was for a long time purchased from the natives of Fiji by the Tongan Islanders, who used part of it and sold the remainder to the Samoans, by whom it was used for perfuming the coconut oil with which they grease their naked bodies; for this purpose it was first grated on one of the mushroom corals (*Fungia*).^{*} As soon as the existence of sandal wood in Fiji became known to European traders, it was speedily carried away to the Chinese and Polynesian markets, so that in 1816 there was scarcely enough left for home consumption, and to save the tree from extinction, one was planted in the gardens of the Mission Station at Buia, in Vanua Levu, the island where it was most abundant. From this tree Dr. Seemann obtained the specimens used for illustrating the plant in "Flora Vitiensis." In 1840 the tree was so rare that even the Fijians paid fancy prices for pieces of the wood. The interior of these islands has, however, not been thoroughly explored, so that it is possible some trees may yet be found there.

Santalum austro-caledonicum, Viell.—The sandal wood of this tree was obtained from Marc in 1841, and from Vato in 1843. In New Caledonia it is known to the natives as *Tibeau*. The natural woods having been nearly exhausted in New Caledonia, the tree has lately been cultivated, and a small quantity, valued at £8, was exported from Noumea to France in 1828.

S. Cunninghamii, Hook., is said to yield sandal wood in New Zealand.

Erocarpus latifolius, R. Br.—A specimen of the wood of this tree was exhibited as West Australian sandal wood ("S. latifolium") at the International Paris Exhibition of 1878, and is now in the Museum of this Society. It possesses but little fragrance.

Australian sandal wood is received in this country from Adelaide and Freemantle. It yields less oil of a less fragrant odour than the wood of *S. album*, *Fusanus spicatus*, R. Br. (*Santalum cynnorium*, Miq.) This tree has a wide range through South and West Australia, and a large export of the wood has gone on annually, chiefly to China, the exports in 1854 having amounted to 2620 tons, at an estimated value of £8 per ton, that of *S. album* being about £40 per ton. The export is expected to continue for some years to come before the source is exhausted. There is a duty of about 5s. per ton on all the sandal wood exported.

Fusanus persicarius, F. Muell. (*S. persicarium*, F. Muell.) as stated by Rosenthal to yield sandal wood in West Australia, and *S. lanceolatum*, R. Br., in North Australia, New South Wales and Queensland, but I can find no account of their exportation.

Eremophila Mitchellii.—Dr. Bancroft presented a specimen of this wood to the Museum of the Society, stating that it was known in Queensland as sandal wood. It has a weak fragrance not exactly like sandal wood, and the heart wood is of a deep brownish-red colour.

Venezuela Sandal Wood.—A specimen of this wood was presented to the Museum, together with a fine sample of the oil, by Messrs. Schimmel and Co., of Leipzig, who stated that it came from Puerto Cabello, in Venezuela. It is the source of the W. I. sandal wood oil of commerce. It has already been pointed out in 'Pharmacographia,' second ed. p. 803, that this oil may be distinguished by deviating the ray of polarized light 6-75° to the right, while oil of sandal wood deviates it 18° to the left in a column 100 millimetres long. The name of sandal wood bark having been applied in Mexico to what is probably the bark of a species of *Myroxylon*, and *Bacida capitata* being

known in the West Indies, according to Griesbach, as sandal wood, it seemed probable that the name might be applied in Venezuela to some other tree, since the specimen of wood presented to the Society appeared unlike the wood of *Myroxylon* or, so far as I could ascertain, that of Combrataceous trees. Accordingly, I wrote to Mr. R. Coum, the British Vice-Consul at Puerto Cabello, who has kindly forwarded a living specimen of the plant and two dried specimens, but unfortunately neither leaves nor fruit were then obtainable. So far as can be judged from the leaves the plant belongs to the *Rutaceae*.

As the plant does not appear to exist in the national herbaria at Kew, or at the British Museum, a brief description may be placed on record here. The stem if branched in an irregularly dichotomous manner, the branches being erect-patent. The bark is thin and brittle, resembling in general appearance that of jaborandi or quassia. The leaves are alternate below, becoming more or less opposite on the twigs. The leaves are five-foliolate and imparipinnate. The leaflets are opposite, with a petiole about a quarter of an inch in length, entire at the margin, thin but somewhat rigid when dry, ovate, mucroless, and acuminate, somewhat shining above but glaucous underneath. When held up to the light they are seen to contain innumerable oil receptacles, which, like those of jaborandi, vary in size in the same leaf. The odour of the leaves and bark also recalls that of jaborandi. In shape and venation of the leaves the plant approaches the genus *Spiranthea*, but the leaves are much thinner. Until flowers and fruit can be obtained the plant must therefore, be considered to be one hitherto undescribed.

Mr. W. Kirkby at my request has kindly cut sections of the wood of *Santalum album*, the Macassar sandal wood, and that from Venezuela presented by Messrs. Schimmel and Co. The first two present very little difference in structure, but the Venezuela wood has the porous vessels arranged in distinct lines, as seen in the transverse section.

Of the Japanese sandal wood mentioned in 'Pharmacographia,' I have been able to ascertain nothing, except that true sandal wood (*S. album*) does not grow in Japan. The only trees mentioned by Franchet and Savatier belonging to the order in that country are *Erocarpus latifolius*, R. Br. (*Santalum latifolium*), and *Buckleya lanceolata*, Miq., but neither of these appear to have native Japanese names, and presumably are not used like sandal wood. Nor have I been able to ascertain what wood it is that is exported from Nossi-be under the name of sandal wood, or the source of the kind exported to this country from Zanzibar, but I am informed by a distiller of sandal wood oil that the latter is considered almost worthless for purposes of distillation.

Oil of Sandal Wood. Of all the different species of sandal wood above mentioned there appear to be only two used at the present time as sources of the volatile oil of commerce (unless the wood yielding the Macassar oil proves to be derived from a distinct species), viz., *Santalum album*, furnishing the East Indian and Macassar oil, and the Venezuela tree furnishing West Indian "Sandal wood oil." Inquiries kindly made for me by Mr. C. Umney show that all the sandal wood during the last two years imported into this country has come from Bombay, except two lots from Zanzibar, offered on February 19 and April 16 of 1884, and a small quantity from Champion Bay, but these were regarded as of indifferent quality.* The Bombay sandal wood as imported varies so much in yield of oil that those who are accustomed to buy the wood for distillation are often greatly deceived in their estimate of its yield. Mr. Umney states that the largest percentage obtained by him has been 15, but that sometimes less than a third of this quantity will result from careful distillation. The amount obtained also greatly depends upon the fine state of division to which the

* In reply to an inquiry I made at the British Museum Mr. S. O. Ridley informs me that the species of fungus most likely to be used is *P. deliifera*, Dana, which is sometimes five inches long, and has large strong teeth. Being elongated it could be readily grasped by the hand, and would answer the purpose well. As a new name for this species will probably soon be published I have not mentioned the species in the text.

* I learn from another source that sandal wood from the Pacific Islands and Australia has very little scent, and is used in this country for furniture and cabinet work only.

wood is brought before distillation. This is effected by first incising or clipping the logs by powerful machinery, and then disintegrating them with special tearing or rasping apparatus or with mill stones.

The Indian oil, in Mr. Umney's opinion, is imported into this country to the extent of not more than 1500 lbs., and often reaches England in a discoloured state, containing fixed oil and traces of water, and is rejected by wholesale druggists for medicinal purposes, the whole import being purchased for use in perfumery.*

The essential oil distilled in this country realizes a higher price than either Indian or German oil; the latter in some cases contains oil from cedar wood or inferior sandal wood mixed during the process of distillation. Mr. Umney believes that the continental distillers are far in advance of the British in their superiority both of plant and of the knowledge necessary for the production of this and other essential oils, two well known German firms probably distilling three-quarters of the whole quantity used in Europe.

The above statement concerning the adulteration of oil of sandal wood having reached me from several sources, I obtained a sample of the oil, as well as a number of commercial samples of sandal wood oil, with a view to ascertain what variation might exist in their specific gravity. Examined at my request by Mr. W. H. Ince the following results were obtained:—

Distilled in	Sp. gr.	Source.
1. Germany	0.9797	E. Indian wood
2. Germany, same, firm ...	0.9754	E. Indian wood.
3. Germany, different firm ...	0.9756	E. Indian wood.
4. Germany, same firm as 1, 2	0.9738	Macassar wood.
5. Germany, same firm as 1, 2	0.9650	W. Indian wood.
6. English	0.9713	E. Indian wood.

It will be observed that with the exception of No. 5 all the specimens were of higher specific gravity than that recognized in the new British Pharmacopœia, 0.96, although lower than a sample obtained from the India Museum, and which had a specific gravity of .9901. The Pharmacopœia of India gives the specific gravity as .980, and the United States Pharmacopœia .946. It is probable, therefore, that none of the samples examined by Mr. Ince could have been adulterated with cedar wood oil, since the addition of that oil (of specific gravity .9480) would have lowered the density. The low specific gravity given in the United States Pharmacopœia indicates, however, the possibility of the West Indian oil being used extensively in that country. This supposition agrees with the information I have received from distillers of the oil, that this oil is chiefly exported to the United States. Mr. T. Farries also informs me that it has very little sale either in this country or in Australia.

The oil of cedar wood obtainable in commerce is even more free from colour than sandal wood oil, and if prepared, as I am informed, from the refuse of cedar pencil works is probably rectified carefully to free it from colour, since the oil distilled from a closely allied species, *J. Bermudiana*, in Jamaica, by M. Bowrey, judging from a specimen recently presented by him to the Museum of this Society, has a reddish-brown colour. A sample of oil of cedar obtained in English commerce has been, at my request, examined in the Society's laboratory by Mr. W. H. Ince, who finds that it has a specific gravity of .9480, and treated with various reagents presents, as compared with a sample of East Indian oil of sandal wood of specific gravity .9901, received from

	Cedar oil.	Sandal wood oil.
Concentrated sulphuric acid ...	Burnt sienna colour.	Brown with black clots
Chromic acid ...	Brown with black clots	Ditto.
Nitric acid ...	Brown colour	Brown colour.
Concentrated solution of chloride of zinc	No result.	{ Makes it gelatinous.
Solution of bromine in chloroform ...	No result.	No result.
Mercuric chloride.	No result.	No result.
Hydrochloric acid.	No result.	No result.

The specific gravity of oil of cedar wood being considerably lower than that of sandal wood, it occurred to me that it would be important to determine the quantity of the former that could be added to sandal wood oil without being readily detected by the difference in specific gravity. Mr. Ince kindly made some experiments for me with this end in view. These were conducted in a room, the temperature of which was 65° F.

The addition of 10 per cent. of cedar oil was found to lower the specific gravity of the oil from the India Museum to .9789, or rather higher than the average specific gravity of the "East Indian" oil of commerce.

In order to see if this quantity of adulteration could be detected by the greater or less solubility of the oil in alcohol, some experiments were made on the solubility of the various oils with alcohol of different strengths. From these experiments it results that cedar wood oil forms a white cloudy mixture with its own volume of methylated alcohol of specific gravity .839, while No. 1 (see table) is perfectly soluble; but one volume of an equal mixture of sandal wood oil and cedar oil under the same conditions dissolves perfectly.

It being thus evident that sandal wood oil might be adulterated with half its volume of cedar oil without being detected by the use of spirit of this strength, proof spirit was next tried, but neither oil being perfectly soluble in it, a mixture of 1 part of proof spirit and 3 of rectified spirit was used. This had a specific gravity of .920. With this solvent the following results were obtained:—

Nos. 1 and 3 dissolved in an equal volume of it. Of the oil from the India Museum and No. 6, one c.c. required 1.1 c.c. to dissolve it. Of No. 4, one c.c. required 1.3 c.c. of the solvent. One c.c. of oil of cedar required 5 c.c. for solution, but 10 per cent of the latter oil added to the India Museum oil increased its insolubility very slightly, 1 per cent requiring only 1.3 c.c. of the solvent.

Conclusions.—From the above facts it appears that whilst oil of cedar may be recognized by its insolubility in an equal volume of alcohol of specific gravity .920, its admixture with sandal wood oil to the extent of 10 per cent cannot be easily detected. It is quite possible that the higher specific gravity and less solubility of the oil from the India Museum may be due to an admixture* of some fixed oil, possibly of sandal tree seed oil, which is used for lamp oil in Mysore. This question, however, can only be settled by the distillation of the wood and examination of the oil in India by a competent chemist. The west Indian oil, as shown in 'Pharmacographia,' may be detected by its optical properties, and is probably derived from an undescribed Rutaceous tree. The specific gravities obtained indicate that the figure given in the B.P. is too low. The oil originally recommended for use in medicine by Dr. T. B. Henderson in the *Medical Times and Gazette* (June 3, 1865, p. 571) was that of *S. album* var. *S. myrtifolium*, the wood of which is said ('Pharmacographia,' 2nd edition, p. 602) to be nearly inodorous. But it

* According to Dr. Dymock as much as 12,000 lbs. of this oil are imported into Bombay from the Malabar coast, the oil being worth 8½ rupees per lb., and it is used chiefly for perfumery.

† I am informed by Mr. A. C. Abraham that two samples of the oil purchased in London gave respectively the specific gravity .9753 and .9771. The German specimens were obtained from firms of the highest reputation.

* Tested for sesame and cotton seed oils negative results were obtained. But the greater insolubility of the Indian oil and higher specific gravity indicates the probability of fixed oil being present in it.

is only during the last few years that sandal wood oil has extended its reputation widely. The question arises therefore, is the therapeutic property of the oil due to true oil of sandal wood, to oil of cedar, or to the oil of the Venezuela tree? The species of the genus *Juniperus* are known to have physiological effects on the urinary organs, and cedar wood oil may be possessed of as great, or greater, therapeutic value than the sandal wood oil. Since all these oils are to be met with in commerce, it would be more satisfactory to know which is the most valuable remedy, but this point is one to be determined by the medical profession.—*Pharmaceutical Journal*.

TAR WATER AGAINST INSECTS.—Water strongly impregnated with tar, is becoming very popular in Europe as an insecticide.—*Gardeners' Monthly*.

ARTIFICIAL MANURES.—Notwithstanding the analyses of chemists, in regard to the perfection of chemical manures, and the fact which they so easily demonstrate that the greater part of stable manure is nothing but water and other material of no possible value and costing immense labor to handle, it is remarkable that the demand for stable manure is greater than ever. People find it best in spite of chemistry.—*Ibid*.

HEER E. BOMBELO announces that he has succeeded in isolating from the betel-nut, a volatile alkaloid, resembling nicotine, to which he has given the name "arekane." He describes it as being left on the evaporation of an ethereal solution, as a colourless oil, smelling like weak meat broth, and with a strongly alkaline reaction. It forms varnish-like salts with tartaric, citric, hydriolic and salicylic acids, the salicylate having a tobacco-like odour. The hydrochlorate gives with platinic chloride a yellow, with gold chloride a light yellow, with mercuric chloride a white, and with tannin a whitish precipitate. The taste of the free alkaloid as well as of the salts is said to be at first imperceptible, but afterwards becomes acrid. The alkaloid increases the secretion of saliva, slackens the pulse and has a purgative action.—*Pharmaceutical Journal*.

MR. WORTINGTON SMITH, in an article in the *Gardeners' Chronicle* (March 6, p. 309,) brings further evidence in support of his opinion that the berberry blight and corn mildew have no connection with each other. He shows that the appearance of the blight on the berberry plant on which the corn mildew has been sown is no proof of any connection between the two fungi, inasmuch as the berberry blight may be previously in the plant, and *vice versa*. In support of this he gives illustrations of the corn mildew fruiting in the seed of an oat and the *Aspidium Berberidis* in the seed of the berberry. He believes that the fungus is thus carried from one individual to another, traversing the plant from the roots to the cotyledons.—*Pharmaceutical Journal*.

SOME INSTRUCTIVE experiments have been made by M. S. Grosjean on the development of the leaf of *Eucalyptus globulus*. He finds that in the youngest stage the tissue of the leaf between the epidermis, with the exception of the vascular bundles, consists of a uniform tissue composed of cells equal in diameter in each direction, which the author calls primitive mesophyll. If the leaves are forced to remain in the horizontal position they develop the usual leaf structure of palisade cells on the upper and spongy tissue on the lower side of the leaf; but if the leaves assume the vertical position, palisade cells are developed on both side of the leaf next to the epidermis. He therefore arrives at the conclusion that there is in leaves a tissue which is capable of differentiation, and that under the influence of light there is a tendency to form palisade tissue, while shade favours the formation of spongy tissue (*Gard Chron.*, March 13, p. 338, from *Bull. de la Soc. Bot. de France*). If this conclusion be confirmed it is evident that it may be possible to determine from the texture of a leaf whether the plant prefers shade or sunlight, a point of some importance to horticulturists.—*Pharmaceutical Journal*.

NITROGEN FROM CLOVER ROOTS.—Dr. Voelcker found that the average weight of clover roots on an acre was about three tons, and that this furnished 100 pounds of available nitrogen, the most stimulating of all manures. This is one reason why a clover sod plowed under is such good preparation for a wheat crop. Why clover sod will not always bring good wheat is due to the lack of phosphate, which this grain must have if anything more than a crop of straw is to be grown.—*Southern Planter*.

HORSES should be bedded with chaff or finely cut straw. This will absorb the liquid droppings better than uncut straw will. The manure in this fine condition will ferment very rapidly, and with a very little heating will be ready to spread evenly on the land. If horses are bedded with coarse straw the fermentation will be uneven. Some parts of the heap will be dried up and "fire-fanged", while the coarse straw is not in good condition for spreading.—*Southern Planter*.

SOUTHERN TOBACCO GROWING.—Much of the desolate appearance noticed by strangers in the southern country, is due to the exhaustion of the soil by continuous tobacco growing. A very large portion of what was known as tobacco land, has been thus reduced to a condition of poverty, in which it has been "turned out" to grow up to old field pine or broom sedge. As every fault brings with it its own punishment, so this has done, not only in the loss of the use of the land for many years, and the cost of reclaiming it, but also in the injury which results from the adverse impression upon the minds of the visitors from other states, who are seeking homes in the sunny and fertile south. This fault should be prevented in the future, and there is no need to stop growing tobacco either. Tobacco is the cash crop of the southern farmer, and every farmer requires a certain amount of money coming in, to meet expenses which must be paid in cash. But first of all, the food and fodder crops should be grown, then clover or cow peas should be grown for fodder for pigs, cattle and sheep. These may be sowed after two crops of tobacco have been taken from new land, and one tobacco crop may safely follow after either clover or cow-peas have been plowed in to enrich the soil.—*American Agriculturist*.

CULTIVATING THE MAMMOTH SEQUOIA OF CALIFORNIA.—To the Editor of this magazine, one of the most interesting lessons learned in California, was one which only one experienced in the culture of trees could learn; namely, that the Sequoia gigantea is by nature a swamp tree. The places where they grow now are comparatively dry; but two or three thousand years ago they followed the track of receding glaciers, and they received the melting snows from the tops of mountains that have no summer snows now. The ground on which these mammoth trees stand, once very wet or even swampy, has become drier through the long ages. Horticulturists know that swamp trees generally grow very well in ground that is comparatively dry, but seeds of such trees will not sprout in anything but the moist, oozy moss on the top of a swamp or damp ground. Hence, the only young trees we find in the mammoth tree locations, are where a chance seed happens to fall on a moist rock, or other damp situation. Young trees are common only in one location where clouds condense against a mountain, side, and the whole situation abounds with springs and oozy spots. Here in the east hundreds of trees have been planted during the past quarter of a century, but rarely has one lived more than a few years. They do not mind the winters. We have known them stand 20° below zero uninjured, but some fungus, favored by a dry atmosphere, carries them off gradually during the summer season. Profiting by these facts, the writer brought three strong plants from California and set them in a swamp. Usually when we set swamp trees in a swamp, they will not grow unless they are suffered to grow into the swamp themselves. We make a mound and plant them in the mound, from whence they root down as snits themselves. These three plants have had two winters and one summer; the past winter being a terribly severe one. To day they look perfectly sound and flourishing, and the Editor believes that he has at last discovered how to make the great tree of California thrive in eastern gardens.—*Gardeners' Monthly*.

TEA AND OTHER PLANTING INDUSTRIES IN CEYLON in 1885. A good field for investment. By A. M. and J. Ferguson, Colombo. This is an interesting book on the subject of tea in all respects—culture, consumption, the family tea-pot, &c. &c.—*Southern Planter*.

HINTS FOR PRUNING.—When it is necessary to prune large limbs the saw should cut a little way up on the under side to prevent the branch from splitting off down the body when the main cut is made from above. All wounds more than an inch in diameter should be covered with paint to exclude air and promote rapid healing over of the cut surface. Cuts made with a saw, however small, should be painted.—*Southern Planter*.

THE ELECTRIC LIGHT vs. GAS.—As regards the matter of cost the electric light, according to Mr. Preece's experience, comes to just twice that of gas, but he is of opinion that there can be little doubt on which side the balance would appear, if the value of steady light, pure air, absence of heat, matches, candles, and oil were taken into account, as well as other advantages, such as cleanliness, durability of decorations, etc., which entitle electric light to a preference over gas.—*Pharmaceutical Journal*.

PARA RUBBER.—From Messrs. Hecht, Lewis & Kalm's Comptech Report for 1885 we learn that an increase took place in the crop of Para rubber, the imports into London and Liverpool amounting to 4800 tons against 4610 tons in 1884—the total exports from Para to all parts for 1885 being estimated at 12,500 tons against 10,900 tons in 1884. Of Ceara scrap rubber, from Manihot Glaziovii, the imports into Liverpool amounted to 85 tons, the quality being most satisfactory. Of Central American the imports were 100 tons, and of other kinds the imports and sales were good.—*Gardeners' Chronicle*.

The Editor of the New York *Pharmaceutische Rundschau* (Dr. F. Hoffmann) has been giving a considerable amount of attention to a "non-secret" remedy that has been put forward, under the name of "Kaskine, the New Quinine," with the modest claim, based on alleged certificates from eminent medical men, that it "stands unequalled and unrivalled in the world of science as the only medicine that can destroy the germs that cause each particular disease." Kaskine appears to have been sold in small flat green glass bottles at a dollar a bottle, each containing about twenty grains of a sweet odourless white granular powder, freely soluble in water, which Dr. Hoffmann ascertained to be finely powdered sugar puret simple!—*Pharmaceutical Journal*.

PEROSPORA OF THE VINE.—This fungus is almost as much dreaded in France as the Phylloxera itself; nevertheless, according to Professor FLEURY, it is easily kept in check by the application of dilute kerosene emulsion with a small quantity of carbolic acid, applied with a spray-producer. Sulphur, which is so useful for the Vine mildew, is of little use for the Peronospora. Another remedy is made as follows:—Take Sulphate of copper 1 lb., to 22 gallons of water, and 34 lb. of lime mixed with 7 gallons of water. Mix the two solutions, when a bluish paste will be formed, which may be applied to the leaves with a brush, taking care not to touch the berries.—*Gardeners' Chronicle*.

HIMALAYAN BAMBOO.—In a note read before the Royal Society of New South Wales, Dr. Brandis, the late Director of the Forest Department of India, mentions *Arundinaria falcata* (not the plant generally grown in this country under that name, and which the late General Munro determined to be *Thamnoclamus Falconeri*) and *Thamnoclamus spathiflorus*. The canes of the latter are exported to the plains of Hindustan for water-pipes, fishing-rods, baskets, &c. This is the kind commonly known as Ringal. It grows with the *Decodar*, *Cupressus torulosa*, *Abies Smithiana* and *Webbiana*, generally inhabiting moist climates. Dr. Brandis gives an account of the characters of the two species, and takes the opportunity of correcting some errors of detail into which he fell when describing the plants in the *Forest Flora of North-West and Central India*. Both species would probably thrive in our south-western counties, and in South Ireland.—*Gardeners' Chronicle*.

THE OILO WATE IN FLORIDA.—As a good deal of interest has of late attached itself to the reports of

the Weather of Florida, it may be worthy of note that a report on the subject has just been issued by the American Government. In this it is stated that an abnormally cold wave passed over the State between Jan. 9 and 14, sending the temperature down to 15° F. in some of the northern counties, and on two mornings forming ice, on ponds of water 3ft. deep, of sufficient strength to bear a man. At one place, ten miles east of Tampa, the thermometer marked on one morning 23°, and ice formed three-quarters of an inch thick in shallow vessels. In the northern counties the oats were all killed, and further south all tender garden vegetables suffered the same fate. The citron, lime, and lemon trees suffered severely, as did also the smaller and diseased orange trees. In the middle counties the large and healthy orange trees lost one-half their leaves, and in places further north all the leaves are gone. All over the State oranges have dropped off and been lost. It is estimated by those best informed that the loss to the State, in consequence of this cold spell, will be at least £200,000 in fruit, and another £100,000 in the gardens. The absolute damage to the State is greater than in 1835, when the thermometer at St. Augustine marked 8° F., and when most of the orange trees were killed outright. The reason for this is that since that date the number of trees have increased a thousandfold. Owing to the small shipment of cattle last year and the abandonment of cotton planting in all those portions of the State where fruit growing has been exclusively entered upon, this loss by the cold falls exceptionally heavy, and must result in much financial embarrassment. The agent for the United States in Florida hopes that the result will be to call attention to the necessity for a greater diversity of crops than at present.—*Field*.

COCA.—We are indebted to the courtesy of Dr. Bidie of Madras for a copy of his pamphlet on Coca. It consists of the lecture delivered by Dr. Bidie in March last, and which we noticed some time back. The pamphlet is accompanied by an illustration of the plant, which is now speedily assuming such importance. Dr. Bidie has favoured us with the following remarks on the subject:—Subsequent to the publication of my lecture in the Madras papers, several planters wrote to me making enquiries on the subject, but the difficulty hitherto has been in getting seeds or plants to begin the culture. Some, I believe, have sent to South America for supplies of seed, and one or two are in possession of plants, and they will now of course propagate as fast as possible. The local Agri-Horticultural Society has also plants, and will no doubt do its best to meet the demands for seed. So far as I have heard, the Coca in south India does not seed freely at elevations over 3,000 feet, but this may not be confirmed by further experience. In Madras town it grows well and seeds profusely, so that we shall have no difficulty in pushing the culture on this side of India. I have a few plants in Madras raised from the original stock, brought direct by Mr. Cross of (Onchons fame) from South America, and also one raised from a single seed that I found amongst some old American leaves. Lately also a London friend sent me some few seeds picked out of a consignment of Bolivian leaves, but they have not yet germinated. I rather think the coca does not get on very well in Calcutta, but Dr. King will be able to give you information on this point. At present I am trying to get a quantity of leaves of an indigenous species—*Erythroxylon Monogynum*—collected for analysis, with the view of ascertaining whether they contain any principal like that of *E. coca*, *etc.*, *cocaine*. During the late famine the leaves of the indigenous species were largely eaten by the starvored, and this, at the time, led me to suggest that they also contain some alkaloid, capable of allaying hunger and staving off fatigue. Dr. Bidie has very kindly promised to send us a sample of a few leaves and we shall await their arrival with interest. We may here note that Dr. Bidie's lecture contains all the information available about this plant; and those who wish to know anything about coca, should get a copy of this pamphlet, which is published by Higginbotham and Co., of Madras.—*Indian Agriculturist*.

PLANTING IN UVA ON "DAYS OF OLD"
AND THE PRESENT TIME.

(A letter from Mr. Irvine to the Provincial Agent).

Badulla, 22nd April 1886.

E. King Esq., Government Agent Province of Uva,
My Dear King,—Referring to our various conversations and more particularly to your letter of 17th inst. I have only been a short time in Badulla and without books or papers for reference but the following may be of some use to you with reference to the past and present condition of your Province of Uva, and as I had promised to write to the press on this subject before I saw you and had prepared much of what I am now writing I will send copy of this letter for publication.

You ask me as to the Uva coffee crops from 1855 to 1875, a period of 20 years and 30 years from this date. My own knowledge of Uva only dates back to 1862; but the Ceylon Directory gives returns of native coffee for 20 years from 1849 to 1869 the largest crops being those of 1865 and 1868, respectively 214,806 cwt. and 218,584 cwt., the average price of native coffee during the same period being £117s 6d, but for the last 15 years of this period the average was £2 sterling per cwt. and no less than £6,986,321 sterling was distributed amongst the natives of which the Uva villagers got their full share, and I maintain that Uva produced half the native crop of the island, taking the annual average roundly at 150,000 cwt. will give to Uva 75,000 cwt. which at Badulla prices, say 30s. = £112,750. It was about the year 1868 or 1869 that Mr. Reid first called attention to leaf-disease and by 1873 the disease had obtained firm hold of the village coffee and the decadence became much more rapid than on plantation coffee. And I may here mention that prior to 1873 the Uva coffee crops were simply enormous: in 1864 Kirklees estate about 200 acres of coffee gave upwards of 20,000 bushels parchment coffee; and Cahagalla, Odowerre, Kotogodde and Old Spring Valley gave equally large crops, and the native coffee bore proportionately. It was only between 1860 and 1870 that Badulla, Haputale and Madulsima were really opened up by Europeans. Previous to this the estates actually giving crops were Haputale, Cahagalla, Old Spring Valley, Kotogodde, Odowerre and Oetunne (quite young) Waywelheena, Gorrakelle, Nalawelle, Canavarella Glealpin (quite young), Ballagalla (quite young), Passara or Gonakelle, Wewesse and Debedda, and the acreage of these estates in bearing was very small comparatively. Of the Udappussellawa estates there were only Kirklees, Tulloes, St. Margarets, Alhwick and perhaps Stafford; these were all the estates on this side Nuwara Eliya, so that it is really within the last 20 or 25 years the bulk of the European estates were opened and planted, but it was between the years you mention, viz. 1855 to 1875, that the native coffee interest was in its greatest prosperity. Every native village was a thicket of coffee, growing naturally without care and without cultivation. The town of Badulla was a wilderness of coffee including the Government Agent's grounds; the church, burial-ground and all the adjoining land where the gaol now stands, the temple lands, the land in front of the Government Agent's house and all the village gardens were one mass of magnificent coffee, and there must have been growing within what are now the graveyards of the town of Badulla not less than from 500 to 600 acres of coffee, yielding at least 5 cwt. per acre, the trees were literally laden to breaking with their crop, and Badulla was no way different from any village in Uva. I do not think 75,000 cwt. too high an estimate for the crop over a period of 20 years; some years it must have been greatly in excess of this, and I believe it to have been in excess of the Kandyan crop. The native trade of Uva centring in Badulla was at this time peculiar. The only road by which a cart could with difficulty reach Badulla was by the Nuwara Eliya road. The whole of the rice and other supplies for the troops then stationed in Badulla, as well as the towns people and plantation labourers, was carried on pack bullocks from Batticaloa and

Hambantota, and a considerable portion of the rice was Batticaloa grown rice, but most of it was imported direct from India in native vessels, the Moor traders purchased this rice or bartered for it, Uva native grown coffee at the seaports and sent it to Badulla on pack bullocks where the rice was again exchanged with the Badulla merchants for native coffee, which on the return of the tavlamas to Batticaloa or Hambantota was again bartered or sold to the owners of native vessels, and much of the native crop of Uva was shipped direct to India, and am doubtful if much of it ever passed through the Custom House at all. The native trade at this time was a large and remunerative one. Rice, curry-stuff and sundries from India to Batticaloa and Hambantota sent into the interior and bartered for Uva coffee, and this with salt from Hambantota formed principally the return cargo of the native vessels. This trade is now extinct and the present poverty-stricken condition of the villagers may readily be understood when you consider that the native coffee was worth fully 30s in Badulla and the Moormen made large advances against the growing crop, the villagers were paid partly in money, partly in cloth, fish, curry-stuff and the ordinary necessaries of village life, and, as I have already shown, even at the low estimate of 75,000 cwt. native coffee at 30s, the villagers have lost by the extinction of their coffee £112,500 sterling annually; half of this was probably spent in English imported goods, cotton and other cloths, common cutlery, hardware, and crockery of the commonest sorts. (To digress from the immediate text of my letter this is a matter of equally serious import to the British manufacturer, first: there is the actual loss of trade but there is even more than this, the skilled workman is made out of the boy apprentice and it is only in markets like this that the "prentice hand" can find the purchaser for his work and if you will go through the bazaar and examine the various articles for sale, especially cotton goods, you will be astonished to find how far Germany has ousted the British manufacturer on his own ground—(pardon the digression.) As I have already said the whole of the money or coffee is gone and the coasting trade with all its various ramifications is extinct. Just at the time that native coffee proper began to decline, what were called native coffee gardens rapidly sprung up along the roads and more accessible places; they were in extent from two or three acres up to fifty; they were generally the property of estate kanganies, artisans and others who had saved a little money on estates and who got money readily from the money-lenders and perhaps from less legitimate sources. During the high price of coffee these gardens were as well cultivated as any European estates, but as crops failed they gradually fell into the hands of the money-lender, who in turn found them so unremunerative, that they have nearly all become abandoned; and this source of revenue has also been entirely lost. It is only the very large profits made by the native traders on the old system of double barter which has enabled them to continue trade at all, and many have succumbed. Is it therefore any wonder that the villagers cannot pay their taxes? And what makes matters worse is that the paddy crops have greatly fallen off both in price and in yield. The cause of falling off in price for the small quantity of native paddy available for sale is twofold; first, the villager will take an advance against his growing crops at any price rather than have his field sold for taxes; second, the demand for hill paddy was confined principally to Europeans who kept horses and poultry, and this for obvious reasons has fallen off and bazaar prices are regulated by the fall in price of imported grain. The condition of the peasantry in Uva at present is very similar to that of the Irish peasantry after the potato famine; and if here are no great landed proprietors to eject their tenants, I fancy the Sinhalese villager finds Government quite as hard a taskmaster. The Ceylon Government are everyday selling up the peasantry for their land tax or even for road tax. (This points a moral to our present Irish legislation.) So poor are the Uva villagers that they cannot

give even one meal of rice to their children daily; they are living on roots and yams and any jungle produce they can get. I myself have seen a "wee thing that could hardly toddle" given a roasted corn cob for its noon-day meal (perhaps the only meal of the day), and this was considered good. The wonder to me is, not that crime is rampant in the province, but the astonishing thing is that it is not more so. Another thing which has militated and greatly helped to impoverish the ordinary villager is the almost entire stoppage of contract work on European estates. Formerly the villagers in the vicinity of coffee plantations could always get work at felling or cutting roads and drains or similar work; there is now almost no work for Sinhalese on the estates, in fact most of the estates work their coolies short time and the coolies themselves do not spend a tenth of the money in the villages they used to do, for eggs and fowls and garden produce; there are not half the number of coolies in the first place, and Ramasami working short time with few pickings, has, like master, to economise on the small pittance he receives. It may be true, and to a certain extent it is true, that the peasantry are lazy and do not make the most of their fields, but life after their own fashion was so easy when coffee grew freely without care or cultivation and cropped till the ground was red under the trees with fallen berries, and when money could always be got for a few days' easy work on a neighbouring estate, they have lost much of the skill as well as the energy to well cultivate their fields; another thing is that for years past murrain has been decimating the cattle and buffaloes, and more especially the buffaloes, which alone are used to plough the paddy-fields. I am told some villagers have lost their buffaloes altogether, and it is only by one village community helping another that buffaloes can be got to plough the rice fields and often the "sowing" is so late that the prospect of crops is the smallest, and now the remnant of the cattle are being sold, to the butcher to pay taxes, and keep the owner from gaol or from having his small "holding" sold. I heard of a good bullock being sold the other day for Rs 2 to pay poll-tax—four shillings for a bullock—and when summing up all this I add that the Badulla gaol is full of an ever-increased number of prisoners, principally for minor offences or non-payment of poll-tax. It exhibits a very dreadful and distressing state of affairs. Here (I speak of Uva generally) we have what was once a populous and prosperous community reduced to the most abject poverty principally from the loss of their staple crop by a dispensation of God, over which no man had any control, and the loss of their cattle by scurra and disease; the trade of Upper Uva to the ma has also been cut off by the opening-up of new outlets, and the native coasting trade between India and Ceylon has also been destroyed partly by British India steamers and the "Serendib" taking the produce direct to Colombo, but principally by the failure of the staple crop for export which has rendered this trade of almost no value. With steamboats on the Coast carrying the little trade of Lower Uva direct to Colombo, and the Kandyan railroads with their converging cart-roads drawing everything to Colombo, the whole wealth and energy of the country is being centralized in the capital, and Uva, naturally the richest Province in the island, is practically shut out and cut off from Colombo or from any benefit which may flow from centralization owing to the difficulty of transport over our mountain roads, and the little wealth and enterprise left on Uva is rapidly being drawn away whilst the peasantry are starving; and unless Government step in at once to the relief of the people, "as Ahpota now is so will Badulla rapidly become," and the Government Agent will have to administer and collect the revenues of an almost deserted country.

No one now doubts the success of tea planting in Uva, it is a reorganized fact, and I anticipate that the prosperity of the planting interest will be fully re-established within the next three years. There is much good coffee left in Uva on high estates where cultivation has been kept up, and what has been lost in coffee will be fully made up in tea and cinchona, and

returned prosperity to the planter means a large help by villagers, and is the first step to that full prosperity—but the great native question of the day is, how is the extinct native coffee and healthy native trade of Uva to be replaced or renewed? I have frequently been asked, if tea could be made to replace native coffee, and I can answer this question largely in the affirmative. Although tea will never grow "shumma" like coffee about the house under the shade of jak and other trees, it must be grown in the open, pruned and cultivated. Tea is a much harder plant than coffee, but to manufacture tea the plant must be so treated that it will throw out a succulent flush every eight or ten days during the season. I have already seen some small native tea gardens on the Kandy side which promise well, and the cultivation is well adapted for small gardens along the roads such as I have already described as coffee gardens, and I fully anticipate before long that the whole of the road from Badulla to Lunungalla will be a succession of native tea gardens each with Frater's hand-roller and curing on chulias with charcoal which I find is easily procured and cheap; and the burning of charcoal will be one little help to the villagers if the new forest ordinance does not step in and prevent the people burning charcoal in the chenas. I have also no doubt if Government will distribute good tea seed that a large number of the more intelligent villagers will grow tea in their gardens, but cattle trespass and want of fencing is a sad drawback to planting. The product which I would most like to see largely planted as being sure and certain to produce immediate relief would be the introduction of cotton, and every encouragement should be given to the villagers to plant cotton in the chenas and about their houses; the fact that cotton has failed in several places in Ceylon, does not necessarily prove that the plant cannot be grown remuneratively in Uva. I have seen the plant growing in the greatest luxuriance up to 4,000 or 5,000 feet elevation, and it is well-known that till recently cotton was largely grown and manufactured in Batticaloa, and Badulla was the principal distributing point for these goods. For many years I never saw any towels, napkins, or table cloths in an Uva bungalow but those made in Batticaloa, and the natives used principally Batticaloa cloths and cambays; this trade has also gone, principally owing to the stringent rules regulating the burning of chenas, but the hill climate of Uva is far better adapted to the cultivation of cotton than the lowcountry. Cotton requires plenty of rain but if it gets rain when the boles are bursting it is utterly ruined, and here is where the perfection of the Uva climate comes in. I have just risen from my writing to measure a young cotton plant, it is about nine months planted, is growing on anything but rich soil, and has had no manure; it is ten feet in height and has 150 well-formed boles in different stages of maturity and plenty of blossom to come, the spring rains of March and April have sent the plant into blossom and the boles will burst during the driest months of the year the plant is perennial however and will blossom and pod all the year round. The cotton referred to is Egyptian. I got the seed from a friend many years ago who brought the seed from Egypt and I planted it in the garden at Oodoverre, from there the seed has been distributed over the country and there has been no deterioration in the plant though fully twenty years since I first got the seed. A friend took home a sample, it was very highly valued in Liverpool at the time and said to be equal to the best Sea Islands cotton—this was of course a hand picked sample. Here is a product which may be cultivated to any extent, brought to Badulla to be baled and the seed pressed for oil and cake. The common tree cotton may also be grown in the valleys to any extent. Once valueless as a commercial product it is now most valuable for upholstery. The seed of this plant is also valuable for oil and cake. Tobacco of fine quality can be grown to any extent; and so can castor-oil and a variety of products, but to think of carrying out any of my projects for

the profitable amelioration of the people they might as well remain in dreamland if we are not to have the means of transporting our produce. The sole chance of rejuvenating Uva in the early future, or at all in a railway not only to Haputale but to Badulla, is a myth. If we are successfully to introduce new products amongst the natives, there must be a central market to receive them. If cotton is to be grown in small quantities by the villagers, it must be purchased, cleaned, perhaps ginned, bulked, prepared and baled in Badulla. The same with tobacco; and if cotton seed be pressed for oil in Badulla, the cake will be available for cattle food on the spot, the same with castor beans, the cake going for manure. As for garden tea, it would have to find a market in Badulla, be bulked there, sorted and refired and packed for shipment. I am not sure that it would not pay handsomely if some of the large proprietors in the immediate vicinity of Badulla were to send their green leaf into town and cure and pack it here; they would find it much easier to manage both in the withering and in the fermentation. At any rate a railway is the first necessity of the day. Just fancy a million bales of cotton being dragged wearily up to Haputale, not to speak of Nannoya! The European planter may very well be left to look after his own interests so far as planting new products are concerned, or where the cultivation of his estate may be concerned; but if anything for the native is to be done, the Government must step in at once and help, but no help can be of any real use till by a thorough and efficient railway service, we have opened up Uva to the markets of the world, not only for the present produce of the country, but to develop the latest resources of the country. The railway need not be prodigally costly like the Nannoya line, but we must have one unbroken gauge. I demand for Uva, on the grounds of common humanity, that something be done for the people: in many places they are starving and many are thrown into gaol for road-tax and for minor offences, the outcrop of poverty, misgovernment and starvation. I would suggest that Government at once select suitable grounds for a tea garden which shall be devoted entirely, to the cultivation of the best of jats of acclimated Ceylon tea seed with some select seed from India, the tea to be grown solely for seed to be distributed amongst the villages and that a cotton plantation be established on a sufficiently large scale to fully test the capabilities of the soil and climate and the quality of the cotton grown. The seed to be distributed amongst the villagers. These plantations should be principally cultivated by prison labor. The use of the prisoners in this way will be doubly beneficial, first they will be usefully and remuneratively employed, second they will have learned something new when they return to their villages. A small beginning has been made in the way of an experimental garden but why the site chosen should have been adopted is more than I can tell. First of all it is the poorest ridge in all the Badulla paidy fields, the soil is a hard clay mingled with iron, and the land has been sodden with water for centuries till the clay is as hard and poor as a burnt brick, and the iron has oxidized till it is like the Blackband of our Scotch Moorlands, rendering the land barren and worthless; besides this the field is swept during the north-east monsoon by a blast of hot dry wind which blow out of the gorge of the Badulla Oya with such withering effect that not a green thing is left during the dry months, and during the south-west monsoon, the field is equally exposed to the cold winds and heavy rains blow down from the hills. A more unpromising site could not well have been chosen or found for a garden in all Uva, it will be like the famous experimental farm in Colombo on a small scale. That the ridge may be made productive by trenching and abundance of manure and by planting hardy trees for wind-belts and shelter is true, but it will be costly and take years to accomplish.

As to the traffic of the town of Badulla, I will write you later on, for as this letter already far too long I think; however, the figures you have got from the native traders may be considered fairly reliable.—Yours truly,

FLORIDA: FROST AND FRUIT.

Yellow Bluff, Fla., Jan. 27th 1886.
EDITOR AMERICAN "GROCEER."

Thinking, perhaps, a letter from South Florida would be of interest to your readers, I write you what the cold has done for us. The oldest inhabitants claim it the coldest weather ever seen in Florida. It has not done the injury to orange trees that the cold did in 1835, as the cold days previous to the hard frost caused the sap to go down in the trees.

My orange trees were full of oranges and all appeared to be frosted more or less. About one-third have fallen; those on the trees are sound and I believe will stand two or three months; those that fell are sweet, as good as I ever ate, and do not show many signs of decay. Our people are eating more oranges than they ever did in the same length of time. As to the frost causing them to be poisonous, that is all a hoax, as far as our oranges are concerned; I have eaten six at one time without any injurious effect. Most growers are letting the oranges that drop lie on the ground and rot. I am housing mine and will see if they will keep, and also picking and housing those on the trees; if I should chance to send our Northern friends any I will venture to say they never ate better. Lemons, limes, guavas, pineapples, bananas, coconuts, mangoes and fig trees on my place, with a few exceptions, are killed to the ground. Orange trees will only lose their leaves, and some have begun to bud; it is thought we will have an average crop another year. We learn that large trees are killed in the counties north of us.

Vegetables are being planted more than ever. It is not believed that the cold will depreciate the value of orange groves in this section, but rather make them more valuable. I know of a sale of an orange grove that sold for as much as was asked before the frost.

Orange land is selling here from \$10 to \$50 per acre, according to location.

The lowest that the mercury stood in the most exposed place was 23 above at this place, two or three miles back from the gulf; 18 lowest heard from.

W. V. FUTRELL.

We agree with our correspondent that the recent frost in Florida will not permanently injure the orange-growing interests. As to the healthfulness of frozen fruit, there are two opinions. We incline to Dr. Edson's view that oranges so frozen are not fit for public sale without some restriction.

[If orange trees can stand a temperature of 18 deg. surely they can stand anything. What is the lowest temperature at which the orange grows and ripens fruit in Ceylon? Nothing lower than 40 deg. we should say.—Ed.]

FIJI AND ITS PRODUCTS.

The following items are from the Levuka correspondent of the *S. M. Herald*:—

I gained the other day, through the courtesy of the Receiver-General, and of Mr. J. M. Borron, manager of the Mango Island Company, the following particulars computed for the year 1885:—The Colonial Sugar Refining Company have exported 7,531 tons of sugar; Mango Island Company comes next, with 685 tons; then Tasmania (on the Navua), with 583; Deuba estate, 453 tons; and Idaniburst, on Tavuni, 393 tons. The other mills have sent out much less.

Going into other statistics concerning the country, I find that there are of Fijians and Polynesians in the colony about 128,000. There has been an increase in the number of Indians in the group of, in round numbers, 1,000, but a decrease of from 1,000 to 1,500 Polynesian labourers, these having been returned in numbers to the island of the north-west, whence they came; and very few compared to what has formerly been the case, have been brought in labour vessels to Fiji. There has been among the Fijians themselves a very saddening decrease during the past year, even

of births. Amongst the Europeans, on the other hand, the death-rate is very considerably lower than the birth-rate; but so it is with our prolific Anglo-Saxons all over the world. May their bowabide in strength. In commercial statistics one healthy sign may be mentioned—the exports largely exceed the imports. The most noticeable fact as regarding imports is the marked falling-off in the item of hardware, which is owing to the fact that most of the machinery required on the various estates had been imported previous to 1885. A severe blow has, by this mail, reached the coconut planters, copra merchants, and small traders, in the news of the fall of the price of copra by £1 per ton. "Just slices away our margin of profit," cried a small trader the other day. A ray of light, nevertheless, comes brightly through the rack in the awakening of the heche-dermer industry. There is a magnificent harvest of the sea, and some vessels visiting the outlying reefs have done very well. A good price is obtained, and there is a full demand. One Chinese merchant in Levuka did in one year a business in this highly interesting and surpassingly delicious *bonne bouche* for the Celestials amounting to £20,000. There is a greater demand for our tea than the small production can as yet overtake, though a fine new plantation is coming into bearing at Mausu, Wainunu (Messrs. Mackinnon & Barrett). The Fiji tea, though well spoken of by experts, is not enjoyed by every tea-drinker. "It is far too good for that," say some of the knowing ones. "The opinions of the public as to either tea, wine, or anything else, are no test of excellence," asserted a mercantile gentleman, "and the taste of the generality of consumers and that of connoisseurs and experts are not alike," "Caviare to the general" is all very well in its way; but one would think the *vox populi* would come nearer to the truth nevertheless. An industry that may yet be indefinitely extended in Fiji is that of fruit-preserving. Oranges boiled in sugar, bananas, and pineapples canned San Francisco-wise, and various forms of candied peel, dried fruits, and preserves. These things are possible to Fiji, where the sugar can be produced as well as the fruit at a cheaper rate than in Australia or New Zealand. That there is a future for Fiji in the matter of exports is evidently believed in by the great steamship companies, which continue to run their boats at a present loss merely for the purpose of securing the trade of the future. The Colonial Sugar Refining Company has very creditably given a bounty to the native producers of sugarcane, from whom they have received much material for their all-devouring mill-rollers to operate upon; and this bounty has been to the amount of £1,600.—*Queenlander.*

TRADE AND COMMERCE OF CEYLON.

(By American Consul Morey.)

IMPORTS.

The imports for the year 1884 (including coal and coke, 200,000 tons, worth \$1,621,000) aggregated 155,871 tons, valued at \$17,393,740, and the duties thereon amounted to \$1,009,473. Eight-tenths at least of the whole came from Great Britain or her colonies, and although many of the articles enumerated are more cheap and abundant in the United States than elsewhere nothing is credited as coming from there, except \$39,000 worth of kerosene oil, whereas \$69,800 worth of the same commodity are credited to British India, which country, of course, got it from America. I trace, also, about another \$67,000 worth of American goods, viz., salt beef and pork, clocks and watches, plated ware, notions and tobacco as coming indirectly from America, consequently there were about \$175,000 worth of our products imported here during the year. The notions consisted of mostly the following articles, viz.:—A cotton-gin, a rice-huller, stencil combinations, wharf and warehouse swivel-trucks, coffee-hullers, steel bar-fencing, Marviu safes, rifles and revolvers, saws and locks, canned goods and sewing-machines, type-writers, &c.

The principal dealers in those articles say the demand for them is increasing. One leading firm has the agency for the Waltham Watch Company and Seth Thomas' clocks and probably sells more of those goods, especially the watches, than any other

firm here, as almost everyone now requiring a strong and reliable timekeeper patronizes the American article.

I notice also that a few American carriages are being imported privately, and railroad locomotive head-lights for the Ceylon Government, likewise some wood-working machinery for the government factory.

EXPORTS.

The exports were 135,208 tons, valued at \$13,403,316, or \$3,990,324 less than the imports. If, however, we add to the exports at least \$1,500,000 for coals supplied to steamers, and therefore being practically "imports re-exported," shall have exports, \$15,000,000, and a difference of less than \$2,500,000 in favor of imports. How much of this difference may be made up by the value of precious stones it is hard to say in these times when large quantities of gems are being returned unsold from Europe; it is probable, however, that the account is balanced in that way.

There are no marked features in the export list especially distinguishing it from last year's except the increased shipments of copper to Europe and a corresponding falling off in the quantity sent to India; besides an increase in coconut oil to the United States and a diminished amount of plumbago to our country. The export of copper to Europe and kapok (tree cotton) was alluded to incidentally in my last annual report as a novelty, and I now observe that the shipments of the latter commodity amounted to, in the calendar year 1884, 229,443 pounds, worth \$21,826.

COMMERCE.

The navigation for the year inward and outward, amounted to 4,976 steamers and sailing vessels, reported 5,572,104 tons. Of this vast aggregate, 2,598 members, totaling 5,168,850 tons were steamers, and 2,378, registering 398,264 tons, were sailing vessels. Great Britain and her colonies' contribution to this immense fleet was 2,096 steamers, registering 4,048,986 tons, and 2,061 sailers, grossing 262,236 tons; total, 4,157 steamers and sailing vessels, aggregating 4,311,222 tons.

The United States contributed, counting them double, in and out, 18 sailing vessels, aggregating 12,210 tons, which is the largest showing in our favor since the year 1863.

The above numbers are taken from the records of the master attendants at the three principal ports of the island, viz., Colombo, Galle and Jaffna, and they contain much tonnage calling at Ceylon only for coals or orders. The actual amount of shipping, entering and clearing, at the several custom-houses, and really participating in the carrying trade was about 4,230 steamers and sailers, aggregating about 3,350,000 tons. Nearly eight-tenths of the total tonnage first named above must be credited to Colombo, which, therefore, may now be regarded as one of the chief maritime resorts of the world, and perhaps the largest in the Indian seas. This condition is mostly due to the opening of the Suez Canal and the building of a breakwater here, as, prior to the former event, the navigation of Colombo was comparatively insignificant, whereas now being in the direct track of steamers bound from the Red Sea to India, Burma and China and vice versa, and possessing a safe and most accessible harbor, besides being in telegraphic communication with the whole civilized world, it now attracts and offers superior facilities for coaling and communicating to all steamers cruising in those directions and to sailing vessels seeking for freights.

French commerce in Ceylon ranks second to British, the figures being 220 steamers and 2 sailing vessels, aggregating 555,321 tons. A very large proportion of this, however, represents steamers engaged transporting troops and stores to and from the Far East in the prosecution of the Franco-Chinese war. Austro-Hungary comes next, her contribution being 67 steamers and 2 sailers, aggregating 120,156 tons. Holland ranks next, and Germany, Norway, Italy, Spain, Russia, Arabia, Portugal, Japan, and Siam, so far as steamers are concerned, come in the order named, while the two nationalities represented by sailing ships only were the United States and Maldiv Islands; the only

other country mentioned in the list in that category being Sweden, a country amalgamated with Norway, which is separately scheduled.

In compiling the foregoing particulars, all ships bearing a Government commission of any sort, except transports, have been excluded; nevertheless, men-of-war of various nationalities and departmental vessels are daily calling in at Colombo, and not infrequently at the other ports; so that, were their tonnage included in the list, the total would be enhanced amazingly.

TRADE WITH THE UNITED STATES.

As hereinbefore mentioned, the import from the United States direct was \$39,408 worth of kerosine oil; and the exports to our country were 11,039 tons, valued at \$942,537. The only marked feature in this return is the increase in coconut oil, of \$12,543, the total quantity being \$150,000, and largely in excess of any previous years' showing. There was also an increase of nearly \$70,000 with respect to plumbago, though the quantity shipped was below that of the previous year by 3,000 tons; a circumstance probably indicative of a renewed demand in America for a superior quality of that article.

PLANTING IN NETHERLANDS INDIA.

(Translated for the Straits Times.)

A Mr. Booth at Pasuruan in Java has just made a very important invention in the shape of a centrifugal which can be filled with sugar and emptied of it without its speed being in any wise lessened. Mr. Sargent, an engineer in the employ of the well known firm of Manlove, Elliott, Fryer & Co., found it so efficient that after getting full particulars about the invention, he left for Britain direct to inform his employers of the discovery, in order to make arrangements with them for the manufacture of improved centrifugals.

Throughout Java, good Manila cigars have proved so hard to get except at high prices since the abolition of the tobacco monopoly in the Philippines, that Dutch cigars, never at any time an enjoyable article, are beginning to oust the Manila ones especially since they are now made in Holland more carefully, so as to suit the climate of Java.

THE INDIAN GOVERNMENT AND THE CINCHONA BARK TRADE.

Mr. L. M-Iver asked the Under-Secretary of State for India whether during the last two years the Government cinchona plantations on the Neilgherry hills had been extended by nearly half a million trees; whether it was true that a large amount of private capital had been invested in cinchona cultivation on the Neilgherry hills; whether, with regard to the statement contained in the despatch, April 4th, 1871, of the Secretary of State for India, "It should be clearly understood that the Government have no intention of embarking permanently in the bark trade. In sending their cinchona bark to the London market, one object is certainly to repay the cost of introduction and experimental cultivation of the plants; but the principal intention of the Government in sanctioning this measure is to act as a pioneer in establishing the reputation of the Indian-grown barks, and not to injure the prospects of private planters, whose success would give the Government very great satisfaction;" whether it was true that the Government of India since that time had continued and extended their investments in that branch of commerce; and whether it was the intention of the Indian Government to continue in competition with private enterprise.

Sir T. Kay-Shuttleworth: I can answer my hon. friend's first three questions in the affirmative, only reminding him that the Duke of Argyll, in a despatch to the Government of Madras of the same

clearly necessary that the Government should retain the plantations in their own hands for the present. The time has not, therefore, arrived for finally deciding upon the question of their retention or eventual sale. As at present informed, however, I incline to the opinion that a portion of the plantations, with the manufactory, should remain permanently under Government superintendence." Though it has never been the intention of the Indian Government to continue permanently in the bark trade, the time for withdrawing from it has been deferred during scientific investigations on the subject of the production of a cheap febrifuge.—*Home News.*

CRYPTOMERIA JAPONICA.—We are glad to learn that the Local Board of Nuwara Eliya have purchased 5 lb. of the seed introduced by Mr. Deane from Japan, and Mr. Nock wants Government to buy the balance, as the tree is one of the finest and fastest growing at Hakgala. We recently obtained some seed from Darjiling, where the tree has long been established, and is growing freely. We mean to plant our 10-acre lot near the Nuwara Eliya Bund with this Japan pine, with *Toona cedrela* and *Gravillea robusta*, all 6x6 to allow thinning out. Can any reader offer objection or suggestion? What other tree is recommended, apart from eucalypts, of which there is a superabundance on Abbotsford? A correspondent advises planting *C. Japonica* "in belts as closely as cotton trees. The lower branches die and you have a perfect wall of timber."

THE BLACKSTONE TEA ROLLER.—Mr. Barber writes as follows:—"You will remember favoring us with a call, a few months since, with the manager of Carolina accompanying you. He is now studying the achievements of the "roller" at his own leisure, in his own factory, as the enclosed will show you. With the power he can bring to bear on the "roller" at that model factory I learn he gets in 120 lb. at a fill, and works it off in 20 minutes. This includes the filling and discharging. The K. A. W. rolling may be a trifle longer and heavier than mine, to suit the system and mode of manufacture adopted there, no doubt, but it is gratifying to know that with sufficient power the capacity of the "roller" is raised to 120 lb. at a fill. Mr. Armstrong thought I could drive it much faster and finish much quicker. It may be of interest to know that English-made machines will be shipped from next month. Tea is down in the higher grades quite 2d per lb. and I have been no exception. If things don't mend I shall run the gamut for 10-penny teas against all comers and play tennis in the afternoon."

K. A. W. Tea Factory, 28th April 1886.
T. H. Barber Esq.

Dear Sir,—The Blackstone "roller" in use here gives great satisfaction, though leaf received at this factory is coarser than what is usually plucked, a charge of 120 lb. withered leaf is well rolled and twisted in 20 minutes. Very little power is needed to drive the machine.—I am, dear sir, yours faithfully,
W. MCGONSON.

Strictly speaking, this communication is an advertisement and ought to be paid for as such. The agents of Mr. Jackson's machinery include testimonials in their advertisements, and we have been asked why we make exceptions in other cases. Our reply is that in the earlier stages of inventions calculated to be of advantage to the great enterprise of the country, we feel bound to afford such encouragement as we can to those who direct labour and ingenuity to the benefit of the whole body of planters as well as their own. When the merits of an invention have been thoroughly tested and are well-known, however, the case is different and future testimonials in favour of the Black-

CINCHONA.—Then the Government has something better than many a gold mine in its cinchona plantations on the Nilgiris. These estates, occupying an area of 850 acres, represent an outlay of £203,174, and the actual amount realised has been £199,260. So that virtually the Government has been recouped for its whole investment, and it now owns upwards of half a million of cinchona trees, of which a moiety are *Officialis* and *Succubra*.—*Madras Mail*.

TEA BULKING.—In the number of your journal for January 7th 1881, there is an article headed "Tea Bulking in India and China," from which I would ask your permission to reproduce the paragraph which describes the method of bulking adopted by the Chinese. The method is as follows: "Immediately after the final firing, and while the tea is still hot, it is spread in even layers, two or three inches in thickness, one on top of the other at the end of a godown, the height and breadth of the heap being according to the size of the parcel, or chop as it is there called, to be made. An ordinary wooden rake is then drawn down the face of the pile, thus raking an equal quantity from all the layers, and securing (the all-important point) a thorough mixture of the tea. As fast as it is raked down it is shovelled into baskets and weighed, an equal quantity being put into each chest."—*Home and Colonial Mail*.

TEA: THE WEATHER REPORTS FROM ASSAM are generally favourable, although the nights continue rather cold in some parts, and a few gardens in the Dibrugarh District have had their tea plants and buildings damaged by heavy storms. A good deal of injury has also been done by hail to many gardens in Kachar the plants being completely stripped of their leaves. Those gardens which have escaped the hail promise a successful season. Good rain has at last fallen in South Sylhet, but the season must from the long drought prove a late one. The reports from the Darjiling and the Terai are fairly favourable, but more rain would be acceptable and in the Duars, where it has been very dry good rain has now fallen Chittagong has also had a good fall of rain, and there has been a little in the Hazaribagh District but the continued cold weather has rather damaged the prospects in the Kangra Valley.—*Calcutta Englishman*.

THE U. S. GOVERNMENT'S TEA FARM.—Commissioner Colman, of the Department of Agriculture, has quite an unfavorable report upon the government tea farm at Summerville, S. C. Mr. Vardell, the superintendent, writes him that the severe winter and protracted cold weather have stripped the tea plants of their foliage. He says that he thinks some varieties are dead to the root. He has found one variety standing in certain places that endures the cold better than others, and from which no leaves have fallen. He is now engaged in plowing between these plants, but says that he discourages all applications for them, because they are evidently enfeebled by the cold weather and in no condition for removal. Commissioner Colman is understood to be of the opinion that this experimental tea farm had better be abandoned, as he is having propagated on the grounds of the department tea plants sufficient number to meet all calls for them. *Grand street March 1886.* [Full details of this failure will be given in the *Tropical Agriculturist*. Ed.]

EFFECTS OF THE LATE HURRICANE IN FIJI. The cry of "Pity poor Fiji!" may well again be raised. In the midst of severe depression the archipelago has been desolated by a hurricane. Details like the following ought to make us thankful that we are beyond the influence of Cyclones:—During the morning news of a specially disastrous character was received from the natives on the windward side. They reported that on the Wednesday night the sea had broken in on them and

had rushed up in furious strength to between 50 and 60 feet above the usual high tide level. This had completely wrecked the whole windward side of the island which is undefended by a sea reef, and the water had done more damage than the wind. The towns of Vadravadra, Yedna, Ureta-Nacavanadi and Vabuaso and Malowai were completely washed away. Lamiti was partially destroyed and in Vabuaso a shark was killed among the houses. The whole coast line is completely wrecked and changed in appearance and the condition of the people is pitiable in the extreme.—*Fiji Times*.

THE LATEST REPORT OF A "PERFECTED" MACHINE FOR CLEARING RHEA FIBRE is thus given in the *Gardeners' Monthly* in a letter from New Orleans:—Mr. I. Innemat has on exhibition in Machinery Hall a machine for cleaning and preparing for use Jute and Ramie taken in their rough state from the fields where grown. It would seem that he has perfected his machine; if so he will really be a second Whitney to the Southern States. The cotton States use millions upon millions of yards of jute bagging every year. The jute can be made a very successful crop in the Southern States—the only difficulty is to sufficiently cheaply prepare it for use. With a machine that will properly and cheaply do its work the South will have a new paying crop and millions of dollars that now go abroad can be kept in the country. What it would do for jute it would do for ramie cloth firms which nearly rivals silk.

THE RISE OF THE TEA INDUSTRY IN CEYLON.—It is not surprising that some at least of those who have invested their money in Indian tea, and adhered to the industry through good and evil report should feel somewhat anxious upon the subject of Ceylon rivalry in tea. It is not soothing to the feelings of the pioneers of an important industry to find that ere their projects are completed, and before the sunshine follows the rain, a neighbouring island, which had been regarded by many as played out, should suddenly assume a new vitality, and blossom out in tea which is not only of excellent flavour but which owing to the favourable geographical and topographical conditions under which it is grown can be placed at a favourable price on the London market. Some of the pioneers of tea who, to use a phrase taken from our trans-Atlantic cousins, have put "their bottom dollar" on tea in Assam, Cachar, Darjeeling, and the Kangra Valley, must, as we say, feel anxious lest some of their well-laid plans should "gang alee." Let them take heart. There is more than room enough for all. Undoubtedly Ceylon is a rival and a formidable one, but this should serve to stimulate rather than to weaken the efforts of Indian tea planters. Their common enemy is China, if the term may be used in regard to a trade competitor. Tea planters in India and Ceylon are on their metal. They are anxious to make good tea, and they wish to do this cheaply. They are keeping their eyes open very wide, and are earnest in seeking the best methods of ensuring these objects. We believe that it is impossible to keep down the unflinching enterprise of the Briton, and that as obstacles beset him he takes in fresh quantities of determination to overcome them. Already the import of teas from India and Ceylon has made some havoc in the shipments from China, and the game goes on merrily. The consumer is beginning to realise that there is economy in the teas grown by his own countrymen. They are strong and possess a flavour, which grows on the palate. Dealers, wholesale and retail, recognise this, and there never was a better prospect than at the present time for these teas. Let the friendly rivalry between India and Ceylon continue, and may planters profit by the experience of each other.—*H. & C Mail*

Correspondence.

To the Editor of the "Ceylon Observer."

COBRA BRAND TEA: ENGLISH AND FOREIGN BUSINESS—A DISTINCTION?

LONDON, April 9th.

SIR,—My attention has been drawn to a paragraph against "Cobra Brand" tea in the *Ceylon Observer*. Although it is not stated in plain language, yet it is hinted that Cobra Brand Tea is not pure Ceylon. With the English business, since November 3rd of last year I have no connection, and therefore am in no way responsible for the way in which that business is conducted. But prior to November 3rd a guarantee under a penalty of £100 was affixed to every parcel and packet, vouching for the contents being pure Ceylon Tea and nothing else. That guarantee I continue to use (though I understand the Ceylon Tea and Coffee Company Limited have dropped its use) upon my packets which go to America, South America, the West Indies, Sweden, France, Italy and many other countries. I affirm that I send nothing but pure Ceylon Tea unmixed with any other, neither have I ever, since I commenced to sell Ceylon Tea, sold any other.

I question whether many of the retailers of Ceylon tea in London could truthfully make a similar statement. On the other hand deception is rife. Tea is sold everywhere under the name of Ceylon and I intend, on the arrival of Mr. J. L. Shaud, to make certain representations to him which may induce action to be taken.

In the face of present prices this loyalty to your article has been very hard upon me, but I hope for easier terms in the future. I am continuing to do good work for Ceylon in pushing her tea into fresh countries where, until my consignments enter, Ceylon tea is often unknown. I pack a good liquoring, good leaf Ceylon, looking ahead for my reward. My bond packed teas could never be described as rubbish and it is very painful to me, after all the good work that has been done under the "Cobra Brand," that it should thus be dragged in the mire. I enclose my circular with testimonials, which prove that my tea is appreciated abroad. Yours faithfully

A. HUTCHISON.

P. S.—Although the last *Ceylon Observer* has been in some days, it is only now, just at post time, that my attention has been called to the editorial and foot-note. I shall treat of this later.

Who then is responsible for the English business in Cobra Brand Tea, we ask?—Ed.

CROTON-OIL PLANTS AND THEIR ENEMIES: CATERPILLARS GALORE.

Negombo, 27th April 1886.

DEAR SIR.—My good friend Mr. Holloway, at the Planters' Association meeting held on 28th Jan. 1881, stated that even bees would not approach a croton-oil plant to gather pollen from its blossoms, implying thereby I presume that so virulent was its poison that no insect would attack it. I have also heard others express very much the same opinion, and was myself inclined to endorse it. This idea has been exploded in a most effectual manner as you will see. About a week ago the conductor in charge of my little place between Polgahawela and Kurunegala wrote to say that caterpillars had attacked the croton-oil plants and were destroying them rapidly. I went up as soon as I could, expecting to see something like the sight that

presented itself to my view about three years ago when caterpillars attacked a field of castor-oil plants, and after devouring everything but the trunks, began upon the Liberian coffee and cocoa! What I did see was not quite so bad, yet it was bad enough. The insects (one of the hop caterpillars, the larva I fancy of the common brown and black butterfly, rather numerous there just now) had made a clean sweep of every leaf over about three acres of croton-oil plants; there was nothing left but the main stems and the primary branches: all the young twigs were eaten, and the bark from the secondary branches clean eaten off. The trees had erop on and were laden with blossom, but nothing came amiss to these voracious creatures; their stomachs must be as case hardened as that of the sailor who drank off a glass of *aqua fortis* and who when told what it was he had drunk coolly replied: "Aqua forty or aqua fifty I'd like some more of it"; so no doubt would these insects. The rest of the erotons, over other 25 acres, were only slightly affected as they had been taken in hand in time: the bushes were shaken and the insects killed on the ground. This had to be done three times; and so tenaciously do they hold on with their I suckers that it is very difficult to get them off; this however is a very effectual way of getting rid of them. The trees on the 10 acres will, I think, shoot out again as the weather is wet; but had this occurred at the beginning of the dry weather I believe they would nearly all have died. Not a leaf of the cocoa was touched, evidently it was too insipid a diet after the strong and stimulating eroton. I should like to know if anyone else has had a similar visitation,—Yours truly,

WILLIAM JARDINE.

TEA-MAKING: A REMEDY FOR "ALLEGED DETERIORATION"—THE PROPER TEA-DRIER?

Colombo, 29th April 1886.

DEAR SIR.—During a visit to Dimbula last week, my Benjamin and I made an excursion to the Templestowe estate where one of the "Fluc Tea Driers" is erected. After reaching Watawala by rail, we stepped along nearly two miles of railway sleepers, and then ascended a steep path for a mile and a half, unacademised with tolerably large boulders. We were not sorry therefore when we got to the top of the hill, to see the Bungalow of the hospitable Mr. McCausland looming in the distance below us; this we reached in due time and did full justice to a good breakfast.

After digesting it we inspected the brand new tea-house in which the "drier" is placed. As both the furnace and chimney are outside the building, there was not a particle of dust or dirt in the tea-firing room, which, everything being spick and span new, was perfectly clean, tidy and well arranged. I found the "drier" being worked properly, with one or two slight drawbacks, which will be rectified when the small ovens, to contain the firing trays, are placed upon it.

We tasted some of the tea which Mr. McCausland just made, and, though I am an inexperienced tea taster, I know sufficient of its manufacture to be able to distinguish between good and bad brews. I was much struck with the very fine color of the infused leaf, and the dark strong appearance of the liquor. I asked Mr. McCausland if he could account for this. He said he thought the great heat of the tea-firing room, was conducive to a good wither of the leaf, in the room above it, and also to the fermentation of the leaf, which was twice rolled in one of Jackson's new small rollers.

On thinking over the matter on my way to Colombo, I determined to have a sample of the Templestowe tea, if I could get one, tested by my friend Mr. Caldecott Smith, in whose judgment I have great confidence. The agents of the estate were kind enough to give me samples, and yesterday, they were tested by my friend, who pronounced the color of the leaf, and the strength of the liquor to be as near perfection as possible, and he added that "no tea equal to it in quality had in his opinion been sold in Colombo for six months."

A well-known, and hilarious tea expert happened to run upstairs, whilst the samples were drawing. I seized him by the collar and insisted upon his giving his opinion on the important points. He concurred with Mr. Smith.

It is extremely gratifying to me to find the first working of the "Fluc Drier" in the Central Province has fallen into the hands of so careful and intelligent a Manager as Mr. McCausland. I have no doubt as favorable results will be obtained by the experienced tea-makers on "Meray," "New Brunswick" and "Gallamudena," where "driers" are being put up. I was unable to visit these estates when I was in Dimbula, as the distance to walk was rather beyond my capability. When these and several other "driers" which have been applied for are completed, the question whether great economy and efficiency in tea driers cannot be combined, will be definitely settled.

I should mention when watching Mr. McCausland's people making tea, I was struck with the apparently large quantity of fermented leaf put on each tray: more, I think, than we are accustomed to put on each tray. No doubt, the process of drying is prolonged, but the question naturally presents itself whether slower firing is not rather a good thing? On Templestowe time was no object; all I know is that whether it was wither, or the ferment, or the slower firing, a very beautiful tea was made.—Yours truly, C. SHAND.

CROTON OIL PLANTS AND CATERPILLARS.

Dumbara Valley, 1st May 1886.

DEAR SIR,—I have seen the same thing as Mr. Jardine describes. In this case the caterpillars had eaten off every leaf and had been caught. The croton plants appeared to be quiet dead, but they have since come round and are now flourishing. This is *one* reason why I always disliked crotons as shade for cacao. F. W. GRAY.

THE DETERIORATION IN TEA.

DEAR SIR,—If an unprofessional may hazard an opinion as to the lessened value of Ceylon tea! what say you to leaves being plucked too young, before they have any pronounced flavour, and the tea being fired before sufficient fermentation has taken place? Perhaps it is these defects which cause our tea to be shut out of the American and Australian markets where it is said the middle and lower classes complain that it will not stand a second water. VERB. SAP.

[The real objection is its quality and consequent price compared with rubbishy China.—Ed.]

TEA PACKING.

SIR,—Touching the agitation about corrosion to tea lead, I would ask, is the lead packing allowed to touch the wood case?

The Chinese paste paper on the lead packages they use, is this done in Ceylon? and if not, why should it not be tried?—Yours,

HONG KING.

CROTONS AND CATERPILLARS.

Haputale, 3rd May 1886.

DEAR SIR,—Mr. Jardine in your paper of 29th ult. records a visitation his croton-oil trees have had, I regret to say he is not the only one whose trees have been so attacked by caterpillars.

An army of them paid a visit to one of my croton clearings during the last week of November 1884, and devoured every leaf, blossom and fruit on many of the largest trees, and would have soon gone over the whole clearing, but that coolies were at once put on to shake the trees and gather the fallen enemy from the ground.

As November of last year advanced a careful watch was kept, for the approach of the expected visitors and from their first appearance, about the 22nd of the month, an average daily force of 55 able-bodied coolies at work for five consecutive days shaking the trees and gathering the caterpillars were unable to stamp them out before they left the greater of two clearings, as if they had been exposed to a week's sharp frost. The trees, however, soon renewed their foliage and are now loaded with fruit and flower. It is proposed that the attack in November of this year shall be from our side before the enemy are fully armed for destruction.—Yours truly, J. W.

A POUND of bananas, it is said, contains more nutriment than 3lb. of meat or as many pounds of potatoes, while as a food it is, in every sense, superior to the best wheat bread. It is not generally understood that bananas fried, baked, or roasted are very appetizing, and that sliced and placed in a dish, with alternate slices of orange, they make a most delicious dessert.—*Queenlander.*

OPINION OF AN EXPERT ON UVA TEA.—I have liquored the sample of Uva tea sent me. The character of the leaf is hard and leathery; fairly well rolled, color good, fermentation equal, rather underfired, liquor strong and pungent, a hard rasping tea well adapted for mixing, value about one shilling—your sample may be considered for first or early making, good. My opinion of Uva tea is that it will be generally characterised as a strong pungent tea, if you wish to get a high flavored fine tea you must pluck very fine.

NATAL TEA FOR THE LONDON EXHIBITION.—The exhibits are as follows:—

J. L. Hulet, Kearsney Estate, Nonoti.—Show cases of syringa wood containing teas, as follow:—18 lb. pekoe souchong, 18 lb. pekoe souchong F, 19 lb. pekoe B, 17 lb. pekoe, 25 lb. pekoe A. 21 lb. golden pekoc, 16 lb. flowery do., and 19 lb. pekoe.

A note to this consignment says:—This estate produced and placed in the market the 1st 500 lb. of tea grown in Natal, season 1881-82, from seed imported by the Lower Tugela Division Planters' Association, from Calcutta, with the advice and assistance of Mr. J. Brickhill, of the Umbilo, who had previously successfully imported a few Assam hybrid plants. In Natal there are 282 acres under cultivation in Victoria County, 20 in Durban County, 70 in Lower Umzinkulu district and about 200 acres are being prepared for next season's planting.

The yield per acre is exceedingly large, viz.:

Within 3 years, 200 lb. dry tea.

" 4 " 400 " "

" 5 " 600 " "

" 6 " 800 " "

We should doubt exceedingly 800 lb. being obtained save over a few acres under such cultivation as will scarcely pay.

LONDON TEA LETTER: TEA DRYING.

You will soon be hearing of fresh developments and improvements in tea-dryers. These are certainly not the days for resting on one's oars in the race of life. Our friends whose special vocation it is to supply the enterprising tea plantation of to-day with the best means of harvesting his crop, are evidently imbued with a thorough faith in the "survival of the fittest" doctrine. Mr. Greig is convinced that his X. L. ALLI. dryer, is the machine of the future, and has anticipated the general verdict somewhat by bestowing upon it his own, by way of designation. This sieving machine for sorting is nearer perfection in its line than anything I have yet seen. I was vastly pleased with the one on exhibition at South Kensington. Planters who now ruefully contemplate the loss of so many pluckers, in the height of a vigorous "flush," now required in the tea-house, will do well to write for particulars of these sieving-machines. Their price is very moderate, and they are really most effective and they allow of the tea being broken by hand on the upper sieve at will. His tea-roller is a handy little bag machine for small gardens, and cheap. It has several very great improvements on Lyle's, and may even be worked by hand on gardens not yet able to afford steam power. Mr. Davidson is bringing out a vastly improved dryer on the "Sirocco" principle, called the "T. Sirocco," from its shape, which is somewhat that of the capital T, with the corners between the arms of the cross and perpendicular filled up with flues. This is the evolution and perhaps the completion of the "No. 3 Sirocco," type now so well thought of by those who have tried it. This new shape will probably be found to give a greatly increased yield. I have not yet seen more than the drawing, so cannot speak from personal observation as to the result of splitting the draught. Mr. Davidson, in whom personally all who know him must have great faith, hopes big things of this type and speaks enthusiastically of it, and it is not to be supposed that he would do so without having assured himself of his grounds beforehand; consequently we may take it for granted that the merits of this new "Sirocco" are well worth investigating by those about to purchase dryers. Messrs. Gibbs and Barry are also bringing out a great improvement in the dryer, and one that has been tried with marked success in Mr. Gibbs's grain dryers, and which is therefore no longer a mere theory. The improvements relate principally to the method of applying the draught. As the petitions for patent are only just being sent out to India by this mail, I am not at liberty to enter into particulars.—*Indian Planter's Gazette.*

JAPANESE FOOD PLANTS.

A list has been published by Herr Mueller-Beeck, Yokohama, where the compiler fills the post of Consular-Assist. of the German Empire. The list goes far to prove the omnivorous character of the Japanese in the matter of goods selected from the vegetable kingdom. As with us the Brassicas come in for a large share of attention, and in all cases for the leaves only. The following may be mentioned.—*B. chinensis*, *B. orientalis*, *B. campestris*. *B. Rapa* of the last named both roots and leaves are eaten. Of *Raphanus sativus*, the Radish, eleven sorts are given, of which the roots are eaten fresh, salted, pickled in Rice spirit, and also decayed. Oranges, Shaddockes, and Lemons are found in six species. Peas and Beans are used both for the seeds and pods; but they differ much from our new kinds. *Sonch. hispida* (the Soy Bean) is grown in twenty-four varieties, and are chiefly used for seed and meal. The roots of *Dolichos hirsutus* are employed for the preparation of starch and meal. In the case of *D. hirsutus*, *D. umbellatus*, *D. bicolor*, *D. ensiformis*, and *D. ensiformis*, the seeds and pods are used for the same purpose. The seeds of plants allied to our *Scirpus Baccarum* Linn., viz. *Phaenolus radiatus*, *P. p. pendulus*, *P. r. satibolatus*, and *P. vulgaris* are used.

The fruits of *Prunus tomentosa* are used in the ripe state for eating raw and for jam, and in the unripe state in salt and vinegar as pickles. The petals of the flowers of *P. Pseudo-cerasus* are salted, and likewise used in water as a flavour to drink. The fruits of *P. japonica*, which were figured in the *Gardener's Chronicle*, No. 576 p. 45, and those of *P. incisa* are eaten. The Pear, the Quince, the Apple, and several other varieties of *Prunus* occur in the list.

Under *Umbelliferae* are *Foeniculum vulgare*, *Coriandrum sativum*, and *Daucus carota*. Under the name of *Shim-giku* the leaves and flowers of *Chrysanthemum coronarium* are eaten, and the flowers of *Pyrethrum chinense* are eaten steeped in vinegar. The roots of *Tussilago japonica* and the leaf-stalks of *Petasites japonica* are used as spices. Dandelions, Lettuces, and Thistles are used as with us. The leaves of *Phytolacca Kämpferi* and three other species are used, the first as a vegetable, and the others for flavouring. *Rumex palmatum* and *R. acetosella* are used in medicine. The fruits of *Viens Carica* and *F. pumila* are in use as dessert, and those of *Castanea vesca*, *Juglans regia*, *J. Sieboldiana*, and *J. mandshurica*.

Amongst *Coniferae* the seeds of the *Salisburia adiantifolia* and *Torreya nucifera* are eaten. In *Cycadaceae* the leaves, pith, and seeds are eaten, sago being manufactured from the pith. The roots of several species of *Araucis* and *Alcornoques* are used as food. The *Liliaceae* furnish the Japan kitchen with many fine bulbs that are cooked for the table, and those chiefly of sorts which find their greatest appreciation as decorative plants in flower-beds with us. Apparently all the roots of Japan Lilies are eaten as vegetables, as well as many species of *Allium*, viz., *A. Schumpramii*, *A. acrocarium*, *A. senescens*, *A. odorum*, *A. cepa*, *A. fistulosum*, and *A. ascalonicum*. Even *Ferros* do not escape being eaten, as we find the young fronds of *Pteris aquilina* and *Osmunda regalis* are made use of for food; and among *Lichens*, *Bacomyces digitatus* and *Usnea florida* share the same fate. Of *Fungi*, *Puffballs*, *Agaricus campestris* and one other species of *Agaricus*, and *Tremella auricula* are consumed. Two species of *Algae* are in a manner cultivated in Japan; small branches, on which *Euteromorpha intestinalis* and *E. complanata* attach themselves, are stuck into sea-water in September, October, and December, and taken out in November and January, when the sea-weed has grown to a usable size. The above is merely an extract from an interesting list published by the German Government, which intends further to supply agriculturists, gardeners, and others connected with vegetable cultivation, with seeds of the various plants named in Consul Mueller-Beeck's report. Amongst the varied productions of Japan and China there are doubtless many plants which can be acclimatised in the milder parts of Europe, and turned to good account. Our vegetarian enthusiasts should also welcome any addition that would lend piquancy to a fare which, to say the least against it is unimpaired by its sameness.—*Gardener's Chronicle.*

ADVANTAGES OF BEET SUGAR OVER CANE SUGAR.

- The great advantages that the Continental agriculturist and manufacturer have over the Colonial are—

 - 1st.—A plentiful supply of willing hands to labour at moderate wages.
 - 2nd.—Short time necessary for raw products to come to maturity.
 - 3rd.—Favourite crops to rotate with beet and a climate suitable for growth of cereals and potatoes, feeding of stock, &c., &c.
 - 4th.—The roots of such a texture that they can be easily manipulated, while the residue is of considerable importance as cattle food.
 - 5th.—Cheap fuel, with proximity to the best and largest market in the world, and low freights.
 - 6th.—Climate of Europe more favourable for working saccharine solutions owing to absence of ferment germs rendering the manufacture so much more simple.

On the contrary the Colonists have to contend against:—

1st.—A sparse population who, in the absence of a winter and all inducement to lay by something for old age, cannot be depended upon for any continuous labour; hence necessity of importing strangers at a great cost to prosecute the sugar industry.

2nd.—The sugar cane takes from 12 to 16 months to come to maturity, and is accompanied by a luxuriant growth of weeds. In a tropical climate much labour is required to keep these down, and also to promote the circulation of air and allow the sun to penetrate among the ripening canes.

3rd.—Absence of any crops other than plantains to rotate with canes, and as the former are perishable, and the home wants limited, they could only be grown at a loss.

4th.—The flinty texture of the sugar cane stalk and its being as yet only of value as fuel, militate against any process of manufacture that would destroy its value as such.

5th.—The nearest market in which they can purchase coals is Great Britain, and freight and charges, raise their cost to 36s. and 37s. per ton before they can be delivered at furnaces. Freight home is also high.

6th.—The necessity of manufacturing the cane into sugar immediately after being cut, as immediate deterioration sets in—all saccharine running into acidity and fermentation.

ADVANTAGES OF CANE SUGAR OVER BEET SUGAR.

1st.—A large weight of cane can be grown on a given area of land, and at a cheaper rate than beet roots. 18 tons of sugar cane per morgen are grown with good tillage at 12s. 6d. per ton—beet costs 13s. 1½d. per ton, and produces 10 tons per morgen.

2nd.—The sugar contained in the sugar cane is of greater purity than is found in the beet, hence less loss in purification, and the finished cane sugar is on an average 6° higher in analysis, and brings in to the manufacturer at least 2s. 6d. per cwt. more, even after allowing for the extra cost of freight from Demerara, as compared with that from North Germany to this Country.

3rd.—Beet sugar must be sold as made, and is often forced on the market at unfavourable times, because it suffers heavily from increase of glucose if stored, and a heavy penalty is enacted for delivery of any but fresh-manufactured beet-crystals. In Paris, at present, beet crystals of old crop are almost unobtainable.

Weighing all these pros. and cons., it is evident that the two industries are very evenly balanced, and that those of the sugar cane planters who are in a position to avail themselves of the very best appliances in manufacture might, under improved conditions of labour, look forward to times when they would hold their own against their formidable rival. One thing is evident, and that is, that strict economy must be practised in our colonies. The days when sugar at £25 to £30 could stand the enormous public expenditure which characterised some of our leading West Indian Colonies are past, and both governors and governed must be prepared to reduce taxes and expense to the extent required for producing sugar at one-third less cost than hitherto.—*Sugar Cane.*

THE ADVANTAGES OF TOBACCO.

Dr. Pereira states in his *Materia Medica* that he is "unacquainted with any well determined ill-effects from the practice of smoking," and Christien speaks of it as a luxury used all the world over without any bad effects having been clearly traced to it." In a letter of Dr. Parke's author of "Parke's Manual of Practical Hygiene," in the *Lancet*, page 384, 1880, he confesses that he has searched in vain for any satisfactory evidence of the harmful effects of tobacco, and that it was for this reason that its consideration was not given place in the work mentioned.

The fact has been pointed out that men are on the whole as healthy as women, while nine out of ten of the male population of the world use tobacco, and women as a rule abstain. In the learned pro-

positions, about one-half of the ministers are addicted to it in some form, likely, three-fourths of all physicians, and nine-tenths of members of the legal fraternity.

In looking calmly at the tobacco question, there is one feature calculated to excite alarm, and that is the habit of chewing and smoking so widely practised among boys. This, to young growing boys, is unqualifiedly hurtful. They voluntarily endure the first disagreeable effects of the tobacco to acquire what they consider an accomplishment, the habit is finally confirmed, and with an entire ignorance of its powers, added to a tendency to immoderation, the growth and development is often seriously interfered with, and the worst results follow. They smoke and chew generally the worst tobacco, and to a degree which would positively be harmful with the majority of adults. This matter should be corrected by proper action of our legislators, with whom the responsibility rests. Smoking, when done at proper times, facilitates digestion. The sense of relief obtained by a cigar, after a heavy meal, is well known to smokers. Dyspepsia sometimes follows the discontinuance of tobacco, and is removed when the habit is resumed. While the abuse of tobacco weakens the system and leads to emaciation, used intelligently it exerts favourable influence upon nutrition.

Hammond, by observation upon himself, found a gain in weight with the use of tobacco. Fiske attributed an increase of twenty pounds in three months to tobacco. "Tobacco, when the food is sufficient to preserve the weight, increase it; when insufficient, and the body is losing, tobacco restrains the loss" (Hammond), Boerhaave, of Holland, over two hundred years ago, referred to tobacco as being antilothal to hunger. It seems that the power to undergo severe exertion and fatigue, either mental or physical, is aided by tobacco. "Soldiers of all nations use it. It was a standing injunction of Napoleon that his troops should have tobacco, and it was of great advantage in the retreat from Moscow." (Fiske.) During our late war the soldier would be patient under very severe privations, if he but had a good supply of tobacco to smoke or chew, and when on picket duty would risk his life to strike a match for his pipe.

Situations for loneliness are always rendered more tolerable by tobacco, and it is the constant companion of those who lead lives of solitude, such as that of the herdsmen or ranchmen. A feeling of unrest or discontent made up of ill-defined longings, of imaginary disappointments, and unpleasant anticipations, commonly known as ennui, is responsible for much unhappiness. This unfortunate condition of mind is removed by the soothing influence of a cigar, and the moroseness and gloom are quickly dispelled. As much of every day is filled up with care, our degree of comfort in this life will depend largely upon our ability to bear it uncomplainingly. That tobacco assists us to do this; that it enables us to look upon life more complacently, must be the conclusion of every one who has experienced its influence. That it enables us to toil with less fatigue, is equally true. The readiest writers generally use tobacco, and cannot accomplish the same amount of work in the same time without it, and those connected with newspaper and other literary work, who have often to write against time, find it of inestimable value.

Tobacco formerly enjoyed a deserved reputation as a medicinal agent, and was extensively used in scabies and other cutaneous disorders. It has been largely supplanted, however, in modern practice, by other remedies. The use of tobacco during a mercurial course decreases the risk of salivation, and cases of ptyalism have been reported cured by its employment. Before the discovery of chloroform, tobacco served a useful purpose in the hands of the surgeon in cases of strangulated hernia for obtaining complete relaxation. Tobacco constitutes a most valuable addition to the ordinary poultice in local painful affections. In two cases of carcinoma of the breast, by incorporating it in a local application, a marked advantage was noticed by the writer in the relief of pain. As

an ingredient in asthmatic cigarettes, with belladonna, stramonium, etc., it is entitled to share in the remedial effect.

The limited medical range of tobacco is unimportant in comparison with its social and physical influences. Among its many beneficent powers, it appears to allay worry and lighten toil. It is an aid to mental work, and a help to reflection and complacency. It promotes sociability, and in the words of one of its champions, "makes a man act more like a Samaritan." While it is neither liked nor needed by animals, who loathe it, it seems to be required and craved by man, to whom its characteristic properties appear peculiarly grateful and often useful. It has repeatedly and unjustly been called a curse, but those who have written most of its beneficial effects, as a rule, have never used it. Indeed, this comforting substance is so far removed from the idea of a curse, that it should not be forgotten when we recount the many blessings of mankind.—*Indian Agriculturist*. [Apart from the undoubted and direct injury done to young persons by the use of tobacco, the worst probably that can be said against it is that a good many who smoke much drink in proportion. On the other hand it enables many to dispense with alcoholic stimulants. If smokers would only smoke where the habit is not a nuisance to nonsmokers there would be no cause of complaint. But it seems rather hard that smoke inhaled and sent round the salivary glands of one person should be ejected by him into the atmosphere breathed by his neighbours.—Ed.]

PRUNING FRUIT TREES.

Much has lately been written on this subject, but plain instructions showing the best means and mode of checking exuberance of growth and inducing fertility are still wanted. Is it not a deplorable fact, in view of all that has been written about pruning and its effects, that in nearly every garden one enters or sees, be it large or small, where ordinary fruit trees are grown, the trees, though they may be annually pruned, are usually run wild, showing a maximum of growth accompanied by a minimum of fruit buds or fruit? The trees are not infrequently beautifully formed—the result of much careful pruning to this end. This is particularly noticeable in them after their annual winter pruning; but, soon in summer or autumn, they usually present a plethora of strong immature shoots, instead of an abundance of fruit. This is especially noticeable in the case of apples on the crabs and pears on the wild pear stock. The object the various pruners seem to have in view is probably twofold—pruning to keep the trees circumscribed and at the same time induce fertility. But, judged by general results, the latter is by no means realised. Many of those who prune vigorous trees must surely begin to see that it very ineffectually secures the object in view, viz., constant fertility. For more than a year I have been acquainted with a small neglected garden, the house in connection with which was, until just recently, uninhabited for more than twelve months. In the garden, in a clump rather closely planted, are about three dozen pear, apple, plum, and cherry trees. Their trunks vary from 4 in. to 6 in. in diameter, and their heads, previous to being pruned last month, ranged from 10 ft. to 15 ft. or more in height, and all, without exception, beautifully proportioned and balanced. A few, of course, were perhaps too dense, especially some of the varieties of pear of compact, upright growth. Evidently—and I took particular notice of them—they had never been pruned from the time they were planted out as low-stemmed standards. Their hard port, strong leaning shoots and branches, literally beset with nut-brown fruit buds, indicated a degree of prolific force seldom exhibited in over-nursed, much-pruned fruit trees. To keep such trees healthy and fertile, some, I presume, would recommend that they be allowed to keep on and upward, unchecked by either knife or saw at their tops or roots. Others, with a view to keep them circumscribed, seeing that they are already well enough for all practical purposes in a small garden, and fertile, would root-prune them, and probably thin out a few of the branches. But that is

not what has been done. The garden last month was let to two men to dig and prune; the outcome is, that those once handsome trees are fore-shortened half-way back, and the stumps almost divested of their flower-buds! They are practically spoilt. Instead of the prolific force already referred to, when they start into growth a week or so hence, they will exhibit what some call "concentrated vigour," and will take some time, perhaps a series of years' growth, unpruned, before they again attain the highly fertile condition enjoyed by them previous to being ruthlessly pruned.

I might with propriety stop here, but I should like to make a few remarks on another by far too prevalent phase in the growth-condition of fruit trees, quite distinct from the healthy, vigorous, and prolific phases we have already considered. I refer to trees that are known to have relapsed into fertile ways. It is usually exhibited by trees about fifteen and over fifteen years of age. They are, as a rule, neither vigorous nor quite exhausted. I have more particularly in view a few pear and plum trees trained to the walls of a garden in Scotland; I saw them about this time last year. They are, as near as I can judge, eighteen years old. I know that for many years they were highly fertile—bore heavy crops of fine fruit. They do so no longer, notwithstanding that their extended branches are well furnished with rather large branching spurs. Nevertheless, flower buds are now seldom formed thereon, or when they do, and blossom, fruit seldom results therefrom. It is a clear case of exhaustion. They lack the prolific force of early days, and it can only be renewed in the trees as they now stand by pruning the stay-roots that have wandered deeply into the hungry subsoil, and by freely mulching with good manure. There are thousands of trees in a similar condition that are greatly in need of similar treatment.—G. S.—*Field*.

TOBACCO CULTIVATION IN CEYLON.

The following is the result of our observation and experience: and we are of opinion that if our friends in Colombo only take the trouble of studying this branch of Agriculture, they are sure to be able to enter the field as competitors, and the Western Province may vie with the North in the Produce of Tobacco. The district of Udakinda and Badulla at one time produced excellent tobacco. In hill districts the declivity of a hill, rather gradual than abrupt, or a spot that is sheltered from winds was found most suitable for the growth of the plants; but at the same time it is necessary that the plants enjoy a free air; for without that they will not prosper. The ground or wood land for planting tobacco must be well burned, as the greater the quantity of wood-ashes the better. The spot must be well strewed with ashes, laid smooth and light; then blow the seed from the palm of the hand gently on the bed, and cover it with palm or plantain leaves. When the plants are about three inches high, draw them and plant them, about two feet asunder; and when they become as high as one's knees, cut or pluck off the top, taking care to let the best alone for seeds. The plant should now be daily attended to, to destroy caterpillars that infest it, as also to take off every sprout or sucker that puts out at the joints, in order to throw the whole vegetable nourishment into the large leaves. When the edges and points of the leaves begin to turn yellow cut down the stalks and see that moisture is fully off the plant. As fast as it is cut, let it be carried into the tobacco room, which must be so close, as to shut out all air, and hung up on lines tied across for the purpose of drying. When the stalks begin to turn brownish, take them off the lines, and put them one upon another, and lay on them heavy weights for about a week or fortnight; and they are fit for sale. It is a common practice in Jaffna, after the ground is prepared for planting, to bury a few inches deep, at the place where the tobacco plant is to be put in, green leaves of an oleaginous species as the tobacco tree quite enjoys such feeding. In a dry climate the irrigation of the land with water from the well is no doubt a matter of great importance. We are sorry to observe that our tobacco

as lost much of its former estimation, in the market. Perhaps a supply of fresh seeds from Virginia is desirable to improve the stock. But a monopoly, were we afraid, has led people both to scamp the work and the curing. It is time that this branch of agriculture should be better looked to. India is going in for tobacco cultivation. Time was, when the Pravanore Rajah engaged the services of merchants in Colombo by sending large sums of money to purchase Jafna tobacco. Many a Tamil broker and tobacco merchant can look back to that period as the time when they turned the corner on the road to fortune.

In Uva what was called Badulla cigars were looked upon as quite worth the money you paid for them. Fill a monopoly of the trade, by Moonmen and a ready market for the leaves, led to scamping, and dishonest preparation of cigars, green and inferior tobacco being largely used. Those who were duped at first in making large purchases, were disgusted and from mouth to mouth the report spread that the Badulla cigars were an imposition and cheat; and so both preparation of tobacco, and its agriculture, are the history of the past. In trade, as in agriculture, honesty is the best policy. Let our tobacco planters and cigar-makers and merchants make this the rule and not the exception.—“Ceylon Patriot.”

ORANGE GROWING IN FLORIDA.

During the season of 1884-5 a few boxes of Florida oranges were shipped, as an experiment, to England. They sold, both in London and Edinburgh, at prices which, though justified for the nonce by the novelty and the unquestionable superiority of the fruit to that common in the home markets, were nevertheless “fancy” prices. There is no doubt that the experiment, having once succeeded, will be repeated on a larger scale, and the time will probably come, before long, when the oranges of Florida can, and will, be sold in England at prices at once remunerative to the seller and within the means of most consumers. The question, however, will still remain whether the price they will command in any market can reasonably be called remunerative to the grower.

Apart from the many “English colonies” established in recent years throughout Florida, there are few spots in the peninsula which have not a few young Englishmen among the number of their settlers; and, while it is not my intention to discourage such of my young fellow-countrymen as are inclined to seek a home and a living in Florida, I wish dispassionately to examine the prospect which is influencing their choice of a new country. Before doing this, let me preface a word or two defining my own position. Three points only need be touched upon in this connection—(1) That my choice of Florida as a temporary home was dictated solely by considerations of health, and was absolutely free from any considerations of money-making; therefore I can justly claim to be impartial. (2) That I own a tract of land in Florida, and am therefore interested in the progress and development of the state; and (3) that I have not planted, and do not intend to plant, an orange grove upon any part of my land, and have, therefore, nothing to gain or lose by competition, and have no interest but that of a consumer in the success or failure of the orange-growing industry.

With this preface let me turn to the main question, “Is it possible to make a living by orange culture in Florida?” I have asked this question hundreds of times of older settlers than myself—men whose experience should qualify them to answer it without hesitation. As was to be expected, the answers have differed widely in different cases; but when I have put the further question, “Have you made, or are you now making, a living by orange-growing?” there has been much more unanimity in the replies. I do not, of course, pretend to say that there are not those in Florida who are making, not a mere living, but a handsome income, by the produce of their orange groves. Several groves could be mentioned whose fortunate owners are netting twenty, thirty, and even forty thousand dollars a year by the sale of their golden fruit; but these are exceptional cases. Inquiry will almost invariably elicit

the facts that these men are amongst the earliest settlers; that they had the choice of the best land in the State of Florida at a time when that land was to be had for the asking; that they went through years of toil, privation, and anxiety, before they could see any return for their outlay and their labour; and that their groves are now costing them every year a small fortune in wages and cultivation, to say nothing of the incessant anxiety which makes the handsome return they afford an uncommonly hard-earned income.

And such being the case with the old settlers, what is the prospect for the new comer? Growers of oranges in Florida are divided into two very clearly-defined classes. The one consists of that large and ever-increasing body of wealthy Northerners whom the severity of the Northern winter is driving year by year to the sunny skies and mild climate of the southern peninsula. Having spent one winter in Florida, they are fully determined to spend more, and, with a view to creating an interest for themselves in their Southern home, they buy a parcel of land, plant it with orange trees, and look forward hopefully to reaping a golden harvest. With most of them it is not a mere pastime to which they are devoting a portion of their superfluous wealth; it is a speculation upon which they intend to make a handsome profit, and, considering it in this light, they are willing to lavish their dollars upon the preliminary stages, looking to the future to recoup their outlay with interest. During their absence in the summer months the grove is left in the hands of a caretaker, who sees that it is duly ploughed, cultivated, and fertilised, and that his own bill is duly presented and paid by his patron.

The other class consists of those who for various reasons have chosen Florida as their permanent home, and, induced by the example of those around them, look to orange culture as a means of making a living. For them the prospect, when reduced to hard practical fact, is less hopeful. They have brought with them a sum of money, large or small, which is really their capital, upon the judicious investment of which they depend for subsistence. They find that land in Florida has already risen in the estimate of its owners to prices far beyond those at which really good arable land in other States is held. The owners are shrewd enough to know their market, and to see that the ever-growing tide of winter travel will enable them sooner or later to get whatever they choose to ask for the commodity they offer. In many cases it cost them nothing at first, and they are therefore sacrificing nothing by holding it till the “good time” comes. The *bona fide* settler must therefore pay their price or go without, and, having once made up his mind to do the former, he finds that he has made a considerable hole in his capital when he comes into possession of his title deeds.

Orange-growing lands may be roughly divided into two classes, pine land and “hammock.” The former, as its name implies, is in its natural state covered with pine trees, more or less thickly, and generally, too, has an undergrowth of what is known as scrub-palmetto and scrub-oak, or “Black Jack.” Hammock is the name given to the more densely-wooded land lying upon the margin of lakes or rivers, and covered with cabbage palms, wild orange, magnolia, and oaks, and other deciduous trees and shrubs, forming a perfect jungle, and mated with vines of every description. Hammock land, owing to the nature of its growths, is far the more valuable for cultivation, as the decay of countless generations of plants and leaves have supplied the soil with the rich humus which is the one thing wanting to the soil of the rest of Florida. It therefore commands much higher prices than pine land equally well situated as regards facility for transport, and in another way, shortly to be touched upon, the preliminary expense of a purchase of hammock comes heavily upon the would-be orange grower. There is also the important consideration prior to purchase of land, that, whereas the “high pine” is the healthiest locality in Florida, standing above the reach of marshy exhalations, and affording as a rule a plentiful supply of wholesome water twenty or thirty feet beneath its surface, the hammocks are most invariably uninhabitable—the very richness of soil,

which constitutes their value as arable land being noxious, if not actually fatal, to human life. The great national curse, malaria has its chosen home on this fertile soil, and the purchaser of such land is, therefore, perforce compelled to increase his outlay by the purchase of a second site within easy reach of his grove land, but free from its drawbacks for his residence.

Having bought his land in a state of nature, and with due regard to the proximity of transportation, supplies, and labour, the next step is to clear it of timber, and prepare it to receive cultivation. The new settler will be well advised not to attempt this task himself, but to put it in the hands of one of the white or negro "clearers" to be found in every part of the State. These useful men will contract to prepare land for the plough at regular rates, according to the nature of the growth and the prevailing wages in the vicinity. High pine land can generally be cleared for \$20 to \$30 per acre (25 being an average rate), the clearer having the trees as his perquisite. For this sum he contracts to remove the pine trees, stumps, and roots; but, unless so stipulated, his contract will not include grubbing, *i. e.*, the removal of the scrub-palmetto and other long fibrous roots, which effectually impede the ploughshare, and must be eradicated prior to cultivation. This grubbing the same man will undertake, but he will generally prefer to be paid by the day for his labour in this department, and will employ the necessary hands at his employer's expense. Unless the palmetto is thick—and this is a sign of poor land—grubbing will rarely cost more than \$5 per acre, and on much high pine land it is practically unnecessary altogether. Clearing hammock is quite another matter. The clearers always look askance at a job of the kind, alleging the difficulty of getting hands to take the work, and the purchaser will be fortunate if he succeeds in getting hammock land moderately well-cleared and scrubbed for \$100 per acre. Many purchasers of such lots content themselves with "deadening" the oaks and other tall trees by fire, burning off the undergrowth, and merely clearing small spaces, to allow of planting an orange tree in each space, trusting to time and natural decay to do the work of clearing. I have myself visited a grove—that of Capt. Sims, of Ocoee, Orange County—commenced in that way, and subsequently cleared out little by little as opportunity offered. The orange trees had not suffered, but had made good healthy growth year by year, and the owner estimates his crop for the coming season—the first since the entire clearing was completed—at no less than 70,000 oranges, his grove covering just seventy-five acres. Where wild orange trees are numerous in the hammock, they should be carefully preserved and laded with good varieties, thus saving all the time lost in the growth and maturing of young trees, and insuring an early return and a hardy stock.

The land, being cleared and grubbed so far as the purchaser intends to carry these operations, requires a fence. The most satisfactory and most generally adopted for orange groves is the barbed-wire fence, of four strands of wire and one good stout rail—the latter being required by law for the purpose of rendering the obstruction visible to horses and cattle. This style of fence will cost altogether about 60 cents a rod, or, say, \$100 for five acres of land. Ploughing the land will cost \$2 or \$3 per acre, and then all is in readiness for planting the grove.

Now it is that the important difference between pine and hammock land begins to make itself felt. The former has a white sandy surface, and a depth of only a very few inches of cultivable soil. The latter is black rich soil, full of leaf mould, and possessing in itself all the essentials for successful orange culture. Whatever is wanting in the former must be artificially supplied, and innumerable "commercial fertilisers" are in the market, each of which claims to be the one thing needful. It is not my purpose to recommend any one of the number, or to dwell on this part of my subject. Suffice it to say that all the well-known brands, certainly of us orange-growers, and that they may be bought for price varying from 20 to 30 per ton, or 25 cents, and that the prices are paid in a great measure on the locality, and the rates of freight paid by the agents for the carriages of the stuff from the factory. Every tree

planted on pine land will require large and frequent applications of "fertiliser," the purchase of which soon become an important item on the debit side of the ledger. The trees themselves will cost about half a dollar each, if two or three-year-old trees are set out; and this, reckoning sixty trees to the acre, adds \$30 per acre to the initial outlay, without allowing anything for the time of the "hands" employed in the planting. Most hammock lands are sufficiently rich to render the application of manure at the time of planting unnecessary, and some good authorities go so far as to say that this condition of the soil will remain unaltered for many years. Hammock groves are, however, generally treated with a moderate quantity of fertiliser after their first two or three years, the amount being regulated by the general appearance of the trees, and being always much less than that required upon pine land.

The orange grove is now set out, the future trees looking like little wands stuck upright in the earth, and giving scanty promise as yet of what they will become. The remaining requisites are careful frequent cultivation, sufficient supplies of fertiliser, minute investigation and constant vigilance to guard against the attacks of disease and insects, and last, but not least, patience. The orange grower who fondly imagines that he has only to set out a grove, and then take his ease till his oranges are ready for market, is reckoning sadly without his host. No tree requires more care and attention than the orange, and it is only just to add that no tree better repays the care expended upon it. Certainly none shows more readily, even to the inexperienced eye, whether it has or has not received its due meed of attention. Not only are the insidians and often fatal diseases waiting to seize the ill-cared-for tree, but the eye of every neighbouring orange-grower is upon the groves around him, and a pallid, irregular growth will as surely betray the owner's carelessness or laziness as if the trees had tongues with which to proclaim it. The amount of labour actually necessary to success was well described to me by a gentleman whose place I visited shortly after coming to Florida. He has, or had, besides his grove, a very pretty and apparently very productive garden, which, however, he told me he was going to abandon to its fate. I ventured to remonstrate, gardeners being rare in that section of the State, and in my ignorance suggested that surely his trees might be trusted to care for themselves, while he gave his attention to his flower beds. With a smile of compassion for my innocence, he replied, "I can spend every hour of every day, from sunrise to sunset, busily occupied with my trees, and if I were able also to stay up with them all night I should not have an idle moment."

In their fourth or fifth year blossoms will appear upon some of the trees, a few of which will set; but the proud owner will be disappointed to receive the sound advice to remove all the fruit as soon as it appears. The reason for doing so for a year or two is that, hardy as the orange tree appears to be, there is perhaps no fruit so exhausting to its parent. Scarcely has one year's crop been removed when the next commences to form, and, with no period of rest, the tree is occupied in the development of its fruit during almost an entire year. Allowing young trees to fruit will therefore lessen their growing powers, and dwarf them unnecessarily; besides which, the oranges, if allowed to ripen, are valueless as compared with those of older trees.

Two or three more years must pass before the fruit becomes moderately thin-skinned and juicy, and the grove yields sufficient to be worth boxing, and distributing among the grower's friends as an earnest of future performances; and it will not be until the trees are ten or twelve years old from the seed—*i. e.*, eight or nine years from the planting of the grove—that sufficient fruit can be shipped to cover the year's expenses and yield some small profit as interest upon the outlay of previous years. From this time onwards, if due care be taken, and no unforeseen accidents occur, the yield may be expected to increase pretty steadily; but the same vigilance will still be necessary to repel the advances of disease and the insect enemies of the orange tree.

Such is, briefly sketched, the orange-grower's early career; and I think it must be sufficiently plain from

these facts that there is room for grave doubt whether my original question can be answered affirmatively. Any industry, to be remunerative, requires a moderate preliminary outlay, moderate working expenses, and a regular and accessible market for its produce. Florida orange-growing, at the present time offers none of these advantages. Land in the neighbourhood of railroad or water communication is forced far above its true value; hired labour, owing to scarcity of hands, is very costly, and the market, offered by the great cities of the North and West very precarious. Want of organisation has hitherto placed orange growers completely at the mercy of the commission merchants, who, even if perfectly honest and trustworthy themselves, cannot guard against the disastrous effects of frost *en route* or a glutted market on the arrival of their consignments. Consequently, it is nothing unusual to find that, while A. has been fortunate in placing his fruit in New York at a moment when the supply was short and prices high, and has netted a dollar a box on his shipment, B., although shipping from the same point only a day or two later, has lost half his fruit by bad weather on the journey, and has not realised sufficient on the remainder to pay freight. An organisation is now being formed among Florida growers, which proposes to control the shipment and distribution of fruit and other produce to the north and west, and, if it proves successful, we shall hear of fewer cases of loss, and injury to the oranges, and of more satisfactory returns to the growers.

But still, the prospect cannot be described as encouraging for the beginner. The heavy original outlay, the length of time before any return can be expected, and the risks from frost, disease, and insects, are all considerations which must be faced by any young man who looks to Florida oranges as his source of income; and a very rough calculation will suffice to show how great the risk is in proportion to the chance of success. Suppose a purchase made of 20 acres of good fine land with fair shipping facilities. Such land will cost at least \$50 per acre, generally considerably more. Allow \$30 per acre for clearing and grubbing; \$200 for fencings, \$60 for ploughing, and \$30 per acre for trees. We have thus a preliminary outlay of \$2,460, without allowing anything for the fertiliser used in planting, or for the time and labour of the planter. The cost of cultivating and fertilising subsequently may fairly be estimated at \$40 per annum per acre or \$800 per annum for the grove. Here again I am making no allowance for losses through frost or disease, preferring to take the lowest possible estimate. Supposing the trees to be three years old at the time of planting, and to come into marketable bearing at nine years old, we have six years at least without returns representing an outlay of \$4,800 on caretaking. The whole cash outlay, then, up to the time at which returns commence, is \$7,260, and in order to state the case fairly, the interest on the original investment and on each subsequent year's outlay should be taken into account. Now, in Florida 10 per cent is considered a moderate rate of interest, and is the usual rate at which mortgages are effected. If, then, the original \$2,460 had been invested at this rate, and in each subsequent year \$800 had been added to the investment, the total sum standing to the investor's credit at the end of the sixth year would be rather over \$10,500. If he were then to commence drawing his annual interest, his income from the investment, still at 10 per cent, would be \$1,050. This sum, then, he must net from the sale of his oranges in order to make a fair return on his outlay; and to do this he must market, in such condition as to bring a clear net profit of one cent per orange (which would be considerably above average prices), no fewer than 185,000 oranges every year, allowing, as before, \$800 annual outlay on his grove. I do not say that his trees, with due care and good fortune, will not produce this number, or even more when they have attained their full growth; but, all things considered, it is the game woe his candle?

The object of the above calculation I have not, or rather than over state it, expressed, and who ever may consider they are in favour of the grove. I have omitted to add anything to annual outlay for the taxes and packing, or even for freight, which are all considerations. The new-comer then must have at his command

a sum of \$2,460 (roughly £510) with which to lay out a 20-acre grove, and sufficient, in addition, to keep him and pay the expenses of grove-tending for at least six years, before he can look for any income from the sale of his fruit. Part of the annual expenditure will, of course, be saved if he is able and willing to do field-hand's work himself, or if he applies himself to some other method of earning money to pay expenses. But, in either case, it is still fair to estimate the cost as above, since his own time and labour must be considered equal in actual money value to that of a hired hand.

So far I have written only of orange-growing, and I have endeavoured to put the case fairly and impartially. The conclusion I have been forced to arrive at is, that the risks were too great and the outlay too heavy to justify expectations of returns commensurate with the expense and anxiety. How far time and matured experience will alter the case, I am unable to prophesy. Rates of freight, which are at present almost prohibitive, may be so far reduced by the extension of the railroad system in Florida, and the increase of competition, as materially to better the orange-grower's position; but so long as the tide of winter-travel increases, and it continues to be the fashion among wealthy northerners to own a grove in Florida, the cost of production will not diminish. How, then, are *bona fide* settlers to make a living?

This question may be answered very easily, and here is a grain of comfort for the intending emigrant. There are three ways open. The first, and hitherto the most successful method, is to trade, not in oranges, but in orange-groves. Land cleared and planted with young trees finds a much readier market among the visitors than wild land of equally good quality, and at prices which afford a good profit upon the outlay. In this way the original investment can be rapidly turned over, and an income realised almost from the outset. A second method is "truck-farming," or, in other words, market gardening for the northern cities, or for the supply of fashionable southern resorts. The small fruit and vegetables of Florida are in immense demand in northern markets, and strawberries, green peas, tomatoes, cabbage, and cauliflowers (all of which can be ripened in the open air in Florida in February and March) bring returns which seem almost fabulous. A gardener in Alachua County recently told me that four barrels of cauliflowers which he shipped to New York early in 1884 brought him a net profit of \$27 (about 55 12s.) per barrel; and a gentleman in Jacksonville during last winter raised radishes in large quantities, and sold them at that town for a cent apiece. These two instances are sufficient to show that there is a field for the gardener, and they might be multiplied indefinitely from the experience of other Floridians. More care is necessary in the selection of land for gardening than for orange-growing; but there is abundance of such land in the State, and its prices are not as a rule so high as those asked for grove lands. Thirdly, there is always the consideration that Florida is a new State, as yet sparsely settled, but growing so rapidly in popular favour that towns are every day springing into existence where hitherto a few scattered cabins in the woods have been the only signs of human habitation. Each new town increases the demand for labour in all its branches, and the man who is able and willing to work need never be without employment. Manual labour in America does not involve loss of caste. The gentleman (I use the word advisedly) who has spent his working hours with a can of paint and a sheaf of brushes on the top of a ladder will be as welcome in the drawing-room in the evening as if he had lounged away the day, cigar in mouth, upon the hotel piazza; and where wages are as high as they are here, and all honest work is honestly paid for, the dollars accumulate with wonderful rapidity.

Lastly, I would add a word of warning to the possible settler in Florida. Do not be deluded by the offers of those who, for a "premium," are willing to teach tyros the art of orange-growing. It is a stale old trick, but yet it is occasionally played in many parts of the State. These accomplished gentlemen find the rate of wages demanded by field-hands a serious bar to success; and it

is no doubt more agreeable to receive a well-educated young Englishman, with a cash premium, into the bosom of their families, than to have to pay \$30 per month to a negro labourer. The one will soon be as capable as the other, and will have the additional attraction of giving his work gratuitously. Hence the willingness of these philanthropists to impart their secrets. Unfortunately, however, for their schemes, there are hundreds of reputable orange-growers, equally knowing and equally capable of teaching, who will not only waive the premium question, but will gladly give board and lodging, and a salary to boot, to any decent white man who wants to gain experience, and is willing to gain it practically. An advertisement in any of the Florida newspapers would speedily find such an opening for the beginner; and his cash in hand will be more satisfactorily invested in the purchase and clearing of land than in the pocket of his would-be preceptor.—BERNARD HASTIE, De Lance, Florida.—Field.

YATYANTOTA AS A TEA DISTRICT.

Sir,—Enclosed I send you Weather Report for April. The temperature was taken by a self-registering thermometer placed in a verandah with a north aspect and protected from the direct rays of the sun. The rainfall was taken by my neighbour on Balgownie, but, as the estates are quite close to one another, the report may be considered correct for both places.

I think we may challenge any district in Ceylon to show a better leaf-producing climate.—Yours faithfully,

W. B. HOPE.

Morton Estate, Yatyantota, May 5th.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter).

PARIS, April 17.

The daily annual average milk from a cow varies from 4 1/2 to 8 quarts; ten quarts of milk will produce 1 lb. of butter and 4 lb. of cheese. In some parts of France, 26 quarts of milk are required for one pound of butter, while half that quantity in the case of a Jersey cow, suffices for the same amount of butter. It is a maxim in French dairies, that "young cream will produce butter of the finest quality, but less in quantity; while "older" cream gives the opposite results. Thus, in Isigny, the farmers churn twice a week, and forward direct, not to the Paris butter market, but to the wholesale-dealer—just as they consign direct to London and New York.

Churning has the effect of breaking the membranes of the little sacs in the milk or cream, enclosing the

fatty or butter ingredients, and these agglomerate like the rolling of a snow ball. In Normandy, the hand-dash turns at the rate of 35 to 40 strokes per minute; when driven by steam or horse-power, fifty revolutions is the rule. Isigny farmers prefer a temperature of 57 degrees Fah. at the time of putting the cream and milk into the churn—the temperature is raised 10 degrees by the churning, and 15 minutes in summer, and often 60 in winter, are necessary before the butter can be taken off. The "Normandy" is the favorite churn, barrel-shaped, 33 inches long and 32 in diameter, working on supports. The butter is kneaded both with hand and spatula. In summer the milk is creamed every 24 hours, and in winter every 48 hours. Naturally, the best butter will be obtained from pure cream, and next, from whole milk. In the latter case, a slight acidity is considered essential before churning.

In Germany, brewers' grains are being more and more extensively employed for pig feeding. They must not be sour and should have the chill taken off them. If acid, they cause scour; to remove the excess of sourness, the grains are often washed. They are best employed when mixed with other food; this will also make up for any deficiency in the grains of albumen.

In Hanover, a Theisen apparatus exists for the drying of brewers' grains for cattle feeding. Professor H-mberg, of the Gottingen Agricultural station, undertook to test the comparative value of the grains in the ordinary or fresh state, and the dry. In the former, they contain 77 per cent of water, and in the latter, 14. Briefly, the Professor found, that in point of nutritive and assimilative value, the dried were four times more valuable than the fresh grains.

In the East, sorghum is extensively employed as fodder. In other places, it has been cultivated for its sugar. For neither object has it met with favor on the Continent. It had, as a fodder, the reputation of irritating the kidneys. The cause of the latter appears to have been found. Berletot discovered that nitrate of potash or saltpetre existed in all plants in all parts more or less abundantly. It was not drawn directly from the soil, but formed directly in the tissues of the plant itself. The soil supplied the potash, but the plant worked up the nitrogen, partly from the soil and partly from the atmosphere—the latter a disputed point still with scientists—in the form of ammonia and its salts and nitric acid.

Professor Deherain has detected notable quantities of saltpetre in the pith of maize stems, not more so in sorghum. Stalks of the latter when stripped, contained over 2 grains of saltpetre per lb.—Now 88 lbs. of sorghum per day means an absorption of 6 ounces of nitre and two ounces of saltpetre, form at any time a very powerful diuretic. This may explain the grave maladies—and some reported deaths of stock fed on sorghum, due to its richness in nitrate of soda. Nettles are often consumed in spring by many people as a substitute for a scarcity of "greens," cases of sickness have been reported from this peculiar way of "grasping your nettle." May not the cause be attributed to the known richness of the plant in saltpetre? Professor Deherain states the stems of sorghum can be recognized as dangerous, if on being dried and then burned, they crackle or spit. It is the base of the stem which is richest in the nitrate; hence, not a bad plan is to cut it within 8 inches from the soil.

In dry, sandy, and hilly districts of France, forze when bruised, is given as feed to cows, and occasionally to horses. Dr. Macreker has instituted in Germany experiments to test the comparative feeding qualities of turzo versus oats for horses. During 95 days, four horses, instead of oats received crushed turzo or whins, plus chopped straw. The latter was supplied to four other horses but with 9 lb. of oats to each, instead of the turzo. All the horses had 21 miles or more of less hilly roads to traverse daily, and with carts more or less laden. The animals fed on the turzo, improved rather than fell away, and 87 fr. were saved under the head of oats.

There is nothing exactly new in resorting to saline solutions, as a means for separating sound from dubious seeds. Only the practice is becoming more extensively

followed as an additional safe-guard against seed merchants say—accidentally dishonest. A few preliminary siftings of the seed having been made, the steep is prepared: the stronger, relatively, the brine is, the more it will allow only the plumper and heavier seeds to fall to the bottom. On the latter is placed a fine sieve, which receives the sinking seed. The contents of the sieve are next spread out on a sheet and rapidly dried in the air, when the seed can be immediately sown by hand or machine.

Potato-culture is likely to receive a new impetus, since the plan of selling them peeled, sliced and dried like certain fruits, seems to hit the tastes of the export market. The drying of the potatoes can follow the period of the desiccation of fruits. The method obviates decay and germination of the tuber, and occupying a less volume, transport will be cheaper and less difficult. The potatoes are peeled by machinery: next carefully washed, sliced into rounds, and left for 20 minutes in a strong solution of kitchen salt. The brine induces firmness in the slices and prevents their changing color—thus securing what sulphur does for fruits. Later, the cuttings are left to drain, placed in the drying apparatus on hurdle shelves, and submitted to a temperature varying from 176 to 194 degrees Fah. They thus remain a little longer in this hot air bath than fruit. Before using, the slices have to be steeped twelve to fifteen hours in water, when they will become as fresh and as flavory as new potatoes.

Professor Schribaux draws attention to the scarcity of good beet seed this year, and the fraudulent processes of merchants of drying inferior seeds, as well as steeping, to deceive the unwary. The real grain of seed of the beet is contained in a capsule, but at least these capsules ought to give from 70 to 80 sprouts of germs. If this percentage be realized, by a test germination, the seed may be accepted.

STRAWBERRY GROWING IN ENGLAND.—Strawberry growing by the hundred acres was surely an American invention, but our English cousins are fast following in our wake. *Gardening Illustrated* says that H. E. Vinson & Co., of Swanley in Kent, have 500 acres, which yielded about 1,000 tons last year. They employ about 1,000 hands in the marketing season, 300 being pickers. These live in tents, scattered over the fruit farm. The worst fruit is not sent to market, but is made into jam on the spot.—*Gardeners' Monthly*.

GERMAN METHOD TO GRASS A BANK.—For each square rod to be planted take half a pound of lawn-grass seed and mix it intimately and thoroughly with 6 cubic feet of good dry garden earth and loam. This should be placed in a tub, and liquid manure diluted with about two-thirds of water added and well stirred in, so as to bring the whole to the consistency of mortar. The slope must be cleaned and made perfectly smooth, and then well watered, after which the paste just mentioned should be applied with a trowel, and made as even and thin as possible. Should it crack from exposure to the air, it must be again watered and smoothed up day by day until the grass makes its appearance, which will be in from eight to fourteen days, when the whole declivity will soon be covered with a close carpet of green.—*Gardeners' Chronicle*.

COCONUTS IN NEW JERSEY.—The following is from a Philadelphia paper:—"It will no doubt surprise our readers to learn that successful efforts have been made by English capitalists to domesticate in England certain species of coconut palm that is now growing there at all seasons and producing fruit, which, if it be true, we shall have efforts made to domesticate the same tree on the Jersey coast, so that the seaside resorts along that shore may in due time assume a tropical aspect with palm trees growing in the open air." The original paragraph was of course intended, as the English say, as a "rig" on the ignoramuses who do not know that tropical heat, and a temperature never

lower than 45°, is necessary to grow a coconut palm of any "species." Our Philadelphia friend had better get out of the hole by asseverating that he was simply playing a game on the Jerseymen. Still, with the dense popular ignorance of the simplest facts in gardening which so thoroughly prevails, the nurserymen and seedsmen will soon, as in the case of the famous Eucalyptus, be run down with orders for coconuts of "a certain species" for planting along the coast from New Jersey to Labrador, and they had better provide themselves with something, even though they be Osage Orange balls, for the silly people who will have something or do even you "one-horse concerns, not up to the times," if you have not what they ask for.—*Gardeners' Monthly*.

MANY SPECIES of Australian native trees are known to be extremely rich in tannin, notably several kinds of wattle; but in many cases much the same difficulty is experienced in economically extracting the valuable ingredients as has so long frustrated the efforts of iron smelters to extract iron from the Taranaki sands. An Adelaide firm has, however, lately patented a new process of their own invention for extracting the tanning material from the wattle tree—a process in which the whole of the tree is used, and an enormous waste thereby prevented. If this process can be applied to other trees containing tannin a double economy will be effected—first, of the wood which is consumed in the extraction of the tannin; and, secondly, in the increased facilities for preparing Australian hides. The discovery of a new tanning-yielding plant lends additional interest to the invention, and at the same time affords another illustration of the value of scientific botany as applied to the study and conservation of the flora of the Colonies. The Conservator of Forests in South Australia has found a new species of *Acacia*, to which he has giving the name of *Acacia Spilleriana*, and the bark of which contains 15 per cent of tannic acid. It was discovered in the Mundral of Bright, but has since been found in the Wirrabara Forest. It seldom exceeds 8 feet in height, but is occasionally met with as high as 10 feet. The bush forms a handsome evergreen shrub, is well branched, comparatively dense in foliage, and when in flower is a pleasing feature in the scrub vegetation where it abounds.—*Colonies and India*.

SEEDLING FERNS.—If you want Ferns to luxuriate, and seedlings to spring up by hundreds, you must keep the water-pot in use winter and summer; the very life of Ferns is water, as anyone may prove by the luxuriance of our hardy native Ferns, as well as the great variety that are naturalized in localities where the moisture is excessive, and their almost total absence in dry, arid districts. Look at the healthy, luxuriant specimens that one finds hanging to the bricks or stones at the top of wells, where they are daily drenched with water winter and summer, and compare them with the same varieties under a glass roof where the water-pot and hose are put by for months during winter. I know many very successful amateur Fern cultivators who keep their plants in robust health with but very limited accommodation, for, unlike flowering plants, they do not require strong light, but do best in the shade; and as to soil, they will grow in nearly any kind if the drainage is good, and when this is perfect they can hardly be overdone with water. To anyone anxious to try the raising of seedling Ferns who may not have a glass-house of their own, I would advise the half-filling of a shallow box with rough, porous material with a little fine soil worked amongst it, and on this lay any old Fern fronds that have the seed-spores visible on the backs of them. Keep constantly moist by means of a very fine-rosetted water-pot or syringe, and cover with a large sheet of glass to prevent evaporation, set in any sunny position, and await the result; if successful, the surface will soon be covered with green scale-like growths, and then the various forms of leaves will spring up; let them make two or three good leaves, and then carefully lift with all the roots that can be got, and pot in 3 inch pots in light, sandy soil. A mixture of turf that is partly decayed, peat, and sand, will grow any of the ordinary kind of Ferns to perfection.—*Gardening Illustrated*.

TEA INVESTMENTS:—CEYLON VERSUS ASSAM.

A correspondent interested in Ceylon writes to us that he lately met at home a gentleman who has extensive interests in tea planting in Assam, with whom he discussed the relative position of the Indian and our island districts in respect to the prospect the former affords of successful competition in the matter of tea-growing. As regards quality, there appears to be no doubt but that Assam—at least on certain gardens—is fully able to hold her own; but it was acknowledged by the authority referred to that the good qualities, and, in fact, the present average of tea crops of Assam can only be produced at such a cost that Ceylon teas must ultimately oust a large proportion of them from the London market. Indeed he seemed to think that as a paying industry, tea planting in Assam must in a few years, begin to go down before the increasing and more cheaply produced crops of Ceylon, and he talked of investing in this colony so as to be prepared for the evil days which he foresees. It may be that this is a rather pessimist view to hold; but it is evidently shared by many who are engaged in tea planting in the Northern districts of India. As we have often said, the greatest praise of the tea districts of Ceylon and of their probable future has come to us from the mouths of visitors who are acquainted with "tea" in India.

In support of the opinions so formed, our visitors generally refer to the advantages possessed by Ceylon. They assert that the more equable distribution of rainfall which this island enjoys is not alone more favourable to the growth of the plant and the development of its leaf, but must enable more frequently pluckings to be made, and that too at seasons when the leaf is in its most approved condition. Secondly, they advert to the great advantage available to Ceylon planters in its labour supply. One authority declares Assam quite unable to compete with Ceylon in this particular, and he can see no hope of the adverse balance being redressed in the future. Equally despondent was the view expressed by this same Indian tea proprietor as to the relative transport facilities possessed by the two countries from the tea-growing gardens to the port of shipment. Others again there are who attach much importance to the special reputation for activity, intelligence, shrewdness and care which mark the mass of the Ceylon planters: the way in which they rub against and emulate each other—in striking contrast with the isolation and somnolence of most of their Indian brethren. Taking all these things into consideration, one authority after another can see no hope (as they maintain) of any escape by the districts they are interested in from the final consummation of the fears above expressed.

Now there can be no hesitation in accepting the weight and force of several of the arguments put forward by these tea authorities. Here in Ceylon we are advancing in the matter of tea cultivation with such rapid strides, and there is such a want of limit to the future possibilities of further advance, that the day must be within the reach of the present generation, probably, when the production of the two countries will be equal. What then it may be as well to ask, will be the position of Ceylon when that parity is attained? We have plenty of land available for almost any extent of development at least in the low and middle districts. And sooner or later, when our home authorities shall have had forced upon them the conviction

they are now so slow to accept, that their duty lies in fostering and promoting the credit of this colony by themselves showing their confidence in its future and by permitting the incurrence of an increase to our comparatively small public debt for the execution of needed paying public works—there will be a superabundance of capital flowing in to permit of that development being realized to the fullest extent.

But what then? Behind this picture of future prosperity based on a wide development of the tea industry there looms for us one difficulty, at least, which must be grappled with. If dealt with in time—if taken firmly in hand at once,—that difficulty may never receive accentuation. If, however, the matter should not be put on a sound basis, the bright picture of the future here may be over clouded to an extent which may hereafter find Ceylon in a position as dark as what which now confronts our competitor, Assam. We allude of course, to the Tamil Labour Supply once so plentiful on our estates. Whatever the cause of the falling-off may be, the lessening number of coolies who make Ceylon their annual place of resort is a fact apparent to all. Something must be done to state this if we are to hope to realize our fullest hopes in the future. The Planters' Association has already been moving in the matter; but we fear the cure for the evil is not to be found in Government measures, or in any mere reform of the present Cooly Immigrant Service, unless at all events, these measures are concurrent with personal efforts among planters and receive full support from that body. The credit of Ceylon in this respect, which used to stand so high among the Tamils of Southern India, has been shaken by many regrettable occurrences. That wages have been temporarily lowered is a matter that cannot be helped. The reduction was forced upon all concerned by circumstances over which they had no control. But, if the implicit belief of the Indian coolies in the certainty of their wage is to be restored,—if thereupon they are to flock to these shores in the numbers with which we have in past days been familiar—the confidence they left during the "days of old" in their European *daratis* must be fully restored. Legislation in this direction to some extent has been tried, and in spite of the support given to it by ourselves and others it failed to secure that co-operation which could alone ensure adequate result. But the chief resource must always be found among planters themselves. Wages will no doubt increase as demand for labour increases, but this factor of temptation towards securing a full supply of coolies will be of little avail unless Ramasami can be once again inspired with the confidence he felt in the palmy days before leaf disease. If we are to see the bright picture we have drawn, realized to the full of our hopes and expectations; it must be by the efforts of those who are most concerned in its realization.

There is another side to our Labour Supply Question however, which must not be lost sight of, and that is the large and increasing extent to which, especially in the lowcountry, Sinhalese are doing the work on tea plantations. It will be seen that in the Kalutara district, on many gardens, Sinhalese are almost the only employees, and their women and children are described as being superior as "pluckers" to the Tamils. We trust it will be the object of every planter concerned to maintain and foster the good relations which in the low as well as in the middle (and as we have heard in some of the high) districts will tend to secure the assistance of the "sons of the soil," the poor among "people of the country" in aid

of the European tea planters. For there can be no doubt that there will be room and to spare, for all the Sinhalese and Tamils who can be induced to work, when our exports rise as they are bound to do to 30, 40 or 58 millions of lb. of tea per annum. As regards our Indian rivals, as a Calcutta authority said not long ago: a fall to 10d or 11d per lb. in the London market would mean a practical embargo on the export of half the Indian crops or say 30 millions lb. of tea per annum. But the vast majority of Ceylon plantations, if labour fail not, ought even at 10d to 11d per lb. average in London, to go on and prosper until even the 60 millions lb. of tea now shipped from India is exceeded!

BEEKEEPING AND ENGLISH SCHOOLS: A HINT FOR SUB-TROPICAL EDUCATION DEPARTMENTS.

Sitting in the greenhouse of Acton Vicarage, Suffolk, where the late Bishop of Ripon and the present Dean of Lichfield were born, and where the Bishop of Norwich, Earl Grey, and his two brothers, and many men of light and leading were pupils, one of our representatives had a long conversation with the Rev. Arundell Leakey on the question which he has made his own—namely, the adoption of beekeeping as a subject under the new code. He said that he had the approbation of Mr. Mundella and the sympathy of Mr. Cloughton, Her Majesty's Inspector of Schools, but complained that what the Government gave with one hand it withdrew with another, for it allowed no child to take the subject up as a specific one under the Fifth Standard. All that was now needed, Mr. Leakey said with enthusiasm, was the removal of a very small stone, the making it necessarily a specific subject and allowing it to be treated as an ordinary one. "But surely you would not put it in competition with the three R's?" "No, not with needlework, but I would with geography, for surely it would be better for a child to know how by keeping bees a whole year's rent might be obtained than the position of the Andes." He dilated on the value to the agricultural labourer of this additional means of income, saying that it required no capital, no premises, and hardly any time. Another peculiarity he dwelt on was that bees trespass on other people's property with the unique result of improving it. Mr. Leakey further said that schoolmasters, from their permanent residence in a place and having time on their hands after school hours, were peculiarly adapted for beekeeping. The master in Acton village, for example, had no less than eight hives, some of which he had patented. Further asked if he knew of any schools which would take the subject up if able to do so, he replied that he knew of several, and he added that, where two hives would pay an average labourer's rent, he thought if these days, when every one was anxious to improve the labourer's condition, his plan was worth consideration. In reply to questions from our representative as to wax imported from abroad, Mr. Leakey gave the following startling figures:—From the West Indies, 1,183 cwt.; from France; 1,905; from Germany, 2,289; from China, 2,414; from Japan, 1,404; from Portugal, 6,918; and from America, 8,163—a total of 32,639 cwt. This, he pointed out, was independent of the best and most remunerative point, the honey, of which from America only the purchases amounted approximately to £50,000. Absence of bees was, Mr. Leakey insisted, detrimental to fruit, and their absence was supplied by wild ones. Bees, he said, find pasture, not only on clover, but on all the

innumerable garden and field flowers, from the early snowdrop and primrose to the late violet, while the lovely fruit-tree blossoms which deck the spring with exquisite white and crimson wreaths at the same time hold out to the bees petals on which they may rest as they drink deeply the nectar of a thousand chalicees. Space prevents our going more into the practical details of the matter, which showed that the enthusiasm of Mr. Leakey, for which he has been thanked by the Beekeepers' Association, rests on a substantial basis, and the subject at least is worthy of consideration, and many will share Mr. Leakey's hope that the Education Department will facilitate the carrying out of their own concession.—*Pall Mall Budget.*

[Query, if the "wax" from China and Japan was all the product of bees. There is wax produced on trees by quite another insect.—*Ed.*]

CEYLON UP-COUNTRY PLANTING REPORT:

DIVERSITY OF OPINION RESPECTING TEA MACHINERY—
WANTED A "PLANTING NOLESWORTH"—ALSO A TEA-SEED
PRICE CURRENT.

10th May 1886.

In regard to the question of what is the best kind of machinery for tea manufacture, there are as many opinions current in the planting districts as there are districts in Ceylon. Men have their favourite Roller, their pet Drier, besides having a leaning toward, some particular kind of Sifter, Cutter and even Packer. This diversity of opinion is only another evidence of the marked individuality which so strongly obtains among the Ceylon planters, and which when crystallized into nervous language takes the form of "allow me to know best." There are some men, however, who have not had the needful opportunities of seeing or testing the capabilities of the various competing tea machines, and who have not yet made up their minds regarding the relative merits of the different claimants for public support. Many of these men are in the market from time to time as buyers, and it is a very marked want which ought to be remedied, that, as far as I know, there is no firm in the island to which you can go, and see for yourself on its premises all the different machines from which a man might choose.

Of those who sell not one seems to be free: all appear to be bound down to sell or expose for sale one particular make, or the machines of one particular maker, and the trouble in consequence to the public who would like to have a choice before investing is indeed very great. What is wanted is a show-room where one might go and see samples from every workshop and where your order would be taken when you had satisfied yourself what kind of thing was going to suit you. I suppose to be a sole agent for a popular maker is a profitable position to get into; but I should say that it does not show much knowledge of the future, when by so doing you shut yourselves out from partaking of the fruits of other inventions. It seems too absurd when you go into such a firm as Messrs. Walker & Co. and ask to have a look at say Kerr's new Roller or any other for that matter save Jackson's, to be told that they only sell the latter. Why should one have to wander here and there to enable one to have a sight of all that is offering? It may be that every individual maker sees in his particular product potentialities embracing and capable of meeting the wants of every tea garden now existing or yet to exist in Ceylon, and that the sole agent dreams the same fond dream. But therein they stand alone, and are subject at any day to a rude awakening.

While on the wants of the community, it has frequently occurred to me that there is a niche unoccupied in the series of Planter's Manuals. We have no "Planting Molesworth." To the enter-prise of the *Observer* press, tropical planters all over the world are much indebted for the handy little volumes which have from time to time appeared on the different products which have engaged the attention of the Ceylon planters, and from which they have tried to make fortunes and have not as a rule succeeded. These however have been all special, and although they contain much information, which might and ought to find a place in the "Planting Molesworth," yet what is wanted is a *rudè mecum*, constant companion, to which the planter could turn at any time to refresh his memory as to what was a fair day's work for a cooly at the numerous occupations he is from time to time called on to perform. It should of course embrace far more than that: prices of building, cost of wood work, current rates charged by blacksmiths, and other artificers. Indeed from the cooly it might radiate out wide enough until it would embrace within its covers even agents' charges and brokers' actual disbursements! What a valuable little volume that would be and still it need not either be big nor yet dear—and there should be a public to buy it.

Yet a last want—this suggested by another, a seller of tea seed, who differs with me regarding the course that article is likely to take in the matter of price. Both buyers and sellers he inclines to believe are often working in the dark, and with the view to let in light, and that the pulse of the market might be felt by all, he suggests that the *Observer* might have a Tea Seed Price Current. In this price current which was to be a column of the daily paper all estates which wished to avail themselves of the privilege might for a fixed monthly sum have the advantages of the publicity which would in this way be given. The buying public too would be able to see where to apply and at what rates they might expect to purchase. The tea-seed price current would run as follows:—

Agar's Land .. Open for orders at R—
Bitterne .. Seed all booked
and so on.

PEPPERCON.

INDIAN TEA COMPANIES.

TEA.—The report of the Managing Agents of the Adulpora Terai Tea Company for the past year shows that the outturn was 690 maunds, against an estimate of 700 maunds, the average price realised being As. 10-4 per lb. The revenue amounted to R35,652, and the expenditure to R30,525, leaving a profit of R5,127; and after adjustment in the Profit and Loss account the sum of R4,638 is available. A dividend of 4 per cent. has been declared and R238 carried forward. The estimate for 1886 is for 700 maunds of tea at a local expenditure of R21,175, which includes 85 acres of extension lot in bearing.

The report of the directors of the East India Tea Company shows that the outturn was 200,190 lb. against an estimate of 184,000 lb., the net average price realised being As. 10-5½ per lb. The revenue was R190,393 and the expenditure R165,429 leaving a profit of R24,969; and adding the balance brought forward from last season, the available profit is R35,307 which admits of a dividend of 3½ per cent. The estimates for 1886 provide for a crop of 3,800 maunds at an expenditure of R163,000.

The report of the directors of the Kalaherra Tea Company shows that the outturn was 104,184 lb. which realised an average price of As. 10-9. The gross receipts were R69,966 and expenditure R58,574, leaving a profit of R11,392, which reduces the debit at profit and loss to R3,127. The estimates for 1886 provide

for an outturn of 108,000 lb. at a total expenditure of R52,500.

The report of the Managing Agents of the Kamptee Gwallie Tea Company shows that the outturn was 106,000 lb., which sold at a net average price of As. 11-6 per lb. The revenue was R76,711 and expenditure R65,457, leaving a profit of R11,257, which reduces the debit balance at Profit and Loss to R6,568. The estimates for 1886 provide for a crop of 1,600 maunds at a garden outlay of R40,000.

The report of the directors of the Kunchupore Tea Company shows that the outturn was 93,610 lbs. against an estimate of 100,000 lb. the average price realised being As. 9-3½ per lb. The gross receipts were R54,814 and the expenditure R49,380, leaving a profit of R5,434 which reduces the debit balance at Profit and Loss to R9,162. The estimates for the current season provide for an outturn of 100,000 lb. at a total expenditure of R51,000.

The report of the Managing Agents of the Second Mutual Tea Company shows the outturn was 1,690 maunds, realising an average price of As. 11-10 per lb. for fine and As. 6-7 per lb. for coarse tea. The gross revenue was R87,807, and the expenditure R59,235, leaving a profit of R28,572, and deducting the debit balance from the previous season the amount available is R20,923. Dividends aggregating 10 per cent. have been declared, and R623 is carried forward. The estimates for 1886 provide for 1,850 maunds of tea at a garden outlay of R61,488.

Dividends have been declared by the Kuttal Company of 14 per cent.; Bishnauth 4 per cent.; and East India Tea 3½ per cent.—*Pioneer Cor.*

COFFEE CULTIVATION IN MYSORE.

BANGALORE, April 22nd.—The Coorg planters have recently memorialised Mr. Girdlestone, the Chief Commissioner of the province, for the reduction of assessment on coffee holdings from two to one rupee per acre for coffee in full bearing and to eight annas per acre for all other land included in the coffee estate. The coffee enterprise in Coorg has suffered greatly in late years by disease, drought and low prices in the home market. Many planters have been utterly ruined, and many driven to sell out for a mere song, and it was hoped the Resident, who professed to have the interest of the planting community at heart, would grant the reasonable concession prayed for by the planters. Mr. Girdlestone's reply now published is extremely disappointing, and declines to accede to the request of the Coorg Planters' Association. The Resident says during the course of his tour through Coorg he visited many estates, and had the advantage of studying on the spot the varied conditions of the aspect of the soil, the slope, the shade, treatment and age, and in conversing with the proprietors and managers succeeded in acquiring valuable statistical information concerning the industry. The planters pointed out that the rate of two rupees per acre on the whole culturable area of the estate fixed when coffee planting was in its infancy and is heavier than the tax on coffee or tea lands elsewhere for the past twenty years in Coorg and shows it to be excessive. The Resident replies that the settlement necessarily must be determined by the system as the averages, Government deriving no direct gain from the high prices which have in past times prevailed. Whilst admitting to some extent the statement made by the Association that far from the industry proving remunerative it has turned out to the great majority to be the reverse, the Resident feels bound to point out that besides the loss from leaf-disease, borer, rat, drought and the like, there have been other detrimental causes at work, which might have been avoided. The land is often unsuitable in character and much in excess of one man's power to manage. The planted coffee cultivation is

continued year after year from borrowed capital. The high interest is large; and advances for labour given without sufficient discrimination. Moisture, which is requisite, is diminished by over-felling, the cultivation is careless, and so on. The Government are not responsible for these mistakes. For special reasons the remissions conceded to nearly two lakhs lately to certain groups of estates, but a strong case must be made out before the Government could lessen the demand on the coffee lands in Coorg.—*Madras Mail*.

COL-IND EXHIBITION.

(From the *Journal of the Society of Arts*, April 16th. Ceylon.)

The Executive Commissioner for Ceylon is Mr Arthur N. Birch C. M. A., and Mr W. E. Davidson, the Honorary Secretary, is busily engaged superintending the installation of the exhibits. The General Committee at Colombo is presided over by the Hon. Sir Arthur Hamilton Gordon, G. C. M. A., and includes amongst its members the Government Agents for the various provinces of the island, the Director of the Botanical Gardens, and the Chairmen of the Chamber of Commerce, the Planters' Association and the Agricultural Association. Sub-Committees also represent the different provinces.

Of the exhibits from the "Spicy Island," the most important will undoubtedly be the representation of the planting industry, to which Ceylon owes much of its past prosperity and to which it will, it is hoped, be much indebted in the future. The collection of the exhibits has been placed in the hands of the Planters' Association of Ceylon; and tea and coffee will here be more adequately represented than at any previous exhibition.

A handsome building, designed by Mr. J. G. Smither, to be known as the Ceylon tea house, has been erected in the gardens between the court and "Old London." It will be devoted to the sale, exclusively, of these Ceylon products.

The entrance to the court will be through a Kandyan porch in carved woods, flanked on either side by a dwarf wall, pierced and ornamented in the fashion of the ancient decoration of Kandy. The porch and wall are faithful representations of portions of the *Dalada Maligawa*, the Buddhist Temple of the Sacred Tooth. On either side of the porch, the first exhibits to catch the eye will be, appropriately enough, trophies of the chase; for Ceylon is perhaps the most accessible country for sportsmen in search of big game. On the right hand, charging out of a jungle with unfilied trunk, will be a notorious rogue elephant, shot expressly for exhibition here. On the left will be represented the leopard, elk and varieties of deer, grouped with the gaudy birds of the tropics.

The decorations of the court have been faithfully copied, both in colour and design, from the Buddhistic art of Ceylon. Facing the entrance will be a colossal gilt figure of Buddha, sitting in the attitude of contemplation, the representation being especially appropriate as coming from a country where the doctrines and the learning of Buddhism have been maintained in their highest purity; and a special case will be devoted to a series of Buddhistic figures and ornaments. Below this figure stands a gateway, elaborately carved in ornamental wood, an exact reproduction of the principal gateway at *Yapahu*, an ancient capital of Ceylon, whose ruins, though not so majestic as those of some others of the buried cities of the interior, are the most picturesque of any.

On the left of this gateway will be ranged a collection of the timbers of Ceylon. Some two

hundred "hand specimens," so cut as to show the grain in every section, will be backed by specimen planks of ornamental and cabinet woods, such as calamander (or coromandel), ebony, tamarind and satinwood. On the other side will be seen the same native woods when carved by native carpenters into cabinets and articles of furniture. This group will be relieved by a collection of elephant tusks mounted on stands of ebony and calamander.

Precious stones, especially those for which Ceylon is famous—the catseye, sapphire, ruby and pearl—will be represented by a collection which will include some of the finest gems in existence. On stands, adjacent to the central jewel cases, will be arranged specimens of the flagree gold work of Jaffna, and of the *repousse* silver work of the Kandyan districts, as well as characteristic sets of Sinhalese and Tamil jewellery, and a special collection prepared by the Kandyan Art Association. There will also be shown, in the front half of the court, an exhibit of lace—the making of which is an important industry in the maritime provinces—as well as tortoiseshell work and ornamental work in porcupine quill, carving in ivory, ebony and coconut (the latter a speciality of Ceylon) and a collection of the quaint Kandyan pottery and of the painted masks used in Sinhalese drama. Basket and lacquer work will appear in this section; and a number of paintings and photographs on the walls will supplement and illustrate the table exhibits. Models of fishing canoes and boats of the pearl fisheries, &c., will aid to illustrate the industries and peculiarities of the people.

The second half of the court (which is divided by a cross thoroughfare) will be mainly devoted to exhibits of the economic sections. Plumbago, the only mineral of Ceylon which is at present remuneratively worked, will be adequately shown in commercial samples and by photographs of the industry and its uses. Cinnamon and the products of the coconut palm, the mainstay of low country cultivation, will be represented by complete collections. A model distillery and casks, containing the various qualities of the spirit, will show the arrack industry as befits its importance, considering the revenue derived by the Government from the arrack farms in Ceylon, and the large export of arrack to Southern India.

Mention must also be made of the unique collection from the Maldiv Islands acquired from Mr. Rosset, a German traveller who has made the group his special study.

Several fine examples of ferns, sent over from Ceylon some months ago have been housed during the winter by the Royal Horticultural Society at Chiswick.

Six Sinhalese, two of them expert cabinet-makers and carpenters have arrived, and will be employed in the court during the Exhibition.

NOTES ON SCIENCE AFFECTING VEGETATION.

By DR. J. E. TAYLOR, F. L. S., F. C. S., &c.

Mr. F. Darwin has just read a paper before the Linnean Society on the "Bloom of Leaves." The "Bloom" is a waxy coating which can be removed by hot water, or even by the heat of the fingers. Mr. Darwin finds that leaves devoid of "bloom" on both surfaces have 64 per cent. which possess no *Stomata* or "breathing-mouths" on their upper surfaces. Leaves which have no "bloom" on the upper surface have 83 per cent. containing *stomata* on their lower surfaces only; leaves having "bloom" on their upper surfaces, but none below, have 100 per cent. of *stomata* on the upper surface, whilst leaves with "bloom" on both surfaces have 62 per cent. possessing *stomata*

above. Mr. Darwin, therefore, concludes that the accumulation of stomata accompanies that of "bloom," and that it is functionally protective against undue wetting by rain, &c.

Speaking of "bloom" reminds me of a most important and valuable patent which has just been granted in the United Kingdom to Messrs. Peacock, of Melbourne, for "Improvements in the Preservation of Fruit." The invention was suggested to the patentees by the discovery of Pasteur that the "bloom" on fruit was the cause of its fermentation, and that if it were removed the fruit could be easily preserved. By permeating fruit with sulphurous acid the "bloom" is removed, and ripe fruit can be kept any length of time, or sent to any distance for use in jam manufacture. Both the taste and smell of the sulphurous acid employed are entirely removed by heat. Mr. Peacock's patent will enable Australia to send its fruit as well as mutton.

It has been discovered, from experiments on floating or submerged leaves, that the gases exhaled by the same plant differ to a marked extent according to whether the sky is cloudy or the leaves exposed to bright sunshine. Those of *Potamogeton lucens* gave 3.6 per cent. in the former case, and 6.9 per cent. of oxygen in the latter case.

A German botanist has recently shown that where the interstices between the finer veins on the upper surfaces of leaves are strongly convex the leaf offers much greater resistance to the tearing force of heavy rain or hail than the lower surface does. When however, the upper surface is quite flat the resisting power of the two surfaces of the leaf is nearly the same.—*Australasian*.

MADRAS GOVERNMENT INTERFERENCE WITH THE CINCHONA TRADE.

The number of trees which were growing in the "permanent plantations" on the 31st March 1884 and 1885:—

Name of Plantation.	No. of trees 31st March 1884.	No. of trees uprooted, coppiced, planted, 1885.	No. of trees 31st March 1885.
Dalabetta	48305	209	5018
Naduvattam	26810	5052	1837
Hooker	334851	2985	22900
	1122766	7987	7185
			513370
			1820741

The total amount of bark taken from the trees on the estates during 1881-85 was 118,017 lb. Besides this there remained over on 31st March 1881, 92,526 lb. making a total of 210,543 lb. Of this quantity 81,880 lb. were disposed of during the year, leaving a balance in stock at its close of 125,663 lb. The receipts on account of the plantations for 1883-81 and 1881-85 were:—

Particulars.	1883-84.	1881-85.
Value of bark sent Home	R. 18,142	R. 82,314
Do sold locally	55,896	1,710
Do supplied to Bombay Medical Department	1,710	1,007
Do supplied to Madras	4,352	1,023
Sale-proceeds of seed and plants	208	510
Miscellaneous		
	R80,338	81,891

The total expenditure by the Madras Government in the cinchona enterprise since it was first undertaken, in the year 1860-61, including establishment, supervision, buildings, working charges and interest, amounted to R26,05,860, and the total revenue has been R31,57,603; so the net result is a surplus of R5,51,743. Consequently the Government has not only recovered the "cost of introduction and experimental cultivation," but now owns a property worth a very large sum of money—possibly 50 lakhs. Can it be for a moment pretended that it is necessary for the Government to possess upwards of a million and a half of trees in order to conduct "scientific investigations" in view to the production of a "cheap febrifuge"?

Mr. McIver reminded the Under Secretary to our purpose that the Duke of Argyll had stated, in the dispatch referred to, that "the principal intention of Her Majesty's Government in sanctioning this measure is to act as a pioneer in establishing the reputation of the Indian-grown barks, and not to injure the prospects of the private planters, whose success would give the Government great satisfaction. Mr. Grant Duff was the Under-Secretary for India, and he may have drafted the dispatch to the Madras Government which condemns the activity of his own Government in extending the plantations, to the great injury of private planters, long after the reputation of Indian-grown cinchona has been established.—*Madras Mail*.

PROGRESS OF THE BRITISH POSSESSIONS IN THE LAST QUARTER OF A CENTURY.

BY P. L. SIMMONDS.

In 1861, we possessed 2,133 steam vessels, of 506,308 tons; in 1883, 6,241—3,725,229 tons. It will thus be seen that we have trebled the number, whilst the tonnage has increased sevenfold.

In 1861, our imports from India and the Colonies were to the value of £52,676,010.

In 1881, we received from India and the Colonies produce and specie to the value of over £92,500,000.

The tonnage entered and cleared with cargoes from British possessions in 1885 was 9,739,456.

If we look at what has been done in ocean and land *Telegraphs*, we shall be surprised at the wonderful progress that has been made in the means of rapid communication with our distant Possessions, all of which are brought now within an hour or two of transmission and reply. Ocean telegraphs have been laid across the Atlantic to our North American colonies, in the Mediterranean from Gibraltar to Malta and Cyprus, from Aden to India, across the Bay of Bengal to Singapore and Hong Kong and Borneo, to North Australia, across Bass's Straits to Tasmania, and we can now communicate hourly even with New Zealand.

The land wires are even more important. India, which in 1861 had only about 1,000 miles of wire, has now upwards of 23,000 miles of telegraph, and the Eastern colonies about 1,500 miles more. Australasia has more than 33,000 miles, Canada 17,000, and South Africa about 8,000, besides small extents in the West Indian colonies.

If we pass on to *Railway*, which have done so much to open up unsettled districts, and to afford cheap communication with the seaboard, we find even more startling progress has been made in the quarter of a century; and this has been money well laid out, both in giving employment to labour and manufacturers, and in the result of the remunerative traffic obtained.

In 1861, India had little over 1,000 miles of railway, Victoria 250, South Australia 56, New South Wales 73.

In 1860, the first lines of railway were commenced in Mauritius. A line of 7 1/4 miles, between Kandy and Colombo, Ceylon, was opened in 1867. What do we find in operation now, independent of the many miles of lines in course of construction? The official returns for 1884 show that India had over 12,000 miles of railway, and Ceylon and Mauritius 270; the Australasian colonies 7,500, the Dominion of Canada 9,600, South Africa 1,750, and the West Indian colonies 130.

The Gold produced in the Australasian Colonies since the first discovery in 1851 to 1881 has been

as follows, as near as can be determined :—

Colonies.	Ounces.	Value. £
Victoria to 1855	54,500,000	218,000,000
N. S. Wales ..	9,995,825	37,142,631
Queensland ..	4,529,280	18,117,120
South Australia ..	89,720	343,950
Tasmania ..	289,151	1,115
New Zealand ..	10,552,279*	42,327,907†
Total ..	79,457,624	315,932,723

—*Journal of Society of Arts.*

IN SEARCH OF A HOME IN TASMANIA.

(By "Old Colonist," F. R. C. I.)

A TRIP UP THE DERWENT—THE EARLY SETTLERS—
WAYSIDE TRAINS—POOR-HOUSES IN TASMANIA—NEW
NORFOLK—HOP-GROWING IN TASMANIA—SUMMING-UP.

"And yet, perhaps, if countries we compare,
And estimate the blessings which they share;
Though patriots flatter, still shall wisdom find
An equal portion dealt to all mankind."

GOLDSMITH.

My next trip took me once more along the banks of the beautiful Derwent, one of the few really fine rivers in Australasia, and excelling our finest British rivers, the Tay, in the length and depth of its navigable portion, while its mountain scenery, and evergreen glades, are not excelled by anything I have ever seen, even in that land "where every prospect pleases."

My destination was Glenora, 37 miles from Hobart, and I had a choice of conveyances, viz., boat, or rail and coach. I chose the latter leaving the quiet little railway terminus on one of those lovely March mornings which add such a charm to life in Tasmania at this season. The Botanical Gardens looked their best and freshest, as we swept slowly through them. On the right, the blue water shimmered in the rising sun. Here and there, little dots of fishing boats, with sails idly flapping, lay on the smooth bosom of the river, while perched on many a protruding rock sat the patient disciples of the immortal Isaac. The first station is *Risdon*,—or "*Rest down*" as some old books have it,—which I have before mentioned as the spot where the first English settlers pitched their camps. This was in 1803, just 30 years after Capt. Cook visited the island, and sent adrift the first billy goat, the skull and horns of which, in after years, were found on the top of yonder hill, now known as "*Goats' Hill*." Lieut. Bowen who came here in 1803, with the few settlers, soldiers and prisoners as we have seen, soon fell foul of the aborigines. For this act of inhumanity, he did not escape unscathed, for it took them all their time to defend themselves from their exasperated neighbours, who very naturally disputed the right of the white man to take possession of their native land, and shoot them down. So much so, that all cultivation had to be abandoned, and when in 1801 Governor Collins arrived from Port Philip he found the new colonists starving, and engaged in a life-and-death struggle with an enemy who outnumbered them 100 to 1.

It is curious too, in glancing back at the early history of this wonderful Australia, to find Governor Collins deliberately *abandoning* Port Philip, now the marvel of the world. His remarks are found in a Garrison Orderly book dated 27th January, 1803 :—"It has never," he says, "been my wish to make Sabbath any other than a day of rest and devotion, but the sooner we are enabled to

leave this unpromising and unproductive country the sooner we shall be able to reap the advantages and enjoy the comforts of a more fertile spot."

Here, in the valley of the Derwent the settlers now took firm root, gradually spreading northwards, and ultimately, some of them across the Straits again to Port Philip, where they found the "*unpromising country*" of Governor Collins, so productive, that they induced many hundreds to follow them. In 1835, when the colony was about 30 years old, we find Tasmania sending over sheep to stock the plains of Victoria to the value of £500,000. In 1853 the gold fever broke out, and the bone and sinew of the island crossed the straits in a body numbering 34,000. More than half her able-bodied population left at this time, and though, by this means, she got rid for ever of most of the "old hands," she has not to this day, recovered from the loss of labour, which rose to, and is still at a prohibitory rate. Hence those half-abandoned gardens,

"Yon straggling fence that skirts the way
With blossomed furze unprofitably gay."

We are now at New Town station, and it is the fashion to say in passing this spot : "How home-like!" "How much these lanes remind us of dear old England!" But if these somewhat slovenly hedge-rows were as trimly kept, and the soil as well tilled, there would be few scenes in old England or even in Scotland to compare with the valley of the Derwent. As it is, it is a strange struggle for the ascendancy, between the Wattle, Hawthorn, Furze, Thistle, Scarlet Geranium and *Sweet-briar*. The Geranium pluckily pushes its way to the top, and crowns the fence with its magnificent clusters of brilliant flowers, and even when rudely hacked down and thrown into the ditch or quarry hole, will take root again and throw up such spikes as would carry off the prize at any flower show I ever saw. But it is evident the sweet-briar is gaining; its hops so abundant and sweet, seem to be the favourite food of horses and cattle at this season, and by this means its innumerable seeds get distributed all over the ground, where its roots take a very firm hold. It is quite evident indeed, that, unless labour becomes more reasonable and plentiful, the sweet-briar will soon take possession of this locality.

Yonder palatial building on the brow of the hill—commanding a view which any rich English lord might well envy—is, we are told, *The Institution*. A building for a similar purpose at Launceston is pointed out as *The Depot*, and it takes some little time for a puzzled stranger to discover that these are simply *Poor-houses*. The building we have just seen contains some 700 paupers, costing the public between £8,000 and £9,000 a year. Paupers! There are no paupers in Australasia, the guide-books say and popular lecturers repeat the statement, but the truth seems to be that the poor workman in this colony is so pampered and *protected*, that he very often becomes demoralized and useless. I have come a long way to see the conservative working-man, but here he is at last and I am not enamoured.

There is evidently something wrong here, for as John Ruskin says, "The world is so regulated by the laws of Providence, that a man's labour, well applied, is always amply sufficient to provide him during his life with all things needful to him."
* * * But by those same laws of Nature and Providence, if the labour of the nation or of the individual be misapplied, and much more if it be insufficient,—if the nation or man be indolent and unwise,—suffering and want result, exactly in proportion to the indolence and improvidence, to the refusal of labour or the misapplication of it.

Wherever you see want, or misery, or degradation, in this world about you, there, be sure, either industry has been wanting or industry has been in error."

But we are now nearing another station—"O'Brien's Bridge," so named after the famous Smith O'Brien, who lived for some years in exile here. You can just see the little wooden shanty near to the public road, with a burnie trickling past its gable end. At its best, it could only have been a poor little "but and ben" now frail and tenantless. Imagine the six great Irish patriots forgerather here—as they often continued to do:—Meagher, O'Donoghue, McManus, Mitchel and John Martin. I fancy I hear the *coo-ee* of the approaching visitors, answered by the expectant O'Brien,—the warm greeting, the row on yonder bay, the jolly evening, the chaff and story—all spiced with a little sedition; then the serious part of the business, the plans of escape.

It was here that P. J. Smyth, the well-known M. P., met them; he came out ostensibly as correspondent of an American paper really, to further the escape of his countrymen. Meagher, I remember, wrote some beautiful letters to his friend Sir C. G. Duffy dated from here. Mitchel, too, wielded a very facile and charming pen. Men wholly bad could scarcely write as they did. Nevertheless, O'Brien was the gentleman of the lot, and most favourably remembered here. But I must hurry on from this pretty little clachan with its thriving hop gardens, and tolerably well kept orchards.

The lion of the locality seems to be, the *landslip* which is invariably pointed out to strangers with the remark that "it is over 100 acres and the whole came down one dark rainy night with a terrific roar." On expressing my doubts, that there were more than 30 acres; the village official said: "You have no idea how steep it is"! There are evidently Irishmen here still. About five miles from here is *Bismarck*, said to be a very thriving township, the frugal German settlers numbering about 300; this I mean to visit on my return. Meanwhile we go swinging along on our $\frac{3}{4}$ feet railway, still keeping close by the water-side. *Berriedale* and *Austin Ferry* stations are soon passed and we come to Norfolk road, where we part company with the train which now crosses the Derwent, while we take the coach and continue our journey up the river side. I do not know if the name of the officer who traced this road has been preserved; but this I know, had any Ceylon planter been guilty of such a piece of work, the inevitable sack would have been his reward.

Fortunately the iron horse is creeping up the other side of the water, slowly of course, for with labour scarce at 6s 6d to 7s per day, it is not much, a poor country can do in Railway Extension. Better times for road-makers, when the Hobart and Launceston road was made, one of the very best thoroughfares in the world. What very picturesque peeps of river scenery now open out at every turn, as we briskly canter along! The reflection of the tall gum trees in the still water is very striking and beautiful, and here comes a large paddle steamer heavily laden with hops and fruits. I wonder how many millions Melbourne would give for a river like this? The marvel is that there is so little cultivation in a locality so highly favoured as this: the melancholy fact again forces itself upon us, that for 100 miles on either side of this river the land has simply been frittered away, and converted into very indifferent sheep-runs, with here and there a smiling little orchard, hop garden or dairy-farm, showing what it might have been, and may still be, when the land has been recovered from these barbarous sheep-owners who,

though owning or holding 4-5ths of the best land in the country, cannot supply half the mutton required by its scanty population.

A beautiful little oasis in this wilderness is New Norfolk, at which we have now arrived, 23 miles from Hobart. An air of substantial comfort pervades the township, with its two excellent Hotels well-plenished stores, neat churches, schools and library, to say nothing of the capacious Lunatic Asylum—for, strange to say, men and women go mad even in this perfect climate, where bare existence is a luxury.

I much admire the beautifully kept little gardens sloping down to the river side, the first *bona fide* bit of cultivation I have seen since I left England. On the opposite side of the river is Valley Field, the extensive hop-plantations of Mr. R. Shoobridge, which I purpose visiting on my return. Meanwhile, I take coach again, and go on a dozen miles further to visit "The Member" at his spacious demesne *Bushy Park*, and to those who know *Bushy Park*, it is needless to speak of the cordiality of our reception, or the hospitality of the entertainment. I have rarely spent a more pleasant afternoon than in wandering along the banks of the placid Derwent, and the shady rippling Styx, and never met more keenly intelligent agriculturists than the Messrs. Shoobridge, the chief hop-growers and orchardists of Tasmania. The hop-picking had just commenced, and I had the opportunity of seeing the whole process of picking, drying, cooling and dispatching.

5,000 busy fingers at work in one paddock, looks something like business, and what a delightful outing it must be for the women and children of Hobart! The process of picking is simple enough and a fairly active woman can make her 5s per day easily, indeed, I'd back Carpie to do more; her nimble, black fingers would be just in their element amongst these hops. Splendid hops they are too. I do not for a moment believe that Kent can produce better, though it is not easy for an Englishman to overcome a prejudice—especially in anything relating to his beer; and the fact remains, that the price obtained for the best Tasmanian hops is still considerably under that for the ordinary home-grown. The soil here is a very good, rich alluvial, capably cultivated and irrigated. Irrigation is absolutely necessary in this climate, and by cutting a water-course from the Styx this has been easily accomplished here, the arrangement for distributing the water, excellent, simple and effective. Anyone accustomed to the management of estates can see at a glance that the whole system of cultivation here is admirable. The average yield in a good year is about 15 cwt. dry hops per acre. The cost of cultivation, say somewhat over £20. Prices vary tremendously—from 9d per lb. to 4s 6d. The present prices are not encouraging. "I based my cultivations on taking over this place two years ago," said a planter to me, "at 2s per lb.; now I am receiving 10d."

The arrangement for drying and cooling the hops at *Bushy Park*, are perhaps, the most complete in Australasia. The system of drying is almost identically similar to the "*Ceribeh*" adopted by the coffee planters of Ceylon 30 years ago. The metal pipes, the mode of applying the fire is the same; only the heated air chamber is circular, the floor revolves, and the fans are at the top of the building. Coffee can scarcely be dried too rapidly whereas hops must be dried slowly, in order to preserve the essential oil and toughness. This has altogether been a splendid season, and if a novice in hops may judge from the sample at *Bushy Park*, Tasmania will more than maintain its reputation for good hops this year. But *Bushy Park* has more than one string to its bow,

and the extensive orchards were fully more interesting to me than the hop gardens. The season for small fruits was past, and that for plums, peaches, and apricots almost over, but enough remained to test the quality, which with soil, climate and cultivation so perfect could scarcely be otherwise than first-rate. The rainfall here varies from 19 to 24 inches per annum, and with brilliant sunshine nearly all the year round, it need scarcely be said, irrigation is necessary for heavy bearing trees. Apples are the great stand-by here, grown upon very small standards which for their size bear enormously. I was now able to confirm the estimates I made a few days ago, near Hobart, and find that 450 bushels per acre is a good average crop, that by keeping the fruits for a few months, an average price of 7s 6d is readily obtained, that trees come into full bearing in six years, and give paying crops for about 10 years. The small fruits, such as gooseberry, strawberry, &c., productive as they are, are not so remunerative, owing to the high price of labour.

I have now said enough of this pretty paradise, and hive of industry, to show what may be done under favourable conditions, but sorry as I would be to discourage those intending to migrate hither, they would do well to bear in mind that all the best of the land is already disposed of, that the cost of labour is almost prohibitory, and the import duties on necessities of life, such, that at present there is little hope of reducing wages. That with oatmeal at 100 per cent over home prices, there is little hope of importing labour from Scotland, and with rice at 300 per cent above usual rates, Indian labor is out of the question. That numerous estates at one time employing 150 to 200 labourers are now worked with one or two shepherds (this I have from what I consider the best authority in the island), and as a matter of fact, there are 24,500 acres less under crop now than there was 20 years ago, that the imports and exports per head have declined from £16 4s, 30 years ago, to £11 9s last year. Still, all this is, I believe, curable in time and there must be a bright future in store for an island so enriched by nature and advantageously situated as Tasmania, but it will take many a long year and a very radical change of Government to accomplish this; meanwhile, it remains a delightful sanitarium for Australia and India, and *nothing more*.

In visiting this locality I have a pleasure, apart from the great privilege of inspecting Bushy Park. It reminds me I am following in the footsteps of two infinitely better men—valued friends from Ceylon—who visited the same place seven years ago, and it is with no small interest and pleasure I listen to the comments on my friends, who are still favourably remembered wherever they seem to have touched. The one is spoken of as "*The Specialist*," the other as "*The genial old gentleman who smoked the pipe of peace*." "I recognize the latter," I would remark, "dear old fellow! but what is meant by '*The Specialist*'?" "Well," said one, "no matter what subject we broached, this gentleman talked like a very interesting book, every conceivable subject seemed to have been made a special study by him; hence in speaking of him we speak of the *Specialist*."

ARCA-NUT PLANTING.—The best mode of planting arcanuts is first to keep the nuts in a vessel of water for about three weeks, and drain off the water and allow the nuts to remain for about a week or so, when the nuts will begin to sprout; then take them out and plant before the leaves are spread.—*Cor.*

PLANTING IN NEW DISTRICTS IN CEYLON: DOWN THE KALUGANGA AND THROUGH THE KALŪTARA TEA DISTRICT:

DOWN THE RIVER—THE RAPIDS—NAMBAPANE—EARLY
PLANTING BLOCKS—SUGAR AND TEA—MR. J. G. FORT'S
PURCHASE—36 MILES DOWN IN 94 HOURS.

Some of the bends on the Kaluganga are extraordinary for their abruptness: you see no opening before you, but rather a landlocked basin, until you begin to think the boatmen are going to run you ashore, when instead an opening almost at right angles to the course you have hitherto pursued, appears, and you turn back on quite another vista of this most tortuous and beautiful of Ceylon rivers. At other times we had wide straight reaches and I was reminded of the splendid St. John's river of Florida, save for the greater breadth and depth of the latter and the contrasts presented in the richer and more varied tropical vegetation festooned with creepers from the water's edge upwards along our Ceylon stream, together with the chattering of monkeys and cooing of birds unknown in Florida. The Kaluganga (black river) too is true to its name in its dark waters, while one of the most striking peculiarities of Florida is the clearness of the water, so that tiny objects can be seen at a depth of 40 to 60 feet with the utmost distinctness. Kangamosaanga and Karawitteganga are two tributaries from the left or south received, and Balagolla, Malwilla and Dodampe are some of the stations passed on the Kaluganga, before we reached the first of the well-known rapids. Fortunately we had sufficient water in the river to make the passage with no more discomfort than a little tumbling about of the boat and the shipping of some dashes of spray. Just enough of sensation to show the justification for getting out of the boat and walking on the shores when the water is low and 'bump, bump' along the inclined rocks is often the experience of the boatmen. A little later in the full monsoon, the water will be so high that no rapids will be perceptible at all. The navigation up the river either in high or low water is a much more formidable undertaking as the bolts and chains in the rocks opposite the rapids to help in warping boats upwards made manifest. At Idangoda, we had a strong current carrying us along well and later on we observed some fine jungle and after the Kurugasmodera station we took special notice of the fine large tributary to our river in the Kooroganga entering from the right. The scarped faces of some of the detached hills rising from amidst a sea of vegetation presented a curious contrast and after passing a considerable river tributary from the left we arrive opposite Nambapane, the well-known station on the road between Kalutara and Ratnapura which is always going to be—but never is—finished.

We are now approaching the scene of some of the earliest attempts at planting settlements in the Western Province. It was near Nambapane, or between that point and the Perth estate lying towards Horane, that Sir Wu. Reid, the old Demarara planter, early in the Forties, selected land for sugar, for his nephew Mr. C. Shand and the latter with Mr. Wm. Ferguson, surveyed 1,200 acres in one compact block which was bought from the Crown at the then upset price of 5s an acre. So plentiful was the land and so few the buyers in those days, that so soon as a pioneer had settled what he would buy, he began cutting out the boundaries and indeed, if need be, clearing, before survey or transfer were completed, it being a point of honour that no one offered competing bids for land so selected at its sale. Fortunately for Mr. Shand, it was proved to his satisfaction on the

Perth estate that sugar would not do—the cane grew, but the saccharine matter would not crystallize properly in the over-moist climate and poor soil—before he had been to clear and plant, and he sold the Nambapana block to Messrs. Gibbs Clark & Co. for 10s. an acre. What has become of this property now, it is hard to say, unless it be the block in the hands of a native which it was rumoured lately was to be transferred to a Limited Company, with a view to the cultivation of tea. On Perth or Etgala, sugar cultivation and manufacture was continued by Mr. Gay till after 1860, but the result was very poor financially, and now this property is devoted by its Parsee proprietors (like so many other old sugar estates in Ceylon) solely to coconuts.

But in this neighbourhood tea has already made a start, for I heard later on of the purchase of fine forest land by Mr. J. G. Fort in the neighbourhood of Perth and Horane stretching in fact to the borders of the Sappity Korale, which after clearing looks very promising for tea. Although the Kalutara tea estates are all south of the river, yet there is no doubt a good deal of land on the Northern or Colombo side at any rate towards Nambapana which may be expected to be selected and taken up for tea.

The lowest and most formidable of the rapids is the Periaigalla, and here with the water of the wide river confined to a narrow passage by huge masses of rock midstream and with a really sudden descent, the passage looks like a service of some danger as the waters boil and surge in small breakers below. But although there is more rooking and spray than at any of the other two or three rapids, yet our boatmen take the matter coolly and we are soon in smooth water with no further obstacle between us and Angurantota Ferry which—36 miles from Ratnapura—we reach about 3 p.m., or within ten hours of starting. Not bad work considering there was a good deal of hard pulling over many miles, that we got aground once or twice, and went ashore at least once. Of course we had breakfast and tiffin with us in the boat from the Ratnapura rest-home. The charge for the boat too was moderate enough R5 each or R10 for the 36 miles. The boatmen had one native passenger besides who was going on with them to Kalutara 16 miles ahead and which in consequence of the greater slowness of the current and indeed the opposition of the sea or tidal water, they did not expect to reach before 9 or 10 p.m.

The improvement of the navigation of the Kaluganga has been a problem of long standing, specially considered by Governors Sir Hercules Robinson and Sir William Gregory and finally disposed of as an unprofitable work, on which to spend public money, I believe, by Mr. J. F. Churchill. I refer of course to the blasting of the rocks and clearing of the rapids on the upper portion. No civil officer ever urged this work more strenuously than did Mr. E. N. Atherton when Assistant Agent at Ratnapura in 1872-1. He got Governor Gregory to travel down the river and R10,000 were promised as a beginning, for the purpose of blasting rocks and widening the channels at the rapids; a proper towpath along the margin of the river was also designed, with the special object of helping pada boats upwards which sometimes took a fortnight between the first rapid and Ratnapura—a distance of seven miles! A mile a day up the river was indeed slow progress. Mr. Atherton was very sanguine in those old days that a steam tug to tow a dozen pada boats between Colombo and

Ratnapura and back in 3 days could be got to work readily and should not cost more than R18,000. But nothing came of these and several other stirring proposals. True the river was surveyed and levelled with the result that at Ratnapura it was found to be only 30 feet higher than at the sea! Twelve years ago with heavy coffee crops and much prosperity, as much as R150 was paid for a single pada-boat-load down the river. But later on much of the traffic disappeared. Now that tea is coming on with "a rush," it may be a question if something should not be done at any rate on the lower half of the Kaluganga and Mr. L. Jackson, engineer, says he is anxious to put a steamer on the river. But there is also some idea of the Government starting railway boats (pada) to bring freight to the Kalutara line which would otherwise go all by the canal to Colombo. How this can be worked is the trouble; for water carriage by river and canal is being made available to the Kalutara estates, so that for 20 cents a full chest of 100 lb. (R150 a ton!) they can send their tea from their stores to the Colombo depot! Not much margin here for the railway to make a profit including the cost of transhipment,—although I dare say the planters would pay a little more for the guarantee of freedom from tampering on the way.

How little can one realize in an ordinary season with the water sluggishly moving along, what our Ceylon rivers are like in time of flood. In 1872 the Kaluganga rose at Ratnapura 40 feet in the course of a few hours! That was on the 8th-9th September—the whole town (save the lofty heights) was submerged and R80,000 represented the damage done. Such a flood is not recorded before or since at that point and may it not recur, but it would not do to trust to that chance. The Ratnapura folk should have their places of refuge ready to flee to.

FROM THE RIVER TO GEEKLIYANAKANDE—LORD ELLIOT-STONE'S HISTORICAL PROPERTY—FOULKES AND KNIGHT—"ONE OF NATURE'S GENTLEMEN"—CITRONELLA GRASS CULTIVATION AND EXPORTS OF OIL FOR 30 YEARS—LIBERIAN COFFEE—THE SINHALESE AND KNIGHT'S PAPER CURRENCY—TEA PLUCKING BY SINHALESE—THE KALUTARA TEA ROLLER AND LAW'S KALUGANGA WORKS.

Starting from the Angurantota Ferry about 3-30 p.m. we had during the course of a four-mile walk, an opportunity of observing the nature of the country to the west of Geekliyanakanda property. The road, a gravelled one, is a continuation of that from Horne (6 miles distant across the ferry) and goes on through the Pasdum and Wallawalita Korales, uphill and down dale after Sir C. P. Layard's usual plan, to Agalawatte and round to Bentota. The good pasturage and open park-like country near the river provoked remarks as to the splendid tea gardens that might be formed on the flats, though manuring might there become a necessity. The evidence of advancing cultivation in coconut and fruit gardens in all stages of growth along the roadside—showing however, in too many cases, the common native neglect in promising plants all choked with weeds and grass—was very observable. We got to Lord Elliot-stone's citronella grass fields and farther on in time to inspect, with Mr. David on and Mr. Knight, the 6-acre flat of tea opened under Liberian coffee (which is being gradually taken out). This field is close to a vast pit of citronella grass refuse calculated to contain many thousands of tons of manure, and manure too which evidently suits the tea. Already results from the flat only comparable to those obtained on Mariawatte, have been recorded, and nothing could exceed the fine appear-

ance and flushing of the bushes, now 5 or 6 years old, when we saw them. We had also time before daylight closed to go over the "orchard" of select Liberian coffee trees which were instrumental through their wonderful growth and richness of crop in sending scores, perhaps hundreds, of visitors during the rush of ten years ago, to buy land and plant the West African coffee. Even now, the trees are a grand sight with their show of cherries in all stages amidst the laurel-like leaves, the tree off which two bushels of crop were taken in one picking season, being not the least noteworthy. How hard to think of all the capital (at a time when money could ill be spared) and time and labour spent over Liberian coffee. But harder still is the necessity which now forces the planter to cut down and dig up, his still splendid-looking groves of coffee trees. I had not the opportunity of seeing Patupaulakande which lies lower down on the river-side; but we learn that the Liberian coffee trees there which when laden with crop excited the admiration of "W. Mek" and induced so many more to go in for this new coffee, are now nearly all superseded by tea, which is succeeding splendidly. The pity seems to be that both coffee and tea cannot be left to flourish together; but I had repeated evidence on both Gikiyanakande and Culloden that although for the first year or 18 months, the coffee may be spared, after that date any patience or mercy shown to the old product will only be at the expense of the younger, more vigorous and more promising rival. If the tea is to grow and flourish as it ought, there is no escape from it that out must come the umbrageous groves of coffee.

Gikiyanakande with its 3,230 acres—5 square miles—in one compact block, about 14 miles inland from Kalutara and 3 to 5 south of the Kaluganga, is undoubtedly one of the historical plantation properties of the island. The land was selected and reported on, in 1810-1, for Messrs. Norris and Sim by Mr. Wm. Ferguson. It then became the property of Lord Elphinstone at a time when there was quite a host of Indian civil and military officers ready to invest in the El Dorado of Ceylon. The idea on the part of the Lord Elphinstone, who was then Governor of Bombay, or of his business managers, was to cultivate sugar, and this had already been done by them at Paraduwa on the Matarra river—on the property which, after many years of abandonment, was eventually sold by Lord Elphinstone to the late Mr. J. W. Home for his first venture, the cultivation and preparation of plantain fibre. On Gikiyanakande, a careful selection was made of land suitable to cane-growing, and, besides having a portion cleared and cultivated, the manager went so far as to take levels from a stream passing through the property and to erect a most substantial masonry dam (still to the fore with its native cement of chunan, blood and white-of-egg), in order to be ready for his water-wheel and extensive sugar machinery. But, fortunately, here as in Mr. Shand's Nambapane, the testing of the cane took place before further expense was incurred, and on the report from the Paraduwa Manager that the Kalutara cane yielded little or no crystallized saccharine matter, the attempt at sugar cultivation in Gikiyanakande was given up. The place then seems to have had nothing done on it for a number of years. But on Capt. Elphinstone, *u.n.c.*, succeeding to the title and property as Lord Elphinstone (15th Baron) in 1861, he expressed a desire to utilize his land in Ceylon. Through a relative in England this wish reached two young Englishmen resident in Cape Colony, who, after 14 or 15 years' sojourn in the Western Province there, had been

drawn together by the fact that each had lost a brother in the place, while both were anxious to try their fortunes in a new land. Accordingly Messrs. S. W. Foulkes and C. Knight shipped from the Cape to Ceylon, the Eldorado in those days of coffee, fully expecting that Lord Elphinstone's big block was well-fitted the staple for cultivation. They had difficulty at first in learning where the property was situated, and no wonder, for the story runs that the Agency had been for a good many years held by a Galle Firm who, for the life of them, could not tell the noble lord where his Gikiyanakande estate was to be found! But on being discovered, some time in the early "sixties," by the Cape colonists, they were naturally disappointed to find that coffee (Arabica) was out of the question and they were nearly falling in with a proposal of Mr. J. T. White of Messrs. Murray, Robertson & Co., to whom they had letters, to take places as Superintendents of coffee estates on the hills. However, they visited Gikiyanakande, found that Sinhalese labour could be commanded and that there was room for developing an industry in growing citronella grass, the expressing of the oil leaving a good profit at the then handsome prices and limited competition. Not anxious to be separated with the strong ties subsisting between them, Messrs. Foulkes and Knight were well content to give up their more brilliant prospects in the hill country and to settle down to hardwork and a lonely out-of-the-way life in the Raygam Korale; and to make a long story short, for well-nigh twenty years they continued to devote their close attention to the industry they had made their own, planting up some 700 to 800 acres alongside the district road which ran through the property, with the fragrant grass, and struggling on against unpropitious times and lowering prices. The first roots of the grass put in were got from the neighbourhood of Galle and the further cultivation and extension took place very much after the fashion of Guinea grass. A good crop can be counted on within a year after planting; but the great difficulty arose out of the wonderful uncertainty of the prices. The development of our export trade in essential or grass (Citronella, Lemon and other grass) oils may be judged from the following statistics taken from our "Handbook":—

ESSENTIAL OILS: EXPORT OF, FROM CEYLON.

	1850.	1860.	1863.
Quantity Oz.	133,785	388,411	471,621
Value (Customs) ..	£8,238	6,983	6,732

	1870.	1880.	1881.
Quantity Oz.	1,119,622	1,361,780	4,800,228
Value (Customs) ..	£10,018	20,139	37,608

The enormous development of export in ounces of recent years, is not due to a parallel extension of cultivation or to some new process of extracting more oil from existing grass, but as might almost be judged from the valuation, to a means discovered in Colombo and Galle—as current report goes—of mixing the pure Citronella oil with inferior stuff, it is even said with imported kerosene (!), after a fashion that prevents detection. Whether that be the case or not, it is certain that Messrs. Foulker and Knight had nothing but the genuine article to depend on, and that they made very little profit for proprietor or lessees. The era of "new products" too had arrived and Lord Elphinstone determined to develop on his own account, so that a few years ago, Mr. Foulkes proceeded to South Australia where we regret to say, fortune as yet, has scarcely smiled on him, while Mr. Knight continued in charge of the Citronella grass division—600 acres are still cropped—of the Gekkiyanakande property and the distillation.

The distilling is done after a very inexpensive simple fashion, the chief outlay being for firewood, the men employed about the still being paid by results while the oil passes under lock and key to the store-room from the still. I was glad to meet and make the acquaintance of a 22-years Colonist in Mr. Knight, 36 years away from his native Devonshire, and still full of life, good spirits and good health:—

One of nature's gentlemen,

as he has well been called by a member of the Civil Service. Universally respected by all who have met him—successive Assistant Agents and Magistrates especially—Mr. Knight has had the tea-planters of the Kalutara district under a lasting debt of gratitude to him, by the trust and good feeling he has inspired among the natives, by his uniform considerate, patient and honourable treatment of the Sinhalese people in his district. "The Sinhalese here will do anything for Knight" is the opinion we found expressed in successive bungalows. They all look up to him and trust him far more than any Government servant or any Rajah that ever came to the place. A curious illustration of this fact is found in "Knight's Paper Money" which circulates in the korale and is more readily received perhaps than the Government notes! This has originated in a very simple manner. There is nothing the Sinhalese are fonder of than of getting ready cash for any work they choose to do. Unlike the Tamil coolies, they do not at all like long accounts, or to have their money kept against advances in rice in the hands of their employers for months together. Contract jobs with liberty to do the work at their own hours and prompt settlement on completion, form the key to the successful employment of Sinhalese on plantations, and it is of the greatest importance to tea planters in the lowcountry districts who will have to depend so much on Sinhalese labour, to study their character and to take the utmost pains (after Mr. Knight's example) not to prejudice a people who having their own bits of land in their own country will not submit to treatment they deem in any way unfair or even brusque, but who, if humoured, are likely to afford most valuable assistance in the tea industry. Mr. Knight's plan of dealing with the Sinhalese was by means of small ehits or tickets, the amount whether 10, 25, 50 or 75 cents or R1 or upwards being marked on each with the date on which they must be presented for exchange for specie. It was manifestly impossible to keep a supply of money for the frequent payments required by Sinhalese grass and firewood cutters and the many other workers on Geekiyanakanda, and accordingly the "tundu" system was adopted and the surrounding villagers from finding that the Englishman's paper and promise to pay on a given date were as certain as anything within their experience, began to do business among themselves with the same, the butique-keepers being quite ready to give full value for the Geekiyanakanda paper notes! Had Mr. Knight once failed in his promise to pay on a given day, all confidence would have been at an end; for as was well said to me by a planter in the district, a Sinhalese carpenter or labourer will make a dozen journeys if need be, day after day, to get from you a balance of even 8d. if due—not counting the time wasted as anything—but after any such experience or a failure to pay as promised, he will never except under dire necessity, trust or work for that careless offending employer again.

Another very practical illustration of Mr. Knight's influence over the Sinhalese people about him was lately afforded in his clearing with their aid a large block of forest for a Colombo merchant

at some distance across the river—felling, burning, clearing ready for planting in so short a time as the owner deemed wellnigh incredible. Of course Geekiyanakanda is always well supplied with Sinhalese labour and the people look to the bungalow for medicine and especially quinine, during the prevalence of fever. (The past has been one of the driest seasons in Mr. Knight's experience and consequently when the rains commenced, fever became very prevalent.) When Mr. Knight first erected a rain-gauge and explained its purpose, an intelligent agriculturist thought it of little use unless it brought or foretold rain when required; but the common people to this day believe that the weather prophet lives on Geekiyanakanda and when anxious about their fields, they are very ready to try and draw from their "prophet" when he looks for rain!

It will be judged from all this, that our visit to Geekiyanakanda was full of interest: the property itself with its undulating grassy and tea fields, or grove-like coffee and tea divisions afforded much food for reflection. The main tea valley opened on soil that certainly looked very ferruginous and Ambagannua-like in many parts, showed a most vigorous growth of the young tea plants and "good strong liquor" may be expected from trees growing amidst laterite and iron-stone. The best part of the forest and richest soil on Lord Elphinstone's property are said to be unopened—untouched as yet, so that there is room for the expansion of tea by perhaps 1,000 or 1,500 acres if the 250 acres now cultivated, warrant that operation. Mr. L. W. Davidson in charge of the tea is very strong on the superiority of Sinhalese to Tamil labour, more especially in tea plucking in which he says Sinhalese women and children excel, and this we believe is the experience of other planters in the district. With an abundant Sinhalese population ready to aid the planter—very much owing to their experience of Mr. Knight who ought to be made Labour Superintendent generally—the Kalutara district in the struggle just approaching ought to have a great advantage over many upcountry districts. And there are several other decided advantages to which we shall refer later on.

Tea preparation is, so far, conducted after a primitive fashion on nearly all the Kalutara estates in bearing; but we had evidence in Geekiyanakanda that there is still another Roller to compete with the Jackson's, Thompson's, Barber's, Kerr's and Frater's—one for which thorough rolling and twisting of the leaf, with economy in first cost, and cheapness in working are claimed. No more need be said until the patent is announced, although it is evident from all we heard that in Mr. J. R. K. Law of the Kaluganga Works, the Kalutara district has a mechanical genius inferior to none in the island.

THE KALUTARA TEA ESTATES EXTENDING FROM THE KALUGANGA TO THE BENTOTA RIVER—ABUNDANCE STILL OF GOOD LAND—THE OLDER GROUP OF ESTATES—MAKING TEA UNDER DIFFICULTIES—THE HEALTH OF THE DISTRICT—ITS GREAT ADVANTAGE IN CHEAP LABOUR AND TRANSPORT FACILITIES—50,000 ACRES OF GOOD TEA LAND SAID TO BE AVAILABLE ALTOGETHER.

The Geekiyanakanda property lies: we have described, to the North of the main portion of the Kalutara Tea District; but there is one outlying tea garden on a tributary of the Kaluganga still farther North. It is called Ossington and belongs to Mr. E. H. Koelman, 75 acres being opened out of a block of 162 acres. Away again to the North-east along the Agalawatte road and in a direction where, on the authority of such com-

petent residents as Mr. Robt. Morison (Chairman of the Kalutara Planters' Association) and Mr. Cochar, lies some of the best land in the province,—is found Mr. Shelton Agar's investment called Horagoda-Mukalane, 426 acres, 140 of which are opened. This is situated a good few (perhaps 12) miles farther from the river than the main cluster of Kalutara estates, but there is a capital road all the way, labour is abundant and cheap, and the soil is pronounced if anything above the average of the older estates. Farther to the South, inland from Bentota, but still North of the river so as to be in the Kalutara district or revenue division, lies Peliyagoda of 270 acres, 100 of which have been cleared ready for tea this present season. This is known as "Wardrop and Watson's land" and the soil and lay of the clearing are said to be all that could be desired, while, although Tamil coolies have been employed by the superintendent, Mr. F. W. Poppenbeck to do the main portion of the work, lowcaste Sinhalese women have been found to work readily at weeding for a Tamil Kanganai who had won the villagers' favour, his Tamil wife superintending the gang of Sinhalese weeders. Sinhalese men of better caste readily take contracts for road cutting and draining and they appear to be much interested in learning the mysteries of lining, pegging and holing for tea under Mr. Poppenbeck's direction. The benefit conferred on the poorer class of Sinhalese in these inland Western districts by the work and money introduced by the tea planters is incalculable, and apart from a larger consumption of food, we may expect thousands of the people to manifest an interest in "Manchester goods" and "Brunnaggen wares" as time rolls on, in a way which cannot fail to cheer the spirits of the British merchant!

Having travelled so far afield, we must now return to the Kalutara Tea District proper, but first a glance at the map will shew that already the Kalutara revenue district has been regularly entered on at all points by tea planters and it only remains for the Government to throw into the market the good lands in the neighbourhood of Agalawatte and Horagode, not to speak of the forestland up the rivers, in order to secure very animated competition and good prices. The story in the district is that further sales would have come off before now save for a controversy started by the *pukka* Assistant Agent who wished to override the Surveyor-General and have his own way about cutting up the forest into blocks of 100 acres or thereabouts. Be this as it may, we have the assurance of competent authorities that better prices are likely to be paid for blocks of three or four times that area, which would enable capitalists to open plantations sufficient for one charge on which they could pay a really good salary to men whose labour in a hot lowcountry deserves a fair reward.

But we might go even farther afield in describing the extent to which planting operations have extended along our Western Coast, only that in crossing the Bentota river we get into a new province and to ramifications which extend to Matara on the one side and the Morowa Korale on the other. Our present duty is rather to dispose of the Kalutara Tea district. How refreshing after a hot day's occupation, long journeying or estate walks in this lowcountry, is the warm bath, the cheerful evening meal with its

feast of reason and flow of soul,—

and the interchange of reminiscences of days gone by from the comfortable inside of a long arm-chair! Only more enlivening are the early tea and morning stut, after a good night's rest, such as we had before leaving Geekiyanakande on foot through the several tea clearings, the flat subject to floods, the

slope with the best jät, and so through the old sugarcane fields, on our way to Culloden. From the Geekiyanakande valley glimpses can be got of some of the clearings of Rogart—the new name given to the property of Messrs. F. D. Mitchell and Mackay. But our morning walk first brings us to the foot of Dean Park, a very promising clearing of Messrs. Robertson, Hendry and Davidson with a desirable lay of land. Beyond it to the east lies this now extensive property of Rogart of 776 acres, of which 200 acres in tea are well advanced, and 200 more will probably be planted this season. Right in front rise the heights of Culloden the most extensive estate in the district, next to Geekiyanakande, with 450 acres planted out of 1,100. This is the property of Messrs. Duff and Leechman, and was one of the earliest and most successful scenes of Liberian coffee cultivation, the well-grown apparently flourishing trees being only finally condemned this season. The difference between tea in the open and tea within the shading or root influence of the coffee at once justifies this decision, hard as it may be to sacrifice a product to which so much attention was at one time given. Culloden has the largest area under tea in the district and it also affords the means of judging of the product in a variety of situations from the easily undulating forest valley to the gently sloping hillside, and from rich alluvial flats (owite) reclaimed by deep drainage, (the land in fact suitable for paddy) to as steep and rocky eminences as can be found in the Central Province. Culloden is in the care of one of the best planters in the country, Mr. R. Morison, the local "Chairman," a gentleman esteemed and liked by all, and who in Kotmale, Dinbula, Morawak Korale, Hunasgiriya and several other districts has, during the past twenty years, seen as much of the vicissitudes of planting in its various phases as most men. His hospitable bungalow is 500 feet above sea level,—the highest inhabited point in the Kalutara division of the island we suppose—and the climb up from the flats after the sun rises and heats the massive numerous boulders on the hillside, is a caution. More particularly will this be the case if the unwary visitor follows the invitation of the Manager, after a morning walk from Geeka, to come "along the flat" meaning the path through a decidedly rocky up and down field to the store before ascending to the heights; but there is one advantage gained in that, this enables a capital idea to be got of the different portions under cultivation. Nothing can be finer than the tea in the valleys and on the flats, but very vigorous also to our idea was the growth all the way up the hill side. Passing through a part of the Torwood property of Messrs. Rutherford, Tod and Mackay, where Mr. Cochar's pluckers were busy at work, we had time to notice the even nicelooking tea on this fine property. It is absurd to see the shifts to which some of the Kalutara tea planters with large areas in bearing are put for the preparation of their leaf as compared with the style in which machinery is lavished on brand new estates in other parts of the country. Verify, the proprietors 'ca'anny' in Kalutara and perhaps they are right until a little more light is seen through the great contest of rival machinists and machines. But in the meantime such Kalutara managers are undoubtedly placed at a considerable disadvantage. To pass for instance from Mariawatte or Kadawelle with their magnificent factories—withering room *ad libitum* and array of machinery equal to a big factory,—to Culloden, or Rogart or Geekiyanakande, is to run from the most artificial and advanced to the most primitive mode of working. But this will no doubt be remedied ere long. Being only 10 to 12 miles inland, there are from Cul-

loden and several other bungalow heights in this district, the most cheering and charming views of our Western sea-coast imaginable. Over an almost unbroken sea of forest—much of it in reality, cultivated trees, palms, &c.—the blue water line, or in the monsoon season, the line of reefbreakers (white horses galloping inwards) is readily marked and every passing steamer and other vessel can be noted. From some points, notably Torwood, the forest is broken by stretches of paddy fields;—pictures of living green framed in the sombre forest.

One can understand from these heights how Kalutara planters regard the common talk of their district being hot and unhealthy—because in the low-country, as so much nonsense. Hot it can be undoubtedly, especially on rocky land and enclosed flats towards the afternoon, when the sun has done his worst. But unhealthy never. The pure unadulterated sea-breeze comes far inland across the Kalutara district; the river not far off creates a current of pure air and health is maintained among Europeans, as well perhaps as in most districts in the country. Mr. Knight with his 22 years of good health is ample evidence and among the tea-planters there are men who have been 5 and 6 years opening clearings and planting and who have scarcely known fever or ache. This is not the uniform rule of course; but Kalutara can certainly claim to be a healthy part for the planter. The great point is to get the major portion and the real hard out-door work done in the early morning and forenoon as much as possible.

Beyond Rogart, lies Polgahakande, a fine block of 215 acres belonging to Messrs. Wight and Fairweather of which 160 acres are under tea. Clontarf is a young promising clearing in the same neighbourhood and not far off is the established garden of Heatherley with 200 acres of fine tea under the care of Mr. Algie who also looks after Mr. Hadden's Hattagalla, south of Culloden. Away to the Eastward is also Ambettenne under the care of Mr. Cochar (as well as Rogart and Torwood) and in this neighbourhood is situated a good deal of the 500 acres of forest-land purchased by the son of the well-known and wealthy "Johannis Peries Esq." of Colombo. A part of this is said to have just been sold to the Messrs. Strachan at a rate which has not transpired. We were sorry to have no time to go and see Arapolakunde estate belonging to the Ceylon Co. Limited, said to have over 200 acres of as fine tea as any in the district, but which has this year suffered from an ill-timed pruning. Crurie and Glendon (formerly Ferrinob) in the same neighbourhood have good tea, and the purchasers of the latter, the Messrs. Booth, are well pleased enough to meditate extending their investments. Travelling from Culloden to Kalutara, on foot or horse-back for the first few miles, one sees something of Becherton, St. Andrew's and Ensalwatte properties with promising tea, especially on the flats, while farther back lie Pullerton and Kaluganga estates. Altogether the 5,000 acres opened out of 11,000 acres in private hands in the Kalutara district, afford good promise of satisfactory returns to the owners. It is, of course, the day of small things so far, in respect of the outturn of crop, most of the clearings being under age; but, while the older Kelani Valley plantation (of 9,000 acres out of a total of 19,000) are giving crops this year estimated at 1 million lb., we suppose the outturn for Kalutara district will not be much under 250,000 lb.

Talking of these two young tea districts, it is evident there is a good deal of rivalry, or at any rate an exchange of a plentiful amount of criticism and banter between them. One story current

as to the decided opinions expressed to a new arrival seeking for information, on the merits of the two districts by two V. A.'s, the one pronouncing very decidedly for Kalutara, the other as much so, for Kelaniya. The enquirer was puzzled until he found that each owned property in the district he backed up: but surely that went to show that each had given the best proof of his faith in his own opinion. At the same time the Kalutara patriots point to the fact that men of experience in the Kelaniya Valley are fond of coming down and investing in the Kalutara district and they point to Mr. Rutherford and still more to Messrs. Wright, Fairweather, and Dawson in support of this view. The greatest doubt perhaps is about the comparative values of the soils, and perhaps, it would be decided by impartial authority that taking the district as a whole the Kelani Valley has the superior soil, although there are selections in Kalutara equal to anything in its rival. As for climate there is not much to choose: both must have an abundance of rain and heat. But in two other important matters, the palm must in our opinion decidedly lie with Kalutara, namely in abundance and cheapness of labour, and in cheap transport facilities. Enough has been said about the advantage of Sinhalese labour, and what Mr. Knight has done should be counted equal to R10 an acre by Kalutara purchasers! But in regard to transport facilities, there are few districts so well-served by roads, canals and rivers as that of Kalutara. There are a few miles of connecting road remaining to be cut and then the road system will be almost perfect both for Europeans and natives. But apart from this under the auspices of Mr. Morison of Culloden, an old Dutch Canal is being cleared out leading from the Kaluganga right into the heart of the principal group of estates—the authorities giving R1000 against a similar amount raised in the district—and when this work is done, paddy boats will take away the Kalutara tea at a total cost of 20 cents per 100 lb chest between the estates and Colombo, and if the Railway authorities work for the same rate with a boat of their own to their terminus, this district getting its tea to Colombo wharf at about R5 per ton, will certainly be the best off of any in the island.

So much for the present. We have said that there are between 11,000 and 12,000 acres already taken up by private proprietors for planting purposes in the Kalutara district. But we are credibly informed that the total area of land suitable for tea and which would easily find purchasers, cannot be less than 50,000 acres situated between the Kaluganga and Bentota river. The prospect of expansion is therefore very considerable, until possibly Kalutara becomes one of the most important tea-planting divisions of the island. Mentions to any one with three or four days to spare we can recommend no more pleasant trip or way of seeing the country than the route we adopted to Ratnapura by coach, down the river to a *garranta* (or *Pattupaniakande*), inland to Gekemalade and Culloden and thence after seeing the principal estates on foot or horse-back, to the end of the cut road on which a drive of seven or eight miles carries the visitor back to Kalutara (at a terminus). We found the agriculturist very busy with his paddy fields as we travelled eastward, and we were struck on this journey, as on several others of late years, with the way in which the Moormen (traders) are filling up the houses, not only in the coast towns, but on the roadside for considerable distances inland. Do they chiefly live by playing a money-lenders and universal trader,—on the Sinhalese?

INDIAN TEA PROSPECTS.—Prospects are reported to have slightly improved in the tea districts, a fair quantity of rain having fallen in Kachar and Assam, although more would be still acceptable. There has also been rain in Darjiling, and the gardens in that district are generally doing well, except where damage has been done by hail. Some rain has also fallen in the Terai and the Doora, but more is still wanted. No public sale has yet been held, as only about 1,500 chests have arrived in Calcutta, the greater part of which was sent forward to London. An invoice of 68 packages from the Spring Side Tea Company, Limited, was sold privately last week at an average of ten annas six pies per pound against an average of eleven annas four pies for the first invoice last year sold about the same time, and of very similar quality.—*Pioneer*, May 7th.

THE ALLEGED DETERIORATION OF CEYLON TEAS AND YOUNG AND OLD ESTATES.—It cannot certainly be that any deterioration found in Ceylon teas can be attributed to the states getting older, for by far the larger proportion of the teas must be maiden crops. Mr. Sharpe of Calcutta said the other day what is very true, that in a falling tea market (and we well know how the same has often been experienced in respect of coffee) fault is always found with the teas. But as a proof that any deterioration is not due to estates losing their first "bloom," we are told how some of the oldest estates in Assam gave the very best teas they ever turned out (from their old fields) last season, and how London Tea authorities confessed the said teas were as good as they could wish for.—Since writing the above, we have received the letter from Messrs. Geo. White & Co. published elsewhere, and which we commend to the attention of tea-planters.

GOOD NEWS FOR COFFEE PLANTERS.—Every year when coffee is prepared for shipment, they separate the pulp from the seed, or rather the pulp that covers the seeds. That pulp which is thrown away and so wasted contains sufficient saccharine matter to become fermented and to give by distillation a kind of spirit or brandy which certainly could be utilised and give a good return. Experiments made in Pondicherry, by the Government botanist, have given such good results that we have the pleasure of calling the attention of the coffee-planters to that new source of revenue which might repay them a part of the expenses of management, if not giving them a large profit. Such large quantity of pulp is thrown away every year that the way of turning it into money must be welcome. The Pondicherry botanist, Monsieur J. Raynard, has made his first experiment on 10 quarts of saccharine juice, and has obtained 150 grammes or more than $\frac{1}{2}$ lb. of good alcohol of 45 deg. centigrade proof. That first experiment gives a return proportionate of one and half per cent. This result may appear small, but we must remember that small rivulets make rivers, and working on a large scale may give results quite worth the serious attention of the planters.—*Madras Standard*.

A NEW DRYING MACHINE.—Notices of drying machines are so thoroughly at home in these columns that no excuse is necessary for describing that lately constructed by Messrs. Thomas Barraclough & Co., Limited, of Manchester, although in this case its original purpose was for drying fibrous and general materials rather than tea. The aim of this apparatus is to obtain the greatest amount of drying capacity with the least expenditure of power and fuel for heating, by the passing through the machine of very large quantities of dry warm air freely, so that immediately it becomes impregnated with moisture it passes out of the

machine, and makes way for a fresh supply of dry air. The exhauster is of great power, and supplies a simple means for removing large volumes of air quickly and cheaply, and the heating apparatus enables large volumes of air to be dried and warmed for use in the chamber. The exhausters used in connection with these machines vary in size, say, from 24 inches to 48 inches diameter, according to the size of the drying machine; each indicated horsepower applied in driving these exhausters has been proved by repeated practical experiments to be capable of moving 15,000 cubic feet of air per minute, as compared with 2,000 cubic feet moved under the like conditions by a fan.—*H. & C. Mail*.

PLANTING IN JOHORE.—Our correspondent now in the Far East writes us:—As a rider to my letter on Johore, I may mention that Mr. McGregor Smith, of Hong Kong, has just had his concession for 70,000 acres of land in Johore renewed. The grant had expired last November, but has been revived. The large tract of land, which is situated on the upper parts of the Johore and Muar Rivers, has been granted free, Mr. Smith only having to pay the survey fees. These, however, amount to the respectable sum of \$20,000, and pertain to Mr. Garland, the State Surveyor. \$7,000 have already been paid, and the survey is to be commenced immediately. Speculation is rife as to who is providing the money for the considerable outlay that will be required to work even a small part of the large concession, which is to be planted with coffee and sugar. Mr. Gibson, formerly of Ceylon, and who has been some time in Johore, has been engaged as manager. Report also has it that a company is very soon to be brought out in London to purchase Mr. Watson's estates. It is proposed to carry on the 300 acres of Liberian coffee already planted, and the balance of the 1,278 acres will be devoted to cultivating Rhea (China grass) and other fibrous plants, which will be treated after Mr. Death's recently invented process. I would hope that the China people who unfortunately, have been "caught" in Johore, will not relinquish the field. They have not been on the right tract before, but there are many projects which are worth cultivating and in which there is money.—*L. & C. Express*.

TEA MACHINERY.—The planting community is indebted to "Peppercorn" for drawing forth an interesting letter from proprietors of the "Colombo Iron Works": the chief, indeed, only complete, Iron Works in the island. Notwithstanding the criticism of "Peppercorn's" idea, we quite agree with him that a Show-Room in which all the machines—good, bad and indifferent—connected with Tea Preparation can be seen and compared under one roof, will ere long become a necessity. It is scarcely perhaps to be expected that any one private firm should undertake this Exhibition; but it may be well worth the consideration of the Planters' Association, whether its Committee should not arrange for some such Show-Room to which patentees might be invited to send specimen machines, and where all could be seen under impartial auspices. As the Tea Industry becomes the power in the land which we expect it to be, there may be full scope and means for the P. A. to do what we suggest, although it may seem premature just at present.—As regards letters and newspaper notices of new inventions, it has always been our practice as that of leading journals all over the world, to notice and encourage new inventions up to a certain point, and, perhaps, no Tea machinery received more attention or notice in the Indian and Ceylon Press than "Jackson's" patents up to the time when their fitness for their work became fully established in public esteem.

Correspondence.

To the Editor of the "Ceylon Observer."

FALLING OFF IN CEYLON TEAS IN THE LONDON MARKET.

2, Great Tower Street, London, 22nd April 1886.

DEAR SIR,—When those of your readers interested in Ceylon Tea are no doubt picturing to themselves a glowing future for that article, it may seem rather ungracious, at first sight, to hint at the possibility of their hopes not being realized. We think, however, as wishing to be the true friends of planters, it is impossible to shut one's eyes to the fact that the majority of recent arrivals is not what it used to be, and by your permission, we should like to call the serious attention of managers of estates to this fact.

The falling-off in quality may not be so conspicuous in shipments coming later, as in those made after the prunings, which have come to hand during the past few weeks. We hope this may be so. But at present there appears some danger of Ceylon tea not maintaining the high place it has won in public esteem. Complaints reach us of many of the teas being burnt, thin in cup, and lacking the richness for which they are justly prized. We would urge upon planters not to go on the principle of "rest and be thankful." It does not do in these times of fierce competition. India will increase her output this year as well as Ceylon, while, despise China as some people will, we do not yet know what she is capable of when driven to fight for the existence of her tea trade. These circumstances combined point to a large increase in the total supply, and consequently to the probability of a lower general average than has hitherto been obtained for all tea. Ceylon need not fear, however, if she can send us teas like those which first made a name for her produce—rich, good liquoring, and free from burntness. If planters would try how their own teas drink, we think they might easily remedy many of the defects referred to.—We are, dear sir, yours faithfully,

GEO. WHITE & Co.

GERMINATION OF LONG-KEPT SEEDS.

Nawalapitiya, 10th May 1886.

DEAR SIR,—In December 1879 I received some seeds of the *Albizia moluccana* from Java, and at the time sowed some of it which are now fine large trees. Finding some of the same seed, which has been in my desk drawer since 1879, a few days ago. Out of curiosity to see if it would germinate after being kept so long, I last week treated the seed with hot water and put it in a box of mould, and to my surprise this morning I see several of the seeds have germinated.

It may be of some interest to your readers to know how long the seed of some trees will keep good and perhaps they will be good enough to give their experience.—Yours faithfully,

F. W. NEATE.

RIVAL TEA MACHINES AND THE PLANTING COMMUNITY.

Colombo Iron Works, Colombo, 13th May 1886.

DEAR SIRS,—We always read your articles by "Peppercorn." They are usually more or less instructive—always amusing—but the writer in last night's article has clearly got beyond his depth when writing on the subject of tea machinery.

"Peppercorn" hints that "such a firm as Messrs. Walker & Co." should have a show-room where all the different tea machines could be exhibited as they are brought out; but will he get the owners of the different machines to see it in the same light? If so let him introduce them to us and we will be ready to treat with them for the exhibition of their machines.

The following remarks by "Peppercorn" are simply absurd:—"Of those who sell not one seems to be free; all appear to be bound down to sell or expose for sale one particular make or the machines of one particular maker."

So far as we are ourselves concerned these statements are not correct. Besides Jackson's machines, (and until we find something better we shall give them the preference over all others where our opinion is asked), we have several machines belonging to other patentees. Last week we had the pleasure of selling a Gore's "Sifter" and there is always one of these machines on view at our place. Two months ago we turned out 6 of Gilruth's "Packers." Two days ago we accepted the agency for a new machine called Parry's "Tea Press" of which full particulars will be advertised in due course, as we do not wish (like some of your correspondents, Mr. Editor), to get an advertisement cheap under cover of a letter.

Finally we are at the present moment in correspondence with the patentees of two Tea Rollers regarding the manufacture of their machines by us.

In deciding whether we will take up any new machine the following points guide us:—

(1) Is the machine really one of utility and likely to be in demand?

(2) Will its out-turn be creditable to us as manufacturers?

(3) Is it clear of all existing patents?

(4) Will it pay?

Give us these points and we will make any machine "Peppercorn" can put in our way. We trust, we have now written enough to show that the above remarks from the "Gup" to which we have specially drawn attention, are not applicable at any rate to

JOHN WALKER & Co.

ON HORSE SHOERING IN CEYLON.

DEAR SIR,—I wish to enlist your interest on behalf of our faithful servants, our horses, and to point out to you some of the faults committed by the artizans to whom are entrusted the shoeing. Horse-shoeing as a rule gets very little attention paid to it, and yet, unless the propellers are sound, the general health is of little service. The subject of shoeing meets with a great deal of prejudice, and the farriers attribute anything that goes wrong in the animal economy, to everything but the evil results of their own work, and in this country it is very difficult to explain to the native workman why one method is good and another bad. Of course there are many good, and intelligent farriers, and this letter will not apply to them. I will now proceed to detail the process of shoeing carried on in forges to which this letter does apply, and afterwards point out to you, dear sir, wherein the faults occur.

Our horse requires shoeing.—The old shoes are taken off, the farrier takes his knife, and pares a way the sole of the foot quite thin, and hollow, then slices the frog into a small neat shape, and opens out the bars, near the heels, to give the foot a nice wide appearance.—He then shapes a shoe, and when cold applies it to the foot with six nails; but the edges of the horn project all around the iron, so he rasps the horn, and the nail clenches at the same time, nice and even, to the dimensions of

the shoe, and the operation is well, and to his satisfaction, completed. The following month the same performance is gone through.

In a state of nature, the wall, the sole, and the frog each bear their proportion of weight, and wear; but with continuous work, on hard roads, the wear is too great, and an iron protection is necessary; but, why cut, or rasp away any part of the hoof, except the wall, and the outer edge of the sole just enough to afford a good bearing for the shoe, and low enough, so that when a moderately thin shoe is applied the frog will sustain beneficial pressure, and wear, and if the shoe be made the size of the hoof, and fitted on red hot for about three seconds, to ensure a close union, and when gradually cooled, nailed on with five nails, the ends being pulled upwards, and then bent downwards and twisted off, about one-eighth of an inch from the hoof, and the clenches laid down evenly on the outside of the hoof; then no rasping is necessary, and the oil-conducting fibres are not severed, and the horn at the base of the hoof is strong, elastic, and durable.

Shod in this manner, in the event of casting a shoe on a journey, there will be no inconvenience to the horse until a new shoe can be fitted. A horse that has had his feet mutilated by paring the sole and frog, cannot travel on his tender feet at once; time must be allowed for nature to repair the damages, and this is where a farrier asserts his knowledge, for if he finds a tender frog bearing on the ground, he cuts it away, and when the horse does not limp on leaving him, he thinks himself a clever fellow, and asserts that frog pressure causes the horse to go lame. I will now quote a few paragraphs from the book on Shoeing by the undoubted authority, G. Flemming, F.R.C.S., M.A.T. There are several quotations in Captain Hayes' veterinary notes after the above authority's ideas, and in almost all ailments in the feet, or limbs, the first advice is "allow frog pressure" thereby inducing many advantages detailed.

Abbreviated Notes from the Work on Horse-shoeing by G. Flemming, F.R.C.S., M.A.T., etc.

Preparing the hoof.—Levelling the wall is an important operation which if unequal in pressure causes the deform of the hoof, and modifies the growth of the horse, etc.

Shortening the wall.—Provided the hoof, before it comes into the hand of the farrier, has the proper inclination, and is equal on both sides of its ground face, but is nevertheless overgrown, the artisan has then only to remove the excess of growth, without disturbing the relations between the several regions of the wall. Or should the hoof be overgrown too oblique, too upright, or unequal at the sides, then in remedying the one defect he at the same time remedies all. The amount of horn to be removed from the margin of the hoof will depend upon circumstances, the limit to which the rasping may be carried will be where the wall is almost, or quite, reduced to a level with the strong unpared sole. It must ever be borne in mind, that if the wall does not stand beyond the level of the sole, it does not require reducing. When reduced sufficiently the rasp should finish the task by rounding off the sharp edge to provide against fracture of the wall fibres.

Paring the sole.—Like so many practices relating to the management of the horse, this paring of the sole is absurd in the extreme, and has not the most trifling recommendation to support it. To remove the growth of the wall is an absolute necessity; but to denude the sole of its horn is wanton injury to the foot and cruelty to the animal. This is easily accounted for. The sole only increases its substance to a certain thickness, never too much, and then the excess is thrown off in a natural manner in flakes. In this way the sensitive foot within is amply protected; the sole can sustain a share of the weight especially around its margin in front, where it is strongest, and

meet the ground, however rough and stony this may be, with perfect impunity. This is its function! It has been mentioned that the horn is secreted from the living surface, and that myriads of beautiful vascular and sensitive tufts, dependent from this surface enter the horn fibres to a certain depth, and play an important part in the formation of the sole. The newly-formed horn is soft, and spongy and incapable of resisting exposure to the air, but as it is pushed further away from this surface by successive deposits of fresh material, it becomes old horn, loses its moisture and in doing so acquires the hardness and rigidity necessary to enable it to withstand external influences; then it is subjected to wear, and if this be insufficient to reduce it sufficiently, it falls off in scales. But the process of exfoliation is not a rapid one. Horn is a slow conductor of heat and cold, and when thick retains moisture for a long period. These flakes, then, act as natural "stopping" to the hoof, by accumulating and retaining moisture beneath; and this moisture not only keeps the foot cool as it slowly evaporates, but ensures to the solid and growing horn its toughness, elasticity, and proper development. In addition to this, every flake acts more or less as a spring in warding off bruises, or other injuries to the sole; and thus the floor of the horny box is thoroughly protected from injury, externally and internally. What occurs when the farrier following out the routine of his craft, or obeying the injunctions of these as ignorant as himself, or so prejudiced as not to be able to reason, pares the sole until it springs to the pressure of his thumb? The immature horn, suddenly robbed of its outer covering immediately begins to experience the evil effects of external influences; it loses its moisture, dries, hardens and shrivels up, it also occupies a smaller space, and in doing so, the sole becomes more concave, drawing after it the wall. For it must be remembered that the sole is a strong stay against contraction of the lower margin of the hoof; and the consequence is that the hoof gradually decreases in size, and the quarters and heels become narrow. The animal goes "tender" even on smooth ground; but if he chance to put his mutilated sole on a stone, what pain must he experience! The tenderness and lameness arising from this maltreatment are usually ascribed to everything but the right cause, and the most popular is concussion etc. etc. Seeing, therefore, the natural provision existing in the sole of the hoof for its diminution in thickness, when necessary, and knowing that the intact sole is the best safeguard against injury, and deterioration to this region, it must be laid down as a rule in farriery—and a rule from which there must be no departure—that this part is not to be interfered with on any pretence, so long as the foot is in health, not even the flakes are to be disturbed.

Paring the Frog.—This part of the hoof is that which in the opinion of the grooms and coachmen, and some others who should know better, most requires cutting "to prevent its coming on the ground, and laming the horse"; and this reason, together with its softer texture, causes it to be made the special sport of the farrier's relentless knife. It is artistically and thoroughly trimmed, the fine elastic horn being sliced away, sometimes even to the quick, and in its sadly reduced form it undergoes the same changes as have been observed in the pared sole. No wonder, then, that it cannot bear touching the ground, any more than the sole. Strip the skin off the sole of a man's foot! How would the elephant, the camel, or even the dog travel, if we pared away the pads on the bottom of their feet? and yet the horse's frog performs the same important function that the pad does on their feet. The artistically shaped frog, so treated, soon wastes, becomes diseased, and at length appears as a ragged, foul smelling shred of horn, almost impalpable between the narrow deformed heels of the pared foot. The function of the frog in the animal economy is one of great moment, and has already been indicated. It is eminently adapted for contact with the ground, and in this resides its most important office. The longer the frog is left untouched by the knife,

and allowed to touch the ground, the more developed it becomes; its horn grows so dense, and resisting, yet without losing its special properties, that it braves the crushing of the roughest road without suffering in the slightest degree; it ensures the hoof retaining its proper shape at the heels; is a valuable supporter of the limb and foot, while the animal is standing or moving, and is an active agent from its shape, and texture, in preventing slipping. Its reduction and removal from the ground, I am perfectly convinced from long observation, have a tendency, directly or indirectly, to induce that most painful, frequent, and incurable malady, Navicular disease, as well as other affections of this organ. The farrier should, therefore, leave the frog also untouched unless there be flakes which are useless:—though this is extremely rare; then these ought to be cut off. So particular am I in this respect, however, and so well aware am I of the morbid desire of the workman to cut into this part, that I never allow any frogs to be interfered with, unless I am present. If any gravel has lodged beneath the flakes, at the side, or in the cleft—which is most unfrequent—this is removed by some blunt instrument. To show the value of contact with the ground, when a horse with a diseased frog is brought to me, I at once order the hoof to be so prepared or shod, that this part, will immediately receive direct pressure—in a brief space the disease disappears. Cases of what groomers call “thrush” of many years duration, and which had defied all kinds of favourite dressings, have been cured, and the rotten wasted frogs have become sound, and well developed in a few months.

Opening up the Heels.—Having done everything possible to ruin the sole and the frogs, the farrier proceed to complete his work by opening up the heels. The operation is quite as injurious, if it is not more so than mutilating the other parts, etc.

Conclusion.—It should be ever most strenuously insisted upon, that the whole lower face of the hoof, except the border of the wall, must be left in a state of nature, etc.

The above paragraphs appear to me to meet the points that I wish horse-owners to take note of with the additional remark that “cold” fitting-on of the shoe is strongly condemned for several very important reasons, but which space forbids detailing. So now, Mr. Editor, I am surprised at the length of this letter, and only trust you will consider the subject worthy of space in your valuable paper, and that if you do, and would send it to be inserted in the native papers, so that our country farriers can read and understand that a horse's foot is not a mere horny block to be hacked at, at their pleasure, I am certain that you will receive a vote of grateful thanks, although a mute one, from every horse treated on the above system.—I remain, dear sir, yours faithfully,

A SYMPATHISER WITH THE MAIMED.

POTATO BREAD.—Boil four or five potatoes, mash them, and add one tablespoonful of flour. Pour over these the water the potatoes were boiled in, stir all well together, and when lukewarm, add half a teaspoonful of yeast. Cover with a cloth and set to rise. When light, make up as wheat bread.—*Queen'slander*.

THE KING OF THE PUMPKINS.—The heaviest Pumpkin (according to M. de Vos); presented at the Paris market in 1881 weighed 130 kilogrammes. Translated into English, this means that the gourd in question weighed about the same as twenty-eight legs of mutton of 10 lb. each.—*Gardener's Chronicle*.

A METAL TEA CHEST.—A new tea chest has been introduced in the shape of a steel box made by machinery. The inventor claims for his new package that the first cost is about one-fourth less than the

present chest with lead lining. It occupies smaller space in the hold of the ship, and consequently costs the importer less freight. Likewise being little more than half the weight of an ordinary chest the carriage from London to the country grocer will, of course, be considerably lower (perhaps 15 per cent), which, in these days of keen competition and heavy transit charges, is a point well worthy of consideration. It is impervious to moisture, and may be placed in a pool of water without the slightest damage to the contents. It will not allow the contents to leak out, and herein is perhaps one of the most attractive features in the invention to our readers. It can be very quickly opened by removing four screws in the lid, and as it does not require to be lined in the inside as an ordinary chest is with lead, all danger of the contents losing part of their fragrance by getting out between the lead and the outer wooden case is done away. Every tea leaf in the package will be in equally good condition. It is needless to point out that for purposes of sampling it is infinitely superior to the old lead-lined chests, as the packages can be opened and reclosed without damaging the box, which circumstances also permit of these boxes being used as bins in the factory during the collection of sufficient tea to form a break.—*H. & C. Mail*.

PRODUCTS OF PALAMA CHRISTI.—Since we replied to the query of a correspondent who had been trying experiments in the manufacture of cold-drawn castor oil (we judge by the clearness and absence of smell of the specimen submitted to us), we have seen, and marked for insertion in the *Tropical Agriculturist*, what is evidently an exhaustive article in the *Indian Agriculturist* on CASTOR OIL AND ITS USES, from which we here quote one passage:—

The uses of the castor plant are many; the oil is the only eligible one for lubricating all sorts of machinery, clocks, watches, &c.; it is the best lamp oil we have in India, and gives an excellent white light, far superior to that of mineral oils, petroleum, rape seed, mustard, linseed, and all other oils whether vegetable, animal, or mineral. This I state after comparison. The slowness with which the oil burns effects a saving of consumption ranging from $\frac{1}{4}$ to $\frac{1}{2}$. Its freedom from danger as lamp oil is another recommendation. All Railways in India burn castor-oil. It gives out very little soot, almost imperceptible, which quality no other lamp oils possess. This is a great recommendation. Most important of all, it is the cheapest lamp-oil in existence, while it is the cheapest and best for the manufacture of all kinds of soaps, candles, pomatums, and perfumed oils. All the great perfumers of London and Paris use castor-oil, for the manufacture of golden oil, and its beneficial effects are due to the demulcent quality of the castor-oil which keeps the head cool and the skin and the pores of the skin and roots of the hair soft and open. It is a medicinal oil, and the most largely used as a mild demulcent laxative. The use of cold-drawn oil gives a splendid light; no other oil can vie with this light, it being almost electrical in its brilliancy. When boiled it does not give such a splendid light; the reason for this is, in the boiling or sweating, or both processes, the electric light-giving portion of the oil gets dissipated to a certain extent. The shelling of seed and filtering processes are comparatively very costly. The oil drawn from unheated shelled seeds without boiling (cold filtration being substituted for boiling) is of the best quality. If cold-drawn oil can be manufactured sufficiently cheap to be within reach of a class lamp oil, it would be used by many. At present, however, it is selling at prices ranging from £40 to £50 per mound in India. The reason for this is that castor seed has first to be exported to Europe, then it is bought by the manufacturers from the traders in castor seed, and after manufacture of the oil, it is bottled, labelled, corked, expanded, packed, and shipped to India.

INDIAN AND CEYLON TEA AVERAGES.

Messrs. Walker, Lambe & Co., under date April 12, give the following as some of the averages realised during the month:—

—Home and Colonial Mail.

EFFECT OF ARECANUT UPON A RETRIEVER BITCH, WHEN GIVEN AS A DRENCH.

Sir, Two days ago I put rather less than 1½drs. of powdered arecanut in to 4oz. clean medicine bottle, and filled the bottle half full of warm milk and water, shaking the bottle well, and administered the contents, as a drench, to a retriever bitch, five years old, and say 50 or 60 lb. weight. The result was, the bitch turned once round, and then fell down apparently dead; I removed her head from under her body, and in

about half a minute she got up, with her back much arched, a peculiar glazed look about her eyes, foamed at the mouth, breathed very heavily and with great difficulty; her tongue became shrivelled, narrow, and concave, and of a sort of dull leaden colour; lips and gums the same colour. In this state she staggered, and reeled into her kennel, some twenty yards distant, and fell into the kennel, being unable to lift her hind quarters over the entrance of the kennel (some eighteen inches high). In the course of three hours she passed a large quantity of worms; continually tried to vomit but only raised a small quantity of thick mucus; and breathed with great difficulty all day. This is written at the end of the third day since the drench was given. The bitch is very weak has only taken a little milk since; she still experiences some difficulty in breathing, and if she goes out for a walk, a sort of tissoek, or slight cough (as in distemper) comes on. I believe she will recover. With the exception of having worms, the bitch was in perfect health, in thorough good condition, and active and lively. She had won puppies about eight weeks previous. I inclose some of the powder, which is simply grated arecanut, and I have given some of the same powder out of same box to other dogs, with beneficial results. During the last thirty years I have never seen arecanut otherwise than beneficially. Can you, sir, or any of your readers, enlighten me? Again, what is the action of arecanut?—RETRIEVER.

[We have known similar results from drenching with arecanut, but not from the drug when given as a bolus, or swallowed in broth voluntarily. We are led to believe that some of the powder enters the trachea when given forcibly as a drench. This is the only explanation which we can offer of the above case.—Ed. Field.]

FOREST TREES.

The following is a list of New Zealand trees which should be introduced here,* as likely to flourish and become of great value. *Dammara Australis* or Kauri Pine is a splendid timber tree rising to a height of 100 feet without a branch, it is therefore free from knots and very useful for house building, it also yields the valuable Kauri gum worth fifty pounds a ton. The annual sale of the timber from New Zealand amounts to one hundred million feet, and five thousand tons of gum, this latter is made into a varnish resin and much used in the United States, it resembles amber in colour, and is often found by the diggers in pieces larger than a man's head, it is supposed to be the produce of forests that existed tens of thousands of years before; the gum yielded by living trees is not so much esteemed. There are said to be but 150,000 acres of this noble tree living, and its disappearance is expected, as but few trees are planted to supply the enormous demand. There is a tree of this species growing in the Lal Bhang at Bangalore, it may be twenty years old, and is some forty feet in height, the situation is too hot for it.

The next tree in order of value is *Podocarpus totara*,—some indeed consider it superior in value to the Kauri pine. Lindley says, that so highly was this noble tree esteemed, that the possession of forests of it was often the occasion of wars. The *totara* grows to a hundred feet in height, and its diameter often exceeds eight feet. The wood is red in colour, close grained, easily worked, and is exceedingly durable, posts in the ground lasting for more than fifty years, it is also impervious to the attacks of the teredo worm. There is a variety known as mountain *Totara* which will stand a climate as severe as the Highlands of Scotland. There is but one *Podocarpus* in Southern India, discovered by Colonel Bechdom on the Timaveilly Hills at an elevation of about 6,000 feet. *Libocedrus Durriana*, the Arbor Vite of the colonists, is another valuable tree growing to nearly one hundred feet in height, the wood is red heavy and very durable, and considered valuable for masts spars, and it is scarce even in New Zealand, and when its qualities are fully known it very probably will be exterminated. There is another of this genus *L. Bidwilli*

*The Nilgiris, and what answers there will generally flourish on the Nuwara Eliya ranges.—Ed.]

which produces the cedar of the colonists, a very useful timber but not so durable as the former. Then there is *Podocarpus Spicata* esteemed for its valuable timber much used for bridges, sleepers, houses, and its durability is said to be wonderful, and it is abundant in both islands. *P. dactyloides* is highly valued for the inside work of houses owing to its lightness, evenness and smoothness in working. *Artocarpus Cupressinum* is remarkable for its beauty, its timber is excellent, much esteemed by furniture makers, as the red color of the wood takes many shades, and it is easily worked, for all work when not exposed to wet, it is not to be surpassed. The Tancakka tree *Phyllocladus Trichomanoides* is a handsome coifer of medium height, its wood is of first rate quality, very durable, pale red, strong and close grained. The bark of the tree is prolific in tannin, containing nearly 25 per cent. a large amount of the bark is sent to Grenoble in France, in one year more than two laes of Rupees of bark was sent.—*South of India Observer.*

THE SUGAR INDUSTRY.

NEW SUGAR CANES IN THE WEST INDIES.

For some years efforts have been made to bring together into one collection all the different varieties of sugar canes which are known under cultivation in the sugar-producing countries of the world. It would appear now that this object has in a great measure been accomplished in the extensive collections of sugar canes under experimental cultivation by the Department of Public Gardens and Plantations in Jamaica. The collection, as a whole, embraces about eighty varieties of canes, and it has been pronounced by a competent authority connected with the Department of Agriculture, Washington, "as probably the best collection of sugar canes ever gotten together."

As indicating the wide area from whence these canes have been obtained, it may be mentioned that the "Elephant" cane, so called from the size it attains under favourable circumstances, was obtained from Saigon, Cochinchina; the Salangore cane is a native of the Malay Peninsula, where it is highly esteemed. The Tiboo cane is also East Indian, and is a productive cane of great merit. From Mauritius there come the Horne, the Mauritius, and the Barkley canes. From Queensland, there are the Brisbane, the Green-Rose Ribbon, the Queensland and the Hillisi; while from the Pacific Islands (probably the home of the sugar cane) there are the Lahaina, the Cuban, the Pua-ole and the Ko-Kea. The Lahaina cane is described in Hawaii (Sandwich Islands) as being the most universally esteemed of all canes, and everywhere, excepting at great elevations, it is planted to the almost total exclusion of other varieties. This cane has yielded as much as an average of 6 tons of sugar per acre on areas as extensive as 100 acres, and $7\frac{1}{2}$ tons per acre on an average over areas of 20 acres.

The Pua-ole cane, another great favourite in Hawaii, is called the flowerless cane, because it never tassels, or throws out a flowering shoot. It is described as a soft, rich cane, yielding juice of high specific gravity, and specially adapted for cultivation at high altitudes. The Cuban, Ko-Fake, in Hawaii comes next to the Lahaina. It is rich in juice, rattoons well, grows rapidly, and is entirely free from "cane itch."

The Samui cane is the favourite cane with the sugar planters of Fiji. It is hardy, grows rapidly, and yields sugar freely. Of dark-rind canes, such as violet purple, and black, there are numerous varieties. Many of these, such as the Egyptian and the Martinique, are admirably adapted for dry, arid regions, and grow luxuriantly where other canes would fail. Others, again, are adapted only as fodder plants, and are often grown for that purpose when grass is scarce. The Mamuri cane, of a dusky brown colour, is certainly a strange-looking cane. It would appear to be covered with a thin dry bark, which marks it at once as a distinct and specialised variety. This is a hardy slender cane, which would grow in the driest situations. Of striped canes there are very handsome specimens, such as the Green-Rose Ribbon and the Red Ribbon, which attract attention, and are likely to be great favourites with planters.

In the West Indies generally the favourite canes are the Otahete, the transparent, Mont Blanc, and the Bourbon. These may be said to yield the bulk of Cuban and West Indian sugars, but several others are being tried, with the view of testing their capabilities for different soils and climate. As the sugar cane has lost the power of producing seed from which plants may be raised, it is now entirely propagated by shoots or pieces of the stem which are furnished with eyes at every joint. These eyes give rise to new plants, which necessarily must be identical with the parent plant and keep true for an indefinite period. The importance of introducing new canes, and so testing the highest producing powers of the land, in these days of low prices and keen competition, is self-evident.

From the supplement to the *Jamaica Gazette* we find that the collection of canes above mentioned sent to the New Orleans Exposition has lately been carefully tested by Dr. Crampton, chemist, attached to the Bureau of Chemistry Department, Washington, D.C. Planters in the West Indies would do well to procure these analysis and carefully consider whether some of these new canes do not offer them advantages in a cultural and economic sense superior to the old. We may add that a full description of these canes was given in the last report of the Director of the Botanical Department, Jamaica, and Dr. Crampton's analysis are intended to supplement these descriptions and give sugar planters every possible information on the subject.—*Colonies and India.*

CULTIVATION ON TEA ESTATES.

The question of cultivation is one to which we think sufficient attention is not paid on tea estates as a rule. It appears to be more the object of every manager to put out a small extension, rather than consolidate and improve his existing area. It is no wonder that nowadays more attention should be paid to measures of various kinds by which a large outturn of good, sound marketable tea may be produced. To a larger yield per acre is due in a large measure the difference in cost at which one planter can turn out his tea cheaper than his neighbours. An outturn of four maunds per acre at a local cost of four annas, if reduced to three maunds, means 20 per cent more; or an increased outturn of five maunds, enhances the possible profits, so that the planter's attention in these times should be given more to endeavouring to turn out a larger quantity per acre than to rushing out extensions, even on a small scale. Many planters are not quite satisfied unless they "put out" a small bit every year; forgetting that had the same labor been utilized in the cold weather to giving a good deep hoeing, and filling in any vacancies in the old garden, the outturn of tea per acre would have increased more than the area put out will yield even in full bearing, that is provided no extra labor has been imported. The system of cultivation adopted on the estates is not as a rule good, for the simple reason, that planters have not sufficient labor at their command to cultivate when they consider it most judicious, but are driven into cultivating in all weathers, in order to keep on terms with the jungle that springs up so quickly and luxuriously in Assam. The traveller in Assam, go where he will, invariably finds that, in the rains day after day hoeing goes on. On one or two of the most rainy days there may be a little variation in all hands filling up vacancies, but this is rather an exception than otherwise, and yet the planter cannot help himself, owing to shortness of labor. It may not be recognized generally, but still there are some planters who thoroughly believe, that cold weather cultivation is the best, and a good many more gardens are now cultivated deeply in the cold weather* than was formerly the case. On (teahs or high plateaux a good deep hoe does more in the way of pulling out weeds, and its preventing wastage of soil, than several repeated ones in the beginning of the rains; and it invariably gives an early flush. The first hoeing should be finished soon after the pruning; a advantage should be taken of any dry weather, say in May, to give the soil a second good

* Dry season in Ceylon.—Ed.

deep cultivation, after which sufficient hoeing should be given to prevent any exuberant growth of jungle. As a rule, if two or three good hoeings are given before August, the trouble and expense of keeping down jungle becomes infinitely less. It is not in every planter's power to regulate his cultivation, but it is very possible that many planters in their anxiety to extend their area in the cold weather very often neglect cold weather cultivation, and go on extending and allow their old garden to get a little dirty. They are thus never able to catch up the jungle and frequently lose a good deal in outturn. An idea is prevalent that pruning and cold weather hoeing should go on side by side; those who follow this course are not likely to regret having done so. Cultivation in a large measure determines the character of the flush, whether it will be weakly, or a good healthy vigorous one likely to go on increasing throughout the season. Some planters are of opinion that deep cultivation in the cold weather causes great evaporation of moisture, but provided the soil is well pulverised this will not happen. Again, some are of opinion that a great wastage of soil takes place on tealah land from deep cultivation, this is, however, due more to frequent light hoeing than deep cultivation. In fact, if deep hoeing is not resorted to on tealah lands the wastage is something marvellous. In the heavy downpours that occur in Assam at the first burst of the rains, if the hoe is only put in say three or four inches, the result is, that the hard sub-soil does not freely absorb the water, and the consequence is that the loose soil above saturated with rain simply slides down to the foot of the tealahs.* The deeper and looser the cold weather cultivation on the tealahs the greater the protection from wash. When the soil is, thoroughly loosened to a depth of 10 to 12 inches the rainfall percolates through it and descends gradually to the bottom of the tealah, taking very little soil with it. Of course, in most tealah gardens, terraces are recognised as the correct system of, what may be called, surface drainage, and if terraces are established then any depth of cultivation can be indulged in.—*Indian Planters' Gazette*.

METHOD OF PRESERVING TIMBER IN JAPAN.

Now that we are getting tea boxes from Japan, the following extract from the *Journal of Forestry* will be interesting:—Be it noted, then, that the Japanese use only wood previously preserved as follows:—

PRESERVATION PROCESS APPLIED TO TIMBER STORE.

At a distance of 20 or 30 chos (1 cho=about 120 yards) from the sea, and near the mouth of a stream, a large pond is dug, so that the sea may have free access to it. This is called Kakoi-ori (or storing pond). Its size is not fixed, but generally it contains an area of 14,000 or 15,000 tenbos (1 tenbo=about 36 square feet), and its owner keeps his office near by, so that he may transact his business on the spot. The circumference of the pond is built of stone or wooden walls, and a canal is dug on one side to communicate with the river and thence with the sea; the flow of the tide being regulated by means of a sluice. The pond should not be deeper than 5 feet in the central part at full tide and not shallower than 2 feet in the margin at ebb tide. The right proportion of salt and fresh water for the pond is 6 parts of the former to 4 of the latter; for if the salt water exceeds this proportion, timber becomes blackish in colour, and is liable to be much eaten by worms; if, on the other hand, the proportion of salt water becomes less, it is much sooner decayed than otherwise. The velocity of the flow of tide should also be very carefully regulated, for if the current is either too rapid or too slow, timber is again very liable to be much injured by worms. Hence, in those places where there are two or three ponds near one another, their owner generally amalgamates them, on agreement, by means of small canals, which arrangement regulates the flow of tide very considerably. Timber for storing is usually piled in five layers according to its quality; the lowest layer consisting of middle-class timber;

the next layer of first-class timber, the next layer above again of middle-class timber; the next layer of third-class timber; whilst the uppermost layer, which is usually exposed above the surface of the water, consists of very low quality, and by its weight the lower four layers are kept sunk under water. Those five layers are piled one upon another alternately at right angles, so that the whole arrangement presents the appearance of a toothed cube. Sometimes, however, the pile consists of only two or three layers; in that case they are tied to a big timber (about 12 to 15 feet in length, and 7 or 8 inches in diameter) standing near by, and are thus prevented from floating about freely; sometimes also one or two separate pieces of different kinds of timber are kept in the pond for specimens. The durability of timber depends greatly on the amount of care bestowed on it, and to this end the washing is the most important. Twice in a year, generally in June or November, the cubical mass of timber above described is disengaged, and each piece is well washed by means of a straw brush. The different pieces are then reconstructed in a cube, but with the following alteration in the arrangement: the middle-class timber which before constituted the third layer, now forms the lowest layer, and the middle-class timber which in the former case was at the very bottom, now occupies the third layer. If washing cannot be done twice a year, it must be performed once a year at least. In the following table are shown (in the first column) the names of different kinds of timber, in the second column the number of years for which they may be preserved in the timber store, and in the third column the period at which they are best adopted for use:—

	I.	II.	III.
Hinokai (<i>Thuja obtusa</i>),	...	for 8 after 3	
Matsuo or Moni (<i>Abies firma</i>),	...	4 " 1.5	
Sugi (<i>Cryptomeria Japonica</i>),	...	5 " 2	
Tsuga (<i>Tsuga Sieboldii</i>),	...	6 " 2	
Hiba (<i>Thuja dolabrata</i>),	...	8 " 3	
Tawara (<i>Thuja pisaifera</i>),	...	8 " 3	
Reyaki (<i>Zelkova Kuyaki</i>),	...	8 " 3	
Kashi,	...	10 " 4	

(The number of years is calculated from the day of felling, and the time which is spent before timber comes to the store is reckoned to be one year.)

A pond of 15,000 tenbo in area can, on the average, store up about 10,000 pieces of timber. They are of various lengths, as the following table shows:—

Lengths of timber (in kens), 2, 3, 2.5, 4, 3.5, 4.5, 5, 6

Percentage number, ... 50, 20, 10, 5, 10, 5, p. ct

Thus one-half of the whole timber in the pond is of 2 kens in length, one-fifth is of 3 kens in length, etc. (1 ken=2 yards.)

At ordinary times, only three or four men are employed, whose daily wage is 35 to 45 kens (?), but at the washing season 15 men are employed daily for a period of about half a month.

MUSHROOMS.

The conditions most favourable for the production of fungi are warm showers descending on a heated surface; these conditions exist in a pre-eminent degree just now on the Nilgiris. The spring was unusually prolonged, and proportionately hot and dry. Rain in April and May held off most unaccountably, or only descended in very slight showers, and the south-west monsoon, accordingly, burst upon the hot soil, abnormally quickening vegetable life, more especially that of a fungoid character. Mushrooms have sprung up in great abundance everywhere, and are gathered and carried about the stations for sale. Lovers of the esculent look forward to indulging to their heart's content in their favorite vegetable, which is deservedly popular, as an article of food, for delicacy of flavour, and highly nutritive qualities. But as the order of fungi has many poisonous varieties, which, to an inexperienced eye, appear not to differ materially from the wholesome sorts, some caution is necessary before partaking of a luxury of such uncertain qualities

* Steep lands.—Ed.

as the mushroom. Cases of fatal poisoning are rare—at least we do not hear of them very often—but indisposition attended with acute suffering is of frequent occurrence. Mushroom collectors are generally women and children, some of whom, from long practice and an observant eye, can detect a wholesome from a noxious variety—but these experienced hands are sometimes accompanied in their excursions by novices, who gather promiscuously whatever comes to hand, and the result is that some gourmet falls a victim to excruciating stomach-ache, or to one of the numerous forms of indigestion, and while still suffering the consequences of an irritant poison in the digestive organs, vows he will never touch a mushroom again; a pledge violated on the very first occasion the appetising fungus is again put before him.

Edible fungi are everywhere distinguished empirically, but the botanical characteristics of both the poisonous and the harmless kinds are so well marked, generally, that little difficulty is experienced in tracing them in a basket of mixed mushrooms by an observer of ordinary intelligence, although it would prove no easy task, even for an accomplished botanist, to trace the numerous and insensible gradations by which the 29 edible species which science has classified and named, are distinguished from the 31 poisonous sorts. Fortunately, mushroom collectors, in this country, have to deal with a limited number of varieties only, and these in a few well-known localities, to which they resort year after year. It seldom happens that a poisonous variety, like a parasite, overpowers an edible kind, and forces it out of existence from a particular spot. More frequently a harmless mushroom acquires deleterious properties from some change in the conditions of growth, and then there is reason to fear consequences as the collectors gather these mushrooms from habit, without suspecting the change of character, which, however, is not altogether undisclosed, for in appearance, odour, and flavour the mushroom tells an intelligent observer whether it can be safely consumed or not. As in the best regulated families, so with the genus *Agaricus* accidents will sometimes happen, and it behoves every lover of the mushroom to take care of himself, and make himself acquainted with the salient features of the edible and the poisonous sorts. On the hills, as in England, we have the true meadow mushroom, *Agaricus campestris*, and the horse mushroom, *Agaricus arvensis*. The former is not often, or abundantly found, and affects open pastures, where it frequently gets trampled down by grazing cattle. The horse mushroom is the most common and most abundant, and is the variety usually offered for sale. It is very plentiful on recently manured coffee estates, and in open sholas where the sun-light can freely penetrate.

It is a generally accepted truism that mushrooms which grow under trees are dangerous, because they are supposed to feed on decayed roots; but the mushrooms of the Nilgiri sholas are an exception to this rule, for some of the best and most delicate sorts are gathered under the shade of the forest. In the absence of reliable or scientific information on the subject, consumers of mushrooms are content to apply the vulgar tests of wholesomeness, namely, cooking them with a bright silver coin, or an onion, the discoloration of which is supposed to indicate danger. But these are perfectly worthless tests, and nothing but the recognised botanical peculiarities are to be relied upon. Edible mushrooms, in form, size, color and habit are distinguishable from the noxious congener, and when once these features are pointed out and understood, they cannot be forgotten or overlooked. The small white-topped, pink-gilled mushroom of the open, is of course the most delicate of the fungus order, but the yellow-topped, and grey-gilled, though coarser in flavour, is not to be despised or rejected as of doubtful character. In both the cap is fleshy and the gills quite free from the stem, round which, on the under-side, an open channel runs. This is a salient feature of an edible mushroom, as all the poisonous sorts have the gills touching the stem. The cap at the outer circumference, further laps over the

gills and is pendulous, which is not the case with the cap of a poisonous mushroom, which terminates at its juncture with the gills. The stem should, moreover, be solid, when cut through, and have a collar round midway between the cap and the root. No poisonous or doubtful mushroom will possess this collar. The cap is sometimes silky, sometimes hairy, and sometimes scaly, all points perfectly consistent with wholesomeness, and should be dry, never viscid, which is an unmistakable indication of noxiousness. The colour may be white, or smoky, or tawny, or dark brown. The color of the gills may be white or pink, or salmon or brown, or even black, and the spores of the gills purple, or brown, or black. The gills of poisonous mushrooms never grow black, however long they may be gathered, and the flesh of the cap never changes color. The horse mushroom, as its name suggests, is of large size and springs up in clusters, a condition of growth which is said to be peculiar to the harmful varieties, but not always so. This variety affects the neighbourhood of trees and hedges, and woods, but cannot for this reason be rejected as doubtful. Indeed, the horse mushroom is the natural as well as the cultivated article, with peculiarities developed by scientific treatment. A mushroom presenting all the salient features of an edible variety, which we have described, may be safely eaten either in a raw state or cooked, but if the consumer will neglect what has been said, and partake of whatever is offered to him as a mushroom, he may incur the penalty, sooner or later, of his want of caution.—*Leader*.

SUGAR-REFINING WORKS AT FIJI.

Fiji is now enjoying the proud pre-eminence of this one distinction—that of having the largest sugar-mill in the world. The Khedive of Egypt has until very recently had the honour of possessing the greatest cane-crushing and cane-juice-boiling apparatus in the universe, but now an Australian company has taken the crown from him; and of the many fields occupied by that rich New South Wales proprietary, our colony has been selected to possess the site of the Champion Mill. As the C. S. R. Company is far and away the most important of the financial concerns and developing enterprises of this country, I have proposed to give it a special (if necessarily brief) notice in this letter, and for the purpose have just made a personal visit to the head establishment on the Rewa.

The work referred to are on that part of Fiji's chief river, known as the Middle Rewa, and the site bears the Fijian name, spelt "Nausori," and pronounced Now-see-ree, with the accent on the second syllable. This place is about 12 miles from that mouth of the Rewa which opens into Lauthala Bay, where the large ships come. Nausori is where the hills begin, that roll on until they grow into highly picturesque mountain ranges that form a strikingly fine background to the river scenery. Down the river right to the sea the country is one immense flat, a superb delta covered with trees, or reeds and jungle, and strongly exciting the imagination of "sugar men" coming from the Mauritius or from the West Indian Possessions. Between the river and the Bau coast is a large extent of fertile country, walking across which one sees what a reserve of producing capacity is here for future use, and what facilities exist for getting at the produce by easily-laid tramways. A study of the district clearly shows why such an immense mill is erected here. Coming upon the works themselves from the landward side affords a great surprise. Emerging from the cool green forest, where nature is in an almost primeval state, you come suddenly upon a great space, with buildings crowded together in parts of it; cottages on every hand, with laues and streets; a two-storied residence crowning a hill, with three large hospitals past that again; and in the foreground an immense factory, ironclad, towers before the sight, with the highest chimneys in the Southern hemisphere. You almost expect to find the institutions of a city close at hand—to see the inevitable telegraphic insulators,

and to hear the locomotives scream, and the rumble and rush of an incoming train. The latter is not perhaps far off, and will doubtless be required within a year or two. Down in the river is a fleet of huge red punts, of lighters, tugboats, and launches. The company has in use upon the river three steamers and six steam launches, 50 iron punts of 60 tons each, and 10 lighters or 180 tons each, besides an ocean-going steamer—the "Fiona." In the crushing-season which between June and Christmas, the cane is brought from far and near in these big barges to the rivers' bank. A detachment of Indian coolies at once board the red punts and hurl the long canes on to the carriers, which in three cadless hands bring their freight to the slow revolving ponderous rollers. There are three double sets of rollers, each cylinder 60 inches long, 32 in diameter, and the whole of them weighing together 168 tons. The power driving them is that of a 45 h.p.-engine, with 65 lb. steam. The cane is not only crushed but afterwards macerated in boiling water and steam, and further subjected to crushing until it is actually passed four times through the mill, so thorough is the treatment and complete the expression of the juice; 15 tons of cane an hour passed through the rollers is considered a good average, or nearly 7000 tons in a week. "It needs scarcely to be mentioned that the largest mills in Australia are small in comparison with this," remarked an expert, "and it is probable that the world cannot show its equal." The juice passes into 14 "cold subsiders," then to 14 copper circular clarifiers, each with a capacity of 500 gallons; thence to 38 "hot subsiders," and on to the supply tanks. The "triple effects" are very fine, a new set, with the latest additions and 10 feet 6 inches internal diameter, being by far the largest in the colonies—perhaps the largest that have yet been made at all. There are five vacuum pans which strike on an average about 32 tons of stuff which is whirled around in centrifugals (21 of them Weston's patent 4 feet in diameter) that revolve so swiftly that to the unpractised eye they appear to be standing still. By an cadless canvas belt the now manufactured product is passed to the elevator, and into a bin, from which receptacle it is bagged and carefully stacked. When the ships are in Laucala Bay immense quantities of sweetstuff are set down to them by the Leviathans called "lighters," towed by steam-tugs; and it is carried by barges and steamers to the company's refineries in New South Wales, where it passes into the very purest forms of sugar, and becomes delicately fit for the confectioner's delightful and varied art. No inconsiderable quantity of coal is imported from Newcastle to keep these mills going, for, in addition to the eight engines that drive the rollers, there are 24 extra engines for general mill work; 14 locomotive boilers (40-h.p.) generate the steam, and all mean a large consumption of coal, as well as of megass, to keep the inferno red hot. The main building of the factory is 320 feet x 201. The coal-hoist is an inclined wire tramway, and discharges 12 tons per hour. When work has to be continued through the night electricity and gas are both brought into play for a bright illumination of the premises, and the night is turned into day that the busy scene may go on uninterruptedly and time be saved.

To keep the monster crushing rollers well supplied with profitable food, the company has seven plantations of its own, with at present 2,500 acres under cane, and this quantity is being rapidly increased. Most of the planters on the Rewa grow cane under contract for the mill; but it may be mentioned *en passant* that these same planters dolefully exclaim that under present circumstances the contract price—which they agree to take for a term of 10 years—does not remunerate them for their outlay and their toil. But on the other hand it is only right to say that a gentleman not connected with either party, and peculiarly well fitted to give an opinion, asserts that the Rewa planters would have been ruined out and out before this had it not been for the C.S.R. Company. There are about 2000 acres cultivated in this way, and, in addition, the Fijians of the Delta grow for the Nausori mill. They have to grow some-

thing to pay their tax assessment with, which has to be done in produce; and, of course, there is nothing in this neighbourhood like the sugar-cane. A Government tutor is sent to teach them how to till their brakes; and at a given time they attend and load up the barges with the cut cane from the banks above. 450 acres (made up of patches here and there) may be reckoned to be the quantity of land covered by the native sons of the soil with *Saccharum officinarum*, otherwise called *ndova*. The cane on the Rewa this season is pronounced by various authorities to be magnificent, and the whole district looking busy and prosperous. But, as a general rule, so an expert informs me, the crops do not equal the enormous returns per acre that we read of as yielded by the land on the Clarence, Richmond, and Tweed Rivers. Yet, there is this compensatory fact, that the Fijian cane can be cut annually, and does not take two years to mature as in the above-mentioned districts of Australia. It was publicly stated, too, in Levuka last year, by a gentleman who had been a planter in Northern Queensland, that whereas there the yield of sugar was one ton per acre, here in Fiji it was at the rate of two tons per acre. During the wet season cane in this climate deteriorates very quickly. For the removal of their cane when cut the company has tramways with liacs of trucks worked by horses and by locomotives—horsework now being an important factor in working estates to advantage—and their navy does the water carriage, dropping down with the stream to the mill. The C. S. R. has an army as well as a navy, employing masses of labourers, tinted and white; 2,000 Indians are kept busy on the Rewa alone, also a lesser number of Polynesians, and any quantity of Fijians, off and on, for job work. There is also a contingent of engineers, artisans, and mechanics, who are better paid than they would be in Australia—"and equally hard to please," adds one who speaks from experience. It is contemplated, however, that nearly all the work will yet be done by dark labourers, who are said to readily adapt themselves to anything. There are also many estate managers, overseers, and specialists who have been trained on the Clarence and at the company's works in Queensland, and over the whole great enterprise (including a new mill at Viria, miles further up the river, and large works on the Ba) presides the Hon. James Robertson, M. J. C., who is the Company's manager in Fiji—an energetic, stirring gentleman, who received a thorough sugar education in Demerara, and made himself favourably known to his present directors by the success with which he ran the Chatsworth Mill, Clarence River, in the season of 1882, and the Homebush, Port Mackay, during the following season. Under him work a trained staff, including Mr. Russel Dowling, deputy manager; Mr. Henry Brook, cane inspector (also hailing from the Clarence), who has the onerous work of keeping this large mill supplied with its proper food; and Mr. Thomas Ferguson, chief engineer, prominently known in the C.S.R. as a man who has served them for years, uniting in his devotion to their interests, and pushing through a vast amount of work with great success.

Immense has been the sum of money already expended by this great colonial sugar company in opening its operations in Fiji; great has been the work accomplished, and great will be the field yet to be covered by their enterprise.—*Sydney Morning Herald*.

INDIAN TEA DISTRICTS' ASSOCIATION REPORT.

The following is the sixth annual report of the Association:—

The committee of the Indian Tea Districts' Association have the pleasure to submit to the members the following statement at the conclusion of the sixth year of its operation:—

Proposed Increased Duty.—In deference to the opinion expressed at the last annual meeting of the association with regard to the reported intention of Government to increase the duty on tea, in order to meet a deficit in the Revenue—a petition in opposition

to the proposal (which first appeared in the *Times* newspaper) to increase the duty was prepared and presented by your association to the Right Hon. C. E. Childers, M.P., then Chancellor of the Exchequer. This step was in accordance with the views of the Indian Tea Association of Calcutta, from whom a telegram was received as follows:—"Urge strong representation against proposed tea duty—are moving Government of India to protest." In this petition your committee drew attention to the fact that the existing duty of 6d per lb. amounted to over 70 per cent of the market value of the teas imported from all countries, and, in the case of at least a moiety of the import, to as much as the prime cost of the article, and thus constituted a distinctively onerous tax on a commodity of such universal consumption in this country as to be justly regarded as one of the prime dietary necessities of life. It was further pointed out that the effect of the increased duty upon the Indian tea industry would be seriously detrimental, while it would tend to restrict the consumption of tea, and be likely to check the promotion of habits of thrift and temperance among the people. It is satisfactory to be able to state that, as prayed by your committee, the duty on tea was not increased.

Revised Customs Regulations for Weighment.—The London Wholesale Tea Dealer's Association having expressed a desire that certain alterations in the direction of greater clearness should be made in the rules issued by the Commissioners of H.M. Customs, in September, 1883, for regulating the conditions of net weighment of tea, your committee having duly considered and approved of the proposal, a joint communication was addressed to the Lord of Customs asking them to sanction these alterations; and, on the 9th November last, the following order was issued containing the revised regulations on which Indian teas are now weighed:—

"General Order, 65-1885.

"Custom House, London, Nov. 9, 1885.

"Sir,—I am desired by the Board to acquaint you that, in consequence of representations made to them on behalf of the Indian tea trade, they have approved of the following regulations for ascertaining the weight of Indian teas on importation in lieu of those laid down in General Order 5-1884, which is hereby cancelled, viz.:—

1.—The packages on arrival to be weighed to ascertain the gross weight of each package.

2.—The importers to give with each entry a statement that the teas in each break have been bulked in India, and that the chests of each break contain even net weights.

3.—In order to test the accuracy of this statement, ten per cent of each break to be turned out and weighed net, but in no case are less than three chests to be turned out.

4.—If the variation in weight of the test packages, from each other, be found to exceed two pounds, the whole parcel is to be tared. For instance, if the test packages weigh net 79, 80, and 81 lb. respectively, the variations would not exceed two pounds, but if one package be found to weigh 79 lb., and any other 82 lb. or more, then the whole break to be tared; unless the importer and surveyor consider that an average tare can equitably be given, in which case the tarers must not vary more than two pounds, as in the case of the net weights.

5.—Duty is to be charged on the average weight of the packages weighed net, provided that, when the average of the packages weighed net amounts to so many pounds and a half or more, the half or more will be charged as a full pound; when the fraction is less than a half, it may be disregarded.

6.—All Indian teas bulked in this country are to be weighed gross and each chest tared.

"I am to add that the importers are to be allowed the option of having teas dealt with under the above regulations or under the general regulations on this subject laid down in General Order, 19-1882.—I am, Sir, your obedient servant.

"H. MURRAY, Secretary.

Factory Bulking.—With reference to the bulking of teas in India, so as to send the crop forward in a condition to be sold on arrival in London without the delay incurred by having to perform that operation in this country, there is still room for much improvement, many invoices, as noted recently in a trade circular, being marked as "bulk'd" which, on inspection, prove to be so uneven that re-bulking here, to make the tea merchantable, is imperative. It cannot be too strongly urged upon managers of tea estates that to reap the full benefit of bulking in India and not weighing here, the necessary conditions must be rigidly adhered to, viz., *thorough bulking at the garden, and an even quantity packed in each chest of the break, otherwise the labour and cost of bulking at the factory will have been to no purpose.*

London Warehouse Rates.—The increased rates for warehousing tea imposed by a joint committee of dock companies and warehouse keepers, at and from the first July last, without notice to your committee were made the subject of correspondence, and your committee were informed that such increased rates were to last until the 30th June next, any alteration in the enhanced rates being a question for the consideration of the dock companies and warehouse keepers themselves. Your committee have to report that the dock companies and warehouse proprietors have issued a revised scale of rates and charges for warehousing and working Indian teas, to take effect from 1st July, 1886; the reductions to be made in the present charges are equivalent to about seven per cent., but as the warehouse proprietors will allow only five per cent. discount from first July next, instead of ten per cent. as at present, the actual reduction in charges on teas in private warehouses will amount to only about two per cent. from 1st July next. Under these circumstances your committee have completed satisfactory arrangements with the proprietors of Butler's Wharf, Southwark, for warehousing and working Indian teas on reasonable terms which will be communicated to the members, on application to the secretary of this association, and it may be stated that the Wholesale Tea Dealers' Association give a preference to teas lying at Butler's Wharf.

Bonus to Coolies.—Your committee have approved of the revised rules framed by the Indian Tea Association of Calcutta, for regulating the rates of bonus to be given to coolies on their leaving one garden for another, by which it is hoped that economy may be promoted and disputes avoided.

Colonial and Indian Exhibition, 1886.—A Colonial and Indian Exhibition will be opened by Her Majesty the Queen on May 4. Your committee have arranged with Messrs. H. S. King and Co., who act as agents for the Royal Commission, that they shall perform the executive duties connected with the Indian tea exhibit in co-operation with a special sub-committee of the association. Samples of teas from different estates will be exhibited in a uniform manner. Selected teas from the various districts, in attractive packets, will be on sale. Infused tea, carefully prepared, will be offered to the public at moderate prices. The careful manner in which the arrangements are being carried out, will, it is believed, have the effect of popularising Indian tea both at home and among colonial and other visitors.

Fresh Markets for Indian Teas.—Your committee are glad again to report that the trade with Australia and New Zealand continues to show a satisfactory rate of progress. The exports from Calcutta to these countries for the period, January 1 to December 31, 1885, have been 1,867,925 lb., against 1,029,467 lb. for the same period in 1884, and 606,479 lb. for the same period in 1883. It is to be regretted that the trade with America does not progress in the same satisfactory manner, but your committee still believe that patient perseverance efforts to open up this large field will eventually meet with success—and also that a field will be found on the Continent for Indian teas.

Tea Statistics.—The imports and deliveries for home consumption of Indian tea (including Ceylon) in the United Kingdom for the last nine seasons have been

as follows, taking the season as from June 1 to May 31:—

IMPORTS, IN MILLIONS OF POUNDS.				
1870-7	1877-8	1878-9	1879-0	1880-1
20	37	36	40	45
1881-2	1882-3	1883-4	1884-5	
50	57	63	64	
DELIVERIES, IN MILLIONS OF POUNDS.				
1876-7	1877-8	1878-9	1879-0	1880-1
26	34	36	36	47
1881-2	1882-3	1883-4	1884-5	
47	57	61	71	

Of the whole consumption of tea in the United Kingdom only 3 per cent. was Indian in the year 1864, whereas the proportion of Indian and Ceylon tea in 1885 was nearly 40 per cent.

Burmah and Assam.—The recent extension of the empire by the annexation of Upper Burmah to the dominions of the Crown will probably lead, at no distant date, to the construction of a railway between Bhamo, Cachar, Sylhet, and Assam, by which it is confidently hoped that the prosperity of the latter provinces will be promoted.

The members of the general committee as usual offer themselves for re-election, and it is proposed by Mr. J. B. White, and seconded by Mr. J. M. Hall, that the name of Mr. Henry Earnshaw be added to the general committee.—ERNEST TYE, Secretary, London, March 30, 1886.—*Home and Colonial Mail.*

COATING FOR WOODWORK.—Good lime salked with sour milk, and diluted with water till it is of about the consistency of ordinary whitewash, is recommended by the *Landscape* as an excellent coating for woodwork. Fences, rafters, partitions, &c., are, it says, effectually protected against the weather for at least ten years by this application. The casein of the milk in combination with the lime forms a permanent film, which dries so quickly in warm weather that heavy rains falling directly after it has been laid on will scarcely effect the work.—*Indian Gardener.*

NATAL TOBACCO.—A considerable amount of the tobacco consumed in Natal is grown in the Colony, and no doubt, a contemporary says, the increasing demand for the leaf grown on the Riet Valley Estate at Umhlahi is evidence that Natal tobaccos should have a place on the London market, and do away with the necessity for importing leaf from America. The Riet Valley tobacco, which has received much favourable notice at the hands of exhibition judges, was shown largely in sample at the recent Agricultural Show and received first and second prize for leaf, first and second for cut, and also a "highly recommended" for the former. It will thus be noticed, on comparison with other descriptions of tobacco grown in the Colony, that the Riet Valley brand fully sustains that excellence for which it is already so widely known.—*Colonies and India.*

IMPROVED METHOD OF PRESERVING WOOD.—The improved French method of preserving wood by the application of lime is found to work well. The plan is to pile the planks in a tank, and to put over all a layer of quicklime, which is gradually slaked with water. Timber for mines requires about a week to be thoroughly impregnated, and other wood more or less time according to its thickness. The material acquires remarkable consistence and hardness, it is stated, on being subjected to this simple process, and the assertion is made that it will never rot. Beech-wood prepared in this way for hammers, and other tools for ironwork, is found to acquire the hardness of oak, without parting with any of its well-known elasticity or toughness, and it also lasts longer.—*Indian Forester.*

THE TREE IN PRINTING HOUSE SQUARE.—The ancient tree which Mr. John Walter, M.P., preserved with much care in the square of the *Times* office, fell on the same day that Mr. Glandstone, the eminent tree-feller, resigned. Is this "an omen"? The tree was a mystery to most people. Its foliage was unlike any other met with in London. Some South

Americans visiting the office are said to have recognised it at once as a specimen of the striped maple. Some one has suggested that it may have been a specimen of the Becu—a South American and South African drug. One authority on arboriculture christened it a Sophora from Brazil. But it was really a specimen of bush *Ptelia trifoliata*, allied to the elm, a native of North America.—*Journal of Forestry.*

THE LANDOLPHIA PLANT.—Major I. Campbell Walker, Conservator of Forests, in charge of Southern Division, wrote to the Secretary to Government, on the 5th ultimo:—"In reply to the Under Secretary's official memorandum of 13th ultimo, No. 267, I have the honor to state that of Mr. Ferguson's plants of *Landolphia* at Calicut, only two remain alive, and they show no growth or vigor. So far as is known, all the plants distributed by Mr. Ferguson in the Wynaad and elsewhere are dead. The twelve plants planted by Mr. Morgau in the experimental garden at Madantoidy all died within eighteen months, but the plant received from Ceylon Botanical Gardens and planted at Nilambur in August 1882 has grown 2 feet 9 inches since the last annual report, and is now 6 feet 6 inches in height, healthy and robust. Mr. Ferguson gave one plant to Mr. Lawson last January, which is healthy under glass in the Government gardens here." The Government order thereon is as follows.—"The result of these experiments is poor, but the Government are nevertheless of opinion that of the India rubbers lately introduced the *Landolphias* are probably the best suited for cultivation in this Presidency."—*Madras Mail.*

CEDEIRA SINENSIS is the only member of a genus of large trees which is hardly in this country. Jamaica or West Indian Cedar is furnished by *C. odorata*, which is cultivated in stoves or green-houses in this country; and the timber of *C. Toona*, largely used in Australia and India for furniture and general ornamental work, is also grown in England under similar conditions. At Kew, however, *C. sinensis* seems as hardy as the *Ailantus glandulosus*, which it much resembles in general aspect. It was introduced from China to the Jardin des Plantes, at Paris, rather more than a score of years ago, and for a long time was known in nurseries under the name of *Ailantus flavescens*. It, however, does not possess the strongly disagreeable odor of the foliage of the *Ailantus*, and the whole plant has a yellow hue. The roots, too, are red and not white, as in the *Ailantus*. Like that, it is readily propagated by means of root cuttings, and, in rapidity of growth and general adaptability for decorative purposes, it seems likely to rival the *Ailantus*.—*Garden.*

PLANTING IN THE WEST INDIES.—At the same time cocoa, coffee, and what are commonly called the "minor" products, ought to be cultivated as much as possible. Trinidad and Grenada have practically acknowledged this, and their cocoa is a considerable element of prosperity. Jamaica, with its coffee and its fruits, deserves to succeed, for there is plenty of room for these products side by side with sugar. The Jamaica population, too, is especially adapted for the kind of occupation made available by these industries. Jamaica has also a special reputation for its rum, and it is satisfactory to see that, while the production will this year be lessened by the drought, compensation will be obtained in a better market, which has already shown signs of strengthening. The coffee market is quiet, and Trinidad cocoa is selling at firm rates. The moral of all these remarks is that for sugar, with strictly economical production in cane countries, there is a prospect of remunerative rates. For Jamaica rum (and to some extent for Demerara) there is also a fair prospect, especially considering the large use made of the best qualities of Jamaica rum for various purposes on the continent of Europe. And that for coffee, cocoa, cinchona and spices, with a moderate increase of production, to suit the consumption, and with the best and most careful preparation (for Jamaica coffee is sometimes spoiled in price by the careless way in which it is prepared and forwarded), such a market may be obtained as would justify the tropical Colonies in placing some confidence in these products as well as in sugar.—*Colonies and India.*

NEW FIELDS FOR CEYLON TEA.

We have pleasure in calling attention to the letter of Mr. A. E. Scovell given below. In bidding good-bye to the Ceylon planting Commissioner, we expressed the earnest hope that he would visit America and take some trouble to make known there the good qualities of Ceylon Tea. Mr. Shand in answer said he was not quite sure if his commission would cover a trip across the Atlantic; but if not, the sooner this is arranged for by the Planters' Association, in our opinion, the better. America, that is, the United States and Canada are the two great countries that have to be conquered for tea. They are peopled mainly by Anglo-Saxon and Celtic peoples—by the same people in the main who constitute the great tea-drinkers of the United Kingdom. And yet strange to say, no sooner do these same tea-drinkers cross the Atlantic than they fall under "the customs of the country," the old example established by Germans and Dutch and take to drinking nothing but coffee. This is no wonder, perhaps, considering that nearly everywhere in the United States, at railway stations, hotels, restaurants, &c., you can, as on the Continent of Europe, always get a good cup of coffee, whereas the tea served—if served at all—is of the poorest description. This is of course owing to the quality of the teas imported by America from China and Japan, much of it fæced and adulterated. Now, it is quite evident that there is a large population in America quite ready to fall back on their old habit of tea drinking if only the good tea to which they were accustomed in the mother-country is brought within their reach. The Calcutta Tea Syndicate through its New York Agents has been doing a little, not much however, to make Indian tea known. Old Ceylon planters—Mr. R. E. Pinco among others—have also been reported to be selling Indian and Ceylon teas in the "Empire City." But we are convinced that nothing would serve to strengthen and extend the incipient business in our teas, so much as a judiciously managed lecturing tour through the States and Canada. The Americans are fond of lectures, and they make much of a good lecturer who talks, and talks well, on a subject of which he is evidently master. Mr. J. L. Shand would be certain to satisfy them in every respect. He could also carry and distribute samples of our teas, and, if possible, establish agencies for the sale of Ceylon teas after giving his lectures, in such towns as Washington, Baltimore, Philadelphia, Pittsburg, Cincinnati, Chicago, Toronto, Montreal, Quebec and throughout the New England and New York States. The result, we are convinced, would be found in a new demand for Ceylon teas, a result which could not fail to repay the constituents of the Planters' Association for the expense incurred in this campaign.

THE NEED OF OPENING UP FRESH MARKETS FOR CEYLON TEA.

Strathallie, Nawalapitiya, 16th May 1886.

DEAR SIR,—The recent fall in prices of Indian and Ceylon teas, brought about in a great measure, we are told, by the collapse of trade in one portion only of the United Kingdom, suggests the importance of co-operative efforts being made on our part to assist in the opening up of fresh fields and outlets for our produce.

Statistics show that the increase in consumption of Indian and Ceylon teas in the United Kingdom has risen, during the past 20 years from 3 per cent to 40 per cent. Messrs. Gow Wilson & Stanton in their interesting analytical review of the position and prospects of Ceylon tea remark: "We believe that these varieties (Indians and Ceylons) only require to be placed before our fellow-countrymen in other quarters of the globe in adequate quantities and constant supplies to ensure the development of the same improved taste which now distinguishes the home market and that every pound of Indian and Ceylon tea which they consume will, provided the present high standard of quality be maintained, have the effect of ultimately displacing a proportionate quantity of China tea."

There can, I think, be little doubt but that the existing channels are capable of expansion and that there are fields available to us where our teas are at present practically unknown. A stray shipment at long intervals from individual estates will not have much effect (in fact this has been tried) and unless we combine and are prepared to share losses on first shipments, our teas will continue to go, almost exclusively to London.

With this in view I think it desirable that the Planters' Association should take the matter up, and if possible organize some co-operative action. We are expending a considerable sum of money in connection with the exhibition of our products at South Kensington this year, the results of which world-wide advertisement we hope to reap some benefits from; but to give full effect to these and to bring our Commissioner's work to a practical and useful conclusion, I would suggest that his attendance at the Exhibition be followed up by a visit on our behalf (and as our Commissioner or Agent) to America and possibly other countries. This, however, and kindred suggestions are matters which I should like to see fully discussed by those concerned, the details of an organized scheme being determined on by a Sub-Committee consisting of influential men interested in tea and Ceylon's prosperity.

The endeavour to open up fresh markets, involving as it does a considerable amount of trouble and some loss (loss though for ultimate gain), is a matter which we are apt to neglect until the necessity for action is forced upon us; but it is one to which all interested in Ceylon should give their attention and support, and combine as far as is practicable to send regular and adequate supplies to fresh markets.

In the hope that this matter will be taken up with as little delay as possible and with the earnestness which, I submit, it deserves, I am, dear sirs, yours faithfully,

ARTHUR SCOVELL.

ANCIENT COCONUT CULTIVATION IN CEYLON.

Amongst much learned lore in Mr. Nevill's latest *Ta-probationum*, we find the following notes on the formation of a coconut estate in the South of Ceylon so long ago as the latter portion of the sixth century of the Christian era, or 1297 years ago:—

In the last note we have seen that Agrabodhi, nephew of Mahanaga (A. D. 589) planted a coconut estate three years in extent. He also built the Agrabodhi Vihara which we have identified with the Agrabodhi Vihara at Veligama. Now tradition, noticed by Prabhakara, Tennent, and others, ascribes a remarkable statue of a king, carved out of the live rock not far from this Vihara, to a king who first introduced coconut cultivation in Ceylon, and taught the Sinhalese its

value. Previously it would seem not to have entered into the diet of the people, though undoubtedly grown in orchards for its tender fruit, the juice of which was not only used for drink, but to mix lime into a cement. This agrees with the earliest name, *kasapengedi*, or astringent water-fruit. The tradition is precise, universally believed, and bound fast by the existence of the statue. The only variation in it is that he is sometimes called Kustha Raja, or the Leper king, and it is then added that he caused this statue to be cut in gratitude for his cure, after bathing in the sea here. It is not unlikely Agrabodhi was afflicted with a cutaneous disease, was cured of it by sea-bathing here, and the free use of coconut oil prescribed by some voyager both as food and ointment; and that he caused his own statue to be carved as a grateful memorial, erecting the Agrabodhi Vihāra, and planting up the coast, for three yoduns in length, with coconut groves.

The dress and ornament of the statue are consistent with the theory that the Kustha Raja's portrait is that of Agrabodhi himself.

The coconut groves of the coast for three yoduns in length, from Veligama to Dondra, are certainly of considerable antiquity, and those ports are also of extreme antiquity. I do not hesitate then to say, that the account in the Mahawansa, and the tradition at Veligama so consistently support each other, as to leave no doubt they refer to one event.

The introduction of coconut cultivation in order to supply the daily wants of the people being thus inaugurated, we next learn from the Mahawansa, that Kasyapa, the Yuva Raja who succeeded his brother Sri Sangabodhi, and successfully contested the throne with the rival line under Dhatōpa Tisa, planted coconut gardens.

After this the cultivation probably became general, as we hear no more details of plantations made by the kings. Probably the innovation of toddy drawing, and distillation of spirit, which naturally followed such extensive cultivation, caused the plantation of coconuts to be viewed with distrust by the Buddhist hierarchy, who ceased to record this cultivation as a work of merit.

—The record of the plantations of Agrabodhi, and Kasyapa, undoubtedly shows that spirits were not then distilled from the coconut toddy.

I propose to have a careful drawing made of the Kustha Raja statue, for publication hereafter in this journal. For a further extension of a Kustha Raja tradition, see next note.

EDITOR.

COCHIN LEGEND OF KUSI RAJA AND THE COCONUT PALM.

This same tradition of a king being connected with the introduction or creation of coconut palms, is found in Cochin. I find in Day's *Cochin*, p. 535, that traditions there state that Kusi Raja, a strenuous worshipper of the Divine Unity, rejected offerings to inferior divinities, and became almost equal to a god, creating many grains now grown by man.

Becoming ambitious, he meditated creating a superior race of men, but after completing the head, the demigods, alarmed, persuaded him to desist. The head became a coconut tree, and was dedicated to Ganesa, lord of science, and protector of learned men.

There seems little doubt that this legend and that of the Kustha Raja are connected. It is quite probable that Malabar merchants, finding the Agrabodhi statue revered as that of the king who first planted coconuts for general use as food, hastily confused it with the legend of Kusi Raja's creation of the tree, and perhaps gave offerings under that impression. It would follow that the villagers of Veligama, gratified by the honour shown to their local celebrity, would accept the Kusi Raja tradition as part of their own, whether the king was already known as Kustha Raja, or whether that name and the "leper" incident, grew up out of the Cochin legend of Kusi.

The explanation already mooted in the previous note, seems, however, most natural. If Agrabodhi, afflicted with skin disease, was cured by the advice of a Malabar, who prescribed the free use of coconut as an article of his diet, and its employment as an unguent, telling the king the legend of the miraculous creation of the tree

by Kusi Raja, lingering traces of the name Kusi would readily suggest the epithet Kustha, for the king. Even now the use of coconut as food, is regarded as a help to the cure of skin disease, so common among the natives, and arising from an irritating diet.

In this view of the case, the statue may have been carved in honour of Kusi Raja. As, however, no traditional type of effigy existed for Kusi, even in that case it is likely enough Agrabodhi's own effigy was adopted, and he himself regarded as a rebirth of Kusi, just as Maha Sen was treated as an incarnation of Skanda.

The name and account of Kusi at once suggest the Cochin legend is a version of the Greek tradition regarding Dionysos. The name Kusi itself may be a tatsama with the Greek *chusis*, a libation, &c., *chumos*, sap, and the other derivatives from the same root. In Sinhalese *kusi* means agriculture, whence *kusaka* the plough, and also the ploughman. For the Indian traditions identified by the Greeks as referring to their own Dionysos, the reader is referred to the *Indika* of Megasthenes, as collected and edited by Schwanbeck. For an English translation by McOrindle see the *Ind. Ant.*, Vol. VI. p. 113.

In connection with this interesting notice of the coconut palm, we should be glad to receive information as to the earliest mention of the tree in Sinhalese literature and whether such mention favours the idea of the palm being indigenous.

CEYLON PRODUCE IN THE LONDON MARKETS.

Political uncertainty combined with general trade depression has tended to keep the produce markets in London in a quiescent and languid state during the first quarter of the present year, and, although the position of some articles is undoubtedly stronger owing to the recent prevalence of low prices having somewhat checked supplies, an entire absence of all outside speculation prevents any appreciable change for the better taking place. In fact, the position is unchanged—no better, and no worse. But the next move of importance can hardly fail to be an upward one for most articles in Mincing Lane, and yet so far people are very loath to believe in this probability. In the same way when everything is most prosperous, and men are coining money, it is generally most difficult to make them believe that values are inflated, and a collapse will be the result. The market for PLANTATION CEYLON COFFEE, especially for well-made and colony coffee on the whole has been fairly satisfactory, and decidedly higher than at this period last year. The smaller supply naturally accounts for this. Coffee generally shows but little change. Stocks on the Continent are still enormous, whilst supplies from Brazil are steady, regular and continuous. On the 31st March the average daily receipts at Rio amounted to 8,300 bags, and the stock to 250,000 bags at Santos at the same date, the average daily receipts were 3,700 bags, and the stock was 320,000 bags, the local market there being quoted weak. In the face of these large totals, the immediate future of coffee, except for scarce colony and bold kinds, can scarcely show any rise of importance.

As regards CINCHONA our natural presumptions, we are bound to acknowledge, have been somewhat faulty. The rise we expected has so far not taken place. Although indications of a rise in a special article may be justly relied on from figures, some circumstance not previously calculated on may occur to delay or postpone beyond

our anticipations the almost certain event we had looked for. In the case of cinchona no one would have supposed that the shipment from Ceylon up to the end of March would show an excess of two and a quarter million lb. beyond the shipments at the same period of last year and to the end of April a comparative excess of 3,100,000 lb. For the first seven sales of the present year the average unit has not varied more than a farthing in the London market. In no period that we have records of has such stagnant dullness characterized these sales. Yet, if we look into the statistical figures of this article, we find the deliveries during this period have been well maintained and compare favourably with previous years, especially if we bear in mind that the deliveries not only equal in number of packages those of previous years, but the average size of the package is considerably larger being mostly made up of Ceylon bark. Take for instance the total deliveries for the first three months of 1882, which amounted to 14,798 packages and the total deliveries for the same period in 1886, which amounted to 16,217 packages, the increase in the number of packages amounts to 1,419, but the average increase in the size of the package must be something very considerable. The deliveries for the first three months of 1885 were 15,042 packages, against 16,817 in 1884 and 16,438 in 1883, those of 1885 and 1886 being almost entirely of East Indian bark with its larger package. These facts show a steadily progressive increase over former years. We opened the present year with a stock of 62,217 against 80,874 packages at the beginning of last year. The stock increased as follows:—

	1886.	Total Stock.	1885.
January 31st	67,653 pks.	against 80,039
February 28th	65,873 "	" 80,067
March 31st	63,700 "	" 78,635

The increase then in the three months amounts to 1,453 packages. If we take the package at 250 lb. average say, for the purpose of discussion, we have an increase to the stocks since the commencement of the year amounting to some 363,250 lb., a mere bagatelle in dealing with an article like cinchona bark. The exports from Ceylon show an increase of some 3 million lb. over the same period of last year, yet three-quarters of this extra amount exported has been quietly absorbed by the deliveries, and does not remain hanging over the market. The stock at the end of March shows a decrease of some 15,000 packages compared with the same period of 1885. These facts all point to an improvement in the value of bark and quinine provided the shipments from Ceylon during the next few months do not show an unreasonable increase over those of last year during the same period.

The unsettled position of Irish affairs has especially affected CEYLON TEAS. The Irish who are very particular about their teas, and insist on having it good, seem to have a predilection for Ceylon tea. The tea market generally, from our latest advices, was very quiet and prices for Ceylon tea had fallen. The general complaint was that the quality just now for all Ceylon tea was not so fine as usual, and the numerous small breaks that are constantly arriving had temporarily affected our market. The imports of all teas for the first three months of 1886 amounted to 16,739,000 lb. against 36,786,000 lb. in 1885, and 39,080,000 lb. in 1884. The deliveries are returned at 51,684,000 lb. against 69,131,000 lb. in 1885, and 51,172,000 lb. in 1884. The abnormal delivery for the first three months of 1885 are accounted for by the unfounded fears as it proved, that it was contemplated adding an extra duty of 3d per lb. to

the already existing one of 6d per lb. The stock on the 28th February amounted to 89,171,000 lb. against 86,837,000 in 1885, and 114,894,000 lb. in 1884. It becomes more imperative than ever for Ceylon with her increasing exports to maintain her quality, and increase the size of her breaks. The falling-off in quality being so general can only be attributable to climatic conditions which, as we know, have shown considerable variation this year.

There has been a good deal more stir in the CARDAMOM MARKET during March and April, and although the rise in value has been immaterial, there has been no difficulty in finding purchasers at a fair valuation. The demand is said to come from the Continent more than from America just now. In March the landings amounted to 337 chests, and the deliveries to 453 chests, leaving the stock at the end of the month 936 chests against 836 in 1885 and 708 in 1884, whilst in 1883 the stock at this period of the year was only 482. The total deliveries for the first three months of 1886 amounted to 916 chests against 729 in 1885, 344 in 1884, and only 262 in 1883, which shows an increased Continental and American demand of some 300 per cent in three years. The future of this market is uncertain. If exports continue to increase at the present ratio from Ceylon, it is an impossibility that prices will continue even at the low ebb to which they have descended.

LETTERS FROM BRAZIL.

(Special for "Ceylon Observer".)

GRADUAL FAILURE OF COFFEE—CULTIVATION OF PAYING PRODUCTS—SUGARCANE—THE FOOD OF THE COUNTRY—CORN-GROWING—FARINA AND FUBIA—POSTSCRIPT: COFFEE, THE SEASON, LABOUR SUPPLY AND EUROPEAN COLONISTS—THE PRIME MINISTER OF BRAZIL A READER OF THE "CEYLON OBSERVER."

Prov. Rio de Janeiro, 15th March, 1886.

The planters in the lower part of the Província of Rio de Janeiro were slow in making up their minds that there was nothing more to be hoped for from coffee. Those lost the least who were the first to give up hope. There was no chance of selling out, yet needless expenditure could be withheld and the labour spent on it devoted to something else.

I mentioned before that the Brazilian coffee planter as a rule grows all the provisions needed for his labourers in addition to his principal agricultural product, coffee. These are Indian corn, beans, and mandioca. Since coffee would not pay, there was no help for it, but to extend the cultivation of these products, and sell what was not required for home consumption. Although railway extension, like your Pimblula-Via line, came too late to help them when they could transport coffee, it was now ready to assist them in the carriage to a market in Rio de Janeiro of their provision crops, and fortunate for the farmer it was so, for corn and beans will pay for a long distance carriage on pack-mules.

Sugarcane was tried by some, but machinery being expensive and prices of sugar low, nothing could be made of it. Those, however, who turned the cane juice into rum managed to make the two ends meet. Cane is easily grown, and the seaside of the Serra-de-mar is the best place imaginable for it, but the transport from the fields to the engine-house, the enormous quantity of fire-wood required for the open evaporators, and the skill and care required for manipulating so as to give a fair sample, made cane growing for sugar making by a private farmer a losing game.

Those who grow cane for distilling had not the same expenditure in fire-wood, there was little labour required after the cane was once at the mill, and there was generally a good local consumption for the spirit which was made up to a proof of 20 or 21 degrees. Cane-growing to supply a central factory is quite another thing, both for planters and factory owners, but this I will notice at some other time.

The principal food of the country consists of beans, jerked beef, pork, and farinha, the latter can be made from either Indian corn or mandioca. The consumption of these is large over the whole Empire, but there is no part of the latter where, with the exception of jerked beef, they are not produced in quantities to supply the local consumption. The town of Rio de Janeiro having a large population requires a large quantity of these provisions.

To grow corn requires little labour and no agricultural skill. The abandoned coffee fields are cleared with a bill-hook and burned off; the corn is planted, by one man going before making small cuts on the ground with a hoe, and another following putting seeds in these cuts and covering up with the foot. The clearing of the land with the bill-hook is done in the dry weather, the burning when there is appearance of rain, and the planting after a shower has fallen. Beyond the Serra, Indian corn is planted from September to December, and as a rule one crop a year. Below the Serra the climate is somewhat different, is a little more forcing, and consequently in many instances two crops are got, and planting seasons are September, October and January and February and March. Various opinions are held as to which is the best time to plant. Within 10 and 15 days after planting a rush of small weeds comes up. These are hoed down, dry weather being chosen for this work. If this weeding has been well done, the later weedings are not at all heavy. Many fields have only two weedings but most have three; one is not always sure of a crop on the lands below the Serra although a failure beyond the Serra is rare; sometimes a month or six weeks of dry weather may come and the corn crop planted at some particular time may be lost. The farmer does not plant all at one time but extends his planting over two months or so; one half may be killed by the drought and the other half may be all right. In gathering the crop only the heads containing the grain is picked; the straw is left standing. Different modes are adopted; some give a basket to each workman and he fills it and carries the heads of corn to the nearest heap, which is beside a track where a bullock-cart can come and take the corn to the storehouse; others have part of the workmen picking and throwing into small heaps and another part carrying to the large heap. The head of corn has the dry leaves attached to it when taken to the storehouse, and as these form a compact mass round the grains some work is entailed in getting this husk off. This husk is kept on until the corn has to be sent to market, were it is taken off, the grains would heat it not properly dried in the sun. As a rule those who grow corn for sale sell it as soon as they can after it is picked. It is generally sold before the husk is taken off. The unhusking is generally done in the evening after dark, on farms where the workmen are slaves, and on rainy days, when the work is done by free labour. To one not accustomed to the work the progress is slow, but a good hand knows the exact leaf to open and gives the requisite tear and a jerk, and pitches the clean head into the heap, and in a circle around him is the

empty husks. These latter are pulled outside and if there are cattle on the place they are offered to them, if not the husks are burnt outside the storehouse. I believe in the States there are machines for unhusking Indian corn, but I have not seen any here. The next process is to take the ears off the centre corn, called in English the *corn-cob*. There are several machines for this, and some driven by steam or water-power do the work admirably. Machines are not much used on the farms. The head is held by one hand and rubbed in the palm of the other, in the latter is often a *cob* with the ears off, which saves the palm a little; some negroes do the work very dexterously and leave the cobs clean which a great many machines do not. The clean corn called in Portuguese *milho*—pronounced "meelyo" (and called in the British African colonies "mealies" from the Portuguese) is put into sacks of eighty litres, each sack weighing about 60 kilos (the weight of a sack of coffee) and sent to the purchaser who may be a storekeeper at the nearest railway-station or the nearest sea port or water carriage port. It is only where railway or water transport is near that corn *milho* can pay the farmer as a substitute for his former coffee planting, and fortunately for the old coffee planters who first felt the brunt of the coffee destroying pests these have been and are being well extended. There is the Don Pedro Segundo railway which brings in a large quantity; the Cantagala Railway from seaside of Serra-de-mar, not much less; then there is a large fleet of coasting vessels, both steam and sailing, from the small ports north and south of Rio de Janeiro which bring their quota. We cannot tell exactly what quantity has come from the old coffee districts, but we are safe in calculating that three-fourths the consumption in the town of Rio de Janeiro is from them.

In 1885 by Don Pedro II. railway was brought	1,014,786 sacks.
" by Cantagala approximately	2,000 "
" by coasting vessels	173,377 "

6,188,163

The River Plate sent to Rio in 1885 in addition to above 98,761. The enormous number of mules used on the tramways in Rio make the consumption so large. The prices ranged from 3\$600 to 5\$200 during the first six months of the year and from 3\$800 to 5\$200 the second.

Owing to there being an abundance of farinha de mandioca produced on the coast districts there is very little of the corn made into corn meal—or *fabu* in Rio, and also very little of what is called farinha de milho u-s-d. This latter is a substance made from Indian corn as follows:—The corn is soaked in water for some days until it is quite soft, it is then beaten in a wooden mortar into flour. This flour being damp is dried on a large iron plate with a gin underneath. It is roasted enough not to brown it. This is eaten along with boiled beans forming, in districts beyond the Serra, a substitute for farinha de mandioca amongst the free class of the population. *Fabu*, or the corn made into meal with a mill-stone, is made into porridge and is, along with beans which have been boiled in some jerked beef and pork, the principal food of the slave in the districts beyond the Serra and they fatten and keep shiny on it and the beans. This is a food more substantial than "shore." To use Ceylon language, as a "new product" and substitute for coffee, unless there is a market at hand to sell it right off without much expense in transport, it will not pay. In this

country, coffee planters all grow it, but this is to make them independent in their food supply from any other source than their own farm. They, the planters, use it in the far interior to feed pigs, and to be food for their cattle and mules in crop time; and in the districts where the Brazilian coffee crops now come from, it would pay as a "product" to take the place of coffee.

Before I conclude this on Indian corn, I would suggest that it may be tried on some of your estates to supply local consumption. It could, I think, be grown all over Ceylon, as it is all over Brazil. Different districts would require different times to plant it. The month of April would suit the most of your districts as a planting season. During the S.W. monsoon in June or July it would be in nice time to come into full flower: "after the blossom is well set," all is secure.

I was to have touched on mandiocca and beans the other two *sub-substitutes* for coffee in our exhausted districts, but these must be left for another occasion.

A. SCOTT-BLACKLAW.

P.S.—*Coffee*.—You are in the habit of receiving the regular price-currents and must be as well informed as I am about our exports: from Rio was shipped to 31st December 1885, 1,206,911 sacks of 60 kilos, against 3,897,113 in 1884. Santos, I am not so much connected with as formerly, so have not the figures.

The Season has been a dry one and complaints are made in the newspapers of the young berries falling off the trees in many parts. It is the crop season after a dry year, in which the coffee crop suffers diminution.

Labour Supply keeps up: slaves are not diminishing much, but at same time, owing to recent legislation, slavery is said to have its limit fixed to 13 years.

European Colonists are helping the labour supply in Sao Paulo very much. On the whole, I see nothing to stop further extension of coffee planting, but a stoppage in railway making. Government is assisting this latter consummation by giving out no more guarantees, and seeking every excuse for the evasion of stipulated conditions in the contract on the part of Railway Companies to withhold the guarantee and rescind or cancel the concession. This course is necessitated by the state of Government funds which are not over-plentiful, and owing to the recklessness of former Governments in the giving of guarantees. Some of the railways already opened within the last two years guaranteed by Government in virtue of a law empowering it to make contracts with concessionaries for railways, provided three per cent of profit could be shown as a minimum, the Government at most losing the difference between this and the six per cent guaranteed on a stipulated sum approved by Government as capital of the Company, have been worked at an enormous loss, and others not yet opened are expected to be no better. Conselheiro Antonio Prado, the present Minister* has his work before him. It is lucky that Brazil has such an able statesman as its Minister of Agriculture and Public Works. The son of a wealthy coffee merchant of Santos (now retired) and himself a most successful coffee planter and introducer of Colonial labourers on his own account from Europe, he brings the practical to bear on the somewhat conventional usages of a department which at the present time has to give new life to this expansive country. Some of his late acts in withdrawing guarantees have the appearance of rashness and entire want of sympathy with a speculating public.—A. S. B.

* He used to be a reader of the *Cultivo Olla* when I knew him a few years ago, criticized my writing severely, but we remained good friends. I scarcely think he has forgotten my letters on Slavery in 1882.

DUTIES ON TEA AND CONSUMPTION.

(From the *Product Market Review*, April 17th.)

The following British Colonies and Possessions impose no duty on tea: India, Straits Settlements, Labuan, Hong Kong, Falkland Islands, St. Helena, Sierra Leone, Gambia, Gibraltar, and Malta. The duty in Mauritius is 1d per lb. In Newfoundland it is 2½ per lb., and 15 per cent. The following colonies charge 3d per lb.: New South Wales, Victoria, South Australia (61 in the northern territory), Tasmania, Fiji, and Barbados. The following charge 4d per lb.: Western Australia, New Zealand, Antigua, and Montserrat. Ceylon charges 5½d. The colonies that charge 6d. per lb. are Queensland, Turk's Island, St. Lucia, St. Vincent, Grenada, Tobago, Dominica, Trinidad, and British Guiana. Natal charges 7d and the Cape of Good Hope 8d per lb. The following charge 1s per lb.: Honduras, Bahamas, and Jamaica. Canada charges 10 per cent *ad valorem* on imports from the United States; other teas are duty-free. Lagos and the Gold Coast charge 4 per cent *ad valorem*. Bermuda charges 5 per cent, *ad valorem*. The Virgin Islands charge 7½ per cent and St. Christopher and Nevis 8 per cent, *ad valorem*. The remarkable discrepancies between neighbouring colonies cannot be helped when self-government has been granted to them, but our Colonial Office is surely to blame in allowing such a confused system to prevail in colonial groups under its own control. For instance, there are no less than six varieties of tea duties in the West Indies. Ceylon is allowed to levy a duty of 5½d., which can serve no purpose, now that so much tea is grown there, unless it be a protective one. The other Crown Colonies levy tea duties on no perceptible principle. The above figures are taken from the *Colonial Statistical Abstract*.

The following from the *Statist* gives the general consumption of tea in round figures:—

TEA IN CHINA.

Sir Robert Hart has done Chinese tea growers a kindness, in urging their Government to impress upon them the danger they run in the near future from foreign competition. The tea exported to foreign countries has, he declares, been steadily deteriorating of late; and Chinese merchants, seeing that notwithstanding its inferiority it is taken at the same, have been encouraged in their careless manufacture, "forgetting that, by this manner of making profit, they are running to certain ruin." Chinese dealers may be supposed to know something about the increasing production of Indian and other teas, but the grower is probably quite ignorant of the danger. Sir Robert Hart would have it impressed upon him that, besides Japanese tea which is being exported everywhere,

India and Ceylon are not only increasing their production but are turning out a better article; and if the Chinese do not take warning and improve their tea also, they will find themselves shortly in a very awkward predicament. How serious the Indian competition is becoming even Sir Robert's letter fails adequately to show—fails, that is, if the figures given in the translation we lately published can be relied on. It would seem likely, however, that there must be, here, a clerical error. So accomplished a statistician is hardly likely to have spoken of the Indian export for 1884 and 1885 as sixteen and nineteen million cattles respectively, when, as a matter of fact, the import into London alone during the nine months ended March 31st last was nearly three times that quantity; 68,023,000 lb. is the figure attained by India and Ceylon teas during that period, against 60,097,000 lb. in the corresponding period of 1884-5. And when we read that over 100,000 acres have been planted this year in Ceylon, calculated when in full bearing to yield 40,000,000 lb. for that island alone, it must be admitted to be high time the Chinese producer was awakened to the gravity of the prospect. India and Ceylon together will very shortly, at this rate, rival China in quantity as they already excel in quality; and a fresh illustration will then occur of the Darwinian doctrine of "survival of the fittest." Teas which have "spurious things added" to them, which are "made heavy by keeping them wet," and in which the "labour of manipulation has been economised," will not be favourably circumstanced in the race; and we repeat that the Chinese are indebted to the Inspector-General of Customs for pointing out the fact. It is a pity none of the many officials through whose hands the document passed were able to enlarge upon the text, so as to bring home more precisely to tea producers the nature of the competition which awaits them. All they do is to hand down from one to another Sir Robert Hart's letter, with the sole and quite erroneous addition that "since the establishment of commerce with foreigners the amount of silver that has flowed into foreign countries is very considerable." We had occasion, only a few weeks ago, to quote Sherard Osborn's plaint over the drain of silver that was taking place from Europe to China; and, as a matter of fact, the movement has always been in that direction. The Tsungli-yamen are however right in emphasising the value of tea and silk in establishing a balance of trade; and from that point of view as well as for the sake of an important national industry, it is to be hoped Sir Robert Hart's warning will bear fruit.—*L. & C. Express.*

THE SEASON IN INDIA.

(For the week ending the 5th May.)

GENERAL REMARKS.—Slight rain has fallen throughout Southern India and most parts of Bengal and British Burma. In Assam the fall has been heavy. With the exception of a few showers, Northern and Central India have been rainless. In the Madras Presidency, with the exception of the Ganjam District, agricultural prospects continue fair. In Mysore the standing crops promise well on the whole, though rain is wanted in some parts. In Coorg prospects are good. In Bombay the *rabi* harvest is approaching completion, and preparations for the *kharif* are in progress in that Presidency and in Berar. In Hyderabad, Central India, and, with the exception of Ajmere, Rajputana agricultural prospects continue generally good. The *rabi* harvest is still in progress in the Central Provinces and has been nearly completed in the North Western Provinces and Oudh. Ploughing for *kharif* cultivation has commenced in some districts in the Central Provinces. In the Punjab the *rabi* harvest is in progress

and promises well. The recent rain in Bengal has been very beneficial to the crops, and the *aus* rice and jute where sown are coming up well. Sugarcane, indigo and *chenou* are thriving. The *boro* rice harvest is proceeding, with a good outturn. Seasonable weather prevails in Assam, where ploughing and sowing are still in progress. Seasonable weather prevails in British Burma. The public health is generally fair. Prices are fluctuating in the Punjab, rising in Mysore and falling in Coorg. Elsewhere they are for the most part stationary.—*Madras Mail.*

TEA IN INDIA.

The following Circular from the Indian Tea Association of 8th May, will be of interest:—

"The General Committee are now enabled to hand you the following figures, giving an estimate of the outturn of the Indian Tea Crop of 1886 as compared with the original estimate of the crop of 1885:—

	Estimated Out- turn of Crop of 1886. lbs.	Estimated Out- turn of Crop of 1885. lbs.
Assam	35,133,404	33,168,091
Cachar and Sylhet ...	22,908,180	19,620,413
Darjeeling, Terai, and Dooars	13,302,800	11,422,891
Chittagong and Chota Nagpore	1,346,800	1,274,000
Dehra Dun, Kumaon and Kangra	3,250,000	3,250,000
Total	75,941,274	68,735,458

"With the exception of the North-West Gardens, and a few others whose outturn has had to be estimated, the returns are those actually received from agents of Gardens.

"In their circular of the 26th March last the General Committee published a statement showing that the actual crop of 1885 amounted to 68,730,219 lb., so that the above figures point to an increased production of more than 7 millions lb. over that of last season.

"The consumption in India itself and the exports to the Australian Colonies and other places may take off about 3½ million lb.; thus leaving 72½ million lb for shipment to the United Kingdom."—*Pioneer.*

PLANTERS and others in Perak, Selangor, Sungei Ujong, and Johore will be glad to learn that emigration from India to those States has been formally authorised by the Governor-General of India in Council from the 1st instant. Henceforth there should be no more complaints of want of labourers.—*Singapore Free Press.*

THE QUANTITY OF TODDY SPIRIT issued for sale in the City of Bombay fell from 281,365 gallons in 1883-84 to 16,857 gallons in 1881-85, while the quantity of mowra spirit imported from Uran rose from 415,979 to 531,425 gallons, and there was an increase from 113,79,459 to 15,99,036 in the amount of duty derived from both classes of spirit. The consumption of mowra spirit would no doubt have been checked by the enhancement of the duty, but for the fact that there was very little toddy spirit procurable. The only trees tapped for the production of toddy spirit within the town of Bombay were 200 brab trees, and the average out-turn of spirit 25 U. P. was only 10½ gallons per tree,—a result which the Commissioner attributes to pressure brought to bear on the distiller by Bhandaris and other interested persons. The rate of production of the 3,000 brab trees tapped at Giranj, for the supply of toddy spirit to Pritchard's was also, however, considerably below Mr. Pritchard's estimate of the average yield of coconut and brab palms. They were tapped for six months, and the average outturn for that period was 5-9 gallons per tree.—*Madras Mail.*

CINCHONA BARK IN HOLLAND.—The public sales of bark held at Amsterdam on April 15th comprised 1,500 bales and 560 cases, weighing about 145 tons, the whole being sold with strong competition. Some lots of druggists' barks fetched extraordinary prices; among others, *Callisaya Javanica*, in long quill, containing 1.75 per cent quinine, at 3.86l. per 1 kilo; and ditto, containing 0.67 per cent, at 3.43l. per 1 kilo. The maximum realised by *C. Anglica* (2.11 per cent) was 2.31l.; *C. Schukraft* (1.47 per cent) 1.51l.; and *C. Succirubra* (1.47 per cent), 1.10l. Of the latter variety, the assortment offered was not remarkable for good appearance. Among the buyers present were the managers of the Francfort, Mannheim, Brunswick, and Auerbach quinine works. —*Chemist and Druggist.*

ENTOMOLOGY.—The *Asian* suggests to the Government of India the necessity there undoubtedly exists for appointing an Imperial Entomologist, whose work would be to study the life, habits, &c., of such insects as the tea-bug, the rice-pest, the red-spider, the locusts, &c., which periodically cause immense damage to crops, and to suggest such measures as may be deemed feasible for their eradication. The appointment of such a specialist would ensure continuity of investigation and study. One of the duties of the Imperial Entomologist should also be to report fully and exhaustively on all insect plagues whenever they occur. This kind of work is done admirably in America. The exigencies of the situation demand that this blank should be filled up without much delay.—*Madras Mail.*

THE DECLINE OF COFFEE.—The merchants engaged in the coffee trade are complaining that the consumption of coffee is so rapidly decreasing that before long the importation of this once important commodity will be reduced to insignificant dimensions. Year by year the demand for tea has advanced with remarkable strides, and the consumption of cocoa has also largely increased. But coffee is becoming less and less popular. Last year the quantity imported only amounted to 41,000 tons, which is not much more than half what it was four years ago. It is, of course, quite possible that this falling-off may to some extent be coincident with the general depression in trade, though the augmented consumption of tea and cocoa scarcely bears out this theory. At the same time it must be remembered that coffee-drinking, though it had the start of tea, never obtained a firm footing in this country. We are, indeed, still ignorant of the art of making it properly. Its popularity was of comparatively brief duration, and at no time did it find much favour with the people at large.—*Standard.*

DRAINING WASTE LANDS UNDER CULTIVATION WITH FOWLER'S STEAM PLOUGHING MACHINERY.—A set of this machinery has recently been most successfully started on Capt. Chapman's estate at Bari near Allahabad. It is on the double engine system, one engine at each end of the field and the implement hauled backwards and forwards by means of winding drum and steel wire rope. This system is now adopted in all parts of the world for opening up jungle lands, and as the engines can be applied for sawing, pumping or driving the machinery when the land is too wet to work there is no doubt it can be successfully used in many parts of India. The set alluded to is now breaking up new land in a way acknowledged by those who have seen it, far more satisfactory than it would be possible to do with ordinary digging and the country plough. The cost inclusive of European mechanic in charge at 1500 per month, coal at 114 per ton and allowing 20 per cent for interest of capital and depreciation of machinery is only about 163 per English acre, and on estates where wood fuel is procurable this price can be reduced considerably. As the success of steam ploughing machinery depends greatly on having implements specially suitable to the land to be cultivated, Messrs. Fowler & Co. inform us they will be pleased to visit

any land intending purchasers may think of cultivating and advise as to plant necessary.

LETTERS ON TEA.—Messrs. Davidson & Co., of the Sirocco Works, Belfast, have issued in a neat little pamphlet, the circulation of which will do good, the letters written to the *Belfast News Letter* by Mr. S. C. Davidson and Mr. Joseph Anderson which we summarised in our issue of the 21st April. The following is the preface to the pamphlet:—

LETTERS ON TEA. PREFACE.

The following correspondence was originated by the publication of an advertisement in the *Belfast* newspapers, headed "The Tea Trade," and signed by Mr. Joseph Anderson, of North Street. In order that the subjects dealt with in these letters may be properly understood, and their relative bearings appreciated, it is necessary that a copy of this advertisement should precede the correspondence. It accordingly receives first place, and the several letters follow in their consecutive order of date. My letters in this controversy have been mainly statistical, their object being to give the public facts and figures to more accurately define the superficial inferences and partial statements embodied in Mr. Anderson's advertisement above referred to, concerning the cost and manufacture of Tea, and to elucidate what he also in it alludes to as "*misleading descriptions and unambiguous terms*" employed by unscrupulous vendors to deceive the public." My last letter in this correspondence appeared in the local newspapers on the 9th March, and alongside it Mr. Joseph Anderson published a further advertisement, in which by inference he accused me of having in my letters subjected him to "persistent misrepresentation," and of making a "determined effort to cry down the sale of the Finest Teas." This accusation I distinctly repudiate, and in support of my repudiation I herewith publish the entire correspondence in pamphlet form, so that any of the public who may be interested in the matter may have an opportunity of critically comparing all the letters side by side, and thereby ascertaining accurately whether the "persistent misrepresentation" is on my side or his. In no place have I advocated any reduction in the quality of the tea sold; on the contrary, the hard statistical facts which I quoted should greatly promote the demand for finest teas, by urging their sale to the consumer at fair, instead of at unduly high prices. From the figures given in my letters it will be apparent to what extent consumers have been paying artificially high prices for their tea. The extra price might be roughly estimated at about a shilling per lb. over and above a reasonable margin for profit on the rates ruling in the London auction sales for good qualities. It is believed that the majority of the tea imported into Belfast might be classed as of good quality, and a shilling per lb. on the 7,792,960 lbs. of tea imported into Belfast during the single year of 1885 represents the immense sum of £389,648 sterling. This tremendous sum of money (or even the half of it) ought surely to do more good if left annually distributed amongst the vast multitude of consumers, than it can possibly do in the pockets of the comparatively few sellers. About a third of a million sterling is a long price for consumers to pay for retaining to Belfast the "distinguished position" referred to in Mr. Anderson's letter of 23rd February.

Tea is now an article of diet, and most so to the working classes. It is subject to the heavy import duty of sixpence per lb., and it should not have to bear a further taxation to the consumer in the form of exorbitantly high profits usually charged by sellers to cover their losses on other articles, and for the slight work and labour required in its retail sale.

As a grower of Indian Tea, I am directly interested in seeing the qualities designated "worthless trash" (the supplies of which come mainly from China) driven out of the market to make room for Indian teas, the average quality of which is so greatly superior to that of the China teas. If good tea be supplied at fair prices, "worthless trash" will be a natural death.

S. C. DAVIDSON.

Sirocco Works, Belfast, 22nd March, 1886.

TOBACCO.—The crop this year does not appear to be a large one. High prices are demanded for the best stuff which is grown in parts of the Patebellapallai District and at Karatchi, Pouvern and Ilupakkadawai in the Mainland and which is all converted into cigars for the Colombo market. I am informed that in certain localities the tobacco plantations have been damaged by a species of leaf disease due to the presence of worms.—(Ceylon Patriot.)

BEE CULTURE.—Much attention is being paid in British India to bee culture. Bees can be kept in all parts of the country and Ceylon with the most satisfactory results. A gentleman recently returned from India, who has been very much interested in this subject, says: "I look forward to the time when bee culture will yield no inconsiderable revenue, and I fear the time will come when Brother Jonathan will find that his tons of delicious nectar will have to compete with honey gathered in India."—*American Grocer*. [Whatever may be the case ultimately, it is not true, as yet, that either in India or Ceylon, beekeeping has been attended with satisfactory results.—Ed.]

MR. MORRIS, the ex-director of the Public Gardens at Jamaica, prior to taking up his appointment at Kew, has been making a tour of the West Indian Colonies. Being interviewed at Castries, on the subject of bananas, he said that the quality suited for the American market is the Fige Martinique, which is of pale greenish yellow colour. Each regime must have seven patates. The price paid by buyers is 2s. per regime at Jamaica. This trade has grown wonderfully. Ten years ago Jamaica exported only 85,000 bunches, valued 6,000l. In 1884 the exports of bananas were 1,900,000 bunches, worth 192,000l. An acre planted in bananas should give a profit varying from 15l. to 25l. after the first year. Mr. Morris also recommended the cultivation of oranges. The white blight or "mealy bug," he added, could be got rid of with attention. They should be packed wrapped up in paper, and put in barrels having plenty of holes drilled in them. It may be hoped that St. Lucia will profit by this information.—*Colonies and India*.

SALT.—Calcutta imports every year 300,000 tons of salt for the consumption of the inhabitants of the Bengal Presidency and of the N. W. Provinces. Formerly Madras was supplying about $\frac{1}{3}$ of that quantity. All the ships going from Mauritius and Bombay to Calcutta used to call here, and load salt either at Covelong or Ennore, and, as they were proceeding in ballast, it did pay them at small freight. At that time they were allowed to pay the cost of the actual quantity of salt landed, or a deduction of so much per cent was allowed them for wastage at the port of shipment. This 80,000 or 1,00,000 tons salt shipped from Madras was, no doubt, adding to the revenue of this Presidency under that head, but a great reformer came and the allowance granted to the ships for wastage was suppressed, with the result that not one ton of salt is now shipped to Calcutta from the ports of this Presidency. The goose that laid golden eggs was killed. We call the attention of the Commissioner of Salt and Abkary revenue to this former current that could be easily revived, and would give an impetus to the salt revenue, where a decrease of 50 lakhs is announced.—*Madras Times*.

JAPAN TEA MACHINERY.—We have inspected at the offices of Messrs. J. M. Robertson & Co. a set of models of Japanese Tea machinery, which Mr. H. D. Deane of Maskelyna is about to present to the Colombo Museum. The set is a most complete one, including all utensils used in the manufacture of tea, down to the paste pot, used in covering

the boxes with paper, and a fan! The models are all beautifully made with a correctness which only Japanese workmen can attain. It is impossible to enumerate all the articles included in the set but our readers got a good idea of the same when we discussed "Tea Preparation in Japan" a short time ago. The principal items in Mr. Deane's set, are: steaming furnaces—steaming taking the place of withering—firing boxes,—extraordinary arrangements which are entirely air-tight, the fire apparently burning without the slightest draught; at the top of these boxes are fitted paper trays on which the leaves are spread—steaming trays, square baskets, sorting baskets, sieve, picking table, tray rack, tea boxes, papered and unpapered, with lead lining, &c. The little baskets are beautifully made, as indeed are all the other articles. They are all made to scale and with the greatest attention to detail so that they may be relied on as correct models of the utensils in use amongst our Japanese friends in the preparation of their tea. Ceylon however, has nothing to learn from Japan either in the way of manufacturing tea or the machinery with which it is prepared. The word "machinery" is a misnomer, for the Japanese have not yet advanced to the use of machinery but are content with the simplest utensils. The collection is a valuable one and thanks are due to Mr. Deane for a very interesting gift to the Museum. Our upcountry readers will no doubt be interested in an inspection of them at the Museum, when in Colombo.

EFFECTS OF A HURRICANE IN FIJI.—The following details ought to make Ceylon planters thankful that they are beyond the reach of cyclones:—It was a scene not to be forgotten—the inky darkness, the roaring of the storm, through which could be heard the crashing of timbers, the falling of trees, and the occasional shouting of laborers seeking shelter. By the time named most of the buildings on the estate had been blown down. From 10-30 p.m. till 11 15 p.m. there was a dead calm, a most unnatural calm after such a tempest, stars came out for a short time leading the uninitiated to believe that the storm fiend had done his worst. Suddenly at the last-named hour, the storm set in again, this time from S.W. harder than ever with perfect cascades of rain. It was about this time (although the hour of low water) that the high wave came in, which from its effects and other evidence, must have come up like a solid wall, from 4 to 6 feet high. This swept over the beach and low flats carrying everything before it, including the debris of the falling buildings with a vast quantity of other material, lodging them in a great layer from 100 to 300 yards inland. It must have been at this time that the loss of life referred to took place, viz., an Indian man, an Indian woman, and two Indian infants. In the earlier part of the blow the Polynesian laborers cleared out of their houses and took refuge in the fibre store and cotton house, but the Indians remained in their houses until they were blown down, and then sought other shelter to which they were materially helped by the Polynesians. Some, however, would not accept their help or aid, with the above result. The scene of desolation that met their view as the day dawned, is indescribable—not a standing building to be seen—where the coolie lines, the overseers' houses, factories, stores, &c., had been, was swept over clean by the tide and the whole flat between the bungalow and the sea was covered with uprooted trees, coconut husk, leaves, sheets of iron, timber, bags of sugar, rice, flour, nails, fibre, copra, tanks, broken boats, punts, &c., in one general chaotic mass.—*Fiji Times*.

EUCALYPTUS PRODUCTS.

Eucalyptus Kino.—An astringent exudation occurs in most species of eucalyptus, filling cavities or cracks in the wood and barks; when dry it is brittle and presents an appearance similar to Indian kino. It varies greatly in different species, both in quantity and in character. According to Wiesner it consists of a mixture of a tannic acid, giving a dirty green precipitate with solutions of ferric salts, pyrocatechin, a little catechin, and a very variable quantity of a substance insoluble in water but soluble in alcohol, and which has been variously described as gum resin, kino-red, or eucalyptus-red.

The amount of the astringent exudation afforded by different species may be seen from the following table:—

	Per cent.	Per cent.
<i>E. leucocylon</i>	21.91	
<i>E. macrohyncha</i>	11.12	to 13.41
<i>E. longifolia</i>	8.3	
<i>E. rostrata</i>	8.22	
<i>E. riminialis</i>	4.88	to 5.97
<i>E. globulus</i>	4.84	to 5.97
<i>E. resinifera</i>	4.38	
<i>E. gomicalyx</i>	4.12	to 4.62
<i>E. mellitoides</i>	4.03	
<i>E. obliqua</i>	2.50	to 4.19
<i>E. polyanthema</i>	3.97	
<i>E. Gunnii</i>	3.11	
<i>E. amygdalina</i>	3.22	to 3.40

The relative quantity of kino-red present in the tree appears to determine in great measure the value of its timber, as it renders the wood almost impervious to decay when under water, and prevents the attacks of insects and marine animals. The species in which it is most largely present contain from 17 to 19 per cent, as in *E. marginata*, *E. rostrata* and *E. robusta*, which are the most valuable of the timber trees of Australia for shipbuilding, piles and similar purposes. The kino of *E. resinifera* also contains a quantity of kino-red, only one-sixth of it being soluble in water. It is to this last-named species that Botany Bay kino has generally been attributed; but Sir F. von Mueller states on the authority of the Rev. Dr. Woolls that it is much more extensively collected from *E. siderophloia*, to which indeed the name of *E. resinifera* has been applied by Allan Cunningham.

Several species yield a kino containing but little kino-red, and consequently dissolving readily in hot water, although forming a turbid solution when cold.

Those of the following species have been examined by Wiesner*:—*E. globulus*, *E. leucocylon*, *E. citriodora*, *E. amygdalina*, *E. pitularis* and *E. fissilis*. There is great difficulty in ascertaining the exact botanical source of the eucalyptus kinos at present imported into this country, partly owing to the same name being applied to distinct trees in different parts of Australia. Thus the name of red gum, under which name a eucalyptus kino is employed in this country, is applied to *E. rostrata*, *E. tereticornis*, and in West Australia to *E. calophylla*. The first two of these yield a kino only partially soluble in water, while that of *E. calophylla* is easily soluble and contains but little kino-red. This species is said by Mueller to afford a liquid kino in considerable quantity by tapping the trunk. It is caught in casks as a material for tanning and dyeing purposes, and is said to fetch £20 to £25 per ton in the London market. It indurates on exposure to the air, and can then be used as medicine internally, like true kino, or in powder, as an application to wounds. Two species which yield a kino perfectly soluble in water are *E. obliqua* and *E. piperita*. That of the former resembles Indian kino in appearance, and forms a deep-red neutral solution; the latter is of a zircon-red colour, is translucent, and forms a yellowish-red, neutral solution. The tannic acid of *E. obliqua* differs from that of most other species in giving a dark violet precipitate with solutions of ferric salts. The number of these inspissated juices suitable for replacing true kino in pharmacy is there-

* See Pharmaceutical Journal, [3], ii, p 102.

fore very limited. A great deal of other interesting matter is contained in 'Eucalyptographia,' under different species, such as the use of the acid sap of *E. Gunnii* to form a kind of cider, the employment of the roots of *E. microtheca*, *E. olivosa* and *E. populifolia* as a source of drinking water in the desert land where they flourish, the manna of *L. riminialis*, and the value of the rugged barked variety of *E. leucocylon* as an indication of gold bearing soil. Much of interest for the botanist will be found in the details concerning the development of the seedling plants and the structure of fruit, leaf, flower, wood, and bark, but these have no practical bearing for pure pharmacy.—*Pharmaceutical Journal*.

ACCLIMATION OF TREES YIELDING INDIA.

RUBBER AND GUTTA PERCHA.

BY JAMES COLLINS.

The care and oversight of forests is now generally recognised and accepted as a State duty, beyond the limits and capabilities of private individuals. Such duties consist in the protection of trees from reckless destruction, replanting denuded portions, and introducing useful plants from their natural habitats to other localities having isomeric conditions of heat and moisture, and where such introduced plants are likely to prove of general utility. This latter operation is known as acclimation. The constitution of plants is a subject of great interest, and has to be considered with great judgment and abundance of information; plants have certain limited ranges, and such ranges of heat and moisture have to be clearly defined, for by no process of acclimation can a plant be made to tolerate a degree more or less than its proper limit, except to its detriment. If they be subjected to conditions other than their natural ones, they either die or become so modified as to fail to develop those special features of structure, habit or constituents, which are their characteristics in their native habitat. A single instance may be quoted here, by way of example, to show how a plant may be altered by different climatic influences. In Europe for ages the common hemp (*Cannabis sativa*, L.), has been cultivated for its fibre and oily seeds,† whilst in India the same plant shows a wide dissimilarity, especially in its medicinal characteristics, its leaves, flowering and fruiting stalks yielding a resin volatile oil, known, under various names as bang, dhurros, gauga, &c. having powerful narcotic properties, the resin being apparently formed at the expense of the fibre, as the stalks are usually burnt as useless †

The ascertainment of the extremes and mean annual temperature and moisture which best suit certain plants is the result of experiment, and is sometimes surrounded with so much difficulty that frequently trials should be made simultaneously, in two or more localities judged to possess similar climatic conditions.

All these experiments entail expense, especially in the case of those trees the utilisable portion of which consists of timber, milky juices, &c., which require a period of ten to thirty years or more to elapse after planting before they come to maturity, or any return can be expected on the initial expenditure and upkeep. This outlay, together with the long delayed returns, even if the experiment be finally crowned with success, naturally will and must fail in procuring the accomplishment of such trials by private enterprise. Government must at least give its aid in the initiation of such schemes.

In the case of the cinchonas the Indian Government did, with rare forethought, listen to such men as Pereira, Howard, and Markham, and undertook the initiative:

* The great dissimilarity between the European species led Lamarec to consider the latter a distinct one, and designated it *Cannabis Indica*, but it is now agreed that no specific difference exists between them.

† Why burn the stalks of the Indian hemp? Why not utilise them? I have suggested to several planters that they might make capital paper material, especially if sent over here as "half-stuff."

and as soon as the experiment proved successful, private planters at once showed their willingness to expend their money in the same undertaking. So has it proved in a minor degree in the present instance.

Another fact is also worthy of remembrance, namely, that acclimated trees invariably improve, and their products, from the care and attention paid in their preparation, acquire a much higher value than spontaneous or uncared-for produce. As instances, mention may be made of the much higher percentage of quinine yielded in India from cultivated trees than from those of South America; and also that a specimen of Assam rubber, prepared according to my suggestions (I think by the late Mr. Leeds) was valued by one of the highest authorities in London, Mr. Edward Till, of the firm of Messrs. Jackson and Till, at from 8d. to 10d. per pound more than ordinary Assam rubber.*

Fortunately, with respect to the special question of guttapercha trees, some of these difficulties do not exist. There, in their natural habitats, and in territory, too, under Imperial rule and influence, are numbers of these trees ready for conservancy and cultivation, and where nurseries of plants can be started for acclimation elsewhere. Although some twenty-five years will have to elapse after planting before the trees are ready for tapping or the axe, yet, in the interim, a revenue could be secured, to pay working expenses at least, from the trees already existing, by "farming" them, or by royalties on the output. A stringent rule in all such contracts should be that four to six trees should be planted in place of every one cut down.

As to what species should be cultivated on the spot, or to be introduced, gutta-taban, gutta-durian, gutta-waringau, gutta-kalapeich, and gutta-mukas, stand in the front. Many others, although passing under other designations, may prove equally valuable.

Amongst pseudo guttaperchas, or substitutes recommended as supplementary to the true guta, I would certainly single out the balata gum (*Mimusops balata*, Gaertner), as it would prove a most valuable addition to our trade supplies. As to the Indian varieties of this group, I would strongly recommend that the pancheotee should receive careful attention, and its product collected and prepared in proper manner. Such specimens so prepared would then allow of the question being, probably, set at rest. I have not much hopes of cattinandoo, mudah, and some other substances, but other uses might be found for them if good samples and guaranteed qualities were available.

As to the climatic conditions necessary for the cultivation of guttapercha trees, Borneo, Labuan, Sarawak, Singapore, and, more especially, the Southern States of the Malay Peninsula, being the natural home of these trees, present the first localities in which cultivation should be essayed. Ceylon, like some localities in Assam, and, possibly, the Nicobar islands, would form a congenial home for these plants.

On the whole question of Indiarubber, guttapercha, and pseudo-guttas, there is much still to be learned. There may be yet many improvements to be made in the collection and preparation, but these facts can only be gleaned by one somewhat conversant with market and manufacturing requirements, added to some amount of botanical and chemical knowledge. Such a task undertaken on the spot, if well executed, would clear up many a doubtful point, and render great and lasting service to commerce and science.—*Journal of the Society of Arts.*

* In a paper on Indiarubber, delivered at the Society of Arts (*Journal of the Society of Arts*, December 17th, 1869), and again in my report on the same subject to the Indian Government in 1872, I strongly recommended the cultivation of the native *Ficus elastica*, and the acclimation of the *Hevea Brasiliensis*, yielding Para rubber, and also other species from which are obtained valuable commercial varieties. Backed as I was by Mr. Clements R. Markham, C.B., and Mr. Gustav Mann, of the Indian Forest Department, the Indian Government took the matter in hand.

TEA CULTIVATION IN THE WESTERN DUARS

is thus noticed in a visit to Kuch Behar, the Bhutan Duars and Assam, in the *Indian Forester*.—

Jalpaiguri, on the banks of the Tista river, is no longer a Military station, as it was for several years after the Bhutan war, but is becoming a large centre of trade, and tea cultivation has spread over a large extent of country at the foot of the hills. It is worth notice that 3,000 strawberry plants which I sent there last October from Mussoorie, have grown most vigorously, and have borne a fine crop of fruit from February to May, as the damp climate and sandy soil when well manured suits them admirably. Here I visited a tea garden belonging to the Tundoo Tea Company, and had a day's mahsir fishing in the Jaldoka river, but only succeeded in hooking one fish. It was at this garden last year that a *mest* elephant killed sixteen coolies in one day, and yet I hear that no compensation was paid to their families by the owner, who is the most influential Zamindar in Berar, but perhaps has never rightly understood what occurred.

The tea seed for these Western Duar tea gardens is imported from Assam, and it is an important question whether tea seed is good when the testa or skin is separated from the embryo inside the shell. I referred this question to Mr. Logan of Dhubri, who for many years passed tea seed on its way from Assam, opening the boxes and testing a certain proportion of the seeds, but his opinion was that provided the embryo was all right, that the separation of the testa was not prejudicial. Mr. Peal also says that opinion is divided on this point, but does not consider it prejudicial provided the seed is fully ripe, and he has promised to test the question thoroughly by planting two lots with and without the testa. From Jalpaiguri, I went by the Northern Bengal Railway and steamer to Dhubri, and thence by the new daily steamer service to Tezpur, the civil station of the Darrang District in Assam. The best tea gardens in Darrang are on a plateau of forest land which approaches within 10 miles of the Brahmaputra, and except for the clearings for tea cultivations is covered with virgin forest, known as the Charduar forest, up to the Akha hills. A large area consists of pure forest of *Mesua ferrea*, the Assam nahor and Bengal nagewar, the timber of which might surely be utilized for railway sleepers, for which there is a large demand at present, as I hear that the creosoted Norway pine sleepers imported for one of the Bengal Railways have proved a complete failure. The jutuli, *Altingia excelsa*, is another social species, and the amari, *Amora spectabilis*, the sama, *Artocarpus Chaplasha*, the poma, *Cedrela Toona*, and the gond-soro, *Cinnamomum glanduliferum*, also yield fine timbers and are disseminated through the forest. Whilst old tea gardens with bad jhat of plant are being abandoned in parts of Darrang, the fine young gardens of high class hybrid and Assam indigenous plant on the forest plateau land, and even on grass land below it, are doing very well, even at the present low price of tea, and I hear that Re. 0-10-6 per lb. was the best average price realized in the Darrang district for last year's crop. The dark Assam hybrid plant is now preferred as more hardy than the light-leaved indigenous. These forest gardens, on undulating plateau land surrounded by a wall of *Mesua ferrea* trees, have a singular appearance, but are said to be more healthy than the grass land gardens. As formerly, the labor question is a great difficulty, but machies are now largely used everywhere, Davidson's Sirocco doing the work of a large range of *chulus*.

To take an example of a fine tea estate, that of the Borili Company has 7,500 acres of fee simple forest, and uses up annually 35,000 maunds of firewood in its engines, and the wood for 4,500 boxes, each containing 18 superficial feet, or $\frac{3}{4}$ cubic foot with $\frac{3}{4}$ -inch planking, or taking in waste in sawing, we may allow 1 cubic foot per box. A quantity of timber is also used annually in repairs to buildings, so that perhaps we may some day hear of the large tea companies managing their forests scientifically. Many gardens which have no private forests still

purchase teak boxes in Calcutta, and pay Rs. 2-8-0 each landed at the nearest river-gât. I heard that the Assam Company imports 35,000 teak tea boxes annually from Calcutta.

In the Borelli Company's gardens, the steam saw was hard at work preparing wood for tea boxes. I was told that provided the wood was properly dried there was not the slightest fear of its injuring the tea, and all species which would saw well, and are not too heavy or hard, were used, the koelian (*Dubautia sonneratioides*) having the preference. On the islands and banks of the Borelli river there are nearly pure forests of this tree, which is of rapid growth, and a Marwari merchant has started a saw-mill to prepare tea boxes for the planters at the Balipara Haut, which he sells at 1 rupee each. Mr. Lumsden, the Manager of the Borelli Company, showed me how he was gradually eradicating China plants from his gardens, by pulling them out by ropes attached to an elephant, at the rate of 200 plants per diem. Twenty acres of China plant are thus removed every year, and the ground replanted with indigenous or high class hybrid plant, and the yield thus increased from 2 or 3, to 7 or 8 naunds per acre. The bad results of former heavy prunings were evident in the diseased stalks of the old tea, many of which were furrowed by white ants up to the top of the bush. The beneficial results on the growth of tea of the sau tree, *Albizia stipitata*, have attracted the attention of many planters, and I saw for myself that bushes under the shade of this tree were more vigorous than their neighbours. A small pamphlet on the subject has been published by the Indian Tea Association, in which many Assam planters give their experience on the subject, all being favorable to the sau tree. Mr. Peal considers that all the Assam *Albizias*, namely, *A. data*, *stipitata procera* & *obovatisima*, have the property of improving the growth of tea directly under their shade. The sau tree has very long superficial roots and bears quantities of seed, the former may assist in draining the soil, and the pods and leaves falling on the ground may enrich it, whilst the shade is not too great to affect the production of leaf in the tea bushes. The greatest attention is now paid to the water supplied to tea garden coolies, and their huts are far better than those of villagers in the Dûn, but there is still a good deal of sickness amongst those freshly imported.

The planters are a fine healthy set of men, and play polo regularly, and the gardens are so numerous, that the old solitary life in the jungles is a thing of the past in Darrang. It is worth noting that certain species of forest trees sprout up naturally in tea gardens. In Darrang the simal has the preference, in the Western Dûars it is the kudam, *Anthecephalus Cadamba*. In the Dûn, it is the tûn, *Cedrela Toona*.

COFFEE.—The writer sapiently adds:—If coffee planting succeeds in Assam it will be some compensation for the extensive area of now tea cultivation in Ceylon, where splendid yields of leaf have resulted. It is probable, however, that the tea plants will not long stand the forcing climate and seemingly poor soil of Ceylon. All vegetation requires some rest, and the old tea plants in Dehra Dûn, where the severe cold of winter and the dry west winds of May and June, necessarily put a long stop to tea making, is still perfectly healthy and free from any blight or disease, and contrasts well in this respect with the more luxuriant plant in Assam, though there are probably tea bushes in the Dûn older than any in Assam.

TOBACCO CULTIVATION IN THE BRITISH ISLANDS.

The tobacco plant (*Nicotiana Tabacum*) must be considered as a tender annual, completing its growth, flowering, and ripening its seed within the compass of one season, and finally destroyed by our early frosts. If sown simply in the open ground it will not germinate soon enough for our purpose; therefore the young plants should be raised under glass, and pricked out into large pans, boxes, or contrivances of a similar nature. The planting out may be done at the same time with the

ordinary ornamental bedding-out stuff early in May or as soon as two or three strong leaves have been made; and as a rough and ready rule the crop may be cut when the gardener is making his first *Pelargonium* cuttings for next year.

PREPARATION OF THE GROUND.—This is perhaps the most important part of the whole business. If the crop is grown upon the flat the lower tier or two of leaves, which are the most valuable part of the plant, as being the first to ripen, will inevitably be injured by slugs, caterpillars, and heavy rains. Therefore, the ground must be laid in high and wide ridges, as for Swede Turnips, but on a larger scale, and flattened or ploughed at the top, so as to allow of a zig-zag arrangement in planting. This is the American plan, I believe, and was adopted by me from an account given in the *Gardener's Chronicle* some years since. The advantages are manifest. The plants grow, as it were, high and dry, with the lower leaves hanging over and supported by the sides of the ridges, which latter should be sufficiently wide apart to admit of the tread or free passage of the cultivator.

SUMMER CULTIVATION.—As the plant progresses laterals are formed at the base of every leaf. These must be removed as soon as they can be handled, and care taken that none steal a march from being hidden by the lower leaves. Fresh ones will spring from the base of those first pinched out, and, as they are rapidly produced, this will be daily but absolutely necessary work. The flower-spike should be removed as soon as a few blossoms have expanded, and all subsequent attempts to flower must be checked. This part of the matter requires skill and judgment, for some of the plants will run into flower when too little developed to be profitable, in which case a lateral may be encouraged to grow till it becomes the leading shoot, and in turn ready to undergo the same treatment.

THE HARVESTING PERIOD.—To produce anything like good quality it is essential that the crop should be cut before the sun has lost too much power. In our English autumn, when cool damp nights are the rule, a rank luxuriance is induced in many plants, and eminently so in the case of Tobacco, when the bulk of the plant increases enormously at the expense of quality. Consequently a crop left to the last moment before frost appears will be a long time in drying, requiring artificial heat from lack of that of the sun. It follows that it is better to cut too soon than too late, and this may be done as soon as the leaves at the base begin to turn yellow, when the whole plant will undergo the proper change in curing. It is recommended that the plants when cut should be allowed to lie an hour or two on the ground, when the leaves will become wilted and drooping, as this will be found convenient when the next process, that of hanging them up, is performed. For this purpose a wall nail is driven into the stem, near and at right angles to the base of it, thus forming a kind of hook, whereby each plant may be hung to a number of stretched wires, cords or other supports, in such a place as a large vinery. Here the leaves will soon begin gradually to assume the rich brown colour proper to the commercial article. The lamina or blade will change first, and subsequently, the midrib and larger veins; but until these last become perfectly dry this part of the process cannot be considered finished, for if in the stripping and packing an imperfectly dried stalk is included, mouldiness will assuredly set in and injure the sample. The footstalk, if properly dry, should be sufficiently brittle to be snapped in two on a hot day. The eye, however, and tooth will soon become sufficiently practised to judge when the leaf has attained this state.

THE FERMENTATION.—The leaves must now be stripped from the stalks, dumped, and tied in bundles of a dozen or more of leaves, by string towards the base of the footstalk. These bundles, when flattened out, will take a fan-shaped form, and are then technically called "hands." The damping process may be done in various ways and should precede bundle making, to avoid loss and disfigurement owing to brittleness. Sprinkling with water is dangerous, for if a leaf be packed actually wet, mouldiness is likely to be the result. Some hours in a damp cellar, or even out-

doors when there is no fear of rain, may suffice, as the leaf is exceedingly hygrometric and sensitive to a moist atmosphere. The boudles are now packed symmetrically in boxes or between boards, and heavily weighted. The packed material should remain for some months under shelter and in a moderately warm temperature, such as may be afforded by a room in the dwelling-house, or in the same glass structure in which the drying process was effected, but a really damp atmosphere will now be detrimental. A species of slow fermentation succeeds, analogous to that of hay in the rick, and until this has worked itself out, the Tobacco is not fit for use, in fact it is not proper Tobacco at all.

MANURE—I do not recommend the application of much manure, as this would tend to induce the over-luxuriance which I have indicated as undesirable. Potash has been suggested, or rather inferred from the existence of it rather largely in the plant itself. I might myself suggest a top-dressing of superphosphate of lime as inducing early maturity, but I have no experience on this point. The lime, too, might have a good effect in inducing the smoker's desideratum of a "white ash."

SORTS FOR CULTIVATION.—The Tobaccos may be conveniently divided into broad and narrow leaved sorts. To the former belong the Maryland and Labanon kinds, which are nearly identical, while the narrow-leaved Havana and Latakia are equally near each other in character. The Virginian (broad) is considered to produce a stronger Tobacco. The Schiraz, or Persian, is a distinct-looking form, and, with me produced a paler and milder smoking Tobacco. *N. rustica*, a distinct species with green flowers, is harder, but somewhat unmanageable in cultivation, and I do not recommend it. A curious hybrid was raised by me between this and the true Havana, which made a fine coloured leaf of good quality, but all the sorts I have grown seemed to turn out of much the same quality in our climate.

RECAPITULATION.

Under this head I bring into notice the absolute essentials only, namely:—

1. The cultivation on ridges.
2. The removal of all laterals.
3. The earliest harvesting of the crop consistent with a proper ripening of the leaf.
4. The absolutely dry state of the leaf before packing for fermentation.

Note also, a much larger crop may be gained by leaving the cutting to the last moment in late autumn, but the quality will be inevitably bad—woody and watery, so to speak, and of inferior colour.

In a good season, and under the treatment recommended, a perfectly coloured leaf may be produced, and the resulting Tobacco will be of fair smoking quality—always, however, more or less pungent, and with a peculiar *Gout*, which may be described as earthy.—R. TREVOR CLARKE, Assistant, April 23. [An abstract of this paper was read before the Scientific Committee on Tuesday last.—*Yn. J.—Gardener's Chronicle*.

MANILLA HEMP IN INDIA.

(Experimental Cultivation of the *Musa Textilis* at the Government Experimental Farms at Bhalgaon and Hyderabad and the farm attached to the College of Science, Poona.)

Letter from H. Strachan, Esq., Superintendent, Government Experimental Farm, Hyderabad, Sind, to the Collector of Hyderabad, Sind, dated 29th September 1885.

Musa textilis plant.—This plant thrives very well here under irrigation. Fifty young plants have been planted out, and 127 more are ready for transplanting; 29 stems are fit for manufacturing into fibre. A number of the oldest stems have been cut and used for tying vine canes and rose buds, &c.; for such work we find the plant very useful. The girth of some of the stems, 6" above the ground, is 2 feet $\frac{3}{4}$ inches

the length 14' 2" and the middle circumference 1' 9". The fruit when ripe may be said to consist of little else than skin and seed cells, the pulp is almost nil and of no very pleasant taste. As a fruit I would say it is useless. The flower spike in most cases is from 5 feet to 6 feet long, but the fruit seldom extends further up than 1 foot to 14 inches from the base, the flowers fall from the other portion of it. With a view of obtaining a hybrid between this plant and some variety which yields good fruit, fifty shoots of the Bombay red plantain were planted out towards the end of last year; they are growing well, but will not flower for some time yet. The first trial at extracting the fibre failed on account of our having no proper machine to bruise the stems. We experimented a two-roller mill, but as it had no cog-gearing to cause both rollers to turn together, the one only on which the handle or crank was fixed turned with the result of grinding the stems to pulp instead of simply bruising them. This machine is being altered so as to make both rollers work together and it will then be capable of crushing one leaf or the whole stem at one time. The pressure which is regulated by two levers attached to the upper roller can be varied at pleasure to give a bruising weight of from 5 lb. to 200 lb. or more if required. It only wants a couple of cog wheels or pinions to make a very complete and useful implement for preparing any kind of fibre from stems which require to be crushed. As soon as it is ready further trials of extracting the fibre from this plant will be put in hand.

REPORT ON MANILLA HEMP (*MUSA TEXTILIS*) CULTURE.

The plantation of Manilla hemp on the College Farm is two years old. From a plot measuring half guntha, eleven stems were cut down and the fibre prepared as follows.—

The leaves were cut off and the midribs laid aside. The (false) stem was separated into the leaf sheaths it is composed of, the sheaths torn up into narrow strips and hung up in the shade to dry and subsequently soaked in water until the fibre separated easily. The weather being cool the time required for retting was ten days. The quantity of fibre obtained was 7 lb. This is equal to 500 lb. per acre. The cost of production is per acre:—

Land rent	5
Irrigation	18
Manure	40
Labor cultivating	10
Do. watering	13

86 for 500 lb.

A crop of *Sua* (*Crotalaria juncea*) will give 600 lb. per acre of a better fibre at a cost of Rs25 in this district. An attempt to produce a cross between Manilla hemp (*Musa textilis*) and Sonkale (*Musa sapientum*) has been made. The pollen of the Sonkale (the finest of our varieties of Banana was applied to the flowers of the Manilla hemp without effect. The pollen of the Manilla hemp was applied at the same time to the flowers of the Sonkale; the fruit ripened during last month and has given about half ounce of seed. Whether a cross has been effected is doubtful, but I have never seen the Sonkale produce such large seed, and it is probably due to the pollen of the Manilla hemp. The seed will be ripened by March next when it will be sown. As the wild Banana takes about five years to attain full development, I expect the cultivated variety, when raised from seed, will take a like period, and the effect will not be apparent until the plant is full grown and in fruit. I attach samples of the fibre prepared from the Manilla hemp plants and also from the Sonkale grown in similar circumstances. It will be observed that the fibre of the latter is little inferior to the fibre of the former, while the latter (Sonkale) has a valuable fruit, and the fruit of the former (Manilla hemp) is uneatable. From this I would infer that a cross bred between those two plants will not be of practical value. It will probably be an inferior Sonkale with its fibre a little improved, which would not be an improvement on the whole. The necessity for and the

high cost of irrigation precludes the cultivation of Manila hemp in the dry parts of the Bombay Presidency, and in the wet parts there will not be found many places where the Manila hemp would thrive that are not at present occupied by more valuable crops. (Signed) G. M. WOODROW, Lecturer in Botany and Agriculture, Poona, February 1886.

Letter from A. Stormout, Esq., Superintendent Government Experimental Farm, Khandesh, to the Collector of Khandesh, dated Bhalgaon, 13th February 1886.

A reference to the reports of Saidipet farm shows that (1) the plants attain full size after two years' growth, (2) they refused to thrive unless grown on a deep well-manured soil, and (3) the fibre produced was insufficient in quantity and rough in quality being the result of unskilled labor. The correctness of the above statements is fully confirmed by the results of the past year's cultivation on this farm which, however, do not contribute much in the shape of progress. The Manila plants grew well under the same condition as the common plantains are cultivated, but showed no inclination to flower up to the age of two years when they were cut down and the fibre extracted. The mode of extraction was the same as practised in the locality with *Anabadi* (brown hemp) and *anna hemp*, with the exception that the stems were in the first place passed through a sugarcane mill which got rid of sap averaging 50 per cent of the whole. The stems were next rotted in water from 10 to 12 days, and afterwards washed by hand and sun dried. The output of fibre was 1 1/2 lb. per 100 lb. of fresh stem, a percentage considerably higher than the average shown in the Saidipet experiments; it was, however, of bad color and defective in strength. Cords of equal weight and thickness of this fibre and ordinary Ambari broke with the following weights—

	lb.
Manilla hemp	117
Ambari	330

It has to be remembered that these fibres were prepared by people who from natural instinct and life, long practice, understand to perfection all the minute and important details of *winding, rotting, stripping, bleaching, &c.*, in the case of Ambari, while they know nothing at all of the process necessary to be followed in that of Manila hemp. Now although there are certain natural laws which regulate the growth of all fibre plants, others, and by far the greater part, apply to individual species only. So that each kind of fibre has its own particular physiology which requires to be studied and understood before successful manipulation can be reasonably looked for. Two of the points to which attention is specially drawn by the Director of Agriculture remain still to be dealt with; these are (1) can the fruit be utilized? (2) can a hybrid variety be raised between the *Musa textilis* and the *Musa Parviflora*? The growth of the present year, it is expected, will afford ample opportunity for further observation on these points, and the results will be given in next year's report.

WHAT TO DO WITH OUR BOYS.

Agricultural Education in Canada.

For anyone who intends to settle a son in the United States or Canada the Agricultural College at Guelph in Ontario is well worth visiting. There are several so-called agricultural colleges in the States, viz., colleges which to obtain special State aid include agriculture in their course of studies; but with the exception of that at Lansing, in Michigan, these are really institutions for general education. Guelph, however, is for the farmer, and the farmer only—not the gentleman farmer, or squire who holds one of his farms in his own occupation, like our English colleges, but for the working farmer who has to gain his bread by the sweat of his brow. The college is supported by the Province of Ontario, one of those exceptional commonwealths which is beforehand with the world

and has a nice little capital laid by on which to draw at need. Thus it can afford to work, not for the present, but for the future; to loose money in order to raise the general standard of agricultural education, and consequently of agriculture and output throughout the province; and is even willing, in default of filling up the numbers of its college with natives, to admit outsiders to share benefits afforded at the expense of the Ontario taxpayer, though charging these outsiders of course considerably more than is charged to Ontario students. What this means may be judged from the following extract from the prospectus for 1884:—The entire cost to an Ontario farmer's son, able and willing, with considerable experience in farm work, is \$40 to \$55 a year for board, washing, and tuition. To an Ontario student without any previous knowledge of farming, \$50 to \$65 a year for board, washing and tuition. To non-residents (of Ontario) \$120 to \$150 a year for board, washing, and tuition. Some students, by regularity and industry, succeed in encaseling almost their entire board accounts."

This is effected by their labour, for which allowance is made at from "four to ten cents an hour, according to its value as estimated by the Farm Superintendent and his foremen,—in no case to exceed the charges for board and washing." I may mention that the charge for washing 30 cents per dozen pieces, and that the wash which may be sent is unlimited; so the Ontario taxpayer contributes considerably to the encouragement of cleanliness among the students in the matter of linen, besides affording a liberal provision of baths in the building, with hot and cold water laid on—which said provision cost \$5,000 (say £1,012) quite recently. Now, before giving my own impressions of the college, I will refer to the opinions of competent persons regarding it, viz., Professor Henry, of the Lansing College, Michigan, Professor Sheldon, of our Downton College, Mr. Anderson, farmers' delegate from County Kerry, and Mr. Curitts, farmers' delegate from Yorkshire. The three latter visited the college in 1880, when it was only six years old, and I refer to their general reports on Canada published by the Dominion Government. The former's visit was in 1883, and his description appeared in the *Farmers' Review*, from which I saw it quoted by the *Indian Agriculturist*. Mr. Anderson writes in 1880:—

"I cannot conclude my remarks on Ontario without mentioning the Agricultural College at Guelph. Guelph itself is a fair-sized town in the county of Wellington, in the centre of a well-cultivated district. The land is pretty good, but not so rich as some other portions of the Province. There are several extensive breeders of both Shorthorns and Herefords in the neighbourhood; indeed, all the cattle in the district were particularly fine. The college is about a mile from the town, and is supported by the Province of Ontario. The farm connected with it contains about 500 acres. I inspected the system of instruction, which is very complete, including not only ordinary agriculture and stock-raising, but a practical knowledge of chemistry and veterinary science, two very valuable branches to the farmer and very little known. The ordinary education of the student is not neglected, for I see an English and mathematical course laid down, which, if taken advantage of, will give the future farmer something more than his bullocks to think and talk of. Nor is horticulture forgotten, and I saw for myself that the student had, in the extensive gardens connected with the college, ample opportunity of making himself acquainted with that art which will enable him hereafter to beautify his homestead and supply his table with vegetable luxuries.

"Among the live-stock six breeds of cattle are represented, i.e., Shorthorns, Herefords, Devons, Aberdeens, Galloways and Ayrshires. Of sheep they have Cotswolds, Leicesters, South Downs and Oxford Downs. There are also some very good Berkshire pigs. The fields which, as nearly as possible, contain 20 acres each are fenced with straight board fences, and are extremely clean. "Turn where you will, evidences of careful management and sound

judgment meet you; but one would expect nothing else after having conversed with Professor Brown, who has the practical working of the farm. Professor Brown is making some experiments in cattle feeding and breeding and with various crops, which I am sure will result in much good."

Mr. Curtis's notice and that of Mr. Sheldon (Professor of Agriculture) are shorter and more general, and may be seen in the Delegates' Report, procurable from the Dominion Agent in London—a most valuable pamphlet which I studied intently before proceeding on my prospecting tour. The remarks of Mr. Henry (Professor of Agriculture at Lausung) I quote *in extenso*:—"It was early on a bright morning of the present month that I started from the hotel in Guelph for a visit to the Agricultural College. Leaving the quiet little city with its walls of dull-grey limestone behind, I passed out on the Dundas-road, and after a brisk walk of a few minutes found myself at the college gate. The first rapid sweep of the eye over the scene brought nothing very interesting or striking to view; in the back-ground on a rise of ground fronting me stood a long three-storey building of the same grey limestone as that used for buildings in the city. This main building was flanked on one side by a couple of neat dwellings, and on the other by a cluster of barns and out-buildings, while in front of these last, half-hidden in the trees, stood a green-house. The grounds in front of the main building were treeless, and having been recently ploughed lay bare and brown. "To one brought up in the United States, where the idea largely prevails that immense buildings are prime factors in the make-up of a college, the sight was not very prepossessing, and yet this institution, situated away to one side of the centre of our American civilisation and almost on the outskirts, has of late attracted much attention from those studying the problem of industrial education, and caused many persons like myself to make long pilgrimages, even in some cases from across the Atlantic to study the causes of its success. In the United States we have scores of colleges with buildings far more massive than these, and whose age renders them venerable compared with this new thing, yet their fame has scarce extended across the borders of the county in which they exist.

"But I have kept the reader entirely too long outside the grounds contemplating the earthy campus and the grey-stone buildings. I was not long in making my way to the office of the president, James Mills, who gave me such a welcome that I felt at ease at once. With him as guide, the professor of agriculture was soon found, and I now had my two main sources of information at hand. Let me give to the reader some of the facts gathered. This college accommodates 130 agricultural students, who all reside in the main building under the direct supervision of the president. Each candidate for admission has to pass a thorough examination in the common English branches upon entering. The course of study is two years in length, and is made to combine both the practical and theoretical. All students naturally fall into one of the two classes—'First Year' or 'Second' students. Each class works daily five hours in the fields, barns or works, and have five hours for study and recitation. The work and recitations of the two classes alternate: thus while the first year boys are with the professors in the class-room during the forenoon, the second-year students are employed under the guidance of proper superintendents at manual labour in the fields, barns or shops. During the afternoon the order is reversed. For this manual labour the student is allowed from four to ten cents per hour according to his ability. His earnings are credited on his board account. For board, washing, and lights the cost is about ten dollars per month. The cost of the year's schooling is, to a good working student, not over sixty dollars per year for all expenses, except clothing.* All students are treated alike as to hours of labour, and the endeavour is to make each familiar with all the varied farm operations.

To be sure, with only a two-years' course, and half of the day spent in the field, no extended course of instruction can be given; yet, since no time is spent on any foreign language, the student is given a fair start at least in such sciences as botany and chemistry, and is given a good drill in English. The range of study and thoroughness is more than one would suppose at first thought. The average student leaves the college an intelligent man, if not an educated one. It is in the practical operations that this school excels. Let me illustrate by showing how the young men are taught in regard to stock. When Professor Brown takes up this topic, his lectures are illustrated by the living animals. When talking about Shorthorns, for instance, a bull or a cow of this breed is led into the lecture-room and studied. Before the subject is left, several individuals are brought in at once and compared. After this course with each breed, representatives of different breeds are placed before the class, as Herefords, Short-horns, and the Polled Angus, and comparison made. Nor does this end the matter. Each student must pass an examination upon these lectures, and in a most rigid way. When being examined the student is alone in the room with the stock, the Professor and some practical stockmen chosen for the occasion. It is not to be wondered at that these young men become very proficient in such matters. It is in ways like this that the whole farm is made to serve as illustration. The farm is very complete, and I wish this whole paper could be given up to an account of it. It consist of 550 acres of choice land. There are twenty-one fields of twenty acres each; there are seven fine teams of work-horses and all sorts of farm machinery, without limit almost; there are on the farm seven breeds of cattle, six of sheep, and three of swine.

"The college is now about to take a step in advance. Several years ago \$10,000 were spent in blooded stock. This has paid handsomely, as over \$15,000 have been realised for surplus stock sold out of this herd. This fall they propose to hold a clearance sale and restock the farm with a larger number of animals of a higher type. Not only is there to be a great change in the stock, but the college grounds are to be metamorphosed. Mr. Miller, who laid out Fairmount Park, Philadelphia, has been employed to remodel the grounds, and the work has already begun. This accounts for the large lawn in front of the main building being ploughed up, as mentioned at the beginning of this article. In place of their present small green-house they are to have one costing over \$10,000, and all the barns are to be torn down and new ones built on a new site. These progressive changes are a measure of what the Ontario people think of their agricultural college. President Mills informed me that if he wished he could fill this school with young men from England alone, and that the cities of Canada would over half supply the list. His endeavour, however, is to have the sons of farmers from Ontario fill the school. So long as this is not the case outsiders will be admitted. Last year sixteen young men from England were in attendance, Ireland and Scotland sent three each, and Turkey, Wales, the United States and West Indies each sent one. Each term he has to refuse many applications for admission. President Mills says that, so far as he knows, every student who came to the college from the farm has gone back to the farm when through. Let those who claim that education drives young men from the farm ponder over this statement. The reasons for the success of this school can be found in the men and the methods. Those in authority have turned themselves squarely to the farmers of Ontario, and sought to know what under present conditions should be taught to their sons to make good farmers out of them. They have not looked to classical colleges for guidance, but have been governed by the needs of the common people. Who could expect anything but success when such methods have been employed. No wonder money is beginning to flow towards this school like water, and both political parties of Ontario are claiming the college as their own particular child. Without fear of successful con-

* This refers to outsiders, and the charge for them has just been doubled.

tradition, I call it the model agricultural college of America. Less than ten years of age, it is fairly rooted in the hearts of the farmers of Ontario. How can it have other than a bright future? It was the afternoon of the second day when I closed my visit. I felt as I left that I could profitably stay a week studying the reasons why this young school was so rapidly gaining distinction."—*Pioneer*.

THE TOON TREE IN QUEENSLAND.—Mr. Simmonds, in a recent paper stated:—"Irrespective of the immense home consumption in Queensland, there is a large export trade, ranging in value from £30,000 to £60,000. Already the Government have seen it necessary to pass a measure for the conservation of the red cedar (*Cedrela toona*.) This tree grows to a height of 100 to 150 feet, with a diameter ranging from 3 to 7 feet, is easily worked, and is in dry situations very durable. Some trees have been cut on the Richmond river yielding 30,000 feet of saleable timber. The market value of this tree in Queensland is from 20 shillings per hundred superficial feet, according to colour and size."—*Indian Forester*.

INFLUENCE OF PLANTS ON THE ATMOSPHERE.—The Willamantic (Conn.) Thread Company some time since accidentally illustrated the influence of plants on the atmosphere. The nature of the operations of this company demanded a reasonable and constant humidity of the atmosphere in their shops. To obtain this they had employed two men and a spraying machine; but Colonel Barrows, desiring to increase the comfort and a pleasure of his operatives, commenced the cultivation of plants around the factory and placed many in the rooms, employing one gardener to take care of them. The atmosphere was at once changed in character; the spray machine was no longer needed, one man's wages were saved and the operatives were surrounded by beautiful flowers, and their lives made more pleasant."—*Gardeners' Chronicle*.

THE TOON TREE IN NEW SOUTH WALES.—In a review of a book on the Timber trees of New South Wales in the *Indian Forester*, we find the following information:—"Our author has divided the softwoods into three sub-classes—(1) Cabinet and fancy woods, (2) Coach-building woods, (3) Stave woods. Under the head of cabinet and fancy woods, the red cedar, our Indian friend *Cedrela toona*, is placed first as the most useful and valuable of all. It is said to attain a height of 150 feet with a girth of 10 feet, and to yield sometimes upwards of 30,000 superficial feet of saleable timber per tree. The great demand for tin timber has completely extirpated it in many localities, although it was formerly abundant in all the brush forest, and fears are entertained that unless protective measures are shortly taken, it will soon be no longer found in the colony. Many of the other woods are of great beauty, strength and durability, and often exquisitely veined, marked or fragrant, but are little known and seldom used, though superior to many kinds now largely imported. Amongst the coach-building woods, we have 'coachwood,' *Ceratopetalum aptatum*, and many others. The silky oak, *Grevillea robusta*, is excellent for copper's work, as well as the green wattle (*Acacia decurrens*) and the silver wattle (*Acacia dealbata*), and many others whose names are hardly known in India.

THE PHYLOXERA IN FRANCE.—This malady still makes great devastation in the wine districts in spite of the energetic measures taken against its diffusion. The prize of 30,000 francs offered by the Government has brought forward no remedy that answers the requirements, so that the means for the destruction of the pest are those which have been previously recommended and with only partial success hitherto. It is notified that several departments have become infected, and that others have received permission to employ the American Vines, which are either wholly or but little susceptible of injury from the Phylloxera. Since its introduction into France over 1,000,000 hectares have been destroyed, but so rapidly have new plantations been laid down that at the present time not more than 500,000 hectares are fallen out of vine

cultivation—about one-fifth of the whole area under Vines. By ministerial décret fields for demonstration (*champs de démonstration*) are to be set apart, wherein infected Vines be practically treated for the instruction of the wine farmers, and from which good results are expected. The insect has appeared in a few vineyards in Algiers, and the difficulty of meeting the danger there is increased by the refusal of the shipping companies to transport the rather dangerous compound used in its destruction.—*Gardeners' Chronicle*.

TOBACCO CULTURE BY FARMERS.—The *Daily News* of April 19 states:—"Under authority from the Lords of the Treasury the experimental cultivation of Tobacco is to be permitted in the United Kingdom. Any occupier of land intending to plant Tobacco must, on or before May 5, give notice to the Secretary of Inland Revenue, Somerset House, setting forth the extent of the land to be planted, and the place, parish, and country where situate. Bond under approved securities will be required in a penalty of £100 if over an acre of ground be cultivated, and £50 if under an acre, in order to secure that all Tobacco grown and gathered shall be removed to drying rooms and kept there until properly cured, when it shall be packed in bags, bales, or casks of an approved size, and must then be weighed by a revenue officer. After weighing the packages the duty must be paid, or the Tobacco be deposited in an approved customs or excise warehouse. In answer to letters addressed to the Inland Revenue Department by the Ensilage Society, of which Lord Walsingham is President, and Mr. Kains Jackson, Hon. Secretary, replies have been received that permission will be granted to certain responsible agriculturists named by the Ensilage Society to make experiments in the growth of Tobacco, provided they comply with the memorandum printed above."

THE JARRAH OF WESTERN AUSTRALIA. It has been confidently asserted, can resist the attacks of oven *teredo navalis*, but this has recently been denied. In the *Indian Forester*, however, occur the following statements:—"The wonderful capabilities of the Jarrah of Western Australia, *E. marginata*, was the theme of the majority of speakers in the discussion following Mr. Simmonds' paper. Of the twelve saw-mills in the colony, the most important are the Jarrahdale Company of Rockingham, with a railway to the port 23 miles long, employing nearly 200 hands; the Western Australian Jarrah Company, at Lockville, with 16½ miles of tramway; Davie's Karicdale saw-mills at Angata and Port Havelin, with 6 miles of tramway, and employing 100 to 150 men; and the Canning saw-mill, with 8½ miles of tramway, employing about 50 men. In 1882, there were shipped, chiefly to the neighbouring Colonies and India, 18,730 loads valued at £93,650, £5 a load; and in 1883, 19,910 loads valued at £79,769, £4 a load. While there is a palpable diminution in the supply of scented wood (*Santalum eggiporum*), the other valuable export of the colony, Western Australia, has more than 30,000 square miles covered with eucalypts, 24,000 miles of which consist of the white gum (*E. resinata*) and jarrah (*E. marginata*). Mr. Simpson, who has thirty-two years' practical experience of the colony, stated that almost everything in Western Australia was made of this timber, work-boxes, pianofortes, buildings, wharves and jetties; it seemed to defy all known forms of decay, and was untouched by white ants and all other insects, so that ships built of it did not require to be coppered. A specimen on the table, cut nearly thirty-two years ago, which had been exposed to bush fires, to the summer sun of Australia, and to wind and rain in the wet season, was as sound now as the day it was felled. Another as sound piece was exhibited cut from a bridge certified by the Government resident to have been thirty-six years in use. There were about fifty varieties of the timber, and it could be obtained of any reasonable length up to 60 or 80 feet, the trunk of the tree having no branches whatever. It did not burn freely, but only charred. If a sheet of glass and a piece of this timber were put into a white ant's nest, the ants would bore through the glass rather than touch the jarrah.

MARKET RATES FOR OLD AND NEW PRODUCTS.
