On the authority of information and data which I received and examined on the spot, I am able to state that the coffee-tree in the Rio zone—for instance in the Serra Acima—attains on an average the age of from 25 to 30 years, in the Serra Abaixo and Espirito Santo it leaves scarcely 18 or 20 years.

I think it not quite superfluous to note in passing that, by age, I mean the period during which the paying fazendeiro thinks it to his advantage to maintain the plantation, consequently the period of production.

I have visited old cafeses where very vigorous and healthy-looking trees were pointed out to me (for instance on the fazenda Fortaleza de Sant Anna, belonging to Senator Diogo Felbo), which could boast of having attained the venerable age of 40, 50 and even 60 years. But these were regarded as a curiosity.

It is very well known that trees upwards of 30 or 35 years of age are, as a rule, of very little further value to the *Grande lavouza*; consequently the fazendeiros do not take them into account when valuing their plantations, though they will be the first to affirm that the Brazilian coffee-tree may bear fruit for 50 years and upwards.

So those old trees are never met with in extensive plantations; but here and there, by fives and sixes, in old plantations which, so to say, have gradually been planted afresh.

As regards the height of the shrub, though it is difficult to state an exact average, seeing that the breadth and growth of the plant frequently depends on the altitude of the plantation, yet we may safely assume that in the Rio zone the full-grown coffee-tree is from 8 to 12 palms high, while in the Santos zone the standard varies from 10 to 16 palms.

The value of the plantations may be gathered from the subjoined:—

According to Senhor Luiz van Erven, who has been for more than 10 years superintendent of all the fazendas belonging to the Viscondes de S. Clement and Nova Friburgo, and is frequently called on as an expert to value plantations, the trees could be valued six or seven years ago after the following standard:—

Trees of	1 year old	=	60 reis	=	1½ d.
" "	2 "	=	100 "	=	2½ "
" "	3 "	=	160 "	=	3½ "
" "	5 "	=	200 "	=	4½ "
" "	8 "	=	280 "	=	6½ "
" "	16 "	=	180 "	=	4½ "
" "	20 "	=	120 "	=	3 "
Upwards of	25 "	=	60 "	=	1½ "

To what extent these prices are to be obtained at present, will appear below.

As a general rule plantations from 12 to 15 years old are maured. But artificial manure is never used, and stable manure very seldom. All that is employed is the offal of the coffee, that is to say, the red and the horny husk, which in point of fact, is gathered very carefully. A few fazendeiros have indeed tried experiments by manuring their cafeses with guano, stable-manure, lime, calcined bones, &c., but the results were so unsatisfactory that the experiments were finally abandoned.

He then proceeds to enumerate the different diseases and enemies of the coffee-plant, the harvesting and picking of the crop, and further operations for preparing it for the market. The different kinds of coffee then come in for discussion; but it would carry us too far to mention all the heads deserving of attention. We will therefore conclude, merely recommending those who wish to know more about the matter to the book itself, which is published, London, W. H. Allen & Co., 13, Waterloo Place, The Hague, Martinus Nijhoff.—*Indian Mercury*.

CINCHONA-BARK STRIPPING.

At present one of the great industries in India is the production of cinchona bark, and a very lively interest appears to be taken in this branch of commerce, if we may judge from the prominent place which it occupies in periodicals that reach us from that part of the world. Several of these have called attention to the careless manner in which trees are felled and bark stripped from them. Experience has, however, now come in time to allow a remedy to be applied, and in numerous plantations the cinchona trees are dealt with very differently. Various plans are in use. One, which is very common, consists in stripping off the bark in longitudinal strips, taking, say, four strips from each tree, and then immediately bandaging the stripped parts with damp moss. This process is found to protect the cambium between the bark and the wood, and to prevent the wood drying while the bark on either side of the wound is extending itself to cover the part. Another process, called the "Karslake method," consists in making two longitudinal cuts in the bark at such distances apart as it is intended to strip, then passing some sharp instrument through from side to side, moving it up and down, and so separating the bark neatly from the wood, leaving it uncut at the top and bottom of the strip; but as soon as the separation is effected, the bark is allowed to return as neatly as possible as it was before. This bark is intended to be cut, top and bottom, when the process of healing has fairly set in and the new bark has begun to form underneath the severed portion. This method is said to be really economical and ready way of securing the crop. We may also add that the *Calisaya Ledgeriana* and some other varieties are now largely grown by planters in Jamaica, as well as in the East Indies. It is asserted that any elevation of 5,000 feet above the sea in Ceylon and about 6,000 feet in Jamaica are the most favourable altitudes, above which cultivation of the cinchona is more or less profitless. [So writes the *Chemist and Druggist*, but we believe MacIvor's stripping process has been largely superseded by shaving, while we are not aware that the Karslake process has been in practice and largely a success?—En.]

▲ WORD TO THE WISE.—It is a great mistake to stop advertising when trade is dull. In "dull" times people have more time to read the advertisements; in "dull" times business changes are made, and plans matured for the coming season; in "dull" times men are more easily impressed with the advantages of new things which seem to promise a change from the existing dullness. Advertising is planting, and the harvest follows in due season. The truly wise plan is to advertise *all* the time—but, whatever you do, don't drop off in the dull season—people will think you are dead, and customers usually prefer live firms to deal with.—*Indiarubber and Guttapercha Journal*.

TEA PLUCKING.

[What follows applies to Darjeeling, which is in 27° North and close to the Himalayan snows, and to Kangra, which is still further north and much colder. Both places, equally with Dehra Dun have marked winters, and of a real winter we in Ceylon know nothing, except in shape of chill mousoum winds and rains. But the remarks on plucking are of general application. The proprietor of the estate in Ceylon which has sent the highest quality tea (judged by prices obtained) into the market states that his two chief secrets were fine plucking and rather under fermentation than over.—En.]

Picking Leaf.—For the first two years, from seedlings, all that is necessary in this way is to present any shoots running away from the main body of the plant; and in the third year, when picking properly commences, great care should be taken not to overtax the energies of the plant. In Kangra, at any rate, if one gets during the third year from sixty to eighty pounds per acre, and double that quantity in the fourth, it is as much as can be expected, though in Darjeeling one might get one hundred pounds for the third year, and three maunds (two hundred and forty pounds) for the fourth.

We place the average yield of an acre in full bearing in Kangra at rather more than 200 lb. per acre; taking the whole of large area; though in a small acre, highly cultivated, and carefully tended 300 lb., or in exceptional instances even more, might be obtained.

In Darjeeling the average of a first-rate garden making really good tea ought to be placed from four to four-and-a-half maunds per acre; and for an area, say of a hundred acres, the property of an able man, managing on his own account, an outturn of 400 lb. per acre of good tea might reward his exertions.

Of course, the amount of tea that could be obtained from a limited area, under special treatment, is more a matter of interest to the curious than of practical value to the planter. The greatest amount of tea we ever heard of being made from one acre of land (belonging to an Association with gardens running from the hills to the Terai) under such special treatment, was nineteen maunds (1,520 lb.) Possibly in Assam or elsewhere a higher result may have been obtained. The different systems of picking leaf now in vogue all have their advocates. Most are in favour of what in Darjeeling is called *Kuppo paro* (leaving a portion of the lowest leaf plucked to protect the coming shoot); but it is difficult, especially in a heavy bush, to make the cooly follow this system, and pick a proper quantity of leaf, especially as the top of the thumb and top of the first finger can alone be used to do it properly, and these soon get tired when very much has to be picked. It is a great protection, however, from tearing the leaf off the trees, which coolies are only too fond of doing.

The third leaf often happens to be unsuitable for picking: leave that leaf; but where the shoot has a sufficient quantity of leaves (five or six), not to pick the third is to delay the new shoot, as it (the third leaf) as well as the lower ones on the shoot, have to harden before a free flow of sap can be afforded to the new shoot.

Of course, the finer the leaf that can be obtained without plucking it before it is ready, and thus injuring the tree, the higher price will be obtained for the tea; and considering the high cost of carriage, and the general disfavour that medium and inferior Indian teas experience in the Home market, our attention must be devoted to the manufacture of really fine tea; but it is very easy to run into the other extreme, and in seeking to avoid the Scylla of inferior tea, get (for the season, at any rate) wrecked on the Charybdis of making such fine tea that the outturn hardly pays working expenses. Two hundred pounds an acre at fourteen annas a pound, will probably leave a profit; one hundred pounds at one rupee two annas will likely, if not inevitably, bring a man on the wrong side of his books. As the main object of the planter, and of

these whose capital is invested in the enterprise, is pounds, shillings, and pence, and not amusement or philanthropy, the happy medium must be hit. The most paying tea in Kangra would, as a rule, be what in an ordinary market would be a fourteen anna tea; and, if this price is not obtained all round, it is hardly worth of a man's while to engage in the enterprise, with its attendant risks. In Darjeeling a twelve-anna tea would pay very well; but viewing what has been already stated, fourteen anna standard might also be kept in view, and would doubtless, by raising the character of the teas, improve their value, the further and further they were removed from the ordinary run of China tea; and it is from falling into this category that all the Indian hill districts have to keep aloof, if they wish to maintain their distinctive character. It is to the London market that Darjeeling, at any rate, has to look as the purchaser of its teas, as it costs the same to land a tea that fetches fifteen pence, as it does to land one that realizes two shillings.—*Indian Tea Gazette.*

ARECANUT PALM CULTURE.

Sir,—I feel very much obliged to your correspondent for the further information he has kindly taken the trouble to collect in reply to my questions regarding the areca palm cultivation at the Straits. It certainly, as regards the correct distance apart to plant, entirely supports what he said before; and further directly corroborates Mr. Borron's opinion. Still "fact" is an unassailable argument, and, however true it may be for particular localities that wide planting is to be preferred, with the proofs existing from which I have drawn my own conclusions, I can only believe that it rather argues a similarity of climate between the Straits Settlements and Malacca East (was it not stated, either by your correspondent or some one else recently writing from the Straits, that, whilst Liberian coffee was a success, tea, though the plant grew well enough, was practically an unquestionable failure there, owing to the long-continued droughts, sufficiently severe to crack the soil?) than supplying a rule applicable generally; and it will take a good deal of practical evidence to shake my faith in the belief that on a closer system the heaviest gross yield is to be obtained in a climate similar to Udagama, by liberal cultivation, or on conditions of soil being similar without. I even am almost inclined to go so far as to believe, from what I have been able to notice, that the number of nuts per tree will hardly be much less on the closer system. But your correspondent has raised a fresh point, one on which I could not venture any certain opinion at present, and that well deserves considering, viz., that the widely planted tree produces a finer sample, which no doubt must raise the market value, and would tend to equalize the yield by weight. All I can say on the subject of sample is that I believe that in the arecanut it is markedly influenced by the quality of the soil, whether rich naturally or manured; and also by not merely the variety, but by the standard sample of the produce of the trees of any given variety from which the seed nuts are taken, though I do not know that it would be right to say that an accidentally small seed from a select tree would necessarily manifest much deterioration in its offspring! I can give you, I think, in each case an instance in point. I bought a good number of "Hamban" peccas last year from different villages, and from one of which they invariably averaged at least double the size of those from elsewhere. On inquiring the reason I was told it was on account of the better soil! Again, on a well-known property near Kandy, on which I am not aware that the soil is exceptionally poor, as I believe it has grown fine cocoa, as well as fruit trees and other products luxuriantly, there are a number of areas of the "Singalee" variety, but their produce is so small that, on very good authority, I was told they brought far

below the ordinary price. Now, to what other cause can this be attributed than that the trees sprung from deteriorated seeds—to degeneration in fact? It may be true—I should be very sorry to write dogmatically—that the wide system is generally better for estate cultivation, but, on the other hand, if not invariably found so, those who adopt it prematurely may have reason for regret hereafter, and as it does not cost much extra to put in the additional nuts at stake, my advice, certainly for wet localities, would be meanwhile to do so, and, if unable to sum up the courage yourself to do the thinning, if eventually thought best, trust a neighbor: it will be at least two years before the plants are likely to affect each other. Your friend at the Straits I see seems to differ from Mr. Borron as regards the advantage of shade. But I would wish him to tell his native friend that the “bamboo trick” will hardly get over the difficulty of collecting the nuts here—unless indeed the plant be adopted of going in for two curing processes, viz., the ripe nuts whole, and the green nuts sliced! Green unripened nuts would certainly, I should say, not produce a highly-priced or sound sample, and, if all were to be cured whole, to ensure this, the nuts, as for coffee, must be picked on as they ripen; this would be impossible with a bamboo, and must be done by hand. But, further than this, however it may be at the Straits on whatever system of planting (and grafting the varieties are as your correspondent supposes identical), in Ceylon, as the trees grow old they would entirely outreach the longest bamboo, and therefore to be able to pass from tree to tree without descending is, I must maintain, an advantage. The common or Singalee variety I think grows tallest as a rule, but I may instance a “Hamban” tree, growing quite in the open, and apart from other trees, which at my request was stripped, the result being at least 1,000 nuts for the one crop (I counted over 750 and was assured that fully a third had already been gathered) and the bunches of which no bamboo much shorter than a giant stem from Peradeniya could have reached. We live to learn, but on a comparison it must not be overlooked that for better results, planted so wide as 10' x 10' the yield per tree requires to be enormously greater, or the sample immensely heavier or more valuable.—C. R.—Local “Times.”

EUCALYPTI.

The very limited number of Eucalypti capable of cultivation in this country, does not convey to the mind any idea of the vast importance of this genus to the great Australian continent, nor of the large number of species which it comprises, although, according to Baron F. von Mueller, it is second only to *Acacia* in this respect. The Eucalyptus trees, he tells us in his valuable *Eucalyptographia*, “form the principal timber vegetation nearly all over the wide Australian continent, and for all ages the inhabitants of this part of the globe will have to rely largely, if not mainly, on eucalyptus for wood supply.” The rapidity of growth of some of the species and their salubrious effect in miasmatic districts have led, in great measure through Baron von Mueller’s energetic and persevering efforts, to their widespread cultivation in other countries, wherever the climate has been found suitable, so that the leaves and oil obtained from Eucalyptus globulus grown at Nice already form articles of export from the South of France.

Comparatively few of the species are suitable to the English climate, only *E. coccinea*, *E. Gumii*, *E. pauciflora*, *E. crnigera*, and *E. vernicosa* being able to brave frosts and snowstorms. Neither of these are remarkable for beauty. *E. globulus* will not bear severe winters, but forms a very effective shrub for planting out in summer, and will withstand mild winters. *E. Gumii* contains so little volatile oil in the leaves that it is readily browsed upon by sheep and cattle, wherever the dwarf procumbent form of the tree is met with near the coast. The young foliage of *E. pauciflora* must also be possessed of some value as fodder, for

opossums are so fond of it that the tree often dies out where these animals are not kept down by the hand of man. The sugary Eucalypt (*E. corynocalyx*) appears to be the only other species attractive to cattle, which readily feed on its sweetish leaves. This species, however, is better fitted for arid deserts, being capable of bearing the protracted droughts and extreme heat of such regions. Other species also suitable for such districts on account of their rapid growth are *E. bicolor*, *E. ochrophloia*, *E. polyantha*, *E. salmonophloia*, *E. terminalis*, and *E. salubris*. The last named is also remarkable for the large quantity of volatile oil contained in the leaves.

One of the most important economic products of the Eucalypti is the volatile oil obtained from the leaves. This varies very considerably in amount in the different species. Although *E. globulus* is often mentioned as the source of the Eucalyptus oil of commerce, this is by no means always the case, and for the simple reason that it does not yield so much oil as other species. A table given under *E. amygdalina* shows that, whereas 1,000 lb. of fresh leaves of *E. globulus* yield only 120 ounces of oil, the same quantity of *E. oleosa* gives 200 ounces, and of *E. amygdalina* 500 ounces. The two last-named species have been until lately the principal source of Eucalyptus oil, which is now prepared also from *E. dumosa*. Further details concerning the percentage of oil in other species may be found under *E. oleosa*. Eucalyptus oil is started to be produced in Mr. J. Bosisto’s factory to the extent of 12,000 lb. annually, and is extensively used as a solvent of various resins especially of the Kauri resin, asphalt, and some varieties of copal. It also dissolves indiarubber, and is used in anti-septic surgery. The odour of the oil of a few species is remarkably pleasant—*E. citriflora*, which is regarded by Baron Mueller as a variety of *E. maculata*, possessing that of the Citron in a remarkable degree, and *E. Staegeriana* that of Verbena, so much so, that the oil might easily be mistaken for that of the oil of Verbena of commerce.

The sap of several species contains a considerable amount of astringent matter, consisting of kino-tannic acid, mixed with a variable amount of a resinoid substance, the first constituent preponderating in some species, and the second in others. This gum, as it is called, either exudes from the bark or collects in fissures in the trunk. It is most abundant, according to a table given under *E. leucocylon* in that species, and *E. uacrorhyneba*, the former being said to yield 21.94 per cent, and the latter 13.41 per cent of kino-tannic acid. Several varieties of this astringent exudation have from time to time been sent over to this country under the name of kino, but have not met with a ready sale, owing to insufficient care having been taken to collect the kind most soluble in cold water; that of *E. obliqua* is, however, stated to dissolve completely in boiling water and to remain clear when cold; that of *E. Planchoniana* is recommended for its great astringency. For tanning purposes it is quite possible that a small percentage of resinous matter might prove advantageous rather than otherwise in enabling the leather to better resist external disintegrating influences.

The species of Eucalyptus which are most valuable as sources of timber appear to be those in which resinoid matters are present in larger proportion than the kino-tannic acid. Of these, *E. marginata*, yielding the celebrated Jarrah wood is one of the most important to the colony; white ants will not touch it, it is unsurpassed as regards durability, and is worked with greater care than most other Eucalyptus woods. *E. rostrata* also affords a much prized timber which is capable of bearing an enormous downward pressure, and is only slightly subject to longitudinal shrinking, and is very durable in wet ground and in fresh or salt water, but is harder and more difficult to work than the Jarrah wood. *E. leucocylon* also yields timber of extraordinary hardness and strength. These three woods are placed in the first class for ship-building by the Australian Lloyds, and *E. globulus*, which is valuable chiefly for its extreme rapidity of growth, is placed in the second class;

E. corymbosa, *E. diversicolor*, and *E. obliqua* come next in value; *E. reduca*, *E. resinifera*, and *E. corouta* are also mentioned as yielding excellent timber.

A remarkable use is made by the natives of the roots of *E. micranthera*. These are lifted up from the depth of about a foot, and at a distance of about 15 feet from the tree; they are then cut up into pieces, about as thick as a man's wrist and about 18 inches long, and are allowed to drain into a vessel, or blown into by the mouth at one end. In this way a quart of water may be obtained from good samples in about half-an-hour. Roots nearer the stem are less porous, and do not yield water so easily. The water is stated to be beautifully clear, cool, and without any unpleasant taste. The roots of *E. oleosa* and *E. populifolia* are used for the same purpose, but yield water less readily.—*Gardeners' Chronicle*.

DO PLANTS ABSORB ATMOSPHERIC NITROGEN?

Probably no doctrine in the whole realm of agricultural chemistry makes a greater impression on the mind of the student who hears it for the first time than that which teaches that, although four-fifths of our atmosphere consists of free nitrogen gas, plants are nevertheless unable to assimilate this valuable ingredient directly from so inexhaustible a reservoir. To every farmer the doctrine is brought home forcibly and practically enough in the sums of money he pays away in the purchase of nitrate of soda and other nitrogenous fertilizers. The experiments, well termed classical, of Boussingault on the one hand, and of Lawes, Gilbert, and Pugh on the other, were regarded for a long time as setting at rest any doubt which might be entertained on the subject. And yet in later years the Rothamsted investigators themselves have felt some difficulty, and have suggested perhaps somewhat extreme hypotheses, to account for the behaviour of leguminous crops, which, after providing themselves with the large amount of nitrogen they are known to require, yet leave more nitrogen in the soil than the latter contained at the beginning of growth. Facts such as these are sufficient to justify the increasing feeling of scepticism as to whether the nitrogen question—for such we may briefly term the discussion as to the sources of the nitrogen of vegetation—has been fully sifted, or whether more remains to be discovered. In any case, it is a difficult point, which can only be settled by the most laborious and exact experiment, and the few remarks we have made are simply prefatory to passing briefly under notice some recent investigations by Mr. W. O. Atwater, of Middletown, Conn., "On the acquisition of atmospheric nitrogen by plants," the full report of which appears in the *American Chemical Journal*.

The investigator rightly observes that it is very difficult to explain how certain plants, particularly legumes, obtain their nitrogen, if not from the air, and he sets himself to attack the problem as to whether plants, grown under normal conditions, acquire any considerable amount of nitrogen from the surrounding atmosphere. Two sorts of experiments were made, the plants employed being "Early Philadelphia" dwarf peas. It is not necessary to give the details of manipulation, but every care appears to have been taken by the experimenter. The first series of experiments showed in every case an excess of nitrogen at the end of the experiment over that contained in the manurial solution and in the seed, while the more detailed experiments of the second series gave larger gains of atmospheric nitrogen. Rain and dew, which carry down nitrogen in solution, were prevented from gaining access to the plants.

In those experiments in which the conditions of growth were approximately normal, the excess of nitrogen in the plant over that supplied by the nutritive solution with which the plants were watered, and by the seed, averaged 20 lb. per acre. In the

case in which there was no considerable apparent hindrance to normal growth the appropriated nitrogen rose to 122 lb. per acre—twice as much as the total nitrogen in grain and straw of a wheat crop of thirty bushels, and more than the total nitrogen of three tons of clover hay. And, observes the author, this remarkable gain cannot represent more, and may be less, than the actual quantity of atmospheric nitrogen which the plants acquired during the brief period of seventy-two days of growth.

In discussing the results the first question asked is, was the atmospheric nitrogen absorbed directly by the foliage of the plants, or was it first absorbed by the nutritive solutions and thus communicated to the plants through their roots? Experimental and other evidence is adduced to show that the plants in which the conditions of assimilation were most nearly normal, absorbed an amount of nitrogen which was probably more than 47 per cent of the total nitrogen of the plant (equivalent to 113 lb. per acre), which could have come from no other source than the atmosphere, and through no other channel than the leaves.

It is next inquired, Was the atmospheric nitrogen acquired by the plants in the form of combined nitrogen? Of course, this nitrogen must have been either free or combined, but the author quotes Sir John Lawes and Dr. Gilbert to the effect that the broad-leaved root crops, turnips and the like, to which the formation has with most confidence been attributed, do not take up any material proportion of their nitrogen by their leaves from combined nitrogen in the atmosphere. But Mr. Atwater, although he admits that plants do obtain some combined nitrogen in the atmosphere, maintains that in his own experiments the supposition that the plants could have obtained more than a fraction of their atmospheric nitrogen in this form is out of the question.

The only possible remaining question is, Did the plants acquire free nitrogen from the atmosphere? To answer this question in the affirmative is to enter the lists against all the best authorities on the subject. Mr. Atwater points out that the experiments that are most decisive against the assimilation of free nitrogen, namely, those of Boussingault and of Lawes, Gilbert, and Pugh, were conducted under glass covers connected with the earth. Berthelot has shown that free nitrogen may be assimilated by vegetable substances—dextrine, cellulose, &c., under the influence of electricity of tension similar to that which a brick obtains near the surface of the earth, in the strata of air in which our cultivated plants grow. It may be inferred that the compounds in living plants may assimilate nitrogen in the same way. But this electrical tension might probably be absent in the experiments with plants under glass. So Mr. Atwater thinks that the hypothesis of the assimilation of free nitrogen by plants through the agency of electricity, and the absence of that agency in the experiments of Boussingault, and of Lawes, Gilbert, and Pugh, would, with the effect of scanty food supply, explain the discrepancy between their experiments and his own, in which the conditions of growth were normal, and which would clear up the greatest difficulty in this much-vexed question of the sources of nitrogen of plants.

We can sympathize with the author's desire to interpret his own results in such a way as shall be consistent with those obtained by the renowned investigators of Rothamsted. Much—we may say everything—depends on the scrupulous care with which the experiments have been conducted. Presuming they are thoroughly trustworthy—and there does not appear any evidence to the contrary—the nitrogen question is presented to us in a new and interesting light, and it is possible that we may now be on the threshold of a fresh stage of the controversy, the ultimate settlement of which may not unlikely be fraught with a great, a significant, and a salutary modification of some of the cardinal practices of modern agriculture.—*Mark Lane Express*.

[The above article has been sent to us by the writer, Mr. John Hughes, who made reference to

its subject in a recent communication to the Dikoya Planters' Association, on analyses of rain water. There seems no doubt that leguminous plants equally with clover leave more nitrogen in the soil than they found in it, but if leguminous plants absorb nitrogen from the air, the puzzle is why pulses should in this respect have advantage over wheat, oats and other grains.—Ed.]

PALMS IN THE OPEN AIR.—The cultivation of these noble plants is fast making way in Southern France and Algeria. Some that are shown at the Exhibition of Paris by M. S. Chevier, of the domain Aube, in the Riviera, were grand robust specimens, abundant in foliage, exceedingly handsome, and capable of withstanding much ill-usage, as house decorative plants. In our account of M. S. Chevier's exhibit in the report of the show last week, the species cultivated are noted.—*Gardener's Chronicle.*

BURMAH CHEROOTS.—The following account of cigar making in Burmah is given in a recently issued official report. Little or none of the native grown Tobacco it seems is used, the only kind made up into cheroots being imported from Madras and Rangoon. The cheroots are made somewhat in manilla shape, but they are about the same thickness at both ends. The leaves are first damped and then put away for a day; they are then rolled very carefully with small wooden rollers to smooth out the creases, and are kept for four or five days wrapped up in a cylindrical form, they are then ready for manipulation into cigars. Women only are employed in this manufacture. One woman can make about 400 to 500 cigars in a day of twelve hours. No machinery is used, the leaves are simply cut into their proper shape by scissors, and then rolled by hand into cheroots. The small ribs are not removed as is often done in Havana, and this omission often gives the Burmah cheroots a rough uneven appearance.—*Ibid.*

CALIFORNIAN CITRUS FRUITS.—An Associated Press telegram, dated New Orleans, April 4, says:—"Today California has been awarded the sweepstakes Gold Medal against the world for the best varieties of Citrus fruits; also, two other Gold Medals, eleven silver ones, and thirty premiums. The most formidable competitor was Florida, which had the advantage of nearness to the place of exhibition, and made great efforts to carry off the prize. Her advantage was overcome by the liberality and public spirit of the Southern Pacific Railroad Company, which not only carried exhibits free of charge, but made special efforts to excite the interest of Californian fruit-growers in the contest. Over 100 car-loads of goods were carried gratuitously to the Fair from California. Great strides have been made in fruit-growing within a comparatively recent period. There are now no less than ninety-eight varieties of bearing Orange seedlings in Los Angeles and San Bernardino counties that were unknown to our soil fifteen years ago. California Oranges, Lemons, and Limes are now formally and officially declared to be the best in the world."—*Ibid.*

JAMAICA FERNS.—Jamaica, as is well known, is particularly rich in Ferns. Although the island is comparatively so small, it contains about 500 species of Ferns, which is one-sixth of the Ferns of the whole world. To express its richness in another form, it is mentioned in the last report of the Botanic Gardens of Jamaica, that within an area about the size at Wales, Jamaica, contains twelve times the number of Ferns found in the British Islands, and more than ten times the number of Ferns found in the whole of the United States. The Jamaica Ferns are remarkable, not only for their number, but also for their great variety and beauty. They are found in all sizes, from those scarcely a quarter of an inch long to large tall-towering trees 40 to 50 feet high, and with stems 6 feet in circumference. Again they are widely distributed and found in all districts, from the arid plains of St. Catherine and Clarendon to the highest peaks of the Blue Mountain; from the calcareous rocks of the northern coasts, bedewed with ocean spray, to the cloud-capped ridges of the highest mountains.—*Ibid.*

THE MANUFACTURE OF CUTCH IN BURMAH.—The manufacture of the well-known astringent substance, Cutch, from the wood of *Acaia Catechu*, so much used for tanning purposes, is carried on in Burmah chiefly in the Thayetmyo, Prome, and Tharrawaddy districts. Three men generally work together, one to cut down the trees and to drive the buffaloes that drag them to the site of the furnace, another to clear off the sapwood and to cut the heartwood into chips, and a third to attend to the fires and boil the chips down. The chips are put into cauldrons filled with water, each cauldron holding 4 gallons, and the whole is boiled for twelve hours. The chips are then taken out, and the liquid placed in large iron pans, and boiled and stirred till it attains the consistency of syrup, when the pans are removed from the fire, but the stirring is continued till the mass is cool. It is then spread on leaves in a wooden frame and left for the night; in the morning the substance is dry, and ready for cutting into cakes for the market. The daily output varies from 25 lb. to 36 lb. It is calculated that three men working steadily for eight months can make about 3,650 lb. of Cutch.—*Ibid.*

USES OF VEGETATION.—The proper function, or one of the right uses of all vegetation, is to produce food and clothing for us from the refuse matter of our large towns. Every little green leaf, apart from its individual beauty, has a share in the great work of purification which all leaves carry on. In malarious countries the Blue or Fever Gum trees is now largely planted, because it grows rapidly, and its roots and leaves suck up moisture so rapidly that a few of these trees actually drain any swamp or marsh near or to which they are planted. It is so with our own Poplar trees, which in wet low-lying places act most efficiently as the best of natural drains for a stagnant bit of marsh land. Now, if you drain a swamp in the ordinary way you simply carry pollution from one place and deposit it in another place; but tree roots suck up offensive matter, and tree leaves actually purify it. The leaves throw off pure water by evaporation, and with it life-giving oxygen, instead of the poisonous gases of the atmosphere. What is true of large trees is in degree equally true of the smallest window plant. The highest mission of plants is not merely to please our eyes with colour, our mouths with delicious fruits; not only do they do this and more, but they are ever silently but surely eating up what is impure and injurious to ourselves in the atmosphere and in the earth all around our homes; and any dwelling in which plants are well healthily grown will be more likely to be clean and healthy house than if the plants were not there.—*Ibid.*

RAINFALL AND SUGAR.—The report of the Botanic Gardens of Jamaica observes that the question of rainfall is one of great importance to the well-being of that island; indeed, the prosperity of its planting industries is dependent so directly and entirely upon the maintenance of a high rainfall that Mr. Maxwell Hall has been able to form a comparison (stated in the "Jamaica Rainfall" published in the Supplement to the *Jamaica Gazette*, October 4, 1884), between so many inches of rain per annum and so many casks of sugar per acre. These are indicated by the returns of several years, as follows:—1559 cask per acre with 79 inches (preceding) rainfall and 1411 cask per acre with 56 inches (preceding) rainfall, "so that," as he says, "the difference due to a larger or smaller island rainfall is on an average nearly one-tenth of the island export (sugar) crop." This one-tenth of export crop (for sugar and rum) represents in value nearly £100,000. If, however, we take into consideration coffee, pimento, and other island produce, the difference in export value dependent on good or bad seasons as regards rainfall, would amount to a very considerable sum. These considerations indicate to a large extent that the present generation is responsible for the maintenance of forests on all well-marked lines of watersheds, for the protection of the feeders of the streams, and, in fact, for the care of all that concerns the preservation of rain-water and the due humidity of the climate.—*Ibid.*

PLUMBAGO:—CEYLON'S ONLY MINERAL OF IMPORTANCE.

(Summary of a Paper read before the Ceylon Branch of the Royal Asiatic Society, on Aug. 28, by Mr. A. M. Ferguson, C. M. G.)

PLUMBAGO: With Special Reference to the Position Occupied by the Mineral in the Commerce of Ceylon; and the Question Discussed of the Alleged Existence in the Island of the Allied Substance, Anthracite.

Mr. Ferguson commenced by stating that the mineral of which his paper treated was a form of carbon, the substance which constitutes so large a portion of organized nature, more especially of the vegetable world. Graphite was in truth vegetable matter mineralized by those various forces of moisture, heat, friction, pressure, and electricity or magnetism, which have so marvellously metamorphosed the primitive rocks in which the mineral is generally, if not exclusively, found. In Geikie's Handbook of Geology, graphite is mentioned first in the list of rock-forming minerals, sulphur and iron following, before silica in its protian forms is specified. In a more or less definitely crystallized, foliated, columnar, needle-like, or massive shape, the mineral embodies the altered remains of some of the earliest plant forms which appeared on the earth, when the fiat was uttered in the far back ages of creation, "Let the earth put forth grass, herb yielding seed, and fruit tree bearing fruit." Those of the audience who entertained a vivid recollection of the fascinating paper by Dr. Trimen on the Flora of Ceylon, recently read in that hall, could imagine the delight it would afford that eminent naturalist and thousands of other scientists, could the brilliant steel-grey to jet-black ore they were considering reveal the secrets of its vegetable origin and show the fibres, the leaves, the flowers, and fruits of the earliest herbage of the morning of the times, from which it has been transformed, in like manner as ordinary coal also generally speaks of the early days of the geologic ages. But graphite (so called from its earliest use in the formation of pencils for writing and sketching,) which there can be little doubt is closely allied to coal, although generally older in origin, and the subject of more intense and long-continued metamorphic influence than the carbonaceous substance so valuable as fuel, is too highly mineralized (with the exception, perhaps, of the formations in Canada) to display a trace of the vegetable tissues from which it claims its descent.

To the seeker for fossil remains of ancient organic life, therefore, graphite, like our other primitive rocks, gneiss and crystalline limestone, is less interesting than are the coal measures, with their wonderfully preserved specimens of plants and animals and shells, on which human eye probably never looked until the operations of the toiling miner revealed their, in some cases, almost perfect lineaments. Graphite seems, in truth, to be the most highly crystallized form of carbon next to the peerless diamond, which poetically, if not with perfect scientific accuracy, has been described as a drop of pure liquid carbon crystallized. Graphite (to which, when burnt, the diamond reverts) has a beauty of its own, and as small diamonds have actually been formed by artificial means, the time may possibly arrive when the form of carbon which mineralogists rank only next below the diamond may, by means of the appliances of progressive science, be advanced from the second to the first place. Let us only attempt to imagine a mass of pure graphite equal to a quarter of a ton, such as that sent to Melbourne in 1880, and the still larger mass which will probably figure in the Court of the Colonial and Indian Exhibition of 1886, metamorphosed into diamond "of purest ray serene," and try to conceive the thing of beauty it would be, even if shrinkage in the transformation process reduced its size to one-tenth or even one-hundredth of the original bulk. Meantime it is curious that Ceylon, so rich in "precious stones" which with all their brilliancy are simply crystallized and coloured clays, should be utterly destitute of specimens of the king of all gems, seeing that diamonds are found close by us in Southern India and in formations similar to those existing here; but, it is, occasionally, and especially in association with corundum, which in Ceylon is so common and of which our most precious sapphires and rubies are but higher forms.

The paper then stated that of more value to Ceylon economically, beyond all comparison, would be the real discovery

amidst its rocks of that form of carbon which ranks next to the diamond and graphite, and which seems to be graphite and perhaps diamond in a less altered form. It needs scarcely be said that coal is referred to.

The authority of the late Dr. Gardner, formerly of the Royal Botanic Gardens, Peradeniya, the late Rev. Dr. MacVicar and Dr. William King of the Indian Geological Survey, was quoted, showing the improbability of the existence of coal where, as with us, primitive rock formed the surface strata, and the reader proceeded to discuss fully and to show the utter baselessness of statements made by Dr. Gyax, a Swiss mineralogist, and endorsed by Tennent, to the effect that in addition to millions of tons of iron, which could be laid down in Colombo at £6 a ton, anthracite, in association with plumbago and basaltic rock, was equally abundant and could be laid down in Colombo at 18s per ton, after cost of digging and conveyance from Sabaragamuwa. If Gyax and Tennent considered the alleged discovery of anthracite important with reference to steam navigation in 1848, how much more important would such a discovery be now, when the powerful but odourless and smokeless heat which the form of coal called anthracite yields would be just what is wanted by our expanding tea industry, while, as regards the requirements of steamers, it need only be mentioned that between 1880, when Colombo Harbour first afforded moorings for steamers, and 1884, the imports of coal into Ceylon had gone up from 80,000 to nearly 200,000 tons, the average value being over £20 per ton. But while bituminous coal was found in India anthracite did not exist there, the nearest approach to it being crushed coal near Darjiling, which had been converted into semi-graphite. But, while dogmatism was deprecated, entire scepticism was expressed as to the existence in Ceylon of anything more closely resembling coal than the peaty matter found, amongst other places at Nuwara Eliya, and which, compressed and dried, might be useful as a fuel. What seemed beyond question certain was that neither Dr. Gyax nor any other human being had ever seen anthracite in our gneiss rocks, and as to the alleged discovery of the mineral in enormous quantities, Mr. Ferguson said:—In the history of scientific exploration and report, and of colonial history and progress there seems to be no greater fiasco.

A curious circumstance in connection with the alleged existence of anthracite in Ceylon was mentioned. The late Mr. John Armitage, a well-known and enterprising merchant, saw in the British Museum a specimen of fine iridescent anthracite labelled as from Saffragam, Ceylon. It was said to be from the collection of a Colonel Greville, a name not prominent in the annals of Ceylon, and Mr. Ferguson added:—To show how confusion may arise, I need merely mention that through the dropping of a comma, plumbago is represented in successive works, including the *Encyclopædia Britannica*, as found in "Travancore Ceylon," as if the localities were one. There is the case of *columba* root, too, which received that name because ships touching last at Colombo brought the bitter root to Europe from India. But the crowning absurdity was that the Emigration Commissioners, who had in 1846 the ordering of such matters, instead of saying to Messrs. Armitage and Tindall, "We will refer to the Governor of the colony for information," or, "You go and prospect and let us know what you find and under what circumstances, make your offers, and we will consider them," jumped instantly to the conclusion that anthracite of such quality, in such plenty, and in such circumstances of cheap acquirement, existed in Ceylon, that 30 per cent would be a fair royalty to charge! There the matter ended, until Gyax's alleged discovery was announced, two years subsequently. It seems just possible that in both cases the supposed anthracite was the rocky hard form of plumbago, which the natives call *yabura* or iron druss. It was suggested that finally to set at rest the question of what minerals or metals might and might not be expected to occur in our Ceylon formations, the Asiatic Society should press on Government the propriety of asking for the loan of the services of a competent geologist like Dr. William King of the Indian Geological Survey, who, with his experience acquired in India, could pronounce on all important points in a period of time probably not extending beyond a year.

Passing over much detail of a more or less interesting character, we quote as follows:—

But if the diamond, amber, coal, and petroleum are absent from our rock formations, happily there can be no question as to either the quality or the quantity of our mineral carbon in the shape of Plumbago, of which indeed, in the form most valuable for the manufacture of metal-melting crucibles, Ceylon seems to have as much a natural monopoly as she has of first-class cinnamon in the vegetable world. There are, no doubt, vast deposits of graphite in North America, especially in Canada, but the mineral seems to be generally diffused in rock from which it is difficult and expensive (labour being scarce and dear) to separate the small particles. Graphite, although rare in a form economically valuable, seems very widely distributed over the face of the earth. In India plumbago has been found in a large number of places, and has been the subject of many experiments and much discussion, but the results have been hitherto disappointing. It generally appears sparingly in very quartz rock, and in heavy ferruginous gneiss. The mineral is deficient in lustre, contains much iron, and one specimen gave 35 per cent of lime. Lime is, perhaps, even more fatal to the value of plumbago than iron, and although graphite may occur in the magnesian limestones of Ceylon (I never heard of but one instance), it is quite manifest that digging in the dolomite need never be resorted to, the mineral being so plentiful in our quartz gneiss, where the only enemy encountered, and that, happily, not very frequently, is iron. Like some other adversaries, this one sometimes appears in guises the most radiantly beautiful, in the present case as pyritea varying from splendidly crystallized masses, with facets polished like finest silver, and again simulating auriferous treasures by putting on the most glorious colourings of gold, shading away to a lovely and delicate green, indicative, this tint, it is supposed, of the presence of sulphate of copper.

This auriferous enclosed pyrite is appropriately named in Sinhalese *dīya rat-va*, or "water gem-gold," the recognition of water as the agent to which the formation and its brilliant colours are largely due being, curiously enough, in perfect accord with the conclusions of the most advanced geological scientists.

To Mr. Williams, Acting Government Agent of the North-Western Province, I am indebted for a collection of interesting specimens from Polgola on the road to Dam-bulla, showing how plumbago is associated with and forms round a nucleus of crystalline or semi-opaque and sometimes gemiferous quartz (the position of the minerals being, I am told, occasionally reversed), and quite a number of pieces of rock which the non-scientific might well be excused for regarding as coated and permeated with brilliant golden ore. These may be regarded as the flowers of the subterranean regions where plumbago is mined. I am bound to state, however, that the brilliancy of iron pyrites has no effect in modifying the inimical feelings with which those connected with the plumbago enterprise regard the mineral, while they talk with disapproval and disgust of the *yabora*—(a *ya* iron, *bor* dross : iron dross, the hard iron-like form of plumbago; and anyone desirous of procuring specimens will be made heartily welcome to what in the eyes of the plumbago dealer is associated with a rocky inferior and unsaleable product. But truly the pure scint mineral itself, in its various forms of crystallization, the most prevalent being a radiating star-like arrangement, and its variation of sparkling colours from steel grey to plates of jet black, may be regarded as a veritable "thing of beauty." A collection of first-class lumps, each highly polished and lustrous, intended for shipment to Germany, which could be seen at Mr. W. A. Fernando's store recently, was certainly a striking sight. In connection with this collection of silvery masses, Mr. Fernando showed us specimens of a dark-coloured variety, of needle-like formation, which he said he had been requested by his customers to make up separately, as the ordinary mills could not easily grind that particular quality. Graphite generally, like iodine, shows a bright metallic sheen, but it is at once distinguished from the true metals by its soft and unctuous mechanical condition. I am speaking of first-class mineral, for, showing us a specimen of plumbago formed, apparently, over an ironstone nucleus, Mr. Fernando declared such ore to be unsaleable. In truth, the reasons why our Ceylon graphite is so much sought

after, are the entire absence of lime from the mineral, and in most cases its equal freedom from ferruginous particles, the small proportion of foreign substances, if any, being volatile matter and minute fragments of silica and alumina. Besides grinding to extreme fineness, an acid bath is used thoroughly to purify graphite used for certain delicate purposes, such as electrotyping, when the finest and purest dust is required to coat surfaces of wood, plaster of Paris, and gutta-percha, &c., to render them conductive. An authority, of all in the world, perhaps, best qualified to speak, describes Ceylon plumbago as combining the two qualities of being almost as refractory as asbestos and at the same time the most perfect conductor of heat.

The various portions of the world in which graphite is found were then enumerated, from North America to Japan, and the first mentions of Ceylon plumbago were traced, evidence not being forthcoming to prove Bennett's assertion that Ptolemy, who wrote in the second century of our era, had referred to the mineral. The historical records of Ceylon are as silent regarding plumbago as they are with reference to cinnamon, but a medical treatise of the fourteenth century, (about the date of a MS. extant in Europe said to be ruled with black lead) speaks of *kaluminivan* (black mica), as a medicine when boiled and subjected to the detergent influence of *Euphorbia* juice. The Cumberland black lead was also sought after as a medicine about a century and a half ago.

To quote again:—The officer of the late Ceylon Rifle Regiment who wrote a book on Ceylon stated that Thunberg, the Scandinavian naturalist, who wrote in 1777, was the first to notice plumbago as a product of Ceylon. This was an error. Robert Knox, who wrote in 1681, mentioned the existence of the mineral; and Valenty gives a letter of a somewhat earlier period by the Dutch Governor Ryklof van Goens, dated 24th September 1675, addressed to his successor the Governor-General Jan Maatsuyker, in which he mentions veins of plumbago (*patloot*) in the hills and minea in the lowcountry. He described it as a product of quicksilver, an error which, repeated, may explain the alleged discovery of a mine of quicksilver near Kotté soon after the British took possession of Colombo. So important was the latter discovery deemed at the time that a military guard was placed over the mine; but subsequently the existence of quicksilver in Ceylon became as mythical as that of anthracite seems now to be, or the alleged discovery of coal by the Dutch who are said to have disregarded it in view of the abundance of wood fuel. * * * A Mr. Ives, who wrote apparently in 1755, professed to have discovered "black lead" and copper ores in Ceylon. Mr. W. P. Rancesinghe has unearthed for me the tradition that the last King of Kandy, intam for his cruelties as he is famous for his aesthetic taste, added to his many-sided character a development of the commercial instinct, supplying, it is said, plumbago to merchant ships, more than seventy years before such enterprising traders as the Fernandes and De Meis appeared on the scene. The tradition seems also to indicate that some of the plumbago in which the monarch traded was dug from a mine on the lands of Mollignda Disawa.

Then followed references to notices of plumbago by Cordiner and Davy, Bertolacci, although he dealt with every export of any importance in detail up to the end of 1813, makes not the slightest mention of plumbago. The export of the stride must have commenced between 1820 and 1830, however, for Mr. Joseph Dixon, the founder of the great America Crucible Company, obtained a shipment of Ceylon plumbago in 1829. In that very year Col. Colebrooke, one of the Commissioners on Ceylon affairs, stated in his report that provision had been made for the delivery of cinnamon and black lead in the Kandyan Provinces (then including the Seven Korales) at fixed rates. Reference to the Government Calendars shows that there is no mention of plumbago until 1831, when it was included in the list of articles liable to export duty, the rate being 10d. per cwt. The amount of revenue at this rate in 1832 was £22 18s 6d. The mineral did not, however, assume real importance in the commerce of Ceylon until 1834, and for the half-century which has elapsed between that year and the end of 1884 I possess, thanks to the courtesy of the Assistant Auditor-General, Mr. C. Dickman, full details of the rise, progress and fluctu-

ations of the trade until from small beginnings it has in the past five years attained truly important dimensions, whether regard be had to the quantity and value of the mineral exported, or the revenue derived by Government from a royalty finally fixed in 1877 at the very moderate rate of R5 per ton.

For the first three years of the period beginning with 1834 no export duty was levied on this article. From 1837 to 1846, and again from 1855 to 1863, a duty of 2½ per cent was levied, which yielded in the earlier period sums so low as R12·25 in 1839, rising to R759 in 1846. In the second series of years, when export duties were levied expressly for railway purposes, the duty rose from R1,190 in 1858 to the appreciable sum of R22,240 in 1869. The latter sum was levied on 226,132 cwt. valued at R899,620. The rated duty seems, therefore, to have been as nearly as possible one-tenth of a rupee per cwt. The only customs impost to which plumbago is now liable is, apart from the royalty, 7 cents per barrel, recently exacted for harbour purposes. As each barrel contains 54 cwt. net of mineral, the burden is only a fraction over one cent per cwt., in addition to the royalty which since 1877 has been levied at the rate of R5 per ton, or 25 cents per cwt., equivalent to 2½ per cent on the Customs valuation of R10 per cwt., but rising to 5 per cent if the real value is only about R100 per ton. Previously to 1851 no royalty was levied, and the varying rates since then have been:—

In 1851 per ton...	4s.	In 1864 per ton...	16s.
" 1852 " " "	5s.	" 1869 " " "	30s.
" 1859 " " "	7s. 6d.	" 1873 " " "	R10
" 1862 " " "	14s.	" 1877 " " "	R5

There can be no possible question, it would seem, of the propriety of exacting a royalty, moderate in proportion to its market value, on this mineral, which is entirely an article of export, and which is as much the property of Government, or the people of Ceylon, as are the pearly treasures of the "oyster" banks off Arrippu,—providing, too as the revenue from plumbago does for the construction, amongst other public works, of means of communication which facilitate and cheapen the operations of the diggers. We could only wish that copper, tin, nickel, and other ores which have been so positively written about as occurring in Ceylon, with gold, which beyond question does exist, were found in quantities sufficient to add appreciably to the revenue in the shape of royalties. The one necessary qualification is, of course, that the amount of the tax should be such as not to bear heavily on an enterprise which is always toilsome and often precarious. Taking the average value of plumbago at R10 per cwt., the Customs figure, the present impost of 25 cents is, as noticed above, only equivalent to a rate of 2½ per cent, which certainly cannot be complained of as unduly onerous, however justifiable complaints and remonstrances were when 14s, 16s, and even 30s per ton were exacted, or R10 between 1874 and 1877. The present rate has the merit of being light, easily collected, and productive, for in the five years ended 1884 an average export of nearly 12,000 tons per annum, of an annual value of R2,400,000, yielded royalty equal to a yearly average in round numbers of R60,000. When the proceeds of digging licenses and leases of Crown lands, and stamps on those leases, are added, the average may be raised to R65,000. The maxima of quantities exported, total value, and total revenue were reached in 1883, when the figures were:—

Plumbago exported	cwt. 262,774
Value @ R10 per cwt.	R2,627,737
Royalty	...	R65,694	}
Leases & licenses	4,727		
Total revenue	R70,421

Wonderful contrasts these, even if we reduce the Customs valuation by one-half, to an export of only 423 cwt. in 1839, valued at only R490, or a little over R1 per cwt., and yielding to the revenue of the Colony only R12·25, a sum scarcely worthy of collection! The totals for the whole period of half-a-century of the export trade in Ceylon plumbago are striking, viz. —

Quantity exported	...	cwt. 3,526,000
Value of this quantity	...	R25,742,000
Contributions to revenue	...	R841,000

Crediting plumbago revenue with items brought to account under stamps and other headings, the amount might be raised to R900,000, and, had Government always

got its own in the shape of royalty, the round million of rupees would be considerably exceeded.

Taking averages of qualities and periods, it is probable that R200 per ton is too high a valuation for this mineral, and that twenty millions of rupees would more nearly than twenty-five millions represent the total value of the plumbago exported in fifty-one years, for which figures are given. At any average price of less than R100 per ton it would probably not pay to dig plumbago, and as a matter of fact what was evidently over-production between 1880 and 1883 led to a reaction in 1884, when not only did exports fall off but operations in the preparing yards in Colombo were stayed for a time by general consent, some not opening again even when the probability of a war with Russia gave a fresh fillip to the trade.

It is a melancholy fact that plumbago is one of the class of articles like "villainous salt-petre" and some others, the trade in which prospers when war has broken out or when warfare is threatened. The reason in the case of our staple mineral is, that the chief use by far to which Ceylon plumbago is put is the manufacture of crucibles, nozzles, &c., employed in the preparation of Bessemer and other steel, now in such large requisition for shipbuilding, plates for ironclads, torpedoes, shot, shell, &c.; this, in addition to the melting of the precious metals, for which crucibles of refractory plumbago are eminently suited from their superior strength and perfect smoothness. There are many minor uses to which plumbago is put, as will hereafter be shown, but I believe I am right in stating that its extended consumption (if that word can be correctly applied to an article which is almost unconsumable) in recent years is due to the great and rapid advance of the steel industry on both sides of the Atlantic, not merely to provide materials for ships, durable and light, but for the dread weapons and appliances of modern warfare, such as Kropf and Armstrong guns, steel shot, &c. But the abundance of the ore in Ceylon, and the enterprise and activity with which the mining, preparing and shipping of the mineral have been pursued, have in this case, as in so many others, recently led to production considerably in excess of demand, so that the profits of the pursuit, never very great and always precarious, have recently been low or nil.

When at its highest market value I do not suppose that Ceylon plumbago ever sold for more than £50 per ton; indeed the highest price of which I have evidence is £45 realized by Mr. W. A. Fernando, of Brownrigg Street, Colombo. What is this to the celebrated Borrowdale pencil "black-lead" mines, which, after having been worked since the reign of Queen Elizabeth, recently gave out, so that now pencils picked up at Keswick as curiosities cost six pence each! In the report of the Matara district for 1870 the Assistant Government Agent stated:—"To meet Ceylon plumbago in Cumberland was certainly a surprise; but when recently at the English Lakes I learned that plumbago from this Island was mixed with the local graphite to make good pencils."

In the palmy days of the plumbago mines of the North of England the black-lead obtained from them was valued at 30s. per pound, or over £3,000 per ton, or within about two-thirds of the price of ordinary gold. We cannot be surprised therefore to learn that a couple of centuries before the world heard of the gold escorts of California and Australia, the black-lead of the English Lake region was guarded in its transit, in carts, from mine to manufactory by parties of military, the robbery of black-lead mines being, by an Act of George II., constituted a felony. The Act, curiously enough, recited that black-lead was employed for divers useful purposes, and more especially for the casting of bomb-shells, round shot, and cannon-balls. The connection, therefore, with the art of war of the mineral so long associated with the most intellectual and humanizing of the arts of peace—writing and drawing, to wit—does not date from yesterday. The quality of the Borrowdale ore, dark-coloured, pure and soft, rendered it eminently suitable for pencils of the finest descriptions, and for about two and a-half centuries the world was practically supplied with pencils from this one source. From one pound of the ore, worth 30s., or at the rate of £168 per cwt., the number of pencils cut averaged from 18

to 20 dozens. The mineral was stated to be found in pipes, strings, and irregular masses called "sops," a description which, substituting modern terms for olden, applies equally to the Ceylon graphite formations. Since the exhaustion of the Cumberland mines, the best ore for pencils is said in some books to be obtained from Siberia, while no doubt the massive and soft stove polish black-lead, occurring in various parts of Germany—Bavaria, Bohemia, &c.—is applied to the manufacture of pencils. It cannot be questioned also that some of the finest quality Ceylon plumbago is thus used in Britain, and also in the United States.

Then followed notices of the various methods of manufacturing pencils, from the period when blocks of black-lead were sawn into pieces until Count de Paris in 1795 discovered the method now universally adopted of mixing finely ground graphite and clay together and subjecting the mass to pressure and heat, plumbago crucibles being used to give a final firing to pencil leads. In the one city of Nürnberg 250,000,000 of pencils, worth £400,000, are turned out annually, so that Mr. Ferguson felt justified in estimating the production of the whole world at 1,900 millions, worth at least £1,500,000. Clay in varying quantities is used to give adhesion to crucibles, but those with the largest proportion of plumbago are of course the best.

To quote again:—The Canadian and United States plumbago is of as pure a quality as that of Ceylon, but good as the American ore is, when freed from the rock in which it is generally scattered after the fashion of mica, I suspect the high cost of the labour necessary for first mining and then separating the mineral by the wet process—for the dry has proved a failure—will prevent continued and successful competition with Ceylon. We shall soon see, however, for the Joseph Dixon Crucible Company had produced in 1882 a quarter of a million pounds of native plumbago, against 16,000,000 pounds imported from Ceylon, and a determination to "go ahead" was expressed. Some as yet unthought of machinery, cheap chemicals, and appliances must, however, be brought into play before the pure, massive Ceylon product and our far cheaper labour are distanced in the race. And if, as Professor Dawson states, some of the Canadian ore is fibrous enough to indicate by its texture its vegetable origin, there is room to suspect that, however pure the mineral may be as carbon, its mechanical condition cannot be so good as that of the more highly crystallized Ceylon plumbago. One important element in the question is, that, according to our American friends themselves, enterprise and competition have had such influence, that Ceylon plumbago can now be obtained by them at 25 per cent of what it cost some years ago.

The effect of compelling demand for the substance, however, between 1850 and 1870, chiefly on the part of the Battersea Crucible Company in England and the Joseph Dixon Company in the United States, was to enhance the value of the ore to such an extent in Ceylon as to produce temptations to cheating, which the native headmen, whose business it was to weigh the output and collect the royalty at the pit's mouth, were unable to resist. These estimable servants of Government cheated the diggers out of bribes by threatening to report them as having surreptitiously removed plumbago on which royalty had not been paid, and they impartially educated Government by accepting bribes to largely under-report the quantities really dug and removed. The Customs figures enabled the Government authorities to appreciate the vast extent to which the demoralizing system had gone, and so in 1873 legislation was initiated, the main object of which was the collection of the royalty at the custom-house—a mode in itself far preferable to the direct system of collection previously in force, and securing every sixpence of royalty due, because, practically, every hundredweight dug is exported, the quantity as yet used in local foundries or for any local purpose being quite insignificant. I believe a few crucibles for gold and silversmiths' use are locally made, and the result of inquiries made by Mr. W. P. Ranasinghe at my request, is that Ceylon potters occasionally employ the mineral for giving a glaze to pottery, as is the practice in India.

The mercantile community strove hard in 1873 to make out a case for the entire abandonment of the royalty, but the Press supported Sir William Gregory's Government in resisting the pressure brought to bear in this direction, only that the *Observer* strongly urged a rate so low as 15 per ton, which after four years' experience of 110 per ton, under which exports declined, was conceded in 1877. Under this

rate, which is still in force, the exports more than trebled in the six years between 1878 and 1883.

Then follows a description of the largest plumbago mine in Ceylon:—

Mr. De Mel has been amongst the most prosperous of all who have engaged in the plumbago digging enterprise in Ceylon, his prosperity being mainly due to the rich yield of his Kurunegala district mine, which is by far the most important in Ceylon, having been sunk to a depth of 450 feet near the base of a hill, Polgola, which seems to be largely composed of fine quality plumbago. From this mine Mr. De Mel obtained an average of 800 tons annually for eleven years, his profits, he authorizes me to say, being at the rate of £2,000 per annum. No wonder if, notwithstanding lessened production and profits in the past two years, connected with this mine there is a steam crane for raising water and a considerable length of Deauville railway for the carriage of the ore from pit mouth to cart, or that the enterprising owner has commenced a base level tunnel at an estimated total cost of £2,000 to free and keep the mine free of water, whether the result of springs in the rocks or of monsoon rains. The effect of the latter during the recent exceptionally heavy burst of the south-west monsoon in May was to fill up the pits and put a stop to digging everywhere. This, irrespective of a fall of £2 per ton from the price to which the mineral had been sent up the warscare.

The tunnel in Mr. De Mel's mine, when completed, will not only carry away water but facilitate the output of mineral from the lower which are generally the richer strata, besides ventilating the mine so as to prevent injury from mephitic gases or inconvenience from the smoke of the explosives employed in blasting. The draft will also all-viate the heat in the interior of the mine, which the workmen now complain of as sometimes intolerable. For blasts under water large quantities of dynamite cartridges are employed, in addition to gunpowder used in portions of the galleries comparatively free from moisture. The wages paid to diggers in this mine, chiefly lowcountry Sinhalese, vary from 9d. per diem for coolies to 11 for those who perform the boring and blasting operations. In the Pasadu Korale there is a system of payment for labour by shares in the profits, after all preliminary expenses defrayed by the capitalist have been reimbursed.

The hill in which Mr. De Mel's mine has been opened—Mr. W. A. Fernando having another at a higher elevation than De Mel's with a depth of 350 feet—seems to be permeated in its whole extent by generally horizontal veins of the richest plumbago, associated with beautifully snow-white crystalline to semi-opaque quartz, the latter occasionally showing specks of garnet and bands of soapstone, and Mr. De Mel brings to the surface practically pure plumbago. As regards the generality of pits, he agrees with the estimate of Mr. W. W. Mitchell (who has probably purchased, prepared and shipped to America as well as Europe more plumbago than any European merchant who ever resided in Ceylon,) that the (strange matter in the shape of earth and rock brought to the pit's mouth is equal to one-half of the whole, about 10 to 15 per cent being the proportion carried to Colombo and separated from the ore in the preparing yards. Mr. Fernando's estimate, however, of foreign matter brought to Colombo is 5 per cent for pieces of quartz round which plumbago adheres, and 2½ per cent for minute fragments of silica, iron, &c., mixed with the smaller pieces and dust. Any person who has witnessed and appreciated the difficulty and the expensiveness of the processes whereby small fragments of rock are separated from the lower classes of plumbago in Ceylon, can well imagine the obstacles to profitable separation of the mineral from rock in America, where there are no masses but only scales of the mineral distributed throughout the rock.

Then followed a notice of a mass of plumbago only 14 lb. short of 6 cwt. which De Mel exhibited when the Prince of Wales visited Colombo, and the statement that large masses are sometimes although pure carbon yet of such hard consistency as to be commercially valueless. Mr. Ferguson suggested that this form of plumbago and not the softer kind should be used for sculpturing elephants and other objects. Then followed a description of the various systems in force in the three Provinces to which plumbago mining is practically confined. In the North-Western Province all the mines are on private property. In the Southern

Province only licenses to dig are charged, at the rate of R10 per annum, but no rent. In the Western Province, besides the charge for licenses, a rent-royalty of one-tenth of the plumbago dug or its equivalent value is levied, which adds considerably to the revenue. Sir Wm. Gregory in 1873 announced: that the policy of the Government would be to lease and not to sell plumbago lands, so as to prevent a monopoly in the hands of the rich. Mr. Saunders is, however, in favour of selling such lands outright, but only in small lots. He quotes in favour of his view the results of a sale in 1880, when a lot of 1 acre, 1 rood and 13 perches realized RS,150. As a general rule the rent-royalty exacted in the Western Province is somewhat below the sum of R5 per ton charged on export, so that the total impost on such plumbago is R10 per ton. Owners of private mines and diggers on Government lands in the Southern Province pay only R5. Mr. Ferguson said of the leasing system:—

The merit of the system, provided the rent-royalty is moderate, is that the lessee of the land pays only and just in proportion to the productiveness of the land he has leased, payment being accepted in money or in kind. At the end of each year the lease can be either renewed or abandoned, and plumbago lands which have been for a certain time abandoned, and which evidently do not contain appreciable quantities of the metal, are sold on the terms applied to ordinary Crown lands.

At present, as sources of plumbago the North-Western Province seems entitled to first rank, the Western following as a good second, while the Southern is a distant third, the Galle Customs returns showing an export of one-tenth of the whole plumbago sent away against nine-tenths from Colombo. Three fourths of all the plumbago exported from Ceylon are dug in the Kurunegala and Kalutara districts. It was then noticed that exaggerated figures have appeared in the bluebooks as to the number of plumbago mines in the island, from the inclusion of abandoned pits and mere holes. While the pits opened from first to last must amount to thousands, those being worked at any one time may be taken at a few hundreds, from 500 to 600. Water in the soil and from rainfall is the great difficulty. To quote:—

As a general rule, graphite seems to exist not far from the surface, on which its presence may be revealed through fissures, while, in regard to this mineral as well as gold and other ores, indications in streams guide explorers up to the including rocks, generally quartz gneiss, in which the mineral is embedded or diffused. Mr. De Mel tells me that very good plumbago is often found near the surface, but that, as a general rule, the lower the digging operations go the better the quality and the larger the quantity of the mineral. Of course, the purer the finds are, and the larger the masses the better, but a visit to any of the preparing yards in Colombo will show that besides the cost of prospecting and mining and the uncertainty of ultimate success, a good deal of expense is involved in conveying a considerable proportion (already noticed) of extraneous matter to Colombo, there to be hammered, cut with small axes, picked, sifted, and washed out.

Still, with all its drawbacks, the plumbago enterprise is valuable to the country, not only for the revenue it yields but for the generally remunerative employment it has given to many thousands of the population (from 15,000 to 20,000 men, women, and children, probably, including cartmen and carpenters), especially since the period when the collapse of the once great coffee interest led to so much distress in the country. The Kurunegala Administration Report of 1873 stated that in that district alone the plumbago industry had given employment to some 5,000 persons. The Galle report for 1872 estimated that each mine required from two to eight or ten miners, and even up to fifty or sixty, at high wages. At a period when the plumbago industry was at the height of its prosperity, Mr. De Mel and other mine owners had almost concluded an arrangement with Messrs. John Walker & Co. for a light railway line from the mine region to the Government railway. Depression in prices caused this design to fall through, but the day cannot be far distant when Kurunegala at least will be connected with the Government railway system at Polgahawela, forty-five miles from Colombo. The Western Province plumbago found in the Pasdun Korale (a korale which is famous for the quality as well as the quantity of ore it produces) does not come on the railway at Kalutara

Once it is loaded in boats it comes by water all the way to Colombo.

A return furnished by Mr. Pearce shows that nearly one-half of all the plumbago exported from Ceylon comes on the railway at various points, mainly at Polgahawela, the quantity so carried in 1882 being no less than 5,612 tons.

To show the vicissitudes of the plumbago enterprise, I may quote from the Sabaragamuwa Report of 1873 to the effect that plumbago, which formerly sold at R200 per ton, then realized only R90, while the working expenses had considerably increased in consequence of the enhanced prices of labour. It will be remembered that 1873 was the year in which the change was made to the collection of royalty at the Custom-house, in anticipation of which the great manufacturers in Britain and America had provided themselves with stocks of the mineral. Hence a fall in exports and prices. Eleven years subsequently, in 1883, Ceylon sent away her largest export of plumbago, but the depression had even then set in, which led to greatly reduced shipments in 1884. In the one matter of cask-making, however, the increase in the export of plumbago during the past five years must have largely filled up the void created by the decrease in coffee. Now, one of our most inferior timbers, can be utilized for plumbago casks and as the casks are uniformly made to hold a quantity somewhat over a quarter of a ton (5½ cwt. nett), an average of 45,000 casks per annum for the past five years, or a total in the quinquennium of 225,000, must have given, in their manufacture, remunerative employment to a considerable number of carpenters who had previously been largely dependent on cask-making for coffee.

The industry now so wonderfully successful in the North-Western Province is apparently of quite recent origin. Gate Mudaliyar Jayatilake states in reply to my queries as to whether there were anything hereditary, or a system of payment by shares, amongst the mining cases:—

"All the plumbago quarries that are now worked in the District are purchased from the Crown. No licenses have ever been applied for or granted to dig plumbago. The diggers are paid wages, and they are called from the Siyane and Hapitigam Korales, in the Western Province. Very few Kandians are employed, as they are not handy in blasting and excavating any depth of more than 15 or 20 feet."

I may add that but few Tamils are employed in the Ceylon plumbago mines, which are, I believe, exclusively owned by Sinhalese, although no doubt the ubiquitous Chetty of Southern India is interested in the recovery of advances made or supplies furnished in some cases.

To Mr. G. S. Williams, the Acting Government Agent of the North-Western Province, I had previously been indebted for responses to my questions, thus:—

"The pits are about sixteen miles north-east of Kurunegala on the Dambulla road. There is a good resthouse at about the 12th mile, and the journey in decent weather is easy enough."

"The trade altogether failed last year—I mean no digging was done—on account of the fall in price, but this year operations have been resumed, and I am told that about 2,000 men are employed. The plumbago is found in rocky ground in which are very large crystals transparent like Derbyshire spar.* De Mel is the owner of the principal pit. The resthouse is at Gokkerella. It is not mentioned in Fyers' Itinerary, but is between Polgola (about a mile beyond it) and Ambanpola. On page 20 of the new edition (1881), Part I, you will find Wetakeyyapota, which is 15-55 miles from Kurunegala, and 0-55 mile beyond that, or 16-10 from Kurunegala, 'minor road to plumbago pit on right.' There are other plumbago pits, somewhat by the roadside."

It thus appears that the best deposits of plumbago at present worked in Ceylon are situated at the base of the north-western portion of the mountain zone. The mineral exists at high elevations, up to Nuwara Eliya indeed, but apparently not in paying form or quantity. It would appear that while the veins of plumbago run generally from south to north in the Western Province, their direction in the Kurunegala district are from east to west.

It seems possible that if digging for gems and plumbago continues on a large scale, and becomes widespread, legislation may be needed such as exists regarding the pro-

* Crystalline quartz, of course, as lime taking the form of spar, seems to be non-existent in Ceylon?

tection of wells, and that measures to prevent accidents from subterraneous blasting and the collapse of tunnels, as also to secure free ventilation, may be necessary. Though not so much so as gem-digging, plumbago mining is, no doubt, largely a speculative pursuit, involving the loss and demoralization which ever accompany gambling pursuits. The ultimate result is, however, beneficial to the people and the country.

From some of the Administration Reports consulted, it would seem that the plumbago industry is a recent one in the district of Sabaragamuwa, although the existence of the mineral must, surely, have been revealed to the gem-diggers who have for ages been engaged in searching for the sapphires and rubies for which the region around "the city of gems" (Ratnapura) is so famous.

A vivid idea will be formed of the extent to which Government—that is, the public—were formerly cheated under the system of collecting the royalty at the pit's mouth, when it is mentioned that while cwt. 226,000 were exported in 1869, the royalty recovered was only £16,000, against £65,000 on cwt. 263,000 in 1883, the rate in the latter year being only one-third of that in the former.* The extreme rate of 30s per ton in 1869 evidently proved an irresistible temptation to diggers and headmen, and the royalty recovered was only one-tenth of the sum which ought to have been collected.

As has been proposed in the case of chips in the cinnamon trade, it would almost seem desirable that low quality dust should be excluded from the exports. Buyers are strongly inclined to confine their attention to lump of best quality, and I have heard that some of the local dealers have injured their own reputation, and that of the article in which they deal, by mixing lower qualities with the higher. As matters stand the proportions in which the mineral seems to be exported are:—lumps, 1st and 2nd quality, 50 per cent; chips and dust, each 25 per cent; so that dust is only one-fourth of the whole. In the home market during the past five years of unprecedented output I am informed that prices have ranged from £20 per ton, the highest for lump, down to £10. In Colombo, apart from the exceptional case in the experience of Mr. W. A. Fernando, already mentioned, the highest prices ever known are stated to be £320 per ton for fine, £270 for ordinary, £95 for dust. In the old sailing ship days plumbago was taken at an exceptionally low rate of freight as "dead weight." Since 1880 the average rates for a ton of 20 cwt. have been:—steamer 40s; sailer 35s.

The United States are our best customers in the case of plumbago, the Ceylon form of which the late Mr. Joseph Dixon saw and appreciated in 1827, and of which he secured a first shipment in 1829. In 1882 the quantity received in the United States from Ceylon was stated at 16,000,000 lb., and of the comparatively small quantity of 22½ millions of pounds sent from Ceylon in 1884, more than half went to the United States. But a memorandum showing the various countries for which the plumbago exported in the past five years was destined will clearly indicate how important a customer for our mineral we have in the United States with its large steel manufacturing industry. The general result is that of the whole export of 1,170,000 cwt. in the five years, 641,000 (or very considerably more than one-half of the whole) went to the United States, the United Kingdom taking the bulk of the remaining 529,000 cwt.

Out of an export of 263,000 cwt. in 1883, Britain took 119,000 and the United States 142,000, leaving only 3,000 cwt. for all other places. The memorandum referred to is appended as a note.† It seems probable that three-

* How striking is the illustration here afforded of the value of indirect (and especially Customs) taxation, rather than a direct levy, in the case of Orientals. No greater fiscal boon could probably be conferred on the people of India and Ceylon than—if it were possible—the collection of all Government dues through the Customs Department, so saving an amount of oppression on the one hand, and of bribery and corruption on the other, of which European administrators never get more than a faint idea.

† Plumbago exported in each of the last five years, showing the countries to which the mineral was shipped:—

fourths of all the plumbago which Ceylon exports is used in the great crucible factories of Britain and the United States, that established by the Messrs. Morgan Bros. at Battersea and the crucible factories of Jersey City, New Jersey.

Notices then followed of the Battersea Crucible Works, and those of the Joseph Dixon Company, New Jersey, and it was stated that a vast fund of information regarding plumbago and the very numerous and varied uses to which it is put were quoted from descriptions of those extensive establishments.

The Battersea Works were founded by the Brothers Morgan in 1855. The American establishment had been at work long before this period, but no doubt its productions did not go beyond local demand, for in a notice of the Battersea works we find it stated that previously to 1855 crucibles were almost exclusively imported from Germany. Now that country, together with other centres of industry on the Continent, is principally supplied from Battersea, where crucibles are turned out at from 8d per dozen, up to a gigantic melting pot costing £65s and capable of taking in 1,000 lb. of steel. Such a crucible can bear from 8 to 10 meltings, while in the case of gold a crucible taking in 1,200 ounces can sometimes stand seventy meltings. So in the case of brass, while crucibles for assaying the precious metals are very carefully manufactured, being rendered porous by the use of charcoal. The absence of coal fuel from Ceylon is probably a fatal objection to local iron or steel manufacture or any extended scale, but for small quantities of superior steel for special local use, I would, with some diffidence, suggest that crucibles composed of our indigenous plumbago and kaolin clay, both abundant and cheap, might be profitably used. The existence of "millions of tons" of iron ore in Ceylon is not so apocryphal as that of anthracite, and those who owe their origin to Britain are not likely to forget that her wealth in iron quite casts into the shade all the treasures of the diamond mines of Golconda and the gold diggings of California and Australia.

Mr. Ferguson said, commenting on a very able paper by Mr. Orestes Cleveland, of the Joseph Dixon Company:— "In most of the works consulted in the preparation of this paper—and they have been many and various—the credit of having first made and used plumbago crucibles has been given to the Germans. Mr. Cleveland awards the credit to the Dutch, and it is certainly significant that the Dutch name for the mineral should be *potlood*, or pot lead, the lead of which crucibles are made (?)."

Again:— "And so our plumbago, like our coffee, suffers from the 'ways' that are literally 'dark' of the adulterators. Mr. Cleveland, in a kind of despair, exclaims:—'Perhaps no article except mustard can be so successfully adulterated as plumbago.' He means, of course, rot stove polish, because adulteration in the case of plumbago used for crucibles would soon be betrayed in the trial by fire, one great value of the pure plumbago in crucibles being that it conserves carbon in steel when being melted."

As a lubricant for metal surfaces, journal boxes, carriage axles, and all metal bearings, we can easily understand why only the very finest plumbago should be used, the choicest lumps being pulverized till the particles will not glisten but the mass becomes a dead black. It cannot, Mr. Cleveland states, be made fine enough by bolting (he means sifting through silk), but must be floated either in water or air.

I notice, however, from advertisements in the American papers, that "mica grease" as a lubricant is competing with plumbago, but how far successfully I cannot say.

What I know is that the writer of a recent article on American minerals strongly supports Mr. Cleveland's view as to the great superiority of plumbago as a lubricator. I am not aware that it is so used to any extent in Ceylon, either in foundries or on the railways, although if all stated regarding its value be correct, Ceylon plumbago ought to be much more largely used in Ceylon than it is at present, as a lubricant and for other purposes. For all uses it would seem that grinding to extreme fineness is essential.

We now, said the reader, come to some miscellaneous and curious uses to which plumbago is put, the mineral being applied to articles so different as musical instruments, hats and boots, bottles, paint, boats and yachts. Listen:—"For pianos, plumbago is employed to coat the bridge over which the wires are drawn, because of its perfect lubrication; it prevents the wire from adhering to the wood, and should be as free from impurity as that used by the electro-typist, but need not be pulverized as finely. For organs, it is used to lubricate the sides, and should be the same as that used by piano-makers. The German black-lead imparts a peculiar tone to the colours and a softness and smoothness to the touch of felt hats. The very best lump only should be accepted. As it has once been washed and dried in lumps, they will readily separate again in water, and no pulverizing is needed. For colouring dark glass for carboys, bottles, &c., the best German black-lead is used in lumps, but no inferior grade will answer. For paint, plumbago has long been known as possessing great value. The elements do not exhaust it, water sheds from it as from oil itself, and fire does not affect it. The grade need not be the highest. For the bottoms of boats and yachts it has long been used, especially for racing boats; but only the best Ceylon plumbago, very finely pulverized, is valuable."

A substance which, used as a paint, resists the action of the atmosphere and is both waterproof and fire-proof, is surely of great economic value, and ought to be specially useful as paint for the numerous tea factories erected or in course of erection in Ceylon.

To quote again:—

Mr. Cleveland's very interesting and valuable notices of the American Crucible Company, and their varied manufactures of plumbago, is supplemented and brought down to so late a date as 1883 by the writer (Mr. John A. Walker) of an article on Plumbago in a volume on the "Mineral Resources of the United States," prepared by the National Geological Survey Department, and supplied to our Library by the Smithsonian Institute, to which my attention was attracted by our Honorary Secretary, when he asked me to write this paper. In the summary prefixed to this volume it is stated that the amount of graphite mined in the States in 1882 was 425,000 lb., worth crude at the point of production 34,000 dollars, equivalent to about R70,000. During the first six months of 1883 the production was estimated at 262,500 lb., worth 21,000 dollars. From Mr. Walker's detailed account we learn that graphite is, as a mineral, widely distributed in the United States; as an ore it is found in but few places in sufficient quantities and purity to be profitably worked.

The attention being paid to the mineral in America may be judged from the fact that samples had been received and reported on by the Joseph Dixon Crucible Company from no fewer than 33 localities between October 1877 and January 1882.

The Joseph Dixon Company had laid themselves out to produce 500,000 lb.; altogether 525,000 lb., valued at 8 cents per lb. Let us say 18 cents of our ropee currency, and we get the high value (founded on cost as well as quality?) of R20 per cwt., or R400 per ton. The local production, however, was certainly not much to place against 16,000,000 of pounds imported from Ceylon in 1882, with considerable quantities in the two following years.

Referring to analyses of Canadian and Ceylon graphites, quoted from the American authority, Mr. Ferguson said:—"Both are almost absolutely pure, and did the Canadian and United States mineral occur in such a form in the enclosing rocks that it could be cheaply mined and prepared, there would of course be an end of the export of Ceylon plumbago to America. But if, in America, plumbago, however pure, is only distributed in the proportion of 8 to 15 per cent mineral to 92 to 85 rock, those connected with the Ceylon enterprise need not, it would seem, concern themselves

greatly with the competition in America of indigenous ore with that from our island.

Under the heading "Manufactures" there is interesting summarized information, which I quote:—

Proportionate Amounts of Graphite used for Different Purposes.		Per cent.
Manufactures.	Kinds of Graphite used.	
Crucible and refractory articles, as stoppers and nozzles, crucibles, etc.	...Ceylon, American	35
Stove polish	...Ceylon, American, German	32
Lubricating graphite	...American, Ceylon	10
Foundry facing, etc.	...Ceylon, American, German	8
Graphite greases	...American	6
Pencil leads	...American and German	3
Graphite packing	...Ceylon, American	3
Polishing shot and powder	...Ceylon, American	2
Paint	...American	1
Electrotyping	...American, Ceylon	1
Miscellaneous—piano action, photographers', gilders' and hatters' use, electrical supplies, etc.	...	1
		100

A table like this will give many of the readers of this paper a new view of the multifarious uses of the mineral carbon called plumbago. It will be observed that, next to the manufacture of crucible articles, the great use of the mineral is for polishing and preserving from rust the ranges of stoves and other cooking appliances, which contribute so much to the neatness, cleanliness, health, and comfort of modern abodes. The proportion used for this purpose in Europe—in Britain at least—cannot certainly be below that given for the United States. There are graphite greases as contradistinguished from lubricants, and the mineral seems to be used for the packing of engines. From the largest forges where tons of steel are manufactured in Pittsburg, down to the studio of the photographer and the shops of the gilder and hatter, plumbago is of valuable use. And not only is it called into requisition to produce the highest order of steel guns and steel armour for war-ships, but it is good for polishing the sportsman's powder and shot. Gunpowder used for blasting operations is also greatly improved by receiving a glaze or varnish of graphite, the philosophy of the operation being that thus the grains are prevented from absorbing the moisture which exists in mines and quarries.

Graphite enables the electrotypist to prepare and present to the world, cheaply and at will, casts of coins, woodcuts, copperplate maps, &c., equal in the most minute and intricate detail to the most highly prized and costly originals. But next to the boon which the real discovery of anthracite or natural coke in Ceylon would be, is the certainty, of which we are assured, that in our teeming supplies of plumbago the tea planters of Ceylon can get a paint for their stores, equal in its fire-resisting properties to asbestos paint. If this should prove to be correct, and we see no reason to doubt the statement, the prospect is that Ceylon will be speedily exporting, instead of importing, fireproof paint. Mr. Walker may well say in conclusion:—

"The growth of the graphite industry has kept pace with the age, each new development in metallurgy and engineering offering some new field of usefulness for graphite. For instance, it furnishes the pos for the manufacture of cast steel, and the nozzles and stoppers used in the Bessemer process. It is used in the manufacture of electrical supplies, &c. Fifty years ago graphite was little known and mis-named. Now it is constantly increasing importance. From an insignificant beginning in the present century the industry has grown to its present proportions."

A list is then given of twenty-five American firms engaged in the plumbago industry, of which the Joseph Dixon Company of Jersey City, New Jersey, takes the lead, employing 500 hands in the manufacture of everything for which graphite is used. The same number of hands finds employment from the Eagle Pencil Company; while A. W.

Faber, probably an immigrant or descendant of an immigrant from Nürnberg, employs 150 persons in his pencil factory. Others employ lesser numbers, six firms giving crucibles as their exclusive manufacture; three, lead pencils; four, foundry facings and lubricants; seven, stove polish and lubricants. It will thus be seen that except in the branch of pencil-making, and perhaps electrotyping, the New World has gone, or is rapidly going, in advance of the old in the plumbago industry, which means corresponding advance in the steel industry. It is surely a striking incident in the romance of commerce that this ancient eastern isle of "Serendib," the scene of the mythical adventures of Sindbad the Sailor, should be the main source of supply of an article so useful in the industries and elegancies of life, the appliances of peace and war, and the pursuits of the artist and literary man, not only to countries in the eastern hemisphere, but to the regions of the Far Western world.

Having noticed the leading establishments in Europe and America, where our Asiatic ore is so largely utilized, let us now turn to one of the compounds, or yards, with its brick and tar "barbecue" or platform, and surrounding sheds, in which Sinhalese men, women, and boys prepare, assort, and pack the mineral when received in Colombo from pits, none of which are nearer than thirty miles, and some of which are so distant as the District of Hambantota at the eastern extremity of the Southern Province. The chief exhibitor of plumbago at the Melbourne Exhibition of 1880-81 was Mr. W. A. Fernando, of No. 1, Brownrigg Street, Cinnamon Gardens, Colombo, and a description of his establishment, which the editors of the *Ceylon Observer* gave in their paper of August 12th, 1880, is, in all substantial details, correct in August 1885.

The description was then stated to be reproduced, and the closing remarks were to the following effect:—

We now feel confident that the number to which the present levels employment was much under-estimated in 1880, and that, considering that 5,000 persons were said to be engaged in mining in one year in a single district of the North-Western Province, our higher estimate of an average of 20,000 men, women, and children at present engaged in the various operations of mining, carrying, preparing, packing, and shipping Ceylon plumbago, is not beyond the truth.

It is curious that the Sinhalese women should entertain a prejudice against plumbago as poison, seeing that it is included in the native pharmacopœia. We should have expected members of what Artemus Ward called "the female sex" to have been more troubled about the soiling of their persons and clothes by contact with the mineral, but in truth a coating of the shining ore, while easily got rid of by the use of water, produces no such hideous effect as that so familiar to us now in Colombo of the truly mean-looking cooling coolies, when proceeding to their houses after loading or unloading the bunkers of one of the multitude of magnificent steamers which now resort to our harbour. A polish of person, if not of deportment and manners, is the result of working amongst even the dust of plumbago, and it is curious to see the dark-skinned coolies of the plumbago stores walking about with their bodies shining as if they were electrolyte statues vivified.

In its further metamorphic progress from vegetable to mineral, the form of carbon we call plumbago has certainly taken a great step in advance of the carbon we call coal, in getting rid of smoke entirely, and also of dirt. Coal, however, cannot be accused, as plumbago justly is, with causing a whole roof-covering of tiles suddenly to fall off, from the slipperiness created by wind-blown particles of the greasy mineral. We were greatly amused by Mr. Fernando's statement at the time, but others, Europeans included, who have to do with the preparation of plumbago, have fully confirmed his representation as to the incompatibility of plumbago dust and tiled roofs. In this connection we would advise visitors to plumbago compounds to be careful how they bear themselves in such slippery places. A sudden step on to the polished platform may end in an unedified tumble. And this reminds me of the sensation produced many years ago in Mining Lane by the peculiar appearance of some Ceylon coffee which had been dried on a barbecue where plumbago had been previously spread. An attempt to impart a factitious colouring to the beans was suspected until the requisite explanation was afforded.

As this paper may be read beyond the limits of Ceylon, it may be as well to explain that *cajayan* is a word, curiously enough of Malay origin, applied in Ceylon to plaited branches of coconut palms, used for roofing houses, sheds, carts, &c. *Compound* is a yard or enclosure, and *barbecue* is a platform.

I have already shown, what I may be allowed to repeat, that for the average shipments of 12,000 tons per annum of plumbago from Ceylon for the past five seasons, the yearly supply of casks must have been 45,000 and that the manufacture of these alone must have given welcome and remunerative employment to carpenters out of work by reason of the partial collapse of the staple colonial industry; this apart from the large numbers of persons (estimated above at 20,000) engaged in mining, carting, preparing, packing, and shipping the mineral.

Let us, therefore, hope that the plumbago industry of Ceylon may continue to prosper and extend, not as the result of wars or rumours of wars, but because of the steady and beneficial progress of the peaceful industries and arts which contribute to the elevation of humanity in all that constitutes comfort, happiness, and means to cultivate the loftier instincts and destinies of our race.

THE CULTIVATION OF LIBRIAN COFFEE in the Mergui experimental plantation in Burma continues to be successful, but it is yet doubtful whether Arabian coffee will thrive in Mergui. The experiments in the cultivation of cocoa, nutmeg, and vanilla tend to show that these trees can probably be grown and propagated successfully, but further trials in the propagation of the nutmeg, and the foundation of the vanilla plant are necessary to demonstrate this.—*Madras Mail*.

PUMPKINS AS FODDER.—Attention has been directed in Queensland to the value of pumpkins as fodder for horses. One writer says:—"I consider pumpkins a first-rate winter feed, keeping the bowels open and giving a gloss to the coat. It is very hard to get horses to take to them. I have tried almost every way I could think of—chopped the pumpkins up and given it with chaff and corn put salt in the nose-bags, boiled it—to no purpose. We had a good supply last winter, and wanted to feed our horses on it but they would not touch it. The only way is to get a horse which has been fed on pumpkins and let them go with your horses. When once a horse takes to them he becomes very fond of this feed. For feeding prize stock they are of great value. One boiled pumpkin is worth two uncooked ones."—*Madras Mail*.

THE TEA TRADE IN AUSTRALIA.—Mr. Jules Joubert writes from Melbourne to a *Cadetta* paper:—"Sir, During my stay in India I used recommending efforts to induce parties interested in the tea trade to alter their tactics and enlarge their business with our colonies, where a large and profitable market exists for Indian teas, provided it be properly and judiciously exploited. May I once more venture to advise tea planters or tea syndicates to open in the great centres of population in these colonies retail depôts of the genuine article? Let a trial be made in Sydney and Melbourne first; the expense would not be very great. Indeed I know many trustworthy people in each city who would gladly undertake the 'business' and make all necessary advances, provided an agreement be entered into by some responsible firm or syndicate to keep them supplied with regular shipments. As it is, the majority of the tea shipped is used for mixing with rubbish. The consequence is that 'Indian teas' are not in the demand they would be if they were sold in their unadulterated state, when I feel confident they will very soon take the lead of all others." [We believe that Messrs. James Hunt & Co. of Melbourne and Messrs. Inglis, Brown & Co. of Sydney have done so and are doing their best, but the Australian colonists do not yet extend giving an adequate price for a good article, having been so long accustomed to cheap China rubbish.—Ed.]

CEYLON TEA IN THE LONDON MARKETS.

We give prominence and specially call attention to the letter with which the eminent firm of London Brokers, Messrs. W. J. & H. Thompson, have favoured us by this mail. Their remarks will be carefully weighed by our planting readers, and it is most encouraging to note that we have in Ceylon—in the managers of Loolecondra and Blackstone estates—the models whose practice may be copied with advantage in regard to the preparation of our teas. We notice that a respected member of the Maskeliya Planters' Association has given notice of a motion "that a Sub-Committee be formed in order to obtain all possible information from tea-makers, in and out of the district, on the subject of Tea-planting, Manufacture, Transport, Machinery, &c." This is a good idea, and we would suggest that as the most practical step for the present, the Sub-Committee of the Maskeliya planters should resolve themselves into a Deputation to visit—with the permission of the proprietors of course—the Loolecondra and Blackstone estates and draw up a report on the result of their observations and on the "wrinkles" which we have no doubt the managers would be glad to point out or illustrate as aiding to secure the marked success referred to by Messrs. Thompson. There can be no particular mystery; because as is mentioned, other well-known marks of local estates approach closely to the fine prices received for the teas in question, and nearly all our bearing tea plantations have at one time or another secured tip-top prices, although with the greater rush of crop, and perhaps less care in manufacture, a falling-off in price has been, in some cases, latterly noticeable. Care, patience and intelligence, in fact, comprise all the mystery, and our rising generation of tea planters will do well to lay to heart the lesson which Messrs. Thompson considerably afford in the following letter:—

CEYLON TEA IN THE LONDON MARKET: REPORT BY MESSRS. W. J. & H. THOMPSON.

33, Mincing Lane, 7th August 1885.

To the Editor, "Ceylon Observer."

Dear Sir,—We forward herewith a copy of our circular containing details of the important business which is passing in Ceylon Tea. In the last two weeks 5,800 packages have been sold, as compared with 2,400 packages during the same time last year; and it is most encouraging to find that a growing demand enables us to sell these larger quantities without having to make any abatement in the price. The rapid development of the industry is attracting attention in new quarters: that is, among some of the larger consumers, who have hitherto held aloof on account of the unevenness of supply and the difficulty of buying regularly, sufficient for their requirements.

You will observe in our circular a special reference to the teas from Blackstone and Loolecondra estates—these standing away from others in the prices realized. The results are so exceptionally good that information as to the assortment in the invoices is likely to be asked for: we have therefore printed the FULL PARTICULARS—just as the teas were sold IN OUR AUCTION—the transactions, as far as this market is concerned being public.

As it will be asked by many: "In what points are these teas so superior to others?" we would say in anticipation: "In almost every point, which distinguishes 'fine' from 'ordinary' tea." Although of different appearance and type, both the Loolecondra

and the Blackstone teas have a very fine, closely-twisted leaf, quite free from coarse reddish or flaky leaves: the latter has also plenty of bright yellow tip: the firing is perfect, abundance of aroma, without approach to the "scorched" or burnt flavour: the infused leaf is deep reddish with scarcely any of the green or darkbrown leaves usually seen, while the liquors are rich and full, and in each case possess the *distinctive Ceylon flavour*.

These are by no means the only good Ceylons now coming forward, as the quotations for the Kookwood, Glentit, Curric, Barnagalla, KAW, and many others show, but we have written you specially about them as we feel the transactions to be of more than ordinary interest.

The lesson which they teach, seems to us to be the reward in store for those who determine to make "quality" their aim and object—a lesson which we have from the beginning endeavoured to inculcate, and which we are extremely glad to see is being impressed upon planters in the *Tropical Agriculturist*.—We are, dear sirs, yours faithfully,

W. JAS. & H. THOMPSON.

From another well-known firm of Tea-Brokers we have a communication, from which we quote remarks which are also of practical service:—

13, Rood Lane, London, E. C., 7th Aug. 1885.

Dear Sir,—We thank you for your notice of our circular on the subject of Ceylon tea in your valuable paper. In reply to one or two of your observations, we would point out that we suggest that "when necessary an occasional dust should be made": and as to size of breaks we would remark that though in the slack season it is not of so much importance, yet when the large sales begin there are often over 300 breaks for buyers to taste and value between 9-30 and 12 o'clock, and this has to be repeated four days in each week, so that small lots have but small chance of being looked at by the large buyers. We take this opportunity of sending you our circular issued today, and with reference to ours of 24th instant would correct an error in our list of averages, viz: for 51 packages, Abbotsford which should have been 10½, not 9½ as printed.—We remain, yours faithfully,

GOW, WILSON & STANTON.

Apart from the information given in our commercial column, we may mention that the *Produce Markets Review*—the organ of wholesale Tea-dealers—has been declaring that although the Indian tea this season are beyond the average, they are surpassed both by "the new China black leaf and Ceylon teas," which "just now offer much better value than Indian growths." The *Home and Colonial Mail* on this remarks that "undoubtedly Indian tea-planters have very formidable rivals in their Ceylon competitors, and it behoves the former to do their best to maintain their hold on the market." The piece of advice may, of course, be equally applied of our local planting readers, who, we hope, will do all in their power to maintain the prestige of Ceylon teas.

THE ELEPHANT SUGAR-CANE IN JAMAICA.—The Elephant-cane, says Mr. Morris in the report of the Botanic Gardens of Jamaica, continues to maintain its pre-eminence as a rapid grower, with early maturity; but it requires very rich soil, a moist climate, and to be taken off as soon as it is ripe. It "ratons" well the second year, but, like most vigorous growers, it requires to be renewed in the third or fourth year. In favourable localities the Elephant-cane, where it has been tried, throws immense canes, looking almost like clumps of Bamboos; the yield per acre has not, however, been quite equal to the show of canes, but it has yielded at the rate of 2 to 2½ tons of sugar per acre, which is far beyond the average of ordinary canes in Jamaica.—*Gardener's Chronicle*.

CEYLON.

The "Tropical Agriculturist," published monthly at Colombo, Ceylon, by the Messrs. Ferguson, and sold in this country, together with a variety of other Cingalese publications, by Messrs. John Haddon & Co., 3, Bouverie Street, Fleet Street, contains a variety of information valuable to those who engage or intend to engage in tropical agriculture, including principally coffee, tea, cacao, sugar, cinchona, rubber, palms, rice, cardamoms, and a variety of fruits. Its articles teach how a planter should act in reference to the insect enemies which attack the crops, the modes of cultivation, soils, &c.

A pamphlet, also published by Messrs. Haddon, entitled "Tea and other planting industries in Ceylon in 1885," undertakes to show how that Ceylon is "a good field for investment." The question of how much capital is required to start with is often asked as well of Ceylon as of other places, and in reference to Ceylon at a meeting of the Royal Colonial Institute Lord Dunbigh asked the chairman, Sir Charles Clifford, "What capital is required to start in the island as a planter?" to which Sir Charles Clifford remarked that he had also been asked the same question in reference to New Zealand, and he said—

"I will answer it by one short anecdote. I myself took out two servants. They landed in New Zealand both with wives and families, and when they landed they only had their clothes on their back and eighteen-pence in their pockets—that was the whole of their worldly goods. I also knew another man, who had £150,000 when he landed in the colony: In result the one who landed with eighteenpence has now an estate worth £40,000; while the gentleman who landed with £150,000 died a pauper. Anybody with brains can do well; and, of course, anybody with brains and money can do better than in England; but if a man has neither brains nor money, he had better stay in England, where he will have the work-house to fall back upon."

This was a good general answer, but of course it needs a specific answer, for a man having ever so many ounces of brains in his cranium must have some money to make a start with, for if he manipulates his credit arrangements as to mortgages or rental of the soil and buildings, he must have a working plant, and even if that were arranged for, he must have cash for wages and other expenses, and he must make his outs and ins so dovetail as to meet his interest too. It is shown on page 7 that a tea planter having a *tea garden* of 200 acres should have a capital of 5000*l.*, which should give him "20 per cent., or 1000*l.* per annum. On page 51 a smaller capital than 2000*l.* would not be recommended for a cinchona estate of 100 to 150 acres. Ceylon is but three weeks' run from England, and those who do not object to a warm climate might do worse than enter upon the cultivation of some of its attractive crops.—[From the *Estates' Roll* a monthly sheet published by Dowsett & Co. of Landed Investments, &c.]

MANILA NEWS.

(Translated for the "Straits Times.")

PHILIPPINE TOBACCO CONTRACT.—Telegraphic advices have been received announcing that the contract for supplying cigar factories in Spain with 201,264 quintals of Philippine tobacco has been adjudged to the Philippine Tobacco Company at the rate of \$22.75 per quintal.

PROVINCE OF NEGROS.—From Bacolon a correspondent writes to us as follows under date 12th inst.:—There is now splendid weather here for the growing cane crops, notwithstanding a prevalent

scarcity of small coin and the low prices cultivators get for their produce. Greater exertions in cultivating are now being made and more land has been put under cultivation than had been expected. The slight rise in prices setting in at the close of the crushing season has, so to say, not been of much advantage to cultivators from most of them having sold their crops before the rise took place.

NETHERLANDS INDIA: COFFEE DISEASE.

(Translated for the "Straits Times.")

In the district of Assahan, so reports the Resident of the east coast of Sumatra, several Europeans have been looking out for land suitable for tobacco growing with such success that the opening out of several estates there may shortly be expected. On the Esperance Perbaungan estate in Serdang disturbances recently broke out from forty coolies' withstanding the arrest of two of their number by the Controller of Serdang for ill treating a tindal, until the police on the spot making use of their firearms wounded four coolies, put the others to flight, and subsequently arrested seventeen of the rioters. On another estate in Labuan Batu, order was restored without bloodshed by the Lieutenant of the Chinese with the aid of eight policemen, the ringleaders being afterwards duly punished.

By last accounts, the coffee leaf disease has reached Bali. In Java, so says the Sourabaya Courant of the 25th July, matters are going from bad to worse so that should the disease go on at the present rate, not a small tree in mid Java will be free from it within two years. On the Sakiwong estate in Cheribon a complete diffusion apparatus for extracting sugar from cane has been set up and is in full working order by way of trial, the technical difficulties encountered being so far overcome that there is every prospect of the experiment proving successful. Eydman's method for drawing sugar out of canes without cutting them is also being experimented with in Java in combination with Steffen's process for the extraction of that article from molasses. Should these methods stand the test, a grand future awaits cane growing in that island and Java sugar may ere long hold its own brilliantly against beet root, were every effort made to check a disease called *sereh* which by attacking the roots of canes withers and dries up the stalk, no remedy has been found effective in stopping it. This disease has also seized upon maize and growing paddy crops and may result in bringing on famine should it steadily gain ground as at present.

THE TEA REPORT FOR ASSAM.

Taken in the light of recent political events the Assam Tea Report for 1884, which has just been published, is a document of considerable importance. It has already been long known that the past season was a bad one in many respects, prices falling lower than they have done for some years past, and the output of tea falling considerably below the careful forecasts of the Indian Tea Association. The official report on the subject, which is mainly a compilation from the various tea reports from district officers, naturally throws a great deal of light on these points, and it will be read with considerable interest and anxiety by many whose faith in tea as a money-making commodity has received many a rude shock of late. Out of the 970 gardens which exist in Assam, 294 are in Sillhet and Kishar, the Surma Valley, and the remaining 676 are all included in the upper districts, or the Brahmaputra Valley.

This great superiority of the one valley over the other in the number of gardens is not maintained when the acreage under tea and the outturn of tea is compared. Whereas, the gardens of the Surma Valley number less than one-third of the total number of gardens in the province, the acreage under tea in the Surma Valley—which, including both mature and immature plants, amounts to 83,195 acres—is not less than two-fifths of the acreage under tea in the whole province (139,852 acres). Moreover, the area under mature plants in the Surma Valley shows an increase over that returned last year, whereas the same area in the Brahmaputra Valley is decreasing; besides which the area under immature tea in the Surma Valley greatly exceeds that in the Brahmaputra Valley, showing thereby that more capital and energy is being expended on the new *bits* lands in Silhet than on the older gardens of Assam proper. Similarly the outturn of the Surma Valley is more than one-third of that of the whole province, the figures given by the Tea Association, and confirmed by the Tea Report, showing an outturn of slightly over 17 million lb. in the Surma Valley, as against a total of 31½ millions lb. in the Brahmaputra Valley. The moral to be drawn from these figures is that the tea trade of the Surma Valley is rapidly increasing in importance, and that before long the *bits* of Silhet will be formidable rivals to the slopes of the northern hills. After an elaborate explanation of how the apparently large diminution in the area of land held by tea-planters in the province is mostly due to a careful overhauling of registers and correction of statistics, the compiler of the report comes to the conclusion that there has been a merely nominal diminution in the number of gardens, and that, although land has been relinquished, it has been relinquished only in small and really unimportant quantities.

In this the author of the report is almost certainly right, as, while many a garden has struggled against much adverse fortune of late, the managers are still hoping against hope that there is a good time coming, and have not got to that stage in which large retrenchment is absolutely necessary in order to carry on business at all. This question of area is treated of very fully in the report, and as the Tea Association confines itself mainly to statistics of outturn and shipment, and the endless reports of brokers are wholly concerned with these matters, it may be worth while to look into them somewhat more closely. A comparative statement of the land under mature and immature plants for the last six years shows that there has been more planting out done in the past year than in any year since 1880, the total acreage under immature plants amounting to no less than 31,694 acres. At the same time the acreage under mature plants has really increased (the figures for the Lakhimpur district being set aside by the author of the report as untrustworthy) which shows, as is remarked in the report, that the relinquishments of the year have not been sufficient to counterbalance the extensions. Taking the figures of the various districts separately we see that Káchar stands above any other district so far as the area under cultivat on is concerned, having 52,333 acres under both kinds of plant, and is followed in the list by Sibagar, which has 43,882 acres under cultivation, Silhet come third on the list, and Lakhimpur fourth, the other districts following at a very respectful distance behind the last-named. On the vexed question of outturn we have several sets of figures given in the report, from various

sources, for purposes of comparison, and by combining figures given by district officers with those shown in the trade returns and with those given by the Indian Tea Association, we should be able to attain to some considerable degree of correctness. The estimate made by the Tea Association, on May 3rd, 1884, of the crop of the year, gave 33½ million lb. as the probable outturn in the Brahmaputra Valley, and 18½ million lb. as that of the Surma Valley. This estimate was reduced on various subsequent dates, and on May 4th, 1885, the actual outturn was announced to have been 31½ million lb. in the Brahmaputra Valley, and rather over 17 million lb. in the Surma Valley. The figures given by the Assam Government Trade Returns show smaller totals than these, but on the whole attest their correctness. The returns furnished by district officers give a higher total, founded in many cases on somewhat optimistic estimates by sanguine managers. On the whole the figures given by the Tea Association are probably the nearest to the truth, erring, if at all; on the side of caution. The crop of 1883 was returned by the Tea Association as something over 29 million lb. in the Brahmaputra Valley, and something over 17 millions lb. in the Surma Valley. Thus, while the outturn in the Brahmaputra Valley has increased, the other valley's production is stationary for the present, although the rapid maturing of many acres of immature plants will probably soon produce a change in this respect. The total outturn shows an increase of two million lb. over that of 1883, an increase less than that of former years, but one that shows that the demand for Assam teas has not yet been substantially checked. The wonderful development of the Assam trade in the past few years is demonstrated by the fact that an outturn of about 33 million lb. in 1880 has increased to one of over 48 million lb. in 1884.

Taking the outturn of the various districts separately, we find Sibagar heading the list in the position held in 1883 by Káchar, with an outturn of over 13 million lb., Káchar comes next with 12½ millions lb., and Lakhimpur next with 11½. After them *longo intervallo*, come Silhet and Darrang. The outturn in Káchar has fallen from 284 lb. per acre to 272, and the total is diminished by 261 per cent. Sibagar has increased its outturn by 4·96 per cent., and Silhet by no less than 8·08, another proof that the last-named district will become before long one of the most important in the manufacture of tea. The figures for Lakhimpur are unsatisfactory, giving as they do an outturn of 457 lb. per acre, any may be rejected as fabulous. Of the other districts, those in the Brahmaputra Valley show an average outturn of about 324 lb. per acre, and in the Surma Valley Káchar produces at the rate of 272 lb. per acre, and Silhet at 298. These rates are all higher than that taken by the Chairman of the Indian Tea Association in his statement at the meeting of the 26th February 1885. In that statement he gave his reasons for putting the average outturn at 257 lb. per acre, but the present report would seem to show that by an overestimate of the land actually under tea he was led to reduce his estimate per acre unduly. In calculating such an estimate the area under immature plant should not be included, as it produces no tea at all, and consequently if that be excluded the figures of actual outturn given by the Tea Association will show an outturn per acre of 305 lb. This is probably a more correct figure than the one of 323 lb., given in

the report, and shows a considerable advance on the 286 lb. produced per acre last year. The failure of prices last year is too well-known, and has been too sadly commented on to need further remarks. It will be sufficient to state that this report fully confirms preconceived impressions, and goes far to show that the fall amounted on an average to nearly two annas per pound. On the vexed question as to how far the fall in prices was due to the inferior quality of the teas sent forward, the report speaks on the whole on the side of the complaining London brokers. The Chairman of the Tea Association, in his statement above referred to, expressed his opinion that the complaints were unfounded, but in this report we have the Superintendent of a large company, the Deputy Commissioner of Sibsagar, and the Deputy Commissioner of Káchar, all plainly hinting that coarser leaf was plucked, and that quantity was made to do duty for quality. From all sides, brokers, managers, officials give evidence pointing to less careful manufacture, and it is greatly to be feared less Assam tea may be by these means discredited in the home market. The season is shown to have been an unfavourable one so far as climate considerations were concerned, and the red spider and Assam bug blight proved greater pest than usual. The rainfall in all parts of Assam shows great variations from year to year, and even from month to month, and it is seldom indeed that rain is so fairly distributed as to give a year of 'bumper months.' The figures of the export of tea seed show that something like 15,000 maunds were exported in 1884, or nearly three times as much as in 1883. This would show a large demand for Assam indigenous tea seed, and an increasing appreciation of that species of plant. These are the chief points that are dealt with in this important statistical report, but it is to be regretted that some information, which might have been easily compiled as to the ultimate destination of Assam teas was not given. The returns of the Tea Association would show that most markets except that of Great Britain are closed to us. The exports to Australia are, it is true, more extensive than in 1883, but even in 1884 they do not reach two million lb. The exports to America, always insignificant, are dwindling to vanishing point, and 6½ millions of our total output flood the markets of Great Britain. The report is, however, a valuable and satisfactory one, and the repeated thanks given to managers for their submission of returns show that, when returns are of real use and serve some visible end, the tea planter is by no means so contumacious about sending them in as some officials are apt to suppose. The importance of the report cannot be gainsaid when it is considered that, out of some 60 million lb. of tea yearly exported from British India, about 50 million lb. come from Assam, and it is to be hoped that next year's figures will show some decided improvement on those of this year, as although the season of 1884 was not an altogether bad one, it is impossible to say how long some of the gardens and companies that have been of late apparently burying their capital in tea will be able to struggle against the depression from which at the present moment the Indian tea trade is suffering.—*Englishman's Overland Mail.*

BRITISH SCHOOL OF FORESTRY.

It will be of interest to learn what course the Ceylon Government is likely to pursue when the new School or College for the study of Forestry is opened in England. The British in the past, have been so far behind the great Continental nations in the study of this important branch of Agricultural science that it is matter for congratulation that the apathy that has heretofore been displayed with respect to it, is no longer to be permitted to exist. That Forestry, should rank high among those sciences which are submitted to close study has long been acknowledged; but, until the subject was dealt with during the present Session of Parliament, no steps were taken to give effect to that acknowledgment, and we have, as a nation, remained dependent for the training of the officers destined to serve in the Indian Forest Department upon the Schools of France and Germany. Although the scheme for the establishment of a similar School in England is as yet but in embryo, no doubt is entertained, but that it will before very long, become fully developed, and that the Empire will then possess an institution fitted by the varied experience which its Professors will possess to impart instruction of as high a standard as any of those Continental Schools upon which we have had heretofore to rely.

Now, what is to be the course that will be followed by the Government of Ceylon when such a School is established, as to its relations with our own Forest Department? Most of the gentlemen who have acted in the past, as Foresters in guarding and preserving our large reserves of woodland, were, when they entered upon their duties, wholly untrained in Forestry. They had, in fact, to proceed by rule of thumb, or at best upon such acquaintance with the subject of forestry as they could acquire by study of publications relative to the science produced by the Governments of India, France, and Germany. It will not be denied that, so far as it has been possible for them, most of our Foresters have done good and efficient work; but it will be acknowledged even by themselves, we should presume, that they are even yet deficient in many of the branches which go to make up the sumtotal of the acquirements desirable for thorough efficiency. They have had to learn their business at the expense of the colony; for during their training it is impossible but that many mistakes must have been committed by them. Indeed, Mr. Vincent's Report on the Forests of Ceylon proclaimed and sustained such an indictment; and, if this is to be removed in the future, it is evident that it can only be done by restricting further admissions to the Department to those who have become conversant with their work before responsibility is entrusted to them. In this light, a recent appointment must be excepted, for it is well-known that Mr. Alward had a special training as Forester before he came to Ceylon.

We learned from Mr. Vincent's Report before alluded to how varied are the attainments necessary to constitute a thoroughly efficient Forestry Officer. Forestry is like all other professions: proficiency in it does not and cannot come by intuition. It involves not only questions to be dealt with by the scientific Agriculturist, but others of a purely economic character, the knowledge of which can only be acquired by study under those whose experience had been large and varied. To those who have attentively read Mr. Vincent's Report the importance of this division of the profession of

Forestry will have been strikingly apparent. The course to be followed in dealing with our forests must be largely dependent upon the condition of the markets in which their produce is to be disposed of. It is manifestly injudicious to foster the growth of timber which at maturity costs more to remove to our coasts than it will fetch in the markets of India, China or Europe. The tastes and wants of the consumers of timber elsewhere must be studied and consulted if our forests are ever to be made to yield any financial return for the expenditure incurred in their preservation and development. We may cite in illustration of this point the extraordinary results observable in America owing to the want of the knowledge which should control forest operations. We have heard of one case where the stumps of destroyed trees of the wild cherry on land in that country, had sold for six times the sum originally paid,—but a few years before—for the land on which they had been grown. The American walnut, which is now in such extensive use for furniture and cabinet work in England, was for a long time a mere drug in the market; but of late years we are told it has more than trebled in value, and the demand for it is growing far beyond the possible rate of supply.

Having thus briefly illustrated some of the points involved in the profitable study of Forestry we may return to our original question, as to the best course for our Government to pursue when the English Forestry School is open to receive students. It seems to us that most of the gentlemen who now compose our local Department might well be sent home one by one to undergo a course of training. There are, we should imagine, but few of them who would object to this arrangement were their reasonable expense guaranteed, and then, future advancement might and should be made dependent upon these Forestry officers being able to furnish evidence that they had profited to the full by the course of study opened to them. We do not want to see our present staff, who have borne the heat and burden of the day, superseded by men from the English School. But we must not sacrifice efficiency even to this consideration, and promotion should be made dependent upon present members of the staff qualifying for it, if the means for obtaining such qualification are afforded as we have suggested, by the Government. But apart from thus dealing with our present staff, it is manifest that we ought to look, in the case of all future appointments to qualified students who will receive the diploma of the new School. Under such conditions we may hope to see removed any cause for such strictures as were contained in Mr. Vincent's Report.

RICE CULTIVATION IN JAPAN AND CEYLON.

It is a curious fact that just as we have been discussing the profits from Rice Cultivation in Ceylon under Irrigation, and comparing these with the results achieved by the Sinhalese in other agricultural industries, papers from Japan should reach us full of a discussion on the same subject and advocating in some cases the supersession of rice growing altogether. This is the policy which a contemporary most unjustifiably attributed to one of the speakers at the recent meeting who, however, never said one word about the people abandoning existing paddy fields or turning them to any other purpose than the cultivation of rice. The controversy in Ceylon, however, has a direct

bearing on the future extension of native cultivation: whether, under the auspices of Government it should be solely directed to rice-fields and the growth of paddy under irrigation works which may be restored or repaired; or whether Government should not rather in certain districts encourage other agricultural industries suited to the climate, soil and the genius of the people. This latter policy, we need scarcely say, has received our support. But we find our Japanese contemporaries after comparing the great advantages which their huge neighbour China with its far-extending alluvial plains has for rice-growing over their own islands with their broken rugged configuration,—(just as we have been comparing Northern India or Burmah and Ceylon)—calmly advocating the total abandonment of rice cultivation and the conversion of their fields into mulberry plantations for the establishment of sericulture! The following summary from the *Japan Weekly Mail* shows that English editors well acquainted with the condition of the country give the proposal of their Japanese contemporaries a general approval. The reasons adduced by the *Mail* are of considerable interest to us in Ceylon. We secured, when in Tokiyo, a series of photographs by a native artist of the various operations connected with the outdoor work in the rice (and tea) fields in Japan, and there can be no doubt of the superior advantages of sericulture to a people and land so admirably adapted for its promotion. And in the same way there are districts in Ceylon where official encouragement might well lead the natives into new industries likely to prove as beneficial to the people and the country at large, as paddy-growing. We quote as follows:—

SERICULTURE VERSUS RICE-GROWING.

China being a country of grand rivers has been, in a manner, condemned by nature, to periodical inundations. But the case is different with Japan, where, owing to the peculiar configuration of the islands, no river of more than second class magnitude is to be found. Japan ought therefore, to be proportionately free from inundations, were it not for her people's peculiar device of bulking up the streams until, their beds becoming raised above the level of the surrounding country, they are converted into huge mill-races, ready to pour their waters out upon the neighbouring district through the smallest flaw in their banks. This is especially the case in the regions about Kyoto and Osaka, and the consequences have been forcibly illustrated by the recent disastrous floods. The *Jiji Shimpō*, with characteristic thoroughness and daring, recommends a heroic remedy against the recurrence of similar disasters; namely, the abandonment of rice cultivation and the conversion of the rice fields—for the irrigation of which these elevated rivers are used—into mulberry plantations. Our contemporary points out that the gross income derived from an acre of land devoted to sericultural purposes is from 80 to 150 *yen*, whereas the income derived from the same area devoted to the production of rice is only from 36 to 48 *yen*. To this argument may be added, what is unquestionably the case, that the labour entailed by the cultivation of rice is of a far severer and more degrading nature than that required of sericulturists. Considering these things, it seems to us that the *Jiji Shimpō* has struck a note which ought to harmonize with the instincts of all true reformers in Japan. In connection with the special object of the suggestion, namely, the prevention of inundations, an objection of course presents itself. The mere act of abandoning rice cultivation will not confine the rivers to their everyday beds. Doubtless the Tokyo journal's meaning is, that these elevated streams have ceased to perform the functions of natural drains, and that their waters should be conducted out of such artificial channels into routes where an overflow would no longer be

a calamity. But, in all probability, this could not be effected without an outlay of toil and funds which would suffice to secure the rivers, in their present form, against serious accident. We do not profess to speak with any confidence upon this point. It is one that demands special knowledge acquired *in loco*. We only say that whether rice cultivation be abandoned or persevered with, the rivers cannot be left to take care of themselves, in their elevated channels, and that unless the trouble of caring for them can be obviated, the advantage of the proposed exchange of industries ceases to have any direct bearing on the problem of inundations. But with regard to the general question of sericulture against rice-growing, the recommendation of the *Jiji Shimpo* deserves support. Rice farming has long been recognised as one of the most trying forms of labour. Nothing could be more injurious to the health than a business which keeps people, from morning to evening, wading in deep mud with a fierce sun beating down upon their heads and pestilential exhalations rising up all round them. It is a cruel sight to see women and young girls condemned to such toil, and one feels that the intelligence of the rice-farmer must necessarily remain undeveloped or his lot would become intolerable. Sericulture, on the other hand, makes no large demand on the physique, and is essentially an occupation consistent with refinement and civilization. It is at least as well suited to the soil and climate of Japan as rice-growing, and very much better suited to the nimble fingers and artistic instincts of the people. It possesses also another advantage, not to be lightly regarded in this country; namely that it provides for women an employment not only adapted to their capacities but calculated to improve their social status. In no parts of Japan are wives and daughters so happy or so well considered as in the silk districts; whereas the wives and daughters of the rice-farmers are condemned to toil that degrades their mind and disfigures their bodies. There is no apparent reason why rice-land which requires elevated rivers for its irrigation should not be converted into mulberry plantations, to the great moral benefit and largely increased profit of the people. That such a change would result in over-production, we do not for a moment believe. It may be a long while before the people of Europe and America use silk as largely as the people of Japan, but the demand is likely to increase steadily, and will certainly not be outstripped by the productive powers of these islands. The time ought to come, too, when the Japanese will export their silk not raw but manufactured. Labour is cheap, and the intelligence of the working classes is considerably above the average. It is a pity that the abilities of that remarkable outcome of Japanese civilization, the artist-artisan should be confined to the production of objects of *vertu* and that the exquisite fancies which make the weaver and dyers of Kyoto so famous in their own country, should not be employed in the wider field of manufacturing silk goods for the world.

NETHERLANDS INDIA: COFFEE, CINCHONA, BREWING.

(Translated for the "Straits Times.")

BATAVIA, 8th Aug.—The present year's Government coffee crop in Java was officially estimated at 814,890 piculs on the 30th June, the estimate being 81,840 piculs lower than on the 31st May, and about half the average yearly yield. The estate coffee exported from Java during the first and second quarters of this year show a falling-off amounting to 39 per cent when compared with the figures for the corresponding period last year. More sugar has been exported in the same period owing to large stocks of it having been held back at the close of last year.

The German New Guinea company intended, on the 6th July, to despatch from Berlin an expedition charged with making the needful arrangements for establishing stations there. It will pro-

ceed *via* Marseilles and call at Batavia to engage labourers there.

The Government cinchona crop in Java for the present year is estimated at 400,000 pounds. The system of shaving the bark from Ledgeriana trees has proved so unsatisfactory from trees thus dealt with becoming so diseased that many of them had to be uprooted, the result being that experiments in that line will only be conducted on a small scale.

BATAVIA, 11th August.—From what we hear private plantation enterprise is going forward with rapid strides in Assahan. No less than four tobacco estates have been started there of late.

A novel branch of industry is about to be taken in hand at Batavia. Often has the question been put why it is that we have to import beer here at heavy expense from Europe while it is quite possible to brew the article on the spot. The possibility of doing so has become greater still by quicker communication with grain producing countries. Moreover British India and Australia, lying as they do at shorter distances from the colony, may at present furnish the grain required for beer brewing. Hence it does not surprise us to hear that Mr. Dermont Van Schereningen intends, along with his brother, to start here a brewery the machinery and other appliances for which along with the working staff to manage them are to leave Holland for Batavia this month. When shall we drink the first glass of Batavia brew?—*Batavia Dagblad*, 12th August.

NEW GUINEA PRODUCTS.—A few days since a notice appeared in the *Gazette* giving the boundaries of the British and German possessions in New Guinea, and portion of the public were reminded that such a place was marked on their maps. A correspondent who has spent some time in that tropical laud gives us some interesting particulars as to its resources. Sugarcane and coffee produce good crops, ginger grows wild, pepper and nutmeg are found on the moist coastlands, the sago palm flourishes on the south-west coast, while tobacco is cultivated in all parts; cotton grows luxuriantly in the upper valleys, where the land is also suitable for cocoa, cinchona, maize, and arrowroot.—*British Trade Journal*.

CEYLON TEA IN MINING LANE.—A gentleman in the "tea" business in the Lane writes under date London, 14th August:—"The *Tropical Agriculturist* for June and July reached me in due course, for which accept my best thanks. I ought to have written before this, but my time has been so fully occupied with the new season's China and Indian teas, that I have not been able to give as much attention to Ceylon teas as I should have liked to have done. Our market for Ceylon teas still remains firm, although for the commoner grades it is a trifle easier. For Indian teas the market has not been in as satisfactory a state as importers could have wished, many of the Calcutta bought teas showing a loss of 3d and 4d per lb., and in some cases even more. One of the principal features of the sales last week, was the high prices obtained for some teas from the Blackstone estate, the broken pekoe fetching 3s 2d, the pekoe 2s 2½d, and the pekoe souchong 1s 7½d, giving the splendid average of 2s 2½d. An invoice from the K. A. W. estates sold yesterday brought very good rates, an orange pekoe going for 2s 2½d, and the broken pekoe 2s 3¾d, which is an improvement on former shipments. An improvement is also to be noticed in the teas from the Blackwater estate, especially in the firing."

FRAGRANT FLOWERS.—The perfume manufacturers of Nice and Cannes crush 154,000 lb. of Orange blossoms, 13,200 lb. of Acacia flowers, 154,000 lb. of Rose petals, 35,200 lb. of Jasmine blossoms, 22,000 lb. of Violets, 8,800 lb. of Tuberoses, and a relatively large amount of Spanish Lilacs, Rosemary, Mint, Lime and Lemon blossoms every year.

TOMATOES.—An American contemporary states that during the past season there were put up 48,508,248 cans of Tomatoes in the United States, being one-third less than the pack of 1883, the decrease in acreage being heaviest in the eastern States. It is said that a farmer in Salem County, New Jersey, last season raised 83 tons of tomatoes on 6 acres of land. The crop was sold in the canning establishment for 7 dollars (nearly 30s.) per ton.

KAOLIN IN THE MADRAS PRESIDENCY.—It is stated that Mr. Foote, of the Geological Survey, has come across, during his operations about 20 miles from Trichinopoly, two veins of kaolin and felspar which promise to be of good quality. Instructions have been issued for these veins being investigated, as these materials (the latter being calcined and used chiefly in the manufacture of plaster of Paris) can be utilised largely and is required much by the local school of art.—*Madras Times*.

A NEW VINE PEST.—The unfortunate province of Bessarabia which has been suffering grievously for some time from a visitation of locusts is now subjected to a fresh misfortune. It appears that a destructive insect whose rapaciousness exceeds that of the phylloxera has made its appearance in the extensive Bessarabian vineyards. The insect is described as of similar size to the phylloxera, but of a different and unknown species. A special commission is leaving Odessa for Bessarabia in order to consult on means for the destruction of this new plague.—*Daily News*.

A NOVEL USE, says an Eastern paper, is being made of oyster shells by a Hartford, Conn., man, who is earning money in his new enterprise. The shells are placed in a patented mill and ground. It has a capacity of five tons a day. By an ingenious arrangement sieves are kept at work assorting the dust into fine, coarse and insufficiently treated. The fine and the coarse are taken by the elevator belts to the floor below, where, through canvas chutes, regulated by wooden slides, barrels are rapidly filled. The product is sold for chicken feed. Twenty tons and more are sent yearly to San Francisco, orders are filled from Western States, and Bermuda and the Sandwich Islands have been supplied.—*European Mail*.

CINCHONA BARK SALES.—Local sales of Government cinchona (crown) bark will continue to be held in Madras until further orders. To give stability and certainty to the market, however, and so to reduce the risk of loss within the narrowest possible limits, the Government directs that sales be held in Madras on the first Monday of September, October, November and December in each year. To add still further to the stability of the market, and so to enable home dealers to make arrangements, if they wish, for buying bark in Madras through correspondence, the Government resolve to guarantee that for the next two years, a quantity of "crown" bark, not less than 17,500 lbs. will be placed on the market at each of the four sales to be held in each year. They will also arrange that samples of the bark to be offered at each sale, with chemical analyses attached, shall be available at Madras for a fortnight and at the India Office for six weeks or so before the dates of sale in Madras. For this purpose, the Director will send the samples direct to the Master Attendant in time to enable that officer to ship them, so that they may be at the India Office by the proper time.—*Madras Mail*.

PLANTING IN BRAZIL.—A well-informed resident in Rio de Janeiro writes to us by this mail:—"The planters here are really hard-up. As yet there is no interest manifested in the improved methods of cultivation which your journal so ably discusses; but I am inclined to think that when slavery goes the old planting methods will begin to go also."

TEA MACHINERY.—A planter writes:—"I send you a lithograph of Baillie's Tea Breaker made by a Glasgow House; also a lithograph of a Tea Drier by the same firm. One or more of these driers have been sent to India and a report is waited for. The breaker gives satisfaction in India. The drier is in shape like the old sirocco; the firing arrangement is quite different, being much stronger and I believe better in so far as the quantity of fuel required is concerned. Could you make known some particulars of the patent law in Ceylon? [Our correspondent can have a copy of the Patent Ordinance No. 6 of 1859 for a few cents.] As far as I have heard it, it is monstrous. I suggested to my friend a top for his drier like the newer Sirocco, but before he could adopt it the newer Sirocco was brought out, and is, I am advised by Messrs. Davies & Co., patented. The late tea roller cases too seem hard on new arrangements. When at home many years ago I saw a machine at work in Glasgow. The motion, so far as I can remember it, was the same as Jackson's tea rollers. The machine I refer to was called a steam mason, and was used for grinding down stones to an even surface. Would the importation of that machine be an infringement of Jackson's patent? I am writing home for particulars of it."

FEARFUL MORTALITY OF POLYNESIANS IN FIJI.—"A Fijian White" writes to the *Planters' Gazette*:—"With further reference to labour, the men who have experience of other labour, such as may be obtained in the Southern Provinces of India, are the best judges as to the value of the Fijian as an estate labourer; and they have informed me that the Fijian is utterly useless for general work. I am glad he refers to the Polynesian slavery as being 'repugnant to the sentiments of humanity,' but as he has omitted to state the rate of mortality, I may as well enlighten humanity at a distance. In 1882 the death-rate on an estate on the Rewa River was upwards of 60 per cent; on another place in 1884 seventy odd men were recruited at a cost of £27 per head; they all died within six months. On another place in 1881 or 1882 forty-seven men were recruited, and they all died to a man within a few months. Items of this sort are not included in my statement of cost at 2s per day. Your correspondent is further mistaken as to the cost of Indian coolies in 1884, they cost £24 per head, with a recent intimation from the immigration department that the rate for 1885 will exceed that of 1884. That is, double the cost to Mauritius and some of the West India islands. The immigration department itself is probably the worst managed of any in the colony, and the man who till recently occupied the appointment of 'Agent-General,' is held in the greatest contempt by planters great and small. The service in Fiji, or as they themselves term it, the 'forlorn hope,' consists of ruined cotton planters and some reformed tipplers, who have been excommunicated from the society of their early life,—with the exception of the very able man who has been acting as administrator during the absence of Sir Wm. Des Voeux and Mr. Thurston, there is not one among them who has had experience of official employment out of the Colony. True, Mr. Horn did write a pamphlet on the nature and resources of the country, and it is equally true that he arrived at conclusions that have since been proved to be erroneous. Where are the coffee estates that he said would rival Ceylon? where the cotton, cinchona, and half-a-dozen other products he refers to? they remain only in the memories of the informates who possessed them, and in the peculiar imagination of your correspondent."

SUGAR MAKING.—The following extract from the "American Cultivator" describes a new process which, if successful, ought to revolutionize sugar production:—"The new process of sugar making brought forward in Berlin by Trobach is purely chemical differing materially from the mechanical process now in use, and in the opinion of authorities on the subject, will, if it shall prove to be all it is claimed to be, effect a revolution in sugar manufacture and cheapen the article still more. This method dispenses with crushing and pressing altogether. The cane is cut into slices by means of machinery, and the water extracted from it by alcohol vapor, which, having an affinity for the water, absorbs it, but leaves the saccharine in the desiccated cane; this is then treated with liquid alcohol, which extracts the sugar, and afterwards the sugar is extracted from the alcohol, or the alcohol from the sugar, by filtering through lime and chalk. There is by this method no difficulty in extracting all or nearly all the saccharine from the cane."

OSTRICH FARMING.—I paid a flying visit to the flourishing and picturesque little town of Gawler, during my stay in South Australia, and visited the ostrich farm about four miles away. This particular farm, I understand, pays remarkably well; and there is no reason why more of them should not exist in Australia. The farm includes about 170 acres. The intelligent manager of the farm, Mr. Rankine, was very ready to give me all the information required. There are about 100 adult ostriches, which are enclosed in 26 paddocks formed of wire fencing. The ground is left in its natural and uncultivated state of bush. One male and one female bird are usually enclosed in each paddock, for although ostriches are not monogamic, yet if two females are placed in the same paddock with the male, the latter usually selects one as a favorite, to the neglect of the other. The eggs take about six weeks to hatch. Formerly the hatching was artificially performed by incubators, but it was subsequently found that the birds would sit and hatch the eggs themselves. In this task the male assists the female bird, so that the old story about the ostrich burying its eggs in the sand and leaving them for the sun to hatch is a zoological libel. All the birds were in a most healthy condition, as was evidenced by the bright colour of the legs and mandibles. They are fed twice a day on lucerne and cabbages, with an alternative diet of maize and turnips, and of course the birds get the necessary pebbles and stones for gizzard trituration for themselves out of the ground. I was much amused as I drove round the farm by the humorous old manager, a genuine Scotchman, addressing the long-legged, long-necked birds—which frequently came much too near to be pleasant—by antique Scottish patriotic names. One is "Roderick Dhu," others "Bruce" and "Wallace," &c. The breeding birds for this farm (which was only started four years ago) cost £100 each. In some of the paddocks were flocks of six and eight young ostriches—pretty little objects, with peculiar striped markings. They are altogether of a different colour to the parents, and in the Zoological Gardens I was very much struck with the striking resemblance the young of the emu bear to those of the ostrich—illustrating the zoological truth that the young of the species of the same or nearly allied genus approach each other much more nearly than do the adults. It is not until the young male is a year old that he begins to assume his characteristic black coat. When the young birds are only eight months old some of their feathers may be taken. As they get older the feathers are plucked every four months, and as many as weigh one pound and three-quarters are not infrequently taken from a single bird. There is a feather storeroom at the farm, where we saw the harvest. I was pleased to hear that the Gawler Ostrich Farm was a success, inasmuch as it is only one out of numerous similar enterprises which the climate of Australia will probably enable its inhabitants to undertake.—*Australasian*.

JAPAN TEA.—It is said that the Yamashiro districts produce nearly one-third of all the tea grown in Japan, and that very little more than half the tea-plants will be saved from destruction in those districts in consequence of being so long submerged by the recent floods.—*Japan Weekly Mail*.

A WASH TO KILL SCALE.—Kerosene, three gallons whale oil soap, half pound; water, one gallon. Dissolve the soap in hot water and add boiling hot to the oil. Churn the mixture at least five or ten minutes, if possible through the spray nozzle of a good force pump. The emulsion is a thick cream which should adhere to the surface of glass and show no oiliness. For use dissolve one part of emulsion with ten parts of water. The above formula is for thirty gallons of wash.—*Gardeners' Monthly*.

SUGAR, CACAO & C. IN TRINIDAD.—Says the *Domestic Dial* of 20th June:—"The *Port of Spain Gazette* "understands" that Mr. L. Agostini has formulated a scheme for loans by the Government to the Trinidad sugar planters, on the security of their annual crops. The cash is to be advanced by the Colonial Bank on the guarantee of the local authorities, the Bank waiving all claim to crops. The Trinidad Agricultural Society have passed resolutions with the view of "preserving birds and cultivating fibre." Much apprehension has been awakened in Trinidad in respect of the locusts, a "swarm of young creepers" having been found destroying cacao leaves.

TOBACCO.—I send you a sample of Deli tobacco grown at Kndat by a peripatetic Australian. It is only partly fermented, but is declared by Mr. Lind, Manager of the German Tobacco Company's Estate at Banguey, to be a really good sample of tobacco of fine tallow colour. This sample is from a small trial planting produced on Success Hill Estate with a view of testing the soil and to obtain acclimatised seed for next year's operation. There are thousands of acres of land equally suitable for the production of tobacco without going far away. If the Company will only give reasonable encouragement to enterprising Europeans this industry can be made a source of substantial wealth to the North Borneo Company.—*Strait Times*.

COFFEE FLOURISHING IN ASSAM: WHAT NEXT?—Fifteen degrees north and south of the equator have always been given as the outside limit for the successful growth of our old staple; but we learn of a coffee clearing in Assam extending over 100 acres being in a most flourishing condition with no sign of leaf-disease and with the portion in bearing yielding at the rate of 1½ lb. of a fine sample of beans per tree. The history of the experiment is that Mr. T. C. Anderson, of Dikoya, when passing through Calcutta on a visit to his brother, an Assam tea-planter, took with him some coffee stumps from the Calcutta Botanic Gardens which so succeeded in growth that it was determined to give coffee a full trial. Mr. Anderson accordingly sent a supply of carefully selected and sulphured seed from Ceylon, and he also sent up some coolies to do the nursery and planting—the said coolies being also sulphured to get rid of any of the fungus germs! The result is a clearing of 100 acres of fine coffee as could be desired; it was reported of very favourably not long ago by a Ceylon planter, his only doubt being if the berries would ripen up properly. But the latest news is that the crop is coming in most satisfactorily. It will be a curious circumstance, if coincidentally Ceylon planters should give their Assam brethren a new and profitable product in coffee, just as they are beginning to compete with them seriously in tea.

MR. C. SPEARMAN ARMSTRONG'S LATEST
CONTRIBUTION TO THE LITERATURE OF
THE TEA ENTERPRISE IN CEYLON.

Surely the Colony, the Government and especially those engaged in the culture and manufacture of tea owe a heavy debt of gratitude to Mr. Armstrong. One of the earliest pioneers of the enterprise in its practical and appreciable aspect, Mr. Armstrong has brought to bear on our new staple faculties keenly observant and a mind singularly retentive of all valuable facts, whether developed in the culture or the manufacture of tea. But he has not contented himself with storing up facts and principles for his own use and guidance. On the contrary, nothing has been more conspicuous in the career of this model planter and gentleman, than the frank and unreserved readiness he has ever shown, at the various stages in the progress of the industry, to place at the disposal of his brother planters and the public at large *the results—confirmed correct or modified—of his accumulated experience as a tea-grower and a tea-maker. In his successive papers we have information on which we can rely as conscientiously correct, including his latest deliverance to the effect that from Ceylon estates tea can be placed free on board at Colombo for a maximum of 36 cents of a rupee per lb., a fair average being 30 cents. Mr. Armstrong adheres to his high estimates of yield, stating his conviction that estates giving an average of only 300 lb. per acre will be more rarely found than those which yield 500 lb. He takes the sensible business view that good, substantial pluckings, realizing average prices of 1s 3d to 1s 6d in the London Market, will, in the end, pay better than very fine picking with correspondingly high prices. Mr. Armstrong, also, while deprecating and avoiding "odious comparisons," holds that, after a certain period of growth, the yield on elevated hill estates and low valley gardens will be fairly equalized, the finer flavour of the high-grown leaf asserting itself more than it seems yet to have done. If the charge of optimism is brought against Mr. Armstrong, he has a ready answer in the encouragement which his own experience has afforded for "lengthening the cords and strengthening the stakes," of the well-managed and evidently profitable "concern" he has built up on Rookwood amidst the ranges, over which the monarch of Ceylon mountains, Piturutalagala, looks out, to and beyond the plantations of Hewaheta. All who have profited by the knowledge so freely communicated by Mr. Armstrong will cordially wish him success in a degree which, the greater it is, the more they will rejoice in its realization.

A great and most valuable characteristic of all Mr. Armstrong's utterances is the candid honesty with which he gives his opinion as to the relative merits of the appliances for the manufacture of green tea leaf into the dried product, which are competing for the favour of the tea planters. Like the vast majority of those who have practically tested the merits of varied and rival machinery, Mr. Armstrong emphatically awards the palm to Mr. Jackson's rollers; the Hand Roller, Universal and Excelsior being good, better, best, only in their superior capacity for work. But, when it comes to drying the tea and sorting it, he prefers Davidson's siroccos (giving his reasons) for the one process and Gore's recently invented

and very moderately priced sifter, for the other. He is not blind to the merits of Jackson's machinery, but he evidently feels as we do that the eminent tea engineer, whose inventions receive such justice at the hands of Messrs. Marshall & Co. of Leeds, is in no sense a cheap Jackson. But Mr. Armstrong shows his appreciation of quality, by advising planters to spend their last cent, rather than not have at their disposal, when the "rush" crisis comes, a large, well-ventilated, well-furnished factory. In justice to Mr. Armstrong's political economy and financial morality, however, we feel bound to point out his recommendation that the last cent is only to be spent on a complete tea-house and tea machinery, when it is available, in gradual instalments, as yield and profit increase. In the matter of a hand roller at £500 and its performances, however, while accepting Mr. Armstrong's account of his own experience as beyond question, we feel bound to say that ours has not by any means been so favourable. The roller, whether worked by cooly or water-power, has done its work well, but, so far from its capacity being equal to 40 to 50 lb. of green leaf at a fill, 37 has been the maximum on an estate in which we are interested. Half-an-hour, too, has been much nearer than 20 minutes, to the time required for rolling. Altitude, which is high, but not much higher than Rookwood, may account for the longer period required for the rolling; but even a gentleman interested in the roller, to whom we left the filling of it, did not blame our leaves. We fear we should require Mr. Armstrong's help to get 1,600 lb. of leaf rolled in 10 hours by the hand roller. But more curious still, while Mr. Armstrong is emphatic in his approval of the Universal roller, which costs considerably more than twice the price of the hand roller, he represents the former as doing very little more work than the latter, 1,600 lb. of green leaf rolled in a day of 10 hours, or 2,000 lb. if pressed. The logical conclusion from Mr. Armstrong's statements would seem to be that the owner of a tea estate should (the Ceylon roller, prepared at Mr. Armstrong's recommendation, not being ready) pass from the hand roller to the Excelsior, which is stated to be capable of rolling 8,000 lb. green leaf (the equivalent of 2,000 lb. of dry) per diem. The difficulty is that most coffee estates, converted into tea estates, have got water-wheels of only 16 feet diameter, with buckets the capacity of which was estimated with reference to the friction offered by a coffee pulper. That is our difficulty, requiring as we do the services of an excelsior, and during our recent trip through the tea districts, this question of water-wheels and their power was a subject of special interest to us. On Imboolpittia, thanks to the courtesy of Mr. Hogg, we saw a wheel 21 feet in diameter, but with buckets narrower even than those of our 16 feet water-wheel, while the water-supply did not certainly exceed that which for most of the year we can command for the whole of the year by means of dams; evaporation at nearly 6,000 feet altitude not being great. *By the help of a fly-wheel* the Imboolpittia wheel was equal not to one excelsior merely, but, we believe, to two. Then on Windsor Forest and Pen-y-lan we saw twin wheels, 14 feet in diameter, but with buckets of fully one-third capacity more than those of our 16-foot wheel. Those 14-foot wheels turned Excelsiors easily and with power to spare. Having observed all this, we ventured to dispute the dictum of the leading engineering house in Colombo, although endorsed by Messrs. Jackson and Armstrong, to the effect that a 16-foot water-wheel, as supplied by Messrs. John Walker & Co. for working a pulper,

could not be made equal to working an Excelsior roller. "The capacity of the buckets can be increased," we insisted, "and a fly-wheel can be added, to increase momentum," and finally we made a "paction" with our good friends Messrs. John Walker & Co., that if a member of their firm would make the alterations and additions we wished, the responsibility of failure to work the Excelsior, if failure accrued, should be ours, not their's; and, accordingly, the experiment of adapting a 16-foot diameter coffee pulper wheel to the working of an Excelsior roller will be shortly tried at Abbotsford and the result published. The letter of "D. K. M." which reached us while writing, which will be found elsewhere, and which impeaches Mr. Armstrong's infallibility as to hydraulic laws, or at any rate the principles on which the power of water-wheels depends, gives us fresh hopes of success. In fact, we believe our good, though at first sceptical friend, Mr. Walter Lamont, of Messrs. John Walker & Co., is himself now convinced that success is possible and is determined to achieve success even if he has to gratify our whims of enlarging the wheel buckets and having a fly-wheel attached.

We feel bound, after some observation and reading, entirely to agree with Mr. Armstrong's preference for the upright water-wheel as compared with the turbine. But we cannot help believing that Mr. Armstrong has not sufficiently appreciated the value to Ceylon tea planters of what our American consins call "water privileges." To a very large number of the mountain plantations of Ceylon can be applied the dictum of the Scotchman about a place in Ambagamuwa. Addressing the proprietor, he said, "I dinna ken about yer breed, [bread], but, my certy, yer water will be sure." It is not simply the volume of water but the fall which can be secured that tells in the obtainment of power, and we think our readers will sympathize with the feeling which led us to resent the suggestion of importing a steam engine to an estate which is known to the Tamil coolies as *Aruet Tottum*, the Water-fall Garden. A steam engine requires skilled attendance, and if not carefully managed is apt to "burst up." Of course steam power must be employed where water is scanty and the fall slight or nil.

But on the vast majority of the hill plantations, at least, of Ceylon, water power is abundant, and we may be doing some of our readers a service, by quoting a few details regarding the force of element, and how that force can best be utilized:—

(From Moleworth's Pocket Book of Engineering Form-
ule 21st Edition.)

Theoretical power being	100
Undershot water-wheels	35
Poncelet's undershot water wheel	60
Breast wheel	55
High breast	60
Overshot wheel	68
Turbine	70

From the above it will be seen that the superiority in power of the turbine is not such as to compensate for its admitted greater liability to accident. Where there is abundance of water, there is, clearly no motor so effective and at the same time so simple and so little liable to get out of order as the overshot water-wheel. But the effectiveness of the overshot wheel depends not only on the number and capacity of the buckets and the mass of water projected on to the wheel, but also on the direction in which the water is made to fall, so that in running

away it may offer the least amount of resistance to the movement of the wheel in its lower portion. This is very clearly explained in the well-written article on water power in *Chambers's Encyclopædia*:—

The most usual, and generally the most eligible, mode of applying water to the driving of machinery is by means of a vertical wheel; and the wheel is put in motion either by the water acting on blades or floats by impulse derived from its velocity acquired in falling, or by the weight of water being applied to one side of the wheel. The former mode of applying the water is generally adopted in low falls, say under six feet or thereabout, and to what is called an undershot wheel—i. e., a wheel where the effective head of water is below the level of the centre; and to make the application efficient, that portion of the periphery of the wheel measuring from the point of impact of the water to a point directly below the centre, requires to be surrounded by a casing generally of stone, but sometimes of cast-iron, called the arc, closely fitted to the extremity of the floats, so as to prevent any considerable escape of water.

The other mode of applying the water to a vertical wheel by making it act by its gravity, is the more perfect and economical mode, where circumstances will admit of it, and is generally adopted in falls of any considerable height, say of six feet and upwards, and where the water can be let on above the level of the centre. The wheels are called respectively *breast* and *overshot wheels*, according as the water is let on more near to the level of the centre (r to the crown of the wheel; and they have, instead of straight floats curved or kneed buckets, according as they may be made of iron-plate or of wood, and of such a shape as to retain the water down to the lowest possible point. There are generally in good wheels ventilating openings in the sole for the escape of air. The overshot wheel has this disadvantage that, as the water has little or no power until considerably past the top centre, the wheel is burdened with a useless weight of water.

The direct overshot wheel without changing its direction, right over the top, which arrangement has this advantage that as the top of the wheel moves in the same direction as the stream, it gets the benefit of the whole initial velocity and impulse of the water; but, on the other hand, the bottom of the wheel, if at all immersed in water, which it generally is to some extent meets with obstruction by moving against the current.

The *pitch-back overshot* is a modification of the last, making the water to pass alongside the wheel, and then to return and be let on the top of the wheel in a contrary direction. This requires longer and more complicated troughs, and by the change in direction, part of the impulse from the water is lost, but the bottom of the wheel moves in the direction of the tail-water, and is not liable to be impeded by being immersed in it.

On the whole, it is generally thought better to apply the water at about 30 degrees from the top of the wheel. In such high-breast or nearly over-shot wheels, the water is let on the buckets over the top of the sluice, which is made to open by lowering, and shut by lifting. In this way, however small may be the quantity of water, it is always applied the highest possible level, which is of importance when it is its weight multiplied by the height of decent, and not its impulse, that yields the effective power.

The structure of the overshot and breast wheel is nearly the same as that of the undershot, excepting in the substitution of curved buckets, or angular buckets, for straight floats; but even in the undershot wheel the floats are sometimes made with a slight curvature.

In reckoning the power of water, its weight being $62\frac{1}{2}$ lb. to a cubic foot; theoretically, 528 feet falling vertically 1 foot a minute, would be equal to 1 Boulton and Watt horse-power of 33,000 lb. lifted 1 foot a minute; but the effective power is far short of that, and 60 per cent of it, requiring 880 cubic feet, falling 1 foot

a minute, is generally reckoned a fair allowance for an effective horse-power. Seventy-five per cent, requiring 704 feet, falling 1 foot a minute, is about the highest that has ever been spoken of, and it is doubtful whether even more than 70 per cent has ever been attained; while with low falls and imperfectly constructed wheels, it is often reckoned that a horse-power requires nearly 1,000 cubic feet a minute.

Even without the diagrams, we think the main principles here enunciated, will be easily understood by intelligent readers and will justify our contention that the 16-foot coffee estates water-wheel, so numerously scattered over the country, either is or can be easily altered into a motor quite sufficiently powerful to work at least an excelsior tea roller. The experiment will at any rate be tried. Mr. Armstrong agrees that a coffee store can be transformed into a good tea factory, a fact of which we have entertained no doubt since we saw the transformed store on Ononoogalla.

But not only does the tea planter, even if he dries his tea by means of siroccos, instead of Jackson's motive machines, require more, more complicated and more expensive machinery than did the coffee planter, but the difference in additional cubic and especially in horizontal space, necessitated by the exigencies of the new and more delicate staple, is tremendous. A single pound of green tea leaves, thinly spread so as to enable the "withering" process to be properly carried out, will occupy 6 square feet of floor or Hessian cloth shelf. Supposing, therefore, that a tea estate yields the quantity of leaf which Mr. Armstrong estimates will give an Excelsior roller employment for a day of 10 hours, viz., 8,000 lb., the horizontal space required for the withering leaf alone would be 48,000 square feet, and as passages must be left clear, the real space enclosed must be about 60,000, counting floors and superimposed shelves. But the time is coming when at certain seasons of the year, the leaf gathered on good sized estates will be not merely 8,000 lb. per diem, but fourfold that quantity. For such a gathering 200,000 feet at least of square horizontal surface would be required, and the feeling of despair superinduced by the contemplation of such a requirement, causes us to turn with thankfulness to Mr. Armstrong's assurance that, after all he has said in favour of withering in a moist atmosphere, and a shade temperature, not exceeding 80°, drying in the sun's rays can, in cold weather, be resorted to without damage to the tea, or any chemical effect beyond a red colour which the men of "the Lane" do not object to. Now, although we are aware, that the exposed thermometer is not altogether a safe guide, when it indicates, say, 160° in the sun against 80° in the shade, yet we know that between the subduced temperature of a shaded space and that of a bare spot, exposed to the full glare of the head and light rays of the sun, is exceedingly great. While, therefore, not disputing a statement which we feel sure was well considered and the result of sufficient experience, and which had often previously been made in Indian publications, especially with reference to the preparation of green tea, we should much like to be informed of the philosophy of the matter. If withering in the sun answers so well as Mr. Armstrong points out, why are planters generally so anxious to protect their gathered leaf from the direct action of the sun, and why do Mr. Armstrong and other experts press upon them so emphatically the provision of enormous shaded space for drying in a comparatively cool, if moderately moist atmosphere; the suggestion being made that blankets should be placed over

heated siroccos to secure the *sine qua non* of warm-moisture. But surely all external moisture and a good deal of internal must be rapidly dissipated by the direct rays of the sun? In truth our mind is much exercised in regard to this question of withering. Our inclination was to believe in cool, breezy, frequently changed air, and so we strongly recommended the use of Blackman's air propeller. We felt rather inclined to question if harm instead of good was not done by the warmth of the siroccos, but we feel bound to accept Mr. Armstrong's testimony in favour of warm moist air, exposure to which will give the softness of fine silk to the leaf, without either soddening or desiccating it. But we are still considerably puzzled about withering in the sun. Perhaps a good compromise would be, a very short exposure to the outside sun and a finishing off on shaded but not darkened floors and shelves? Rolling, thanks to Mr. Jackson, is now "rolling made easy," but when we come to consider the fermenting process, its delicacy, difficulty and frequent uncertainty, owing to atmospheric causes, we are deeply impressed with the conviction that to be a good, efficient tea-planter, a man must not only be a competent engineer, able to appreciate the principles of machines, and when need arises to put them together and repair them; but have also a fair knowledge of chemistry, and especially the doctrines of ferments. The change which takes place in a soft moist covered-up mass of tea leaves, the tissues of which have been crushed, and the cells of which have been broken by the action of the roller, cannot, with strict scientific accuracy be called "fermentation," but rather oxygenation, because neither opportunity nor time has been allowed for the operations of the minute organisms on which the setting up of fermentation depends. But Mr. Armstrong significantly speaks of the danger of delay until *signs of decomposition appear*. In such a case, we suppose, true chemical fermentation would speedily supervene, and the difficulty—the great difficulty of the tea-maker seems to consist in so using a kind of instinctive sense, the result of long experience and careful observation, as to draw the line where the oxygenizing should be stopped before it passes to the boundary where the ordinary chemical fermentation process, dependent on the presence of peculiar spores, is ready to be set up. Withering, though it requires care and attention, and all possible light and fresh air, can be conducted in conditions so varying as sun and shade. The worst effect of severe rolling, appears to be the obliteration of "tips," whether silver grey or golden yellow; while the question of properly firing the fermented "roll," seems to depend on long or short exposure to a temperature, not much exceeding 250°, so as to desiccate without burning. But, with all the care and attention which the most accomplished tea-maker can bestow on the process of so called "fermentation," the final result seems so largely dependent on meteorological conditions which cannot be controlled and only slightly modified, by all the appliances of skill and science, that the more we know and the more we read of the tea enterprise, the more we feel the importance of the factor of "weather" in the production of first-class, or inferior "makes," for which the superintendent sometimes gets more credit than he merits, but much more frequently greater blame than he deserves. A short time ago, we asked the owner of an estate famous for its exceptionally high prices, what the secrets of his success were. He replied: "Fine picking and

under rather than over-fermenting." And so we determined that the system should be tried. But here is Mr. Armstrong, our great and trusted tea authority deeming very fine plucking and stating that, as regards fermentation, we must use our nose as well as our eyes, after periods extending from $1\frac{1}{2}$ to $6\frac{1}{2}$ hours—the longer the period, the greater the necessity for frequent examinations! It is in truth evident that a skilful and successful tea-maker must have all his senses alive and active and intent on the various and complicated process of his vocation.

Those processes, unlike the few and simple operations connected with the pulping, washing and partial drying of coffee—water and not fire being the chief agent employed—go on, more or less all the year round, and, unless there is space to spare and machinery galore, the work of day frequently steals more than a few hours from the night. Tea-planting is comparatively easy work, but the manufacture of green leaf into dry is anything but child's play. Where space, machinery, tea and money are plentiful, however, there are compensations for hard and continuous work, which we trust may amply reward Mr. Armstrong and all our tea-planter readers.

May we ask Mr. Armstrong when the Hibernian element came into his family? It asserted itself when he wrote:—"I have seen, we have all seen young bushes *picked to death*, to give fine teas." And then he naively added:—"How can these bushes ever develop themselves and give us the cover which we should get?" Aye, how indeed can these dry bones live? When they do, we may expect trees which have been "*picked to death*" to be able to perform the feat of developing themselves. There has been nothing better since the Irish Colonel in India said to his men: "Ye ate too much, and ye drink too much, and ye kill yourselves; and then ye write home and tell yer mothers that the climate killed ye!" There is a story of a Glasgow baillie insisting that "*the defunct*" should be called into court, but that must be "a weak invention of the enemy," as Scotchmen never make bulls: they are supposed not to have imagination enough. But Mr. Armstrong deserves free forgiveness for a slip due to the vehemence of his indignation against the practice of destructive picking of immature tea. Let planters lay this and Mr. Armstrong's other lessons to heart, and let them be grateful for the full details given respecting the best style of bin construction, for which many another man would have secured the benefit of a patent. Besides Mr. Jackson's rollers, Mr. Armstrong strongly recommends a tea-cutter by the same inventor. We had somehow got the idea that tea-cutters had been banished as unorthodox, and, of course, the finer sorts of tea are not subjected to their action. Mr. Armstrong feels strong objection to the far travelling of tea-leaf in the process of sifting, confirming the feeling we have long entertained, that the sifting process, as generally carried out, the finishing off being by coolies, is about the most trying of all to the quality of Ceylon tea. Frequent handling is deprecated, but the severe friction which too often accompanies the sifting and sorting processes seems to us, besides accounting for a large proportion of broken tea and dust, to be the solution of dull-looking and inferior pekoe. The swinging arrangement described by Mr. Armstrong seems certainly superior to the knocking of sieves against hard substances, in vogue amongst the sorting labourers. Mr. Armstrong contemplates a cement floor (than which nothing could be better), masonry pillars

and wooden walls, posts, rafters, reepers, and, we presume, shingles. Such being the case, we are rather surprised that he did not enjoin precautions against fire: at least that the woodwork should all be carefully coated with asbestos or plumbago paint. The manufacture, or introduction from America, of the latter substance, by the way, should engage the attention of Messrs. John Walker & Co. Factories composed mainly of iron would, no doubt, offer more chances of immunity from fire, but we fear that such buildings must be very expensive. We are not aware if any information has been published regarding the mammoth iron-buildings imported and erected on Mariawatte? We cannot doubt that accompanying models of tea factories and manufacturing appliances, which are to be sent by the Planters' Association to the London Exhibition (after being shewn locally), much valuable information will be given as to Mr. Megginson's shelves and other improved contrivances. Mr. Armstrong anticipates the best results for tea leaf naturally dried in a temperature of 75° to 80° . We suppose he means shade temperature, not influenced by sirocco heat. In that case, how are the high Diambula estates and especially the very lofty plantations of Nuwara Eliya, Kandapola, Udapussellawa, and Maturata, to manage; a shade temperature of 75° being rarely attainable, while 80° is a very exceptional extreme? We observe that Mr. Armstrong believes in separating large leaf from small before withering, but he does not advert to Mr. Megginson's practice of separating the two classes of leaf after partial rolling: firing the small and returning the large into the roller for further manipulation. He is properly careful to warn planters not to allow their coolies to squeeze or bruise the green leaf, which is, in truth, to be treated as gingerly as Isaac Walton treated his worms used as bait for fish. We have heard many stories of tea being fired by a proportion of 1 lb. of firewood to 1 of tea. Mr. Armstrong's average of $1\frac{1}{2}$ lb. of dry wood is much nearer the mark. 2 lb. being required if the firewood is not well-dried. The difference in toughness and delicacy of leaf in different districts is recognized, and of course season has its influence. Mr. Armstrong, too, reminds tea planters that superior tea cannot result from the first few pluckings after pruning: the leaves being what the Scotch call "*insionless*," with abundance of moisture, and but little tannin, theine and essential oil. It is a "*wrinkle*" to "*take note of*" that tea is not to be left in the drier until fully desiccated, but taken out with moisture in it which will soon evaporate; while the finishing off is to be done at 260° and the leaf is to be packed while hot; hermetically closed at once, of course. Mr. Armstrong speaks of good teak as the best substance for roller tables, but what about paper, which, subjected to severe pressure, actually takes a polish, and can by chemical treatment be made transparent, like glass? We are still looking for papier-mâché tea boxes, and meantime Mr. Armstrong bears favourable testimony to the wooden boxes from Japan. It is quite evident that too much attention cannot be paid to keeping the roller table clean, as also the cement floor, on which Mr. Armstrong suggests that in the case of a full bearing estate "*bulking*" should be performed, that is that each particular kind of tea prepared on different days should be carefully mixed so as to secure uniform quality, really inferior makes being, of course, excluded. In the case of a young estate, it is recommended that a one-kind of tea should be sent to market, which

is just what the owners of young places will specially object to doing.

Mr. Armstrong's valuable paper is so suggestive that we could add further remarks and queries. But here we must close our review, with a renewed expression of our own gratitude as well as that, we feel sure, of our readers, that gentlemen like Mr. Armstrong are so ready to make public the results of their experience and observation.

THE MANUFACTURE OF TEA: MR. ARMSTRONG'S PAPER.

D-Dlota, 24th August 1885.

Mr. Chairman and Gentleman.—It is my pleasing duty to give you today my experience, so far as it goes, of the manufacture of tea and the machinery we at present use to aid us in this. It may not perhaps be out of place to digress a little, and begin with what I consider the cheapest and most suitable form of building for our purpose. The ground floor of our factory should be 24 ft. wide from centre to centre of the pillars, with wings 14 ft. wide at each side, thus giving us 52 ft. clear width for all machinery, bins, packing &c. and this floor should be of cement. Above this we should have two floors at 24 feet wide for withering. Length of factory depends on the size of the gardens but say 132 ft. by 52 ft., upper floors 24 ft., giving us space as follows:—24 ft. by 52 ft. for rollers. Motive power being in an outside building—24 ft. space, then sirocco pit at 18 ft. by 8 ft. by 5 ft. 6 in. Again with 24 ft. between each, two more Sirocco pits—each pit at 18 ft. by 8 ft., by 5 ft. 6 in. holds two T siroccos, we have thus, for withering purposes, spread our siroccos well over our building, giving ample room between each for bins, picking, sorting, packing &c. Should more withering space be required a building at 24 feet wide with three floors can be carried out from the centre of the factory, and if a Blackman's air propeller was in use, this could be moved to the end of the addition and serve the whole of the withering space, except the lower floor of the addition.

Withering Shelves.—The cheapest and best I know of are those invented by Mr. Megginson at "Carolina," Jute Hessian, cut in lengths to suit the factory, but not to exceed 24 ft. say, being rather unmanageable if longer than this; a reeper $1\frac{1}{2}$ in. square is nailed at each end of the length of Hessian, and projecting $1\frac{1}{2}$ in. beyond its width at each side; one end is rounded, the other left square, we then have uprights at 45 in. between each, i. e. the width of the Hessian, and at the required distance apart, one of which has keyed slots cut at 6 in. apart, the other a $1\frac{1}{2}$ in. augur hole at 6 in. also. One eooly fixes the reeper at his end into both uprights, another eooly oppo site fixing in the rounded end only, rolls the reeper till this is pulled forward at a goul slant when he then pulls the square end back into the slot thus stretching the Hessian quite taut. If the shelves are more than 12 feet in length, an upright, about the centre of the shelf will be required with reepers at 6 in. apart nailed across it, which supports the shelf, and prevents sagging, 24 ft. lengths suit best, and are most economical. In collecting leaf for the roller, each shelf is lifted out, its contents emptied into the trolley, or on the floor, and replaced ready for fresh leaf. 12 shelves at 6 in. apart will be found most convenient.

Withering Floors.—We cannot obtain a healthy wither without light and fresh air, and lots of both. The tendency in Ceylon is, I fear, towards too wide a building with a floor at 36 to 40 ft. wide as some are. It is almost impossible, however many windows we may have, that light and wholesome air should get to our centre shelves, through the mass of leaf intervening. A double row of Mr. Megginson's shelves down the centre of the floor including 6 in. centre posts, will take up 8 ft. 6 in. At the side walls we have windows 6 ft. by 3 ft., at 6 ft. apart, and withering shelves between each; these with supports &c. will take up 4 ft. 6 in. clear, leaving a passage 3 ft. 3 in. between them and the centre shelves,

Shelves may be stretched across the windows at night, when pressed for room, being taken down the first thing in the morning, when the leaf can be re-spread on the other shelves, as they are emptied for the roller; every scrap of room may be thus utilized.

Withering.—Leaf can hardly be spread too thin, provided the day is not too hot or dry; 6 feet will hold 1 lb. of leaf *thinly* spread, a shelf 24 ft. by 3 ft. 9 in. will hold therefore 15 lb. of leaf *thinly* spread, or up to double this should necessity arise, make your calculations at 20 lb. say, and you will be right. Leaf cannot have too much light and fresh air, and the best results will be obtained from leaf withered naturally, in a temperature of from 75° to 80° with all windows open. In our wet, cold weather, withering is our one great difficulty, and at present we have no machine to help us here. Charcoal won't do, nor will Siroccos, with leaf applied direct. Hot moist air is what is required, drawn rapidly through our leaf, and I hope to obtain the desired result by drawing the hot moist air through my withering loit from the T Sirocco after it passes through the roll it is firing, with the aid of a Blackman's Air Propeller, to which our friends of the *Observer* have so often called our attention. The Siroccos are spread throughout the whole length of the ground floor as already shown, there are doors in the upper floor above each Sirocco, so that the heat may be closed off if not required. Should we have no roll to fire, we can get our moist heat by spreading a blanket over the siroccos kept damp by an occasional sprinkling of water. I have every faith in this succeeding, and am now thus adapting my own factory. The sooner after plucking, the leaf can be withered—naturally—ready to roll, the better, but as night work should be avoided if possible, it is best for us to arrange to have our morning's delivery ready for rolling by 4 to 6 o'clock the next morning, when our wither from the morning's leaf will be found perfectly sweet, even up to 10 o'clock. We can generally manage during the dry hot weather to keep our leaf from first delivery till morning, by excluding light and spreading it a little thicker than is usual. Improperly withered leaf cannot result in good tea, either as to liquor or outturn, and our careful attention is necessary in the withering loit. When leaf is properly withered it is soft and silky to the touch, and should not be hard or dry, pricking the hand when squeezed. If from leaf getting ahead of us, our plucking is coarse, separate the finer from the coarser leaf with a No. 3 sieve, and wither each separately. Do not allow your pluckers to bruise or squeeze the leaf in their hands or baskets, and as they empty their plucking basket or cooty sack, as the case may be, into their store basket, make them turn over the leaf in the basket, so that it lies lightly. Do not collect your withered leaf for the roller till just before it is wanted. If necessary leaf may be sunned to bring it up to the proper point. In cold weather I have found no harm result from withering my leaf entirely in the sun. Care must be taken to see the leaf does not get dry, and it should be moved indoors before it is quite fully withered and allowed to cool, by which time it will be withered to the degree required. Sun-withered leaf gives a reddish make and fine strong liquor. A reddish make is not disliked in the Lane provided it is well twisted. *Underwithered* leaf gives a thin light-coloured liquor with a light greenish outturn. *Overwithered* or dry leaf gives a thin liquor fairly pungent with a dark irregular outturn. Leaf spread too thickly and allowed to get sodden gives a dark thick mawkish liquor, strong and flavorless, sometimes sour, and a dark outturn. Allow yourselves double the withering space you estimate you will require, even if a temporary shed has to be built, or when your best months come, you will find yourselves with lots of leaf and nowhere to put it, or so overcrowding it as to make your worst teas when you should be making your best. A strong healthy flush, resulting in heavy pluckings, will give the best tea. And simply for want of withering-room you may stand to lose 2d per lb on your teas. Four to six coolies will attend to 1,600 lb of leaf, with an occasional time off, for picking out red leaf or work at tea below stairs,

Rollers and Rolling.—There is no doubt, I think, that Jackson's rollers are immeasurably superior to all others. They will roll, according to pressure and speed, coarse, medium, or fine leaf, equally well. Other rollers, many of them admirable in their way, will only roll well withered, *fine leaf*, satisfactorily; and are at the best not half the machine Jackson's is, so I need not take up our time in expatiating on their good or bad qualities individually.

As you are aware Mr. Jackson has been trying experiments with marble and stone tables, the marble table I understand has so far not been found a success, and the *Observer* tells us a brass table is to be tried. It may be considered great presumption on my part to advise so clever a patentee as Mr. Jackson, yet I do not believe any table will be found better than wood, and for this reason—no matter how careful we are, we cannot prevent sand and grit getting among our leaf. It is this grit that in time wears away the bottom table, and I fear so it will brass or any other material used. My table in constant work, all the year through, sometimes day and night, lasted me 2½ years. With ready planed teak planks from Messrs. Walker & Co., one carpenter can fit in a new table in a day. As far as cleanliness goes, if we souse our tables well with water as soon as our day's work is over, we leave them as clean as the day they were made. Jackson's Rollers are so well-known it is hardly worth while my going over them. They are:—

His Hand Roller, price at Colombo R500, taking at a fill 40 to 50 lb. of withered leaf, working best at the smaller fill. Re-quiring 4 coodies at 25 minutes up to 30 minutes to finish the roll. *Maximum* capacity 1,600 lb. green leaf per day of 10 hours; if worked by power ordinary working capacity 1,000 to 1,200 lb. green leaf per day of 10 hours. And this roller may be attached to a water-wheel or other motive power, a 14 ft. wheel with lots of water will work it.

The Universal Roller, price at Colombo £92 15 sterling. About the same capacity as above, 2,000 lb. green leaf maximum, or 1,600 lb. per day if not pressed. Roll finished at 20 to 25 minutes.

The Ceylon Roller, price at Colombo £130 sterling, capacity about 150 lb. withered leaf at a fill, say 5,000 lb. green leaf per day of 10 hours.

The Excelsior Roller, price at Colombo £138 15 sterling, capacity 240 lb. withered leaf at a fill or 8,000 lb. green leaf per day of 10 hours, roll finished at 20 to 25 minutes.

In starting our Factory if we have not a 16 ft. water-wheel, or if we have, and economy has to be studied, the Hand Roller should be purchased. With this before us, hand-rolling itself is not to be thought of. If in the future our motor is to be steam, then is there all the more reason to purchase, to begin with, the hand-roller, as there are often days on which we have small pluckings when it will pay us better to work by hand than to get up steam. And with steam a hand-roller is never thrown away, as one never can tell when it may not be wanted.

If we have a 16 ft. wheel and lots of water, and money to spare, then begin with the Universal, which is everlasting.

The Ceylon Roller.—This was built at my suggestion to suit our special wants, it can be driven by a 16-foot water-wheel, and with one of the smaller rollers to back it, is equal to a 200 acre garden, to at a pinch even 250 acres if we have lots of water. Most of us who are converting our poor diseased coffee fields into everlasting fieldist of tea, already have valuable 16-foot or 18-foot water-wheels, without the *Ceylon Roller* these are useless lumber. Any garden therefore of from 100 to 250 acres with water-wheels really fixed and water to drive them, have here the very roller to suit their purpose, always beginning with one of the two smaller rollers.

The Excelsior.—This requires at the least a strong 20 ft. to 22 ft. wheel with lots of water to drive it, and may be purchased by any garden of over 200 acres having no motive power really fixed. If an engine is to work it, I would recommend 10 H. P. to be purchased,

6 H. P. will work an Excelsior, but the more power we have the more economical it will be in the end, and we may have to work 2 Excelsiors at one time, besides other machinery.

Motors.—The most satisfactory and the most economical is the water-wheel, but we must first satisfy ourselves we have lots of water and to spare. A dam will be of no use, as it will be required most during the dry weather, and we are not now working a coffee-pulper, a matter of 2 to 4 hours. It may be necessary to work 8 to 10 hours at a stretch if not longer. A dam must be larger than we can generally make, to be of any use to us. We will require to conduct half as much water again to our wheel as we used in our coffee pulping days. I know but few *large* estates that have sufficient water to work all the year through, although perhaps they can do so for 8 to 9 months. A water-wheel when once started costs nothing. Use this power then if you can for 8 months, and work your engine for four; the saving in fuel and upkeep will be great.

The Turbine has its advocates. Of these I have not sufficient experience to write for or against, further than to note, they *do* require a large water-supply and they *do* get out of order. If there is any doubt as to water-supply, steam should be our motive power, rather than risk the turbine. I know from sad experience it does not do to work with too low a power, rather allow 2 to 4 H. P. over what you calculate you will require. Machinery is then under command, and full work can be got out of it, with less strain to it. Running power too close to actual requirements is the falsest economy we can be guilty of. Working then a garden of 100 acres, 4 H. P. is the least we should have. 150 acres 6 H. P.; 200 to 250 acres 8 to 10 H. P.; above 250 to 500 acres 12 to 14 H. P.

Rolling.—The roller box should be packed evenly and not too tight. Do not put too much pressure on to begin with, but keep on taking it off for the first five minutes, to let your leaf work well; for the second five minutes put on more pressure, only occasionally easing it; at the end of this five minutes take all pressure off, and turn your leaf well, thoroughly breaking it up, aiding the machine in doing this, by the hand; when for the last ten minutes (we are supposed to finish our roll in twenty) allow full pressure, taking it off, half way up, twice, to break the roll. It is only necessary to see that the press works with the leaf, rising with a jump now and then as the roll turns, if the press is not working with the roll, take off pressure for a little and break up the roll; if after this it does not work, remove some of the weights on the press, which are arranged to allow of this being done. Work with full weights if you can, but the press must work with the leaf or an uneven roll, or a mash, will be the consequence. It takes me with ordinary leaf 20 minutes, working at 100 revolutions with the Universal. The Excelsior should be driven at about 90 revolutions. All the rollers from the hand to the Excelsior are worked in the same way and take the same time to complete their work. On some gardens it takes 30 to 45 minutes to complete the roll; this is owing to some local peculiarity in the leaf, stoutness or toughness. Once find out the right time for each class of leaf, and it need never be changed. Rather over-roll than under-roll. Under-rolled tea, although it may have a good appearance, opens smooth in the outturn, and does not give out its full strength. Well-rolled tea shows a crinkly outturn, and gives out its full strength. Very tippy tea, from light rolling, pleases the eye, but will not give as good liquor as the same leaf, heavier rolled with the tips stained out of all recognition, and it is liquor we want more than appearance nowadays, although a good make, *i.e.*, a tight even twist, is a great thing, and this with Jackson's roller will always be the case with good liquor. Our roll, if properly finished, will show a well-twisted leaf—not in any way mashed—soft and gummy to the touch. If tippy

tea is wanted, when the roll is half finished, sift it through a No. 4, and ferment of what comes through, re-rolling what remains in. Directly the day's work is done, thoroughly wash the roller, easily donesthen, but very difficult if left till the juice begins to harden. Have the top table always turned over out of work; it is then easy to be seen whether it is clean or no, and gives no chance to the cooly to leave bit work half done.

Fermentation, or, as it is now expressed, **oxidization**. I think though we should hold to the former, thoroughly sift the roll through the bands and break up allumps and put *lightly* into a basket 18" x 9" x 6" at bottom, or into a tray 2 ft. x 2 ft. or 3 ft. x 3 ft. and 3 inches deep, occasionally shaking it down, not pressing it. This, covered with Hessian or blankets, not damped unless the weather is very dry, should be put in the coolest part of the factory, and left alone for an hour. Roll thus treated should not be turned during fermentation, nor should fermentation on any account be hastened. No time can be fixed for fermentation to reach perfection, if kept as cool as possible, it will take any time from 1½ to 6½ hours, the longer the time the more constantly must it be examined. Examine it after the first hour, and directly, without too close an examination, it shows a bright copper colour; turn it out on the tables, break it up well, a light hand rolling will do it no harm, and put it in your driers. With properly withered leaf well rolled, except in very dry weather a bright copper outturn is a certainty. In very dry weather we cannot get a bright outturn, and there is no use in waiting on the roll to get it. Young leaf *i.e.*, leaf for the first three to four rounds after pruning, will not give a good outturn, being a dark olive green in color, with a smoky burnt flavored liquor. In deciding on our color we must use the nose as much as the eyes. So long as the roll has a bright appearance and smells sweet, we may wait to get color; but without gaining color (copper color) should it begin to look dull, wait no longer or the nose will next tell us we have waited just too long—and decomposition has begun.

Driers and Firing.—I need only, I think, refer to two makers with regard to driers, viz., Davidson and Jackson. Both driers are excellent in their way, it being a mere matter of opinion which is the best.—my fancy leans towards the Sirocco; (1) because the outlay at any one time is less; (2) because they are most simple to work and require no motive power; (3) because I would rather have three driers for my money, than one, as even the best machinery will get out of order; 4 because I can spread the heat for withering purposes more evenly over my factory; (5) because in slack time I can roll up to one or two or more Siroccos as required. For an ordinary sized garden of 300 to 350 acres say, I would prefer Jackson's Venetian to his Victoria—the former is said to fire off 80 lb tea per hour, about the same as the sirocco, costing £100 sterling in London or £127.15 sterling at Colombo as against £90 sterling for the T Sirocco. As then I could afford three or more Venetians, instead of one Victoria, but although there is not so much difference in cost here as compared with the Sirocco yet again comes the objection as to motive power being required. This where steam is used is felt all the more, as after all our rolling is finished we have to keep up steam to work our driers. For ordinary sized gardens then I would select before all others the T Sirocco; this will work off 80 lb. made Tea per hour easily, and as now built are much more lasting than formerly, and should the diaphragm plates burn through they are easily replaced. A pit 18 ft. by 8 ft. by 5 ft. 6 in. will hold two of these, and if our garden is only a small one we might have only one in each pit, a loss in stoking only, so as to spread the heat throughout the withering lofts, a pit 8 ft. by 10 ft. by 5 ft. 6 in. will then be large enough. If the factory is built according to the plan I have suggested, the smoke chimney should be led beyond the upper floor through the roof of the wing, by an elbow

bend, thus not interfering with our withering shelves—a chimney running through the withering floor is an objection also in the way of drying leaf in its immediate vicinity, and causing extra labor (if space is not wasted), in moving leaf perpetually as it withers and before it gets dry.

The T Sirocco is too well-known to need description. Nor need I waste your time in explaining how it is worked, as very clear instructions are given by Mr. Davidson with each Sirocco. Suffice it to say I find 14 lb. of roll to each tray give the best results. It should be rolled at 275°. 80 lb. an hour of dry tea is well within its capacity, 1 cooly will stoke 2 Siroccos if in the same pit. With 2 coolies to each sirocco to attend to the firing, and 2 coolies carrying and preparing roll, thus 7 coolies are required to work 2 sirocco in one pit; if 4 Siroccos are in use 1 cooly can be saved in preparing roll, or 4 Siroccos will require 13 coolies, and will turn out 320 lb. made tea per hour, at a consumption of 1½ lb. of dry wood per lb. of tea. Some small gardens of 100 to 120 acres may still with advantage work the old form of No. 1, and I hope Mr. Davidson will keep a few on hand and give them to us cheap. If the old form of No. 1 could be obtained at a *low figure*, it would pay young gardens, or gardens of small area, to purchase one or more of these, even in preference as I said above to the T Sirocco, as No. 1 will work well up to the limited rolling power then used. Firing by charcoal should be avoided if possible, as the waste in firewood and cost is so great. That different gardens owing to some local differences in leaf give different results is quite patent. In rollers taking twice the time at the same speed and with the same pressure to give the same results, and in driers worked at the same temperature turning out far less tea, as witness the difference in Mr. Hay's experience at Blackwater and mine at Rookwood, as previously shown; my No. 1, turned out 46 and 48 lb. made tea in one hour whereas Mr. Hay's trial only gave 30½ and 33 lb. in the hour. I quite lately tried my No. 1 with the result that in 6½ hours' working I got an average of 43.70 lb. per hour, and from a converted No. 1 at 6½ hours' work an average of 73 lb per hour: both were worked at 275° as near as we could keep it, and the converted No. 1 was working under the greatest disadvantage being in a temporary earth-pit with no draught. In making pits for the T Sirocco we must provide for a good draught by opening a funnel to the outer air, or having windows close-by and low down. From experiments tried I am perfectly satisfied that the T form of sirocco will turn out an even brighter outturn than the No. 1, and complaints brought against it of stewing the roll or causing a dull outturn is the fault of the manager and not of the drier. We are constantly hearing of our teas being overfired. Tea should never be turned out of the drier completely fired, it should be crisp yet moist (steamy slightly) to the hand. Evaporation goes on for some time by itself from the heat of the tea, and tea slightly under fired will the next morning when taken out of the receiving bin be found quite crisp and dry. At the side of each sirocco we should have a receiving bin: on no account should freshly fired tea be turned out on the floor. I find a very convenient arrangement is this. A bin 3 ft. 6 in. high and say 7 ft. long by 3 ft. wide. The lid opens in two halves: on one half the spare tray ready loaded rests; the other half is opened, and the tray just taken from the sirocco is put in bedly; the newly-filled tray takes its proper place on the sirocco, when the tray previously emptied and left in the bin can be cleaned and placed ready for refilling and the bin-lid shut down. The back of the bin should have an edging say 4 in. high on which the back rim of the tray rests, causing the tray to slope and so allowing any fine tips to drop through. As the lid is lifted these tips fall into a trough fitted at the back of the bin to receive them, and are fired separately. Each half of the lid should have an edging 1½ in. high round sides and front. This form of table bin is most useful also in final firing, receiving any dust or fine tea remaining in the pekoe sou-

chong, and which will fall through the tray as tea is spread, which may be turned out into the trough at the back by opening the lid.

Sorting.—As soon after firing as our tea gets cold, we may begin to sort. Before beginning this operation it is as well to taste the make from each siccoco to see if all is right. It is as well to sort and pack separately all inferior teas, if our garden is of any size; as inferior teas will only bring down the value of our best makes, without proportionately increasing their own value. Do not therefore try to disguise inferior makes by mixing them with your better teas. All being found as it should be, on tasting, we will now proceed to turn out all our receiving bins, and put the bulk into a No. 8 sieve. Teas retained by No. 8 are souchong and red leaf; this is put aside to have the red leaf picked out, after which the souchong is broken through No. 5, broken tea and dust removed, and then mixed with pekoe souchong natural, made in a No. 10. Teas passing through No. 8 are then put into No. 10 which retains pekoe souchong natural; pekoe, broken pekoe, broken tea and dust pass through. These are then, according to make, put into a No. 12 or a No. 14; if fine the latter; if coarse the former; which retains pekoe; broken pekoe is then separated from the broken tea and dust, with the shologoo (ordinary rice winnow) and dust separated from broken tea by No. 24. This will be pekoe dust. In firing quite 50 per cent of broken pekoe, dust, &c., passes through the siccoco tray and is not of course mixed again with the bulk, but sorted by itself and then mixed with its class. In cleaning the souchong, broken through No. 8, the dust taken from it is tea dust. The broken tea is mixed with broken tea natural taken from the broken pekoe. Souchong is best cleaned through a No. 12, or if only a little of it, by the shologoo as with broken pekoe. If our plucking is at all coarse, congou, a round knobby-looking make, will be left in No. 8 after breaking souchong through; this may be shipped as congou or broken by the machine and mixed with the broken tea. So much for sifting by hand, resulting in broken pekoe, pekoe, pekoe souchong, and broken tea, or 4 classes. With tea dust and pekoe dust which need not be looked upon as a class, and are unavoidable. In sifting by machinery we have to choose from Ansell's, Jackson's Eureka, and Gore's. The first is very good although rather expensive; the second also expensive, £81.5-9 at Colombo, is a most ingenious and clever sifter, but the tea travels over a too much ground to please me, giving a grey make. In Gore's sifter we have a cheap and very efficient little machine: its cost is R350 and it's out-turn about 100 lb. teas per hour, of 4 classes as above. A little hand work is necessary to clean the broken pekoe out properly, which is also necessary with the other machines. Gore's has one advantage over the others in that it separates the broken tea from the broken pekoe and the tea travels over very little ground. This machine is for work by hand, one coolly turning it easily whilst another feeds. A larger and stronger sifter can be made to order, to be driven by power, costing R450 to R475, but I do not think it is yet determined what work this will do per hour. I can strongly recommend the purchase of Gore's hand sifter at R350. A very good and cheap sifter can be made at the factory necessitating the cleaning by hand of the broken pekoe only, thus—sling three trays one above the other, strung joined together and about 18 in. apart. Each tray is 8 ft. by 3 ft. inside measurement. These are slung inside a strong framework or on to strong cross beams and worked with an ordinary crank, 6 in. stroke fixed on to the bottom tray all must be good work and strong. The top tray is No. 8 mesh and receives the bulk, souchong passing out in front. The second tray is No. 10—the tea falling through No. 8 drops on to a sheet of galvanized iron leading from the mouth-end of the top tray to the feeding end of the second at a good slope, thus delivering all teas that have passed through No. 8 to one end of No. 10; this passes out pekoe souchong to the right end (of No. 10) by a little iron spout. Teas passing through No. 10 are delivered by another sloping sheet of galvanized iron to the head of the bottom tray, which as explained in sifting by hand

should be a No. 12 or 14 mesh according to circumstances; this delivers pekoe to the left end of the tray, by an iron spout sloping in the opposite direction to that delivering pekoe souchong above. Under No. 12 or 14 and at a good slope forwards should be fixed No. 26 mesh,—on light reapers only. The broken pekoe and broken tea falling on to this are dusted and fed into a box in front of the sifter to be then separated by shologoo as in hand sifting. A sifter like this I made for myself, sorted 600 lb per hour as above, and cost about R300—this cannot be driven by hand, but is a very efficient and cheap machine. If wood has to be purchased teak will be the best, but it will bring up the price to R350 to R375 about. Unless then one's garden is a very large one, it will pay best and give least trouble to buy a Gore's.

I have spoken above of breaking souchong and congou &c. We have a very efficient machine and perhaps the best in Jackson's recently invented one, the Inviocible Cutter, price at Colombo £23-10-0, which may be seen at Messrs. Walker's. A breaking machine is almost a necessity and saves much labor. I have so far been using a Reid's machine; this is an excellent machine for making congou or faunings into broken tea, but is not good for use with souchong. Therefore, Jackson's is the one to get beyond all others.

After sorting for the day is finished our teas are packed away in bins. A skeleton framework 7' x 3' x 6' high inside measurement of wood 3" x 2½" lined with zinc sheeting which costs about R20 per cwt., 8 to 9 sheets running the cwt., makes the neatest and best bin. There may be a wooden partition in the middle, of ½ inch planking, and the bottom should be of 1 inch planks; there should be a sliding door of ½ inch plank at the top through which teas put into the bin, and directly underneath it, at the bottom, another sliding door by which the bin is emptied. So that one padlock may suffice for both doors, the lower door may have a handle reaching level with the top of the bin, the staple is fixed on to this handle, the hasp on to the top door, and all can be made secure with one padlock. A bin of the dimensions above will take 7 zinc sheets to line it top and sides. Bins can be made of any size to suit the factory, but should never be less than 7 ft. long, and in large factories to save space may be 8 ft. high. All bins should be raised off the floor say 6 inches to allow of the floor underneath being swept. Stale tea lying about in corners or under bins may be the cause of ruin to a break, or breaks by getting mixed accidentally, during the packing or bulking.

Packing and Fina Firing.—In an ordinary sized garden say of 200 acres, packing should be done every Monday; or in the busy time it may be done twice a week. The sooner tea is packed the better. Monday is a good day, as there is no manufacture to be done. Final firing in siccocos should be done at 260°. The tea need only be turned once a tray takes from two to three minutes, and tea should be spread quite level with the wooden edge of the tray. It is sufficiently fired when the hand (not a horny hand about pruing time) can just bear the heat, and when held to the face it does not feel steamy. Final firing requires as much attention as any of the other operations, and our best firing-men should be told off for this. Tea should be packed hot, straight from the siccoco. I have a No. 21 mesh for firing broken pekoe and broken tea, or muslin over an ordinary siccoco tray will do, but the No. 21 mesh is preferable. In packing we have a pad of hessian to fit our chest and tea is pressed well down by the coolies' feet, a cooly standing inside the chest "marking time." I know of no better plan than this. Half-chests may hold 4 to 6 oz. more than the declared weight; chests 6 to 8 oz. more. The size of package entirely depends on the accessibility of the garden. The chest is the cheapest as we well know, but if we have any carriage to the main road the half-chest is infinitely preferable. Mr. Deane has well met our requirements in the way of chests now. For gardens on the cart-road his No. 1 chests at 83 cents will be found most suitable. For gardens further off the road his No. 3 at 62½ cents will be

found the best. The chests are light and the tares are even, and good as our Ceylon chests are, the Japanese are better and cheaper. Ceylon made half chests need not be hooped; chests must be. Japanese chests of any size will not require hooping, another advantage they have.

Marking.—Do not write a book on the sides of your chests, as is sometimes seen. On the lid have your garden No. and shipping mark, say initials of consignee in diamond, with London underneath; in front have No. corresponding to that on lid, and garden mark; at back have class of tea and nett weight only, the other two sides plain. We are advised to make our breaks as large as possible to get full value for our teas, and we are told that the sale of breaks of under 5 chests or half chests or 20 boxes are postponed till after the general sales, when the best buyers will have left the room. With young gardens then, after picking out red leaf, I would break all teas through No. 8, dust and ship as pekoe souchong; put congou and red leaf through the breaking machine and after mixing ship as broken tea.

Bulking.—If this is done at the factory and it will be a saving if it can be done, "factory bulking" should be stenciled above the class of tea in the chest. Bulking must be done after final firing, and the teas thus packed cool, a slight disadvantage, but not so great perhaps as the teas suffer in being bulked at the docks. To bulk then, have all your siroccos at work, throw your tea as fired into one large heap on the floor and as soon as any one class of tea is finished firing rake out the heap well over the floor, say 3 in. thick, then heap again, the coolly working from the centre toward s him, forming a ring round him, the coolly then leaves the ring, again piles the tea in a heap, and again rakes it out and heaps, when the bulking will be finished and tea ready to pack.

I have purposely in this paper, so far, omitted all mention of cost; of the works touched on. We have these so often given us before, I would but have wasted your time in again going into them. I may however briefly state, that gardens in full bearing can put their teas f. o. b. at Colombo at from 27 cents to 36 cents per lb., that with careful management and with good machinery, on an ordinary average garden you may positively count on being able to ship your teas at 30 cents per lb. In August 1883 when I had the honor of reading a paper on tea before the Dikoya Planters' Association, I then estimated cost f. o. b. making every and ample allowance at 39 cents, and stated it was more than I should allow at a yield of 400 lb. per acre, and it is 3 cents per lb. over what you will find tea need cost you. With regard to yield a garden giving an average yield of 300 lb. per acre will found to be more uncommon than one giving 600 lb. as an average at 6 years upwards. Longer experience has shown us that there is not so much difference in yield between the lowcountry and the hills. Hill tea is slower at first, but wherever it has soil to work on it will be found I think at 5 to 6 years and upwards equal to any tea of the same age in the lowcountry, and when we put our millions of lb. before the market our hill flavor will go for something depend upon it, where all is good, comparisons are odious, so no more of this.

To revert again for one moment to factory and machinery. Having formed your garden, spend your utmost farthing in erecting a large and commodious factory, with ample machinery, and it will all be returned to you one hundredfold. You may begin your factory as soon after your planting is done as you like, and you must begin at the end of your first year, money is always object so it is not to be supposed you are to build the whole of your factory right off. Adopting the plan I have suggested you would begin then with a building say 36 ft. in length by 24 ft. wide, with two upper floors. Your bottom pillars would be 12 ft. high by 2 ft., on them 18 in. pillars 8 ft. high and on the top floor posts 6 in. by 6 in. to support the wall-plate. The two upper floors can be walled by either weatherboards, or wattle and daub plastered inside and outside with lime. The bottom floor is walled with a temporary wattle and daub wall weather-boarded outside.

When the time comes to add the wings both weatherboards and windows can be used for them, so there is no waste. Here is the foundation of our permanent factory then—to be added to as more space is wanted or as funds allow. If you have a good coffee store which can be converted into a factory by all means let this be done, but if your store is not a permanent one, and you can do without it pull it down, and use what timber you can for your factory. Temporary factories are most unsatisfactory things: an actual waste of money in themselves, and perhaps losing your pence per lb. on your teas. If then you cannot begin your factory on a proper basis sell your leaf till you can.

In deciding on your machinery it must be borne in mind that to finish your work in daylight you are working your roller 5 to 6 hours not 10, and your driers also half time. Estimate then what you want and multiply by two—the same with withering space. A few large flushes come upon us and we cannot avail ourselves of them as we ought, for want of space. £1,000 or so spent in more withering room will be represented in the gain on tea both by quantity and market value in one month perhaps or even less. Money if it can be spared will be well spent in the purchase of a small circular saw for cutting firewood into lengths without waste, among which firewood alas! comes our coffee trees, just too long in many cases for the sirocco, and they are tough subjects for the axe. In clearing out your coffee do not burn the trees to waste, as I have seen done, merely to clear the land in a hurry, but stack them for firewood, or for making charcoal. Do not aim at making 100 fine teas. It is pleasing to see an out-of-the-way average, but what does it mean? Too fine plucking, costly, and resulting in injury to the bush, a less yield which with heavier cost, quite I think, outbalances enhanced value, a large yield with good medium teas fetching a fair average value at from 1s 3d to 1s 6d will pay better and keep our bushes healthy and everlasting. I have seen, we have all seen, young bushes plucked to death, to give fine teas. How can these bushes ever develop themselves and give us the cover we should get. Apart from the injury to our bushes, and as I do not believe a low yield and high price pays as well as a high yield and lower prices, why educate the public taste up to a standard which we will not be able to maintain as time goes on, both on account of impoverishing the bush and—with no coffee to rob of its labor insufficiency of pluckers. Let our standard be an all round average according to the richness of our soil and suitability of our climate at from 1s 3d to 1s 6d per lb. and we will have no cause to grumble, I can assure you, with our tea gardens a permanency.

And, now, Mr. Chairman and gentlemen, I must close. As you are aware in a paper of this kind, it is impossible to enter fully into the subjects you were good enough to ask me to bring before you, as time is insufficient. I trust however I have said enough to be of some assistance to those who require it, and thanking you for the honor you have done me in asking me here today, I leave my humble effort in your hands.

C. SPEARMAN ARMSTRONG.

TEA IN JAMAICA.—By the way Mr. D. Morris is very hopeful of making Jamaica a tea-pro lucer. He has 4,000 plants in bearing in one of the Government Gardens under his charge, at an elevation of 5,000 feet, and a sample of made tea which he sent home recently has been very favourably reported on by Messrs. Geo. White & Co., who valued it at from 1s 6d to 1s 8d per lb. Mr. Morris estimates that by the labour of boys and girls tea can be produced in Jamaica, so as to be laid down in London at 7d per lb., but experienced planters would, I fancy, add considerably to this, if they were to revise the calculation in detail. Mr. Morris thinks that Jamaica may occupy herself for some time to come with supplying the local consumption, and that of other West India colonies, without competing in the London market. He is planting out 15 acres on the Government cinchona estates with tea, so as to test it on a commercial scale.—*London Cor.*

CEYLON UPCOUNTRY PLANTING REPORT.

RUBBER CULTIVATION IN CEYLON—"TIPS" FOR TAPPING
—A NEW PRUNING KNIFE—A WONDERFUL CHANGE
FOR THE BETTER IN CACAO—EXTENSION OF ROOKWOOD
—RAIN WANTED—A CHECK TO PRIDE AND VANITY.

31st August 1885.

We hear very little in these days of rubber, and yet there are amongst us those who firmly believe that it will yet become one of the paying products of Ceylon, and that it has a fine future before it.

"But we must wait," they say, there being as little reason in trying to draw milk from a calf, as tackling a young rubber tree, and expecting it will "bleed" for your advantage. They add also that it must be grown in large acreages, so as to be economically cultivated, and cheaply gathered. There is no doubt that the plant grows well: once established it is very difficult to kill; "ringing" seems to have little effect on it. As to this "sweet by and bye," however, only a few believe in it, and those few strengthen each other's faith by inventing tappers, double-bladed knives, sappers, and other requisites. Every now and again there is a gleam from the outer world, which encourages their hearts and brightens their prospects, as for instance the new indiarubber armour plating—and how anxiously they await the result of this novel experiment can well be imagined. I got the other day the latest "tips" in tapping; a sort of summary of the faith of the faithful few, and well worthy of record. "Use Dobree's double-bladed knife, cut upwards, after having peeled the outer bark, and go on tapping the trees once morning and evening. Take sixteen trees say at a time—or even up to thirty—which after finishing go back again to where you started and gather what has coagulated. Go on with this process for at least a fortnight, adding a few fresh trees every day. The first tapping will not be so rich as the following ones, but don't run away with the idea that there is no rubber in the tree because it cannot be seen. Immediately the roller (Fraser's) touches the tree, or the bark be run over obliquely with the thumb, a small fine string will appear, and a slight pressure of this against the roller will make it adhere and it will come off in strings. A little patience and practice will develop good results. In the case of a tree producing a gummy liquid—leave it as not yet ready for tapping. Rubber, with due patience shown to it, will pay. There is no faster method for collecting than by Fraser's roller. A cooly can, when practised, collect from half a pound to one pound daily, but he must have his heart in his work." So far for the method, and as for the future, let me raise the curtain and give you a peep at the vista which dazzles the eyes of the believing rubber grower:—"My trees," he says, "will be allowed to grow, and the day shall come when they shall show hundredweights of this valuable product"! Although this is a kind of note which has been often heard in Ceylon, and also too often has proved a mocking one, still it usually comes before an enterprise has been at all tried. To hear it of an industry which has been all but universally pronounced a failure, changes its tone somewhat.

I had a specimen of a new Pruning Knife sent me the other day. It is imported, I understand, from Smyrna, where it is used for vine pruning. It is made of a fine thin steel, with an edge like a fine saw, and is a good tool. It can cut through a thick branch of a tea bush with much greater ease than an ordinary English pruner, and is intended I understand to do away with the necessity of a saw in the field. It is

really astonishing what thick stems it can sever and with ease. It has one fatal objection—the price, costing more than the ordinary English pruner. If cheap enough I have no doubt it would be a favourite knife for heavy pruning, and if the importers really mean to place it regularly in the market, they should see to this.

It is a pleasure to report a wonderful change for the better in cacao. What a sickeningly ghastly sight some of it was a few months ago, need not now be dwelt on; rather let us rejoice at the change. Trees which looked before as if they had been blasted are now trying to cover themselves, and on those less severely attacked there is blossom as well as foliage. But it is clear to all of us that cacao is a fancy article, whose ways may lead us a dance at times; a prize nevertheless to those who have all the necessary requisites for its successful growth, and worthy of a good stout fight to gain them. In Ceylon what will a man not "clout" his enemy with? Think of helopeltis. Will the cacao planters have taken as allies against this foe the red ant: in Dumbara. Sinhalese bringing them in by the sackful, at a few cents a nest; they have dusted its back with unslaked lime, tried even a mixture of sulphur and lime, and some are taking to growing the tomato on their trees, hoping that will rout the dreadful fly. Ah! it's pathetic. V. A.'s tell you that they hate to hear the very name of cacao, and, as that is about the lowest deep the thing can touch, there comes the improvement, and we take heart of hope again, and like all the race of planters forget the past, and think of the future.

I hear that Mr. Armstrong is opening out more land near Rookwood. He will soon have over 800 acres.

Here we are sadly in want of rain, and yet it does not come. It is very trying on the tea seed planted at stake, although after all it can stand a good deal. For giving a man something on which to keep his mind employed, commend me to a fair acreage planted at stake. There is food for thought and a check to all pride and vanity. What with not coming up at all regularly, the more promising being laid low, eaten down by some insect or another, the ever-changing appearance of the field, inspiring you with hope today and despair tomorrow; the insane hunt at times to see if the seed was ever really put in; the worry with the weeders and your own impatience—all this does not make you feel as if you were in Paradise, nor incline your heart to talk the language thereof. Yet troubles must be good for the Ceylon planter; if it had been otherwise he should have been a fiend long ere this.

PETERBORO.

COMMERCIAL REPORTS: JAVA.

From the report by Consul McNeill on the Trade, Commerce, and General Matters relating to the island of Java for the year 1884, marked Commercial 19 (1885) [C-4,416], we extract the following:—

The past year, though not marked by any serious natural disturbance, such as the volcanic eruption at Krakatau in August, 1883, has in another respect, namely, from a financial point of view, been a calamitous one for the island of Java. The low prices ruling for sugar brought heavy losses on both planters and merchants; three large firms of old standing suspended payment, and several mercantile and banking institutions were involved in difficulties, from which they were only extricated by the issue of debenture shares. These were almost exclusively taken up in Holland, and what threatened at one time to become a most serious commercial crisis was happily averted. The total amount subscribed was over £2,000,000 sterling.

EXPORTS.

SUGAR.—The crop was an abundant one, being generally estimated at about 6,000,000 piculs, against about 5,000,000, 4,500,000 and 4,000,000 in the previous three seasons respectively; the quality too was all that could be desired, but owing to the exceedingly low value of the article in the consuming countries of the world, the result to planters has been on the whole disastrous. Nearly two-thirds of the crop was shipped to Europe on planters' account. Should the present low value of sugar continue, many plantations will be unable even to pay expenses, while others, already in difficulties, will be compelled to stop working altogether. On the other hand, there is no doubt that owing to improved machinery now used on most estates, a more scientific system of working generally, and the yearly increasing facilities of transport, the cost of production of Java sugar has of late been very materially reduced, and estates well situated and well managed may still be worked without loss. Some mills are indeed able to produce sugar at a profit even on present rates, but this is quite exceptional. On the whole Java, owing to its favourable soil and climate, and last but not least its unlimited supply of cheap native labour, will always compare favourably with any other cane sugar-producing country, and it is to be hoped that some improvement in the value of the article may soon again restore the industry to its former prosperous condition.

COFFEE.—This year's crop has generally been unsatisfactory, both in quantity and quality, which may be attributed in a great measure to the ravages caused by the leaf-disease in the early months of the year, in the plantations situated in the central and eastward districts of the island. Should this disease not show itself during the wet monsoon months in the beginning of 1885 a considerably better yield may be looked for next season; but it must not be overlooked that the late frequent attacks of this disease have greatly exhausted the trees, and it must take some time before they again recover their normal producing power. The Government Java crop shows a decrease, viz.: 1,011,787 piculs, against 1,472,492 in 1883.

The tobacco crop has been above the average of late years, and the quality has proved superior; the cultivation of the leaf has not, however, much increased, and bears no comparison to what it was formerly.

TEA.—This industry is continuing to make rapid strides, but it is doubtful whether, with the low prices ruling in Europe, the returns to planters are very remunerative; the opening up of the new gardens points, however, to the probability of the estates being worked without loss. The total exports in 1884 were 2,904,567 kilns, of which it is worthy of note that more than two-thirds went to the London market.

CINCHONA.—The cultivation of this tree is being pushed with energy, and though the exports from the Government gardens show a falling off, those from private estates show an increase. Prices in Europe, although considerably lower than in past years, are still at a paying level, and enable planters to extend operations with vigour.

GOVERNMENT RAILWAYS.—During the past year great progress has been made with these railways, and several lines have been completed. The main line from Sourabaya to Soerabakarta, *via* Paron, Modjo, and Sirgong, has been finished, so that there is now rail connection between the principal coast ports, Sourabaya and Samarang. The rail between Toeloenggoeng and Blitar is finished, thus completing the branch from Kertosogo to Blitar. Passeroean and Probolinggo have also been connected during the past year. The western line was completed as far as Tjitjalenka last September.

BATAVIA HARBOUR WORKS.—Operations during the past year have been confined to completing the permanent way and constructing sundry Government offices in the immediate vicinity of the harbour. The marshes surroundg the harbour are being filled up by ditches and the albizzia and sunflowers which have been planted there have produced good results. Fever does not appear to have been nearly so prevalent at the harbour during the past twelve months as in the previous year,

and the complaints of ship captains regarding the health of their crews whilst there are considerably less than formerly.

TRAMWAYS.—Two steam tramways have been completed during the past year—one between Samarang and Joana, *via* Demak, Koesoes, and Pati; and the other between Batavia and Meester-Cornelis. The former line has a length of sixty miles, whilst the latter is about seven and a half miles long.

SUMARANG.

The report by Consul H. G. Kennedy on the trade and commerce of Acheen during the year 1884, with a notice of the Deli tobacco districts issued in the same volume, states:—

The total quantity of pepper exported from Acheen (Oelieh and Edie together) in 1884 was about 73,000 piculs, of which nearly 68,000 piculs were sent from Edie. Comparing this total with the quantities for the preceding five years the result shows as follows:—1884, 73,000 piculs; 1883, 122,579; 1882, 106,255; 1881, 107,180 piculs.

The average price of pepper ruling in the Penang market during the past year has exceeded \$17 and for a considerable period there was none at all offering for sale. The average price in 1882 was \$14.71; in fact, pepper has continued to rise steadily in value since 1878, when a picul of Acheen pepper fetch \$9.82 in Penang.

DELI.

The Deli district is about 4° north of the equator, in longitude 98°—99° E., and is made up of three States: Deli, the oldest, in the centre, under a Sultan; Langkat, to the north, under a native chief, called a Pangheran; and Sirdang on the south, also ruled by a Sultan.

As is well-known, the main cause of the prosperity in Deli is the tobacco, the first crop of which was shipped, as I am informed, in 1869.

The crop for 1884 will turn out about 122,000 bales (each bale equals 176 lb. English), valued at £2,080,000. Prices for Deli tobacco have ruled on the whole fairly high, the special quality of the leaf lying in the fact of its being light and elastic in texture, with thin fibres. The tobacco estates consist of grants of land taken out by individuals or companies, and are, as a rule, of such an extent that every year a new district can be cleared and used for the coming crop, and this state of things will continue for many years to come. The planters consist of three or four large companies, principally Dutch—such as the Deli Company, the Amsterdam Deli, and the Batavia Deli,—as well as of individual planters of many nationalities, German and Switzerland being strongly represented, while there are also a good sprinkling of Englishmen, the principal English firm being the Langkat Plantations Company, with its headquarters in London. The grants of land are taken direct from the chiefs before-mentioned, and are only valid after confirmation at Bengkalis. The term is for seventy-five years, and for such a grant a sum of money, amounting to from \$1 to \$2 per bouw (equal to an acre and two-thirds), is paid in cash, while an annual rent of c. 40 a bouw, payable at the expiration of the fifth year, is also reserved. It is estimated that at least £2,000,000 sterling is now invested in the tobacco industry in the Deli districts. The tobacco when ready for shipment is all sent to Lamblia on the Langkat river, to the Deli river, or the Sirdang river (as the case may be), and is dispatched thence via Penang or Singapore to Amsterdam. It is worth remarking that the whole of the carrying trade in connection with the Deli tobaccos is in the hands of Messrs. Holt's line, the rate of freight from Deli to Amsterdam being about £3 2s. 6d per ton. The shipping season may be said to last from January to June. The tobacco crop of 1884 is estimated to yield about 20,000 bales in excess of that of 1883, but the crop in 1883 was a short one, owing to unfavourable weather. The 1884 crop is the best one ever obtained, both as regards quantity and quality.

The forests when cleared for tobacco plantations afford splendid timber, and this is utilised for constructing drying sheds and coolies' quarters, but a good deal of the wood which might be exported for building or fuel is wasted for want of conveyance and burnt on the ground. As a compensation there can be no

doubt that this burnt timber, or rather the ashes of it, supply an excellent manure.

The labour employed may be distributed under three classes. There are, firstly, Malays and Batak tribesmen, who fell heavy timber, do general clearance, and build sheds; then come the Klings from the Madras districts, who occupy themselves with drainage and roadmaking; and lastly, we have the Chinese for planting, sorting, and preparation of the weed. The planting is conducted on a co-operative system. Coolies have their fields allotted to them, and plant at their own risk under supervision. Their payment depends on the yield. An industrious coolie would, on an average, net in the course of a year 100 to 150 Dutch florins, and on this sum he pays to the Dutch Government 2 per cent by way of income tax. The coolie, however, arrives in the country with a debt of from fl. 100 to fl. 150, and thus as a rule is not clear and able to leave with a balance in hand till the end of the second year. The coolie is engaged for a year, but he generally re-engages, and takes his departure in the beginning of the third year.

The Dutch Government regulations with regard to the maintenance of a medical man by every estate and to the erection of hospitals for sick coolies are stringent, and, on the whole, the coolie-lines, considering their temporary nature, are adequate, so that the lot of the coolie in Deli may be regarded as a favourable one, even when compared with places where he is under British control.

The importing of British Indians, as is well known, is not tolerated, though many have found their way into the country under the stimulus of high wages, the latter running from \$7 to \$10 a month, according to capacity. The act recently passed by our Indian Government to regulate coolie emigration to the Straits Settlements will, it is generally feared, close the outlet in Deli for British Indian labour. This is a matter for regret, more especially in respect of those coolies who, having already worked out their contracts in the Straits, are anxious to improve their prospects.

The difficulties of communication of course tend to make the cost of living dear, and as a consequence of the isolated position of most of the planters the choice of food is very restricted. On the whole the health of the country may be considered good, the nights and mornings being fresh and cool, though unseasonable weather often brings with it epidemics of fever and berri-berri, especially among new comers, many of whom arrive in a sickly condition, which naturally predisposes them to such ailments.

DRY LANDS IN SOUTHERN INDIA AND SUITABLE CULTIVATION.

Southern India is more liable to drought than the rest of the country. It is nearer the equator. Its rivers are entirely rain-fed; they have at their sources no snow-capped mountains to supply them during the hot season; and the courses of most of them are short, and, on the whole, steep; and the land in which these have their source and course, has not much forest to retain moisture; and hence the rivers are either in high and rapidly flowing flood, or dry. For a few days or weeks in the year they cannot be crossed from the excess and violent flow of water; for a few more weeks they have water enough in them to justify their being called rivers; and then they become sandy or stony wastes, nearly as hard to cross to the bare-footed pedestrian, from their burning heat, as at flood time. The high western mountains, which have much soil on them, and at whose base there are considerable forests, receive much more rain throughout the year than the country east of them, and are more retentive of the water they thus receive than the other hills in Southern India, which are generally bare and rocky. Hence the rivers that rise in the Western ghats have more water in them than those that rise in the central table-land or among the Eastern ghats; and their longer course is less steep on the whole. Of course,

all the rivers have more water, and have water longer in them, at their mouth, and in the long belt of low-land plain between the Eastern hills and the sea, than in the interior; and there their flow is gentler. It is in this plain, therefore, and at the deltas of the larger rivers, that there are the most considerable dams and canals for irrigation in all India. And in the interior, in most of the places where the contour of the country admits of it, dams are constructed and a little at least of the annual rainfall is retained. Thus it comes about that in the Madras presidency there is a larger proportion of irrigated, to what is called dry, land than in the rest of India. For all India the proportion of irrigated land to cultivated dry land, is less than seven per cent. In Southern India it amounts to twenty-one per cent. But even this is far too little. And, indeed, it must, we fear, be admitted that the high ratio of wet to dry land is in part due to the large extent of dry land which, though cultivable, is not cultivated. If the area of irrigated land were compared with the area of all the cultivable dry land in the presidency, the ratio would show less favourably for the irrigated land. In Southern India not only is there a vast area of cultivable waste land; but much of the cultivated dry land, though of good quality, yields very poor results, because of drought. The land parched, and the air is dry. In the low Carnatic plain, and in the Northern Circars, the soil contains moisture throughout the year to a far greater extent than in the interior uplands, from which the drainage comes to it, while its low and level condition prevents its passing its moisture on to the sea as rapidly as it receives it. Moreover, as the atmosphere of the plain near the sea, receives moisture from the sea, it is far less dry and siccant than in the interior, and there is, therefore, less evaporation from the ground. For these reasons, even with less rainfall, and with a poorer soil (as soils are commonly estimated) cultivation can be carried on through a greater part of the year, and yield better results, in the littoral regions than in the plateaus. In the latter, here and there, near a large tank or reservoir, there is an oasis during the early part of the hot weather; a thousand or two acres of a second sowing of paddy or other wet grain preserves a little moisture in the air above it, and in the immediate vicinity. But when even that crop is taken up, so dry does the air become, that none but hardy plants can endure or survive it, even though watered and sheltered from the fierce sunlight. This fact—the extreme dryness of both the soil and of the air in the interior—seems to have been overlooked by Mr. C. K. Subba Rau, when, in a lecture before the Agricultural Students' Association in March last, he argued thus:—“Of the 16½ millions acres of dry land in this Presidency, only 478,371 acres, or scarcely half-a-million acres, carried a second crop during 1882-83, when the season was very favorable, as the Administration Report for that year will show. What was done with 16½ millions acres of dry land during the year? It must, of course, have been lying waste. These 16½ millions acres could have been made to produce two crops of horse-grain for green manure or fodder, one before, and the other after the cold weather crop. Even the 478,371 acres could have been made to produce one crop of horse-grain previous to the hot weather crop. The weather was very favorable in 1882-83 for growing horse-grain during any three months between January and May, and again between May and September. In ordinary seasons, the harvesting of the cold weather food corn crops may be arranged to take place early in January. It will

then be possible to grow horse-gram even in the absence of any rain, provided the land is ploughed on the very day that the crops are reaped. . . . Three or four ploughings even with the country plough and about six measures of seed are all that is required to produce a crop of horse-gram for manure. It is the duty of all men who have the welfare of the country at heart, to use their influence towards the general adoption of this highly beneficial practice of green manuring. In this manner many million tons of organic matter may be added annually to the soils of the country. As any number of crops can be grown on dry land without extra assessment, I do not see what difficulty the ryot will have in adopting it. Some of the dry lands are so deficient in organic matter as to be unfit for cultivation."

Mr. Subba Rao then advises that such lands be planted with casuarina, of which the sheddings ought to be allowed to enrich the soil. And he also suggests that there can cultivation between the lines of casuarina. But all the above argument is materially affected by the fact that the lecturer argued from the condition of things at the Sydapet farm to what may be done in country which is under very different conditions. On soil very poor in organic matter horse-gram was grown in the Sydapet farm. How is it that horse-gram grows on such soil? Because it is nourished simply by air and water, just as casuarina trees are. And the soil is simply the medium through which the nourishment contained in air and water is most conveniently conveyed to the plants. But it is quite possible that casuarinas will refuse to grow both on similar soil in other parts of the country where there is no moisture; and also that, even though there may be moisture, they will refuse to grow on land which is very unfavorable to its ready percolation and to the penetration of air to the roots of the plant. And so it is with horse-gram. It is not much moisture that it requires; but some it must have; and the soil on which it is planted must be rather loose or light, so as to admit of air penetrating to the roots. On the Sydapet Farm, with all its "blowing sands," it would be impossible at any time of the hottest year to dig a few inches below the surface with the hands or with a stake without coming upon moisture, or to dig a few feet without coming upon water. And, however hot the surface of the sands may be, that very heat must be constantly bringing up vapour from below to the surface. In fact, the sub-soil moisture is inexhaustible, because the soil is loose and the sea is near. But how totally different in regard to moisture and the condition of the soil is most of the dry land in the interior! A little below the surface it is in many places as hard as rock, and the digger may go down to primeval granite without finding water, as the tentative borings for artesian wells showed. And in some places even the upper soil is unfavourable to the penetration of air. Then again, it is not only by their rootlets that plants and grasses receive nourishment, but through every part of them; the very leaves and grass-blades absorb air and moisture. And when the air is destitute of moisture, even watering the soil of individual plants does not, in some cases, avail to their nourishment. Moisture in the air is essential to their existence. And what a difference there is between the atmosphere of the coast and that of the interior in this respect! Only when the landwind greatly prevails do we in Madras experience anything like the parching scorching heat that prevails in the interior. The greater density of the air and the moisture it contains near the coast, make the heat there more oppressive to animal life; but these conditions are more favorable to vegetation than the arid heat of the in-

terior. The absence, therefore, or great deficiency of moisture in both the sub-soil and in the air in the interior of the country is the reason, which Mr. Subba Rao could not see, why the ryot cannot adopt the plan he proposes of raising three crops a year on dry land!!! So far from being able to raise one crop of horse-gram before, and one crop after, the winter crop of food grain—and that on all the 16½ million acres of dry land that now bear but a single crop a year—Mr. Subba Rao must learn that on many an acre of land the ryot would be glad if he could always raise but one good crop of horse-gram as his winter crop. And if he could, so far from using it for manure, the poor fellow would eat the gram himself, and feed his cattle on the rest of the plant—roots and all—which is full of nourishing matter for cattle, and is most carefully preserved and doled out to them daily with the other fodder as a treat. The students and others at the Sydapet Farm should be on their guard and about generalizing too freely from their experience or observation on the farm. As we hope to show further at some future time, very good land in the interior is at a great disadvantage, in some respects, compared with the inferior soil of the Sydapet Farm. —*Madras Times.*

PLANTING IN DELI.

(Translated for the "Straits Times.")

New Staple Products.—Planters in Deli who, this year too, may rejoice in splendid financial results arising from the sale of the 1884 crop, have, often and not unjustly, been reproached with the fact that, in this country, so pitifully little has been done in paving the way for growing new products and setting the example in cultivating them, from every effort and all their energies being directed upon tobacco only, without paying heed at all to the likelihood that, some day or other, all may be over with high prices. We do not range ourselves among those who hold gloomy views as to the future. We on the contrary, are convinced that Sumatra tobacco, within the last few years, has gained a particularly high reputation throughout the commercial world and that hence it can only be ousted from this vantage ground by a product possessing at least the some good qualities. Moreover, one tranquillising circumstance for Deli planters is that the country competition from which most has been looked forward to, is still an unexplored region. But, notwithstanding this it is our opinion that prudence counsels the utmost attention to be steadily directed upon the cultivation of all tropical products likely to make the East coast of Sumatra more independent of tobacco. For that Deli tobacco will continue to be a permanent exception and that the vicissitudes which characterize wholesale trade in all colonial produce articles will never betail it we would rather not believe, the more so from tobacco being concerned, as to which trade and cultivation have often undergone changes for the worse. We rather look upon a reaction as being merely a question of time, than feel uncertainty whether it will come or not. That many planters are regardless of the future so long as they do well in the present is easy to understand by bearing in mind the price ruling within the last few years. Neither is it any wonder either that they do not feel the least inclination, in consequence, to make experiments. When, however, low prices once set in further delay will be dangerous, and the question what is to be done will we hope not be, then, put too late. What we fear is that, then, the

needful information and guidance will be lacking upon which the cultivation of new products can be started in this settlement; from the few experiments in growing different crops taken by the Deli Company and several private individuals having led to unsatisfactory results, so that, when the time comes, no produce article sure to be in great demand can be pointed out as a culture suitable for future plantation enterprise here. The indigenous nutmeg cultivation has, within the last few years, wholly come to nought from the trees dying out and other products such as coffee, cocoa, and rambé, experiments with which have been tried, have only been slightly successful. As crop for 1884, about 400 piculs of coffee were recently forwarded from here to Holland. Regarding the Mariendal estate, where the Deli Company cultivates this article on the largest scale, it is stated in the latest Official Colonial Report that one important subsidiary crop grown on the same is common and Liberian coffee with every prospect of further extension. According to available particulars the number of trees increased there in 1883 to 215,000 including 200,000 of the common kind which in general presented a very promising appearance, of which the older portion, numbering about 50,000 trees were beginning to be more and more productive, so that in 1883, one hundred piculs of berry were gathered against 35 in 1882. This product brought 40 cents per half kilogramme in the Netherland market. The 15,000 Liberian coffee trees looked less promising. They suffered severely from leaf disease and died in great numbers. Regarding the Petanic estate worked by the same company it is reported that an experiment with Liberian coffee wholly failed from the young plants all dying out within a few weeks. Respecting the St. Cyr estate, we read that of the coffee trees under cultivation, the Liberian ones only looked flourishing but that the remainder presented a stunted appearance. Thus, while so far as coffee is concerned the outlook is unsatisfactory, matters with regard to cocoa are not one whit better. The Deli Company report about it that the cultivation of the same will be extended, but it is still uncertain whether success would be achieved, though the crop growing on the St. Cyr estate appears to promise well for the future. The rambé regarding which, at one time, great expectations were entertained, has of late years, been shoved more in the background owing to the expensive and wholly unsuccessful trials with it in Java. The Deli Company which made experiments in growing this article on a large scale, reported that trials in cultivating it were being continued with regard to the kinds styled *virea* and *utilis*. The crops looked well in the fields and several times yielded fair crops. Samples forwarded to Holland did not, however, answer expectations from the machinery used proving unsuitable for separating the rambé from the stalks. Shortly, however, improved machinery will assuredly become available. Without regarding the cultivation of the three abovementioned produce articles as having proved a failure, everyone will agree with us that they cannot be looked upon as future products for Deli, and that it is worth while to look round for something else wherever there is anything to learn on this point. Would it not be worth while, for instance, to try jute, the cultivation of which has proved so successful in Bengal?—*Deli Courant*, 8th August.

COFFEE AND GOLD IN SOUTHERN INDIA.

The annual statements of the quantities and official valuation of coffee shipments from India begins to show the declining prosperity of the enterprise of coffee planting, and the decreasing area of cultivation. The wonder is that the statistics have taken so long to reflect the melancholy change that has come over the position and prospects of planters. The figures we refer to are as follows for the last twelve years, it being premised that we have reconverted the pounds sterling in the official statements into rupees, at par of exchange:—

Year.	Quarterly.	Official Value.	
		cwt.	R.
1873-74	...	367,132	1,49,94,960
1874-75	..	312,874	1,30,79,190
1875-76	...	373,499	1,63,33,950
1876-77	...	304,158	1,35,45,880
1877-78	...	298,557	1,34,46,380
1878-79	...	342,268	1,54,84,510
1879-80	...	361,037	1,63,30,320
1880-81	...	370,713	1,60,25,940
1881-82	...	351,981	1,46,07,290
1882-83	...	364,008	1,41,91,310
1883-84	...	340,025	1,43,88,630
1884-85	...	328,317	1,24,55,600

It thus appears that the quantity of coffee exported fell between the beginning and the end of the period, to the extent of 38,865 cwt. or by about 10½ per cent, and the value by Rs. 29,900, or by 17 per cent. This is serious, but not nearly so much as one might look for from the actual state of affairs in the coffee districts of this Presidency. The explanation of that state of things is not far to seek. Planters have been disappointed of seasonable weather, and have been victimised by borer, leaf-disease, and maistries; but their chief cause, for complaint is that the coffee that they have succeeded in sending to market has fetched unremunerative prices. The consumption does not increase with the supply, or with the increase of population, and the cheapening of the article. Compare, for example, the consumption per lb. per head of population, in the United Kingdom, of coffee, tea, and cocoa, for twelve years:—

Year..	Coffee.	Tea.	Cocoa.
1872	... 1.00	5.047	0.25
1873	... 1.01	5.502	0.26
1874	... 0.99	5.940	0.28
1875	... 1.01	6.517	0.31
1876	... 1.02	6.839	0.32
1877	... 0.99	5.666	0.30
1878	... 1.00	6.007	0.30
1879	... 1.04	6.113	0.30
1880	... 0.96	6.233	0.31
1881	... 0.90	6.277	0.31
1882	... 0.89	6.230	0.34
1883	... 0.90	6.636	0.36

Taking, as before, the first with the last year of the period under notice, and the consumption of coffee is found to have declined 10 per cent, while that of tea has increased 31½ per cent, and that of cocoa 35 per cent. A glance at the official average of the price of coffee in the United Kingdom in the latest ten years of which statistics are yet available, show the real cause of the distress now prevailing in the planting districts of this Presidency.

1874	£5.03 per cwt.	1879	£4.44 per cwt.
1875	4.73 "	1880	4.44 "
1876	4.68 "	1881	3.87 "
1877	4.83 "	1882	3.81 "
1878	4.06 "	1883	3.51 "

"O, Hamlet, what a falling off is here!"

From 1855 to 1865 the young fellow who "went into coffee" was usually regarded by his friends as one who was bound, if he exercised but ordinary prudence, and lived economically, to make a very neat competency wherewith to return to his native land, and the bosom of his family, long ere the prime of life had been passed. He was, at the same time, regarded with much amiability by Banks, bankers, and the devotees of commerce. But, by a lamentable concatenation of events, for which they are not themselves responsible, the planters, with few exceptions have been reduced from comparative affluence to approximate poverty. The bankers who were once so ready to advance money to them on mortgage for the extension of estates or in anticipation of crops, now, with one consent, refuse to advance a rupee, and are foreclosing in self-defence. The credit of plant planters has thus temporarily gone, and only those planters remain in India who are unable to get away without sacrificing the savings and labours of a lifetime. Estates, when forced on to the market, fetch the most ruinous prices. Coffee is overdone; cinchona is overdone; and tea, it is feared, is also in course of being overdone. The gloomy position of coffee in India, Ceylon, Java, Brazil, &c., deters the entrance of new men into the business; prevents the investment of fresh capital; contracts the area of cultivation (for the estates of some planters who had no funds to go on with, have been abandoned, and have returned to jungle); and must, in the course of time, reduce the supply of the berry to the consumer, and thus bring about a partial remedy for the present state of things. But it will need many good years to restore the confidence of capitalists in planting enterprise. All this must contribute to the commercial disadvantage of Southern India.

There is reason, however, to hope, that what the Presidency may lose by coffee, it may make up by gold, and other minerals. The prospects of gold mining in Mysore are certainly very encouraging. The Mysore Company is said to be winning gold of the value, on an average, of over £8,000 per mensem. It is weighted with a capital of £135,000, which is out of all proportion to its wants. £45,000 of this went to pay for a square mile of unproved land, and much of the rest was dribbled away. Any profit now being made will afford but a small dividend on the whole capital, but if £30,000 be taken as the fair value of the comparatively small piece of land now being worked, and of machinery purchased and mining operations to date, then it will be seen that the Company is doing well. It has convincingly established the existence of gold in paying quantities, within (as compared with Australian mines) a short distance from the surface. The greatest depth reached, so far, is 235 feet, and the deeper the shafts are sunk, the more rich is the stone. Probably the Mysore Company will reduce its capital by selling bits of land advantageously. The Nundydroog and Ooregum Companies have actually resumed operations, and the Ballaghat is hard at work, and hopeful.

The home public having been once bit about Indian Gold Mining, will be shy about further investments in the development of the latent wealth of what they can but regard as the Land of the Golden Fleece. But in 1880-82 the public was grossly misled, and again and again did we protest against the folly of the hour. Now, however, the case is different. "Results" which were vainly craved for in 1880-82, are now before us, so far as Kolar is concerned, and these are handsome enough to encourage further enterprise. Gold is the crying want of the age, as the supply is far

below the world's requirements, and prices are being disarranged by the portentous fact. If, then, Madras should eventually become—as seems probable—the outlet for a large and steady supply of the commodity, her own fortunes will be beneficially affected. We wish we could add that gold mining prospects are improving in Wynaad, but the industry is believed to be hopeless there, though the revival of interest in the Kolar field may exercise an encouraging influence upon the Western Coast. The business of gold mining will now, it is fair to believe, be conducted on sound business principles; and as in Australia, so here, success in a search for gold should stimulate investigation into the iron, copper, and coal resources of the Presidency.—*Madras Mail.*

NATAL: DEPRESSED AGRICULTURAL PROSPECTS.

From Sir H. Bulwer's Speech to the Legislative Council:—The past season has been accompanied by a drought of unusual severity, which has entailed, I am sorry to say, considerable losses among the natives living in the thorn districts, and has already caused a rise in the price of produce above average rates; but although farming has been carried on under somewhat exceptional difficulties, the year has been marked by increased activity on the part of those engaged in agricultural and pastoral pursuits. The evidences of this are visible in an enlarged area of cultivation, in many improvements in the method of farming, and in the extensive enclosure of land. The variety and excellence of the articles exhibited at the different agricultural shows recently held, affords a proof of what can be done in the colony; and a comparison of the entry lists of the agricultural societies with the list of imported articles affords a further proof that many things now imported can be produced in the colony. The sugar planting industry in this, as in all the other colonies where it is prosecuted, has entered upon a period of serious and anxious depression in consequence of the severe competitive struggle that it has to carry out with the produce of the beet in the home markets. The best way for carrying on this struggle will probably be found in the improved modes of growing the sugar-cane and in the careful prevention of all waste, whether of material or of labour, in the manufacture. It is satisfactory to know that the sugar planters of the coast have not been discouraged by the great reduction in the prices obtained by them, but have on the contrary shown renewed activity, and are steadily adding to the area of land under cane cultivation, while the recent partial recovery of prices in the home market is a cause for further congratulation. Notwithstanding the leaf-disease and other causes which have led to a falling-off of late years in coffee planting, this industry has now been to some extent resumed with a fair prospect of success. The growth and manufacture of tea gives promise of developing within a few more years into a profitable enterprise. At present the consumption of these two products is almost exclusively limited to the colony; but I trust that it will not be long before they take place among the articles of our regular export." From the reply of the Council we quote as follows:—

"We regret the continued depression which exists in commercial circles; this depression, however, is not peculiar to Natal. No doubt, the decrease in our imports is partly caused by the diminished prices obtained for our chief articles of export, whereby the purchasing power of the community is reduced. This is beyond our control; but it will be our

duty to watch and take care that the recent increase in our tariff has not acted prejudicially on the internal trade of the colony, and that it has not also diverted the course of trade into other channels. If the extent of our trade with the Diamond Fields has decreased, it is a question whether adverse tariffs have not had more to do with the diminution than the inactivity mentioned by Your Excellency. The interest taken in all farming pursuits at the present time is in gratifying contrast to the apathy which but too recently prevailed. If the country is to prosper, it can only do so by the persistent and intelligent working of the land, out of which all wealth must come. It is to be hoped that the sugar industry has now seen the end of the severe struggle it has had to maintain in the markets of the world; and the fact that our planters have not been discouraged by the adverse circumstances with which they had to contend in recent years, must be a source of congratulation to every true colonist. We trust the day is not far distant when our supplies of coffee and tea will be produced in the colony, and that these products will soon take their place in our list of exports."

SEA-SICKNESS.—An eminent American physician has discovered a certain preventative for sea-sickness. The remedy is simplicity itself; and so, probably, is the promoter of it. The patients are simply required to stand on their heads while afloat, and the miseries of *mal de mer* are banished from the catalogue of ills that flesh is heir to. I do not, however, think that the ingenious doctor's treatment is likely to be universally adopted. It would be somewhat inconvenient; though, on the other hand, the spectacle of the Channel boats arriving daily at the pier at Folkestone of Dover, with the whole of the passengers in an inverted position, would add considerable zest to the pleasure of the usual rowd which delight to meet them.—*Weekly Echo*, July 25th.

"TERNE" PLATE can easily be distinguished from properly tinned sheet iron by the sense of touch when handled by experienced persons, unless the terne coating contains an unusually small proportion of lead. Fordoz's test may, however, be depended upon as final. Clean the surface of the suspected plate, using a little ammonia to remove every trace of grease, and dry thoroughly in a gentle heat, after applying a drop of nitric acid. Let a drop of the official solution of iodide of potassium fall on the place where the nitric acid was laid. A yellow spot will appear if the less lead is present. This test, as has been shown, is a good one for examining the quality of enamels of cooking vessels.—*American Cultivator*.

The following, which we extract from the *Farmer's Review*, is not cheerful reading:—"Prof. Riley, Entomologist for the Department of Agriculture, announces that this year we shall have two distinct species of locusts, the seventeen and seven year locusts. It has been two hundred years since these two kinds have appeared in the same season. Neither are destructive to crops; their chief injury is to trees by depositing their eggs in the tender twigs of the new growth, which cause the portion beyond the egg deposit to die. The Hessian fly and chinch bug is reported as at work this spring in the wheat in those districts where it was present last fall. These are the new crop hatched from the eggs deposited on the plant last fall. There is no remedy for them now or nothing which can be done to prevent their damage to the wheat. Grasshoppers are already reported at work in Texas, and the bark louse is present in unusual numbers upon fruit and shade trees in wide districts of the country. Altogether we are likely to have a *buggy* season."—*Indian Agriculturist*.

NEW GUINEA.—The following from *Colonies and India* is of more than ordinary interest:—There is a strong desire amongst Australasian Colonists at home to know what the new Conservative Government intend to do in regard to New Guinea, and with a view to eliciting some information Viscount Lynton questioned Colonel Stanley on the subject in the House of Commons on August 5th. The hon. member for Barnstaple wished to know whether Her Majesty's Government had decided upon the form of Government under which the English portion of New Guinea was to be administered, upon the proportion of the expenses of government to be borne by the Imperial Exchequer, and upon efficient means of permanently securing the yearly contributions of the Colonial Parliaments. Colonel Stanley, in reply, said he was not in a position to make any definite statement. It was hardly necessary to be told that the proceedings which had taken place in respect of New Guinea had been somewhat interrupted by the change of Government, but it may be hoped that the various arrangements which Colonel Stanley says "are not yet concluded" are progressing satisfactorily, and that Her Majesty's Government will shortly be in a position to make some definite and satisfactory announcement on the subject. We seem to hear more about the German than the English half of the island. From the last number of the *Neurichten für und über Kaiser Wilhelm's Land und den Bismarck-Archipel*, published by the New Guinea Company, we learn that Friedrich-Wilhelm's-Haven "is the best and safest haven on the north coast of the island." The largest armour-plated vessels, we are assured, could lie there securely, as the harbour is land-locked. The natives cultivate plantations on the coast, and it is remarked that it would be a difficult matter to find out the real proprietors, since several settlements take part in one plantation. A high mountain chain, far inland from Astrolabe Bay, and rising some 5,000 or 6,000 metres, but not given on any map, has been named the Bismarck range. The land opposite Bill Bill, in which are large plantations, is said to be extraordinarily rich and fertile. Behind Astrolabe Bay, however, all is different. From Cape Rigby for sixty miles east are creeks with low banks bordered with trees. There are no coral reefs, but the sea attains a great depth. Havens and anchor-grounds are also lacking. The land is considered well suited for cattle and sheep rearing, and also for flax cultivation. It is everywhere accessible for horses and beasts of burden, so that travelling is easy. There must be an abundance of water even in the driest season, for Dr. Fiesch, who sends the above information accounted 19 large rivers. While the advices received from Dr. Fiesch concerning the northern part of the island and its climatic conditions are of the most favourable character, the New Guinea Company is desirous that all reports, whether favourable or the reverse, should be received with caution pending the result of further investigation. It may be remembered that a short time ago an expedition, under the leadership of Herr Grabowsky, left Germany for New Guinea. It is to call at Java for the purpose of recruiting labour, so that it will not arrive at Kaiser Wilhelm's Land till October. But the real scientific mission which this explorer has to guide into the interior will not leave Germany until November or December next. Herr Grabowsky is a naturalist of repute; he has had some experience in the management of plantations in Borneo, and is, withal, an excellent linguist, so that he is particularly suitable for the leadership of so difficult an expedition.

Correspondence.

To the Editor of the "Ceylon Observer."

PLANTING IN BOLIVIA.

COFFEE—CINCHONA—COCA.

[We attract the attention of Messrs. John Walker & Co., Mr. Westland, and others interested, to the following letter.—Ed.]

Hacienda "San Francisco," Prov. Yungas, Bolivia, April 10th, 1885.

Messrs. Bats, Hendy & Co., Agents of the *Weekly Ceylon Observer*, 37, Wallbrook, London, E.C.

DEAR SIRS,—Towards the end of last year, and through the medium of Mr. G. A. Witt, agent in London of Mr. Otto Richter, La Paz, we became subscribers to the *Weekly Ceylon Observer*, which since has been regularly forwarded to the address of Mr. Maximo Schmidt, c/o Messrs. Richter, Lehne & Co., Lacua. The numbers received by us up to the present we have read with great interest, and also found therein several articles of great importance to the planting districts of Yungas, situated in the interior of Bolivia.

Allow us to remark that "planting" in Yungas meets with nearly every imaginable difficulty, with perhaps the only exception of climate and ground, these being of the best. Scarcity of labour is a great drawback; the Indian almost the only workman to be had, belonging to a most stubborn, lazy, sluggish race, and takes no heed of the future, and only works with but few exceptions when he is compelled. The indifference of the white native is equally astonishing; the meaning of "Go ahead" and "Time is Money" being absolutely unknown to him, nothing can induce him to abstain from following the example of his ancient ancestors the "Incas," whilst a foreigner (so-called "gringo" here) most naturally looks for progress in every direction. All work is done by hand, a machine of any kind being a completely unknown thing, and even looked upon as most superfluous. We have endeavoured to construct a pulper and a peeler for coffee, although in a primitive way, but sufficient for a small crop of coffee. We began, however, extending our coffee plantations, and would now wish to introduce a more practical system of coffee cultivation than has hitherto been known here, the old system being still in its childhood one might say. It is desirous of doing this that we take the liberty of addressing you on the subject. No doubt you will be able to furnish us with drawings, or at least full descriptions (price list) of the new machines now used in Ceylon. Especially obliged we would feel to you if you would kindly indicate the best peeler, pulper, and drier now used, and also give us full details regarding Westland's improved sieve, mentioned in your No. of 1st Dec. 1884, p. 1000. Climate and ground here being very adequate for the cultivation of coffee, coca, &c., &c., and we are of the opinion it would be so for "tea" also, and would esteem it a great favour if you could procure us, through your Ceylon friends, some fresh seeds of the best Ceylon tea, in order to make a trial. A few pounds would be sufficient, but as we have never tried the cultivation of tea before, we would request you to send us at the same time a Tea Planters' Manual, in every consideration as complete as possible, especially as regards the planting, etc.

LIBERIA COFFEE.—What is your opinion of Liberia coffee? Do you think its cultivation here would be of great use? Would it be possible to obtain some fresh seed? We received some seed some years ago through Mr. Christy, but it arrived spoiled. We believe a business with Liberia coffee could only be made by a very heavy crop. Yungas coffee is of the finest quality, and we believe even better than Ceylon.

BARK.—Besides coffee we have for years past cultivated "best calisaya of 6½ and 7½ per cent," and as several of the foreign houses in La Paz (four days' journey from here) have often sent, and still send,

"best calisaya seed" to India, perhaps it might suit your Ceylon friends to receive some direct from us. We could offer some at more moderate prices, and even of better quality, especially as we ourselves gather the seed with greatest care, and would dispatch same to London ourselves at the lowest possible rate, availing ourselves of the services of our partner in La Paz.

COCA.—This product we also cultivate on a large scale, and having heard that some of the foreign houses in La Paz have begun to export plants as well as seed to London, presumably for the Colonies, we could also, if convenient to you, and desired by you to do so, send you plants and seed as well as coca of first quality, under the same favourable conditions as referred to under "bark."

TERMS.—You may rest assured that any order from you would be executed by us with the greatest possible care, and as cheap as possible, i.e., cost price. At the same time we request you, on transmitting your orders, to name the firm in London you authorize us to draw on against shipping documents and invoice attached to draft. The amount to be drawn on 90 days' sight for value of invoice on board "Arica."

The amount of my order above, if possible to execute same, you may receive from Mr. G. A. Witt, London, 4, Cullum Street, on delivery of the parcel with orders for same to be forwarded to Mr. Maximo Schmidt, c/o Mr. Otto Richters, La Paz, Bolivia. Awaiting your esteemed reply, we remain, dear sirs, yours very truly,
LOHSE & SCHMIDT.

P. S.—We are sending copy of above letter to Messrs. A. M. & J. Ferguson, Colombo. *Vale.*

FERMENTATION—AND NEW PRODUCTS.

London, E. C., 31st July, 1885.

DEAR SIR,—Following up the information contained in "New Commercial Plants," No. 8, upon the question of "fermentation," as I have furnished some papers with information, I send you details for your readers as the channels through which I have communicated the information may not reach Ceylon for some time. I found that many plants that yield grain do not sufficiently mature their seed, and that, by assisting nature in the following plan, a very superior article of food is produced as in cocoa. I would suggest the following experiments, if not already known to some of your readers in Ceylon and India.

When they observe that the rice is considered ripe, that is to say, before the flag or stem is entirely dead, if these plants are cut down and rapid fermentation set up, while the grain is still in the ear, and it is then cooled off and dried and the grain taken out, it will be found to have immensely improved the quality and flavour of the rice. The length of time of fermentation depends upon the size of the grain, and also upon the maturity of the rice when cut, but it would be safe to let it run up to 135° Fahr, if not rather higher. I need hardly say how glad I shall be to receive through your medium the information of correspondents who will try this and report their results.

In the edition of the *Ceylon Observer* just to hand, the editorial note is perfectly correct, and I have done my best to get a supply from Ceylon and India of the different varieties of *Erythroxylon Coca*, and I hope shortly to be able to record tests for cocaine from leaves obtained from South Africa. A small quantity was sent home by Dr. Bible from Madras, but when I applied to the authorities at Kew, they could not spare me sufficient to make a test, hence there has been a delay of many months, and now that *Erythroxylon Coca* leaves have fallen to 1s 6d per lb, there may not be the same anxiety to obtain new varieties.

I am now ready to supply plants of *Citharexylon letum*. This tree yields a good timber, is hardy in character; the fruit is very much the shape of the olive, and the stone or berry when stripped of the pulp yields a beverage, the flavour of which is considered to be between cocoa and coffee.—I am, dear sir, yours truly, THOS. CHRISTY.

MR. J. HUGHES ON TEA MANUFACTURE AND OTHER TOPICS.

London, 14th Aug. 1885.

DEAR SIR,—I have to acknowledge with thanks receipt of the work on the coconut palm, which is full of valuable information to those interested in such plantations. As regards the scientific manufacture of tea there can be no doubt that young men with a knowledge of chemistry will prove useful in tea factories. It is true that the whole operation is mechanical, but the different stages depend on the result of chemical changes going on, and when the best method of treatment is once decided upon a few simple tests will enable assistants to carry out the manufacture with great precision and to obtain uniform results.

Mr. Arnold White, late of Ceylon, has an article in the August number of *Good Words* which you may have noticed already. I had hoped to have written more, but am much engaged at present.

An article in the June *Tropical Agriculturist* on the Queensland sugar enterprise, copied from the *Field*, was written by a personal friend to myself from Queensland.—Yours very truly, JOHN HUGHES.

CINCHONA BARK.

6, Mining Lane, London E. C., 14th Aug. 1885.

DEAR SIR,—We beg to hand you copy of a special circular which we have issued on the subject of cinchona bark grown in your island, which may be of interest to you.—Dear Sir, yours faithfully, LEWIS & PEAT.

6, MINING LANE, LONDON, 14th August 1885.

GENTLEMEN,—In our regular fortnightly Price Current on this important article, we had the gratification of reporting a very satisfactory result of the enormous auctions held last Tuesday, when nearly one million pounds of Ceylon and East Indian Bark were sold at firm prices, the finer qualities at some advance.

In this sale many parcels were of good rich quality, a large part of *renewed* (in proportion to natural, about one-third) both *Officialis* and *Succirubra* testing extremely well. The quality and condition of Ceylon shipments has certainly much improved this season, and the estates are reaping advantage from the greater care in harvesting and packing.

Succirubra *Spoke shavings* when bold clean and of fresh color, have been competed for frequently for *Druggists'* purposes; *quills*, mostly for the same purposes, have sold at low and disappointing prices, and generally speaking we doubt the profit of sending such, unless when grey mossy quills can be shipped; but only moderate quantities can be sold to the *Druggists*, and they must be bold even lengths, not broken, and in cases. We have had much less of *twigs* and *young branch* than in former seasons—all odd mixed poor lots, cut too thin or too woody have sold at relatively low rates. Several parcels of good clean *Root* have sold at high prices as high as 2s 4d per lb. for *Officialis* and 1s 4d per lb. or *Succirubra*, but the average of the latter is very low compared with the former.

In recent auctions stem and trunk chips and shavings of which the greater part consists sold at—

	per lb.		
	s.	d.	s. d.
Officialis, part renewed and renewed	...	0	8½ to 2 11
natural	...	0	5 to 1 5
Succirubra, part renewed and renewed	...	0	6 to 2 0
natural	...	0	3 to 1 7

Calisaya has been very disappointing and sold at low rates; Hybrid rather better. The total quantity offered (and practically all sold) since 1st January reaches the large total of

	Ceylon.	East India.	Java.
	lb.	lb.	lb.
7,200,000	361,200	83,300	in 1885
Against same date	5,120,000	404,000	61,250 in 1884

The almost total cessation of *Imports from Central America* of *Soft Columbian, Pinyon, and Copra*—only about 923 packages since 1st January and of *Calisaya* (*Bolivia*) about 915 packages—and the continued good *deliveries* to date, viz:—

45,099 pkgs. delivered to 1st Aug. 1885	}	*
Against 49,240		
50,385	1883	
Result, in our Stock being reduced to:—		
75,552 pkgs. of all sorts...	1885	
Against 88,946	184	
94,068	1883	

The unprecedentedly low prices for *Sulphate of Quinine* has attracted the attention of speculators; today's lowest quotation of 2s 11d to 3s per oz., shewing an advance of 3d from the lowest price reported by manufacturers, who have been unwilling to sell in large quantities both here and in America; therefore we are hopeful that the worst is over regarding prices, and that though trade generally is so depressed, we may see firm if not higher rates maintained for *Cinchona*; as we do not think we shall receive any quantity from *Central America* for some time to come, on account of the revolution there which stops all trade and collecting of produce. It is almost needless for us to remark that odd parcels of 1, 2 or 3 packages do not meet with attention always, and sell below their actual value as, when manufacturers have so many samples to test, they do not all analyse the small lot.—Your obedient servants, LEWIS & PEAT, Brokers.

COCA AND COCAINE.

London, E. C., 14th Aug. 1885.

DEAR SIR,—It is as well for planters who are now on all sides demanding seeds and plants of "Erythroxylon Coca" to know that they have got the South American markets against them which yield an enormous weight of coca leaves a year, and a few pence would induce the planters to sell to shippers in place of selling to the shop and storekeepers for home consumption. The Italians have been purchasing coca leaves at a high price to make an exchange operation, as they require a medium for payment of their goods.

The price of coca leaves has fallen today for good quality in London to 1/ per lb., and cocaine is selling here at 3/ per gramme tube or 60/ per oz. They have got up the yield with the new leaves to as high as two grammes of cocaine to 1 lb. of leaves. There is no doubt that the coca will be used in Ceylon and India for making liqueur and wine, and as the process has been so fully described in your journal for manufacturing cocaine, there is nothing to prevent chemists making it on the spot when the price of leaves falls.

We have today received from Bolivia cocaine of really good quality and white in colour for us to examine and report upon. To save freight, one house has started a manufactory at Lima for making the crude extract of cocaine, which will enable them to finish off the cocaine here at a low price. On considering the future prospects of price, it is not improbable that it will go down to 1d a grain for first quality cocaine, or 40/ per ounce.

No doubt you will have called the attention of your readers in the *Observer* or the *Tropical Agriculturist* to remarks that have appeared in the paper

* East India packages as a whole are now larger than formerly.

this month, showing that low quality silk can be treated with a preparation of glycerine and converted into imitation catgut, which has finer properties than that ordinarily supplied, for it is stronger than catgut and is not so easily acted on by the atmospheric changes.—I am, yours obediently.

THOS. CHRISTY,

ECONOMY IN TEA-LEAD.

The Ceylon Tea and Coffee Co., Ltd., 1, Guildhall Chambers, 33, Basinghall St., 21st Aug. 1885.

DEAR SIR,—Amongst the many things in which keen competition here has necessitated strict economy being practised, there is one item which may be serviceable to your planters. In commencing to lead boxes, half-chests and chests for our English and foreign trade, tea-lead in the ordinary sheets was used. But the cutting to waste was great. I then considered the possibility of obtaining the lead in three pieces for each case: a top, a bottom and one piece for the four sides. I have had the tea-lead for 20, 50, and 100 lb. cases cut at the works in these three pieces, thus saving waste, time, and soldering. I commend this to your tea-planters, who, I find on examination, lose greatly in the turnover and extra solder and labour, a chest often containing six pieces and rarely less than five. I pack all sorts of tea here, large and small.—Yours faithfully,

A. L. HUTCHINSON,

Managing Director.

[Very like an advertisement?—Ed.]

THE YIELD OF TEA PER ACRE IN CEYLON.

22nd August 1885.

DEAR SIR,—In commenting on my letter which appeared in your "Overland" issue of 19th instant you ask: "But how about the low averages worked out by Mr. Rutherford?"

Now, in the first place, I would carefully avoid committing myself to an average of 400 lb. per acre for the island, for some years to come at all events, although I see no reason why that rate of yield should not be obtained under fair average conditions as to soil, climate and cultivation, without sacrifice of quality in the 6th year from planting. Individual estates may produce heavier crops whilst others are left far behind, and will be so probably to the end, for reasons which are obvious enough without particularization.

Mr. Rutherford's statement affords its own explanation of the point raised by your inquiry, inasmuch as he attributes the low yield for 1885 which he puts at 210 lb. per acre to the immaturity of our plants; and that this does in great part account for it may be seen from the fact, that whereas according to his table the average yield rises in 1886 to 212 lb. per acre, it falls in the following year to 175 lb. owing to the addition of 39,000 acres planted in 1884 and yielding only 100 lb. per acre to the bearing increase for 1884-7. It is this disproportion in the early years of the new enterprise between the acreage of tea only just commencing to give leaf and that of our older tea—the ratio being 50 under 4 to 19 over 4 years old—which reduces the average yield. In 1887-8 the disproportion is lessened, the rates being 69 to 30, and a correspondingly better average yield is shown.

We have however to account for the low average yield shown by Mr. Rutherford for tea 4 years old and upwards in 1885-6; and you will observe that I do not challenge the substantial accuracy of his estimate.

The reason must, I think, be sought for in the fact that at first we planted much too widely, and thus had too few trees to the acre. This wide

planting would tell most unfavourably in poor land. Thus 4 x 1 or 4 x 5 may be the right distance apart for tea under certain conditions, whereas under others 3 x 3 or even 2 x 2 would have to be the distance in order to secure a remunerative yield of leaf. I know of gardens which were originally planted nominally 6 x 6 and actually 8 x 8 to allow for the sprud which was expected from the magnificent jāt supposed to have been laid down. This was carried out under Indian authority; and years afterwards the same authority agreed that interplanting would be advisable. I have no doubt others than my self are acquainted with the same process.—Yours faithfully,

C. W. H.

EXPORT OF CINNAMON.

Colombo, 24th August 1885.

DEAR SIR,—In your last London commercial letter reference is made to the rumours circulated there to the effect that there would be "a marked decline in the exports of cinnamon from Ceylon during the next few months." Why or how this decline is anticipated I cannot guess. But I find that the exports of cinnamon during the present and the past three years were as follows, viz. :—

Bales	lb.
From 1st Oct. 1881 to 20th Aug. 1882	1,180,510

" " " 1884	1,242,372

This shows that the exports of 1883-4 were much in excess of those of 1882-3 or 1881-2. There was a slight falling-off in the exports for 1884-5 as compared with 1883-4, but they compare very favorably with the exports of the two preceding years. The slight falling-off is due to the late setting-in of the south west monsoon, which is the season for peeling and curing. But this will not materially affect the trade. Cinnamon is not usually affected to any very considerable extent by the failure of rain or protracted dry weather. To say that cinnamon has been short in production owing to the extension of cocconut and tea planting is simply a fallacy. Cinnamon has in no place been uprooted or burnt out to make room for other new products. But those who urge this as a reason to account for the decline in the exports of cinnamon forget to take an account of land which is being newly converted into cinnamon plantations. The slight decline in the exports, besides being due to the lateness of the working season, may also be accounted for by the unprecedentedly low prices which have ruled for some time in the cinnamon market—prices which held out little or no inducement to proprietors of cinnamon properties to prepare the article for shipment. That the lighter kinds are in greater favour is easily explained. The owners of small patches of cinnamon do not grudge to pay higher wages to the peelers and others engaged in the curing trade in order to give to their small consignments an appearance very much the same as if not quite equal to that of the product of large estates. This is easily accomplished by giving the bark a finer appearance. But after all this consists only in appearance, not in quality. Cinnamon is an article which has to be tested by taste, not by sight.—Yours truly,

II.

THE USE OF COAL IN TEA FACTORIES; EXPERIMENTS ON KINTYRE.

Kintyre, 27th August 1885.

DEAR SIR,—Annexed I send you the result of experiments made with coal in my tea factory. I think as far as the sirocco experiments go, they are satisfactory. The coal cost R45-00 a ton on the estate and was not, I think, of very good quality being small in size. Of course, in calculating cost

COFFEE VERSUS TEA.

Langdale, Lindula, 4th Sept. 1885.

SIR,—I send you an extract from a home letter:—

"You ask if we drink Ceylon tea? and the answer is, the grocers do not care about it, they say it cannot be depended upon, it varies so much; and if so, why cultivate it? Then again, doctors are setting their faces against tea: two doctors advised me not to drink it at all. So we only use it for afternoons, and even then at many houses coffee is offered at afternoon tea-parties, so many people are not allowed to touch tea. In the hospitals now coffee is given as a stimulant instead of brandy, and everywhere it is being preferred; so why turn your coffee into tea plantations?"

You may make any use you wish of the above extract.

Weather still very dry, not at all seasonable; we want some rain.—Yours faithfully,

ARTHUR HEELIS.

[The reply to which is that the consumption of coffee in Britain has decreased, while that of tea has rapidly increased. If coffee trees continued to grow and yield well in Ceylon, no one, of course, would think of superseding them by tea bushes; but, alas! in a large number of cases there is no choice but to say of coffee: "Why cambereth it the ground?"—Ed.]

THE POWER OF WATER-WHEELS.

Colombo, 4th Sept. 1885.

DEAR SIR,—In reply to "D. K. M."’s letter in your valuable paper of 3rd instant, the difference in power between a 16 ft. and 20 ft. diameter water-wheel with 480 cubic feet of water per minute passing over them is that the 20 ft. water-wheel will develop 13.7 H. P. while the 16 ft. wheel will only give 10.9 H. P. The power of a well-made water-wheel or turbine may be easily calculated by multiplying the cubic feet of water per minute by the height of the fall and dividing by 700: the quotient will be the horse-power of the wheel.

In driving a double pulper and crusher about 2½ H. P. is generally used, and most of the water-wheels on Ceylon estates have been built for working at that power, but they are calculated for 4 H. P. which gives a good margin of safety for the purpose they were intended; if driven above that they are liable to break down, as neither shrouds, axles nor spur-wheels are safe for more.

Mr. Armstrong in his paper on Tea Machinery is inclined to give his preference to water-wheels instead of turbines, and I agree with him that where small power is only wanted with medium falls the water-wheel has many advantages, but there are few estates in Ceylon that can afford 400 cubic feet of water per minute on falls of 20 ft. (equal to about 11 H. P.) which is what a medium tea estate will require, but many of them with half that quantity of water and double the fall when turbines can be used with good effect.

I extract the following from one of the best publications on water motors that I know of, which I think will be interesting to many of your readers:—

"If a ponderous vertical wheel be applied to a very high waterfall, its diameter will be so large, and its revolutions so very few, that it must be connected with a great deal of auxiliary machinery to impart that rapid motion which is generally required. On the contrary, the turbine being comparatively so small and its revolutions so numer-

ous:—given time, its motive power can be at once transmitted.

"Moreover, what operates as a disadvantage in the ordinary wheels, contributes to the more efficient working of the turbine; for the higher the waterfall, the smaller, and consequently the less expensive, the turbine adapted to it; and also it is applicable on falls of water so high that the ordinary wheel cannot be used. Another great property of the turbine is its constant and uniform motion, which arises from the diffusion of the impelling water over the whole of the circumference at the same instant. This perfect uniformity of motion is a peculiar feature of the turbine. The turbine is capable of working under the back water as long as the surface of the fluid in the reservoir remains the highest, during which time it will produce a moving force proportional to the difference between these two levels, without a perceptible diminution of the useful effect, thereby evidencing that it is exempt from the casualties to which the vertical wheel is so often subject.

"If a turbine be connected to a steam-engine during the dry months while water is scarce, it can be made to transmit the highest obtainable power from the quantity of water by which it may be supplied, and it can be made so large as to drive all the works in the wet months. Saving the expense of fuel, economising that liquid that commonly runs to waste, and giving sufficient time for any repairs that might be required on the steam-engine, clearly showing the great advantages of the turbine over the vertical wheel, for it could not be made so large as to receive the extra water in wet weather, without lessening the effective power of the smaller quantities in dry weather.

"It is a fact of vast importance that turbines on the improved principle of construction, supersede in America, France, and many other part of the Continent every other description of water-wheels, and after long experience of their superior working power in impelling machinery, however ponderous and complex, have been stamped with the approbation of the most eminent mill-owners and manufacturers. And I am firmly convinced that their general introduction is now a mere question of time."

I trust the above may be of service to some who may be seeking information about water-power, and remain, yours truly,

WALTER LAMONT.

Colombo, 7th Sept. 1885.

DEAR SIR,—I am pleased to see in your issue of Saturday evening that Mr. Lamont, an acknowledged authority, has stepped to the front with an answer to my simple question on the power of water-wheels. Those who have investigated the subject are aware that the various works treating on water power as applied to the ordinary vertical wheel, although at one approximately, yet do not all agree in detail, important facts being pointed out which are worthy of consideration when estimating the effective power of small wheels, such as are employed in Ceylon; as, however, the columns of a newspaper are not the place to enter into calculation, I accept Mr. Lamont's theoretical formula, and apply it to the case of the numerous water-wheels in Ceylon (which he says are mostly calculated for 4 H. P.) as follows:—

175 cub. ft. of water per minute applied to a 20 ft. wheel give exactly 5 H. P., while the same quantity of water applied to a 16 ft. wheel gives a result of exactly 4 H. P., but credit the latter with the advantage it possesses over its bigger but

* Name?—Ed.

less active brother, the 20 ft. wheel, in not having so much of its power absorbed in the raising of speed (a point ignored in theory) and it will be found that the difference in *power available for transmission to machinery* has been materially reduced, while in the case of the 18 versus 20 ft. wheels the hair-splitting has become a very fine operation indeed. But to the point; we have the 20 ft. wheel giving 5 H. P. with a supply of 175 cubic feet of water per minute, increase the supply of water by 45 cubic feet (only $\frac{3}{4}$ of a foot per second) = 220 cubic feet and apply it to the 16 ft. wheel, when the same power will be obtained theoretically, but somewhat more in practice; add another $\frac{1}{4}$ of a foot per second and we get over 6 H. P. and so on; these figures, I submit, make good my assertion that the *diameter of a water-wheel* is not the all-important key to power that our teachers would have us believe.

The common water-wheel is one of our oldest motors, and having been practically cast aside by the modern engineer of the great machinery-using countries, it has escaped the "paring-down" process to which other motors and machines have been subjected, and retains the proportions it received from the "old school" men, proverbial for erring on the safe side as regards strength of material. Makers of the present day claim improvements and point to their wheels as models, but when compared with the models of over a quarter of a century ago very little difference will be observed either in proportion or design; in short, their strength is such that I have no hesitation in saying, that the despised 16 and 18 ft. wheels calculated by the orthodox rules for 4 H. P. are capable of carrying water sufficient to develop a power far exceeding that of the motor known as a four-horse engine.—Yours truly, D. K. M.

[We are, personally, much indebted to this writer for his encouraging statement as to the power to which 16 ft. water-wheels can be worked. What we were told by experts was, that if we attempted to turn an Excelsior roller by means of such a wheel the resistance would tear the wheel to pieces. We mean, however, to try the experiment.—Ed.]

SULPHURIC ACID.

DEAR SIR.—Since you were kind enough to turn my platinum into iron-pyrites, I have been favoured with the loan of a pamphlet on the subject of the local manufacture of sulphuric acid, by the late Mr. O'Halloran, so long ago as 1874, with extracts largely from your own columns.

The study of this has proved to be most interesting, and fully answers the question "How is sulphuric acid manufactured?" When I asked that question, I had it in my mind only as a subsidiary process and aid to the local manufacture of quinine; but this pamphlet shows that that would only be one of a very great many important uses to which this acid is put in agriculture and various manufactures.

But the subject, as set forth by the late Mr. O'Halloran, is a little surprising. After proving to the planters the immense importance to them of an inexhaustible supply of cheap sulphuric acid, he offered to commence to manufacture it in Colombo, and to sell it at £11 a ton (against the limited supply only that it was possible to import at £37 6s 8d per ton) if only orders should be guaranteed to him of 500 tons! equal, as he put it, to only 7d an acre for the coffee then under cultivation!

Looking back now, it is amazing that this encouragement was not given to him, for, had it been, who shall say that much, very much, of

the coffee now gone out would not still be in existence and paying well? With an abundant and cheap supply of sulphate of soda, and of dilute sulphuric acid, all these years, the leaf fungus itself might have succumbed! But surely what was possible then is possible now? And with the now added demand for sulphuric acid for the manufacture of quinine, with so much tea planted in patana soils, and with a possible supply of iron pyrites in the country, the manufacture of this acid ought to be the best paying speculation of the day in Ceylon. PLATINUM.

[In the case of Mr. O'Halloran's proposed company, "the senior editor" for once, and in view of the public benefit likely to result, broke through the editorial rule against becoming connected with any local Company, helping Mr. O'Halloran to all available information. We received a rather severe lesson to adhere to our rule. Makers and importers of manures were all antagonistic, and the design collapsed.—Ed.]

WATER-WHEELS.

SIR.—Fred. J. Bramwell, in his address to the Institution of Civil Engineers, makes the following statement:—"I will merely call your attention to the improvement in water-wheels in France, an improvement by which it is asserted that as much as 85 per cent of all the energy residing in a low fall of water has been converted into power, a result due to the decreasing of the speed of the periphery of the wheel, and to the making of the buckets very narrow and great depths. In turbines, also, there has been considerable development in these twenty-two years, and they now take their place as very efficient motors, possessing many advantages, where, on the one hand, a very high fall of water has to be utilized, or where, in the case of a low fall, great differences in the working head and in the level of the tail water, have to be provided for." C. E.

DEAR SIR.—It is not surprising that your correspondent "D. K. M." should have such "feeble hold" of the object he writes on—water-wheels; but it is a little, that he has the tenacity to criticize Mr. C. S. Armstrong's remarks on the same. The man who can make such teas as Mr. Armstrong does must have spent much time and care in finding out *how and the reason why*, and it is not surprising that he should have a correct idea about water-wheels as well.*

The laws which govern the motion and power of a water-wheel were found out long ago by Newton and others, are quite fixed beyond dispute, and have only to be understood to be applied. If "D. K. M." would consult some elementary work on the laws of *matter and motion* &c., he would find that Mr. Armstrong is right, and that he ("D. K. M.") has, probably with the best intentions, prematurely rushed into print—with crude ideas. Oh ye teachers! Beware!

Come to the rescue, you, I had almost said *thou*, of the great "Old Rag" sitting there, surrounded with cart-loads of books of reference, and a head on your shoulders, like to long for more! What is wanted is a chapter on *water-power* in the new Directory, or if more convenient in pamphlet form. Then every planter could have a copy, and, after paying for it, be happy for ever, at least on that one thing. Such a publication at this time would save voluminous cor-

* We have great respect for Mr. Armstrong's opinions, and yet we have ventured to differ from him as to the power of water-wheels.—Ed.

respondence with agents and absent proprietors &c. about dams, rainfall, wheel-pits, relative cost of steam, &c., &c. But to the point: a 16 ft. water-wheel with a given quantity of water gives 4 h. p.; then a 20 ft. wheel with the same will give 5 h. p., and a 24 ft. wheel will give 6 h. p. (allowance for friction &c. must be noted). Why, oh! "D. K. M."? Because in the one case a weight has been acting through a fall 16ft. and in the other through 24ft. So you see the diameter of the wheel is not "really of secondary importance." Try it on the weights of your eight-day clock. This in regard to overshot water-wheels of ordinary construction; re-action, centrifugal and other forms of water-wheel or motor, requires separate consideration.

Mr. Editor, your idea of fly-wheels for Jackson's rollers with water-power is good. A water-wheel for ordinary purposes seldom requires a fly-wheel, but in case of driving that roller, the advantage is likely to be great. By using a heavy fly-wheel at high speed, you will be able to run your water-wheel at the lowest speed possible, and so utilize the greatest possible amount of the available power.—Yours faithfully,
WATER.

RICE.—The *British Trade Journal* says that "Rice occupies no less than one-half of the cultivated land in Japan, where there are 250 varieties of seed. Probably no country raises such a variety of leguminous plants for food."

A VALUABLE REMEDY FOR HEADACHE.—We desire to call attention to a simple, and at the same time wonderfully efficient, treatment for headache. We lay no claim to originality, nor do we know who the originator was, but having used it for a year or more, and in many cases with remarkable results, we feel disposed to give our endorsement, and desire to make it more generally known. The remedy is nothing more nor less than a solution of the bi-sulphide of carbon. A wide-mouth glass-stoppered bottle is half filled with cotton or fine sponge, and upon this two or three drams of the solution are poured. When occasion for its use occurs the mouth of the bottle is to be applied to the temple or as near as possible to the seat of pain, so closely that none of the volatile vapor may escape, and retained there four or five minutes or longer. For a minute or so nothing is felt, then comes a sense of tingling, which in a few minutes—three or four usually—becomes rather severe, but which subsides almost immediately if the bottle be removed, and any redness of the skin that may occur will also quickly subside. It may be reapplied, if necessary, several times in the day, and it generally acts like magic, giving immediate relief. We believe this was the basis of a once popular nostrum. The class of headaches to which it seems especially adapted is that which may be grouped under the broad term of "nervous." Thus neuralgic, periodic and hysterical headaches, and even many kinds of dyspeptic headaches, are almost invariably relieved by it. True, the relief of a mere symptom is quite another thing from the removal of the cause, yet no one who has had the distress, and even agony, caused by severe and frequent recurring headaches (and who has not seen it?) but will rejoice to be able to afford relief in so prompt and simple a manner; besides, it is sure to secure the hearty gratitude of the patient if he has suffered long. As to the modus operandi we have nothing more definite than a theory to offer, and that is that the vapor being absorbed through the skin produces a sedative effect upon the superficial nerves of the parts to which it is applied. We know by experiment that its influence is not due to its power as a counter-irritant. We, however, know that it does act, and if we do not clearly see in what way it acts, that is no more than can be said of several other remedies which are firmly established in professional favor and confidence.—*Physicians' and Surgeons' Investigator*.

TEA WITHERING.—From the London Tea Letter of the *Indian Tea Planter's Gazette* we quote as follows:—Mr. Greig—not the one already known to planters—managing director of the Blackman Air Propeller Co., is at work on an appliance for drawing off moisture from wet leaf to assist withering, in which appliance he proposes to use a Blackman Air Propeller. He has an initial effort on show at the Preston meeting of the Royal Agricultural Society of England, but it is too embryonic to allow of any opinion being passed upon its merits as yet. This much may be said, it is a step in the right direction, and may have in it the making of a success, which is indeed much to be hoped, as some means to properly effecting the end aimed at is badly needed.

A VALUABLE DISCOVERY has been made in California by a Mr. George Downie, of the efficacy of Eucalyptus for removing scale from steam boilers, which has proved to be of more than ordinary value, so the *San Francisco News Letter* says. The Downie B. I. R. Co., of that city, to whom his many patents from different countries have been assigned, have already built up a thriving industry that gives promise of attaining much larger proportions in the near future. At their works at Piedmont they have already manufactured nearly 100,000 gallons of the preparation from the Eucalyptus for removing scale. A majority of the boilers, both on land and steamboats, on the Californian coasts, are using the preparation, and the engineers speak of it in very high terms. A good scale remover has long been sought by engineers, and if this preparation is what it appears to be it will be a great boon.—*Leaders*.

CEYLON IN THE LONDON EXHIBITION AND BIRD LIFE.—A home correspondent writes by the mail:—"I read your article on the Exhibition with pleasure as I quite agree in your views as to the objects which should be exhibited, with the exception of stuffed animals which should be left to India, unless indeed you could send a specimen of an authenticated devil-bird, but that has yet to come. I also much dislike the notion of at all denuding our Museum. Remember Ceylon is being visited by persons of all countries, and these visitors will be in many cases grievously disappointed if they find specimens which they would wish to study, removed. I greatly wish you had some very active secretary going about and collecting such articles as would be suitable.—I hear a very unpleasant account of the slips on the new line, that most of them might have safely been predicted as being the results of bad work. I heartily hope the extension will be placed in the hands of the P. W. D. which will carry it out far more economically and completely than any contractor. Pray keep 'pegging away' at the destruction of small birds in Ceylon. It is both cruel and mischievous, and I have no patience with the toleration of cruelty and mischief in order to foster a stupid and vulgar taste. I hear it is expected that the Princess of Wales will do her best to discourage this kind of finery as heartless as it is underbred." We entirely agree with our correspondent's sentiments as to the barbarity involved in the destruction of small birds merely to foster female vanity. The case is bad enough on the continent of Europe, where the little birds are killed for food. As to stuffed specimens, in any case, we should send the birds figured in Legge's book as peculiar to Ceylon.

FLIES AND BUGS.

Beetles, insects, roaches, ants, bed-bugs, rats, mice, gophers, chipmunks, cleared out by "Rough on Rats." W. E. Smith & Co., Madras, Sole Agents.

less active brother, the 20 ft. wheel, in not having so much of its power absorbed in the raising of speed (a point ignored in theory) and it will be found that the difference in power available for transmission to machinery has been materially reduced, while in the case of the 18 versus 20 ft. wheels the hair-splitting has become a very fine operation indeed. But to the point; we have the 20 ft. wheel giving 5 H. P. with a supply of 175 cubic feet of water per minute, increase the supply of water by 45 cubic feet (only $\frac{1}{3}$ of a foot per second) = 220 cubic feet and apply it to the 16 ft. wheel, when the same power will be obtained theoretically, but somewhat more in practice; add another $\frac{1}{3}$ of a foot per second and we get over 6 H. P. and so on; these figures, I submit, make good my assertion that the diameter of a water-wheel is not the all-important key to power that our teachers would have us believe.

The common water-wheel is one of our oldest motors, and having been practically cast aside by the modern engineer of the great machinery-using countries, it has escaped the "paring-down" process to which other motors and machines have been subjected, and retains the proportions it received from the "old school" men, proverbial for erring on the safe side as regards strength of material. Makers of the present day claim improvements and point to their wheels as models, but when compared with the models of over a quarter of a century ago very little difference will be observed either in proportion or design; in short, their strength is such that I have no hesitation in saying, that the despised 16 and 18 ft. wheels calculated by the orthodox rules for 4 H. We know by experiment that its influence is not due to its power as a counter-irritant. We, however, know that it does act and if we do not clearly see in what way it acts, that is no more than can be said of several other remedies which are firmly established in professional favor and confidence.—*Physicians and Surgeons' Lexicographer.*

TEA WITHERING.—From the London Tea Letter of the *Indian Tea Planter's Gazette* we quote as follows:—Mr. Greig—not the one already known to planters—managing director of the Blackman Air Propeller Co., is at work on an appliance for drawing off moisture from wet leaf to assist withering, in which appliance he proposes to use a Blackman Air Propeller. He has an initial effort on show at the Preston meeting of the Royal Agricultural Society of England, but it is too embryonic to allow of any opinion being passed upon its merits as yet. This much may be said, it is a step in the right direction, and may have in it the making of a success, which is indeed much to be hoped, as some means to properly effecting the end aimed at is badly needed.

A VALUABLE DISCOVERY has been made in California by a Mr. George Downie, of the efficiency of Eucalyptus for removing scale from steam boilers, which has proved to be of more than ordinary value, so the *San Francisco News Letter* says. The Downie B. I. R. Co., of that city, to whom his many patents from different countries have been assigned, have already built up a thriving industry that gives promise of attaining much larger proportions in the near future. At their works at Piedmont they have already manufactured nearly 100,000 gallons of the preparation from the Eucalyptus for removing scale. A majority of the boilers, both on land and steamboats, on the Californian coasts, are using the preparation, and the engineers speak of it in very high terms. A good scale remover has long been sought by engineers, and if this preparation is what it appears to be it will be a great boon.—*Leaders.*

CEYLON IN THE LONDON EXHIBITION AND BIRD LIFE.—A home correspondent writes by the mail:—"I read your article on the Exhibition with pleasure as I quite agree in your views as to the objects which should be exhibited, with the exception of stuffed animals which should be left to India, unless indeed you could send a specimen of an authenticated devil-bird, but that has yet to come. I also much dislike the notion of at all denuding our Museum. Remember Ceylon is being visited by persons of all countries, and these visitors will be in many cases grievously disappointed if they find specimens which they would wish to study, removed. I greatly wish you had some very active secretary going about and collecting such articles as would be suitable.—I hear a very unpleasant account of the slips on the new line, that most of them might have safely been predicted as being the results of bad work. I heartily hope the extension will be placed in the hands of the P. W. D. which will carry it out far more economically and completely than any contractor. Pray keep 'pegging away' at the destruction of small birds in Ceylon. It is both cruel and mischievous, and I have no patience with the toleration of cruelty and mischief in order to foster a stupid and vulgar taste. I hear it is expected that the Princess of Wales will do her best to discourage this kind of fancy as heartless as it is unwholesome."

We entirely agree with our correspondent's sentiments as to the barbarity involved in the destruction of small birds merely to foster female vanity. The case is bad enough on the continent of Europe, where the little birds are killed for food. As to 'stuffed specimens', in any case, we should send the birds figured in *Leige's* book as peculiar to Ceylon.

FLIES AND BUGS.

Beetles, insects, roaches, ants, bed-bugs, rats, mice, gophers, chipmunks, cleared out by "Rough on Rats." W. E. Smith & Co., Madras, Sole Agents.

the privilege of being introduced to Mr. John G. Horsely, the managing director of the company, who, finding that I was interested in the subject, kindly invited me to visit the works, and I was well repaid for the hour and a half spent in following the life-history of a brush, more especially as every detail was carefully pointed out and explained by the very intelligent and obliging manager of the works, which are situated in Copperfield Road, Mile End. Enormous quantities of bass or Piassaba, as well as Kittool are used by this company, and as they have large contracts both for the Government as well as for some of the principal railway companies, are always very busy. At the time of my visit the *employés* were for the most part at work on Piassaba.—*Gardeners' Chronicle*.

INSECTS AND AGRICULTURE.

PETROLEUM, in its various forms, has long been recognised as one of the most effective insecticides in our possession, all only substances being particularly deadly to insects. Unfortunately they are also injurious to plants, and one of the problems, the solution of which I have had in mind for many years, has been their use in such dilution as to kill the insect without injury to the plant. Refined kerosene has been used to a limited degree by forcible attenuation in water and spray, while some plants withstand doses of the pure oil. But the safe and general use of kerosene for the purpose under consideration dates from the year 1880. Of the various substances used in attempts to emulsify and mix kerosene with water none are more satisfactory than soap and milk, both being everywhere accessible and cheap. Milk was first suggested in 1880 by Dr. W. S. Barnard, while carrying on experiments for me against the Cotton-worm, and subsequent experiment, especially by another of my assistants, Mr. H. G. Hubbard, has given us the simplest and most satisfactory method of making the emulsion quickly and permanently. An emulsion resembling butter can be produced in a few minutes by churning with a force pump two parts of kerosene and one part of sour milk in a pail. The liquids should be at about blood-heat. This emulsion may be diluted with twelve or more parts of water to one part of emulsion, thoroughly mixed, and may be applied with the force-pump, a spray nozzle, or with a strong garden syringe. The strength of the dilution must vary according to the nature of the insect to be dealt with, as well as to the nature of the plant; but finely sprayed in twelve parts of the water to one of the emulsion it will kill most insects without injury to the plant. An equally good emulsion may be made as follows:—

Kerosene, 2 gal.; common soap, $\frac{1}{2}$ lb.; water, 1 gal. Heat the mixture of soap and water, and add it boiling hot to the kerosene. Churn the mixture by means of a force pump and spray nozzle for five or ten minutes. The emulsion, if perfect, forms a cream, which thickens on cooling, and adheres without oiliness to the surface of glass. Dilute with cold water before using, to the extent to which experience will indicate is best.

The simplest discoveries are often the most valuable, and this discovery of so simple and available a means of diluting *oil libitum*, oil with water is important and far-reaching in its practical application.

PYRETHRUM.

Pyrethrum roseum, a plant native to the Asiatic countries south of the Caucasus Mountains, and Pyrethrum cinerariifolium, a native of Dalmatia, have long been known to possess insecticide properties, especially in the powder from the dried and pulverised flowers. The powder, sold under various names by druggists, was chiefly used against household pests, however; and though Mr. O. Willemet, as early as 1857 in France, and Mr. William Saunders, in 1879, in Canada, tried it in powder form on some that are injurious to plants, its importance as a field insecticide did not appear till in 1880, when, in prosecuting

the work of the United States Entomological Commission, we discovered that it could be used in liquid solution. Both species proved to be hardy throughout the greater portion of our country, and Mr. G. N. Mileo, of Stockton, Cal., has for some years cultivated cinerariifolium quite extensively at great profit, the product being sold under the name of "Buhach." The insecticide property dwells in a volatile oil. It acts only by contact and its action on many larvae is marvellous, the smallest quantity in time paralysing and ultimately killing. Its influence in the open air is evanescent, in which respect it is far inferior to the arsenical products; but being perfectly harmless to plants, it can frequently be used on vegetables where the more poisonous substances would be dangerous.

Pyrethrum is supposed to have no effect on the higher animals, but that is a mistake, as my own recent experience is that the fumes in a closed room have a toxic influence, intensifying sleep and inducing stupor; while the experience of Professor A. Graham Bell with the powder copiously rubbed on a dog showed that the animal was made sick and was affected in the locomotive organs very much as insects are. The wonderful influence of this powder on insects has led me to believe that it might prove useful as a disinfectant against fevers and various contagious diseases by destroying the microzoa and other micro-organisms, or germs, which are believed to produce such diseases. It should be tried for that purpose. It is remarkable that these two plants of all the many known species of the genus should alone possess the insecticide property.

BISULPHIDE OF CARBON.

Of all insecticides to be used against root-feeding or hypogean insects, naphthaline, sulpho-carbonate of potassium, and bisulphide of carbon are the chief. Dr. Ernst Fischer, in a recent work, has shown that naphthaline in crystal may be satisfactorily used underground, destroying by slow evaporation. But bisulphide of carbon still holds the first place in France against Phylloxera vastatrix. It is conveyed beneath the ground at the rate of one-half to one kilogram per vine by special injectors, or by more complicated machinery, drawn by horses. I believe that petroleum emulsions will supersede it as an underground insecticide, and prove to be the best we have, cheapness, safety, and efficiency considered. After the discovery of a satisfactory insecticide, however, various important problems must be solved, and particularly how to apply it to greatest advantage, having safety to man and stock, harmlessness to plant, and economy in mind. The solution of these points, and others that the peculiar habits of the insect to be controlled involve, brings us to the question of mechanical contrivances and appliances; for while much ingenuity has been exhibited in devising mechanical means of directly destroying noxious insects without insecticides, it is chiefly in the proper application of these last that the greatest mechanical advances have been made both in this country and in Europe. Here, again, the subject is so vast that I cannot enter into details.

It will already have been gathered, from what has preceded, that the chief insecticides are applicable in liquid form, and as liquids have an advantage over powders in field use, instruments for atomising and distributing liquids constitute the most important part of insecticide machinery. The desiderata in a spray-nozzle are, really regulation of the volume to be thrown; greatest atomising power, with least tendency to clog; facility of cleansing or ready separation of its component parts; cheapness, simplicity, and adjustability to any angle.

I will content myself with exhibiting one which meets, perhaps, more of these requirements than any other in use, and which works on a new principle applicable to many other purposes than that for which it was designed. It is what has been described and illustrated in my late official reports as the eddy or cyclone nozzle, and consists of a small circular chamber with two flat sides, one of them screwed

on so as to be readily removed. Its principal feature consists in the inlet through which the liquid is forced being bored tangentially through its wall, so as to cause a rapid whirling or centrifugal motion of the liquid which issues in a funnel-shaped spray through a central outlet in the adjustable cap.—Prof. RILEY in *American Entomologist*.

EDIBLE BIRDS' NESTS.

The nature and composition of the edible birds, nests of which everyone has heard, and which any visitor to the International Health Exhibition at South Kensington might have tasted if he pleased, is a problem the solution of which has puzzled naturalists as much as did at one time the question concerning whitebait.

The nests in question, so much prized by the Chinese, are made, as most people are aware, by a species of cave-haunting swift of the genus *Collocalia*, which breeds in colonies, in caverns sometimes by the sea, sometimes inland, according as they are found suitable for the purpose. They are to be found in India, Ceylon, Borneo, and Java, and we have seen some very perfect nests of the kind which were brought from the Andaman Islands. Mr. E. L. Layard has described the appearance of a cave tenanted by these birds in the breeding season in Ceylon; and Mr. W. B. Pryer has published an equally interesting account of a visit which he paid to the so-called "Birds-nest Caves" at Gomanton in North Borneo, where hundreds of the nests were to be seen glued, as it were, to the sides of the cave, many of them at a considerable height, from which they were detached by the natives with the aid of light bamboo ladders. The formation of the nests differs. Some appear to be formed of flakes or threads cemented together, making an almost solid nest; others are composed entirely of viscous matter. The exterior exhibits many nearly straight threads, which incline or are attached to each other; the interior, which is rather shallow, shows many layers of irregular network, formed of a multitude of threads that cross and recross each other in every direction.

The best—that is to say, the whitest and clearest—are of a semi-transparent fibrous texture, having the appearance of being formed of isinglass. Those less sought after are much discoloured, sometimes almost black, and are intermixed with dry grass, hair, or feathers. The question which naturalists have sought to determine is "how the nest is made, and of what it is composed?" Several theories have been advanced on the subject, and different observers have professed to detect in its structure either a vegetable origin from seaweed or fungus, or an animal origin from agglutinated and dried fish spawn, or the hardened saliva of the bird itself, produced in large quantities from special glands secreting it. Mr. Pryer, who has collected a great number of these nests in Borneo, says (*Zoologist*, 1885, p. 46): "The nests are made from a sort of fungoid growth that incrusts the limestone in all damp situations. It grows about an inch thick, outside dark brown, but inside white. The birds make the black nests from the outside layer, and the best quality of white nests are of course from the inside. It is taken by the bird in the mouth and drawn out in a filament backwards and forwards like a caterpillar weaving its cocoon."

Upon this statement Mr. G. Murray remarks (*Zoologist*, 1885, p. 147): "The alga of microscopic dimensions found by Mr. Pryer in the cave inhabited by the swifts which build the edible nests is an undescribed species of *Urococcus*. The members of the group to which it belongs are very commonly found growing on the walls of caverns. In this case the incrustation produced by the accumulation of the alga is of unusual thickness and of horny consistency when dry, but turns pulpy when soaked in cold water. On the outer surface there is a dark layer (black to the naked eye, but very dark greenish yellow when viewed with the microscope), consisting of the living alga. Beneath this outer dark layer the mass of the

incrustation is white, and consists of a dense accumulation of innumerable dead bodies of the alga, the structure of which is barely distinguishable. In none of the edible nests which I have examined, however, is there any trace of an alga, and it appears to be definitely settled that these are constructed from materials which are the intrinsic product of the bird. Mr. Pryer states his opinion that certain nests are made from the black outer layer of the incrustation. If such a nest were examined, it would give conclusive evidence either way, since the black layer, as just mentioned, consists of living alga, the structure of which would be far more readily discernible than the traces of the white part of the incrustation."

We do not know whether Mr. Pryer has seen this note, being, we believe, still in Borneo, but in a further communication of his own, which has since been published (*Zoologist*, 1885, p. 298), he appears to have altered his former opinion on the subject, for he says, "With regard to the material from which the nests are made, I regard the alga theory with great doubt. The natives say the birds skim up froth or scum from the water, and use it as the material. I myself think it is simply a natural secretion of the birds themselves." That is to say, he adopts the view expressed by Mr. Murray, and before him by Dr. Jerdon ("Birds of India"), Blyth, and Sir Everard Home.

Dr. Jerdon writes: "The nest, when pure and of the first make, is composed entirely of inspissated mucus from the large salivary glands of the bird." In a posthumous article on the Cypselide, published in the *Zoologist*, 1881 (pp. 300-327), the late Mr. Blyth observes: "The animal origin of the edible nests is at once detected by simply burning a bit of one; and Mr. Laidlay informed us that, upon analysis, he found the constituent elements to be those of inspissated saliva." Sir Everard Home, so long ago as 1817, published the results of a dissection made by him of a specimen of the bird (*Collocalia nidifica*) from Java (*Phil. Trans.* 1817, p. 337), wherein he described a peculiarity in the gastric glands, pointing out that a membranous tube surrounds the duct of each gland, which, after projecting a little way into the gullet, splits into separate portions like the petals of a flower, and suggesting that the material of which the nest is composed is secreted by the surfaces of these tubes just as the gastric juice is secreted by the glands themselves.

One of the latest writers on the subject is Mr. J. R. Green, of Trin. Coll., Camb., who in an article in the *Journal of Physiology* for April last, after quoting Sir Everard Home's views, points out that they have since been confirmed by Dr. Bernstein (*Journal für Ornithologie*, 1859, p. 111), who found in *Collocalia nidifica* two large salivary glands, which secrete mucus in large quantities. He then proceeds to detail the results of a microscopical and chemical examination made by himself of a specimen of the nests used for soup at the International Health Exhibition.

The most careful examination, he says, with both low and high powers, failed to show the presence of vegetable cells, or of any debris arising from such; while the chemical tests applied appeared to him to indicate that the material of which the nest is formed is the product of the activity of some gland in the body, which bears out the view advocated by Sir E. Home and by Bernstein. It does not appear, however, from them whether the gland is a peptic or a salivary one. Evidence on this point, says Mr. Green, is not forthcoming so far; for "the most careful examination has failed to show any ferment property attaching to the nest." The result of Mr. Green's experiments, nevertheless, sufficiently refute the theory of vegetable origin, and support his view that the substance in question is an animal product closely allied to mucin, and is derived from glands which are remarkably developed in the nesting season, as remarked by Bernstein, and afterwards become atrophied.

Capt. Lewis, who saw such of these birds in the Nicobar Islands, states that the edible nests, as we see them, are only the lining, which comes out entire

though independently affixed to the rock, being underlaid by a network of some vegetable fibrous substance placed on the ledges (the Urocoelus above-mentioned), which the gatherers are careful not to remove. It is generally supposed that those edible nests are made by only one species of swift, *Collocalia nidifica*; but Blyth determined the birds which Capt. Lewis found making similar nests in the Nicobar Islands to be *Collocalia fuciphaga*, remarking that the natives who gather the nests are much given to mislead inquirers when interrogated on the subject, which may account for the erroneously published statements that *Collocalia fuciphaga* does not produce an edible nest.—*Field*.

◆
THE PITCHER PLANT.
TO THE EDITOR OF "NATURE."

The variety of the Pitcher Plant (*Sarracenia variolaris*) found in North America is carnivorous, being a feeder on various animal substances. Mrs. Mary Treat, an American naturalist, made a few years ago several experiments upon the plants of this species to be found in Florida; and to the labours of this lady the writer has been indebted, in some measure, in the preparation of this paper. The *Sarracenia* derives its name of "Pitcher Plant" from the fact of its possessing the following curious characteristics. The median never is prolonged beyond the leaves in the manner of a tendril, and terminates in a species of cup or urn. This cup is ordinarily three or four inches in depth, and one to one and a half inches in width. The orifice of the cup is covered with a lid, which opens and shuts at certain periods. At sunrise the cup is found filled with sweet, limpid water, at which time the lid is down. In the course of the day the lid opens, when nearly half the water is evaporated; but during the night this less is made up, and the next morning the cup is again quite full, and the lid is shut. About the middle of March the plants put forth their leaves, which are from six to twelve inches long, hollow, and shaped something like a trumpet, whilst the aperture at the apex is formed almost precisely in the same manner as those of the plants previously described. A broad wing extends along one side of the leaf, from the base to the opening at the top; this wing is bound, or edged with a purple cord, which extends likewise around the cup. The cord secretes a sweet fluid, and not only flying insects, but those also that crawl upon the ground, are attracted by it to the plants. Ants, especially, are very fond of this fluid, so that a line of aphides, extending from the base to the summit of a leaf, may frequently be observed slowly advancing towards the orifice of the cup, down which they disappear, never to return. Flying insects of every kind are equally drawn to the plant; and directly they taste the fluid they act very curiously. After feeding upon the secretions for two or three minutes they become quite stupid, unsteady on their feet, and whilst trying to pass their legs over their wings to clear them, they fall down. It is of no use to liberate any of the smaller insects, very fly, removed from the leaf upon which it had been feeding, returned immediately it was at liberty to do so, and walked down the fatal cup as though drawn to it by a species of irresistible fascination. It is not alone that flies and other small insects are overpowered by the fluid which exudes from the cord in question. Even large insects succumb to it, although of course not so quickly. Mrs. Treat says:—"A large cockroach was feeding on the secretion of a fresh leaf, which had caught but little or no prey. After feeding a short time the insect went down the tube so tight that I could not dislodge it, even when turning the leaf upside down and knocking it quite hard. It was late in the evening when I observed it enter; the next morning I cut the tube open; the cockroach was still alive, but it was covered with a secretion produced from the inner surface of the tube, and its legs fell off as I extracted it. From all appearance the terrible *Sarracenia* was eating its victim alive. And yet, perhaps, I should not say 'terrible,' for the

plant seems to supply its victims with a Leth-like draught before devouring them."

If only a few insects alight upon a leaf no unpleasant smell is perceptible during, or after, the process of digestion; but if a large number of them be caught, which is commonly the case, a most offensive odour emanates from the cup, although the putrid matter does not appear to injure in any manner the inner surface of the tube, food, even in this condition, being readily absorbed, and going to nourish the plant. In fact, it would seem that the *Sarracenia*, like some animals, can feed upon carrion and thrive upon it.

In instances in which experiments have been made with fresh, raw beef or mutton, the meat has been covered in a few hours with the secretions of the leaves, and the blood extracted from it. There is, however, one difference between the digesting powers of the leaves when exercised upon insects or upon meat. Even if the bodies of insects have become putrid the plant, as has already been stated, has no difficulty in assimilating them; but as regards meat, it is only when it is perfectly sweet that the secretion of the leaves will act upon it.

The Pitcher plant undoubtedly derives its principal nourishment from the insects it eats. It, too—unlike most other carnivorous plants, which, when the quantity of food with which they have to deal is in excess of their powers of digestion, succumb to the effort and die—appears to find it easy to devour my number of insects, small or large, the operation being with it simply a question of time. Flies, beetles, or even cockroaches, at the expiration of three or four days at most, disappear, nothing being left of them save their wings and other hard parts of their bodies.

The *Sarracenia* is, indeed, not only the most voracious of all known species of carnivorous plants, but the least fastidious as to the nature of the food upon which it feeds. W. C. M.

Perhaps you will allow me to set "W. C. M." right with regard to *Sarracenia variolaris* and pitcher plants generally. I am afraid the sources from whence he obtained his information were not very reliable, as will be seen from the following:—

There are six species of *Sarracenia* found in North America, all of them characterised by the same trumpet-shaped leaves growing in tufts, and in several of the species attaining a length of a yard. In addition to these there is the *Darlingtonia californica*, which has long twisted trumpet-shaped leaves, the top of which is curved over, forming a sort of hood, and having a rather small aperture on each side. These constitute the whole of the pitcher plants of North America. "W. C. M.," whilst professing to describe the "curious characteristics" of the *Sarracenia*, really describes the leaf and pitcher of *Nepenthes*, which, as almost everybody knows, are tropical plants, mostly natives of the Indian Archipelago, and well known in this country as ornamental stove plants. The pitchers vary much in size, some of the species producing them quite eighteen inches long and capable of holding a quart of water, whilst others have pitchers no larger than a thimble. "W. C. M." is quite wrong in saying that the lids of the pitchers of *Nepenthes*, or indeed of any pitcher-plant known, close again after they have once opened. When the pitcher is about full-grown, the lid pushes open, widely in some species, only slightly in others, and remains quite stationary till the pitcher dies. When the lid opens, the pitcher is found to be about one-quarter filled with a sweetish watery liquid. Under cultivation it is necessary to keep the pitchers filled with water, or they soon shrivel; and it is found that, however frequently the water is renewed, it soon acquires a slight sweetness; so that the secretion of "honey" going on in the pitcher must be somewhat copious. If the water which is in the pitcher when it first opens dries up, there is no further secretion of liquid—at least such is the case with cultivated plants. At Kew the oldest pitchers on the *Nepenthes* attract insects as long as they contain moisture. The *Sarracenia*s have their pitchers formed by the folding and joining of the edges of the

leaves, so as to make a long funnel which is wide at the mouth and narrowed to almost a point at the base. Over the mouth the flap-like lid is fixed and in some of the species stands erect so as to admit rain-water into the pitchers, whilst in others the lid curves over in such a manner as to hinder the rain from falling into them. In 1815, the then President of the Linnean Society, Dr. James McBride, read a communication on the fly-catching propensity of Sarracenias, from which the following is worth quoting, as it describes accurately what we have repeatedly observed in the collection of Sarracenias cultivated at Kew. He says, writing chiefly about *Sarracenia variolaris*: "If, in the months of May, June, or July, when the leaves of these plants perform their extraordinary functions in the greatest perfection, some of them should be removed to a house and fixed in an erect position, it will soon be perceived that flies are attracted by them. These insects immediately approach the faces of the leaves, and, leaning over their edges, appear to sip with eagerness something from their internal surface. In this position they linger, but at length allured, as it would seem by the pleasures of taste, they enter the tubes. The fly, which has thus changed its situation, will be seen to stand unsteadily, it totters for a few seconds, slips, and falls to the bottom of the tube, where it is either drowned or attempts in vain to ascend against the points of the hairs. The fly seldom takes wing in its fall and escapes. In a house much infested with flies this entrapment goes on so rapidly that a tube is filled within a few hours, and it becomes necessary to add water, the natural quantity being insufficient to drown the imprisoned insects. The leaves of other species might well be employed as fly-catchers; indeed I am credibly informed that they are in some neighbourhoods. The leaves of *Sarracenia flava*, although they are very capacious, and often grow to a height of three feet or more, are never found to contain so many insects as those of other species. The cause which attracts flies is evidently a sweet viscid substance resembling honey, secreted by, or exuding from, the internal surface of the tube. From the margin, where it commences, it does not extend lower than one-fourth of an inch. The falling of the insect as soon as it enters the tube is wholly attributable to the downward or inverted position of the hairs of the internal surface of the leaf. At the bottom of a tube, split open, the hairs are plainly discernible pointing downwards; as the eye ranges upwards they gradually become shorter and attenuated, till at, or just below, the surface covered by the bait, they are no longer perceptible to the naked eye nor to the most delicate touch. It is here that the fly cannot take a hold sufficiently strong to support itself, but falls. The inability of insects to crawl up against the points of the hairs I have often tested in the most satisfactory manner" (*Trans. Linnean Society*, vol. xii.). I have again and again released blue-bottle flies after they have been trapped, and have never yet found them act in any way that would suggest an intoxicating property in the secretion which they had fed upon—this is contrary to the information of "W. C. M.," who says:—"After feeding upon the secretion for two or three minutes, they [the insects] become quite stupid, unsteady on their feet, &c." To prevent the pitchers being injured by the large number of insects which are lured into them, we find it necessary at Kew to fill the mouths of the pitchers with cotton-wool; this prevents the insects from falling in. Before this precaution was taken many of our finest pitchers were lost, owing to the decay which was caused by the rotten mass of insects which had accumulated in the bottom of the pitchers. "W. C. M." will be surprised to hear that, in spite of this cutting off of the supply of insects to the pitchers, the plants were in no way affected as regards growth or vigour, but that the length and general health of the pitchers were more satisfactory after the insects were not allowed to enter them, than before. The concluding sentence in his remarks is rather startling, as, so far as investigations conducted by physiologists have gone

hitherto, the Sarracenias are not known to be carnivorous. Mr. W. H. Gilbert, of the Quckett Microscop. Club, says:—"The pitchers contain fluid, but nothing corresponding to a digestive fluid has been detected in them; so that, if the insects which perish in the pitcher are of any value to the plant and afford any nutriment, it must be simply by maceration, and the glands can be regarded as absorbent only." Of course it may be said that Sarracenias would not have been constructed with what appears to be a view specially to catching insects, if the insects were not to serve some useful purpose in the economy of the plant. Anyhow, at present it is only safe to say of Sarracenias that they allure and ultimately destroy insects, but we do not yet know that they obtain nourishment from them. Certainly under cultivation there is abundance of evidence to prove that these, and in fact all those plants which are considered to be distinctly carnivorous, grow and thrive at least as well when insect food is not allowed them as when it is. Kew. W. WATSON.

CINCHONA NOTES.

About the time of the Franco-Prussian war, when scientific observation was more or less paralysed over the greater portion of Europe, some seeds of *Cinchona officinalis* were sent by the late botanist, DeCausse, of the Paris *Jardin des Plantes*, and by M. Morio, to the small French colony of Réunion, and were immediately planted near the shore.

The little shoots were soon afterwards transplanted to the neighbouring hills, where they were set at an altitude of about 2,500 feet above the level of the ocean. For the next four years the plants were watched with much anxiety. At the end of that time the experiment was proved to be not only interesting but practically successful; a cutting from one of the first little plants had then become a tree more than 6 yards high.

These cinchona plants at Réunion produced both flowers and fertile fruit; and the bark, when submitted to analysis, proved rich in alkaloids. As early as 1875 Dr. Vinson, a resident, had upon his own plantation in the island no less than 300 cinchona trees, and his example was soon followed by several other gentlemen who possessed land in that district. It was in this way that the culture of *Cinchona officinalis* in the island of Réunion, which is said to be giving promise of becoming very profitable to the landowners, was set about in the first instance. When the trees of the original plantations were about eight years old, the bark taken from them and analysed showed that so far the attempt to introduce cinchona had proved an evident success; 2 lb. of this bark yielded 210 grains of quinine and $\frac{7}{8}$ grains of cinchonine.

It thus appears that the maritime climate of Réunion Island, and, perhaps, its volcanic soil also are well adapted to the cultivation of *Cinchona officinalis*. It is, perhaps, needless to remark that among our British possessions are to be found a very considerable number of islands which would show similar favourable conditions, but where, up to the present time, no attempt has been made to introduce the cinchona trees.

While we were all discussing, not long since, the prospects of the cinchona plantations in Ceylon, to which we shall refer presently, a letter appeared from Dr. Saec, written at Buenos Ayres, in which he treats of the culture of the cinchona trees in Bolivia, and on certain other chemical and pharmaceutical products of that country.

Many readers will call to mind that it was the reckless manner in which the Bolivian trees were and are still struck down in order to collect the bark which caused it to be feared that in the course of a comparatively short space of time the supply of cinchona bark from South America would fall short of the demand; and finally, perhaps, cease altogether. It was this circumstance which caused such strenuous efforts to establish cinchona plantations in Java, India, Ceylon, Bourbon Island, &c.; so that at present these various districts are actually competing, more or less

energetically, with South America as sources of quinine barks of the first quality.*

Nevertheless, the most contradictory testimony exists as to the comparative value of the barks grown in the new and old localities. It may be taken for granted that Sacc's letter above referred to, which was addressed to the French Academy, endeavours to make out that the South American barks are still the best, though we have occasionally seen directly opposite statements. It is probable that many years must be allowed to elapse before it will be possible to decide this question with anything approaching to scientific accuracy. The plants in the new districts must have time to acclimatize themselves thoroughly before their full alkali-yielding power can be expected to become manifest.†

However that may be, the results from India and Ceylon have been most encouraging, and clearly indicate that better results still are probably in store for these Eastern localities.

It is satisfactory to know that for the last ten years great efforts have been made in Bolivia to improve the culture of cinchona trees and the modes of collecting the bark, advantageous efforts that will be felt throughout the world; and we are assured that the wanton destruction of the trees has been checked. Dr. Sacc informs us that new plants are being reared by millions. These are sown in special beds, whence the owners of plantations come and fetch them as soon as the shoots are large enough to find a permanent home on the mountain slopes. There are, at the present moment, seven Bolivian villages where the number of young cinchona plants amounts to a total of no less than 3,942,000, all of which will be at their prime in ten to fifteen years hence.‡

Two lb. avoirdupois of the calisaya bark of Bolivia yields about 1 oz. of sulphate of quinine, according to the French chemists; and in spite of the well-known difficulties of transportation, 2 lb. of this bark, which is said to be worth 5s. on the spot where it is produced, can be sold in Paris at 8s. or 9s. [Hem!—Ed.]

One of our correspondents, writing from South America last year, informs us that it is still the custom to cut down the trees in order to strip them of their bark; but that endeavours are being made to induce the planters to make some trials of stripping without felling, as is done in Southern Europe with the cork trees. In this way it is hoped to obtain the bark and preserve the tree.

Bolivia occupies a space much larger than that of Great Britain; its superficies is estimated to be twice as great as that of France. It is covered with mountains to the west and south, whence numerous streams arise and flow down into the torrid plains of the northern and eastern districts, which are thus irrigated and enjoy a most fertile soil. The new railroads which are in contemplation, or in course of construction, will, no doubt ensure for Bolivia better prospects for the future; and their influence will make itself felt in some few years' time, when a line of railway that connects this vast province with the Argentine Republic, and other lines in contemplation, shall be in full working order. Thus Bolivia would eventually be connected on one side with the Pacific and on the other with the river Paraguay, finding a ready outlet for its cinchona bark, coffee, cocoa, maize, sugar, alpaca wool, Vigonya wool, gubl, silver, mercury, copper, lead, tin, bismuth, sulphur, alum, nitrate of soda, guano, jaguar skins, tapir skins, guanaco skins, &c. But to inspire the confidence of Europeans, and to induce them to invest capital in Bolivia, something more than the natural resources of that country and its actual exports must be taken into consideration; namely, the character of the popul-

ations, their capacity for work, their numbers, and the nature and stability of the Government.*

New species or varieties of cinchona are continually attracting attention, the idea being prevalent that some kinds are more easily acclimatized and more profitably cultivated in various parts of the world than others. A very short time ago *Cinchona Ledgeriana* absorbed a large amount of notice, and now a good deal of attention centres on *C. cuprea*.†

Other valuable varieties have been talked about in London as likely to become more or less celebrated, whether grown in Ceylon or elsewhere. Among these we may mention "Calisaya morada veluta" (or *Cinchona calisaya*, var. *Boliviana*, subvar. *pubescens*) and the so-called "Calisaya verde" (*Cinchona calisaya*, var. *albomarginata*). Besides these two we have also the "Calisaya fina" (*Cinchona calisaya*, var. *vera*.)

We trust that the species and varieties of cinchona have ceased to form the subject of pharmaceutical examinations; otherwise, we pity the candidate who has to answer the questions!

Of the *Calisaya verde*, Mr. Markham says he was told it was a very large tree, wholly devoid of any red colour on the leaves, and usually growing very far down the valleys, and even in the plains. From 600 to 700 lb. of bark is the habitual yield of a tree of this kind, whilst the *Calisaya fina* is said to yield only about half that quantity.

On the other hand, Mr. Holmes seems to affirm that *Calisaya verde* is the most satisfactory cinchona plant for profitable cultivation, and something to the same effect reaches us from Bolivia. It is asserted that, although this tree yields only 6½ to 9 per cent of pure sulphate of quinine, while the best *Ledgeriana* bark yields about 13 per cent in favourable circumstances, and other varieties not more than 6 per cent, yet, as the *Calisaya verde* yields about twice the amount of bark that the others do, its product is equivalent in reality to 13 or 18 per cent of sulphate of quinine.

The *Calisaya verde* appears certainly to be a more vigorous tree than the more delicate *Ledgeriana*, and as it will grow at a lower elevation, it is obvious that it might be cultivated to a much greater extent. It may also prove valuable for grafting the *Ledgeriana* upon it; though the attempt to graft the latter upon *Cinchona succirubra* has proved quite unsuccessful up to the present time. [This is new to us and will be new to Mr. Moens.—Ed.]

As we have just mentioned *C. succirubra*, we may allude, in a few words, to the effects of altitude on the yield of quinine, as brought to light by the cultivation of this species of cinchona in Ceylon. Very careful analyses have been made of this bark, taken from two trees of common origin, one of which had been planted at an altitude of 5,500 feet, and the other at a height of 1,500 feet only above the level of the sea. Both trees grew in the plantations started in 1863, and, when the said analyses were made, were close upon twenty years of age. According to Trimen, they had vegetated in precisely similar conditions, with the exception of the difference of climate due to 4,000 feet difference of altitude. The tree at 5,500 feet had reached 37 feet in height, measured from the ground to a point where the stem is only 1 inch thick. Near the soil it was 37 inches in circumference. It yielded 25 lb. of dry bark, which is equal to about 77 lb. of fresh moist bark.

The other tree was about the same size, but only measured 20 inches in circumference near the soil, and yielded not more than 7 lb. of dry bark, equivalent to about 21 lb. of fresh moist bark). Here are the analyses alluded to:—

	Altitude as above.	Altitude.
	5,500 Feet.	1,500 Feet.
Sulphate of quinine ...	2.75%	1.67%
Quinine ...	2.06%	1.67%
Cinchonidine ...	3.47%	1.67%
Cinchonine ...	0.61%	1.67%

* Labour is dear and bad, and the country is generally in a state of anarchy.—Ed.

† Which is not a true cinchona.—Ed.

* We do not believe that Réunion has exported a bale of bark.—Ed.

† At an early date in the enterprise Howard declared the East India Bark to be superior, and nothing from South America can compare with the *Ledgeriana* bark of Java.—Ed.

‡ "All of which"! No; only a percentage will survive.—Ed.

	Altitude, 5,500 Feet.	Altitude, 1,500 Feet.
Quinidine	trace	0.30
Amorphous alkaloid	0.66	1.06
Total alkaloids	6.80	3.55

The much larger yield of sulphate of quinine from the bark grown at the greater altitude is not only remarkable, but agrees with a former observation by Broughton respecting *Cinchona officialis* (*C. peruviana*). This species, as cultivated at Neddiwattam, is notable for the large amount of cinchonine which it contains (3.84 per cent), and by the absence of quinine. When, however, it is grown at a greater elevation—on the most elevated peaks of the Dolabetta Hills—the amount of cinchonine diminishes, and that of quinine comes up to 0.67 per cent.

It is obvious that these observations, like those referred to by Howard, De Vrij, and others, point to the great influence which the altitude exerts upon the yield of total alkaloids.

The relative value of the different cinchona alkaloids in the treatment of intermittent fever, and in that of other kinds of pyrexia, has attracted considerable attention of late years. Much stress has been laid recently upon the advantages likely to accrue from substituting cinchonidine for quinine in cases of intermittent or remittent fevers. The reputation of quinine and its salts is well established in this respect, but positive facts leave no doubt that other alkaloids of the cinchona bark possess the same properties to a very great extent; and when the cost of quinine compared with that of cinchonidine, and their respective therapeutic properties taken into consideration, there is much to be said in favour of the latter alkaloid.

Cinchonidine was discovered by Pasteur in 1853. It is anhydrous, and isomeric with cinchonine. It deviates the plane of polarisation to the left, and does not give a green colour when treated with chlorine water and ammonia, as both quinine and quinidine do.

According to Howard and Weddell, not only certain barks yield no quinine at all, but the forests which yield the best bark, as far as this particular alkaloid is concerned, are fast failing to supply it. Moreover, the Indian plantations have proved that the barks which appear to be the most robust in that climate are not those which contain the most quinine. It became, therefore, an exceedingly interesting question to investigate the therapeutic properties of the other alkaloids, and to this effect careful observations were made in India with cinchonine, cinchonidine and quinidine. Upwards of 1,000 patients were treated with these three bases in lieu of quinine, and a report issued at Madras stated that the therapeutic effects scarcely differed at all from those obtained with quinine. Of 1,145 patients, 1,111 were cured in almost equal proportions, which ever of the three "other" alkaloids was given.

It would appear, therefore, to be a matter of indifference whether patients suffering from intermittent fever are treated with quinine or with one or other of the different alkaloids present in the cinchona barks. This being admitted, the preference would, of course, be given to that alkaloid which could be obtained at the smallest cost.

Howard has shown that quinidine cannot be got cheaper than quinine, so that the question has to be fought out commercially between cinchonine and cinchonidine, either of which can be obtained at about one-third the cost of quinine.

Cinchona accumulates in manufactories where the cinchona barks are specially treated for quinine (which it usually accompanies). Its price is now low, but that would cease to be the case if physicians should recognise that other bases can replace quinine. Then cinchonine will accumulate no longer, and, as it rises in price, attention will be turned towards cinchonidine. It does not appear probable that the price of the latter will rise for many years, for not only the trees whose barks yield it exist abundantly in the forests of South America, but the most robust tree of the Indian cinchona plantations is the *Cinchona succirubra*, the bark of which is rich in cinchonidine.

The medium does of sulphate of cinchonidine for adults appears to be between 4½ and 6 grains, and Weddell goes so far as to say that certain cases of intermittent fever which quinine failed to cure were immediately relieved by sulphate of cinchonidine.

It is not very long since the Government of Madras gave an order for 16,000 oz. of sulphate of cinchonidine at the price of 1 rupee per oz. (about 2s.), and it has been largely used of late in some of our London hospitals, so that it is not improbable you may hear more about it, either one way or the other, as experience is gained.—*Chemist and Druggist*.

INDESTRUCTIBLE FENCE POSTS.—A farmer writes that twenty-five years ago he set split white Oak posts for his garden fence, putting about a peck of air-slaked lime about each, and they are all good yet. He attributes their good condition to the effect of the lime, in which he is doubtless correct. A board that has been used in a mortar bed, and thoroughly saturated with lime, is almost indestructibly from decay.—*Florida Dispatch*.

THE "TROPICAL AGRICULTURIST."—Mr. W. T. Thiselton Dyer, in an article on the square bamboo in *Nature* of Aug. 27th, refers to the *T. A.* as "an astonishing repository of everything relating to the economic botany of the East." To the above favourable opinion we may add the following from a planter, who explains his reason for discontinuing the *Indian Tea Gazette* by remarking:—"Your *Tropical A.* is really ample for anyone." It certainly contains every scrap about tea and in the handiest form for reference. Mr. Dowling, author of the "Tea Notes," also writes to us as follows:—"I am indebted to your valuable paper which I receive regularly, for several hints. I went over Ceylon in Dec. 1881 when tea was in its infancy, and am much interested in reading in your valuable paper of the strides it has made since then."

LOCAL SALES OF TEA AND LONDON PRICES.—Referring to the remarks made by us on this subject in yesterday's issue, a mercantile correspondent writes to us as follows:—"No doubt the purchaser of the break of Agar's Laid tea that realized 2½ in London made money on the transaction, but this is not always the case. It is generally very difficult to trace tea bought at public auction here, but here are a few which may interest your readers:—

		Colombo price.	London average
Theberton ...	96 hf-chs. ...	64 cts	1 3/4
" "	56 hf-chs. ...	70 "	1 1/2
Doranakaude	12 chs. ...	68 "	1 5/8

The buyers of the first two lots did not make much on the bargain.—*Local Times*.

HIGH PRICES FOR COFFEE IN LONDON.—With middling plantation quoted at 68s., there must be some difficulty in realizing really high prices for coffee of however excellent quality; it is therefore all the more creditable to an estate, and particularly to the curers of the coffee, when an exceptional rate is realized in Mincing Lane. The mail just in brought what is really a splendid sale of Berragalla coffee, the results of which we subjoin:—

Sale of Berragalla Coffee (Haputale), London, August 26th.			
OO ...	3 casks	...	104.6
O ...	5 "	...	93.6
No. I. ...	2 "	...	71.
P. B. ...	1 "	...	90.
Triage ...	2 "	...	55.6

It is estimated that these prices will nett 78s. per cwt., equal to at least 151 f. o. b. in Colombo, which is most satisfactory. The coffee was cured by Messrs. Win. Law & Co.—*Ibid*.

MARKET RATES FOR OLD AND NEW PRODUCTS.

PRODUCTION OF TEA IN INDIA: QUALITY AND PRICES.

Some time ago we quoted from the Calcutta *Englishman* a notice of the official report for 1884 of tea cultivation in Assam, and now we take over an elaborate article from the *Pioneer*, in which some thing more than cultivation is dealt with. There is considerable ability and equal inconsistency displayed by the writer. He first shows that the lands held for tea cultivation have doubled in six years, and that, from the tendency of separate estates to aggregate in the hands of Companies, economy in working will be more and more secured, and yet he ends by anticipating the collapse of the Indian tea enterprise in the face of competition from China tea which is heavily burdened (besides its inferior quality) with export duties plus multitudinous squeezes! The addition of 30,000 acres in one year does not look like being conquered in the race, even although prices in 1884 were unprecedentedly low. On the other hand, cost of production and manufacture has been so economized that on teas produced at a cost of about 10d, a profit of 2d per lb. is estimated. The area taken up by tea-planters in Assam is somewhat less than a million of acres, giving an average of about 1,000 acres for each property, but as only 190,000 acres are under tea, in all stages of growth, the average per estate of cultivated acreage is only about 200 acres. The yield per acre of land in bearing, which, a few years ago, was reckoned at 280 lb., has been increased to 305. The estimates are now subjected to such checks that they can be fairly relied on. Counting Ceylon, the yield of Indian tea is increasing at the rate of five millions of pounds per annum, and the *Pioneer* is at a loss to know where a million additional consumers per annum is to come from. But the writer forgets that in Britain the consumption of tea per *caput* has increased, and is likely to increase, considerably beyond increment to population. That Australia should soon grow its own tea, we consider, looking at the labour difficulty, a wilder idea even than that of the process now going on being reversed, and China forcing Indian teas out of the market. The writer himself says: "It seems on the whole improbable that tea cultivation in India will seriously decrease," and he adduces the provision of a better and swifter class of steamers and the extension of railway facilities as good reasons for this belief. We prefer the optimism of the *Pioneer* to its pessimism. To the article from the *Pioneer*, we add two from the *Indian Tea Gazette* as well as a paragraph speaking highly of a new sifter.

The writer of "The Tea that Pays" takes the commonsense view that it is *medium* and not very fine teas which will pay the producer, but surely twenty year old estates cannot be so worn out as is represented. We observe, however, that the manager of Singell, one of the oldest estates in the Kurseong division of the Darjeeling district, is thus quoted in the report of the Company:—

"Want of soil," the Manager says, "is another cause of decrease in the output. In a garden that has been in existence as long as this, the loss of soil from wash and other causes becomes very apparent, and to correct this, as far as possible, is the work the importance of which can hardly be overrated."

But climate and season must have very much to do with the quality of tea, judging from what tea planters write, for instance:—

John H. 16th August.—Our Jorhat correspondent

writes:—We have been having a good deal of rain this last week, which though favourable for leaf has not been counted by good manufacturer. Leaf coming in wet is difficult to wither, and it has to be kept perhaps for two days when it dries up rather than withers and gives a dull fermentation in the cup. This last week has been rather a poor one for output, but the weather is more promising now for good flushes.

Again:—

N. Lakhimpur, 15th August.—Leaf has been coming rather stiff during the past week, and looking a bit hardish in most gardens.

And in a review of the season 1884-85, the paper from which we quote attributes disastrous effects to the failure of the *chota bursat* or little monsoon and to the great heat which accompanied rain when at length it came. The tea bushes were not able to renew their withered rootlets until comparatively late in the year. The rain when it came was excessive; in Sylhet beyond precedent. Low prices were not solely due to inferior tea, but to a reaction from the China war and the budget scare. Teas produced in the second half of the year we are told, are always more mellow and ripe than those of earlier growth; but the great point for Indian planters to keep in view is to produce their teas at a price which will defy competition. How the demand of the English brokers for extra fine teas and this advice are to be reconciled, is the difficulty, but the writer in the *Planters' Gazette*, contra the *Pioneer*, sees no reason why with the experience of past years "we should not be able to run our Chinese neighbours out of the market," notwithstanding the receipt of several driers by the Hongs in China. What we in Ceylon as well as in India have to do is to produce good quantities of tea per acre which will go into consumption on its own merits, without either adulteration or blending, with as few distinctions of quality as possible. To this end simplicity of machinery as well as efficiency, especially in the important operations of sorting and sifting, are desiderated. The writer in the *Planters' Gazette* evidently has not seen Jackson's leaf-breaker, and we confess neither have we. We do not think the coolies can influence the use of machinery to the extent attributed to them. The more we consider the matter, the more, certainly, do we share the sentiments of Mr. Armstrong as to short travelling of tea on the sifting machine, and those of the Indian writer we quote as to the loss of aroma inevitable from long exposure to the atmosphere (and to handling) in the final manipulations by coolies.

PADDY (RICE) CULTIVATION IN CEYLON.

The fact, that Moormen and Chetties, who know the real value, and relative value of Rs. and cents, as paying investments, think it a fortune to be owners of paddy fields, proves that it is all gammon, and downright nonsense to tell us that paddy cultivation is not paying, more especially, as to a large number of peasants, out of town, labour has no marketable value. Men work in paddy fields not so much for money, but for food and sake of company.*

But we should like to put down our thoughts why there is such a large import of grain from India. The larger number of people who consume the import are the coolies in our estates, and the town people chiefly composed of Moors, Chetties, Portuguese, Dutch and English descendants and others who as natives neither possessed lauds nor inherited them. All over the interior the native paddy affords the rice, which is the staple food of the Natives.

* This is an amusing sample of the native style of *non-sequitur*, because labour has no marketable value, therefore paddy cultivation pays.—Ed.

The native paddy is not converted in large quantities into rice. When the rice is wanted for food, the paddy is boiled and exposed to the air, under shade, and then the husk is pounded off, and the required noilium is ready for food: Consequently unless driven by necessity, native rice is never seen in market. What we want is persons, who would buy in our paddy, and convert it into rice; and this requires knowledge of the science; we use the word science advisedly. Paddy in the granary, for at least five or six months goes through a process of fermentation; and the paddy then is called sour; after which it becomes sweet, and is fit for conversion into rice. Then native rice being full of saccharine and glutinous matter is liable when in large quantities to be infested by weevil; hence in India in curing rice they use a large quantity of lime. So Europeans, who have lazy cooks, careless about cooking rice, go in for dysentery in eating rice and curry; and we know of long residents in the island, to whom physicians have prescribed rice and curry, to keep their inside in good condition; yet it is a fact beyond discussion, that rice and curry is the most wholesome food.

The truth is, the cooking of rice is a greater art than the cooking of curries. The Tamils say that if the rice be properly cooked, there is no need of curries. Thus the Tamil youthful peasant when asked why he sacks a wife, readily answers that he wants some one who would cook his rice (soru) for him. The exported rice must be well pounded in a mortar, till all the lime is brushed off; then it is to be sorted, taking off all husks, and picking out the black grain, which is the consequence of over fermentation; then it is put into a chatty, which is like a sieve, where it is rubbed down, till every particle of lime has no chance of keeping on the grain: then it is repeatedly washed, till the last bucket of water receives no colouring matter, but is as pure as spring water. The water in the sauce-pan is boiled to steaming heat, and handfuls of the grain are put in. A gentle fire gives you your dish of rice. When it is brought to table, it is pearly white; and when the delicious curry and gravy are poured on it, and you turn it up with the spoon, adding just a tiny bit of sambol, you taste ambrosial food. We, as Natives, therefore, prefer our rice and curry to all what English cooks can make out of fish, flesh or fowl, boiled, roasted or baked. Now native rice not cured by lime, requires no such process, and yet when brought to our doors, we beat it down in price, and refuse to buy it, but at very low rates, simply because it is native rice. Nothing is good in Ceylon, but what is of a foreign market. So hawkers come to our doors and say that it is "Rudgess" cloth, "Rudgess," note paper "Rudgess" pen, simply because the steel of Rodgers manufacture is thought to be the best. We know of a native trader who, whenever he presented his goods for sale, said, it was "England made" and "London bought." So we do not go in for native rice, we turn up our noses at it: we beat it down in price; and run it down with faint praise and cry that native rice is nowhere.

If rice cultivation in Ceylon is to obviate the import of rice, then the land to be looked to for such produce is the Central Province. The valleys are rich with the alluvial deposit of the acaebryon; the floods: they are fed by the crystal streams cold and sweet, flowing from the summit of hills and mountains, where rain clouds rest, after travelling from the Eastern and Western seas, bringing refreshing showers: even the sun sheds a mellow heat, that bring the sap gently to be the blade, and full ear of corn. The peasants go in only for one cultivation. They scrape only the surface for the planting of the Paddy. They use no manure. They do not care for weeding: even this so called "tidying" of water is done slovenly, for in the night, the man who is bound to do so, prefers his warm bed of straw rather than expose himself to the bleak cold wind of the mountain. Go to Wilson's bungalow: I'kundine: go to I'va: go to the valleys of Kadugunnava: go to the range of land sloping down into the valleys, the terraces of our paddy cultivation, and then visit the granaries bursting with corn: look at the men and women, the very picture of health,

a living evidence of an abundance of food supply, and tell us if we are exaggerating, when we say that the Central Province can yet produce rice enough to stop the import of grain. Batticaloa and Matara can do no more.—"Jaffra Patriot."

JOHORE TEA AT HOME.

(From the London Tea Letter of the *Indian Planters' Gazette*.)

I had some Johore tea sent to me this week by a friend from Singapore. It was made on a European owned garden, the first opened out in Johore, and the tea certainly promises well. It was not of a make to compare with teas made for the market, as it was "rough tea," and being somewhat highly fired its real quality would be unfair to gauge. I have seen, however, much worse "rough tea" than this in India, and the growth of the bushes is more luxurious than in Assam even, judging by accounts I have received—ten feet high in twenty months!

THE SIERRA LEONE KOLA NUT PLANTING AND TRADING COMPANY, LIMITED.

Under this comprehensive title a company has just been formed in the West African colony, with an influential local Board, and a capital of £2,300 to buy land and plant the kola nut. At any rate, this is its primary object, but let the prospectus speak for itself as to the multifarious and rather mixed intentions of the directors:—

"*Agricultural*.—To grow besides cocoa and coffee, 10,000 kola trees, which will produce nuts of commercial value in five years with the aid of artificial manure as prepared by Messrs. Ohendorff and Co., of London, for the colonies, to meet the increasing demand for this valuable dietic article eaten in its green state by the natives of West Africa and the interior, and in its dried state for export to Europe as a 'New Temperance Beverage' in connection with coffee, &c. 'Kolatina' will in the near future be 'the cup that cheers but not inebriates.' About 15 acres will be set apart for experimenting in tobacco, potatoes, cichona, &c.

"*Commercial*.—This Company will open a small factory in the plantation for the convenience of labourers and others, and to buy palm kernels, &c.; and barter manufactured trade goods with the natives at Quiah Land and its vicinity, and to burn lime in the vicinity of the plantation where oyster shells in abundance can be had; and to supply Freetown with mangrove wood."

There can be no doubt that the demand for the nut is steadily increasing, for we see by the Customs returns of Sierra Leone that in 1883 nuts to the value of £35,000 were exported, whilst the value reached a little over £40,000 last year. A correspondent of one of the local papers who has been engaged in the cultivation says:—

"I am glad to learn from the inaugural address of the president of the Sierra Leone Association that the article was mentioned among others in that address for encouraging its systematic cultivation in our gardens and yards in the settlement.

"The kola nut is a hardy plant, and a tree in full growth has been known to produce nuts in one year to the value of twenty pounds. It commences to be a fruit-bearing tree on the fifth year after planting, and to decay in its fiftieth year. One of its peculiarities is, that it sends its roots not so deep in the soil as the surface. It is singular enough that all the largest kola nuts are exported from the settlement (as the export trade demands) and that almost all the smallest and unhealthy-looking ones are consumed in it. It is generally known that the Africans who habitually use the kola nut live to a very old age, and when toothless from age the nuts are ground before eaten. It has the wonderful properties of alleviating hunger, keeping away sleep and when made into a decoction, an immediate cure for drunkenness. I have been told that in an island on our coast the natives, from circumstances, subsist for weeks solely on palm wine and kola nuts, that is before the yam season. I therefore cannot say too much in recommending this article for extensive cultivation."

TEA CULTURE IN ASSAM.

(From the Pioneer.)

The annual report on tea culture in Assam, bringing facts and figures down to the end of 1884, is a more interesting work than official documents of this sort usually are. Not only does it possess the advantage of dealing with the living energies of a great industry instead of dry statistics representing merely the manipulation of Government machinery, but it actually shows traces of an intelligent interest in the subject. Pains have been taken to correct extravagant estimates and to get at the true area and outturn of tea gardens, or as near it as calculation can go in those cases, yearly becoming rarer, where planters, from suspicion or dislike, or indifference, have refused or neglected to furnish the needful information. The fact which comes out clearly after all these corrections is that in spite of flooded markets and low prices, tea cultivation in Assam is certainly not going backward. If land has been relinquished, it is only in places which have been found unsuitable for tea, and when the total extent of tea-grants is stated as 913,000 acres in 1884 against 923,000 acres in the year preceding, it must not be forgotten that a good deal of this apparent decrease is due to the more exact ascertainment of areas, in the same way as a more careful classification and numbering of gardens has led to their reduction from 1,030 to 970. Of course the whole of this 913,000 acres is not cultivated; the Assam planter takes up large extra spaces of land in view of future extensions, and also to supply the garden with the needful timber for his buildings and forest produce for the domestic requirements of his coolies. The tea-producing area is little more than one one-sixth of the total extent of estates, or 158,000 acres, and 32,000 acres besides are under young plants, which will be yielding tea in the next two or three years. The extension of tea culture during the last six years is very remarkable; there were only 112,000 acres of mature plants in 1879 and only 605,000 acres of tea grants altogether, so that the increase since that date has been one of 50 per cent., and there is every prospect of its continuing, for the area under young plants is larger at present than in any previous year. A great advance was made in 1883, when new gardens to the extent of 20,000 acres were opened on the southern edge of the Sylhet district among the low hills and jungle-smothered plains which abut upon the native State of Hill Tipperah, a virgin border-land into which the dense population of the rice-tracts further north, though subsisting in some places upon half an acre of cultivated land to each human being, has not yet spread itself in its slow southward overflow. Yet this fringe of hill and jungle, though untenanted save by a few families of roving Kookies, who practise the kind of nomadic agriculture known as *ghuming*, is subject to claims on the part of distant land-owners who have never even secured the capabilities of the land for tea have been obliged to compromise these claims, or at least to purchase the good-will of their most powerful neighbour by sums which can be counted in lakhs of rupees. No better example could be cited of the power of land-ownership to tax the earnings of labour and capital.

The outturn of the tea gardens of Assam can be estimated with tolerable accuracy by means of statistics obtained from three different sources. The Indian Tea Association makes its own calculations on information supplied by planters. The trade-registering stations at Dhubri and Bhairobazar give the declared exports from the Brahmaputra and Surma Valleys respectively; and in the third place there are the figures furnished by the official returns. The outturn rendered by each of these three methods is respectively 48½, 45½, and 51 millions of pounds. The trade-registrars do not catch the whole export trade of the province, but only that by the two main waterways, and the lowness of their estimates can thus be understood. It is doubtful, again, whether the Tea Association embraces all the 970 gardens of

Assam, but the discrepancy between its estimate and the official one arises not so much from this cause as from the high average outturn officially reported from a single district; and if this be corrected into something more modest and probable, the official estimate of 51 millions falls to 49½ millions of pounds, and comes into close agreement with the Tea Association's return. These figures exceed the outturn of 1883 by three million pounds, and the average produce per acre appears as 305 lb against 286 lb in 1883. The Sylhet and Cachar planters, however, do not seem to have shared in the benefit of this increased productiveness, which was peculiar to the valley of the Brahmaputra, and even there the season was not regarded as a good one. The cost price of a pound of tea varies greatly on different gardens, but in 1884 it may be reckoned, on the whole, at about 3 annas 8 pies for cultivation and 4 annas for manufacture, or 7 annas 8 pies altogether. This is a small figure; but the cost of production has not yet been set down to the level of the low prices, which must henceforth be expected. In 1884 prices fell unprecedentedly low. The average of the Calcutta sales from May to December was 8 annas 11 pies per pound, and generally the fall is estimated at 2 annas per pound—a decrease which, for the majority of gardens, means a frightful diminution of profit upon the tea delivered in Calcutta. The causes of the fall in prices are variously alleged as the extension of tea cultivation, the rapidly increasing supply from Ceylon, the plucking of coarser leaf, the spoiling of the tea by too rapid drying in the new machinery, and, in the last resort, climatic causes which give a crop of inferior flavour. It is certain that the London brokers have been complaining of the poor quality of Assam tea, but the main reason why tea is so cheap seems to be the fact that the production of tea has increased faster than the habit of tea-drinking. A few figures will illustrate the strides which production is making. The crop of 1884 throughout all India (excluding Ceylon) was 63 million pounds, of which Assam furnished 48½ and Darjeeling 10½ millions. The crop of 1885 is estimated at 68½ millions. Then Ceylon exported 1½ million pounds in nine months of 1883-84 and 2½ million pounds in the same nine months of 1884-85. The increase in production during a single year may therefore be reckoned at four or five million pounds, even after a large reduction for over-liberal estimates. This means an additional supply sufficient to meet the wants of a million new consumers, and it is evident that consumers cannot go on increasing at the rate of a million a year.

The talk about raising the duty gave a momentary disturbance to trade, but something like a revival of activity has now set in. There are only too good reasons for suspecting that this cannot last. The stocks of Indian tea in London have suffered a temporary diminution, and stood at 11½ million pounds last June against 17 million in June 1883; but they will soon be replenished if export go on at their present rate. During the months of May and June, 2½ million pounds were exported to the United Kingdom in 1885, 2½ million in 1884, and nearly 1½ million in 1885. Any deficiency there may be in stocks will obviously soon be made good, and if the crop of 1885 answers to expectations, stocks will be larger than ever by the end of the year. It is becoming plain that the Australian market cannot be counted on to take any larger quantity. It took 1½ million pounds in 1884, but this is hardly worth counting, and the time is not far distant when Australia will begin to grow its own tea as it now grows its own sugar. The Assam planters feathered a dart against themselves when they sent tea-seed to Noumea, where the introduction of the new industry has caught the eye of the Australians. In short, tea cannot hope to escape the influence of the general tendency to lower prices, which our best authorities on economic matters are beginning to recognize as a great characteristic of the modern industrial age. It seems on the whole improbable that tea cultivation in India will ever seriously decrease. Gardens are not likely to be abandoned because it no longer pays the owner to produce tea upon them. The effect of falling prices will rather be to awaken efforts

towards the reduction of the cost of cultivation and manufacture. In this attempt the planters will be helped to some degree by the general progress of India in material civilization. This can already be perceived in Assam, where the new swift daily steamers on the Brahmaputra, replacing the old weakly ones, have materially reduced the average cost of each coolie to the tea-planter, and the further extension of the Kani Railway towards Assam will cheapen the cost of transport still more. In Sylhet and Cachar there is every prospect of a daily steamer service or at least a service of swift steamers twice a week, taking the place of the present tedious method of bringing up coolies in country boats—a method which may strictly be called a slow process of cholera inoculation, attended by a frightful mortality, deplorable alike in the interests of humanity and in those of the planter, to whom each coolie safely landed costs so much the more in proportion to the number of the batch who have succumbed to the poisonous effects of the water of the rivers and creeks, from which they drink in their three weeks' progress upcountry within the cramped and noisome limits of a covered Bengalee river-boat. Improved communications will doubtless do much towards reducing the cost of production; but there is another way in which still larger savings can be made, and that is by the aggregation of tea estates; in a word, by an industrial revolution similar to that which we see going on in the great agricultural States of America. Wealthy companies dealing with large areas are able to effect economies in labour and superintendence, to apply machinery to the fullest advantage, and to bring outlay and outturn towards an average uniformity which tends to counteract fluctuations in prices and variations in the character of seasons. The days of single gardens seem to be numbered. In Assam at least it is probable that in the future we shall see less and less of the planter-proprietor and more and more of the great companies which add grant to grant and effect each successive extension at a smaller proportionate outlay on labour, management, and appliances. One result will be the disappearance of what little interest native Indian capital now has in the tea industry, and monopolisation of the business by English capital more exclusively than ever. Yet large as is the stake of English capital in Indian tea, we cannot get rid of a feeling of uneasiness in contemplating the whole business, as if it existed really upon sufferance. Indian tea has not yet come seriously into competition with Chinese tea, for the demand for the latter has scarcely begun to show signs of diminution, and it is evidently not the interest of the China houses to push matters to extremities. But if ever the competition should become vital, there can be little doubt which of the two rivals has the larger resources and the greater staying power. If the China houses should see cause to force down prices, it might speedily be discovered that tea in India is only an exotic, and that the task of supplying the world with tea had better be left to other countries where Nature has prescribed more favourable conditions for its production.

THE TEA THAT PAYS.

The season opened with a great flourish of triumphs, and for a couple of sales fairly high values were obtained. Things are rather different now, and we are anxious to see how, at the end of the season, the brokers are to get out of their dilemma, unless by again resorting to the old stock excuse of deterioration in Indian tea. We could point to some well-known marks celebrated both for liquor in cup and general manufacture, which last year, in an extremely depressed market, commanded high rates, whilst this year they are relegated to a lower than even the medium class. How are the brokers to account for this? Quality, quality has been the cry for the past few years, and we firmly believe that this has been sacrificed* at the expense of quantity. The tea bushes thus stripped yearly have lost somewhat of their vigor, and, in consequence

somewhat of their former properties which gave full and pungent liquors. Doubtless in this statement we are running counter to a great deal that has been written on this subject. In the annual tea report we are aware that more than one Deputy Commissioner gives it as his opinion that quantity has been more attended to than quality, but we venture to hold an entirely opposite opinion, and if our readers take time to consider, we believe they will agree with us. It does not stand to reason that tea planted 20 years ago, which has been contending against red spider, mosquito blight, white ants, *et hoc genus omne*, besides being expected to give a good yield per acre, can give the same vigorous flushes it used to. Some of our planter friends may say, "Oh, but then look at our extensions made with high class plant"; true, but then bear in mind that these extensions are not more than representations of perhaps one-third, or one-quarter, of the bearing area. Indeed, if we take away those new extensions from many gardens, there would be precious little left to leaven the mass, and we would see those old gardens of twenty years' standing left behind, and distanced in the race for prices, instead of being nearly always as they are now placed. If Indian tea has deteriorated so much as we are made to believe by the *Cognoscendi* at home, will they explain how it is that low class Indians are holding their own notwithstanding the drop on the market? If our readers carefully examine our tabulated list of prices, and compare them for some sales back, they will see that low class Indians hold their own well. A year or more ago we ventured the statement that the high prices for Ceylon would not hold; and that in a short time we should see these running side by side with Indians. In the review of the year's outturn and manufacture, we note that the Home brokers say that Ceylon have receded to Indian prices, with the exception of one or two well-known marks, which have well held their own. Now, exactly the same might be said of Indian teas, only it is not so much noticed, because the names of the estates are legion, whilst in Ceylon, although the list is increasing fast, up to date the marks that stand out were easily seen and followed. We flatter ourselves, too, that for some time back we have been insisting upon our planter friends producing so much per acre at a price that would defy competition, the only sure basis upon which to go. We feel sure that our views have not been lost, and that those who have followed us will not now repeat of doing so. Quantity is quite as much to be kept in view as quality if Indian tea is to hold its own and be a paying speculation. The drop in the price of high class teas this year, we think, points conclusively to the advancement made in cultivating the British taste for pure Indians; and besides, the growers and dealers find that it is cheaper and more suitable for their customers to get a tea quite unadulterated, or, if you wish to call it by a more polite term, "blended." This is why low class Indians are holding their own. They offer better value for the same money than the same class Chinas; they require no blending; they pass straight from the box in which they are packed on the tea factory into the hands of the consumer, except, and so far as in being handed out in small packets according to the consumer's requirement. The market for fine teas to be used in this way is but limited, and to be used as a blend entails various petty expenses which constitute a profit in the other lines. Whilst thus advocating a large outturn per acre we by no means desire to create the impression that quality is of no account. We are merely suggesting a likely method to give the best results in a large outturn per acre of good sound tea, the greater proportion of which could be passed straight to the consumers as a good drinking tea, whilst the remainder could be made into a higher class, suitable for blending purposes.—*Indian Planter's Gazette.*

"ROUGH ON RATS."

Clears out rats, mice, roaches, flies, ants, bed-bugs, beetles, insects, skunks, chipmunks, gophers. Druggists, W. E. Smith & Co., Madras, Sole Agents.

* The writer meant "gained."—Ed.

TEA MACHINERY AND THE QUALITY OF TEAS.

Simplicity is giving place to elaboration in machinery. If we compare the "Excelsior" in use in most factories with the antiquated production which Mr. Jackson first brought out—a conglomeration of steel rods, and extraordinary looking joints, the change is very apparent. We believe that those well-known makers, Messrs. Marshall and Company, have expressed satisfaction with the design of the "Excelsior," both on account of its durability and simplicity. As yet it cannot be said that we have progressed in the way of sifting machinery. It is true that we have the "Ansell," the "Eureka," and one or two more old-fashioned sieves, imitations of winnowers at home in the one case, and of an ingenious method formerly used to separate the leaf into different grades before firing—none of them combine a perfect sifter. We should like to see the tea put in at one end as it comes from the driers, and turned out at the other end of the sifter in its different grades. So far, a great deal of manual labor is necessary with all of those machines above referred to, and without, over and above this, a breaker of some kind in conjunction are comparatively useless. The breaker most commonly in use is one known as the Reid's. That the breaking machine has been a great boon we do not wish for a moment to deny, but like all other machines it has its defects, although perhaps, to judge from its popularity, these are fewer than its rivals; some complain that it makes a large quantity of dust, some that it gives the tea too much of a made appearance and arouses the suspicion of the broker. So far as we have been able to judge there are ways and means supposed to exist to prevent all these defects, for one seldom goes into a factory in which he does not get a tip as to the right way to do this and to do that, for our Assam planter is by no means a protectionist. But the most of those ways and means are dependent upon the services of that universal helper in a tea factory—a cooly, and entirely depend upon what view he may take of this innovation, whether it turns out a success or otherwise. So long as his master is in view he will no doubt follow strictly the *hookum*, but in most instances, when the planter's back is turned, he has an idea that he can improve matters, and very often finds to his cost that his idea does not meet with approval. What is wanted is machinery to turn out tea in a uniform manner day by day, and the less elaborate such a machine is the better. In the damp, moist climate of Assam a great deal is lost by the escape of aroma, etc., from a longer than necessary exposure whilst the process of assortment is going on. During the last five years a tendency has been observable by following the course of the London market towards quoting Medium Pekoes as rather lower. Now, what is termed Medium Pekoes would have been a few years ago taken as good lines, if not first class, and the above is we think merely a proof, that our new medium Pekoes are suffering a little, as they are not quite good enough for mixing purposes; and yet they show better values to pass straight into consumption than Chinas, and we feel sure that a good medium Pekoe is the tea to make, of course always observing that there is a large percentage; and in many instances it is almost certain that making a large proportion of medium Pekoe would show better results than trying to make a good Pekoe Souchong without making a really first-class Pekoe. The day is not far off when Indian planters must be able to give the grocer a slightly better quality for the same money over what he could obtain in China. The whole tendency latterly in the London market, and by which we must be guided is to depreciate anything but first class lines, so that any thing with a tendency to medium has often lost money, and the safest lines we think to go upon, is to assort into as few kinds as possible. We are glad to notice that brokers have been advising a considerable reduction of numbers of class lately, but we think there is still room for more. One of the best

judges in tea a few years ago advised the following assortment, a first class Broken Pekoe and Pekoe, a Medium Pekoe Souchong and a Broken Tea containing everything else. His reasons for this were sensible, and these were that the high class grades obtained such prices that they carried off the lower grades, and the result was a fair average price. We consider, however, that now-a-days times have changed considerably and had the same authority been alive now he would probably, have recommended the assortment into three classes, say, Pekoe, Broken Pekoe, or Broken Pekoe Souchong and a very high class Broken Orange. The heavy fall that has taken place in prices this year is principally in the high classes, which naturally leads to the inference that there is but a limited market for these lines and that they are decidedly overdone. It must be well known that such high class teas are seldom, if ever, sent into consumption pure, but are principally used for mixing and blending purposes, and that possibly the only place in which they are drunk in any quantity is in the north of Ireland. For some time past quality has been so dimmed into the ears of planters that a good few have made nothing more than these fine teas, and in consequence the market cannot stand the strain, and simply because when it has to be blended the grocer is beginning to find out that he can help himself to an equally good article all ready to his hand, in the large assortment of medium from which he has to pick and choose; and which render blending, packing, and repacking unnecessary, thereby effecting a considerable saving to himself, in fact adding largely to his profit, for he makes no allowance to his customer. The small quantity of high class Orange Pekoe made by the class of assortment we recommend would be quite sufficient to meet the requirements of the trade for blending purposes, and in the Pekoe, or Broken Pekoe, or Broken Pekoe Souchong left in the assortment we would have a tea ready to go into consumption that would beat any China out of the field for quality in cup and price. This would reduce the cost of sorting to a minimum, and would invariably give a uniform tea. If in addition to this a factory could bulk its crops, the advantage would still be greater, as the buyer at home instead of having any trouble and expense could take his tea from the docks, and pass it over to the grocer, who in turn would make it over to his customers pure and unadulterated, a savoury beverage, which would soon make its way into every hearth and home in England.—*Indian Tea Planters' Gazette*.

THE PEPPER-TREE.

Dr. Taylor, editor of "Science Gossip" has the following paragraph in the *Australasian*:—

South Australia had been panting and thirsting for rain for many weeks, and a few days before I landed the rain had at length descended. The hot and fertile earth had burst forth in grateful greenery, and the revived vegetations had broken out into a new spring. The gardens were full of bush, almost tropical growth. What surprised and pleased me was to see how almost all kinds of trees and shrubs grow comfortably and prosperously together upon Australian soil. Some of the larger gardens are like botanical parlaments, where representatives from all parts of the world meet side by side—"pepper" trees (*Schinus molle*) from the Brazils, drooping their graceful leaves and clusters of pink berries, palms from Africa and India, cactuses and aloes from America, pines from California and Norfolk Island, and a floral crowd of herbaceous plants of cosmopolitan distribution. Not even in their native countries do these several species grow more rapidly or luxuriantly than in Australia. Formerly it was imagined that the best way to account for one kind of plant being found in one country, and a different plant in another, was that they were placed where the soil climate, &c., were best fitted for them. But horticulture has upset that idea by growing all sorts of plants together in the same spot. Consequently we know that the geographical

distribution of plants—the reason why one kind grows in America, and a second in South Africa, and a third in Australia—is connected with the repeated physical changes which the surface of our old planet has been undergoing ever since vegetable life began. Hence we see how plants of high antiquity may become extinct in one place, so that the only evidence we have that they ever lived and grew there at all is from their being found in the fossil state.

Have we the pepper-tree in Ceylon? Is the *Schinus molle* the tree which grows on the border of the bay of Naples lining the Chiaga? The following is the reference in the *Treasury of Botany*:—

SCHINUS.—The Greek name for the mastie-tree, *Pistacia Lentiscus*, but now applied to a genus of *Anacardiaceae*, consisting of trees and shrubs, natives of tropical America, &c. The leaves are unequally pinnate, the terminal leaflet very long. The flowers are small white, in terminal or axillary panicles, dioecious; calyx five-parted, persistent; stamens ten, inserted beneath a waxy fleshy disk; ovary solitary; styles three or four, terminal, very short; fruit succulent round, the stone one-celled one-seeded, its outer surface traversed by six longitudinal channels filled with oil.

“The leaves of some of the species are so filled with a resinous fluid, that the least degree of unusual depletion of the tissue causes it to be discharged; thus some of them fill the air with fragrance after rain; and *S. Molle* and some others expel their resin with such violence when immersed in water as to have the appearance of spontaneous motion, in consequence of the recoil.”—*Botanical Register*, t. 1580.

S. Acreia is said to cause swellings in those who sleep under its shade. The fresh juicy bark of this shrub is used in Brazil for rubbing newly-made ropes, which it covers with a bright dark-brown varnish. The juice of this plant is used in diseases of the eyes. The root of *S. Molle* is used medicinally in Peru, while the resin that exudes from the tree is employed to astringe the gums. From the fruits is prepared a kind of wine in Chili. The small twigs serve for toothpicks. The specific name *Molle* or *Mullis* is an adoption of the Peruvian name for the shrub. [M. T. M.]

“QUAKERS” IN COFFEE.

(From the *American Grocer*.)

We present below, from the pen of the leading broker in mild coffee, the first of an article in relation to “quakers,” or the white beans that are frequently found in roasted coffee, together with some comments upon trade peculiarities. We are not prepared to endorse all he says, especially in regard to manipulated coffee. We do, however, unqualifiedly agree with him in his denunciation of the frauds practiced by placing “milled” or “sweetened” coffee in other than the original bags. There is at least one company that stealthily refuses to resack manipulated coffee in other than original coverings. That is a fraud too frequently practiced, and it is only by exposure it can be checked. In referring to these various matters, “B oker” says:

The common grades of any given variety of coffee will, as a rule, roast freer from white beans than the higher grades. Genuine Mocha, the highest-priced coffee on the list, has the greatest proportion of white beans.

Java, the next highest-priced unwashed coffee, the best varieties of which come from Sumatra, contains many “quakers,” and yet it is justly a universal favorite all over Europe and in the older settled portions of the United States. Next in order we have a coffee almost entirely consumed in the United States viz., Maracaibo. The highest grade is called Ocuta and is to a great extent used in place of Java coffee, which it so closely resembles in flavor that it would be safe to say that no “committee” of coffee experts could pick out from a dozen cups of an infusion made from the two sorts, the six which were made from Padang Java and the six from Ocuta. This favorite Maracaibo almost invariably roasts, showing many “quakers.” When a seller shows a sample of it roasted that is entirely free of white beans, I would consider it a point in favor of

doubting if it was genuine Ocuta. I believe the bulk of the real Ocuta is retailed as Old Government Java, and that much of the Maracaibo sold consists of the common grades, which are generally better roasters than the higher grades, or some one of the numerous substitutes palm'd off by dishonest dealers as the genuine article. For this purpose any quantity of inferior coffee, such as Santos, etc., is used provided it is cheap enough to make the fraud pay. The imposition is facilitated by the buyer, who insists on having milled instead of “natural” coffee. These imitations frequently roast much better than the genuine, but the flavor does not seem to be taken into account. This milling business is a comparatively new thing, the advantage gained being a smoother-looking roast. No one, however, has as yet claimed that it improves the drinking qualities, Mochas or Javas are not milled by any one, and they certainly roast rough enough. The practice has opened the door to fraud wider than ever. As an instance, we might mention the importation of Maracaibo coffee, which can be roughly set down as 230,000 bags, yet perhaps 500,000 are sold. It is said some people buy little or none and sell much, having an unlimited supply, at short notice, of any favorite mark. Now, how is it done? The seller takes a Santos, worth say 9 cents, has it milled, and sells it for say 9½ cents, having had it resacked in Maracaibo bags and then sold as a straight Maracaibo coffee milled. If it looks well and roasts well the buyer, who, ten to one does not care how it drinks, takes it and does not want to inquire too closely into its pedigree, so that he can sell it with a clear conscience for what he knows it cannot be, as he did not pay price enough to get a straight article. He tacitly aids and abets the deception. A large percentage of the buyers, however, certainly want straight goods whatever grade they ask for, and they pay enough for their goods to entitle them to an honest delivery. Yet, in the face of facts, these buyers insist on “milled” coffee, often being shown a sample roast free from white beans, the latter result being obtained by a breed of nimble-fingered and rubber-conscienceed salesmen who pick out the quakers. Milled coffee should be bought only when milled by some reliable concern that will not put coffee in bags different in kind from that in which it was when imported. It should not be difficult to find or create such a concern, as it would soon have all the honest business.

In all coffee consuming and producing countries, excepting the United States, the test of desirability is the cup quality. They buy for the palate and not for the eye. Many a lot of coffee that looks poor green is, when roasted, excellent in the cup. The drinking quality is the true test, and no one should buy an article, such as tea, coffee, chocolate, etc., that comes to our table in an entirely changed form except for its agreeableness and purity. The coffee most pleasing to the eye is frequently sold roasted for a higher price than one showing “quakers,” yet really of greater intrinsic value.

An enormous quantity of “quakers” might make a coffee drink as if made from peanuts. It is also quite safe to say that no one, no matter how “cute” he thinks he is, could pick out drawings made from coffee with an average quantity of “quakers” than if made from others entirely free from them. This “quaker” business must appear ridiculous to outsiders, and so it is; but it has assumed such enormous proportions that it has become a great evil in the coffee business. It is based on the rankest nonsense. What a trouble it is people will understand when they are informed that large buyers roast samples of almost every 50-bag lot of mild coffee before purchasing. Sometimes five or six jobbers do this on one invoice of coffee in succession, exhaust the samples and they do not buy “because it is quakery.” If coffee was roasted sufficiently high instead of merely having it toasted, and then consumers know how to properly prepare it, which is the principal secret of obtaining a good cup of coffee, we would hear less about white beans. Some can make a fair cup of coffee from most any kind, and some could not get a good cup out of the finest.

TEA AND COFFEE CONSUMPTION IN THE UNITED STATES AND BRITAIN

are thus noticed by the *American Grocer* :—

The detailed yearly statement from the Bureau of Statistics enables us to study from official data the consumption of tea and coffee.

During the past four years of depression and liquidation the country has steadily increased its per capita consumption of coffee, while that of tea has steadily declined.

The imports of coffee for the year ended June 30th were the largest on record. Those of tea exceed the previous year about five million pounds, and with that exception are lighter than for any year since 1879. The tables below exhibit the gross imports of both articles, exports of the same, the difference between the two being considered consumption.

TEA.			
Year	Imports.	Exports.	Per Capita.
ended	lbs.	lbs.	lbs.
June 30th			
1885.....	81,843,988	5,730,591	66,372,765
1884.....	78,769,000	7,603,969	60,061,911
1883.....	73,479,164	3,821,219	69,597,945
1882.....	67,665,910	1,578,000	77,194,600
1881.....	72,103,356	2,713,139	79,130,849

The population is based upon bureau estimates, except for 1885, we estimating it at 57,000,000. We believe this reduction in the popularity of tea as a beverage largely due to the average quality of the leaf being below what it should be to captivate the palate. It has always been a mystery why the people cling so tenaciously to the harsh flavored Japan in preference to the delicate and deliciously aromatic teas of China or some blend with the rich and full flavored product of India.

COFFEE.

Year ended	Imports.	Exports.	Consump.	Per Cap.
June 30.	lbs.	lbs.	lbs.	lbs.
1885.....	572,599,552	33,335,146	539,264,406	9.46
1884.....	534,785,542	26,152,679	508,632,863	9.48
1883.....	515,878,515	37,376,390	478,502,125	8.83
1882.....	459,922,708	24,343,479	435,579,289	8.25
1881.....	455,189,534	31,913,062	423,276,472	8.23

Here is a gain of 1-23 lb. per capita in the consumption. Why is it? Because the coffee trade has taken pains to secure the distribution of the bean in a roasted rather than a green state, and this added to the competition of rival dealers and the portable coffee mill has resulted in enabling consumers to make a more uniform infusion than when the beans were roasted at home in skillet or frying pan. In the South, where five years ago scarcely any roasted coffee was sold, it is fast displacing the raw bean.

In the United Kingdom, where China and India teas are consumed and no Japan of account, and where adulterated coffee is the rule, we find that the per capita consumption of tea has increased, while that of coffee is about stationary, as the following table exhibits:—

	Tea.	Coffee.	Per capita.	
	lbs.			lbs.
1884...	176,007,983	4,82	83,018,256	0.91
1883 ..	170,812,677	4.74	82,448,080	0.90
1882...	165,079,881	4.62	81,002,560	0.89
1881...	1,022,578	4.51	81,043,403	0.90
1880 ..	158,770,331	4.6	82,668,824	0.96

The *Times*, in a leading article on the report of the Inland Revenue Commissioners, says: "The consumption of tea, it is true, continues to increase, which is a sign that the mass of the people were better off in 1884 than some people would have us believe."

Statistics are looked upon as dry reading, but we think the above tables are very suggestive and mighty interesting to every merchant handling the articles and in love with their business. We can see no good reason why the same determined effort on the part of dealers in tea to improve flavor and raise the standard should not result in a gain in consumption quite as pronounced as that in the world's most famous berry.

In referring to this matter, James Cook & Co., of London, in March last said:—"If we had some clear-sighted men in our coffee trade, such as you have, the consumption could be pushed very much; but we expect cheapness has much to do with it. Tea here is relatively cheaper with coffee than with you, and probably one pound would make seven or eight gallons of an infusion such as the working classes would be satisfied with." Taking the economical view of the question, we must then conclude that the resources of the working classes here are far greater than in the United Kingdom, whereby they are enabled to become free consumers of coffee. But we must not forget that beer costs consumers in Victoria's realm far more than coffee costs consumers in the United States; and that is no reason why the moral tone of our laboring classes is so far above that of those living in the United Kingdom.

BARLEY OR BEARDED WHEAT IN CEYLON?

We have received two stalks, inscribed "Barley grown at Hakgala from Indian seed?" The grain, which is well developed and set, may be barley, but the heads look remarkably like the "bearded wheat" we first saw growing in Italy and subsequently around Muttra, in Northern India. From the latter locality we brought some heads, sowed the seeds on Abbotsford estate, and obtained several successive crops. Wheat can be obtained so cheaply from India, that we should think there cannot be much encouragement for its culture in Ceylon, but we noticed in the recent report of the proceedings of the Ceylon Agricultural Society, that Mr. C. H. De Soysa had reported a successful experiment on his own part. We suspect the Bakers were not over-successful with their experiments in barley-growing at Nuwara Eliya. At any rate, we know they imported malt from Britain and complained grievously when a duty was imposed on it with reference to its relation to imported beer. It remains to be seen what the new Brewery Company will do. Not only barley but hops can, we suppose, be grown in Ceylon, but we suspect the Company will find the imported articles cheaper and better. Some of the finest hops in the world are grown on the banks of the Mitchell River in Gipps Land, Victoria, and on the banks of the Derwent in Tasmania.—Unfortunately, before publishing, we have had the advantage of Dr. Trimen's opinion. He was a little puzzled at first, but finally pronounced the grain to be "six-rank barley," *Hordeum hexastichon*.

MANURING TEA WITH BONE-DUST AND CASTOR-POONAC MIXED, AND WITH CASTOR-POONAC ALONE.

Mr. F. McL. Carter, the Manager of Chandpore Tea Estate, Chittagong, has communicated to the *Indian Tea Gazette* the results of an interesting and evidently a very carefully conducted experiment in the manuring of tea. The substances chosen were those so familiar to coffee-planters—bone-dust and castor-poonac—and it will scarcely excite the surprise of readers familiar with the subject of manuring to learn that, while the phosphatic substance alone told more effectually with us in increasing the fruit crops of coffee, the ammoniacal substance alone gave the larger increase in the leaf crops of tea. It is right to mention, however, that bone-dust alone was not used by Mr. Carter in his experiment, but that the comparison was between 18 cwt. per acre of bone-dust

and poonac (in the proportions of one-third bone-dust and two-thirds poonac), and 24 cwt. of poonac alone. The increased yield may, therefore, possibly have been due to the 6 cwt. additional fertilizing matter. In both cases there was a very considerable increase of crop over the unmanured plot, besides improvement in the quality of the tea. The good effects of the manuring, it had become evident, too, would last up to the third year, at least, and it seems reasonable to conclude that bone-dust would contribute materially to this lasting effect. But we trust similar experiments conducted in Ceylon may lead to certainty on this and other questions in regard to the manuring of tea. It will be curious if the extended cultivation of tea in Ceylon has the effect of reviving the large demand which existed in the best days of coffee for bones and castor-oil cakes.

Mr. Carter commences by explaining that the elevation of the land is "about 80 feet above *dhankeys*," probably, creeks or sea inlets (?) perfectly flat, surface soil sandy loam and sub-soil ferruginous clay and sand. The climate is hot, moist and forcing, for, although Chittagong is in 22° north, yet the mean temperature is as high as 77° (3° only cooler than Colombo). The average rainfall at the station is given at 106.50, and there are heavy dews and fogs at night. The estate on which the experiments were tried, some twenty-seven miles inland, apparently, has a lighter rainfall, and Mr. Carter complains that

The season was unfavorable for quantity, and likewise for the quality of the crop, although the rainfall amounted to 91 inches 16 cents, which was only 6 inches 54 cents below an average in 15 years of 97 inches 70 cents annually. The rainfall, however, in August, one of our best leaf-producing months, was 10 inches 45 cents only, or about half the average.

I attribute the falling off in yield and quality to a great extent in consequence of the general lowness of the temperature throughout 1881 as compared with previous seasons, which was, so far as my register indicates, quite exceptional. Thus the average of the three previous years at 6 A.M. the max. and min. thermometer on cold side registered 71° 3, and on hot side 79.75 in the year, whereas in 1881 at 6 A.M. the thermometer averaged on cold side 65.75, and on hot side 70.25, which shows how much cooler it was in that year; in fact, the temperature in *daytime* was actually less than in *nights* of years 1881 to 1883.

The exceptionally cold season, therefore, makes the forcing effect of the manures on vegetation the more remarkable. Mr. Carter gives the following interesting details regarding the property which was the scene of his experiments:—

Jat of plants, a fair Assam Hybrid, transplanted from nurseries, in 1867, at 4' x 4' 2.722 per acre. Pruned down to 24 inches in January 1884, and all old non-leaf producible wood removed as usual. Prunings buried between lines when green, as in all other seasons. Deep hood to 12 inches once on 26th February, and weeded at intervals three and half times subsequently = total 4½ hoeings and weedings in season. Average height of bushes at

	end of year on No. 1 Plot = 29 inches.
Ditto	ditto 2 " = 33 do.
Ditto	ditto 3 " = 34 do.

therefore No. 1 plot had grown 5 inches in season.

" 2	ditto 9	ditto.
" 3	ditto 10	ditto.

Commenced plucking on March 18th.

Finished ditto on December 31st.

Style of plucking.—From former date to June 1st inclusive, or 3 months, two and three leaves with stalk, the bud counted as one, were taken from shoots that carried 3 and 4 matured leaves above pruning mark,

and from 22nd June to end of season, the system of taking off three leaves together with the stalk was given up, and the usual method hitherto pursued on this garden of plucking off 2 leaves, and 2½ leaves (the bud as one) again reverted to as being the most profitable. There were 23 flushes in the season over entire area of cultivation of 550 acres.

It will be seen that 23 flushes were gathered at intervals of 12½ days, and that out of the 365 days there were only 77 days of rest. Our readers will notice that the growth of the pruned bushes on plot No. 2, where the mixture of bone and cake had been applied was 9 inches against 5 on the unmanured plot, and 10 against 5 where cake alone, but in larger quantity had been used: that is to say, that 24 cwt. of castor-cake per acre doubled the rate of growth of vegetation between pruning time and the end of the season. As our readers will see from the extract which we are about to take over, the yield of tea per acre was increased by bones and poonac, from 629 lb. to 825 lb., rising to 914 lb. where a large quantity of poonac alone was applied. The ready inference might be that poonac alone was the manure to use, but in this case there were 6 cwt. additional to pay for, carry and apply, and Mr. Carter's carefully arranged and analyzed figures would seem to show (?) that while in the case of the second plot the profit on the increased yield of 196 lb. was 55.3 per cent, the profit on an increase of 285 lb. in the case of the third plot was only 10.35 per cent (?). But the smaller profit is a very good one and the results of manuring are altogether encouraging. Here are the details:—

The experimental plots Nos. 1, 2 and 3 comprised ½ acre or 680 bushes each, and were contiguous to each other, and properly fenced in. The three areas were always plucked by the same women (the best), and green leaf weighed accurately by beam scales: therefore I can guarantee the absolute correctness of the results.

On plot No. 1 no manure was applied.

On plot No. 2 { 4 oz. Bone dust p. b. = 6 cwt. p. acre.
 { 8 oz. Castor Cake, &c. = 12 " " "

Total...12 oz. of the combination = 18 cwt. p. acre.
On plot No. 3. 1 lb. Castor cake alone per bush = 21 cwt. per acre.

The manure on both foregoing plots was, previous to application, mixed with *three times* its bulk of dry earth, (in the absence of anything better) to ensure equal distribution in the soil, and was put round the bushes about 12 inches from the stems and 4 to 6 inches below the surface of the ground, and covered over on the 25th March, previous to which date the 1st flush in season had been gathered, but this was practically of no importance. If the manure had been applied earlier, say 1st or 2nd week in February, I am of opinion better results would have been obtained. The 1st flush from the plots was taken off on 8th April, and the last on 23rd December, making 22 gatherings from them in the season.

The out-turn of green leaf was as follows:—

	lbs. oz.	lbs.	lbs.
From No. 1 plot of ½ acre—	628	12—	2,515 p.a. or 629 tea.
" " 2 do do	825	8—	3,392 do or 825 do
" " 3 do do	913	14—	3,656 do or 914 do

On a comparison of plots Nos. 1 & 2 the increase of crop per acre on the latter, due to the manure, is equal to 196 lbs. of tea, or 31 per cent; between Nos. 1 and three,—an increase on the latter of 285 lbs. of tea, equal to 45½ per cent. To ascertain what the profits will be, if any, per acre; or what is the same thing, whether it pays to apply the above mentioned manures according to the quantity specified in each of the two plots, the cost of the same, and all the expenses for transport and putting it in the ground, must be calculated.

The castor cake was obtained from Calcutta packed in bags which contained 2 maunds each, or one ton in 14 bags, and cost R28 per ton. The bone dust was also procured from Calcutta packed in bags, and containing 2 maunds 5 seers in each or 1 ton in 13 bags and cost R55 per ton.

The different items for a ton of each of the manures on garden are as follows:—

	R. A. P.
To 1 ton castor cake at R28 ...	28 0 0
" Freight account per steamer from Calcutta to Chittagong at R16-7-4 per ton	16 7 4
" Landing charges for do., at 4 annas per bag	3 8 0
" Transport for do., via the khali in boats, (about 25 miles) from station to Pookareah garden, at 4 pie per bag	2 14 8
" Transport of do. in carts (a distance of 2 miles) to Garden, and applying do., at 6 annas per cwt.	7 7 0
Total cost per ton ...	58 5 0
" " cwt.	2 14 8
" " maund	2 1 4

To 1 ton Bone dust, at R55 per ton ...	55 0 0
" Freight account on do. from Calcutta per steamer to Chittagong, at R25 per ton	25 0 0
" Landing charges at 4 annas per bag...	3 4 0
" Transport from Station in boats to Pookareah Garden, at R0-3-7 per bag	2 14 8
" Transport of do. in carts to Garden, and applying the same, at 6 annas per cwt.	7 7 0
Total cost per ton ...	93 9 8
" " cwt.	4 10 11
" " maund	3 5 6

Cost per acre.

	R. A. P.
On plot No. 2.	
The Bone dust applied at 6 cwt. per acre will cost	28 1 0
And Castor cake applied at 12 cwt. per acre	35 0 9
Total cost of combined manure of 18 cwt. on plot No. 2 per acre ...	63 1 9

On plot No. 3	
Cost of Castor Cake applied alone at 24 cwt. per acre	70 0 0

Result per Acre.

No. 2 Plot—	
No. 1—629 lb. tea per acre, selling at say an average of 8 annas per lb.	314 8 0
No. 2—825 lb. do do do	412 8 0
In favor of latter an increase of 196 lb. or 31 per cent at 8 annas	98 0 0
Less cost of manure at 18 cwt per acre	63 1 6
Therefore profits per acre ...	34 14 6
or 55.3 per cent.	

No. 3 plot—	
No. 1—629 lb. tea per acre, selling at say an average of 8 annas per lb.	314 8 0
No. 3—914 do do do	457 0 0
In favor of latter by an increase of 285 lb., or 45.3 per cent.	142 8 0
Less cost of manure at 24 cwt. per acre	70 0 0
Therefore profits per acre ...	72 8 0
or 103.5 per cent.	

In the foregoing calculations I have assumed that the realizations of a garden's tea will average annas 8 per lb., but if the crop exceeded that price, the profits derivable from the application of manure would also be higher, and *ceteris paribus*, of smaller amount if the tea averaged less than 8 annas per lb.

It should be pointed out that the quality of the tea will be improved, also, when the ground is adequately manured, enhancing the value by 2 pie per lb. and upwards according to the broker's report on the samples from the experimental plots; but I have not taken this item into the account; otherwise, the results could be shown to be more satisfactory still.

It would, therefore, seem that while an increased yield of 31 per cent gave a profit of over of 55 per cent, an increased yield of over 45 per cent gave a profit of 103.5. What we should now like to see, would be experiments with bones alone, poonac alone, and a mixture of the two, at the rate in the three cases of one ton per acre, instead of the varying quantities of 18 and 24 cwt. But, in looking at the experiments from our Ceylon point of view, we suspect we must add very materially to the cost of both bone-dust and oil-cake, as compared with prices in Chittagong. Will anyone, possessed of the necessary information favour us with figures for bone dust and castor poonac, in the Colombo market at present? Our transport charges per rail and road would generally be heavier than the Chittagong boat charges.

In writing that a mixture of bones and castor cake gave a less profit result than castor cake alone, Mr. Carter writes

On a comparison between the yield on plots 2 and 3 (the castor cake costing R6-14-6, or 11 per cent more per acre on latter), the increase of crop over former was also 11 per cent, and the profits due to this excess equal 107 $\frac{2}{3}$ per cent, which is conclusive that notwithstanding the greater cost of the castor cake when applied at 24 cwt. per acre, it is much more remunerative than the mixed manures at 18 cwt. per acre on plot No. 2 that were less expensive. I do not say, however, that because these experiments have proved the castor cake alone in the proportions given per acre the most suitable of the two for this garden, it would answer similarly elsewhere.

I would strongly recommend this manure, nevertheless, for tea bushes on soils akin to "Chandpore," where it is being used largely in current season, and let me add with marked success. In order to convince my planting friends that if the castor cake can be laid down on the gardens, applying 24 cwt. per acre (I should not advise a lesser quantity on worn out soils)—at even double the cost I have stated, or R70 by 2 = R140 per acre, there would still be a small profit of R2-8, or 1 $\frac{2}{3}$ per cent. per acre, subject to conditions stated further on.

There is no reason why any of the Tea estates in Chittagong district should not be able to apply this manure at the price I have done, and may be for less; but for tea properties at a great distance from Calcutta, such as those in As-sam, Uchar and Sylhet, &c., the cost of freight and local land transport, &c., will probably be much higher than it is here: therefore the profits will not be so remunerative.

Now, I do not suppose the cost of carriage, &c., to the more distant gardens situated in above provinces or districts will be so excessive as to increase the entire outlay by 75 per cent per acre above the price the article can be landed here for; but assuming such will be the case, then the profits per acre stand as follows—viz:—

No. 1 plot no manure, 629lb. tea per acre, at as 8	314 8 0
" 3 ,, castor cake 24 cwt. ditto 914 at as, 8	457 0 0

In favor of latter by 285lb at as. 8	...	142	8	0
Less cost of manure per acre (increased by 75 per cent)...	...	122	8	0
Therefore, profits per acre	...	20	0	0

I do not think those results are to be despised. I must again reiterate that the improved quality of the tea due to the manuring and consequent enriching of the soil has not been allowed for in this calculation either. In addition to what has already been recorded, I may notify that the experiments on plots 1, 2 & 3 in 1884 are being continued this season also and *without* any further application of the respective manures, in order to ascertain whether the bushes derive any benefit in the 2nd year; and so far as the outturn shows at present, i. e., to 26th July, when only 11 flushes have been plucked out of the 26, there will be in this season the increase of leaf on plot No. 2 over No. 1 of 13 per cent., and on plot No. 3 the excess amounts to 32 per cent. of leaf over the non-manured plot No. 1, which is most satisfactory, as it will still further augment the profits per acre.

It seems, therefore, that for the first year at least, the experiment is largely in favour of a heavy application of castor poonac alone, against a lighter application of a mixture one-third bone-dust to two-thirds castor-cake. Mr. Carter then goes on to show his brother planters that he has obtained his castor-cake this season at a price 32 per cent lower than last, and he shrewdly suggests:—

I am disposed now to think that a single application of 24 cwt. of castor cake per acre will extend its beneficial influence in the soil for nearly three seasons; therefore it would be advisable at commencement of the 4th to manure again; otherwise the yield would fall off which is only natural when the plants or bushes find the food they have been accustomed to, and thrived upon, is no longer at their service. We all know the close analogy between the animal and vegetable kingdoms, and I am sure if we had been for some time accustomed to good wholesome diet which agreed with us, we should suffer materially if suddenly deprived of it.

And he adds

Judging from experience derived from trials conducted on this estate, there can be no doubt that when *one stimulating manure* has been applied to an exhausted or even weak soil, the practice must be continued every 3rd to 5th year, dependent upon the description and quantity used per acre, and age of bushes. If from any cause this is neglected the results will be disastrous, and the money expended on the previous manuring will have been to a great extent wasted.

Those, therefore, who are thinking about supplying their tea bushes with *stimulating manures* should, once resolved upon, make up their minds also to *continue using them at certain fixed periods*, which ought to be ascertained experimentally for each, as soils differ so much that a general rule could answer for all, especially when located in other districts, and I may say, also, when gardens are situated some distance apart in the same district even.

Mr. Carter enters into calculations as to the ordinary yield per acre of an estate which would justify manuring, and he sums up thus:—

It will thus be seen by the above computations based upon the data actually obtained on experimental plot No. 3, that the ordinary or normal outturn of a garden must not be less than *3 maunds of tea per acre*, (320 lb. *l. b.*) otherwise the cost of manuring with castor cake (whether in quantities of 24 cwt., 18 cwt., 12 cwt., or even 6 cwt. to the acre) will not be recovered. This holds good however on the supposition, 1stly, that the cake costs exactly R70 per acre; 2ndly, that 24 cwt. for that area will benefit the tea bushes for one season only; and 3rdly, that the tea is not improved in quality by the manure, and sells at same price as the crop from bushes on

land without any. Now I have shown previously that in this season the same quantity of castor cake per acre was put in the ground for R53, which is much less; and 2ndly, that the original application is increasing the yield also in following year; and lastly, experts have valued the tea 2 pie to 3 pie per lb. higher on manure plots in the 1st season, though I doubt if there would be any difference in the 2nd year; consequently, when these altered conditions are allowed for, the average outturn of tea per acre in an ordinary season on a garden that has *never been manured* need not be so high as before stated, in order to cover the cost of the manure.

He then enters into calculations to show that it will pay to manure gardens yielding 2½ maunds per acre or 180 lb., or even less, and then he goes on to add together the two years' profits on his manured plots, thus:—

The nett profits I ought to have shown before, per acre, in 2nd season on plot No. 3 when the manure costs R70, I estimate due to an increase in yield of 30 per cent. at R99-8	142½ per cent
To which add 45-30 per cent.	
at R72-8	103½ "
Total in two years 75-3 per cent.	
equal R172 or	245½ "
The nett profits per acre in both seasons, when the manure costs R53 as in 1885, I estimate as follows:—	
No. 1 plot 629 lb. tea per acre	
@ 8s.	314-8 per acre
No. 3 914 lb. tea per acre	
@ 8½	466-8 "
Increase of yield, 285 lb. or 45-3 per cent.	152-0-0 "
Less cost of 24 cwt. manure per acre	53-0-0 "
Therefore, profit	99-0-0 "
	or 186½ per cent

The 2nd year by estimation.

On this Garden 1-3rd or 33-3 per cent. of season's outturn, is generally made by 26th July, which happened to be the exact date the last flush was plucked from experimental plots; therefore the final outturn on these acres at end of season should be in

Plot No. 1 663 lb. tea per acre, at 8s.	331 8 0
Do. No. 2, 862 lb. tea per acre, at 8s.	431 0 0
Increase in yield, 199lb. or 30 per cent.	99 8 0
Less cost of manure	nil

Therefore net profits	99 8 0
per acre, or	186½ per cent.
Add profits 1st year	99 8 0
	or 186½ per cent.
Total profits in 2 years	198 8 0
	or 37½ per cent.

Mr. Carter promises to give the actual results of the second year on his manured plots, and the valuable paper winds up thus:—

It should be observed, by judging from the experiments with Castor cake alone, at 24 cwt. per acre, that this quantity will not probably be of much benefit to the tea bushes beyond the 3 year, if so long; therefore at the expiration of that period a renewal of the application, or some other, will become a necessity, and I am not quite sure whether a larger quantity per acre would not be more remunerative, and continue to do good over a longer time; but this is merely conjectural, and cannot be made sure of until ascertained experimentally. I hope next season to make trial of 30 cwt. and upwards per acre, and as many believe *small quantities* applied at shorter intervals will give the best results, and be more profitable than the former method, it will be as well at same time to experiment in this way also. I hope, however, Mr. Elitor, that some of our correspondents will co-operate in the work, as I am assured by experimental s'g, to be of very practical value, the great care, constant attention, some expense, and not a little trouble. Those who contemplate manuring with Castor cake can draw their own conclusions from foregoing trials, and I hope I have made everything clear and understandable; but if an *entire garden* is to be manured similar to Plot

No. 3 from 3rd. to 1/4 that at least of the area must be done *yearly*, and for the reason I have indicated. I hope to send you for publication trials with other kinds of manure, and on pruning and weeding, &c., when I can get the papers ready.

Tea planters in Ceylon, as well as in India, owe a debt of gratitude to Mr. Carter for the information he has furnished. Of course, manure made on an estate and collected in cattle sheds or otherwise is of great value. But to keep cattle merely for manure and occasional sales for the butcher, is very expensive and can only in rare cases be profitable. When the time to manure tea estates, therefore, arrives, and it will come early in the case of old coffee estates, "planted up" with tea, it is well to know that if we can get our old friend *white castor* poonac, at a moderate price, it will furnish just the combination of ammonia and potash desiderated for the growth of flushes of vegetation, while, for the sake of wood as well as leaf, the addition of small quantities of steamed bone-dust or superphosphate, would be advisable.

CEYLON UPCOUNTRY PLANTING REPORT.

TEA SEED PLANTED AT STAKE—UNCERTAINTY OF OUT-TURN—DIFFERENT OPINIONS—THE PROSPERITY OF CEYLON DEPENDENT ON THE PLANTER—THE REAL BACKBONE—SUPERINTENDENTS' PAY—THE INDIAN SYSTEM—A GOOD EXAMPLE.

As to tea seed planted at stake, it is wonderful how well it stands where it is already through, but when it is not above ground it's a real vexation of spirit: you may speculate till your heart is sick, as to what proportion you will lose, or whether any will come up at all, but, like most forecasts, there is also in this one a vile element of doubt, more than usually tantalizing from its instability, and which varies according to the clearness of the skies, or the cloudiness of your own mind. Ordinary speculation is barren enough: but to begin guessing at the probable outturn of tea seed planted at stake with little or no rain for nearly a month is as barren an employment as the wits of man can be set to. And yet a good many of us are at it. "It's sure to come all right," said one man to me; "I had some of the seeds examined, and there are roots six inches long although it has not begun to shoot up at all." There was a kind of comfort in hearing this, but when another man looks even wiser and says: "You don't catch me planting at stake again if I can help it," you feel that a good deal of your former joy has somehow evaporated. To bother yourself about it, is a vicious circle to get into, tending to shorten your days with worry, without increasing in any way the success of the stake-planted clearing.

Since the evil days of the failure of coffee it has been too clearly demonstrated to every class that the prosperity of the whole island depends on the planter. When he is suffering there is suffering everywhere, when he is prosperous all the land rejoices. I don't fancy any will gainsay this—the truth is today too patent to all.

Now the backbone of the planting interests is not the moneyed man, nor the agent who is authorized to lend, nor the inspector, nor the cooly, but the superintendent. Without him what would have become of the planting enterprise in Ceylon? In the worst days of the failure of coffee he clung to his old ship until his allowances had in many cases almost reached the vanishing point. I remember of one man who got so very little at last for his services, that he used to do his work from his verandah of his bungalow with a field glass in his hand, explaining with sorrowful regret that it was the most he

could do for the pay he got! I believe he adopted this unique style of service on the grounds of the field-glass being a link connecting him with happier days when he had the pay of a European gentleman, instead of that of a native conductor, and he did not like altogether to lose touch of civilization! But he was an exception, and for that reason he is introduced here; others did good work for very little and made very little by it, for estates were pretty much in the position of a man who had unobserved fallen overboard in mid-ocean and whose ship was fast leaving him.

Again, when the new tea enterprise was started the superintendent was ready to do his best to make it a success, working for bare subsistence with the hope that if it turned out a paying spec he too would eventually prosper. Now it is not he said that tea does not pay, and yet I have heard of proprietors who are making very handsome profits indeed, and yet give to their responsible managers a remuneration which is miserably mean. I don't believe this sort of thing pays in the long run.

In Indian tea gardens it has been long recognised that to give the manager a direct interest in the concern is the best thing for all, and this style is also being found out to be a good plan for Ceylon. It can be carried out in different ways, by a salary and commission, or simply by a percentage on the receipts. I know of one Ceylon proprietor, a gentleman who knows the value of the rupee as well as any man, who likes to have his work done cheaply and well, and who has adopted the Indian system with marked success. Before this he had his managers on salaries, but somehow his teas did not fetch high prices nor get for his estate a good name. All this, however, was changed when the fixed remuneration was dropped and a 10 per cent commission on the gross proceeds was awarded to the manager and 5 per cent to the assistant. From that day the qualities of the teas steadily improved, the working was as cheap if not cheaper, and now his mark is rapidly taking a high position in the list of the crack estates. With the results he is perfectly satisfied, his profits have been considerably enhanced, his managers work for him with heart and soul, while they themselves are more than satisfied, having almost doubled their former incomes.

It is a pleasure to be in a position to record a case of this kind, such a pleasing contrast to the graball meanness of some proprietors who could well afford to be liberal. I can hardly expect that the screws" will see it to be their advantage to adopt a more generous treatment of their men; still for all that the policy they pursue is a bad one. There are so many ways opened for a superintendent who is satisfied to reciprocate in the same kindly spirit in which he has been dealt with, which the under-paid man fails to see, or seeing, fails to avail himself of.—LEFFERCOR.

THE ISLAND OF REUNION.—The sugar-cane is the principal article of cultivation in the island, the quantity exported in 1883 being 33,000 tons. But these are now being replanted, and the exports for 1883 were about 600 tons valued at £32,000. Vanilla is also grown in the eastern part of the island, the exports for 1883 amounting to 23 tons, varying in value from 8s to 16s a pound according to the quality. Tobacco, cotton, tea, quinine, silkworms, cocoa, and cloves are also grown, and within the last two years experiments in vine-growing have given promise of being very successful.—*Overland Mail*.

FISH-CURING EXPERIMENTS IN THE MADRAS PRESIDENCY.

Now that the Ceylon Government is about to initiate the system of issuing salt at a cheap rate for the purpose of encouraging fish-curing on a larger scale and on better principles than have been hitherto adopted by the fishermen, we naturally regard with more interest than ever the very interesting reports prepared by Mr. Bliss, the Salt Commissioner of the Madras Presidency, and which we owe to the courtesy of the Madras Government. While good, well-cured fish is a wholesome and nutritive article of diet, it is pretty well established that the use of putrid salt-fish, often badly cured with salt earth or mud, is the cause of leprosy, elephantiasis and other loathsome diseases. It is of much importance, therefore, that all legitimate encouragement should be given to the capture and improved curing of large quantities of the numerous and varied fishes which swarm round our coasts. We trust the example of the Madras authorities will be followed in liberality which led at the outset to some loss of money which is now being rapidly made good. Officers of the Government, too, have been successfully employed to teach the fishermen a better way of curing, by which means and the experience gradually obtained, the proportionate weight of salt to fish has been pretty accurately ascertained. The result is that somewhat under 14 lb. (about the consumption *per caput* of the population of Ceylon) is sufficient for the curing of a maund weight of fish. We suppose that in this case the usual Indian maund of 80 lb. is meant. If we are right, then it would appear that the proper proportion of salt to fish is about 17 per cent. Some fish, such as shark, will require a large supply of salt, while long thin fishes require quantities below the average. The natives have to be corrected in their wasteful and inefficient modes of curing. We hope that some one acquainted with the best modes of fish-curing, will be appointed to aid the experiments in Ceylon.

Mr. Bliss states that the demand for the superior fish cured by his officers cannot be met. The apathy and the ignorance of the people have to be combated, and seasons will be unfavourable for fishing, while in the latter portion of 1883, cyclones, floods and a violent monsoon destroyed curing yards, boats and nets, and in some places put a stop to fishing operations. But in the face of all difficulties, the first quarter of 1885 gave most satisfactory results as compared with the corresponding quarter of 1884, the number of yards worked shows an increase of 14, viz., 123 against 109, and, in spite of the damage by floods in some portions of the Southern Division, there has been an increase in the quantity of fish brought to be cured of 62 per cent., namely, 14,841 tons against 9,141 tons. The applications for cheap salt had been 83,838 against 51,883; weight of fish brought to be cured 404,074 maunds against 248,836; weight of salt issued 65,686 maunds instead of 42,246; value of salt sold R43,524 against R28,027; salt to each maund of fish 13-33 lb. against 13-97; expenditure incurred by Government R13,622 against R12,701.

We may quote a few suggestive passages from the Commissioner's Report:—

Chicacole Division.—Compared with the corresponding half of the previous year, the result of the division as a whole, are very encouraging, the number

of applications, the quantity of fish brought to be cured and the weight of salt issued having more than doubled. The most remarkable feature of the half-year under report, however, is the fact that all the yards of the division, without a single exception, have made a start. This result is doubtless due to the greater efficiency of the preventive operations of the department, as already explained in Mr. Willock's letter printed with the Board's Proceedings, No. 311, dated 29th January 1885. The difficulties experienced in this division, more especially in the Vizagapatam District, in starting the industry on the new basis, are now in a fair way of being overcome. The proportion of salt issued to fish cured has decreased, being 9.05 lb. per maund against 11.35 lb. in the corresponding half of the preceding year. This is mainly due to the fact that for about two months of the half-year under report, the greater part of the takes of fish along this part of the coast consisted of a long narrow fish, the name of which is apparently unknown, which required little more than drying in the sun, and for the curing of which, therefore, very small quantities of salt were used. The increase under expenditure was due to the increase in the number of yards and to the expansion of operations generally.

Masulipatam Division.—The reason for the comparative failure of the yards in this division appears to be the want along the coast of the Godavari and Kistna districts of a fishing population provided with adequate appliances for the capture of a larger quantity of fish than can be consumed locally while fresh. The yards cannot, however, for this reason be closed, as such a course must either endanger the salt revenue or prove oppressive to the fishermen. Backward though the yards are all but two yards have advanced, and the quantities of fish cured and of salt issued in the division have more than doubled since last year.

Nellore Division.—The result have been satisfactory in all but two yards, Kottapatam and Kundurpalam, where the season is reported to have been unfavourable for fishing. On the whole, the division shows a marked advance, the quantities of fish brought in and of salt issued having been 7,633 maunds and 938 maunds, against 4,657 maunds, and 392 maunds, respectively. The operations in the northern part of this division are, however, still but small owing to the poverty of the fishing classes. Some Mussalmen have lately started a wholesale curing business at Pakala, however. This may stimulate the industry. The proportion of salt issued to fish cured was 10.12 lb. per maund, against 6.91 lb. in the corresponding half of the previous year. This proportion is still low. Still, it goes to show that the successful experiments conducted by Inspector Mr. Beeson in this division have had a good effect. The meaning of this is that under European superintendence fish had been better cured with a much smaller proportion of salt than the wasteful natives used. In one case the method adopted by the fishermen was

Sprinkling the fish with salt and shaking the latter off before the removal of the fish. The fishermen, it would appear, decline to use the refuse salt a second time for fear of maggots and prefer its periodical destruction by the Inspector.

To quote again:—

Central Division.—The progress made by this division, which comprises considerably more than half the operations of the whole presidency, is exceedingly satisfactory, there being an increase of over 60 per cent under all heads. The bulk of the operations is, as usual, in the Malabar district, all the important yards in which show a steady advance. The quantity of fish cured in the yards had risen from 1,336 tons in 1880-81 to 20,108 tons in 1884-85.

THAT HUSBAND OF MINE

THE AGRICULTURAL POLICY OF THE
MADRAS GOVERNMENT.

Extract from Gov. Order dated 16th February
1885.

The proposal was revived last year on the ground that all other educational charges were charged to "Provincial-Educational." The Director of Public Instruction was consulted, and in paragraph 4 of his reply (printed in G. O., Report, 27th July 1883 No. 919), advocated the separation of the functions of Principal of the School and Superintendent of Government Farms. The views of the Board and Director of Agriculture were then called for on this and other matters. Their replies are recorded in G. O., 7th January 1884, No. 3. Mr. Wilson, with whom the Board entirely agreed, was of opinion that an Agricultural Reporter could not travel about and make himself acquainted with the agricultural conditions of the presidency so long as his connection with the School of Agriculture remained unsevered. He showed also that the school had been a failure chiefly because it was impossible to give the students that careful and individual training in practical farming, which was an indispensable preliminary of the scientific course, and which in other countries is given beforehand by independent farming their own properties. His proposed remedy involves the separation of the school from the Agricultural Department, and the bringing of the latter into more practical and veridical relations with the agriculture of the country, as contemplated by the Government of India. Under his scheme the School of Agriculture would be purely scientific, and the Agricultural Department nothing if not practical. After a while, it would be made a condition precedent of admission to the school that the candidate should have studied practical farming for two years. For the purpose of affording this practical training, Mr. Wilson at that time contemplated the establishment of Government example farms. But this idea he seems since to have abandoned. His Excellency the Governor in Council concurs entirely with the latest expression of the views of the Director of Settlement and Agriculture. With regard to the future agricultural policy of the Government, His Excellency the Governor in Council proposes in the first place to abandon the Sai-lapet Farm on its present scale as a practical failure. The work there has excited some general interest among the agricultural population in improved agriculture machinery, but little more than this has been accomplished. The farm is too small for stock breeding, its soil is unsuitable and our knowledge of Indian crops too limited as yet for useful experiments. No new farms will be instituted, but experiments will, where necessary be carried out, with the assistance of private agency under the general supervision of the Agricultural Department. Meanwhile, native agriculture and the analysis of districts will be carefully studied by the Agricultural Reporter with a view to introduce better methods where they are wanted, but they are only. Further than this the Government are not at present disposed to go. To assist the Agricultural Reporter in investigation, the Government propose eventually to entertain a small body of District Agricultural Inspectors, whose salaries will be met from the savings which will accrue from the abolition of the farm. These men will, previous to their appointment, have undergone a course of training at the Government Agricultural School.

The further proposal of the Director of Public Instruction to attach some 30 or 40 acres of land to the college, as a farm annexe, as a field for practical demonstration and training for the students of the college is approved; the management of this land will be under the control of the educational Department. The necessary details of administration of the agricultural school, and the course of instruction to be followed therein, will receive consideration in the Educational Department, to which department these papers will be now communicated.—*Madrass Mail*.

PROFESSIONAL TEA TASTERS.

MEN WHO SIP THE CUP THAT CHEERS AS A BUSINESS PURSUIT.

A large, somewhat bare looking apartment; a number of shelves along the walls, like those in a druggist's shop, upon which are ranged row after row of small tin canisters containing samples of tea; here and there a print of a scene in the Flowery Land looking dim and feeble, as if exhausted in the effort to shed an Oriental glow over anything in the hopelessly matter of fact locality of Wall street; in a corner a large office desk; in the centre of the room a circular table upon which stands a burnished urn, flanked by a diminutive copper scales and surrounded by a number of tiny China cups—such is the orthodox tea broker's office in this city. Offices of this kind there are about two dozen in New York, that being the number of tea brokers, large and small, engaged in the trade in this city. These offices are chiefly situated in Wall, Water and Front str. ets.

TEA TASTING.

One of the most important figures in the tea broker's office is the professional tea taster. To him is intrusted the work of testing the various samples and fixing their respective grades and values. The manner in which this work of testing the samples is conducted is as follows:—A silver half dime is thrown into the scale on the one side and enough tea to balance the coin is dropped in on the other side. The tea thus measured is drawn into one of the little cups, which are capable of holding half a gill. The samples to be tested having thus been disposed of in the various cups, boiling water is poured upon them from the urn.

The tea taster then holds each of the cups in turn beneath his nostrils to catch the aroma, which is of great assistance to him in determining the quality. When the tea has sufficiently cooled to be not much more than lukewarm the expert proceeds to test it by tasting it. This operation is conducted with much deliberation and even solemnity, the tea taster closing his eyes as if to shut himself away from the outer world and sometimes even insisting upon the most absolute silence being maintained by those about him as long as the test is in progress. He only takes a few dainty sips from each cup, and sometimes he applies himself a second, a third and even a fourth time to the same sample. The tests having been made, he renders decision as to the quality of the different teas he has sampled and the values at which they should be rated in the market.

DELICACY AND ACCURACY OF TASTE.

By many it may be thought that the decision as to the quality of different kinds of tea must depend largely upon individual ideas and tastes. As far as the professional tea taster is concerned this is a mistake. Tea tasting is very decidedly a profession in itself, and has to be learned by dint of application and experience. That it is not merely a question of individual taste is demonstrated by the fact that when, as is often the case, a certain set of samples is submitted to several tea tasters acting independent of each other, the various opinions rendered as to quality and value are almost invariably identical. So delicate are the perceptions of the professional tea taster that he not only quickly and accurately grades the different samples submitted to him, recognizing the most minute gradations, but he is also in many instances able to determine the part of the country in which a certain tea was grown. In the same way the judgment of the tea taster purchasing the tea in China for the importers here, as a general rule, coincides with that of the tea tasters here.

PROFITS AND PENALTIES.

The tea trade in this city is divided into four distinct branches—the importer, the broker, the jobber and the retailer. The wholesale price of tea ranges from ten to seventy cents* per pound. The importer's profit is a moderate but remunerative one. The largest percentage of profit—from forty to sixty per cent—goes to the retailer. When a cargo of tea is received by the importer, samples of the consignment—often

* Of a dollar, of course.—Ed.

consisting of various kinds of tea—are sent to the broker. He disposes of it to the large retailers or to the jobbers, who in turn sell in lesser quantities to the smaller retailers. The broker receives one per cent commission on all sales effected by him. The tea taster acts in the interests of the broker, to whose advantage it is to have a correct estimate as to the qualities and values of the different teas he is handling, in order to meet the requirements of his customers. —*New York Herald.*

EXPERIMENTS WITH MANILLA HEMP,
PLANTAIN AND THE WILD PLANTAIN
OF SOUTHERN INDIA.

cleaned in Death & Ellwood's machines, are recorded in a paper sent to us by the Madras Government, and are of the usual unsatisfactory nature:—

Read—the following letter from J. W. Minchin, Esq. Manager, Glenrock Company (Limited), to the Collector of Nizhin, dated Pundalor, 1st April 1885:—I have now the honor to inform you that a trial in the treating of Manilla plantain hemp was made here in the Death & Ellwood machines, belonging to the Company, on 31st January last. Mr. Guard sent from Captain Cox's Naiken Shola estate well-grown Manilla plantain stems obtained from Manilla hemp stock received from Mr. Ballard, Collector of Malabar, in 1863-64, and since growing on that estate. One hundred and seventy-nine large stems were delivered at the mill, which weighed 10,973 lb or about 60 lb each stem, and after passing these through the Death & Ellwood machines there was produced 159 lb of clean fibre, say 1.49 per cent of the green stuff. The cost of treating this fibre, drying, sorting, and preparing for market, was R4-3-0, or at the rate of R63-8-0 per ton of clean fibre valued in London at £28 per ton at present depressed rates. I enclose statement of the outturn. There is 50 per cent of water in the green plantain stalks, of the remaining dry vegetable matter we saved 15 per cent of good fibre.

In the Philippine Islands the cost of preparing the fibre is calculated at one-half the value realized on the coast, and the people employed at this work are paid accordingly, an expert hand being able to prepare about 12 lb. of fibre per day; and the average produce is one pound of fibre from each stem said to average 100 pounds in weight.

Wild plantain stalks have also been treated here at this Company's mills; some being sent to England with the Manilla plantain fibre from Naiken Shola estate for valuation and comparison. The stalks of the wild plantain are not so large and well grown as those of the Manilla plantain, very few attaining to 50 lb. in weight; but there seemed little difference in the strength or appearance of the two fibres.

I find the Rhea fibre most worthy of consideration, and hope to have 250 acres under this cultivation shortly.

Outturn of Manilla Plantain from Mr. Guard.

January 28th 1885, number of stems, 179; weight, 10,973; number of machines worked, 6; time occupied, 5 h. 25 m.; good fibre, 140½; discolored, 4½; waste or beatings, 14½; total 159½ lb.

Result 1.49 per cent. clean fibre: say one machine in 32½ hours. 337 lb. green stuff per hour 4-9 lb. Fibre per hour.* Labor cost R4-3-0 or R63-8-0 portion of fibre for treatment in machine and preparation drying.

* Eight men machine. Six women drying and sorting.
One boy carrying. Two men beating.

(True Copy)

(Signed) C. J. LARGE.

" " J. W. MINCHIN.

Endorsement by J. F. Price, Esq. Acting Director of Revenue Settlement and Agriculture, dated Madras, 9th July 1885.

Submitted for the information of Government. This paper has been delayed in view to obtaining the results of the valuation of the fibre; these have now been received.

The account of the experiment, though interesting, contains no details of the number of the plants carried on an acre of ground, or of the number of cuttings

of which can annually be made, or of the cost of carriage of the raw material from the place where it was grown to that where it was prepared, or of the charges connected with the carriage, &c. of the fibre to England.

The valuation of the Manilla fibre is given at not more than £10 per ton, say R125. The cost of treating, drying, sorting and preparing it for the market was, at the place of manufacture, alone R63-8-0 per ton, or rather more than half of the value of the fibre in the English markets. When other charges come to be deducted, there would be, if any margin of profit, but a very small one indeed.

Although the stems used for the experiments were evidently of considerable age, the plantation from which they were obtained having been put down so far back as 1863-64, the outturn of fibre as compared with the stem used was not quite 1½ per cent and this is described by the experts who examined it as containing a very considerable proportion of exceedingly indifferent stuff, so poor as to render the price per ton of the whole far below that mentioned by Mr. Minchin. The wild plantain fibre was still worse.

It seems clear that unless much improvement, both in the method and cost of preparation of this fibre, can be made, cultivation of it cannot possibly be made remunerative.

A copy of the report of Messrs Collyer & Co. on the fibres transmitted to them by the Glenrock Company is enclosed.

Copy of Messrs. Collyer & Co.'s Report.

Wild Plantain.

Very mixed and irregular, mostly very weak, a small portion fairly strong, a good deal being flaggy refuse with scarcely any fibre in it. When the fibre is fairly strong, it is fairly well cleaned, but apparently a good deal is intrinsically too poor to bear cleaning efficiently. The proportion of stronger fibre may be too small to be worth separating, otherwise it would appear desirable to ship that portion only in future, and then it might realize £15 per ton and upwards mixed as it is; the bulk is too poor for use alone, and for mixing purposes it will only realize very low prices, say 7 or 8 per ton.

Manilla Plantain.

From Captain Cox's Naiken Shola Estate.

A somewhat similar fibre to above, with a larger proportion of strong, a small part being good, useful, clear fibre of good color, somewhat approaching ordinary Manilla hemp, but the great bulk is poor, weak, flaggy stuff; the same remarks as to cleaning apply; where the fibre is sufficiently bold and strong result is satisfactory, but on the whole, unless the stronger fibre can be kept separate, the price must be very low, say about £10 per ton the best alone should be worth £25 upwards.

“CEYLON AS A FIELD FOR
INVESTMENT.”

Reading the pages of a work called “Tea and Other Planting Industries in Ceylon, in 1885,” has opened a field for argument and thought, which I feel inclined to step into, and I vain would touch upon some of the subjects in a desultory sort of a way. In a report of the coffee industry of Ceylon, in 1875, emanating from the *Observer* Office, the following sentence occurs:—“The export of coffee in 1875 was 924,266 cwt. and, as the value in the consuming markets was probably five millions sterling, we have here a proof of the overshadowing importance of coffee in Ceylon. Take it away, and exports dwindle to a small sum.”*

Things have altered very much since 1875, for I find, on reference to the statistics of 1883-84 that the exports, other than coffee, do not dwindle away to a small sum. On the contrary I find the export of cinchona, oil, tea, &c., so large, that one is surprized at what a few years has brought forth. The following quantities and

* Quite correct at the time.—Ed.

values are the best arguments in favor of Ceylon as a field for investment, as showing that, although coffee may have succumbed to disease, the resources of the island are far from being at an end. The export of various articles, for 1883-84 and the estimated values thereof are as follows:—

Tea, 2,263,000 lb. at 60 cents	..	Rs. 1,357,800-00
Cacao, 9,863 cwt. at R40	..	394,520-00
Cinchona, 11,500,000 lb. at 22 cents	..	2,530,000-00
Cinnamon and palm tree products		10,000,000-00

Mention is made of the capital which had been introduced and the revenue which had been created by coffee, and which had enabled Government to devote large sums to the restoration and construction of irrigation works, and in supplying village sluices and tanks where the people were ready to make use of them. During my wanderings in the lowcountry, I came across plenty signs of the coffee planters' money spent on these irrigation works, but in no one instance did I come across a native ready to make use of them. Indeed some splendid fields, handy to those tanks, were lying idle, and felt strongly inclined to apply to Government myself for the right to cultivate them, thinking that I could get the work done by the Sinhalese living near by, but, on making enquiries, I found these lazy fellows much more inclined to sit down and wait for the paternal Government to send them rice to prevent their starving, than to make any attempt to help themselves. That there are paddy fields near these tanks that would pay well for cultivating, I feel quite sure, but the labour question is the difficulty to be solved, as no dependence could be put on the Sinhalese for help. How differently the two races behave under trying circumstances; when anything happened to the paddy crop, the natives sat down and waited for assistance; but, when coffee failed, the Europeans did not look to Government for help, but just set their teeth and worked the harder at the cultivation of new products, with the splendid results we now see. As an old coffee planter I more than ever grudge the money which has been wasted (yes! wasted) on irrigation works which the natives never use* and in making roads over which scarcely a score of carts roll during twelve months. Had that money been spent in carrying railway communication into Uva and in completing the Colombo harbour works, already a marked difference would have been seen in the welfare of the country, and the revenue would have reaped something more than it has done from such unproductive works as roads radiating that the ruins of Anuradhapura, to the various seaports of the island. One cannot help wishing that coffee would hold its sway still to a certain extent, and who knows but the reduced acreage now under this shrub may drive the fungus back to its original lair. I trust that, when 150,000 acres are under tea, no blight will come to drive it away as *Hemileia vastatrix* has done with what was once the staple of the island. To me the finest flush of tea leaf or the heaviest crop of cacao pods can never compare with the perfumed sheet of white which clothed an estate when the coffee blossom burst, or the red which flashed from the bushes when a shower of rain brought crop on with a rush.

A good deal of the advice given to young immigrants has been dearly bought in the past, and yet even at that time there were those who preached moderation. I remember ask-

ing some of the planters in the young districts why they built large bungalows and stores on their ground, when they did not expect to reap any crop for two or three years. I was in an office at that time, and had not yet become a planter, so I was only laughed at when I asked the question. I gave what I considered to be parallel cases in the way the squatters of Australia and New Zealand acted, when they took upcountry in the back blocks. There, for the first two or three years, they lived in small huts and shored their sheep in temporary sheds—I myself once shored my sheep in a shed made by stretching grey blankets over a frame built of rough bush sapling—sand not until the returns warranted the outlay did the squatters of these days build a good shed or a respectable-looking house. I was laughed at again, squinting and coffee planting were two very different things, more money had been made by sales of estates than sales of crop, and there was more chance of selling an estate with a good bungalow than one with a house like a set of coolie lines. This was too true, and was one of the reasons why speculating in estates became so fashionable. Young immigrants nowadays have the past experience of planters for nothing, and will know not to spend money in an unproductive way, such as building stores for a crop which is not due for some years, and in erecting bungalows that require considerable capital to keep up. With the splendid climate of the hill districts in Ceylon, one does not require to build a palatial residence and live in the most extravagant manner, on the plea that one's health would suffer otherwise. With all the experience that a past generation has paid for, and which is at the disposal of every one, the immigrant landing in Ceylon has a much better chance of doing well than he would have had in years gone by, and the thousand and one ways that the planters of today could, if they would, reduce expenditure must be a great saving to those with short funds and no O. B. C. to give cash credits. For instance, the plan adopted by Mr. Rossiter, who sends his own coolies to pluck on other estates, bringing the leaf to his factory and paying the estate owners by weight. Why this plan is not more commonly adopted, I cannot conceive: a group of estates all taking the tea leaf to the one factory, where the best machinery could be erected, either by one man or by the proprietors of the whole group conjointly. Nor do I see any reason why, when two estates are opened up, one bungalow is not sufficient for the two proprietors, some terms being arranged for the payment of the one upon whose estate the bungalow is built, for the use of it by the other. Several clerks in the offices in Colombo live together without quarrelling, and surely two planters might do so. There are many other ways of economizing, which were never dreamt of in the palmy days of the coffee enterprise, but strict economy is the burden of every one's song now, not only Ceylon, but in every part of the world. COSMOPOLITE.

THE APHIDES, or plant lice have hitherto been supposed to be the most prolific of living beings; and it is disappointing to find a writer in the *Field* who has been at the pains to count the progeny of a single rose aphid, declaring that the individuals only number 32,768,000,000,000,000,000. He no doubt did not take a fair sample of aphid, and we hope he will try again with a result that will do more justice to this interesting insect. If he would also take the trouble to write the result in words instead of figures, he would gratify many persons, —*Madras Mail*.

* Our correspondent—an ex-Ceylon planter, now at home,—had not read Mr. Elliott's paper, nor heard of the good results from irrigation expenditure in the Batticaloa and Matara districts when he wrote.—Ed.

AGRICULTURE AND LABOURERS' PAY IN ITALY.

According to the Report of the Commission appointed by the Italian Parliament in 1877, and whose inquiries extended over several years, the lot of proprietors and farmers, if not brilliant, is at least tolerable, whereas anything worse than the condition of the labourers it is hard to conceive. The members of the Commission failed to arrive at any exact conclusion as to the average pay of these unfortunates. According to some it runs from threepence to fourpence a day, according to others to sevenpence, without making any allowance for loss of time, either through bad weather or ill-health. For this pittance they have to work like galley-slaves, and out of it such of them as have families must provide food for their children, and keep a roof of some sort over their heads. The utmost that a labourer can earn, *with the help of his family*, says Signor Arcozzi Manio, a large landowner, is 384 lire a year, equal to a little more than twopence a day. Their food consists of a coarse black bread, made of a mixture of rye and maize of inferior quality, rice soup, and dry haricots dressed with rancid oil. Wine and flesh-meat they never taste. "Hard labour, combined with insufficient food," writes Signor Mereu, in the *Bibliothèque Universelle*, "necessarily reacts with disastrous effect on the health of our agricultural masses, who are forced by want to live in wretched hovels, destitute alike of sunshine and fresh air." The Report of the Commission gives in this regard details which cannot be read without a shudder. In Lombardy, as well as in the South, whole families live pell-mell in huts reeking with every sort of abomination, and "in a state of revolting promiscuousness." "It is in the neighbourhood of rich and opulent Milan," writes Commander Jancini (a gentleman who has published a summary of the chief facts contained in the Report), that the labourers are the most wretched; the fever of exhaustion (*pellagra*) and phthisis make terrible ravages amongst them. They are worse fed than dogs." The supposed fertility of the Peninsula is a pure myth. Two-thirds of it are occupied by the Alps and the Apennines, a vast region with a rude climate and an ungrateful soil. Of this region 56,000 square kilomètres are either covered with snow of strewn with rocks, and utterly irreclaimable. In other districts denudation has wrought irreparable mischief, and the neglect of past generations and former Governments has allowed once fertile plains to become malarious swamps. Even the legendary luxuriance of more favoured regions turns out to have been greatly exaggerated. With the exception of the Valley of the Po and of a part of Lombardy, the soil is only moderately productive, not only because it has been impoverished by long-continued croppings without any adequate return in the shape of manure, but by reason of the dryness of the climate, which in the absence of an artificial system of irrigation puts really efficient farming out of the question. Italy does not even grow a sufficiency of cereals for her own wants, albeit the area of arable land is reckoned at 4,500,000 hectares (11,215,000 acres). The average yield of corn per hectare is equal to 11 hectolitres, as compared with an average yield of 33 hectolitres in England, 22 in Holland, 20 in Belgium, 23 in Germany, and 15 in France. Facts like these should make us more tolerant of our own variable yet not unkindly climate, and less envious of that blue Italian sky under which, while there are so much of grandeur and beauty, there is also so

terrible an amount of misery and want. The young and vigorous who desire to better themselves leave the country in droves. Those of them who can raise a few liras go to Australia or America; the less fortunate foot it over the Alps, and seek work in Germany, Switzerland and France. According to official figures, there are now living in divers foreign countries upwards of 1,200,000 Italian immigrants; and this estimate is believed to be much below the mark. Ten years ago the emigration was at the rate of 40,000; last year there left the kingdom 140,000 individuals, by far the greater part of whom were adult males in the prime of life. But this exodus has its good as well as its evil side; for, although the vast majority of the exiles never revisit their native land, a certain proportion return in greatly improved circumstances, and few in their prosperity forget the less fortunate whom they have left behind. In France, for instance, there are at present some 200,000 Italian workmen, all employed; and it has been ascertained that they send to their kinsfolk at home half their earnings, said to be fully four francs a day. If this estimate, which is given on the authority of Signor Mereu, may be trusted, the amount received in this way by Italy from France alone averages very nearly five millions sterling a year.—*Spectator*.

A GERMAN paper says that forty parts of paper pulp, ten parts of water, one part of gelatine, and one part of bichromate of potash, with ten parts of phosphorescent powder, will make a paper which will shine in the dark, and which will be suitable for labels, signs, &c.—*Indian Agriculturist*.

THE GERMAN AGRICULTURAL COLONY IN BRAZIL.—From an interesting account of a recent visit to the German colony in Rio Grande do Sul, the most southerly province of Brazil, written by Herr W. Spielberg, member of the Landtag, we learn that the colonists first settled in the Sao Leopoldo and Hamburger Berg districts, favourably situated for trade with Porto Alegre. The clearing of the land they secured has been a difficult task, but many of the older settlers are now on the point of deforesting the last quarter or third part of their sections. Several later colonists have secured more favourable situations on the Lower Marata, in the neighbourhood of Sao Sebastiao, Sao Lourenço, &c., but they have the same hard work in clearing the forest. Still later arrivals have, as at Triumpho, on the Jacuhy, near San Joao, on the Cahy, &c., begun by settling on the so-called "enclosed land," a wrong term since enclosure and forest alternate, and the real enclosed land runs in a southerly direction from the Jacuhy. This land is not much inferior to the forest land in the first years in fertility, but it is lighter and can soon be worked with the plough, while the proximity of the lands to the rivers Jacuhy, Taquary, Cahy, Sinos and Gravatahy, navigable at all times of the year, and running into the estuary of Porto Alegre, makes trade with this port easy. The climate of this delta is quite as cool and temperate as in the mountain districts. Herr Spielberg does not think the position of the colony is anything like what it has been represented to be—and certainly cannot be compared to that of the twenty-year-old colony in Ontario—but there is nothing like want, and the people all live and clothe well, the old ones being able to give their children a little money to set them up. Of the social circumstances of the colony not so favourable a report can be given.—*Kuhlow's German Trade Review*.

Correspondence.

To the Editor of the "Ceylon Observer."

CITRONS.

Prince of Wales' College, Moratuwa, 27th Aug. 1885.

DEAR SIR,—I read with interest the communications which appeared in your valuable journal on the subject of the culture of lemons in Ceylon, and now take the liberty of sending you per train a few specimens of the fruit grown here from a cutting sent to me by Mr. Fonseka of Pittagott Eliya estate, Kalutara. Please let me know your opinion of them. Crops of from twenty to forty are plucked each season. I have seen the parent tree in Kalutara in a most thriving condition.—I remain, yours faithfully,

W. S. GOONEWARDENE.

[We regret that this letter should have been overlooked. The fruits sent were not true lemons, but "citrons," which are less juicy and much more thick-skinned. A preserve is made of the citron skins, but the fruit is less valuable than the lemon.—Ed.]

BARLEY GROWN ON UVA PATANA LAND.

15th September 1885.

DEAR SIR,—By this post I am sending you a sample of barley grown on Uva patana land, at Albion. The seed was sent to me by the Murree Brewery Company, but did arrive in Colombo till late in January, and the dry weather setting in so soon after it was sown was very much against the experiment proving the success I believe it would have been, had the seed been available for sowing in December. As it is I only got about the same quantity that was sown, but being only a small patch the rats and fowls from the lines did a lot of damage before it was ripe, and it suffered very much from drought.—Yours faithfully,

ARTHUR J. KELLOW.

WATER-POWER ON TEA ESTATES.

Matale, 16th Sept.

SIR,—The enclosed simple directions for ascertaining the quantity of water available from any given stream may, perhaps, be of service to your correspondent "Planter, No Engineer," and to others.—Yours faithfully,

R. R.

Turbine wheels have gone into such general use in this country that an overshot wheel is now very seldom seen. The turbine is so much cheaper and so much easier to set up and manage that it is generally preferred wherever its merits are known; but in tropical countries the turbine has not yet become very much known and is little understood. It is a very simple wheel to understand and manage, and in many localities is by all odds the best wheel that can be used. The turbine can be used anywhere that an overshot can be used, and in many places where an overshot would be practically out of the question. For high heads and a comparatively small quantity of water the turbine is the only wheel fit to be used.

We frequently receive inquiries and orders for wheels without any data being given to enable us to judge the kind or size of wheel needed. For instance, a planter will order a certain sized sugar mill "with a water wheel of the proper size to drive it," without giving us any intimation of the quantity of water or the height of fall. As a large quantity of water and low head requires an entirely different wheel from a small quantity of water and a high head, we are, of course, unable to build the wheel until we are furnished with these data. They should always be given by those inquiring about or ordering a wheel. The quantity of water in a large, open stream can be ascertained with sufficient accuracy by giving the velocity of the water, and the area of a cross section in square feet.

The velocity may be estimated by throwing a floating body on the surface and noting the time required in passing a given distance. The area of cross section may be ascertained by measuring the average depth and width of the stream. For smaller streams the weir dam measurement, as illustrated on a following page, is best. It is always well to send us a rough sketch of the stream and ground where the wheel is to be located and inform us on which side of the stream the machinery is to be located. In ordering turbines state which way they must run, whether with the sun, that is from east to west on the south side or against the sun, that is from west to east on the south side; the former is sometimes called right-handed and the latter left-handed.

To construct a weir dam for the purpose of measuring the water, a single board or plank, long enough to reach across the stream and rest in the bank at each end, should have a notch cut in it about two-thirds the width of the stream, and deep enough to pass all the water to be measured. The bottom and ends of the notch should be beveled on the downstream side, so as to pass the water freely; then go several feet up stream and drive the stake B in the bottom of the stream till the top of the stake is on a level with the water when it first begins to spill over the bottom of the notch in the weir dam. When the water has reached its height, and a full volume is pouring through the notch, the depth of the water above the top of the stake B can be easily measured as shown in the engraving, and will give the length of the line C D or the depth of the water passing over the dam. Then knowing the length of the notch A C by referring to the table on the next page the number of cubic feet per minute passing over the dam can be ascertained. The height of the fall can be ascertained by measuring from the surface of the water below the fall to the level of the surface above the fall, as shown by the line E in the engraving. Then in writing to us give us the depth of the water over the top of the stake B, or in other words the length of the line C D, also the length of the notch on the line A C, also the height of the fall on the line E, and we can then easily determine the size of wheel needed.

[Unfortunately we cannot reproduce the sketch of the waterfall, &c., but our correspondent, who does not give his full address, has forgotten to send the table referred to. We have further letters with useful information on this subject to publish.—Ed.]

DO. USEFUL FORMULE.

Colombo, 19th Sept. 1885.

DEAR SIR,—In reading the communication of "R. R." in your issue of last night one is impressed with the idea that something more complete and more concise is wanted as an aid to planters in estimating the power residing in their streams.

Construct a temporary sluice with square sides (for small streams an old door with a panel knocked out will do), place it on the brink of the fall, direct all the water through the aperture and lower the slide until it is skimming the surface, then measure the opening and multiply its area in feet by the square root of the height in feet and by 216; the result will be cubic feet of water discharged per minute.

Suppose a sluice is set as above described passing all the water a stream supplies and the aperture measures 1 ft. 3 in. wide by 1 ft. 3 in. high, then

Area	Sq. root of height	
in sq. ft.	in ft.	
1.56 ×	1.42	× 216 = 377 cub. feet

water discharged per minute, nearly. The approximate h. p. will be found by multiplying the cubic feet water by the height in feet of the fall and

dividing by 700. The fall in this instance is, say 16 feet, then

$$\frac{377 \times 16}{700} = 8.6 \text{ h. p. nearly}$$

—Yours ully,

D. K. M.

No. 11.

Colombo, 17th Sept. 1885.

Sir,—Referring to the article in the *Ceylon Observer* of 14th instant, headed "Water-power on Tea Estates," I beg to enclose extracts from Moore's "Universal Assistant" and Trautwine's "Civil Engineer's Pocket Book," which I believe may prove useful.—I am, yours faithfully,

(Extracts referred to.)

In the measurement of large open streams, first ascertain the mean velocity in feet per minute, and also the area of the cross section of the stream in square feet, when the product of these two quantities will give the required quantity of water afforded by the stream. The velocity of such stream can be estimated by throwing floating bodies on the surface of near the specific gravity of the water and rating the time accurately required in passing a given distance. It is generally best to ascertain the velocity at the centre and from this ascertain the mean velocity, which has been found by accurate and reliable experiments to be 83 per cent, or about four-fifths of the velocity of the surface of the stream. The cross section may be estimated by measuring the depth of the stream at a number of points at equal distances apart (these points being in a line across the stream) adding the depths together, and multiplying their sum by the distance apart in feet of any two points. This will give the result required in square feet of cross section, when the product of mean velocity in feet per minute and cross section in square feet, obtains the quantity of water that the stream affords in cubic feet per minute.—*Moore's Universal Assistant.*

The *Surface Velocity* should be measured in perfectly calm weather so that the float may not be disturbed by wind; and, for the same reason the float should not project much above the water. The measurement should be repeated several times to ensure accuracy. In very small streams the banks and bed may be trimmed for a short distance so as to present a uniform channel way. The float should be placed in the water a little distance above the point for commencing the observation so that it may acquire the full velocity of the water, before reaching that point. Remember, if the channel is in common earth, especially if sandy, the loss by soakage into the soil, and by evaporation will frequently abstract so much water that the discharge will be less and less, the farther down stream it is measured.—*Trautwine.*

TEA IN JOHORE:

LIBERIAN COFFEE—CLIMATE SOIL—LABOUR.

Sir,—Under the above heading your correspondent "W. H. G." endeavours to answer to the question "Will tea pay in Johore?" and the conclusions he appears to arrive at are

(a) That the rainfall, though sufficient, is not well distributed;

(b) That the soil of Johore consists almost entirely of clay, and that the root of the tea plant cannot penetrate;

(c) That the class of labour available, and not so much the cost of it, I gather, is unsatisfactory.

Hence tea cannot be grown in Johore to pay.

It is not my intention in this letter to discuss the question of tea cultivation *per se*, but rather to draw attention to a few facts in connection with the climate, soil, and labour of Johore, and thus enable your readers to form a fair estimate of the capabilities of the country.

In the opening paragraph of his letter to his friend, "W. H. G." makes a statement to the following effect: "that planters of experience have given the country of Johore a lengthened and determined trial which has proved unsatisfactory and unprofitable without an exception." This remark calls for considerable modification, almost tantamount to contradiction. The words "unsatisfactory and unprofitable trial" must be confined to the original attempt made to grow *Coffea Arabica*, and which venture, as is well-known, proved a failure.

Though the time has scarcely arrived when we can speak with certainty as to the ultimate result of Liberian coffee cultivation, yet I can state from personal observation and experience that no product tried here gives fairer prospect of success than this. Leaf-disease, which has proved so detrimental, not to say fatal, to this plant in Ceylon has little or no effect here beyond retarding the growth for a short time, the trees throwing off their sick leaves and resuming their normal vigour very speedily.

Crops are now coming in, one group of estates at least having already shipped produce home which, I learn, has realized very satisfactory prices. Other estates will shortly follow suit, and the prospective returns may be looked on as anything but unsatisfactory and unprofitable. Liberian coffee at any rate appears to have found a congenial home in Johore.

Climate.—Your correspondent seems to speak more from hearing than from actual observation for any length of time of the climate. The usual sicknesses (fever, ague, &c.) attendant upon the opening-up of new land are no exception in Johore. The town of Johore-Bahru, or the shore of the Straits, is, as might be expected, healthy. In the villages situated otherwise that on the sea coast, on gambier and pepper plantations worked by Chinese, fever is not at all uncommon; and though mostly found in a mild form is of frequent recurrence. On the other hand properties which have been under cultivation for some time are quite healthy.

The rainfall varies in different districts or parts of the country, the further inland the greater the amount; but speaking generally I think I am within the mark when I give the annual average for the last four years at over 100 inches. I speak under correction as I have not the figures by me at this moment. This quantity is pretty evenly distributed throughout the year, the driest months (and this year they were the driest on record) being those from January to May. For the remainder of the year the rain is well distributed, and tea flushes freely, a ten-day plucking being necessary. The daily temperature in the shade ranges from 75° Fahr. to 92° in the lower districts; on the hills, from 70° to 85° Fahr.

The "hill districts" so-called are Gnanong Pulai (700 ft.) and Batu Pahat. Where tea is planted in Johore, the land is very little above sea-level and very slightly undulating, though to the eye of an Assam planter this may seem otherwise.

Soil.—The soil of the country, though not a rich one, is good, the magnificent timber standing in virgin forest being a sufficient proof that the soil is very far from a poor one. Many analyses have been made and will compare very favourably with those of average Ceylon soils, the only chemical compound of which there appears to be a general deficiency being lime.

It is fair to the country and to the tea gardet to which allusion is made by your correspondent "W. H. G." to say that the estate was opened upon what was once a pepper and gambier plant-

ation, but having become exhausted by constant cropping was abandoned and had, at the time operation began, become a field of lalang. Such land is plentiful in the neighbourhood of Johore Bahru, and being easy of access was in this instance taken up and opened for experimental purposes. That the "clay" which "W. H. G." speaks of is of such a consistency that even the tap-root of a tea-plant cannot penetrate it, is contrary to fact, your correspondent himself contradicting the statement when he writes, a few lines, lower down, that "the growth of the tea plant here (Johore) as far as wood is concerned, is, I must say, very rapid."

Labour.—The experience of those who have been longest in the country does not support the ideas of your correspondent on the subject of labour in Johore. The labour available for the cultivation of estates consists of three classes: Chinese, Javanese and Malay, with occasionally a few Klings. The first-named furnishes an almost unlimited supply, but except for contract work and the opening-up of new land (roading, draining, holing) is too expensive. Javanese are also easily procurable from Singapore, though in limited numbers. Malays are always to be got for felling contracts, and generally, as occasion arises, for such works as holing, line-building, &c. That the type of Chinaman procurable in the Straits is not of the best, and that Javanese are not the most industrious workers, I am ready to admit; but pioneers must be content to take and adapt to their purpose such labour as they find in the country, moulding it by degrees into workable material. There are many reasons why Chinese are impracticable as *day-labourers*, but chief amongst these is the fact that they are ever-shifting, never remaining more than a few months at the outside on one place, though the *mandore* may continue the same originally engaged; secondly, on account of our inability to converse with the coolies directly in their own language, all instructions having to be given in Malay through the *mandore*, whose knowledge of this is always very meagre. Javanese, on the other hand, though slow, are steady workers, and will in time, doubtless, settle down to our European ideas of quantity and quality. Contract work seems unintelligible to them, or, as is most likely the case, they find it more advantageous to themselves to engage for daily wages. We anticipate being able soon to obtain Tamil labour on the same terms as those imposed upon planters in the Native Protected States, if report speaks true as to the preliminary arrangements in connection with the immigration of Tamil coolies to Johore having been satisfactorily settled during the Maharajah's visit in England. Meanwhile we must be content with the labour which is to our hands, and which, though sufficiently plentiful, is not yet as cheap as we could wish.

Tea.—Given a good jüt, the making of good tea depends, I take it, *ceteris paribus*, upon the skill of the superintendent in charge of the estate, whether in Johore or elsewhere. Your correspondent must have been on this tea garden at an unfortunate and exceptional season, when he saw what he describes as "seed developing at nearly every axis of the leaf." It has been my good fortune to see flushes in every way as healthy and regular as tea flushes in Ceylon, and this extending over many months. The question of cost and supply of labour, much more than that of flushes, is the one which requires solution in connection with the query "Will tea pay in Johore?" W. H. G. seems anxious to call in the support of 'others' to his statements, thus showing weakness of conviction on his part or perhaps lack of what is termed *experience* in the country of which he has become a devil's ad-

vocate. Perhaps in his next he will enlighten us further, but meanwhile the country has not much to fear from the idle outpourings of one who, whose residence in Johore has been but too evidently a brief one.

PIONEER.

Since writing the above I have succeeded in obtaining the rainfall returns for five years, and herewith enclose them for publication. At Gunung Pulai, where only consistent and regular records have been kept, the average over this term exceeds 100 inches. Unfortunately Batu Pahat figures are not to hand: there the rainfall is higher than at Gunung Pulai.

Johore, September 1885.

VENTILATION.

DEAR SIR,—About 15 years ago I was for a time considerably troubled and perhaps somewhat alarmed, that the signs of extremely rapid deterioration of beams, joists, &c., &c., of an upstairs floor built for and adopted as a copra store. Deterioration of timbers generally resulted from moist heat from copra, arising from contact with semicircular corrugated iron roof, such contact during the night giving rise to condensation and a constant drip, drip, drip, back to the floor again. In my efforts to remedy the evil, if possible, I tried the *double draught ventilator* I have drawn your attention to, and I believe very much good resulted therefrom, drip being considerably reduced and the room less favourable to fungus. My experience seems to say that variable measure and degree of humidity is no mean factor in the promotion of atmospheric circulation. Such being the case, a portion at least of "J. B."s arguments are greatly in favour of, yours respectfully,
TRY.

A VENTILATOR FOR A TEA-HOUSE.

DEAR SIR,—I forward this rough sketch of a double draught ventilator which I venture to think would answer well for tea-houses, especially for those who have a pretty tight roof on them which all ceiling ventilators absolutely require. It should be attached to and flush with a ceiling and will work well under such circumstances. Any ordinary good tinsmith could fit them up on the

estate. Size such as would slip down between two rafters. Scale of this sketch is about 1-12th. Best material, stout zinc. Parts A, B and C should be well stiffened with a ring of 3's round iron.

If the building be a two-storied one, and the lowermost specially needs ventilation at some given point, the cylinder of this ventilator by being prolonged through the upper room and floor would accomplish it and be always under control needing no power.

I have lived in an old English house built two and a-half centuries ago, and all the window panes were cemented into stone mullions, and our sole means of ventilation were back and front doors and one of those ventilators over the well of the staircase, and our atmospheric condition was first-class. For tea-house purposes 1, 2, 3, or 4 of them could be fixed and draught regulated by opening or closing any one or all at pleasure. Most suitable roof, I think, would be zinc tiles underlaid with Willesden paper.—Yours &c.,

TRY.

[We are sorry we cannot reproduce the diagrams, but a gentleman whose opinion we value writes as follows.—Ed.]

DEAR "OBSERVER,"—The enclosed plan of ventilator is of approved pattern, and works well in suitable conditions. It is constructed on the principle, that, with two tubes (or two sides of a divided tube) forming two perpendicular conduits from the outside to the inside of a heated room the cold air will come down one, and the hot air go up the other. The one admitting the cold air has no advantage in being beside the other or descending perpendicularly, so far as effectiveness is concerned. It would be equally good at the bottom of the room; only the arrangement is more convenient, as it requires only one hole in the roof, and one ventilator.

Its conditions are, that the heat of the room be considerably greater than that outside. If the room and outside air be of the same temperature no ventilation ensues. If outside air be 40 deg. and inside 60 deg. there would be a considerable current. If outside 30 deg. and inside 60 deg. a much stronger one. If the room be not very large a good-sized ventilator will suffice with a moderate current. The conditions of the tea-house are different. The room is large and ventilation is most needed when the temperature outside is hottest, i. e. when the current force is least. Suppose inside temperature 100 deg. and outside 100 deg., there would be no current at all. The air outside is rarely more than 80 deg., so with a wide enough exit and entrance ventilation could be effected; the taller the perpendicular tube that carries off the heated air, the stronger the current; the wider the tube, the more heated air will be carried off. It is just another form of a chimney, furnace, and furnace-door. A high wide chimney affords scope for a large current of air. If it be highly heated the air goes up quickly; if the door allowing air to the furnace is opened, a great deal of air will pass.

To have a good current in this country, a tall wide tube is required, or a fan. A plan for ventilating a tea-stern would have to be made to suit the arrangements of the store. Give me plans &c. and I would furnish one for the same.—Yours truly, B.

P. S.—I see the writer of this has not understood the principle on which his ventilator works. In his sketch he places arrows showing air currents going out at both sides of the dividend tube. The only advantage of the division is to make two passages out of one hole in the roof, so that cold air may enter by one

and hot air escape by the other. I see no use for your incurring the expense of engraving it, as it is the ordinary ventilator in use. Of course if either the back or front door of the house described were opened, the hot air would go out at both holes, the cold air entering by the door; but in that case of course the division of the tube is no advantage. J. B.

BUG,—NOTHING BUT BUG.

DEAR SIR,—I am glad to see that the publishing of Dr. Gardner's Report on Coffee "Bug" has attracted your "editorial" notice. You have had many hints of late about the damage "black-bug" was doing, but up to now you have shunned the subject as if it was a Gould-created scandal.* I trust, that, now you have taken the matter up, you will worry away at it as if it was a "railway extension to Uva." Your oftstart, however, is not encouraging, and I trust you will see the error of your ways, like Macbride, and mend them.

I have just re-read your paragraph to make sure of what you have said, and really the article is so unlike anything you put forward usually, that I fear you must have been very busy when you wrote it.

You begin the article by saying "Dr. Gardner's report on coffee 'bug' first saw the light in 1848 when it was fully discussed in the *Observer*." Will you please say how many of the present generation of planters this discussion enlightened? What we do know is that it was barren of any good result.† You go on to say: "It (the report) is of historical and personal rather than of practical or scientific interest. In fact, it is so far behind, in its scientific portions, the level of the knowledge of the present day, that it would probably be treated as absurd and childish by advanced scientists." So far I entirely agree with you. You then quote a passage from the report itself to the effect that "black-bug" must wear itself out; but conclude your article by saying "and there the discussion of 'bug,' like that of leaf-disease, must, we fear, rest for the present." Rest for the present: I repeat your closing words with emphasis, and ask, is the *Observer* going to change its motto of *Fiat Justitia* to *Ichabod*? Here is a scourge sweeping over the land ruining all it touches. We don't know anything about it, beyond the great damage it does. We appeal to Government, who tell us a Dr. Gardner wrote a report upon it 40 years ago. This paper is got and handed to the conductors of the "press" for public enlightenment. The *Observer* in noticing the report calls it "absurd and childish" but finishes off by saying "here the matter must rest for the present." Perhaps 40 years ago when the subject was last discussed in the *Observer* this conclusion was come to, and perhaps this may be repeated 40 years hence, when the subject again comes up for discussion. I always understood the editors of the *Observer* took up a matter of this kind like an Irishman did his "Billalah," and rapped everybody over the heads till they found out "who bit me, father."

I have just paused to light my cheroot, and seeing how much and what I have written, I tremble, and I must conclude by hoping you won't be hard on me. But before closing let me earnestly entreat you to take this matter up, and never stop, till

* We have repeatedly noticed it as a very old topic on which there was nothing new nor profitable to be said.—Ed.

† Quits, so, and why reprint the paper or discussion? —Ed.

we know as much about it as we do of leaf-disease. This last-named pest has been "worked out," and we know the worst, which, if a poor, is a reliable satisfaction. We are expected to "leave footprints on the sands of time." Dr. Gardner's "footprints" you admit are no good on this subject. Why then should we let the matter "rest for the present"? No, no. "Now 's the day and now 's the hour," I say: let us know the worst, if worst it is, so that 10 years afterwards our work can stand the light of day and not be called "absurd and childish."

I don't expect you will do all I ask for my sake, and I don't think you would do it for your own sake, but I do expect you will do it for your adopted country's sake.—Yours truly,

A BLACK-BUGGED SUPERINTENDENT.

Does this much-tried superintendent wish us to advocate the employment of another Mr. Marshall Hunt to observe the working of bug, in order to write its life-history, and to tell us, that, as in the case of the coffee fungus, the phyloxera, and other similar pests, there is no practical remedy within the reach of the agriculturist? After the "leaf-disease campaign" we should suppose that even "bugged" superintendents "would have cried 'Hold' enough," in reference to further discussions of the same complexion. However, if our present correspondent, or any other sufferer, has observations to record, or opinions to express, we shall be glad to hear from him and to discuss his views.—Ed.]

A PIECE OF AMBER, weighing eight pounds, is at present being exhibited in the Mark Museum at Piantzig, for which the owner has refused £1,500. It is probably the largest piece in the world without blemish.—*Pioneer*.

DR. GARDNER'S Report on Coffee "Bug" which first saw the light in 1848, when it was fully discussed in the *Observer*, and is now reprinted at the instance of the Planters' Association, is of historical and personal, rather than of practical or scientific interest. In fact it is so far behind, in its scientific portions, the level of the knowledge of the present day, that it would probably be treated as absurd and childish by advanced scientists. Dr. Trimen is responsible for reminding the Planters' Association of the existence of this Report, but we question if the worthy Director has been flattered by the request to have it reprinted after a lapse of well-nigh forty years. However the paper is a curiosity in itself, and we may reprint all, or selected portions, in the *Tropical Agriculturist*. As regards remedies, Gardner had just the same story to relate as regards "bug" as we have since experienced in respect of "H. V." or the leaf fungus;—numerous remedies tried; none have had the desired effect. Dr. Gardner closed his report, with the passage we have so often quoted, namely:—

"From all I have seen of the pest, I am inclined to believe that it is not under human control; and that, if ever it disappears from the island, or at least becomes unproductive, it will be by running itself out as blights of a somewhat similar nature have been known to do in other countries. But whether this may prove to be the case with the cocculus of the coffee is uncertain, as the experience of the last five years goes to prove its permanency. And there, the discussion of 'bug' like that of 'leaf disease' must, we fear, rest for the present. In a subsequent communication to Government, we think Dr. Gardner recommended pumping warm water on bug-infested coffee trees!

THE DOMINICA ESTATES.—A contemporary says:—"The sugar crop for the year is over. Notwithstanding many drawbacks during cultivation, it is not below the average. The greater part of this crop has been sent to New York, as was done last year in consequence of the depressed state of the English markets. A temporary advance in these markets a few months ago, it was expected, would cause a larger proportion of sugar to find its way to England this year than last, but the rapid decline in prices which has lately taken place, with a still downward tendency, has rendered a much further trial of the English market this season exceptionally doubtful."—*Oerland Mail*.

FIJI TEA.—Mr. Inglis, of Inglis, Brown & Co., Sydney, writes in a letter to our address. "The Indian branch keeps steadily progressing. We have had very good samples of tea from Fiji. I send you a couple. Ceylon tea we would like to handle, but as long as you can get such good prices for Ceylon-grown tea in London, it would be no use sending it here, as the colonial mind still hesitates at giving a good price for a high-class article. If we could have a real and not a sham inspection at this port to exclude deleterious and artificially doctored China stuff, both India and Ceylon would reap large benefit."

To Mr. Wilson of Messrs. Somerville & Co., we are indebted for the following opinion on the Fiji teas, Pekoe Soucheong, 10½d—rather loosely twisted blackish greyish leaf, rather dull flavor thin. Orange Pekoe, 1s 10d on account of tip—blackish brownish mixed leaf, some pekoe ends dusty, fair flavor rather thin.

N.B.—In consequence of the above samples having been kept so long in paper, they have been rendered dull, the valuations are therefore a little uncertain.

ANTHRACITE IN CHINA.—Four centuries ago China obtained procelain clay from Ceylon. It is impossible, in view of the following paragraph, that China may yet, by a reverse process, send anthracite to Ceylon for tea drying and other purposes. China is more richly blessed with coal than almost any country, and is remarkable chiefly for its enormous deposits of anthracite. Raphael Pumpelly estimates the area of the anthracite fields of the Chansi Province at 11,000 square miles, with an average thickness of 40 feet of coal, while the smaller basin in the south of Hunan has the advantage of being tapped by a navigable river.—*American Grocer*.

AN INDIAN TEA COMPANY. The report of the directors of the Durung Tea Company for the half-year ending 30th June last is not a very inspiring affair. The balance in hand at the commencement of this year, after making provision for a dividend, &c., appears to have been some R9,808. Tea sold subsequently has realized R23,019, and there is due to the National Bank and to the Agents R9,237. Some R40,099 has been expended on account of 1885, and there is some R2,069 in the manager's hands. Of the R40,099 so spent, only R15,138 appears to have been expended on cultivation, new cultivation, plucking, manufacturing, and bonus and freight on coolies; the balance having gone in European establishment, agency charges, and the thousand and one little items which make a tea company's account resemble a coachbuilder's bill, much cry and little wool. Of course there has been red spider and early blight—no tea agent's report would be complete without them; if there could only be a murrain among the charges extending into the agents, the shareholders could better endure it, but tea agency charges always show a "flush," and unfortunately there is no one to prune them.—*Pioneer*. *Calcutta Cor.*

THE SOMA PLANT OF HINDU MYTHOLOGY.—The naturalist with the Boundary Commission has, he believes, found the Soma plant, the existence of which has for so long remained a mystery. The plant grows like a weed near Herat; and is a most insignificant specimen of the botanical world. There are two kinds found there, one with a large reddish brown fruit, and the other bearing a smaller fruit. The plant has no leaves, but consists of a number of jointed twigs like the fingers of a hand starting from a stumpy stem. It answers the various descriptions given of it very closely, and is still used by the fire worshippers in Persia and Bombay for their fire worship. The Pathans make an infusion of it, which is extensively used as a tonic and stimulant; and it is also dried and afterwards pounded for use as snuff.—*Madras Mail.*

COFFEE CONSUMPTION IN AMERICA goes on increasing after a fashion which leaves Europe entirely behind. The *American Grocer* states:—While the consumption for the first third of the year shows a gain of over 28 per cent, the decrease in May and June has reduced it to a gain over the first half of 1884 of 16.67 per cent. We will not be surprised if the movement for the next six months cuts down the increase to 10 or 12 per cent. We recognize, however, elements at work that must result in heavier gains in consumption than could be expected six to eight years ago. Fifty years ago there was not a complete apparatus for roasting coffee in this country. The first was brought over from England in 1833 or 1834, prior to which time a machine operated by hand filled all the requirements of this great city. Now we have giant establishments, one of which employs dozens of large cylinder roasters and turns out 1,000 bags of roasted coffee daily. In every city of respectable size one finds the large cylinder roaster in operation. This is the work of the past twenty years, and the result is a slow revolution in changing the demand of consumers, especially in the South and Southwest, from green to roasted coffee. This has made the berry a greater favorite, because the professional roaster has given the consumers a better and more uniform roasted berry than they could secure at home by means of skillet or frying pan. The result has been the infusion is more pleasing to the palate, and therefore more generously used. Within a few years it has become the fashion to have coffee served at lunch counters and soda water fountains, it being a popular beverage with tens of thousands who have taken to its use in lieu of spirits or malt liquors. It seems to be a pleasant and powerful stimulant, and as its good qualities become more widely known, it grows in favor as a beverage, and is supplanting other articles of drink in and out of the household. While the consumption advances here it has not gained much, if any, in Europe. The May deliveries were 54,247 tons, against 53,503 for the same month in 1884, and 39,630 in 1883. For the first five months of 1885 they were 159,157 on the Continent, and with the deliveries in the United Kingdom added they foot up 173,901 tons, against 148,992 in 1884, 200,059 tons in 1883. The European trade fell off heavily in 1884 as compared with 1883, and thus far the loss has not been recovered, the deliveries for the first five months being slightly below the average yearly distribution for five years. Messrs. James Cook & Co. of London report the deliveries for Europe and the United States to May 31st at 273,134 tons, against 227,272 in 1884, 279,115 in 1883. If the consumption in Europe had increased as rapidly as it has in this country prices would undoubtedly range higher.

A GRAVE MISTAKE.—The following is from the *American Exporter*:—"We get coconut oil from India and Ceylon at great cost for freight, etc., each tree being taxed one rupee by the Government, while right under our noses the coasts of Honduras are fringed for miles and miles with coconut palms which pay no tax and cost not a cent to anybody for creature. The "cochon" palm or the "coroso," as the Spanish call it, is absolutely unknown to our commerce, and yet the oil produced in the comparatively small kernel of the adamantine, marble like nut is as delicate as the finest olive oil, and with American machinery could be made an important adjunct to our wealth." Coconut palms in Ceylon pay no tax, unless they are devoted to supplying juice which ferments as toddy and is distilled into arrack. Trees producing nuts, used as food or expressed into oil, pay not a cent.—"American papers please copy."

SWAMPS.—Our swamps produce abundance of vegetation—white papery-barked melaleucas and other aromatic plants—which may account for their non-malarious nature. Supposing, by circumstances, that these swamps lost their coating of vegetation, an unhealthy atmosphere would most likely be generated and malarious fevers be produced. Probably the paper-barked melaleucas would be better in warm countries than *Eucalypti*. Their leaves give off much oil of the *Cajuput* quality, and they will live with their roots for long periods submerged in water. When, however, permanent water forms over their roots, a quantity of fresh rootlets are thrown out at the surface of the water, so that such roots can respire the air necessary for the vitality of the submerged roots. These submerged roots are never water-logged, and small sections of them made will even float from the quantity of air they have circulating through them, and such roots no doubt tend to aerate water-logged soil and ameliorate its exhalations.—*Queens-lanter land Pand Farmer.*

THE PROPOSED LOANS TO PLANTERS.—At a recent meeting of the Trinidad Legislative Council, Sir Arthur Havelock, the Governor, said:—"I have to communicate to the Council a telegraphic message which was received by me from the Secretary of State on July 4th. At the time of its receipt I communicated it to one or two of the unofficial members of Council, and the message became a matter of public notoriety. But before taking further action on this telegraphic message I thought it would be as well to await the possibility of receiving further expression of opinion from the Secretary of State, but by the mail which arrived on July 31st I have merely received from the Secretary of State a duplicate of the telegraphic dispatch that he sent me on the 4th, without any further explanation. I think it probably useless for me to await further information, and I will therefore bring it before the Council. (His Excellency after reading the telegram, which had already been published, continued.) This matter seems, in the opinion of the Secretary of State, to rest with the Legislative Council, and it seems to me that perhaps the best plan for arriving at some definite idea of what is wanted would be to ask a committee of the Council to consider the terms of this despatch, and to lay the result of their deliberations before the Council for further consideration. I would therefore ask the Colonial Secretary, Mr. Fenwick, and Mr. Finlayson to be kind enough to form a Committee to consider this despatch, and report whether there is any matter arising out of it which they can recommend for the consideration of the Secretary of State." The suggestion was agreed to.—*Colonies and India.*

A PHYSICIAN of S. Paulo, Dr. M. Arruda, claims for the juice of the *mangabeira* (*Hancornia speciosa*) great curative properties in pulmonary consumption. The immense mortality caused by this disease all over the empire makes this question one of interest. A drawback to the treatment is that the patient must reside on the spot where the plant grows and take the juice freshly extracted.—*Rio News*.

GREEN ROSES.—A correspondent writes:—"There is to be seen in the compound of the School of Arts a green rose tree, the property of the Superintendent. The plant was originally imported from Darjeeling by Captain Tuftnell, of the Commissariat Department.—*Madras Mail*. [Credat! Some shade of yellow, probably, affected by an abnormal growth, petals being but another form of leaves.—Ed.]

GINGER.—The *British Trade Journal* says:—"The cultivation of Ginger in Jamaica is said to be dying out, on account of the persistent cultivation of the same plant on the same land for a long series of years. Only the richest and best lands are suitable for the cultivation of Ginger, and as it is a very exhausting crop, the production of the article on the island depends on the reserve of good land still available where it is cultivated."

MACARONI WITH TOMATO SAUCE.—Break half a pound of macaroni into inch-lengths, and cook twenty minutes in boiling salted water. Meantime, take a cup of broth from your soup; strain, boil and skim it, and slice into it four ripe tomatoes. Stew tender and strain through net or tarlatan, into a saucepan. Season well; stir into it a great spoonful of butter rolled in flour. Simmer five minutes; put the macaroni into a deep dish, sprinkling grated cheese over each layer, and pour the hot sauce over it, opening the masa with a fork, to let it reach the lower layers.—*Dinner Year Book*. "As tomatoes seem now to be plentiful and cheap, some of our readers may like to try the above.—Ed."

TEA CULTURE IN NATAL.—Mr. Hullett, in the course of a letter to the *Witness* on the subject of tea culture, says:—"It may be safely assumed that 50,000 lb. weight of tea will be made in Natal during the coming season, with a very large increase each succeeding year." Mr. Hullett and other experts show in the *Witness* that the acreage devoted to tea plants is rapidly increasing in Natal, where a dozen plantations already exist, and the climate is not too dry for the scrub. Coffee, however, does not thrive, as it requires a heavy rainfall and humidity to give fair crops. It also requires altitude, which causes much expense in labour and transport. The Natal tea is now prepared skillfully, and is liked by connoisseurs.—*Colonies and India*.

The *Kolonial Politische Correspondenz*, in an article upon the German stations in Eastern Africa, states that the German East African Company has succeeded in bringing under the German flag 4,500 square miles of fertile and salubrious territory in a central situation. The article continues as follows:—"The experiment of establishing a factory and a first agricultural station at Usugara has already been made and the company now proposes to establish five military stations, upon an agricultural basis, which on the one hand will serve for the military instruction of the negroes by capable officers row on the spot, with the object of forming a native corps of defence, while, on the other hand, experiments will be made of working plantations by means of native or Asiatic labourers. Messrs. Krupp have provided guns of the new construction for the defence of these stations, which are to form the central point of the labours of the German East African company, and a field for the investment of private capitalists interested in Eastern Africa."—*Overland Mail*.

A MANGANESE MINE.—For some years past (says the *Port Augusta Dispatch*) the existence of a deposit of manganese ore near Gordon has been well known, and the lode was once worked for some time by an Adelaide Company. The first shipment of ore sent to England realized about £2 per ton profit, the second just paid expenses, but on the third there was a loss, and the mine was then stopped. Mr. George Prout, a gentleman well known in mining circles in this colony, has now taken the property in hand, and will give it a more exhaustive trial than it has yet had. He has visited the locality, and is confident that he can raise a large quantity of ore of a percentage sufficiently high to yield a profit after defraying the expenses of working and shipment of ore to England.

DECAY OF GUM FORESTS.—The Rev. Peter M'Pherson's paper on some of the causes of the decay of Australian forests which was read before the Royal Society last week was both valuable and interesting. There is no doubt concerning the fact of the decay. In some districts there may be seen hundreds of acres of gum forests in this condition. Mr. M'Pherson advances the theory that the destruction has been caused by opossums having devoured the leaves, and in this way produced the disease of tree consumption. The circumstance that this decay on such an extensive scale is a recent phenomenon Mr. M'Pherson explains, by the assumption that the opossums have largely increased in consequence of the disappearance of the aborigines, who used to eat the animals, and by that means unintentionally limited their power to do mischief to the forests. There are weak points in the induction; but Mr. M'Pherson's theory is supported by intelligent squatters and farmers, and also by the blacks.—*Sydney Mail*.

Many square miles of withered gums which we saw near Sale, in Gipps Land, were said to have been destroyed by leaf-eating moths.—Ed.

TEA-DRYING BY SIROCCOS.—With reference to the complaint of a correspondent signing "A. F. S." in our columns some weeks ago, Messrs. W. H. Davies & Co. forward to us a letter from Messrs. Davidson & Co. of Belfast dated 3rd September, from which we quote as follows:—"We notice 'A. F. S.' the writer to the *Observer*, on the 30th July states in italics that we laid considerable stress in a circular issued some time ago on the fact that 'tea could not be burnt in a temperature of 300 deg. F.' Now we never did say any such thing, and 'A. F. S.' must be quoting from our pamphlet No. 62, copy of which we send you, and on p. 8 you will note that we say 300 deg. F. can be used if the teas have become soft-flavored, but very great attention is required at this temperature, because, left long in this temperature, discoloration of the infused leaf would be the result, whereas at 260 deg. F. the leaf is scarcely perceptibly darkened in color no matter how long it may be left in the machine at that temperature, &c. We always pointed to 260 deg. F. as the right temperature for air to pass through the tea at. Although our No. 3 Sirocco thermometers were marked at 320 deg. F. yet the currents mixing therewith ought to have reduced it to 260 deg. F. before striking the bottom of the lower row of trays. In point of fact however in the No. 3 this dilution did not properly take place, and point of impact on first tray was often over-dried and burnt. In the T shape, however, the mixing and dilution is perfectly effected, and we now do get the amount of drying done claimed for and at the safe temperature of 260 deg. instead of 320 deg."

CHOCOLATE FROM PALM-TREES.—The good people at home seem to be uncommonly bothered by the two products cacao and coconut. Messrs. Fry & Sons, who have made a speciality of "Ceylon chocolate," illustrate their advertisements of it with the picture of a man climbing a coconut palm and throwing cacao beans down to the gatherers below!

ROTTING TIMBER.—The *Builder*, referring to the rotting of timber, makes the following remark, which should be noted:—"The *Merulius lacrymans* is the common wood fungus that destroys nine-tenths of the wood with which we are acquainted. The reason of it being common to new buildings and not to old, is that moisture, one of the constituents, of its existence, is more present in new green buildings than in old dry seasoned ones. The two prime conditions of its existence are moisture and heat; if moisture is present without heat it will not grow, and hence its depredations in the winter time are unknown. If heat is present without moisture, it will not grow, and hence ventilation for the passage of a current of dry air will prove fatal to its existence.—*Indian Agriculturist*."

THE DEPRESSED POSITION OF FIJI is thus indicated in an article in the *Fiji Times*:—"Production has ceased and labourers are in excess of demand because proprietors are no longer cultivators. In many cases the tardy Indian relief was too long in arriving. Before the small planters could avail themselves of it, cash and credit was exhausted. In others, even the advantage so offered, cannot tempt to a doubtful venture under conditions as to the return in labour which reduce the chances of success to a minimum. Therefore those who aforesaid actively devoted their energies to agriculture now vegetate as coconut collectors. Instead of cultivating, they watch palm trees grow. To gather the nuts and to raise the little produce necessary for household consumption a few local labourers are employed, where the once prosperous settlers can afford it; or if he cannot, he, his wife, and children, make the copra and grow the yams. As a simple naked fact, there is no class of small producers. Those who once composed it have succumbed to the force of officially created circumstances. Hence the prevailing stagnation; and hence the triumphant success of the Government policy evidenced by Fijians seeking in vain for work; by Polynesians and Indians in excess of demand, because demand has ceased; and by small proprietors who, from the fact that they are no longer small producers, are neither in want of labour now, "nor likely to be in any want for some time to come." If Fiji is to recover from its present state of depression it must be by again making these small proprietors actual producers. First, the Fijian labour supply must be rendered practically available, so that the men now searching for work may find it on the abandoned plantations, to the mutual benefit of themselves and their employer. When these are profitably engaged, arrangements must be made to renew the introduction under deferred payments—a matter which will then present no difficulty. With the small planter, the small trader must also be recalled to life, by a considerable modification, if not an entire abandonment of the native tax-scheme, and with these two classes actively and profitably engaged the prosperity of the country will rapidly return. If this course is not adopted, there is before Fiji a future as the arena for the operation of a few large sugar Companies, but as a field for settlement its career will close in the irretrievable ruin of all those who have been so long associated with its attempted development.

A SMALL DOSE OF SULPHUR given to pigs once in two or three weeks, will keep them free from disease and greatly increase their general thrift.—*Gardner's Monthly*.
COCONUT BALLS.—One pound coconut finely grated; one pound sugar; two whites of egg. Put them all into a saucepan and stir, over a brisk fire, for twelve to fifteen minutes, then turn out on a marble slab and let it cool. Mould them, with your fingers, into small, round balls, the size of an English walnut, place them on a buttered tin sheet, and bake to a light brown tint, in a moderate oven. They are also called cones, or drops, when they are moulded into those forms, respectively.—*American Grocer*.

SUGAR IN FIJI.—If only labour can be plentifully and cheaply obtained and sugar can be sold at remunerative prices there seems a great future for Fiji as a sugar-producing colony,—that is to say if the average yield is anything like what is recorded in the *Fiji Times*.—It is satisfactory to learn that the Rewa cane yield is even surpassing the expectations founded upon the magnificent appearance of the crops. From a very considerable area the big mill has obtained a return of three tons of sugar to the acre, and in one case this has been doubled. On the Vunibicibi Estate, Messrs. J. C. Smith & Co.'s, a portion has yielded at the rate of over 60 tons of cane, and six tons of sugar per acre. What this means may be guessed from the fact that in other sugar growing countries 25 cwt. is an average yield.

COFFEE IN BRAZIL.—The result of the 1884-85 coffee crop becomes a subject for remark and offers a further proof of how necessary has it become that some system be organized, through which a fairly correct estimate of the probable out-turn of a crop may be arrived at. We have had no syndicate in Rio during the past year, and the stock held by the banks for account of the defenders of Brazilian interests has been shipped, whether for realization, or as legitimate purchases, we are not prepared to state. We were persuaded so far back as October last that the estimate of $3\frac{1}{2}$ million bags as the probable out-turn of the 1884-85 crop was, erroneous, but our information was against our persuasion and we could only repeat what was reported to us. The crop year shows receipts of over 4 millions of bags and furnishes yet another factor for discrediting estimates based upon information furnished by interested parties, such as planters and their immediate representatives, the factors. The explanations given for the large receipts, when the crop was considered a small one, were that the planters were pressed by their factors and obliged to market their crops as rapidly as possible; very favorable weather had assisted to prepare the crop for market; every excuse was offered, except the principal one, that the planters and their representatives were in league to endeavor by unreliable information to influence consuming markets and thus *re-coup* a part at least of losses made in their patriotic attempt to prop up prices. We defy any disinterested person to dispute our assertion, that there is a systematic attempt, year by year, to blind exporters as to the coffee crops. The factors, who are in direct communication with the planters, are directly interested in maintaining prices, and amusing results, at times, occur. It is not new that a crop has been represented at 200 per cent. less* than a preceding one, nor that a planter declaring his own crop to be above an average one, asserts that his neighbors are suffering from all the ills to which coffee planters are liable.—*Rio News*.

* 200 per cent more is possible: but 200 per cent less? Surely 100 per cent less means nothing?—Ed.

THE DARJEELING TEA AND CHINCHONA ASSOCIATION, LIMITED, soon after they had effected the purchase of General Angus's property, now would not profit by cinchona bark. But sometimes for India and Ceylon both have departed and in the late report of the Company they say:—

The cinchona plantation has been kept in good order and the trees are making good progress. It is, however, now proposed not to cut any bark this season as besides the increase another year will make in the thickness and consequent value of the bark, the market at present is so dull that it would not be advisable to make any shipment.—*Pioneer*.

THE RUSSIAN TEA TRADE.—A new danger to British commercial interests is indicated by our Consul at Hankow, Mr. C. Alabaster. Hitherto a large proportion of the tea supplied to the Russian markets has reached its destination in English ships *via* London, but the direct trade *via* Odessa has enormously increased during the past four years. In 1880 only 4,845,453lb. went direct to Odessa, but last year no less than 11,681,140lb. were shipped to that port in Russian and Gennian vessels. The export to Russia *via* Tientsin and the Annu showed a slight falling off, though still largely in advance of past years. Altogether 24,000,000lb. went direct to Russia against 37,000,000lb. to London, showing a steady progressive increase in the former. As everything points to Russia being eventually the chief market for China teas, it means, says Mr. Alabaster, our being ousted in great measure, if not entirely, from the trade.

AGRICULTURAL EDUCATION POLICY IN MADRAS.

—The separation of the School of Agriculture from the Agricultural Department, and the bringing of the latter into more practical and intimate relations with the agriculture of the country, precisely as contemplated by the Government of India. Under his scheme the School of Agriculture would be purely scientific, and the Agricultural Department nothing if not practical. After a while, it would be made a condition precedent of admission to the school that the candidate should have studied practical farming for two years. For the purpose of affording this practical training, Mr. Wilson at that time contemplated the establishment of Government example farms. With regard to the future agricultural policy of the Government, His Excellency the Governor in Council proposes in the first place to abandon the Saidapet Farm on its present scale as a practical failure. The work there has excited some general interest among the agricultural population in improved agricultural machinery, but little more than this has been accomplished. The farm is too small for stock breeding, its soil is unsuitable and our knowledge of Indian crops too limited as yet for useful experiments. No new farms will be instituted, but experiments will, where necessary, be carried out, with the assistance of private agency under the general supervision of the Agricultural Department. Meanwhile, native agriculture and the analysis of districts will be carefully studied by the Agricultural Reporter with a view to introduce better methods where they are wanted, but there only. Further than this the Government are not at present disposed to go. To assist the Agricultural Reporter in investigation, the Government propose eventually to entertain a small body of District Agricultural Inspectors whose salaries will be met from the savings which will accrue from the abolition of the farm. These men will, previous to their appointment, have undergone a course of training at the Government Agricultural School. The further proposal of the Director of Public Instruction to attach some 20 or 40 acres of land to the college as a farm *annex* as a field for practical demonstration and training for the students of the college is approved; the management of this land will be under the control of the Educational Department. The necessary details of administration of the agricultural school, and the course of instruction to be followed therein, will receive consideration in the Educational Department, to which department these papers will be now communicated.

THE BRAKEN FERN, *Pteris esculenta*, seems to be as great a nuisance to the agriculturalist of these parts as the rabbits are to the squatter. The rich volcanic soils feed it well, and it spreads and develops accordingly. It costs a good deal, both in trouble and money, to keep it down. Burning the fern only seems to make it grow all the more luxuriantly next year; chopping the "roots" apparently tends to spread it. Would it be deemed impertinent if I were to offer a hint, for coping with the bracken fern difficulty? Perhaps it would be as well for me to give the reasons why my hint would prove useful. The so-called "root" of the bracken is in reality an underground stem, or *rhizome*, the same part which in the tree fern we regard as the trunk. Within this stem, underground or aboveground, there is stored each year a supply of starch and other plant food. Every year's fronds contribute to the supply. The young opening fronds draw upon the vegetable banking account until they are fully developed, and then they repay the parent by contributing towards the stored up supply in the stem. It is evident, therefore, that if we cut or mow down the young, half-coiled fronds of the bracken, just at the time when they are developing, and when they have been abstracting the nourishment from the stem, the latter will be impoverished. If we mow them down year by year the stems must wither and die. They will be quite bankrupt, in short, for the mowm ferns will have consumed all the available capital. This may seem a rather tedious process, but in a few years it would prove an effective one.—Dr. TAYLOR in *Australasian*.

AGRICULTURAL EDUCATION AT HOME AND ABROAD.—Although the French Government voted 3,512,000*fr.* for agricultural education this year, the *Echo Agricole* says it is not enough, and that the several departments need to complete the organisation. In England we are accustomed to think that agricultural instruction is very liberally provided for in France; but our French contemporary complains that they have in France only one institute of agriculture, one national school of agriculture, and one of horticulture, 14 schools of practical agriculture, two shepherds' schools, one school of practical horticulture, two foraging schools, 23 farm schools, one cowhouse for breeding, two silkworm rearing schools, two primary agricultural schools, one agricultural and two horticultural courses of lectures in primary schools, 42 orphanages and agricultural colonies, 85 departmental professors of agriculture, three chairs of agriculture in Algeria, four chairs of agricultural chemistry, and 31 agricultural stations; while Germany has 14 agricultural institutes, 451 primary agricultural schools, 71 school of agriculture, seven veterinary schools, nine superior institutes of pomology and arboriculture, 61 agricultural schools of various kinds, 15 schools of practical horticulture, 11 dairy schools, five schools of agriculture for girls, one school of sugar refining, one school of distilling, 36 special courses of agricultural lectures, 65 agricultural stations, and 37 professors of agriculture. Italy, most persons will be surprised to learn, has three superior and 22 practical schools of agriculture, all created since 1880, six special schools, four of which are for viticulture and wine making, and 19 agricultural orphanages and colonies dependent entirely upon the municipalities. Even little Denmark has an agricultural institute with 223 pupils and 22 professors, 10 practical schools of agriculture, and 40 superior primary schools which give agricultural instruction.—*European Mail*.

MRS. ATZEROTE, who is said to have raised the first coffee in the United States, now has twenty-five flourishing coffee trees on her plantation at Manatee, Florida.—*American Grocer*.

A NEW SIFTER.—We would direct attention to a very cleverly contrived tea-sorting machine, the invention of Mr. Victor Müller, of the Borelli Tea Co. It is called the Borelli Tea Sifter, and, judging from the certificates obtained by Mr. Müller from managers who have used it, it is a decided acquisition to tea machinery. It gives less trouble and does quicker work than any other sifters, and one great advantage in it is the absence of that deafening noise and heavy dust which render a sorting-house a Pandemonium. A trial of this sifter should inevitably lead to its adoption.—*Indian Tea Gazette*.

THE YIELD OF TEA IN JAVA.—The yield of tea in Java is nearly double that of Indian gardens, but although Java teas are finer in appearance than Indians, they lack strength in the cup. Some very good prices have lately been obtained for Java teas, their appearance being much in their favour. Java teas used to be packed in a somewhat similar manner to Chinese, but from many estates packages are now sent forward plain, to resemble Indian chests.—*M. Mail*, [The average for Indian gardens being 305, it follows, if this statement is correct, that the Java average is 610 lb. per acre. But we should like to see the statement confirmed. As to sending Java tea away in boxes resembling those from China, we may mention that from Mr. Kerkhoven's estate at Sinagar, we took specimens of paper coverings for the chests on which were lithographed Chinese designs, the printing being done in the factory.—*Ed.*]

CALCUTTA AND THE INDIAN TEA INDUSTRY are thus noticed by Mr. Thomas Farr, in an account contributed to the local "Times" of a trip to the Indian tea districts:—

The streets of Calcutta are in most cases a disgrace to such a wealthy city, and the "metal," which is brought over from Ceylon and Bombay by ships as ballast, is only imperfectly blinded with brick-dust. There is, however, an air of wealth about the whole place which cannot but strike one most forcibly, and tea appears to be an important factor in this apparent prosperity. Carts laden with tea are met with everywhere, and in the large sheds along the jetties enormous piles of tea chests are awaiting shipment. In every street of the European quarter of the city, names of tea companies engraved on marble slabs are seen near the palatial offices of the agents, and I cannot help endorsing the opinion of the head of one of the leading houses in Calcutta, that in a few years Colombo will acquire a large share of this prosperity. The high yield of our Ceylon estates, and the high prices obtained for our teas, are attracting considerable attention in Calcutta, and are viewed with some alarm by those interested in Darjeeling, but it is believed that the Doonars, Cachar, Sylhet and Assam will hold their own against Ceylon, both in yield and in the quality of their teas. One can only hope it may be so from increased consumption, and that there is every reasonable prospect of this must be conceded. At present tea has not found its way to any extent amongst the enormous native population of India, whilst the inhabitants of Tibet within easy reach of Darjeeling draw all their supplies from China. It is the winter which prevails in India during five months of the year which should give Ceylon priority in yield, for, if in seven months, four or five maunds per acre is secured in India, surely 10 months' plucking will do as much for Ceylon. I should not wish it to be thought that I write this in any spirit of rivalry. Far from it indeed, for, after the cordial hospitality with which I was everywhere received, I should appear ungrateful, but I merely express my convictions, and I can only hope there will be room in the world's markets for us all.

WILD BIRDS AS INSECT DESTROYERS.—With reference to a resolution passed at a meeting of the Trinidad Agricultural Society, we understand that a communication has been received by the Secretary to the effect that the Acting Colonial Secretary has issued instructions to the Wardens and Police authorities with a view to strictly enforcing the provisions of the Wild Birds Protection Ordinance of 1881, which was taken from the English statute on the same subject (43 and 44 Vic., chap. 35).—*Colonies & India*.

SALT FOR THE THROAT.—In these days, when diseases of the throat are so universally prevalent, and in so many cases fatal, we feel it our duty to say a word in behalf of a most effectual, if not positive, cure for sore throat. For many years past—indeed, we may say during the whole of a life of more than forty years—we have been subject to a dry hacking cough, which is not only distressing to ourselves but to our friends and those with whom we are brought into business contact. Last autumn we were induced to try what virtue there was in common salt. We commenced by using it three times a day—morning, noon, and night. We dissolved a large tablespoonful of pure table salt in about half a small tumblerful of water. With this we gargled the throat thoroughly just before meal-time. The result was that during the entire winter we were not only free from coughs and colds but the dry hacking cough had entirely disappeared. We attribute the satisfactory results solely to the use of salt gargle, and most cordially recommend a trial of it to those who are subject to disease of the throat. Many persons who have not tried the salt gargle have the impressions that it is unpleasant, but after a few days' use no person who loves a nice clean mouth and a first-rate sharpener of the appetite will abandon it.—*The Household*.

A CHARCOAL-MAKING KILN.—In Ceylon as well as Southern India, the Moreau Charcoal kiln, costing about R700 to R750, may be found useful. Mr. Gamble, Conservator of Forests, in applying for one through the Madras Government, stated that the return of charcoal to timber would be 25 per cent. We quote as follows:—

I have the honor to submit copy of an office note with endorsement to the Collector of Nilgiris, No. 8-C, of 4th May, with his reply as well as enclosures, being (1) the translation of a letter from Messrs. Biebon and Co. of Paris, and (2) the description of a closed iron charcoal-making kiln, and to ask that the Board will either accord sanction to my purchasing one of the kilns for experiment or send indent for it on Her Majesty's Secretary of State in the prescribed manner in such a way that it may be received at the beginning of next official year. With the Board's approval the funds necessary will be provided in the budget for 1886-87; this year they would not be available. 2. In regard to the Collector's remarks as to the amount of wood one machine would take, I have the honor to say that the contents of the kiln would be 200 cubic feet nearly, so that, reckoning 70 cubic feet of stacked fuel to the ton, it would hold nearly 3 tons, and give at least one-fourth or 15 cwt. of charcoal. 3. The purchase of the apparatus is, I confess, but an experiment. So far as can be judged by the account of it, it appears to me to be likely to prove very useful and to save the trouble and damage to the ground which result from the ordinary system, while giving a better return and also a considerable quantity of tar. If it proves successful, it will make it possible to utilize the produce of forests now too distant for working, and more especially in the Nilgiris to make the produce of the Coonoor plantations, for which there is at present very little demand and where good flat places for ordinary charcoal kiln, are very difficult to find, available for the supply of Ootacamund and even of places in the plains. If it proves as successful as I anticipate, I expect that the accruing products, tar, &c., will alone pay for its costs the first year.

WOODS AND FORESTS IN EUROPE AND

From a Lecture by Dr. Lyon.—*Journal of Forestry.*

CULTIVATION OF TEA IN MALABAR.

On the higher portions of the Nilgiri Hills and in the Wynaad, 400 lb. of tea per acre per annum is looked upon as an excellent return; but I think the time has now arrived when the South Indian planters should take the initiative from those of Ceylon, and plant at lower elevations than they have hitherto attempted. Taking into consideration the fact that some of the Ceylon tea estates have yielded from 800 lb. to 1000 lb., and even so high as 1,200 lb. per acre per annum, Malabar and Wynaad, with superior soil, facilities for manure, cheaper and more constant labour supply, to say nothing of the forcing climate, should compare favourably with Ceylon, even to the extent of exceeding these excellent results.

According to Ceylon estimates, the upkeep charges are put at 45 rupees per acre, exclusive of manuring; but, as I have advocated the system of liberal manuring, almost from the commencement, I have placed the upkeep charges at 80 rupees per acre, and assuming these figures the cost of a pound of tea should be as follows:—

	400 lb. per acre.	600 lb. per acre.	800 lb. per acre.
Cultivation	3 an. pi.	3 an. pi.	2 an. pi.
Crop charges	1 6	1 6	1 6
Transport, packing & shipping	0 2	0 2	0 2

Cost per lb. free on board 4 11 3 10 3 3

The London charges, including freight, amount to 4½d. per lb., which gives the gross cost as follows:—

	400 lb. s. d.	600 lb. s. d.	800 lb. s. d.
London charges inclusive	0 4½	0 4½	0 4½
Indian charges as above:—			
4an. 11pi. at 1s 8d. exchange	0 6	—	—
3an. 10pi. at "	—	0 5	—
3an. 3pi. at "	—	—	0 4
	0 10½	0 9½	0 8½

Value of the tea at only 1s per lb., the following table will give results:—

Yield.	Profit.	Profit.	Interest on
per acre.	per lb.	per 100 acres.	capital.
	£. s. d.	£. s. d.	
400 lb.	1½	2 10 0	250 0 0
600 lb.	2½	6 5 0	925 0 0
800 lb.	3½	11 13 4	1,168 0 0

[Given as an extract in the *Indian Tea Gazette*, but not credited to any paper, a practice now too common with Indian papers.—Ed.]

MANGO INSECT PESTS.

Dr. E. Bonavia writes to the *Indian Agriculturist* in reply to the question of a correspondent, regarding the larvæ of some insect which destroys the mango fruit:—I regret to say I have not studied the habits of this insect, as in the North-West and Oudh mangoes are not often injured in this way, but peaches are. I think it probable that it may be a moth which deposits its eggs in the flower, and when they hatch they work their way into the young fruit, as it sets, and grow with it and ultimately emerge from the ripe fruit. If some of the mangoes containing the larvæ are sent to the Director of the Entomological Department of the Indian Museum, Calcutta, he may take steps to secure the perfect insect, when it emerges and throw some light on its habits, whether a moth or a beetle which would be a great step. I might also suggest that some one should during the flowering and setting season endeavour to observe what insects—moths especially—visit the mango flowers, either by day or after sunset. They might be able to observe with a large magnifying glass what they are about if they see any. As long as only a few mangoes are spoiled by these insects, it does not much signify, but when the fruit of a whole district is thus destroyed it is time to study the cause and search for some remedy. If the insect deposits eggs on the young ovary, either before or after setting some insecticide syringed over the young fruit when set (not while the flower is in pollen) might destroy the eggs or young larvæ before penetrating the young fruit. Tobacco juice in water is often used for destroying insects on plants; caustic ashes in water, and other solutions might be tried. Of course, the insecticide should not damage the fruit also. But the first step is to get a clue to the natural history of this insect whatever it is. As it destroys so much fruit, there can be no harm done by making some experiments with a garden syringe or pump, and nothing the side of the tree, or the whole tree on which experiments have been tried. Some of the very young fruit should be examined with a good magnifying glass to ascertain whether there be any evidence of a hole or broken surface, through which the minute larva may have crept in, and also to cut open the very young fruit and explore it with a glass in every way. In short to obtain a clue how this insect gets into the mango fruit, and when and then endeavour to work out its history. If the study of Entomology has any uses at all, a great one is to discover a remedy against the worry insects give us, and the loss they entail. But until we learn something about their "manners and customs," we may be only wasting time in fruitless attempts to circumvent them. Another observation is worth making—are all the mangoes in the districts named attacked by this pest? If there be some which are not, then the seeds of those only should be sown there, and grafts from those only taken. The extreme dampness of the climate of those districts may facilitate the ravages of this insect. Other kinds from *opuncy*, such as the solid fleshed ones, *safala*, *bhadania*, and others might be also tried. There may be a hundred dodges by which one can oppose these little pests.—*Madras Mail.*

RICE IN MEXICO.

The United States Consul at Manzanillo says that the State of Colima is the principal rice-producing State of the Mexican Republic, having produced during the year 1883, over 4,000,000 lb., and this production is steadily on the increase. The adjoining State of Jalisco produce, during the same period, over 2,500,000 lb., and Michoacan about 2,000,000 lb. The method employed in the production of rice is as follows:—The field suitable for the cultivation is ploughed in July, and the seed rice is sown broadcast over the field, by hand, then cross ploughed. The irrigation water is allowed to overrun the entire ground as soon as the young shoots are from three to four inches high, and the field is left under running water until the plant has attained a height of about two

feet, which is in about a month or six weeks. The young plant and weeds are then cut, by hand, down to a height of about three inches from the ground, with a curved implement called *guadua*, and during this time the water is dammed up and the field is dry. The cut-off portions of the plant, and weeds, are left on the ground to rot; the field is again put under running water, after which, the rice growing rapidly, it is left to itself until the time of harvest, in November or December, when the cutting commences, with a species of sickle called the *rasadera*. The farm labourer is provided, in addition to the *rasadera*, with a common straw or rush mat, about two feet square, which he spreads on the ground, and upon which, having cut as large a bundle as he can hold in one hand, he strikes the ears a couple of times for the ripe grain to fall out on the mat. When this mat is covered with the grain, it is taken up, and the grain emptied into sacks which are brought to an open platform near the houses of the *hacienda*, made up of a kind of cement or hydraulic mortar, upon which the unshelled rice is spread out and exposed to the sun to dry. When dry, it is again put into sacks, and stowed until the proper time for hulling has arrived. The hulling and cleaning of the rice is performed in the following primitive manner. Under a shed, or in the *hacienda*, are placed at intervals of about three feet, in single or double rows, from ten to fifty round wooden trunks cut from the stems of good-sized trees, about two feet and a half high by two feet in diameter, firmly set into the ground. In the centre of each trunk is carved out an inverted cones-shaped hole, upper diameter about ten inches, and twelve to fifteen inches deep. In this hole is placed some unshelled rice to within about one inch of the top, and a labourer, with a heavy wooden mallet in his hands, hurls the rice by pounding it for a considerable time. The rice, together with the loose husks, is then taken out and put in baskets. The hole is refilled with unshelled rice, and the laborious hulling goes on from day to day and week to week. The rice is cleaned or separated by lifting the baskets up in the air above the head, and letting it slowly fall upon a mat, whereby the light husks are carried off by the wind. This operation is repeated once or twice if necessary. The rice is then put into sacks of about 175 lb. each, and is ready for market. Occasionally, instead of single trunks or mortars being placed separately in the ground, there is used a long, heavy, square log of about two feet square and thirty to forty feet long, with a number of holes carved out at certain intervals.—*Journal of the Society of Arts*.

UTILISATION OF INDIGENOUS FIBRES.

A few weeks ago Mr. Preece, Acting Director of Revenue Settlement, submitted a report to Government on some small bro experiments in Cuddapah, Tinnevely, Tanjore, Vizagapatam and Kurnool, and he took advantage of this opportunity to submit, for consideration, the futility of the amateur experiments with fibres which are, from time to time, carried out by Revenue officers in different parts of this Presidency. He said:—

The results, as far as my knowledge goes, have invariably been financial failure. It could hardly be otherwise when the fibre has to be prepared by hand and by unskilled workmen. I most fully concur with the Board of Revenue in the remarks made in paragraph 3 of their Proceedings, No. 2,458, dated 17th July last. We know most of the fibres, we know the value of a large number of them. What is now required is certainly as to the supply—naturally or by cultivation—of the raw material and means for the cheap, rapid and efficient preparation of the fibres. As regards the former point, it is, in the case of certain fibres, *c. g.*, also, the *Calotropis*, *Fourcroya*, *Susnievera*, &c., assured. The latter is that which still awaits a satisfactory solution. Until this is arrived at, it is, I submit, throwing way time, trouble and money to produce by hand

indifferent samples of fibres which are, owing to the method of their preparation, costly, and which being indifferently got up, are priced at considerably below their proper value. There is, no doubt, a mine of wealth in the fibres of this Presidency if properly worked. I venture to throw out the suggestion that the time has arrived when the subject might well be placed under a specialist, and be taken in hand as that of microalgæ has recently been. The most energetic and zealous of Collectors can really do very little. They are overburdened with other work and have to leave details much with subordinates, and few if any have any but the most superficial knowledge of fibres and the proper methods of preparing them, even after the native fashion.

With reference to these remarks the Government observes that "the problem of cheap, rapid, and efficient preparation of fibres is not one which can be solved by the creation of a special Government agency apart from the Agricultural Department. It is a question for inventive genius and engineering skill, and the prospective profits of a successful invention seem sufficiently bright to encourage private investigation in this direction. It is noted that the prize of Rs.2,000 offered last year by the Government of Bengal was awarded at the Calcutta competition to Messrs. Deane and Ellwood's Universal Fibre-cleaning Machine, the working of which was found to be 'rapid and effectual.' The Government concur in the opinion expressed by the Bengal Government that the further question, whether this or some other machine can be profitably introduced in this country, may well be left to be decided by the commercial public."—*Madras Mail*.

COCA AT THE SOURCE OF SUPPLY.*

The Government organization of the United States has been utilized to ascertain where the best varieties of coca are found, the best mode of preparing it for transportation, and how it can be brought within reach of the American purchaser. Dr. Squibb has had access to the reports received, and has communicated with his own correspondents. He has received a bale of coca from Bolivia by way of the tributaries of the Amazon and Pará, but it had been ill-packed and was badly damaged.

Messrs. V. Farfan & Co., of La Paz, Bolivia, is one of the best and largest houses dealing in the article at the centre of the coca trade of Bolivia. Peruvian coca is smaller, narrower, thinner, and more fragile than the Bolivian; and a small proportion of the leaves want the characteristic faint lines forming a narrow ellipse with sharp ends on the underside of the leaf. Peruvian coca is bright green when fresh, changing to a "duller, lighter, yellowish green"; Bolivian is a dull, deep, olive green on the upper side, much lighter beneath, and becomes yellowish brown or brown. The two varieties shade off into each other, and both are divided into wild and cultivated, the latter being most esteemed.

The tree is cultivated on hill-sides 3,000 to 6,000 feet above the sea-level, on terraces on the sides of deep narrow valleys. The seed is sown in August in beds or boxes, transplanted in June to the terraces about 3 feet apart. The soil must be rich and free from shade and weeds, and is rapidly manured. The shrub grows to the height of from 4 to 6 feet, but the largest do not yield the best leaves. The crop is gathered, leaf by leaf, by Indian women and children. The first gathering, called the March crop, commences in January, the Saint John crop begins in May (St. John's is Midsummer day). All Saints' crop is collected in October, and then the shrub is completely stripped of leaves. Great care is taken not to touch the top of the bush. The leaves are dried in thin layers on hot pavements exposed to the sun, four hours' exposure being

* Condensed from the *Ephemeris*.

generally sufficient. They should not be laid out till the stones are quite hot. They are then packed for transportation across the mountains, and must be kept cool and dry. They are rarely handled or transported in damp weather or during the rainy season, which lasts from January to April. The only safe way of transporting them is in soldered tin or zinc-lined cases. Salaverry, the port of entry of Truxillo, is the principal place of export of the Peruvian drug, Arica of the Bolivian, Mollendo being now closed by the civil war in Peru.

The Peruvian Government records a production of over 15,000,000 lb. per annum, the Bolivian Government 7,500,000 lb. Of the latter quantity, Mr. Gibbs, the United States Minister at La Paz, says about 55 per cent is consumed in Bolivia, 15 per cent each in the Argentine Republic and Chili, and 10 per cent in Peru; while the remaining 5 per cent, or 375,000 lb. is exported to the United States and Europe. If Peru exports the same proportion, the quantity received by the United States and Europe would be about 1,125,000 lb. The market report in New York is that one manufacturer of cocaine in New York and another in Europe have secured the entire crop for the year, while a third has secured "the remainder." A million pounds would yield at least 2,500 lb. of cocaine, while a fourth of that quantity would probably overstock the world.*

Hon. S. L. Phelps, United States Minister to Peru, located at Lima, states that on a plantation producing good coca it is sold in packages of about 14 oz., at a price which—including tins, packing, and transport to the seaport—is equal to \$31.75 per Spanish quintal, or about 32c. (1s. 4d.) per lb. on shipboard. Minister Gibbs states that the price in Bolivia varies from 26c. to 64c. per lb. The whites of these countries seldom use coca except as infusion, and then the first water is thrown away as being too strong. The habitual use of coca is said to prevent toothache and preserve the teeth. There is no evidence that the enormous demand in Europe and America has caused the slightest increase in Peruvian and Bolivian prices! Dr. Squibb points out that a drachm vial of a 4-per cent solution will last the ordinary practitioner a long while, and he asserts that it is highly probable that every manufacturer in the United States is overstocked with alkaloid. With coca yielding 4 per cent of alkaloid, or 28 grains per lb., at a moderate price, cocaine could be sold at 15c. per grain, and any one of the four manufacturers in the United States could supply the whole demand. The Medical Department of the Army offered to contract for 2,000 grains. The competing bids were 18c., 19c., 19½c., 20c., and 22c. per grain or thereabouts. In consequence, Dr. Squibb reduced his price to 20c., less 10 per cent.—*Chemist and Druggist*.

HYDROCHLORATE OF COCAINE.

Dr. Freud, of Vienna, published in August a research on the alkaloid, which stated that it caused local anæsthesia of the tongue. Dr. Koller argued that if it deadened the sensibility of the nerves of the tongue it would have a similar effect on the nerves of the eye. After many experiments on animals, on himself and friends, and afterwards on patients, he published his discovery at the Heidelberg Ophthalmological Congress in September.

We will give a short account of the results that seem to have obtained in various departments:—

THE EYE.—One or two drops of a 4 per cent solution instilled into the eye cause at first a stinging sensation, lasting a few seconds. On repeating the application there is a sensation of cold, then comes a feeling of weight or tension and dryness. The eye protrudes somewhat. If the instillation is repeated the pupil dilates. Five minutes after the first instillation the cornea can be handled quite roughly, cut, cauterised with silver nitrate, pitted by pressure,

without causing the slightest pain or even sensation. There is simply no feeling. When deep incisions are made, as for iridectomy, pain has been observed by some though not by others. It is as yet doubtful how deeply the anæsthetic effect can be made to extend; it passes off at the surface in about twenty minutes, and, as it apparently takes time to reach the lower structures shown by the dilatation of the pupil, it would seem that the application must be repeated to obtain the best effect. The eye remains dilated for some time, but vision is not interfered with, and the eye gradually returns to its normal state. We find reports of three cases where inflammation has occurred after the use of the drug among a very large number in which it was not observed. One patient who had undergone two iridectomies under ether had the globe of the eye excised by Mr. Carnall Jones, under the influence of a 2 per cent solution of cocaine. His remark was that it was a great deal better than that beastly ether.

EYELID.—Mr. Baier has crushed a tumour on the eyelid without causing pain to the patient.

THE TONGUE.—Mr. T. Smith applied a 20 per cent solution to the tongue of a patient three times with in ten minutes. He then applied fuming nitric acid freely two or three times, so as to produce a definite burn. No pain was felt during the operation.

THE NOSE.—Mr. H. J. Butlin records his own experience. He has twice had the turbinated bones of his nose burned by Dr. Semon at intervals of three weeks. The first operation caused intense pain and prostration. At the second the surface of the bones was painted thoroughly, twice over, with an interval of five minutes, with a 20 per cent solution of the hydrochlorate. "The effect was marvellous, far more so than I—or even he, I think—expected. The burning was not felt by me more than the introduction of the brush in painting; I cannot say I did not feel the operation, but the sensation must be described as feeling, not pain."

THE LARYNX.—Dr. Semon has also removed growths from the larynx of a lady in whom, at the seven previous operations, the mere introduction of the instrument had caused alarming shocks. After painting the interior of larynx with the 20 per cent solution once, and waiting five minutes, he was able to introduce the instrument four times, and remove considerable portions of the growths, without the patient experiencing any pain at the moment or subsequent shock hypodermically.

Messrs. J. H. E. Brock and C. J. Akle, of University College Hospital, have tried the effect of hypodermic injections. The effects which were common to all the injections were, smarting, followed by numbness; redness round the point of injection; in from two to three minutes, sensation to touch was diminished, to pain and temperature completely abolished. In every experiment except the last, when half a grain was injected into the forearm, the anæsthetic area was more extensive immediately above the point of injection than below. The extent of surface on which the above effects were produced was about half an inch above and a quarter of an inch below the point of injection; while for about half an inch around this area there was a slight diminution to tactile, painful, and thermal impressions. They have performed two minor surgical operations painlessly after an injection of one-seventh of a grain.

We have given only some of the more striking pieces of evidence that have been brought forward.

Dr. A. Hughes Bennett makes a suggestive remark. He says that in an investigation undertaken in 1872 he demonstrated that the physiological properties of thine, caffeine, theobromine, granatine, and cocaine, when administered hypodermically, were to all appearances the same. "Should it be proved that they have also similar effects when applied externally to the mucous membranes, it would be of importance from an economic point of view, as cocaine is extremely expensive, while the others are comparatively cheap."—*Chemist and Druggist*.

"A NEW THEORY?" FIXED AND SOLUBLE INGREDIENTS IN THE SOIL.

BY SIR J. D. LAWES, BART. LL.D., F. R. S.

A friend residing in Virginia has drawn my attention to an article in the October number of the *Southern Planter*. It is called "A New Theory," and I do not think that I shall misrepresent the views of the author if I sum them up as follows:—That those fertilizing materials which exist in the soil or are applied in manures cannot be washed out of it by water, whatever may be the quantity applied. The author further says, "this arrangement is so wise as to wear the impress of Deity." In the observations I propose to make regard to the new theory advanced in the pages of the *Southern Planter*, it will be my endeavor to show that while some ingredients of plant food are fixed in the soil, others are perfectly soluble; and further, that for the purposes of vegetation it is absolutely necessary that these last should be soluble. In one of our fields at Rothamsted we have four rain gauges, each containing an area of forty-three square feet. One is placed on the surface of the soil to catch the rain as it falls, while the other three are placed underground, and receive the rain after it has passed through twenty inches, forty inches and sixty inches of soil, these being the respective depths at which the gauges are fixed. The soil is that of an ordinary arable field, with the exception that no vegetation is allowed to grow upon it. The rain water which falls on the surface gauge, and that which passes through the three depths of soil has been collected and analyzed for a number of years. Rain water always contains a considerable amount of common salt.* At first more salt was found in the water which passed through the soil than in that caught in the open gauge, thus proving that common salt, or some substance containing chlorine, had been used on the land as manure. All this excess has now been washed out, and for some years the amount of salt passing through the soil is almost identical with the amount which is found in the rain water taken from the surface gauge. Here, then, we have an instance of a food of plants—not I admit, a very important food—which is not in any way fixed in the soil, but circulates with the water.

I now come to a more important substance. Rain water contains a considerable amount of ammonia, and very little nitric acid; but after it has passed through a cultivated soil, it contains very little ammonia, and a considerable amount of nitric acid. If all the nitrogen in the rain water which falls upon an acre of land during a year—both in the form of ammonia and of nitric acid—passed through the drain-gauge soils, we should not obtain more than from four to five pounds, whereas actually we obtain eight or nine times that quantity. We will omit all questions regarding the source of this nitrogen, and confine ourselves to the question of solubility. Here, then, we find a substance of the highest importance as a food for plants, passing through a soil five feet in depth, every year, in such quantities as would, if taken up by plants, be sufficient to grow crops, much exceeding those grown upon an average on the soils of the United States! Such are the results obtained on a soil without vegetation. In our permanent wheat fields we have ordinary drain pipes laid at three feet from the surface, and whenever sufficiently heavy rains occur for the drains to run, the water is collected and analyzed. Portions of this field receive an application of salts of ammonia, and other portions nitrate of soda. If a heavy fall of rain takes place within a day or two of the application of these manures, the drainage water from the plot which received the nitrate will contain a large amount of nitric acid,

while the drainage water from the plot which received salts of ammonia will contain very little ammonia or nitric acid. Your correspondent may possibly say that the nitrate has not had time to assimilate with the soil. This idea will not, however, explain the facts which I am about to relate. In a few days the drainage water from the soil which receives ammonia will begin to yield large quantities of nitric acid, and if the two manures are sown in the autumn with the wheat, and there is sufficient rainfall during the winter, by far the largest part of the nitrogen, applied in the ammonia and nitrate, will be found in the drainage water. On the other hand, if the drain runs in the summer, when the wheat is in the full vigor of its growth, the water contains no nitric acid whatever, though at other times, even on those parts of the field where no substance containing nitrogen has been applied for forty years, nitric acid is always to be found in the drainage water. The only explanation that can be given of these results is that ammonia, on its first application, becomes fixed in the soil, but rapidly becomes converted into nitric acid, which is perfectly soluble in water, and forms no combination with the soil. A great deal of our time of late years has been spent in tracing the course of this substance through the soil and subsoil, and in some instances our analyses have reached the depth of nine feet from the surface. Some of our agricultural plants have very deep roots, and as plants evaporate an enormous amount of water during their growth, it is certain that water, and any salt dissolved in the water, must be drawn up from below the area of the roots.

It is a fact about which there can be no doubt, that while some important ingredients of the food of plants are retained by the soil with great tenacity, others are perfectly soluble, and are only fixed by the vegetation growing on the surface. It is the plant, therefore, and not the soil which prevents the escape of the soluble substance; and we see in this a beautiful explanation of the fact, that the operation of nature is always to cover the soil with vegetation of some kind, while man, to supply himself with food, grows annual plants, the result being that the soil is left bare of its natural clothing for several months in the year. I have more than once pointed out that the exhausting character of grain crops is due not only to the ingredients which are removed in the crop, but also to the loss of those ingredients which the crop has failed to take up; these, in the absence of vegetation, are washed out of the soil. When we find nitrates existing in the sea, in all springs and rivers, and passing through all fertile soils, while they are absent in barren and rocky soils—such as are often found in the highlands of Scotland—and when further, it is borne in mind that European agriculturists spend millions every year in the production of nitrate of soda, we cannot either deny the importance of this ingredient as a food of plants, or the fact of its solubility in the soil. The changes which take place in the organic substances in the soil; the extreme solubility of the nitrogen as it exists in such forms of vegetable matter as coal or peat, and the various changes which occur before it assumes its ultimate acting and soluble form of nitric acid, are likely to occupy the attention of those who study the science of agriculture for a long time to come.

In the slight outline I have given of what I venture to think is more in accordance with the laws of vegetable growth in relation to the food in the soil, than the views brought forward by your correspondent, I trust that he may equally see, so far as they are in accordance with the truth, the impress of infinite wisdom in which the world and all things in it were created.—*Southern Planter*

BUCHU-PAIBA,

Quick, complete cure, all annoying Kidney, Bladder and Urinary Diseases. Druggists.

W. E. Smith & Co., Madras, Sole Agents.

* Yes; and we feel more and more convinced that the anomalous "mortifying" disease which attacked cucalypti and cinchonas in Ceylon in 1882 was mainly to excess of salt in the excessive rainfall.—Ed.

DESTROYING WEEDS ON WALKS (J. C., Cheshire).—A short time ago several methods were described in the Journal of destroying weeds on walks. Salt is only objectionable by making some walks too moist. In the case of dry walks and positions this objection vanishes, and applied in dry weather salt is effective. Arsenical solutions will kill weeds. Boil 1 lb. of powdered arsenic and 2 lb. crushed soda, then dilute with seven gallons of water. Add one part of common vitriol to thirty parts of water, mix and apply. Mix an ounce of crude carbonic acid to each gallon of water prepared, and with this water the gravel. Petroleum will kill weeds; the quantity to use you can easily ascertain by experiment. Whatever is used, Box or Grass edgings must be protected.—*Journal of Horticulture.*

THE SWEET POTATO.—The editor of the *Charleston News* says he has always been of the opinion that the great value of the sweet potato crop in the Southern States was not duly appreciated and sufficiently utilized. Root crops are always more prolific than grain crops. They exhaust land less and give more in return for labor and manure. Of course they are not as nutritious pound for pound, as grain, but in great increase of material they yield more nutrition to a given quantity of land than any of the cereals. [N. B. as regards Ceylon.—Ed.] Irish potatoes, turnips, beets, carrots, both in Europe and in our Northern States, are all justly prized as the most valuable of farm crops. The sweet potato is superior to them all as food for man and beast. It may be used for all the purposes to which the others are applied, and for many others besides. In the first state, just out of the ground, it makes an excellent substitute for arrowroot by grating the pulp into water and allowing the starchy matter to subside. As a vegetable, it is a favorite on every table, cooked in great variety of ways. As a desert it makes a better pudding or pie than a pumpkin. It is good food for a stock of all kinds—horses, cattle, sheep and hogs. We know an old planter once who always raised an abundance of corn and other provisions for his stock, but who was an enthusiasm over the sweet potato crop, estimating it, on the yield returned from the labor bestowed as of more value than any other food-producing crop.—*Southern Planter.*

SPORES FLOATING IN THE AIR.—Those who are puzzled to understand how poeas of *Hemilea vastatrix* get into the stomata of coffee leaves may find some help in the following statement quoted in a recent lecture:—

It was not till 1870 that the systematic observations of air-borne spores was commenced at Mont Souris by Dr. Miquel. Taking the average of the four years, 1879-82, Dr. Miquel found that each litre of air contained from 12 to 15 spores, and that, in general, they were slightly more abundant during hot years. The effects of season were well marked. Thus in winter there were 6.6 spores per litre of air; in spring, 16.7; in summer, 22.8; in autumn, 10.8. By means of a most ingenious registering aeroscope, Dr. Miquel has been enabled to observe the hourly fluctuations in the number of spores. This fluctuation is very great indeed, and the causes of it are not always apparent. One fact seems to come out clearly, viz., that a fall of rain has the effect of partially clearing the air of spores for a time. The causes of the hourly fluctuation are, according to Miquel, mainly two, viz., remote and local. Let us imagine a mass of air travelling from north to south. Coming from regions of ice, and originally very pure, it strikes a continent, and the mass of air which impinges on the soil makes almost a clean sweep of floating spores, and largely enriches itself at the expense, as it were, of the masses of air following in its wake. Thus the richness in spores diminishes as long as the air blows strictly from one direction. Among local causes of variation may be mentioned the neighbourhood of great towns or other centres of spore productions. Again:—Spores of cryptogams are the most common of all organic particles found in the air.

WOODEN LABELS FOR TREES.—A correspondent writes:—I don't know how they preserve the wooden labels used at the Botanical Gardens at Peradeniya, but here is a method which seems to have been attended with success elsewhere:—The following method of preserving wooden labels that are to be used on trees or in exposed places is recommended:—Thoroughly soak the pieces of wood in a strong solution of sulphate of iron; then lay them, after they are dry, in lime water. This causes the formation of sulphate of lime, a very insoluble salt, in the wood. The rapid destruction of the labels by the weather is thus prevented. Bass mats, twine, and other substances used in tying or covering up trees and plants, when treated in the same manner, are similarly preserved. At a recent meeting of the Horticultural Society in Berlin wooden labels thus treated were shown, which had been constantly exposed to the weather during two years without being affected thereby.

DESTRUCTIVE ORGANISMS IN THE AIR AND THEIR INFLUENCE ON HUMAN HEALTH were thus noticed in Dr. Poore's lecture on climate and health before the Society of Arts:—

Seeing how omnipresent are the micrococci, bacteria, and bacilli, of which we have been speaking, how they infest the air, the soil, the water; and seeing again that it is an undoubted fact that the organisms of disease may live and grow in suitable putrescible liquids outside the human body, it is almost a matter of surprise that we are any of us alive to discuss the question. From what we have been saying, however, it appears that for the flourishing of infective organisms three things are necessary, in addition to the organism, viz., some degree of warmth, a suitable condition of moisture, and a "soil" apt to grow the organism. It is when we get the coincidence of all the conditions that we get the disease in its marked form. The cold of the Arctic winter seems to be sufficient to prevent putrefaction, and to prevent the spread of many of the zymotic diseases. In tropical countries, where putrefaction flourishes, zymotics flourish, and if we want to enjoy health in hot countries we must exercise the greatest care and circumspection in dealing with all putrescible matters, whether excremental or otherwise; finally, it is only unhealthy persons who become a prey to parasites, and a healthy man is probably more than a match for most of the so-called pathological organisms.

MR. FORBES' residence for three weeks in the Keeling Islands enabled him to note what changes had occurred since Darwin's visit nearly half-a-century earlier. These are very slight, and seem incompatible with the theory that any subsidence has taken place, because the inner margin of some of the islands next the lagoon are sometimes half-a-mile distant from the outer edge, and the greatest cyclones do not carry the coral debris nearly so far. It is now generally admitted that the celebrated "subsidence theory" of the formation of atolls and barrier reefs is unsound as a general explanation of the facts; yet it so fully and plausibly explained all the details of coral structure known at the time, as to command universal acceptance and unbounded admiration. We have here a remarkable instance of the danger of founding a general explanation of widespread phenomena on an assumed basis, for the fact of long-continued subsidence, which was its very foundation of the whole theory, was in most cases quite incapable of proof. It is also now apparent that the theory was to some extent inconsistent with the views as to oceanic islands which Darwin himself originated and which are now generally admitted to be sound. His great argument, that no single oceanic island possessed ancient stratified rocks or contained a single indigenous mammal, was equally an argument against the view that the widespread coral archipelagoes of the Pacific and Indian Oceans were due to the subsidence of co-extensive tracts of land, since it is almost impossible that all the higher points of these submerged lands, spread over nearly half the surface of the globe, should be without exception of volcanic origin.—*Nature.*

IS COTTON AN AMERICAN PLANT?—Mr. Bourke, in the *Snake Dance of the Moquis of Arizona*, p. 244, says:—"The Tunis weave the same kind of cotton mantle, but do not grow the fibre, preferring to buy this from the neighbours, the Moquis, whose fields, exposed to warmer suns, have yielded the precious bolls from generations long prior to the advent of the Spaniards." He also (p. 241) refers to Davis' *Conquest of New Mexico*, p. 100, which speaks of the inhabitants possessing "blankets of cotton." I always understood that Cotton was an Old World plant used on this side of the Atlantic centuries before American was discovered, and that the first Cotton ever sent from America to England was a little lot, the fill of a woman's apron; as that was approved of, the next shipment was one bale from, I think, Savannah. But if Cotton was an Old World plant how could it be used in the New World "centuries before the advent of the Spaniards"?—J. R. HAY.—*Gardeners Chronicle*.

CULTIVATION IN ALGERIA.—The cultivation of cereals in Algeria is declining, in consequence of the irregularity of the crops, due to the uncertainty of the seasons. A series of good years, it is stated, is often succeeded by draughts, when the agriculturist hardly gathers in the amount of corn he has sown. Competition abroad is so great that he cannot obtain remunerative prices for his produce, and in some places, where the land is best, the means of communication are so defective, that it will hardly pay the Arab to take his grain to market. Near the sea the production of early vegetables and fruit for the markets of Europe promises to be successful, but beyond all doubt the great hope of Algeria is in the Vine. The gradual recovery of this plant from Phylloxera in the South of France will probably prevent the colonists in Algeria from making as rapid fortunes as appeared probable when that scourge first commenced its ravages, but there is every chance of the wine of Algeria commanding a remunerative price both at home and abroad. There is no reason why the European should not imitate the Kabyle, who cultivate his small patch of mountain land with care usually devoted to an orchard or market garden.—*Gardeners' Chronicle*.

THE CINNAMON FLOODS.—The dictum of the late Charles Marsh that forests affect rainfall, long implicitly received, is being queried in many quarters, and in none more emphatically than in the new issue of the *Journal of the Natural History Society of Cincinnati*. The devastating floods of the Ohio of February last have awakened scientific inquiry, as well as popular alarm. And it appears that they are but one of a series, happening periodically since 1774. They have been of greater frequency in later years; but it is only when the river has reached a depth of fifty feet or more that destruction to life and property has supervened. Last year the river rose from a depth of 15 feet in January to that of 65 feet in February, but it gradually subsided to 25 feet deep at the end of that month. On fifteen occasions from 1779 onwards, there have been parallel sudden rises to such a height as that mentioned above, and these have been usually accompanied with signal destruction, human and otherwise. Dr. Dun, the author of the paper, treats his subject in minute statistical detail. He has further been indulging in European travel, during which he has seen the great floods of the Rhine and Danube, as well as of the Po, in 1852, all occurring in countries where the strictest forest conservancy prevails. He holds, then, that the mere planting of the headlands of the Ohio would not prevent floods. The Ohio valley is the track of both warm and cold storms, one setting coming from the Mexican Gulf, the other from the North-West. Hence the snows and rains causing flood. Of course it is not proved that forests might not ameliorate such climatal conditions. Only the natural configuration of a country must be taken as the main factor in aridity or rainfall, however these may be modified by secondary influences.—*Journal of Forestry*. [This is the sober truth of the matter.—Ed.]

PALM-NUT MEAL is commencing to be more extensively employed for stock fattening. For pigs, it is generally mixed with boiled roots or potatoes; sometimes a handful of oats or barley is added to give a flavor; salt is never forgotten. One farmer recommends, whenever the occasion offers of a horse being slaughtered, to secure a quarter and make it into soup to wet the pigs rations. Maize, pumpkins, and Jerusalem artichokes, with the nut-meal, make appetizing feeds for hogs.—*Paris Cor*.

TOBACCO IN BANGUEY.—The German Borneo Company have made considerable progress since they commenced operations some five months ago. On the 20th ultimo, H. E. the Governor, accompanied by Mr. Herrings and the Colonial Secretary, visited the estate and were received by Mr. Lind, the manager, and by whom the party were conducted over the clearings which at present extend over some fifty fields, of which about thirty are under cultivation. Mr. Herrings, who was formerly a Director of the Deli Maatschappij Tobacco Company—a company whose success has been remarkable dividends of as much as one hundred and thirty per cent per annum having been declared—expressed himself well satisfied with the appearance of the plants remarking, that they looked strong and healthy, with a large leaf. A fair bullock road some sixteen feet wide, and about three quarters of a mile long, runs from the landing place at Limbuak to the plantation. Altogether the German Company are to be congratulated on their encouraging prospects especially having regard to the fact that planting was commenced somewhat late in the season. Mr. Herring having completed his visit of inspection returned to Singapore on the same day *en route* for Berlin, but he proposes to return next year with a view to opening up planting on a considerable scale. He has recently been making a tour round the tobacco growing countries, amongst others Sumatra, Java, Philippines and Sulu, and it is satisfactory to learn from a gentleman of his experience that the Banguey tobacco promises to compare favourably with the best samples of the countries referred to.—*North Borneo Herald*.

HOT WATER TREATMENT FOR PLANTS.—A correspondent calls our attention to the following from the *Garden* and inquires whether there is anything in it:—"The *Florist* asks, Has any one tried hot water as a restorative for sickly plants, and then proceeds to say that M. Willermoz some time since related that plants in pots may be restored to health by means of hot water. Ill health, he maintains, ensues from acid substances in the soil, which, being absorbed by the roots, act as poison. The small roots wither and cease to act and the upper and younger shoots consequently turn yellow and become spotted, indicative of their morbid state. In such cases the usual remedy is to transplant into fresh soil, in clean pots, with good drainage, and this often with the best results. But his experience of several years has proved the unflinching efficacy of the simpler treatment which consists in watering abundantly with hot water at a temperature of about 145 degrees Fahrenheit, having previously stirred the soil of the pot so far as may be done without injury to the roots. Water is then given until runs freely from the pots. In his experiments the water at first came out clear, afterward it was sensibly tinged with brown, and gave an appreciable acid reaction. After this thorough washing the pots were kept warm, and the plants very soon made new roots, immediately followed by vigorous growth." To our mind there is a great deal in it. We know to a certainty that sickly peach trees are often restored to vigorous health by the old fashioned German farmers of Pennsylvania by pouring boiling water on the ground about the peach trees. It cools, of course, somewhat before reaching any of the roots. Here, however, it is believed to be beneficial by destroying parasitic fungi. But, let the reasoning be what it may, we are willing to indulge it as good practice.—*Gardeners' Monthly*.

TEA AT A HIGH ELEVATION IN CEYLON.

Ground covered with tea in full leafage, particularly when the landscape features are undulating, is a pretty sight; but for continued and varied beauty old coffee certainly bore away the palm. "Handing" and even pruning in the case of coffee left the soil still well covered, and to luxuriant and handsome foliage were, in due season, added the snow-white and jasmine-scented blossom, and the green, yellow and ruby-red shades of the fruit contrasted with the green of the leaves. But, excepting the few bushes preserved as seed-bearers, tea is not allowed to blossom or fruit, and when the time for a thorough pruning comes there is such a cutting down and away of wood, that, at any distance, the soil looks as if it had been completely bared. In from two to three months, however, the close carpeting of golden green is restored, and the process of picking goes on until the cutting-down time has come round again. Simultaneously with the pruning of bushes of good age, the stems have to be rubbed clear of lichens and mud, by means of the naked hand or the hand aided by a bit of sacking. The stems of the coffee trees would be rubbed also were it worth while to bestow further labour or expenditure on a cultivation which was once reckoned our mainstay. A visitor fresh from the eastern side of the range, where coffee is still worth cherishing, said to us a couple of days ago: "Surely you will preserve that fine-looking coffee." The answer was to point to the miserable sprinkling of berries at distant intervals amongst the really luxuriant foliage. Amidst the crop of leaves the fungus had to be searched for, but so had the fruit, and as the leaves cannot be converted into a merchantable and profitable product, the fine-looking coffee must go, however severe the pang may be of parting with what, if *Hemileia vastatrix* had not so fatally intervened, would be now in its prime of crop-yielding. The final decision to uproot the old product in favour of the new must be much more trying in these young districts than in the old, where coffee did not fail until for more than a generation it gave paying, in some cases largely profitable, returns. But the decision must be arrived at and carried out, to prevent the tea bushes planted, amidst coffee growing up feeble and spindly. The branches and leaves of the coffee bushes will be buried, while the stems go to feed the tea furnaces,—the old king being cremated, in fact, to the tune of *requiescat in pace!* Peace be to its ashes, with their appreciable proportion of lime extracted from a soil, the ferruginous nature of which renders it far more favourable for tea than for coffee, although the latter grew well enough and would have yielded fruit as well as leaves, had the enucleating fungus not been developed in 1869. To be at first made light of, but finally recognized as one of the most disastrous blights which has ever depressed, if not quenched, a great, advancing and prosperous enterprise. Java and the whole Eastern world are rapidly following in the wake of Ceylon experience, in this matter, and it really looks as if those of us who can afford to indulge in the luxury of a cup of coffee must ere long pay the cost of having it imported from the Western Continent. Let us fervently hope that no such dread visitation awaits the now most promising tea enterprise.

Some readers of the *Tropical Agriculturist* may recollect notices of plants, the result of seed obtained from Assam as "indigenous." The plants were put out along the sides of estate paths, at elevations rising from 5,200 to 5,500, in July 1880, and until now their progress has been so slow and unsatisfactory as to lead to

the belief that indigenous Assam tea was unsuited to the climate of this altitude. But whether it has arisen from the recurrence of several genial seasons, or that the plants have, at length, been able to adapt themselves to the conditions of their new situation, certain it is that they have taken a spring and promise to make up for lost time. They are, in common with the superior hybrids amongst which they are scattered, putting forth luxuriant foliage, many of the leaves being large, corrugated and serrated after the marked characteristics of indigenous Assam tea. The progress and comparative yield of these plants will be watched and reported on. Meantime I may mention that the effect of altitude even on hybrid tea bushes is, that some allowed to grow up as future seed-bearers show not the slightest sign of any tendency to blossom, although they are now eight to, in a few cases, ten years old. With similar trees in the hot low country, only a few hundreds of feet above sea-level, the difficulty is to contend with the persistent tendency to run all their strength into flowers and fruits.

Could the conjunction be made to pay, our experience is decisive in favour of growing cinchonas (especially *C. officinalis*) amongst tea, which evidently benefits the fever plants by opening up and draining the soil. But bark prices recently have been such as to make cinchonas stink in the nostrils of planters, almost as much as coffee; indeed more so, because hopes of retrieval were so largely based on this new and at one time most hopeful product. A large proportion of planters will, of course, harvest and market the bark from all their cinchona trees, ceasing to supply the soil with any more. The result may be profitable prices to those who can hold on. Many who would hold on cannot, because at a certain stage the choice must be made between tea and other cultivation—not only coffee but cinchonas. We suppose it is this desire to do full justice to the tea plants, which has led to the ringing of so many encyclipti in the neighbourhood of the Nannuwa station. We take it for granted that the trees which have suddenly changed their hue from bluish green to yellowish white have been ringed, preparatory to their removal. So opinion changes. The blue-gums were and are still believed to be beneficial as wind-breaks and soil-drainers in cinchona fields; but tea, unless it makes an exception in the case of the sau tree,

"Bears, like the Turk, no brother near the throne."

CEYLON UP-COUNTRY PLANTING REPORT.

28th Sept. 1885.

Coffee—what there is on our side—is not looking very promising. There was such an attack of leaf-disease some time ago, that the trees are now left pretty bare, whereas the ground is thickly littered with fallen leaves. When the regular heavy rains of the north-east set in, the drains will amuse us. There is a little coffee ripening up; but the blackening at the points is as excessive as ever in was. Half-a-bushel picking of this sort of stuff, has been gathered at a cooly-sack of cherry, has been gathered at the first round, and even a worse result in some places. The husk is not so empty as one would have expected from the long dry weather and may nett something above the cost of gathering, now that the rupee has fallen among the despised things of the earth. Black-bug seems to be checked somewhat; still it's about, and evidently ready to wipe out what little of the old product remains at the slightest encouragement.

I saw an analysis of some renewed *Succirubra* bark grown on Fairicland estate—just above Kandy—which

showed the handsome figures of 4-35. It is somewhat of a surprise to authorities that at so low an elevation such a good result could have been attained.

Cacao still keeps looking well, and if the fine blossom out is any promise of what the crop in the early months of the year will be, there are good prospects ahead. But then it is such an uncertain, treacherous product, and has so many enemies, that one is afraid to build one's hopes on aught else than the nibs in store. Even the yellow variety, which has been admitted to be so much more robust than the red, does not seem as if it were to escape molestation from the everyday enemies of the cacao. I saw one tree lately every pod on which had been badly punctured by a sucking bug of some kind, if indeed it was not *helopeltis*. It did not seem to have injured the nibs inside, but it could not have done them any good. It will be rather disgusting if what were thought the strong varieties are going to turn out like the disease-resisting Liberian coffee a sell after all.

I have heard it stated by one who ought to know that the variety which we call "Caracas" is really not the true thing, but that it is actually the red which we have growing here, and which is so sensitive to blights of all kinds. It seems that about thirty years or so ago the red was pretty universal in the West Indies, but that it was almost wiped out by some blight or another. It was then replaced by the stronger varieties, such as have lately been imported into this island. The red kind so common with us came from the West Indies before the yellow had taken its place. The full plump bean and fine flavour of our cacao is also said to have been a peculiarity of the true "Caracas," whereas what now goes by that name has a flattish nib, and does not win the London buyers as the other does. Of course, it is only speculation yet, but nevertheless a very interesting one.

I trust it is an exaggeration, but I was told of an unfortunate planter who at the beginning of the late dry season put out 80,000 tea plants, all of which or nearly so have succumbed. Even if it were half as bad, it would be distressing enough; and still the last six weeks have been very disastrous, will, I fancy, be remembered for a long time to come.

PEPPER CORN.

PLANTING IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

Coffee estates in Java have of late been sold for an old song owing to low prices and leaf-disease. The Home Government has directed the authorities there to be less forward in shipping coffee to Holland owing to the depressed condition of the market arising out of the enormous over-production of that article in Brazil. The outlook is gloomier still from the hopelessness of any change for the better in a great many coffee estates in Mid Java where *Hemilea Vastatrix* has got firm foothold.

A disease called *Sereh* which by destroying the roots of growing cane in Cheribon, was threatening the sugar industry there with ruin bids fair to be of a fleeting nature owing to diseased plant cane having produced healthy canes, thereby showing that *sereh* arises from something in the environment or in the soil.

The Sourabaya Courant of the 27th August, recommends as an unfailing remedy for snake bite the juice of the papaya fruit dropped on the wound. The venom becomes speedily sucked up by that milky fluid thereby warding off the deadly consequences of the bite.

By last advices from Java (12th September) the Treasury is so short of cash that in some districts the land tax began to be collected in August instead of in November when it legally falls due, to the great inconvenience of the cultivators whose minds such fiscal exactions render more open to the seditious influence of Zealots and fanatics who leave no stone unturned to stir up a spirit of disaffection against the Government. Their efforts are seconded by a secret Mahomedan sect which is steadily gaining ground especially in west Java, where even native headmen have shown signs of fanaticism. So far the Government has taken no notice of the movement, at least no action is taken against the fanatics, though it is manifest that by taking precautions in time more rigorous measures hereafter will be avoided. The Samarang *Locomotief* of the 26th August points out that, in these times of screwing up taxation, it would not be amiss to take into account that it is one-sided and wrong to have only fiscal gain in view. Care should be taken not to arouse discontent among the people, from fanaticism differing as it does from devoutness, being highly dangerous in Netherlands India as nobody acquainted with both country and people can deny. At present the mischief done is so slight as to be easily remedied, but if the foretokens of danger are disregarded, the responsibility for consequent disaster rests on the Government.

THE CULTIVATION OF TEA IN CEYLON.

To show what a London "City man" interested in tea generally thinks of Ceylon and its new staple products, we publish the following contribution handed to us a short time ago. The writer evidently possessed himself of a copy of our "Tea Enterprise" pamphlet and proceeded to give a summary from a rather sanguine point of view of the prospects before the investor in tea in this island. He stops short before coming to the working out of his estimate, but this may follow in a second paper. The chief point is that this contains the ideas (after perusing Ceylon reports) of one who has had long experience in Indian tea and "city" business. It is well to see what is thought in such quarters:—

(Communicated.)

In consequence of the ravages of the leaf-disease, or coffee fungus, among coffee plantations in Ceylon, and the partial failure of the cinchona industry, estates and land can at present be purchased at very low rates in the cultivated districts of this island, and land is still obtainable from Government at the moderate upset price of £10 (16s) per acre, but the suitable and desirable portions have now mostly been taken up; and of these latter, I am told, Government are disinclined to make any large grant, and I hold a letter from the Ceylon Colonial Secretary, in which he informs me that "the extent now available is limited"; and, however preferable these virgin soils may ultimately prove, great care must be exercised in their selection.

These facts, however, go far to prove that *now* is a very exceptional time for the tea enterprise in the island, more especially for the abandoned coffee estates, or those on which the coffee is

steadily "going out." Also many estates are now in the hands of the mortgagees who are only too desirous of realizing, and in some cases accepting even a loss rather than continue in having their resources locked up in a distant country.

The climate of Ceylon has proved itself simply perfect for the growth of tea, the bushes actually "flushing" all the year round, whilst in India this only occurs, generally speaking, during some 7 months out of the 12, the result is that here we get a most extraordinary crop, some estates raising their returns up to 1,000 lb. of made tea per acre. I propose, however, to base my calculation on the very moderate return of 450 lb. per acre. So many causes bear upon this point that it is somewhat difficult: to arrive at a fair average estimate elevation or rather altitude of the land, richness of soil, and rainfall are the principal things that must be considered. In fair average soil on the low-lands or at low altitudes, the planter may depend on 800 lb. per acre; whilst when he may plant 2,000 ft. to 3,000 ft. higher, his return per acre will probably be reduced to 500 lb. to 600 lb., and then another 1,000 ft. or 2,000 ft. to about 400 lb. to 500 lb. per acre. What he loses in quantity, however, he is likely to gain in quality, for the hill teas undoubtedly possess generally more "bloom" or aroma than those grown on the low-lands. However, in taking 450 lb. per acre, I think I am well within the mark.

As to quality, Ceylon teas have already with their limited import of some 2,500,000 lb. made such a name for themselves on our London market, and are getting so generally appreciated by all who can find the opportunity of securing them "pure" (that is unmixed with other teas), that I purpose merely to state, that from my extended knowledge of teas and the taste of the British public for tea of this character, the more they get known the greater will be the demand for them, and, where they can be procured unmixed with other growths, they will go far to supplant both China and Indian teas: this fact will be found very important, as will be seen from the figures I shall produce further on. The grand peculiarity of well-made Ceylon teas is that they are perfect in themselves, and do not require to be blended with other teas, as do the majority of both China and Indian production—they, of course, at the same time can be successfully used in improving other teas by being blended with them.

The excellent communications by railways, roads, rivers and canals render Ceylon certainly superior to any other tea district in the world, and this fact is enhanced by having the splendid and economical shipping port of Colombo, nearly all Eastern steamers calling there.

The labour in Ceylon is some of the very best that can be procured, Tamil labour, and the supply is inexhaustible, as we have 12,000,000 of this race on the opposite shore of Southern India. These are only too willing to cross over and receive the enhanced pay they command in Ceylon. The present price of labour is about 7d to 8d per diem. In Assam a cooly costs about 1s per diem, after the heavy cost of getting him on to the estate (about £8), and then he is by no means so edicent as the Tamil cooly.

The rainfall combined with the tropical heat of Ceylon alone accounts for the extraordinary growth we see among the tea, the rainfall being so uniformly spread over the year, and not coming in the violent monsoons peculiar to India. This rainfall varies considerably according to the districts: about 130 inches to 250 inches is what may be put down as favouring the tea districts.

The tea plant hitherto has scarcely any enemy in nature, the red-spider, bug and blight being the only ones, but these I find generally only occur where the tea is sickly, or from exceptionally dry weather, neither of which circumstances are likely to occur in this redundant climate. The tea plant itself is a most hardy one, and throws down deep into the ground a long strong tap-root thus sinking deep into the ground for its sustenance, which fact may account for its apparently not exhausting the soil as is the case with coffee, and this enables the tea-plant to be so independent of any drought little as there is any fear of this in Ceylon.

AN AMERICAN PEACH FOREST.

Mr. John H. Parnell, a great American peach-grower, has been letting out some of the secrets of his peach forest, which have more interest as Mr. John Parnell is the brother of another and more famous member of the family, Mr. C. S. Parnell himself. "In my early days," said Mr. Parnell to the correspondent, "I was advised that there were excellent chances for investment in the South, and especially in Georgia. It was my idea that thus located there was money in cotton, so I paid cash down 12,000 dols. for 1,500 acres. To this original purchase I have since added 500 acres, making my possessions 2,000 acres in all. For three years I planted cotton, only to find it a delusion." It was in this fortunate moment that Mr. Parnell made up his mind that there was money in peaches. The great peach forest is described as containing acres and acres of ground, stretching indeed into miles, covered with every variety of tree. The trees, which number 150,000, are planted twelve feet apart, and are kept trimmed to the ground, so that a person standing can pluck the rosy fruit from its fastness. When the first blush comes upon the cheek of the dainty beauties 100 men, women, and children are set to work, each armed with a flat basket, returning to the rendezvous when the bottom is covered. Thus they keep on day after day until the season is over. The story of Mr. Parnell's venture is briefly this:—He invested 12,000 dols. in his plantation. He has spent over 8,000 dols. since in trees, seeds, and labour. Upon this investment he makes from 8,000 dols. to 10,000 dols. a year, and would not sell his peach forest for less than 300,000 dols. Great as Charles Stewart Parnell is as the uncrowned king of Ireland, greater is John H. Parnell, the peach king of America. "I found it necessary to have recourse to English varieties. It was clear that a hard, firm peach which would bear handling would be a gold mine. In 1871 I brought from England 5,000 budded trees—the Beatrice, the Early Rivers, and the Early Louise. I have found that these three varieties meet every requirement. I have developed a hybrid, to which I have given the name of Parnell. This peach is destined to rank in the peach family as the Le Conte does among the pears. I secured it from an accidental seedling. I made my first shipment of this peach five years ago, when it went off at 25 dols. a bushel. I have now seven thousand trees of this variety. It has a dark red skin, white flesh, and is firm and hardy for shipment. The next is the Foster, a peach of yellow skin, saffron flesh, and firm mould. But one crop in three of this peach, however, is fit to ship. Of the Amelia peach, dark-fleshed and brownish red cheek, I have over 8,000 trees. I have spent much time in experimenting, and believe that I have now solved all the difficulties of this neighbourhood. As old trees die I replace them, and also make a regular annual increase of 25,000 trees."

"The worst enemy of the peach orchard," remarked Mr. Parnell, "is the half-taught horticulturist with a pruning knife. There is no doubt but that peach trees understand the art of growing, and should be let alone. The borers will not do as much harm as the man who tries to exterminate them. If a tree yields bad fruit just cut it down and replant. The principal danger, however, is winter killing, which is a misnomer, because the killing takes place owing to the absence of winter. Where no winter comes the sun never sinks. A sudden cold day chills the tree, just as it does a man. I have fully exploded one idea prevalent, that it won't do to plant a new orchard upon the site of an old orchard. Thousands of my best trees are standing upon ground which has been the site of half a dozen previous orchards. Trees set out to the north-east never fail to have fruit. Peaches flourish in alternate years, sometimes one variety and sometimes another. In 1875 there was a wonderful yield of early peaches. In 1878 the crop was equally good, but in 1879 there was a peach famine which caught me two ways. The famine in Ireland deprived me of my rents, and the famine in peaches deprived me of my income here. In alternate years since, with wonderful regularity, the yield has upheld the theory. The earliest shipment ever made to New York was on the 16th of May, and the latest the 10th of August, when the Delaware crop cuts off the Georgia sales."

"The demand for good fruit has never yet been met. I always have more orders than I can fill. New York is the great market, because it is the distributing point, and always offers regular prices. Philadelphia stands next as an Eastern market. Cincinnati is the great peach depot of the West. I once got 25 dols. a crate in Cincinnati. My heaviest shipment in one day was 900 crates to the New York market. Large quantities I send by freight and small quantities by express. In one year I netted 11,000 dols. This year I have already shipped 1,000."—*Pall Mall Budget.*

RICE GROWING AND OTHER INDUSTRIES IN JAPAN AND CEYLON.

The *Hongkong Daily Press* has the following:—"The suggestions made by a correspondent of the *Japan Mail* that there is too much rice cultivation in Japan and that some of the land now devoted to this crop should be put under mulberry and European grain and vegetable crops is well worthy the serious attention of the Japanese Government and people. There is no doubt that among the causes of the inferior physique of the Japanese race, the malaria arising from the rice swamps may be placed in the front rank. With the patient industry and careful cultivation of the Japanese farmer, more remunerative crops than rice could be raised, and the means afforded for a more nourishing and sustaining diet than is at present enjoyed by the mass of the population. The Japanese Government have accomplished something, in an experimental way, towards introducing new industries, but a great deal more might still be done. The attempt to breed sheep in Japan has failed owing to the prevalence of the bamboo grass, which gives the animals lesion of the bowels but could not an effort be made to exterminate this grass in some district or some of the islands in the Inland Sea? It would be a great boon to Japan if this could be done, and it is worth making an effort for. Possibly, too, some breed of mountain sheep not yet tried might be found which would be unaffected by the bamboo grass. Poultry might also we think, be bred successfully on a

much larger scale than is at present the case. There is unquestionably far more poverty in the Land of the Rising Sun than ought to exist. The soil is exceptionally fertile, the people are industrious and ingenious, and there is no waste in their system of agriculture, but nevertheless the vast majority of them live from hand to mouth, and the first failure of crops is sure to plunge them into the direst distress. It is true that only a very small proportion, we believe one-tenth, of the area of the Japanese islands is under cultivation, and that the uplands are almost entirely covered with forest and grass, but more might be made of the available land. The beds of the rivers might be secured against overflow by the aid of engineering science, and some portions of the uplands might be utilised as grazing land if the bamboo grass could be eradicated. The resources of the Hokkaido are as yet undeveloped, and the attempts hitherto made by the Government to open up that valuable island have been too tentative and spasmodic to make much impression. Meantime, the taxation presses heavily on the agricultural classes, and its payment in money instead of produce as formerly aggravates the pressure. The Government must of course have a revenue, and the taxation would perhaps not be unreasonable were the farmers more prosperous. It becomes the duty of the Government, therefore, to help the agriculturists in every way, and this can best be done, as the writer in our Yokohama contemporary points out, by importing fresh seeds from abroad and supplying them at a low rate to the farmers. In any case the cultivation of rice round the towns should be discouraged as much as possible. Wheat, barley, oats, and clover all thrive amazingly in Japan, and almost every kind of useful vegetable can be raised with success, so there need be no difficulty in substituting other products for the rice."

CINCHONA PROSPECTS IN WYNAAD.

To the Editor "*Madras Mail.*"

SIR,—It is about four or five years since cinchona first began to be planted on a large scale in Wynaad, and, at the present day, the whole district is thickly studded with cinchona trees of various ages, and different varieties. In 1880 one paid a rupee apiece for a plant of the *Ledgeriana* species, and now 1,000 of this variety are to be had for R15 to R20. This affords some idea of the strides that are being made in the cultivation of this valuable medicinal product. In South Wynaad, at the present moment there cannot be fewer than five million cinchona plants of different ages. Recent analyses show that spoke shavings from *succirubra* bark from the Vythery district, give two to three per cent of Sulphate of Quinine and fetches 8d to 1s 6d. per pound in the London Market. A *succirubra* tree can be shaved four times in four years with impunity, and will yield at least a quarter of a pound dry bark each time it is shaved; it can then be coppiced, when it will yield as much bark as three shavings. After coppicing the tree will have yielded about 2lb. of bark, which at the very lowest valuation would be worth a rupee a pound, and say the stool is valued at only 8 annas, and it appears that valuing the tree at R18—a figure which would cover a heavy fall in the price of bark—the cinchonas in South Wynaad are worth 75 lakhs of rupees or upwards of half a million of English money. But everything points to a rise rather than a fall in the price of bark. London Brokers value the unit at one-sixth of an ounce of quinine, so that with the unit at 5d. quinine ought not to cost more than

2s. 6d. an ounce in bulk. With quinine at this low price, the consumption should increase enormously with the population. Eastern nations have yet to be educated to its use, and that the Hindoo is beginning to appreciate cheap quinine, is clearly proved by the fact, that enterprising natives are selling quarter ounce bottles in the Wynaad bazaars at 11 a piece. So far as one can see at present, Southern India promises to be the great cinchona producing country of the world, for 5d per unit drives America out of the market. Cinchona will not thrive in the stiff, clayey soil of Jamaica. In Darjeeling the land placed under this cultivation by private enterprise is only about 2,000 acres: so that we are thus left face to face with Ceylon and Java as the two rivals we have to fear. Ceylon planters seem to think that Cinchona leaves them too small a margin for profit to make its cultivation worth their while, and at the last Annual Meeting of the Ceylon Chamber of Commerce, the Chairman, referring to the large exports of cinchona, remarked that this result had only been achieved at the expense of the future, and that they could not, therefore, expect to see exports on a corresponding scale in future years. And it is probable that the exports of bark from Ceylon will never again reach the figure they did this season. Ceylon cannot grow cinchona so cheaply as Wynaad, and the Ceylon planters are now turning their attention more exclusively to tea cultivation. Java is a rival much to be feared, but the long wet season there with its intermittent rain from October to March, and the ravages of *Helopeltis Antonii* may serve as some check on its exports of bark, but it must not be forgotten that Java, with its rich volcanic soil, ought to produce a splendid sample of bark, and the Javanese are the best agriculturists in Asia. The Madras Government, with its 3,000 odd acres of cinchona, stands forth as a formidable rival to private enterprise, and now that the plantations have served their object in encouraging and stimulating the cultivation of cinchona by private individuals, the Government, by putting their estates up for sale, would not only benefit the planting community by retiring from the field, and ceasing to compete with private industry, but if it at the same time threw open the Government Reserve Forests, they would find themselves in possession of some ready cash which might help to make up the Budget deficit. We thus find that, looking at things from an unprejudiced and dispassionate point of view, Southern India bids fair to be the great quinine-producing country of the future, and that probably the part of Southern India where cinchona can be most successfully grown is Wynaad. There is still a large acreage suitable there for cinchona, though not quite adapted for coffee cultivation. When planted with the coffee cinchona costs the planter, if we except a small yearly sum spent in lopping, little or nothing in cultivation, and the idea that cinchona does any harm to the coffee under it, has this year been abundantly proved to be erroneous by the fact that notwithstanding that there is now so much coffee under cinchona, it is being remarked by all old planters that never since the days of leaf-disease has coffee in Wynaad looked so green, so fresh, and so vigorous as now. Wynaad may now be said to have turned the corner, and in the course of a year or so, we shall probably see a great rush of capital into the district: the last four or five years have been trying and anxious ones to all planters, but by their energy in planting cinchona, and the economy practised

in their estate expenditure, they have again proved the truth of the proverb that "Fortune waits for those who have patience and PERSEVERANCE."

THE HAKGALA EXPERIMENTAL GARDENS: CEYLON.

In turning the sharp corner just before coming in sight of the Garden gates the extensive stretch of patna lands of the Uva district suddenly comes in view, and the whole of the district from Idulgashena Gap and Haputale Gap to Nannunakuli and beyond to the Madulsina hills is seen from this point. One hundred yards or so farther on you enter the garden gates, and after passing through the Casuarina and Acacia avenue and turning to the right, leaving the outlet of the new drive to the left, a very fine peep is got of the west peak of the grand Hakgala rock with its almost perpendicular face. The large Wanduru Monkeys are frequently to be seen jumping from tree to tree in the jungle on the top of, and around the rocks, their locality being made known by their peculiar shouting or barking noise. Passing on up the drive and looking to the left a new ornamental piece of water is to be seen, the shrubberies on each side being planted with ornamental trees, shrubs and garden plants. Good specimens of *Cupressus torulosa* are to be seen on the upper side of the drive, and when passing the sharp bend, and looking to the left down the gully, a pretty peep is gained of the water trickling down between banks of native ferns into the sheet of water below.

Rounding the next corner a good specimen of the Flame tree, *Sterculia acerrifolia*, is seen, its trunk being covered with a cream-flowered creeper—*Cobea scandens*, var. *alba*. Close by this are also two good specimens of the Japan Cedar—*Cryptomeria japonica*, and a very fine specimen of *Cupressus macrocarpa*, under which is a branching tree fern, *Hemitelia Walkeri*. This is a well-balanced specimen, with a trunk 5 to 6 feet high and at about 3 feet from the top spring three branches, the largest being about 18 inches long and the smallest fully a foot long, each branch carrying a head of from 4 to 7 fronds. This branching of tree ferns is rather uncommon in Ceylon and very rare in the West Indies.

About 50 yards farther on is the new, or lower, entrance to the Fernery. In the gully to the left there is a very fine clump of young tree ferns the *Alsophila crinita*. Turning to the right into the fernery, and passing a large Fuchsia oed on the left, you come on a piece of rock-work, some 25 yards long, planted entirely with foreign ferns and Begonias, the fern plants being nearly all raised from spores received from England, and among them are to be found some good specimens of the fine-leaved *Adiantums*, or maiden hairs, and one very rare and beautiful *Gymnogramma*, *Gymnogramma schizophylla*. At the top corner of this rock-work is a healthy young plant of the Nilgiri tree fern, *Alsophila latebrosa*. Crossing a path here and going into the body of the fernery a very fine group of the native tree fern, *Alsophila crinita*, is to be seen, with trunks 18 to 20 feet high, and one specially fine one in the centre has a large graceful head of fronds of fully 15 feet in diameter. About 15 feet from this on the upper side is a healthy young specimen of the New Zealand silver tree fern, *Polystichum dealbata*. The under side of the fronds are of a very light glaucous colour which is in striking contrast with the dark green above. The fernery contains about 8,000 plants of ferns, the greater part of these being native, planted among them and beside the nu-

merous winding paths, are such plants as Begonias, Primroses, Cowslips, and a few other plants, including several of the native terrestrial Orchids and on many of the trees, which are left for shade, are fixed epiphytal native orchids and lycopods.

Passing out of the fernery down a path some 40 or 50 yards long with rock borders on each side, planted with similar plants to those in the fernery, and looking to the right just before leaving this, two young plants of Australian tree ferns *Dicksonia antarctica*, are seen, one on each side of the rivulet which crosses underneath the path at this point. These tree ferns, although they are young ones, show how very much stouter the Australian tree-ferns grow than those in Ceylon, though for grace and beauty it is hardly possible to beat the Ceylon species, *Alsophila crinita*, which Col. Bealdome, the illustrator of the Ferns of British India and Ceylon says is the finest of all the Asiatic tree ferns.

Coming out into the drive again the visitor comes to the junction of four ways, and on turning down to the left for about 30 yards a handsome plant of the John-Crow-bush of Jamaica, *Bocconia frutescens*, is seen. The foliage is in shape very like that of the jakwood tree, but is much lighter in colour and is softer. At the present time this plant, which is about 12 feet high, is loaded with over two dozen large bunches of flowers and fruit, the bunches being from 1 to 2 feet long. Retracing this 30 yards and continuing up the road to near the superintendent's bungalow and looking to the right, near the thermometer shed, is to be seen a large handsome specimen of *Pinus longifolia*. This tree is 40 to 50 feet high and its long needle-shaped leaves—10 to 14 inches long and 1 line broad—make it quite a feature in this part of the garden.

Running parallel with the superintendent's bungalow is a terraced flower-garden with the beds cut out in turf and planted with such plants as pansies, violets, geraniums, verbenas, phlox, petunias, mignonette, &c., &c. Passing on across the flower-garden and up the steps the propagating-house is reached. This house is filled with a great variety of plants, chiefly in the rearing stage, and a few stock plants of tender kinds. A curious and interesting fern will be noticed hanging up in the middle of the house. This fern, *Platycegium grande*, is known by the name of elkhorn fern. The top part of the frond very much resembles the horn of the elk. Among other interesting plants here is *Osmanthus ilicifolius*, a Japanese shrub with leaves exactly like those of the variegated holly. From the path in front of the propagating-house a good view is obtained of the rose garden and some very pretty peeps of the Uva and Badulla mountains. Turning to the right near the flower-garden the path leads to the plant sheds, three in number, which are filled with a great variety of plants for distribution. To the right of these sheds is a bed of the medicinal jalap, *Eragrostis purga*. It grows and flowers remarkably well, but does not make many tubers, which, of course, is the main thing from a commercial point of view. The elevation is evidently too low. It is, however, a very pretty creeper and grows rapidly. A little further on from this is the nursery garden in which a large stock of plants are kept in beds for distribution of ornamental trees, fruits, shrubs and garden plants.

Near this nursery, growing over a large rock, is a large plant of "cho-cho," *Sechium edule*, a vegetable resembling a vegetable marrow, recently introduced from the West Indies. The plant is thoroughly established and promises to become a very useful addition to the mountain vegetables; the same may be said of the "arracacha," *Arracacha esculenta*, which is growing near by. Also near this arc

plants of the "tree tomato," *Cyphomandra betacea*, which is thriving very well indeed, plants only a little over 18 months old are 9 ft. in height and bearing a good crop of fruit. A short path from the nursery leads into the rose garden, which is laid out in a large circle and planted with about 80 different kinds of roses. Opposite this is a bank planted with 120 different kinds of trees and shrubs, among which is the English laurel, lilac, laburnum, box, heath, berberis, broom, strawberry tree, winter bark, red trumpet tree, azalea, black and red currants, &c., &c.

Going down the path from the N.E. outlet of the rose garden and crossing the new drive and on down the little path for about 80 yards, the visitor comes to the picnic arbour which faces the Uva country. More of the Madulsima hills can be seen from here than from any other point in the garden. The tops of the church and new mission-house at Haputale can be distinctly seen from this, and the road winding through the rolling and beautiful Uva panasas to Badulla can be made out in several places. Looking to the N.W. from this point is to be seen a fine stretch of unbroken forest which is in great contrast to the panama view looking to the east and south-east.

Turning back over the same ground into the new drive and crossing it again, and going on along the winding path through the shrubbery towards the little summer arbour, and when about half way, looking to the right, is a large specimen of the Abyssinian Banana—*Musa Ensete*—with leaves 10 to 12 ft. long and two feet or more broad. The midrib of these large leaves being a deep red colour sets off the leaf to great advantage. This species is said to be the largest Banana in the world, a full grown plant has a trunk some 20 ft. high and leaves from 16 to 20 ft. long. The bunch of fruit is large and handsome but is not edible. Near this are some young plants of the West Indian "Cherimoyer"—*Annona Cherimolia*—a delicious fruit, in size and shape like "Sweet Sop" but very superior in flavor to that fruit, and said by the Creoles of the West Indies to be the most delicious fruit in the world. It is also by some called the forbidden fruit of the Garden of Eden. A hundred yards or so from this is a plant of the true English Oak, and a few yards farther on, the ornamental pond, and the sexangular shaped arbour is reached. The arbour is covered with Chinese honeysuckle. Looking across the water a very fine view of Hakgala twin rock is obtained. This is one of the prettiest spots in the garden, the reflection of these rocks, which are 1,500 ft. higher than the pond, is often very plainly to be seen in the water. Planted round the pond are several interesting plants, among them being the wedding flower—*Morua Robinsoniana* so named by Mr. Moore of the Sydney Botanic Gardens in honor of Sir Hercules Robinson—from Lord Howe's Island, very like a gigantic Iris; one flower spike contains from 120 to 200 blooms which come out a few at a time but only last 24 hours; the plant is in flower for several months. *Cereus giganteus* is another interesting plant here which flowered freely last year and is again showing a number of flower buds. The flower is about six inches in diameter, white and sweetly scented, but unfortunately it opens in the night and the beauty is all gone by 9 or 10 o'clock in the morning—other plants to be noticed here are Mountain Papaw—*Carica andinauracensis*—the common and variegated New Zealand flax and the tree fuchsia—*Fuchsia arborea*, which when in flower is very much like the lilac and has often been taken for that plant. Leaving the pond to the right, taking the path to the left the visitor again enters the new drive, and just

before entering the old drive which leads back to the entrance gate a very pretty bit is seen looking up the new ornamental piece of water, which is 160 ft. long, at the end of which is a very handsome clump of tree ferns, and looking round in the opposite direction the Matulsima mountains are again to be seen. The Eucalyptus plantation is situated a short distance above the fernery and is reached by a path leading from the N.W. side of fernery. The plantation is planted up with small clumps of between 10 and 50 different kinds and is interesting as containing young plants of some of the largest trees in the world. The "Kauri Gum"—*Eucalyptus collosca*—and the narrow-leaved Peppermint Gum—*E. amygdalina*—have been known to reach a height of 400 ft., and to measure in girth at a yard from the ground 75 to 100 ft. The wood of these and several of the other species grown here is exceedingly strong and very durable. Other interesting species are *E. Gunnii*—the Tasmanian Cider Tree or Swamp Gum of Gippsland, *E. leucocylon*—Victorian Iron Bark, *E. marginata*—Jarrah or Mahogany Gum, *E. piperita*—Peppermint Tree, *E. riminali*—Victorian manna Gum, and *E. citriodora*—the Lemon-scented Gum. W. Nock.

THE LONDON COFFEE TRADE.

At the Commercial Sale Rooms, Mincing Lane, on Sept. 14th a very numerous attended meeting of coffee importers, buyers, and brokers was held to consider the position of the coffee trade in London. Mr. Peat, the chairman, stated that coffee was an important item in the commerce of the world, and especially in the commerce of England; but he was sorry to say that England did not now occupy that high position in reference to coffee which she used and ought to do, and she did not do the fair proportion of the trade to which she was entitled. That was apparent to any one who would compare the total stock of coffee in Europe at any one time with that which came to the port of London. He found that in 1882 the total stock of coffee in the chief ports of Europe was 175,571 tons, and of that London had 28,000 tons, which was a very small proportion. But in 1885 that proportion was still less; for while in the chief ports of Europe there were 217,929 tons, in London there were only 20,000 tons. That very considerable falling-off was due to a variety of causes, and while they had no remedy for some of these causes, he thought they had for others. If there were any regulations in the terms of commissions which tended to diminish their trade, they ought to find a remedy if possible. He then stated that among the questions which deserved consideration, and for which a representative committee might suggest improvements, were the conditions and allowances, which might have been very beneficial in past times, but which were not suited to the altered state of the present day; then there were the discounts, which were very uncertain and objectionable; and another subject for consideration would be that of dock rates. Mr. Asser urged that all the various interests of the trade should join together, not only to keep but if possible to increase their trade, which had been diminishing for some time, and was going to other parts of the world. Mr. Rueker said that at one time London was practically the import port for the whole of the trade, but that time had gone by. As to the Central American trade, they should endeavour to offer some inducements to increase that trade. He should like to see the obnoxious discounts done away with altogether. Mr.

Major also hoped that the discounts and all the antiquated allowances should be knocked on the head. Mr. Whales complained that no specific suggestion had been made to improve their position, and, so far as he could gather, the promoters of the meeting desired to take away some advantages which the trade now had in order to improve the trade of the port of London; but no intelligent body of men would agree to such a course. All the efforts made to bring the trade to London would be futile if it meant making the article dearer. Mr. Hicks observed that the desire of the promoters was to take away the obstacles to trade. After considerable discussion a resolution was submitted for the appointment of a representative committee; but an amendment that the meeting should be adjourned was carried by a large majority, and the meeting closed with a vote of thanks to the Chairman.—*Home News*.

"BRAZIL" IN THE BRITISH ASSOCIATION

Mr. Colin MacKenzie read a paper on Brazil. He held that Brazil was an enormous undulating plain or slightly elevated table land, 3,300,000 square miles in extent, with a coast line of 3,700 miles. There was no volcano, and hardly any desert or barren country. The country might be divided into three divisions—the littoral, the settled belt, and the virgin forest. The littoral contained all the towns, with an extensive commerce in sugar, coffee, hides, indiarubber, and drugs. The settled belt was a mere fringe, comprising all the cattle, sugar, and coffee estates of the country. Land was opened up for cultivation by setting fire to the forest in the dry season, a most wasteful and destructive system. All the rest of the empire was virgin forest. Nine-tenths of it was within the tropical zone, and so rich was the soil, so vigorous and varied the vegetation, that it formed one of the wonders of the world. No industry was carried on in the forest except the gathering of india-rubber and medicinal herbs. The population was 10 millions, the basis of which was of Portuguese descent. They were affectionate to their families and kind to the dependent races, the Indians and the negroes. The latter were being emancipated, partly by the action of the law of free births in force since 1871, and partly by private benevolence. In about 10 years the system of slavery would expire through the causes now at work, and this immense and fertile country would be opened up to spontaneous immigration. The northern races of Europe could not stand the heat, but the Latin races from the shores of the Mediterranean could work and flourish there. Brazil was nearly as large as Europe, and could support a greater population to the square mile. The average population of Europe was 87 to the square mile, which would give for Brazil nearly 300 millions of inhabitants.

In the discussion which followed Mr. R. N. Cust remarked that a large number of natives still inhabited Brazil who spoke no less than 20 different dialects. Brazil is the last stronghold of slavery.

Professor Trail, of Aberdeen, said that when acting as botanist in an expedition sent out to explore the Amazon valley he travelled for many hundred miles in the Amazon river and its tributaries, and found that they were navigable for great distances from the sea. The whole valley was well watered and was extremely fertile, and cattle could be reared there with great advantage. It was to be regretted that the native races were generally treated with great barbarity.—*London Times*.

THE WHEAT SUPPLY OF THE WORLD.

A very comprehensive review of the probable requirements and supplies of wheat throughout the greater part of the world during the new cereal year has appeared in *Beerholm's List*, and as last year's estimates by this authority have turned out remarkably near the truth, the present calculations are entitled to some amount of confidence. The details of the estimates are fully worked out and explained in the article; but we can give only the summary, as follows:—

	Probable requirements qrs.	Probable export surplus qrs.
United States and Canada	—	9,000,000
United Kingdom	17,500,000	—
France	5,500,000	—
Belgium	2,000,000	—
Germany	2,000,000	—
Holland	1,000,000	—
Austria-Hungary	—	1,000,000
Russia and Roumania	—	6,500,000
Switzerland	1,500,000	—
Italy	1,500,000	—
Spain and Portugal	1,000,000	—
India	—	6,500,000
Australia and Chili	—	2,000,000
West Indies and China	2,500,000	—
Greece	500,000	—
Egypt and sundries	—	1,000,000
Totals	85,000,000	26,000,000

These quantities, which include flour reckoned on wheat equivalents, show a probable deficiency of 9,000,000 quarters, whereas last year the quantities about balanced. The conclusion is that, although the deficiency will be somehow made up, it can only be by drawing upon reserve stocks all over the world, the effect of which upon prices can scarcely fail to be great and gradually increasing. As to reserve stocks, it is possible that they may have been over-rated. At any rate, many persons will learn with surprise that returns of wheat and flour held in seven of the eight principal grain ports of the United Kingdom, with the estimated quantity for London added, show a surplus equivalent to only 220,000 quarters of wheat over last year's stocks; and *Beerholm* puts the total reserves of the United Kingdom at only 500,000 quarters in excess of last year's total. A similar calculation for the extra reserve stocks in the United States is 6,000,000 quarters, to which is added 2,000,000 quarters of the new American crop and 1,000,000 for quarters Canada, to make the total quantity available for export in the two countries.

AN AGRICULTURAL CATECHISM.—Mr. M. Bhavani Shenker Rao, Local Cattle Disease Inspector, Coimbatore, has published "A Catechism on soil and their improvements. Embracing Soils, Manuring, Tillage Operations and Irrigation." He says in his preface:—"This country being purely agricultural, the exhausted condition of our soils, and the deterioration of the agricultural produce, claim our attention to a knowledge of the principles of rational agriculture, the study of which is second to none in importance. The object, therefore, in publishing this pamphlet is to aid in diffusing a sound and precise knowledge of the elementary principles that underlie the successful cultivation of soil. It is intended to follow it up by two other similar pamphlets, one on the *Staple Products of the Presidency*, and another on the *Live Stock and its management*, should this find favour with the public." Mr. W. R. Robertson, the Principal of the Madras Agricultural College, states that he has read the Catechism with much interest and pleasure. "It contains much useful practical information, and should prove of great use to persons beginning the study of agriculture in this country."—*Madras Mail*. (Query: if the Ceylon Director of Public Instruction should not introduce some copies of this Catechism into our schools?—Ed.)

PEPPER CULTIVATION AT PONDICHERRY.—Monsieur Reynaud, Professor of Agronomy at Pondicherry, has demonstrated the fact that pepper can be grown with profit on the East coast. He has lately gathered a good crop from a small planting, and the quality is said to be equal to good Tellicherry. The chief considerations seem to be soil and suitable trees for climbing.—*Madras Mail*.

COCONUT FIBRE.—We believe that many of our readers are not aware of the many uses to which coconut fibre can be brought. Among others, it has been found most useful in planting coffee and tea seedlings. A correspondent, who has tried the experiment, says that not only is the fibre a very good protection for the tender rootlets of these plants, but that it acts as a capital manure. Tea and coffee planters should take note of this.—*Indian Agriculturist*. [The fact has been long known and acted on, but the substance is coconut refuse, not fibre.—Ed.]

TEAS.—Fault is still found with the quality of some of the Indian tea now offered. The *Grocer* says:—"As the season is a month later than usual, the quantities coming forward are on a very moderate scale. At the same time, the general quality of the teas is poor, and inferior to the average run for early arrivals, and offers little inducement for the trade to purchase. There is also the increasing attractiveness of Ceylon teas to contend with, as to buy these the dealers more frequently turn from the Assam kinds than they were wont to do a year or two ago, and this withdrawal of support often leads to some weakness in prices. This is more plainly apparent in the commoner sorts than any other, especially as they are most plentiful just now, and are saleable only at and under 1s. per lb., whereas at this period last year the same grades were being disposed of at and about 1s. 2d."—*Home and Colonial Mail*.

A COPRA-CUTTING MACHINE.—Messrs. F. R. Yarte and Co., of Fiji, write as follows in a recent issue of the *Scientific American*:—"We take the liberty of addressing you with respect to a which is greatly felt by the owners of coconut plantations in Fiji; and as in your country inventions for the economy of labour are of daily occurrence, we feel assured you might, through the medium of your valuable journal, induce some of your many inventors to endeavour to make a machine that will assist in the manufacture of cobera (*i. e.*, the cutting out of the kernel) and saving of labour. At present the cutting out of the nut is done entirely by hand with a 6-inch knife, which is very slow process; and as the cost of labour is very high, steadily increasing, and supply limited, it would be of the greatest importance if such a machine could be made satisfactorily. The machine would be required to cut out the kernel of the nut just as it falls from the tree, but with the outer husk on. We could split them open as we do now, with an axe (at present we have no use for either husk or shell, except for fuel). It must be adapted to cut nuts of variable sizes, as coconuts vary very much in size and shape, some being quite round and others of oval shape and all sizes, simple in construction and strong without being heavy, as it would be worked by black labour. The motive power could be either hand or foot. It would not matter what size or shape it cut the kernel out, as long as it cuts it in 'solid' pieces; the size we cut out by hand is about three-quarters of an inch thick by about three-inches long. If such a machine could be made a large number would be ordered, if not too expensive as our principal product of export is dried coconut (called cobera or copra), and every planter would have some." Australian genius has produced a superior water auger, and it may be hoped that it will anticipate American genius in producing a copra-cutting machine.—*Sydney Mail*.

Correspondence.

To the Editor of the "Ceylon Observer."

TROPICAL PRODUCTS: NEW PROCESS OF PREPARING RUBBER; "MANGABEIRA" RUBBER SUITED TO CEYLON; ALSO THE PIASSAVA PALM.

BAHIA, 16th August 1885.

GENTLEMEN.—We have perused with a great deal of pleasure your valuable book on "Indiarubber," and seeing that you are much interested in the "article," we wish to inform you that we are the owners of a new process of preparing rubber direct from the milk doing away entirely with the tedious method of evaporating or smoking. We can at a trifling cost and in a few hours convert into marketable rubber any amount of milk, producing a rubber equal, we say even superior, to the finest Para, out of the "Mangabeira" milk, which is the rubber-tree we have here in abundance, but, unfortunately, all the trees have been so badly cut by the natives that they do not yield any milk at present, whilst, if properly bred, they should give milk every month. We enclose a sample of *Mangabeira* rubber made by our process. As you will notice, it is perfectly dry and differs totally from the spongy stuff known as commercial Mangabeira rubber. We came here a short time ago hoping to get large quantities of milk, as we had been informed that there are here immense tracts of trees, which is true, but we were not aware that they had been so badly damaged. We shall therefore have to move very far into the interior where there are still thousands of trees intact, before we can apply our process on a large scale. We had some thoughts of going up the Amazon, but health considerations have deterred from doing so, one of us here having already being carried away by yellow fever. We should be very glad to make an arrangement with some of your planters to sell them our process for Ceylon; if there is sufficient interest evinced, one of us might go out to Colombo to demonstrate by facts the value of the invention. We should state that samples have been submitted to manufacturers in Europe and America, and after trial declared to be excellent and applicable to all the different requirements of the rubber manufacture.

Cangabeira.—As your book contains very little information about this tree, it may interest you to know that the plateau on which it grows is not 4,000 or 5,000 ft. above the level of the sea, but only about 500 or 600 ft. It grows *only* in sandy soil, and where it grows there are only one or two other trees to be seen.

Piassava (Attalea imifera).—We are interested here also in the manufacture of oil from above palm-tree, the nuts of which give from 50 to 60 per cent of a beautiful oil; besides this same tree supplies the piassava or Mexican fibre used for making hawsers, ropes, brooms, brushes, etc. The shell of the nut is exported to Europe, where it is to be turned into buttons and other articles. There are hundreds of square miles of these trees, especially near the seashore, for it grows only on a sandy soil, or rather that is the soil best adapted to it. It seems to us that this tree could be planted with great advantage in Ceylon and many other colonies, and we will be very glad to give you any further information you or your friends might require.

Coconuts.—In return we should feel much obliged if you could give us any information about the planting and sowing of them, also on the manu-

facturing of the oil and desiccation of the nut; we understand that large quantities of desiccated nuts are shipped to Europe from the Fiji Islands, and, as coconuts are very abundant along the coast, we should like to turn them to account. They can be had for 30 to 40 per 1,000, delivered at a sea-port. Would that be considered a low price with you? Any information about coik would also interest. If you can send us any book treating of these subjects, we shall feel much obliged and remit cost to your agents in London.

Trusting that you will soon favour us with a reply, we remain, yours very truly,

MARVAL IRMÃOES.

We are obliged to our correspondents for this interesting letter. Ceylon is rather too young as yet, as a rubber-producing country, to make much of the patent process, although we shall be glad to put any of our readers interested, in communication with the writers of the above. The sample of rubber, vastly superior to anything as yet gathered in Ceylon, can be seen at our office. We should be glad certainly to see "Mangabeira" rubber introduced, and, if our correspondents send us some seed, they will confer an obligation. The Piassava ought also to be a useful introduction, to judge by the following extract from the *Treasury of Botany*—

1. *Amifera*, called by the Brazilians Piassava, yields a fibre of much value, derived from the decaying of the cellular matter at the base of the leaf-stalks, and the consequent liberation of the fibrous portions. This fibre is much used in Brazil for the purpose of rope-making, and in this country is employed for making brooms to sweep the streets. A fibre, having the same name, is also produced from another palm called *Leopoldinia Piassava*. The seeds of *A. imifera*, are known as Coquilla nuts; they are three or four inches long, oval, of a rich brown colour, very hard in texture; hence they are much used in turnery for making the handles of doors, umbrellas, &c.

We shall send "All about Coconuts" to our correspondents, which will give them the information they require; but, meantime, we may say, that, though Ceylon produced perhaps a thousand millions of coconuts last year, we have never known the price so low as 30s to 40s per thousand—60s, or, allowing for exchange, 15s to 50s, is more like the price here. Another correspondent however suggests, see below, that dollars may be meant.—Ed.]

COCONUTS IN BRAZIL: DOLLARS AND RUPEES.

Dinbula, 7th Oct. 1885.

DEAR SIR.—Allow me to suggest, that, in connection with the very interesting letter that appeared in your issue of yesterday from Messrs. Marval Brothers of Bahia, a mistake must have occurred, by which the price of coconuts is made to appear to range between 30 and 40 shillings per thousand; for shillings, I am pretty sure, dollars would be the correct reading, as accounts are kept in dollars in Bahia and not in English money.—Yours truly,

TAINKAL.

[Very possibly our correspondent is correct, but, the letter being in English, the sign used was clearly that applied to "shillings." Ed.]

FLUID EXTRACT OF CINCHONA.

London, E. C., 11th Sept. 1885.

DEAR SIR.—I send you a drug list by this mail and beg to call your attention to page 14 No. 186 "Fluid Extract of Cinchona." This has been made at my suggestion by Messrs. Howards of Stratford (after considerable work) who have secured a good supply of the Cinchona Calisaya Verde which yields a remarkably rich extract. There is no

IS COTTON AN AMERICAN PLANT?—Mr. Bourke, in the *Snake Dance of the Moquis of Arizona*, p. 241, says:—"The Tunis weave the same kind of cotton mantle, but do not grow the fibre, preferring to buy this from the neighbours, the Moquis, whose fields, exposed to warmer suns, have yielded the precious bolls from generations long prior to the advent of the Spaniards." He also (p. 241) refers to Davis' *Conquest of New Mexico*, p. 100, which speaks of the inhabitants possessing "blankets of cotton." I always understood that Cotton was an Old World plant used on this side of the Atlantic centuries before American was discovered, and that the first Cotton ever sent from America to England was a little lot, the fill of a woman's apron; as that was approved of, the next shipment was one bale from, I think, Savannah. But if Cotton was an Old World plant how could it be used in the New World "centuries before the advent of the Spaniards"?—J. R. HAY.—*Gardeners Chronicle*.

CULTIVATION IN ALGERIA.—The cultivation of cereals in Algeria is declining, in consequence of the irregularity of the crops, due to the uncertainty of the seasons. A series of good years, it is stated, is often succeeded by draughts, when the agriculturist hardly gathers in the amount of corn he has sown. Competition abroad is so great that he cannot obtain remunerative prices for his produce, and in some places, where the land is best, the means of communication are so defective, that it will hardly pay the Arab to take his grain to market. Near the sea the production of early vegetables and fruit for the markets of Europe promises to be successful, but beyond all doubt the great hope of Algeria is in the Vine. The gradual recovery of this plant from Phylloxera in the South of France will probably prevent the colicists in Algeria from making as rapid fortunes as appeared probable when that scourge first commenced its ravages, but there is every chance of the wine of Algeria commanding a remunerative price both at home and abroad. There is no reason why the European should not imitate the Kabyle, who cultivate his small patch of mountain land with care usually devoted to an orchard or market garden.—*Gardeners' Chronicle*.

THE CINCINNATI FLOODS.—The dictum of the late Charles Marsh that forests affect rainfall, long implicitly received, is being queried in many quarters, and in none more emphatically than in the new issue of the *Journal of the Natural History Society of Cincinnati*. The devastating floods of the Ohio of February last have awakened scientific inquiry, as well as popular alarm. And it appears that they are but one of a series, happening periodically since 1774. They have been of greater frequency in later years; but it is only when the river has reached a depth of fifty feet or more that destruction to life and property has supervened. Last year the river rose from a depth of 15 feet in January to that of 68 feet in February, but it gradually subsided to 25 feet deep at the end of that month. On fifteen occasions from 1779 onwards, there have been parallel sudden rises to such a height as that mentioned above, and these have been usually accompanied with signal destruction, human and otherwise. Dr. Dun, the author of the paper, treats his subject in minute statistical detail. He has further been indulging in European travel, during which he has seen the great floods of the Rhine and Danube, as well as of the Po, in 1882, all occurring in countries where the strictest forest conservancy prevails. He holds, then, that the mere planting of the headlands of the Ohio would not prevent floods. The Ohio valley is the track of both warm and cold storms, one setting coming from the Mexican Gulf, the other from the North-West. Hence the snows and rains causing flood. Of course it is not proved that forests might not ameliorate such climatal conditions. Only the natural configuration of a country must be taken as the main factor in aridity or rainfall, however these may be modified by secondary influences.—*Journal of Forestry*. [This is the sober truth of the matter.—Ed.]

PALM-NUT MEAL is commencing to be more extensively employed for stock fattening. For pigs, it is generally mixed with boiled roots or potatoes; sometimes a handful of oats or barley is added to give a flavor; salt is never forgotten. One farmer recommends, whenever the occasion offers of a horse being slaughtered, to secure a quarter and make it into soup to wet the pigs rations. Maize, pumpkins, and Jerusalem artichokes, with the nut-meal, make appetizing feeds for hogs.—*Paris Cor.*

TOBACCO IN BANGUEY.—The German Borneo Company have made considerable progress since they commenced operations some five months ago. On the 20th ultimo, H. E. the Governor, accompanied by Mr. Herrings and the Colonial Secretary, visited the estate and were received by Mr. Lind, the manager, and by whom the party were conducted over the clearings which at present extend over some fifty fields, of which about thirty are under cultivation. Mr. Herrings, who was formerly a Director of the Deli Maatschappij Tobacco Company—a company whose success has been remarkable dividends of as much as one hundred and thirty per cent per annum having been declared—expressed himself well satisfied with the appearance of the plants remarking, that they looked strong and healthy, with a large leaf. A fair bullock road some sixteen feet wide, and about three quarters of a mile long, runs from the landing place at Limbuak to the plantation. Altogether the German Company are to be congratulated on their encouraging prospects especially having regard to the fact that planting was commenced somewhat late in the season. Mr. Herring having completed his visit of inspection returned to Singapore on the same day en route for Berlin, but he proposes to return next year with a view to opening up planting on a considerable scale. He has recently been making a tour round the tobacco growing countries, amongst others Sumatra, Java, Philippines and Sulu, and it is satisfactory to learn from a gentleman of his experience that the Banguey tobacco promises to compare favourably with the best samples of the countries referred to.—*North Borneo Herald*.

HOT WATER TREATMENT FOR PLANTS.—A correspondent calls our attention to the following from the *Garden* and inquires whether there is anything in it:—"The Florist asks, Has any one tried hot water as a restorative for sickly plants, and then proceeds to say that M. Willermoz some time since related that plants in pots may be restored to health by means of hot water. Ill health, he maintains, ensues from acid substances in the soil, which, being absorbed by the roots, act as poison. The small roots wither and cease to act and the upper and younger shoots consequently turn yellow and become spotted, indicative of their morbid state. In such cases the usual remedy is to transplant into fresh soil, in clean pots, with good drainage, and this often with the best results. But his experience of several years has proved the unfailing efficacy of the simpler treatment which consists in watering abundantly with hot water at a temperature of about 145 degrees Fahrenheit, having previously stirred the soil of the pot so far as may be done without injury to the roots. Water is then given until runs freely from the pots. In his experiments the water at first came out clear, afterward it was sensibly tinged with brown, and gave an appreciable acid reaction. After this thorough washing the pots were kept warm, and the plants very soon made new roots, immediately followed by vigorous growth." To our mind there is a great deal in it. We know to a certainty that sickly peach trees are often restored to vigorous health by the old fashioned German farmers of Pennsylvania by pouring boiling water on the ground about the peach trees. It cools, of course, somewhat before reaching any of the roots. Here, however, it is believed to be beneficial by destroying parasitic fungi. But, let the reasoning be what it may, we are willing to indorse it as good practice.—*Gardeners' Monthly*.

TEA AT A HIGH ELEVATION IN CEYLON.

Ground covered with tea in full leafage, particularly when the landscape features are undulating, is a pretty sight; but for continued and varied beauty old coffee certainly bore away the palm. "Handling" and even pruning in the case of coffee left the soil still well covered, and to luxuriant and handsome foliage were, in due season, added the snow-white and jasmine-scented blossom, and the green, yellow and ruby-red shades of the fruit contrasted with the green of the leaves. But, excepting the few bushes preserved as seed-bearers, tea is not allowed to blossom or fruit, and when the time for a thorough pruning comes there is such a cutting down and away of wood, that, at any distance, the soil looks as if it had been completely bared. In from two to three months, however, the close carpeting of golden green is restored, and the process of picking goes on until the cutting-down time has come round again. Simultaneously with the pruning of bushes of good age, the stems have to be rubbed clear of lichens and mud, by means of the naked hand or the hand aided by a bit of sacking. The stems of the coffee trees would be rubbed also were it worth while to bestow further labour or expenditure on a cultivation which was once reckoned our mainstay. A visitor fresh from the eastern side of the range, where coffee is still worth cherishing, said to us a couple of days ago: "Surely you will preserve that fine-looking coffee." The answer was to point to the miserable sprinkling of berries at distant intervals amongst the really luxuriant foliage. Amidst the crop of leaves the fungus had to be searched for, but so had the fruit, and as the leaves cannot be converted into a merchantable and profitable product, the fine-looking coffee must go, however severe the pang may be of parting with what, if *Hemileia vastatrix* had not so fatally intervened, would be now in its prime of crop-yielding. The final decision to uproot the old product in favour of the new must be much more trying in these young districts than in the old, where coffee did not fail until for more than a generation it gave paying, in some cases largely profitable, returns. But the decision must be arrived at and carried out, to prevent the tea bushes planted, amidst coffee growing up feeble and spindly. The branches and leaves of the coffee bushes will be buried, while the stems go to feed the tea furnaces,—the old king being cremated, in fact, to the tune of *requiescat in pace!* Peace be to its ashes, with their appreciable proportion of lime extracted from a soil, the ferruginous nature of which renders it far more favourable for tea than for coffee, although the latter grew well enough and would have yielded fruit as well as leaves, had the enciebling fungus not been developed in 1869, to be at first made light of, but finally recognized as one of the most disastrous blights which has ever depressed, if not quenched, a great, advancing and prosperous enterprise. Java and the whole Eastern world are rapidly following in the wake of Ceylon experience, in this matter, and it really looks as if those of us who can afford to indulge in the luxury of a cup of coffee must erelong pay the cost of having it imported from the Western Continent. Let us fervently hope that no such dread visitation awaits the now most promising tea enterprise.

Some readers of the *Tropical Agriculturist* may recollect notices of plants, the result of seed obtained from Assam as "indigenous." The plants were put out along the sides of estate paths, at elevations rising from 5,200 to 5,500, in July 1880, and until now their progress has been so slow and unsatisfactory as to lead to

the belief that indigenous Assam tea was unsuited to the climate of this altitude. But whether it has arisen from the recurrence of several genial seasons, or that the plants have, at length, been able to adapt themselves to the conditions of their new situation, certain it is that they have taken a spring and promise to make up for lost time. They are, in common with the superior hybrids amongst which they are scattered, putting forth luxuriant foliage, many of the leaves being large, corrugated and serrated after the marked characteristics of indigenous Assam tea. The progress and comparative yield of these plants will be watched and reported on. Meantime I may mention that the effect of altitude even on hybrid tea bushes is, that some allowed to grow up as future seed-bearers show not the slightest sign of any tendency to blossom, although they are now eight to, in a few cases, ten years old. With similar trees in the hot low country, only a few hundreds of feet above sea-level, the difficulty is to contend with the persistent tendency to run all their strength into flowers and fruits.

Could the conjunction be made to pay, our experience is decisive in favour of growing cinchonas (especially *C. officinalis*) amongst tea, which evidently benefits the fever plants by opening up and draining the soil. But bark prices recently have been such as to make cinchonas stink in the nostrils of planters, almost as much as coffee; indeed more so, because hopes of retrieval were so largely based on this new and at one time most hopeful product. A large proportion of planters will, of course, harvest and market the bark from all their cinchona trees, ceasing to supply the soil with any more. The result may be profitable prices to those who can hold on. Many who would hold on cannot, because at a certain stage the choice must be made between tea and other cultivation—not only coffee but cinchonas. We suppose it is this desire to do full justice to the tea plants, which has led to the ringing of so many eucalypti in the neighbourhood of the Nanuya station. We take it for granted that the trees which have suddenly changed their hue from bluish green to yellowish white have been ringed, preparatory to their removal. So opinion changes. The blue-gums were and are still believed to be beneficial as wind-breaks and soil-drainers in cinchona fields; but tea, unless it makes an exception in the case of the sau tree,

"Bears, like the Turk, no brother near the throne."

CEYLON UP-COUNTRY PLANTING REPORT.

28th Sept. 1885.

Coffee—what there is on our side—is not looking very promising. There was such an attack of leaf-disease some time ago, that the trees are now left pretty bare, whereas the ground is thickly littered with fallen leaves. When the regular heavy rains of the north-east set in, the drains will amuse us. There is a little coffee ripening up; but the blackening at the points is as excessive as ever in was. Half-a-bushel picking of this sort of stuff, to a quarter of a cooty-sack of cherry, has been gathered at the first round, and even a worse result in some places. The husk is not so empty as one would have expected from the long dry weather and may nett something above the cost of gathering, now that the rupee has fallen among the despised things of the earth. Black-bug seems to be checked somewhat; still it's about, and evidently ready to wipe out what little of the old product remains at the slightest encouragement.

I saw an analysis of some renewed *succirubra* bark grown on Fairieland estate—just above Kandy—which

WYNAED, Sept. 19th.—Truly it is a difficult thing to please everybody all round. A month or so ago we were crying out, because there was too much wet, and our young clearings, newly planted, were in danger of being swamped out. Now, these are recovering and getting on well, but still there remain the "foolish virgins" (metaphorically) who have waited too late and who are left to mourn over baked earth, and blazing sun, and delicate plants not yet out of the nurseries! It is astonishing how rapidly the country appears to be drying up already. The change in the weather is also affecting the crop, which in places is turning fast, so that the picking season will probably commence early this year. I regret to say that the general verdict on crops seems to be unfavorable as to quantity, but we hope for better things in the matter of prices. I lately noticed a new disease (at least it is an unusual variety) on some coffee trees in this neighbourhood; the young sprouts of leaves seemed suddenly to curl and shrivel up, becoming black and dry. A small *poochee* is generally to be found somewhere about the affected parts. The old cinchona e'earings are exceedingly flourishing in appearance; very little signs of canker, and a general vigor of growth, which, with the report of better prices in prospect, is a splendid panacea for drooping spirits. South Wynaed seems especially adapted for the cultivation of the Ledger variety; and on one estate an analysis, made at home, on the bark of some four year old Ledgers, produced a result of 8 per cent quinine, than which nothing much better could be desired. Canarese labor literally swarms all about here, though our neighbours in the Battery direction still seem to suffer from difficulty in obtaining sufficient coolies.—*Madras Times*.

A HOUSEHOLD FILTER.—A correspondent sends us the following.—In your issue of the 7th instant you give a few remarks on the general results of Dr. Frankland's experiments with filtering media for purifying water for drinking purposes. Many of your readers would, I am sure, be glad to know how to make a simple good filter; and this they may easily do by attending to the following directions which are based on the facts that when water is treated with powdered clean iron, organic matter is decomposed and living organisms killed; that a layer of flakes of talc forms an efficient mechanical strainer not subject to oxidation. The filter may be made with two or three chatties like the common country filter, or a patent filter may be converted on the same principles after the original filtering medium has been removed. The best form of powdered clean iron is cast-iron borings. These can generally be obtained from any workshops where cast-iron is worked up, and may be procured at little cost. Talc abounds in many parts of India, and is for sale in most bazaars. Small pieces, not larger than a rupee, answer best for filters. Boil the talc in water to make the laminae separate easily; split it up into the thinnest flakes, wash it two or three times in clean water with a little permanganate of potash or Cowdy's fluid. If chatties are to be used, make six or eight holes close together in the bottom of the upper and middle chatties. Into these put sufficient of the talc flakes to form a layer about three-quarters of an inch thick. Into the upper chatty put about six table-spoonful of the cast-iron borings, and into the middle chatty about one quarter of a pound of powdered charcoal over the layers of talc. Fill the upper chatty with water, and let it drip through the two chatties until it becomes quite clear; then place the lower chatty with a teaspoonful of the borings in it underneath, and draw the drinking water from that lower chatty only. Once a month or so remove the talc, iron, and charcoal from the three chatties wash the former in permanganate of potash and water, and replace it and renew the borings and charcoal. Water thus filtered should be used not only for drinking but for making tea, coffee, &c., and for boiling vegetables in. The water will be found much more tasty when boiled in filtered than ordinary unfiltered water. When practicable, the water to be filtered should first be boiled.—*Pioneer*.

A PEARL five-sixteenths of an inch in diameter, and estimated to be worth from \$50 to \$100, was lately found in a clam taken from the river in Mids dlesex, Vt., by a citizen of that town.—*American Grocer*.

LOSS OF WEIGHT IN CINNAMON, &c.—In a recent article we commented on the very serious loss of weight which cinnamon account sales show, and pointed to the need there exists for united action or firm individual remonstrance to secure relief. With tea a loss of three per cent is considered excessive; and even the reduced loss of $1\frac{1}{2}$ per cent in a recent shipment was considered by the proprietors of the "Ceylon Advertiser"—enterprising business men in the Fort—to be capable of still further reduction. We have row before us an account sale of cinnamon sold on the 27th July last, and refer to some of the figures in the hope that shippers will carefully scrutinize their own accounts and see how heavy and unjustifiable the loss they are called upon to bear. The shipment consisted of 20 bales weighing 2,600 lb. and two bags (cuttings and clippings) weighing 112 lb.; total weight 2,712 lb. The account sale accounts for only 1,970 lb.—the loss being 142 lb., or about 6 $\frac{1}{2}$ per cent. That proprietors cannot afford this loss at present prices does not need proof; but whether they can afford it or not, is the loss justifiable? We think not. The usual draft is said to be a lb. on every parcel—heavy enough in all conscience—and will account for 22 lb. What then has become of the other 120 lb. worth, according to the prices realized, at least £6 sterling? Appropriated by someone at the warehouses, or by careless weighing made over to the purchasers. Surely, losses like this should not be submitted to without demur. The shipper in question had, by frequent letters, succeeded in reducing the loss in weight from 7 to about 3 $\frac{1}{2}$ per cent, and rested satisfied. His silence for some time has resulted in the loss in weight being doubled again! It cannot be any error in weighing here, because remonstrances led to a reduction in the loss. It cannot be that the loss was due to drriage, because cinnamon shipped with 7 per cent of moisture would not reach in a fit condition to be sold. It will be mouldy and have to be thrown away. The loss represents the carelessness or dishonesty of the employes of the Warehouse and Dock Companies or some of their hangers-on; and London agents should be pressed not to permit such outrageous appropriations. We may say that the shipment was sold within a month of its arrival. This leads us to the warehouse charges which amounted to £8-10-3 on 22 parcels for 3 weeks, and against £113-19-3 gross proceeds. The bulk of the charges is owing, no doubt, to the undoing and re-doing of every single bale of cinnamon—a ruinous operation, which facilitates and explains the loss in weight. The loss in weight is a matter which each shipper must deal with individually with his own agent; but united action, through the Agricultural Association or otherwise, is necessary to do away with the system, involving both loss and expense, of opening out every bale of cinnamon. The only parties benefited, so far as we can see, are those interested in the warehouses; and perhaps London agents are more interested in them than their Ceylon principals are aware. The same system of unpacking every parcel obtained with tea, but rigidly re-entrained has led to its abandonment. Any way, we see no reason why it should not be sufficient to open one bale of each quality for a sample. Shippers are not likely to attempt to practise any deception, and run the risk of having a mixed or adulterated bale opened; for this would regulate the rate for their good cinnamon. It is to their manifest interest to be fair; and if the leading shippers combine, there is no reason why they should not secure the abandonment of a system which imposes an unnecessary charge, damages the spice by exposure, and renders abstraction possible. We trust we have written enough to induce cinnamon proprietors to endeavor to guard against losses and charges which, we think, can be guarded against.—"Examiner."

THE TEA MERCHANTS in Hatima, Tajima, Setson, Tumba, and Awaji have entered into an agreement that they shall not sell adulterated tea, or tea contaminated by any substance injurious to health, sun-dried leaves, or, in fact, anything that is calculated to injure the business of honest merchants.—*Hongkong Daily Press.*

CAPE TEA is heard of as regularly as the sea serpent. A gentleman of Middleburgh, Cape Colony, writes to a contemporary:—"It must be pretty well known that there is a wild tea growing in the western districts. The preparation it undergoes is of a very primitive description. The leaves are gathered from the shrub and placed in an oven until dry and crisp, and afterwards packed in leather sacks, and sold upon you for about six-pence per pound. Staying at a friend's house, I tasted this tea one evening, and considered it very good. The next morning our host gave us tea for breakfast, and enquired how we liked it. We considered it the same as we had the previous evening, until we were assured that it was China tea—so little could we distinguish any difference between the two sorts. It appears that the colonial tea must be boiled before it can be used, which would take some time; therefore, if you are in a hurry you must use the China tea, as you have only to pour boiling water on the leaves when it is ready for use. If this wild tea will grow here, is China tea not worth a trial? I am of course referring to the coast lands. The China tea is successfully grown in other countries as well as China. Even the wild tea which we have may be turned to better account if properly prepared; but, even as it is, I am told it is quite a common beverage in the western districts. Both from patriotism and economy it should be in general use. This Cape tea should become the common beverage of the people, and should be sold in hotels and public houses in the place of beer and spirits: it is far more refreshing than either. In Australia, farmers and travellers drink very little coffee; tea is their favourite drink from morning to night. No doubt it is very healthy beverage, and preferable to coffee. Some farmers have told me that, after great fatigue, they have found the Cape tea a wonderful restorative, and that a taste is soon acquired for it. With some the taste is disagreeable until accustomed to it. Perhaps some one who has Blue-books at home could tell us how much a year we should save, as a nation, by substituting colonial tea for coffee and China tea." We are not quite dependent upon China for our tea supply. Mr. Alabaster, British Consul at Hankow, points out a new danger to British commercial interest. Hitherto a large proportion of the tea supplied to the Russian markets has reached its destination in English ships *via* London, but the direct trade *via* Odessa has enormously increased during the past four years. In 1880 only 1,845,453 lb. went direct to Odessa, but last year no less than 11,681,140 lb. shipped to that port in Russian and German vessels. The export to Russia *via* Tientsin and the Amur showed a slight falling off, though still largely in advance of past years. Altogether 24,000,000 lb. went direct to Russia 37,000,000 lb. to London, showing against a steadily progressive increase in the former. As everything points to Russia being eventually the chief market for China teas, it means, says Mr. Alabaster, our being ousted in great measure, if not entirely from the trade. Of last week's sales of Indian tea, the *Gleaner* says:—"The returns relating to the movements of Indian tea at the Port of London during the month of August will for special remark, they having been hardly so favourable as in 1884, but no increase of stock has taken place, and, as compared with that of last year, there is still a deficiency of 1,911,650 lb. Supplies by auction have been much more considerable than of late, amounting to 17,050 packages, against about 9,000 packages last week, but containing a large and varied assortment, they met a good general demand from the trade, who are tree buyers of strong flavoured teas of all makes, and for these fully previous rates have been obtained. The portion consisting of poor and thin qualities, however engaged only a partial degree of attention, and was in some cases realized at slightly easier prices."—*H. & C. Mail.*

PLANTING IN THE CAROLINE ISLANDS.—The Governor of the Caroline islands has been authorised to obtain seeds of tobacco, hemp, coffee, cocoa, c'c'n, dyewood, indigo, and of every kind of kitchen garden plants for sowing them in those islands, to secure their advancement. The Governor, the head missionary, several private individuals, a detachment of soldiers, and a force of convicts were to leave Cavite for the islands in the transport "San Quentin" on the 14th August. The largest collection of clothing for the benefit of the Caroline islanders was made in La Ermita, a ward in Manila, amounting as it did to upward of 2,000 suits of wearing apparel chiefly for women.

SNAKE BITES AND CURES.—Concerning the question lately raised in these columns of cures for snake-bite, Messrs. Lazarus and Co., of the Medical Hall, Benares, write to us:—"We have been asked to report our cases of snake-bites. If you think it will be of benefit to the public, please insert the following. From 1st August to 6th September we have had 15 cases brought to us. Seven males, eight females. One male, aged 60, was brought in as good as dead, and quite unable to swallow, and died after a few minutes. Another man, not included in the 15 cases, was quite dead and cold when seen by us; he had been brought in from a distance of some 10 miles. The remaining 14 cases were successfully treated."—*Pioneer.*

TAWOY, BRITISH BURMA, 13th Sept.—Products thriving here far beyond my expectations. Some already covering the ground. I have been most successful and the Chief Commissioner, Mr. Bernard, has given me another 100 acres free for 20 years of all taxes. Coolies' pay down to six annas, about 37 cents. I was offered 500 at that rate yesterday, and willing to bind themselves for two years. P. W. D. now only pays six annas per day for their labour, and any amount of coolies offering; they like this district. I am to write you a long letter and give you full details for some time back of my experience here. I am to plant up some 3 acres with hemp, and some 7 acres with maize and tobacco, on other ground outside my grant that I have got for experimental purposes. You are all terribly dull on tea! and Ceylon men deserve success, which is sure to be attained on favourable situations with good varieties of seed, and your most modern machinery. Heavy rains this season: 172 inches already, but I am in excellent health and so also my men; a few got knocked over with fever in the first of the rain.

CINCHONA.—Messrs. Oakes & Co. write to us:—Amexed we beg to hand you results of our sales of Government Cinchona Bark held on the 7th ultimo, and this day, shewing quality of bark, analysis of each by the Government Quinologist, and the prices realized, from which you will see that the rates obtained today are much more favourable than those ruling last month. This may be justly attributable to the fall in exchange, but the market at home for Crown bark is decidedly firmer. We think the advance exhibits a better market generally for bark:—

—*Madras Mail*, Oct. 5th.

MOTHER-OF-PEARL, the material of which ornamental buttons, buckles, fan sticks, card cases and other fancy articles are made, is the principal production of Tahiti, and makes a commerce variously estimated between \$20,000 and \$100,000 a year.—*American Grocer*.

DEPRESSION IN JAVA.—On the 5th September, trade, industry, and plantation enterprise at Batavia continued greatly depressed, one consequence being a heavy fall in the value of real estate and widespread financial mistrust. Withdrawals of working capital resulting in stoppage of work on estates were then of daily occurrence. Cultivation was checked by obstinate drought. Tea estates and other plantations inland were suffering heavily from want of rain. Coffee estates have become so depreciated in Java, since low prices for that product set in, that recently two of them assessed at 117,000 guilders were sold together for only 100 guilders.—*Straits Times*.

WATERWHEEL POWER. I have read with interest what have been said on waterwheel power, but as some of your readers may have waterwheels working badly from some cause—and there are many badly constructed wheels in the country—it has occurred to me to send you a very rough way of ascertaining the working h. p. of a waterwheel. Here it is on a separate sheet if you understand it and think it is correct. I may be wrong, but I think for a rough calculation it will be useful: As one-fourth only of the number of buckets of an ordinary waterwheel contains the effective water, note what depth of water there is in the buckets when the wheel is working. Each cubic foot of water weighs 62½ lb.; therefore multiply the total cubic feet of water in the buckets by 62½ and the product by the number of feet the mean circumference of the wheel travels per minute and divide by 33,000—answer, the working horse-power.—*Cor.*

TEA IN THE LOWER PUSSELLAWA DISTRICT.—Confounding Mahavilla with Riverside estate, some time ago, we did injustice to the latter flourishing property belonging to an old and much respected colonist (Mr. W. S. Bennett), and which has taken a new lease of life under the influence of the all-prevailing new product tea. Riverside, which was first opened in coffee a good many years ago, has 232 acres cultivated, of which 227 are tea, and the remainder cardamoms and cacao. The cacao appears rather a failure as far as can be judged; the cardamoms are fairly good; but the tea (of which the estate almost entirely consists) is looking extremely well, and promises to give large yields of leaf. It is at present too young to crop. The climate is hot and steamy, 120 inches rain, any amount of water power on the estate. On the whole Riverside is a flourishing young estate, and ought to do very well when the tea comes regularly into bearing, so that our old friend Mr. Bennett is to be heartily congratulated on his promising property.

TEA TRADE.—According to trade authorities the tone of the tea trade generally is perfectly steady and settled. This is satisfactory at least. *The Grocer* says:—"All is quiet and free from outside influences; and as regards statistics, there is nothing in them calculated to create distrust in the result of future operations, rather the reverse, as demand at present seems to be overtaking the supply,—and while this is so, low prices cannot be expected to go lower still." This is the pleasant state of things that planters are looking forward to with hope, and the consumer it comes the better for them. *The Grocer* has something favourable to say about Indian tea:—"Notwithstanding the stronger

competition that threatens them on all sides, Indian teas may be said to thoroughly maintain their position in the market, and, having gained a firm hold upon the taste of consumers, there is little fear of their losing it by either undergoing a deterioration in quality, or by becoming permanently dearer than other teas. Whatever may have been thought of some of the earlier imports in July—and we know for certain that the opinion of several experts in the matter of tasting was strictly adverse,—the shipments received since have been of a much improved character, and bid fair to keep up the reputation of the teas grown in Assam for their excellence and superiority over those of other countries. Not only has the assortment on offer become larger and more varied, but it has consisted of more numerous breaks of the choicest and finest growths, which have met with greater competition, and been taken off at stiffer prices. In short, the tone of the whole trade has been much healthier than of late, as even the commoner sorts which were uniformly depressed last month, have been of readier sale; and those importers who held back their teas on account of the depression then existing, have since realized firmer rates than if they had forced them upon unwilling buyers immediately upon the landing of the teas in this port." On the subject of statistics the same authority says:—"The consumption of Indian tea is large and increasing, the deliveries in London alone during the past seven months having reached 39,775,600 lb., against 36,060,350 lb. last year, and 33,758,950 lb. in the same period of 1883. All this while the imports here were on a diminished scale, comprising only 23,077,750 lb. this year, as compared with 25,719,150 lb. in 1884 and 25,019,450 lb. in the first seven months of 1883. The consequence was, that by the end of July the stock remaining on hand or in bond was reduced to 10,568,550 lb., against 13,486,450 lb. and 13,003,900 lb., in the two preceding years. With these deficiencies in the available supply of Assam teas starting them in the face, it is no wonder that both the dealers and the retailers have given more attention to Ceylon and Java teas, which have been found to serve as good substitutes for Indian sorts at the far-end of the season, as they have not only been tolerably abundant, but also rather cheap; and, possessing several characteristics of the tea plant in Darjeeling, Cachar, and the Sylhet districts for pungency and general excellence of quality, the above-mentioned kinds have fairly satisfied the general requirements of the home trade. The early arrivals of Indian tea this summer were of decidedly inferior quality, containing a larger proportion than usual of poor and thin-flavouring grades; for which buyers refused to compete, and importers pressing sales rather than otherwise, a material decline, say of about 2d per lb., was established for these by the beginning of the present month. In comparison with those now ruling for China descriptions, prices of Indian are rather higher for the finer as well as the lower qualities, but cheaper for the medium qualities, besides being also easier to buy than at this time last year." It is useful to read the comments of the trade papers on Indian tea, although they are not always remarkable for profundity of wisdom and foresight. This is what the *Produce Markets Review* says:—"The Indian tea market has been well supplied, chiefly with new season's growths, the proportion of really fine teas being small, although there is a general improvement in the quality offered. Competition was active for the choice parcels of Darjeeling and other fine growths, for which, in most cases, extreme prices were obtained, while all good teas have commanded previous high rates. If the supply of equally fine kinds continues rates are likely to decline, as the consumption of the better sorts has become more limited. Indian teas at about 1s do not compare favourably with China growths, and quotations for the less desirable kinds will probably give way as soon as a better selection is on offer. The imports from the Cachar districts seem, so far, inferior, and unless the quality of future shipments is more attractive, the result is likely to prove disappointing to importers.—*Home and Colonial Mail*.

THE SQUARE BAMBOO.

The cylindrical form of the stems of grasses is so universal a feature in the family that the report of the existence in China and Japan of a bamboo with manifestly four-angled stems, has generally been considered a myth, or, at any rate, as founded on some diseased or abnormal condition of a species having stems, when properly developed, circular in section.

Of the existence of such a bamboo there cannot, however, now be any kind of doubt. It is figured in a Japanese book, the "Sō moku kin yō sū," (Trees and shrubs with ornamental foliage), published at Kyoto in 1829, and the figure is reproduced by Count Castillon in the *Revue Horticole* (1876, p. 32.) It is further figured in a work for a copy of which we are indebted to my friend Prof. Kinch (formerly of Tokyo), called the "Ju-moku Shiri-yaku"—i. e., a short description of trees (of Japan). Finally, in 1880, Messrs. Veitch presented to the Kew Museum fine specimens of the stem of the square bamboo, brought from Japan by their intelligent collector Mr. C. Maries.

M. Carrière states, in an editorial note to Count Castillon's article, that the plant had been introduced into France at that date, and was indeed actually on sale in the nurseries near Antibes.

Nothing, however, till quite recently, appears to have been known as to the existence of the square bamboo in China, from which country, however, it is extremely probable that the Japanese procured it. Thus, Mr. F. B. Forbes, whose personal knowledge of the Chinese flora is only second, perhaps, to that of Dr. Hance, informs me:—"I have never seen the square bamboo growing, and I have always supposed that its 'squarety' was artificially produced."

The first authentic account of its occurrence in China is, as far as I know, due to Mr. Frederick S. A. Bourne, of H. B. M. Chinese Consular Service. Mr. Bourne wrote to us, October 15, 1882, that he had made a journey from Panchow to a distance of 300 miles to the western border of the Fokien province, reaching Wu-kung, the celebrated monastery in the Bohoa hills—a place, Mr. Bourne states, "only visited by a European once before, I believe—i. e., by Mr. Fortune, about the year 1845." In the gardens of this monastery he found several clumps of the square bamboo growing to the height of about eight feet.

The *Tropical Agriculturist* (an astonishing repository of everything relating to the economic botany of the East) contains in its issue for November, 1882 (p. 445), an article extracted from the *North China Herald*, also relating to the square bamboo, plants of which, destined for the park at San Francisco, had been obtained by Dr. Macgowan at Wenchow.***

Dr. Macgowan being well known to botanists for his intelligent interest in all that relates to the vegetable production of China, I ventured to write to him to ask his aid in procuring living specimens of his interesting plant for the Royal Gardens. Through his kindness and that of Mr. E. H. Parker, late acting consul at Wenchow, we were fortunate enough to receive a Wardian case filled with plants of the square bamboo, some of which at least appeared to be alive and likely to grow. Besides these, Dr. Macgowan sent us specimens of walking-sticks and pipe-stems made from it.

I quote the following passages from the very interesting communication with which Dr. Macgowan was also good enough to favour us—

"Its geographical range is from 25° to 30° N. latitude. Internal, and westward farther than I have been able to discover. Unlike other varieties of bamboo here, its shoots are developed in the autumn, not in the spring. It sprouts in September or October, and the stems grow until they are arrested by December cold, by which time they attain a height of from two to four or five feet. In the spring following their growth recommences, when the grass attains its full height, ten to fourteen feet. The lower

portion of the culms bristle with short spines; in the second or third year their squareness is far less striking than when matured by several years' growth; that quality is sometimes so marked that native botanist describes them as appearing like rods pared by cutting instruments. I have seldom found the canes much more sharply defined than in the largest of the specimens herewith transmitted. It is cultivated chiefly for ornament in gardens, in temple courts, &c.; the stems (sometimes as much as an inch-and-a-half through) are used for staves; the smaller and less squarish for stems of opium-pipes; and the smallest and less mature for tobacco-pipes."

He further adds:—"Its anomalousness is attributed by Chinese to supernatural powers—occult agencies varying with each district. The *Ningpo Gazetteer* tells how Ko Hung, the most famous of alchemists (fourth century A. D.), thrust his chopsticks (slender bamboo rods pared square) into the ground of the spiritual monastery near that city, which, by thaumaturgical art, he caused to take root and to appear as a new variety of bamboo—square."

As no flowering specimens of the square bamboo have reached the hands of botanists, its taxonomic position must at present be regarded as doubtful. Rivière "Les Bambous," p. 315 refers to it as the *Bambusa caryi*, and Feenzi, quoting from Rivière, (*Bull. Soc. Tosc. di Ort.*, 1850, p. 461), gives it the name *Bambusa quadrangularis*.

I can discover no reference to it in the late General Munro's classical monograph of the *Bambusaceæ* (*Trans. Linn. Soc.*, vol. xxvi.). Of the three groups into which he divides the genera, in only one, *Triplax*, is there any tendency to depart from the habit of the order in having anything but round stems; and this only occurs in the small genus *Phyllostachys*, in which they are somewhat laterally flattened. The stems of *Phyllostachys nigra* are often used in Europe for walking-sticks and light broom-handles.

But I do not think the square bamboo will turn out to be a *Phyllostachys*. Munro has a *Bambusa angulata* which is distinguished from all its allies by having the branches of the panicle angular. This is the only tendency to angularity of stem which I have discovered among the true *Bambusæ*.

For the present, at any rate, the species must be known provisionally as *Bambusa quadrangularis*, Feenzi W. T. THISELTON DYER.—*Nature*.

THE TRADE IN SAFFLOWER.

With the exception of Madder there is no vegetable dye that has been so largely interfered with as Safflower, by the introduction of the artificial dyes prepared by the chemist. It is chiefly a product of the East, and there it still retains some value among the natives. From 1851 to 1855 the official value of the Safflower imported into this country ranged from £71,000 to £134,000. Sixteen years ago we received over 32,000 cwt. Last year our imports fell below 1,400 cwt., valued at but £3,500. In contrast to this our imports of aniline dyes from abroad (exclusive of those made at home) exceeded in value £710,000. *Carthamus tinctorius* [a Composite plant] is grown extensively all over India, mostly as a subordinate crop. That grown in Dacca is the best in India, and ranks next to that of China. It is an annual, growing to 1 to 2 feet in height.

The plants begin to flower in February, when about 2½ feet high; from then till May the flower are picked off each day as they appear, leaving the flower-heads on the stalk. All that is detached is the fragile-looking corolla, which issues from the summit of the prickly Teazel-like flower-head. When these are picked off, their subsequent treatment depends on whether they are to be made up into the Safflower of commerce or whether they are merely to be prepared for dyeing purposes in the country. If the former is intended the florets are stamped with water and pressed into lumps. A rough strainer is made by stretching a mat on a wooden frame; on this the lumps

of flowers are laid, and water is slowly poured over them, while a man treads them out with his feet, supporting himself on two sticks, used as crutches. In this way the yellow colouring is eliminated from the flowers, the presence of which would detract from the beauty of the crimson tint, for which they are chiefly prized. When the water (which at first is coloured yellow) comes clear through the strainer the process is complete. The flowers are then made up by hand into round flat cakes, the water squeezed off, and they are dried in the sun. In this form they are known as the Safflower of commerce.

Safflower intended for local use in India is not washed in the method above described at the time they are picked. The flowers are simply dried, in which state they are sold by cultivators.

There are thus two pigment principles in Safflower—Safflower yellow, which is extracted by pounding and washing, and Safflower red (or carthamin), which is the dye of commerce. The carthamin is a resinoid substance, giving to cloth a beautiful crimson colour, which, however, oxidises yellow in light. It is one of the chief ingredients in rouge. It is soluble in an alkali, which is used to extract it from the cakes of flowers; an acid precipitates it. The colours, however, obtained from this vegetable dye are not very fast.

The following shows the exports of Safflower from India in the years ending March 31:—

	Cwt.	Value.
1877	7662	£30,467
1878	3698	14,880
1879	4977	18,671
1880	2411	18,145
1881	6675	35,115
1882	2293	9,475
1883	3008	9,203
1884	2333	6,449

The shipments are principally to the United Kingdom, the rest goes to China and the Straits Settlements. There can be no doubt that the competition of chemical dyes has ousted this beautiful and once favourite colour from the home markets, and it is very unlikely that it will ever regain the position it once held.—*P. L. S.—Gardener's Chronicle.*

BURMESE LACQUER.

The lacquer manufactures of India, Burma, and Japan, are, as is well known, important industries. By far the best known in Europe is the lacquer-ware of the Japanese, the production of which has been so well described of late in a report by the British Consul at Hakodate. Specimens of Indian lacquer-ware are also often seen in this country, but are not so common as the last, while the Burmese work is much more rarely seen than either. These three kinds of manufactures are very distinct in their character, in their mode of preparation, and in the material used to give the well-known polished surface. Thus, while the Japanese lacquer is obtained from the juice drawn from the trunks of *Rhus vernicifera*, the Indian lacquer is prepared from lac, which is produced by the puncture of an insect on species of *Picus*; and the Burmese lacquer is the juice obtained from *Melanorrhœa usitata*, Wall. Though this lacquer, or varnish, is largely used in Burma, but comparatively little has been written on its preparation and uses; the following notes from a recently issued report on the subject will therefore probably be interesting:—

The Varnish-tree, as it is called, is a large deciduous tree of Manipur, Burma, and Tenasserim. The lacquer-ware used in Burma is described as of two kinds—that in which the article is made of basket-work lacquered over, and that in which the article is made of wood. All the lacquer-ware of the basket-work-form comes from Upper Burma, where it constitutes a very important trade. In British Burma the trade is confined to the production of wooden articles lacquered over, such as the large round platter with a raised edge in which the family dinner is served, round and square boxes, and bowls. And the Burmese artists produce richly gilt boxes used in the monasteries for

holding Palm-leaf manuscripts, the bowls with a pagoda-shaped cover employed for carrying food to monasteries, and pagodas and shrines on which to place images of Gotama. The coffers referred to appear as if covered with pictures drawn in black on a gold ground, and the effect is so good that a small demand for tables, panels, bowls, &c., of the same work has sprung up. If a black-coloured lacquer is required, the sap of the tree is used alone, but a deep red lacquer is much used, and is prepared by mixing the sap of the Lacquer-tree with vermilion in the proportion of 12½ parts to 10.

The wooden bowls, platters, &c., are scraped down with fine steel scrapers, to make the surface as smooth as possible before laying on the lacquer. All cracks, holes, and chipped edges are filled and built up, as it were, with a putty made of the lacquer itself mixed with Teakwood sawdust. The articles are then put away until the putty is dry and quite hard. The raw lacquer is next rubbed all over the article with the bare hand, so that the least particle of sand or stone may be detected, and the article put in a cool and airy place to dry—not, however, in the sun, which would cause it to crack or blister. The articles are sufficiently dry in three or four days to receive a thick even coating of "thayo," made of "thitsi" (the sap), rice-water, and Paddy-husk ashes. The article is again put away to dry and harden, when it is smoothed down with water and Paddy-husk ashes and stone polishers of graduated fineness from sandstone to a smooth pebble. This process removes all gloss or polish, and the last coating of either black or red is given to the article as a polish. The grounding is invariably black, and only the last coating red, if red-coloured ware is required. The black enamel used is made of two parts lead, one part silver, and one part copper, melted in a fierce fire, and sulphur added at discretion.—*Gardener's Chronicle.*

WOODEN, METAL OR STEEL SLEEPERS.—At the recent Railway Congress at Brussels the question whether it would be economical and desirable to use iron or steel instead of wooden sleepers was fully discussed. It was stated that metal sleepers of various patterns are being used in Holland and India to a considerable extent, and that they are being tried experimentally in Belgium, England, and other countries. An opinion was expressed that sleepers of the description which is being tried in England, would afford good material support for the rails on main lines, although some inconvenience might be felt from a quoin of wood being used with it. It was also considered that other metal sleepers which are being tried in Holland and elsewhere had given satisfactory results. The cost of metal sleepers is higher than that of wood. They require good ballast, and there had not been sufficient experience from their use, in regard to their duration and maintenance, to enable the section to state specifically the relative advantages of the new description of sleepers. It was therefore considered that further experience is necessary. The difficulty of arriving at a conclusion as to what would be applicable in all countries and under all circumstances was exemplified in the discussion of this subject by the representative of the Egyptian railways. He stated that iron or steel sleepers cannot be economically used in Egypt, because they become corroded by the sand. The representative of the Indian railways, on the other hand, informed the section that iron or steel sleepers only can be used in India, because the white ant destroy wooden sleepers. Considerable discussion took place as to the construction of railways in regard to the curves, gradients, and works generally, including the question whether lines with a comparatively small traffic should be laid with heavy or light rails. It was, however, found impossible to lay down any general propositions which could be adopted under all the circumstances in which railways have to be made.—*Nature.*

HOW TO LINE ACCURATELY.

Sir.—When so many are engaged in planting, perhaps the following plan for lining may be of use, as by adopting it the lines are bound to be parallel, however ignorant the coolies may be.

Give the coolies at each end of the rope a carpenter's square, say 3 ft. x 1 ft. or 3½ ft. x 3½ ft.—A B C. Place A on any peg in base line and C on the next peg. The next line will run from B B, and must be parallel, as A B can't be.

at less than a right angle to A C. With a simple 4-foot stick to measure the width, lines vary considerably.

N. C. D.

[NOTE BY ED.—This is a good plan, but unless the squares are held horizontally, and not with the slope of the ground, lines will yet vary considerably].—Local "Times."

FIRE-CULTIVATION IN THE EAST INDIAN HILLS.

Allgemein Forst und Jagd-Zeitung: The General Journal of Forestry and the Chase. Published by J. D. Sauerlaender, Frankfurt-on-the-Maine.

The *Forst und Jagd-Zeitung* for November contains an article of great interest and considerable length by Dr. D. Brandis, late Inspector-General of Forests in British India. It is entitled, "On Fire-Cultivation in the East Indian Hills, more particularly in Burma," and it was written to be read at the last meeting of the Westphalia and Lower Rhine Forest Association, on the 29th of July. It was not, however, read there, as the author was unfortunately prevented by illness from being present at the meeting. In this paper the country is described, with its vegetation and the different races who practise nomadic cultivation, with preliminary burning of herbage and jungle. *Tavejya* (meaning a mountain field), or briefly *ya* (a field), has come in Burma to imply fire-cultivation, and in the forest service the same words are applied to plantations raised after the rice crops on the burnt fields, or to forest covert proceeding from seed sown simultaneously with the rice. It has thus been contrived to turn the customary and almost indispensable fire-cultivation to the advantage of forestry. The credit of having thus turned a destructive enemy into a helpful ally belongs undoubtedly to Dr. Brandis himself, although he does not here speak of it nor claim the distinction.—*Journal of Forestry.* Where chenaing or henaing is permitted in Ceylon, could not the sowing of forest tree seeds with "dry grain" be insisted on?—Ed.]

MANURIAL USES OF TAN.

Has spent tan any manurial value? Applied to grass land, either in a fresh or rotten state, it gives no good result at all—its presence seems, if anything, detrimental. Does it contain any essential plant food? and if so, do certain deleterious properties counteract any benefit that might otherwise accrue from that plant food? At many leather-tanning establishments throughout the country vast accumulations of spent tan exist, for which there seems to be difficulty in finding suitable use; yet I am impressed with the idea that it should have its uses in aiding fertility in the soil, or at least in awakening dormant fertility in close difficultly workable soils.

Poor land, whether of the light dry sandy or extremely stiff clayey order, is greatly benefited by admixture with humus, although the humus contain no plant food in its composition; for humus certainly tends to modify certain defects in both these kinds of land; it lends a retentiveness of moisture to the

dry sandy, and tends to keep open and pervious to water the stiff close clays, by both mechanical and chemical action. That pure humus is not, and does not contain, a plant food, such as plants take in by means of their roots, has long since been demonstrated by Liebig. Usually, however, humus is by no means (chemically) pure, and it is considered that great benefit is derived from it by plants, when, on its decay, it yields up these impurities (probably valuable plant foods) in that soluble condition in which they (the plants) can make use of them. What we now want to know is—Is tan, when fully rotted, pure or impure humus? and, if the latter, are the impurities contained in such humus good plant food, or merely harmless, or really deleterious matters?

Till science has thrown more light on the subject, I hold that quite rotten tan is humus, and it is well known that many kinds of soil are, as before stated, much improved in condition and consequent productiveness, by having humus mixed into them, although that humus contains no plant food whatever.

I have had large heaps of tan placed close to a dead well, and whenever the latter has become full, the contents have been pumped out on to the tan, the water subsequently draining away, while the virtue, or at least some of it, remained in the tan.

This saturated tan applied to grass land appears to give very good results so far. In the absence of scientific conclusions, I am disposed to judge whether the goodness out of the dead-well stuff is retained by means of the tan, or even so much of it as would be retained by using in a similar manner charcoal, dried peat, or earth of some kind. I have also for some years used tan mixed with ordinary farmyard manure, rotted down together, as a mulching for roses and fruit trees in hot dry soil, and the result has apparently been very beneficial. I imagine ground coprolites mixed intimately with tan by being thrown on a heap thereof, and at the same time turning the tan well over, would shortly have the phosphates rendered as soluble as in superphosphate, and in the abovenamed soils (especially where phosphoric acid is deficient) would then make a very valuable manure. Kainit and other potash manures would also have their solubility much increased, and so become much more valuable by being mixed with the tan some time before its application to land.

If any of your correspondents learned in scientific agriculture would give us, through the medium of your columns, their opinions on this subject, they would, I feel sure, interest a large class of your readers.—J. E. E.—*Gardener's Chronicle.*

PADDY (RICE) CULTIVATION IN THE CENTRAL PROVINCE OF CEYLON.

(By a Ceylonese.)

The soil in the Kandyan fields is a species of black clay. When the ploughing is done, and the water is let in, the whole becomes pulpy, for we do not say muddy. And as the sower walks it, scattering his seed, knee-deep in mud, each time he lifts his foot he draws out with it a large clod of clay, so that his footmarka leave, so to speak tiny pits of water, and not soil. Under such conditions, the theory, that making nurseries of paddy and transplanting them would be an improvement among the Kandyans is a dream which will not be realized. The graphic description of grain cultivation in Palestine, as told us in the parable, is but the picture of paddy cultivation in the Central Province. It is noteworthy that the occupation of the sower is the especial privilege of one or two men in a village whose head is thought to be "lucky." It is not every one who can do the work.

The preparation of the seed corn is carefully attended to. The stalks that stand upright without falling to the ground, and, not containing damp, are thought to be the healthy-bearded grain. They are cut; the grain together with the straw is stacked inside the

house, being laid on in a conical shape very much like a dagoba. Then when the cultivation season approaches, the grain is carefully taken out and put into a basket and covered with leaves, or if in a bag, the mouth is tied up, and the basket or bag is left in running water for thirty-five Sinhalese hours, that is, if you put it in the stream at six o'clock in the morning, you take it out at four or five o'clock in the evening. Then it is laid aside for three days, when the grain germinates. Soon afterwards it is taken off and spread on the floor, the heap being so laid as to be three or four inches in depth. You have to cover it thickly with plantain leaves to prevent the action of the air on the seed-corn. This lasts for a whole day. The germinated seeds are carefully separated so as to be all single. Then behold the sower goeth forth to sow; some seeds fall by the way side, the footpath, some on the stony places, as boulders in the field; some on thorns fencing the tillage, and others fall on good ground, and bring forth fruit, some a hundred-fold, some sixty-fold, some thirty-fold. A good number of widows live by giving out seed corn on interest, the rate being fifty per cent, so that one bushel of sowing paddy will bring you another half-a-bushel as interest.

But let us mention what circumstances of late have been at work in the Central Province making paddy cultivation a precarious livelihood. In some districts the denuding of forests on the adjoining hills has dried up the sources of water or lessened their quantity. In other places the water flows from the plantation into the ella or channel, bringing the debris from the pulping house, and the heat of the coffee pulp is no dainty to paddy, which wants cold water, the coldest being the best. The fermentation of the pulp is poison to the young paddy. Then the pasture ground for buffaloes have, by the opening of estates been circumscribed, and so these cattle have not multiplied; they are on the decrease. So that you have now to bring buffaloes far from the interior parts, and pay a rupee as hire, defraying the expenses of the drivers.

Much has been said of late of there being not an overplus of paddy by cultivation. The Kandyan chiefs and owners of extensive fields will tell you of paddy in their granary that is six or seven years in age. After that time it is thought that paddy grows bitter, and every seventh year in a chieftain's village is a year of jubilee, when paddy is freely distributed to the poor. When a Kandyan wants to boast of his wealth, he not only speaks of his extensive lands, but of the quantity of paddy in his granary, and of their age. In our next we shall speak of paddy cultivation in our own Province.—“Ceylon Patriot.”

STRIKING A LIGHT.

In the new edition of Mason's *Burma* we read that among other uses to which the Bamboo is applied, not the least useful is that of producing fire by friction. For this purpose a joint of thoroughly dry Bamboo is selected, about $1\frac{1}{2}$ or 2 inches in diameter, and this joint is then split in halves. A ball is now prepared by scraping off shavings from a perfectly dry Bamboo, and this ball being placed on some firm support, as a fallen log or piece of rock, one of the above halves is held by its ends firmly down on it, so that the ball of soft fibre is pressed with some force against its inner or concave surface. Another man now takes a piece of Bamboo a foot long or less, and shaped with a blunt edge, something like a paper-knife, commences a sawing motion backwards and forwards across the horizontal piece of Bamboo, and just over the spot where the ball of soft fibre is held. The motion is slow at first, and by degrees a groove is formed, which soon deepens as the motion increases in quickness. Soon smoke arises, and the motion is now made as rapid as possible, and by the time the Bamboo is cut through not only smoke but sparks are seen, which soon ignite the materials of which the ball beneath

is composed. The first tender spark is now carefully blown, and when well lighted the ball is withdrawn, and leaves and other inflammable materials heaped over it, and a fire secured. This is the only method that I am aware of for procuring fire by friction in Burmah, but on the hills and out-of-the-way parts, that philosophical toy, the “pyrophorus,” is still in use. This consists* of a short joint of a thick woody Bamboo, nearly cut, which forms a cylinder. At the bottom of this a bit of tinder is placed, and a tightly-fitting piston inserted composed of some hard wood. The tube being now held in one hand or firmly supported, the piston is driven violently down on the timber by a smart blow from the hand, with the result of igniting the tinder beneath.

Another method of obtaining fire by friction from Bamboos is thus described by Captain T. H. Lewin (*Hill Tracts of Chittagong, and the Dwellers Therein*: Calcutta, 1895, p. 83), as practised in the Chittagong Hills. The Tipperahs make use of an ingenious device to obtain fire; they take a piece of dry Bamboo, about a foot long, split it in half, and on its outer round surface cut a nick or notch, about an eighth of an inch broad, circling round the semi-circumference of the Bamboo, shallow towards the edges, but deepening in the centre until a minute slit of about a line in breadth pierces the inner surface of the Bamboo fire-stick. Then a flexible strip of Bamboo is taken, about $1\frac{1}{2}$ foot long and an eighth of an inch in breadth, to fit the circling notch or groove in the fire-stick. This slip or band is rubbed with fine dry sand, and then passed round the fire-stick, on which the operator stands, a foot on either end. Then the slip, grasped firmly, an end in each hand, is pulled steadily back and forth, increasing gradually in pressure and velocity as the smoke comes. By the time the fire-band snaps with the friction there ought to appear through the slit in the fire-stick some incandescent dust, and this placed, smouldering as it is, in a nest of dry Bamboo shavings, can be gently blown into a flame.—*Gardener's Chronicle*.

THE CULTIVATION OF THE STAR ANISE TREE AND THE PREPARATION OF THE OIL IN ANNAM.†

The star anise, or badiane, called by the Annamites “bac-giai-qua” or “qua-hoi,” is the fruit of a tall tree that is cultivated in the mountainous regions of Annam, upon the slopes covered with earth. The natives affirm that it is nowhere met with in the mountains in the wild state. At the village of Na-nam, in the mandarin route, twelve kilometres from Lang-sou, it has been ascertained by inspection that the seedlings and young trees are the objects of attention by the Annamites, who surround them with bamboos; also that the larger trees are planted in a regular manner.

The “qua-hoi,” the trunk of which is as straight as that of the poplar, bears branches resembling those of the eucalyptus. It is met with everywhere in the mountains around Ha-long, Dong-dang, Vau-quan and Pho-vi, which are the principal centres of culture and production. The oil is prepared at Lang-sou, Ki-lun, Dong-dang and Ha-long, industrial centres of manufacture.

During ten years, the “bac-giai-qua” grows very slowly. At the end of that time it attains a height of about three metres. Up to that time it produces very little, scarcely yielding more than one or two Annamite kilograms (1200 grams). From its tenth year its size and its production increase rapidly up to thirty or forty years, at which age the tree commences to fall off and die. A tree of ten to fifteen centimetres diameter yields an average of twenty Annamite kilo-

* It is also made of a solid cylinder of buffalo's horn, with a central hollow of 3-16th of an inch in diameter, and 3 inches deep burnt into it. The piston, which fits very tightly in it, is made of ironwood or some wood equally hard.

† From the *Petit Moniteur de la Pharmacie*, July.

grams of fruit; a full-sized tree, with a diameter of forty to fifty centimetres, gives two hundred kilograms. The fruit is sold whist green to the manufacturers of the oil at the price of four tiens the Annamite kilogram.

The Annamites sow the seed of the "bac-gia-quai" in manured soil. The young plants issue from the soil after about twenty or thirty days, and in two or three years they attain a height of twenty or thirty centimetres. They are then transplanted and pricked out at a distance of five or six metres from each other, but always upon the slopes free from stones and never at the bottom of a ravine. The tree bears a small yellow and white flower in the first or second month of the Annamite year and fruit in the sixth to the ninth month, but it yields fruit only every two years. The collection of the fruit is made by hand. The cultivation is not subject to any impost. The fruit is purchased either directly in the villages, or in the country markets, at a half ligature the Annamite kilogram.

The manufacture of the oil was subject to a tax that was collected by the "tuam-plu," who was at the same time the farmer of star anise for the province of Lang-son. The tax varied according to the extent of the operation; it was three ligatures for a large distillation of ten kilograms of fruit, and one ligature-and-a-half for a distillation of three or four kilograms. This tax was paid for every distillation and authority to distil had to be renewed each time. The only existing apparatus is of the dimensions suited for one or other of these two quantities. The oil is the product of a distillation conducted as follows:— Into a first recipient, which is an iron pan about seventy-five centimetres in diameter, are placed ten kilograms of star anise and water, which quantity nearly fills it. A second iron pan, pierced with a circular opening about twenty-five to thirty centimetres in circumference, is placed upon the first, bottom upwards, so as to form a cover. Over the opening in this pan is placed an earthen vessel, having three small orifices in the lower part, which allow the access of the vapour into this vessel. These orifices are covered, on the inside of the recipient, by small ear-shaped hoods that have for their object to throw the vapour upon the side of the vessel. Lastly, this earthen vessel is covered by an iron pan which performs the part of refrigerator, and into which a continuous current of cold water is made to pass by means of a bamboo pipe, from a vat placed near the apparatus. The joints of the first two iron pans are luted with a mastic, that of the earthen vessel with the refrigerator by means of rag bandages. The vapour, reaching the earthen vessel is condensed when it strikes upon the bottom of the pan holding the cold water, and falls into a small circular trough running round the bottom of the vessel, from which it escapes through a small pipe. The small pipe opens out into a bamboo which conducts the products of distillation into a closed tinued vessel full of water, where the oil, rising to the top, drives out a corresponding quantity of water.

A distillation lasts two days and the yield from ten Annamite kilograms of star anise is two-and-a-half decilitres of oil. The residue of the distillation is thrown away. A single manufacturer, and there are many, would distil 150 to 180 Annamite kilograms of oil yearly.

The oil is enclosed in tinned recipients and sold in China at Long-chau. Before the French occupation of Hanoi and Bac-ninh, a part of the products went by these two places into Tonquin, but since then the Chinese dealers have remained the masters of the market.—*Pharmaceutical Journal*.

Another Tea Merchant at Kobe has been discovered in an attempt to sell sea-damaged tea mixed with sound leaf. The mixture has been confiscated, and the delinquent will be dealt with by the Tea Guild. *Japan Weekly Mail*.

REPORT OF THE COMMITTEE OF THE MADRAS AGRICULTURAL SOCIETY, FOR THE YEAR 1884.

The report of this useful Society, although dealing with circumstances of climate different from those existing in a large portion of Ceylon, will be found very interesting.—*Ed.*

The Society has throughout the year earnestly continued its work with a view to compassing the objects for which it was founded very nearly fifty years ago, namely the promotion of Horticulture and the encouragement of improvements in Agriculture, and its labours have not been unrewarded, though the season on the whole cannot be called a good one. The proceedings of the Committee passed at their monthly meetings show that the Society's energy has not flagged; while the books of account show that its monetary affairs are in an highly satisfactory state. In the office letter books will be found 1,623 letters, many of them of much importance, written and entered during the year, which of course do not include numerous notes written by the officers of the Society of which it was unnecessary or inconvenient to keep a record. The correspondence of the Society, which is to a great extent a rough gauge of the amount of work it is doing, has very nearly doubled during the last 10 years, and tripled since 1869.

The season.—As stated above, the season cannot be called a good one, the even and fair distribution of the rainfall on which Madras gardens depend for their success having entirely failed us, though the average allowance of rain was greatly exceeded.

For the following particulars we are indebted to the returns from the Government Observatory published weekly in the *Port St. George Gazette*. In the month of January, 1884, we had on three days 2-14 inches of rain, in February none, and in March none, against an average fall in the first quarter of 1-65 inches. In April we had a thunder-storm which gave us 1-66 inches. In May we had on four days 1-43 inches, and in June 0-01 of an inch, making in the first half year 5-29 inches against an average of 6-56. In July, August and September there was a fairly well distributed rainfall of 10-70 inches, 3-55 in July, 1-59 in August, and 5-56 in September, giving promise of a very good season, though it brought the total for the 9 months up to 15-99 only against an average of 19-35 for that period.

But promises were speedily scattered by the deluge, or rather deluges which followed. Between October 10th and November 16th we had a fall of 42-1 inches, against an average of 27-6 for the North-East monsoon,—including in October, on one day 3-76, and on another 2-29 inches, in November, on seven of the first nine days 2-31, 3-15, 2-20, 4-62, 5-72, 3-16, and 3-72 inches, and in December, between the 15th and 22nd 13-85 inches. In October, the rainfall was 14-34 inches, in November, 31-23, and in December, 14-41, making during the whole year a total of 78-92 inches against an average of 48-71 inches.

Such excessive rainfall is particularly destructive, more so than a scarcity. Seeds and seedlings in the seed-bed, and plants delicate in this climate perish wholesale as if from chill, while large and hardy trees and shrubs, even casuarinas, die in numbers, drowned by standing water.

To add to the mischief done by the excessive rain we had on the morning of the 21st November, a severe cyclone which did considerable damage in the Society's gardens though happily little, if any, of an irreparable kind. An interesting report by the Superintendent giving the full details of the damage done was published in the proceedings of the Committee of 11th December last.†

Proceedings of Government.—During the year many Proceedings of Government on Agricultural, Botanical, and kindred topics of interest to this Society have been communicated and carefully filed, the receipt of

* 15th July, 1835.

Gardens" but the plants now being raised are from seeds and cuttings of a young plant received in November 1882, from Ootacamund, which has grown and seeded freely. A very powerful anesthetic agent found in the leaves has lately brought the plant into notice, and enquiries have been addressed to Europe as to the method of preparation. The extract of the leaves referred to, is said to be likely to become of very great importance to facilitate a certain class of surgical operations. The dried leaves were not obtainable in London when the last mail left at ten shillings per pound; the extract from the green leaves was selling at ten shillings an ounce, and the alkaloid had been as high as twenty two shillings and six pence per gramme.

Croton Oil.—A thousand croton seeds were obtained from Ceylon, but though many germinated and promised well all died during the rains. This valuable medicinal plant ought to grow well in the Gardens, as many of its near relatives do, but so far all attempts to induce it to do so have failed.

Mahogany.—On a reference from Government, a report was prepared and submitted recapitulating as far as possible the information possessed by the Society regarding the introduction and growth of Mahogany in this Presidency.

Little was unfortunately done during the past year in distributing the tree. Though seed was asked for from Jamaica direct* none was received. Two parcels containing 3,100 seeds were received from Calcutta, but, as is usual when the voyage is in any way prolonged, nearly all had lost their vitality, and 40 plants only were raised in spite of every care.

By actual experience it has been found that a very much larger proportion of Mahogany seeds reach Madras without losing their vitality when sent in bags by post, direct from the West Indies, than when sent in casks first to London and there transhipped. If for some reason it be more convenient to send the seed in casks, it would probably travel with greater safety if tightly packed in soil to prevent shaking and excessive dryage.

Nothing has yet been decisively ascertained to explain why the Society's old Mahogany trees which flower so freely bear no fruit.

A small parcel of seed of *Sapindus saponaria*, the berry of which is used for soap, was received from Mr. Morris, Jamaica, but only one plant survives.

Nothing more has been heard of the success or failure of the Society's attempts to introduce the handsome American Catalpa. The young plant raised and presented to the garden by T. Govinda Row, Esq., mentioned in last report, died.

Plants of the Australian Salt Bush, *Atriplex nummularia* are to be seen growing well in the gardens, but they have as yet shown no signs of sowing their own seed or otherwise providing for taking care of themselves, which is required before they can be said to be successfully introduced.

Seed of *Pentaria virgata*, Australian "Sheep-bush," was again written for and received from Adelaide, but did not succeed.

Aracantha which has been long enquired for was again written for, but not received.

A splendid collection† of seeds was received from Kew in July, large numbers of which germinated, but were caught in the critical seedling stage by the bad weather. Many, however, survive, and it is still hoped that we may succeed in rearing numerous valuable acquisitions from amongst them.

Many fine batches of seeds have been received from the Neilherry Hills, particularly from Charles Gray, Esq., Coonoor, which have been sent to correspondents in other parts of the world, particularly to Kew, Australia, and Natal, where it is believed they are especially welcome.

Agency.—Efforts were as usual made to comply with all demands on the Society made by both members and others in Madras, and at a distance, to act as agents to engage gardeners, and obtain gardening and agricultural books and implements. Many tools were made for sale and to order in the Gardens.

CULTIVATION OF THE GRAPE VINE IN NORTH CEYLON.

(Communicated.)

A good number of your readers know that Jaffna is famous for its grapes. The grapes are ripe in May and September. The cultivation of the grape-vine requires as careful study and attention as any other delicate plant. A grape-vine, carefully attended to, bears at the first year. To those who wish to cultivate the grape-vine, the following may be useful:—

1. You should be careful to select your plant out of the sweet vine. There are two kinds of grapes in Jaffna. One of a greenish colour and sour, however ripe the fruit may be. The fruit is also not so large as that of the sweet vine. The fruit of the sweet vine is of a light bluish colour. The seed could be seen through the rind when the fruit is perfectly ripe. It is as large as an ordinary marble. The plant is obtained by burying one of the branches.

2. The pit, before you plant your vine, should be well manured, at least three or four months previously. It should be about the depth of 10 or 12 feet and 8 to 10 feet in breadth. The manure to be used is cowdung. The vine does not thrive when other manure is used. After the vine is planted a circle about four feet in radius should be made round it, so as to hold the water that is let in. It should then be watered twice a day, till the pit becomes a muddy pool. If it is not done so, the plant dies on account of the heat arising from the manure.

3. After the plant has sent out its branches, and these begin to creep, the next thing it requires is a platform. This is ordinarily made out of Palmirah timbers; and several plants could be allowed to creep on one. It should not be very high; a man's height would be quite sufficient; so that a man could stand underneath and pick out the bugs and caterpillars, that may eat up the leaves.

4. The months for pruning are January and July. The pruning is generally done on a new moon. The pruning consists in cutting off the secondaries or thin branches on which there are leaves. The primaries or thick branches should not be cut. After the pruning the grape vine appears quite bare, with only leafless branches spread out on the platform. What the vine then wants is manuring. This is done by digging out the soil, from the pit, and exposing the roots. You should be careful that the roots, especially the tap or main root should not be cut, while digging; and water should not be then let in at all. After allowing the roots to be exposed and well dried, the pit is then to be filled with manure, and covered up with soil. The manure as I have said before, should be cow-dung, which ought to be dry and well-powdered before it is used. Horse dung, ashes and other manures are destructive to the vine. After the manure is put in, you should let in water twice a day, once in the morning, at sunrise, and once in the evening; at sunset, till the pit becomes a muddy pool. Manuring once a year in July is quite sufficient.

5. The grape vine requires exposure to the sun, and should not be planted where other trees cast their shadow. Coconut and Palmirah trees are destructive to the grape vine as they send out their roots, and hinder the roots of the grape vine from spreading.

Lastly care should be taken that no rubbish or fishy substance be left to accumulate in the pit, where the vine is planted.

If careful attention be paid to the planting, manuring and pruning of the grape-vine, it is sure to grow well, and be remunerative—"Ceylon Patriot."

ANNUAL REPORT ON THE BOTANIC GARDENS, SINGAPORE, FOR THE YEAR 1884.

Of the plants introduced in previous years, the following show signs of acclimating themselves to the soil and climate of the country, viz.:—"Coca" (*Erythroxylon coca*) which has flowered and fruited freely during the year. From this plant is produced an alkaloid called "Cocaine," used in the treatment of asthma, &c., and at present attracting much attention among medical men. I think it might be grown in the Colony with profit.

The plant which produces the so-called Mauritius hemp is a native of South America, and is well adapted for cultivation here. Some planters who have tried it have sent large orders for a further supply, and I believe, ordered machinery from England for its manufacture.

The plants of *Cinnamomum cassia*, which produces the Cassia Bark of commerce, grow very freely in the experimental nursery, and will probably become one of the Colonial products in course of time.

One of two varieties of Cardamom, introduced during the year from Java, has flowered and fruited very freely, and would no doubt pay cultivation well. Liberian coffee has now been carried by cultivators beyond the limit of experiment, and I refer to it only as among the plants introduced into the Colony by this establishment. The Panama rubbers, so admirably cultivated by Sir Hugh Low, were also first introduced by the Botanic Gardens.

Plants of the African "Kola nut" planted in the experimental nursery, have grown well in the alluvial soil there. The plants of "Avocado pear," planted out in the Economic Garden some years ago, where their growth stood almost stationary, have been removed to the nursery just named, and have grown with extraordinary rapidity.

Plants from seed of the Lima Bean of Brazil have been grown in the nursery with great success, and form a desirable addition to our vegetable supply. The names of other vegetables which have succeeded in the nursery were given in last year's report and need not be repeated here.

A quantity of nutmegs and cloves have been introduced from their native habitat as fresh stock for experimental purposes. Plants of Peach, Apricot, Grape Vine, Olives, and Figs in variety have been ordered from Sydney, but the season of the year there when the order arrived not admitting of the despatch of the plants, they were not received within the year, and therefore fall to the share of next year's report. I may be permitted to mention in this connexion that, although there are some good specimen plants in the gardens, a point is not being made of growing such plants to the exclusion of propagation, the object of the gardens being to introduce desirable plants into the Colony and cultivate them for such length of time only as will demonstrate their adaptability or otherwise for cultivation in the soil and climate of the settlements, and to propagate such as appear suitable, for distribution to cultivators and specimen growers.—*Straits Times*.

THE POSITION OF THE CINCHONA ENTER-PRIZE IN CEYLON.

It is really astonishing how little interest is now taken in, or attention paid to, the cultivation of cinchona, if we are to judge of the matter by the reference made to it in the public press. The once all-absorbing topic has completely died out as if such a thing as cinchona never grew in the island. One would hardly think that as much as 10,000,000 lb. of cinchona bark had been shipped from the colony to date since the commencement of the fiscal year, much more than equal in value to the quantity of tea exported from the island during the same period; yet so it is. The cause for this apathy, however, is not far to seek. With the exception of certain localities, restricted in area, cinchona has not been found to be a profitable cultivation. Its indiscrimin-

ate cultivation through the coffee zone from Matale to Madulima has been abandoned, and the planter now looks to tea, and to tea almost alone, to help him over the style. There are, however, certain favored spots in which cinchonas appear to thrive as they do in their native habitat far away on the steep slopes of the Andes, where caker is almost unknown, and all is prolific growth. Even at present prices the cultivation in such places is more remunerative than either tea or coffee was, but with one exception we do not hear of any new cinchona clearings being opened this year, and that one is in one of the favored localities referred to by us. We hear that Mr. Jas. McLaren, of Nuwara Eliya, is so satisfied with the returns from the acreage already under cinchona in the Park estate, that he is putting 40 acres more of jungle under that product. That the vicinity of Nuwara Eliya is the home of *officinalis* in Ceylon does not admit of doubt. No where else does that delicate variety of cinchona grow with anything like the luxuriance and vigor which it exhibits there in certain aspects. Mr. McLaren has shaved some of his *officinalis* as many as four times, and then coppiced the trees, which have thrown out strong, healthy suckers as vigorous as the original shoot. No wonder, considering the high profit obtained per acre from his cinchona, that Mr. McLaren should prefer to put his remaining 40 acres of jungle into cinchona rather than tea, which, though even at that altitude yielding handsome returns cannot hope to equal cinchona. We hope that what will probably prove one of the last large new clearings of *officinalis* in Ceylon may be as successful as the earlier ones in that locality, where the product seems to grow like white weed.

It is useless to attempt to cultivate cinchona where it will not grow, and as the area in Ceylon where it will grow is not large, we look forward to its careful and permanent cultivation in those spots where experience has taught us it thrives luxuriantly, the most noted of which being the vicinity of Nuwara Eliya and Madulima.—*Local "Times."*

PHYLOXERA IN GREECE.—The following official communication has been forwarded to us for publication:—"Considerable alarm is felt here about the possible spread to this country of the Phylloxera, which is said to have appeared in the neighbourhood of Constantinople. Stringent measures will be adopted to prevent its introduction, the importation of all trees, plants, fruit, grass and hay from eastern countries, including Candia and Egypt, being prohibited under very severe penalties. Things are bad enough in Greece as it is, and the scourge, should it reach this country, would almost consummate its ruin from an economic and financial point of view.—I have the honour, &c., (Signed) HORACE RUMFOLD, The Earl GRANVILLE, K.G."—*Gardener's Chronicle*.

MANURING TEA.—In the extracts from Mr. J. McL. Carter's paper on this subject on pages 312-14, there are a number of misprints, the corrections of which, in a later issue of the *Indian Tea Gazette*, did not reach us until after the above pages were printed off. On p. 312, col. 2, line 26 from below, for *four*, read *from*, and in line 30 from below, for *plots*, read *plots*. On p. 313, col. 1, line 16, for *garden* read *garden*, and after at add *As. 3*: line 29, for *garden* read *garden*; in the estimate of cost per acre on plot No. 2, the figures under P. should be, 6, 0, and 6; for *Result* per acre read *Results*. On the same page, col. 2, last line but one, after 914 read *lb*. On page 314, col. 1, line 4, after *acres* read *equal*, and add, between lines 4 and 5, *or 163*. On the same page, line 26, read *R872*; line 27, for *next* read *net*; after line 28 read *The first year exactly*; line 32, after 81 read *as*; line 37, after *profit*, read *equals*; line 39, read *estimation*.

Gardens" but the plants now being raised are from seeds and cuttings of a young plant received in November 1882, from Ootacandum, which has grown and seeded freely. THE POSITION OF THE CINCHONA ENTER-PRIZE IN CEYLON.

It is really astonishing how little interest is now taken in, or attention paid to, the cultivation of cinchona, if we are to judge of the matter by the reference made to it in the public press. The once all-absorbing topic has completely died out as if such a thing as cinchona never grew in the island. One would hardly think that as much as 10,000,000 lb. of cinchona bark had been shipped from the colony to date since the commencement of the fiscal year, much more than equal in value to the quantity of tea exported from the island during the same period; yet so it is. The cause for this apathy, however, is not far to seek. With the exception of certain localities, restricted in area, cinchona has not been found to be a profitable cultivation. Its indiscrimi-

nate cultivation through the coffee zone from Matale to Madulsima has been abandoned, and the planter now looks to tea, and to tea almost alone, to help him over the style. There are, however, certain favored spots in which cinchona appears to thrive as they do in their native habitat far away on the steep slopes of the Andes, where cooler is almost unknown, and all is prolific growth. Even at present prices the cultivation in such places is more remunerative than either tea or coffee was, but with one exception we do not hear of any new cinchona clearings being opened this year, and that one is in one of the favored localities referred to by us. We hear that Mr. Jas. McLaren, of Nawara Eliya, is so satisfied with the returns from the acreage already under cinchona in the Park estate, that he is putting 10 acres more of jungle under that product. That the vicinity of Nawara Eliya is the home of *officinalis* in Ceylon does not admit of doubt. No where else does that delicate variety of cinchona grow with anything like the luxuriance and vigor which it exhibits there in certain aspects. Mr. McLaren has shaved some of his *officinalis* as many as four times, and then coppiced the trees, which have thrown out strong, healthy suckers as vigorous as the original shoot. No wonder, considering the high profit obtained per acre from his cinchona, that Mr. McLaren should prefer to put his remaining 40 acres of jungle into cinchona rather than tea, which, though even at that altitude yielding handsome returns cannot hope to equal cinchona. We hope that what will probably prove one of the last large new clearings of *officinalis* in Ceylon may be as successful as the earlier ones in that locality, where the product seems to grow like white wood.

It is useless to attempt to cultivate cinchona where it will not grow, and as the area in Ceylon where it *will* grow is not large, we look forward to its careful and permanent cultivation in those spots where experience has taught us it thrives luxuriantly, the most noted of which being the vicinity of Nawara Eliya and Madulsima—Local "Times."

PHYLOXERA IN GREECE.—The following official communication has been forwarded to us for publication—"Considerable alarm is felt here about the possible spread to this country of the Phylloxera, which is said to have appeared in the neighborhood of Constantinople. Stringent measures will be adapted to prevent its introduction, the importation of all trees, plants, fruit, grass and hay from eastern countries, including Candia and Egypt, being prohibited under very severe penalties. Things are bad enough in Greece as it is, and the scourge, should it reach this country, would almost consummate its ruin from an economic and financial point of view.—I have the honour, &c., (Signed) HORACE R. MOULD, The Earl GRANVILLE, K.G."—*Gardener's Chronicle*.

MANURING TEA.—In the extracts from Mr. J. McL. Carter's paper on this subject on pages 312-14, there are a number of misprints, the corrections of which, in a later issue of the *Indian Tea Gazette*, did not reach us until after the above pages were printed off. On p. 312, col. 2, line 26 from below, for *low*, read *from*, and in line 30 from below, for *plots*, read *plots*. On p. 313, col. 1, line 16, for *garden* read *garden*, and after *at ad* Ax. 3: line 29, for *garden* read *garden*; in the estimate of cost per acre on plot No. 2, the figures under P. should be 6, 0, and 6; for *Result* per acre read *Results*. On the same page, col. 2, last line but one, after 914 read *th*. On page 314, col. 1, line 4, after *acre* read *equal*, and add, between lines 1 and 5, *or 163*. On the same page, line 26, read R872; line 27, for *next* read *net*; after line 28 read *The first year exactly*; line 32, after 8½ read *as*; line 37, after *profit*, read *equals*; line 39, read *estimation*.

TO COLLECT THE OODOR OF FLOWERS.—Roses and flowers containing perfumed oils may be made to yield their aromatic qualities by steeping the petals in a saucer of water, and setting it in the sun. The water should be soft, or rain water, and a sufficient quantity allowed for evaporation. In a few days a film will cover the water. This is the essential oil of the flower; every particle is impregnated with the odor. It must be taken up carefully and put in tiny vials, which should remain open till all the remaining water is evaporated. A few drops of this will perfume glove boxes, apparel, etc., and will last a long time.—*Southern Planter.*

PROFITABLE FRUIT CULTURE.—Mr. Watkins, a practical fruit grower, in a paper read before the members of the Herefordshire Chamber of Agriculture, cited two successful cases of Apple growing last season that came under his own notice. In one case a small orchard of about three acres was recently planted with standard Apple trees of good sorts for table and kitchen use. The trees were properly cared for and manured, and as some sorts were found to be growing too freely they were root-pruned. The result was a magnificent crop of fruit last season, which realized about £16 per acre after paying all expenses. In an exposed situation plant rather thickly, say 18 feet to 20 feet apart; but if you have a sheltered situation, with a good deep and generous soil, give the trees plenty of room—30 feet or more. Apple or Pear trees may be planted alternately with Plums; the Plum tree is a much shorter-lived tree than the Apple or Pear, and comes into bearing sooner, thus bringing in a return till the other trees get fairly grown. A strong grower and a small grower may be placed alternately each way. Yet another plan is to plant them in hexagonal form instead of square; that is, instead of the trees being exactly opposite each other in adjoining rows, they are midway, thus giving more room to each individual tree without increasing the distance between or in the rows. In filling up old orchards never plant in the old holes; it is better to get the trees planted irregularly than to do this. Deep digging is essential in planting; but the trees should not be put in too deeply. The want of care in picking and packing the fruit is a frequent cause of loss. Mr. Watkins prefers autumn planting, except in cold wet soils, where he would plant in spring, not later than March.—*Gardeners' Chronicle.*

CEYLON TEA AT HIGH ALTITUDES.—We have very encouraging news of tea at high altitudes. We believe the returns from Abbotstford this year will be most satisfactory as to quantity, whilst the young places near Nawara Eliya are giving returns far in excess of previous expectations. As far as can be judged from the evidence before us, we see no reason to suppose that estates situated as high as, or higher than, 6,000 feet will give a very much reduced return of leaf per acre than those at sea level. Some time ago it was thought that the lower estates would give quantity—up to 700 lbs. per acre—but not the best quality, whereas the very high estates might be expected to yield a tea of surpassing flavor, though not in great abundance. So far as we are able to argue from actual facts before us, the superiority of high-grown tea has not as yet been very forcibly demonstrated to us, though we are far from denying that it will eventually establish its pre-eminence. But, as we gain experience from the growth of the industry in the island, one thing is becoming more and more plain every day, and that is that the small yields to be expected from tea grown at very high altitudes are certain to be very much exceeded, and that the tea plant can be grown to pay handsomely at almost any possible altitude in the island. Yields of 800 lb. an acre at the elevation of Nawara Eliya may, and doubtless will, be events of rare occurrence, but we confidently look forward to 500 and 600 lb. an acre as what may be expected from carefully planted, well sheltered, land, no matter what the altitude. The slowness with which the extreme elasticity—if we may use such a word in this connection—of the

tea plant has been realized by planters in Ceylon is somewhat curious, as we have remarked before. Though it was known to flourish in the hot steamy plains of Assam, on the bleak, almost frozen, heights of the Darjeeling hills under the very shadow of the ice-clad Himalayas, yet we in Ceylon were some time in realizing that it could be successfully grown, and be made to produce abundantly, at any altitude in the island. The fact is only now beginning to dawn upon us, and men who are busy planting up coffee land at from 5,000 to 6,000 feet with the more hardy tea plant are not now regarded as madmen, as they were a short time ago. In the same way the suitability of Uva for the cultivation of tea, for a long time denied, is now at last becoming accepted as an incontrovertible fact, which time alone can effectually prove. There are very few places in Uva where cinchona and coffee are now cultivated, which are not admirably suited for tea; and from rainfall returns now before us, many have as well-distributed a fall as the majority of estates on this side of Nawara Eliya.—Local "Times."

ORANGE FLOWERS.—In a paper recently read before the New York State Pharmaceutical Association, Mr. Lemberger stated that he had succeeded in distilling from orange flowers gathered in Florida and salted down a water comparing favourably with that imported from the south of Europe. As orange trees are now grown abundantly in Florida the petals are consequently plentiful, and he suggests that a new industry should be started in that State, in which low priced labour might be utilized in gathering the blossoms, especially of the wild or bitter orange.—*Pharmaceutical Journal.*

TEA: THE GREEN LEAF SEPARATOR AND SIFTING MACHINE, which has been patented by Messrs. Fairweather and Gilruth, of Sombawattie, has been named the "Success," and seems likely to justify its title. The machine, in its first trial with rolled leaf, worked most satisfactorily, finishing off one fill of Jackson's large "Excelsior" roller in five minutes, dropping the fine leaf in the centre, and the larger at the sides. A large machine is now in course of construction in Colombo, capable of being driven by steam-power, and others will be taken in hand for hand or steam. Mr. Gilruth thus writes of the machine:—The machine will be the means of reducing the tea-house coolly staff by 4 to 5; on a larger estate in greater proportion. It will also be a great saving of labor in this way: when the roll in its separated state is fired, it will not require so much sifting, and therefore accomplish at the same time the aim and object of all planters, *ie.*, preserving as much as possible the bloom on the tea. It also offers other advantages. The roll can be separated into three different grades, and in such a marked style. A tea-house manager, with care and knowledge of his work, will be able to accomplish with ease a long-wished-for desire, *ie.*, to have each and every leaf according to their class of the same uniform outturn in the cup, from being able to ferment each kind separately a long or short time according to his fancy; thus preventing the old inevitable complaint being made every time a mistake happens in the fermentation, which on many occasions is used and also abused, namely: as follows:—"Oh, I tried to get my course leaf as near an approach to my Pekoe as I could, and just waited a little too long. That is the reason I have such a dull outturn." And then again, on the other hand, it has a green outturn. Why? "Oh, because I did not want to sacrifice my Pekoe for my Pekoe Souchong or Souchong, as the case might be." Perhaps, if he was an under-stripper, and had no interest to make good tea, as he might think, through not getting a 5 per cent commission, he might try and make any of the above excuses pass when the fault lay on his want of judgment, or he is perhaps careless or too anxious to get away from his work. With the system the "Success" offers this cannot be done, or it is proof positive that it is due to carelessness.—Local "Times."

LETTERS FROM JAMAICA.—NO. 8.

SMALL COFFEE CROPS BUT GOOD PRICES AND GOOD PROSPECTS—MR. COTTAM'S CRITICISMS—JAMAICA AND CEYLON SYSTEMS OF CULTIVATION—THE FRUIT INDUSTRY AND RAILWAY EXTENSION—THE PANAMA CANAL.

Blue Mountain District, Jamaica, Aug. 1885.

Our Blue Mountain crops have, as I led you to expect, turned out small; but I am glad to say that prices so far as the coffee has yet been sold in the Liverpool market have been very satisfactory. Clifton Mount, Newton, Sherwood Forest, Clydesdale, Chestervale and Radnor produce has sold at prices ranging from 139s. to 110s. per cwt.; the first-named continues to bear the palm. The season has again been very dry, the lowlying coffee must have suffered from the drought, but it has been very suitable weather for the top mountain properties. The blossoms have as yet been good; there is another very good one on the eye of coming out, so that, unless unforeseen bad weather comes, we may look for a "bumper" next year. The old experienced planters say it will be a very good season from all present signs.

The remarks of your old correspondent, Mr. Cottam, relative to Blue Mountain coffee estates, which appeared in your *Weekly Observer* of 24th April last, are somewhat too trenchant, and the remarks upon the overseer of Sherwood Forest estate anything but polite. As to Jamaica coffee estates, everyone admits they are not as well or expensively cultivated, as was the rule in the good old Ceylon days when planters could spend £12 an acre, in cultivation, manuring, supervision, etc., and yet make profits of £8 to £12 an acre. Jamaica planters say they "must cut their coats according to the cloth"; they cannot afford high cultivation, and they "must make both ends meet." Of course the question remains, whether, if they weeded and pruned more frequently, the result would not be a success. I myself think it would; but the soil and climate are so good for coffee, that the trees do not seem to suffer as they would in Ceylon from being weeded only 3 or 4 times a year, and it certainly saves "wash," which is a consideration. Had Mr. Cottam had an opportunity of going over some of the properties he names he would have found cultivation better attended to than he supposes, some of the estates being added to by new clearings; and as to Sherwood Forest, he would have found it a very fine property of about 200 acres coffee, kept very fairly clean, trees in decent order, and the most compact of all the Blue Mountain properties. It is therefore not just or correct to state that "there is no extension of coffee cultivation in the Blue Mountains," as Abbey Green, Cleveclands, Arnkully, Corner Post and Whitfield Hall are all being extended, and we also hear of some projected estates on the Northern slopes.

I send you a Jamaica paper which contains interesting articles on our Fruit Industry, and also about the present state of the Panama Canal works. As regards the former it is much to be regretted that the finances of the island do not admit of the extension of our present railway system to connect the northern ports with the capital, for I am sure it would be a success; and not to mention, is as bad as stopping the Ceylon line at Nambaya, and not pushing on all the 6 years to Hapudala and Badulla. It would help to revive the agricultural prospects of the island, and confer benefits not only on sugar planters and fruit-growers but on the general public. I am sure the land along the line could soon be

taken up for banana and coca growing, as well as other tropical products; any scheme that helped the planters and pen-keepers in cheapness and certainty of transport, and enabled them to get up manure at a cheap rate, would be beneficial. I trust therefore the day is not far off when the Governor will see his way to sanctioning the expenses of a survey to select the best and cheapest route; there should be no difficulty in raising a guaranteed loan at home for the construction. Mr. Esprit points out the delicacy of fruit, and that it cannot bear to be kept long; if therefore the railway proves the fastest feeder to the several shipping ports, there is no doubt it would be well supported by the growers both European and creole. As to the Panama Canal, if affairs are as it is stated, matters seem to be in a very bad state for the present bondholders; neither will the work be accomplished as quickly as was promised. Where has all the money gone to? Echo answers where. Indirectly it has found well-paid employment, and as so many sugar properties have suffered from the low prices, and have not been able to employ so many hands as of yore, the work so near at hand must have been a Godsend to the Jamaica creole. Here, on our side of the island, owing to the drought and people being short of provisions we have not suffered from want of labor. We hear moreover of several who have gone to Colon in search of work until better seasons return. Felling and topping, pruning and all job works have been done cheaper on many estates owing to the above causes. The prices for felling, topping and clearing up ready for planting are dearer than in Ceylon, though the Jamaica forest as a rule is not nearly so heavy; the custom has been to pay 1s per square chain, or £2 an acre for the simple felling. W. S.

TEA PLANTING ON THE HILLS OF CEYLON.

TEA PRUNING—EFFECT OF BURYING PRUNINGS AND WEEDS—LUXURIANT FLUSH—THE TEA-LEAF MOTH—USE OF SPIDERS—TWIN AND TRINK TEA LEAVES—"WILD TEA"—OLD KING COFFEE IN HIS DOTAGE—"A SPRING CROP" IN DIMBULA—A MARKET FOR "COFFEE TEA" WANTED.

Tea pruning and the burying in longitudinal holes of the prunings, weeds and rotten timber debris are going briskly forward and wonderfully trim and clean the ground looks where the processes have been completed, while the tea bushes are scarcely cut down when they begin to put forth a fresh wealth of buds and wood. The mechanical as well as the manorial effect of the burying process must be most beneficial to the soil as well as to the plant, as is shown in the luxuriant flush on the trees pruned some months ago.

Yesterday I wrote that the moth prevalent in Dikoya had not reached this locality. That is still true of the higher fields, but on the lower, evidences of the presence of the insect were this morning seen in curled-up leaves. The consolation is that this pest chooses not flush but mature leaves whereon to lay its eggs—eggs whence the maggot escapes, sucks the juices of the leaf and is gone (as a moth?) in a time so incredibly short that it is but rarely the caterpillar can be seen. It is now that the value of spiders and their beautifully ingenious webs of all shapes, sizes and designs can be appreciated. The spider has not heard of the theory of the balance of animal life, but he works diligently on its lines, as the tea moth experiences.

Some of our tea has taken to producing two and even three leaves united, except at the points, and the wild tea, in order, I suppose, to show its affinity, is following suit, a doubled leaf being found amongst a brilliant red mass of foliage this morning. The persistency with which plants of this spurious tea spring up beside "the real Simon Pure" is as curious as it is annoying. But the rich pink shoots of the really pretty jungle plant ought to render mistake impossible. The true tea occasionally shows a dark flush, but pink or red never.

With all due reverence to old King Coffee, it must be told that his present conduct in Dimbula shows him to be in his dotage. Having heard of railway extension to Uva, he evidently fancies himself there, and has been making desperate efforts to produce a spring crop. Not only has blossom been profuse over large surfaces, but a good proportion has set. We are not to be deceived, however, for we know from past experience, that, of the many rows of incipient cherries, only a small percentage will arrive at the "palau" stage of redness and ripeness. If there were only a paying market for coffee tea, the temptation would be strong to utilize the tender leaves, before it is finally said of the once valued bushes: "Away with them to the tea factory furnace! Why cumber they the ground?"

CEYLON UP-COUNTRY PLANTING REPORT.

DRYING COCOA—CURING COCOA: A TRIAL—THE RISE IN THE CINCHONA MARKET—THE COMING "BOOM"—THE WEATHER AND NURSERIES—OLD COFFEE AND YOUNG TEA.

12th October 1885.

The drying of cocoa in wet weather has ever been a trouble, and the great expense some estates have gone to in erecting "Clerihew" and such like stobs—not to speak of the quantity of firewood consumed—has made this matter rather a serious one for the cacao-grower; yet we all know that something had to be done, as liable is cocoa to mould in showery or damp weather.

Where the acreage is not very large the difficulty can be got over by the use of "chulas," which have been very successfully employed for this purpose, turning out at the same time a fairly good sample. But to this there is a limit. From the "chula" to the "Clerihew," has been recognized as the necessary step to take; but now that Jackson's "Victoria" tea drier has entered the field, there is opened up a new era in the curing of cocoa, and let us hope also of profit to the manufacturer of the drier.

A trial of curing cocoa by passing it through the "Victoria" drier was made last week, with the following results. A bushel or so, in its prime shiny condition, was fed into the drier at a heat of 200°, and this in one passage through the machine brought the nibs to a state of dryness, equal almost to a first day in dry weather. But through a second time at a higher temperature, it was still more dried; and a third passage, I was told, finished it off. Between each passage through the machine there should be an interval enough to allow of the nibs getting perfectly cool. A sample of cocoa, which had been treated in this way, and which I saw, seemed to have quite as good a colour as sun-dried. How long a time it took to pass the stuff through I did not learn, but to be independent of weather, and to have a handy machine of this kind, to run one's cocoa through, when

the weather is unfavourable for natural drying, is likely to prove acceptable for the growers of this product. It is possible also that a machine on the same principle, but less expensive than the present tea drier, might be made and become popular.

The rise in the cinchona market is a matter we all hail with pleasure, and just hope it will continue. And yet what a lottery is bark growing. I heard of a very fine sample of quill bark, which had all the appearance of being rich in quinine, but when analyzed had hardly a trace, some 0.03 being the result obtained, whereas 3.00 might with reason have been more naturally expected. On the other side, again, some branch bark with some chips thrown in sold at over 30 cents a lb. to the astonishment of the worthy man who owned it, and who secured his broker's cheque as a sort of "treasure trove." Another man sent down a very fine sample with an enquiry as to what prices were ruling, and got a reply to the effect that for such a superior quality of bark as his parcel consisted of there was not at present very much demand! It was quite a treat to listen to the planter on receipt of this letter, as to the inscrutable ways of the Colombo broker, and the difficulty the agriculturist had in trying to please him. Yet "all's well that ends well," and with little or much demand the planter has realized at about the rate of R1,000 an acre. Lucky dog!

I was glad to see the other day in the *Observer* that in the world's metropolis the feeling of confidence in Ceylon is gaining ground, and taking the practical form of investment of capital. I too had been enquiring of a gentleman just from home if he had heard or seen aught of the coming "boom" when in London, but had not a very cheering reply. He found everyone delighted with tea and tea prospects, but the holders of property were all sellers; and as to the buyers—well, they were like "the boom," had not come to the front yet. Everything in time.

The weather has just been perfection for planting, and we have all been busy putting out tea plants. The only drawback is the failure of nurseries to meet the calls upon them.

Coffee is ripening up somewhat, and the sample coming in is fairly good. But there is so little of it to be had, that we go about that part of our work with the melancholy satisfaction one feels at a funeral when you are paying your last respects to an old and valued friend. Meanwhile the young tea is growing apace and hope grows with it. Young tea in Elkaduwa is coming on well. I heard of a place in that district where the year old plants have now reached from two to three feet in height.

PERFECTION.

THE TEA TAX IN CHINA.

From the *Pekin Gazette* of Sept. 19th quoted by the *North China Herald*, we have some curious information as to the doings of the Chinese Government in connection with their levy on tea:—

A Memorial from the Acting Governor of Hunan reporting on the difficulties which he finds present themselves in the way of imposing an increased tax on tea as suggested by the Board of Revenue in their Memorial to the Throne on the methods of improving the Imperial Revenue. One of the three ways by which it was proposed to secure this object was to effect a reorganization of the taxes on tea by one of three alternative methods viz:—

1.—To adopt a system of "labels" on packets, as in Kansu, one label being attached to every five catties of tea, and costing three taels mace which is collected from the grower.

2.—To adopt the system in force in Ning-hsia, Yun-an, Yufu and Szech in Shensi, where offices are established in the tea producing districts at which the tea is picked and assessed, and granted to the exporters, for 100 catties (on paying T\$ 9, in addition to the 100 cattie tax) at Barrier along the line of trade.

3.—To charge, in addition to the above fee of T\$ 3.9 for each 100 cattie license, a further sum of T\$ 3.9, on T\$ 1.25, in all, which is to free the tea from all further local charges whatsoever.

The proposals of the Board, with the elasticity of which the Memorialist was profoundly impressed, were at once reported to the Commissioner of Finance and the Board of Revenue for consideration as to the best means of carrying out them, and a report on the subject has now been forwarded to the Financial Commission and the Board of Revenue of the *tekin* offices.

In the report the latter state that "red tea," of which An-hua Hsien is the great producing centre, is the staple of the tea grown in Hunan; other producing districts, such as La-ling Hsien, &c., name their price in accordance with the fluctuation that occurs in An-hu. In earlier days the tea-grower of An-hua Hsien used to sell their teas at an average rate of about 10 odd strings of cash (say, 10,000 cash) per 100 catties, but of late the price has fallen to thirty string, more or less, while no reduction is possible in the charges for rent of land and cost of the labour required for picking and drying the leaves. If, therefore, a tax of three tael (once per five catties) be levied in accordance with the "label" system of Kansu, every picul of tea will have to pay T\$ Six more than it does at present, thus increasing the charges upon it and diminishing the profits proportionately, an eventuality which has caused much agitation among the growers.

It is suggested by some, say the Commissioner and Taotai, that there could be no harm in slightly raising the price of the tea at the time of its sale, and that by this means the grower would not, after all, be the sufferer by an increased tax; but this suggestion is made in ignorance of the fact that foreign merchants keep down prices by so many means that no dealer would care to augment them.

As regards the system of purchase pursued by the tea merchants, the tea is picked and prepared at An-hua, where, by the rule which has always prevailed in Huuan, it pays a preliminary duty of T\$ 1.25, per 100 catties, this payment being repeated upon arrival at the Hankow Customs, making a total levy on tea the of T\$ 2.5 per picul. Add to this the prime cost of the tea and the cost of water carriage, etc., and the total value comes up to something over T\$ 20. If, in addition to the above, a further tax of T\$ 3.9 is charged, exclusive of *tekin* and other dues at business route, or the alternative total duty of T\$ 28, the tea would be laid down something more than T\$ 30 per picul, while it now sells at T\$ 20, or at the most T\$ 25, it had to realize. Under these circumstances, the dealers, whose only aim is to make a profit on their tea, naturally would not care to pay the proposed tax, and the result would be a total stoppage of the tea trade.

The tea, according to the Ordinance of Hunan of 1884, is to be sold to the public, whether at home or abroad, at the rate of 25 taels per picul, and An-hua Hsien, consequently, pays per picul their *tekin* into the public stores. In the An-hua Hsien, the produce of the tea is sold at the rate of paying *tekin* in advance (one per cent) of the price of the tea at the time of its sale. In 1884, the payments in advance made amounted to more or less, T\$ 50,000 to T\$ 60,000, but the payments on

account of the new season's teas this year placed on the market were very inconsiderable. Careful enquiry into the origin of this falling-off has elicited the discovery that the run-out of an additional import caused the dealers to form such anticipations of the results that would accrue that they were unwilling to go into the country to make purchases. Thus, before the intention of increasing the duties has been put into effect, a marked and sudden diminution of the *tekin* revenue has manifested itself, and a general consideration of the whole question induces the framers of the report to request that the Memorialist will pray His Majesty to allow the old system of taxation to be continued.

In submitting the foregoing remarks for His Majesty's consideration, the Memorialist begs to state that they represent the actual facts of the case. While, however, an increase of revenue from this source is not feasible, it is essential that measures be taken to prevent any diminution, and in order to remove all doubts on the subject the Financial Commissioner and Taotai determined to issue proclamations through the *tekin* office announcing that the *tekin* on Hunan teas would continue to be levied on the old scale. The result has been that during the last month or so dealers have gone one after the other into the hills to purchase tea. None the less, the receipts at the *tekin* office from preliminary payment of duty have only realised T\$ 30,000 odd.

The Memorialist, in conclusion, while expressing his entire sympathy with the endeavours of the Board of Revenue to raise additional funds in these days of financial exhaustion, regrets that the circumstances of the tea growers of Hunan are such that any attempt to make them contribute to the desired increase would have no beneficial results, and would even do harm instead of good.

Every effort shall be made to give effect to the other proposal of the Board for the improvement of the revenue, and these will be considered in a separate Memorial.—Rescript: Let the Board of Revenue take cognizance.

THE PLANTERS' ASSOCIATION OF FLI.

We have received a copy of the Annual General Report of the Committee of this Association for the year ending 30th June 1885, presented at the annual general meeting of the Association, held at Levuka on the evening of August 6th, 1885, the Hon. R. Beckwith Leete, Chairman, presiding. The first subject dealt with in the Report was the Native Labour Ordinance, it being stated that though the special committee appointed to enquire into and report upon the best means (if any) of improving the enactment had not sent in their report, the over rigorous administration of the Ordinance formerly complained of had been very sensibly relaxed, so that it is now by no means difficult to obtain annual laborers either for short term or under annual contracts of service. The next subject referred to was Cully Labour, and it was stated that the recommendation of the Committee as to the desirability of enjoining the Tamil with the Bengalee Chinese was not successful. The dilatory nature of Ordinance No. X, 1881 again created serious difficulties in the way of carrying out the general scheme, but these were removed by Sir William Des Vaux's introduction of Ordinance No. XVI, 1882, to appropriate £10,000 for this service from the unexpended balance to the credit of the public account; and the introduction of coolies for allotment under the system of deferred payments has already commenced. The third subject dealt with in the report was the interruption and subsequent

resumption of correspondence between the Association and the Government, the latter refusing to receive communications signed by the Secretary, who was a *persona ingrata* with the Government. The other subjects referred to were as follows:— Association Meetings at Suva, Reciprocal Commercial Treaty with Victoria, Annexation of New Zealand, Meteorological Record, Fiji Committee, Contributions &c., and Finance and General. With regard to the last we learn that the financial position of the Association is a sound one, and that it carries a balance forward to the new year. Nevertheless, the expenditure has again exceeded receipts, and the Association has had still further to draw upon its cash balance. After the reading of this Report the Chairman delivered an address, reviewing the events of the year. We quote as follows:—

The labor question, which is one of the chief factors in all agricultural undertakings, and which has lately brought our neighbors in Queensland to the brink of ruin, does not here, now, assume so serious an aspect. Many of the coolies by the "Leonidas" are now free men. Planters are well supplied, and year by year this will become a subject of diminishing un- easiness to the planters of the colony. The Poly- nesians, may I think, be considered as practically played out, for from various causes, which it is unneces- sary for me to mention, such a dead set has been made against their indenture that it is impossible for so small a community as ours to "kick against the pricks;" and although we know that, so far as at any rate as this colony is concerned, the abuses have been enormously exaggerated, and that under an in- telligent system the men are still to be had, yet we must, I think, in policy concede the point and be con- tent to look upon coolies and Fijians as the labor of the future. The Fijians, our third supply of labor, are being more and more dispensed with, although, personally, I look upon them, more particularly for the hard work of opening plantations and landing machinery as the best of the three. The reasons for this are not far to seek, but will be found in the un- wise restrictions placed on their engagement by the Labor Ordinance of January 1883. Planters got dis- gust, despaired of overcoming the obstacles in their way, and supplied themselves with other labor; the result being that, as his Honor the late Admin- istrator has lately told us, there are large numbers trying for employment and cannot get it. Well may the Fijians say "protect us from our friends." In my inaugural address I pointed out several particulars in which in my opinion, improvement in the Ordin- ance could be effected. These, I think, have not since been touched upon owing to the commission appointed by the Crown to examine into the whole subject not having sent in its report. At any rate that report has not yet reached it; when it does, I trust it will receive very serious consideration at our hands. But of one thing I feel sure, that were Fijians only paid, as is the case with coolies, for the days on which they worked, they would be the best labor in the world. Whilst on this subject I wish to say a few words on the annexation movement for a closer connection with New Zealand. Fears have been expressed by some, not otherwise inimical to the measure, that if it came about our supply of coolie labor would be stopped, that the Indian Government will not allow coolies to be sent to a colony enjoy- ing representative Government, and that Queensland and South Australia have in vain tried to get them. Now gentlemen, this is a delusion. It is not that the Indian Government will not allow their people to go to colonies having representative government, but it is this, that the Indian Government will not al- low them to go to any country until certain pro- tective measures which it insists on have first been passed by the legislature, and it is because in the colonies I have named the democratic and immigrant elements have hitherto been strong enough to prevent these measures passing, that coolies are not there now, and I cannot therefore but think that these fears have for us no foundation whatever.

TEA AND COFFEE IN BRITAIN.

Strange as it may seem, it would really appear to be the fact that English people are drinking less liquid, of any sort, than they formerly imbibed. The Excise has fallen off, and this was thought to mean that temperance drinks, more particularly tea and coffee, were in the ascendant. As regards tea precise information is wanting, though there is no doubt that more tea is now drunk than formerly; but, on the other hand, coffee is much less patronised than it was. This painful fact came out very plainly from some statistics quoted in the course of a City meeting of coffee buyers, importers, and brokers lately held in Mincing-lane. The gathering was unanimous in its lamentations on the small amount of coffee which finds its way to London compared with former years. Three years ago the stock of coffee carried to London came to twenty-eight thousand tons, while in all other European ports put together the stock im- ported was one hundred and seventy-five thousand tons; now the Metropolitan coffee supply has fallen to twenty thousand tons, while the European stores of the luxury have risen considerably above two hundred thousand tons. A drop of eight thousand tons in three years is of course a very serious matter in any business where the article is entirely imported. There were many sugges- tions made to account for this deplorable state of the coffee market, and it was asserted that dock rates, brokers' commissions, and other obstacles of the kind seriously affected the prosperity of the trade in London.* This may be the case, and any- thing which injuriously affects the profits of im- porters and sellers must be harmful to the public, for they will be supplied with a worse article. It would certainly be of no use to make coffee dearer in the hope of recommending it to the consuming public; but at the same time "cheap and nasty" is a pleasure as applicable to coffee-dealers as to any other tradesman. The worst policy to recuper- ate lost trade is to foist on the public an article of bad quality, with the bait of cheap price; for the coffee or tea drinker becomes disgusted, and the whole trade suffers.

A reason for this falling-off in coffee-drinking may possibly be found in a direction which the importers and merchants seriously suspect. The restaurants in London, the eating-houses, coffee- shops, coffee palaces and taverns, where coffee of really good quality can be obtained at any price are lamentably few. In many so-called coffee- houses the principal attention is paid to the supply of chops and steaks, or plates of meat and potatoes, and it seems to be considered by the proprietors that so long as these solid articles of nourishment are fairly good and reasonably cheap, the customers do not much mind how inferior the accompanying drink may be. This is undoubtedly a very great cause of the comparatively small success which coffee-palaces, so called, have en- joyed in the Metropolis. They began some years ago with a great flourish of trumpets, and from the number of these establishments which sprang up in nearly every street, it was confidently hoped that intemperance had been conquered, that no Englishman would henceforth care for his "drop of good beer," when he could obtain a drop of good coffee, and a slice or two of bread and butter, at the undoubtedly reasonable rate at which the

* Of course the lost business more immediately complained of was a re-exporting and distributing, rather than a home, business.—Ed.

coffee-palaces supply them. There are some temperance restaurants where proper care is taken over the production of the tea and coffee; and in these places the management reaps its reward in the accession of custom which ensues on the supply of a good article. As a general rule, however, it is lamentably true that the stuff which is sold as coffee in coffee-houses and coffee-palaces would fail to be recognized as such by a discerning Arab. It is, to begin with, not pure coffee at all, but adulterated either with chicory, which is not so bad, or with burnt sugar worked up into the form of "caramel," which makes it both nasty and injurious to health. This so-called coffee is handed round to customers in large cups at a small price, and most of them would probably be heartily glad if the cups were smaller and the amount of coffee essence proportionately increased. The working man cannot be rationally expected to prefer this weak and watery compound to a glass of ale, although the consequences of continued potations of the latter are more disastrous than those which follow drinking any amount of weak coffee and warm water. It would certainly be difficult either to cheer or to inebriate anybody on the stuff which is unflinchingly sold as coffee in so many London restaurants. Some authorities on dietetic matters recommend the use of coffee in preference to that of alcohol as a stimulus to the brain; others declare that the coffee-drinker is exciting his heart to a dangerous degree. The student, however, who desired to solve a difficult problem in mathematics, or the poet who was in the habit of "gaining a pious rapture," from an occasional "cup of finely-tempered coffee," would neither of them go to the average vendor of the Arabian luxury in London in search of an adequate stimulant for their intellectual toils. Every evil has its accompanying consolation, and it is at all events well to know that the warm water and chicory solution vendred to the average consumer of hot drinks could not harm the nerves even of an infant. The hot fluid might interfere undesirably with the baby's digestion, of course, but its nerves would be undisturbed by the coffee itself, and its slumbers would not be in any way impaired. Nervous patients who are recommended "never to touch strong coffee" had better take their Mocha regularly at a Metropolitan coffee-palace.

It would be a thousand pities if coffee were to go out of use altogether as a favourite drink among all classes. Yet there is more precariousness about the tenure of the berry than about that pertaining to the leaf of the Bohea shrub. When it was first introduced into England, coffee-drinking became all the rage. Coffee and talk were the staples of the tavern-keeper's trade, and snuff-taking and tobacco-smoking were additions to the enjoyments of these places. Very possibly the coffee-house when first started would not have sprung into such general and instant favour but for the fact that it answered all the purposes now subserved by clubs and newspapers. There the visitor was sure to meet his friends and men worth knowing, and there, too, all the news of the day was heard. The coffee-house was the Londoner's home, as Macaulay has said; and foreigners who wished to find a gentleman did not ask how he lived, but whether he frequented the "Green" or the "Rainbow." The Court and the Government looked on these establishments with little favour; they avoured too much of public opinion turned into a "fourth estate." At this period a multitude of coffee-hops and coffee-houses were established to meet the prevailing fashion, which it was fondly trusted would prove a permanent one. Soon, however, clubs sprang up, and the proprietors

of coffee-taverns saw with disgust that coffee was a passing fancy in the high world of fashion, and that the ordinarily Britisher preferred his strong ale to any foreign concoction. There was a dangerous rival, too, in tea, which entered into use in England like the proverbial lamb, and has grown, to more than the dimensions of a lion. So the coffee-house keepers found it to their interest to cater for the more substantial needs of "cits"; and gradually they transformed themselves by common consent into chop-houses, patronised by the clerk and the apprentice during their midday interval of repose. Of course the rise of tea into popular respect has curtailed the sale of coffee; but it may well be questioned whether as a breakfast drink, coffee is not medicinally superior to its rival. If tea be taken in the morning, then tea recurs again at eventide; and doctors, although they agree about hardly anything else, are almost unanimous in asserting that two or three large breakfast-cups of tea during the day is more than is good for any constitution. The dire consequences of tea-swilling are periodically trotted out for inspection—flatulence, gastric catarrh, dyspepsia, tremours of the hands, and other physical mischiefs are said to arise from it. Coffee-drinking in the morning and tea-drinking at night do not seem to produce such terrible results; but it can hardly be denied that coffee is less used than formerly as a morning drink. It is more and more taking its place as a modest after-dinner beverage, sipped out of very small cups of dainty and delicate workmanship, and so is developing into a liqueur. It is thus that the Algerian Moor drinks it at this day, without the unnecessary Anglican additions of milk or sugar; and he relishes the grounds as the best part of the beverage. At present the bodily effects of taking any hot drink whatsoever are often pronounced to be hopelessly bad; so that soups would be prohibited as well as tea and coffee. Yet as long as mankind shows its existing liking for raising the internal temperature of the physical frame artificially, coffee should hold its own as being at least equally nourishing and inspiring with tea, cocoa, chocolate, or any of its numerous substitutes. And the only way in which the sale of coffee can be much increased in the Metropolis and elsewhere is for dealers in the ready-made commodity to manage to combine cheapness with an excellence of quality which is now chiefly conspicuous by its absence.—*Daily Telegraph.*

PLANTING IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

Mr. Zylker, the holder of a concession to work petroleum springs in Langkat, has returned to Batavia bringing word that the trial borings on the spot under direction of an official mining expert have yielded enough petroleum to prove that there is abundance of that oil underground.

The cultivation of Deli tobacco has been so successfully introduced in the Lampong districts in Sumatra, that ere long a case containing samples of the yield will be sent to Deli to be fermented and sorted there.

Of local matters there is not much to say here. Commercial, planting, and industrial enterprise is still heavily depressed though quotations for sugar give some reason for satisfaction. From Surabaya transactions in that article at 12 guilders per picul were recently reported. Another remarkable fact worth also drawing attention to is that, according to statistics in one of our contemporaries, no less than 22 Netherlands vessels are lying on

TO COLLECT THE ODOR OF FLOWERS.—Roses and flowers containing perfumed oils may be made to yield their aromatic qualities by steeping the petals in a saucer of water, and setting it in the sun. The water should be soft, or rain water, and a sufficient quantity allowed for evaporation. In a few days a film will cover the water. This is the essential oil of the flower: every particle is impregnated with the odor. It must be taken up carefully and put in tiny vials, which should remain open till all the remaining water is evaporated. A few drops of this will perfume glove boxes, apparel, etc., and will last a long time.—*Southern Planter.*

PROFITABLE FRUIT CULTURE.—Mr. Watkins, a practical fruit grower, in a paper read before the members of the Herefordshire Chamber of Agriculture, cited two successful cases of Apple growing last season that came under his own notice. In one case a small orchard of about three acres was recently planted with standard Apple trees of good sorts for table and kitchen use. The trees were properly cared for and manured, and as some sorts were found to be growing too freely they were root-pruned. The result was a magnificent crop of fruit last season, which realized about £16 per acre after paying all expenses. In an exposed situation plant rather thickly, say 18 feet to 20 feet apart; but if you have a sheltered situation, with a good deep and generous soil, give the trees plenty of room—30 feet or more. Apple or Pear trees may be planted alternately with Plums; the Plum tree is a much shorter-lived tree than the Apple or Pear, and comes into bearing sooner, thus bringing in a return till the other trees get fairly grown. A strong grower and a small grower may be placed alternately each way. Yet another plan is to plant them in hexagonal form instead of square; that is, instead of the trees being exactly opposite each other in adjoining rows, they are midway, thus giving more room to each individual tree without increasing the distance between or in the rows. In filling up old orchards never plant in the old holes; it is better to get the trees planted irregularly than to do this. Deep digging is essential in planting; but the trees should not be put in too deeply. The want of care in picking and packing the fruit is a frequent cause of loss. Mr. Watkins prefers autumn planting, except in cold wet soils, where he would plant in spring, not later than March.—*Gardeners' Chronicle.*

CEYLON TEA AT HIGH ALTITUDES.—We have very encouraging news of tea at high altitudes. We believe the returns from Abbot'sford this year will be most satisfactory as to quantity, whilst the young places near Nuwara Eliya are giving returns far in excess of previous expectations. As far as can be judged from the evidence before us, we see no reason to suppose that estates situated as high as, or higher than, 6,000 feet will give a very much reduced return of leaf per acre than those at sea level. Some time ago it was thought that the lower estates would give quantity—up to 700 lbs. per acre—but not the best quality, whereas the very high estates might be expected to yield a tea of surpassing flavor, though not in great abundance. So far as we are able to argue from actual facts before us, the superiority of high grown tea has not as yet been very forcibly demonstrated to us, though we are far from denying that it will eventually establish its pre-eminence. But, as we gain experience from the growth of the industry in the island, one thing is becoming more and more plain every day, and that is that the small yields to be expected from tea grown at very high altitudes are certain to be very much exceeded, and that the tea plant can be grown to pay handsomely at almost any possible altitude in the island. Yields of 800 lb. an acre at the elevation of Nuwara Eliya may, and doubtless will, be events of rare occurrence, but we confidently look forward to 500 and 600 lb. an acre as what may be expected from carefully planted, well sheltered, land, no matter what the altitude. The slowness with which the extreme elasticity—if we may use such a word in this connection—of the

tea plant has been realized by planters in Ceylon is somewhat curious, as we have remarked before. Though it was known to flourish in the hot steamy plains of Assam, on the bleak, almost frozen, heights of the Darjeeling hills under the very shadow of the ice-clad Himalayas, yet we in Ceylon were some time in realizing that it could be successfully grown, and be made to produce abundantly, at any altitude in the island. The fact is only now beginning to dawn upon us, and men who are busy planting up coffee land at from 5,000 to 6,000 feet with the more hardy tea plant are not now regarded as madmen, as they were a short time ago. In the same way the suitability of Uva for the cultivation of tea, for a long time denied, is now at last becoming accepted as an incontrovertible fact, which time alone can effectually prove. There are very few places in Uva where cinchona and coffee are now cultivated, which are not admirably suited for tea; and from rainfall returns now before us, many have as well-distributed a fall as the majority of estates on this side of Nuwara Eliya.—*Local "Times."*

ORANGE FLOWERS.—In a paper recently read before the New York State Pharmaceutical Association, Mr. Lenberger stated that he had succeeded in distilling from orange flowers gathered in Florida and salted down a water comparing favourably with that imported from the south of Europe. As orange trees are now grown abundantly in Florida the petals are consequently plentiful, and he suggests that a new industry should be started in that State, in which low priced labour might be utilized in gathering the blossoms, especially of the wild or bitter orange.—*Pharmaceutical Journal.*

TEA: THE GREEN LEAF SEPARATOR AND SIFTING MACHINE, which has been patented by Messrs. Fairweather and Gilruth, of Sembawattie, has been named the "Success," and seems likely to justify its title. The machine, in its first trial with rolled leaf, worked most satisfactorily, finishing off one fill of Jackson's large "Excelsior" roller in five minutes, dropping the fine leaf in the centre, and the larger at the sides. A large machine is now in course of construction in Colombo, capable of being driven by steam-power, and others will be taken in hand for hand or steam. Mr. Gilruth thus writes of the machine:—"The machine will be the means of reducing the tea-house coolly staff by 4 to 5; on a larger estate in greater proportion. It will also be a great saving of labor in this way: when the roll in its separated state is fired, it will not require so much sifting, and therefore accomplish at the same time the aim and object of all planters, *ie.*, preserving as much as possible the bloom on the tea. It also offers other advantages. The roll can be separated into three different grades, and in such a marked style. A tea-house manager, with care and knowledge of his work, will be able to accomplish with ease a long-wished for desire, *ie.*, to have each and every leaf according to their class of the same uniform outturn in the cup, from being able to ferment each kind separately a long or short time according to his fancy; thus preventing the old inevitable complaint being made every time a mistake happens in the fermentation, which on many occasions is used and also abused, namely, as follows:—"Oh, I tried to get my course leaf as near an approach to my Pekoe as I could, and just waited a little too long. That is the reason I have such a dull outturn." And then again, on the other hand, it has a green outturn. Why? "Oh, because I did not want to sacrifice my Pekoe for my Pekoe Soehong or Soehong, as the case might be." Perhaps, if he was an under-strapper, and had no interest to make good tea, as he might think, through not getting a 5 per cent commission, he might try and make any of the above excuses pass when the fault lay on his want of judgment, or he is perhaps careless or too anxious to get away from his work. With the system the "Success" offers this cannot be done, or it is proof positive that it is due to carelessness.—*Local "Times."*

LETTERS FROM JAMAICA.—NO. 8.

SMALL COFFEE CROPS BUT GOOD PRICES AND GOOD PROSPECTS—MR. COTTAM'S CRITICISMS—JAMAICA AND CEYLON SYSTEMS OF CULTIVATION—THE FRUIT INDUSTRY AND RAILWAY EXTENSION—THE PANAMA CANAL.

Blue Mountain District, Jamaica, Aug. 1885.

Our Blue Mountain crops have, as I led you to expect, turned out small; but I am glad to say that prices so far as the coffee has yet been sold in the Liverpool market have been very satisfactory. Clifton Mount, Newton, Sherwood Forest, Clydesdale, Chestervale and Radnor produce has sold at prices ranging from 139s. to 110s. per cwt.; the first-named continues to bear the palm. The season has again been very dry, the lowly coffee must have suffered from the drought, but it has been very suitable weather for the top mountain properties. The blossoms have as yet been good; there is another very good one on the eve of coming out, so that, unless unforeseen bad weather comes, we may look for a "bumper" next year. The old experienced planters say it will be a very good season from all present signs.

The remarks of your old correspondent, Mr. Cottam, relative to Blue Mountain coffee estates, which appeared in your *Weekly Observer* of 28th April last, are somewhat too trenchant, and the remarks upon the overseer of Sherwood Forest estate anything but polite. As to Jamaica coffee estates, everyone admits they are not as well or expensively cultivated, as was the rule in the good old Ceylon days when planters could spend £12 an acre, in cultivation, manuring, supervision, etc., and yet make profits of £8 to £12 an acre. Jamaica planters say they "must cut their coats according to the cloth"; they cannot afford high cultivation, and they "must make both ends meet." Of course the question remains, whether, if they weeded and pruned more frequently, the result would not be a success. I myself think it would; but the soil and climate are so good for coffee, that the trees do not seem to suffer as they would in Ceylon from being weeded only 3 or 4 times a year, and it certainly saves "wash," which is a consideration. Had Mr. Cottam had an opportunity of going over some of the properties he names he would have found cultivation better attended to than he supposes, some of the estates being added to by new clearings; and as to Sherwood Forest, he would have found it a very fine property of about 200 acres coffee, kept very fairly clean, trees in decent order, and the most compact of all the Blue Mountain properties. It is therefore not just or correct to state that "there is no extension of coffee cultivation in the Blue Mountains," as Abbey Green, Cleveclands, Arnkully, Corner Post and Whitfield Hall are all being extended, and we also hear of some projected estates on the Northern slopes.

I send you a Jamaica paper which contains interesting articles on our Fruit Industry, and also about the present state of the Panama Canal works. As regards the former it is much to be regretted that the finances of the island do not admit of the extension of our present railway system to connect the northern ports with the capital, for I am sure it would be a success; and not to go on, is as bad as stopping the Ceylon line at Nantoya, and not pushing on all these years to Haputale and Badulla. It would help to revive the agricultural prospects of the island, and confer benefits not only on sugar planters and fruit-growers but on the general public. I am sure the land along the line would soon be

taken up for banana and cocoa growing, as well as other tropical products; any scheme that helped the planters and pen-keepers in cheapness and certainty of transport, and enabled them to get up manure at a cheap rate, would be beneficial. I trust therefore the day is not far off when the Governor will see his way to sanctioning the expenses of a survey to select the best and cheapest route; there should be no difficulty in raising a guaranteed loan at home for the construction. Mr. Esquent points out the delicacy of fruit, and that it cannot bear to be kept long; if therefore the railway proves the fastest feeder to the several shipping ports, there is no doubt it would be well supported by the growers both European and creole. As to the Panama Canal, if affairs are as it is stated, matters seem to be in a very bad state for the present bondholders; neither will the work be accomplished as quickly as was promised. Where has all the money gone to? Echo answers where. Indirectly it has been a fine thing for the Jamaica labourer, who has found well-paid employment, and as so many sugar properties have suffered from the low prices, and have not been able to employ so many hands as of yore, the work so near at hand must have been a Godsend to the Jamaica creole. Here, on our side of the island, owing to the drought and people being short of provisions we have not suffered from want of labor. We hear moreover of several who have gone to Colon in search of work until better seasons return. Felling and topping, pruning and all job works have been done cheaper on many estates owing to the above causes. The prices for felling, topping and clearing up ready for planting are dearer than in Ceylon, though the Jamaica forest as a rule is not nearly so heavy; the custom has been to pay 1s per square chain, or £2 an acre for the simple felling. W. S.

TEA PLANTING ON THE HILLS OF CEYLON.

TEA PRUNING—EFFECT OF BURYING PRUNINGS AND WEEDS—LUXURIANT FLUSH—THE TEA-LEAF MOTH—USE OF SPIDERS—TWIN AND TRINE TEA LEAVES—"WILD TEA"—OLD KING COFFEE IN HIS DOTAGE—"SPRING CROP" IN DIMBULA—A MARKET FOR "COFFEE TEA" WANTED.

Tea pruning and the burying in longitudinal holes of the prunings, weeds and rotten timber debris are going briskly forward and wonderfully trim and clean the ground looks where the processes have been completed, while the tea bushes are scarcely cut down when they begin to put forth a fresh wealth of buds and wood. The mechanical as well as the manual effect of the burying process must be most beneficial to the soil as well as to the plant, as is shown in the luxuriant flush on the trees pruned some months ago.

Yesterday I wrote that the moth prevalent in Dikoya had not reached this locality. That is still true of the higher fields, but on the lower, evidences of the presence of the insect were this morning seen in curled-up leaves. The conclusion is that this pest chooses not flush but mature leaves whereon to lay its eggs.—eggs whence the maggot escapes, sucks the juices of the leaf and is gone (as a moth?) in a time so incredibly short that it is but rarely the caterpillar can be seen. It is now that the value of spiders and their beautifully ingenious webs of all shapes, sizes and designs can be appreciated. The spider has not heard of the theory of the balance of animal life, but he works diligently on its lines, as the tea moths experience.

their rations, that they would like the climate and they could work well in the climate, because he and his brother fathers work with the spade and hoe out at the Mission Station at Rapid Creek. So certain is he that Silesians will come, and so interested in it too, that he has written a letter to an influential gentleman (Herr Heinrich Foerster, of Trebnitz), fully stating the case, asking him to ascertain whether his countrymen would be willing to enter upon engagements on the terms specified. He, of course, only puts it as a hypothesis, and requests an immediate reply. I have endorsed his letter with the following sentence:—"I should be glad if the information asked for by the Rev. Father Christian can be obtained and communicated as early as possible, with the view of bringing the subject under the notice of the Government of South Australia." Great praise is due to the Hon. Mr. Parsons for the interest he is taking in endeavouring to provide suitable labour for our Northern Territory, and I think the shareholders of this Company should take steps to bring the question prominently before the Government and urge upon them the desirability of immediately taking action to induce a number of Silesian emigrants to settle in the Northern Territory. Provided cheap labour is procurable, I am convinced that the Territory has a great agricultural future before it, as from a personal inspection of the Government Gardens at Palmerston and from conversations I have had with the talented gardener, Mr. Holtz, there is no doubt in my mind that a large variety of tropical products may be successfully cultivated. Messrs. Gardiner and Boul were elected Auditors. Mr. Solomon, referring to Mr. Moule's motion in the House of Assembly re the extension of time for the bonus of sugar-growing in the Northern Territory, said they ought to be thankful to him for introducing it. In the interests of their Company, however, it was desirable that the period should be three years instead of two. It was resolved that a deputation should wait upon the Minister of Education the following day, and request the Government to extend the time for the bonus, three years.—*Adelaide Register.*

ALOE FIBRE IN CEYLON.—We are glad to hear from Mr. Alfred Payne that he has exported about 30 cwt. of aloe fibre with fairly satisfactory results. The best quality realized at the rate of £18 per ton, the second £16, and third, or refuse fibre £12 per ton. The latter was really the most profitable quality, as it required less handling than the better sorts. The fibre was cleaned with a machine of Mr. Payne's own construction, but as he has a large acreage under cultivation he is strongly of opinion that special machinery would enable him to realize handsome results. Mr. H. Brown of Matala is, we believe, also successfully growing and exporting two or three different kinds of fibre.

OYSTERS.—Edible oysters are numerous in Jaffna and easily procurable. At the rainy season you can have them for the trouble of picking. The moormen here, look upon it as a luxury and under the name of *Mottee*, you find the little tambies carrying bundles of them. At Bentota while the little oysters stewed or pickled are raw with a pinch of pepper and few drops of vinegar are delicacies to please the most fastidious taste, the oysters here seem to be too heavy and clumsy and certainly hard to digest. Perhaps we are getting old and our digestive organs are not strong as when we roosted at Bentota. At Mullaitivu at the rainy season the women go with pots to Chinair and gather oysters (*Mattae*) and also pluck the leaves of a plant called *Musotta*. These are both boiled together, and make quite a breakfast in their poverty. In the evening they return home; and the *Musotta* leaves make a *chundal* or minced leaf greenage while the oysters as a curry make the vegetable diet a delightful repast.—*Ceylon Patriot.*

THE TRADE IN CABUL WITH TEA.—It may not be generally known that there is a fairly good trade between the North-west and Cabul in tea, the figures for 1884-5 showing supplies sent forward of 8,826 mds. This trade is capable, however, no doubt, of much further expansion.—*Indian Tea Gazette.*

COFFEE IN COORG.—MERCARA, Sept. 25th.—Our labour supply has again been very short, work has been delayed, and the coffee has suffered from being so long buried in weeds. There are estates which have had no coolies upon them for six months, and are, only, at this present time securing their labourers no planting has been done, consequently a year's delay is incurred. Tamil coolies were plentiful for two or three years, some coming from Salem, and others from Vellore. Of these maistries who had contracted to supply coolies, upon the estates, not 10 per cent have come in. Crop promises were brilliant, and the wages for men were then Rs½ against Rs3 per month in Coorg, so no people could be got to come. Tumkoor labor has also failed, various reasons are given for it, but our demand was so great during June, July and August that 10,000 coolies at Rs a month could have found employment, and steady work: our Mysore labour is only now coming in, and the dry season is fast approaching on. This year seems to have been most unusual in surprises. A steady monsoon from the 2nd of June, continuing rain without intermission until the 2nd of August; again it poured without ceasing from the 10th until the 22nd of August. After which no rain has fallen—ceasing as suddenly as it began. Such weather has not occurred before in any man's experience. Rice was successfully transplanted before the present drought came on, and as two-thirds of the fields are watered by irrigation, it will not suffer much. Cardamom picking commenced about the first week in September, the capsules are large, and well-favoured, there should be a good harvest this season as the drying weather, always so showery, has been all that could be desired, and the coloring of the pods, so important an item at selling time, will assuredly be a certainty. Prices were very low last year, and hardly paying for the gathering, curing, and hire or rent of the cardamom jungles.—*Madras Standard.*

THE QUININE MANUFACTORY AT MILAN.—We have learnt several interesting particulars concerning this well-known quinine factory from Mr. C. E. H. Symons, who took the opportunity when in Milan the other day to visit it. It is not strictly correct, however, to designate it as a "Quinine Factory;" it is in reality a manufactory where a great variety of alkaloids are produced. Amongst other chemicals made here is that deadly narcotic "strychnine," but, without doubt, quinine is the chief article turned out, and just now they are producing about 130 kilos daily, equal to 260 lbs. weight. Our readers will doubtless remember the circumstance which some time ago caused the firm working this factory to pass into liquidation. They are still wending up the affairs of the old concern, but are allowed, during that process, to carry on the manufacture, on the understanding that they make only in execution of actual orders; consequently, they cannot put themselves in stock. They are, therefore, only buyers to a limited extent, buying merely from hand to mouth. Our informant, who has just returned from Italy, after paying a visit to the factory, describes the premises and the proceedings therein as highly interesting; and, though he was not of course inducted into the mysteries of quinine-making, he came away with the knowledge of a simpler and more perfect mode of analyzing cinchona, which he intends turning to good account in Colombo. So soon as the affairs of the late firm are closed, a Company will be floated to carry on the manufacture, when they will at once enter the market as active buyers. No doubt the entry of the new Company, when formed, on the cinchona market will help to impart strength to quotations, and it is a noteworthy feature that the managers of this large concern use little else than Ceylon cinchona, with just a modest admixture of cuprea, but they do not appear to care about South American bark.—*Local Times.*

TEA PLANTING ON THE HILLS OF CEYLON.

EXPERIMENT AT WORKING AN EXCELSIOR ROLLER WITH A 16-FEET WATER-WHEEL—300 LB. OF LEAF ROLLED IN AN HOUR—TEA AT HIGH ELEVATIONS REQUIRING MORE TIME TO ROLL THAN THAT AT LOWER ELEVATIONS—THE TURBINE ON CALSAY—THE "TEA PLANTER'S VADE MECUM"—TEA AT HIGH ELEVATIONS IN CEYLON—INCORRECT P. TREE STATEMENTS—THOUSANDS OF ACRES OF FOREST LAND SUITABLE FOR TEA CULTIVATION.

UPPER LINDULA, 13th Oct.

The weather is simply glorious, and today we were able to try our Excelsior roller with a feed of 300 lb. of well-withered tea leaf. Readers of the *Observer* may recollect our contention, that, with the addition of a fly-wheel, a 16-foot water-wheel (such as are so common on coffee estates) ought to supply motive power sufficient to work an Excelsior. We took upon ourselves the full responsibility of the experiment, and the trial, which occupied between 12 and 1 o'clock today, gave at least satisfactory promise of success. The addition of a fly-wheel does not, we are told by engineering authority, add to the power of the water-wheel, but it so regulates the power exerted as to render it more effective. The result, today, was, that the Excelsior roller, when loaded with 300 lb. of withered tea leaf, was worked at a rate rising from 44 revolutions per minute to 53. We are told that 70 revolutions per minute can be attained, but the newness and consequent stiffness of the machinery and gearing must be taken into account in regard to today's trial, the result of which was that the 300 lb. of leaf were thoroughly rolled in a few minutes short of the hour. We feel perfectly certain, therefore, that, as machinery and gearing get eased with use, we can accomplish the thorough rolling of 300 lb. of leaf in 15 minutes. That would be equivalent to 4,000 lb. of withered leaf or fully 1,000 lb. of made tea per day of ten hours. The volume of water which moved the wheel was 1½ inch in depth by 22 inches wide. As the 22-inch wide pipe is 6 inches in height, it is just possible that greater flow of water might secure more power. Be that as it may, the details of our experiment today are as follows:

About 7 minutes were occupied in pushing 180 lb. of leaf into the orifice of the roller. Not a pound more could be crammed in, and so the water was turned on and the roller commenced operating on the leaf.

Eight minutes further were required to add 120 lb. more of leaf, which found room as the leaf already in was compressed by the rolling process. An attendant was constantly employed not only in adding the new leaf but in counteracting the tendency of the rolled leaf to collect in the lefthand side of the orifice and form solid masses. This, I understand, is an invariable effect in the earlier stage of rolling, and of course the blocking-up hindered considerably the revolutions of the roller. The leaf had constantly to be pulled out of the lefthand side of the receiving orifice and pushed in at the right side. In 15 minutes from commencing to fill the roller and in 8 from the time of turning on the water, the whole supply of 300 lb. of withered leaf was fully under the influence of the rolling apparatus, and in about 40 minutes more the leaf was turned out beautifully finished, only a small proportion of leaves having escaped the bruising and twisting process.

Of course 300 lb. taking one hour to finish is different to 320 lb. in half-an-hour, to which the Excelsior roller is said to be equal; but, apart

from the stiffness of new machinery and gearing, our leaf at this altitude (tea-house situated 5,800 feet above sea-level) seems to require appreciably more time to roll than that grown by our friends lower down. If, as I feel perfectly certain, our anticipations are realized, and we get an average of 600 lb. rolled every three hours of a working day, we shall be well satisfied. We intend trying the experiment of loading the Excelsior with only 200 lb. of leaf, putting 50 lb. into the Universal, and working both simultaneously. In that way we may get leaf rolled at the rate of 250 lb. in half-an-hour, which would be 500 lb. per hour, or 5,000 lb. (equivalent to 1,250 lb. of made tea) in a day of ten hours. The results of further experiments will be made known for the benefit of other planters who, like ourselves have 16-foot water-wheels available, supplied by Messrs. John Walker & Co. in the days when the machinery sought to be moved consisted of only a coffee pulper, and who may be doubtful as to the power they can get out of such a wheel. Ours was supplied with reference to the tea factory, but we believe it is identical, in construction and power, with the other 16-foot wheel, which stands, (literally stands) 1,200 feet lower down in the coffee store, and by means of which (a fly-wheel supplied) we hope at no very distant date to turn another Excelsior.

The well-qualified engineer gentleman from Messrs. John Walker & Co., Mr. Malcolm, who erected our Excelsior and added the fly-wheel to the motive machinery, is now up at Calsay (the fields and buildings of which are in full view in this lovely weather) completing the more powerful motive machinery of a turbine, and we and the rest of the planting community will be glad to hear of a full success in that quarter. We, at one time, thought of a turbine for Abbotford, but happily our water-supply (judging by the minimum in thirteen years) was considered insufficient, and so (at a saving of probably £300 at least,) we have tried what could be done with an existing 16-foot water-wheel with a fly-wheel added.

Oct. 14th.

In the recently published "Tea Planter's Vade Mecum," at Calcutta, in which we find that the compiler, Mr. Wyman, adopts a characteristic article by the *ci-devant* editor of the local "Times" as truly representing "Tea Climates in Ceylon." As we read the terms of this article we wonder whether it is all a dream that our tea bushes are basking in tropical heat and yielding at the rate of nearer 600 than 500 lb. per acre per annum. For did not the writer utter his dicta, thus:—

"A contemporary, who ought to be an authority on tea, has been writing in praise of high altitudes for that cultivation, and bases his arguments in their favour on the alleged facts that certain estates in Darjeeling at 3,000 feet have done better than was expected, though we are not told what constitutes 'better,' and, the writer in question goes on to argue that if tea will do well at 3,000 feet in a latitude of 27° from the equator [*per*, of course, wrote 27°] we may safely go to 6,000 feet and over in Ceylon: a theory from which we beg to dissent. In an island like Ceylon, exposed to the full violence of the south-west monsoon, very much depends on position and exposure. Were we writing of the Uva side of the country, we should unhesitatingly adopt the theory, but certainly not on the Kandy side of Nuwara Elyya, where, as a compensation for the heavy rainfall, there must be heat, if paying flushes are to be had. Will anyone venture to assert that the upper portion of the Ramboda Pass, or the bleak, exposed portion of Upper Lindula, can ever become profitable localities for tea? To talk of the healthi-

ness of such situations is altogether beside the question." And then follows a quotation of Colonel Money's long exploded fallacy, untrue almost everywhere in Ceylon:—"A really pleasant climate cannot be a good one for tea."

We need not tell our readers that tea is grown, and with profit, on such estates as Tukvar in the Darjiling district, up to and above 5,000 feet, and experience on the place where we now write has more than confirmed our contention, that if tea could be well and profitably grown at 3,000 feet altitude in 27° north latitude, in the heart of a great continent and on the sides of the vast mountain range which is named "the abode of snow," the cultivation might safely be carried to twice 3,000 feet in an insular locality only 7° from the equator. We felt sure in our theory, and we feel more than satisfied with an experience, which is not ours alone, but that of Inverness, Dessford, Calsay, and many other places, which are situated in "the bleak, exposed portion of Upper Lindula," as much as is the property specially sought to be depreciated. The owners of tea estates up the Ramboda Pass can speak for themselves and defend their interests so wantonly assailed to gratify personal spite, but as regards tea in "the bleak, exposed portions of Upper Lindula," we know that visitors to Abbotsford are loud in their admiration of the tea on the higher fields from 5,400 to 6,000 feet altitude, from which rich pluckings of flush are now being taken; but we are quite contented to refer to Calsay, with a similar altitude and higher up the "bleak" valley, where results and prospects have demanded the erection of new buildings and machinery, just as here we are preparing room for produce which next year is likely to approach 150,000 or even 200,000 lb. of made tea. So much for the performance of "bleak, exposed Upper Lindula." The true and honest statement about tea in Ceylon is, that, while the plant flourishes at low elevations, it flourishes also at altitudes up to the verge of 7,000 feet above sea-level, and that not in genial Uva alone, for Oliphant estate is in the district of "bleak, exposed Upper Lindula." But "the pity of it, oh lagoon," is that the statement is enbalmied in "The Tea Planter's Vade Mecum" as a true and honest representation, by a Ceylon authority, of "Tea Chinates in Ceylon." Ceylon readers can make the correction for themselves, but Indian planters and others, who do not know the value of the authority quoted in the "Vade Mecum," will accept gross misrepresentation as truth. From where I write I look up over an expanse of thousands of acres of forest, rising from "bleak, exposed Upper Lindula" to the sides of Kirigalpotta and Totapala, a large portion of which can be successfully cultivated with tea, if only some fuel can be found for the Nanuoya-Haputale railway, which will enable Government to set the mountain forests free to healthy and profitable enterprise. But, if the *et-avant* editor is to be believed, it would be equally "a fatal mistake" to grow tea along the railway line, as, in his opinion, it would be to make the railway on which Uva depends not only for revival but for very existence. I believe that the railway will be made, and that profitable tea cultivation will follow its course, until the fields of "bleak" Lindula are joined in one bright chain to those of genial Uva.

Oct. 15th.

The intense heat, succeeding to the dense mists and pretty copious rainfall, which ended with the night of the 10th, is having the effect which might

be anticipated on vegetation generally, but especially on tea. A long walk through fields of the plant this morning was most interesting. I read last evening in the "Tea Planter's Vade Mecum," that the varieties of hybrid tea amount to one hundred, and of these we have a good proportion. Our intelligent Tamil conductor confirmed this morning the opinion which the Europeans connected with this estate have long held, that the largest leaved bushes are by no means the best yielders of flush. What we desiderate is a bush with a wide, dense surface of long and pointed leaves. On one twig of such a bush Ahira this morning counted a dozen leaf shoots and remarked: "If all the bushes were like this, 1,000 lb. per acre would be regularly gathered." The end bud or tip of such plants is possessed of concentrated strength, such as is not to be found in the very large-leaved plants, even when the latter show "tip," which some of them seldom do. Venturing to differ from Col. Money on this question as on that of tea climate, I have always held that the introduction of China seed by Mr. Fortune into India, in Lord William Bentinck's time, and the resulting hybrid between the Assam and the China plants, was fortunate instead of the reverse. Pure Assam indigenous for low elevations, by all means, but for all altitudes above 3,000 feet I suspect good hybrid is best.

Since yesterday our Excelsior worked alone, has been finishing off rolls of 250 lb. of withered tea leaf, in forty minutes and in excellent style, with no tinge of dark colour. I have no doubt that, ere long, we can regularly accomplish the full load of 320 lb. I take this opportunity of correcting an error into which I fell in previous communications, in dividing withered leaf by four for made tea. That rule applies to green leaf as gathered, which loses one-fourth of its weight in moisture in the process of withering. 300 lb. of withered tea represents 100 of the finished article.

THE VICTORIAN FORESTS.

BY DR. J. E. TAYLOR, F.G.S., F.L.S., EDITOR OF "SCIENCE GOSSIP."

My English agricultural friends know little or nothing of the hard labour and great expenditure requisite to keep an Australian "station" in good condition. One of the squatters with whom I stayed (and whose station is by no means the largest) told me he had fenced no less than 100 miles of it, and that that had cost him £80 a mile.

Our route to the forest lay along grassy, unused, one-chain roads, along which waggons and other vehicles were in the habit of winding their devious ways. In many places it was a euphenistic form of speech to call them roads, for they differed from the rest of the country in nowise, except the rough fencing on either side. Guntrees, dead and living, and also abundance of tree stumps, of all sizes and in all positions, crowded the "road," along which, I hope, few people are obliged to travel by night. Processions of dead trees—studied in black and white—seemed to pass us by as we drove along. They are the scarred remnants of bush fires, and they alone are sufficient to mark the road. Flocks of brilliant green parakeets rise up from beneath our horses' feet, lovely lowry, rosella, and Blue Mountain parrots flash across us in the sunshine like living gems, crowds of cockatoo parrots (cori-la) soar above our heads; numbers of white sulphur-crested cockatoos screech as if a screeching match were on, and every bird was confident of winning. They fly from dead guntree to dead guntree, and

cluster on the branches as if they had broken into blossom. All along the road the Australian "robins" precede us, flitting from fence-top to fence-top, and turning their glowing, incandescent red breasts towards us, as if they were asking whether our humbler English robin red-breasts could equal them. The crow shrieks, or magpies (surely the most delightful as well as the most useful of Australian birds), were everywhere, basking and frolicking in the sun like so many kittens, and piping their lovely flute-like notes like the half-forgotten refrain of some old song. The pretty but more silent and smaller magpie-larks were almost equally numerous. Occasionally we got a glimpse of the male of the beautiful blue wren, but he was too proud to show much of himself. The yellow wrens were not half so shy or so scanty, whilst the fly-catchers were abroad, and busy in great force. The black crows had possession of the semi-cleared country, except where a few jays disputed with them. Overhead, a pair of kites or an occasional hawk soared and screamed. But the parrots and parakeets and cockatoos were by far the most numerous and varied of all the feathered tribes, as it is right and proper they should be in an Australian forest. In one place a number of those stately gallatorial birds known as "native companions" were going through all the movements of a quadrille party, bowing to each other, retiring, advancing and retreating, as if to some unheard music. They are handsome birds, for their crimson heads contrast well with the generally French grey plumage. The ordinary blue cranes were not uncommon, plovers or curlews were numerous, and we saw a few of those much sought-after birds, the bustard, better known to sportsmen, perhaps, as the "turkey."

The forest grew denser and swamper as we penetrated it. There was a thick and almost impenetrable undergrowth of young gumtrees, heath, myrtaceous plants, prickly acacia, climbers and bracken, and one felt what a capital haunt and breeding-ground such a place must be for snakes. One had to reverse the old proverb about not being able to see wood for trees, here we could hardly see trees for wood.

Snakes are gradually getting scarcer in Australia. A war of extermination is being waged against them, which is getting hotter and fiercer every day, for there are more people joining in the attack. The more a country gets cleared for pasturage, the less are the chances for snakes. They are then better seen by their natural enemies, among which, perhaps, their most deadly are the laughing jackasses (*Ducula gigantea*)—a kingfisher which has taken to killing and feeding on snakes instead of on fishes.

We arrived at a clearing in the forest, where there are one or two small but comfortable wooden houses, at one of which we passed the night. A good many half-wild cattle roam about (my friend owned 2,000). They lead a semi-savage life, a few being trained to come near the station to be fed and milked. A number of rough forest horses, brought up in a similar way, also hung around the place. We mounted these, and rode about eight miles into the more infrequented parts, where the kangaroos still abound. They had recently been much disturbed through rabbit shooting; but I saw two red wallaby kangaroos and one "old man" (*macropus major*). I had never seen them before alive, except in menagerie and zoological gardens, and as a naturalist and geologist I was therefore deeply interested in seeing them in their native haunts. They are the oldest race of mammals in the world, and lived in England during the Secondary period, which must have been many millions of years ago.—*Australasian*,

THE MANUFACTURE OF QUININE.

The price at which sulphate of quinine, the quinine of the druggist, is now selling is lower than it has ever before been in the history of the trade. At the time the 20 per cent. duty was removed, in July, 1879, quinine of American manufacture was being offered at \$2.35 per ounce in bulk, or \$3.10 in ounce vials, while the price of the foreign article, duty unpaid, was about 50c. per ounce less. As soon as the duty was removed the price of the foreign drug advanced to about the level of the American. Foreign manufacturers, finding the American market open to them, sent large quantities of quinine to this country during the six months immediately following the date of the removal of the duty, which in the face of the light demand caused prices to fall, the price of American quinine near the close of 1879 being \$2.60 an ounce in vials. Shortly after January 1st, 1880, there was an active demand both in the United States and abroad for quinine, and prices advanced to \$3 an ounce at the close of the month. Since that date the price of sulphate of quinine has fluctuated, the foreign and domestic article both being offered today at about the same price, 80c. per ounce.

What has been the cause of this great reduction in the price of quinine since 1880? Has the removal of the duty alone had the effect of cheapening the drug so greatly during the past five years, or have there been other causes that have contributed to this result? While the removal of the duty has been an important factor in the cheapening process it has by no means been the only cause. The law of supply and demand, which largely regulates the prices of all commodities, has to a great extent led to the reduction of the price of this drug. Quinine is cheap to day in England and on the continent of Europe as well as in the United States, partly because the cinchona bark, from which it is obtained, is cheap, and the cinchona bark is cheap because it is in large supply. For many years South America supplied practically all the bark used by the quinine manufacturers of the world, but through the active exertions and costly experiments of the British and Dutch Governments over twenty years ago the cinchona plant was introduced from South America into the East Indies, Java, Ceylon, etc., so that large quantities of bark are now yearly obtained from these sources of supply, in addition to the amount furnished by South America.

Ceylon is now one of the main sources of supply for bark, and it has only been during the past ten years that the shipments from this island reached any appreciable amount. In 1861 the first seeds were received in Ceylon, and in 1869 the export of bark was only 28 ounces, but in the season of 1882-83 the exports were 6,925,595 pounds, and in the season of 1883-84 they were 11,500,000 pounds.

The American manufacturers do not seem to have been so seriously affected by the removal of the duty on quinine as to be compelled to close their works. While they are not producing as much quinine as before the removal of the duty, it is certainly a noteworthy fact that they are running and obtaining a profit even with free quinine. The American manufacturers claim that the result of the removal of the duty has been to make the United States a battle-ground for foreign manufacturers; that the surplus product of these manufacturers has been sent to this country in large quantities, and that the freeing of quinine has stimulated and increased its production abroad. As all of these results have contributed to the cheapening of the price of quinine, the American consumer is thereby so much benefited by the removal of the duty, even if the quinine manufact-

ories of this country, of which there are but five, three in Philadelphia and two in New York, are compelled to restrict their production. The greatest good to the greatest number is the proper view to take of the matter. Instead of our manufacturers closing their works it would seem from the imports during the past year of cinchona bark into the United States that they were increasing their output of quinine. In the fiscal year ended June 30th, 1884, the imports of bark into this country for the manufacture of quinine were 2,580,052 pounds, valued at \$717,614, while during the fiscal year ended June 30th, 1885, the imports were 3,513,391 pounds, valued at \$911,508, an increase of nearly 1,000,000 pounds in one year.

As the sulphate of quinia is upon the free list, and it is undoubtedly the intention of Congress to keep it free, refusing, as it did, when the tariff bill of 1883 was under consideration, to reimpose the duty, it is certainly not the intention of our legislators to close the American quinine manufacturers by offering a premium to the foreign manufacturer by taxing the raw materials used by our own manufacturers. If our producers can make as good and as cheap a brand of quinine as foreigners, and certainly no one can say that American quinine is inferior to that made abroad, they are justly entitled to free raw materials. As quinine is free of duty all the raw materials used in its manufacture should be exempt from taxation. Our manufacturers of quinine import the bark free, but pay a tax on the raw materials used in extracting the quinine, while their product competes in the home market with foreign quinine made with free barks, free solvents and cheap labor. The item of increased labor cost is a sufficient drawback to the American manufacturer with further discrimination in the way of taxed raw materials.—*Bradstreet's (New York) Journal.*

MORE IMPROVEMENTS IN TEA-PREPARING REQUISITES.

The latest improvements brought under our notice are "Giltruth's Continuous Withering Webs," of which the following is a description—a patent has been applied for:—

The arrangement and working of this machine seem very simple and plain, after a little close inspection; its advantages, which are many, are at once better seen than described, and it has been found on careful calculations that it will be likely to supersede all other systems yet in use, either in Ceylon, Java, or Assam, and will economize by 50 per cent. or more, in labour, space it occupies, &c. &c., on the now old-fashioned window-blind system introduced some two or three years back in Assam and lately in Ceylon on some of the tea estates. For cheapness, compactness and neatness undoubtedly it has no equal and cannot but be sure to continue to warrant these important advantages, especially when it is made and constructed of the very best material; it may be termed almost everlasting, and cannot help taking the place of all others which are so unsatisfactory and costly in the long run.

The following are the advantages claimed for this apparatus:—1st and most important, the great saving of labour brought about; 2nd, smallness of space it occupies; 3rd, large amount of leaf it will take, leaving no part of the level web but what can receive leaf; 4th, leaf easy to spread, leaf on the webs, as all parts of the webs pass within easy reach of the leaf spreaders stationed at the ends of the apparatus and who are able to spread while the webs are in motion which can be made to go fast or slow at the will of the leaf spreader. 5th, easy to handle and not liable to get out of order; 6th, the machine can be made any size, length or height; 7th, by the motion or action of one wheel all

webs are equally moved for receiving or delivering leaf and which last operation can be performed by one man whether there is a large or small quantity of leaf; 8th, the web is never rolled up whether leaf is on it or not; if the web gets wet through wet leaf it is not liable to rot through the web never being rolled up or doubled together or covered close up; 9th, the machine can be increased in width every year as the tea garden increases its yield by lengthening the rollers or web drums at a very small cost; 10th, the webs have pliable galvanized strand wire sides which run into grooves cut into the side of each roller, preventing the web from slipping or bellying in any way.

According to Mr. Armstrong's calculations it requires 6 feet space per 1 lb of leaf; such being the case, one of these machines, 10 feet high 15 in. broad and 80 feet long, webs 6 inches apart, would take about 3,800 lb.; if the webs were placed 3 inches apart it would of course take more than double this, i.e., over 7,600 lb. Two men can put this leaf on the webs at one operation, while one man puts the webs in motion fast or slow as the two spreaders require it. It only requires one man to discharge the leaf from the webs and which can all be acted upon at the same time to discharge large or small quantities without any trouble or loss of time while filling the rolling machine.

By a system adopted in connection with this apparatus of giving either a vertical or side motion to the webs, leaf can, with perfect safety, be spread much thicker and get withered as fast from the air around and about the webs being kept in motion by an arrangement fixed in the centre of the webs connected with a spring or other mechanical driving power, and consequently causing a much more rapid evaporation, which is a great desideratum where leaf comes in wet or moist. Withering web machines are in course of construction and will be fully advertised at an early date.

PEARLS.

The over-fishing of the last fifteen or twenty years is doing for pearls what it long ago did for oysters. Fashion also bears its part in raising prices, and a good set of three black-pearl shirt-studs cannot now be got wholesale much under £40. Four years ago they could be had for less than a third of the price. Mother-of-pearl has risen in the market too, and now costs nearly 1s the pound at the fisheries, where four pounds could be obtained for the same money twelve years back. The fisheries of the Red Sea and the Bay of Bengal are still, however, as celebrated as they ever were in classic days, although the fair can no longer hope for the produce by the peck, as Varro—at second-hand—said they used to do: "Altera exorat virum semodium margaritarum." For all the scarcity of pearls, we now get them also from the Sunda Isles of the Malay Archipelago, the seas of China and Japan, from Panama, Tahiti, the Gambier islands, and from Australia. The pearl-market is no longer at Rome, at the Margaritarius porticus; but in the hands of the Amsterdam, Hamburg, London and New York dealers, who buy up all this harvest of the sea.

There are numerous bivalves which give pearls, had, indifferent, or better; but the true pearl-oyster—if oyster it can be called, for it is exactly like an exaggerated cockle—is the *Mytilus margaritiferus*, or *Pinctada m.*, which measures from four to six inches in diameter and an inch and a half in thickness. The oceanic variety differs from the East Indian, and gives a finer gem. The Tuamotu Archipelago, to the east of the Society Islands, is perhaps the greatest pearl-fishery in the world. Of its eighty islands there are only some half-dozen whose waters do not produce the pearl-oyster. The natives of this group know no

industry but fishing. Men, women and children, they all dive like sea-fowl, and the women are the most expert. Two women especially of Faiti, and one of Anaa or Chain Island, are well-known in this trade—more dreadful far than samphire-gathering—for plunging into twenty-five fathoms of water, in the teeth of the sharks, and remaining as long as three whole minutes under water. A famous diver of Anaa escaped not long ago from a shark with the loss of a breast and an arm, and many of them go down never to come up again. If they make too many plunges in their day's work at the beginning of the season, which comprises the summer months, from November to February, they bring on hemorrhage or congestion; and after some years passed in the occupation, paralysis is certain. Few of these divers work for themselves, but can earn 4s a day from the pearl-traders. With a wooden tube some 16 in. long, 10 in. square, and glazed at one end, they prospect from their boats the bottom of these translucent seas: the glass end, which is put into the water, serving the purpose of suppressing the eye-puzzling surface-ripple.

The diver of the Persian Gulf or of Ceylon attaches a weight of some 20 lb. to his feet to aid in his descent, and carries 7 lb. or 8 lb. more of ballast in a belt. He protects both eyes and ears with oiled cotton, bandages his mouth, and goes down forty feet with a rope. He remains down from fifty-three to eighty seconds, and helps himself up again by the rope. But the Pacific diver practices the conjuror's boast of "no preparation." Just before the plunge he or she draws a full breath rapidly three or four times running, and finally, with the lungs full of air, drops feet first to the bottom, not forty feet but twenty-five or thirty fathoms (150 ft. to 180 ft.), and comes to the surface again with extraordinary swiftness, unaided in any way. Each dive generally lasts from sixty to ninety seconds; and only very occasionally the astonishing maximum of three minutes. The divers hardly ever bring up more than one oyster at a time; but this is chosen as likely to contain pearls by some fancied rule of thumb of their own, grounded on age, form and colour; and they hold the shells tightly together as they mount, lest the envious oyster should shed the pearl, which the divers themselves are very quick to conceal by swallowing if the employer's eye is not fixed on them. Diving-bells have been introduced by some houses in the trade; but the natives will no longer work in them, saying they bring on early paralysis of the legs.

Like his edible relative, the pearl-oyster also has his enemies and parasites. A flat-fish, called *tabereta* by the natives of this Polynesian archipelago, makes great ravages among the young fry; it resembles the eagle-ray, which is so destructive in European oyster-beds. There is another, a long fish with powerful jaws for crunching the full-grown oyster, which is called the *oiri* or *kotohc*; and does not seem to have been identified by naturalists. There are also two univalve shell-fish—a *murex*, which spends its time boring holes right through the oyster, and a *pholade*, which occupies a nest for itself in the upper shell, just as his fellows do in the rocks of our own coasts. But the worst pest of all is probably a marine worm, locally called the needle-worm, which pierces a network of galleries, like the book-worm or the teredo, between the outer and inner surfaces of the shell, and so ruins the mother-of-pearl; which when so damaged is known in the trade as worm-eaten. There is a small parasitical sponge, too, which stains or "spots" the mother-of-pearl.

Polypi, A cidians, and Serpule all mingle in the fray; and while the older crabs remove the young oysters from their beds with their pippers, to be eaten at leisure, the crab fry get inside and billet themselves in bed and board on the grown oyster until they have eaten their host out of house and home. It is very possible that some of these enemies are the irritant causes of the pearls; in the centre of which there is almost always some foreign substance, such as a grain of sand or a fish's egg. A great number of small pearls are sometimes found in one bivalve; one with 115, from Elizabeth or Toan Island, in the Toanotu group, was shown in Paris in 1878. Some pearls reach a great size; and one from Panama, which was presented to Philip II. of Spain in 1579, is recorded to have been as big as a pigeon's egg.

Imitation pearls—and admirable imitations the best of them are—are not uncommon just now. They were first invented in 1656 by one Jaquin, a French enameller on glass. The little glass globules of which they consist are first lined with a mixture of singlass and "essence of the East," and then stuffed with melted wax. This essence d'Orient is made of the pearly matter which is found at the base of the scales of the whiting, preserved in ammonia.—*St. James's Gazette*.

A CEYLON "ESTATE."

"ESTATE" OR "GARDEN"—NO SUCH THING NOWADAYS AS A "COFFEE ESTATE"—R. I. P.—"LAY" OF ESTATES—THEIR SITUATION AND ELEVATION—HOW WORKED—COFFEE LAND—TEA LAND—WEEDING—ROADS AND DRAINS—SUPERINTENDENT'S WORK—LINES—BUILDINGS: (1) COOLY LINES; (2) TEA FACTORY; (3) BENGALOWS; (4) CATTLE SHEDS—WHO ARE OUR COOLIES?—A DAY'S ROUTINE—GRANDMOTHERLY GOVERNMENT ENCOURAGING CRIME—CONDUCTORS—TEA-MAKERS.

Now, in the 'eighties, the tendency seems to be to prefer the word "garden" to "estate," in accordance with the custom that obtains in India. The old planters, however, will continue to use the word to which they have been so long accustomed, and which the eternal fitness of things appears to warrant; for a property of many hundreds of acres, valued when in full bearing at many thousands of pounds, is surely an "estate," and a very desirable one to boot, while in Ceylon a "garden" has hitherto meant only a native's patch. The word "plantation" long ago fell into disuse, being retained only to designate the coffee produced on an estate.

A "coffee estate" pure and simple, such as was universal only a very short time ago, scarcely exists in Ceylon in the present day, and to describe one would be a work of supererogation. They are either defunct and abandoned, or so much mixed up with "new products" as no longer to be recognizable in their old glorious and lamented simplicity. Let, therefore, their memory rest in peace, and turn we to the things of today.

The Ceylon estates, then, for the most part, occupy all the high land from 2,000 to, say, nowadays, 6,000 feet elevation, covering the steep sides and hollows of the mountainous region occupying the centre of the island and tea is also being planted in districts only a very few feet above sea-level, where coffee would not grow. As, therefore, tea flourishes, and will be cultivated, at altitudes both considerably higher and considerably lower than was possible with coffee, the ultimate area under tea will be much larger than was ever under coffee cultivation; especially as, in addition to this fact, much of the land on the old estates—considered unsuitable for coffee is being planted up with tea. Before the advent

of the Briton in 1815, what are now "estates" was trackless forest, the sons of the soil never having, for thousands of years, pitched their villages higher up than the open country far away down in the valleys. This was possibly owing to the depotism under which they always lived, but it also suited their own temperament and love of a hot climate and lazy habits. There are often several thousand feet of difference in elevation between the bottom and top of an estate; and to get about it, in looking after the various works going on, is no child's play, but requires all the go and strength of vigorous youth. Steep land, as a rule, bore the best coffee; but for tea an easy "lay" (as it is called in Ceylon parlance) is far the best. For this there are two reasons; one, and the principal one, being, that tea thrives better in flats and is cultivated with greater ease, efficiency and economy; the other reason being the greater number of times in a year the ground is gone over by the coolies than was the case with coffee. The land is, or should be (in Ceylon), weeded once a month for ever; narrow drains are cut across the sloping fields, and narrow paths or roads wind and zigzag through every part of the estate. It is part of the work of the superintendent to trace all these roads and drains, in new estates and in new fields of old estates, and to mark out the land in "lines" or rows, 3 to 5 feet wide, along which the tea is planted from 2½ to 4 feet apart.

The "buildings" of an estate consist almost exclusively of (1) "lines" for the coolies, of very primitive architecture, being only rows of rooms about 12 x 12 x 8 feet high, with a door (but no window) opening on to a six feet wide verandah running their whole length. (2) The tea-factory and withering-house, which may be as simple or elaborate, as small or extensive, as the proprietor's means will permit: some have cost thousands, and others not so many hundreds; some are expensively fitted up and filled with costly machinery, at others they still "roll" by hand, and "fire" over stone-built "ehulas," but this is the exception, not the rule, and machinery for every possible purpose will soon be universal. (3) The bungalow, one or more for the manager and his assistant, conveniently placed to be central to the work, and away from the coolies, whose neighbourhood is not always very odiferous. (4) Cattle-sheds.

The coolies are immigrants from the coast of India to Ceylon, specially to the estate for which they have been engaged, and upon which they often stay for many years, though at liberty to leave at any time by giving a month's notice; or only 21 hours' notice if their pay is more than three months in arrears.

They are called to work early every morning by beat of tomtom, or sound of bugle, and are "mustered" by the superintendent and told off in gangs to work by 6 o'clock, and at 1 o'clock in the afternoon the "horn blows" again to "knock off."

The work of the estate *has to be done*, and, as coolies *will* shirk all they can, they *have* to be looked after by the superintendent and his assistant, how much or how little depends upon the man himself. Besides this field-work, and the work of the tea-house, the construction and maintenance of the buildings, and the care of the machinery and cattle, the superintendent has to keep all the accounts of coolies' pay and work, and of all that is expended on the estate, and produced by the estate, to be furnished monthly to the proprietor, with ruled spaces for every conceivable particular of work, crop and expenditure. In addition to this a grand-

motherly Government insists also upon certain returns being made quarterly, and that an estate "register" be kept; and that all cases of illness, or death, or birth, be reported within 24 hours. This restlessness of certain Government officials in framing laws "for the protection of the cooly" has defeated its own object by tending to sap up the interest and humanity of the superintendent, who in return for being harassed by Government throws upon Government all the responsibility which he can by any possibility avoid.

The same Government keeps the jails of the country choked with starving and lazy natives, by turning them all into convicts for the sake of the fat fare supplied to them in prison. This single cause is rapidly demoralizing a great part of the native population, who commit the most atrocious crimes for the sole purpose of getting into prison to be fed on the fat of the land, warmly clothed and lightly worked (or rather only gently exercised) during the day. But this *en passant*.

I have thought it desirable to add this separate chapter on the "working of an estate," which will make much of the first part of the "50's and 80's" intelligible and be valuable to enquirers at home.

If a superintendent has no European assistant, he has nearly always an English-speaking and English-writing native "conductor," many of whom are exceedingly useful and trustworthy men, keeping the fieldbook (checkroll) and tools, rice and other accounts, and are out with the coolies all the day. They also act as interpreters whenever occasion arises for a serious confab, but the "tea-house" also requires the exclusive attendance of either another assistant or professional native "tea-maker."

PLANTING IN CENTRAL AMERICA (GUATEMALA).

(By an *Ex-Ceylon Planter*).

The effect of these revolutionary times on my cinchona nurseries was the worst thing that could possibly have happened. Most of the labour was taken off the plantations, and the planters lost interest and heart in everything, and quite neglected the cinchona plants. This happened unfortunately just at the time that "pricking out" operations were in full swing. However, I think that, altogether, I have over a million left, which is much better than none at all.

I should like to tell you a lot about this country and its present position, but as I leave tomorrow morning at 1 o'clock, on a visit of inspection upcountry, and have to make some preparations, call on the President, and say "good-bye" to our Consul, my time is short. I have to ride 150 miles before I reach the coffee districts where my work begins, I cross 10,000 feet elevation on the way, so you see it would not take me long to trot round Ceylon with my mules; by the time I had got round, I should only have begun to feel I had started on my journey. The Indians here will beat the cooly out and out in carrying burdens or running distances. The maximum burden allowed by law is 100 lb., but this is never adhered to; the load ranges from 100 to 150 lb. and often a great deal more. In regard to running, a week ago I visited Antigua and Zapote, and returning from Zapote to Antigua I found my servant had forgotten my shoes; I was very wroth, and ordered him back at once for them, and to punish his forgetfulness I left Antigua and rode to Guatemala without him the next day. What was my astonishment to find the "boy" in Guatemala at 8 o'clock

the next morning with my shoes! He had gone from Antigua to Zapote 25 miles, back to Antigua 25 miles, then to Guatemala 27 miles, altogether 77 miles in 28 hours.

In regard to the endurance of these little mountain mules I may mention that I rode "Mootamah" from Colan to Ranzos in 27 hours; I only stopped on the road to unsaddle, and let the dear little thing roll and pick a little, then mounted and went on again. I would not have been so long, but I had a pack mule which I had to lead, and it was very troublesome. These stoppages were never longer than half-an-hour. I had to catch the steamer and was in a hurry. No more till next time.

ENEMIES OF TEA.—A planter writes:—"I sent you yesterday some caterpillars which I found eating the young flush on lately pruned tea trees. Have you heard of their doing damage on other estates? Are they likely to do much mischief?" Our entomological referee writes:—"The caterpillars appear to be the larvæ of some moth. I do not think their identification would be of any service towards getting rid of them. The only remedy would be to collect and destroy them, if it could be done at an expense that would be less than the loss caused by injury inflicted by the creatures." An Ambagamuwa planter sends us some tea leaves covered with white scales, on which our entomological referee reports as follows:—"A minute species of scale bug that appear to be very common on tea, judging from the number of specimens that have been sent to me. It is to be found in some Colombo gardens, but much scattered and only on a leaf or two of the same plant, and does no harm."

ORANGE WINE.—Some time ago in the *Querists' Column* of the *Queenslander* the subject of making wine from oranges was mooted. In response to our request for practical information a vinegrower and wine maker who has within the last few years visited many of the European continental vineyards called upon us. He informs us, and wishes the fact to be made widely known, that a most excellent wine can be made from the juice of the orange, and that since the troubles caused by the phylloxera a large proportion of the "sherry" of commerce is orange wine. Moreover if properly prepared, he says this orange-sherry is a most pleasant and healthful wine; indeed, in his opinion it is only a matter of a few years and the greater part of the wine in the world will be made from oranges, for the product is equal to that made from the juice of the grape and the yield per acre considerably more. His argument is that in consequence of this discovery the planting of orange groves in suitable localities in Queensland cannot be overdone. As endorsing these conclusions, in the *Melbourne Leader* we find the following paragraph:—"It is stated the manufacture of orange wine is developing into a very extensive business in Florida, where a magnificent American wine is being made in large quantities from the juice of the sweet oranges surpassing in purity any of the European wines. 'It is said to be the best tonic, medicinal or otherwise, that can be taken into the human system. It is nourishing, of agreeable flavour, and, what is more, a perfectly pure native wine.' No part of the fruit is used in the manufacture of the wine but the pulp of the perfectly ripe oranges, and none of the wine is bottled from the casks until it is at least three years old. In taste, it is marvellously palatable, and contains but 8.61 per cent of absolute alcohol and slightly over 5 per cent of sugar. Florida, filled with orange presses, says the *Philadelphia Times*, will entrain the faunons vineyards of France and Italy in time, for the manufacturers of this splendid wine are pushing ahead with new and improved machinery, are setting out countless orchards of the precious fruit and investing thousands of dollars in the enterprise, which they are satisfied will soon become one of the greatest industries of the country. The supply now is no ways equal to the demand."—*Queenslander*.

CEYLON TEA IN LONDON.—Messrs. Geo. White & Co., the well-known Tea Brokers, in the course of a business letter to our publishing office, add the following encouraging note:—"It is a matter for congratulation to notice the increasing demand for Ceylon Teas and the way in which they continue to grow in favour. Judging from the information we receive from time to time, this industry promises to become a very important one, and we trust that plantors will use every effort to maintain the quality which has so justly earned for them the high position they now hold in public esteem."

COFFEE IN YERCAUD, October.—The result of this abnormal weather seems yet destined to bear a bitter fruit in the future, if we may judge from what has already been disclosed. A planter, on cutting some coffee berries to see how the beans were developing, found, to his surprise, they contained only the empty parchment skins and on others doing likewise to ascertain if they were in a similar predicament, arrived at similar results. One planter went so far as to get a measure of berries, I am told, and on opening them, found that the whole, with perhaps a few exceptions, contained only the empty skins without any beans! Cheering results to arrive at after spending and being spent in coffee, to be sold outright in the end! Anyhow, dark though the prospect is at present, let us hope there are bright days in store for us, and that the star of coffee will yet be in the ascendant and maintain its character.—*Madras Times*.

COPRA.—Five or six hundred sacks, partially opened, lay on a San Francisco wharf the other day, and were the object of much curiosity. The contents consisted of small particles of some substance that resembled dried leaves, and the lookers-on wondered what possible use such apparent trash could be put to. Inquiry showed that the bags contained copra, which is one of the leading staples of the Polynesian islands. The copra came from Tahiti. In a conversation with one of the sailors the following facts were learned about the product. Copra is nothing but the dried meat of the coconut. The natives break the fruit into small pieces and allow them to dry in the sun until the meat is thoroughly dried and hardened. When the coconut is thus exposed it becomes of a dark brown color. It is then packed and shipped. Copra is made by all the islands of Oceania. The natives manufacture coconut oil out of copra, and also a marine soap, which lathers with the sea water. But the great bulk of the staple is shipped in its dried form to the United States and Europe. It is used in the manufacture of candles to a large extent. Beside pomades and coconut oil, copra furnishes a volatile oil which is used in the manufacture of perfumery. The importation of copra into the United States is yearly increasing.—*American Paper*.

EXTRACTION OF ALOE FIBRE.—The Mauritius Government recently sent to the Government of Madras, to acknowledge the receipt of a letter asking that working models or specimens of the 'Casse-tête' and 'Grattuse' used in Mauritius for the extraction of aloe fibre might if possible, be despatched to Madras. With reference thereto, writes the Colonial Secretary, "I beg to transmit to you the enclosed copies of the reports from which you will see that the machines mentioned in Mr. de Chazal's pamphlet are the same that were used on the estates where the accidents alluded to in Mr. O'Connor's report occurred, and that they are considered inefficient. Some improvements have been made rendering their use safer, but they are still considered as machines requiring caution in their use. The feeding of these machines is reported to be dangerous, although a guard has been devised to prevent the operator's hand from coming into contact with the 'gratte' as it revolves. But this has not quite attained its object." The Government of Madras has decided that "in view of the existing imperfections pointed out in the letter read above in the various machines used for the experimental extraction of the aloe fibre, the Government of Mauritius will be informed that no specimens or models will at present be required by this Government."—*Madras Mail*.

MARKET RATES FOR OLD AND NEW PRODUCTS.
(From Lewis & Peat's London Price Current, September 24th, 1885.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.		QUALITY.	QUOTATIONS.	FROM BOMBAY AND ZANZIBAR.	QUALITY.	QUOTATIONS.

MINOR INDUSTRIES IN CEYLON AND INDIA.

GARDEN PLANT LABELS AND TALIPOT LEAVES—KAPOK COTTON—PRESERVED BANANAS—PALM OLA FANS.

The prosperity of any country cannot rest solely upon a few chief items of production. The staple exports may, and of course do, constitute the chief factor affecting the trade and revenue; but, socially speaking, a very great deal depends upon the successful exercise of minor handicrafts available for the employment of those unfitted, either by sex or owing to physical defect, for active or arduous labour. Hitherto in Ceylon our leading industry furnished wide employment suitable for women and children, such as the picking and sorting of the coffee; but in the present, and for—it must be feared—some time to come at least, though the drying and packing of cinchona bark, the picking of cardamoms, &c., have afforded some little relief,—there is the certainty that this branch of employment must be largely curtailed. We, therefore, desire to see an extension of what we characterize as minor industries and that these be made available for the employment of those who come within the category abovenamed. We are induced to turn to this subject by the perusal of a letter from Dr. W. C. Ondaatje to the *Gardeners' Chronicle*, which will be found below, on the subject of the adaptation of the leaf of the talipot palm for plant labels. We see in that adaptation the creation of one of those subsidiary industries which we greatly desire, in the interests of our native population, to have widely extended. It affords an instance of what may be produced in this direction, and we would thankfully give publicity to any hints which may tend towards further extension. A proper substance for plant labels to resist weather and tear and wear generally, is a matter of great importance in thousands of public and private gardens throughout the civilised world.

It cannot be doubted, we think, but that there are many further adaptations of our common island produce which might find a market in Europe. *Ex nihilo nihil fit*, and we would strongly recommend that every attempt be made, by the furnishing of hints such as we have expressed our desire to receive, to start further employment for the many thousands of Ceylonese women and children in their homes which may aid their chief bread-winners. Our Agricultural and even our Friend-in-Need Societies might, if suggestions were invited and considered by them, exercise a markedly beneficial influence in this respect. How often does the remark occur to us, based upon some passing notice, that such and such articles of native production would meet with ready sale in England. It is in order that publicity should be given to such impressions and that they should be followed up by practical experiment, that we now write. As affording evidence of the value such suggestive hints might possess, we may recall a proposal referred to some time back in the letters of our London correspondent that the delicious preserved bananas, so common a sweetmeat among us, should have a trial shipment made of them. That proposal passed unheeded by, and now we are informed that there is not a confectioner's shop in England which does not offer for sale those preserves, a ready and increasing trade being done in them. We are told that our enterprising American cousins are the authors of this new industry, which promises to be a very remunerative one for them. Had our correspondent's suggestion been acted upon at the time it was made, it is just possible, notwithstanding greater distance from the market, that Ceylon might have forestalled America in the new effort, and a really

paying employment, one which might have brought comfort into many of our island households, would have been secured to us. To give an instance again, of the successful initiation of a new minor industry, we can refer to "Kapok" or tree cotton as a regular article of export, but which was not heard of under that term or for shipment, before notice was called to it by the Ceylon Commissioner at the Melbourne Exhibition, and now the export trade affords regular employment to a goodly number of the Ceylonese employed in gathering, carrying and preparing this article (used in stuffing mattresses, &c.) for export.

Such instances, it appears to us, should prevent us from regarding as worthless even very slight or slender suggestions. Big things, we know, spring from little things, and the more sources of employment are multiplied among its members the more prosperous must any community become. In Dr. Ondaatje's little promising venture we see what may possibly be one of those aforesaid "little things." Cannot many of our readers afford help in the way we have pointed out, so that similar efforts may in the end furnish resulting "big things"? The avidity with which the trifles offered by the natives who board ships calling at our ports are purchased by the passengers as mementos of their visit would seem to show that such things only demand a wider market to secure an extent of sale which would lead to a widening of the area of employment in the Island. Such shops as "Liberty's" in Regent Street, London, would probably gladly add to their stock of eastern curios and fabrics which have so extensive a sale, the elephant-tooth paperweights and similar little matters which sell so freely to our island visitors. All we can ourselves do in directing attention to this subject is by way of suggestion; but those of our readers who have the welfare of the Ceylonese at heart will do well to endeavour to add to its scope. We are told that the Japanese now do a large trade in ola fans, a trade with which our natives possess great facilities for competing. A higher taste shown in decorating these, such as we have occasionally come across, would probably secure for a Ceylonese export a successful competition. Our palm trees offer almost boundless opportunity for the exercise of ingenuity and taste in utilizing and decorating their lesser products in a manner fitted to tempt European purchasers. As we have said, instances are of daily occurrence which cannot fail to strike the observer as affording capacity for development. Even in respect of raw products, as lately shown in our series of articles on "Curiosities of the Customs," there is much room for the extension of trade in minor industries. It will be a pity if our notice of them, and the opportunity for utilizing them, be lost in the same measure as attended the proposed export of our preserved bananas. Everything must have a beginning, and it would afford evidence of public spirit, if, under the auspices of the local Agricultural Association, some of our exporting houses would undertake trial ventures. These could, at the most, entail but a less trifling in amount; whereas, if the taste of our European friends was once seized, many profitable openings for the extension of small home industries among our Ceylonese population might be created. The Government Agricultural School might possibly afford an opportunity for experiment in respect of some of our various minor products in turning them to use for export purposes. We trust our remarks on this subject may not be altogether without fruit, in new and profitable directions.

TALIPOT PALM LABELS.

Since my arrival in England, in May last, from Ceylon, my friend, Mr. E. M. Holmes, kindly drew my attention to a paragraph in the *Gardeners' Chronicle* of March 28 last on "Palm Leaf Labels," and I have through your courtesy been able to read the paragraph, so as to be able to give such additional information about the labels referred to as may be of some interest to your readers.

The labels are made from the unexpanded frond or leaf of the Talipot palm (*Corypha umbraculifera*). The leaf is fan-shaped, about 30 feet in circumference when full grown, and divided into 112 divisions, the tip of each division being emarginate and green. Each division is split into two, made into small rolls, and boiled in water for a few hours. After boiling the strips are dried in the shade, soaked in water for a few minutes, and both sides smoothed with an iron. The smoothing used to be performed in a primitive manner by rubbing the strips on a polished cylindrical piece of wood fixed between two stumps or trees. After smoothing it is necessary to roll up the strips of leaves quickly, to prevent curling, each roll containing 50 to 100 or more strips. When the surface is polished it is easy to write on it. The use of the smoothing-iron facilitates the process greatly, especially when the strips are spread on a table covered with a piece of blanket—the manner in which I have frequently performed the operation. The strips when thus prepared are called "Olas" by the natives, and used for writing upon with a style, as is well known in the East.

It is a fact that Palm-leaf books have been preserved for more than 500 years. It may be noticed that the durability of the leaf is owing to its being covered with a silicious cuticle, which is one of the most beautiful polarising objects of the vegetable kingdom, displaying the colours indigo, blue, violet, red, orange, yellow and green.

One of the Buddhist priests of Ceylon informed me that the Talipot leaf was used for writing Buddhist doctrines in the Buddhist era 132, or before A.D. 510. An Oriental scholar, also of Ceylon, is of opinion that the leaf was used in this way more than a thousand years ago. The exact time, however, cannot be ascertained. In India there is reason to believe that the leaf has been in use for the last two thousand years or more.

To return from this digression to the subject of making the labels, I may state that the "Olas," or strips of the leaf, are laid on a piece of smooth board. The labels are cut out by means of a stamp, which is hammered with a wooden mallet, and twelve or more labels can be cut at one stamping. The dimensions of the strips for making the labels may be briefly stated as follows:—

Length of longest strip	6 feet 7 inches.
Breadth of broadest part	2½ inches.
" narrowest part	1 inch.
Length of shortest strip	4 feet 9 inches
Breadth, the same as longest strip.	

One strip makes on an average forty nine labels of ordinary size. One hundred strips give 4,900 labels.

As regards the question of the mode of writing upon these labels, I can only endorse your suggestion, viz., of scratching the leaf and applying the colouring matter. The common mode of writing as practised in the East is by means of a style, and Indian ink, charcoal, or other colouring matter, is rubbed upon the scratched writing. A specimen of a label written on with a style I send herewith for your inspection. The mode of writing with a style is no doubt foreign to Europeans, and may not be so easily accomplished as by the natives

of the East; but some pointed instrument may be devised for writing on the Palm-leaf.

I have used these labels extensively attached to animal and vegetable specimens immersed in spirit, and found them in good preservation for a long time. The parchment labels attached to stone corals which I took with me to Ceylon turned into a pulpy mass in some months. Talipot labels attached to plants exposed to the tropical sun and rain were uninjured for a long time. According to Mr. Holmes' suggestion, I had some labels written on with strong sulphuric acid, and held to the fire in order to develop the writing. The acid was used with a quill pen.

The cost of 1000 labels, without brass eyes, is 2s. 6d. I shall be glad to supply any one with a few labels for trial.—W. C. ONDAATJE, F. L. S. (retired Colonial Surgeon, Ceylon), 85, Finborough Road, S. W., Sept. 3.—*Gardeners' Chronicle*.

COFFEE PRODUCTION AND CONSUMPTION:

THE ENORMIOUS DEVELOPMENT OF BRAZIL AND FALLING-OFF OF CEYLON—BRAZIL COFFEE THE BEST BY ANALYSIS IN THE WORLD.

Under date "London, Sept. 23rd," our esteemed correspondent "W. M. L." sends us the following interesting report on what the Brazilians are doing about their staple:—

I lately sent you some remarks, taken from the New York Chamber of Commerce, on the consumption of coffee in the United States.

I have since chanced to come across a pamphlet dated this year and entitled "The Empire of Brazil at the World's Industrial and Cotton Centennial Exposition of New Orleans," the special object of which is to make known the overpowering supremacy of Brazil as a coffee-producing country and to promote the further development of its resources in that direction.

The information collected seems to be not quite of so recent a date as that given by the New York Chamber of Commerce; for whereas in the latter the per capita consumption of coffee in the United States is stated to be nearly 10 lb., in the pamphlet now in question the United States is placed fourth among the nations of the world as a coffee-consuming country with a consumption of 8.27 lb. per head. Holland comes first with 17.90 lb. per head, Belgium second with 9.13, and Norway third with 8.73. The pamphlet goes on as follows:—

"Taking the whole population of the United States into account, Mr. Joseph Nimmo jr., the chief of the Bureau of Statistics at Washington, rightly places the United States in the fifth place as having a per capita consumption of 7.42 lb. next to Cape Colony with 7.72. But if, leaving aside the general rate per capita, we consider the real quota of consumption of the different groups of States, we shall find three-fourths of the consumption belong to the country from New Orleans to Chicago and that the consumption per capita is 15 lb. for the inhabitants of that region, which would place it in the second rank, next to Holland with 17.90 and above Brazil with 10 lb., which two countries probably, on account of the extensive use of this beverage, are considered as the most temperate in the world."

And then, with the combined object of making the Yankees sober and increasing the consumption of Brazil coffee, direct communication is advocated betwixt the Brazilian ports and New Orleans, so that the coffee in place of reaching the great consuming districts by New York and thence by rail should have the advantage of water carriage up the Mississippi.

The present producing power of the Brazilian Empire is thus dealt with :—

“ Brazil has received the name of the land of coffee, and certainly it deserves the appellation, since it produces 55 per cent of the world's total production. This total production is at present 660,000,000 kilogramme per annum and is thus distributed :—

Production of Brazil..... 360,000,000 kil.
Production of all other countries 300,000,000 „

Total world's production.. 660,000,000 kil.
And yet in 1800 Brazil exported only 13 bags of coffee !; in 1817 it exported 66,985 bags ; in 1820, 97,498 ; in 1830 484,222 ; 1,037,981 in 1840, and 3,765,122 in 1876. Today the annual production of Brazil is more than 6,000,000 bags of 60 kilogrammes each.”

What a painful contrast to the figures for Ceylon coffee ! The exports thence, which in 1870 were about one-tenth of the world's supplies, are now shrunk to less than one-thirtieth, and that in face of an unprecedented expenditure of capital on extension, directed too by the much and justly vaunted skill and energy of the British planter and yet for several years the doctrine was preached, aye and faithfully believed in too, by many among us, that the day that should see the slaves of Brazil emancipated would see also her failure in the race of coffee production, and that then at last was the good time coming for Ceylon and her planters. As regards quantity Ceylon must now fairly admit herself completely outstripped and beaten in the race. But it will probably be a surprise to Ceylon producers to learn that in quality also Brazil stands first. The analyses given in the pamphlet under review show that Brazilian coffee has 1.16 to 1.75 per cent of caffeine against 0.87 per cent in wild Ceylon (as they term it), 0.709 to 0.849 per cent in Java, and 0.54 to 0.83 in Plantation Ceylon and 0.60 in Mocha. The percentage of caffeine in all other kinds of coffee is given at much lower. Of the remaining chemical constituents of coffee of nutritious value, viz., the fats, the albumenoids and the sugar, an equally favourable report is given. But, your readers will ask, if this be so, why does not Brazil coffee top the market ? Hear the sad answer to the question :—

“ At present, as we have shown, no coffee in the world excels in intrinsic value the good Brazilian grades, and but few can be compared to them. Up to the present this important fact is known only to the producer and the dealer ; the consuming public, even the best informed, not knowing that the best coffee in the market comes from Brazil. The cause of this in the handling of the intermediaries through whose hands it passes in going from the producer to the consumer. The planter consigns his coffee to a commission merchant, and from him it goes into the hands of the sacker who assorts it, habitually mixing the better with the poorer sorts. It is next bought by the exporter in quantities from 500 to 5,000 sacks and shipped *en masse* to Hamburg, Bordeaux, Havre, Marseilles, Liverpool &c. Here a commission merchant sells it by wholesale to the speculator, who subjects it to all the manipulations from which he expects an advantage to his pockets. He assorts it again ; gives to the better sorts the name of ‘ Superior Moka,’ ‘ Java,’ ‘ Ceylon,’ and introduces them under these names into the markets. Only the inferior sorts, the refuse, are sold as native Brazilian coffee ; and even these are still further deteriorated by the admixture of the poorest Costa Rica and Venezuela coffee. In this way the speculator secures a double

gain, since he lessens the demand for Brazilian coffee as such, thus compelling the planter to sell his crop for low prices, and on the other hand selling the greater part of his cheap purchases for the best possible price. The indifference of the planter who even at a low price reaps large profits from his coffee plantations has made these manipulations of the speculators quite easy.

“ In view of these it is easily understood that, in spite of the enormous quantity of the coffee of Brazil imported into Europe, and despite its excellent qualities, so little should be heard of it. As a matter of fact the greater part of that coffee planted, gathered and sold in Brazil, and which we so much enjoy and buy so dearly as ‘ Moka’ or ‘ Ceylon’ has been rehatpized by the speculators of Hamburg, Bordeaux, &c., with a false name and sold at a large profit.”

The aggrieved Ceylon planter, much suffering at the hands of Colombo and Kandy agents, will surely shed the tear of sympathy with the deeper woes of his Brazilian brother. His coffee at all events (if indeed he is lucky enough to have any) is not forced from him at a low price only to support the reputation of his competitors. The remedy proposed for the evils complained of is publicity, which is sought to be obtained mainly by Exhibitions of Brazilian coffee to be held throughout the world and in a lesser degree by the publication from which I have quoted.

COCOA-DRYING IN MATALE.

Mr. R. S. FRASER, proprietor of Wariapolla, is good enough to report :—

MR. JACKSON'S TEA DRIER is a perfect cocoa drier both in the very large quantity it will get through in a very short space of time, and the way in which it does it. The fan is the whole secret. It would almost do it without fire heat—the draft of cold air, I mean. Then again it is perfectly innocuous to any tea work that it has to perform as well, there not being a vestige of taint left, after the fan has run for ten minutes. I think Mr. Jackson as lucky a man as you can well find anywhere in these days, as in trying to kill one bird he has unwittingly made a machine that can be applied to several purposes. It will alter the whole idea of cocoa, and with the big drier of Jackson's to overcome the first difficulty of drying cocoa, after the washing, anybody fortunately possessing a No. 3 Dehydrator can compass a lot of cocoa drying in a day. And the dehydrator also makes a capital finisher or puckabattying machine, as it will do a large quantity at a time. It also comes in handily as a witherer in the case of very wet leaf. I have ordered a Venetian to meet my immediate wants, and have ordered a large drier for next year when the Venetian will take its position in order of merit and utility. By the bye Mr. Jackson's killing two birds in this way, unexpectedly reminds me of the account in your paper yesterday of the feat performed by Mr. Turner in killing two tigers. Mr. Turner is a great friend of mine, and so is his companion B., who was an old Eton schoolfellow. They are both of them inveterate sportsmen. And one of them, B., the eldest son of a wealthy Baronet, accompanied me out here in the ‘ Hydaspes’ in 1879, on his way to India on a sporting trip, and as guest of the Duke of Buckingham, and so great is his love of sport that he has never returned home since, but has devoted himself heart and soul to his loved pastime, much to the chagrin of his people at home.

VEGETABLE MARROWS.

The Colombo School of Agriculture, Oct. 12th, 1885.

DEAR SIR,—I hope the following account of my vegetable marrow plantation may interest, if not be useful, to your numerous readers, as I have heard it said marrows do not often prove a success in the low-country.

In the ordinary cinnamon garden soil round holes were dug a foot and a half in diameter and depth, four feet apart, and dry leaves and other rubbish put in and burnt. Well-rotted cow-dung was then applied. The seeds three in each hole were put in on the 10th of August last and were found germinated in a week's time. On the 10th September pigeon-dung dissolved in water was applied to plants in a few of the holes only, the others being left to feed on the ash and cow-dung previously applied. This afforded me a good opportunity for comparison, and the result has shown me the decided advantage of the application of pigeon-dung. For these plants to which I applied this rich manure are very healthy and productive. The heavy downpour which we had lately has been very destructive to my marrow-plants; many pistil flowers and young fruits have decayed. But notwithstanding this drawback I have been able to get a good produce from the vines, and several of those to which pigeon-dung were applied have yielded fruits weighing from 4 to 7½ lb. I may also remark that these latter plants have braved the late inclement weather much better than the others. Care also was taken to wrap the young fruits round with rags to prevent attacks of insects which infest the plants. This is a very important precaution for very rarely does a fruit enjoy immunity from these creatures when it is not thus treated.—Yours faithfully,

J. A. G. RODRIGO, *Agricultural Student.*

TEA: AN INDIAN CRITIC ON CEYLON TEA PROSPECTS.

We must congratulate the tea-planters in Ceylon upon having brought their wares before the market in a most noticeable way. At a time when India was producing about the same quantity as Ceylon now is, little, or nothing, was heard of it. Judging from the prices at first obtained for Ceylon growths, we are forced to the conclusion that any new country producing a small quantity in what we may say an experimental way, can always command more than its market value, and we are already beginning to hear a complaint now and again that Ceylon teas are going off, even although the quantity to date is so small, and we have not the slightest doubt that all with one or two exceptions, as in Assam, will come to the same level of prices, and that in a year or two. It will not take Ceylon teas so long to suffer so-called deterioration as it has done Indian teas, for as the supply increases so will the fastidiousness of the brokers and dealers. When Ceylon tea was first talked about we heard of nothing less than 10 to 12 maunds per acre, Mariawattie and some others being quoted as examples. Now, it is strange that the yield should have come back to something like what we predicted when first we noticed this point, so far our predictions were correct, and we very much doubt whether Ceylon will ever be able to turn out its tea as cheaply as India can. As instances of large yields in individual cases we can point to Doloo in Cachar, and Panitola, Doom Dooma, Talup, and Hilika in Assam, and Chalapore and Chandpore in Sylhet, so that we may say that every district in Assam has its own "Mariawattie," but it does not necessarily follow that every inch capable of growing tea will turn out at the same rate. Ceylon will not for many years be able to come up to the average of outturn of India, and we therefore fail to see

how Ceylon tea can be any better an investment than Assam. We do not think that there is any doubt, that given a reasonable time, the consumption at home and abroad will expand sufficiently to take off what will be produced, but if extensions go on at the rapid rate they have been doing for some years past, we do not believe that the result can be anything but disastrous, and we will not be at all astonished if there is somewhat of a panic in a few years, as prices are bound for a time to fall below cost of production on many old estates. Looking through the tabulated list, the cheapest rate which anyone can lay down his crop in London is 9½d, Chargola Tea Co., Ltd.; whilst the most expensive is 1s. 7d, the production of the Mungledye Co. We will now take the lowest price obtained, which is 11½d, obtained by the Panitola Co., whilst the highest is that of the Borokai Co., namely, 1s. 8d. The quantities per acre stand as follows: Chargola, 304 lb.; Mungledye, 168 lb.; Panitola, 660 lb.; and Borokai, 297 lb. With regard to profit, Borokai makes the largest per cent, Panitola next, Chargola last; whilst Mungledye is out of the running, making a good loss. We must not forget to take into account the capital per acre, which is respectively £48, £61, £48, and £102, thus Panitola and Borokai carry the same capital, whilst the Mungledye Co. has double, and Chargola, we may say, one-third more; taking this into consideration Borokai pays a better percentage, and can afford to stand a decline in prices better than any other, but it is an exception, and must not be counted upon as a general factor, and we consider that Chargola is a better representative than Borokai on the one hand or Mungledye on the other; there may be circumstances particularly favorable to the one and as disastrous to the other. Suppose we take Chargola as an instance then the initial cost of the tea is 9½d., and the gross price realized is 1s 1½d., or a net profit of 4d per lb., equal to 7½ per cent on the capital; supposing the market should drop 2d per lb. all round, this reduces the profit by half, and is scarcely an investment much to be desired. The question then comes to be, can the Chargola and other companies turn out these teas any cheaper than they are doing? and this we doubt much, but we will even go so far as to say they can buy 1d per lb., that is to say, for 8d per lb., and say the market does drop considerably, yet the crop realizes 1s per lb., and we still retain our 7½ per cent. That the market will be affected by the large extensions coming into bearing, we do not doubt for a moment, but so long as companies can be managed in this way there need be no fear. We come now to the question of Ceylon teas, and naturally ask the question can the tea be turned out on a cheaper scale than the above? We unhesitatingly say, No! It is true some of those heavy yielding gardens to which we have referred, may do so, because they were begun under particularly favourable auspices. Had they not the old factory buildings to fall back upon? had they not the lands cleared, and ready to plant? abandoned coffee lands at least. Allowing all these advantages we come to the more important one of labor, and this is perhaps the equalising point; the Ceylon planters are the same as our Indian planters, obliged to import the article, and if they do not give bounties they give higher rates of pay, and we imagine with one thing and another they cannot import more cheaply than their Indian brethren. So far, we have heard but little of the many pests that tea is heir to, but it will be indeed be a land flowing with milk and honey

if they should escape all these. There is nothing, however, like a flourish of trumpets to bring an article into public notice, but we are not in the least afraid that our Indian planters will be beaten in the race by their juniors of Ceylon; and so long as our managers give 1d per lb. profit, shareholders need not gumble, nor be afraid.—*Indian Planters' Gazette*, Oct. 13th. There is nothing like hearing the other side of a question, and seeing ourselves as others see us!—Ed.

REMINISCENCES OF A TEA DEALER IN ENGLAND.

In your issue of 8th ultimo I observe your London Tea Correspondent again warns planters against going home, to set up retail tea agencies. He should have said wholesale and retail, for those who only "retail" tea do not as a rule employ "travellers." In support of his caution let me give you a glimpse only of some of my experiences in the tea trade at home.

In 188— I left Assam to commence business under very favorable circumstances, in the City, of— as a wholesale tea dealer, making a speciality of "Assams," but selling Chinas as well. I bought my teas in the best market, engaged travellers, (experienced men, mind,) and "placed" a lot of tea. As an extra precaution against making bad debts, I even went so far as to subscribe to a number of "Trade Protection private enquiry offices," and before teas were forwarded, I had ascertained by telegraph the supposed stability of my would-be customers. Although a considerable discount was allowed for "payment on delivery," my cash buyers were very few and far between. Some of the travellers, however, did not do sufficient business to pay their salaries and expenses; for which they gave the following reasons. Many of the trade had just laid in a stock; other, again were satisfied with the treatment they received from the firms with whom they had dealt for a number of years, and consequently were not desirous of opening a new account, etc.; and a few hinted they could "match those samples at half the price," which was of course absurd. This took a considerable amount of the gilt off the gingerbread, but that was not all. At the expiry of three months from date of sale, when the different accounts fell due, more than one grocer had gone to the wall; some were offering a compromise, failing to arrange this, they threatened bankruptcy, and the remainder either squared up in full or paid something "on account," with a request that the balance might be allowed to stand over till "you next come round."

When a profit and loss balance was struck at the end of the second quarter, I found myself several hundred pounds on the wrong side, and finding out, when it was too late, that there was nothing to be made in the "wholesale" business, I decided to try the "retail," making a speciality of what is known as the "packet trade," which was all the go then. It is true more profit is to be made in the retail business, which may be looked upon as cash, but the amount sold is so small compared with the "wholesale," that of the two, were it not for bad debts the latter would prove the more remunerative. A shop in a good quarter means a heavy outlay in the first instance, for fittings and fixtures alone, besides which the rent, necessarily very high, must be thought of; also gas taxes, etc., and shopmen's wages. In the "packet" trade the "paper-bag" and "printer's bill" is no small item, and—just to stop to consider for a moment the number of pounds, half pounds and quarters which must be sold to pay for all

these and provide an income for yourself, and perhaps family as well. I hear you say "surely a shop selling nothing but really good tea at a moderate price ought to pay, and moreover, you might establish agencies throughout the length and breadth of the United Kingdom (if you have capital enough to do so, and if not then as far and wide as your capital will go) for the sale of your tea?" "This ought to pay," you reiterate. So anyone, who has not tried it, would think. I will try to show you why a beginner cannot make it pay.

I found when I had launched forth in the retail and packet business, that the upper and middle classes have, as a rule, a running account with their grocers, and they find it more convenient to order their tea with the groceries. The balance of these two classes and the lower, continue to buy theirs from the places where they are accustomed to deal or from the nearest shop to their homes. In every town of any size there are establishments which sell nothing else but tea—and perhaps coffee—thus rendering it simply impossible for a man to make any thing at the game, unless he has set the ball rolling years ago. As regards the "Agency" business, that also is equally overdone. Point out a public house at home where you will not see a show card of "The Licensed Victualler's Tea Company," where the non-teetotal British workman buys his quarter or half pound after receiving his wages on Saturday, in some cases getting a glass of beer gratis. Where is there a small post office in the United Kingdom whence packets of what is known as "Post Office Tea" may not be purchased, supplied by a big London tea dealing firm trading under the name of the "Post Office Tea Company, Limited"? Who has not heard of the "Book Tea Company," a wholesale house which has agencies throughout the length and breadth of the British Isles? They, like the rest, are not particular who represents them so long as the money (which is generally paid on delivery) is right; confectioners, down to China-ware dealers and baby linen establishments, sell their tea. For two shillings you get a pound of tea and a new six-penny book; a shilling book and a pound of tea for two and sixpence, and for three shillings and sixpence, a two shilling book and one pound of tea! Good books they are, some of them. I wish I could say as much for the tea. Show me a big commercial street in a large town where there are no "Gift" or "Present" shops, finest in the window you will see "two pounds of fine tea and this rare old curiosity for four shillings"—or "any one of these handsome articles given away with three pounds of tea for six shillings." And so on, *ad lib*. The curiosities and handsome articles are, however, not worth much. Then, again, there is Horniman, every person knows Horniman, by name at all events. I remember seeing his teas advertised when I was quite a little boy. He must have made a pile anyway. He is still to the fore, and heaps of other tea companies and people of whom neither you nor I have ever heard. Since the license for the sale of tea was abolished every little shop sells tea, even chemists and druggists are agents for different firms. Who then is left to sell or buy your tea? The trade, wholesale and retail, is so cut up, that, except for old established firms, there is no getting a livelihood let alone a competency out of it now-a-days. The foregoing remarks will apply equally as well to Indian teas by themselves, which by the way the general public do not relish "pure and unadulterated." Hence the excuse the trade make for adding China. The only thing against the

practice is that instead of mixing a little good classed China with it to soften down the tone of the India, they use cheap stuff to enable them to reap a larger profit.

I believe, Mr. Sam. Davidson, an old planter, is about to start a big retail store in Belfast for the sale of his tea at one price, viz., two shillings a pound. He will have the advantage over most of us—I mean those who have gone or intend going into the tea trade at home—from the fact of his being in a position to offer to the public tea direct from the gardens in which he, the retailer, is largely interested, where but one kind of tea will be produced, i.e., one hundred per cent. put through a Pekoe sieve, minus the dust, as well as from the knowledge that he is a man who "can live where others starve" or, in plainer words, he will succeed where others have failed. More power to his arm, say I, and may his shadow never grow less. But this is a digression. Finding the tea trade, like every other trade in England, overdone, and no money to be made in it, I drank the profits, smoked the losses, gathered together the pieces that nothing (more) might be lost, as well as to pay the rent, and returned again to "sudden death" and curry *bhat*, a wiser and certainly a poorer man.—*Indian Planters' Gazette*.

THE GROWTH OF THE INDIAN TEA TRADE.

It is apparent that the rapid growth of the Indian tea trade of late necessitates some departure from the customs which have hitherto regulated its sale. Some correspondence has recently appeared in these columns on this subject, and the letter of Mr. Shillington draws attention to a state of friction in one department of the trade, which requires a remedy. The question is not one between broker and dealer alone. The planter is interested in the removal of all obstacles in the way of the development of the Indian tea trade and although he has no control over the method of transacting business in Mincing Lane, he will be anxious that any "clog to the machinery" as one correspondent puts it, which regulates the customs of broker and dealer should be removed.

There is another and in some respects a kindred question, viz., that of tasting samples. Considering the magnitude of the trade now as compared with a few years since, it must be recognised that the work of tasting is rapidly becoming a super-human task.

Some suggestions have been discussed among the Indian tea buyers for lessening their laborious work of tasting 200 to 250 samples before the noon sales. In giving publicity to some of the ideas mooted in the Lane we are desirous of hearing both sides of the question, and willingly open our columns to buyers and sellers alike for their opinions. As a means of facilitating the work of tasting it is suggested, in the first place, that the size of non-sampling breaks be raised. The minimum of sampling breaks at present is:—

8 chests, or about	680lb.
8 half-chests	400lb.
20 boxes	400lb.

We think the net weight of tea, rather than the packages, should be taken as a basis to work upon, and if the limit be increased to 12 chests, 20 half chests, and 50 boxes, the weight in each instance would be about 1,000 lb.

Next, it is suggested that the plan of general bulking should be adopted by importers. Breaks of 10 or 15 chests of similar teas might be bulked into one lot wherever it was at all practicable. This would dispense with the numerous small sampling breaks

found in every catalogue. It is thought that buyers could not grumble at 30 chest lots as they do at three lots of 10 chests each. The different garden marks could be given or if too numerous could be printed as "various." Thirdly it is thought that greater facilities should be afforded by the Custom authorities to the importers for bulking two or more shipments together, especially in the case of garden invoices arrived by different steamers, and, lately, the opinion is that second-hand teas should follow on with the small breaks at the close of auctions,—only a very small minority of the trade being interested in either of them.—*H. & C. Mail*.

THE PROGRESS AND PROSPECTS OF INDIAN TEA.

Thanks to the compiler of the Directory and Handbook published at this office, there are fairly accurate figures available showing the progress of the tea enterprise in Ceylon, and that progress is such as to create astonishment and even alarm in the breasts of our Indian friends, who seem by no means sure of the correctness of the figures representing the progress and position of their own great tea industry. On the one hand, we see it stated that large areas taken up for tea cultivation have been abandoned, not because the land was unsuitable for the culture, but because the culture itself had become unremunerative. The *Indian Planters' Gazette* contends that it must be so in all cases where the annual average yield per acre does not come up to 5 maunds, that is 400 lb. per acre. In that case the vast majority of Indian "Gardens" must be worked at a loss, for no returns that we have ever seen for India as a whole have exceeded 4 maunds or 320 lb. per acre, although in exceptional cases 500 lb. 700lb. and even 1,000 lb. per acre have been gathered. The figures contained in the official returns are denounced as too low in some case and too high in others, and certainly, when Government officers attempt to guess the cost at which tea is produced, they make a mess of the matter, their estimates varying from the ridiculously low figure of 4½ annas per lb. to the equally ridiculously high figure of 8 annas 9 pie, or more than half a rupee. The Deputy Commissioner of Nowgong is considered to have come near the mark when he stated the cost of cultivation at R70 per acre per annum and the cost of manufacture at 7 annas per lb., the equivalent of nearly 44 Ceylon cents. It is difficult to see how any price less than one shilling per lb. in the London market could leave the slightest profit in such a case. But much Indian tea sold for considerably less than this average last year, a year in which yield is asserted to have been specially lessened by the almost universal prevalence of drought and blights, drawbacks from which Ceylon has been remarkably exempt. In all the tea districts of India, without exception, the rainfall is said to have been less than the average of the previous five years, and this is taken to account for the poorer quality as well as the lesser quantity of tea made. But in the face of all difficulties, including heavy Government cesses, and while some have abandoned land taken up originally for tea culture, others have gone in for large extensions, especially in Sylhet. The truth seems to be that only by extension can some old and unprofitable places be retrieved, and many Indian planters, especially companies, have enormous areas over which to operate. The original Assam Company, for instance, possesses somewhat over 6,000 acres of land. In many such cases, plots on which to cultivate rice and other

provisions are given to the labourers and their families, and, when we hear of low money wages in Darjiling, we must not forget the fact that the coolies get land to cultivate in addition to their money wages. The large sales of tea seed required for the extensions we have mentioned in India and for others in Ceylon and elsewhere have helped a good many old estates in India, but this source of revenue is now likely to diminish. We may mention in passing that the crop of tea seed on many estates in Ceylon, especially on those at a high elevation, has this year been a great disappointment. We know of a "lowcountry" estate where the trouble is to prevent the bushes running to blossom and seed, while on another, between 4,600 and 6,000 feet altitude, large trees of eight and nine years old show sign neither of blossom nor seed. Probably the removal of superfluous wood and the application of bone-dust, might be useful in that later case. But to return to tea in India. From gardens and extensions recently opened, crops at the rate of 7 to 10 maunds per acre (560 to 800 lb.) are expected, in which case the most productive properties in Ceylon must look to their laurels. From an article in the *Indian Tea Gazette* we quote as follows:—

Unless tea can be produced at some very low figure indeed, it cannot pay. Prices are low and the tendency, allowing for an occasional temporary spurt upwards, is downwards. And yet we hear of new extensions in every direction, not only to existing gardens, but also the opening out of entirely new ones. In South Sylhet and in the Dooars new gardens are being made at a rate which seems incredible to the old stagers. The South Sylhet Tea Company has put some six to seven thousand acres under tea within the last two years; the North Sylhet have done a good deal of extensions chiefly in the Dooars; and Messrs. O. Steel and Co. open out their new gardens in blocks of 800 to 1,000 acres per annum. Ceylon, too, is rapidly extending its area and increasing its outturn and other countries are taking to growing tea. Will demand keep pace with supply, or will prices fall so low that it will not pay to manufacture?

Will the increased quantity of higher class teas, produced by the increase of area of good *jât* plants, and the greater care yearly exercised in plucking and manufacture, readily find purchasers at existing rates? The argument in favor of extensions of area, and opening new gardens is, however, a strong one. It is generally admitted that many of the old gardens, with their broken up and scattered cultivation, their inferior *jât*, and small yield per acre, will not pay now, though they used to do so. Good *jât* and good outturn per acre,—at least five maunds—are necessary to enable a garden to pay even a small profit. Old China gardens must either extend largely with good *jât*, or expect to work at a loss and shut up eventually. They cannot hope to compete with the gardens recently opened out under the new lights, many of which give, or will give when in full bearing, seven to ten maunds an acre.

A cogent argument in favor of new extensions on old gardens is that, as the profit on a pound of tea is so small now, so many extra pounds must be turned out to realize anything worth having. When a planter could clear sixpence a pound on his outturn, he only wanted to put 49,000lb. of tea on the market, *i. e.* make about 500 maunds of tea, to clear £1,000. But if he can barely clear a penny a pound, by most careful and economical working, he must naturally turn out six times as much as before to clear the same profit. Of course, extensions do not grow spontaneously; they cost money and labor, and thus add to the cost of production of the bearing tea. But many of the leading planters of the day believe strongly that they pay in the end, notwithstanding the outcry against over-production. Such being the feeling and such being the consequent action, the great question is how to find markets for the increased quantities of tea which India, plus Ceylon, will speedily pro-

duce. A writer in the paper from which we have already quoted states:

There is no doubt that in a few years, with Ceylon opening out at the rate it is doing, tea outturns will be doubled. We have all along contended that, in the native bazaars throughout India, a splendid field for Indian tea has been neglected for many years past. Instead of being able to calculate the consumption in thousands, we ought by now to have been calculating by millions. We hope things will not be allowed to drift on, or matters dealt with, as, in the case of the Australian market where a large quantity of tea was wasted for no good apparently, although, possibly, it may have introduced Indian tea to some who never saw it before. We have now an Indian Tea Association, which is supposed to have the interests of tea in its care, and it might not be altogether outside the limits of its functions to adopt measures for the opening out of new markets. In addition to the ordinary bazaar market, which is eminently suited to take off coarse teas in small packets, we have heard of no attempt being made to introduce our Indian tea in brick shape to the Thibetans.

And then the writer proceeds to show how the Indian planters might utilize their coarsest leaf to supply bricks to the Thibetans, if only the Thibetans would accept them. That question will be soon tested, for the probabilities are, that, owing to the present friendly relations between Britain and China, the long-sealed land of the Lamas is likely speedily to be opened to trade and travellers from India. But conservatism has to be overcome and the Thibetans have become as much accustomed and as much attached to the cheap and nasty brick tea of China, as the mass of Australians have, from long use, come to like the cheap inferior leaf tea sent them from the same source. For good Indian and Ceylon teas to make their way in Australia and the Western Continent, will be a matter of time. So with Russia and other continental nations. What we have mainly to trust to is the largely expanding demand in Britain for really good teas. Were the millions of natives in India and Ceylon only somewhat more wealthy than they are, local markets for our second-class teas and dust would open up and expand indefinitely. That day will yet dawn, but it is in the still distant future. Our wisdom in the present, no doubt, is to go on supplying the London market with the high quality teas which have already found so much acceptance with the tea drinkers of Great Britain, next to China itself the greatest tea-drinking country in the world.

CEYLON UPCOUNTRY PLANTING REPORT.

SHOWERY WEATHER: ITS TWOFOLD EFFECTS—A "SHUCK" COFFEE-TREE AND A POOR BELIEVER—TEA—WHITE-ANTS—COOLIES—THE "T. A."

26th October 1885.

The fine showery weather we have been having for some time now, however suitable it may be for the planting community and the young tea plants, is a dead stop to anything like floating news. Every day lately has been bringing its extra work; everybody has been busy, and the neighbour who usually drops in with a cheery remark, or the latest "tale that is told," has been absent, being as fully occupied as one's self. And still the days pass: ah! how swiftly—and the time is round again for another letter.

It is not to church one goes for planting news, and yet one sometimes hears funny things about it from the pulpit. I was much interested the other Sunday, at a preacher working out the analogies between a "shuck" coffee tree and a believer in poor circumstances. Up to a certain point the thing went along beautifully, and told, as only illustrations

drawn from real life can. But "the rub" came when the teacher tried to show the unimportance of the present, and the high future destiny reserved even for the poorest believer, and to work that idea around the "shuck" coffee tree at the same time. How interested I became, feeling assured that we were on the verge of an important discovery, regarding the future of coffee, and that to me should be given the opportunity of bringing it before the public, in the space you reserve for these letters. Alas! alas! like many another honest man who has had to do with coffee, the preacher was landed in difficulties, made a stout fight to get rid of them, and, amid big swelling words and much noise, was at last glad to drop all connection with coffee, "shuck" or otherwise, and try something else.

Tea is growing well in this forcing weather, and plants and seedlings are doing their very best to make up for lost time. I saw some tea seed which the hard surface of the soil, baked in the late hot weather, had prevented from pushing through, and it was looking very queer. The shoot had wandered about in the loose soil inside the hole, vainly endeavouring to discover a weak point through which it might pass into the light until it had become an entangled mass. I question if it will come to much good, now that the conditions for its growth are more favorable.

It is rather disgusting to see fine young tea plants die out here and there over a field, ringed just under ground by some grub or another. But besides this "pestilence that walketh in darkness," I observed the white-ants busy *above* ground attacking the living plant, having eaten a branch through, which was almost as thick as a pencil. I have seen living rose trees destroyed by white-ants, and should the termites follow the public taste, and take a liking for our teas, they will be rather a formidable foe to meet. That is a kind of patronage we will be all willing to dispense with.

Coolies are plentiful and to spare, and I hear of cases of gangs paid off, that cannot get work elsewhere, and hang about their old estates in the hope of being taken on again. By-and-bye there will be lots of work for them, and for the Sinhalese also, if they care for it. Coffee is ripening up in the low districts, and the late showery weather has brought the little there in with a rush. The natives too have been showing their customary liking for the old King, and have as usual been helping themselves. In this part of the country we are, however, nearing the end of this wood, and don't exactly as yet see the form in which the coming one will clothe itself. Still that *there will be* a coming one we never for a moment doubt.

Looking over some Indian agricultural papers the other day, I was struck with the number of quotations, and extracts taken from the *Tropical Agriculturist*. Evidently they looked upon your monthly as the fountain-head of all reliable information, in things relating to agriculture in the tropics, and well they may.

FERRERSBORO.

A NATIVE BOTANIST IN ENGLAND.

The *Indian Daily News* writes:—In the spring of the year we took pleasure in wishing Godspeed to our fellow-townsmen, Babu S. P. Chatterjee, the proprietor of the Victoria Nursery, Narcondangah. The Babu in the pursuit of his business, had visited all parts of India, the Straits, China, the Philippines, and Australia, but this year he decided to visit England and the Continent. Many of his compatriots had made the same journey for pleasure, to study for the Civil Service, the Bar, the medical profession, on political missions; but as far as we know Babu S. P. Chatterjee is the first instance of a native proceeding to England to extend his business connections, and to gain a further knowledge of his trade. The Babu left Calcutta on the 30th April, taking with him a considerable collection of orchids and rare plants, and armed with numerous letters

of introduction from his Indian clients. On his arrival he first called on Sir Joseph Hooker, to whom he carried a letter of introduction from Sir Richard Garth. Sir Joseph was kindness itself to his Oriental visitor, entertaining him as his private guest and personally acting as his Cicerone to all the wonders of Kew. Babu S. P. Chatterjee, who, having visited many gardens in Australia, is no mean judge, was overwhelmed with the beauties and perfections of the out-door gardens and the celebrated Palm House, but was less impressed with the conservatories, which, in his opinion, could not compare with some of the private collections. Through the kindness of Sir Ashley Eden, the Babu obtained an introduction to Lord Hartington, who at once commended him to the good offices of Mr. Thomas, the head gardener at Chatsworth; the gardens and conservatories of which splendid estate the Babu places first in the list of those he visited, one of the most beautiful features being a rock garden of some five acres in extent, veined with rivulets and waterfalls and planted out with pines and ferns. The fernery is almost by itself a glass palace, having been built at an expenditure of £65,000. The collection here is perhaps the finest in Europe, and Mr. Thomas, with the sanction of the noble owner, presented his visitor with cuttings from the collection of the famous Chatsworth Pines. The Babu also visited Worsley Hall, the seat of the Earl of Ellesmere, and here, as apparently everywhere else, he was made a welcome guest. The rhododendron avenue, and the out-door bedding especially attracted his admiration. The collections of Mr. Hardy, Mr. Gaskill, and Mr. Percival, all near Manchester, were also visited. Each of these gentlemen is noted for his collection of orchids, several varieties of these plants being named after them. Babu S. P. Chatterjee was made none the less welcome by being introduced to these gentlemen by Mr. Bruce Findley, the well-known Director of the Botanical Gardens at Manchester. At Trentham, the Duke of Sutherland's seat, the Babu met an old friend in the *Musa Cavendishii*, vulgarly known in Bengal as the Cabuli Kala. This esculent fruit was flourishing under glass, and, as the hothouse pine in England is always superior to its out-door fellow in the tropics, so was the Duke's plantain a more delicious morsel than our familiar and somewhat despised Calcutta friend. His Grace grows for the market, and his hothouse plantains bring in a handsome revenue. Messrs. Veitch and Son's celebrated Nursery at Chelsea was also visited, and the Babu was received with the greatest kindness and interest by the proprietors. The show of orchids, lilies, and carnations, and the enormous extent and ramifications of the business of this establishment, with its connections all over the civilized world, filled the visitor with surprise. Thousands of Wardian cases, huge specimens of palms in enormous framework boxes, were being prepared for transport to the Continent and America. The packing and despatching of seeds from the perfectly arranged and ventilated seed houses was another interesting study. We regret that our space will not allow a further reference to many other interesting visits to well-known gardens and collections, amongst which we may mention Mr. Chamberlain's famous orchid collection at Birmingham, which supplies the Radical Member with the rare button-holes, for which he is noted in the House. Privately and publicly Babu S. P. Chatterjee has been received with a kindness of which he speaks most feelingly. His professional brethren recognised his merit and worth with a

hearty enthusiasm, which will doubtless result in a valuable connection in the future. We must not omit to mention that the Babu served a week's apprenticeship at Covent Garden in preparing bouquets and wiring flowers, and we shall be surprised if the result of his experience is not very noticeable in our ball-rooms during the forthcoming season. During his stay at Covent Garden, he was allowed to assist in preparing the bridal bouquets for H. R. H. the Princess Beatrice. The Babu has brought back with him some forty cases of South American orchids, and a large variety of horticultural sundries, ferns and roses, all of which will doubtless be in bloom at the Victoria Nursery in a few weeks. After leaving Eng and Babu S. P. Chatterjee visited Brussels, Ghent, Antwerp and Paris, to all of which places he carried introductions to the various curators, &c., from his English friends. *Pioneer*.

MANUFACTURE OF SULPHURIC ACID IN JAPAN.—It is stated that the extensive sulphuric acid factory of the Japanese Mint at Osaka has been leased to the Tokio Drug Company for seven years. The export of sulphuric acid from Japan to China is very considerable.

FOR KEEPING OFF MOSQUITOES the *Angler* recommends 3 parts olive oil, 2 parts oil of pennyroyal, 1 part glycerine, 1 part ammonia. To be well shaken before applying to face and hands. Avoid getting the mixture into the eyes.

TEA CULTURE IN CALIFORNIA.—An effort is being made to introduce the cultivation of tea in that state, and it is said there are now over 200 plants in a very thriving condition. There is no reason why tea should not succeed there, if only labour cost can be kept sufficiently low.—*Indian Tea Gazette*.

TEA CULTIVATION IN ARAKAN.—A very fair amount of success appears to have attended the attempt to grow tea in the Hill Tracts of Arakan. At the Paletwa Garden the trees which were cut down short appear to be again sprouting, and are looking very well and healthy, and this tea garden, with a smaller one a few miles off, has been leased to a Mr. Pereira of Akyah for R100, for one year, up to the 21st of March next. At the Kyaukpaung Garden tea cultivation is on a much larger scale, the number of plants, the number of trees and young plants exceeding 12,000, of four different kinds. The gardener in charge has been ordered to make one pound of tea from each of the four, which are to be submitted to an expert for inspection.—*Pioneer*.

NATAL TEA.—A correspondent writing with reference to our comments on Cape tea says:—"Is it generally known that Natal (next door neighbour) produces tea equal to any of the finest samples of Indian or Ceylon growth to be found in Mincing Lano? The quantity is certainly small at present, but the quality is A 1, and the acreage under cultivation is increasing every year. From four new samples submitted last week to a leading firm of brokers, a Natal-grown golden flowery pekoe was tasted against a similar sample from Ceylon, with the result that the Natal Pekoe was considered of equal value with the Ceylon, and was valued at 1d to 1½ p-r lb. more on account of its magnificent appearance. The Ceylon tea had been sold the previous day at 2s 6d per lb. (less duty)." Will there be an exodus of Indian tea planters to Natal in consequence?—*H. & C. Mail*.

PLANTING BONUS IN NORTHERN AUSTRALIAN TERRITORY.—Mr. Moule moved "That the time for the bonus-for-sugar-growing in the Northern Territory be extended for two years." He was sorry the Government had forced him to bring in a formal motion for this extension of the time, because if there was anything worth encouraging it was our natural productions. Some year ago £5,000 was placed on the Estimates for the encouragement of sugar growing in the Northern Territory, and the then Minister of Agriculture proposed to advertise the bonus in all the sugar-producing countries of the world. He said the very liberal terms upon which

the land was to be given for plantation purposes in the Northern Territory could not fail to induce many persons to undertake the cultivation of cane. Since then nothing had transpired to justify in any way the withdrawal of the bonus. The Daly River Company held 10,000 acres of land situated on the Daly River under the conditions of the Act of 1880. W. was now being vigorously pushed forward with every chance of ultimate success. Mr. Otto Brandt had spent £25,000 in the attempt to grow sugar and the Government Resident reported that Mr. Brandt and the Daly Plantation Company would probably be the only competitors for the bonus during the next two years. Brandt's cane was magnificent, but the mill could not be erected in time to crush it. Good results were expected next year. He found that at the Government Gardens, at Fannie Bay, about twenty acres had been planted; the cost was not known. The DeLima Company held 10,000 acres and planted 189 acres at a cost of £20,000, and had since abandoned their land. Owston's Daly River Company held the same area and had also abandoned it. The Palm Company held 10,000 acres; fifty were planted, and then the lease was abandoned. Sergeison's (now the Hon. James Munro's) lease comprised 10,000 acres and was shortly to be started. Otto Brandt had 751 acres. Last year he planted 70 acres, and next year would plant 250 acres, but he had spent £2,500. The Daly Plantation Company with 1,000 acres was to be started, and John Munro had 30,000 acres on the Adelaide River, which would probably be successfully cultivated. Erison and Clappenberg and Harris and Head both held small plantations at West Point, and were cultivating rice, arrowroot, &c., as well as sugar. To cut off the bonus would be a great injustice. The conditions of the Northern Territory were the same now as ten years ago. We still needed to develop it. Besides the two large plantations in operation we had Sergeison's and Munro's both about to be started, but they would not start if the bonus were not continued. Mr. Tennant, seconding, said the bonuses stimulated private enterprise, without which the resources of a country could not be discovered or developed. He hoped this bonus for sugar growing would be continued. Mr. Basewell supported. He would sooner encourage native industry by bonuses than by a high tariff. North Queensland had succeeded in sugar-growing, and the Northern Territory was similar to North Queensland. Bonuses were not a new thing, and some help was necessary to start new industries in a country, as experience had to be obtained at the greatest cost. Mr. Furner said that there had been great mismanagement in connection with the sugar industry in the Northern Territory. He believed from his personal observation that the industry could be made a success, and he would support the motion. Mr. Beaglehole saw some objections to bonuses, but believed them specially applicable to the industry in question in the Northern Territory. The bonuses should be extended for at least three years, as a plantation could not be established in two. He moved the substitution of the word "three" for "two" years. Mr. Lambour seconded the amendment. Good sugar could be grown in the Northern Territory, but the undertaking had not been long enough extended to make it payable. It had only been owing to the extraordinary depression that sugar growing had not been the most successful pursuit in North Queensland. The Minister of Education moved the adjournment of the debate. Carried on the Speaker's call, vote, nineteen yeas, six nays. Adjourned for a week. *Adelaide Observer*.

CELLULOID.

The applications of celluloid are legion, and only the more prominent can now be mentioned. It is best known as a substitute for ivory. In this capacity it has been very successfully employed. So perfect is the resemblance that a close inspection is required to distinguish the counterfeit from the genuine. The absence of "grain" is, perhaps, the readiest peculiarity by which celluloid goods may be detected, but for all practical purposes it is not only as good as ivory, but, in some respects, better than that material. It possesses the strength and elasticity of ivory, but it does not warp or discolour with age. On these accounts it is now largely used instead of ivory in making piano and organ keys, and billiard balls, combs, backs of brushes and hand mirrors, frames, handles, &c. Not the least of its advantages is the fact that it can be moulded so that the most delicate and elaborate decoration can be produced at a fraction of the cost of the same ornamentation executed in ivory. For most purposes hard rubber, on account of its cheapness, can hold its own against celluloid very well; but tortoise-shell, malachite, amber, pink coral and other costly and elegant materials are so successfully imitated that an expert must look sharply to tell the original from the copy. In imitation of tortoise-shell it is made in such articles as combs, card cases, cigar cases, match boxes, napkin rings, &c. The pink coral, so popular for jewellery, is admirably imitated and sold at low prices, as are also the imitation of malachite and amber. It is a very common substitute for the last-named material in the mouthpieces of pipes, cigar holders, &c. As a substitute for porcelain in dolls' heads, celluloid stands any amount of hard usage. It is used instead of hard rubber in many spectacle and eyeglass frames; and also for shoe tips, emery wheels, knife sharpeners, &c. In combination with linen, cotton, or paper, it is manufactured into shirt bosoms, cuffs, and collars, which are at once elastic, strong and durable, and when soiled only need to be wiped over with a damp sponge to restore them to their original lustre.—*Indiarubber and Gutta-percha Journal*.

ORANGE CULTURE AND SOIL.

Correspondents have written to us respecting the analysis of soil suited for orange trees in our issue of 9th instant, saying that it was tantamount to pure silica, in which nothing will grow; also pointing out an error in the figures, making the sum total 104 instead of 100. This error arose through the quantity of coarse sand being printed 78 parts instead of 74 parts, but it makes no difference to the assertion that such soil must be almost pure silica, and consequently as barren as soil can be. Nevertheless the fact is as stated in our issue. It is a fair analysis of the soil of the celebrated orangery belonging to the late Mr. Pye, of the Parramatta River. Of course it must be understood that we state this upon the authority of the work from which we quoted the analysis, and which we again mention to be a book published by the authority of the New Zealand Government, and entitled "Orange Culture in New Zealand," by Geo. E. Alburton. In writing of this matter the author says (page 17):—"In Australia, Mr. Pye, the oldest orange planter, finds that a suitable soil will take care of and kept free from weeds, is all that is needed; and says further that artificial stimulants only spoil the fruit. And one thing is very certain, that there can be very little organic matter in his light sandy soil; the mulch of forest leaves he uses supplying the sole vegetable matter for his fine trees. In another place it will be seen by the analysis made of his soil by Mr. Skey, of the Wellington Museum, that it consists of nearly pure sand. Nevertheless, I feel that most people will persist that they know better, and will go on using strong manures, to the great detriment of the industry. Any one who will study the matter closely will find

that the orange tree succeeds best not so much from any inherent fertility of the soil as from an abundance of moisture and heat; in fact, it lives on the heated humidity of the atmosphere." Our readers must not argue from this that they can plant orange trees in sand and get good crops without further trouble, but that if they possess sandy soil and heat and moisture, then by keeping it free from weeds and applying annually a light dressing of organic matter in the form of mulching—old forest leaves for instance—then they may expect to get the best of oranges.—*Queenlander*.

EUCALYPTUS.

You publish from time to time in the *Gardeners' Chronicle* notes on Eucalyptus, which greatly interest me. I have not only studied the numerous species, but I also interest myself in propagating them wherever there is a chance of success. This explains the interest that I have in reading in your journal of the attempts that are made in England. The greater part of the experimenters only work with *E. globulus*, which is not the one that succeeds best in Northern climes. There are species much more hardy, such as, for example, *E. viminalis*, *E. Gumii*, *E. polyanthema*, *E. coriacea*, and *E. cocifera*. It is believed, moreover, that *E. globulus* is the quickest grower, and certainly it is classic under this head; but I possess another undetermined species which grows at least twice as quickly. My tree at the present time, five and a-half years old since the sowing of the seed, is over 12 metres (more than 37 feet) in height, and more than 1 m. in circumference at the base. It is a very handsome tree, and of regular pyramidal form. Moreover, it is about to flower, and probably will yield seeds; so that the species may be propagated. I have reason to believe that this remarkable tree has not yet been described or recognised among other species of similar appearance, for here the confusion of species is easy and frequent when there has been no opportunity of examining the young plants. If it is really new—and that is extremely probable—I will publish it under the name of *E. Muellieri* to commemorate the labours of the great Australian Eucalyptographer, who has contributed more than any one else to the propagation of Eucalyptus in the South of Europe and Algeria. The services which he has rendered us are inestimable, although the public is too prone to forget them. It is an injustice to be repaired. The *Gardeners' Chronicle* has frequently noticed the *Eucalyptographia*, which contains a detailed description of a hundred species. To properly understand the difficulty of such a work it is necessary to be occupied specially with Eucalyptus, the incredible variability of which seems to defy the perspicacity of the most skilled botanists. Bentham himself, with the information supplied to him by F. Mueller, declared this difficulty "almost insuperable," and this assertion is not exaggerated. I have now hundreds of young Eucalyptus obtained from seeds, where individuals vary from germination to such an extent as not to be recognisable. It is said that the same species take different characters according to the locality whence the seeds are collected, and the question is presented, "Are there truly fixed species in the genus Eucalyptus?" *Acacia* and *Melaleuca* seem to me every bit as difficult to unravel, but that is a matter I leave to others.—*CH. NAUDIN, Gardeners' Chronicle*.

DISINFECTANTS.—A great deal of disappointment may be experienced if people do not realize that deodorizing substances, and even antiseptics like green vitriol, are not true disinfectants. They have their advantage in removing evil odour, or checking putrefaction, but they do not necessarily kill the germs on whose life and activity many epidemic diseases depend. Destruction by fire of infected material, and, where that is not practicable, chloride of lime is the best germicide for general use.—*Gardeners' Chronicle*.

ROOT STRUCTURE.

The variation in the appearance of roots according as they grow below the surface, in the air, or in water, is well known. Latterly M. Constantin has pushed the inquiry further and has examined the internal structural modifications which accompany the more obvious external changes. M. Constantin examined the structure of the root in terrestrial and in epiphytal Orchids respectively, and also made comparative experiments by causing aerial roots to grow underground, and others exposed to light or immersed in water, and so forth. M. Constantin's general conclusions are as follows:—

The growth of roots in the air—1, diminishes the bark, and, on the contrary, increases the pith; 2, causes an increase in the fibrous system of the bark, as well as of the centre; 3, causes an increase in the number of ligneous vessels; 4, renders the endodermic cells harder and more impervious.

When, on the contrary, the root develops in water, the following results are apparent:—1, increase in the size of the spaces between the cells; 2, diminutions of the pith; 3, reduction of the fibrous and vascular systems.

These observations show plainly that the roots adapt themselves in the same manner as do the stems when under different conditions.

Like the aerial stem, the aerial roots are characterised by the great development of the central cylinder, of the fibrous and vascular systems.

Like the rhizomes, the subterranean stems are distinguished by the great thickness of their rind, the reduction of the pith, and the small importance of their fibres and vessels.

Like aquatic stems, the roots produced under the water are similar in structure to subterranean organs, but differ in having intercellular spaces, and in the lesser development of the vascular elements.

The analogy remains even when bleached stems are compared with roots, which have grown in air and obscurity, the rind and ligneous system being of less importance than in subterranean organs. The root is therefore as liable to modification as the stem, and if its organisation seems very uniform it is because it is most often developed under the ground. It is to the influence of the medium, terrestrial or aquatic, that we must attribute the feeble development of the pith of roots. The absence of this tissue consequently does not serve to characterise the root anatomically. The most striking result of these experiments upon the root as well as on the stem, is that the woody matter is formed with relative difficulty under the ground, in water, and in darkness. The consequences of this are very important, as the functions of the fundamental tissue and of the endoderm, are thus found to be entirely altered.—*Gardener's Chronicle*.

GREEN MANURE.

TO THE EDITOR OF THE "MADRAS TIMES."

Sir,—In your issue of yesterday you say: "Of the dry coast lands, some we may consider deficient indeed in organic matter * * * * *". But not all the dry lands in the plains along the coast may be deemed deficient in organic matter and require green manure." If there is any class of soils in the plains of India which contain more organic matter than others, it is the black cotton soils, as everybody knows. Even these do not contain as much of organic matter as would satisfy an English or American farmer. A soil containing all the elements of fertility in very fair proportions should contain about 12 per cent of organic matter at least, and a moderately fertile soil, not less than 5 per cent. Soils containing less than 5 per cent of organic matter are considered but poor in it in England and America. In the "Standing Information regarding Administration of the Madras Presidency," *vide* page 204, it has been very rightly remarked of the black soil that "it contains very little organic matter, usually not more than 1 per cent." Can there be any doubt, then, that the other kinds of soils contain

but far less? When I wrote that the black soils are rich in organic matter, I meant, of course, that they are so in comparison with other kinds of soils met with in the plains. The prevailing soils in this Presidency are light-coloured, which are, of course, extremely deficient in organic matter. It cannot be disputed that in a tropical climate like this, there is greater need of organic matter in the soils than in England. It must also be borne in mind that, while the organic matter in the soils of the Indian plains is naturally liable to be slowly dissipated by the great heat prevailing there, the ryot makes matters worse by burning all things which would in England and America go to form vegetable compost and thus add organic matter to the soil. Green-manuring is really quite as beneficial to the black cotton soils as to others which are very poor in organic matter. A very serious defect in the black soils is excessive stiffness. One of the best and simplest means of improving them is green-manuring. By this, very stiff soils, it is well known, are rendered looser, and very loose soils, on the other hand, more stiff.

If horse gram is to be treated as a food-crop, the best time for sowing it is towards the cessation of the heavy monsoon rains, for instance, about the end of November in Madras and a little earlier in the interior parts. If not sown in its proper seed-time, it cannot mature satisfactorily enough, and is then best treated as a fodder or green-manure crop. It is, on the whole, preferable indeed to use the catch-crop for fodder, provided the ryot conserves the dung and urine of his cattle properly and applies them to his land. But since the temptation to use catch-dung as fuel, either through pressure of poverty or through ignorance, is too great for the ryot, green-manuring may be specially recommended. In most parts of the Presidency, scarcely 5 per cent of the cultivated dry land carries two crops in the year, and consequently the ryots and their cattle are idle during a great part of the year. I have shown how the ryot might find useful work for himself and his cattle by growing catch-crops of horse gram for fodder or green manure at times when his land would otherwise be idle.

G. K. SUBBA RAO.

A MALAYAN FOREST.

Tropical forest would be a better term than jungle, and less likely to be misunderstood; for it is a forest of noble trees, mingled with saplings, tall and slender, growing as close as may be. When one tries to analyze the constituents of the mass, the eye soon loses itself in the confusion of stems, vines, branches, and foliage. There are, however, three kinds of tree conspicuous, that is, tall saplings, shorter trees as tall and straight, a foot or so in diameter, with a green or grey smooth bark; and finally the large brown heavy stems with rugged scaly bark (*Dipterocarpus* and *Dumrao Pines*). From the latter hang loose swinging vines of every size, from the thickness of twine to stout bawser, sometimes leafy, sometimes like loose cordage, or the tangled rigging of a ship. Then the leaves are of every shape—minute or immense, opening like huge umbrellas, or spreading in feathery sprays like a mist over the water.

I must not omit to mention that several of the fruits are very ornamental. The crimson *Modorea* is just like a large *Capsicum*; the fruit of a *Dysoxylon* like an Orange, while the open seed-pods of some *Pithecolobium* equalled any flower in brilliancy. The Malays brought us in wild fruit such as *Mangosteen*, *Lansats*, and some wild Grapes, but none very savoury; indeed, some of the party suffered much from a burning throat and tongue after eating the Grapes.

For vegetables we had *Vans* (*Dioscorea*) and the white inner leaves of a *Cabbage Palm*, which was very agreeable when cooked, besides the stalks of the *Begonia* leaves already referred to. All the

shrubs are juicy and succulent, as one might expect in a country where rain, rain, rain is the usual weather.

Gutta trees of the genera *Icosandra*, *Bassia*, and *Willughbeia* were common. A small incision into the latter, which bears a large edible fruit, exudes a thick viscid white juice, which one can wind off in round balls. In a few minutes it becomes elastic, like Indiarubber. There are many trees here with milky juices, but only a few harden into a good gutta. The Malays of Keddah, however, have a method of hardening some of these sufficiently to make them useful in adulterating the valuable kinds of rubber. My men showed me how this was done. They collected about a pint of juice and mixed it with common salt, which caused it to curdle. The compressed curds from this juice made a hard white ball about 1½ inch in diameter. It was not elastic, but broke into pieces like enamel, yet not without a hard blow. The substance wants all the elastic qualities of good gutta, but still might be turned to many useful purposes. The tree from which the juice was obtained was conspicuous for its enormous leaves, shaped like a Fig leaf, and often 2 feet in diameter. It is a species of *Pterospermum* (*acerifolium?*), and is common throughout the Malay peninsula and China. I also noticed it as one of the most common trees in North Borneo.

It was rather amusing to notice one way in which the Malays made use of the true gutta juice. When their thin calico clothes were torn—the lacerations, I need hardly say, being frequent and considerable—they used to mend them by bringing the edges together and plastering the rent with gutta juice. This made a permanent and strong joint, with the additional advantage of being waterproof. J. TENISON WOODS.—*Gardeners' Chronicle*.

RUBBER NOTES FROM BRITISH AND AMERICAN CONSULAR REPORTS.

ZANZIBAR.—A volume of British Consular Reports, presented to Parliament in May, 1885, with which we were unable to deal last month, owing to pressure of space, contains an interesting communication on the subject of native African guttapercha, sent in December, 1883, by Sir John Kirk, our Consul at Zanzibar, to Earl Granville, the late Secretary of State for Foreign Affairs. This report was accompanied by a sample of guttapercha, the produce of a practically unknown tree, which Sir John found at Mombasa. It appears that several samples of this article had been brought to Mombasa from time to time, and offered for sale by the natives; they had, however, been set aside as useless, and regarded as an adulteration of Indiarubber until the Consul detected their nature, and indicated the great demand likely to arise provided it could be had to any great extent. Sir John Kirk, in his despatch, stated that he was not aware that guttapercha had hitherto been discovered in Africa, and in view of the importance of the matter he requested Lord Granville to send a sample of the guttapercha to the Director of the Royal Gardens at Kew, with a view to a technical opinion being given with regard to its probable value and quality, remarking, further, that it was not ten years since he "established Indiarubber collection from plants growing wild on the mainland, the value of which amounted last year (1882) to £300,000, and the plants which yield this are now being grown in India and all our tropical colonies." In a supplementary despatch Sir John reports the success which has attended the planting of rubber trees in Zanzibar. He says: "Five years ago I received from the Director of the Royal Gardens, Kew, in exchange for plants of our African Indiarubbers of the genus *Landolphia*, other sorts of Indiarubber-giving plants, amongst which were the Para tree, or *Mahoti glaziovii*. This, I find, grows here with the greatest rapidity, and propagates itself freely in the worst soil. It is only now, however, that I have been able to obtain a sample

of the Indiarubber likely to be produced, and on which the value of the new introduction entirely depends. I find that trees only begin to yield when five years old, and no doubt these are, even then, too small to be remunerative. I have collected a sample of the produce, which I forward by this mail, and which I would ask your lordship to be good enough to forward to Sir Joseph Hooker, at Kew, to be reported on. If the quality of this Indiarubber is found to be good, I can then confidently encourage the Sultan to plant widely the new tree in the unoccupied parts of the island. It stands the climate, grows freely, needs no care, and would be a source of income on which his people might fall back in the event of other crops failing." In compliance with the wishes of Sir John Kirk, the samples were sent to Sir Joseph Hooker, who placed them in the hands of Mr. S. W. Silver, F. L. S. The latter, besides studying the samples himself, consulted other experts, and the results of the examination may be briefly stated. First, as regards the guttapercha, there is a general opinion that the kind discovered in Zanzibar will prove an acceptable addition to preseat supplies. Sir Joseph Hooker considers that the discovery of a substance resembling guttapercha in Central Africa is of extraordinary interest, though the authorities at Kew were not unprepared for it, the floras of tropical Africa and of Malaya being so similar "that guttapercha-producing trees, which are so characteristic of the latter, might be confidently expected to be represented in the former. The rubber-producing vines of each area are, though distinct, so closely allied, and, indeed, mutually representative, and the possibility of the same fact should be borne in mind in connection with guttapercha." Mr. J. V. Bailey, of the Indiarubber, Guttapercha, and Telegraph Works (Limited), writing to Mr. Silver with respect to the samples sent by Sir John Kirk, remarked: "The sample of guttapercha is not so good a specimen as we get from other parts of the world; nevertheless, in its present state, we may put the value at about 10d. per lb." Secondly, as regards the specimens of Indiarubber from Zanzibar, it is pointed out that there is some discrepancy, as Sir John Kirk appears to have mixed up two distinct plants. It is tolerably clear, however, to the experts that what he has sent is Ceara rubber, and not that of Para, and that the plant producing this is cultivable with such ease, that it is much to be hoped that it may form the basis of a new and profitable industry in the Zanzibar dominions. Referring to these samples of Indiarubber, Mr. Bailey says: "Indiarubber collected from the trunk of the tree would be at the present time commercially worth about 1s. 9d. to 2s. per lb. The sample collected from the ground we could put no value to." The action taken by Sir John Kirk might be imitated with advantage by British Consuls in other parts of the world where there is any possibility of Indiarubber or guttapercha being produced.—*Indiarubber and Guttapercha Journal*.

THE DATE PALM.

In the *Gardeners' Chronicle* for February 21, 1885, page 240, the following statements occur, quoted from *Nature*, under the heading of "The influence of direct sunlight on vegetation." Regarding the Phoenix dactylifera, L. it is stated that "it never forms dense forests;" that "the Date Palm is indigenous to the Great Desert (Sahara);" that "nowhere else does the plant vegetate so rapidly;" that "when cultivated with success, it is also in a desert climate, as, for instance, in that of Murcia in Spain;" that "the cause of its being without fruits in the Mediterranean is the dry summer, their being no subterranean wells, as is the case in the Sahara."

I think these theories are erroneous, as I shall endeavour to show further on, but before doing so, I would call attention to an article in the *Gardeners' Chronicle* of February 28, 1885, page 165, on the "Palms at Bor-

dighera," in the Mediterranean. It says, "But by far the most lucrative trade is in Palms. They are planted in every available spot, and most carefully cultivated; the soil is excellent and suits them well. As the plants attain a certain height they are swathed, or tied up in the same way that we treat Lettuces. Large quantities thus blanched are sent to Rome and other places for Palm Sunday, while a considerable number find their way in the month of August to different Jewish communities for the Feast of Tabernacles." See also illustration in *Gardener's Chronicle*, April 8, 1875. Further on, it states that "Many old Palms have strings or orange-coloured Dates depending from the crowns, but these are never fit for food." The group of Palms selected for the illustration in the *Gardener* certainly does not show careful cultivation. They are growing out of a hillside, where they could get little water, either from rain or other sources.

I do not know whether the Date Palm is indigenous to the Sahara desert; but this I know, that it has been disseminated wherever the Arabs have gone. All along the North of Africa, up the Nile, into the Soudan, into Spain, whence it could have been easily introduced into Bordighera, on the Riviera, by "Dominican monks some centuries ago," as the *Gardener* states. In Mooltan, Sindhi, and adjacent countries the Date Palm grows in hundreds of thousands. There is a legend that the seeds were introduced by the Arab conquerors of Mooltan in the seventh century. It is largely grown on both coasts of the Persian Gulf, whence the best Dates found in the London shops come. The Date Palm is more likely, I think, to have been indigenous in Arabia (or wherever the *Phoenix sylvestris* has its home), and thence to have found its way to the Sahara with the Arabs. There is no doubt that most trees require direct sunlight to grow luxuriantly and strongly, provided they get moisture at their roots, and I should say the Date Palm is no exception to the rule. I know it grows badly under trees, but I would not be certain that this happens because of the absence of direct sunlight, and not because it is robbed of nourishment by the trees. The *Phoenix dactylifera* and the *P. sylvestris* are, I believe, botanically identical. At the foot of the Kalka Hill, in the Punjab, there is a dense forest of the latter. The wild Date Palm is also to be seen all over India. It is one of the "Toddy" Palms in Mysore, the Decan, North-Western Provinces, and even farther north. In many parts of this district (Etawah) there are groups of the wild Date Palm, with numbers of young Palms growing at the foot of the old ones; and in the latter case their source of water can only be from the clouds, in the rains, as the subsoil water is too deep (often 60 or 70 feet) to suppose that their roots get down to it.

I think the Date Palm will vegetable rapidly wherever it gets water at its roots, at the same time that it has a suitable soil and a sufficiently warm atmosphere.

In Bengal immense plantations are made of the *Phoenix sylvestris*. Date-sugar is made from its sap. In Jessore alone, in 1882-3, official reports state that there were 21,122 acres under Date cultivation, and that the value of moist and dry sugar in that year, came up to Rs. 48,46,241. In Bengal the canal water is near the surface, and the atmosphere is more or less damp through the year. The Palm is grown there only for its sap, and the Palms are so planted that their leaves touch, when full-grown.

As to the *Phoenix dactylifera*, the cultivated variety, I have studied it more closely. In the Persian Gulf there is a great trade in Dates with Europe and America. From information obtained through the British Political Resident, it appears that in the Gulf there are upwards of one hundred varieties of Dates, that some do not ripen their fruit beyond the red or yellow stage, which is crisp and astringent, or sweet, according to the amount of ripeness. These are called "Kharek," and those kinds which are exported to Europe in boxes, after passing through their "Kharek" stage, become soft and sweet, and acquire the well-known amber-brown colour, and when allowed to be-

come semi-dry on the trees are picked and packed for exportation. These are called "Khoorma."

Now everywhere in the Gulf the Date Palm is very carefully cultivated. Plantations are formed of female offsets only, the trees are irrigated from whatever source may be possible—rivers, wells, springs, rain torrents. Irrigation appears to be an important matter in Date cultivation. The trees are also well manured; in short, they are treated in every way as fruit trees are from which a first-class crop is expected. When in flower artificial fertilisation is practised, without which, they say, a crop cannot be relied on. Moreover, they say that "infertilised Dates are stoniless and insipid, and only fit for goats." If the Palms are well cared for and in good soil, they begin to bear in five or six years from offsets. All along the Gulf, at Busra, Bushire, Lar, Bunder-Abbas, Babrein, El Hasa, &c., the Date Palm has the influence of the sea; in the interior of Arabia it has not. Palgrave met with it throughout his journey, but always in oases, where it could be watered from some source or other. He says, "it is the staff of life and the staple of trade." In Muscat it has also the sea air. There the annual rainfall is only 6 inches. On the other hand, in Mooltan, it grows from seed spontaneously. It is never cultivated. In Sindhi, Bahawalpoore, Dehra, Ghazi Khan, Dehra Ismail Khim, and as far as Bannu, it is equally abundant. Mr. O'Brien, Deputy Commissioner of Mooltan, informs me that the *P. dactylifera* grows literally in hundreds of thousands, so that in the Mooltan district alone the Government revenue, at the nominal rate of one anna per female tree (four farthings) comes to Rs. 12,081. At this rate there cannot be less than 193,341 female trees. There are, however, many exemptions, and the male trees are not taxed. The annual rainfall in Mooltan is 7 inches, and there is no such thing as sea air.—E. BONAVIA, M. D., Etawah.—*Gardener's Chronicle*.

♦ ♦ ♦ "COLORY" COFFEE.*

In the *Mooltan Mail* of Aug. 11th, the above subject is continued and Ceylon planters are defended, as follows:—

Sir,—Allow me a little further space to tell "An Indian Planter" that I entirely agree with him, that leaf disease is the sole cause of the deterioration of the coffee bean, and am sorry I did not say so, but it is a matter I have always taken for granted. If he will re-read my letter, he will find I do not venture to give the Wynaad planters an answer to their questions, nor a specific method how to grow coffee, but out of my parallel experience advise them as to the best way of securing color in a particular year. I said plainly that I thought the discussion as to color futile, because, in my opinion, easily to be inferred in my former letter, color has not deteriorated in nearly so great a degree as the size and fullness (quality) of the bean; they really fix prices, not the color, for color is not the criterion, but the confirmation of quality. Coffee is apparently doomed, and the most intelligent planter can hardly do little against leaf disease. If ever the pest abates in virulence, the bean will improve, and up will go prices and color. As to low prices of Ceylon coffee in 1884, I cannot speak from personal knowledge, being absent most part of the year, but would attribute them to deficient rainfall during the early months, and consequent want of size in the bean. Surely an "I. P." is aware that cultivation has been cut down in Ceylon from Rs. 20 to Rs. 45 per acre during the last few years; so he must not attach the whole blame to planters.

I am very sorry to hear from an "I. P." that Ceylon men turn out badly in India, but find it difficult to reconcile the statement with his reference to the "several superior Ceylon men" now in the Wynaad; an "I. P." may assure himself a great number of "superior" Ceylon men have been given occasion to leave the island. Mr. Jovitt is one pretty well known Ceylon man India has secured. He is the Wynaad (chairman and (in confirmation of my theory) is the leader among those trying to gain information

* See p. 210 of *sq.*—Ed.

"experimentally" as to the cause of the deterioration of the coffee bean. I imagine the large majority of the Wynaad men were weeping and wailing and gnashing their teeth, but doing nothing, and he, with others, is doing his best to pull them together.

Ceylon or Indian, we are all of one blood, and it only needs earnest and sensible men like an "I. P." and Mr. Jowitz to remind their brothers in affliction, that they are Englishmen, for them like the chivalrous knight of old,

"To fight the fight"
 "Though e'er the night"
 "Their 'tollans' pass away."

5th August.

M. P.

Another correspondent writes as follows:—

Sir,—The Wynaad Planters' Association, in bringing forward the very important subject of the deterioration of their coffee bean, may perhaps find some consolation in the fact (although it seems hard to say so) that the other districts of the country could tell much about the same tale. I find from particulars of London coffee sales for the past two years that coffee from all the planting centres of Southern India has been reported upon as more or less poor in quality—not excepting even Mysore, if we leave out Cannon's and one or two other standard brands, the remarkable prices paid for which no fellow can understand, especially when Shakespeare says "what's in a name?" And E. I. coffee, while being generally poorer in quality, is in itself not solely to blame, because all medium to good middling qualities have suffered from undue depression, while fancy prices have been paid for a few choice lots of particular boldness and color. The last two months have witnessed a considerable turn for the better, and a rise in the prices of our B. and A. qualities of 10s. to 15s., and they are again, I find, taking the lead of M. P. Ceylon. This is as it should be. A good sound coffee, although lacking somewhat in color, will generally find its level—and what I would say in the matter in this "Don't despair." We shall yet have Pulney days. I have read with interest the several and various theories put forward by numerous correspondents in your columns regarding the deterioration, or want of color, in the bean, and as a practical planter I can't say there seems to me much to be learnt in these days about the curing either on the estate or the coast—if there were, the logical deduction would be that during the last two seasons every planter and every Coast Agent had been careless in their curing—a palpable absurdity. I should say it is something in the seasons, and it would not be a bad idea for our omniscient Government to import a special Meteorological Reporter for the benefit of the planting community, now they have a craze on that way! Combined with topsyturvy seasons, I think there is one point—and a very material one—that seems to have been either entirely lost sight of—or but barely alluded to, and that is, what do the majority of planters now spend per acre on their properties? It used to be nothing under 100 Rs. as a rule; then 80 Rs., and now it has come down to, well goodness knows what. I hear some parties who have had a large experience in the industry expect estates to be worked on R40 per acre! And so we go on,—we shall be landing into the twenties eventually—and then I should think the cry will be, not where's the color and quality, but where's the bean?

As far as Wynaad and the Nilgiris are concerned too, I am persuaded that the gold mining mania of a few years back has much to answer for. Many a poor coffee bush could tell a tale of those days. Why, of what value was coffee if you could only prove that you had a gold reef or two under ground, not to mention a *true fissure vein*? Was not every one hastening to be rich with gangs of estate coolies delving into the bowels of the earth all over the country, and besides the prospective lakhs, was not all the talk about the "dip" and "strike" of one's reef?

I don't forget that grand stalking horse "leaf disease" it is so convenient to trot out and put all the blame on. It is an insidious disease and does its work stealthily, but you will find it delights to revel

in neglected plantations and, like all diseases, may be expected to attack our coffeeebled constitution first. It has been, and always will be, I hope, of little consequence on well-cultivated and manured estates—with rare exceptions. I am alluding to Southern India, solely, I may add not to Ceylon. I don't want a Ceylon man to vent his spleen on me. The conditions in the existence of coffee have always been different in that far-famed spot of the earth, I maintain. Coffee wants a dry season to give the tree a rest, winter in, harden its wood, force out blossom, and free it, or the soil from fungoid and parasitical growths, such as leaf disease for instance. It is a wonder to me coffee has lasted so long in Ceylon, with its all-the-year-round moist climate. I fear few coffee planters in Southern India realise what a blessing our dry season is, because, unhappily, it often lasts too long. I don't think the Wynaad Planters' Association can be congratulated on the wording of some of their queries, which is a pity. For instance, it said "and variably fetches a lower price, compared with that of other districts, than it did in former years." I have said at the outset of this letter enough to show that other districts have also suffered, and if it would not be that I should be taking up too much of your space, I could fill in a huge column of prices from Mysore down to Cape Cononin for comparison; and I am much surprised to find that the Association should apparently be ignorant of the fact that coffee produced on the Travancore Hills—about Permaad—is invariably the lowest type of coffee produced in India, if I am to judge from the prices it always sells at. And surely one would have expected them to know that there are still estates in Wynaad that can show a record of good prices even in these days. While the older districts in Wynaad in the open seem to have about had their day, there are several promising young districts sprung up protected by shade. One wonders rather at the Association damning its district with such faint praise. Surely, with a favorable situation, good soil, and careful cultivation, coffee yet does and will yet do as well as ever it did, but for, say, an occasional attack of leaf-disease, or a bad season. Leaf-disease, I think, we must expect more or less of at times, but according to the degree we cultivate will be determined the extent and damage of the attack. I can't believe, myself, that there is any deterioration in the coffee tree as such: for the simple reason that seed is always picked from the robust and healthy trees, and although it is quite right to say that, this, it can scarcely be believed has always been carried out; yet even if it be allowed that seed has been picked from poor trees too, it can scarcely amount to any argument in support of a deterioration in the tree in general.

Before closing, I would also state my belief that shade under 4,000 feet does seem generally to improve both the size and colour of the bean. From my own experience on two properties adjoining each other—one under shade, the other in the open—the one under shade does better, both in colour and size. But both quality and colour depend, I think, a good deal upon whether you have a heavy crop, a medium one, or a light one. The coffee crop of South Corg of 1884-85 was a heavy one, and prices, as a rule, were very low, quite as low as Wynaad coffees. The crop of season 1885-86—just past—was a light one, and has generally been well reported on for quality and colour, and has fetched wonderfully good prices generally. Take Naiduvattum coffee—the synonym for the Ouchterlony valley. Their crops for the past two seasons have not been large ones, and their prices correspondingly good, but two seasons back, I remember, when they had rather a heavy crop—the general run of their prices was much lower.

Nilgiris, 31st July.

AXON.

A MICA MINE, from which sheets twenty feet in width are taken, is said to have been discovered about ninety miles from Virginia City, Nevada.—*American Grocer*.

COCA AT THE SOURCE OF SUPPLY.*

BY DR. SCIBER.

Very soon after the effects of cocaine on the mucous membranes were established beyond reasonable doubt, and the scarcity of good coca, from which to make the alkaloid, was realized Dr. F. M. Gunnell, the Surgeon-General of the Navy, took an active interest in the subject of the supplies of coca, and the causes of the scarcity, and the inferior quality as received in this country. Having written to the medical officers of the Navy on duty along the western coast of South America, he took the subject to the Hon. W. E. Chandler, Secretary of the Navy. Secretary Chandler addressed the State Department on the subject, and about the middle of January the Hon. F. T. Frelinghuysen, Secretary of State, addressed a circular letter to the diplomatic and consular officers of the United States in Peru, Bolivia and Chili, "in regard to the difficulty of procuring coca for the United States of a reliable quality, and inquiring where the best varieties of coca are found, and the best mode of preparing it for transportation, and how it can be brought within reach of the American purchaser."

Medical Director L. J. Williams, of the Navy—himself personally familiar with the western coast of South America—had some good correspondents there to whom he wrote on the subject; and finally the writer corresponded with several intelligent gentlemen more or less familiar with coca at its source of supply.

The writer is very much obliged to Dr. Gunnell not only for his own efforts in the matter, and their importance, and for copies of his correspondence, but also because through him was obtained all information from the correspondence of the Department of State. The writer is also very much indebted to the Hon. Richard Gibbs, U. S. Minister to Bolivia, for some years resident at La Paz; and to the Hon. S. L. Phelps, U. S. Minister to Peru, who has for some years been located at Lima. Each of these gentlemen favoured the writer with private letters on the subject, as did also Consul F. W. L. Danielsberg, of Arica, and Mollendo. Dr. William H. Jones, of the Navy, also supplies much useful and important information.

The writer has long had a very intelligent correspondent at Paris, Brazil, and knowing that the tributaries of the Amazon ran through fertile coca districts of both Bolivia and Peru, he supposed that a commerce in the article might be started down the Amazon, thus avoiding the transportation across the Andes to the western coast. An opportunity offered of meeting this correspondent, Mr. William Brambeer, of Paris, on his way home. He was shown the article, which he had never seen at Paris, and was instructed in points of identity and quality, and took with him a sample of Bolivian coca of fair quality; and in less than three months' time the writer received from him a shipment of coca which came down the Amazon to Pará.

* From *Ephemeris*, May.

† This shipment, however, turned out badly. The leaves were evidently a very good variety of wild Peruvian coca, just what they purported to be, and there was no discoverable admixture of other leaves. But when the bales were opened the leaves were found to be damp and mouldy, and with neither the odour nor taste of coca. Although put up in three thicknesses of bagging, and one clumsily applied covering of tarred cloth, they had evidently become damp and heated during transportation. Upon assay these leaves, although looking pretty well, yielded a very small proportion of alkaloid, and were not worth working. The whole cause of this great sacrifice of an originally good article, was in the very bad way in which they were put up for transportation. Had they been put, when quite dry, in metal lined boxes and soldered up, they would have been worth 13¢ dollar per pound on their arrival, and even in ordinary times would have brought half that price. Any such price as 65¢ would have yielded a profit of say 20 per cent to the shipper. It is very much to be hoped that such results will lead to better packing.

From all these sources the following information is compiled; and the information is believed to be more complete, more recent, and perhaps more trustworthy than any hitherto published.

The most elaborate and most complete of all the communications on the subject, is the report of U. S. Minister Gibbs, of La Paz, to the Department of State. La Paz is the great centre of the coca trade of Bolivia, and the business in it there is very large, the Government deriving a very large revenue from the tax upon the coca. There are many large dealers there, and Mr. Gibbs gives the names of Messrs. V. Farfan & Co., as one of the best and most important, as it is one of the largest commercial houses of Bolivia dealing in coca. This house has four large plantations in as many yungas,—or deep narrow valleys in the sierras or mountains. Mr. Gibbs states that much of his information was obtained from this firm.

There appear to be two very distinct varieties of coca, the Peruvian and Bolivian, each country claiming each variety as being the best. Peruvian coca is a smaller, narrower leaf, and so much thinner and more fragile in texture that it is much more broken in gathering, drying and packing. It is of a much brighter green colour when in best condition, and by age and change during transportation it becomes of a duller, lighter, yellowish green, while the Bolivian becomes yellowish brown or brown. The Bolivian is the larger, broader, rounder, thicker and stronger leaf, less broken up, and when in its best condition is of a dull, deep olive-green on the upper side, and much lighter beneath. The characteristic faint lines on the under side of the leaf, which form a narrow ellipse with sharp ends (laucelate), the midrib passing through the centre,—are more faint and more frequently unrecognisable in the Peruvian than the Bolivian variety; or, rather, the lines are seen on every leaf of good Bolivian coca, but are not discoverable in a small proportion of the Peruvian leaves, even when unadulterated. The odour and taste of the two varieties are almost identical, but differ much with the quality.

In both the quality is uniform throughout each package, and is good or bad, not so much from the original character of the leaf, as from the damage in curing and transportation. These two varieties, of course, shade off into each other, as the districts from which they come lie nearer to each other, so that it is often difficult or impossible to tell whether certain parcels are Peruvian or Bolivian.

Each variety is subdivided into the wild and cultivated leaf. Coca from wild plants is larger and thinner, and is generally considered inferior, but of its inferiority there is much doubt. It reaches the markets more broken, and less carefully put up, and this may cause a prejudice against it. In good condition it yields about the same proportion of alkaloid as the cultivated coca; but as there is undoubtedly a value to coca which is not measured by the yield of alkaloid, the proportion of alkaloid does not disprove the alleged inferiority.

The general method of cultivation seems to be common to Peru and Bolivia. The best coca is said to be produced on hill sides which are from 3,000 to 6,000 feet above the sea-level, and it is grown upon terraces of various widths on the sides of deep narrow valleys called "yungas." The seed is sown during August in beds, or boxes filled with earth, and by the following June, when the plants are 8 or 10 inches high, they are transplanted on the terraces about three feet apart, in a soil kept free from shade and from any other growths. By November the first or lower leaves are of the deep olive-green colour which marks maturity. A rich soil is needed, but fertilizers are not used, and, however good the soil, it is said to be rather rapidly exhausted by the plants, so that a succession of fresh plantings is kept up. The shrub grows to the height of from 2 to 6 feet, but the largest plants do not yield the best leaves. Each bush yields, as a rule, three crops a year,—or in exceptional localities four crops. The first is called

the March crop, the gathering commencing in January. The second is the Saint John crop, beginning in May, and the third is All Saints, collected in October, and then the shrub is completely stripped of leaves. Moist seasons produce the most delicate leaves of finest quality, and droughts are very destructive to the crops, but as droughts in these mountains do not extend over very large districts, the total crop is not often seriously varied from this cause. The crops are gathered leaf by leaf, chiefly by Indian women and children, who stoop in front of each bush and collect only the leaves which are mature, in their aprons. Minister Gibbs's authority tells him that the women are careful not to touch the top of the bush, for, if this be touched by man or animal, "it withers and dries up." Men visit the women from time to time, and take the gathered leaves, in large sacks, to an enclosed yard, which is paved with smooth flat stones or slates, laid with very close joints and kept very clean. These pavements are so situated as to get the full force of the sunshine, and the first gathering of leaves is not brought to them until they are very hot from the sun's rays. The leaves are then spread thinly over the hot pavements, and being loosely raked and turned from time to time, are dry in from three to four hours in favourable weather. Sometimes, however, they have to be left overnight, and are then liable to be damaged by dew. No gathering is done in very cloudy or damp weather, and damage only occurs from changes during the day after the collection has begun. When dry, the leaves are packed at once by means of a rude wooden press in square bales, of coarse cloth, of a cesta or about twenty-five pounds each. Two of such bales are put together under another envelope, generally made from the bark of the banana tree, and such a package of about fifty pounds is called a tambor, or drum, and measures about 11 x 15 x 17 inches. When these parcels have to be sent across the coast range of mountains for exportation, three are put together in a tarpaulin-covered package of one hundred and fifty pounds, and two of such packages make a load for a mule or other pack animal for this transportation of several hundred miles through mountain passes. Coca is very easily damaged by the combined effect of heat and moisture, and is, therefore, always stored in cool, dry warehouses, and rarely handled or transported in damp weather or during the rainy season. This rainy season is from January to April, and, therefore, that stored on the west side of the coast range is alone available for export, during the rainy season. When exported it is said that it usually starts in very good condition, and will reach its destination in the same condition, if carried in a cool, dry place. Such transportation is always stipulated for in bills of lading, but the proper precautions are generally neglected, and hence the worthless condition in which it is often seen. The only absolute security for it in transit is, therefore, to have it soldered up in tin or zinc, enclosed in wood, and such parcels generally contain two tambores, or about a Spanish quintal of a hundred pounds. Although shipped from many ports along the whole coast, the principal port in Peru seems to be Salaverry, the port of entry of Trujillo or Truxillo, and the principal port for Bolivia is Arica.—Mollendo being now closed by the civil war in Peru.

Much of the difficulty in getting good coca during the past year or two is attributed by all the correspondence to the demoralization incident to the civil war.

Coca seems to be produced throughout the whole Andean plateau from Ecuador to the Argentine Republic. The Peruvian Government is said to record and tax a production of over 15,000,000 pounds per annum, and the Bolivian Government about 7,500,000 pounds. Of the latter quantity, Mr. Gibbs says, about 55 per cent is consumed in Bolivia;—Argentine Republic and Chili, each 15 per cent, and Peru, 10 per cent, while the remaining 5 per cent is exported to the United States and Europe; thus giving about

375,000 pounds as the export of Bolivia. As Peru produces about double the quantity credited to Bolivia, it seems probable that about double the quantity may be exported, or, say, 750,000 pounds; and if this, too, goes to the United States and Europe it would make an aggregate of about 1,125,000 pounds.

The market report here is that one manufacturer of cocaine in Europe and one in the United States have each secured this entire crop for this year, and a third manufacturer has secured "the remainder." If these reports be true in the aggregate, cocaine will be very plentiful, since 1,000,000 pounds of coca would yield at least 2,500 pounds of cocaine, while one-fourth of that quantity would probably overstock the whole world.

Mr. Phelps gives some important statistics in regard to cost price. His data are obtained from the owner of a hacienda, or coca plantation. This hacienda of Señor Don Carlos A. Gonzalez Orbegoso, of Lima, Peru, lies north-east of Lima, and about thirty leagues in extent, and yields about as good coca as is to be found. On the estate it is sold in packages of about fourteen ounces, each at 2½ to 3 cents. The cost at Trujillo would be about 35 sols of silver per Spanish quintal of one hundred pounds. The cost of tins and packing, and of transportation to the seaport, Salaverry, would be about 6 sols additional,—total 11 sols, equivalent in bills on New York to 31.75 dollars per Spanish quintal of one hundred pounds, or, say, 32 cents per pound on shipboard, with freight to New York at about 1.50 dollar per cubic foot. But the owner qualifies this estimate by saying that any unusual demand might put up the price.

Minister Gibbs says the price in Bolivia varies with the supply and demand of different years from 1875 to 1881, between 8 and 20 "soft dollars" per cesto. The "soft dollar" is stated to be equivalent to 80 cents, and the cesta or cesto is about twenty-five pounds, so that the extremes of price seem to be about 26 to 61 cents per pound,—and this, by inference, at the seaports of Arica or Mollendo, the shipping charges and freight still to be added. It is retailed to the consumers by the small shops and on the sidewalks, from the original packages or cestas, at the rate of about 5 cents for twenty-one or twenty-two grams, or three-quarters of an avoirdupois ounce, or about 1.00 dollar per pound—or by the single pound at about 80c.

The consumers of coca both in Peru and Bolivia are the native races, and among these the consumption seems to be a nearly universal habit, and this habit must have descended from the times of the Incas, since Mr. Gibbs says he has found buried with the ancient Peruvians small quantities of coca and the small earthen vase used with it to hold the lime or potassa of the coca-chewer.

The whites of these countries seldom use coca except as an infusion, and then the first water is thrown away as being too strong.

Mr. Gibbs is informed that habitual consumers of coca know nothing of toothache, and have their teeth in good condition to the greatest ages attained.

The habit seems to be not unlike that of chewing tobacco, and the effect obtained from it,—or supposed to be obtained,—is of a similar kind, although it is doubtless a restorative or gentle nervous stimulant, rather than a narcotic.

There is no allusion in any of this voluminous correspondence to any advance in prices, due to the late excitement and demand, either in Peru or Bolivia, and it is therefore probable that the enormous advance in prices here and in Europe has yielded enormous profits to the holders, while the supply at these high prices, in the New York market, has been abundant, though the quality has been very low.

Looking back over the past six months in the lights of all the transactions of the market the writer now believes the scarcity in this market to have been a fictitious one, maintained solely in the interests of price and profit. And the reasons why a fictitious scarcity could be maintained so long were, first that

the holders were very few in number, and could control all arrivals, while the demand was very sharp and greatly beyond the real necessities of the case. Next, because the excitement in the market came at a time between the October and March crops, and during the rainy season, when but little coca could safely cross the coast range to the seaports. And finally, by the civil war among a people who, at best, are very slow to respond to the demands of trade, though very greedy of gain, and always impeccable.

The great danger now seems to be that all this will produce a corresponding reaction. The writer has not known the time when a ton or two of coca of inferior quality, yielding fairly of alkaloid to the improving process, could not have been easily bought in this market, but at very high prices,—say, from 1.25 dol. to 1.75 dol. per pound, while for two months past the arrivals have not been large enough to make much impression on the price. The March crop is now gathered and in the home markets, and if, stimulated by the reports of the high prices in the United States and in Europe, large quantities are thrown into these markets, the price may be ruinously depressed.

No one seems to think how small a quantity of the alkaloid will really be required for all the uses to which it can be put,—or how far a drachm vial of a 4 per cent solution really goes in the ordinary practice of any physician or surgeon. It is now highly probable that every manufacturer in this country is, in common with this writer, overstocked with alkaloid, and wishing that he could find a sale for it that would enable him to make it on a larger and therefore more economical scale. The writer has assayed samples of good coca sent by Dr. Jones, Mr. Gibbs and Mr. Daulsberg, and they all yielded over 35 per cent of cocaine or about twenty-five grains to the pound. Assays of two lots, which arrived during the past month, gave each about 4 per cent equivalent to about twenty-eight grains to the pound. But thus far all these lots are controlled in the interests of high prices, none that was good having been met with at less than 1.00 dollar per pound. From such coca, at a moderate price, the salt of the alkaloid could be sold at a fair profit at 15c. per grain instead of the recent price of 30c., and any one of the four manufacturers in this country could easily supply the entire demand.

Late in April, however, the price of the hydrochlorate, though pretty firmly held in the wholesale market, was reported to have declined in private channels. The Medical Department of the Army was in the market for 2,000 grains, and although the quantity was so small, the competing bids were said to be 18, 19, 19½, 20 and 22 cents per grain, and this report, if not entirely correct, was believed to be very nearly so. This gave the writer another opportunity of reducing his price without risk of being bought out for competition. He had been selling at 30c. per grain, subject to the 10 per cent discount of his list, and had not varied from that price. But when others were offering at 18c., he also reduced his price to that figure on May 20, that is, to 20c. per grain, subject to 10 per cent discount upon the conditions of his list of prices. This price is quite high enough now that coca of fair quality is coming in so freely that the high prices cannot be longer maintained.

The quality is improving very much with the quantity arriving, and soon, upon the arrival of that shipped in tins, there will be an opportunity of making a good fluid extract again.—*Pharmaceutical Journal.*

♦
 GROWING FOREST TREES.—Save in the case of high mountain sites, or where large tracts have to be laid down under wood in a short space of time, and with a scanty supply of labour, modern foresters have clearly established the superiority of planting over sowing, on the grounds both of economy and the better results obtained.—*Fidd.*

DOUNDAKÉ AND ITS BARK.*

("Quinquina african." or "Kina du Rio-Nunez.")

BY E. HECKEL AND F. SCHLAGDENHAUFEN.

The doundaké although doubtless used from the remotest antiquity by negroes of Africa, has only during the last seven or eight years been suspected by Europeans to have any true value. It was only in 1876 that it was pointed out by M. Venturini, a French naval pharmacist, as being possibly capable of other use than as a charm or fetish among the negroes. This author affirmed that the active principle of the bark was salicin, a statement that has not been confirmed.

The doundaké plant was first described, though imperfectly, by Atzélius,† who created for it the genus *Sarcocephalus*, and named it *S. esculentus*, on account of the agreeable taste of its fleshy syncarpic fruit, which caused it to be much sought after by the natives. The description has been reproduced in a condensed form, but with some additions and rectifications by Oliver.‡ This author, however, whilst mentioning the popular names of the plant in two or three dialects, such as "doy" (Bassa) and "ameliké" (Sierra Leone), does not mention the name "doundaké," in the Sossou dialect, which is certainly the designation under which this plant is best known. Oliver places the genus *Sarcocephalus* in the tribe Nucleæ, in the Rubiaceæ, and he only mentions two species as occurring in Africa, *S. esculentus*, Atzél., and *S. Russeggeri*, Kotschy. The former is almost exclusively limited to the littoral of the western coast, whilst the latter grows in the interior. So closely do these two species resemble one another that Messrs. Heckel and Schlagdenhaufen think it probable that what is said about the bark of the doundaké will apply equally to the bark of the tree growing in the interior. On the other hand, Dr. Corré has reported that he saw a plant in the forest of M'hour, between Joal and Portudal, which had the general appearance of the doundaké, though its bark was white and devoid of bitterness. But as he did not see the flowers it is not certain whether this plant was identical with *S. Russeggeri* or a third species.

The authors of the present paper having received further information concerning the doundaké plant, together with flowers, leaves and branches preserved in spirit, have drawn up the following description:—
Sarcocephalus esculentus, Afzel.—A shrub, with a short, robust and knotted trunk, gnarled and thickset like the small Breton oaks, but of less dimensions, sometimes attaining the thickness of a man's leg. In young plants the branches spring from the stocks, forming a loose cluster, and attaining a great length without any ramification, or at the most, in a very slight and apparently aborted form. The smooth or puberulous shrub occurs sometimes under the aspect of a climbing bush, three to seven metres high. The stem is covered with an unequal, rugose, fissured bark, but differing very much in appearance according to the age of the plant and the locality in which it has grown. In the adult state the barks coming from the Rio Nunez differ in appearance from those coming from Sierra Leone. The former have a corky aspect, which explains the name of *Nuclea sambucina* given to the plant by T. Winterbottom. Usually, this bark is grey in the young condition, but later is of a more or less deep yellow. The subjacent layers, which separate in thin lamellæ throughout the whole length of the stem, are of a more or less decided orange-yellow colour, but most frequently rather bright. The young branches have a thin greyish bark, fissured longitudinally, and covered with small blotches or small bluish, nearly cylindrical, or slightly tetragonal spots. Leaves opposite, coriaceous, slightly acuminate, obscurely narrowed or nearly rounded at the base, with limb entire, glossy, glabrous on both surfaces, slightly asymmetric, undulated,

* Abstract of a paper in the *Journal de Pharmacie* for April 1 and 15, [5], xi., 469, 468.

† *Transact. Hort. Soc., London*, vol v.

‡ *Flor. Trop. Africa.* vol. iii., p. 38.

with seven or eight strong nerves on each side, terminating in an arc before reaching the margin of leaf, shining green below, pale green above, 0.05 to 0.20 m. long; petiole short (0.005 to 0.020 m.) twisted; and rose coloured. Stipules intermediate to the leaves, short, obtuse or slightly acuminate at the summit, minutely ciliate and of a purple-brown colour. Calyx tubes coherent; calyx-teeth 4 or 5, provided with filiform clavate appendages, caducous, and disappearing rapidly on the development of the corolla. Corolla white or yellowish-white, funnel-shaped, much narrowed at the base, slightly fleshy, 4 to 6 lobed, and with imbricate ostivation. The corolla is coaducous, and has an agreeable odour of orange-flowers or honeysuckle. The stamens are inserted in the throat of the corolla, and have a very short filament supporting an elongated anther dehiscient longitudinally. Disk, none, or inconspicuous. Style brown, filiform, longer than the corolla-tube, supporting a snow-white stigma, thicker than itself. Ovary buried in the syncarpium with two cells formed by septa that never unite completely. Syncarpic fruit 0.032m. to 0.08m. in diameter, globular, with small parietal cells separated by membranous septa, reddish-black to brown when mature, with a fleshy core occupying one-fourth of the diameter of the fruit. Seeds small, whitish, ovoid, smooth. Old plants are said to produce a gum, a specimen of which is in the museum at Kew.

The *Sarcocephalus* is distributed widely in Africa, from Senegal to the Gabon, especially in Senegambia, Dakar, Casamance, Iles de Loos, Rio Pungo, Sierra Leone, Upper Guinea, Monrovia, and the Niger. In Sierra Leone the natives call the fruit the peach or fig of the country. At Dakar it is sold commonly in the markets, being obtained from a neighbouring locality called Hann, where the plant grows spontaneously in abundance. The tree flowers in May, June and July, and the fruit is ripe in October. According to Schweinfurth the fruit may be compared to a strawberry, but its colour is rather that of the apple. Eaten in excess it acts as an emetic. The plant prefers the neighbourhood of the sea-coast, but it is also met with to the interior. Schweinfurth says it occurs in the Nile region, and also that it is cultivated in the north of Guinea.

The bark being the only part of the plant employed in medicine, the authors have submitted it to a close examination, and give a number of histological details, from which the following are taken:—

Primary Bark.—A section of a young branch shows a villous epiderm, with short lymphatic, not very numerous conical hairs. Below this epiderm is a collechymatous zone, with elements rich in protoplasmic contents and a great number of them in addition showing reddish-yellow contents. It is in this zone, and in these cells, that the yellow resin considered to be the active principle is thought to be probably partially localized at first. This zone, consisting of only three or four slightly thickened oval cells, passes to a layer of similar cells, but polygonal in form. Immediately below these two, which the authors term the collechymatoid and describe minutely, is a lacunous parenchyma composed of spherical elements with thickened walls, half of the cells being strongly coloured. This layer is in virtue of its size the most important in the primary bark, but no more than a trace of it remains in the definitive bark. Below it a dense parenchyma prevails, in which the cells are polyhedral. The contents are of the same nature, coloured matter occurring in a certain number of elements. Next comes an intermediary zone, closely approximating to the liber, which may be considered as liber parenchyma, and which is composed of very small elements, interrupted by numerous large, closely packed, ovoid elements full of yellow colouring matter. A soft liber finishes the cortical series.

Secondary and Definitive Bark.—In the adult bark of the stem and old branches is found a suberous zone, which extends to the sclerous elements and is composed of brownish cells with sinuous walls. This

suber is produced by the formation in the secondary parenchyma of a generative zone, which occurs next in order, but which becomes effaced in old barks. The secondary parenchyma constituting the remainder of the bark is formed of cells with somewhat thickened sinuous walls, colourless and without contents, except some shining granules of a proteic nature. Throughout this tissue sclerous cells are distributed abundantly, either singly or in groups varying from one to fourteen. The sclerous elements are of varying lengths, have their walls thickened and strongly coloured yellow, and do not at all resemble the fibres of the wood or liber.

To sum up: doundaké bark, from whatever source, presents first a suber layer, and secondly a cellulous parenchyma with sclerous elements. The layers in the primary bark, referred to as the lacunous parenchyma, the dense parenchyma, the intermediate zone and the soft liber, disappear with the primitive epidermis. It is thought probable that these primary layers, at first much reduced by compression due to the secondary development of cellular parenchyma, become atrophied or crushed against the wood, and remain adherent to it when the bark is removed.

The authors distinguish between two forms of this drug, differing in aspect, if not in chemical composition and structure; one of these comes from Boké (Ile Nunez) and the other from Sierra Leone.

The Sierra Leone bark, from adult branches, is externally greyish and fissured, but has a general smooth appearance on the surface, with here and there small hard excrescences of a darker colour. As the branches become older the fissures multiply and the suber cracks in plates; the colour moreover deepens, so that the blackish excrescences, which also become multiplied, are lost in the general yellow colour predominant in the bark; some plates of grey suber are, however, still noticeable. The very old barks are rougher still; the fissures multiply in every direction, especially around the black excrescences, which become larger, and the underlying yellow cellular parenchyma becomes exposed to view by the removal of the suberous plates, which assume a russet-grey appearance and fall into a reddish powder. The interior of the bark is of a yellow-ochre colour and the surface is striated longitudinally. The cellular parenchyma, which constitutes the greater part of the bark, separates easily in thin flakes uniform thickness. The taste of this bark is freely bitter, resembling that of quassia amara. It is localized in the yellow tissue of the parenchyma with sclerous elements. The suber, easily separable in square flakes, owes its astringency to the tannin it contains; it has no bitterness.

The Boké bark (derived from full grown branches resembles the preceding externally, but in that taken from branches and stems, the suber rapidly assumes an ochrey colour, and becomes spongy and pulverulent; it is much smoother than the Sierra Leone bark, and free from the blackish excrescences. The internal surface is a deeper yellow, but it has the same lamellar fibrous structure. The suber is less astringent, as it contains less tannin; the cellular tissue has a clearer, more decided and less ochreous yellow colour; the taste is rather more bitter. There is the same anatomical structure in the two barks.

The doundaké barks frequently arrive from the coast of Africa mixed with barks from the *Morinda citrifolia* and another species of *Morinda* which the authors suggest might, if it proves to be a new species, be named *M. Doundaké*. These barks resemble doundaké bark in many respects, and are said to be used by the natives for the same purposes; but they may easily be distinguished by a histological examination.

As a result of an earlier examination of doundaké bark, Messrs. Boche-fontaine, Feris and Mareus had announced that they had succeeded in isolating an alkaloidal substance crystallizing in rhombohedral form, and soluble in water and in alcohol. This body, which they named "doundakine," was described as

being obtained by exhausting the bark with dilute sulphuric acid, filtering the extract, adding excess of lime, evaporating to dryness, and exhausting the residue with alcohol. They also described the result of some physiological experiments made with this substance. The authors of the present paper operating in a similar manner obtained a substance which gave the same physiological results when administered to frogs, and guinea pigs, but did not correspond to the chemical and physical characters attributed to "doudakine." It is true that it was precipitated by the double iodides and the phosphomolybdate and phosphotungstate of sodium; but it was devoid of alkaline reaction, did not combine with acids, and could not be obtained in the specified crystalline form. The authors, therefore, operated upon the bark with a series of solvents after the manner laid down in Dragendorff's 'Plant Analysis.' The bark reduced to a fine powder was first exhausted in a continuous displacement apparatus during six hours with light petroleum spirit. Upon evaporation the spirit left equal to 1.2 per cent of residue, consisting of two fatty bodies which were not completely investigated.

The bark was then treated with boiling chloroform, the percolate being yellow liquid with a very intense green fluorescence. This liquid left on evaporation a residue which gave up to very dilute hydrochloric acid a small quantity of yellow matter. This hydrochloric solution gave with double iodides and phosphotungstate of sodium reactions which seemed to point to the presence of an alkaloid. But when it was evaporated to dryness, the residue treated with water, and the solution slightly acidulated and carefully filtered, the reaction was no longer obtained. The authors, therefore, consider the precipitates obtained in the first place were not characteristics of an organic base. The portion of the chloroformic extract insoluble in acidulated water dissolved to a considerable extent in cold alcohol, and the remainder was soluble in boiling alcohol. The cold alcoholic solution left upon evaporation a very bitter residue which proved to contain nitrogen, and yielded to water some substance which gave with double iodides precipitates analogous to those of organic bases. But the addition of a small quantity of acid to the solution caused a fresh precipitation quite as voluminous, and the residue after evaporation dissolved in potash in the cold and behaved generally like the petroleum spirit extract. The authors therefore conclude that chloroform removes several bodies from the bark, one containing nitrogen, of a resinoid nature and soluble in alcohol, the others being a mixture of wax and fatty bodies.

The bark was next extracted with alcohol as long as any colour was imparted to the menstruum. The tincture was of an intense yellow colour, with a very pronounced green fluorescence. Examined spectroscopically it gave results corresponding with the presence of chlorophyll. Upon evaporation equal to 6.95 per cent of residue was obtained, which was only partially soluble in cold water. The aqueous solution gave reactions showing the presence of a small quantity of tannin, and it reduced Barreswil's liquor. It was also precipitated by the double iodides, picric acid, phosphomolybdate and phosphotungstate of sodium. This precipitate appeared to show the presence of an alkaloid; but when the solution was concentrated and treated with dilute hydrochloric acid, it gave a similar precipitate, from which the authors concluded that the principle dissolved was of a resinoid nature and not an organic base.

The pitchy-looking residue, insoluble in cold water, was first treated with hot water and then with boiling alcohol, and in this way three separate bodies were obtained, two of them containing nitrogen and the other not. The first (a) was of a yellow-red colour, very bitter, soluble in hot water and in alcohol, and gave upon analysis results represented by the formula $C_{28}H_{19}NO_{13}$. The second (b) was yellow, insoluble in boiling water, but soluble in alcohol, and is represented by the formula $C_{19}H_{16}NO_9$. The

third (c) was kerries brown, insipid, insoluble in boiling alcohol or water, but soluble in caustic potash. Evidently this last was a product of alteration, probably a colouring matter. Both a and b can be used to dye silk or linen and give with indigo blue fine shades of green.

Further treatment of the bark with acidulated water removed 23.12 per cent of albuminoid, amylicous and salt matters, leaving 67.98 per cent of ligneous residue, yielding 5.57 per cent of ash on incineration.

Doudaké bark from Rio Nunez (Boké) when treated in the same manner gave similar results. A larger yield of the yellow matter soluble in water and that soluble in alcohol was obtained, which is what might be expected, as the Boké bark is much more intensely yellow than that from Sierra Leone. The Boké bark, on the other hand, contained only a trace of tannin, whilst the alcoholic extract gave no indications of the presence of chlorophyll. The authors are of opinion that the active principles of the Boké doudaké bark consist of two colouring matters, having a pronounced taste, and identical in respect to chemical and physiological properties with those obtained from Sierra Leone bark, but differing manifestly in the brightness of their tint.

Further examinations of the two barks by other processes gave identical results. The authors therefore consider themselves justified in saying (1) that "doudakine" as a crystallizable alkaloid does not exist, but it is suggested that the name might be appropriated for the colouring matter to which the bark owes its physiological action; (2) that the bitterness of doudaké bark is due to two colouring principles of a resinoid nature, both containing nitrogen, one soluble in water and the other in alcohol; (3) that the barks yield another principle, tasteless, insoluble in water, but soluble in caustic potash, as well as glucose and traces of tannin.

Upon a consideration of the foregoing facts, and of the different solubilities of the two resinoid bodies that appear to be the active principles, Messrs. Heckel and Schlagdenhauffen recommend the use of a dilute spirit in making a preparation of doudaké bark for therapeutic purposes. In their experience the best results have been obtained in using 60° alcohol, which gave a dry extract equal to 21 per cent of the bark. The use of a hydro-alcoholic menstruum is also in conformity with the practice of the natives, who macerate the bark in wine. In this form it has been reported to be a good substitute for cinchona bark, especially as it is better tolerated by the stomach for a long time. The authors are, however, disposed to accord to doudaké bark a secondary place, similar to that occupied in relation to cinchona bark in South America by the barks of *Zanthoxylum caribaeum* and *Z. Perrottetii*. There appears to be no doubt that doudaké bark possesses astringent and tonic febrifuge properties, but the authors consider there is no absolute justification for its designation as "quinaquina" africana or "quinaquina de Rio Nunez."—*Pharmaceutical Journal*.

TO RESTORE AND PRESERVE FLOWERS.—Faded flowers may be generally more or less restored by immersing them half way up their stems in very hot water, and allowing them to remain in it until it cools, or they have recovered. The scalded portion of the stems must then be cut off, and the flowers placed in clear cold water. In this way a great number of faded flowers may be restored; but there are some of the more fugacious kinds on which it proves useless. Flowers may also be preserved, and their tints deepened, by adding to the water a little solution of carbonate of ammonium and a few drops of phosphate of sodium. The effect of this in giving the flowers a deeper colour and a stronger appearance is quite wonderful; and, by cutting off every other day about half an inch of the stems of the flowers with a sharp knife, they may be kept as long as their natural life would last.—*Indian Gardens*.

EUCALYPTUS GLOBULUS IN FLOWER IN SCOTLAND.—Mr. Dunn, of the Dalkeith Gardens, kindly forwards a branch of this in flower with the following note:—"The plant, or tree, was raised from seed I received from Melbourne, Australia, in 1879, and sown in the early spring of 1880, and grown under glass for two years. In 1882, when about 5 or 6 feet high, it was planted out, in the month of June, in the middle of a Rose bed in a sheltered spot in the grounds, where it has grown freely and uninjured since. It began to show its adult leaves last season, and on the branches on which they were borne the flower-buds appeared in May this year. The first flowers opened on the 16th inst., and they are now opening freely, and present rather a striking appearance on the young tree. The tree is about 18 feet high, and the flowers are produced on the branches from the middle upwards. I am not aware that it has flowered out-of-doors in Scotland previously.—*Gardeners' Chronicle.*

TEA FROM JAMAICA.—What a Colonial botanist can do to stimulate flagging industry and develop new resources is well exemplified by Mr. D. Morris, the Director of the Botanical Department, Jamaica. We have before us the broker's report on the first commercial sample of Jamaica-Grown Tea, sent into the market mainly through the energy and forethought of Mr. Morris:—"We have carefully examined the sample of Tea, and now beg to hand you our report on it. The leaf is very fairly made, though if intended for our market we think it would be well if the slight glazy appearance it possesses could be avoided. After infusion the leaf is bright, indicating good quality and careful preparation; while the liquor has fair strength and good flavour, combining to a great extent the peculiar characteristics of a fine China black leaf, and a Ceylon Pekoe Souchong. We consider the value of the Tea here to be from 1s. 6d. to 1s. 8d. per pound (in bond), and if you could send a fair-sized parcel, no doubt it would meet a good reception from London buyers. If at any time we can furnish you with information, or assist the development of the Tea industry in your island, we shall have much pleasure in so doing. We beg in the meantime to be permitted to congratulate you upon the specimen of the manufactured article you have now sent us.—(Signed) GEO WHITE & Co."—*Gardeners' Chronicle.*

BAMBOO.—In Burma, as in most tropical countries, the Bamboo is in great demand, and to the mass of the people is invaluable. Of Bamboo alone a complete and comfortable house, absolutely proof against the tropical downpour of rain, can be erected in an incredibly short space of time. A roof made of large Bamboos split in half, and laid over and under, like tiles, is absolutely waterproof. The drawback, however, of Bamboo as a house material is that it lasts but a few years, and is, of course, simply swept away by fire; but to a native of a country abounding in Bamboos, from which in three days he can reconstruct his dwelling, this is a trifle. Other everyday uses are scaffolding, bridging, fencing, and decoration—carts, boats, fittings, matting and domestic utensils, and a variety of industrial and economic purposes too numerous to detail. A fine mat of split Bamboo forms the basis of the exquisite Burma boxes, the one industrial speciality of Upper Burma. The young shoots of Bamboos are edible, and pickled by the Chinese, whilst the softer wooded species yield a highly promising material for the manufacture of paper. Silica is contained in large quantity in both the leaves and stem of Bamboos, and is held in solution in the fluid contained in the growing stems of many species. This fluid is often limpid, but as it dries up it becomes milky, and finally deposits a cake of gelatinous opaline silica at the bottom of the joint, known as "tabasheer," possessing curious optical properties. These little discs of "tabasheer" may often be picked up in a bamboo forest after the bambu which yielded it has decayed; and when a bamboo forest has been destroyed by fire, these white calcined discs form quite a feature ground.—*MASON, Gardeners' Chronicle.*

VEGETARIANISM.—Professor Gubler, in his recent researches as to the causes of cretaceous degeneration of the arteries, has made the very interesting discovery that a principal cause lies in a vegetable diet, and thus explains the frequency of cretaceous arteries among the French rural population at the early age of forty. This is the more important, because it is well understood that "a man is as old as his arteries," and that chalky degeneration of the arteries is the most fatal kind of premature ageing. Further proof he finds in the fact that the Trappists, who live exclusively on vegetable food, very soon show arterial degeneration. In districts where chalky soils load the drinking-water with earthy salts a vegetable diet acts more rapidly in affecting the arteries than regions of siliceous formation.—*British Medical Journal.*

TO KEEP DOWN WORMS IN POTS.—There are few who have gardens and plants in pots who do not require at some time or other to place the pots out upon the ground—perhaps in the shade during summer, or plunged in ashes in winter. "Worms in such cases," writes a correspondent of a gardening contemporary, "are often troublesome, and to keep them from entering pots is a desideratum. Having during the past winter, to set a large quantity of plants in small pots in a frame placed on the ground, I first leveled and flattened down the soil, and then strewed all over it fine slaked lime to the thickness of about a quarter of an inch; over this again was placed half an inch of fine ashes, and on this bed the pots were placed. As a result, although three months have elapsed, not a worm has given sign of its presence in any of the pots, and I feel that the plan has proved entirely successful."—*Indian Gardener.*

COMPRESSED TEAK FOR LOOM SHUTTLES.—A correspondent in the *Garden* states that the increase in the price of Box-wood, largely used in the manufacture of loom shuttles, has directed attention to the possibility of producing some cheaper material equally suitable. It has been found that compressed Teak will answer the purpose, and a powerful hydraulic press has just been made by Sir Joseph Whitworth of Manchester for Mr. Robert Pickles of Burnley, to be used in compressing this class of timber for the manufacture of loom shuttles. The press consists of a strong cast iron top and bottom steel cylinder, with a large ram. In the centre of this ram is fitted a smaller one, with a rectangular head fitting into a die which is placed on the top of the large ram. The timber is put into this die and a pressure of 14 tons per square inch applied. The timber thus treated is made very dense, uniform, and close grained, and is capable of taking a very high finish.—*Indian Gardener.* [Query:—whether satin-wood, thus compressed, would not be equal to box for wood engraving.—Ed.]

PHORMIUM TENAX AND OTHER PLANTS IN SCOTLAND.—The finest plant of New Zealand Flax in this district is growing in the garden of Mr. Wm. Walker, Strathkiness. Some of the leaves are nearly 8 feet in length. At present there are two flower-stems, the tallest of which is 9 feet. This bears a dozen trusses of deep crimson flowers. (I know of one catalogue and one dictionary in which white is given as the colour.) Note was taken of the rate of growth, when at its quickest. This was found to be 2½ inches in 24 hours—½ during the day, and 1 inch during the night. The soil is strong loam, and there is but little shelter. This plant, which has flowered twice before, is a seedling from seed ripened in the open air by Dr. Traill, Orkney. In the same plot is a fine example of *Veronica Traversii*, 4 feet in height, 6 feet across, and completely covered with bloom. In a small cool greenhouse, amongst luxuriant native and hardier exotic Ferns, is an *Adiantum petatum*, with stems 20 inches in length, and leaves almost 2 feet from tip to tip.—J. W., St. Andrews, N.B. [The usual colour of *Phormium tenax* is orange.—Ed.]—*Gardeners' Chronicle.*

Correspondence.

To the Editor of the "Ceylon Observer."

THE JAVA PLANTERS ANXIOUS TO GET INFORMATION ABOUT CINCHONA CULTIVATION IN CEYLON.

Bandoeng (Java), 20th September 1885.

DEAR SIR,—Requested to acquire as much knowledge as possible relative to the cultivation of cinchona. I take the liberty of requesting you to enlighten me as to the following questions:—

a. How large is the plantation at Ceylon? and from what year does it date?

b. What rates are on the products directly or indirectly, such as emphyteutic rent, ground tax, license patents, &c.?

c. In what way is it cultivated? how is it gathered, dried, packed and transported?

d. To how much do those costs amount?

e. How much must be paid for warehouse dues, shipping, insurance, landing, expenses in Europe, commission fees, &c., &c.?

f. How and for what price may analyses be had?

g. What machines are used in gathering and drying the bark?

h. What is the average quality of the bark?

Any further information as to expenses, kind of cinchona that has been planted, &c., will be gratefully accepted, as I shall be happy to give you any details acquired also from foreign lands.—I have the honour to remain, respectfully yours,

W. TOUSSAINT,

Secretary of the Planters' Association at Bandoeng.

The above is of interest as showing how our neighbours in Java concern themselves about our Cinchona planting industry. We shall send Mr. Toussaint our publications with the useful information, as far as it is available: as for "emphyteutic" (improving) leases, such are unknown in Ceylon.—Ed.]

RE WATER-WHEELS.

The Scottish Trust & Loan Company of Ceylon, Ltd., London, 10th Oct. 1885.

DEAR SIR,—When a proprietor has two water-wheels on his estate or group of estates, let him place one behind the other, tandem fashion, the one uphill running free, but connected with the one below driving the machinery, by a wire rope, and my conviction is, good power will be obtained. I mean to see it tried on my Knuckles properties.—Yours truly,

THOMAS DICKSON.

A very good idea. Our own was to have a separate shaft for the extra wheel, with belting connecting it with the shaft by which the machinery was moved. We suppose Mr. Dickson means that the wire rope should go over and under each other wheel in a groove on the rim of the wheels.—Ed.]

WATER-WHEELS AND TEA-ROLLERS.

Colombo, 16th Oct. 1885.

DEAR SIR,—Referring to your senior's article "From the Hills" in last night's *Observer* giving the performance of the "Excelsior" worked by a 16 feet water-wheel, will you permit us to say that a 12-feet water-wheel has recently been erected by Messrs. J. Walker & Co. on Blackstone estate, and is now working the No. 3 Challenge roller with a small supply of water? The proprietor of the estate informs us that the machine now turns out with the greatest ease 80 lb. of withered leaf every quarter of an hour, or 3,200 lb. per day of 10 hours, against about 2,000 lb. obtained by hand power. This is not so bad for a beginning.—Yours faithfully,

W. H. DAVIES & Co.

TEA LAND IN THE LOWCOUNTRY.

SIR,—Referring to Mr. De Soysa's lands in the Western and Southern Provinces you state that some of these undulating lands would rouse the envy of A... planters. Now, I do not mean to depreciate Mr. De Soysa's or anybody's land, for there are exceptions; but as a rule, when diligently hunting in the lowcountry districts favored with a good rainfall, in company with an *Assam planter*, we found such lands, as a rule, very poor and the hilly and high lands near or adjoining much superior. I can only account for it by the system of "chenaning" in vogue in ancient times. Only 20 miles from Colombo in the neighbourhood of Labugama could be found flats suitable for tea but of poor soil and not of a *lasting* character, while a few miles off, in the hilly track round the reservoir, are plots very desirable for a product like tea, but unfortunately the preservation of these forests is necessary for the Colombo water-supply and they are most properly reserved, save a few hundred acres which Government are likely to sell. The lands referred to by you are well suited for other products, as well as tea, and Mr. De Soysa should be "a pioneer" as respects these. Without disrespect to that gentleman, I think it absurd to call him "a pioneer" of an enterprise which has made its stand three years ago and when this gentleman, like others of his nationality, would not have dropped one cent in it. R.

Our correspondent should have seen by our second paragraph that Mr. De Soysa began planting tea three years ago, and is therefore, decidedly, a pioneer in the neighbourhood to which we referred.—Ed.]

ANOTHER TEA-ROLLER: THE INVENTION OF A LAWYER-PLANTER.

Nawalapitiya, 25th Oct. 1885.

"The cry is still 'They come.'"—*Shakespeare*. "The more the merrier."—*Popular proverb*.

SIR,—As everything connected with the economy of tea-machinery is of immediate public interest, I venture to send you a few remarks on a new roller which I saw at work yesterday. It is no secret that the energetic proprietor of Blackstone, who may be said to be in tea manufacture the senior wrangler of the year, has been for some time devoting his natural acumen, doubtless considerably sharpened by the study and prolonged practice of the law, to improvements in tea-rolling, and the result of his labors is a machine which, combining quantity and quality of output with economy of cost and motive power, bids fair, I think, to supply the great practical want of the day. The machine, which is at present driven by a 12 ft. water-wheel, or by six coolies, turns out easily eighty pounds of withered leaf, thoroughly rolled in fifteen minutes, without breakage of leaf or discoloration of tip; and the great advantages it possesses are that little time is wasted in loading or discharging and that it will turn out any smaller quantity as well finished as the maximum to which it can be worked. I am not a sufficiently good mechanic to be able to describe the roller to you, and it would be premature to do so if I could, but I send you by this post samples of the grades into which I saw a roll from this machine sifted, which, I think you will agree with me, leaves nothing to be desired. Mr. Barber is about to patent his invention, and, I believe, it will be found at a greatly reduced expense of money and motive power to compete favorably as regards output with any of the heavier and more costly machines now in vogue.—Faithfully yours

J. L. SHAND,

TOMATO CULTURE IN COLOMBO.

Agricultural School, 28th October 1885.

DEAR SIR.—The following experiments in tomato cultivation have been tried by me at the Agricultural School. My first experiment was tried in ordinary cimanon garden soil. Seed was sown in a box filled with soil and manure (cow-dung). Meanwhile holes two feet apart were dug in the selected ground, the soil therein being enriched by a slight addition of well-fermented farmyard-manure. When the plants in the nursery attained the height of about three inches, they were carefully rooted out and transplanted, two in each hole. When the plants were just beginning to put forth flowers, liquid-manure (cow-dung dissolved in water) was applied to a few of the holes, a topdressing of saltpetre (potassium nitrate) to some more, and the rest were left to feed on the manure first applied. The result of this experiment was, that the plants to which liquid manure was applied yielded a greater produce than those left to feed on the manure first applied, whilst those that received saltpetre yield about twice the produce of the liquid manured ones. Besides this, some of the plants were topped. These yielded fruits that were actually much bigger and better shaped than those produced by the others.

Having been successful in this experiment (performed about January last) I proceeded to follow the same course of treatment with some plants grown in June last upon a somewhat moist soil of a peaty character. These at first, to my great satisfaction, grew more luxuriantly than those on the sandy soil, but suddenly plant after plant began to show symptoms of declining health which was indeed a very sad sight, because at this time all the plants had young fruits. A tree once attacked never recovered. On examination I found that the sudden change the plants underwent was partially due to the excess of water in the soil, caused by the few heavy showers that fell during the month. Another probable reason was, that, as the plants increased in size, their roots began penetrating into the sour soil beneath, thus allowing the injurious matter to complete the rest of the destructive work. The chief lessons to be derived from my experiments are as follows:—

1st, that tomatoes thrive better on rich sandy soils than otherwise; 2nd, that an excess of water is highly injurious; 3rd, that manure applied in a liquid state is very desirable; 4th, that a topdressing of saltpetre makes the plants more productive; and 5th, that topping increases the size of fruits.

During these experiments the plants were not quite secure from disease. Black spots on the surface of the leaves and blisters upon the stem were caused by a minute fungus, which was prevented by the application of bisulphide of potassium during the early stages of the attack, but when the disease was fully established the plants never recovered.—Yours truly,

W. ARTHUR DE SILVA, Agricultural Student.

CINCHONA BARK HARVESTING.

SIR,—Can you or any of your correspondents give me information on the following subjects?

What is the most advantageous length of time (after first shaving) to wait before shaving healthy 5-year old succinbra trees a second time? When trees have been covered with mana grass for six months, is it advisable to remove the covering during the wet monsoon weather? Is it advisable to shave Ledger trees? Does renewed Ledger bark analyse better than original? CINCHONA.

[A year is the usual time, we believe, to wait between each scraping, but the longer the interval the better. We should think covering would be needless in the wet weather. Renewed Ledger bark is decidedly richer than original. See Owen's *Cinchona Planter's Manual*.—Ed.]

FLIES AND BUGS.

Beetles, insects, roaches, ants, bed-bugs, rats, mice, gophers, chipmunks, cleared out by "Rough on Rats." W. E. Smith & Co., Madras, Sole Agents.

THE RAINFALL at Cherrapunji from the 1st of January this year up to the 27th of August has been 280.11 inches, as compared with 222.45 inches during the same period of last year.

RAVAGES OF THE YELLOW RIVER AND REPAIR OF THE BANKS.—Says the *Japan Weekly Mail*:—A correspondent of the *North-China Herald* sends an account, which reads like a romance, of the methods employed to check the ravages of the Yellow River. It appears that double lines of embankment are erected, the larger of the two being about a mile from the river on each side, and having a width of 75 feet at the bottom with a height of 10 feet. This barrier, however, has proved quite ineffectual. The river burst over and through it last June twelvemonth, and the work of repairing appears to have been going on at intervals ever since. The method of effecting repairs is extraordinary. It is thus described:—

Earth and kaoliang stalks by the million are added in either end of the broken dyke, the two ends are so made as to approach gradually, and when all is finished the appearance is somewhat that of a horse-shoe curve. When the two ends have approached sufficiently near, cablelike ropes are passed back and forth net fashion upon which are placed mats and stalks and earth, layer upon layer, all pressed down by stone weights lifted by a score of men. When this new formation has reached a sufficient height, about equal to the depth of water swiftly flowing underneath it, the supports are suddenly removed; all goes down with a rush and a splash and a plunge. Sometimes the same thing is effected by means of an old boat heavily loaded, whose bottom has been previously knocked out. In either case this huge plug, so to speak, loaded with workmen as well, is not infrequently overturned by the force of the water thus suddenly arrested in its wayward course, and lives not a few have thus been hurled into a watery grave. At one time thirteen persons perished, and during the year a hundred or more have been drowned or killed in connection with the work on the river. Some of them were hired men from the country near by, but most of them were soldiers. They are kept at work in dangerous places by means of the lash in unfeeling hands. The officials are not supposed to know of this loss of life. It is never reported, except in the case of some official or *wei-yan* who has fallen with his men. For this more dangerous kind of work the men demand extra reward. One way they are paid is as follows. Each couple of men carrying a heavy load of earth between them, Chinese fashion, are allowed to have as many cash as they can grab at one snatch as they pass along each time, the loose copper cash being in an open basket on the ground. If considerable time elapses before the gap is filled, a good round sum of money may thus be picked up. The men risk their lives for the grab. Payment at other times is by the barrow load according to distance, or by the foot. Ten feet square one foot thick pressed down hard rolled and pounded are paid 180 real cash. Very much depends upon the nature and time of the ponding. If done well it will be to the advantage of the Government and the flooded districts, but the poor workman will have less money for his good work. If done hastily the number of square feet will be increased; but the bank thus made will not resist water. There is, strange to say, a sort of premium upon poor work. Low wages, poor pay, and many squeezes make it the advantage of the workmen to pile up as much earth as possible before the ponding is commenced, and then by making the outside very hard and level to raise more quickly the high and fine looking mound. If well done, the inspecting official is none the wiser. The sub-inspectors do not report the fraud, being somewhat interested in a squeeze of their own when the work is paid for. The work on the whole appears much better this year than last, and but for the large opening made last year and still open, the second bank would probably be effectual in its object.

Mr. E. J. C. BRACE, formerly of the Nilgiris, a well-known tea-planter, who wrote an essay on tea for us some time ago, writes as follows:—"I hope to be able to send you ere long a paper on the laying-down and management of eucalyptus plantations as a source of fuel in connection with the tea industry, a matter of no small import when your plantations begin to yield heavily. Just at present I am fully occupied with a translation of M. Arthur Noddi's valuable 'Essai sur les Itepenulemantis Arociels.'"—

CACAO IN KANDAPOLA, HAPUTALE.—We learn that a field of about two acres of the so-called "Caricaes or pale yellow variety of cacao," (but "Caricaes" is usually spoken of as red) planted with seed at stake during November 1882, is now loaded with fruit and blossom. The fruit, when about half-grown, has a beautiful pale-green tint, which gradually changes into yellow. The ordinary cacao planted during the same monsoon has also grown well and is in fruit and flower but not to the same extent as the yellow variety. Our informant is one of the pioneers of new products in Haputale and is in great spirits over the prospects from cacao, having over 150 acres of fine forest thoroughly suited to the cultivation of this product.

PEARLS IN THE PERSIAN GULF.—Major-General Sir Lewis Pelly, writing in the *British Trade Journal*, says:—"The pearl trade of the Gulf has been famous from the earliest historic period; and the pearl banks of the island of Bahrein, and of the small maritime chieftains known as Dobai, Shargh, Amulgawaine and Basulkhyma, on the Arab shore-line of the Gulf, are still the richest pearl-fishing grounds in the world and yet, perhaps, the finest pearls still swim about on the sands at the bottom of the Gulf waters. The law seems to be that the deeper the water the finer the pearl or the oyster, and the deeper water along the banks has never yet been fished. The Arabs pursue their fishery by diving from small craft, which during the pearl season may be seen anchored by thousands along the banks. Seven fathoms is the maximum depth of their diving, while their ordinary fisheries are pursued in from four to five fathoms of water. Now, as the water deepens very slowly off the Arab coast, and as this shoal water over the banks extends some hundreds of miles—from the reefs of Bahrein and El Khatiff to Cape Mussendoom—it seems probable that, were the deeper water along these banks to be exploited by steamers fitted with regular diving apparatus, innumerable draughts of pearls might still be obtained."—*Pioneer*.

COLONEL HUNT'S LECTURE ON STOCK-FARMING in India travelled outside the lines of the subjects generally discussed at the Simla United Service Institution, but was none the less valuable on that account. The lecturer entered at much detail into questions regarding the improvement of cattle and sheep by better grazing and the storage of fodder supplies. He warmly approved of ensilage, the experiments in which he considered were promising in India. He pointed out how much the ryot would benefit if better stock were raised and means taken to secure an ample supply of forage fodder. Mr. Buck expressed his pleasure at finding the important question of the improvement of agricultural stock taken up outside his own department, and endorsed the lecturer's views on ensilage. He hoped that the experiments would be continued. Sir Stewart Bayley, who presided, said that the subject was of extreme importance not only to Government, but to the ryot. The latter had more cattle than he could feed in bad seasons, and consequently many were allowed to die. This would be prevented by the introduction of the silo system. The great object was to secure publicity being given to the results of experiments.—*Pioneer*.

THE INDIAN TEA DISTRICTS.—News from Assam and Darjeeling districts still continues to be unfavorable, and from the Terai there are serious complaints of blight, which will affect the outturn. In Cachar, blight is on the decrease, and the weather is reported more favorable.—*William Moran & Co.'s Market Report*, Calcutta, 6th October.

MARIWATTE, which gave 1,000lb. per acre last year will not repeat the performance this. I believe the manager does not expect get to more than 800 lb. I myself think this an excellent result after such a heavy crop, but I think the proprietors expected at least 1,000lb. an acre would be obtained which is most unreasonable. The average price obtained for all the teas of this estate I am certain will be about 15.3d. and I know for a fact that the average cost *f. o. b.* in Colombo is not more than 31 cents. A simple arithmetical calculation will show you the profit made by this estate annually when you know that were the rupee at par, 34 cents is just a trifle more than 8d.—but then the rupee is far from being at par and this still further increases the profit.—*Ceylon Cor. "Indian Planters' Gazette."*

MALTA LEMON PLANTS FOR CEYLON.—Amongst communications to the Horticultural Society of India we find the following:—From Dr. H. Trimen, Director, Royal Botanic Gardens:—"Dr. Bonavia, of Batavia, has lately written to Ceylon strongly recommending the introduction of a 'Malta Lemon' and has suggested that we might obtain plants from your Society. I should be glad to give the plant a trial here and should feel obliged if you could afford me a few plants. The easiest plan to send them to me would be to forward them to Dr. King at the Botanic Garden, who is in frequent communication with this establishment, and could forward them in the next Wardian case he is sending us. If I can be of any service to your Society in return, I should be glad."

COFFEE PLANTING PROSPECTS.—Our Kopra (Mysore) correspondent writes:—"We are having very good weather for the late plantings, which a number of planters have gone in for, in consequence of a former scarcity of labour. The ryots now appear content with the amount of rain we have had, which up to the 30th ultimo was more than the total gauged for the whole of last year. The coffee crop in the Bamboo will turn out a fair average one, and if the prices will only go up, there will be good times for the bamboo planters. Plantation prospects have changed considerably for the better. Coffee looks charming; this season's plants especially, have put on a spurt, as if to brace themselves up against coming hot weather. This sunshine and rain will go a long way towards bringing the crop to maturity, and picking may be expected to commence a month, or at least a fortnight, earlier than usual. Labour is scarce and it is with difficulty that estates can keep their weeds under. In a month or so the 'kandayam' may compel many, who are now having a happy idle time, to seek estate work.—B. S.—*Madras Mail*.

A LARGE QUANTITY of land in North Eastern Bengal has, says the *Tea Planter's Gazette*, been given up by tea-planters as unsuitable for tea. This is due a great deal more to the unprofitable nature of transactions in tea for the last few years than to the nature of the land. A few years ago it was quite easy to start any number of tea gardens, in fact, the name of a new garden had but to be mentioned and the investment was jumped at. In consequence of this many young planters took up large tracts of land, and after paying rent for a few years found the burden so heavy that they had to abandon the idea of trying to open out an estate. People are not so sanguine now-a-days with regard to tea as an investment. Although much land has been abandoned, there has also been a large area put under tea in Sylhet and Cachar, in districts proved to possess a more rapid tea-producing soil than any yet discovered.—*Madras Mail*.

THE NEW BIT.—The *Indian Planters' Gazette* writes that the attention called to the perfection of the American indianruber trotting bit led to such a run on them that all Calcutta saddlers are sold out. Indents have, however, been telegraphed, but the bits are only procurable from the patentees in New York, some time must elapse before their arrival.—*Pioneer.*

RED BARK.—Messrs. Patry & Pasteur have the following paragraph in their market report of 21st Sept.:—We are happy to be able to inform growers of red bark that the sterling qualities of *Succiruba* have been recognized in the new British Pharmacopoeia, the legal standard for the manufacture of all druggists' preparations. In the new edition just issued, the cinchona decoctions will in future be made from Red Bark instead of as hitherto from the Yellow Bark or *Calisaya flava* of South America; this will probably cause an enhanced demand for the Red Ceylon and East India barks.

COCONUT PLANTATIONS: HOW TO DESTROY BEETLES. Have you or your valuable contributors on coconuts never heard the latest contrivance to destroy beetles in young coconut plantations which are so destructive to you as you know? I have this from a well-known Kurnnegala plumbago-dealer who is proprietor of extensive coconut plantations, and, as I have no reason to doubt what was told me, repeat it here for the benefit of your readers. It appears that he and some of his neighbours fix a hoghead in, say, a 10-acre block of his property, which hoghead is brimful packed with "kekuna leaves" over which water is filled, some tender twigs and branches are also thrown in. Within a fortnight a strong smell, I would say stink, arises from this cask, which attracts all the beetles in its vicinity and lures them into the cask. In the evening a couple of boys are told off with a gunny bag, to go round the property and pick off the cask all the beetles that have dropped in; as many as 30 or 40 beetles it appears are sometimes picked off one cask alone. In a short time, the beetles gradually disappear. Of course all the beetles gathered are daily destroyed over a special bonfire. As I said before, I have never heard of this cheap method of curtailing the ravages of one of the enemies of coconut plantations, and will be glad to hear if any of your readers have ever heard of it or given this system a trial.—*Cor.*

KAJU GUM.—We translate the following from the *Indische Mercur* of 3rd Oct.:—Mr. J. H. Ferguson, the Netherlands Minister in China, has made an interesting communication to the Council of Management of the Colonial Museum at Haarlem regarding kaju gum from the West Indies, which variety of gum is eminently suited to take the place of gum arabic, which is becoming dearer and dearer. According to Mr. Ferguson, the kaju trees are found, not only on the island of Aruba, but also in exceptionally large quantity on the island of St. Martin, where they thrive well in the moist sandy soil between the mountains and the sea, being nourished by the rain-water which springs up from the mountains through the sand. This variety of gum is found in such quantity in St. Martin that it is used in the whitewashing of houses, to give the lime-water sufficient cohesion, on which account it is used for the painting of woodwork. Doors, window-blinds and also outer woodwork are painted with the lime-water thus prepared with kaju gum, to which any coloring material is then added. Considering the great value, from a commercial point of view, of kaju gum, the cultivation of the kaju tree (*Anacardium occidentale*) in the East and West Indies is recommended by the Colonial Museum. In the West Indies these trees grow wild, and in the East Indies they thrive very well. The well-known 'Achin nuts' are derived from these trees. The fruit is called in Malay *jambu nyepet*. Fine specimens of kaju gum are to be seen in the Museum. The attention of Government will also be drawn to this subject by the Committee.

PRESERVING PLANTS, &c.—Mr. P. Hennings states that during the last three years certain fruits, flowers, and other portions of plants have been preserved in the botanical museum of the Berlin University by means of a solution consisting of 4 parts of water and 1 part of alcohol, saturated with allylic acid.

THE BONE INDUSTRY of the United States is an important one. The four feet of an ordinary ox will make a pint of neatfoot oil. Not a bone of any animal is thrown away. Many cattle shin bones are shipped to Europe for the making of knife handles, where they bring \$40 per ton. The thigh bones are the most valuable, being worth \$80 per ton for cutting into tooth brush handles. The foreleg bones are worth \$30 per ton, and are made into collar buttons, parasol handles, and jewelry, though sheep's legs are the staple for parasol handles. The water in which the bones are boiled is reduced to glue, the dust which comes from sawing the bones is fed to cattle and poultry, and all the bones that cannot be used as noted, or for bone black, used in refining the sugar we eat, are turned into fertilizers and made to help to enrich the soil. As regards waste, it is the story of the pig. Nothing is lost except the squeal.—*Exchange.*

A SUBSTITUTE FOR COFFEE.—At the Commercial Exchange, Cape Town, there were recently exhibited some specimens of a root, *umpinyisa*, which had much in common with chicory. The following letter from Mr. Hampden-Willis, Under Colonial Secretary, accompanied the exhibits:— "With reference to a letter from the Civil Commissioner of Peddie, I am directed to forward, per separate parcels, some specimens of a root known by the name of "umpinyisa," viz., a piece cut off the root, some pieces roasted after being passed through a mincing machine, and two packets of the ground material. The root is largely used by farmers and others, who make a beverage from it resembling coffee in flavour, but sweetish. The process employed in preparing it is to pass it through a mincing machine, roast, and grind it. Some Cape farmers also make a syrup from it, by cutting up the root, boiling, and skimming it. This resembles golden syrup, with a slight cinnamon flavour. It is thought that, with proper machinery, this root could be utilised as a substitute for coffee as an article of commerce."—*Colonies and India.*

SUCCESSFUL POTATO-GROWING NEAR NUWARA ELIYA.—22nd Oct.—I have just taken up a crop of potatoes which I think will show that they can still be grown in this locality very profitably. On the 3rd of August I planted 36 sets which weighed 5 lb., and I have today—11 weeks and 3 days from the time of planting—taken up 356 sound marketable tubers weighing 56 lb. They were planted in a single line on ground that had been trenched 18 inches deep last year and a good dressing of manure was applied to the ground then. The sets, which were whole tubers, were planted about 1 foot apart and 4 inches deep. No fresh manure was used but a little lime and wood-ashes was sprinkled round each set at the time of planting and they received 4 doses of liquid manure during the dry weather when they were in active growth. They were also earthed up after each watering. It is only fair to mention that two plants were destroyed by grubs and 1 died before any tubers were formed, so that the 56 lb. were taken from 33 roots. We had heavy rain yesterday from the E. It began at 1 p. m. and by 3 o'clock 1.83 inch had fallen; from then light rain continued to fall, and this morning the total for the 24 hours was 2.43. There was scarcely any wind with it and the total horizontal movement of the air for the 24 hours was only 61.80 miles.—*Cor.*

THE NILGIRI CINCHONA PLANTATIONS.

The report for 1881-85 has reached us, and we find it specially interesting in view of the fact that Mr. Hooper, the new quinologist, has taken up the important work of analysis and comparison so sadly interrupted by the mysterious disappearance of poor Broughton. The one great fact that strikes us in reading the cinchona reports from both Northern and Southern India is, that, apart from the successful introduction of the Andean plants and the cheapening of the febrifuge, beyond what could possibly be expected, the operation viewed merely in the light of a commercial transaction, has yielded a high money return. Apart from the value of the properties which still remain in the hands of the Madras Government, their own balance-sheet shows that while the expenditure from first to last, including simple interest, was Rs. 2,605,000, the net revenue was Rs. 1,57,000; showing a profit of Rs. 52,000. In the past year, notwithstanding the lower price of bark and the almost entire cessation of demand for seeds and seedlings, the balance to the good was no less than Rs. 2,174. In Northern India much was done to cheapen febrifuge and place it within reach of the poorer classes by the preparation of the mixed alkaloids, against which the only objections have been that large doses of it produced nausea (itself a curative process) in some cases and that a considerable proportion of the alkaloids failed to be extracted by the cheap and simple process adopted. As the bark has been produced so plentifully and so cheaply, this latter objection was so far weakened. The result of Mr. Broughton's failure to produce a satisfactory febrifuge in the south of India, led the Madras Government to sell the bark from their plantations, first in London and of late years in Madras, and they have also tried the experiment of getting parcels of their bark manufactured into the various alkaloids in London on their own account. Lately they placed about 2,000 lb. of bark at the disposal of Mr. Cleaver, a chemist got out, apparently, by Messrs. Arbuthnot & Co., and others, with a view to establishing the manufacture of quinine and other alkaloids in Madras, and in the government resolution on Mr. Lawson's report, it is deemed probable that a company will be formed and a manufactory established. Meantime, Mr. Hooper the new quinologist, had been so successful in preparing a liquid preparation of the bark that Surgeon-General Cornish, before his departure, had requested that 1,000 lb. of the febrifuge in this form might be supplied to the Medical Department. The one objection to what appears to be a most efficacious medicine, in this case, applies to the bulk and the danger of breakage. But stone bottles can be used, and as to cost of carriage, we have to set against this the fact that the liquid febrifuge is ready to be administered, without weighing or mixing, doses being indicated by a quarter of a wineglassful, a half or a full glass. We cannot but confess to a strong feeling in favour of the liquid preparation, although, of course, we are aware, how easily and rapidly Howard's elegant preparation, to which physicians are naturally wedded, can be diluted by means of sulphuric

acid (itself medicinal) and water. We await with interest the report on the thousand pounds of liquid febrifuge which Mr. Hooper was ordered to prepare, and the result of Mr. Cleaver's mission and experiments. It is stipulated that the "cinchona liquida" should contain 40 grains of alkaloids to the fluid ounce. Mr. Lawson takes no such favorable view as the Government of Madras does of the result of Mr. Cleaver's experiments, but he distinctly enunciates the opinion that "the cinchona alkaloids can be isolated as well, and much more cheaply in India as in any other part of the world." It is natural to think so, but attempts in the home of the plant in Bolivia have failed. The Howards and others have secrets, by which they are enabled to extract the last trace of alkaloid from the barks they operate on, but now that the raw material is so exceedingly cheap, the necessity for such exhaustive chemistry is not apparent. Mr. Hooper seems to have pursued the special study of quinology at the Hague, under the direction of Dr. de Vrij, the originator of preparations of mixed alkaloids, obtained by the cheap chloride of sodium process. One of the first services he rendered to the Government was to supply analyses of barks which they had for sale at Madras, the figures regulating the reserve prices. Mr. Hooper made analyses of 16 specimens of crown bark (*C. officinalis*) and 6 red bark. The crown bark gave such excellent results, in quinine alone as, from natural bark 3-18, mossed 4-09, renewed 1-22, branch 1-60, and root 4-10. In this case only the total alkaloids in red bark were shown, but quinine is separated in other reports. The percentage of total alkaloids in the red bark were:—Natural 5-10; mossed 6-87; renewed 6-81; branch 1-15 and 3-07; and root 8-17. The percentages are, of course, calculated on the dried barks, which are lighter by nearly one-third than the green bark. Our readers will observe that the mossing process, first adopted by poor McIvor, is still persevered with in the Madras plantations, and rightly so, where moss can be obtained abundantly at a low price, for an experiment made by Mr. Hooper confirms the conclusion arrived at by Mr. Broughton many years ago, that exposure to the sun and light is adverse to quantity and quality of alkaloids. Here in Ceylon but few owners of cinchona trees can afford covering of any kind.

Mr. Hooper gives a table (quoted on pages 417-418) in full, showing the alkaloidal value of the principal species of cinchona growing in Government and other estates. From the figures we gather that *C. officinalis*, natural bark, gave 5-21 total alkaloids, of which, 2-71 was quinine and 1-28 cinchonidine; mossed 6-07, of which quinine 3-58 and cinchonidine 1-31; renewed, only 5-94 total alkaloids, but then 4-49 of this was quinine and only .90 cinchonidine. The increase of the more valuable alkaloid in the renewed bark (renewed under moss), is very marked, it will be observed. The narrow leaved variety of *C. officinalis*, known as *angustifolia*, when mossed, gave 8-35 total alkaloids, of which 5-40 was quinine. This looks well, but the trees are too small to be worth cultivating extensively. The hybrids are really better, because they yield so much more bark. The bark of *C. pubescens* gave 6 total alkaloids of which 3-32 was quinine. The best *Ledgeriana* from South Wynnad (one of Capt. Cox's trees, we suppose) gave 9-94 total alkaloids, of which 8-41 was quinine. This, of course, would be the kind to cultivate if climate and soil were suitable and plants of the true type procurable. *C. morada* and *C. rubea* of 20 months old gave such promising results as 4-78 total

alkaloids, of which 1.53 was quinine. The crown bark was taken from trees growing on Dodabetta, some of which were 22 years old, some 19 and some 14. The younger trees gave better results than the older, and, whatever may be the case in the Andean forests, it seems clear that here in India, cinchonas pass their prime soon after the tenth to fifteenth year of their existence. As the hybrids are now so largely cultivated in Ceylon, we quote what Mr. Hooper writes about these:—

The bark from hybrid trees between *C. Officialis* and *C. succirubra* has received of late a great deal of attention from planters. There are two kinds, named respectively *C. Magnifolia* and *C. pubescens*. The first approaches in general appearance the *Officialis*, and the second very much resembles in growth and shape and size of the leaf the peculiarities of *Succirubra*. But as regards the alkaloidal composition, as far as my analyses have gone, the reverse seems to be the case, for in the alkaloids of the *Magnifolia* bark the cinchonidine predominates as in *Succirubra*, but the *Pubescens* bark forms chiefly quinine, and so exhibits a relation to the *Officialis*. In the accompanying table, the analyses of the Natural *Magnifolia* bark is the average of seven analyses made on selected trees at Naduvattam. The chief alkaloids are cinchonidine and quinine, and the totals very often reach as much as 8 per cent. The highest total in a bark, I have met with, was from a hybrid tree grown in the Ouchterlony valley; it gave on analyses 14 per cent. of quinine, the other alkaloids bringing the sum up to 10 per cent. This bark very readily yields more quinine by stripping, mowing and re-growing, a fact which is seen in the table where the increase appears to take place at the expense of the cinchonidine. This feature will be observed more distinctly by quoting the analyses of some samples lately received, also grown in the Ouchterlony Valley:—

	Quinine.	Other Alkaloids.	Total.
Original bark ..	1.35	5.87	7.22
Once renewed ..	2.46	4.22	6.68
Twice renewed ..	3.60	3.99	7.59

The analysis of the *Pubescens* was made on a natural tree planted in the year 1866; there is a fair amount of total, more than half of which is quinine. The *Ledgeriana* barks operated on were found to be very thin, whereas the specimens we saw from Yarrow estate in the Pussellawa district, were remarkable for their thickness. A *succirubra* tree 23 years old, 31 feet high, growing at Naduvattam was divided into parts each of which was analyzed, with the general result thus stated by Mr. Hooper:—

The table shows that the minimum yield in the stem was in that part at which the branches were given off, and that the smaller and thinner bark of the summit and branches contained more than the thicker bark at the base. The ratio between the quinine and cinchonidine remains constant throughout the stem and branches. The root is an exception to this rule as the quinine is in the ascendant, and as usual is rich in quinidine. The whole examination is a proof that trees when neglected and exposed deteriorate very perceptibly in their alkaloidal value; also that in fast-growing cinchonas a maximum yield of alkaloids is reached at a somewhat early period, and unless the yield is encouraged by removal of the natural bark and renewing under shelter, a decrease of the alkaloids takes place.

As a general rule, cinchona bark gives 3.50 per cent. of ash. Ceylon tea gives 1 to 2 per cent. more, which seems an unexpected result? Mr. Hooper analysed other products, and we quote the results in two cases as of local interest:—

Moringa Gum.—The gummy exudation of the Horse-radish tree (*Moringa pterygosperma*) consists chemically of a large quantity of bassorin or insoluble gum with a small proportion of arabin or the soluble kind and a trace of moringa-tannic acid. It swells up to a remarkable extent when steeped in water, gelati-

nizes with ferric chloride, gives an abundant precipitate with subacetate of lead, and is soluble in caustic alkalies. In these and other respects it resembles the Gum-Hogg of America. Gum-Hogg is derived from an unknown source and imported from the East Indies; it is used in marbling paper for binding books. It seems not improbable that Moringa gum if not identical with it, could be used for the same purpose in the arts.

Deposit from the milky secretion of the Jack-fruit (*Artocarpus integrifolia*).—This was a thick white tenacious substance similar to bird-lime, with no marked odour and taste. It contained 20 per cent. water and the residue burnt with a bright flame giving off a sooty smoke. It was insoluble in water, partly so in alcohol, and entirely in benzol. It was a variety of caoutchouc, and as such would be useful as a bird-lime, and a cement for broken articles.

The season had been distinguished by drought at Dodabetta, only 61.20 inches having fallen spread over 123 days, most of the rain falling in storms. At Naduvattam, which gets the south-west monsoon in force, the rainfall was 92.96 inches spread over 111 days, a great deficiency on ordinary years. A storm of 19.38 inches in July with fierce wind destroyed the June planting. The following passage will sound very strange to Ceylon planters; who believe in keeping the ground perfectly free of weeds:—

Of the 11.80 inches which were recorded in October, no less than 11.0 inches fell in about thirty hours. Of course such a continuous downpour necessarily caused some wash, but owing to the ground being well covered with weeds, the damage done was comparatively trifling. Again, Mr. Lawson writes:—

Dodabatta.—The trees on this estate, taken altogether, are in a fair condition. Those parts of the plantation, the trees on which I stated in my report of last year to be past their prime, have been coppiced and interplanted. The coppiced stumps have already nearly all of them thrown out shoots, and the inter-planting is also doing well. For fear of denudation of the soil taking place during the heavy spring rains and before the ground would be covered with weeds, I had a number of brushwood revetments made on all the steeper slopes where the trees had been cut down.

Naduvattam, which had been neglected, was in course of resuscitation, and the plantings of 1882 and 1883 looked exceedingly well because they had been liberally manured. Much attention is paid to manuring on the Nilgiri plantations, cattle being easily and cheaply kept and Mr. Lawson had added to the establishment. Of course a great deal of the bark which went from Ceylon in former years received the benefit of the manure applied to the coffee in which so many of the cinchonas grew. About 400 plants of *C. Cartegena* are reported as growing well and so with a single remaining specimen of the *Santa Fé* species. Mr. Lawson states in his report on Naduvattam:—

I propose grouping together in this part of the estate all the different species and more strongly marked varieties of cinchona which have been grown in Southern India, in order that those who take an interest in the history of the introduction of the cinchona into this country may have an opportunity of studying the different kinds side by side. Again, because many of the species so freely hybridize, the plants which I propose to establish here have all of them been raised from cuttings which have been taken from the trees originally introduced by Mr. Clements Markham and others.

It will be convenient to mention here that Mr. Jamieson has raised from the seed sent by Mr. T. Thistleton Dyer from Kew about 200 healthy plants of the *Kenjia*, which yields the *Cayena* bark. These I shall, before the end of the season, plant out also at Naduvattam.

We should think it scarcely worth while to grow this latter tree beside the true cinchonas. The trees on the Wood estate had been destroyed by "the pestilent sambar," what we call the elk in Ceylon and which seemed to have ceased their ravages in Ceylon. Mr. Lawson makes rather an Irish statement:

I have ordered at a cost of Rs91-11-6 barbed wire, with which to entirely fence the estate, as I have found that trying to shoot the sambar down is of little avail; for as fast as one is shot another takes its place. Mr. Rhodes Morgan, Deputy Conservator of Forests in the Southern Circle, who has spent much time in patiently investigating the habits of these pests, informs me that the sambar is migratory, and that there is a constant stream of them passing at one time of the year from the plains to the hills, and at another time of the year from the hills to the plains. This, if correct, fully explains why there is no apparent decrease in their number notwithstanding the assiduity of the Government sikhari.

Now, surely, whether the sambar (*Rusa Aristotelis*) is migratory or stationary, surely constant shooting would thin the numbers if it did not extirpate the deer. From our hills this great animal is likely soon to disappear. We quote what Mr. Lawson writes about hybrids:

There are two notable species of cinchona, viz.:—

- (a) *C. succinbua*.
(b) *C. officinalis*.

These two species freely hybridize. Some of the hybridize approach more closely to *C. succinbua* while others approach more closely to *C. officinalis*.

C. robusta is the name which has been given by Dr. Trimen to all such hybrids.

C. johannensis is the name given on these hills to those hybrids which more closely approach *C. succinbua*. This form thrives best at a moderately low situation and in more sheltered places. It has the light green tender leaf of *C. succinbua* and the same habit of growth, but it is slightly more hardy.

C. magnifolia is the name given to those hybrids which more closely approach *C. officinalis*. This form grows well at high elevations and on exposed and rocky ground. The leaves in its most characteristic form are of a dark, rich glossy green; they are also tough and leathery, which enables it to resist better the evil effect of high winds. In its habit of growth it is similar to *C. succinbua*, but is much more sturdy.

Experiments which I have made on the keeping properties of cinchona seeds show that it loses its germinating power if kept several months exposed to the air, but that if the air is excluded, the seed retains its vitality for a considerable time longer.

Perfectly fresh ripe seed ought to be a pale green color, but a short exposure to the air turns this to a dull red. This change is due to the oxidation of the fixed oils which the seed contains in great abundance. This change in color is by no means necessarily indicative of the seed having lost its germinating power.

The bark taken off the trees in the year was 118,000 lb.

The following items are interesting:—

FUEL SUPPLY.—In my last year's report, paragraph 80, I stated that the sholas upon which the estates had hitherto been dependent for fuel were nearly exhausted, and that I proposed replanting the old sholas with *Eucalyptus* and *Acacia malacalypha*. This was in a great part done, but owing to the unseasonableness of the weather immediately after the planting had been effected, nearly the whole of the trees died out. I do not now intend making any provision for a fresh supply of fuel trees as I have recently learned that the Forest Department will be able to give all that is needed by the estate at a reasonable cost close at hand.

LABOR.—I am happy to say that I have been able, at last, to do away with the system of paying the maistries on the Naduvattam and Hooker estates a commission on the earnings of the coolies employed. The maistries are now paid fixed salaries only. This alteration has been made possible during the last year only on account of the great decrease which has occurred in the demand for labor in the Wynad.

The proper storing up of manure has hitherto been sadly neglected, the subordinates on the estates having been utterly ignorant of the first principles upon which this branch of agriculture ought to be conducted. I have, therefore, during the past year paid special attention to this subject. Formerly the daily produce of the cattle sheds was thrown out in loose heaps, where half of the valuable ammoniacal salts, according to the season, were either evaporated or washed away. I have now had pits dug eight feet deep and the produce of the cattle sheds well trodden down when it is put in and, whenever necessary, watered. I have also at Naduvattam, Hooker and Wood, where the rainfall is excessive, put a roof of thatch over the pits. By these means I look to being able to turn out in all seasons exactly the sort of manure I wish to have—that is a short well rotted compost very rich in ammoniacal salts.

NURSERIES.—Owing to the small demand there is now on the part of the public for cinchona plants, I have reduced the number of nurseries on all the estates to one a piece. This is ample for the requirements of the plantations and will also suffice to accommodate 100,000 of each of the more commonly grown varieties, should a demand for plants again arise. Last year some 1,000,000 seedlings were thrown away as useless.

From the accounts we see that the expenditure on manure last year was no less than Rs6,361. We notice that the quantities of green bark obtained from trees under the stripping and mossing processes, were 3 lb. per tree; coppicing and uprooting 1 lb. per tree; seraped 1 lb.

The Government order on the reports takes it or granted that the Nilgiri hybrids will be represented in the collection which Mr. Lawson proposes to bring together; the result of the application in former years of artificial manures is asked for, and it is stated that the result of Mr. Lawson's experiment with silos will be watched with great interest. From this order we gather that the liquid preparation of cinchona can be obtained 30 per cent cheaper than the North of India febrifuge and that it is hoped the price may be still further reduced. The sales of bark were better than had been expected. The estimates were 600 bales of 100 each at Rs75 per bale, but the actual sales reached 819 bales at a fraction over 100 rupees each,—that is Rs1 per lb. average.

The detailed papers (which are given on pages 117-118) will be found interesting and useful, now that cinchona is rather looking up again.

REPORT ON THE GOVERNMENT CINCHONA ENTERPRISE IN JAVA FOR THE 2ND QUARTER 1885.

(Translated for the "Tropical Agriculturist.")

The weather continued very rainy during the first part of the quarter. About the middle of May a severe drought suddenly commenced, which lasted till the end of the past quarter. The drought was accompanied by strong east winds, and the temperature went down at night almost to freezing point; at Tjibitoeng night frosts even were experienced, which however did no harm to the plants. The dry weather and the high temperature during the whole of the day exercised, after the continuous and abundant rain, a very favourable influence on the plants, and the harvesting was carried on vigorously without hindrance. Of the crop of 1885, which was estimated to

reach about 400,000 pounds, and of which about 130,000 half-kilograms have been gathered, 81,850 half-kilos were dispatched to Batavia by the end of the quarter. At the beginning of the second quarter several *Ledgeriana* descendants, which were shaved on both sides during last year, began to droop to such an extent, that it was considered necessary to uproot the sickly individuals. At Tjinjroean and at Nagrak only traces of a temporary drooping were noticed, at Tjibeneum such was in a small measure the case, while at Tjibitoeng and at Rioenggoenong the damage done is pretty considerable, and an unseasonable harvesting is therefore absolutely necessary. The drooping and dying of the scraped trees is probably due to insufficient working of the soil in some plantations, so that the trees were unable to recover quickly from the operation performed on them, and also originated in an insufficient expiry of time between the successive operations. But in all probability the abundant and continuous rain also exercised an injurious influence. Altogether about 5,000 six to seven year old *Ledgeriana*, chiefly of inferior quality, were dug out. But in close plantations also at Rioenggoenong, which had yielded only a single crop of *Ledgeriana* shavings, the scraping method gave less favorable results. It is true that no dying trees were there met with, but the plants remained drooping for a considerable time, and the long-continued rain caused the unpeeled portions of bark of a very few individuals even to begin to rot. As the experiments carried out with the scraping method have not yet given a decisive answer to the question, how and when it ought to be performed, the results obtained call for reflection and caution, and the experiments will for the present be carried out on a more limited scale. Should it appear that the trees in close plantations cannot undergo the operation without danger, then, on account of the great advantage which such close plantations offer, through the formation of a maximum of product with a minimum of upkeep and the formation of humus in a large measure and the physical and chemical improvement of the soil which accompany it, the practice of the scraping method must be entirely abandoned as soon as possible. At the end of the past quarter a commencement was made with the clearing of a *Calisaya* plantation at Tjibeneum which yields a pharmaceutical bark perhaps surpassing in form and appearance anything sent as yet into the European market either from the American forests or the Asiatic plantations. On 7th May and 5th June sales of cinchona seed were held, which realized respectively /1,652.25 and /339. The search for *Ledgeriana* trees of high quinine yield among the descendants of the mother trees 23 and 38, resulted for artificial propagation and for the production of rich seed plants, has been carried on also during this year. The results were again very satisfactory, as among the 7 and 8 year old descendants were found eight specimens which seem to contain more than 11 per cent quinine in the bark. A series of analyses of *succubra* hybrids raised from *Ledgeriana* seed gave rather important results, as will be seen by the accompanying statement. Although shape of blossom and habit of a tree give no right to infer a very high quantity of quinine in the bark, yet the hybrids chosen, agreeing with *Ledgeriana* either in habit and form of leaf or blossom, were distinguished throughout by a very high collective yield of quinine. Analyses 3 and 4 are specially noteworthy, as they exhibit, with a medium yield of quinine, which is also met with in typical *Ledgeriana* of a similar age—8 years, a yield of cinchonidine which exceeds even that of *succubra* barks. The experiments are being continued, chiefly with the object of finding among these hybrids trees which can be set apart for the supply of seed like No. 23c, whose bark is distinguished by a high yield of quinine of 10.33 per cent and in which neither cinchonidine nor cinchonine is met with.

VAN ROMUNDE,

Director of Hort. Cinchona Enterprise.

Bandoung, 3rd July 1885.

PLANTING IN AUSTRALIAN NORTHERN TERRITORY.

The following is from an abstract of the very interesting and voluminous quarterly report on the Northern Territory by the Government Resident (Hon. J. L. Parsons):—

Palmerston, 1st, July 1885.—The cloud of misfortune has not lifted yet from Agriculture, about which I, for one, however have an unshaken confidence of its ultimate prosperity, and of the settlement here of hundreds of happy families engaged in the cultivation of tropical products. It is, no doubt disheartening to see failure after failure, and delay succeeding delay, for which not the climate nor the soil are responsible, but the want of prudent foresight and of business management. Even liberal expenditure will not make amends for the want of timely preparation and readiness, when everything depends upon the season. Two strong survey parties, under Messrs. Hingston and Cutbertson, have gone to the Daly. By the close of the present dry season it is expected that the whole of the suitable land on both banks will have been surveyed, and the Government will then be in a position to place agriculturists upon a large area of country. Letters continue to reach me from Queensland, Fiji, Mauritius, and elsewhere, containing enquiries respecting our land laws, climate, soil, and other particulars, with reference to tropical agriculture.

Port Darwin, 21st Sept.—Mr. Otto Brandt has completed his sugar factory at Shoal Bay. Although the cane is several weeks past its prime, he obtained the satisfactory average of nearly one ton and a half of fine white sugar per acre, He

expects to have 250 acres under crop next season.

The Daily River Plantation Company are vigorously planting their nursery for next season's rattoons; they are also trying other tropical products.—*South Australian Register*.

TEA MANURES.

By MR. JOHN HUGHES.

EXPERIMENTS WITH BONE-DUST AND CASTOR-POONAC.

Analytical Laboratory, 79, Mark Lane,
London, E. C. 9th Oct. 1885.

I have carefully read the interesting account of Mr. F. Carter's experiments with the abovenamed manures, as published in the *Tropical Agriculturist* (see page 311), and have no doubt that the elaborate and detailed calculations in reference to the results obtained thereby have long since been duly criticized by many experienced planters in Ceylon as well as by numerous fellow-workers in India.

The general opinion will probably be that the increased yield of made tea was not sufficient to compensate for the heavy cost of manure, and that the outlay of R63 in one case and as much as R70 in another experiment is far too great, if any substantial profit is to be made from the estate.

The experiments however, so far as they go, are highly suggestive, and the author deserves the gratitude of planters for publishing his results.

It is perhaps a matter of regret that the two experiments were not made more directly representative of *bone-dust* as opposed to *castor-poonac*, each being used separately; instead of a mixture of these two in plot 2, and an immense dose of castor-poonac in plot 3.

It will be remembered that in plot 2, 18 cwt. of a mixture consisting of one-third *bone-dust* and two-thirds *castor-poonac* was applied per acre, the result being an increased yield equal to 196 lb. of made tea, as opposed to an increased yield of 285 lb. from plot 3, where 24 cwt. of *castor-poonac* alone were applied.

If we assume that, for the extra 6 cwt. of *poonac*, there was an equivalent increase, as compared with 18 cwt. (if such had been used over a separate plot), we can reduce the increased yield of 285 lb. to 214 lb.; and this result would still compare very favourably with that from plot 2 where the mixed manure was used as stated at the rate of 18 cwt. and cost R60, whereas the 18 cwt. of *castor-poonac* would only cost R52½.

Be this as it may, there can be no doubt that the general result of these experiments suggests that *castor-poonac* is, weight for weight, a more remunerative manure for tea during the first year or two than ordinary *bone-dust*, but whether the results are likely to be so lasting, is, of course, another matter and remains to be seen in the future crops.

Mr. Carter does not state anything respecting the composition of the materials used, but we may conclude that the *bone-dust* was of good quality, containing 50 to 52 per cent phosphate of lime and 3.70 nitrogen equal to 1½ of ammonia.

As regards the *castor-poonac*, it is important to know whether the white rich cake containing as much as 7 per cent of nitrogen was used, or the common brown cake which only contains 1½ per cent.

In comparing the relative advantages of *castor-poonac* and *bone-dust* we must remember the character of the crop we propose to take off the land. As I have already shown in my original article on tea manures, nitrogen is the element

which is most required; next comes potash; then phosphoric acid; and lastly lime. Now in every 100 parts of the white *castor-cake* we find at least 90 parts of nitrogenous and carbonaceous organic matter containing from 7 to 7½ parts of actual nitrogen which on decomposition will be equal to from 8½ to 9 per cent of ammonia, while the remaining 10 parts of mineral matters are specially rich in potash and phosphoric acid in a form admirably adapted for assimilation by the young rootlets of the tea bush.

If brown *castor-poonac* is used the percentage of nitrogen is only from 1 to 1½ per cent on account of the larger proportion of husks left in, while the amount of mineral matters is also reduced in proportion. In bones however we have only 33 parts of organic matter yielding 3.70 of nitrogen in every 100 parts, while the mineral portion is as much as 67 parts containing at least 50 per cent of phosphate of lime in a comparatively hard condition so that some years are required before the full value of the fertilizing elements can be utilized as plant food. Lastly, the proportion of potash in *bone-dust* is very small and cannot be considered as a ready source of supplying this element. In conclusion I may remark that it seems much more reasonable to apply a moderate dose of manure every other year, than to give 24 cwt. of a highly rich nitrogenous fertilizer one year and to allow the tree to suffer from famine during the next ten years, which would be especially trying under a stimulating climate. Where we have a poor soil and an exhausting climate it appears imperative to apply manure in small doses, year by year or at least every second year. In days gone by there have been plenty of examples in Ceylon alone, when over-manuring has very materially contributed to the premature abandonment of many good coffee estates.

In regard to tea it may therefore be well to proceed carefully in this matter, and to be on our guard against producing a coarse quality of leaf, which would certainly be the result of too much manure. Used in moderate quantity I have every hope that *castor-poonac* will be found a most excellent manure for tea.

TEA PLANTING IN CEYLON.

Extract from Mr. Irvine's letter dated Awisawella, 20th October 1885:—

You may put the following remarks down as general and simple axioms:—

1st. Tea, though a hardy plant, requires more care and skill in cultivation than coffee.

2nd. Tea will frequently be found to grow well on soil not adapted for coffee, or on worn out coffee land. Tea however will not grow well or remuneratively on every poor soil and frequently not well on soils commonly supposed to be rich. Good soil will tell both in the yield and quality of the tea as with any other plant—the better the soil, the better the tea.

3rd. The quality and flavor of the tea will vary with the soil, aspect, climate and elevation: no two estates will produce the same tea.

4th. The cultivation must vary or be adapted to the climatic and other conditions of each district.

5th. What is commonly called the jāt of the plant is not sufficiently considered with reference to climatic and local conditions, principally of elevation and soil: a variety of tea good on one estate may be worthless on another.

6th. Climate, soil, aspect and elevation are already having a most marked effect on the tea plant; a few years hence the acclimatized tea plant of Ceylon will have as well defined and distinct

characteristics as the "Robusta" amongst cinchonas, which by the way is not a "hybrid."⁶

7th. Cultivation good or bad will have as marked an effect on tea as on any other cultivated plant.

8th. The system of cultivation on some estates is already telling injuriously on the tea plant, which shows unmistakable signs of deterioration or stagnation.

9th. The "manufacture" of tea begins in the field.

10th. A bad leaf can never make good tea.

11th. Pruning and judicious plucking are the first requisites in making good tea.

12th. Tea making is in itself simple and requires no elaborate process, but constant care and watchfulness is absolutely necessary to produce a good tea even from the best leaf.

13th. Machinery will never make finer tea than carefully made by hand tea, but machinery of the best description will be found absolutely necessary to meet the requirements of a large estate and insure the minimum cost of production and a "uniform grade" of tea.

JAMES IRVINE.

PLANTING IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

NEW GUINEA—JAVA—SUGAR: COFFEE AND RAILWAY.

The *Batavia Dagblad* of the 24th September makes public the Charter granted by the Emperor of Germany to the German New Guinea Company in which the territory brought under its jurisdiction is defined as that portion of New Guinea not under British or Netherlands sovereignty now bearing the name of Emperor William's Land and stretching out, on the N. E. Coast of the island, from 141° East longitude southwards to the 8th degree of South latitude on the E. coast, and on the West coast, to where the 5th degree S. cuts the 141st meridian. It also takes in the Bismarck archipelago which comprises the islands lying off the coast of this portion of New Guinea, as well as those heretofore included in the New British Group and all others to the N. E. of New Guinea between the equator and 8 deg. S. and between 141 deg. and 151 deg. E. In return for the company undertaking to organise the government of the territory and meet the resulting outlay it is granted full governing powers along with the exclusive right to take possession and dispose of land within the boundaries fixed, and make treaties with the natives regarding land and claims thereto, under reservation, however, of the right of the Supreme Government to frame rules and regulations for the protection of the natives. The Supreme Government also reserves to itself the power to settle the administration of justice and direct the management of relations between the authorities of the protected territory and foreign Governments. The company must, however, be, legally formed and recognised as such before the 17th May next. A notification has also been published announcing that securing land there without permission from the German Government will henceforth, be not legally valid, and that only long standing rights will be protected and recognised. Arms, ammunition, and explosives as well as spirituous liquors may at present not be supplied to the natives. Natives may not be carried away from territory under German protection for employment as labourers except for German plantations but in this case, only from those portions of the Bismarck Archipelago where it has hitherto been permitted, but exclusively under control of German officials.

* The general opinion, scientific as well as popular, is opposed to Mr. Irvine's dictum.—Ed.

The second yearly report of the Deli Railway Company dated 25th September 1885 has been published, showing that the works in hand had been delayed by long continued heavy rains. It is, however, anticipated that the railway will be completed before the 3rd November 1886 the term fixed in the concession. There is every prospect of heavy traffic when the line is once open, from the spread of tobacco growing and the establishment of coffee plantations. It is becoming more and more apparent that Deli and Langkat are eminently suitable for tobacco cultivation and are far preferable for that purpose to the other petty states on the East Coast of Sumatra. Landholders in Deli seeing this, are exerting themselves in keeping their fallow land in cultivable condition by encouraging the growth of a jungle thereon. These circumstances point to increasing prosperity as being in store for the railway company.

The Java Government *Gazette* contains the report of the Netherlands Consul General at Saigon for the year 1881 in which, besides giving much information on other matters, he calls attention to the circumstance that sugar growing in Annam is carried on extensively, the raw sugar extracted with native appliances being exported on a large scale. Sugar making in the European fashion has fallen into disuse for some time from experiments on two estates proving very unsatisfactory. Though tobacco plants under cultivation there look strong and healthy, they seem to lack the chemical constituent part so highly prized in Europe. This at least may be inferred from the fact that the Government have stopped further experimenting with tobacco cultivation. Coffee growing in Cochin China nowhere yielded satisfactory results, though it must be acknowledged that no endeavour has yet been made to plant coffee at as great height above sea level as in Java. Of Netherlands Indian products such as coffee, arrack, and coarse sugar, not more is imported than is necessary for the troops. In Cochin China 100 kilogrammes of coffee brought 17-3 francs while 100 kilogrammes of sugar 57-5 were laid out on the average. The trade in arrack which was formerly great from its great consumption among the natives has greatly lessened in consequence of high import duties.

TEA RULES FOR NET WEIGHTING.

(From the *Home and Colonial Mail*.)

It will interest our readers to learn that a joint application in the following terms has been made to her Majesty's Customs by the representatives of the planting interest and the tea trade for permission to have certain slight alterations made in the above rules so as to admit of the satisfactory working of the system. The advantage of Indian tea reaching the consumer in its original package without having been turned out and repacked is now generally recognised.

The following is the application referred to:—

To the Commissioners of Her Majesty's Customs,

Indian Tea Districts Association,

14, St. Mary Axe, E. C.

Ober 1st, 1885.

We, the undersigned, speaking on behalf of both importers and dealers, beg respectfully to draw the attention of the commissioners of her Majesty's Customs to certain grave defects revealed in the practical working of the new rules, issued on Sept. 11th, 1883, for the weighing of Indian teas in bond, which go far to frustrate the objects aimed at in framing them and to propose a few simple amendments by which those defects would, it is believed, be effectually removed.

We here subjoin the rules as at present in force, and in the amended form proposed for adoption.

EXISTING RULES.

1. The packages on arrival to be weighed to ascertain the gross weight of each package.

2. With each entry the importer to give an endorsement or statement of the net contents of each package.

3. To test the accuracy of the endorsement or statement of the net contents, ten per cent of each break to be turned out and weighed net, but in no case should less than three chests be turned out.

4. If the variation in weight of the test packages be found to exceed one pound the whole parcel to be weighed net.

RULES IN AMENDED FORM.

1. The packages on arrival to be weighed to ascertain the gross weight of each package.

2. With each entry the importer to give a statement that the teas in each break have been bulked in India and the chests of each break contain even net weights.

3. To test the accuracy of this statement, ten per cent of each break to be turned out and weighed net, but in no case should less than three chests be turned out.

4. If the variation in weight of the test packages from each other be found to exceed two pounds the whole parcel to be weighed gross and tare. For instance, if the test packages weigh not 79, 80, 81 lb, respectively its variation would not exceed 2 lb., but if one package be found to weigh 79 lb. and any other 82 lb. or more, then the whole break would be weighed gross and tare.

5. That all teas bulked in this country shall be weighed gross and tare.

The declaration of net contents required by rule 2 is for all purposes of utility virtually superseded by rule 3, which determines the actual contents of the packages liable for duty to the Customs and for which the buyers have to pay.

But while thus of no practical beneficial use or protection to either her Majesty's Revenue, importers or dealers, it is found to be a constant source of inconvenience and disturbance to the satisfactory working of the system as a whole.

This arises from the restrictive influence it is made to exercise on the free operation of clauses 3 and 4—in the requirement that the contents of the 10 per cent test packages shall not only be of even net weight in themselves, but shall also be in exact accord with the "endorsement or statement of net contents" contained in rule 2.

Whether from atmospheric influence or other causes discrepancies, more or less material, are very frequently found between the weights invoiced from the tea gardens and given in the declaration under rule 2 and those actually ascertained under rules 3 and 4 resulting in the entire contents of the invoice being turned out to the serious detriment of their condition, and regardless of the fact that the 10 per cent test packages may have fully fulfilled the condition of uniformity of weight prescribed in rule 4.

The proposed amendment in rule 3 is made merely to bring it into harmony with rule 2 as amended.

As the margin now proposed is still well within the range of variation allowed in the treatment of China teas, we trust this as well as the other amendments will be sanctioned.

Our chief aim, in fact, is to assimilate the two systems as far as possible in all essential points while retaining the privilege of net weighing for teas bulked in India so as to obviate the necessity in such cases of a uniform tare weight.

For the India Tea Districts Association,
 ERNEST TYE, Secretary.
 For the Wholesale Tea Dealers' Association,
 R. SNOOWICKS, Hon. Secretary.

SOME SAMPLES of Queensland sugar that have come under my notice lately have created not a little astonishment among Mincing Lane experts in such matters. What has been most noticeable in the specimens noted is their extremely high sweetening power as compared with good West Indian varieties. Certainly, if Queensland can send us sugar like that in question, a very large trade in this direction may be very certainly anticipated with the United Kingdom.—*European Mail*.

THE DUTCH GOVERNMENT AND COLONIES.

THE NETHERLANDS TRADING COMPANY.

From the August number of the *Revue Coloniale Internationale* we translate the following:—

During 1881 the Company received from the Dutch Government the following produce, which was sold publicly by the Company on account of the State:

927,800 bales of coffee which realized	33,547,062 40
123,938 bars of Banca tin	
3,932 " " Billiton " "	4,261,064 72
2,989 packages of cinchona bark	347,818 51

Total.../33,556,812 69

On its own account, the Company sold 75,259,606½ worth of produce, comprising coffee, Billiton tin, cinchona, tobacco, tea, copal gum, figs, rum, arrack, margarine, petroleum, and gold from Surinam. It disposed of this produce for 3,117,359 17 florins in the Dutch markets, and 1,812,217 05 florins in the English markets. It also exported, on account of third parties, the following produce:—

To Netherlands India to a value of	3,661,583 florins
" British	93,390 "
" China and Japan	89,593 "

It likewise exported, also on account of third parties, a sum of 2,193,953 78 florins in specie.

With regard to the operations of the agency (*factorij*) of the Company at Batavia, the report gives the following details:—

The Company cultivated on its own account 1 coffee and 1 sugar plantations; it assisted in the cultivation of 1 coffee plantation, 1 sugar estate, and 1 sawmill; the contracts of the Company comprise 25 sugar factories, 6 coffee plantations, 1 cinchona estate, 1 indigo do., 1 arrack distillery, 1 sawmill, 1 tea estate, 1 birdsnest concern; of these, 13 sugar factories, 1 coffee plantations and one arrack distillery are hypothecated to the Company. The poor production of the coffee plantations has been the cause of somewhat serious losses in the working, and the estimated value of these plantations has had to be considerably reduced. The working of the sugar factories has also given rise to losses, in spite of the largeness of the crops, in consequence of the fall of the produce; the estimated value has been kept at a low figure, in spite of the extension of one of the factories, necessitating a considerable sum. The next crop promises to exceed that of 1881. The dissolution of the connection of the Company with a rice plantation and a sawmill has been equally unfavorable in both cases. Altogether the agricultural business has caused a loss, in round numbers, of 1,100,000 florins. The various concerns produced:—1,019,937 piculs of sugar (the picul equals 61 76 kilos, or 133 33 English lb.), 27,320 piculs of coffee, 135 piculs of indigo, 113,151 pounds of tea (the Amsterdam pound equals 0 49 109 kilo, or 2½ English lb.), 691½ casks or arrack, 5,182 pounds of birdsnests, and 266 piculs of cinchona bark. The sugar crop of 1881 was sold in Europe at prices unremunerative on the whole. The new crop is selling better. The Company has done all in its power to assist the companies and houses threatened by the agricultural and financial crisis, even those in which it had no direct interest. The financial operation of the Company in Netherlands India have been greatly extended; a sum of 7,700,000 florins was advanced on the security of merchandise, of produce and of titles; a sum of 6,100,000 florins was received in deposit by the agency of its branches. The total result of the operations of the agency was, in round numbers:—

Profits:			f.
On account of commission	611,000
" interest	981,000
" bills of exchange and insurance	316,000
from which must be deducted:			f 1,908,300
Expenses of working		...	394,000
Losses on produce and merchandise	40,000
Losses on debtors	153,000
" agricultural concerns	1,100,000
Balance to the good...			f 220,000

With regard to Dutch Guiana, the report records the following facts:—

The return from the sugar plantation "Resolutive" was much below that of 1883: it was only 527,000 kilos, against 1,039,000 the preceding year. The great drought which prevailed in 1884 totally destroyed many fields of canes. The price obtainable for the produce was low, so that the working entailed a considerable loss. The cultivation of cacao on "Mon Tresor" plantation is progressing slowly. The central sugar factory received 16,600,000 kilograms of canes, the yield being advantageous from an industrial point of view, but the financial result was nevertheless unfavorable, on account of the fall in sugar. The working of auriferous lands was equally barren of good results. Finally, in consequence of the fall in sugar, the estimated value of the properties has been lowered, so that the Surinam agency gives a total of losses amounting to 619,000 florins. The pronounced rise in sugar permits the hope of a better result in the future, although the greater part of the last crop has been already sold at a low price, so that the financial year 1885 does not promise much.

The Company holds, to the value of 9,371,700 florins, stock and shares of the State, of colonies, towns, mortgage banks, colonial banks of issue, of railway companies both in India and in Holland, of steamship companies, of canals, of dry docks and coasters, of agricultural, commercial and industrial societies. The interest and dividends yielded, in 1884, 802,000 florins, while the loss by the end of December had reached 222,000 florins. The Company has obtained the concession of a railway from Batavia to Bekassie, which concession it has given up to the Eastern Railway Company at Batavia, which was started to work this line with a capital of 1,700,000 florins, of which capital a large part was subscribed by the Trading Company.

The total result of 1884 has been for the Company, in round numbers:—

Profits:			f.
Batavia agency	220,000
Commission	913,000
Interest	1,806,000
Stores and property	16,000
Bills of exchange	19,000
Foreign debtors	1,000
Various receipts	10,000
			2,485,000
Deduct for losses:		f.	
Merchandise from India	..	24,000	
" to	..	6,000	
Agricultural enterprise	..	619,000	
Stock and bonds	..	222,000	
Expenses of working	..	185,000	
			1,054,000
Balance to credit			f 1,431,000

to which must be added a balance of 76,003.30, from the year 1883, which allows of the distribution of a dividend of 10 florins per share of 1,000 florins on the capital of the Company, which amounts to 35,783,000 florins.

THE SYRUP of Maidenhair fern is surely a novelty. It is said to be valuable as a medicine. Few would have thought that there was much to be got from this beautiful and fragile fern though of course there is any amount of sweetness generally speaking in the maiden, abstractedly from the fern. The maidenhair abounds on these hills and if it can be made useful as well as ornamental our chemists ought to be up and doing.—*South of India Observer.*

CANARIES.—I have been very successful both here and in England in rearing canaries. I find that here the young birds are very weakly and do not leave the nest nearly so soon as in England. The nests here should not be lined and the cages kept in a cool place. If the cock-bird does not destroy the eggs, or disturb the hen, it is better to have him in with her. Only once I reared four young ones out here, out of one nest. I left home for three or four days, leaving the birds in my boy's charge; when I returned they were all dead of starvation at the bottom of the cage. The way that boy ran round the bungalow would have been amusing to see.—*Cor.*

THE "QUARTERLY JOURNAL OF VETERINARY SCIENCE IN INDIA."—The October number of this quarterly, which has reached us, contains a good deal of interesting matter relating to veterinary science in India. The following extracts from a paper on "Snakes and the Prognosis of Snake Bite," by "Snipe," may be useful to our readers:—

I have often been surprised at the ignorance displayed by members of the profession on this subject in a country where snakes are so common. The truth, however, I suppose is that so very seldom do they do mischief to man or animal that our attention is but rarely called to them in the course of our professional duties. Usually when a snake is killed the nearest native is appealed to, who, a hundred to one, declares it to be a "bura kharab sanp," the sahib gives a slight shudder at having been so near such a brute, and goes on his way rejoicing, unconscious that he has killed an animal as innocent as a lamb and one of the greatest destroyers of rats, mice, and such like noxious vermin, that we have in India. One minute's trouble would have settled the matter satisfactorily, if he had only known how to set to work. When you have killed a snake and are doubtful about him, put your foot on the side of his head so as to force the mouth open, and pass the blade of a penknife or a piece of stick along the edge of the upper jaw, this will erect the fangs if it be of a poisonous variety, if there are no fangs it is harmless. . . . The *Daboia Erygans*, also called *Russel's Viper* and the *Chain Viper*. In Ceylon he is well known and much dreaded, and goes by the name of the *Tie Polonga*. Once noticed this snake will afterwards be always recognized, for his flat triangular head, blunt nose, well marked nostrils, and constricted neck are unmistakable. On opening the mouth the enormous fangs at once attract attention; he is a true viper, and does not bite but strikes with these fangs. In the larger specimens which run up to 3 feet 6 inches or perhaps 4 feet, there are series of oval white rings which make quite a handsome pattern on the dark skin; in the smaller ones there is a chain of these oval rings running from head to tail. He is far from uncommon round Secunderabad, and I have seen him at Bangalore, Bellary, and Saugor, so that he is fairly distributed over the Madras Presidency. He is a stolid brute and if lying across a path is just as likely to stay there till you tread on him as not; should you do so, his stolidness vanishes at once and he strikes like a flash of lightning.

TO RICE FARMERS.

We are indebted to the Government Agent for the following:—

KEROSENE OIL AS A MEANS OF KEEPING OFF
FLIES FROM LADY CROPS.

Report by H. G. R. Ratemahmaya to the Government Agent at W. North-Western Province, No. 451, 130, Hulugalla, 27th Sept. 1885.

Sir, I beg to report that kerosene oil is evidently a preventive to keep off flies from paddy crops. Numerous tracts have been seriously injured this current year, and others have been totally abandoned in consequence of these flies, notwithstanding every conceivable preventive the people appear to have adopted to protect their crops, until I thought of trying the effect of kerosene oil in a tract I have cultivated. Just as the crops began coming, swarms of these pests were known to be troubling the rice. As it had been discovered, I did not have a very simple plan for the suppression of these flies. Taking a thin rope to the length of the paddy beds, I soaked this in oil, and getting two men to stand at the two ends of one side of the bed, I drew the rope over the crop, I had them draw it quickly on over to the other end and continue this operation that day only in a few lines, where I could see the crop had less complaint of being, and the flies were consequently prevented, and for fear, moreover, that the oil might perhaps damage the ears. The day following and the next the flies had disappeared to that part of the tract where I had not tried the experiment, and, so far as I could have judged, beyond reach of the smell of the oil.

I subsequently discovered the oil to be perfectly harmless, so far as the tender ears were concerned, in the manner I had apprehended, and, not being too late, I repeated the application in the remaining part of the tract where the crop had now begun coming too. The tract has since been quite free from flies, and the crop, I am glad to report, is doing as well as I could have possibly expected.

I communicated the success I have experienced to many, but I regret to state that this has been rather late, the time for sowing having already elapsed, and the destruction occasioned by flies being now irremediable.

I think this experiment might be tried in the other districts, with advantage, where flies are equally destructive; and I have no doubt the people will readily adopt it when they come to be satisfied of the result I have experienced.—I am, Sir, C. G. R. Ratemahmaya of W. North-Western Province.

CHLORINE AS PLANT FOOD.—A German exchange says that chlorine is a very important nutrient for plants. To all appearance the chloride of potassium exceeds the nitrate in nutritive value as long as the quantity does not exceed a definite limit. When there is too much of the chloride, the quantity of chlorophyll decreases, the plants ripen sooner, but the oxalic acid increases in quantity. In fact, it acts just like hydrochloric acid would.—*Zeits. f. Pflanz. u. Thierzucht.*

DRAIN NEWS. (*Translated from the Standard Times.*)—The approaching winter crop does not look so well as the preceding one. Such is our answer to inquiries on the subject made by a reader in Europe. The long continued drought at the beginning of the year, whereby putting young plants out was prevented and the increasing rains in July and August, have, in a great measure, taken away every hope of securing a crop as heavy as that of last year. On the numerous estates in preference, the yield is neither so large nor of such good quality as was the case in 1884. The plantations opened out for the last year have had less to suffer but the complaint is general that never before have there been so many worst cases of loss. It is not only to such low fertile have been the victims of warmness some states. Where these drainage or others have spared has been destroyed by heavy rains and high winds. Though it is hard to make an estimate, it is the general belief that the crop will be 20 to 25 per cent. shorter than that of the year before.

THE PAPAW.

The accounts given by travellers and collectors of the uses and medicinal properties of the papaw tree (*Carica Papaya*) are as well-known to students of plant history as is that of the upas tree. We have most recently read how the application of the juice of the Carica fruit to a piece of tough meat would cause disintegration of the fibres and consequent tenderness. In his "Natural History of Jamaica," Browne says that meat quickly becomes tender if it is washed in water to which some papaw juice has been added, and if left in such water for ten minutes it will drop from the spit while roasting, or separate into shreds while boiling. It is also said that in Barbados, as well as in other West Indian Islands, it was once the custom to feed pigs on the green fruit; but it was found that if the animals consumed any very large quantity without sufficient proportion of other food, they not only suffered in health, but death actually followed in some cases from the intensity of the chemical action.

The Papaw tree is a native of the tropical parts of South America, but it has become common in many parts of the world. It usually attains to the height of about 20 ft., with a stem averaging 12 in. in diameter tapering towards the summit. The leaves are sharply pointed and deeply cut into seven large lobes. The margins are irregularly wavy or gashed. They often measure as much as 2 ft. in diameter, and are borne on long foot stalks. The flowers, which are small, are borne in racemes which start from the bases of the leaf stalks. The sexes are on different trees. The fruits vary in shape and size, but are more or less ovoid, sometimes ribbed or lobed and from 6 in. to 10 in. in diameter. They are orange-yellow in colour when ripe, and consist of a thick fleshy mass, with numerous black seeds in the centre.

The Papaw tree is often seen in cultivation in this country, and some good-sized plants are in the national collection at Kew. Owing, however, to the interest that has of late sprung up, not only with us but also on the Continent, regarding its chemical action, a great demand has arisen for the plants. In Brazil the tree is scarcely cultivated, or with but very little care, its continued planting being self-effected, not by shoots, but by seeds falling to the ground and germinating. Seeds often get sown by the use of the fruit as manure, or by the agency of birds, and trees thus rise up. The tender young plants brave all weathers, and are very tenacious of life, are not eaten by animals, and after growing to a height of about ten inches, few vicissitudes affect their quick growth, which is even more rapid than that of the banana. One writer says:—

The improved variety called "Mamao melao," which yields a fruit as large as a pumpkin, is treated with somewhat more care, and its management may even be called cultivation. The seeds are planted together with the flesh of the fruit, in a light soil, not too moist, and containing abundance of organic matter. If they be planted without the flesh of the fruit, only trees that yield the original fruit of the uncultivated kind are obtained. I had doubts respecting this, but have satisfied myself of its correctness by numerous experiments. When the plants are about three or four inches high, they are transplanted, and for this a lighter soil is selected, which is not too shady, and too much watering must be avoided; this is usually left to the weather. After fourteen or eighteen months the tree-like plants bear fruit through the entire year without cessation. After four or five years of this fruit-bearing existence the top commences to decay, and it lies from above downwards, the stem being eventually completely destroyed by the wind, if not previously removed by man.

This fruit, like the banana, is collected in the full-grown, but still green, condition, so as to ripen in the house. If perfectly ripe (that is, when the tree, the flesh, especially in the neighbourhood of the skin, is bitter, moreover the ripe fruit is difficult to secure against destruction by birds, &c., &c.)

MR. FARR ON UVA AS A TEA PRODUCING DISTRICT.

Sir.—The suitability of Uva for tea, the subject of your "special correspondent's" article in your issue of the 17th October, is of great importance to a large portion of the planting community; and, although I would not wish to detract from the merits of Uva as a tea-producing district, I would suggest caution before embarking heavily in this product. My acquaintance with Uva is limited to a stay of a few months on Pitaramalie Dambatenne, and the neighbouring estates in 1870, but I can remember enough of those places to feel confident that tea can be successfully grown in that part of Uva.

Whether the drier portions of the district would prove as suitable I dare not say. On my return from the Darjeeling tea districts, I, too, like Mr. Christie, modified my views with regard to the suitability of various climates for tea; but, upon mature reflection, I am not prepared to accept without reservation the statement that a rainfall of about 100 inches per annum in itself constitutes a suitable climate for tea.

My impressions, after becoming acquainted with the climate of Bengal, with its five months of winter or drought, were that by comparison the climate of Uva would be far more suitable for tea than that of Darjeeling, but the rainfall returns as given by your correspondent are not to my mind so satisfactory as they might be, whereas I should consider the rainfall of Sington (Ringtoun), as given by Mr. Christie, very nearly perfection for an *Indian* tea estate. By reference to the figures before me, I note that of the total rainfall of 119.40 inches, as much as 118.29 inches fell in eight successive months, unbroken by any semblance of a drought.

Now, although excessive rain with no gleams of sunshine has a prejudicial effect on the flushing capabilities of tea, there are no climatic conditions for luxuriant vegetable growth equal to drought and excessive moisture *with heat*; and the Darjeeling climate when tea is growing is more like a vapour bath than anything I know. A thick and steady drizzle all day, with an occasional break in the clouds and a gleam of sunshine alternated with heavy showers, is the nearest description of the Darjeeling climate I can give. Ferns, orchids, mosses, and begonias simply revel in the moisture, and if pulled up and thrown down on a bare rock in May would probably be found growing in September.

Now, has Uva 7 or 8 months of anything like this? And is the rainfall distributed in the same way as in India? If so, with its more genial climate all the year round, and its rich soil, this favored district might have every acre under tea with safety. There is nothing in Nature so prejudicial to the rapid and free circulation of sap as lack of moisture in the soil; and if during the rainy months in Uva droughts of 3 or 4 weeks should occur, I fear flushing would be checked very materially, and the planter would be divided in opinion as to whether he should prune a second time or not in the same year. For tea to give high yields, continuous flushing is necessary, and on the duration of this continuous flushing depends the number of maunds per acre secured. I do not fear a drought for tea by any means, but what I do fear is two or three droughts or a plucking season broken by intervals of very dry weather combined with a light and free soil. The intention and scope of this letter is not to sound a note of alarm with regard to Uva as a tea-producing district, but to urge caution in embarking in it on a large scale. In a soil retentive of moisture, tea would probably stand a few "spells" of dry weather without any appreciable diminution in yield, but it must be borne in mind that the even and vigorous flow of sap desirable for free and continuous flushing may be checked by excessive wet on a cold and clayey soil or by droughts on a free and dry soil, and these checks induce "hangy," and consequently a decreased yield; but I have no doubt that the figures of the Uva rainfall will in numbers of cases be found all that could be desired.

With regard to Kaluphani, if wind is the only obstacle there to the successful cultivation of tea, I would say plant it by all means, for steepness is of no consequence if surface wash is provided against; and in the Darjeeling hills wind is not feared by the planters except for their buildings, the roofs of which are kept on by means of large stones placed upon them, though these are occasionally carried away, roofs and all, in the windy months.—THOS. FARR, Lyndford, Oct. 19.—Local "Times."

ABOUT THE PRESERVATION OF WOOD.

CARBOLINEUM AVENARIUS.

(Important for Exportation.)

[The substance thus noticed in the *Indian Mercury* is worthy of attention, especially now that it is so difficult to obtain railway sleepers which will not rapidly decay. If Carbolineum will really enter the pores of the wood, than the only limit to its use will be its price.—Ed.]

Everywhere where wood is much exposed to the weather and the wet, constant and just complaints are to be heard respecting its speedy decay. All the coatings of paint or tar are useless in the attempt, of staying the ravages of decay, for they cover only, stopping the pores, the surface of the wood, and thus at most resist the influence of air and damp from without. But in the case of timber which is only imperfectly dried, these means prevent evaporation of the natural moisture of the wood, causing stagnation when it will frequently be observed that timber left entirely uncoated will withstand decay a much longer period. In the preservation of wood the success depends not alone upon the exclusion of air and water, but equally upon an application of such a means as may secure the destruction of the nitrogen embodiment of the same.

Already some years ago a specific preparation to oppose the cause of these complaints—an antiseptic oil known by the name of "Carbolineum Avenarius" found introduction, which owing to its incontrovertible advantages in the preservation of every class of timber and its extremely low price, has recently been accorded in Germany, Austria, Switzerland, &c., a much more general and ever increasing application by the state, the military and civil authorities, for railways, in carriage-building, house-building and in the industrial establishments, as likewise and prominently in agricultural circles.

Few discoveries of recent date will be of such general interest to so many branches of trade and of agriculture at the same time, as a cheap and approved practical preparation, which may be applied by anybody with the greatest of ease for the preservation of timber.

That a demand exists for a means of preserving wood which is used for such a variety of purposes, is evidenced by the manifold efforts made everywhere to achieve the object.

"Carbolineum" is a very liquid oil, of less gravity than tar, and far exceeds the latter in efficiency, beauty of appearance, relative cheapness, in fact to such an extent that even gas-companies producing tar as a bye-product are able of disposing thereof without costs, prefer to apply the former.

Carbolineum is easily applied, to dry wood as well as green timber, readily enters into the pores of the wood conferring upon the same a tasteful appearance resembling a coating with varnish, whereby the grain of the wood is not extinguished, and durability united to cheapness.

Carbolineum may be applied even on the top of old tar, or oil-paint coatings, as on the other hand also after complete drying, linseed oil varnish or oil-paint may be coated upon the former. In connection with railways for the coating of goods-sheds, goods-wagons, &c., it appears of imminent importance. Tar affords only a black, after some little time a dirty grey lue, which is not to be compared with Carbolineum.

Respecting the costs we are instructed that in comparison with oil-paint Carbolinum is just astonishingly cheap and compared to a coating of tar, of the liquid oil only a very small quantity is required for the same superficial space; 1 kg. being usually calculated to 6 □ m.

In danger of catching fire Carbolinum is by no means,* and if stored it will keep unchanged for any length of time. For the purpose of rendering damp walls dry, against fungi &c., Carbolinum has likewise proved effective. In stables it has proved not alone a means of preservation but a disinfectant as well, as it is said to eradicate vermin and even rats. Owing to the great and universal interest felt for the preservation of every woollen structure and utensil from the evil effects of the weather and the wet, to which they may be more or less exposed, to save building-timber, verandahs, wood-ornamentations and panelling, sheds, fencing, doors, shutters, field and garden utensils of every description, vineyard posts, &c., from rot and decay we may be pardoned in drawing attention to so valuable a material, which is at the same time so simple in its treatment. The material to which we here desire to draw attention is obtainable from Mr. P. Leehler in Stuttgart, where from the Factory-south, and Middle-Germany, and the entire Export funds supply, where every further information is furnished on application, and where small quantities for intended trials are obtainable.

TEA TASTER'S OCCUPATION.

A medical writer of an article in the *Medical Record* on tea tasting by brokers and dealers in tea, maintains that it is a healthful occupation, which is not in accordance with the conceived opinion of other writers on the subject. In support of his assertion he reports cases of living men far advanced in life who have followed the business of tea tasting for periods ranging from thirty to forty years without injury to their health. But whether the writer's conclusions are correct or otherwise, the life of a tea taster is a curious one, and the process of examining and deciding upon the qualities of the article is one not generally known.

There are, says the correspondent of the *Medical Record*, probably more than a hundred firms engaged in tea tasting in the City of New York, for instance. In all of their offices there are large tables with round, revolving tops. A circle of teacups is placed along the edge of these. The tea taster sits down before the display of crockery, and tastes one cup after another, moving the table-top around. In the centre of the table is a pair of scales with a silver half dime in one of the balances. One or two large kettles are kept constantly with boiling water in them. When a sample of tea is to be tasted, as much is weighed out as will balance the half dime. This is put in a teacup and the boiling water poured on. The tea taster then stirs up the leaves, lilt them on his spoon, and inhales the aroma. At the same time he generally takes a sip of the infusion, holds it in his mouth for a short time, and then spits it out. Enormous brass cuspadores, holding two or three gallons, receive the tea thus tasted and the contents of the cups that have been examined. On some occasions, when a large amount of tea of a certain kind is to be bought, many samples of this are brought in from different houses. The buyers and sellers sit around the revolving table with the samples made into infusions into the cups before them. These are tasted all around, the "body", "finesness", "toastiness", &c., are learnedly discussed, and the poorer specimens discarded. Then those that are left are tasted again and the number further reduced. So it goes on until the article which unites the desired quality and price is obtained.

The skill displayed at these "drawings" is quite remarkable. A tea taster will detect not only the

quality of a tea as regards age, strength, flavor, fineness, &c., but he can tell in which of the numerous districts in China the tea was grown. The facts regarding the different samples are sometimes put on the bottom of the cups, are then mixed up, and the infusions tasted again and sorted out by their flavors.

A great deal of tea may be tasted before these tea drawings are finished. It is hard to tell the amount that a tea taster takes during a day, for it varies a great deal with the activity of business. Few of the gentlemen whom I asked could give any idea. Sometimes, however, as many as four or five hundred cups are tasted in a day. It is quite the custom to have to be tasting tea steadily for the most of a day, or for hours at a time. Probably an average of two hundred cups a day throughout the year is a low estimate. The poorer kinds of tea are often not sipped at all. But the sense of smell is depended on. Of the better qualities of tea, some is swallowed, and some spit out. Indeed whenever tea is taken into the mouth a little of it is swallowed. The tea gets into the system, therefore in three ways: by inhalation, by absorption through the oral mucous membrane, and by the stomach. More tea is simply taken into the mouth without swallowing than is inhaled alone; but all the tea is inhaled, even if it is tasted also. It is only a small proportion, amounting to not more than two or three cups a day, that is swallowed. A silver five cent piece weighs 1.18 grms. (gr. XVIII). Estimating that an average of two hundred cups of tea are tasted per day, about one-half of a pound would represent the whole amount used.

Japan tea has of late years become by far the most popular variety,* and more of it is imported than of all other kinds together. Green tea, on the other hand, is much less extensively used than formerly.—*Lidian Mercury*.

THE BOTANICAL GARDENS IN JAVA.

During the last few years so many useful and important improvements have been made in the botanical gardens at Buitenzorg and Tsi-todas that it might not be amiss if the attention of the readers of *Nature* were again drawn to these valuable seats of systematic and philosophical research.

On entering the gardens at Buitenzorg the stranger is at once struck with the wealth and luxuriance of the vegetation he sees, the great height of the trees whose trunks and branches are in many cases covered with heavy creepers, the dense copses of the different species of bamboo, the eccentric-looking screw-pines and the handsome palm trees; but the scientific observer is also struck with the care that has been taken to arrange all these many varieties of tropical plant life in, as far as possible, their systematic order, and that each specimen has its scientific, and in many cases its Malay name also, clearly and distinctly printed on a little board by its side.

It is not difficult for any one to find his way about the garden, and in a very short time he can discover the particular family or group of plants which he may desire to study. Many families have probably more representatives in these gardens than in any in the world. The Sapotaceae, for instance, so rarely seen in Europe, are here represented by a great variety of genera and species, and the Palmaceae, the Rubiaceae, the Burseraceae, the Orchidaceae, and other families have now a large number of rare and interesting representatives.

The herbarium which is attached to the garden contains a large collection of dried plants and seeds collected together from the many expeditions into the little or unknown parts of the archipelago and from other sources. Attached to the herbarium there is a comfortable and convenient little library which

* The German idiom is amusing.—Ed.

* In the United States.—Ed.

contains most of the important botanical books and journals.

The laboratory, which, thanks to the energy of Dr. Treub, the director, is now completed, is a large, lofty and, for these climes, particularly cool room, and is well fitted out with reagents and apparatus for carrying on botanical research. The generous invitation which Dr. Treub has issued to naturalists, and to which the attention of the readers of *Nature* has already been directed has attracted several scientific men of different nationalities, and some excellent research has already been made in this laboratory.

When I arrived in Buitenzorg, Dr. Treub was at Tsi-Bodas; so, after spending a few days in study in the gardens, I made the journey across the mountains to pay him a visit. The road from Buitenzorg to Tsi-Bodas crosses the Poenbuck Pass and is full of interest and beauty. On the way the traveller passes quite close to the Talaga Werner, the crater of an extinct volcano which is now filled with water, and forms a most beautiful little lake hidden in the dense foliage of the mountain slopes. The path from the road to the lake is through a dense wood of fine forest trees, and amongst the undergrowth is found many fine shrubs and plants which are not found in the low-lying country beneath.

The gardens at Tsi-Bodas are situated on the slopes of the Gedeh Mountains, at an altitude of 5,000 feet, and here I found Dr. Treub at work in the comfortable little house which is attached to the gardens.

From this spot a very wide range of vegetation may be studied, from the rich and varied vegetation of the plains to the interesting vegetation of the Gedeh and Pangeranso peaks, at an elevation of 10,000 feet. In the gardens themselves a very fine collection of Coniferae from America, China, Australia and other parts of the world has been got together, and spaces have been cleared for the growth of the various species of Eucalyptus, Ciuchona, and other plants. Year by year the surrounding forest is being encroached upon by these gardens to make room for new importations. I was extremely sorry that I could not prolong my stay at Tsi-Bodas, but I had to return to Batavia to catch the Molucca boat. I saw, however, enough to convince me of the great importance of these gardens for the advancement of our botanical knowledge and the great opportunities they afford for research into all branches of the science.

I need hardly say that the climate in this region is extremely pleasant and invigorating, and the neighbouring village of Sندانaya is much resorted to on the coasts or low-lying districts of the Archipelago. At Buitenzorg the climate is by no means unpleasant or unhealthy, but as it lies a few thousand feet lower than Tsi-Bodas, it is naturally a good deal warmer; but I am assured that several Europeans have worked there for several years without feeling their health the least bit affected.

It is hardly necessary to add that every one who has come over to Java to work in these gardens has been amply repaid for the time spent in the long journey over the sea, for the insight which can be gained here into what tropical botany really is one which can be gained nowhere else in the world so well, and leaves an impression which is not likely to be forgotten in a lifetime.—SYDNEY J. HICKSON.—*Nature*.

UTILISATION OF IRON SLAG.—An ingenious application of a material hitherto regarded as worthless has been made in the utilisation of iron slag as an ingredient in the manufacture of foot pavement cement. The powdered slag being harder than the cement with which it is mixed, wears down less slowly, always presenting a rough surface, which is not slippery, and apparently of great durability. The pavement has been laid down in front of the Gaiety Theatre in the Strand.—*Field*.

RICE CULTIVATION IN THE CENTRAL PROVINCE OF CEYLON.

Sir,—The Central Province is a good large territory and it's not given to everyone of your readers to know the boundaries, but, when we have distinct reference to Uva, including Udakinde and Wilson's Bungalow, we know where we are, and probably the writer of this glowing description could not have hit upon a worse exemplification of his theory. The people of Udakinde are some of the poorest in the Central Province, and have lately been actually fed at the expense of Government, and, perhaps, it would be as well if the reason of this poverty were explained, and I may by and bye state what my experience has taught me. In the meantime the great reason why Udakinde, and the rest of Uva cannot grow more rice lies in the fact that all the irrigable lands have already been occupied: this of course as a general rule. There are doubtless small pieces of land here and there that with great labor might be irrigated, but after all the total of them is insignificant. That this is the fact is plain enough to anyone who passes through the country and keeps an eye open for the purpose. The miles upon miles of elas, from the Totapella and Nuwara Eliya ranges, convey the water an immense distance, and all available lands connected with them are already cultivated, and the only way to bring into cultivation any other portions of appreciable extent is the construction of reservoirs and channels at great expense and with little result. I am perfectly well aware that the idea prevails, amongst Europeans especially, that the villagers could cultivate rice to a much greater extent than they do. But if careful consideration is given to the subject, and something more than mere casual observation when travelling through the country, it will be found that whenever water can be got amongst the hills, advantage of it has been taken to asswalamise the land; even the smallest portion is not neglected. Then again I presume the writer in your contemporary suggests that with more care and trouble the villager could get a greater return for his labor; and here again there is a good deal of supposition that is in error. The surface of the soil is 'scratched' as deep on the hills as it is in Jaffna, and with double the amount of labor, from the nature of the small terraces on the steep hillsides, and the expenditure of time and trouble on the paddy fields of the hill country exceeds in an immense degree that on the same cultivation in the lowcountry, where so much hand labour is unnecessary. Then the hill fields are weeded, and left clean by gangs of women, with no small amount of trouble. There is little or no manuring; where are the villagers to get the manure from, and what appreciable benefit would they get from the return? The whole system of terrace cultivation, where the water flows over the land, precludes anything but careful, expensive manuring operations, and after all the resulting benefit would be very small.

As for neglect of attending to the water-supply, there may be such in fever-stricken and poverty-stricken villages, where disease and despair render the people callous and indifferent, but such is not the rule. Of course, as the writer puts it, on cold, wet nights a warm bed under cover is preferred to a tramp in the dark up and down steep slippery paths, but we must recollect that on such occasions the falling rain obviates any necessity for water to be turned on the fields. Laying all these aside, suppose for the sake of argument, each field in Uva could be made to double its present yield, the result wouldn't feed the villagers, the coolies, and the general inhabitants of the province itself, much less stop the import of rice.³ And what is true of Uva holds good in respect to all the hillcountry of the Central Province. You see a tract of land apparently capable of cultivation, and you will find it is Crown land, or in the hands of Europeans, or there is no water-supply, or something which has prevented its being availed of for the purpose.

In one respect, the Jaffna "Patriot" is right, though he evidently doesn't mean it. The Central Province is not altogether confined to the hills, and in on

portion at least encroaches on the low country to a great extent, and there is the place to grow rice, a stride to the Buitone country. (5) down to Buitone during the South-West monsoon and see what can be done by the one bank of Heralowwa, and then the turn along the bank of the Mahavalliganga and see the immense volume of the river, swollen and muddy with the monsoon rains, with its millions of tons of fertilizing water and silt, flowing idly and uselessly to the sea, through a parched and dead-up country, few-stricken and almost uninhabited.

Let the "Laffa" "Patriot" picture to himself the result of one or two ancient thrown above the bed of the river, or one or two pumps at work, throwing this fertilizing water over the surrounding country, where in places you might have level beds a mile in length. There is the water, and there is the soil; what is required is the application and that is in the hands of man. And it must not be forgotten that the exposure, over a large surface of water on the ground, has a corresponding effect on the climate in drawing moisture from the clouds, and in course of time altering the condition of the climate itself. In this portion of the Central Province there is room for extension, but this is evidently not what the "Patriot" is thinking about, he speaks of the hills-country, and his conclusions are wrong.—D. E., Pallerakelly, 8th September, 1885.—Local "Times."

CALIFORNIA.

(TO THE EDITOR OF THE "TIFLD.")

Sir,—Seeing in your issue of May 9 a letter under the above heading, signed by Mr. H. A. Vachell, and boasting on my own part of some experience in this State and in the vine and fruit interest, I leave space in your paper for a few words on the subject, and to show that the inferences to be drawn from the letter referred to are totally at variance with the condition of things existing here. With all due deference to the writer of this letter, I do not agree with his statement to the effect that California offers a good opportunity to emigrants, and indirectly a competency from vine and fruit culture; and I will endeavor to prove to you, by figures and facts indisputable, that the business is not what it is represented to be.

All the accessible and easily obtained land in localities suitable for vine culture has long since been taken up, and held at prices that do not justify reasonable expectations of a fair return some for capital and labour, to say nothing of a competency. A little land is still to be had in the foothills of the Sierras, but some distance from market, and everyone acquainted with farming operations knows that a hillside entails a costly business. Some land is also to be had in certain parts of Southern California at reasonable figures, but best to hold it without migration as a safe alternative.

The average of the last year in question estimates profit per acre at \$50. Let me go in for a few details. We will begin with a vine of four or five feet, 23 in girth. At the usual distance of 8 ft. apart each way, 60 vines cuttings will be carried per acre. These cuttings will cost 12s. per 100,000. Preparation of ground by deep ploughing, twice and harrowing, then marking out and planting, after that careful cultivation to keep down weeds, will cost £3 10s. an acre for first year; for second year, ploughing and constant cultivation, and to destroy weeds, will cost £2 8s. an acre; the same expense for third year; the fourth season again ploughing, the owner may consider himself fortunate if he can gather 1½ ton per acre for first year, and 3 tons thereafter as an average crop; irrigation and pruning such following year will cost £1 18s. to £2 10s. an acre.

A friend of mine in the Napa Valley planted some of his acres with Zinfandel vines; this was in the spring of 1881, and in 1881 he gathered his first crop, receiving in round numbers 600 dol., or £120 for same. From this amount must be deducted—cost of boxes, picking, and hauling two and a half

miles to the winery. The Zinfandel grapes (a cluster grapes, by the way) fetched the highest price at the winery last season, £14 10s. With regard to the above return, I may mention that one of the most practical men in the district considered it a very fair one for a first picking. The value of haul in this case was £20 an acre, at the least.

Truly, in some localities larger returns are to be obtained from cultivation of table grapes, but the market for this article is very limited, and the cost of boxing and freight to an Eastern market, after deductions for commissions, &c., is so considerable, that little margin is left. The estimated wine yield of this State was some 17,000,000 gallons for 1881, about equal to the demand. Taking into consideration the immense acreage of vineyards that will come into bearing during the next three years, it is estimated by practical men that the wine yield will at least reach 80,000,000 gallons by 1888; and where is this to be disposed of? The Americans are not consumers to the extent the French are; and again, California wine has not been favourably received in Europe; whether this is from prejudice or not I am unable to say. Already the price for wine grapes is on the decline. In the season of 1883 the wine makers made offers for the crop before it was ripe, the average price being 6s. all round, per ton. Last year, 1884, matters were reversed, for the wine makers formed a ring and dictated their own prices, the lowest figures being offered for mission grapes, £1 12s. a ton, less a dollar (1s. 2d.) per ton per degree of saccharine strength below a fixed standard of 22, the average being 18° obtained by the usual test.

In certain houses in California, notably at Palace Hotel in San Francisco, if native wine is called for, you are informed that only the French article is kept. But it is generally well-known where this so-called French wine comes from; the "brand," truly, is French.

Now as to the possibilities in the fruit line people in this State have grown almost cranky on the question; the yield within the next three years will be so enormous as to overcharge the market, and so fetch little or nothing. I will mention, by way of illustration, one instance of a nurseryman, who disposed of 10,000 fruit trees this spring, and in the same town there were two others who had a fair share of business. This wholesale planting is not confined to one locality; it has been going on all over the States? Where is it to end? With present supplies the market is often glutted; and as for canning and disposal eastward, the cost of same, adding heavy freight charges (for the railway monopolies have the Golden State by the throat), not forgetting also that labour here is considerably dearer than in the States, where, by the way, a lot of fruit is grown—will not amount to making a fortune; often the balance is on the other side.

The vine business has been overdone before. About nine years since vineyards were rooted up for this very reason, and we shall have the same thin over again, all of which is quite characteristic of the country, and an insatiable love for the "almighty dollar." To say anything of mildew, &c., phylloxera is making terrible havoc with the vine, which will not stand above ten or twelve years, under such conditions. The result of planting resistant stock does not yet seem to have been fully demonstrated. So anxious have people been to embark in the vine and fruit business, that mortgaging has been the order of the day. The mortgages in one small county, Napa, represent nearly three million dollars. Mortgages have been very general on the whole of the Pacific Coast, and I do not think it will be found that 10 per cent of the farms are free from incumbrances.

As for California being a favourable field for white labour, Chinese are so very plentiful that white men cannot compete with them. They are paid at the rate of 4s. 2d. a day; and 6d. a day will keep a celestial, who is content with any kind of shelter.

I have heard a great deal about the glories of the "Golden State;" but what strikes me as being most inconsistent with a "golden" condition of things is the presence of so many tramps looking for work—swagmen as they are termed in Australia, the swag being a bundle of blankets carried at the back.—O. H. GODFREY, Napa, California.

"MADAR."

BY C. J. H. WARDEN (ON FURLOUGH) AND L. A. WADDELL, Surgeons H. M.'s Bengal Army.

Botanical Characters.—In India, under the popular name of "Madar," two plants belonging to the Nat. Ord. of *Asclepiadaceae* are known—the *Calotropis gigantea*, or *Asclepias gigantea*, and the *Calotropis procera*, or *C. Hamiltoni*. The former is one of the commonest weeds throughout India, and is most abundant in the lower provinces and Eastern India; while the *C. procera*, which most closely resembles it, is found chiefly in the drier parts of Northern and Central India. Botanically, the *C. gigantea* is thus described by Drury* :—Shrub 6-10 feet; leaves stem-clasping, decussate, oblong-ovate, wedge-shaped, bearded on the upper side at the base, smooth on the upper surface, clothed with woolly down on the under side; segments of corolla reflexed, with revolute edges; staminateous corona 5-leaved, shorter than the gynostegium; leaflets keel-formed, crenately recurved at the base, incurved and sub-tridentate at the apex; umbels sometimes compound, surrounded by involucreal scales; follicles ventricose, smooth; seeds comose; flowers rose-colour and purple mixed. Flowers all the year. Both varieties grow well on the poorest soils, and are largely cultivated in some parts of the country as a hedge (Watt). * *

Economic Uses.—Certain of the economic uses of the madar plant have already been noticed, and we would here refer to the employment of the inspissated sap as a substitute for gutta-percha, and to the use of the fibre for paper making. Dr. G. Watt, in his work on "The Economic Products of India," states that madar is, in fact, the most interesting and most hopeful plant not belonging to the natural order of Sapotaceae, which can be said to yield a substance resembling gutta-percha, ever likely to obtain a commercial reputation as a substitute. Dr. Riddell, the Superintendent Surgeon to the Nizam's army, was apparently the first to separate and experiment with this gum, and his results were first published by Captain (the late Colonel) Meadows Taylor, in a letter to the Secretary of the Agri-Horticultural Society of India.† Afterwards, Dr. Riddle republished his discovery in the *Bombay Trans.* As these letters may not be accessible to persons likely to be interested by this subject, Dr. Watt republishes the more important parts, narrating the actual experiments.

"My dear Sir,—I observe in the last number of the *Society's Transactions*, that the madar—*Asclepias gigantea*—affords a very valuable kind of hemp or flax, and I have now the pleasure to communicate to you another valuable property it possesses, which has been lately discovered by a friend here, under whose permission I make the present communications to you.

"Dr. Riddell, the officiating Superintendent Surgeon of the Nizam's army, had for some time been employed in extracting or determining by chemical experiments, the well-known medicinal properties of this plant, and during his investigation, having had occasion to collect the milky sap, and expose it to the air, found, as it gradually dried, that it became tough and hard, and not unlike gutta-percha. This induced him to treat the juice as that of the gutta-percha tree is done, and the result has been the obtaining of a substance apparently precisely analogous to gutta-percha, of which I have the pleasure to send you a specimen, bearing the impression of his seal marked No. 1.

"The mode of preparing this substance is as follows:—

* "Useful Plants of India."

† *Agri-Hortic. Soc. Journ.*, vol. viii.

"The juice or sap to be collected by incision. An open slit may be made in the bark, and a pot tied to it, when the juice will flow into it; or it may be collected by cutting the bark and catching as much as flows out at once. Dr. Riddell calculates that ten average-sized plants will yield as much juice as will make a pound of gutta-percha substance, but it is not known yet how far the plant will bear tapping without injury, nor how often, or at what intervals the extractions of the juice might be made. The juice extracted may either be exposed to the sun in a shallow vessel, or left to dry in the shade; by the former process the substance becomes a little darker than by the latter. When it has attained a tough consistency it may be well worked up in very hot water with a wooden kneader, or boiled; either process serves to remove an acrid property of the juice, as also all other matter but the gutta-percha itself. It is believed that the more it is boiled and worked up, the harder it will eventually become when cool.

"Comparison with the true gutta-percha gives the following results.

"Sulphuric acid chars it.

"Nitric acid converts it into a yellow resinous substance.

"Muriatic acid has very little effect upon it.

"Acetic acid has no effect.

"Alcohol, ditto.

"Spirit of turpentine dissolves it into a viscid glue, which, when taken up between the finger and thumb, pressed together and then separated, shows numberless minute and separate threads.

"The above tests correspond exactly with the established results of the real gutta-percha. The substance, however hard it may have become, becomes immediately flexible in hot water, and readily takes any form required, receiving and retaining impressions of seals, etc., etc. . . .

"If the madar could be profitably grown for its hemp alone, it is evident, if this new substance proves in practice what it now appears to be, that an acre of cultivation of it would produce a large quantity of juice, and thus materially enhance its value. The poorest land suffices for its growth, but I have no doubt that if cultivated, and plentifully irrigated, not only would the yield of juice be larger, but the growth of the plant, and the fineness of its fibre when made into hemp, materially increased."

Dr. Riddell subsequently wrote—

"As regards my experiments with the madar juice they are as follows:—Having collected about 18 fluid ounces I had it strained through a cloth, and exposed 13½ ounces to solar evaporation on a flat dish. In three days it became firm, separating itself from the dish, and easily removed. I then placed it in boiling water, and worked it well about with a spatula, and when cool enough to handle, kneaded it with my fingers; when cool I found it to weigh a little more than six ounces. I then boiled it, and, as it cooled, worked it well again; and on weighing the substance found it had lost one ounce. I then pulled it out into shreds and boiled a second time, kneading it whilst cooling, and four ounces two drachms, apothecaries' weight, was obtained, of what I call madar gutta-percha.

"The next experiment was with four ounces of the juice, and placing it in a basin I poured about one quart of boiling water on it, stirring it up, and leaving it to stand, when it broke into curds which fell to the bottom.

"I then partially poured off the fluid, and filtered the residue through paper, and on its being sufficiently dry to be removed found it to weigh one ounce six drachms. It was then worked well in hot water two or three times, and formed into a mass which weighed six drachms, thus losing one ounce. On the whole it will be seen that the most economical method of preparing the juice is by solar evaporation, the residue being nearly double that of the second experiment."

Dr. Watt* states that Mr. Leotard publishes, in his memorandum on the materials in India suitable for the manufacture of paper, the opinion of Professor Redwood upon madar-gutta. "The Professor considers it possesses many properties in common with gutta-percha of commerce. The specimen so reported upon was collected by Captain G. E. Hollings, Deputy Commissioner, Shahpur (in the Punjab), in the year 1853, little more than one year after the date of the original discovery of the gutta. We have learned nothing further in thirty years, and uncountable riches of fibre and gum have all the while been wasting along every roadside and over every rubbish heap."

Mr. W. S. Strettell, of the Forest Department, in his 'New Source of Revenue for India,' states that the muddar must "afford a material for paper as good as, and cheaper than esparto." In this opinion he is strongly supported by the Curator of the Victoria and Albert Museum, Bombay, who pronounces this as one of the finest of Indian fibres, its extended use being restricted only by the difficulty of extraction. In the New Report for 1881, however, an opinion is expressed by Mr. Routledge quite opposed to this; he believes that "neither it (muddar) nor any other exogenous plants of similar characters can ever compete with esparto, nor be produced at a sufficiently low cost to admit of its being employed as paper-making material." Paper is prepared in the following districts:—Bellary, Madras, Furruckabad and Meerut, in North-Western Provinces. The plant is abundant in the Punjab, and, together with the next species, is a small extent made into paper. The cotton or crown of hairs from the seeds, as also the fibre from the bark, or both, is capable of being used for paper (Watt).†

Two other economic uses of muddar may be mentioned. The fibre known as *hoisting hemp* is obtained from the stems, and is perhaps the most valuable, as it is the strongest, of Indian fibres. While this has been well known for many years and the fibres repeatedly brought to the notice of Europe, it has up to the present day not attracted the attention which it deserves (Watt).‡ The milky sap is well known in tanning. It is made into a paste with the flour of the small millet (*Pennisetia spicata*) and is used previously to colouring the skin with lac dye. Alone it imparts a yellow colour to the skin (Watt).§ The juice is also stated by Dr. Watt to be employed to remove the offensive smell of fresh leather.

The fact that the sap of the madar plant contains in addition to caoutchouc two principles analogous to the alban and fluavil of gutta-percha is a point of some interest, especially as madar gutta-percha has been recommended as a substitute for the ordinary commercial article. Whether or not the madar plant can be employed as a commercial source of gutta-percha is a question which can only be solved by actual experiment. The supply is unlimited, and, as already mentioned, the plant will flourish on sandy plains, where other vegetation cannot grow.

We are well aware that our examination of madar is by no means exhaustive, but we trust at a future period to be able to resume our investigations.

In conclusion it only remains for us to acknowledge the kindness of Professor Dr. Sell, of the Gesundheits Amt, Berlin, for permitting certain of our experiments to be performed in the chemical laboratory of the institution, and for his ready advice in the conduct of our experiments.—*Pharmaceutical Journal*.

MACASSAR OIL.—Sunflower oil, 100 grammes; goose grease and "kamfett", of each 15 grammes; liquid storax, oil of eggs, oil of thyme, cacao butter, of each 8 grammes; neroli, 1 gramme; Peruvian balsam, 0·6 gramme; otto of roses, 0·05 gram.—*Indian Mercury*.

THE DROUGHT IN ENGLAND.—Mr. G. J. Symonds writes to the *Times* (Aug 1885) as follows:—"Rainfall observations have now been made uninterruptedly in this country for 100 years, not, alas! at any one place, but by careful calculation I have obtained values which are, I believe, very near the truth, for every year from 1720 to 1885. During the whole of this long period there is no instance of more than five consecutive years being wet until we come to recent years, and then we have the unprecedented fact of nine consecutive years (1875 to 1883), each wetter than the average; in short, the quantity in those nine years was as great as usually falls in ten years and a quarter. In 1881 (just as in 1834, 1844, 1854, 1864, and 1874) the fall was below the average, and complaints of drought and of deficient water supply immediately arose. I have not had time to thoroughly examine the records of the early months of 1885, but my impression is that up to the middle of June the fall did not differ materially from the average, but the latter half of June was very dry. I now come to July, which has been so remarkably dry.—*Gardener's Chronicle*

FUNGOID DISEASES IN FRUIT TREES: PEACH BLIGHT.—A communication was received, through Sir J. D. Hooker, from Mr. T. Kirk, Wellington, New Zealand, asking for advice as to remedial measures. In some districts the fruit trees are being destroyed by the mycelium of a ground fungus—a small Puffball—though the author suspects that several Agarics affects them. When the ravages are most serious the reproductive state is but rarely developed. It first appears as a circular patch, in which all vegetation (as in fruit trees, Oaks, Walnuts, grass, Sorrel, Strawberries, &c.) is more or less "blighted," the plants exhibiting a withered appearance, the leaves becoming slightly curled, droop and fall long before their time, and the plant dies. The roots are more or less covered with mycelium. The effects extend in a most singular fashion, travelling half-way across a garden or orchard from one side only, at others extending in all directions. It is most fatal to fruit trees. It is almost exclusively confined to light soils, on which Fern (*Pteris aquilina*) has grown. Damp or dry soils have no attractions for it. It occurs abundantly in the decaying rhizomes of Fern, transferring its attention to fruit trees whenever the opportunity is afforded. The first parts on which the affection shows itself is the juncture of root and stem. The bark becomes absolutely rotten when permeated by the mycelium, and emits a nauseous odour. Plum trees usually show but little mycelium as compared with Apples, but the trunk is more obviously affected, and exudes gum freely. Experiments are being carried out in the following directions:—(1) Soaking the soil with tar-water and dressing the affected parts with the same; (2) dressing the soil with soot; (3) with sulphur; (4) with mild brine washes, both for trees and soil. So far the tar-water seemed the most effective, but the author was inclined to think that sulphur will have the most permanent effect. The author adds, that in all parts of the country the Peach is dying wholesale, but the cause is most obscure. The trees appear to flower with their accustomed luxuriance, and the fruit to set as usual. If a sudden change of temperature, or a severe frost has been experienced during the flowering time, the fruit does not swell, the leaves make their appearance readily and fall quickly—minute orange-coloured blotches are seen on the twigs. These become confluent and black, and then the buds decay. At this stage the plant may die, or if the season prove favourable, a weak autumn growth may be made, and new leaves developed, tassled-like, at the tips of the branches; but a renewed attack the following spring proves fatal, and the plant dies. Plants one year from the soil are attacked as readily as the oldest. Occasionally a tree partially sheltered has suffered less than its neighbour or has escaped entirely; while two kinds appear to resist the disease more than others, viz. Cornet and Salway, but they are certainly not blight-proof by any means.—*Gardener's Chronicle*.

CULTIVATION OF SUNFLOWERS.—In reply to W. G. and O. P., we give a few notes upon the cultivation of sunflowers as carried out to a great extent in America. The two varieties most commonly grown are the Giant and the Egyptian. The seed is sown broadcast, or drilled in March or April, according to season, at the rate of 6 lb. to 8 lb. per acre, the plants being left about a foot apart. By leaving the plants somewhat close together, they are protected against high winds, and the yield per acre is larger. Sunflowers will grow on almost any soil, but prefer a dry one, and for good returns it should of course be rich. It is the custom to plough in with a good bold furrow plenty of good farmyard manure, and when the seed bed is ready, just before sowing the seed, put on a few hundredweight of guano, harrowing in the seed and guano together with light harrows, as with harley or oats. The yield per acre is about 25 bushels, the crop ripening about August or September. The leaves are sometimes stripped off and given to stock, but we should not recommend the practice. The conditions as to soil and climate described by W. G. appear most favourable for the growth of the plant. We do not know a work on the subject, but will inquire and give results.—**JAMES CARTER & Co., 237 and 238, High Holborn, W.C.—*Field*.**

ANOTHER NEW TEA MACHINE.—We learn that Mr. David Fairweather, of Sembawatte, has invented, and we believe patented, a machine for breaking up the balls of rolled leaf after coming out of the roller. This machine, if a success, will undoubtedly save a good deal of labour. The leaf will now pass from the withered state direct into the rollers, then into the "ball breaker," and will drop from this into the "roll sifter." It is then placed to ferment. Following up the arrangement which is now in force on Mariawatte estate, the tea will then pass through the Automatic Victoria Dryer, red leaf being separated by hand. The tea next passes into the sifting machine, the coarser teas being discharged direct into Jackson's Invincible Cutter which is driven from the sifter. It will be seen that throughout the whole operation the only handwork is the picking out of the red leaf. We are afraid this is a portion of the manufacture that will always have to be done by hand. The above description shews the strides we are making in perfecting and simplifying the art of tea manufacture. Mr. Fairweather deserves credit for not only this latest but many other improvements introduced by him into the manufacture of tea, all of which can be seen by the visitors to Sembawatte or Mariawatte factories.—**Local "Times."**

CACTUS HEDGES.—The Cactus makes an admirable hedge, and is easily propagated by cuttings. Snip off a piece and bury its end in the ground, and it will generally grow. Some nervous people, however, object to it for its supposed property of harbouring snakes or vermin, and the authorities, in some places, wage a war of extermination against this useful plant. A sort of Cacticide epidemic raged some years ago in Madras, and a native medical officer won both honourable mention and a tangible reward by divulging to the authorities his discovery that the "Coccus," or Cactus bug, was the natural and appointed destroyer of the Cactus tree, and should be therefore enlisted for its destruction! The suggestion was rapturously received. The labours of gangs of convicts employed in grubbing up and burning the plant were dispensed with, and in lieu thereof a departmental issue of Cactus bugs was at once ordered on the most profuse scale. For months the luckless postal runners groaned beneath the weight of parcels of the Cactus plant, with healthy "covi" adhering, pieces of which infected plant were to be distributed in spots where the Cactus was plentiful, that the great battle of *Coccus* versus *Cactus* might be fairly fought out. It reads like a scheme disinterred from the archives of the philosophers of Laputa, but was actually conceived and carried out in Madras, and is too curious an example of intellectual idiosyncrasy to be passed over in silence by the conscientious Historian.—**MASON'S BUREAU.**

—**Gardeners' Chronicle.**

CAMPHOR IN CHINA.—Reporting on the trade of Tamsin, Chiu, the Commissioner of Customs says that the trade in camphor is represented in the returns by such an insignificant figure that there is great fear of its total extinction in the near future. The immediate cause of its rapid collapse may be traced to the eagerness of the Chinese to acquire, by all possible means, as much territory as possible. During the last three years hills thickly wooded with camphor trees have been burned over by the Chinese, in order to compel the savages to withdraw. Destruction on so large a scale naturally tells on the camphor trade. Forests of camphor trees do still exist further inland, but the absence of all beaten tracks across the mountains renders them difficult of access.—**Gardeners' Chronicle.**

SEED ADULTERATION.—The Act that was passed a few years ago does not, it appears, suffice to entirely prevent the evil practices of seed-doctors, or probably that fault lies with those who should avail themselves of its provisions and do not. We have before us samples of very old Tifolium seed and other samples of the same seed sulphured and repolished, and intended presumably for mixing with genuine seed. We are informed that as it is requisite to wet the old seed to enable it to take up the sulphur there is an increase of weight of about 20 per cent, which more than pays all the expense of the operation. The value of the old seed, we are informed, is about 4s. the cwt., while the doctored seed sells for 20s. or thereabouts the cwt. We do not know where or by whom this bit of meanness is perpetrated, but are astonished that farmers do not if not taste at least try before they buy. The much derided flower-pot experiments are sufficient to reveal the state of the case, for on trial we find about 23 per cent of failures in the old seed as against 90 per cent of failures in the doctored seed.—**Gardeners' Chronicle.**

VEGETABLE PRODUCTS OF NICE.—In a report from the British Consul on the trade and commerce of Nice for the past year, it is stated that the Olive crop suffered considerably from the long droughts. As the harvest commences in October, and lasts till March, when the drought is very prolonged, the Olives shrivel up and drop off before coming to maturity, while when suffering from drought they seem to be more easily affected by the ravages of the "kreion" insect. The damage done to agriculture in this department by the wholesale destruction of birds is said to be incalculable. The subject is attracting the serious attention of the local agricultural society, and is also being ventilated from other motives by the Societies for the Prevention of Cruelty to Animals of Nice, Cannes, and Mentone, and it is hoped that their united efforts may lead to a beneficial change in this respect. Another instance of short-sighted policy referred to is the wholesale destruction of the forests. The wise *raisonnement* commenced during the Empire has been discontinued, probably from motives of economy, until the last three years, and the ignorant mountain communes have been growing rich on the profits of the destruction of their remaining timber. The matter has, however, been taken up once more by the Government, and the *raisonnement* of some districts is now being energetically carried on. The cultivation of flowers for perfumery purposes and the manufacture of perfumery for exportation have been carried on for years on this coast, but the cultivation of flowers for direct exportation is an industry of quite recent birth, and is due to the additional railway facilities, the accelerated service, and to the establishment of the Parcel Post. They have led to the establishment of the Societe Fiorida Company, who grow their own flowers, and export them to all parts of Europe. The British Consul expresses himself as being satisfied that this is an industry which is capable of great development, and which will well repay the producer. What is wanted for the local grower is to be put into direct communication with the flower shops of London and Paris.—**Gardeners' Chronicle.**

THE NILGIRI CINCHONA PLANTATIONS.

MR. M. A. LAWSON'S REPORTS FOR 1884-85.

In addition to the notice of these reports taken over on pages 401-3, we now give detailed extracts:—

3. SEASON AND RAINFALL.—(a) *Dobabetta*.—Taken altogether the season was not unfavorable for carrying on the general work of the estate. The total amount of rain registered during the year was 61.20 inches, and was spread over 123 days, but of this quantity more than half, or 31.77 inches, fell during the two months of October and November. The early part of the year was unusually dry, and until the end of April, hardly any rain fell. In both May and June 5.0 inches were recorded, but the greater portion of this fell in a very short space of time, during one or two violent thunderstorms. The result of these heavy showers, falling upon the dusty earth, especially on the steeper slopes, was that the water ran off before it had time to sink into the ground beyond a few inches. July, again, was an exceedingly dry month, 1.57 inches only being recorded, and it was not till the end of August that the earth was sufficiently wetted to begin planting. In this month, 6.39 inches were spread over 20 days. The following month of September was very droughty, and some of the plants which had been put out in the end of August died in consequence. October and November, however, were, as I have already mentioned, most unusually rainy, and the ground was thoroughly soaked and our failing springs re-established. Some damage was done on the steeper slopes through the earth being washed away; also in one of the ravines, two hundred trees or more were destroyed by some large rocks which were undermined, and on being dislodged from their site, crashed through a portion of the plantation immediately below them. The trees thus destroyed were some of the finest on the estate. After this heavy burst of rain, the weather continued propitious till the end of December, so that all the plants which had been put out were well established, and able to withstand the prolonged drought of the next five months.

(b) *Noolahetta*.—The rainfall on this estate for the past year was 92.96 inches, and was spread over 141 days. The earlier months of April and May received 3 and 4 inches respectively, and in June 7.31 inches fell. This saturated the ground, so that the planting, of which a very great deal had to be done, was commenced as early as possible. In July, 19.35 inches of rain fell, but at the same time this rain was accompanied with such violent storms of wind that the whole of the June planting, at least all those portions of it which lay at all exposed to the south-west were destroyed, had to be replanted later on in the season. After this the weather continued normal till the end of December. A large portion of the planting was not completed till the end of November, and I greatly feared that the plants would not be sufficiently established before the rains ceased, to be able to withstand the dry weather of the ensuing spring. However, to give them the best chance of prospering, I had them all double ferned, and I am glad to be able to report now, after having received our first spring showers, that they have survived, and are beginning to grow. Of the 11.80 inches which were recorded in October, no less than 11.0 inches fell in a bout thirty hours. Of course such a continuous downpour necessarily caused some wash, but owing to the ground being well covered with weeds, the damage done was comparatively trifling.

(c) *H. H.*.—The rainfall recorded on this estate for the past official year was 101.27 inches and was spread over 150 days. The weather throughout the year was favorable for all kinds of work, and great strides were made in the re-creation of this plantation. The extensive new plantings and renewal are all doing well.

(d) *H. H.*.—The total amount of rain which fell on this estate during the past year was 26.06 inches and was spread over 150 days. So far as the season

was concerned, nothing further could have been wished for.

4. RECEIPTS AND EXPENDITURE.—(a) *Receipts*.—The revised estimate of receipts for the past year (*vide* G. O., dated 8th November 1884, No. 129, Revenue) was Rs. 115,900. The actual amount realized has been Rs. 1,895. The difference between the estimated and actual receipts, viz., Rs. 114,005, has been due partly to a large quantity of bark being sold by auction in Madras than was originally intended, 81,880 lb. were sold instead of 60,000 lb., partly owing to a larger proportion of the more costly crown as compared with the cheaper red barks being sold than was originally proposed, and partly due to a slight recovery in the prices realized. Statement No. 7 shows the rise and fall in the prices which have been offered for the different kinds of Government barks at the auction sales in Madras since December 1883. The receipts on account of the sale of cinchona seed and plants amounted to Rs. 1,033 as against the estimate of Rs. 700. Again, under Miscellaneous items, Rs. 10 were realized as against the estimate of Rs. 50. This increase under the latter head was due chiefly to a market being found for the stems of the trees which were coppiced the year before on the *Dobabetta* estate.

(b) *Expenditure*.—The budget allotment for the working and other charges of the department was Rs. 124,100 (*vide* G. O., dated 8th November 1884, No. 129, Revenue, paragraph 8). This included the sum of Rs. 2,000 for the pay for six months for the Government Quinologist. The actual expenditure has been Rs. 7,903 or Rs. 3,312 less than the budget allotment. Certain unexpected charges have, however, been paid out of the allotment, which altogether amounted to Rs. 535. But for these, therefore, the savings would have amounted to Rs. 2,777. These unexpected charges were partly connected with the establishment of the Quinologist's Department, which altogether amounted to Rs. 853, and partly to an old English debt of Rs. 681, which had been contracted in the year 1882 for the manufacture of bark into f-brufage.

5. PERMANENT PLANTATION.—(a) *Dobabetta*.—The trees on this estate, taken altogether, are in a fair condition. Those parts of the plantation, the trees on which I stated in my report of last year to be past their prime, have been coppiced and interplanted. The coppiced stumps have already nearly all of them thrown out shoots, and the inter-planting is also doing well. For fear of denudation of the soil taking place during the heavy spring rains and before the ground would be covered with weeds, I had a number of brushwood revetments made on all the steeper slopes where the trees had been cut down. The following table shows the number of trees which were growing in the "Permanent Plantation" on the 31st of March last to be 633,487:—

Number of trees on 31st of March 1884.	Number of Trees uprooted.	Number of Trees coppiced.	Number of Trees planted out.	Number of Trees on 31st March 1885.
489,305	200	5,618	150,000	633,487

(b) *Noolahetta*. This estate is improving, but it will be many years before it again arrives at its former state of perfection. The plantings of 1882 and 1883 look remarkably well. This is due to their having been liberally manured. The stumps of the trees which were coppiced the year before last, as also those which were dealt with in a similar manner last year, have thrown up shoots most satisfactorily, and I shall therefore continue to coppice small portions of the estate year by year, whenever the trees show signs of having past their prime. The accompanying table professes to show the number of trees growing at the present time on the estate, but it must be pointed out that the table credits the plantation with all the plants put out during the year, whereas the June and July figures ought to be deducted. Unfortunately, owing to gross irregularities which began to take place

in the management of the estate about this time, the number of these failures have not been recorded:—

Number of Trees on 31st March 1884.	Number of Trees uprooted.	Number of Trees coppiced.	Number of Trees planted out.	Number of Trees on 31st March 1885.
298,610	5,052	1,837	110,370	432,001

About 400 plants of *Cinchona Carthagena* have now been put out in a plot of ground near the drying sheds. They are growing well and seem to prefer the climate of Naduvatom to that of Dodabetta. Some of the other plants flowered for the first time both at Naduvatom and in Sim's Park at Coonor.

The single remaining specimen of *Cinchona Santa Fé*, which I reported last year to have been saved from death by Mr. Jamieson, was planted out last January in a plot adjoining the *C. Carthagena*. It is perfectly healthy and has grown considerably since it was planted out. Besides this specimen, I have a dozen others in the propagating house in the Government Gardens, all or most of which will, I hope, be sufficiently advanced to admit of their being planted out before the end of the season. These dozen are cuttings from the original plant; the largest of them is only about four inches high though nearly two years old. They have been most difficult to raise, and have required the greatest possible care and attention.

(c) *Hooker*.—Great advances have been made during the past year in the renovation of this estate. Large tracts have been cleared of the worthless trees which were growing upon it, and replanted. The ground has been deeply tilled, and all the young trees have been manured. The accompanying table shows the amount of planting which has been done during the past year:—

Number of Trees on 31st March 1884.	Number of Trees uprooted.	Number of Trees coppiced.	Number of Trees planted out.	Number of Trees on 31st March 1885.
331,851	2,685	...	223,000	555,166

(d) *Wood*.—The condition of this estate I can only characterize as being increasingly miserable. The planting which was done in the early part of the year was disgraceful. That which was carried out during the latter months under different auspices was good, but whether good or bad nearly all the plants have been destroyed by the ravages, which have been committed by the pestilent sambar. [See extract in article.]

I append no table to show the number of trees growing upon this estate, as, owing to the evil circumstances which have attended all planting operations, no accurate calculation is possible. I can only hope that next year, after the barbed fence has been put up, I may be able to give a more favorable report.

6. **URKEEP**.—The weeding at proper times, deep tilling, the maintenance of the roadways, clearance of drains, &c., have been thoroughly well executed on all of the three first plantations. On the Wood estate much is still required to be done in this respect.

7. **MANURE**—(a) *Dodabetta*.—The whole of the manure collected during the last year had been used for those plots, which have been more recently planted, so that there was none available for the older trees. I have, however, been able to make arrangements by which the stock of manure will for the future be greatly increased, and next season I hope to have enough to enrich a large portion of the older parts of the estate.

(b) *Naduvatom*.—This estate is very badly off for manure, and measures will have to be adopted to increase the supply.

(c) *Hooker* and (d) *Wood*. Both of these estates are fairly well supplied by the cattle which are brought up by the coolies who work upon the plantations.

8. **SOILS**.—During the last winter the cattle on the estates fell into a very miserable condition, owing to

their not getting a sufficiency of proper food. I have, therefore, put up on the Dodabetta and Wood estates *silos* for the preservation of fodder during the wet season. I have had hitherto no personal experience of *silos*, but it seems to be an established fact that they are most valuable for storing up nutritious food in climates such as obtains on these hills, where herbage is plentiful only at those times when the preservation of it in a dry state would be impossible. I hope I shall be able to report next year that the experiment has proved successful.

There is still a small demand for seed, the varieties which were chiefly sought after last year being *C. succirubra* and *C. pubescens*. A complaint was received a short time ago from a gentleman that an order he had given had not been properly attended to, but upon investigation it turned out to be due to his having been confused by the names *C. pubescens* and *C. robusta*. I therefore give below the nomenclature as understood by this department, with the view of preventing a similar disappointment in the future.

10. **CROP**.—The total amount of bark taken from the trees on the estates during the past year was 118,017 lb. Besides this there remained over on 31st March 1884 92,526 lb., making a total of 210,543 lb. as specified in the table given below. Of this quantity 81,881 lb. was disposed of during the year, so that the balance at present in stock is 128,663 lb.—

Name of Plantation.	Crown Bark. lb.	Red Bark. lb.	Total. lb.
Dodabetta	99,874	...	99,874
Naduvatom	27,580	45,775	73,355
Hooker... ..	100	14,300	14,400
Wood	900	22,011	22,911
Total... ..	128,454	82,089	210,543

15. **THE QUINOLOGIST DEPARTMENT**.—Mr. Hooper was appointed last summer by the Secretary of State for India to act as Quinologist. He arrived in Madras last October. He commenced work immediately, and within a fortnight of his arrival had so far equipped his laboratory that he was able to begin the analyses of the Government barks. Mr. Hooper has submitted a report on the work he has done during the last half-year. It is full of interesting matter and argues the possession of great professional skill and industry on his part. It will be seen from the report that Mr. Hooper has not confined himself to the study of the *cinchona* barks only, but that he has also investigated the properties of many other products of economic interest.

One of the first things which Mr. Hooper turned his attention to was the manufacture on a small scale of the liquid extract of *cinchona* as originally devised by Dr. De Vrij of the Hague. A gallon of this preparation was sent to Dr. Cornish, the Surgeon-General, for experimentation, and just before he left for England, Dr. Cornish reported in very favorable terms upon its therapeutic and keeping value. In consequence of this report, Government have ordered Mr. Hooper to produce 1,000 lb. weight of this fluid extract with the view of having it still more fully tested. Mr. Hooper will, therefore, as soon as possible, carry out these instructions in the laboratories connected with the Medical Store Department in Madras.

The advantage of the above-mentioned preparation over other kinds of febrifuge is the great economy and simplicity of its production. So simple, indeed, is the method that any druggist and chemist could, so long as he had a bark of a determined alkaloidal value, make the extract without any difficulty in his own shop.

If the liquid extract continues to hold the high reputation which has been given to it by Dr. Cornish, and I see no reason to doubt its doing so, Government will have at last as cheap a febrifuge as can possibly be turned out.

Dr. Cornish in some sense speaks rather disparagingly of the febrifuge which is manufactured by Government in Northern India. He says that it produces nausea. Mr. Hooper has analyzed samples of the Darjeeling febrifuge and regards it not unfavorably as a drug; and the experience of those who have told me that they have administered it to their servants and others, when on tour in feverish parts of the country, leads me to regard it as much better than it is commonly believed to be, though no doubt it may frequently cause disturbance in particular constitutions when given in large doses. Of course, if it were possible, one would desire to administer nothing but the pure alkaloids; but the great cost of manufacturing these forbids their being used on any large scale, and one must therefore be content with placing within reach of the poorer classes a supposed slightly inferior but much cheaper commodity.

At the request of Messrs. Arbutnot and Co. of Madras, 2,000 lb. of bark were sent to Calcutta to be there manufactured into quinine and febrifuge by their expert, Dr. Cleaver. The results, so far as they have gone, are not very satisfactory; and no account has yet been given of the proportionate amount of the alkaloids which have been extracted from the bark. But I do not see why further experience should not be productive of better results. There can, I think, be now little doubt that the cinchona alkaloids can be isolated as well and much more cheaply in India as in any other part of the world.

16. MAPS OF ESTATES.—I enclose three maps showing the amount of planting and coppicing which has been done since the year 1882, on the Dodabetta, Naluvatan and Hooker estates.

ENCLOSURES.

Letter from D. Hooper, Esq., F. C. S., Government Quinologist, Ootacamund, to the Director, Government Cinchona Plantations, Parks and Gardens, Nilgiris, dated Ootacamund, 6th July 1885.

1. I have the honor to make the following report on the analytical work conducted in the Government Laboratory for the half-year ending 31st March 1885.

2. I arrived at Madras on the 6th October 1884 and proceeded to Ootacamund. A building had been provided for me, which, after certain adaptations and fixtures made in it, became converted into a moderately efficient laboratory. The chemicals and apparatus which I had used in the special study at The Hague were brought out with me; I was therefore able to commence work about a fortnight after arrival.

3. My appointment was made with a view to advance the practice of cinchona culture at the Government Plantations by analysing the bark of a very large number of their trees in different stages of their growth, when treated under different systems, and when grown at different altitudes.

4. The periodical sales of bark which are now made by public auction at Madras have been accompanied with analyses of the various samples. In November, 18 samples were reported upon, and for the February and March sales four samples were tested. Of these, 16 were crown and 6 red bark. The percentages of sulphate of quinine in the former were—

Natural, average of 5 analyses	...	3.18
Mossed	"	3
Renewed	"	1
Branch	"	3
Root, one analysis	...	4.40

The percentages of total alkaloids in the Red barks were: Natural 5.10, Mossed 6.7, Renewed 6.81, Branch 4.45, 3.97, Root 8.17.

These analyses were printed and circulated amongst the buyers at the sales, and have enabled a reserve price to be placed on the various lots.

5. With reference to paragraph 62 of your last annual report, Dr. W. R. Cornish, the then Surgeon-General, suggested that a liquid preparation might be made of the red bark, which you say does not com-

mand a remunerative price in the market, and the preparation might be similar to those of De Vrij, Schacht, Paul and Vaney advertised in the British Medical papers. When in Holland I was conversant with the process for making "Cinchona Liquida" of Dr. J. E. De Vrij, the well-known Quinologist, and had made a sample before Dr. Cornish's suggestion arrived. At his request a further supply of a gallon was made, and this was distributed to various dispensaries in the Presidency, in districts where fever was most prevalent. Such good reports on the efficacy of the liquid extract were sent in by the resident medical officers that a much larger supply was called for. Having no appliances in this station for manufacture on a large scale, in accordance with a Government order, I went to Madras to see if this could be done in the Medical Store Department. After an inspection of the laboratories, I reported that such a quantity as a 1,000 lb. could be made, but a continuous manufacture would seriously interfere with the arrangements of the department. This quantity has now been ordered, and as soon as I have analysed a sample of the mixed powder, I will be prepared to go to Madras and superintend the manufacture of the first batch, which, according to Dr. Cornish's request, shall contain 40 grains of alkaloids to the fluid ounce.

6. When samples are taken for analysis from trees in the Government Cinchona Plantations, I have always endeavored to be present, so that observations as to situation, soil and habit of the trees might be noted. Most of my visits have been to Dodabetta where the Crown barks chiefly grow, but I have also been to Naluvatan, the home of the Red barks, and to the estates of Hooker and Wood at Pykara. I should like it to be understood that all my analytical results are calculated in percentage on the air-dried barks as they are received.

7. The following table comprises 40 analyses showing the alkaloidal value of the principal species of cinchona growing in Government and other estates:—

	Quinine.	Cinchonine.	Quintine.	Cinchonine.	Cinchonine.	Cinchonine.	Alkaloids.	Total.
C. officinalis, Natural	2.71	1.28	.15	.49	.55	5.21	5.21	5.21

C. morada, 20 months	1.53	1.13	...	1.16	.96	4.78	4.78	4.78
C. vertle, 20 months	1.32	.99	...	1.16	1.19	4.57	4.57	4.57

8. *C. officinalis*.—The samples of this species were selected from typical trees growing on the Dolabetta plantations. The analysis of the natural bark is the average of eight analyses made on trees of 22, 19, and 11 years of age, and differing in having broad and narrow leaves. The mossed and renewed are each the average of three analyses made on trees of different ages. As far as these few results go, it appears that, on the whole, the younger trees are superior to the older ones, and the narrow-leaved variety than the broad-leaved. The following amounts of quinine were determined in three kinds of crown bark from trees of the same age:—

	Narrow leaf.	Broad leaf.
Natural	2.85	2.95
Mossed	4.03	3.47
Renewed	4.48	3.85

These experiments were repeated on three trees of a younger growth which showed a marked difference in shape of leaf. The trees had been planted in 1869, and coppiced in 1879. The respective barks gave the following percentages of quinine:—

Very narrow.	Narrow.	Broad.
3.15	2.71	2.44

9. The variety of this species, named *Angustifolia*, some years ago created a widespread interest on account of the extraordinary amount of quinine found in it by Broughton and Howard. The samples were taken from a tree 20 years old; it was 10 feet high with a circumference of 18 inches. The results of the analysis shows its superiority over ordinary crown barks, but in its present condition it appears to have no claim whatever to be a prodigy in cinchona culture.

* * * * *

12. The *Pitayensis* bark is characterised by yielding an unusual quantity of the alkaloid quinine. The first sample is from a tree twelve years old raised from seed brought by Mr. Cross from Pitayo in New Grenada; the second sample had been raised from seeds not from Pitayo, but from a district passed on his return journey. These two varieties will be subjected to further consideration.

13. The analysis of the *Ledgeriana* tree at Naduvatum is fairly representative. The bark, although old, is very thin. This demonstrates from a commercial point of view, that a planter should not only look for a large alkaloid yield, but he should consider a poorer tree producing rapidly a large quantity of bark to be of equal importance to a richer tree producing slowly a very thin bark. The broad and narrow-leaved varieties were from Coonoor and of three years' growth. The cinchonine is so high in each of them that they cannot be regarded as pure types of a Ledger. The Ledger bark from the South Wynaad was an average sample of shavings taken from 21 trees of 5½ years old; the amount of quinine is equivalent to 11.31 per cent of the crystallised sulphate; this is one of the highest results obtained in South India.

14. The samples of *C. morada* and *C. viride* were from young trees grown in the same estate near Calicut. The first was taken from "20 average trees, with a girth of 5½ inches, broad leaf, dark olive green, red midrib, and under surface purple or flesh-colored." The second was taken from "20 average trees with a girth of six inches, narrower leaf, color light-green, yellowish mid-rib, and upper surface of the leaf smooth." The analysis and thickness of stem are exceedingly good for such young plants, and these results apparently contradict the unfavorable statements made in certain quarters respecting them.

15. *Complete analysis of a tree*.—In December last a tree of *Cinchona succirubra* growing at Naduvatum was submitted to a thorough examination, in order to discover the distribution of alkaloids in its various parts. The tree was 23 years old and 31 feet high; it had grown in an exposed situation, and had never been barked or mossed. The stem was cut into 11

equal lengths from base to summit. The whole yielded of dry bark—

Root	lb. oz.
Stem	2 8
Branch	20 14
Twig	3 2
					1 6

Leaves dried	27 14
					2 ...

A portion of the bark from each length was then examined separately, also samples of the root, branch, twig and leaves.

In the following table the results are recorded; the amount of moisture in each is reduced to the same, so that the whole may be comparable. The first seven are each the mean of two analyses:—

	Quinine.	Cinchonidine.	Quinidine.	Cinchonine.	Amorphous Alkaloids.	Total.	Asb.
Root bark	... 93	... 66	... 45	... 209	1.17	5.30	3.25

Leaves 2302	.45	7.0	5.74

* * * * *

16. The effect of sun-light and shade upon the amount of quinine in cinchona bark was the subject of an investigation by my predecessor Mr. John Broughton, but to know if these influences were still at work, and if so, to what extent, the following experiment was made. A tree of *C. pubescens* of twenty years' growth was taken at Naduvatum. It was on the margin of a plot, and so situated that its south side was freely exposed to the sun, the north side was protected and shaded by the other trees in its vicinity. A strip of bark from each side was taken, dried and analysed. The percentage composition was as follows:—

	South.	North.
Quinine 2.63	4.00
Cinchonidine 1.81	2.05
Cinchonine 0.23	0.22
Amorphous 0.50	0.50
Total	5.22	6.77

17. *Mossing and Renewing*.—The process of "mossing" has now been adopted in the plantations for about twenty years, and has been most valuable in increasing the amount of alkaloids and especially of quinine in cinchona bark. But whether the system is still successful when applied to older trees under cultivation, appeared to be an important subject for inquiry. The following experiments were made upon trees of *C. officinalis* nearly twenty years old from Plot 12, Dolabetta. Early in October last samples were taken for analysis from three individual trees, as natural, mossed and renewed bark in strips. The trees were respectively covered with moss and labelled, and the samples analysed. After six months' interval the trees were again visited and samples taken. The renewals had not sufficiently developed to enable them to be tested, they were very thin and adhered closely to the wood. A portion of the bark which had been under moss six months, and further portions of the mossed and renewed barks were separated.

The analyses of the six samples are annexed.—

	Natural Bark.	Mossed six months.	Mossed Bark.	Mossed six months.	Renewed Bark.	Mossed six months.
Quinine...	3.72	4.21	3.95	4.23	3.90	4.33
Cinchonine...	1.65	1.84	1.91	1.77	0.81	0.67
Cinchone...	0.24	0.21	0.63	0.59	0.51	0.51
Cinchonamide and Amorphous...	0.96	1.03	0.91	1.04	0.65	1.52

Total... 5.87 7.33 7.16 7.33 5.63 6.86

It will be seen that the mossaing has improved in each case the three varieties of bark, and the improvement has not only been in the total alkaloid but also in quinine. From the analyses of such a small number of trees it would be inadvisable to form too strong an opinion; but I think it shows generally (1) that old and original trees still increase their alkaloids by mossaing, (2) that mossed barks are increased by further mossaing, (3) that renewals continue to improve.

18. The scales which form on the outside of Ledger barks, and which are readily detached when the sample is dry, have been considered by some planters to be the richest portion. From the sample of Ledger received from the Wynaal, I was able to remove sufficient of the scales for analysis. The dried quinine scale contained 12.5 per cent. alkaloid, cinchonine 5.5, amorphous alkaloid 0.66; total 18.5 per cent. The analysis is very characteristic of this species, but it will be seen that the total alkaloids are only about half the quantity found in the entire bark.

19. The ash of *C. ...* bark.—In every analysis of bark it has been my custom to determine the amount of ash. The average of over 100 estimations of all the kinds of bark that have come under my notice, I find to be 3.50 per cent. As a rule young and branch barks are the highest, and old barks are lowest in their amount of mineral matter.

20. Besides the work of a chemical nature I have to report on the investigation of some other plant products which you have from time to time forwarded to me. The apparatus and chemicals I have at my disposal are not sufficient to make complete researches into the specimens as I think the course of the work requires. But as there might be some interest in the work already done, the following notes are given.

21. *W...*—The resinous and powdery galls covering the joints of *P...* afford a very peculiar dye and much resemble in appearance the Kanina of the Pharmacopoeia. A proximate analysis of this substance gave the composition as follows.—

Mosses...	3.44
Resins...	7.19
Matter soluble in water...	8.20
Carbure...	2.01
Waste oil...	trace.
Ash...	0.43

Total... 10.27

The coloring principle resides in the resin which is soluble in ether, alcohol, benzol, chloroform and caustic soda solution. When a concentrated ethereal solution was allowed to stand for a day it deposited a mass of granular crystals, similar to those described by Doctor Anderson in "Kanina" obtained from the fruit of an English acacia plant. When the coloring matter of Waras was examined side by side with that of Kanina by means of a spectroscope, the amount of absorption was identical in each case, and the spectrum was identical throughout, except the red end which was somewhat visible. A solution was made of the Waras and pieces of moistened paper were immersed. The color formed was that of a bright orange-brown, and the tint obtained was much superior in the animal tissues as silk and wool,

than in the vegetable tissues of cotton and linen. In these respects it resembles the dyeing properties of Kanama. As a commercial undertaking, however, it would not be profitable to collect Waras, as the amount obtained from the plants is so small in proportion compared with the yield of Kanama.

22. The leaves of *Vertheuglossa Oeri*.—The uses to which cocaine has been put in surgery by the Faculty has rendered it desirable to test the amount and nature of alkaloid from plants grown in India. Some leaves which had been carefully dried in the shade from trees in Bangalore have on three occasions been analysed by me. The first sample was examined by Trupheme's method; it yielded 2 per cent of an alkaloid which gave no characteristic results in physiological action. The second sample was treated according to Castaing's method and gave about the same amount of alkaloid which produced distinct numbness on the tongue, but Dr. Drake-Brockman of the Eye Infirmary, Madras, reported that it produced a smarting when applied to the mucous surface. A third sample had been tested by Dr. Squibb's process which afforded 50 per cent crude alkaloid, and 30 per cent cocaine hydrochlorate. This had a very marked numbness on the tongue and has been sent to Dr. Brockman who has kindly promised to report upon its value.

23. The funicles of the Black Wattle (*Acacia melanoxylon*)—are in the shape of pink contorted bands, and were supposed to contain a dye. They were free from starch and tannin and yielded 6 per cent of moisture and 2 per cent of ash. Their chief constituent is an albuminous matter similar to the white of an egg. About 30 per cent is readily extracted by macerating the funicles in water. When this solution is heated, the albumen coagulates and the pink coloring matter is destroyed. Being of no use as a dye, their peculiar office seems to be that of affording nourishment to the seed.

24. I have lately received a large quantity of indigenous gums, and other vegetable substances for examination. These will be tested whenever an opportunity is afforded, and a report forwarded upon them in due course.

MISCELLANEOUS.

ORDER—dated 17th September 1885, No. 1016, Revenue. In the first of the papers read above, the Director of Government Cinchona Plantations, Parks and Gardens, Nilgiris, submits his report on the cinchona plantations for the official year (1884-85) and the report of the Government Chemist for the latter half of the same year.

2. *State of the Season*.—The season was on the whole not unfavorable, although on the Dodabetta estate some damage resulted in the earlier months of the year from drought and in the months of October and November from unusually heavy rain. At Nilavattam nearly the whole of the June plantings were destroyed by violent winds in the following month, but the damage done was easily repaired later in the season. On the Hooker and Wood estates the weather was all that could be desired.

3. *Cultivation of the Plantations*.—The plantations on the Dodabetta and Nilavattam estates were generally in fair condition, the trees coppiced last year having thrown up shoots satisfactorily. At Nilavattam the plantings of 1882 and 1883 are described as looking remarkably well, the result of their having been liberally manured. It is presumed that in repopulating vacant plots the attention concentrated last year of cultivating particular varieties to particular plots has been carefully carried out. In his present report Mr. Lawrie proposes to convert a small portion of the Nilavattam estate into a kind of botanical garden for the use of students by growing species of the different species and the principal varieties of each, and a new growing in South-east India. This suggestion commends itself to Government and may be carried out, as proposed, by means of cutting from the trees originally intro-

duced from South America. It is presumed, however, that the Nilgiri hybrids will also be presented.

4. No mention is made of the plants of *C. Carthagenia* planted out in former years at Dalabetta, but it seems clear that the climate does not suit them, and that they do much better at Naduvatum and Coonoor (Sim's Park).

5. The one surviving plant of *C. Santa Fe*, which was removed from Dalabetta to the Government Gardens and subsequently planted out at Naduvatum, has grown considerably and is in perfect health. A dozen cuttings from this plant are now in the propagating house at the Government Gardens, and will, it is hoped, be fit for planting out before the end of the season. About two hundred plants of *Hemilya Purdieana*, which yields the *Crocea* bark, have been raised from the seed received from Kew, and will also be planted out shortly at Naduvatum.

6. The Hooker estate has much improved, but the condition of the Wood estate on the other hand is described as "increasingly miserable." This is ascribed partly to the ravages of the Sambar (*Rusa Aristotis*), to counteract which it is intended to fence the entire estate with barbed wire, and partly to the inefficiency of the overseer, Mr. Burrows. On the latter point the Government desire to receive a full report. It is observed that Mr. Burrows has been called upon to take two years' furlough, but the Government cannot regard this as a sufficient remedy for proved inefficiency. By a recent order, the Wood and Hooker estates, which have hitherto been supervised by the head overseers of Dalabetta and Naduvatum respectively, have been combined and constituted a separate head overseer's charge. Mr. Burrows' appointment has thus been abolished, and the Government desire to know whether it is intended to retain him in the public service.

7. The development of private plantations and the present depreciation in the value of cinchona bark have together brought about the extinction of the demand which used formerly to exist for plants and seedlings from the Government estates. The Director has therefore reduced the number of nurseries to one for each estate, which will suffice to meet the requirements of the plantations and will also suffice for the growth of seedlings enough to meet any external demand that is likely to arise. Of seed about 251 lb. were sold during the year, realising R1,033.

8. The drying house and store at Naduvatum commenced by the Public Works Department in 1881-82 were completed during the year under report at a total cost of R37,893. The only new work carried out departmentally during the year was the construction, at a cost of R270, of a set of cooly lines from the materials of the old jail recently dismantled.

9. Excluding the Wood estate, for which no accurate return can be furnished, the number of trees standing on the plantations on the 31st March 1881 was 1,122,766. Of these 7,267 were uprooted and 7,455 coppiced, and 513,370 trees were planted in the course of the year. The total number on the 31st March 1885 was thus 1,620,744. The report does not specify the varieties to which the newly-planted trees belonged. Some information on this point seems desirable.

10. *Use of Manures, &c.*—The stock of cattle manure collected during the previous year was utilized as usual during the year under report, but the supply proved insufficient, and arrangements have since been made for the proper storage of a sufficient quantity in the future. No allusion is made in the report to the effect of the artificial manures applied in April 1883. In the report for 1883-84 it was stated that samples of bark had been collected from the trees so treated, and would be analysed in due course. The Government desire to know whether this has been done, and if so, with what result.

11. It is noted that in consequence of the want of grass experienced during the last cold weather, the Director has constructed *silos* for the preservation of fodder on the Dalabetta and Wood estates. The result of the

experiment will be watched with interest by the general public, and should be carefully reported. A file of papers on the subject of ensilage will be forwarded to the Director from the Government office.

12. *Crop.*—The crop of the year was 118,017 lb. of dry bark against 183,705 lb. in 1883-84. The high figure in the latter year was due, as was noted at the time, to the unusual amount of coppicing and uprooting that was found to be necessary. Adding the balance remaining over on the 31st March 1881, the total available quantity was 210,543 lb., of which 81,880 lb. were

	lb.
Sold by auction in Madras	81,880
Supplied to Bombay Medical Department	1,000
Supplied to Dr. Cleaver for experiment	2,000
Total...	84,880

initially noted, leaving a balance in stock of 125,663 lb. Five local sales were held during the year at which 81,880 lb. were sold for R82,344, the prices realised comparing

favorably with those of the English market.

13. Towards the close of the year Messrs. Jenkins and Phillips drew the attention of the Right Honorable the Secretary of State for India to an improvement in the English prices of bark. A copy of their letter having been forwarded for the information of this Government, the present policy of local sales was reconsidered with the result that it was decided to continue it as it gives a wholesome stimulus to local trade, while, from a comparison of English and Indian prices, it would seem to entail no loss, at present at least, on the Madras Government. In order, however, to give certainty and stability to the market, it was proposed to appoint fixed dates for the sale of bark and to guarantee that for the next two years not less than 70,000 lb. of bark should be offered for sale each year. These proposals were accepted by the Right Honorable the Secretary of State for India, and arrangements have now been made to carry them into effect.

14. *Subordinate Staff.*—In December last the Director reported that several defalcations and frauds had been discovered in connection with the Naduvatum estate. The Collector of the Nilgiris was at once directed to institute a thorough inquiry and scrutiny of the accounts with the assistance of Mr. Lawson, whose establishment was not suited for such work. It appeared from the Director's report that Mr. Hillier, the head overseer of the Naduvatum estate, was unable to account satisfactorily for sums received by him on account of the estate, amounting in the aggregate to R1,605-5-10, and that he had also misappropriated about eighty pieces of corrugated iron, besides timber, window frames, &c., from the materials of the dismantled jail. The result of the Collector's inquiry was that Mr. Hillier was prosecuted for criminal breach of trust as a public servant and sentenced to rigorous imprisonment for two years and a fine of R155. Sums aggregating R1,227-7-3 had to be written off the accounts as irrecoverable, while, as regards an outstanding advance of R2,213-8, a final report is still awaited. The Manager of the Director's Office, Venkataratnam Naidu, was also prosecuted for misappropriating R200, the property of Government, and for accepting an illegal gratification from a contractor. On the first charge he was convicted by the Sessions Court, but was eventually acquitted by the High Court on appeal. A departmental code of rules and forms of account is now under preparation by the Treasury Deputy Collector of the Nilgiris, who has also been requested to undertake the annual audit of the head office accounts.

15. *Manufacture of Quinine, &c.*—Proposals have from time to time been made for the establishment of a private quinine factory in this country. Certain concessions were asked for in regard to fuel and the supply of bark from Government estates, but these the Right Honorable the Secretary of State was not prepared to grant. Certain English capitalists resolved, however, to send out a scientific chemist, Dr. E. L. Cleaver, for the purpose of conducting experiments; and from a letter addressed to Government by Messrs.

Arbuthnot & Co., of Madras, it appears that, in consequence of certain experiments made by him at Calicut with 2,000 lb. of bark supplied to him from the Government estates, the gentlemen who sent him out will now in all probability proceed to form a company for the establishment of a private factory.

16. *Quinine.*—The Government note with pleasure the very useful work done since his arrival in this country by Mr. Hooper. His report shows that a satisfactory start has been made in the scientific investigation of cinchona culture and of the conditions which effect its alkaloidal value. During the year under report, however, his attention has been largely devoted to the practical question of manufacturing at a minimum of cost the liquid extract of cinchona devised by Dr. de Vrij of the Hague. A sample of this preparation manufactured under Mr. Hooper's directions has been tested in some of the hospitals with the most satisfactory results, and instructions have been issued for the preparation of 1,000 lb. of the extract in view to further trials. It has been found experimentally that the liquid extract can be produced at a price about 20 per cent lower than that of the fibrine obtained from Bengal, and there appears to be good reasons for believing that eventually the cost will be found to be still lower. In view, partly, of this fact, the question of establishing agencies under the Local Fund Boards for the distribution of cheap medicines to the poorer classes has been referred to those Boards for consideration.

17. *Receipts of Cinchona.*—The receipts of the year amounted to

Value of bark sold locally	Rs. 2,341 2 0	Rs. 1,895 7 5 as detailed on the margin against a revised estimate of Rs. 5,900.
Value of barks supplied to Bombay Medical Department	1,007 8 0	The bulk of the increase in due partly to the sale of a larger quantity of bark than was anticipated, partly to the inclusion in the lots sold
Sale-proceeds of seed, &c.	1,033 2 0	
Miscellaneous	510 11 5	
Total...	84,895 7 5	

of a larger proportion of crown bark than was at first intended, and partly to a slight recovery in prices. It was expected that some 600 bales would be sold for an average price of Rs. 75 per bale, but eventually 819 bales were disposed of for a fraction over 100 rupees each.

18. The expenditure, as reported by the Director, was Rs. 7,934-10 against a budget estimate of Rs. 8,800 393 lb. fibrifuge £ s. d. and a revised estimate of at Rs. per oz. 209 12 0 Rs. 2,140. This includes a

Packing	4 18 3	sum of Rs. 681-6-2 adjusted during the year and re-
Analysis	3 3 0	presenting the cost of
Labels	0 1 0	manufacture of the 393 lb. of fibrifuge advised in the Secretary of State's despatch recorded in G. O., No.
Total...	217 17 3	

Equivalent at Rs. 72 per rupee. Rs. 681-6-2 705, dated 14 June 1884. Of this amount, however, a sum of Rs. 110-11-1, representing the three latter items noted on the margin, has already been deducted from the receipts of Rs. 585-8-4 in making credit for the net value of the 393 lb. of fibrifuge. The balance, viz. Rs. 570-11-1, should have been deducted at the same time, but was by an oversight omitted from the calculation. The deduction will now be made and the receipts of 1883-84 will then stand at Rs. 7,820-12-2. The charges for the year under report will consequently be reduced by the same amount, viz. Rs. 681-6-2. To be figured there should also be added the charges (Rs. 92-7-8) incurred by the Public Works Department in the construction and repair of cinchona buildings. The whole charges for 1884-85 will thus amount to Rs. 24,641-1-1.

The circular statement which accompany the Director's report have been remodelled as directed in G. O., 17th September 1884, No. 1,010. It is observed, however, that statement III still shows the expenditure of the head office for each month of the

year. This is not necessary, a statement of annual charges being alone required, which should be compared with the budget and revised estimates. The Director is requested to report whether it would not be possible in future years to prepare statements, similar to those furnished in connection with the Bengal plantations, showing the number and distribution of the different varieties of plants on the several estates. A comparative statement should also be furnished, showing the quantity of bark of the different kinds in store at the commencement of the year, collected and disposed of during the year, and remaining in store at its close.

20. The statement of capital and revenue account appended shows the financial results of the cinchona enterprise from its commencement to the end of 1884-85. The net result is a surplus of Rs. 5,743 1-7. In future the exact amount and value of bark supplied to the Government (quinine) should be reported for inclusion in this statement. A statement is also appended showing the receipts and charges of the year calculated in the manner directed in the Secretary of State's despatch, dated 14th September 1882, No. 31.

ENSILAGE OF MULBERRY LEAVES.

During the silkworm rearing season in Northern Italy a large quantity of Mulberry leaves are sent by rail from one place to another, and in many cases the railway administration run special night trains for this purpose. The leaves are packed loosely in sacks, and often arrive at their destination far from fresh, and consequently, if not totally unfit, at all events cannot afford a wholesome food for the nourishment of these insects. An experiment was made during the present season, by a silk producer in Lombardy, in sending the leaves compressed, and for this a bale was made, weighing 116 kilos., by placing the leaves between two round pieces of board (in this case the bottoms of barrels), and compressing them in an ordinary wine-press; the bale was then firmly secured with iron wire. By some oversight this bale of compressed leaves, made on May 23, was not forwarded to Milan, and from thence to Niguarda, until the morning of the 31st, and consequently it did not arrive at its destination until later. On opening the bale the leaves, with the exception of about 2 inches in thickness round the outside, were found to be perfectly fresh and sweet, and even these were only faded, and found to be not unfit for food.

This is a conclusive proof that the nutritive qualities of the leaves can be preserved for some time, if compressed, and the air thus excluded from them; care, however, must be taken not to crush them, and injure their tissues by excessive pressure. From that it would appear that a system of ensilage might be adopted with advantage for preserving Mulberry leaves in the same way that it is for forage. Another advantage of such a plan would be that the leaves so compressed would be reduced in bulk, and consequently fewer trucks would be required to carry a given quantity of leaves than there is in the ordinary way; and by ensiling the leaves grown on the warm side of the Apennines—as, for instance, on the "Reviera" of Genoa, &c.—it would be possible to supply the silkworm rearsers of Piedmont and Lombardy during backward seasons, or when, from other causes, the leaves are scarce and expensive.—*Journal of the Society of Arts.*

THE POTATO

It is the universal custom about here, amongst cottagers, when they dig up their Potatoes to divide them into three parts, according to their quality. The best they eat, the second best they give to the pigs, and the worst they save for seed. Suicidal policy in food. Mr. Terry, the author of the *Life of a Potato Crier*, and a man who has spent the greater part of his life in the business, walks over his 26

acres while the men are digging, and selects the very best at once for seed, and so he is always improving the stock.

The next thing I would mention is about banking-up. Now, this custom is, I think, all but universal in England. Most people think that it is necessary to a crop, but the reason does not clearly appear. If it is thought that the Potatos will grow out of the ground, then plant them a little deeper, taking care that the soil is well prepared before planting. There are many advantages to be gained by letting the ground remain level (or nearly so), especially during a dry season like that we have had lately. It is well known to gardeners that when the weather is dry it is a very good plan to water with the hoe—i.e., continually stir the surface, and the sun will then draw moisture upwards to the roots of the plants. Mr. Terry has experimented on the same soil for years and years, and he always gets the best crop from the level surface. There is also considerable judgment required in our changeable climate as to the time when to plant late Potatos. "To secure the largest yield Potatos demand moisture and coolness during the last month of their growth;" therefore do not plant too soon. I was accidentally hindered this summer from planting my late Potatos about a month; the result is that my Potatos are looking green and flourishing, whilst my neighbours' are as dry as hay.

Now for a little more about the seed. I suppose most people are pleased to see a dish of Potatos served up mealy and about one size. This can be done by careful selection of the seed, and cutting the pieces to one eye. When you get to the top and find several eyes close together, remove all the eyes save one. Take care to cut nice fleshy pieces to each eye, and let each eye have as long a piece of flesh as is possible, and let each piece be about the same size.—AGNES.—*Gardeners' Chronicle.*

THE GROWTH OF PEPPERMINT for the sake of its oil appears to be carried on largely in New York State. According to a statement in the *Oil, Paint and Dry Reporter*, one farmer in Rose County, which seems to be the centre of the industry, has this year over thirty acres of land devoted to the cultivation of the plant, and expects the yield of oil to reach thirty-three to thirty-five pounds per acre.—*Pharmaceutical Journal.*

A NEW ALKALOID, named "lantamine," has been discovered by Dr. Negrete, in *Lantana brasiliensis*, a plant which has been used by Dr. E. Baiza, in the Central Hospital at Lima, as an antipyretic. Dr. Baiza had been in the habit of administering the tincture, which has a very bitter taste. At his request, Dr. Negrete analysed the plant to ascertain whether a better pharmaceutical preparation of it could be made, and this led to the detection of the alkaloid (*Nouv. Rem.*, Sept. 15, p. 282). Lantamine, like quinine, depresses the circulation and lowers the temperature. It is tolerated by the most delicate stomach. Intermittent fevers, which have not yielded to treatment with quinine, have given way under the use of 2 grams of lantamine. The dose hitherto given has been one to two grams during the twenty-four hours, prescribed in the form of pills containing ten centigrams each, given immediately after the commencement of the hot stage. In ninety-five cases out of one hundred, the return of the hot stage was prevented.—*Pharmaceutical Journal.*

COCAINE has already been tried in the vomiting of pregnancy, and now it is brought forward as a remedy for sea-sickness. Dr. Mauassein, of St. Petersburg, reports in the *Berl. Klin. Woch.* (August 2), that he went on a voyage on purpose to test the efficacy of cocaine in sea-sickness. He states that two individuals to whom he administered the hydrochlorate of the alkaloid on starting went, for the first time in their lives, free from sea-sickness during a period of forty-

eight hours of rough weather and enjoyed a good appetite the whole time. A child, six years old, attacked early in the morning with sea-sickness, was able to play about during the storm after taking the cocaine. In another case, in which a girl of eighteen years of age had been sick for twenty-four hours before taking the cocaine, six doses proved effectual. Dr. Mauassein thinks, therefore, that he is quite justified in inferring that in cocaine hydrochlorate there have a certain and harmless remedy against sea-sickness. He reports also that he has used it with success in two cases of cholera nostras. Cocaine and its salts still continue to attract undiminished attention from the medical profession, and it is probable that numerous applications will yet be found for one or other of these products. Sea sickness, as already stated, is one of the latest evils for which it has been used with advantage. The supply of coca leaves is now becoming sufficiently abundant to admit of cocaine being obtained at more moderate prices, and though different parcels are very unequal in their yield of the alkaloid, this circumstance may probably be due to defective procedure in the preservation of the leaves after they are gathered, leading to a total or partial decomposition of the alkaloid. The remarkable facility with which cocaine is decomposed is a reason for especial care being taken in harvesting the leaves and in protecting them from injurious influence during their transit to this country. Some samples of cocaine hydrochlorate have been met with presenting indications of being contaminated with an admixture of some other substance which may be inert or even prejudicial for the purposes to which the salt is applied in medical practice. Whether this foreign substance originates from leaves that have undergone fermentation or heating, or whether it is produced in the course of manufacture, is as yet uncertain, but it is the more important that the true characteristics of cocaine and its salts should be correctly and precisely defined. In this respect, unfortunately, the article "Cocaine hydrochlorate" in the new issue of the British Pharmacopoeia is merely a chemical conundrum. It describes a process by which cocaine hydrochlorate may be obtained, though it is by no means the best among several that are available for the purpose. Under the head of "characters and tests" a definition is given presumably of cocaine hydrochlorate, but it is so utterly erroneous that any substance possessing the specified characteristics would not be either cocaine itself or the hydrochlorate of that alkaloid, and many who take the trouble to follow the directions of this authority in testing the quality of cocaine hydrochlorate would be entirely misled and mystified. Assuming that the definition applies to cocaine hydrochlorate, the statement that it is readily soluble in ether is erroneous, yet this character is assigned to it in the British Pharmacopoeia parallel with the solubility in water, of which cocaine hydrochlorate requires less than its own weight. The definition of the Pharmacopoeia does not apply more correctly to cocaine itself, for, though the alkaloid is readily soluble in ether and alcohol, it is not readily soluble in water, but only so very sparingly soluble in that liquid as to come almost within the limits of substances insoluble in water. Apart from the positive inaccuracy already mentioned, it may be pointed out that the description of cocaine hydrochlorate is extremely meagre in regard to all the more important characters of the salt, and that it really affords no indication of means by which the purity of the substance can be ascertained. Giving a yellow precipitate with gold chloride and being charred by hot sulphuric acid and by heat, are certainly not, in themselves, likely to be of much utility in clearing up a question as to this point, and it would, at any rate, not have been superfluous to have stated the degree of solubility in water and other menstrua, as well as to have given some decisive clue to the identification of the salt and of the alkaloid itself.—*Pharmaceutical Journal.*

TERMS USED BY INDIAN TEA PLANTERS.—“Namouna” is the Hindustani for pattern, specimen, muster, &c. &c. A 12-anna fire is a fire of 12-16ths strength; a full strength fire would be a 16-anna fire (i. e. a whole rupee fire). Thus, a judge who is considered right in 3 out of 4 of his judgments is called a 12-anna judge. Regarding other Hindustani words, “jāt” simply means “caste,” a much more generally intelligible word than “jāt.” “Gyn-hana” is the proper spelling, not “jyukhana”; it means a place of meeting, for feasts—“gyn” meaning a feast, trick, dodge, ingenious way of doing anything.—*Car.*

CULTIVATION OF PLANTAINS.—The difficulty of tabulating the information respecting the acreage under different products may be judged from the following extract of the letter of an extensive proprietary planter:—“Some of the figures are not strictly accurate, correct with regard to tea area. We are planting more tea new and throughout the next few months, and the total area in tea is what the acreage should be before the year is out. There is another thing: a considerable area of tea is planted in the coffee and, though next month of the non-bearing coffee where the tea is growing well will be cut out, it has not yet been cut out. In some cases, too, little patches of my good coffee in certain fields have not been planted through with tea, though the greater part has. It is very difficult, therefore, to be anything but approximate with regard to the area. In a couple of years this will all be rectified.”

TEA.—The *Travels Observer* publishes a letter which has been received from London by one of its correspondents. The writer of this letter writes to his Ceylon friend as follows:—“You ask if we drink Ceylon tea; and the answer is, the grocers do not care about it, they say it cannot be depended upon, it varies so much; and if so, why cultivate it? Then again, doctors are setting their faces against tea; two doctors advised me not to drink it at all. So we only use it for afternoons, and even then at many houses coffee is offered at afternoon tea parties, so many people are not allowed to touch tea. In the hospitals now coffee is given as a stimulant instead of brandy, and everywhere it is being preferred; so why turn your coffee into tea plantations? The writer, I believe, gives the result of his own experience, which, we imagine, is not very great. Ceylon planters are not likely to be influenced in the smallest degree by such a communication, which, in face of the growing demand for Indian and Ceylon tea and the decrease in the consumption of coffee, is absurd. The letter referred to contains a reference to the medical theory about tea which is worth noting. Medical opinion, as those who have had the misfortune to seek it, know to their cost, is very diversified and eccentric on the matter of diet and drink. One medical man recommends strong wine, where another advises abstinence from alcohol. Others tell their patients to drink coffee and avoid tea, while in some cases coffee is strongly condemned. We have no desire to find fault with the various views. Medical advice is frequently conflicting, but who shall attempt the delicate task of deciding under such circumstances. Anyway, some medical opinion is not against moderate tea drinking. Cups of tea, coffee, or any other drink taken at short intervals throughout the day may be as injurious in their way as “nips” of alcoholic drink, but unadulterated tea taken in moderation is not harmful, except in isolated cases. By the way it may interest Indian and Ceylon tea planters to learn that a friend of tea retailers who makes Indian and Ceylon tea especially recently received a letter from a well-known lady, in which the writer praised their tea, stating that Chinese always made her nervous, but she could drink India or Ceylon tea without any ill-effect, and that she should henceforth recommend these teas to her friends on that account. This view may be regarded as a set-off to the medical testimony vaguely referred to in the letter from London to Ceylon, and it is of at least equal value as a matter of opinion.—*Hunt. News.*”

DR. TRIJON ON “CARACAS” CACAO.—We call attention to the letter from Dr. Trijon (on page 121) summing up very clearly the amount of practical and scientific knowledge at present available as to the several varieties of cacao. We may supplement what the Director says by the following extract from “The Cacao Planter’s Manual,” by E. Bertholink, Planter of Surinam, recently published:—

The Caracas sort is red. The Surinam cacao is the ordinary yellow sort, and is planted everywhere. In a Cacao-field many different varieties of Cacao, sometimes even as many as twenty, are found. The best sort, however, is the so-called Porelain Cacao, distinguished by a thin, smooth shell, and the fullness of its beans.

Then you have the Malé Cacao-tree. This distinguishes itself by constantly producing a quantity of “do-soms,” and very few (at most 3 or 4) fruits. These fruits, if they do come to maturity at all, only contain as a rule 2 or 3 small beans. Fortunately this species is very rare, one tree only occurring within an area of twenty acres. The red Caracas sort is rarer than the ordinary yellow sort. The difference between the two is considerable. The Caracas sort shows up more vigorously and luxuriantly, displays more growth, flowers more exuberantly and bears a greater quantity of fruit than the indigenous species; it bears also much better the vicissitudes of the seasons. Caracas cacao long preserves its properties in fields where it is planted alone; but planted between the indigenous, it degenerates and assumes the properties of the common sort. The first seeds of Caracas cacao were brought hither by the Governor R. F. Von Raders in 1845 or ’6, so not more than 40 years ago.

THE “TEA-PLANTERS’ VADE MECUM,” compiled by the editor of the *Indian Tea Gazette*, seems an admirable and invaluable work. No tea planter, however varied his experience or wide his knowledge, can afford, we imagine, to be without it. Every detail connected with the history, growth, manufacture, and market of tea seems exhaustively and systematically dealt with, and brought carefully up to date. The book has a comprehensive index, and an appendix of ruled blank pages for the cultivator’s notes upon his own experience or the contents of the work. The subject is conveniently divided into sections. The first treats of the history and geographical distribution of the tea-plant, and the second of the climate, drought, and rainfall. The third deals with tea from the scientific point of view of the botanist and chemist—the latter leading naturally to section four on tea adulteration and the substitutes used for tea. The next nine sections are concerned respectively with the soils, manures, drainage, seed-sowing, transplanting, cultivation, blight, pruning, and plucking of tea, and one section is devoted to the relations of the saw-tree to tea-growing. Section fifteen describes the necessary buildings, with the latest improvements, and the three following deal with the important subjects of steam and other machinery, and the *malis overland* of manufacture. Section nineteen treats of tea sorting and bulking; section twenty of the timber suitable for tea-boxes. Then follows section devoted to tea weighing, the brick tea of China, Burma, and Tibet, Indian tea outside Bengal, Ceylon tea, tea outside India and Ceylon and finally tea manufactured in China and Japan. From this summary it will be seen that the “Tea-Planters’ Vade Mecum” contains all the knowledge that the vastest tea require, and much that the most experienced planter could not be without. We cannot do better, both for the compiler and the Editor of the *Gazette*, than to say that a copy of this work may be found on the shelves of every person interested in the subject.—*Pioneer.*

DE CANDOLLE calls attention to the fact that a branch of a coffee-tree, preserved in a solution made by boiling water, with about seventeen per cent of common salt, retained its green colour for fifty-three years.—*Indian Gardener*.

THE largest field of pineapples in the world is on an estate in the eastern district of New Province, Bahamas. From one spot it is possible to see at a single glance 1,200,000 pineapples growing.—*Madras Mail*.

THE MEANS OF COMMUNICATION between Assam and Calcutta seem still very unsatisfactory, to judge from the following statement which appears in the *Indian Planter's Gazette*:—The journey of a tea box from Sylhet to Calcutta, if related, would contain some amusing episodes. It is shipped first at Kurimgunge, transhipped again at Fechoogunge, sometimes, we suppose, at Narraingunge, always at Goalundo, and finally transferred by bullock gharry from Scaldah to the brokers' godowns. It seems somewhat incredible that the same steamer that ships the tea at Kurimgunge, should not continue the journey right through to Narraingunge and save all the trouble of transhipments which must cost money, and risk damaging to the tea. Why should a steamer require to lie 24 hours at Fechoogunge? and then only steam the following day for two hours? Wherein consists the profit to the company itself? the steamers can only bank fires, they cannot put them out. There is surely something strange, incongruous in all these arrangements. For a high charge for first-class accommodation, one naturally expects a high rate of speed to be maintained, but here he gets neither comfort nor speed. Our Assam planters in the districts of Sylhet and Cachar should agitate and have this state of things altered. We trust soon to hear that the journey from Calcutta has been reduced to such limits as will not deter intending visitors from undertaking it.

NEW ERA COFFEE.—We have been asked by many of our readers, "What is the *New Era Coffee*? What is it made of?" and if it is a cheap substitute for coffee, etc. We are pleased to inform all who have asked these questions, and for the benefit of others that have not, who, no doubt, have seen the advertisement on the front cover of the *American Grocer*, that New Era Coffee is for people who cannot, or should not drink the regular imported coffee and teas. It is no cheap substitute for tea or coffee, but an article of great merit, and every grocer should keep it in stock, as they all have more or less customers who never buy one dollar's worth of either tea or coffee, and are drinking hot water and milk for their breakfast or other meals, because they have not been informed of something better, and never get rid of their dyspepsia and constipation, nervousness, etc. It is made entirely from wheat by Putnam's patent process of treating, steaming, drying and roasting, which takes several days to complete; it is unequalled as a nutritious, healthful and strengthening table beverage and really supplies a want that has long existed; it contains health-producing elements not possessed by tea or coffee; its energizing effects are not followed by reaction. This scientific process, occupying as it does several days, the objectionable properties of the grain are removed and the starch and glutinous properties are so changed that the kernel is rendered hard, brittle and semi-transparent. One excellent feature of this New Era Coffee is its entire freedom from any properties that can injure the most delicate organisation; therefore, it is very nice for children, who thrive on it as a beverage. We can recommend the goods very highly to the grocers, and we hope they will appreciate its merits and give their customers a chance to buy a good article.—*American Grocer*; but why, dishonestly, call it coffee if made from wheat? It is a cheat of the worst kind.—*Ed.*

THE TEA TRADE IN THE BRITISH PROVINCES.—A provincial tea agent in the old country reports a considerable improvement in his tea business during the past year, in spite of all the principal grocers having Ceylon tea now. He thinks the popularity of Ceylon tea is now at its height. Of those who now sell it, there will undoubtedly be a proportion who will give it up. Several who used to advertise for a while, don't have any now; he supposes because they have difficulty in *matching*, as they sold out, and as all changes of style and quality interrupt trade, they have thought it better to put confidence in their own blends. He attributes his own increase of trade to advertising.

LABOURERS PER ACRE IN ENGLISH AGRICULTURE COMPARED WITH TROPICAL.—Nothing struck us more forcibly in Australia than the small number of hands employed on vast pastoral runs; a couple for each 500 or 1,000 acres, except in sheep shearing time. The following passage from Lord Salisbury's Newport speech, shows that one man per 100 acres suffices for grazing land in England, while in coffee culture and much more in tea culture in Ceylon, at least 3 coolies for every 3 acres are required, or say 300 persons for 200 acres. Here is what Lord Salisbury said:—The growing of wheat has become, over a vast extent of the country, an unprofitable occupation. A farmer knows that on the growing of wheat depends the continuance of arable land, for if the wheat crop does not pay the chance of his arable land paying is very small. The consequence is that in every part of the country, especially on the east of the island, large tracts of land are going into grass. Grass does not pay well, but it pays moderately, and the landowner, farmer proprietor, or occupier naturally takes to farming that which is most profitable to him, and the invariable result is that the number of hands required in agriculture diminishes—three men for every 100 acres required for arable land, and one man to every 100 acres for pasture land.

COCA. The latest information respecting this new product is not very encouraging to would-be cultivators of the *Erythroyylon coca* in Ceylon. An exhaustive paper by Dr. Squibb on 'Coca at the Source of Supply,' which we are republishing in full in the *Tropical Agriculturist* among other things tells us about the production and consumption of coca. Coca seems to be produced throughout the whole Andean plateau from Ecuador to the Argentine Republic. At present, Peru and Bolivia seem to be the exporting countries; and in the former 7½ million lb. are said to be gathered, of which all but 375,000 lb. are consumed in the country. The Peruvian Government are said to tax a production of over 15 million lb., but only 5 per cent. here again, is said to be available for export. That makes a total export to the United States and Europe of 1,125,000 lb. One million lb. of coca would yield at least 2,500 lb. of cocaine, while one-fourth of that quantity would probably over-stock the markets of the whole world. Surgeon-General Balfour, addressing the India Office in July last, mentioned that Mr. Howard had bought all the coca leaves in the English market at 3s per lb., but that, as 50,000 lb. were on the way from New York, it was expected the price would fall to 6s per lb. If, however, the coca leaf, as Dr. Balfour seems to think, may yet take its place in India and Europe alongside of tea and coffee, there may then be room for profitable cultivation in the East. Dr. Balfour's paper will also be republished in full in our *T. J.*

"GILDING REFINED GOLD AND THROWING A PERLE ON THE VIOLET." We in Ceylon have no mean opinion of our tea, but let us listen to Messrs. Lewis & Co.'s superlatives! Here they are:—

NEW SEASON'S CEYLONS.

Half-chests Ceylon downy pekoe (*exhibition specimen tea—a blaze of golden tip, perfection in liquor—absolutely matchless.*) 39.

Half-chests superb new season's Ceylon orange pekoe (handsome leaf, full of tip, full, rich liquor, with superb quality) 23.

Chests extra choicest new season's Ceylon broken pekoe (handsome tippy leaf, strong, ripe, sappy liquor, with exquisite flavour.) 14.

Chests extra choicest new season's Ceylon broken pekoe (very handsome, with tip, strong, telling liquor, with highest quality) 16.

Chests extra choicest new season's Ceylon pekoe handsome leaf, with tip, fragrant, rich and extra fine) 15.

Half-chests extra choice new season's Ceylon pekoe (well made leaf, with tip, strong, thick, powerful liquor, with finest flavour) 13.

Chests extra choice new season's Ceylon pekoe son-chong (handsome, full, rich, mellow liquor, with high est quality) 11.

Chests choicest new season's Ceylon son-chong (handsome, malty great power, choice quality) 11.

Chests choice new season's Ceylon pekoe fannings (tippy, treble thickness; worth 2s in liquor) 11.

Half-chests choice new season's Ceylon broken (leafy, good colour, strong, telling liquor.) 8.

The gradation of adjectives is wonderful and the 11d. tea being worth 2s in liquor is the finishing touch.

"THE QUESTION OF THE DAY: HOW TO MAKE MONEY." Under this heading a correspondent writes to the *Hongkong Daily Press* pointing out various undertakings in the Malay peninsula in which money might be profitably invested, such as mines and agricultural companies; with regard to the latter, he says:

I cannot understand how it is that the rich agricultural soil of a country so well adapted for the production of tea, coffee, sugar, tobacco, gambier, sago, tapioca, and all the tropical products of the East, is almost entirely neglected! There are in Johore only a few small coffee estates, the trees on which, now in their second, third, and fourth years, have surpassed all expectation; and the cultivation of Liberian coffee is now an unqualified success, and new plantations are rapidly being opened up. There is the Johore Tea Planting Co. started by a London syndicate some three years ago which is also a great success; and the company is now clearing and planting on a large scale. Small quantities of tea are being shipped every month to the London market, the quality pronounced equal to the finest produced in Ceylon, superior to the Choia as well as the India teas. I hear of an Agricultural Company about to be started in Johore for the production of tea, coffee, tobacco and hemp and other tropical products. This, I should think, with facts now before me, will meet with success, as every new enterprise which has for its object the opening up of a fertile country richly deserves. I enclose you an article entitled "Liberian Coffee Prospects," which appeared some time ago in one of the Singapore papers, which, if you will kindly insert in your valuable columns, I am sure will be read with very great interest by many of your subscribers. Since this article was written, the Chasserian estate in Singapore has been formed into a public limited company, with a capital of \$250,000 all subscribed for by about twenty-five shareholders. The area of the said estate in Singapore comprises 3,200 imperial acres.

He also adds:—

I have before me a Manila prospectus for the production of hemp in the Philippine Islands, showing a profit of something like 80 per cent per annum. It is well known that the profit on hemp cultivation in the Philippine Islands is over 100 per cent per annum, but English capital once invested in any business in those delightful islands is seldom or never seen again. This I know from sad experience.

A BOMBAY firm is advertising Russian kerosine for sale. This is the first time, probably, that the produce of the famous wells at Baku has reached India. Last year, India imported over 20½ million gallons of kerosine; and nearly all of it came from the United States.—*Madras Mail*.

DELI NEWS.—By last advices from America it appears that the consequences of Deli tobacco of the 1881 crop lacking showy colours were beginning to be felt, it having become difficult to clear off stocks of that article. The imports of Sunnata tobacco into America from June 1884 to June 1885 reached the total of two millions of guilders in value.—*Straits Times*.

THE COUNTRY WHICH THE GERMANS are aiming at from Zanzibar, and which is now to be the scene of another Boundary Commission, has been described by an English missionary, Mr. Last, who has lived in it for eight years. Beginning about twenty miles from the coast, it runs back among mountains which rise to the respectable height of 7,000 feet, and are covered with valuable forests. The fertility of these uplands is depicted in attractive colours. The crops raised by the natives are Indian-corn, millets, beans, pumpkins, cassava, and bananas; of the latter they have eight varieties. The soil readily yields much more than the actual wants of the agriculturist require. Irrigation is commonly practised, especially in a dry season, and the abundant supply of water upon the mountain slopes makes it comparatively easy. At an elevation of 4,000 feet English vegetables can be grown to perfection, and potatoes in particular attain fabulous dimensions. Ordinary English flowers also do well. The fruits are the common ones of India and other sub-tropical countries, while on the higher ranges the raspberry and blackberry grow wild and can be raised to the level of English garden fruit by domestication. Rice is produced in the plains and valleys, together with three varieties of sugarcane. One tract in the hills is famous for iron mines. The climate at a height of 4,000 feet is said to be healthy. There are summer rains for a month about November, and the autumn monsoon from March to June. During the cold season the temperature at sunrise is about 50° Fahrenheit, rising to 70° at midday, and fires are necessary at night; in the hot months the thermometer marks 90°, but one can sleep without a punkah. The people are extremely peaceable, not to say cowardly. If they can possibly run and hide in the jungle, they greatly prefer doing so to fighting. There is said to be plenty of waste land, which the local chiefs will sell for a piece of cloth, or give for nothing to any white man who will do them the favour of coming to live among them. These chiefs divide the country between them, and though owing a nominal allegiance to Zanzibar, they are practically independent. Possibly they will change their views as to the desirableness of white settlers after a short experience of German military colonists. Hitherto the beneficent missionary had been their only type of white man. Mr. Last mentions a report that the Germans are about to make a railway up from the coast; and if this be true, the happy idyllic life of poor Quasher has not much longer to last. At the same time it is more than doubtful if his country will ever be worth anything as a German colony in the true sense of the word. The fertility of the land may be all that Mr. Last describes it, but those who have had practical experience of the tropics will be slow to believe that Europeans can increase and multiply in a country situated six degrees south of the line, and where wheat cannot be grown. —*Pioneer*.

A CURSE FOR BUGS.—An old Ambagamuwa planter of the "forties" and "fifties," who in his day had every tree on the estate bugged and who had long conferences with Dr. Gardner about the pestiferous insect, is certain from what he has lately seen that the bug now troubling the coffee north of Kandy is the same, and that lime and sulphur (though inefficacious with leaf-lungus) will be found a radical and effectual cure for bug. Will our "blackbugged" correspondent try this cure and report progress?

TO BLEACH FERNS. take one half-pound of chloride of lime and one pound of washing soda, add three pints of water to the lime, and five pints to the soda, in separate vessels: let each stand twenty-four hours; then pour them together, and a fluid resembling milk and water is the result. Allow to settle—pour the clear liquid over the ferns, and let them air until bleached; then take them out put them in cold water for two or three hours, take them out upon paper like seaweed, and press thereafter they are a little drained.—*Indian Gardener.*

CANARIES.—Referring to "Enquirer" about breeding canary birds, I have successfully had several out of a pair from China. They should have a well ventilated cage (rather large) in a secluded spot with good air, but not to be caught to a draught; the nest must be covered with lint, allowing them a little cotton, fibre and small feathers to complete it. As soon as you know the hen has laid the first egg remove the male, and as soon as the eggs are hatched allow them to grow up on tender salad leaves and a small quantity of the yellow of hard-boiled eggs with fresh supplies of sops, fresh water, keeping the cage clean with a sprinkling of sand and chunan.—*Cor.*

INDIAN TEA PRICES.—The *Indian Tea Planters' Gazette* contains an analysis of the working of various Indian Tea Companies, and appends the following note:—

Average gross price proceeds sale of crops including all receipts excepting gain in Exchange:—

	1879.	1880.	1881.	1882.	1883.	1884.
	per	per	per	per	per	per
	lb.	lb.	lb.	lb.	lb.	lb.
Assam Company	1 54	1 23	1 12	1 25	1 11	31-32 1 05
Boreh Tea Company	1 54	1 24	1 43	1 14	1 2	1 2 13-16
Bevan Brooma Tea Com	1 32	1 1	1 35	1 19	0 112	1 02
Wilson Tea Company	1 73	1 02	1 23	0 113	1 02	1 0 11-16

What is noticeable is the serious fall in prices in 1880 as compared with 1879, the recovery in 1881, and then the much lower prices for three years ending 1884. The adoption of machinery and other improvements may possibly secure economy of manufacture such as to atone for the serious difference in prices.

PLUMBAGO FROM IRON. It has been announced that M. Fourquignon has obtained graphite, or plumbago, in an unusual manner. He treated cast iron in a vacuum to a temperature of from 1620 to 1800 degrees Fahrenheit without melting, when he found the metal became malleable and its surface uniformly black and dotted with black grains of amorphous graphite, his explanation of the process being "that the formation of carburet of iron, or plumbago, is a function of the temperature." This description is open to objection, for graphite, or plumbago, is an allotropic form of carbon, and is not carburet of iron at all. Certainly, graphite often contains some iron, but the quantity is so small and uncertain that its presence may be regarded as accidental. It is only in old chemical text books that plumbago is described as a carburet of iron. Graphite can now be obtained quite free from the metal. The experiment is nevertheless an interesting one, and it may lead to something of industrial importance.—*Ædipus* in *Lender*.

THE KADDAM FOR TEA BOXES.—Mr. Peal writes:—I am planting out Roghu here (*A. Cadamba*), and expect it will be fit to saw up in 8 to 9 years. Some were planted in June 1884, and now say 18 months old, are 24 feet high, and 12 and 14 inches girth. From what I see I think one inch per annum radius can be relied on for the first eight years, after which it gets slower and slower, down to quarter inch at 16 years. The plants are got from my tea nurseries, and no one so far can raise Roghu from seeds, but thousands sprout in all clearings.—*Indian Forester.* [Has *A. Cadamba* been introduced to Ceylon?—*Ed.*]

NEW ELECTRIC PLANT.—A recent German publication contains a description of a new electric plant that has been christened *Phytolacca electrica*, which possesses strongly marked electro-magnetic properties. In breaking a twig the hand receives a shock that resembles the sensation produced by an induction coil. Experiments made on this plant showed that a small compass was affected by it at a distance of about twenty feet. On a near approach the needle vibrated, and finally began to revolve quite rapidly. The phenomenon was repeated in reverse order on receding from the plant. The energy of the influence varied with the time of day, being strongest at about two o'clock p.m., and becoming almost nothing during the night. It was also greatly increased in stormy weather; and when it rains the plant seems to wither. It is said that no birds or insects are ever seen on or about this plant. The soil where it grew contained no magnetic metal like iron, cobalt, or nickel, and it is evident the plant itself possesses this electrical property.—*Indiarubber and Gutta-percha Journal*.—Hum! [*Ed.*]

LETTUCES AND POTATOES IN MAURITIUS.—The President laid on the table some seeds of the *Cichoua Ledjrina*, *Cichoua Hybrid* and *Didividi*. He said that the *Cichoua Ledjrina* was very rich in quinine. The President then presented two new varieties of lettuces which were sent to him by the Hon. Mr. Fraser who obtained them about two years ago. The Hon. Mr. Fraser said last year he did not succeed with these two new varieties, but this year the result was satisfactory, the lettuces were large and hard, but they were somewhat bitter. Mr. Vankersbylek presented six varieties of potatoes, three introduced by Mrs. Vigier Latour and three by himself. The three introduced by Mrs. Vigier Latour were the "White Elephant," two tubercules of which had produced 110, others and which in Europe gives 50,000 kilos per hectare, the "Anderson" two tubercules of which had yielded 126 others, and the *Magnum Bonum*. The three varieties introduced by Mr. Vankersbylek were the "Saucisse de Hollande," "Bolle Blonde" and "Ma Tante." He presented also some potatoes obtained from cuttings. The Hon. Mr. Fraser said that he planted half an acre with Bourbon Potatoes, and the yield was about 8,000 pounds an acre, out of which 25 per cent were large potatoes, 50 per cent middling and 25 per cent small. This at two cents per pound would give \$100. This result could only be obtained in four months. He had this to say, that the potatoes produced here could not be preserved, whilst those of Reunion kept well. It was the same thing with the Beans. The President said that the best manner to preserve them would be to have them in ensilage.—*The Acclimatization Society, 2nd September 1885.*

* There is also a difficulty about ensuring germination of the *Hulu* (*Adina cordifolia*), a plant allied to the Roghu or Kaddam, but we have succeeded in raising seedlings of the latter, in raised beds of fine charcoal dust, in the same way as *Ficus elastica* is sown in the Charlard plantation in Assam.—*Ed.I.F.*

CATARRH OF THE BLADDER.

Correspondence.

To the Editor of the "Ceylon Observer."

TEA FOR AUSTRALIA.

Sydney, 21st Sept. 1885.

Sir, As the growth and manufacture of tea in Ceylon are making vast and rapid strides, we offer the following suggestion in view of your opening up a more extensive trade in Australia. The classes of Ceylon teas likely to be most suitable for importation into this market are:—

1. *Finnings or broken teas (not dust)*, not too red in the leaf, with thick rich or pungent cup, packed in chests of 80 to 90 lb. costing from 8s to 1s per lb. laid down in Sydney.

2. *Pekon souchongs* with even, fairly small or "milled" leaf, pungent or flavory cup; in chests or half chests, costing from 9s to 1s 1s per lb. laid down.

3. *Pekoes*, good, wiry, well rolled *tippy* leaf, clean rich flavory cup, packed in half-chests only and costing 11s to 1s 3s per lb. laid down.

Avoid teas that are too highly *burnt*. Several patents have been sacrificed lately through over-fering.

The market here for Indian and Ceylon teas must, of course, for some time depend on operations in Calcutta, but for the past 18 months, Indian shipments to the colonial markets have shown satisfactory results, and there is every prospect of their continuing to do so.

We would suggest trial shipments from *different districts* for the purpose of classification which would enable a more decided opinion to be given upon the future prospects in Sydney. Yours faithfully,
CAMPBELL, SYNNOTT & Co.

DISEASED TEA.

Galle, 2nd November 1885.

DEAR SIR,—I have the pleasure of sending you some diseased tea plants from the nursery of St. George estate, Buldigama. The leaves are covered with a peculiar kind of spots, resembling very much like the specks on cinnamon leaves. The plants die away in a very short time. I have some experience of tea planting and I could not remember ever having seen a disease of this nature.

Could you or any of your numerous correspondents let me know what it could be? A corner for this in your valued paper will oblige, yours faithfully,

TOM ROSS MACK.

The tea bushes sent are covered with warty excrescences caused probably by an obstruction to the flow of sap, either by disease or the attack of some insect.—Ed.

CARACAS CACAO.

Pradeniya, 14th Nov. 1885.

SIR, I observe that you have recently called attention, by an extract, to some remarks in my last Garden Report upon the characteristics of the varieties of cacao grown in Ceylon, especially with reference to the so-called "Caracas." It has always been obvious to me that this name had been misapplied here, and I have never used it. Perhaps I may be permitted to quote from a previous Report of mine (1882) as to the nomenclature of these "pale fruited" varieties, so far as could then be judged of them by comparison with the

descriptions of writers on the subject:—"In recent years several other kinds with paler pink or yellow fruit have been imported into Ceylon. Of these some were introduced in 1873 by Mr. Worms, and others by Capt. Bayley, the Ceylon Company, &c. Some were obtained direct from Caracae, and consequently the plants have been generally known as 'Caracae' in the colony. Several varieties of this sort are in the Honaragoda Gardens; the pods vary in colour, pale glaucous green passing into yellow or orange, pale pink or pale crimson, and the seed is always flattish and paler or darker purple in section. It is clear that the true 'Caracae' also known as 'Criollo' (creole) cacao—is a different variety from these, as it is stated to have the pods almost invariably red, and the seeds nearly globular and pale crimson on section. I am thus inclined to refer our pale-fruited kinds to the varieties called in Trinidad 'Verdillo' and 'Cayenne!'"

The fruiting of the selected and named varieties sent from Trinidad in 1880 and 1881, has since shown that all these names (Cinnamon, Cayenne, Verdillo, &c.), are applied to forms of what is known there as "Forastero" cacao, and that none of the purple-seeded kinds are of the "Criollo" or "Caracae" variety. It will therefore be well to use for the future the name "Forastero" for them here also.

This being the case, the question naturally arises as to the ordinary red cacao of Ceylon: What variety is it? and is there anything like it grown elsewhere? For some time I have been becoming more convinced that it is *this* that is the "Caracae" or "Criollo" cacao, and I might have taken stronger ground on the matter than I did in my last Report. Mr. Morris of Jamaica, who has had good opportunity of investigating the cacaos, both in a wild and cultivated state, tells me that he knows of "only one kind with the cotyledons white or whitish, and that is what is known as Caracae cacao." This, it is well known, is now a rare kind in the West Indies, and scarcely to be found in Trinidad estates, having died out, though formerly largely grown there. Evidently Ceylon obtained its plants before this change had occurred. The high quality of "Ceylon cacao" is thus explained, as well as its delicate temperament. I am, Sir, yours faithfully,
HENRY TRIMLEN.

CINCHONA BARKS.—A change of very great importance has been made in the official barks of cinchona and the preparations therefrom. This has been rendered necessary from the increasing difficulty of obtaining the bark from its native sources and from the greater facility with which cultivated bark rich in alkaloid may be procured. Hitherto our Pharmacopoeia has contained three varieties of cinchona bark, the pale bark with 5 per cent of alkaloids, the yellow with 2 per cent of quina, and the red with 1.5 per cent of alkaloids, and the pharmaceutical preparations have been all ordered to be made with the pale or the yellow bark. In the new Pharmacopoeia other varieties of bark are mentioned merely as sources from which the alkaloids may be obtained, and the red alone is to be used in preparations. This is described, under the name of "cinchona rubra cortex," as "the dried bark of the stem and branches of cultivated plants of *Cinchona* *rubra*," and is required to contain not less than "between 5 and 6 per cent of total alkaloids, of which not less than half shall consist of quinine and cinchonidine." Although this is a so much higher percentage of alkaloids, such bark is now easily obtainable in commerce. Notes on the New British Pharmacopoeia, 1875, by N. H. MARTIN, F.L.S.—*Pharmaceutical Journal*.

* A droll idea of "pleasure."—Ed.

NILGIRI FLORA.

The moist evergreen forests of the Nilgiris are grandest on the western slopes and between 3,000 and 4,000 feet elevation, where the trees often attain 200 and 250 feet in height. They are all evergreen, and the great variety of foliage and color render them exceedingly beautiful, some of the young leaves coming out pure white, others a bright crimson, others all possible tints of brown, yellow, red and green. These tracts are exceedingly moist from the first showers in March till the end of December, and during that season abound with lichens. The trees are often covered with *Euphyllor* orchids, ferns, mosses, balsams, and there is a glorious profusion of rattans, tree ferns, climbing ferns, and fine creepers. What may be said to be most characteristic of these forests is the genus *Strobilanthes* (Acanthaceæ), large shrubs which form the principal underwood, and of which at least 30 species are found on these hills. Some of these flower every year, others only after a growth of six or seven years, when they die down, and renew themselves from seed. They have all showy flowers, and many are very beautiful. The two palms *Corypha urens* and *Arecina Wrightii* are very conspicuous in these tracts; also several species of rattan *Calamus*, and two very fine reed-bamboos. Ferns are in great profusion, including several tree-ferns, amongst which the *Allophila cernita*,—not yet we believe introduced into hot-houses—is unmatched in any country. Very beautiful *Suaresias* and *Balsams* are also in profusion. *Gattiferas*, *Rubiac.*æ and *Euphorbiaceæ* are the orders most copiously represented. Above 4,000 feet these forests begin to decrease in size, and towards the plateau they gradually pass into what we term *sholas*. These moist forests never reach quite down to the plains any where round the Nilgiris, though they do so in parts of South Canara, Coorg and Travancore; they always give way at about one thousand feet from the base, to deciduous forest or tracts composed of nothing but reed-bamboos.—*S. of I. Observer.*

Nearly all fruit of our mountain forests in Ceylon, except the abundance of rattans, We have them, but not in "profusion."—*Ed.*

ADULTERATED CHINA TEA.

There has been no outcry of late about tea adulteration, and no doubt many innocent consumers are under the impression that the art of tea adulteration is nearly lost, and that the bland Celestial is mending his ways. The following report from the Commissioners of Customs on the examination of teas in bond, made by their analyst under section 30 of the Sale of Food and Drugs Act, 1875, is therefore interesting reading:—

Report of Examinations of Tea made under section 30 of the Sale of Food and Drugs Act 1875.
Board of Customs.

Honourable Sirs,—The particulars of the analyses of teas under the Food and Drugs Act, for the year ending Dec. 31st, 1881, are as follows:—There were received 870 samples, namely—623 faced green, 56 unfaced green, 30 caper, 88 congou, 37 sweepings, and 36 fannings. The teas, which 850 of these samples represented, were delivered by the analyst for home consumption, their quality exempting them from the condemnatory clauses of the Act.

One sample was delivered by the Board, and the teas represented by the remaining 19 samples were restricted to exportation. The analyses of these 19 samples, representing 978 packages, showed them to be of a very inferior description of different classes of teas, as follows:—203 packages of green teas with a large admixture of decayed and exhausted leaves; 334 packages were congous (these two contained a considerable proportion of leaves which had been previously exhausted); 16 were also congous, which, being packed damp, had become deprived of their proper strength and quality. The remaining 425 packages were capers; these contained from 10 to 11 per cent excess of silica. The number of samples analysed in the last five years, with the manner in which the

teas were disposed of, is shown in the following table:—

	1880.	1881.	1882.	1883.	1884.
Samples analysed...	2,814	1,242	941	852	870
Delivered by analyst	2,440	990	9.5	838	850
Reported to the Board	404	252	16	14	20
Delivered by the Board					
for home consumption	84	14	1
Delivered by the Board					
for exportation...	276	222	2	14	19
Number of packages represented...	30,195	41,143	88	665	978
Seized	41	16	14
Number of packages represented...	6,225	1,153	164

The adulterants present in the teas of the past year were of the usual character, and, with one exception, the parcels subjected to restriction were composed of China teas.

(Signed)

G. EXCELL, Analyst.

Although—owing more to increased vigilance on the part of the Customs authorities than to any qualms of conscience on the part of the Chinese grower, or shall we say manufacturer, the trade in adulterated tea is not so brisk as it used to be, there are indications in the above report that it is not yet extinct.—*H. & C. Mail.*

THE MADRAS GOVERNMENT AND ERYTHROXYLON COCA.

A paper sent to us contains letters on this subject from Sir Joseph Hooker and Surgeon-General Edward Bullour. The first reported that nothing can be added to the statement as to the method of drying made by Deputy Surgeon-General G. Edlie, C. I. E., in the pamphlet upon coca recently published by him at Madras. Slow drying in the sun appears to be the whole art of the matter.

I am also to state that, from a letter received from Mr. Lawson, the Director of Government Cinchona Plantations, Parks and Gardens, Nilgiris, dated 23rd April last, there is reason to think that the difficulty met with had been overcome.

Surgeon-General E. Bullour replied at greater length and managed to make several references to the recently published edition of his *Cyclopdia*. He wrote:—“Your letter of 23rd ultimo enclosed a communication from the Government of India asking information regarding the mode of preparing coca leaves for the market; also instructions regarding the cultivation of the plant, and how the leaves are commonly used in South America. I have given a very considerable amount of information on these points under the headings ‘Coca’ and ‘Erythroxyton’ in the 3rd edition of my *Cyclopdia* of India; but, on receipt of your letter, I waited on Mr. Gale, of Messrs. Bell & Co., who has given me much information, and has obligingly obtained, from Mr. Tanner, the accompanying samples of the leaves, flowers, and fruit.”

2. Mr. Gale is of opinion that the leaves, when drying, naturally retain a flattened form, just as senna leaves do, and it is considered unlikely that any particular drying process is followed. But the Foreign Office, through Her Majesty's Consuls could obtain all the details as to cultivating, and as to gathering, drying and packing the leaves, with the ordinary market price in the locality, and the various modes in which the leaves are used. I could apply to the Consular Department to obtain this information, though such an application might, perhaps, come better from yourself. I have, however, ascertained that at present, the records of the Foreign Office do not contain any notice of this plant.

3. I may here mention some points of interest which have become known to me whilst I was collecting the information necessary for replying to your letter.

The leaves as seen in the market, are of the greenish hue observable in the accompanying sample.

The price of the leaves has fallen so low, with a prospect of a still greater fall, that it is not, at present, deemed advisable for any grower to incur any large expenditure for its cultivation.

I am informed that Mr. Howard recently brought up all the leaves in the market at three shillings the pound; and, as a consignment of 30,000 lb. is on the way for New York, Germany and London the price is expected shortly to fall to six pence the pound.

It is brought to this country in bags, in which the leaves are found much broken.

At present, about ten grains of the cocaine alkaloid are obtained from one pound of the leaves; and, on the 26th June, Messrs. Bell & Co. were selling it to medical men at one shilling the grain, and a retail price of one shilling and three pence the grain.

It is besides the use of the cocaine alkaloid as an anæsthetic in ophthalmic surgery, and during operations on the mouth, ear, and throat, pharmacologists have already prepared from the leaves a medicinal wine and an extract, and I think it possible, even probable, that the leaves may take their place as a tea plant, or as a valuable addition to the tea and coffee of commerce.

5. Also, it is yet to be ascertained whether the species *Erythroxylon* growing in the East Indies* may possess properties identical with that of the *Erythroxylon coca*. When this view occurred to me, I asked Surgeon-General Shortt to ascertain its importance. I meant that the leaves might be chewed as a masticatory, in the manner that they were used by Weston the pedestrian; but Dr. Shortt has not informed me if he tried that mode. He sent, however, to Mr. Edmund Blyth, the Analyst for the Marylebone district, twenty pounds of the leaves of the *E. monogynum*. That quantity was too small for experimenting with, but Mr. Blyth authoritatively ascertained the presence of an alkaloid. There would be a valuable addition to the food plants of the whole human race, if it be ascertained that the Indian species of *Erythroxylon* possess, like the *E. coca*, the staying properties of tea and coffee.

6. The institution of inquiries of this kind has ever formed a prominent feature in the British administration of India, and I think that this is one meriting investigation. But under the headings "Coca" and "Erythroxylon" in my "Cyclopaedia of India," just published, where I have noted the alkaloid and the species of genus, it was necessarily only with the brevity required for keeping each article in the due subordination to the other 35,000 which the book contains. And, if the suggested inquiry be undertaken, it seems desirable that it be conducted, as regards the verification of the plants, under the superintendence of Sir Joseph Hooker, in order to make certain that the proper plants have been gathered from, as the species of this genus have presented difficulties to botanists, and the plants and their species, as they now stand, have been allotted to other genera and other species.

PLANTING IN FIJI: ALPHA TAVUNI.

Qila and Alpha are by no means twin brothers as the one was called into existence long before the other and both are carried on independent of one another as far as men and capital are concerned; nevertheless, they are closely connected, not only because the proprietor is the same, but because Qila is the seaport of Alpha. Here supplies are landed and taken inland, and from hence the tea, coffee, and other produce is shipped.

* *E. b. emanicum*, Gröf., of the Eastern Peninsula, Achenbach, and *Tennisonia*, is *F. retusum*, Bauer.

E. *la. crotatum*, Wright's Ill. Western Peninsula, is *S. bicolor*, neelolata, Thw. and *S. erythroxylodes*, Wight.

E. *le. dum*, Moon's Cat. of Ceylon, is *S. lra acuminata*, R. Wright, Thw.

E. *mo. ogynum*, Mexb. Col. Pl. of Ceylon and Western Peninsula, is *E. Ind. ca.* Bebl. and *S. lra Indica*, D. C.

E. *obtusifolium*, Thw. En., is of Ceylon
 E. *sil. roxyloides*, Fami. is of Mauritius.

Alpha is about four miles inland from Qila. There is a Government road running from the beach to the estate and thence on to Qalesi. I was surprised to find it so clean, and in such an excellent condition as most of the public roads on Tavuni are overgrown with weed. This was, however, explained by the fact that the road is kept clean by men from the Alpha estate. It is a pleasant ride from Qila to Alpha. The view to seaward is magnificent, but I have so much to say about the cultivation of tea that I cannot stay to give a description of it. The road rises gradually until it reaches an altitude of 1,100 feet from the sea level when it enters the Alpha estate which is undulating table land protected by adjacent hills.

It was only when cotton failed that the Hon. Mr. Mason turned his attention to coffee and from the cultivation of the bean he hoped to win the fortune which the snowy and fleecy cotton refused to give him. Operations were commenced in 1875 by felling the bush and forming the nursery. Mr. Lanyon, who had considerable experience in the cultivation of coffee in Ceylon had the honor of opening up, what I suppose must be regarded as, the first coffee estate in Fiji. Small patches of the bean had been cultivated on Wakaya and some other places, but, as the name indicates, this was the first estate that was opened out for the planting of coffee on a large scale. If Mr. Lanyon may be judged by his diary he was an intelligent cultivator of the soil. This document, which is still in the hands of the proprietor, contains much useful information, and many shrewd and valuable remarks on the climate, the soil, the nature of the country cleared as well as the kind and quality of the timber felled to make the nursery. As soon as this was planted, clearing commenced in right good earnest, and day after day the axe gleamed in the sunlight and the crash of falling trees was heard as the woodman felled them. Eventually the young coffee plants were taken from the nurseries and transplanted on the plantation, but three long and weary years had to elapse before the covered fruit could be gathered. It can be imagined how carefully the development of the young plants would be watched; but patience and industry had their reward in the appearance of the first blossom which was soon followed by the fruit; and the maiden crop was ready to be picked. It was a magnificent one, satisfactory both to manager and proprietor. About this time Mr. Stephens, the present manager of Alpha, appeared on the scene. He came from Ceylon, where he managed several large estates and had considerable experience in the cultivation of coffee and tea. Mr. Stephens, like many others, was not satisfied with making money slowly, hence he threw up a good position and came to Fiji where he hoped to make a rapid fortune, and when he saw the maiden coffee crop at Alpha he thought he had found an eldorado. There was a rapid fortune in coffee if crops such as these could be grown. More land was obtained and the Alpha estate enlarged. The confidence, which Mr. Stephens, a practical coffee planter, felt in the ultimate success of coffee inspired the Hon. Mr. Mason with renewed confidence. More capital was invested and another 200 acres of land were cleared and planted which made 400 acres altogether and when this point was reached the results were patiently waited for, but no future crop was equal to the first, and eventually leaf disease, and black leaf made their appearance and played such havoc among the trees that coffee cultivation had to be abandoned and tea has taken its place.

Mr. Stephens brought some tea seeds with him when he came from Ceylon, and planted them at Alpha and the seeds from these plants have been carefully preserved and planted in nurseries. Tea is rapidly taking the place of coffee. Already more than 200 acres are planted; 100 acres more will be planted by the end of this year and another 100 acres will be ready for planting next year, while there are nearly 200 acres of virgin forest suitable for further extension. There are five nurseries of tea seedlings on the estate which are looking remarkably well and which contain plant for 1,000 acres extension if necessary, or for sale to

those going into the tea industry. There are two or three kinds of soil on the estate. There were red and chocolate loams, and scoria, which is so universal on Tavuni. Both climate and soil appear specially adapted to the cultivation of tea. The rainfall is regularly taken every day at noon and observations about the wind and weather duly recorded. The average rainfall is 150 inches per annum.

There are 112 laborers on the estate comprised of Indian coolies, and Polynesians. There are of course the usual houses for the comfort and conveniences of the laborers. The supply of food is plentiful. The soil and climate of Aloha are remarkable for the vigorous growth which they infuse into all plants. I noticed some very tall banana trees which were fully three feet higher than attained by the same kinds on the coast.

Work in all its branches appeared to be in vigorous operation on the day I visited the estate. As I passed over it I saw some laborers picking tea. In another field-weeders were at work, in a third several men were at work holing and preparing for the future extension of cardamoms. At the tea-house I saw a few intelligent Polynesians who could speak English engaged under the superintendance of the manager, making tea.

Mr. Stephens appears the factotum of the estate. Everything passes through his hands. When I went up from Qila in the early morning I found him in the field superintending his overseers and looking after some men engaged in picking a flush of tea. When each man brought his basket of leaf to the tea-house it was examined by Mr. Stephens, and should an old and hardened leaf be found in the basket it was pointed out to the picker and he was directed not to gather such leaves. It may be necessary to say the men were new to their work. Polynesian laborers who had only been two months on the estate, and therefore were under training. After a little experience they become expert pickers. Soon after this the manager is found at the tea-house superintending the manufacture of tea.

The cost of production is reduced to the lowest possible point by the employment of coloured overseers, one of which is a Polynesian and two are Indians, and they appear to manage the labour well and secured obedience. During the summer months there is a flush of tea every ten days and throughout the year the tea flushes regularly, except when it is pruned, when it rests for six weeks before it begins to flush again. Fortunately a flush was being picked when I visited the estate which gave me an opportunity of seeing the manufacture of tea in all its branches.

The large local market absorbs, for the present all that can be manufactured on the estate and the time is not far distant when the importation of tea into the colony must cease. More tea, however, will soon be manufactured on the estate than can possibly be consumed in Fiji, and arrangements are being made for the exportation of the article to the Australian and New Zealand markets. Already samples have been sent forward, and the reports received from colonial tea merchants and tea tasters are most encouraging and gratifying. Should the commercial reciprocity treaty between Fiji and the New Zealand and Australian colonies which is now talked of become a fact the Alpha tea will practically have a monopoly of the market. In anticipation of next year's yield and of entering the Australian markets, timber and tea leaf have been secured for making tea boxes for the purpose of exportation. It is worthy of remark that the tea at present made is picked from young trees, when these get older the yield will be greater and the quality will improve.

Altogether the prospects of tea cultivation appear cheering and encouraging, and if the Hon. J. E. Mason and his capable and energetic manager—Mr. Stephens—succeed in this enterprise, as they deserve they will have no reason to complain. One cannot but admire the plodding pertinacity of Mr. Mason in his search after fortune. Worsted in cotton he turned his attention to coffee and having failed to secure a satisfactory return from the coffee

he turned his attention to tea. Such perseverance and pluck deserve to be rewarded by success. Transferring the estate from coffee to tea was an easy and comparatively inexpensive operation. The land was mostly cleared and the coffee trees were pulled up and the tea plant took their places. The pulping and coffee drying houses have been turned into the houses. In one of these I saw the primitive looking tea trays where the first tea of Fiji was manufactured and which the ingenuity of Mr. Stephens called into existence. These looked insignificant when compared with the sirocco but they possessed an interest for me which the sirocco did not. As I inspected them I could not help thinking here is the beginning of what may prove a great mainstay to Fiji, and which may bring fortune to many. However much the future may develop the growth and manufacture of tea in Fiji to this little primitive machine must belong the undying honor of having manufactured the first tea in this colony.

There are several other matters claiming attention, but I can only refer to them in brief. There is the very excellent climate, the healthiness of which is proved by the fact that only one laborer has died on the estate during the last two years. About 20 acres of cardamoms are planted under shade, and these are looking so well and give such promise of future results that an extension of 15 acres is to be made forthwith. The land is cleared, holed, and ready for planting. A few acres more are planted in the open as an experiment, and these, although looking well do not appear as vigorous and healthy as those under shade.

The cinchona, several acres of which is planted, shows marked improvement during the past year and may prove a success.

I noticed a fine grove of mandarin oranges. A grand crop was gathered about two or three months ago; the fruit was large and the flavor good.

The residence of the manager is large and commodious, and the estate appears to possess every convenience and requisite for successful operations.

Before I close I must refer to the facilities for shipping which Qila and Aloha possess. The interinsular steamer calls twice a month to take produce and connect with the ocean-going steamers, and shipments can be made to the New Zealand and Australian markets with regularity and despatch.—*Fiji Times*.

THE SAU TREE (*Albizia stipulata*), forms the subject of a communication in the October number of the *Indian Forester*, the conclusion of which we quote:—"I have seen tea bushes growing under both the sau and koro trees, and have been much struck by their luxuriance in comparison with adjacent bushes, and have considered these trees the panacea for all tea woes. But a "change has come o'er the spirit of my dream," and no longer have I implicit faith in koro and sau trees. Roaming promiscuously over two different tea gardens 60 miles apart, I found tea growing under koro trees of great growth, and lo! the tea bushes under their shade were, if anything, inferior to those beyond it! A change of quarters immediately afterwards to where tea is not grown, has deprived me of opportunities for further observation, but it would be well worth the attention of well-informed observant men like Mr. Peel, to trace this further. My own experience therefore leads me to the belief, that no advantageous chemical properties are imparted to the soil by either the sau or koro, and that it is only the shade afforded by them which is beneficial, and that only whilst they are young, for once they attain maturity and a great size, the shade, slight as it may be, becomes too dense, and the prolongation of the surface roots becomes inimical. All the evidence obtained hitherto, as far as I can learn, in favour of the sau or koro, rests upon these trees, seen when immature and of small size."—*Indian Forester*. Happily for us in Ceylon, we know nothing of hot winds such as scorch the tea plants in some parts of India. We are, therefore, less interested than our continental neighbours in the sau tree controversy. The writer of the paper acknowledges that his experience has been but limited.—*Ed.*

SUGAR CULTIVATION IN BRITISH BURMA.

A long report was lately published in the *British Burma Gazette* on the system of sugar cultivation adopted in that country. The system seems to be more elaborate, and is certainly more expensive than that adapted in Bengal. The land on which the cane is grown is divided into two tracts, one tract of shifting cultivation, in which the cane grown is generally used for eating, and another tract of permanent cane cultivation, in which the juice is pressed out and manufactured into *gour*. The first is hardly worth noticing, as it consists of only about 280 acres, divided chiefly into holdings of one acre each, cleared in the evergreen jungles along the tidal creeks. The juice contains but little saccharine matter, and no amount of boiling causes crystallization of the sugar. The quantity of land under permanent cane cultivation is about 6,980 acres, chiefly situated in the valleys of rivers, the soil of which is generally deep rich loam. The canes grown are chiefly that known as the Madras or white cane, which grow to a height of from 10 to 12 feet. The mode of cultivation is chiefly by planting. The land is generally turned up with a hoe in May or June, and is let alone till September, when the cultivator digs holes about 10 inches deep and one foot wide, at a distance of about 18 inches from each other. Three pieces of cane, about five inches long, are then placed in each of the holes, and partly covered up with loosened earth, care being taken that one end protrudes about an inch over the top of the hole. There are generally three joints in each of the three pieces, and each joint has one eye from which the new canes spring. About ten days after the pieces have been planted, the earth is loosened in the intervals between the holes, and the cane pieces are further covered up. This operation is again repeated in January, and in May the land is again cleared of weeds and grass, and the plants are left until the month of August or September, when they are cleared of the leaves that have become old and withered. Irrigation is hardly ever resorted to, except in a very dry season. The canes bloom in November, when they are cut down and prepared for the mill. The cost of cultivation in such a plantation, worked entirely with hand labour, will amount to about R90 per acre; but as most of the cultivators with their families work their own land, the cost is estimated at from R15 to R20 per acre. The cost of manufacturing the *gour*, which is at present done in a very crude fashion (although this will probably soon be improved, as a partner of the well-known firm of Thomson & Mylne lately visited Burma and showed the people the advantage of using his mills) comes to about R60 per acre.

The average outturn per acre is about 3,500 lb., which is worth R250; and the net profit per acre, therefore, not including the cost of living, would be about R100. The average amount of *gour* being 2,800 lb. per acre, the amount of sugar produced in one year would come to about 8,750 tons. The whole of this, with the exception of a small quantity exported from Akyab to Chittagong, is consumed in British Burma, and, as about 78,800 cwt. of sugar are imported every year, there seems to be abundant room in British Burma for an extension of sugar cultivation.—*Calcutta Englishman*.

HOW COFFEE IS PREPARED FOR SHIPMENT.

Few people, perhaps, ever give a thought, when drinking their morning cup of coffee, of the ways and means used for procuring them this refreshing beverage. Without going into particulars of the troubles and difficulties experienced by coffee planters in acquiring and opening out land, clearing and filling jungle, planting, and waiting patiently for three years for their virgin crop, a few details of the different processes the bean undergoes from the time it is taken off the trees, till it is shipped, may be of interest.

The coffee berry when ripe is of a bright scarlet colour, and the fruit itself is very sweet and pleasant to the taste. When gathered it is carried to the *pulping-house*, where it is measured and passed up to a loft, from which it passes into a receiver which feeds the pulper. This pulper consists of a cylinder of iron barrel, fitted with copper sheets, which revolves under a toothed comb-like projection; it is generally worked by cattle power or by a water-wheel and admitting the fruit separates the outer skin or rind from the bean or seed, which then passes into a cistern or vat. It is left there and allowed to ferment from 12 to 18 hours, which contributes greatly to facilitate the washing. When the beans are being washed there should be a constant flow of water through these cisterns or vats, and it is therefore absolutely necessary, when a planter chooses a spot whereon to erect his *pulping-house*, that it should be on low ground commanding a liberal and constant supply of water. Failure of water has been known to have seriously inconvenienced pulping operations and ruined the outturn of what otherwise should have been a fair crop. After the bean has been well washed and rid of all the pulpy matter it is called *parchment coffee*. This name is given to it in consequence of the husk or parchment-like covering remaining on the bean after it has been pulped and washed. It is then removed from the cisterns on to the barbecues or drying grounds on the estate, where it remains for a few days till it is dry. In the absence of barbecues, the coffee is dried on tables, made by stretching coir matting over temporary bamboo or other wooden structures. Great care is required in drying coffee before it is despatched to the curing works, as unless the coffee is sufficiently dried it is apt to ferment, and thus discolors the bean and lowers its marketable value. When dried the coffee is sent away in carts to the curers on the Western Coast or elsewhere. (These remarks apply to coffee grown in Coorg.) The ordinary country cart is used, each cart carries 40 bushels or about half a ton of parchment coffee, packed in bulk in mats; the journey from Coorg to the Western Coast occupies from three to four days, the carters however are usually allowed six days and take it easy all the way, travelling when it suits their convenience best. Cart hire varies yearly. A couple of years ago it ran very high owing to the prevalence of disease among cattle, but ordinarily it ranges from R14 to 16 for the double journey; that is to say, a cart that takes down coffee to the coast brings back a load of manure and *vice versa*. This year, however, the shears of economy have been vigorously applied on all sides, and very little manure is likely to be sent to the estates; this will naturally enhance the cost of transport as compared with other years. When the parchment coffee arrives at the curing works it is re-measured, and put out again on the barbecues, there to dry a little more, and when the parchment or skin becomes nice and crisp it is put into the peeler.

The peeler consists of two large iron wheels ribbed round the rim; these wheels are propelled with great velocity by a small steam engine, and run in a circular masonry gutter or groove into which the parchment coffee is shot, and by their rotatory motion the coffee bean is deprived of its parchment-like covering or husk. The coffee thus cleared falls into a cistern from which it is taken up into a loft and thrown into the *sizers*, the chaff being separated from the beans by means of a fanner. This chaff alone is used for working the engine, or perhaps a little wood is sometimes added. These *sizers* are large cylinders of perforated zinc or iron. In three of them the perforations are oblong and of different sizes, and circular in the fourth. The *sizers* revolve and the coffee falls out of four different kinds or sizes.

A or No. 1 the largest

B " 2 the next and

C " 3 the third size; through the circular holes all the globular beans find their way and are called *Pea Berry*. This sort of coffee commands generally a superior

price in the English market. The peeler, sizers, &c., are all connected and the whole machinery is worked by a single engine. When the coffee has been sized it is given out to be garbled or sifted and cleared of stones, broken and blackened beans, &c. This work is done by women, and on the Western Coast the *Thectes* are great adepts at it, as they learn it from their infancy, and it is no common thing to see little mites, no bigger than the sieves they carry, competing with grown-up women in the quantity they are required to garble. After being garbled the coffee is packed in single or double bags in the order in which it has been sized, 1, 2, 3, each bag contains $\frac{1}{2}$ cwt.: it is then shipped per chartered steamer or B. I. S. N. Co.'s boat via the Suez Canal. Most if not all the plantation or parchment coffee finds its way to England, little or none goes to the Continent. The triage or defective and broken beans and black coffee are similarly sized, packed and shipped, the refuse being sold in the country. Even the stones that have been taken out during garbling fetch a good price when sold, less on account of the little coffee they may contain than for the purpose of adulteration hereafter.

What is generally known as *native coffee* is what is shipped to the Continent. This description of coffee receives different treatment during cultivation and curing. The trees receive less attention and are permitted to grow to their natural size, whereas on European plantations they are kept at a uniform height of from $3\frac{1}{2}$ to 4 feet, being regularly pruned and all superfluous wood and new shoots removed at intervals. This is not done on the Native estates. The fruit is gathered in the same manner as parchment coffee, but it is not pulped, it is merely dried. When the cherry is sufficiently dry it is pounded and winnowed. The pounder used in Coorg is of a very primitive description, being simply a piece of wood placed on a pivot and worked by the foot, the coffee being placed in a hole in the ground. When the coffee beans have been cleared of all the chaff they are sent down to the curing works, garbled, packed and shipped in the same manner. It is seldom sized like parchment coffee. Native coffee has a more pleasant flavour, retaining more of the aroma of the fruit which the bean absorbs during the process of drying; it is chiefly for this reason it is so much better liked on the Continent, and it is comparatively cheaper than plantation.—Coorg.—*Madras Mail.*

THE DATE PALM.

In Lucknow I introduced the Date Palm from the Persian Gulf, through the Government of India, both by seeds and by imported offsets. There are some hundreds of many varieties of both kinds in Lucknow, and many hundreds from seeds in many parts of Oudh. In Lucknow they were imported between 1869 and 1873. These had been under my care and close observation up to 1877-8. Since then I have often seen them. They are growing very luxuriantly, and are irrigated during the hot winds from wells 20 feet or so deep. During the rains they are subject to an average annual rainfall of 36 inches. In the winter there the temperature has been down 5° Fahr. below freezing point, and in the hot winds I am afraid to say what temperature they are subject to, and there is no sea-air. Many of the Lucknow Date Palms have been flowering and fruiting—artificial fertilisation is practised in most cases. Mr. Ridley, under whose care they are at present, has stated that their fruit is good, and it is stated that some are delicious. I have tasted some, and found them very sweet and nice. Another officer from Perlaburgh says, that those which ripens fruit are delicious. Even the small skiny fruit of the *P. sylvestris*, when not tapped for "toddy," is eaten by natives. I cannot, therefore, understand how it is that the Date Palms in the South of Europe are said to be without fruit, and that "the cause is the dry summer, there being no subterranean wells, as is the case in the Sahara."

From the study I have made of the *Phoenix sylvestris* and *P. dactylifera* (which are in reality two varieties of the same species) I am of opinion that neither subterranean wells nor a desert climate are essential to its luxuriant and successful growth. We must, therefore, look for some other reason to account for its being "without fruit," or for its fruit "never being fit for food" in the South of Europe.

I have shown that the *P. sylvestris* grows luxuriantly in a moist climate like that of Bengal, and in all other climates, from North to South India. But as it is annually bled, and its sap converted either into sugar or toddy, its fruit, when it is able to give any, and when it becomes fertilised, is not fit to eat. The *P. sylvestris* is nowhere irrigated as far as I know, but depends for moisture upon rain or upon what it can suck up from the subsoil. I have shown also that the *P. dactylifera* will bear a variety of climates and conditions, and still give good fruit. In the oases of the Sahara and all along North Africa and in Mureia, in Spain, probably it does not receive any special cultivation. In the interior of Arabia, where there is not much commercial intercourse, and where the poor people are almost wholly dependent for food on their Date crop, the probability is that a great deal of care is given to it. In Mooltan, Sindh, and adjacent countries Mr. O'Brien says it is nowhere cultivated, but grows spontaneously from seeds. There are many varieties in Mooltan, and he sent me samples of five varieties. They were small (about the size of the Muscat Dates) but sweet, and they formed a great part of the food of the Mooltanis and Sindhis. In Lucknow, where the conditions are different from the places before mentioned, it also grows well.

But the climate where it appears to come to great perfection, and where it is cultivated with great care and skill, is that of the Persian Gulf. There it is tended as if it were a child—irrigated regularly, manured with either fish or other animal manures. As there are only female plantations the flowers of each bunch are carefully fertilised by males brought from anywhere (sometimes from another district.) The irrigation is stopped for several weeks after fertilisation, and finally only from eight to twelve bunches of Dates are left on the tree out of the twenty-four or so that it bears. Nevertheless, with all this care and skill they say that those Dates which by accident have not been fertilised are "stoneless and insipid, and only fit for goats."

Palgrave, in his *Journey through Arabia*, says that of all the kinds of Dates he had eaten the "Khâlis" of El Hasa in the Gulf is the *facile princeps* of the Date kind. He says it bears the same relation to the ordinary Date which the jungle Mango bears to the Bombay Mango. In the Gulf the Date tree receives as much cultivation as Oranges or any other choice fruit trees receive in Europe.

Let us glance now at the cultivation of Date Palms in the Riviera. Irrespective of any irrigation, manuring, &c., which are not mentioned, the leaves at certain seasons are swathed, like Lettuces, to bleach them for church ceremonial. They are cut at Easter, for supplying leaves for Palm Sunday to Rome and other places, and also in August for Jewish observances. Now, considering that the leaves to the plant are what the stomach and lungs are to the animal—that they are required to be, not only luxuriant, but in large numbers, to supply healthy sap for the growth of the tree and the production of its fruit—we need not, I think, trouble ourselves about either "underground wells," or dry summers to account for the Bordighera Date Palms giving either "bad fruit, or none at all." [All the Palms on the Riviera are not so treated, and yet ripe fruit is almost unknown.—Ed.] In the Persian Gulf, they say, the Date Palm is not tapped for "toddy." It could be tapped, however, they say, "but at the expense of the fruit." It is a wonder to me that the Date Palms of the South of Europe continue to exist at all, under such treatment; I should say, however, that they can be swathed, and that their leaves can be cut off, to

supply bleached leaves to Rome and other places, leaving the whole place with a "disreputable look," but all this can be done "at the expense of the fruit." Moreover the Bordighera Palms may all happen to be of the kind which does not become soft and sweet, and goes no further than the red or yellow stage, called "Kharek." In my opinion, the borders of the Mediterranean basin are eminently suited to growing first-class Dates. The sea air appears to be an advantage to the choicer varieties. It is not so partial to a desert climate as one would suppose. All it wants for the production of choice fruit is careful cultivation, like any other fruit tree, with irrigation when necessary, manuring and stirring of the surface earth; artificial fertilisation when the males are not well intermixed with the females. It requires also, like other fruit trees, that half the hunches should be removed to produce fine large Dates. The condition which I think is a great advantage to the perfection of the fruit of the Khoorma kinds is that during softening and ripening time the atmosphere should be dry. Finally, to obtain choice fruit the Date Palm should not be tapped or swathed, or have its leaves blanched and cut off; but that there should be many of them, and the more direct light they get the better, as long as water is supplied to the roots. Whether this come from underground wells or from rivers, or springs, or the clouds, I think signifies little.

I should say Cyprus, Candia, Greece, and its archipelago, Sicily, Sardinia, and the south and east coast of Spain, are all eminently suited to the cultivation of the choicer kinds of Dates. Offsets from the Persian Gulf could be obtained with the greatest ease, and planted in nurseries, and watered regularly till they root, when they could be put into permanent plantations. I think there is no part of the world to which, if the climate and soil were suitable, Date offsets of the proper age and weight could not be taken. They will bear a great deal of exposure before planting without injury. The woody stump acts like a bulb, and throws out roots when planted under proper conditions. If we do not except the cow to give good and abundant milk without proper feeding and careful treatment, it is hardly reasonable to expect the Date Palm to give good and abundant fruit with no feeding and "atrocious" treatment.—E. BONAVIA, M. D., Etawah.—*Gardener's Chronicle*.

FEEDING OF PLANTS.

As the food of plants existing in soils is subject to distribution, and does not remain in solution for any length of time, it is evident that there cannot be a circulation of such food towards the growing plant, but the roots of the latter must go in search of nourishment.

When we consider the vast root surface in the case of a Vine, and that myriads of rootlets and root-hairs unite their action to feed the comparatively narrow stem, we can understand the importance to the gardener of studying the ramification of the roots of all the various species of plants he cultivates in order to adapt his system of manuring to the feeding capacities of these plants. Plant-roots may be considered in three distinct stages of growth, namely, in their primary development, their stage of ramification, and their enlargement in receptacles of nutriment. Supposing, then, moisture, warmth, and air, to be ready in their proper measure, the water is absorbed by the substance of the embryo of the seed, dissolving its contents, carrying them into the young plant as rapidly as they are required; in fact, the seed may be considered as a miniature laboratory, in which numerous chemical actions are taking place for the nourishment and development of the young growing plant.

As the radicle breaks its bonds from the mother seed it will be nourished and fed after a short time directly from substances existing in the soil, and will profit very indirectly by any nutritive matters which may yet remain in the seed itself.

So important to the future welfare of the plant is the addition of elements which can be obtained from the soil only, even in the earliest stages of growth, that before any secondary rootlet is produced the young radicle in many cases pushes out from its superficial cells a mass of delicate fibrils, every one of which is employed in active food-absorption; therefore, while the first wants of the young plant depend directly upon seed nutrition, it must never be forgotten by the gardener that this supply lasts for a short time only, and that the ultimate vigour and productiveness of the plant must depend upon the fertility of the soil; consequently, for the successful raising of any plant from very minute seeds, it is absolutely necessary that suitable food should be within easy reach of the delicate and small roots, and also in an extremely soluble condition. Thus we find pounded rape-cake, soot, or a moderate dressing (10 to 20 lb. per square yard) of superphosphate among the very best materials for application to soils when it is required to raise a crop of healthy young plants in a short period of time.

It is, however, a great mistake to suppose that because plants are often grown without a direct supply of nitrogen in manures they are not dependent upon this substance for their very life and sustenance. Those gardeners who do not apply manurial dressings with their seed depend naturally upon the store of nitrogenous plant-food in the soil. Many a plant which looks vigorous enough on its first appearance above ground soon wears a sorry aspect when the food-supply is deficient or of the wrong kind.

Nowhere is this fact better exemplified than in the extensive experiments at Rothamsted where the conditions as to source of nutriment and disintegration of the soil by root development are so various. In early spring each description of plant experimented with, whatever may be its character or its manurial supply, starts much alike; there is but little difference to be discerned between one plot and another; very soon, however, those without any manure at all begin to show signs of weakness, then the imperfectly manured plots lag behind, while those receiving a full supply of all the necessary ingredients of plant-life—potash, phosphoric acid, lime, and nitrogen—advance steadily on to perfection.

This is further illustrated by the following table which shows the average annual produce of various crops, and the increase obtained by different manures. The quantities are in pounds per acre:—

Description of Crop.	Without Manure.		Superphosphate, $\frac{3}{2}$ cwt., alone.	Nitrate soda, 550 lb., alone.	Mineral manure and nitrate soda.	Farmyard dung, 14 tons.
	lb.	lb.				
Potato	Produce. 5,208	8,246	7,168	16,450	10,186	
tubers	Increase. ...	3,038	1,960	11,242	5,278	
Swede	Produce. 1,232	5,824	2,128	11,424	13,888	
bulbs	Increase. ...	4,592	896	10,192	12,656	
Mangel	Produce. 9,632	11,312	20,792	43,456	31,584	
bulbs	Increase. ...	1,680	20,160	33,824	21,952	
Meadow	Produce. 2,380	2,492	3,962	6,384	4,662	
hay	Increase. ...	112	1,582	4,004	2,282	

We gather from these results that while a certain amount of increase of crop is obtained when superphosphate, which supplies to the plant phosphoric acid and lime, or when nitrate of soda, which furnishes soda and nitrogen, it is not until the complete fertiliser (minerals and nitrate soda), which supplies phosphoric acid, potash, lime, soda and nitrogen combined, is given that a full crop is harvested. This is further illustrated by the fact that farmyard dung, which is supposed to furnish all the essential elements of plant food—but the effects of which are spread over a considerable number of years—rarely yields so much produce as the minerals and nitrate soda together, the latter being so much more easily assimilated by the growing plants. The next question

which arises in connection with plant-roots is the power they have in the selection of their food. That they have some is apparent from the fact that different species of plants in the same soil will appropriate different quantities of chemical ingredients, and that some exhaust the soil more rapidly than others.

Fibrous roots have frequently enormous power of penetration, which enables them to search for food at great depths. This property sometimes becomes a serious evil if the subsoil does not contain the particular ingredients required by the plant. In the orchard many a fruit tree thrives so long as the roots are superficial; but when they penetrate deeper, nutriment, either insufficient or of an improper character, is absorbed, vitality is impaired, and various forms of canker and unproductiveness are the consequences.

One great end attained by pressing the ground of light soils before or immediately after setting out plants, or sowing seeds, is to encourage lateral rootlets as much as possible, that they may avail themselves of the more abundant and more suitable food constituents accumulated in the surface soil.

The third stage to be considered in the feeding of plants and root development is, that many roots become reservoirs of nutriment for future use. Roots vary considerably in character: some penetrate deeply, remaining fibrous and thread-like to the end; some throw out laterals, and luxuriate in the surface soil; some merely absorb the necessary daily food, while others, as Asparagus, Turnips, Carrots, Parsnips, &c., devote certain of their parts or ramifications to the especial office of storing up nutritive matters, often in enormous quantity, and in great rapidity. All underground plant ramifications which serve as store-houses are, however, not to be included in the same category. The bulb of the Onion, the Leek, the Tulip, the Hyacinth, or the tuber of the Potato, &c., though answering to the same end, are either furnished by the base of the leaves, or are underground stems. In certain biennial plants there is a strong disposition to deposit stores of nutriment for the perfection of seed in the ensuing year, while in the case of perennials and in some Orchids a special part is devoted to this purpose. In fruit trees the deposit often takes place in the bark and branches, hence the necessity of rest, and the notorious fact that many trees will bear a crop only in alternate years. Doubtless this, which is the result of exhaustion to a very great extent, might be obviated if proper feeding with nitrogen, potash, and phosphoric acid were adopted.—F. T. W.—*Gardeners' Chronicle*.

ACACIAS AND GUMS ON THE NILGIRIS.

Mr. Gamble, the Conservator of Forests, Northern Circle, recommends that the Forest Department should revert to the propagation, especially for revenue purposes, of the *Acacia Melanoxyylon*, which was the subject of its earliest planting operations on the Nilgiris. The tree is of umbreous habit, the outline mostly pyramidal, and it affords a dense shade throughout the year not being deciduous in character, while it takes a firm hold of the soil by its numerous and widespread roots. It was first systematically planted on the Nilgiris in 1856, when a Captain Campbell was entrusted with the experiment of forming a plantation, at Bleakhouse, Coonoor, mainly for the supply of firewood for the military at Wellington. In Ootacamund the *Acacia Melanoxyylon* has been largely utilised as an ornamental tree. Existing specimens in the station are mostly of the growth of twenty or twenty-five years ago, the propagation since having been practically nil. Where the elevation is suitable, that is above 6,000 feet, it thrives, though its growth is slow. As but a limited number of trees have arrived at maturity, the timber has not been practically and commercially tested. In Australia it is highly valued for carriage building and agricultural implements, being exceedingly tough, but on the Nilgiris it is found to possess few qualities prized by the cabinet-maker and builder. It warps even after many months of

seasoning, is not easily worked, and is not as durable as other timber accessible to the residents of the hill stations. The slowness of growth is much against the tree, and where it has been tried, in two instances, as an avenue tree, it has proved a failure. The worst feature, however, is its liability to attacks from a parasitical plant not unlike the mistletoe, which spreads rapidly among the branches and cannot be easily disengaged. Indeed the complete removal of this parasite has had no beneficial effect in arresting decay, as when it has once become established at the crown the progress downwards and laterally is merely a matter of time, the parasite appearing over and over again as often as removed. Whether its presence is due to unfavourable conditions of the soil and situation is not yet determined, the tree being equally affected in every site and soil in which it has been planted.

With past experience so decidedly against the *Acacia Melanoxyylon* it does not seem desirable to attempt experiments, the success of which is problematic, and which if again unfavourable will be a serious loss of time to the Department. As a fuel tree it is not prized as highly as the *Acacia Dealbata* also an importation from Australia, and known as the yellow-blossomed wattle. Ootacamund was, till recently, completely over-run with this wattle, but owing to the persistent crusade waged against it both by the Municipality and the house-owners its progress has been held in check only a few full-grown trees being left, though much remains still to be done to exterminate it. The myriads of suckers which spring from the extensive and encroaching rootlets come up with renewed vigor and amazing rapidity as fast as they are cut down, and afford an inexhaustible fuel reserve. In alluding to this variety of the acacia, a late Conservator of Forests observed that if Ootacamund were abandoned the whole station would in an incredibly short space of time become an impenetrable forest of *Acacia Dealbata*. A few attempts have been made to open new plantations of this tree and of the *Melanoxyylon*—but these are the exceptions, and results are not encouraging for timber or fuel, the gums being superior and universally preferred. These were introduced to the hill ranges by Sir William Denison, and have taken so kindly to the soil and climate as to be looked upon as the future timber and fuel tree of the district.

The *Eucalyptus globulus*, or blue gum is to be met with everywhere. It thrives in the most exposed situations, and the poorest soils. Under adverse conditions, a growth per annum of from 3 to 4 feet may be ensured, but in forest soil, and a sheltered situation, a growth of from 10 to 12 feet is not uncommon. At an elevation below 4,000 feet, the blue tree has a struggling stunted growth, but above that and up to 8,000 feet, no finer or more rapid growing hard wood tree can be found. Private enterprise has taken up the planting of blue gum for fuel with an energy which in a few years will probably clothe the hill sides with an endless succession of plantations in every stage of growth. The ryot has also become impressed with its value, and is growing it in every available spot in and around his field. The Government possesses 1,000 acres of plantation on the Nilgiris, the greater part of which consists of gums, namely, 600 acres in and around Ootacamund, and 400 acres in the neighbourhood of Coonoor and Wellington. Considering how general the growth of fuel has become, it would seem as if no further attention need be devoted by the State to this subject. At the present time private vendors are underselling the Government. For instance at the Ootacamund fuel depot 1,000 lb. of blue gum wood is charged Rs. 3, and the purchaser has to provide his own cart to remove it. Contractors are offering the same quantity and quality at the same price, and will deliver it free within a reasonable distance of the source of supply. No serious inconvenience will arise therefore if Government should close its depot, and leave the town entirely to private enterprise, in the matter of fuel.

With regard to timber the case is different. Capitalists cannot afford to wait while trees are ripening their wood. Government not only can afford to do this but can grow its forests for more important cosmic purposes, for the amelioration of unfavorable climatic influences or the preservation of favorable ones, for the regulation and distribution of the rainfall, if such can be considered to be the result of forest growth, and the maintenance of springs and streams. As a timber tree the several varieties of Australian gums are unsurpassed. The Jarrah, for instance, when mature, yields a timber that is cheaper than oak; is ornamental in a high degree being close, fine grained and mottled; is capable of taking a high polish; and is of great strength, hardness and durability. It is proof against insects, and especially the destructive white ant. It defies time and decay. The white and red gum are not much inferior to the Jarrah in the above qualities, they are close grained and hard, will stand great heat, and are proof against insect destroyers. Government planting operations are too restricted in the choice of forest trees on the Nilgiris. The oak and the chestnut grow well, and so do the family of Ficus and the Walnut. The Himalayan Cedar grows up to 9,000 feet elevation, and thrives with a temperature ranging in the cold weather from 35° to 50°, and in summer from 65° to 70°. Rainfall and soil are equally suitable for its growth on the Nilgiris. With a wide range of valuable timber trees to select from the Forest Department has confined itself almost exclusively to the acacias and gums, excellent trees in their way—but failing in one important respect to compass the ends of Forest Conservancy. Both the acacias and gums act most prejudicially upon the soil and water-supply. They impoverish the former, and absorb and dissipate the latter. Neither shrub nor weed will thrive under their shade, nor have we any record that they favorably influence their immediate vicinity in the interests of the agriculturists.—*Madras Mail*.

[The tone of the above article in the *Madras Mail* differs from that of the official reports, but we fear there is a good deal of truth in what is said of the Australian trees. The gums grow rapidly, but, except as firewood for the preparation of tea, we do not know that the timber will be of much value. Have sleepers of Ceylon-grown blue gum yet been tried, and, if so, with what result? Oaks and chestnuts are certainly not suitable for the hill-country of Ceylon, although the oak will grow slowly. By the Himalayan cedar we suppose the deodar is meant, and we doubt its suitability for Ceylon. We are much more favourably impressed with the so-called red cedar (*Cedrela Toona*). Of the Australian trees grown on Ceylon estates *Grevillea robusta* seems the most promising.—Ed.]

FOREST DEPARTMENT (STRAITS SETTLEMENTS).

In July 1883 Mr. Cantley, Superintendent of the Botanical Gardens, Singapore, published a Report on the Forests of the Straits Settlements, and the result we are glad to notice has been the formation of a small Forest Department, with Mr. Cantley as Superintendent, assisted by four Europeans, under whom are some subordinate officers, together with a number of forest watchmen.

The report is largely filled with accounts of the topography, geology and meteorology of the country, and the description of the forests shows how greatly they need protection. In the introduction he says that—

"It is apparent that no sufficient attempts have been made to conserve the Government forest lands, and that nothing has been done towards utilising the extensive grass wastes that are to be seen throughout the Settlements. The present state of affairs is the result of a reckless, migratory cultivation carried on by the Chinese, and this extensive deforestation has brought with it its attendant evils.

Our timber supply has fallen far short of the demand, and the climate of the colony is becoming sensibly affected."

The Straits Settlements are formed of four separate districts—

1. The Island of Singapore, containing 226 square miles	
2. Malacca, .. 659 "	
3. The Island of Penang, .. 107 "	
4. Province Wellesley, .. 265 "	

Total area ... 1,257 "

The Government forests occupy about 121 square miles, or nearly 10th of the whole area, the largest forests being found on the mainland in Malacca and Province Wellesley. In addition to this there are about 33 square miles of private forests, whilst the waste lands are extensive in Singapore, occupying about 10,000 acres in Malacca, but are scarcely of any importance in Penang or Wellesley.

The forests belong to that class known as evergreen tropical forests, which chiefly lie within the tropics and in countries subject to heavy annual rainfall, and a high state of atmospheric moisture. Many of the trees are nevertheless deciduous for a very limited period, which in most cases extends over a few days only. The mean annual temperature is above 80°; the highest scarcely above 90°; the lowest not much less than 66°. The humidity of the atmosphere is generally very great, and in Singapore, counting saturation at 100, the annual average is 79.4, and is never below 73. The annual rainfall is about 100 inches, and roughly speaking there is rain every other day throughout the year. Mr. Cantley however, says that, although—

"The total rainfall of the year has not decreased, owing to the removal of the tree covering—that great equaliser of rainfall—showers have become less frequent and more local than formerly; and droughts of unprecedented length have occurred, thereby increasing the possibility of epidemics. These fertilising showers, which once watered the whole surface of the Settlements, are now confined more frequently to the hill tops and higher elevations, the soil and the prospects of agriculture being thus impaired, and the temperature of the plains being raised. The hill streams run with greater irregularity, and many of the smaller streams have become entirely dried up."

In Singapore we find that—

"Such Crown forests as remain uncut are widely distributed in isolated patches over the island. These forest patches or clumps are of various sizes, from half an acre or so to about 25 acres, their distance from each other averaging about half a mile. The interspace is generally waste grass land, which supports as a rule only strong growing grass, which chokes any seedlings of forest trees which might otherwise spring up."

As an instance of the state of the forests in Malacca, we quote the description of the state of the Jus reserve of 25,000 acres, and of the Kesang reserve of 2,000 acres.

"The amount of well-wooded land does not exceed, I believe, one-third of the total area. Within the reserve boundary there are a large number of squatters, whose houses are thickly dotted over the comparatively denuded portions. They are allowed to cultivate paddy in the swampy land of the reserve, and to plant fruit trees on more elevated portions, privileges of which they seem to have extensively availed themselves. The greater portion of the Kesang reserve has been under tapioea cultivation, with the exception of a narrow belt along the outside, which seems to have been left as a screen. There is therefore but little timber of value left in this reserve, and as the denuded portion contains only stray plants of tapioea, it will have to be re-stocked artificially by planting."

In Penang the forests generally occur in isolated patches as in Singapore, whilst in Wellesley good forest remains in the southern districts. The most valuable forest products appear to be the Serayah wood, or Singapore cedar, a species of *Shorea*, Gaharu resin yielded by two distinct species of trees, viz.,

Aquillaria malaccensis and *A. Agallocha*, and Malacca cane.

In the appendices to the report will be found useful lists of indigenous trees, shrubs, creepers and parasites, including a list of those growing spontaneously on waste lands, also lists of exotic trees recommended for introduction, and of trees recommended for roadside planting. Amongst the indigenous trees are several Indian and Burmese species, such as *Pterocarpus indicus*, *Terminalia Catappa*, *Mimosa indica*, *Alstonia scholaris*, *Buzophora nueranta*, and *Hemitelia littoralis*.

It is estimated that Singapore requires annually 810,000 cubic feet of timber, of which more than half is used by Pepper cultivators, and 101,000 tons of firewood, of which half is consumed by Gambier planters and coasting steamers. For the other Settlements no estimate is given, but the consumption is known to be considerable in Penang and Wellesley.

The measures recommended for the better management of the forests are thus summarised—

- (a). Preventing the felling of forests and the clearing of forest lands.
- (b). The redemption by exchange, or otherwise, of such land as is selected for planting with forest trees.
- (c). The survey and demarcation of such Crown forest lands as are still undetermined, and the preparation of good and reliable maps showing the forests and the topographical features of the various lands throughout the Settlements. This is a desideratum that should be looked upon as a first duty of the Survey Department.
- (d). The formation of local forest reserves for the supply of wood for general purposes; and mountain and river reserves for protection where necessary.
- (e). The establishment of a Forest Department to take charge of all Crown forests whether proclaimed as reserves or otherwise.
- (f). The marking of certain blocks of forest near the chief towns of each Settlement of a sufficient size to serve as reserves for the supply of fuel and small building wood.
- (g). The appointment of a body of Forest Police for protective purposes, to be quartered in the country districts throughout the Settlements.
- (h). The immediate collection of seeds of the best indigenous timber trees, and the formation of nurseries for the propagation of such seeds.
- (i). The introduction of an ordinance for the better conservation of the Crown lands.

From the first Annual Report of the new Forest Department, we are glad to find that steps have already been taken to give practical effect to a large number of the measures advocated, so that the recommendations (a), (b), (d), (e), (f) and (g) have already been either entirely or partially carried out, as will be seen from the statement made at the beginning of this review concerning the organisation of the Department, and from the following brief summary by Mr. Cantley of the work taken in hand during the past year:—

“I would point out that the forest reserves dealt with to a more or less extent are 15 in number; that 46 miles of boundary line have been opened, at an average cost of \$83 per mile, including the planting up of 12 miles with fast-growing trees; that the area of land laid out in nurseries is over 20 acres; and that some 390,000 plants have been propagated in these nurseries, at an average cost of \$1 per 100.

“Seventy acres of waste land were planted with about 118,000 plants, at an average cost of \$12 per acre, or per 2,000 plants. The stock in the nurseries at the close of the year numbered about 200,000 plants. It will be noticed that the area of waste land planted with trees is comparatively small, but what was of most importance, viz., the demarcation of reserves, to prevent further encroachment, had to

be first undertaken. Over 1,160 lbs. of seeds have been got together from various quarters and utilized for the benefit of the reserves. The buildings erected include quarters for the overseers, stations for the forest watchmen, coolies' houses and plant sheds: in all 27 in number.”

To conclude, we wish every success in the future to the Forest Department of the Straits Settlements.—*Indian Forester*.

FRUIT PRESERVING IN FIJI.—In addition to their extensive banan trade, Messrs. Armstrong and Co. of Suva, have started a fruit preserving company. The last boat from Sydney brought a first-class man for packing the preserves ready for shipment, also a large quantity of preserving jars, tins, etc., together with the most brilliant labels yet seen in Suva. The preserving industry of Fiji will yet assume very large proportions on the export list.—*Fiji Times*.

ROSES AND CHEMICAL WORKS.—A correspondent writes:—“I send you a parcel of Rose foliage (what a mockery!) which is a sample of what the chemical works about a mile away has done for me. Of course they are not all as bad as this, because some sorts are able to resist it better than others, and while such sorts as Marie Baumann, Alfred Colomb, and Marie Raby are almost destroyed by it, Baroness Rothschild and M. de Castellane are not a very great deal the worse, although, of course, they all feel it more or less. It begins by a sort of purple discoloration on the young foliage, which afterwards turns brown or black, and in some cases the leaves are burnt through. Some of my neighbours won't admit that it is due to chemicals, but I have no doubt on the subject. What do you think? It is a great disappointment to me, as I used to get such pleasure out of them, and now out of 400 plants I have not got one that I could call really healthy, as besides ruining the foliage it takes all the colour out of the blooms.” We share our correspondent's opinion, as the appearances on the leaves are quite consistent with his statements, and, so far as we know, there is no other cause that would produce such an effect.—*Gardeners' Chronicle*.

AUTOMATIC IRRIGATION.—In very dry seasons there is a great demand for water in most gardens, and any apparatus which effects a saving of the gardener's time must of necessity prove invaluable. Messrs. Merryweather, of Long Acre, have devised various systems for automatically distributing water. They devised a system of non-corrosive metallic tubes in short lengths mounted upon easy running carriages and connected with flexible joints. The metal pipes being perforated throughout their entire length, the water will run through a length of 60 or 90 feet, dispersing itself on the land through the whole course of the pipes by means of the perforations. It is very easy to move the apparatus from place to place at intervals. Another system consists in similar movable pipes without the perforations, at the extreme end of which a distributing nozzle is attached. This nozzle is capable of throwing the stream in either a jet or a spray at the will of the operator, who can of course walk about freely dragging the tubes after him. A third apparatus is both ornamental and useful, as it consists in a portable revolving fountain upon a stand to which hose may be connected. Garden hose or lead or iron pipe so small as $\frac{1}{2}$ inch diameter can be connected to the inlet-coupling, and the water supply taken from a source 8 feet or more above the fountain. The sprinklers rapidly rotate by the action of the issuing water, scattering a fine shower over a wide area. The adaptation of this latter appears to be a happy idea, as it is arranged inverted to screw up to the ceiling of fernery or conservatory, and thus scatter the water downwards and sideways.—*Gardeners' Chronicle*.

CEYLON UPCOUNTRY PLANTING REPORT.

TEA MACHINERY—WEATHER: COFFEE AND CACAO—
DIVERSITY OF OPINION.

9th November 1885.

Those who have tea machinery for sale are feeling the effects of the improved times, and are booking large orders for erection next year.

The weather still continues very favourable for all planting operations. It is ripening up the coffee also, which as far as I have seen still continues to be a fine sample. But with little of it, and falling prices, the poor old thing is considerably neglected. Cacao is looking well, where its surroundings are favourable, and the plumpness of the bean now being harvested will surely cheer the hearts of the bonbon manufacturers, and give fine prices to the grower.

I hear that there is considerable diversity of opinion regarding the quality of the sample which was cured in Jackson's tea drier. Some have praised it highly, affirming in addition that the bitter flavour which is sometimes present was completely done away with, leaving the nib sweet and nutty; others again don't esteem it as at all equal to that which has been naturally dried. These opposite estimates are from men who know what they are talking about, and who have considerable experience in cacao curing. What it is to be an authority! The other day I heard a discussion on the merits of tea seed planted at stake, germinated and ungerminated, and the man who had put it in ungerminated seemed to have succeeded quite as well as if not better than the other. If the weather turns out dry after planting, the ungerminated seed does the better of the two; while showery weather, which suits the germinated, is also favourable for the other kind.

PEPPERCORN.

CEYLON AS A FIELD FOR COLONISTS

BY A PLANTER'S WIFE—I.

A good deal has been written lately about colonising in New Zealand and Australia with regard to "What shall I do with my sons?" Perhaps it may not be altogether out of place to say something about colonising in Ceylon. The island is such a short distance from India, that Anglo-Indians are inclined to overlook it as a field for colonising, for, amongst all the planters I have met, I cannot remember having come across one retired Indian officer. Yet they abound in New Zealand and Australia, and they are roughing it there to a far greater extent than they would have to do in Ceylon. Of course I shall be told that Ceylon is played out, and that there is no further field for either adventurers or investors. This may be true with regard to adventurers but it is not so with capitalists who have money to invest; and the Indian officers who go to Australia and New Zealand generally go as small capitalists. I should like, therefore, to describe my own and my husband's experiences in Ceylon as agriculturists.

My husband went out to the colony in 1869, with no more money than would keep him whilst he learnt the language (Tamil) and a little knowledge of coffee planting. Coffee was then beginning to pay in that wonderful way which so completely turned men's heads, and George had no difficulty in getting a berth. As soon as he had gained a little practical knowledge, he obtained work on better pay. The planters, with their bumper crops, were a liberal set of men, and they were rejoicing in prospective fortunes too much to be stingy with their rupees. George was equally led away by the furore, and

was as full of faith in the resources of the island as the rest. Coffee, they said, would grow anywhere, down in the valleys, upon the steep hill sides, even on the cart-road if you could only plant it there. The successful planters built spacious stone buildings for store and pulping houses; imported expensive machinery; laid out new roads, which are a credit to the island to this day, and built bridges, churches, and handsome bungalows in the certainty that their El Dorado was found. On the strength of a remunerative berth, George sent for me in fulfilment of our engagement. He told me to bring out my saddle and piano, and all the pretty things I could gather together for my house, as I should have a good deal of entertaining to do. Full of hope, and congratulated by all my friends, I left my English home under the impression that I should return in a few years with a fortune. George met me at Colombo, and supported by a bevy of his Ceylon friends, we were married. The journey up country was delightful. The line to Kandy is a never ending joy with all its tropical beauties, and to this day it has a charm for me each time I pass along the well-remembered route.

My new home was on the other side of Kandy, high up among the hills. It was a pretty little bungalow, built of wood off the estate, and the necessary furniture, such as chairs, beds, sideboard, tables, &c., was provided by the owner of the estate. I had plenty to do in putting up curtains, and spreading out all my wedding gifts and pretty ornaments. The housekeeping seemed a formidable affair at first sight, but, under my husband's guidance, I soon mastered the intricacies, and took a delight in teaching the cook new dishes. He was a Tamil and very apt at learning. My other servants were West Coast boys—as they called themselves—from Travancore. Servants in Ceylon, who are not Singhalese, always speak of their native country as their "coast," and ask permission to take a holiday so that they may go to their "coast" to see their relations. The comparatively easy and idle life I led was a revelation to me. I had quite prepared myself for hard colonial labour, such as I had heard ladies in New Zealand and Australia undertook, and I was agreeably surprised to find that I was not obliged to cook, or make beds, or clean rooms, or fetch water. In fact the life was more luxurious than the one I had led in England. I had time for gardening, sewing, reading, writing, or music. I rode out to see my neighbours, and entertained them when they could find time to come and see me. I walked out with my husband on the estate, and found amusement in seeing him teach the coolies their work. How often I have seen pruning taught. George would take the knife from the coolie, and cut a few branches himself. Then we would stand and watch the man till he seemed to have got into the knack of it. But the moment our backs were turned the conservative Tamil would go back to his original mode, and slice and chop away at his own sweet will.

We were very happy and free from care in those days, though we were not altogether without our small troubles. What happened to disturb our peace of mind was something which I fancy is a common experience to many young couples. We did not gauge our income. When young people first begin house-keeping they are sometimes hardly intimate enough to go minutely into details concerning the expenditure. The bride shrinks from questioning her husband about how he has been accustomed to spend his income; and the bridegroom likes to give his wife *carte blanche*, and throw the whole matter into her hands with a confidence which is meant as a

compliment. The consequence of this procedure is that young people exceed their income quite unintentionally, and before they know what they are about, they find bills coming in which they hardly know how to meet. This is exactly what happened with us. Our extravagances—I call them extravagances inasmuch as they were beyond our income—were incurred in this innocent and somewhat foolish manner. One day the dinner was not as good as usual; there was a sameness about it which did not make it appetising. I had been so interested in my new garden and its extensions, that I had left the cook to his own devices. George, who seldom grumbled, made a remark to the effect that the cook was falling off in his cooking. "It is the everlasting beef which is so difficult to manage," I exclaimed. "If we could only get fish occasionally, or if my fowl yard would grow a little quicker I could make a change in the food." My husband replied, "You can get fish from Colombo once a week if you like. It will come up to Kandy in five days, and I can send a coolie for it, who will bring it in the same day." And so the fish was ordered, and we rejoiced in the change of food, as well as our friends, who often dropped in to the eleven o'clock breakfast. But when the bill was sent in, and we came to that understanding of our expenses which must inevitably be faced by all young married couples, we found that our income would not meet it. The same thing happened with regard to my pony—an addition to the establishment on my arrival. He, like the fish, was one straw too many. I at once advocated retrenchment, but my husband said "No, there was no need." He was to have a percentage on the coffee crop when the profit exceeded a certain amount and he was sure that that percentage would come, as there was every promise in the blossom of a bumper crop. He suggested that we should pay part of the fish bill, and continue having the supply of fish; and he vowed that the pony should on no account be sold. But this dependence on the future did not suit me. After much discussion, it ended by a discontinuance of luxuries we could not afford. We cancelled the standing order for the fish, and sold one of the ponies.

It was now for the first time that I heard of the Chetties, and their use. They are native merchants and bankers—generally of Indian origin—who supply rice for the coolies, and other merchandise needed for the house, or the estate; they cash cheques, discount bills, and advance money. As their rates of interest are similar to those of the sowcars of India, it is needless to say that the planter is wise who keeps out of their clutches. When I asked how our neighbours, the Browns, managed to live as they did, with no greater income than our own, I was told that Brown "wrote orders on his chetty": that is to say, he asked the chetty to advance the money for the bill. This the chetty did at a high rate of interest; and the Browns were steadily accumulating a debt in this way which they hoped the coffee of the future would pay off. All around me I saw extravagance and expenditure carried on upon the strength of future wealth. I had been brought up in the good old school that taught that there should be no expenditure till the money to meet it was in hand. But now I was in a new element, and my neighbours were existing on golden dreams which had yet to be realized. The substantial storehouse, sheds and pulping-houses, and the expensive machinery—the pride and glory of the planter—were raised partly on borrowed money. The planters were so certain that their crops would pay off these debts in a short time, that they did not hesitate about plung-

ing. They accepted money at the hands of agents and chetties at high rate of interest, and they recklessly burdened their estates with such millstones as eventually dragged them to utter ruin. I trace a good many of my friends' misfortunes to this fatal spirit of extravagance, quite as much as to bad seasons, and poor crops. In all mercantile operations it is necessary to allow a margin for reverses. The merchant or speculator who lives up to his income, or exceeds it in the expectation of an increase in the future, paves the way to ruin. The coffee planters of Ceylon came of a class that knew nothing of mercantile transactions, and they very easily fell into errors. They were the sons of country gentlemen, doctors, lawyers and clergymen, and had been brought up to see their fathers living on incomes which never fluctuated, and might therefore be spent with impunity. Not to spend what honestly came to hand was almost a crime in their eyes. They felt as if they were not acting up to their moral standard if they did not disburse their money as freely and generously as they received it. I have more than once heard a man spoken of disparagingly because he showed himself careful over his rupees, and declined to live up to his income. He was called a "rupee gatherer," and was avoided as unwholesome company. When the heavy reverses did come the despised rupee-gatherer was the only one who weathered the storm.

In my next paper I shall have to tell how we invested in an estate, and with what success.—*Madras Mail.*

VANILLA.—The weather has been very unpropitious to the preparation and we cannot expect any Vanilla of good and sound quality before next month. Owing to the high rate of exchange on Paris and London, there has been a fair demand for this staple in the shape of remittances. A lot of about 150 kilos (fine quality) was sold at R16 per kilo. We understand that the total output of this crop will not be equivalent in quantity to that of last year. The following quotations are nominal.

Crystallised 1st quality	..	R16 to R18	} above 6 inches
" 2nd "	..	14 " 16	
Good to middling	..	12 " 14	
Inferior (reddish)	..	10 " 12	
Vanilloes	..	4 " 8	

—*Mauritius Gazette.*

ASBESTOS.—It may interest some of our readers to learn that an asbestos mine exists on the spur of a hill about two miles from Gundagai, New South Wales, in which the lode has been driven upon for a distance of 90 feet, and a shaft 100 feet has been also sunk. The mineral occurs in a serpentine formation similar to quartz veins, and is mined in the same manner. On the same property another class of asbestos has been discovered and worked in connection with gold. The lode is peculiar in character, and with one or two minor exceptions is almost identical with the famous Lucknow lode, which has proved so rich in gold. In some instances veins of calcspar make their appearance in the lode, bringing gold with them every time. Arsenical and iron pyrites are abundant and so far as the lode has been worked it has proved payable by crushing tests, without one failure.

PLANTING IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

A horticultural journal appearing in Holland asserts that at Tottenham, in England, a very rare plant the *Primula Imperialis* has been induced to flower. This bit of information, however seemingly uninteresting to many, will be found of interest when it is borne in mind that this kind of plant, so far as known, is found only on the top of the Sangerahgon, a mountain ten thousand feet high within the Preanger Regencies in Java. Hitherto endeavours had been made to grow it within hothouses in Europe but always with little or no success. Thirty years ago, unless we are misinformed it flowered in Holland too, but afterwards it was no more seen in hothouses. In the Himalaya, a *Primula* is met with resembling so greatly the above-mentioned variety as to be almost identical.

Messrs. De Lange, Van Den Berg, Sucremond, and Van Delden, four of the principal and oldest European Residents of Batavia, thoroughly experienced in commercial and plantation matters, have petitioned the King of the Netherlands for the appointment of a commission made up partly of officials and partly of private individuals with a high official at their head to inquire into the state of plantation enterprise throughout Netherlands India.

By last advices the coffee leaf disease has shown itself at Bonthain and Macassar, and has even made its appearance at Menado. As contagion is inadmissible, from these places being so widely apart, the disease must have arisen from local causes. On one estate in Java where diseased coffee leaves had been systematically plucked off and burned, the disease has been so effectually checked that the trees looked healthy and bore fruit which fully ripened.

The *Java Courant* has just published returns of the yield of produce in private estates throughout Java and Madura in 1883 and 1884 the figures showing:—

	1884.	1883.	
Coffee ..	250,643	338,143	piculs.
Sugar ..	6,493,218	5,348,867	"
Tea ..	5,335,396	4,941,888	} Amsterdam pounds.
Cinchona ..	667,896	379,728	

Mr. Jata, a retired naval officer and now business manager in Surinam, attirms in a Java planting journal that the Death and Ellwood machine which, during the competition held in November 1881 at Calcutta gained a prize valued at 24,000 guilders as the best working fibre separating machine, answers satisfactorily not only for rameh but also for jute, hemp, aloe, pineapple leaf and New Zealand flax. By means of this machine, within the tropics, during fairly dry weather, rameh may be cut in the morning, passed through the machine, pressed into bales, and forwarded before sun-set. The General Fibre Company at London now buys up rameh at about 120 guilders per ton which yields it a handsome profit. According to him rameh growing will assuredly ensure enterprising persons an abundant source of income.

Another correspondent of the same periodical advises planters in Java now that coffee is borne down by leaf disease, low prices, and enhanced land assessment to take to cinnamon growing. It seems, so he says, that cinnamon growing well as it does up to height of 1,500 feet above sea level requires less care and less expense at the start than coffee besides having the advantage of coming into

bearing within five years. The bark, branches, and leaves of the cinnamon tree all may be turned to profit in some way, even oil and tallow being among its products. He estimates that a cinnamon tree in bearing yields yearly a net gain of 1,000 guilders per *boua*.

HEMILEIA VASTATRIX IN SOUTH AFRICA.

The destructive coffee leaf fungus has now reached Africa, the very home of the coffee plant, and as there is frequent communication between the South African British colonies and Brazil, all the chances seem to be that the disease will soon reach the latter country. We may well ask if coffee is doomed. We quote from the report of the Durban Botanic Society, which has been sent to us:—

Hemileia Vastatrix.—On 24th May, 1884, I received from Lower Umziinkulu three leaves taken from a Coffee Tree affected with "Leaf Disease." After a close microscopical investigation of these leaves, I became convinced that the fungus upon them was undoubtedly the destructive *Hemileia Vastatrix*; but, for further certainty, I immediately forwarded a portion of the leaves to Professor Macowen, Director of the Botanic Gardens, Capetown, a gentleman who has made this class of plants a special study. As he, however, did not feel quite satisfied, he forwarded the specimens to the Director of Kew Gardens, with a request for a telegraphic reply. On the 30th of June I received copy of telegram from Kew, confirming the decision at which I had arrived as to the identity of the fungus. In the meantime, in company with A. H. Bisset, Esq., recently engaged in coffee cultivation on a large scale in Ceylon, where the *Hemileia* had been so destructive, had an interview with the Colonial Secretary on the matter, as a result of which, Government agreed to remunerate the owner of the piece of Coffee for as much of his crop as it might be found necessary to destroy. In doing so, every precaution was taken to prevent the spores from being carried to adjoining estates, and up to the present time I have not heard of the disease having appeared in that locality, and the owner of the infected estate, in answer to my enquiry, says:—"The Coffee in this District is all looking remarkably well, and there is the promise of good crops."

I am glad, therefore, to report that the prompt action of Government in this matter appears to have been attended with complete success so far as the District of Lower Umziinkulu is concerned.

On August 14th, 1884, I received from Mr. Behrens General Manager of the Natal Land and Colonization Company, Limited, specimens of diseased leaves from Coffee Trees on that Company's estate at Reit Valley, which microscopical examination showed to be literally covered with the fungus *Hemileia Vastatrix* in full fructification. It should be stated that the Reit Valley estate is at least 100 miles in a direct line from where the fungus was first noticed, nor can I learn that there had been any direct communication between the two estates. On 16th June, I had written to the Manager of Reit Valley, calling his attention to the appearance of the disease at Umziinkulu, and asking him to keep a good look-out, so that the matter might be dealt with on its first appearance. On the 19th June, he replied "up to this date I have not seen it here." I now learn that nearly the whole estate of Reit Valley is infected and that the trees will have to be destroyed.

At the suggestion of the Assistant Director of Kew, I issued a circular recommending a trial of Morris' Sulphur and Lime process on any estate where the fungus may again appear. Coffee estates in Natal are now so few and so far apart that there is hope that by vigilance the Colony may be cleared of the pest, if planters will only assist by keeping a good watch on their plantations and destroying all abandoned or useless trees.

During the past year, 1884, two other pests have appeared in the Colony, each of which will require careful watching to prevent serious losses:—

Cuscuta sp. (most likely *C. trifolii*, Bab.). This plant appeared in two fields of lucerne, near Durban, and specimens were sent to me for identification. Notice was sent to the local papers urging that every effort should be made to exterminate the plant, and recommending that all lucerne seed should be carefully sifted before sowing. I learn that in Mauritius a plant of this genus threatens to do considerable damage, and I therefore hope that farmers and planters will keep a good look-out, and destroy all plants of this nature wherever they may be found in their crops. It may be as well to mention that we have two, or perhaps more, indigenous *Cuscutas*, one of which bears a close resemblance to *C. trifolii*; but I have not yet heard that this plant has been found in cultivated crops.

The other pest referred to is an *Urticaria* (*U. destruens* Dohy). This parasite has attacked the native grass (*Chloris compressa*), usually planted for lawns, and I have been informed that in some places, the grass has been killed by it. It has made its appearance in the Gardens, but has yet not to any serious extent; it is being carefully watched, and should it increase or threaten to damage the lawns, an attempt will be made to destroy it, and the results duly made known.

Coccoloba Odorata.—A tree in the Gardens which I found without name attached, flowered near the close of 1882, and examination showed it to be this plant, but for further certainty I forward specimens to Kew. The Assistant Director, in reply, says, "This is the West Indian Cedar, the wood of which is so much in request for the manufacture of cigar boxes." This is a handsome tree, and appears, so far as I can judge, not to be a favourite with white ants, and its growth seems to be almost as rapid as that of most Eucalypti. We have been successful in rearing plants both from seed grown in the Gardens, and also from seed sent to us from Kew, and the plants have been distributed to different parts of the Colony, with the view of testing the suitability of different soils and districts to the growth of the tree. We have a large number of distribution now on hand.

Permit me to add to my report that I think that a number of Railway Sleepers should be tried by our Government from *Gum Trees* grown in the Colony. The trees should be identified before being felled, or in consequence of the confusion in the popular names of the Eucalypti no reliable result can be expected. I am convinced that all the replacement sleepers required for all our lines of railway can be grown by ourselves in the Colony to the Colony's profit and advantage; and to this end I offer to co-operate fully with the Committee of the Society.

The attempt to form a *Rosery*, on the slope beyond the conservatory, resulted in complete failure. Sixty Rose plants were set out in spring of 1883, but before the winter (1884) was over, all, except two or three of the commonest kinds, had been destroyed by white ants, in spite of all our endeavours to preserve them. The piece of ground laid out for the Roses has been filled with other plants. We are now attempting to grow a few Roses in tubs; each tub stands upon a square block of concrete, in which four glass bottles are embedded, bottom upwards, upon which the tub stands. So far, this method has been successful; we have not found that the ants in any one case have reached the tubs. We have therefore placed the large pots containing our Tree Ferns on similar blocks, and believe they will be safe from the ants in future. The concrete blocks are made at the Gardens at a very moderate cost, and with ordinary care are almost indestructible. The unsightly steps in the main avenue, which had been formed of tree trunks, have been replaced by concrete blocks, also made by our own people. The improvement is well worth the small expense incurred. The *Conservatory* and *Pervery* have been well attended to, and the display of plants from these Gardens at the Horticultural Society's show, November, 1884, sufficiently marked improvements in this direction, and bore witness to the skill and care of the Head Gardener. The *Pervery* is already too small to contain our collection, increased from less than 20 species, which were in cultivation 3 years ago, to about 160 species, all of which are growing vigorously. I intend adding

to this number whenever opportunity occurs. It will therefore be necessary either to enlarge the present temporary building or to erect another of a somewhat similar character, and I hope to be able before the close of the winter, 1885, to make some addition of this kind.

A PROSPERING CEYLON PLANTATION COMPANY.

It is with no ordinary satisfaction that we reprint the past year's Report of the "Scottish Trust and Loan Company of Ceylon, Limited," which was laid before a meeting of the shareholders in Edinburgh on the 28th ult. It tells its own story in a very succinct business-like way, and that story is of steadily reviving prosperity in the planting industry of Ceylon. The Company may well be congratulated on the result of the past year's operations and on their prospects. The estates which they have been obliged to take over, and which stand in their books at the sum of £42,771, have earned for them during the year the sum of £5,915, or considerably more than 10 per cent, and if the Company only continue to do justice in cultivation and to extend tea judiciously, while very wisely maintaining intact all good coffee and cinchona, there can be no doubt that in a few years their profits from the estates they hold ought to be considerably larger. Messrs. Cumberbatch & Co. are evidently doing all the justice in their power to the properties and business of the Company. We extract from the report at length, because it is of interest to this community generally:—

In accordance with the resolution passed at last General Meeting, the date of balance has been changed to 31st August, and the Accounts from 30th September 1884 to 31st August 1885 are submitted herewith.

Though slow, the improvement in the condition and prospects of Ceylon has steadily continued; Coffee and Cinchona are commanding better prices, while Ceylon Tea has already established itself firmly in public estimation, and promises to be a very important factor in the future prosperity of the Island.

As foreshadowed in the last Report, in connection with the failure of the Oriental Bank Corporation, the Directors have had to take over three other Estates, in order to protect the Company's advances and insure proper cultivation.

Considering the state of these Properties when taken over, the result of the year's operations is encouraging. While Abwick, as in the last year, has contributed the great portion of the Profit, three other estates have been fairly remunerative, and two more—Kalpoogala and Ardallie—would have shown credit balances had it not been for the heavy expenses of foreclosure etc. (£18, 6s 11d), which appeared in last year's Balance-Sheet under Suspense Account, and are now written off.

The estates in the Company's hands are entered in the Balance-Sheet at the net amount of the original loans respectively; all arrears of interest, together with the expenses of foreclosure to date, having been written off.

All the Company's estates have been reported on as suitable for Tea cultivation, and already 800 acres have been planted up. Some return may be expected next year, but the bulk of the Tea now planted will not come into full bearing until 1887-88. The Directors intend to continue the extension of Tea planting, but at the same time they will use their best endeavours to maintain the cultivation of the existing products—Coffee and Cinchona—where their growth is found to yield satisfactory results.

The interest on mortgages has been well met. With the exception of £166, 13s 4d, the interest in arrear has since the close of the account, been either paid or

secured by consignment of produce. Several payments have been received during the year in reduction of loans.

A considerable portion of the produce in hand has been realised since the close of the accounts, at prices which fully warrant the estimated value entered in the Balance Sheet.

The Oriental Bank has already paid 12s 6d. in the pound on the Balance due to the Company, and there is reason to believe that payment in full will ultimately be obtained.

The De-benture Debt has been reduced from £68,820 to £64,925.

The balance at the credit of profit and loss account amounts to £6,805 8 6.

This sum would admit of the Company declaring a substantial dividend on its paid-up capital; but the Directors, after mature consideration, are of opinion that it would be more to the permanent interest of the shareholders to strengthen the Company's working reserves with a view to do the fullest justice to its estates, than to make a present distribution by way of dividend. They accordingly propose to add to

Reserve Fund 3,500 0 0

Leaving £3,305 8 6

which they propose to carry forward until the spring, when the question of an interim dividend will be considered after the requirements of the Company's Estates for 1885-86 have been ascertained and the probable returns estimated.

EXPERIMENTAL CULTIVATION OF PEARL OYSTERS A FAILURE:

REPORT OF CAPT. DONNAN.

Our Master Attendant, Capt. Donnan, got back this morning from Sillavatturai after a very unpleasant trip, the weather being so wet and boisterous. We very much regret to say that his mission has been an unsuccessful one also, since he found all the oysters in the experimental bank on the reef dead, with the exception of a few which looked very soeely and had not grown a bit since they were put into the bank in March last. Capt. Donnan is naturally very much disappointed at the failure, since he fully expected that pearl oysters would have lived and thrived in that bank as well as anywhere, and as they have not he is very doubtful of the success of preserving them anywhere off their "natural beds," which, we fear, must now be looked to as the only source of supply.

☞

COFFEE.—The wet weather of the past few months has brought out a fine blossom, and set it too, on some Nilgiri coffee estates. The berry has not made the necessary progress toward maturity but looks too fresh and tender to carry it through the ensuing dry weather. A late crop will probably be the result, if it does not drop off. In a way this would be the best thing for the estate which will repay handsomely, other circumstances being favorable, next season. Few planters can afford to lose now, to reap ten fold hereafter. We trust however they will be able to weather through the distress and enjoy future prosperity which we have no hesitation in saying will be hardly earned.—*South of India Observer.*

SOME wine has been made from wild grapes grown by Mr. Barnes on the hill slopes of his Vergomont Estate near Naini Tal. It is said to have a very pleasant flavour. Some samples, which were sent to the Punjab, were said to be highly commended.—*Times of India*.

DR. JAMES D. DANA, in the *American Journal of Science* for August, has a paper on the 'Origin of Coral Reefs.' He states that the arguments raised by Dr. Archibald Geikie against Darwin's theory of subsidence as an explanation of the formation of atolls, or barrier reefs enclosing a lagoon, are based on misunderstanding of the facts. The subsidence indicated by atolls is shown to be real, and not an apparent change of water level.—*Athenaeum*.

THE TEA CROP.—It seems now almost certain the *Englishman* says that the tea crop for the current season will fall short of the original estimates by at least two million pounds. After allowing about two million pounds for exports to the Colonies and America and one million five hundred thousand pounds for home consumption, the quantity available for shipment to Great Britain is not expected to exceed sixty-three and a half million pounds.—*Pioneer*.

ADULTERATED TEA IN QUEENSLAND.—From the report of the Queensland Government Analyst, Mr. Robert Mar, F.C.S., for the year ending 31st July last, it appears that of 107 teas examined, thirty were adulterated, and six of these were reported "unfit for human food." The adulterants found were:—Exhausted tea leaves, (from 1 to 10 per cent (foreign leaves, starch, gum, catechu, magnetic oxide of iron, clay, and sand. One of the six teas condemned as "unfit for human food" contained only about 50 per cent of genuine tea. The other five were less sophisticated, and in these cases I added, to the results of examination and analysis, the considerations from physiological experiment—upon myself—before making report. But this is not a convenient method for confirming an opinion, and yet is the only one possible in doubtful cases. I therefore suggested that those teas should be prohibited from going into consumption which in quality fell below the British Public Analysts Society's limit, as is the case in New Zealand. This suggestion has been acted upon, and an extra officer of the customs (whom I instructed, and who has shown aptitude in apprehending and skill in following the instructions given) has been deputed to make a preliminary examination of all teas coming into Brisbane. The result of these arrangements I have tested by making analyses of teas imported in previous years and comparing the same with those of teas presently coming into Queensland, and find the proportion of adulterated tea sent has materially decreased, and a sensible improvement has taken place in the quality of non-adulterated teas. Of this latter fact I give a comparative instance:—

	Tea Imported,	Tea Imported,
	1885,	1883.
Moisture	7.91	6.75
Extract	82.00	81.00
Ash	5.82	5.59
Soluble ash	3.80	3.06

AN AMUSING and sensational article appeared in the *Morning Post* the other day on the Sugar question. Colonial planters and European beet growers were told to look to their laurels, for the insignificant little flower of the "Mahwa" or "Moola" tree, one of the plants of the forests of Central Hindostan, "seemed likely to completely revolutionise the whole of the sugar industry," and the writer went on to say: "It is

already asserted that in a not very distant future the beet will be discarded from the extracting pans of the continental sugar bakers, and the cane of the West Indies become as extinct as the carbonised palm-reeds of the pre-historic coal measures." The readers of the *Morning Post* were favoured with a most minute description of the tree, and were told that it demanded no special culture, called for no attention, no pruning or fertilising, was easily propagated, and that it flourished in the poorest soil. "With a becoming consideration for the capitalist, the tree does not even ask to be picked. It is a deciduous plant, and spontaneously sheds its flowers during the darkness of night. The Bheels residing in the forest have only to stand under the tree and the sweet harvest falls at their feet. A single shower often yields a hundred pounds of the Mahwa blossoms." Such a description is enough to take one's breath away. The writer proceeded to say that an acre, containing from 200 to 250 trees, would produce enough blossoms to give 100 to 120 tons of sugar, and naively added that "competition would be out of the question." We should think so indeed. But the writer, whoever he may be, seems to have written about a subject of which he knows next to nothing. The "Mahwa," or rather "Mowra," trees which abounds in the southern half of Hindostan, has been known for ages past, and has oftentimes been reported upon. It is true the leaves contain a very considerable proportion of saccharine matter, but, so far as we can learn, all the experiments made up to the present have been unproductive of satisfactory results, and the period is certainly very remote when the "Mowra" will enter into competition with either the sugar cane or beet. Our contemporary, the *Produce Markets Review*, points out that Lieutenant-Colonel Miller, officiating Political Agent at Bhopawar and Commandant of the Malwa Bheel corps, gave full particulars of the trees some time since in the *Indian Agriculturist*. That officer stated that probably not more than forty trees could be planted to the acre and that yield per tree appeared to vary from three to six kutchas maunds, or about 120 to 240 lb. of flowers. If it be true that the flowers contain half their weight in sugar, this would mean a yield of one to two tons the acre. The weights given are of the flowers that fall, for the natives do not appear to gather them. There is all the difference between these figures and those of the *Morning Post*, where a ton of blossoms is spoken of as being yielded by each tree, and a yield of 100 to 120 tons of sugar per acre is also given as that which may be obtained from the Mowra, Mahwa, or Moola tree. Colonel Miller, though he gave many particulars of the uses of the flowers and fruit in the article named above, made no mention of sugar being obtained from the flowers, but stated that the juice had "a strong and rather disagreeable smell, like that of wild beasts, tigers, &c." Mr. William Fox, F.R.S., of the Laboratory, Great Tower Street, 140 writes to say that the flowers submitted to analysis gave the following result:—"Honey, 42.03 per cent.; cane sugar, 1.04 per cent.; ash, 2.32 per cent.; cellulose, &c., 12.20 per cent.; and water, 12.11 per cent. total, 100.00. No grape sugar was present." He adds:—"It will be impossible to make ordinary or cane sugar from a substance yielding the above results, so that the cane or beetroot sugar industry can only be affected to a very slight extent, as the sugar contained in the Mowra can only be utilised for brewing or distilling purposes. The flowers, I may add, are all male flowers." After this, it may be expected we shall hear very little of the "Mowra" as a sugar producing tree for some time to come.—*European Mail*.

Correspondence.

To the Editor of the "Ceylon Observer."

EUCALYPTUS OIL IN BOILERS: ALL ABOUT COCAINE.
London, E.C., Oct. 29th, 1885.

DEAR SIR, I learn that you have published some information respecting the employment of eucalyptus oil in boilers.

For fear of its leading to disappointment, owing to the large quantity of oil used for this purpose, I thought it was advisable to apply to my friend Mr. Hawksley, who has obtained a reputation in England for making first-class boilers. He informed me that many boilers arc entirely spoiled by the use of grease and oil for removing shale, so much so that he is now frequently called to examine boilers which are said to be leaking, and he almost invariably finds out that oil has been employed where lime has been found troublesome and to be predominating in the water. He gave me a drawing (which I enclose you) which has been published by his firm, Messrs. Hawksley, Wild & Co. of Sheffield, showing how they get rid of the grease where water is scarce and dear, by using the waste steam which has passed through the cylinder.

Calling his attention to the remarks on eucalyptus oil, he said: "Without having an intimate knowledge of this special oil I should certainly condemn the employment of any sort of oil in boilers."

Changing now to entirely another subject I may report to you that cocaine is being manufactured in very large quantities, so much so that the price of leaves of first quality has risen to 2s and 3s 6d per lb. when fully matured and strong. It is this class of leaf which yields a large percentage, up to 8 per cent of cocaine, but at the same time there is no doubt that these leaves also require very careful treatment, because in several samples of cocaine that I have had lately before me I find they have a strong smell and a tinge of yellow colouring which is objected to by many surgeons where cocaine is required for delicate operations. It is said that the yellow colouring matter, which comes, I believe, from the chlorophyll contained in the leaves, produces irritation in the eye, or in the bladder, or in the urethra. Cocaine has not yet responded to the rise in the price of the leaves, but there is no doubt that it is being well used now that it is sold as low as 2s 6d to 3s 6d per gramme which is 15½ grains. Lozenges and pastilles are being supplied largely containing 1 grain of cocaine, and with these passengers by the steamers report that they have an immunity from sea-sickness. To sift this question thoroughly, as one of the American line of packets would not entertain any proposition direct of purchasing, I supplied some of their surgeons with tubes of cocaine, asking them to bring me back a report of their experience. Anyone having made long voyages knows how quickly anyone prostrated by sea-sickness can recover. Cocaine has a most singular action not only upon the brain but upon the stomach, and paralysing the action of the nerves of the tongue and throat, and greatly assists the action.—Yours faithfully,
THOS. CHRISTY.

JAPAN WOOD TEA BOXES.

Kintyre, Mackelaya, 11th Nov. 1885.

DEAR SIR, As there has been rather a doubt about the smell of the cedar wood of Japan tea boxes, owing to some of the Colombo buyers fighting shy of them,

will you kindly publish the enclosed copy of telegram received from Messrs. Wilson & Smithett (of London) today? and you will oblige myself and many of your readers, no doubt.—Yours faithfully,

H. DRUMMOND DEANE.

P.S.—Of tea from this factory some 20,000 lb. had arrived in London packed in ¾-inch Japan boxes before this message was received.

Copy of telegram translated from code: "Japan boxes are a success: smell does not interfere with tea. Would, however, advise half-inch wood being used." True copy.
H. DEANE.

ORANGES SUCCESSFULLY SENT FROM UVA TO ENGLAND.

Koslanda, 16th Nov. 1885.

DEAR SIR,—It may be of some interest to you and your readers to know that a box of oranges I forwarded to Norwich from Haputale (through the London and Colombo Forwarding Agency) reached that distant locality in capital condition, my friends observing that they looked so tempting and were getting very sweet. When fresh from the tree they are of a very refreshing sweetness with a dash of acidity which gives zest to their flavor, particularly on a hot day. Is this the first shipment of oranges from Ceylon?

S. B.

[We are very much interested in experiments of this kind, and congratulate our correspondent on being the first, so far as we know, to send a considerable quantity of oranges from Ceylon to England to arrive in good condition. Being pulled before they are ripe, while still the acid predominates, is part of the secret; but we suppose besides that our friend packed them in sawdust and had each orange wrapped separately in tissue or other thin paper? Although the distance is too great for Ceylon oranges to compete with those from Spain, the Azores and Florida in England, still something might be done in sending shipments to friends, while peaches in Ceylon ought to be more freely preserved.—Ed.]

MR. CLEMENT L. WRAGGE, late of Ben Nevis Observatory, has been authorised by the Queensland Government to report "as to the best means of establishing meteorological stations in Queensland, including Cape York Peninsula and Torres Straits." Mr. Wragge commenced this important work early in September.—*Athenaeum*.

CANARY BREEDING IN CEYLON.—"Enquirer" writes:—"I have to thank two of your correspondents for so kindly coming forward in reply to my wish for information as to the best method of breeding canaries. The information supplied has been useful, but I can't understand why the removal of the cock-bird should be insisted on after the hen has laid. I have been so far successful that I have the hen-bird sitting on three eggs now; this is the 12th day. This morning after perusal of your last light's issue I took your correspondent's advice and removed the cock-bird, but the poor little hen was so much distressed that I was obliged to remove some part of the covering of the upper portion of the breeding cage, and place the other cage with the cock-bird alongside, after which the hen-bird settled down to her nest. There is no doubt that hard-boiled egg (the yellow) will do; but I find that whenever I do feed my birds on it ants find their way into the cage somehow or other, whether the cage is fixed to a wall or hung on a wire, &c. Can any of your correspondents inform me the best way of preventing ants from getting into the cage; if they do, after the young are hatched, would he to the birdies, their tenure of life will not be long. In how many days can I expect the eggs to hatch?"

LEAF DISEASE.—We learn that leaf disease is very prevalent on some coffee estates on the Nilgiris. The russet extends in some instances over the whole area, in others is confined to particular spots; native estates are more affected than European. The disease must be looked upon as the immediate consequence of the economy, amounting to starvation, practised within the last year or two in respect to upkeep and working expenses. High cultivation is the only known remedy for leaf disease, but this means money, and money is not forthcoming at present, and future prospects are equally dismal.—*South of India Observer.*

TILE-MAKING IN COORG.—The firm of Morgan & Son, of Mangalore is I hear going to open a tile manufactory at Siddapur in South Coorg. A site where abundance of good quality clay is obtainable has already been pitched upon, I believe, but the land will have to be bid for at a public auction most probably before it is secured. The firm already possesses a manufactory of the kind in Mangalore, and the tiles which are called Mangalore tiles turned out are of superior workmanship and finish. The same may be said of the tiles turned out at the Basel Mission factory also at Mangalore, but the tiles made at the Mercara factory owned by Mr. East, a planter, don't give the same amount of satisfaction. If Morgan and Son's factory is one established at Siddapur and turns out tiles as good as their factory at Mangalore does, it must do for the one at Mercara.—*B. S.—Madras Mail.*

PLANTERS here are just now pelted with machines of all kinds—rollers, sifters, and driers—and the individual about to erect a big factory and purchase new machinery suffers a good deal from *embarras de choix*. A planter well-known here and once on an Indian garden, Mr. Fairweather of Sembawattie, has just brought out two improvements in the mechanical appliances of a tea factory. One is a machine which he is about to patent for sifting and separating the fine from the coarse leaves after rolling, and the other is a contrivance for easily spreading leaf on the withering shelves. I have not yet seen the "Leaf Separator and Sifter" as Mr. Fairweather styles his new machine, but from descriptions of it I should say it is likely to be a success, being simple in construction and very effective. The roll passes from the roller into this new machine which breaks up all balls of leaf and drops the fine leaf in the centre of a ring formed of the coarser leaf, thus allowing each to be fermented separately. Naturally this is a great advantage allowing neither the coarser leaf to be sacrificed for the sake of the pekoe, nor the finer leaf to be sacrificed for the sake of the lower grades of tea. The leaf spreader is not a machine, but an ingenious contrivance whereby the coolie spreading can do all his work without moving from one spot. Each shelf or "tat" is of jute hessian on a roller and is drawn along horizontally by a cord worked by a pulley from the other end of the withering loft by a boy. This pulley is so constructed as to have the cords of all the tats attached to it, and as the leaf is spread by the coolie at one end the boy at the other draws the whole out—very much in the same manner as a window blind. More than one large factory here have adopted this method which appears to give satisfaction wherever it is tried. *** Talking of driers reminds me that attention has been called here to the higher temperature at which planters work them as compared to the custom in India. We are told that Indian planters deem 230° Fahr. quite hot enough for their machines, whilst 260° is quite common with us. Inasmuch as our leaf contains far less moisture than that on Indian gardens, it is argued that we overdo the firing and thus burn our teas. This certainly seems plausible enough, for complaints on this score have been pretty frequent of late from London. Why your leaf should contain more moisture than ours it is hard to say, but the fact remains nevertheless.—*Ceylon Cor., Indian Planters' Gazette.*

CINCHONA SALE.

At Messrs. Oakes & Co.'s sale of Government bark held yesterday, 177 bales were disposed of at the following prices:—

Doolabetta Crown Bark.
Natural—6 bales containing 600 lb. sold for R146 per bale.
Branch—54 bales containing 5,400 lb. sold for R48 per bale.
Root—6 bales containing 600 lb. sold for R155 per bale.
Naduwatum Crown Bark.
Natural—58 bales containing 5,800 lb. sold for R130 per bale.
Renewed—27 bales containing 2,700 lb. sold for R165 per bale.
Branch—26 bales containing 2,600 lb. sold for R79 per bale.
The prices are very high when compared with those at the sales in October.—*Madras Times, Nov. 3rd.*

CENTRAL AMERICAN COFFEE.

In the March consular reports Consul Schroeder, of Costa Rica, has an article in reference to American trade with that country, in which he speaks of the coffee of Costa Rica and Guatemala. The government statistics for 1883 give the following table:—

Costa Rica :			
Coffee plantations	7,499
Number of coffee trees	23,446,278
Pounds	40,425,300
Value, at 9½ cents per lb.	\$3,925,330
Guatemala :			
Coffee plantations	5,131
Number of coffee trees	50,084,283
Pounds	43,425,555
Value, at 10 cents per lb.	\$4,342,555

The result of the coffee harvest indicates the superiority of the Costa Rican soil. Its trees give nearly two pounds of coffee per tree, while in Guatemala not much more than one pound of coffee per tree is obtained. Two pounds of coffee per tree is regarded as rather a lean harvest, but a higher average quantity can not be obtained, as the trees have not been manured for fifty years. Men of experience have found that by applying manure the coffee trees will yield easily one pound more. This would increase the harvest 22,446,278 pounds of coffee, or in other words, increase the purchasing power of the country by nearly \$2,250,000. But the people prefer to let nature alone, because to do otherwise would require some labor.—*St. Louis Grocer.*

CEYLON PLANTS.—A systematic catalogue of the flowering plants and Ferns of Ceylon has been published by Messrs. Dulac & Co. for Dr. Trimen. This must needs be a very useful publication.—*Gardener's Chronicle.*

SARCOEPHALUS ESCULENTIS.—Probably many will recognize in this an old friend, as it was said to be common in the gardens around London many years ago, but had not fruited. It is known as the Guinea, or Negro Peach, from its size and shape, but of course has no relationship with the real Peach. It is a member of the Cinchona order, and remarkable in the first place for producing its flowers in densely-packed, globose heads; and secondly, for the exceptional manner in which the separate fruits become amalgamated with one another, and with the receptacle, forming a sort of compound fruit, as we have in the Custard or Pine-apple, the resemblance to which, however, in the present instance is merely superficial; not one of affinity. The flowers are creamy-white, and agreeably fragrant, with long projecting styles, that give the heads a bristly appearance. A flowering specimen may now be seen in the Economic house at Kew, and the plant was figured in the *Horticultural Transactions*, v., t. 18, where it was described by Sabine.—*Gardener's Chronicle.*

SUGAR.—Notwithstanding the depression in the sugar trade, a new kind of sugar is announced. It is made from the date palm by making incisions in the lower branches, and collecting the sap which flows thence continually from November to March. The sap is afterwards clarified and boiled down.—Dr. J. E. TAYLOR in *Argus*.

COFFEE.—At the Commercial Sale Rooms, Mincing-lane, a meeting of importers, buyers, and brokers connected with the coffee trade has been held, to consider the advisability of alterations of the terms for the sale of coffee in London. The chair was occupied by Mr. W. H. Peat, and there was a very numerous attendance. There was a long discussion with reference to the abolition or equalisation of discounts, the abolition or reduction of draft, the sampling of coffee, and also a proposal that the dock and wharf companies should be requested to alter their rates and reduce their cost of re-weighing and re-housing. The chairman spoke of the great importance of the meeting, owing to the depressed state of trade, and the need of the appointment of a thoroughly representative committee, who would give their attention to the matters which affected all sections of the trade. Mr. E. Rucker remarked that whereas in the United Kingdom since 1860 the consumption of tea had gone ahead with enormous strides and the consumption of cocoa had also very largely increased, that of coffee had diminished very much. The imports, which in 1881 were 69,000 tons of coffee, had fallen off to 41,000 tons in 1884, which was not much more than half what it was four years ago. He hoped that all connected with the trade will combine together and see if they could find out the cause of the decrease, and do something to improve the trade. He especially hoped that they would endeavour to tackle the question of adulteration, which, he thought, was greatly injuring the trade. After a long discussion the meeting elected a representative committee of importers, brokers, and exporters to consider the questions affecting the sale of coffee in London for the purpose of reporting to the trade and obtaining their sanction to any alterations which might be deemed advisable.—*L. & C. Express*.

THE SOIL.—As all my readers understand, there are few practical applications of modern chemical discoveries of greater value than those applied to agriculture. Hence the eagerness with which our British scientific agriculturists (and I am proud to note there are such men, and also that their number is daily increasing, notwithstanding agricultural depression) read anything which comes from the pens of Dr. Gilbert, Sir J. B. Lawes, or Mr. Warrington. The latter has just published a paper on "Nitrification." As some of my readers are doubtless aware, about two years ago considerable astonishment was created by Sir John Lawes's expression of opinion that nitrogen was made available for the use of plants by the presence of multitudinous organisms in the soil. Mr. Warrington now steps in to corroborate this opinion by further observation, as far as observation has gone. He has not himself the slightest doubt that soils contain what he calls "nitrifying organisms," and he shows that they are ruled by temperature. He proves that nitrification does not take place in soil brought up from great depths, where his theoretical organisms has not penetrated. Indeed, nitrification seldom takes place at a greater depth than nine inches from the surface. His general conclusions are as follows:—Nitrification proceeds far more rapidly in summer than in winter; it is most rapid in darkness; the presence of oxygen is necessary; a solution receiving an abundant supply of the nitrifying ferment will exhibit speedy nitrification; the latter will not take place in acid solutions; alkalis are necessary, and lime appears to be the best means of inducing it (hence the practice of "liming the land," now nearly disused, was scientifically correct); sewage cannot be nitrified unless

abundant carbonate of lime is present. The strongest solution in which Mr. Warrington has found nitrification commenced contained carbonate of ammonia equal to 365 milligrammes of nitre per litre (the litre being a little more than a quart) when carbonate of ammonia is in excess (and many people think they can't put too much of a "good thing" into their land), the nitrification of the soil is effectually hindered, although all the other necessary elements may be present. In the absence of phosphates no nitrification can take place. If the soil is chloroformed nitrification ceases; if it be heated to a high degree the same thing occurs. When sewage is heated to the boiling point it is useless and sterilized, although nitrification can be started in it when cold by adding a few drops of a nitrified solution. The evidence is gaining weight that our soils are nitrified by the presence of multitudinous bacteria.—Dr. J. E. TAYLOR in *Argus*.

THE USE OF LIME.—It is a sort of axiom among farmers that "where lime is used the land and the farmers are rich." This is an old but true adage and deserves to be made one of the established axioms of agriculture. It is true in two ways—one, that lime is an exceedingly valuable fertilizing agent of itself, and in addition exerts a most beneficial influence upon the soil as a solvent of the silicates, chiefly of potash, and also in decomposing organic matter in the soil and favoring its nitrification and the production of the indispensable nitrates which so greatly enrich the soil, the other that its use is one of those higher attributes of skillful farming which is consistent only with the best culture of the soil and the most thorough and systematic working of it. It is, in fact, in the farmer's hands, one of those instruments which is rarely or never found excepting where every part of the farm work is done in the most excellent manner, so that it is not so much that the farmer uses lime as that he uses it as a part of a system of farming which is thoroughly excellent, and, of course, very profitable. Lime is thus not to be used in a haphazard way, and simply to extract from the soil the last vestiges of fertility it can bring out. When thus used another common adage, that "lime enriches the father and impoverishes the son," will surely be found true, because it is like a last turn of the screw which squeezes the last drop of juice from the cider mill. The place of lime in good farming is its application to the land at the Fall season when rye or wheat is sown and grass and clover seeding follows. The land has then become more or less supplied with organic matter from the roots and waste of previous crops, and it has accumulated a store of nitrogenous and carbonaceous matter which cannot be made available until it is decomposed nor until a sufficient quantity of mineral matter has been set free in the soil to balance the supply of plant food required for a new rotation of crops. Besides, at this season and with Fall grain the regular manuring of the land is given, and the manure is generally coarse and undecomposed. It is precisely under such conditions that lime is of the greatest use and value and fits the soil for a new round of crops. The quantity of lime usually applied is 40 to 50 bushels per acre freshly burned or stone lime. In the air-slacking by which it is prepared for use it swells to three times its original bulk and becomes a fine powder which is spread from a wagon, with a long handled shovel, evenly over the soil. This should be done upon the plowed land immediately before sowing, when it is harrowed in previously. As lime is quite soluble in this fine condition, requiring only 700 times its own bulk of water to dissolve it, it should never be ploughed in, or it will be very quickly carried down into the soil below the reach of the roots of any plants, excepting those clover. Clover is one of the plants which are wonderfully benefited by lime, and it is for this reason among many others, that its use is to be encouraged, because it provides the skillful farmer with one of the most valuable sources of manure, viz., a heavy clover sod to be plowed in.—*New York Times*, given in *Southern Planter*.

MARKET RATES FOR OLD AND NEW PRODUCTS.
(From Lewis & Peal's London Price Current, November 5th, 1885.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.	FROM BOMBAY AND ZANZIBAR.	QUALITY	QUOTATIONS

THE PRODUCTION OF TEA AND THE VALUE OF HUMAN LABOUR IN CHINA AND JAPAN.

The effects of the continued existence of that crime against humanity, slavery, in Brazil, in swamping the coffee markets of the world—bringing down prices indeed to so low a level, as not only to injure competitors employing free labour, but working retribution on the slaveholders themselves,—afford fresh proof, if proof were wanted, that none of us can say: "Am I my brother's keeper?" even though the brethren referred to should be "Indians" in Peru, Mongolians in China, or slaveholders and their human property in the South American Empire. Japan, we are glad to see, by our exchange papers, is going ahead with railways; and, happily, there is now reasonable prospect that in China the era of the iron highway and the iron horse is at hand. But why should we, in this "utmost Indian isle, Taprobane," specially and fervently desire that railway construction, on a scale as gigantic as the Empire is vast, should at once become the policy of China? For all reasons of general philanthropy and for the one special reason that the retrieval of the past and the prosperity of the future in Ceylon depends on the success of her tea enterprise. Railway construction in China on anything like an extensive scale, would at once raise the value of human labour in that densely peopled country, where so many millions of almost starving toilers continually send up the equivalent of the cry,—

"Oh God! that bread should be so dear,
And flesh and blood so cheap!"

What with the burdens in the shape of export duties and "squeezes" imposed on tea in China and the low net prices which the vast bulk of China tea realizes in the consuming market, the reasonable calculation seemed to be that, at length, even the wretchedly poor peasantry of China would cease to cultivate the tea-plant and gather its leaves. It may be that the time for such a result is at hand, comparatively near, because there is ever a natural reluctance to abandon a pursuit which has, heretofore, been profitable. But certainly the figures representing exports of tea from China and Japan for the expired portion of the season show no sign that the tea-growers of the Far East have begun to slacken in their industry in face of the competition of teas grown in India, Java and Ceylon (it will soon be India, Ceylon and Java); on the contrary, after deducting a small decrease on exports to Continental Europe, there is this season, so far, an increase of exports on the same period of last season, of no less than seventeen millions of pounds. In the severe competition, therefore, which seems approaching, our reliance must be on the superior quality of Ceylon tea.

KEMPFERIA ORNATA.—This is a Borean introduction of the Compagnie Continentale of Ghent, and figured at t. 537 of the *Illustration Horticole*. The plant has long-stalked, lanceolate leaves, bright green above, with a central band of white. The lower surface is wine-purple, and the margin somewhat undulate. It is a handsome stove foliage plant, the general habit of which is shown in our illustration, which we owe to the courtesy of the Compagnie Continentale.—*Gardener's Chronicle*.

CEYLON UPCOUNTRY PLANTING REPORT.

TESTIMONIALS FOR TEA-MAKING MACHINES—THE "COLONIAL"—COMPARATIVE FAILURE OF THEIR BEST CROP OF TEA SEED—LOCAL AND IMPORTED SEED—THE WEATHER—TEA ON THE KANDY SIDE.

23rd November 1885.

These certainly seem to be the days of testimonials for tea-making machines. They are about everywhere: you see them in the most prominent page of the public prints in large staring letters; and in the form of hand-bills these testimonials come to you by post. To the budding tea-maker who wants a machine, this plethora of excellence is somewhat confusing. He has little to buy with, and all of them have much to offer, and when he contrasts their fullness with his emptiness, he is inclined to say:

"How happy could I be with either."

This sort of thing will, I fancy, in time work its own cure, like those gushing addresses which in the early days of the Canal, every steamer captain had presented to him towards the end of the voyage. No ship like it; no such superexcellent skipper, officers and crew; no such passengers ever sailed together before; no such joy when the circle was unbroken; no such grief when the parting came. After a bit the monotony of tone became tiresome and ridiculous, and the practice died out. There is one thing about these testimonials to the new tea machines, that they don't do the thing by halves. When a planter is satisfied, he is heartily so, and about that there can be no mistake. It is just the other day that I heard a planter's report on the Basalla firm's tea-roller, "Frater's Colonial," which had this superlative ring in it, so cheering to the heart of those concerned. It was said to give "perfect satisfaction" and "it will drive every other machine out of competition." This is surely more than the inventor ever dreamt of, and if not satisfied,—well, he ought to be.

The multiplicity of rollers, and especially good rollers, is all for the benefit of the planter, and I for one hail the "Colonial" with pleasure and bid it welcome.

Studying a tracing of it I am able to see that the machine consists of three discs with concave faces of wood bolted to centres of iron. The two outer discs go in one direction, and the centre disc and barrel in which they work in the opposite one. The opposite motions are got in rather an ingenious way, and one which, if I mistake not is, quite a novelty in tea-rolling machines, or in fact in any other machine. It is an inverted spur wheel, with teeth inside the rim, instead of outside. This works into a small brass pinion, and it in turn works a spur which is connected to the outer discs. The leaf is placed between the revolving faces which are corrugated, through a door in the barrel or outer shell. Pressure is applied to the leaf by means of two screws, and hand wheels, which are placed in front of the machine. Altogether it is very compact, roller occupying a space of only 3 ft. x 2 ft. The puntum is said to be about 80 lb. of leaf an hour. The price asked for the "Colonial" is R500. When this new roller has been longer in the field, and has had a more extended trial, it will be interesting to see how it will compete with its rivals. In the opening market of Ceylon there is "a fair field and no favour" for all. And let testimonials gush as they like, they won't eventually do any more for a machine than the machine will do for itself. But numerous are the rollers ranging from R400 and upwards, there are many planters who would be pleased to see a serviceable machine for say half that price, something to carry an estate over its first year or two of bearing, and who would gladly go in for the bigger and better article later on, when more able to afford it. But the inventors and engineers of Ceylon are all believers in the day of big things, and the planter who is committed to the new hope has to dance to their measure with what grace he may. All the same, there is room for the small cheap machine I speak of, and a public willing to buy it.

The comparative failure of the present crop of tea seed is sending our planters far afield for a supply of their wants. This failure seems to be pretty general, and has had a tendency somewhat to raise prices for

went towards this, and we had a quarter of the land laid out with young coffee bushes. It never entered our heads to wonder if coffee would grow at that altitude. We took it for granted, like the rest of our sanguine neighbours, that coffee would grow at any height. All our friends congratulated us on having got such a snug little bit of land, and the knowing ones made our hearts glow with pleasure as they praised the cleared soil and the site, and prophesied fortune for us. We should have been wise if we had rested at this stage, and waited to see what coffee was going to do. But wisdom was not a characteristic of the go-ahead planter in those days, and my husband's next step was the placing round his neck a millstone which has been a burden ever since. He raised £1,000 by a primary mortgage on the estate at 8 per cent. "How foolish!" I can hear the wiseacres of the present day exclaim. It was foolish, most foolish, but we did not know it then. I instinctively shrank from contracting any kind of debt, but this was a business matter about which I, as a woman, was supposed to know nothing. There was no iniquity in the matter as there would have been had the debt been made for personal extravagance. I was told. It was purely legitimate speculation, and the lender was as glad to put his money out at such a good rate of interest as the borrower was to secure the use of it. Then the matter was put on paper in figures. The estate would begin to pay at such and such a time. It would bring in an increasing income each year; and at a certain period, not so many years distant, the mortgage would be paid off, and we should be in the possession of an unincumbered estate yielding a handsome income. It all looked so clear on paper, and every friend who came into the house confirmed the calculations, that at last my mind was quieted, and I forget my doubts and anxieties in my nursery duties, even though I had to face the grave fact that from thenceforth for some time we should have to find the £80 interest on the mortgage out of our income. But as we had always lived within our means, and had easily saved money, the liability could be covered by what had hitherto been our yearly savings. It was only to be for a few years, in fact until the estate began to pay.

Thus the rest of our jungle was cleared, and a good deal was planted, and, for a while, all went swimmingly. But before long clouds began to gather. They were very small clouds certainly; but there they were, the forerunners of bad times, though we did not recognise them as such then. The coffee blossom came as usual, making the bushes look as if they were laden with snow, but, owing to bad weather, it did not set properly, and the crop fell off. Then came leaf disease, and crop after crop was poorer than the last. At length, the planters recognised the sad fact that coffee was a failure, just as I am told they had to recognise it in India. Our young plants were then coming into bearing, and, judging from their wealthy appearance, we had hitherto had no anxiety on their account. But, at the time the crop should have come, leaf disease made its appearance amongst our bushes, and we too had to recognise that we were in no better plight than our neighbours. It was useless to try to sell. No one would have unprofitable land, even as a gift. We had nothing before us but to hold on at a loss, or let the mortgagee foreclose. We were thinking seriously of this latter course when there came a new hope to the planters in cinchona. Cinchona was to revive their drooping fortunes, and set them on their legs again. They grasped at it as drowning men clutch at straws.

Cinchona was to fulfil what coffee had failed to perform, and save planter, agent, money lender and Chetty alike from ruin. Like the rest of the community we rushed into the new craze.

Our coffee was undoubtedly a failure. In the best of seasons it would never yield prolifically at that height, and though some of the young plants did fairly well on the lower slopes, they barely paid for the working of the ground they stood upon. It was quite certain they would never give a profit to pay off the mortgage, nor even find money for the interest, however economically they were worked. But to plant cinchona required a certain outlay. We could not do more out of our income than find the interest on the mortgage, unless we pinched, and screwed severely, and then it could only be a small sum which would be useless by itself in the purchase of seed and plants. It ended in our tying another millstone around our necks. My husband borrowed another £500 at 8 per cent on a second mortgage. We hoped by careful living and economy to be able to pay the additional £40 for this £500 out of our salary, and with fresh hope in our hearts we soon saw our money in young cinchona plants on the hill slopes. There was certainly more anxiety with that hope this time, and we felt the additional responsibility of the increased debt. The hope which had flamed up so suddenly was extinguished all too soon. A few seasons passed, and then the verdict went forth. Cinchona was a failure. There was exactly the same folly displayed in the planting of cinchona as of coffee. The planters were filled with the idea that cinchona would grow anywhere, and anyhow. But cinchona refused to grow in straight rows like turnips on slope and plain. It needed even more careful drainage than coffee. It is hardly necessary to repeat the sad tale, for it is as well known, through bitter experience, in India as it is in our Island. The constant showers of the Ceylon climate made the young plants come up full of promise. They grew rapidly, and threw a mantle of bright green over the estates. But those very showers which seemed to make the plant thrive, produced by their moisture, a canker which gradually extended up the stem till the tree was destroyed. For a year or so the young plants looked green and healthy, and then, suddenly, some of the broad glossy leaves turned an autumnal searlet. A close examination of the stem showed an uneven line of blemish from the canker which was spreading upwards, and gradually the plants hung out their red flag, dropped their foliage, and died.

We lost two thirds of our cinchona trees, but the remaining third flourished, and we learnt a lesson from them about drainage, for the survivors were those which were planted on very steep slopes, or at the edge of landships and drains. When they became of a barkable age they brought us in something, and would have proved very profitable if bark had only held its price. But it fell from something like 1s 6d to 1s 6d per pound, quite upsetting those seductive calculations, on paper, of future wealth. It has fallen still more during the last fifteen months, so that where we looked at £1,000 a short time ago in standing trees, we can now only see £500. In spite of the low price of bark our cinchona was a considerable help to us in keeping the estate going. The trees yielded a fair quantity of bark, and grew rapidly, increasing their yield each season. My husband continued to plant as he cut down, on ground that he knew to be favourable for its growth, and he was fortunate, or wise in his choice of plants. He chose a hybrid which has adapted itself to the climate. It is a

cross between *succirubra* and *officinalis*, and its seems likely to answer better than any imported kind, as it possesses great hardihood, as well as a high percentage of quinine in its bark.

With the failure of cinchona came hard times for us, as well as our neighbours. Reductions in expenditure were made on all sides. No more substantial stone sheds were built, or expensive machinery imported, and many of the assistant managers were paid off and dismissed. A great many deserving young men were thrown out of employment, and, worse still, they had no means of conveying themselves out of the sinking ships. My heart has ached for the poor fellows. Many of them were pleasant, well-educated, well-bred young men, the sons of gentlemen, and they really did not know which way to look to procure themselves the barest necessities of life. Some of them were helped by kind and compassionate friends and sent home. Some managed to raise money from relations. A few found their way over to India and got into the Salt and Police Departments; and a few went to the coffee and tea districts of India; but many of them succumbed to fever. The climate of the Indian tea and coffee districts is not to be compared with our Ceylon climate in point of health. Those were Ceylon's darkest days for the present generation, and, in my next paper, I shall have to tell how we weathered the storm, and to what straits we were put in so doing.

III.

With reductions taking place on all the estates around us, it was not likely we should escape. My husband suffered with the rest. First, he lost his assistant, and thus had all the work thrown on his own shoulders. Then came a more serious matter. Our salary was reduced, and certain allowances cut down, which curtailed our comfort as well as our purse. The reduction in our income was a very serious thing for us, although, looking at it in the disastrous light of those days, we might consider ourselves lucky in having kept our berth at all, for many estates, at that time, were actually abandoned, and allowed to revert to jungle. The lantana has since taken possession of them with a firm grip, and nearly effaced the once well-kept trim path. I should not have minded the reduction of salary so much if it had not been for that wretched debt, for which we had made ourselves liable. It had to be paid in English money too, and we felt the fluctuations of exchange severely. Another thing began to trouble us, and this was the irregularity with which we received our salary. Some times the estate was in arrears for want of ready money, and we suffered with other creditors—the chetties, and the coolies. No irregularity, however, was allowed in the payment of the interest. The money had to be ready to the day, and each time as the date for payment drew near, I was tormented with anxiety lest the money should not be forthcoming.

As the first signs of hard times I reduced my establishment, and cut down all unnecessary expenses. I sent away two ayahs; who were receiving, according to Ceylon custom, R25 and R20 a month respectively, and took a good English nurse on R30 a month. She not only saved me in the matter of ayahs, but she also helped me to do without a tailor. In a climate like ours she could stir about, and do as active a day's work as she could in England. I sent away my experienced cook, and took a raw hand, at a fourth of the cook's wages, and taught him to cook. My husband sold

his remaining pony, and learnt to walk his twenty miles a day, when necessary, with the greatest ease. I had always kept cows and been fond of my dairy, but, hitherto, I had used the cream, the butter and milk in the house. Now, I determined on turning my dairy produce into money. I knew I should find a ready market for my butter in Kandy or Colombo, as home-made butter was a scarce commodity. It might be thought that in such a green country as Ceylon, where every square inch of soil is covered with vegetation, cattle would flourish on the grassland, and that good milk and butter would be plentiful. But it is not so. There is a certain supply of milk, but it is from native cows, and the butter is no better than ordinary country butter in India. The cattle are small, and yield poorly, the grassland in the valleys is so infested with leeches, that it is almost useless as pasture for either sheep or cows. The leeches enter their nostrils, so that they are tormented into a restlessness which keeps them thin and un nourished. The patanas are also undrained, and a cow will sometimes lose its life through getting bogged; and they all suffer from the damp. I had always kept fine Mysore cows, which now stood me in good stead. I had a small piece of upland grass on the sunny side of one of our upper hill slopes, where it was too dry for the ubiquitous leech, and here my cows were herded during the day. At night they stood in the spacious cattle-shed once full of fine oxen, but bare and empty now, in these poverty-stricken days. I was obliged to supervise everything personally, as I had rascally herdsmen to deal with. I saw the cows milked, and fed, and I saw my butter made, packed off for sale. I still had plenty of milk for the children, although it was no longer new. In our cool climate it was perfectly sweet after it was skimmed, and it made excellent puddings, and bread-and-milk breakfasts and suppers for my hungry little brood. I sacrificed my flower beds, and turned three quarters of my garden into vegetables, which also found their way to Kandy and Colombo. And we gave up whiskey and beer: This was a great saving; not because we were great drinkers, but because our friends who came in frequently had to be entertained, and our bill for liquor was sometimes alarmingly heavy. Whilst the whiskey was in the house I could not help offering it, but when it was not there, I could honestly say I had none to give. I was very sorry to have to pursue this course, but it was absolutely necessary if we wished to keep our heads above water. My husband was quite ready to become an unpledged tea-totalist till better times came, but he often found it very hard not to be able to offer a drink to thirsty friend who had called in on his way by.

So, by hook or by crook, we managed to tide over stormy times, when we had to see people, as good as ourselves—perhaps better—irrevocably wrecked. Sometimes I used to wish that our estate would serve us as others were being served, and put us through the Bankruptcy Court. We seemed to be only throwing good money after bad; and screwing and pinching ourselves to feed a horse-leech's daughter, which ever cried "give! give!" If we had invested our £2,000 legacy in some safe security at the outset we might have been in receipt of £100 a year from it; and not only that, but we should not have been burdened with a debt. We were virtually paying £120 in hard cash per annum for the luxury of having received a legacy of £2,000. We pulled through some very severe years, thanks to good health, youthful hope, and luck. Our luck consisted in not being sent adrift. Most fortunately for us, the owner

of the estate my husband was working had other sources of income, and he was able to remain in England, and allow us to continue working the estate for him, although, as I said before at a reduced rate of salary, and single-handed. Three years ago, just as we were wondering for the twentieth time if our little property was worth holding on to, came a perfect godsend to us, in the shape of a gift of money. My father, whose sons and daughters were now off his hands, sent us £500. I was for paying off the second mortgage with this sum, but my husband said no, he must have the money for tea. Tea was the new hope—we ought to make one more effort on behalf of our children, and try what tea would do. As for the mortgage, if we could only hold on indefinitely it would one day be cleared off by a little inherited money we might expect to receive in the ordinary course of events. Tea was sure to pay, as it had been tried in the island in a small way for some years previously, and had shown no signs of failure. It was said to grow better at an altitude of 4,500 feet than lower down. Our land would be exactly the right soil—and so forth. It was the same old tale, and it all looked so plausible on paper. I am learning to distrust every speculation that has to be worked out on paper. As soon as the planter brings out his notebook and pencil, and goes in for a golden dream in figures, I only see in it a fatal and delusive road to the Fiscal sale and the Bankruptcy Court. The £500 went in tea plants, and I smothered my anxieties once more in my household duties. Three years have passed, and I am beginning to allow hope once more to spring up in my heart. What coffee there is on the lower slopes pays for its weeding and gathering. The cinchona stands, representing a certain sum, and yielding bark each season. And the tea is really and honestly flourishing, though I can hardly believe it to be true. At present, we sell the green leaf, and pluck very carefully, as the bushes are quite young, but every month we can see their increased growth. If no canker, no bug, no borer, no leaf disease, and no great depression in price comes to work ruin once more, we shall escape shipwreck, and bring our vessel into harbour. But we must not look to tea for a fortune. Tea, even on paper, will not pay as coffee and cinchona promised. The most we can hope for is a competency in our old age, which will be an equivalent for my Anglo-Indian brother's pension. We shall have one advantage over the Anglo-Indian, our income will not die with us, but will benefit our children after our death, and provide an occupation for one at least of them.

My story, so far, may sound like a warning, but it is not meant for that alone. I would not only point out what is to be avoided, but what is to be grasped with judgment and prudence. There are so many estates in the market, so many abandoned bits of land which might be bought cheaply, and opened up for tea, at far less expense than jungle. Money is scarce in Ceylon just now, and capitalists at home are thoroughly afraid of having anything to do with estates there. They are too far off to be able to look after their money. But for men like retired officers, who have time at their disposal, and who have their pensions to back them, it seems a likely field for moderate success. If the retired officer is to become an agriculturist, it is probable that, from his previous knowledge of India, he will make a far better colonist for Ceylon than the raw youth from England. He will not have such a rough

life to contend with in his old age as in Australia and New Zealand, nor will he have to see his daughters become drudges in the house, for want of proper servants. It is very pleasant to hear people talk of the dignity of labour, and so forth, but it goes against the grain to see carefully educated girls labouring in the kitchen with dirty saucepans and buckets of waters, doing work which the most ill-educated woman could probably do better. It is possible in Ceylon, as I have found out by experience, to do a great deal in the house oneself, and conduct the housekeeping on strictly economical lines, but there are always servants to be got to carry heavy buckets, and do rough work. It would be easy for the retired officer to reside in the island on his pension whilst he looked about him. Most of the planters would honestly give advice, or relate experience to a neighbour who sought instruction and information. Being on the spot, he would be able to see for himself what his projected investment was like, and all the advantages and disadvantages of climate and situation. He would be able to make a civilized and happy home for the sons who failed in their professional examinations at home, and see them on small estates of their own before many years had passed over his head. I do not pretend to say that they will make their fortunes, and it will be a mistake to start with that idea, but they will make an honest living, and, after all, that is only what forty-nine colonists out of fifty accomplish. Of course I do not advise any one to follow our example. I have given our experiences, and our follies, just as they stand, that others may know what to avoid. Above all things, I would caution young and old against raising money on mortgages. They have proved more fatal to the Ceylon planter than bad seasons, insects, disease, or anything else. It is also a most excellent thing—and this holds good all over the world—never to live up to one's income.—*Madras Mail.*

WAGES IN TEA GARDENS.—The Superintendent of the Darjeeling Tea Company has issued circulars to planters in the hill portion of the district, asking them to combine and follow the movement initiated by the Terai planters and the majority of those in the Mahanuddy Valley, for the reduction of coolies' wages by R1 all round during the five cold weather months. Upon this the local papers observes:—"That Mr. Harcourt's proposition is feasible is beyond question, if only planters would be true to themselves for once, would bury petty jealousies and personal spites, and unite for the common good. The Darjeeling Company is the largest as well as the most liberal employer of labour in this district, and when the superintendent can see his way clearly, as he evidently does, to what is practically 2 per cent saving on garden working we say without hesitation that those employers of labour who do not back the Darjeeling Company up in this movement will be making a most serious mistake. If the coolies were underpaid or overworked we would hesitate in advocating a reduction of wages, but knowing practically how well off the tea garden coolie is, how much better off he is in every way than the ordinary farm labourer at home, and how infinitely better off he is than in his own country, we say without fear or hesitation that if the employers of labour in this portion of the district do not follow the lead set them, they will only have to thank themselves for the results of their remissness hereafter."—*Pioneer.*

VITALITY OF SEEDS.

With very few exceptions all seeds retain their germinating power for at least a year under ordinary conditions; and, when placed in circumstances specially favourable, they remain fresh for a very lengthened period. Several remarkable instances of this have already been mentioned, but cases even more remarkable than these are recorded. In the ground, when buried deeply, the length of time seeds will retain life is indefinite—according to some authorities, even unlimited. The accounts of seeds which had been taken from ancient Egyptian tombs germinating on being placed under favourable conditions, and other similar cases of an astonishing nature, might be mentioned. These are, however, of little or no practical moment, beyond showing us how wonderfully tenacious of life is the tiny germ which lies enclosed in its often thin and delicate wrappers. How long a seed will remain good when placed under the conditions supplied in the seed-house, or when sown and treated for germination, is a question to which we may turn for more useful information. A seed, when properly matured and kept dry in an even and suitable temperature, will remain healthy for a more or less lengthened period, according to whether it is oily or starchy, or whether it belongs to the exalbuminous or the albuminous kinds. Oily seeds usually perish in a comparatively short time, so that it becomes necessary to sow them as soon as possible after they are ripe; such seeds are those of Tea, Coffee, Camelia, Theobroma, Acorus, Brazil-nuts, Walnuts, &c. Seeds of a starchy nature are generally much longer-lived. It is, however, impossible to draw a hard-and-fast line between long-lived and short-lived seeds, as there are so many conditions other than those we perceive, and often altogether beyond our control, which affect the vitality of seeds. Lindley says:—"Seeds are probably possessed of different powers of life, some preserving their vital principle through centuries of time, while others have but an ephemeral existence under any circumstances. The reasons for this difference are unknown to us." In the case of many of our most popular and long-cultivated plants, however, we have data sufficient to enable us to perceive how long their seeds may be expected to remain capable of germinating. The following list was prepared by the well-known seed merchants, Vilmorin-Andrieux & Co., of Paris, and with it is incorporated a portion of a list printed in Burbridge's *Propagation and Improvement of Plants*—

AVERAGE DURATION OF THE GERMINATING POWER OF THE SEEDS OF SOME CULTIVATED PLANTS.

	Years.		Years.
Acacia	many	Lentil	3
Alder	1	Lettuce	5
Amaranth	5	Maize	2
Angelica	1	Mallow	2
Aoide	3	Marjoram	2
Artichoke	5	Melon	5
Aster, China	1	Mustard	5
Asparagus	4	Nasturtium	5
Balsam	many	Onion	2
Basil	6	Parsley	3
Beans, Broad	6	Parsnip	2
Beans, Kidney	3	Peas	1-5
Beetroot	5	Potato	4
Borage	3	Purslane	8
Burnet	2	Radish	5
Cabbage	5	Rampion	5
Capsicum	4	Rhubarb	3
Caraway	2	Rocket	2
Cardoon	7	Rosemary	4
Carrot	4	Salsify	3
Chervil	2	Savory	2
" Tuberous	1	Scorzoneria	2
Chicory	8	Scakale	3
Coru Salad	5	Sorrel	2
Cress	5	Spinach	5
Cucumber	5	Strawberry	8
Egg Plant	7	Thyme	2-3
Endive	9	Tomato	5
Leek	2	Turnip	5

The above table does not profess to give in every case the longest time possible for the seeds to remain good, but only the average time during which, under the conditions supplied in an ordinary seed-room, they might be expected to retain their power to vegetate. Cabbage seeds have been known to germinate after being kept for ten years, and Kidney Beans after five years. As above stated, the conditions which affect the duration of life in seeds are too often beyond control, or altogether hidden from us.

It has been already pointed out that under certain conditions some seeds will remain dormant in the ground for a long time without losing their vitality; in like manner seeds will sometimes lie for years without commencing to grow, even when the conditions under which they are placed are what we consider favourable to germination. Lindley mentions various instances of this, all tending to show how necessary it is to have patience in the management of seeds, and more especially when the age of the seeds is unknown. Old seeds always germinate more slowly than young ones; the hardening of the testa or seed-coats through long exposure, no doubt, accounting to some extent for their tardiness in starting. By steeping in warm water or by removing the outer shell from seeds, germination, as shown above, is much forwarded. Fruits of Hawthorns, Hollies, Birch, and other hardy berry-bearing trees are generally subjected to a softening process before their seeds are sown. This process is what is termed the "rot-heap," and is managed as follows:—The fruits are gathered in the autumn as soon as ripe, and are thrown in heaps, a quantity of sand, ashes, or light soil is mixed up with them by frequently turning them; they are then buried in a pit, or placed in heaps and covered with turf, where they remain till the following spring. The whole is then prepared for sowing by partly drying and then sifting. In this manner the seeds are separated, whilst the warmth and moisture in which they were stored through the winter has softened the hard shell of the seeds, and, no doubt, has excited the germinative process.

Seeds of plants belonging to the Ranunculus and Primrose families sometimes remain in the ground for several years without moving. Mr. Anderson-Henry states that some seeds of Ranunculus Lyalli, the Shepherd's Lily, sown by him in 1878, did not germinate till 1881; and in the case of seeds of a second species of Ranunculus, germination took place four years-and-a-half afterwards. The same extraordinary slowness has often been observed in seeds sown at Kew. How far this slowness to vegetate may be considered as natural to the plants, or whether it is due to some untoward influence to which the seeds had been subjected, is not clear. Seeds of Ranunculus Lyalli vegetated in about eleven months at Kew. I suspect that with most of those plants the seeds of which usually remain in the soil a long time before growing, it would be better to sow the seeds immediately on their becoming ripe. Mr. A. Henry found *Primula japonica* and *Gentians* slow to germinate, but when the seeds of these plants are gathered and sown as soon as ripe, they generally germinate in a few weeks. It is said that Colchicum-seeds generally take over two years to start into growth. It is always best to select the largest and heaviest seeds in all cases where robustness of growth is the first aim; smaller seeds being slower to get away, and containing less vital force than larger ones of the same kind. It is also supposed that large seeds retain life for a longer time than smaller ones do.—W. WATSON, in "Cassell's Popular Gardening."—*Gardeners' Chronicle*.

THE KING OF THE PUMPKINS.—The heaviest Pumpkin (according to M. de Vos), presented at the Paris market in 1864 weighed 130 kilogrammes, translated into English, this means that the Gourd in question weighed about the same as twenty-eight legs of mutton of 10 lb. each.—*Gardeners' Chronicle*.

MORE ABOUT LOCAL PRODUCTS.

Sir,—Your correspondent "X. Y. Z." seems to think my assertions about being able to live on local products as rather a joke than otherwise—"made more in jest than in earnest—a grin sort of humor." I fancy by the time he has to live on R40 or R50 a month, knock off his milk and butter and all his foreign products, and go on half allowance of potatoes and liquor, and after all find himself some R20 to the bad at end of the month, he will find it a very grim sort of humor indeed, so much so that it will be all grimness and no humor. However, let that pass. He goes on to say my narrative is "entirely a myth;" not possible at all:—two-thirds of the planter's income are spent on articles that are imported" (including rice and flour), "and quite unavoidably so, unless he wishes to live as a native, wear a combay and drink arrack." "X. Y. Z." is very positive in his assertions, but in the first place he has forgotten—or chooses to ignore—my putting Ceylon, India, and the Straits all under the same heading of locality as the silver currency rules in these countries alike, so that rice and flour (or bread), which he says will always be imported, must (coming as it does from Bombay) be put under heading of local products, and of course ditto rice, cotton goods, and a variety of articles which we get from India. He first takes exception to locally-made boots, and uses some rather strong language about them, leading to a belief that he had been indulging in words still stronger when wearing the boots. For (R7) rupees seven he can get from D. Cassin, outfitter, Gampola, a pair of good, strong, well-fitting and good-looking planter's boots, which will last him a long time, and save him from breaking one or more of the ten commandments. And further, I see Colombo men, visiting agents, and others wearing country-made boots very comfortably. This reminds me that years ago we used to get boots for R3.50 at Welikada jail, made by the native prisoners under an European fore-man, who took your measure as courteously as if he was in Regent Street instead of a prisoner in Colombo. If I remember right, the clerk of the works put on 50 cents or a rupee on his own account, and by and bye got into durance vile himself for being guilty of embezzlement. I don't know if the lambs of Welikada and the other jails still make boots; if they don't, there's a tip to Government in the way of employment. Suppose they supplied the troops, say, or the police force, as well as the general public. If "X. Y. Z." really supposes I meant to imply, he could at once, and for all, give up imported articles, say, from to-morrow morning, and live only on local products. I quite go with him in thinking he would have a very hard time of it. It will require time, energy and capital to get everything started; and there will be many failures before success is attained. Salt, of all things, he says, must always be imported—really now you know. I venture to say that in 1860, nine planters out of ten had bazaar-salt cleaned and whitened by their servants. We sent to Saibu for a lb. of salt and a couple of eggs, and somehow or another we got fine clean salt on the table. I have now serving me the same old boy who served me then; and no doubt he will be happy to instruct "X. Y. Z." in the art, say, for a small consideration. But that is not what I want. My proposition is that salt should be bought and refined by the ton under proper regulations, and the import of "table" reduced to a minimum. There will be always some products cheaper to import than to produce—and very probably table-salt would be one.

I do not advise "X. Y. Z." to drink arrack. I say we want a distillery to make a drinkable, wholesome, and cheap spirit. In Mauritius I have seen the inland revenue peon checking the manufacture of rum on sugar estates—and this rum is very palatable. In many places you get rum with a pud of vanilla steeping in it. Why can't we make rum and put in a pod of vanilla? Why can't we make

a spirit from paddy and from toddy—a spirit we can drink and can afford? "X. Y. Z." says it's an impossibility. Why? We have in Ceylon the descendants of a Mauritius gentleman, and some of his *conferres* too, who made spirit out of coffee pulp long years ago. The Government of the day came down on him; seized his still, and fined him, I believe, for illicit manufacture of spirit. If I had said a few years ago "drink your own brewed beer" it would have been an impossibility, but the case is different now; and in the same way locally-produced spirit is quite a possibility, and I think not a little singular such an industry has not claimed attention before.

It is rather a curious coincidence that, whilst my letter was in the press, there appeared an account in one of the papers of the commencement of production of dyed cotton goods in India—Bombay, I think—and here is an extract you have quoted from the *Pioneer*, a good deal to the point:—"60,000 British troops and 100,000 native troops are clothed and equipped almost entirely with materials made by the natives of India, and some 30,000 police are similarly clothed. Harness and accoutrements are turned out at Cawnpore, the clothing from Ombh, tents, ropes, and blankets by the ton from native workshops; beer brewed at Murree; cotton goods for the million are spun in the country; woollen goods, even for the ordinary clothing of Europeans, come from the looms of Oudh." This latter assertion is new to me, and comes as an addenda to my first letter. India seems already to have awakened to the fact that local productions must satisfy local wants. When will Ceylon follow suit? Then "X. Y. Z." will have it jam and sauces must always be imported, whilst your correspondent "Economy" says:—"D. E. speaks of preserves. Surely these can be locally produced; the only objection would be that sugar would have to be imported, for Baddegama could only supply a small portion of our wants. Marmalade, I know, can be made better in Ceylon than procurable from home." I thank you, sir, and you might have gone a good deal further, and mentioned how citrons grow almost wild, oranges of all kinds, and fruits of every description, not to mention wild ones, and then peaches. In Ulapussellawa they grow splendidly, and might just as well be put into syrup as allowed to drop and rot. It is a fact within my own observation that bushels and bushels of peaches were given to the pigs at the big bungalow on Delta estate. In my own garden I have had Seville oranges literally rotting on the ground by hundreds; and, from what I have seen of the old Hewaheta and Maturata estates, I should say there is enough fruit grown on them alone to supply the wants of half the European community of the island, not to mention the villages of Kaduganawa and Kotmale. Fancy a factory of the kind in Kandy, employing a lot of the needy Burgher women that have now to apply to the Friend-in-need Society; yes, and many others who have no such need; and I go further still in this matter. I think that Ceylon fruit preserves might be put into large packages, say, kerosine 4 gallon tins, and exported in bulk for Moir & Sons or Crosse & Blackwell to put into attractive tins and jars. The very names, and labelled "Ceylon," would be sure to procure a rapid sale. What need is there to mention loquots, mulberries, Chinese gnavas, &c., and even the despised punaloo; they are all available, and no one need purchase an imported tin of jam when once a local factory was started.

"Economy" gives us a hint about smoked fish which may be very useful, but there are other native-cured fish which, good as they are at present, may easily be made better. Sardines (Ceylon sardines) pickled with "goraka" fruit, I believe, and tamarind are very nice, and anyone living in native houses at Beruwala will find casks of small fish salted down for use. Then there is (or was) a dried fish known to Tamils as "sinna karrawaddy," a thick,

deep fish, slashed across and across and dried. This is a capital addition to a curry. Then there was a fish in Sinhalese very much of the same name as the ant-eater, "Kabelawa" I think; a small modicum of smoke and less salt would make these fish very like herrings. But I am only wearying your readers, and will only mention that some enterprising individual, according to a recent letter in a local paper, has been rescuing coast sardines from the manure manufacturer, putting them up in tin, and shipping them to Europe. When these sardines appear in such immense shoals as they do on the east coast of Ceylon, at times so multitudinous that at the point opposite Triocmalce where the lighthouse stands—Foul Point, is it?—they can be baled up in hand-nets, and surely some might be cured in some way, and turned into food. One would naturally suppose that, when Government instituted curing yards for fish, they would likely do it where there are fish to catch and fishermen to catch them, instead of at Hambantota, where there is neither one nor the other, and plenty of sand drifting constantly in the windy, dry weather to spoil the lot if it did ever come to anything. I will, if you think fit, I mean by this assertion. And also, if you think fit, I shall be happy to try and prove that the only way to reduce the price of imported goods is to knock on the head the "general emporiums" of Colombo, and go into smaller concerns, each sticking to its own last.—D. E.—Local "Times."

WASTE OF FORTY PER CENT IN SUGAR-MAKING.

TO THE EDITOR OF THE "PRODUCE MARKETS' REVIEW."

Sir,—In a late issue of your valuable publication I noticed with satisfaction some very opportune and pertinent remarks made in the way of comment upon the "Circular of the Agricultural Society" of this island, advocating the establishment here of Central Sugar Factories, &c. That circular is not free from mistakes in some particulars; chief error, perhaps, being found in the statement that "only about 6½ lb. of Sugar and Molasses are obtained by the process ordinarily in use in this island." It had previously been said that "the Cane in Barbados contains 18 lb. of crystallizable Sugar in 100 lb. weight of Cane." It would have been more correct to have said, in 100 lb. weight of juice; and better still, "containing at least 18 lb. of saccharine matter in each 140 lb. weight of juice;" for although theoretically, or by chemical analysis, all the saccharine contained in the cane is crystallizable, it is not possible to obtain practically any such result, a certain proportion of the saccharine in the Cane juice being unconvertible Sugar, yielding Molasses, and being lost and wasted in the operations of converting that juice into Sugar. The statement last referred to is therefore, to some extent, misleading. However, the chief mistake is in saying that "6½ lb. only of Sugar and Molasses, are obtained," &c. It should have been 6½ per cent of Sugar only; for there are also obtained about 2½ per cent of Molasses, making a total saccharine product of 9 per cent, got out of 18 to 20 per cent which does exist in good Cane juice. Surely the case is bad enough, without the argument being weakened by inadvertent statements. I beg to forward to you two slips cut from the *Agricultural Reporter* of this place, and which give somewhat elaborate statements and calculations, treating of the particulars which have been referred to. The object of those articles is to demonstrate, once more, that which should long ere now have been an admitted certain fact, beyond all question, all cavil, and dispute—viz., that Cane Planters who make Muscovado Sugars by the ordinary process, do not get, on an average, more than 60 per cent of the saccharine which exists in the Cane. They lose in absolute waste two-fifths of the Sugar in the plant, and they produce an imperfect, impure article, of which, moreover, after all the expenditure

of time, trouble and money used to get it, one-tenth; part is lost through drainage. Yet, who shall convince such people that Beetroot Sugar, despite artificial aids, lives upon sufferance, and thrives in consequence of the apathy, ignorance and obstinate adherence to routine shown by Cane Planters? The Beet contains naturally a far smaller proportion of Sugar in its juices than does the Cane, but the beet is industrially nearly twice as productive as the Cane. In the making of the Beetroot Sugar nothing is lost, everything practically is gained; Cane Planters lose in sheer waste about one-half of that which Nature has placed in their hands; they will persist in doing this, and instead of endeavouring to help themselves, they howl after fiscal protection, which they never will obtain. The Agriculturist Society of Barbados and the most enlightened men in this community are quite alive to the truth of the position, and are anxious to avail themselves of the advantages offered by the Central Factory system, which is an application of the wise and efficacious principle of a division of labour. But it is to be feared that the most sensible and business-like propositions will fail to overcome the obstacles opposed by ignorant prejudice and stupid self-sufficiency. When there are planters who at this day will still assert that they extract, with their absurdly inefficient windmills and old rattletrap toy engines, of so much donkey-power, all the juice that it is possible to obtain from the Cane (they get in reality 55 to 60 per cent); when there are men, professing to know their business, who declare that they get a yield from the Cane of 10 per cent and more in Sugar, when the fact is they get 6 or 6½ per cent, it is useless to throw away any effort in endeavouring to convert such people so utterly devoid of common sense. They must inevitably be stamped out, and make way for better and more useful men.—I am, Sir, yours faithfully,

PRACTICAL PLANTER.

. Our correspondent's facts are confirmed by the two recent letters he sends from the *Barbados Agricultural Reporter*, treating of this matter in full detail, and arriving at the conclusion that 60 per cent of the Sugar in the Cane is extracted, and 40 per cent lost. At the same time, we can hardly think that any but a minute fraction, if that, of the Barbadian Planters take the views attributed to them by "Practical Planter," or that they are so blinded by prejudice to obvious facts as to deserve the certainly severe remedy of "stamping out," which he names as their inevitable doom. It is, indeed, pretty obvious that it is their poverty, and not their will, which consents to the present deplorable state of things, and an assumed stupidity is often serviceable to those who do not wish to acknowledge lack of cash. The Germans, either by the Strontium, Substitution, or Osmosis processes, now extract the whole of the Crystallizable Sugar from their Molasses, and our Cane Planters can do the same.—Ed. P. M. R.

SULPHIDE OF POTASSIUM.—Your correspondent, Mr. Badger, calls attention (p. 339) to the use of sulphide of potassium against mildew, red-spider, and aphides. Gishurst Compound among other ingredients contains sulphide of sodium; a soluble sulphide has therefore been a long time in use.—The Inventor of Gishurst is the *Gardener's Chronicle*.

A PROPRIETARY PREPARATION brought out recently in Germany under the name of "Eichelcoaco" (acoru cocoa), and which has been reported on favourably as yielding a beverage that has been found useful in cases of chronic diarrhoea, especially in children, is described (*Pharm. Zeit.*, Oct. 24) as consisting chiefly of cacao powder and an aqueous extract of roasted acorns, together with sugar and roasted flour added for flavouring purposes. It is said to form a brownish powder, with a slightly astringent taste, which is accounted for by the fact that Professor Fresenius has found it to contain nearly 2 per cent of tannic acid.—*Pharmaceutical Journal*.

DOUBLE-HEADED COCONUT TREES.

TO THE EDITOR OF THE "MADRAS TIMES."

Sir,—In a place called "Kondall," in Sheally Taluk, Tanjore District, close by a temple, stands a double headed coconut tree bearing coconuts on both the heads, and to profusion. On enquiring further, and on examining it fully, there appears to have been another head about 10 feet below, which the late storms had crushed down. This is quite novel, and one will scarcely believe until he sees. I have seen in several districts date trees having 2 or 3 heads, but never came across coconut trees of the description I now see here. It would be edifying to know the cause of the phenomenon, and men versed in gardening will be thanked for enlightenment on the subject. Banyan trees sometimes take root in palm trees, the seeds having been deposited by crows and similar birds, and palmyra trees also take roots amid the cliffs in large "peepul," banyan, and other trees, the results of the acts of innocent cow-boys, who, after glutting themselves, deposit the nut in a hole that they may happen to see on a tree on which they have their noon-day repast of the sweet smelling Palmyra "fruit" juice. How could a coconut tree, after a height of 15 feet, give out another shoot, and another shoot, after a further height of about 10 feet, is a mystery, to be solved.

Coleroon, Oct. 1. P. R. N. P.

Sir,—If any one would take the trouble of driving into St. Thomé, he would see in the compound of the church of "Our Mother of God" belonging to the Goanese Mission, a coconut tree similar to the one alluded to by your correspondent P. R. N. P. in his letter of October 1. This tree has a double trunk, and a double head too, but, unlike the one at "Kondall," it does not appear to be a very healthy tree, nor does it yield fruit to any great extent.

St. Thomé, 7th Oct. WILLIE.

THE DISPUTED IDENTITY OF THE RED BARK OF THE NILGIRIS.

BY W. T. THISELTON DYER, C.M.G., F.R.S., Assistant Director, Royal Gardens, Kew.

A paper so headed in the *Pharmaceutical Journal* effectually disposes of the fantasy of Mr. Cross that the red barks cultivated on the Nilgiris and in Ceylon were not *C. succirubra* but *C. micrantha*. Botanists like Dr. Billie and Mr. Grant Duff gave Mr. Cross ocular demonstration of his error but all in vain. Trimen effectually disposed of the matter, and Mr. Thistelton Dyer's final verdict is thus given:—

"At Kew we had exceptional opportunities for testing immediately the accuracy of Mr. Cross's statements. Colonel Beddome had sent us a splendid set of dried specimens of every cinchona form grown in the Nilgiris, on which we reported early in 1882. Besides these we possess in the case of *C. micrantha* authentic specimens of the South American plant collected by Weddell and by Pritchett, in addition to what is presumably a type from Ruiz and Pavon's herbarium. Besides abundance of Indian specimens we have one in particular known to have been raised at Ootacamund from Pritchett's seeds, and the accurate determination of which has been verified by Howard. In this case of *C. succirubra* we have Spruce and Cross's own specimens from the slopes of Chimborazo and a specimen, presumably from Ruiz and Pavon's herbarium, verified by Howard. Colonel Beddome's admirable specimens were carefully examined by my colleague, Professor Oliver, the keeper of the Kew Herbarium, and he found no reason to doubt that the species of *Cinchona* which passed as *micrantha* and *succirubra* on the Nilgiris were what they professed to be. Dr. Trimen, the Director of the Royal Botanical Gardens, Ceylon, also examined them (together with the further set collected by Dr. Billie) with me while he was at home on leave in 1882, and we could see our way to no other conclusion."

58

LIQUID EXTRACT OF CINCHONA.

A paper on this subject by Professor Redwood appears in the *Pharmaceutical Journal*, but it is of too technical a character to be extracted. By the agency mainly of hydrochloric acid and heat 90 per cent of the alkaloids are obtained from powdered bark. But the Professor states:—

"In these experiments I have exclusively used red cinchona bark, good samples of which may be readily obtained, especially among the barks taken from cultivated trees. Those on which I have mostly worked have been quilled *succirubra* barks, containing from 5 to 6 per cent of total alkaloids. Most of the samples of flat red bark I have met with have been South American, and have been deficient in alkaloids, but unduly rich in quinine and cinchona red, two of the constituents of cinchona barks that are least credited with any useful properties. I would suggest that for this and other similar purposes in pharmacy quilled red bark only should be used, and that it should contain from 5 to 6 per cent of total alkaloids, of which at least one-half should consist of quinine and cinchonidine. If this proposition were acceded to it would be the duty of wholesale dealers to select bark of the specified description, while it would be the duty of those who might have occasion to use it in the production of pharmaceutical preparations to satisfy themselves that what was supplied to them corresponded in characters and properties with that which was officially required." We may add that Dr. Paul and other eminent chemists were incredulous as to 70 per cent being obtained and objected to hydrochloric acid. It is the main agent employed by Mr. Gammie at the Sikhim manufactory of mixed alkaloids, sulphuric acid being used to precipitate.

WITHERING MACHINES.

Mr. John Greig, Junior, for John Greig & Co., writes a curious letter to the *Indian Tea Gazette*, portion of which we quote, with the remark, that if all which is stated is correct it is strange the Ceylon press has not been furnished with the information:—

The XL-ALL Drier and Witherer is now complete, and together with a whole set of simple and economic Machines are now at work in Natal (XL-ALL and factory-shafting lately sent there) besides single Machines in nearly every district; also a whole set for every stage at Messrs. Jns. Brown & Co., Hatton, Dikoya, Ceylon, who have lately sent a report on the Withering and Drying by XL-ALL, together with samples of tea from the bulk and unassorted, just as it was dropped out of Machine. Report says, actual results of first attempt, without practice, gave, as a self-acting Drier, 130 lb. dried perfectly in 20 minutes. All the samples are marked leaf withered (while in a wet state) and dried by XL-ALL, withering a manual each fill of Machine in a few minutes. A note in Report states that we find that the leaf that was withered by Machine, and after rolling same by our Link and Lever Machine, takes exactly the same time to ferment as leaf withered naturally by the ordinary means. I now come to the report on the bulk and unassorted samples of this same tea by Messrs. Geo. White & Co., of London. "Ceylon tea, black greyish curly, bright infused leaf, brisk and pungent flavor, prices up to 1/10d. per lb. in bond." The point here in evidence of its being, as your correspondent, like many other unprejudiced and thoughtful Planters ardently desire, is the character of all the five samples *Bright infused leaf*; there is also the verbal evidence of the taster of the Civil Service Stores, London, that he never saw a more regular fermentation or a brighter liquor. What does this show, but the most perfect withering (by fire heat) and more rapidly and without labor than any thing else in existence. From the fact of 130 lb. dried in 20 minutes, and with practice, Messrs. Brown say they will be able shortly to declare better results; it shows by the character brisk and pungent flavour, a first-class Drying Machine. But they say as a Withering Machine alone it ought to

take. It enables Planters to make first-class tea during any kind of weather, be it rain, fog or sunshine, as air of any degree of heat can be used accordingly, and they can time the withering to the rolling and, save all chaloones, lots, large sheds, their annual repairs, labor, and worry infinite. It is a rapid Drying Machine one minute, and a splendid Withering Machine the next. Any degree of withering can be given to prevent frothing and loss of watery juice, particularly at the first of the Assam season; concentrates the mucilaginous matter in the leaf, and holds the roll; rolls up quicker, gives bright flowery or orange ribs, enhances the price of the tea. I apologize for this long letter, but your correspondent's exclamation—"Who will come to the front with a good Witherer," has prompted it; and as a duty to ourselves and the Tea Industry, and but for that I would have remained quiescent until the promised still more surprising results, with the staff in thorough trim and practice in Ceylon, where my system of fresh leaf equalizing (making first-rate equalized Pekoe Souchong, or all the classes, without sifting or otherwise, and without broken tea and dust) is being carried out by my several inventions, and by instructions given during 12 months in our Works to a young Engineer who is now there.

THE WEST INDIAN CEDAR (CEDRELA ODORATA).

This tree is a native of Jamaica, Cuba, Antigua, Mexico, &c., and grows to a height of 80 feet or more, with a diameter of from 3 to 5 feet. It is a near ally to the Mahogany, to which the wood has some resemblance, though it is softer, rather more open-grained, and not so durable; nevertheless, when properly seasoned it is a valuable wood, and has an agreeable fragrance, very unlike that of the fresh plant. It is used for wainscoting, cabinet work, drawers, &c., as it is stated that no insects will attack it, on account of its scent. Singles made of it are reported to be very durable, and they, moreover, have the advantage of lightness. Luman, in his *Hortus Jamaicensis*, says, "The trunks of the trees often so large as to be hollowed out into canoes and perinnags, for which purpose it is extremely well adapted, as, from the softness of the wood it is hollowed out with great facility, and being light it carries great weight on the water. Canoes have been made of it 40 feet long and 6 feet broad." It is from this wood that the Cuba cigar boxes are made, and the wood is also imported into Hamburg in logs for the purpose of making boxes for holding German-made Havanas; these boxes are made in exact imitation of those which come direct from Cuba. The wood recommends itself for this purpose on account of its even grain, freedom from knots, and its non-liability to split or crack, and also on account of the ease with which it can be cut into thin planks, suitable for box-making. Three remarkable logs of West Indian Cedar were recently landed at the West India Docks from Cuba, our attention having been drawn to them by Messrs. Churchill & Sim, of Clement's Lane, to whom they were consigned. These logs were from the bases of three separate trees, and were each of pretty nearly similar bulk, measuring about 7 feet high, and 3 feet or more in diameter. They all had their bark removed, and their peculiarity was that instead of the grain running up and down or perpendicularly it ran round the trunks in a spiral manner. So distinctly defined was the course of the grain that the logs attracted the attention of the habitual workers on the timber wharf, and one of the attendants who cut off a few chips for us from what in an ordinary trunk would have been the transverse section remarked, that in order to obtain a section showing a longitudinal grain it was necessary to cut it across the trunk. The three logs were sold by Messrs. Churchill & Sim to Messrs. W. Olivier & Sons, of Bunhill Row, who obligingly cut for the Kew Museum a large slice from one of the trunks. From this it would seem that the arrangement of the woody fibres of the trunk was in their younger state quite normal, but after they had attained about half their full dia-

meter, the course of the grain changed from a perpendicular to a spiral direction, so that in planning what must for convenience be called a longitudinal section, the course of the grain was cut through at three different angles. A section cut across the trunk showed no decided rings, but a continuation of a longitudinal grain running round the trunk. These logs, though curious, would be almost useless for working, in consequence of the continued crossing of the grain.—*Gardeners' Chronicle*.

USE AND COMPOSITION OF OILCAKE.

In purchasing small quantities of cake, when a scientific analysis is not thought necessary, it may be roughly tested by grating (not pounding) a small portion of it. A kitchen grater will do, and will leave the bran and extraneous seeds unaltered. Mix half an ounce of cake with five ounces of water, and if the article is good it will produce a stiff jelly, agreeable to smell and taste. If it has a disagreeable odour, like that of a stale canary-birdage, you may be sure there is a large mixture of camelina seeds in the cake. A microscope will enable you to detect the seeds, which are not those of flax; and after diluting the paste with water and stirring it, you may recognize both the sand and the bran, one of which will sink, the other float. You may test rape cake for mustard by placing six ounces of cold water and half an ounce of powdered cake in a stoppered bottle, kept in a warm room, when the pungent smell of mustard, if there be any, will be developed within twenty-four hours. You may test by tasting too, since rape seed, though pungent in taste is not so strong as mustard seed, and does not bite the tongue like the latter.

In the following remarks on cotton seed cake, I must acknowledge my indebtedness to a useful brochure on "Artificial Feeding Stuffs," published last year and written by Mr R. W. Jones, the manager of the Phoenix Oil Mill Company, Liverpool. The best cotton cake is made of Egyptian seed, which is more free of cotton fibre than any other. Tea Island cotton seed ranks next in that respect, and those who have lost stock from the effect of balls of refuse cotton in the stomach are aware of the importance of purchasing cakes made of superior seed, instead of a low kind of seed which is covered with dense, coarse woody fibre, which cannot be separated from it. Only high-class cake should be used for stock. Its colour should be bright green; the hull or husk, which is not removed, as in the case of decorticated cotton cake, should be ground by powerful machinery that it may be well pulverized, and it should be used fresh, as cotton cake, even of the best quality, moulds easily, and then becomes unpalatable.

Decorticated cotton cake is now exported from the United States ground into meal, which must be put into new bags, and therefore costs about 12s. 6d. per ton more than the cake itself. In regard to an article that varies so greatly as decorticated cotton cake, and which has destroyed a great deal of live stock through its having been too hard pressed, or to a mixture of unwholesome ingredients, the motto *Caveat emptor* should be kept in mind. Decorticated cakes of variable value contain from 10 to 22 per cent of oil, 42 to 49 of albuminoids (rendering them most valuable for manure), and from 3 to 11 per cent of indigestible woody fibre. The buyer may well beware of the Texas cake, which contains the last-named substance in excess.

Dr. Vor-leker gives the following excellent advice: "If you want to improve your grass land. . . I do not know any food more calculated to give an economical result than decorticated cotton cake, if you can get it of really fine quality." The nutritious qualities of the cake, which are contained in the kernel of the seed, are far greater than those of the common cotton seed cake, which has the coarse husk of the seed mixed with it. Nevertheless, the latter may be recommended in preference to the other for feeding on pastures in bad weather, or during the flush of grass in spring, or when the grass is watery, on account of the astringent quality of the

husk, which checks the tendency to scour, so common with cows at those periods. About 3 lb. per head per day of the last-named cake, or 2½ lb. of decorticated cake, have been recommended. It seems rather pedantic to divide a pound of cotton cake into two parts, as well make two bites of a cherry.

Sir John Lawes has laid down a great deal of grass land at Rothamstead, and he attributes the comparatively rapid formation of good turf to the free use of decorticated cotton cake given to his large dairy cows at the rate of 3 lb. to 5 lb. each daily.

In using cotton cake in yards and stalls, without an abundance of succulents, it should be ground into meal, and mixed with ground maize or barley meal, grains which are rich in starch and other non-nitrogenous compounds and comparatively poor in albuminoids; and with this hint, which is particularly applicable to the present season, these remarks must be concluded.—H. E.—Field.

CULTIVATION OF STRAWBERRIES.

Sir,—Would you mind publishing (in reply to "R. L. S.") 26th instant) the following, extracted from an old Indian work in my possession? "Strawberries, *Fragaria*.—This plant multiplies itself from runners and suckers; the old plant, after it has ceased bearing, throwing them out. As soon as the rains have set in, these runners may be removed into a nursery-bed, for their being more easily looked after, and should have the space of nine or ten inches allowed between them; they will throw out other runners, the whole of which may be separated, and transplanted at the proper season.

Soil.—They thrive best in a light soil, with good old stable manure, as well as vegetable manure at first; and as soon as they show a disposition to flower, may have old goat's or sheep's manure added around each plant, a couple of double-handful being sufficient.

Culture.—In no parts of the Deccan should the plants be put out for fruiting before the close of the rains; the latter part of September being quite early enough. Suckers that I planted out for experiment at the commencement of August grew to very fine bushes, and did nothing for ten or twelve weeks but throw out suckers, which were continually removed, and, after all, fruited badly; the finest and most prolific crop were got from suckers put out in the beginning of October. Some strawberries were gathered in November from the plants put out in August, but they were so few as in no way to induce me to try the experiment again. Varieties can only be procured from seed; and to procure the seed, select the finest ripe fruit, rub it on a sheet of paper and dry it. When the rains commence, soak the seed in water, reject all that float; the remainder, sow in baskets in a light loam, when they will be fit to remove in about six weeks, and should be fit to remove into other baskets five or six inches apart, and taken care of until ready to be transplanted into beds, where they are to remain. As these plants throw out suckers very fast, they must be constantly looked after and removed, unless you have a scarcity of plants. They will commence bearing in six months from the time of sowing the seed. You may, as soon as the rains have ceased, put your suckers that have rooted, into square beds, each not less than one foot apart five in a row; this will give you twenty-five in a bed—as many as can be easily looked after and gathered without trampling on the bed and thereby injuring the plants. Where the earth is of a clayey consistence, I have seen the strawberry cultivated on ridges. Some think this is a good plan; however it can easily be tried. It is sometimes necessary, in consequence of flooding your beds, to put this under the fruit to keep it clean, but it is also attracts the notice of birds; if straw or grass is used then the chances are that white ants destroy your plants. This is that makes the ridge system of growing preferred by some, as they say the fruit is cleaner in consequence. All I

know is, that fine fruit may be grown either way and if on ridges, the same distance must be allowed between the plants as in beds—and, even in the latter, the plants may be put in raised cones of earth. The common vegetable manure is all that is required at first, till near flowering, when a handful of goat's or sheep's dung should be put around the plants, opening the earth and scraping it together—water the plant during the evening, and very early in the morning.

I have known finely powdered sulphur, tied in a little muslin bag, and used over the plants, beneficial against the ravages of the caterpillars, white ants, grubs, &c. Another plan is to have a pair of English bellows, with the nozzle fitted with an affair like the rose of a watering pot. Taking off the rose, and putting into it a little lighted charcoal, with some tobacco, begin to puff away at your plants, as much underneath as you can, and you will soon clear out your objectionable visitors. A third plan is to lay a few cabbage leaves in the paths between the beds: then after the dew comes, late on in the evening or very early in the morning, examine your leaves and you will most probably find a few seeds to extinguish. One more is the use of the "Sarcostemma Viminali" (Hind. name, "Soom"). "Take a bundle of the twigs of that plant; put it into the trough or pot by which the bed or field is watered, along with a bag of salt, hard packed, so that it may only dissolve gradually. Water so impregnated destroys insects without injuring the plants. Dry twigs answer as well as green. It abounds in the Deccan, and all Gogah, and the coast of Kattywar."—J.S. DAVIDSON.—*Madras Times*.

CULTIVATION OF THE OLIVE AND WATTLE.

Two reports furnished recently to the Legislative Council of South Australia by Mr. J. E. Brown, the Conservator of Forests in that colony, contain some suggestions which are worthy of much attention from Australian farmers. It will be remembered that the International Exhibition of 1879 in this city afforded, by the completeness of the South Australian Court and the courtesy of the commissioner in whose charge it was placed, a comprehensive idea of the suitability of the olive for culture in Australia. Mr. Brown, in a clear and concise style, shows that such culture should afford good returns for the labour bestowed on the tree. According to his experience, the climate and soil of many parts of Australia are highly suited to its rapid and successful growth, and from the excellent oil which has already been produced in South Australia from the fruit there is every reason to conclude that a highly remunerative and permanent industry could be established in our midst by the extensive cultivation of the tree. It is no exaggeration to state that both the climate and soil of Australia are in many respects more generally suited to the growth and fecundity of the olive than are these physical features of its indigenous habitat. Where land is already fenced and cleared the planting of olives would cost, ordinary farm labour being employed, about 4s. per acre. The trees, planted 25 feet apart, would give 70 trees per acre. They should come into full bearing between the tenth and twelfth years' growth, from which time the net yearly proceeds would be about £3 per acre. It is said that the olive tree reaches maturity between the fifth and sixth year. It, however, continues to bear prolifically after that period, and has been known to live until the age of 300 years and more. There is a great variety of olives. Some grow successfully only in moist and temperate climates, while others again do best with less moisture and a comparatively high solar heat. Again, some varieties are disposed to favour soils of a fairly rich character, but when rare free in consistency; while other varieties prefer sites where the soil is of a warm calcareous character. From these facts, therefore, it will be seen that in the predilections of the various varieties of the olive tree, both as regards soil and climate there could be selected kinds to suit the various local

physical peculiarities of our vast agricultural areas. The great drawback to the industry is the fact that a dozen years must pass before a monetary return can be had for the labour bestowed. Australian farmers are advocates for quicker returns, but, nevertheless, they might in that leisure time which occurs on most farms devote a few hours to the planting of olive plants, the cost of which Mr. Brown estimates to be about 2d. each.

Many farmers of Australia are fully cognizant of the profits derivable from wattle trees, although few have done much in the shape of planting. The Forest Department of this colony is at present making an experiment with wattles on the vacant ground along railway lines; and Mr. Moses, a tanner of Armidale, has a wattle farm. Mr. Brown shows on paper that wattle cultivation, although years have to elapse before a return can be expected, is a branch of agriculture which will pay handsomely. He says:—"At the distances apart which I recommend the trees to be grown—namely, 4 feet to 6 feet—there will be an average of 1,200 trees to be the acre. In order, however, to make due allowance for barks, I shall base my calculations upon there being 1,000 only to each acre. At the present time bark is selling at £7 10s. and £8 per ton, and there is every chance of a still higher price being obtained for it during the next few years. Still, to be on the safe side, I will put its value down at £5 per ton only. I give five tons as the probable yield per acre. That this is a low estimate will be admitted, when it is considered that this only allows for 10lb. of bark to be taken from each tree. I shall now give a statement of the probable revenue and expenditure during a period of seven years, in connection with a wattle plantation, formed upon 100 acres of land specifically purchased for the purpose, and upon which wattles had not previously grown." The expenditure, allowing £3 per acre as the price of the land, would be £1,792; the return would be the value of 500 tons of bark, £2,500; value of property, say £100; total, £2,900. The profit, therefore, would be £1,108. The report upon the subject is one which will repay perusal. Copies of it may be easily obtained by those persons who feel disposed to learn more about wattle culture.—*Sydney Mail.*

KAINIT AND ITS VALUE.

Among the fertilizers that are less known to the general farmer than it should be, and hence not properly appreciated, is the German Kainit. Its use in Germany has become quite general, and in this country its use is rapidly increasing as its value is becoming better known. Kainit is a mineral salt found in Germany at a depth of from 300 to 1,200 feet below the surface and in such abundance as to be practically inexhaustible, being found and mined near Strassfurt; it is also called Strassfurt Salt.

Its great fertilizing power is largely due to the large amount of sulphate of potash it contains as well as other chemical salts. It is imported into this country finely pulverized, and put in sacks of 200 pounds each, and is of very easy application.

I copy from Bulletin No. XXVII of the New Jersey Agricultural Experiment Station, its report of the amount of potash that kainit contains. "Station analysis No. 411; Kainit, Alexander Kerr & Bros., Philadelphia; Potash per 100 pounds of Kainit 12.80 pounds; cost of potash per pound 03.9 c; cost Kainit \$10.00 per ton."

I give the analysis of that of Alexander Kerr & Bros. because it is first on the list and also being superior. A full analysis gives the following composition per ton of 2,000 pounds.

Sulphate of Potash	496	pounds.
" " Magnesia	286	"
Chloride " "	252	"
" " Sodium	640	"
Common Salt	}			
Moisture	288	"
Insoluble	38	"
Total,	2,000	}}

It will be seen by the analysis that the quantity of the Sulphate of Potash is very large, and that of the Sulphate and Chloride of Magnesia also large. The salt, 640 pounds, is also in most cases valuable, leaving only the moisture and insoluble matter a trifle over 300 pounds that is valueless. The manurial value of the potash in Kainit can be easily understood by comparing it with ashes. Unleached ashes, as usually sold in moist condition, contain, on an average, of not over 5 per cent of potash, or 100 pounds per ton.

Kainit, by the Station analysis, contains 12.80 pounds of potash per 100 pounds or 256 pounds per ton. Leached ashes often contain less than 30 pounds per ton of potash. Kainit at \$10.00 per ton, good wood ashes should, to be equal, be worth \$1.00 per ton. The value of Sulphate and Chloride of Magnesia, supplying as they do Chlorine Sulphuric acid and Magnesia, in soils that are deficient in them is sometimes worth the cost of the whole. Kainit is also valuable to mix with compost or for stable use, to absorb bad smells or prevent the escape of free ammonia.

For the above uses it is superior to land plaster, being more soluble, and also from the disposition of the Sulphate of Magnesia with Ammonia to form a double salt of Magnesia and Ammonia, fixing all escaping smells and free Ammonia.

Kainit, similar to ashes, is caustic, and must not be put in contact with the roots of plants, for when applied in so concentrated a form it will burn the plants as quickly as ashes. The best plan to apply Kainit is to sow it broadcast over the land as evenly as possible at the rate of 200 or 300 pounds per acre, as long before the crop is planted as possible, but if that cannot be done it can be sown after the crop is planted, and will mix with the soil while cultivating the crop. I have used six tons of Kainit on corn, beans, potatoes and buckwheat with the best of results at the rate of 500 pounds per acre. A smaller quantity oftener applied will be better in most cases.

On fruit trees its value cannot be over-estimated, especially on peach trees. I have a small orchard of 300 one-year-old peach trees, that before I used the Kainit were yellow and sickly-looking. The leaves were all curled, and were so hopeless-looking that I was advised to dig them up and burn them. I applied 500 pounds of Kainit broadcast per acre, and as much more in a circle of four feet around the tree, carefully spread, and on the balance I used a peck of fresh wood ashes to each tree.

The change made by the Kainit was complete. No finer growth of wood and leaves can now be found. The trees where I used the ashes were, after a fair trial, so far behind the others in vigor and health, to save them I used Kainit also, but as yet are behind them in growth.—By ELI MINOR, Shiloh, N. J. —*Southern Planter.*

[Query, whether not useful as a manure for tea? with same soluble guano phosphat of lime and castor or cocoacae added. Is there any chemical objection, such as compounds being formed, to such a mixture? Mr. Hughes always contended that phosphate of lime gave all needful potash.—Ed.]

THE ACTION OF SAP.

In a paper read by Professor Robson, of Kansas, before the Mississippi Horticultural Society in January 1884, he brought to notice many facts regarding sap, which he had personally witnessed, which went far to overthrow many of the theories extant regarding its circulation. The old theory was that the sap ascending was elaborated in the leaves, then descended, forming wood in its course and became finally lost in the tree. Now the Professor maintains that the sap does not descend, but is elaborated, retained, spread, ripened and compressed over the entire inner surface of the tree during its upward flow." Now this theory is entirely opposed to the old ideas on the subject of the elaboration of the sap; for instance, Lindley a great authority, writes:—"It is the action of the leaves, by the decomposition of their carbonic acid, and of their water; to the

separation of the aqueous particles of the sap from the solid particles that were dissolved in it, to the deposition thus effected of various earthy and other substances, either introduced into plants, as siliceous and metallic salts, or formed there, as the vegetable alkaloids to the extrication of nitrogen, and probably to other causes as yet unknown, that the formation of the peculiar secretions of plants of whatever kind is owing. And this is brought about principally, if not exclusively, by the agency of light." This idea or theory is directly opposed to the Professors who distinctly lays down that the sap is elaborated before it reaches the leaves and is exposed to the light. He proceeds to exemplify his theory by facts. In the year 1832, being in charge of a Conservatory, he trained twelve Black Hambourg vines in the following manner:—The stems were outside the house, the roots in a rich border, at three feet from the ground the vines branched into two stems each thirty feet long, one branch of each vine was trained inside the house, where the heat was early in February 70°. The other branches were trained outside of the glass roof. In a short time the branches inside, pushed their buds, extended their leaves and had large bunches of ripening berries, whilst the branches outside, were just beginning to show signs of life. In the meantime, the fruit inside had ripened; the leaves having performed their functions, had become yellow and were falling fast; whilst the branch outside was making vigorous growth. The Professor asks, how did the descending sap from the branch inside rush down that three feet of stem, through which was rushing a resistless upward flow of sap towards the vigorous branch outside? For eight years this trial was repeated, and yet no protuberance was formed at the junction of the limbs, which should have been the case, if the theory of sap descending was correct. The Professor instances the case of a cherry tree, when some of its branches were enclosed under glass and precisely the same effects observed. Again a fig tree was treated in the same manner, and whilst the figs inside were being gathered fully ripe, those outside were hard and green. Yet another instance,—a lady trained some branches of climbing rose, through the windows of her room, and at Christmas when there was a hard frost outside and not a leaf on the parent trees, the branches inside the room were covered with sweet smelling roses! The Professor declares from numerous examples which he has practically witnessed, that the theory of the downward flow of sap is a fallacy, and that to cause an upward flow, light, moisture and heat are necessary, for if these be excluded, exhalation is entirely prevented. Further, that the flowing sap begins to move in the upper branches, long before the ascending sap begins to move from the roots. We think the Professor has to a great extent made out his case, though perhaps, the other theory of the descending sap may be correct partially. It was always a puzzle to account for the fact, that in many vineries the roots are outside, and when the house is started in say February at 70° the buds at once sprout, whilst the roots which are probably in a temperature of 30° to 40° and the stems are dormant. The facts adduced by the Professor of one set of branches outside and one set inside, explain clearly how the sap may be started in the branches before the flow from the roots begins. Again, the Teak and Blackwood trees have when wounded in the trunk near the ground a curious habit of eliminating from the soil where none exists to the eye, solid pieces of lime, as much as four feet in length and six inches in breadth, now this locks very much as if the lime had been deposited outside of the stem by the ascending sap, rather than by the descending, as the theory is that on descending the sap is gradually absorbed by the tree, consequently so large an amount of lime would hardly have been left to be deposited all at one spot. We are inclined to think that the truth of the two theories lies midway, that much of the ascending sap does under certain conditions deposit in its upward

course, and that in certain cases, a residuum of the sap is left which after being elaborated by exposure through the leaves finally descends and is absorbed in the tree. We think the Professor, when he assumes that nearly the whole of the sap descends, is ascribing to the other theory, more than it claims, or ever even asserted. Practical planters are very much indebted to Professor Robson for his very interesting theory and its practical results.—*Planters' Review.*

TOBACCO CULTIVATION.

Letter from H. Caine, Esq., Assistant Manager, Poosa Tobacco Farms, Tichout, to the Superintendent of Andamaus and Nicobars, dated 6th October 1885.

I have been requested by the Secretary of Revenue and Agricultural Department of India to send you full instructions as to the method employed here for cultivating, preparing soil, sowing, planting and treatment while growing of tobacco. I shall endeavour to do so in as clear and concise manner as possible and hope you will have no difficulty in following out the instructions.

Preparations of Soil.—Tobacco land should be well-drained upland which has lain fallow some time or that has had some light crop in it; this land should be well manured with well-rotted manure. We plough our lands twice monthly. Just before the time for transplanting the soil is ploughed up and well pulverized by a henger or beam of wood drawn by bullocks, over the overturned soil so as to head it and to break up any lumps of earth. The soil should be sufficiently dry for this purpose so as not to cake and harden.

Seed-beds.—These should be made up in a suitable situation, that is, protected from the hot afternoon sun, having some building or grove of trees on the west side. The seed-beds should be raised some six inches off the ground and have trenches dug all round so as to carry off any superfluous moisture, the beds should be well worked with a kodalie and good, rotted manure well worked in. After pulverizing the soil and levelling it, pick off any stones or other rubbish and it will be ready for sowing the seed. The size of the beds should be about 4 feet x 15 feet; this is more convenient than square beds as it enables the plants to be attended to without risk of destroying them by trampling on them.

Sowing the Seeds.—The seed is sown broadcast with the hand, mixed with some sand or ashes so as to sow evenly; care should be taken not to sow too thickly. About one ebittak of seed ought to be found sufficient for one of these beds which would furnish enough plants for one beegah of land. After having sown and if there is a hot sun, it would be advisable to cover the beds with light mats. The seed should germinate in 7 or 10 days at least. American seed does; Sumatra takes much longer. The plants may require water-irrigation, which should be done with a watering can with a rose, when the plants are well up and large. Only water seed-beds in the evening. As soon as the seedlings have leaves of the size of a penny, they are capable of bearing transplanting. Before taking up the seedling to transplant, water the beds well an hour beforehand; this is done to loosen the earth about the roots so that the plants may be taken up without injury. To take up the seedlings they should be seized by the underside of the two largest leaves by the finger and thumb having one leaf on each side, not by the stem, then pull up gently, taking care not to break the leaves. They may then be placed in an open basket. When the basket is full, it should be covered with a cloth if the sun is hot and the seedlings slightly sprinkled with water and then carried off to transplant. The seedlings are planted out in rows 3 feet x 2 feet apart, for which purpose a knotted cord is used—the knots being 3 feet apart. This cord is drawn by two men—one at each end. Across the field or portion of the field at a distance of 2 feet from the outer edge, the cord is drawn out and then trampled upon by oxen. The knots leave an impression in the soil where the seedlings have to be

planted. The cord is then raised and put down again at another distance of 2 feet from the first and so on till sufficient laud has been marked off. This work can be done during the day and the transplanting in the evening.

Transplanting.—Transplanting should be done in the evening if there is any sun; in cloudy weather it can be done all the day long. Rainy weather is most suitable as it dispenses with watering and the plants settle better. A boy takes a basket of seedlings and walks up the row, dropping a plant here and there where the marks have been made; he is followed by a man who makes a hole with a *kurpie* into which he places a seedling and then presses the soil around the roots firmly with his fingers and then goes on with the rest. As transplanting can hardly be done here without watering, a boy carrying a can without a rose follows the man who is transplanting and waters each plant he comes across; but, as I mentioned above, if the transplanting could be done in rainy weather, the watering would be unnecessary. When growing the young plants require some attention. After the plants have been planted about a week or so, weather permitting, it is advisable to loosen and open the soil around them with a *kurpie* and also to eradicate weeds which may appear. Later on a *kodialie* may be used to work the earth between the rows. As soon as the plants have made growth and begin to throw out flower or seed-heads, which will take place in about eight weeks or so, they should be topped, viz., the flower heads should be broken off before they flower in this way. The stem on which the head was found should be seized about two to three feet from the ground and snapped clean off by the hand or fingers. This topping will cause the plant to throw out heavy leaves. The higher up the stem is broken off, so will the leaves of the plant become thinner and smaller. We generally leave about ten to twelve leaves to each plant. After topping, numerous suckers and offshoots will spring up; these should be promptly broken off as soon as they appear, as they take a lot of nourishment from the plant. The plant ripens in about three months. We cut here in January, and none but ripe plants should be cut.

How to cut ripe plants.—A tobacco plant is known to be ripe if the leaf cracks when taken between finger or thumb and pressed, and also when the leaves present a swollen appearance and have a heavy look. The stem when cut is full of sap, very thin and on edge, the leaves are carved over and look mottled, the ribs of the plant get brittle and are easily broken off; when fully ripe, the plant is cut at one stroke close to the ground. The best instrument to cut the plant is with a *kurpie*. When cut, the plant is allowed to hang over on its side and wilt or droop in the sun. This wilting takes from one to two hours according to the strength of the sun. When sufficiently wilted (which is known when the plants look drooping and the ribs can be bent slightly without breaking), the plants are placed in a cart and taken off to the curing-house. Plants should not be cut in rainy or cloudy weather as it is obvious the sun would not be hot enough to wilt were the weather cloudy and the rain washes off the gum and thereby decreases the weight of the plant. Plants should not be cut after the rain unless the gum has returned to the leaves which is known by their sticky gummy feeling. Trusting the above instructions would prove sufficient, I beg, &c.

BULB CULTURE IN HOLLAND.—We quote the following details from the *Illustration Horticole*:—In thirty parishes in the neighbourhood of Haarlem alone, an area of upwards of 595 hectares is devoted to culture of this kind, viz., *Hyacinthus*, 231 hectares; *Tulips* 205, *Crocus* 74, *Spiraea*, *Hotia*, and *Dicentra* collectively, 52 hectares; *Narcissus*, 9; and miscellaneous bulbs, 22 hectares. A hectare is about equal to $\frac{2}{3}$ acres.—*Gardeners' Chronicle*.

BRANCHED PALMS OF S. INDIA.

The most extensively distributed Palms in Southern India are the *Palmyra*, or *Borassus flabelliformis*, and the *Coconut* or *Cocos nucifera*; but of the several genera, the *Hyplophoea Thebaica*, or Doun-palm, alone has a branched stem, the division being dichotomous or in pairs; but there are exceptions to the general rule in the case of the *Palmyra* and *Coconut*, which are sometimes found with branches. Since the subject first attracted my attention, some two years ago, I have been searching for these during my peregrinations over Southern India, in connexion with my own immediate work; and in that time I have seen some millions of *Palmyra*-trees, both on the coast and some hundreds of miles inland; and neither my own researches nor the results of my inquiries have enabled me to trace more than six of the *Palmyra* and two of the *Coconut* with branches. The latter I have not seen, but have received drawings of them from my friend Dr. Pulney Andy.

In the *Palmyra* the branching is irregular; but in the *Coconut* the tendency to division in pairs exists. Twin plants from the *Palmyra* are very common all over this portion of India, but such an occurrence in the *Coconut* is a variety. I have seen but one instance of it, and that was in my own garden at Chingleput; and a couple of hundred yards from it, beyond my compound, a twin *Palmyra* of the same age was found growing.

Since this paper was written, I observe, from a late number of the *Malaya Times*, that in a horticultural show the other day at Travancore a *Coconut* was exhibited with five or six shoots growing out of a single root. At the same time a plant of the *Areka Palm* was also said to be exhibited having from seven to nine heads; this is also an exception to the rule.

The following are the localities in which these branched Palms may be seen:—

1. A few miles from Masulipatam, on the road to Bimtrivally, a *Palmyra* tree existed with twelve branches. During the last cyclone ten of these were broken; of the remaining two, one has withered, the other exists; seven of the broken branches are lying close by, and three stems have been washed away to some distance.
2. At Palghat, about three miles from the town, on the Cornubine road, and about half a mile from the road itself, exists a branched *Palmyra*. It is a twin plant, and one of the two has six branches.
3. At Madura, on the northern bank of the river Vegay, there is a *Palmyra* tree with nine branches; one is broken, and the other eight exist; this is a male tree, shown in the accompanying woodcut.
4. At Ramnad, on the bank of the river Vegay, is to be seen a *Palmyra* tree with four well-formed branches of equal height; below the division the stem is covered with numerous other shoots of different sizes.
5. On the road to Chellembrum from Manargudi, I am told, a *Palmyra* exists with branches, which I have not seen.
6. A *Palmyra* tree, from Travancore, with five branches, sent by Dr. Pulney Andy.
7. Two branched *Coconut*-trees, from Travancore, also sent by Dr. Pulney Andy.

Dr. Pulney Andy thinks that the *Palmyra* *calandria palmaram*, has something to do in the branching of the *Coconut*: as it perforates the leaf-bud, the original becomes diverted to one side, and, he thinks, this in a measure gives occasion for a second shoot forming. This may be possible; but it requires further observation and research to determine the question.

In the genus *Phoenix* the *Phoenix aculeata*, Buch, is common to all the low hill ranges in Southern India to the height of 6000 feet above sea-level. I have seen it on the Shewangs, Kotagerry and the Pulney Hills, where it grows commonly and luxuriantly into a bush caused by numerous suckers thrown out around it, something like the plantain. I have counted

as many as a dozen suckers around the parent stem and, with one exception (on the Paluys, where a plant had attained the height of 8 feet), the stipe never exceeded the height of 2 or 3 feet; and in the exceptional instance where it had attained 8 feet there were no suckers around the parent stem. The natives eat the fruit, and are partial to it. The fronds are also made use of in various ways, but not to the same extent as the *Phoenix sylvestris* and *Phoenix dactylifera*.

A monstrosity, if I may so term it, has been observed as occurring in a Coconut Palm, in which from one of the flowers on the spadix, a shoot of spring leaves is thrown out. There is a slight tendency to fructification from the flower, and then it is converted into spring leaves, apparently forming a young shoot. This specimen was taken from a Coconut tree in the province of Travancore. The plant is of the usual size of an ordinary Coconut tree; but it never puts forth well-developed fruit. On the contrary, the flowers terminate in vernal leaves; thus, at an average, each spadix or branch bears about thirty to forty such shoots at a time. The leaves are generally considered by botanists homologues of the flower, although their functions are different, the former being engaged in the conversion and assimilation of food, whilst the latter takes on the office of reproduction, but the type of all being the leaf. This frequently occurs in the Mango-tree, where, from some inherent cause, the flowers fail to show, and their place is taken up by the pushing forth of numerous leaves.

Plants, we know, require a period of rest to form flowers, and this is obtained by the cessation of the action of the leaves and roots for a time. During this period the vegetative activity of the sap is directed to the formation of flower-buds; but should this rest not occur, it continues to produce new leaves and roots in the place of flowers. Thus the absence of rain proves sometimes beneficial in arresting the formation of new leaves and roots; and this favours the production of flowers.—*Journal of the Linnean Society.*

SUPPLIES OF THE FINER TIMBERS.

The wood exports from India consist chiefly of teak and sandal-wood. The following table gives an idea of their importance. The official years in India end in March.

EXPORTS FROM INDIA.

Years.	Teak to		Sandal-wood.	Ebony.	Other ornamental woods.
	United Kingdom only.	Other woods.			
1877-78	Tons. 13,350	Tons. 1,295	36,396	356	£ 100
1878-79	23,479	2,318	30,778	1,581	814
1879-80	26,575	1,958	37,095	891	193
1880-81	53,715	1,062	26,588	1,091	178
1881-82	48,389	1,273	20,808	937	6,213
1882-83	59,331	1,822	10,293	54	356
1883-84	27,556	1,274	25,534	197	1,188

Sandal-wood.—The revenue derived from sandal-wood in the State forests of Mysore is very large, it having been a Government monopoly for 50 years. The tree springs up from self-sown seed, and grows luxuriantly in many parts. The cuttings were formerly restricted to 500 tons of growing trees, but in 1873 this was extended to 1,000 tons extra, making 1,500 tons in all. The surplus revenue was:—

Years.	Surplus.	Total Receipts.
1835-41	12,789	14,679
1843-53	14,508	16,745
1853-63	17,558	29,852
1873-78	23,017	31,240

In 1878-79, the sales in Mysore were 1,090 tons, at an average of nearly £34 a ton. In the following year 1,292 tons were sold at £35 a ton, bringing in a net profit of £39,431. The marked maturity of the tree is judged to be as soon as possible after the

formation of the heart-wood. The crop value of a fully stocked sandal plantation, cut at 40 years, supposing it at that time to contain 100 mature trees per acre, of a net value of £3 each, will be £300 per acre. The demand for sandal-wood in Europe is inexhaustible, but it is chiefly sent from Bombay to China, where it is used for ornamental work of various kinds.

Indian blackwood (*Dalbergia latifolia*), generally called rose-wood among timber merchants and workmen, is used for furniture; but it is not much in demand. There are plenty of trees of it in the forest of Mysore. The wood is sound and runs large so that excellent slabs and planks can be got from it. From Siam 37,217 piculs (of 1½ cwt.) of this blackwood were shipped in 1870. In 1882, ornamental Indian woods to the value of £78,281 were sent to various Presidency ports, chiefly Bombay. What is known as Moulmein cedar is the Toon wood of India (*Ordelea toona*), universally used there for furniture of all kinds. It fetches in Burmah about £6 a ton. If sent in well squared hewn logs about 15 inches square and 12 feet and upwards in length, it would fetch nearly 3s. a cubic foot, as a substitute for mahogany. In Bengal, Assam and Burmah it grows to a very large size, trees, 20 feet high with a height of 80 to 140 feet of clear stem, being not uncommon in forests which have been little worked, like those in Damsong and some parts of the Chittagong hill tracts.

If it can be delivered in any large quantity at Chittagong or some Burmese port, it might be profitable to send shipments to London, though exports from the forests of Northern India are out of the question. The Sal timber (*Shorea robusta*), for which Bengal has been so famous, exists largely in most of the forest areas. In past days there was much unnecessary destruction and irreparable waste of these trees, and it may be doubted whether the timber resources of the country are now equal to its prospective demand. The Soondri trees (*Heritiera sp.*) of the Soondri-bans furnish the best wood for the boats which are built in such great numbers throughout Eastern Bengal. Time would fail to permit me entering into detail on other Indian woods.

CEYLON.—The timber trade of this island ought to keep up and increase in importance for a long series of years to come. Their extensive forests, of the more valuable kinds of wood, are as yet practically untouched in the Central province, and a proper system of conservation ought to render them comparatively permanent sources of revenue to the colony.

NEW SOUTH WALES.—The reported area of woods and forests under the care of the conservator in this colony, amounted in 1881 to 3,759,796 acres, and the timber cut from them during the year was stated at 3,923,727 feet, from which a revenue of £10,156 was derived.

It is impossible here to enumerate or describe even the principal woods of this colony. The flooded gum is remarkable for its durability as a shipbuilding wood; specimens taken from a steamer flying incessantly for twenty years, were as sound throughout as when built. Black iron-bark (*Eucalyptus leucogylon*) is a wood of great merit for strength and durability, very hard and of good colour, but enormously heavy. It is very useful to the coachmaker and wheelwright, and is also valuable for many purposes in shipbuilding. The blackwood (*Acacia melanocylon*) is a magnificent wood for every description of cabinet work, as it has a beautifully marked richly-coloured grain, which takes a polish freely, and gives an effect not even surpassed by walnut, to which it has many points of similarity. It is very close grained and heavy, and is useful for all purposes where lightness, combined with strength and flexibility, are required. It is largely used by coachbuilders in the colony in every department of their trade. Tulip wood (*Ha pollia pendula*) is a large tree, 50 to 60 feet high, with a diameter of 11 to 21 inches. The timber is very strong, beautifully marked with different shades, from black to yellow. It takes a good polish, and is much esteemed for cabinet work.

QUEENSLAND.—The timbers of this colony are as valuable for their variety and use for commercial purposes as those of the adjoining colony of New South Wales.

The cypress pine (*Fresnelia rhomboidea*) is another Queensland tree, attaining a height of fifty to seventy feet, with a diameter of twenty to forty inches. The timber is an article of great importance, being durable, fine-grained, fragrant, and capable of a high polish. It is used for piles for wharves and sheathing boats, resisting the attacks of the *Teredo navalis* and *Termites*. The root is valued by cabinet makers for veneering purposes. The market value of this wood in the colony is 10s. per hundred superficial feet. The brush or bastard box (*Tristania conferta*) grows to a height of eighty to one hundred feet, with a diameter of four to five feet. It furnishes a valuable timber on account of its great durability and immunity from white ants. As ribs of vessels, it has been found perfectly sound at the end of thirty years. Beech wood and swamp oak (*Casuarina torulosa*, and *C. equisetifolia*) give woods close grained and beautifully marked, and furnish handsome veneers. Rosewood (*Dysoxylum Fraserianum*) is a beautiful wood, dark, hard, close-grained, fragrant, and, when properly seasoned, capable of being worked into the best kind of furniture, and is useful in turning.

Myall (*Acacia homalophylla*) is a dark, close-grained wood, well adapted for cabinet-making purposes, but it is not of large size. There are several kinds of sandal-wood in this colony. The timber of *Eucarpus latifolia* is very hard and fragrant, and excellent for cabinet work. That of *Santalum lanceolatum* is close-grained and takes a good polish. Both these trees are from fifteen to twenty-five feet high, with a diameter of six inches. The timber of the bastard sandal-wood (*Everophila Mitchellii*) is hard, beautifully grained, very fragrant, and makes handsome veneers for cabinet work. The tree grows to twenty to thirty feet high, with a diameter of six to twelve inches.

WESTERN AUSTRALIA is very rich in good timber, which is now being largely developed. The forests of Western Australia cover an area as large as Great Britain. There are more than 30,000 square miles covered with eucalypts, 24,000 miles of which consist of the white gum (*E. viminalis*) and jarrah (*E. marginata*). The latter is a most important shipbuilding wood from its imperishable nature and immunity of attack from insects. The toatoat (*E. gomphocephala*) and red gum (*E. calophylla*) are also excellent woods. The scented sandal-wood (*Santalum cymbarum*) has for some years contributed largely to the productive industry and profit of Western Australia, but unless new plantations are formed, it cannot very long continue to do so, as the distance which even now it has to be carried to the ports of shipment raises its price so much as to leave no great margin of profit. A scentless sandal-wood (*S. persicarium*), called locally manibou, is very plentiful in the colony, and from the fineness of the grain of the wood, might be made use of for wood engraving.

The average consumption of mahogany in the United Kingdom would seem to be about 50,000 tons, and the supply appears to be very even, seldom ranging more than about 5,000 tons above or below this quantity.

Veneers are also imported from abroad, but there are no recent returns of the quantity named obtainable. The imports were in

	Cwts.		Cwts.
1860	3,504	1861	4,886
1861	3,185	1865	4,967
1862	3,772	1870	4,063

After 1870, veneers were, by the Board of Trade, summarized with the furniture woods. The timber used for veneering in the United States is principally curled and bird's-eye maple, beech, birch, cherry, ash and oak. These all grow in the States, and the beautifully-marked and grained timber of the American veneers finds fitting places in the ornamental uses these veneers are put to.

The finest and most costly of the veneering woods is what is known as French walnut, but which does not come from France at all, but from Asia Minor and Persia. The tree is crooked and dwarfed, and is solely valuable for the burr that can be obtained from it. In these large tough excrescences the grain is twisted into the most singular and complicated figures, and the symmetry and intricacy of these is one of the elements determining the value of a burr. Formerly walnut burrs were in good demand, and fetched high prices, some rare ones, as much as £100 to £200; indeed, one shown at the Paris International Exhibition in 1875, sold for £1,000, or about 8s. a pound weight. But now there is very much less demand for burr veneers in the cabinet trade, the consumption being limited to pianoforte makers. There are occasionally met with burrs in rosewood and mahogany, but these are of little or no value.

Of *Satinwood* the imports into Liverpool chiefly from St. Domingo, were in

1877	469
1882	3,320
1883	2,667

The following figures show our supplies of *Walnut-wood* for a short series of years:—

IMPORTS IN THE UNITED KINGDOM.

Years.	Tons.
1860	4,580
1865	5,689
1870	6,536
1883	6,215

Ebony.—Next to walnut, ebony is probably the most valuable of the cabinet woods. Occasionally a fine piece is found, that brings even a better price than French walnut. For a particularly fine piece £1 the pound has been paid, the main thing being size, for it is difficult to get large pieces that can be used without cutting. Prime large logs from Ceylon fetch readily £14 per ton and upwards. Our annual supplies of this wood are never large, 1,000 to 2,000 tons being the greatest imports. The ebony wood of commerce, so much used for inlaying, is the duramen of several species of *Diospyros*, a very large genus of trees, natives chiefly of Africa and Asia. From its hardness, durability, susceptibility of elegant polish, and colour (which has almost become another name for blackness), ebony has always been held in high estimation. Ebony was for a long time supposed

to be obtained from *Diospyros Ebenaster* alone, but, in fact, several other species, scarcely differing from one another, yield this wood, in India, Siam, Ceylon, the Philippines, Madagascar and Mauritius. The commercial descriptions of ebony are generally ranged under three kinds, according to the countries from whence they are drawn—Mauritius, East Indian and African. The Mauritius ebony is the finest grained and the blackest, as well as the hardest and most beautiful, but it is the most costly and unsound. The East Indian is of inferior colour and coarser grained; the African is the least wasteful but the most porous.

DYEWOODS.—Although the various dyewoods can scarcely be classed as timber, yet a brief glance at some of these will not be out of place before I close my paper, forming as they do important foreign forest products, and our imports reaching in value over half-a-million sterling. *Logwood* forms the principal item and has increased rapidly in quantity, for whilst in 1837, we retained but 15,000 tons for home use; in 1850 the quantity exceeded 30,000 tons; now the average annual imports are double that amount as the statistics given below will show. Our supplies come from Campeachy, Honduras, St. Domingo and Jamaica. The other dyewoods we import are red sanders wood (*Pterocarpus santalinus*), sappan wood (*Cassipouia sappan*) both from India; fustic (*Macleura tinctoria*), from the Spanish Main and Cuba; Brazil wood (*Cesalpinia brasiliensis*), and camwood and barwood (*Dalpinia nitida*) from West Africa. Nicuragua, or peach wood, is *Cassipouia echinata*.—P. L. SIMMONDS in *Journal of the Society of Arts*.

TEA MANURES.

On this subject we append an interesting and important letter from Mr. John Hughes, which we recommend to the attention of tea planters. Castor-poonac (white) is one of the best applications to tea, because not only is it rich in nitrogen (7 to 7½ per cent) but it is also offensive instead of attractive to insect life. The importance of Mr. Hughes' letter on this occasion lies in the advice he gives as to the treatment of other manures, such as fish-guano and cattle-dung, so as to prevent their becoming the food of noxious insects, instead of benefitting the cultivated plants to which they are applied. Most of the fish-manure used in Ceylon comes to us from the coast of Malabar, where there is a large fish-curing industry, and, as a great portion of the fish is cured by being simply placed on the sand of the seashore, Mr. Hughes' warning against the existence of sand as a large constituent of the fish-manure offered for sale is worthy of attention. The planter having obtained fish guano containing the minimum of valueless sand, the great point then is so to treat the rotten fish, rich in ammonia, as to render it unpleasant to insects: ants in the lowcountry and lower hill regions and cockchafer or other grubs everywhere, from sea-level to the highest altitude at which tea is grown. What Mr. Hughes advises, and the advice seems sound and judicious, is, that to fish, cattle-dung and all ammoniacal substances used as manures should be added a proportion equal to 10 per cent of superphosphate of lime. This should be done previously to application, time being given for the acid in the superphosphate to permeate the whole mass. We need scarcely point out that the superphosphate, besides the specific effect for which Mr. Hughes advises its application, has itself a highly important manurial value, containing, as it does, some potash besides the phosphatic matter, which will tend to support the trees under the luxuriant production of leaf which the nitrogenous castor-cake, fish or cow-dung will foster.

We cannot but feel that we and our readers are greatly indebted to Mr. Hughes for the readiness with which he places the results of his professional knowledge at our disposal. Where tea estates have been opened on virgin soil and are still young, of course the only manurial application necessary is the burying of prunings, weeds and the debris of rotting timber. But a very large proportion of the tea estates of Ceylon occupy the sites of more or less old and exhausted coffee plantations. For such lands the application of manures becomes necessary at once, if the expense can possibly be afforded. The usual estimate for old coffee land is about 300 lb. of made tea per acre. We should suppose it quite possible to raise this average by means of manuring to 500 lb., the quality of the tea, in respect of strength, following the increase of quantity. The whole question, then, is one of comparative expenditure and additional returns with higher prices obtained. We will know how expensive manuring is, not so much in its first cost and carriage to the estate, as in its application, not to 1,200 bushels per acre as in the case of coffee, but to from 2,500 to 4,000 in tea cultivation. If the necessary money can be obtained, however, we feel certain the returns would be profitable in every sense.

79, Mark Lane, London, E.C.

23rd October 1885.

In my remarks upon Mr. Carter's experiments (contained in my letter of October 9th), I pointed out the probable reason why the results of the application of castor-poonac had proved more satisfactory than those obtained from the use of London-dust, namely, that, inasmuch as nitrogen was the principal manure ingredient required by the tea-plant, it was only reasonable to conclude that the fertilizer which supplied the largest proportion of this valuable constituent in a form suitable for assimilation was the most suitable and economical manure for tea plantations.

If, therefore, white castor-poonac containing 7 to 7½ per cent of nitrogen can be purchased in Colombo at about 135 per ton, it is to be preferred for tea to bone-dust containing only 3.70 per cent of nitrogen, and which would probably cost 160 per ton. In addition to castor, other kinds of poonac will doubtless be found useful, thus dried blood, woollen refuse, fish guano (which is finely ground dried-fish), and many other materials of a similar character whose value, however, will be largely regulated by the proportion of nitrogen they may be found on analysis to contain.

Indeed, well-prepared fish manure free from sand should be a cheap and readily procurable fertilizer for tea in Ceylon; but, if it is used, I should like to add a word of caution to the effect, that, if planters wish to benefit the tree, and not to feed ants and grub, it will be necessary to treat the fish manure with some chemical such as sulphuric acid or soluble phosphate of lime. In other words, to mix the dried fish already finely ground into a meal, with some concentrated superphosphate, say, 90 parts of the former to 10 of the latter, and allow the mixture to remain in a heap for some days before applying it to the land.

In the West Indies, I am informed, that in dry seasons on any soil fish manures have helped to feed ants rather than to nourish the sugarcane, and it is highly important that planters in Ceylon should take all necessary precautions to avoid similar results on their tea estates. Of course, the climate of Ceylon is naturally humid and long droughts are very unusual on the hills, still it is quite possible that many of the severe attacks of grub at the roots of coffee trees may be indirectly due to the previous use of cattle-manure, fish, or even poonac—and that if such materials were mixed with some superphosphate in a heap protected from the weather, for some days before application, the future results would be more satisfactory, and, while improving the character of the fertilizer, would also make it unpalatable to insects and grubs. This is a matter certainly worth the careful consideration of practical planters, for it seems a distinct waste of manure to apply it in a condition in which it may contribute food for grubs, &c.

That tea plantations will require manure sooner or later, there can be no doubt whatever, and the poorer the soil and the more forcing the climate, the more immediate necessity will there be for its application, hence the importance that planters should select those manures which are likely to prove practically the most economical. Judging from the letters I have already received in connection with this question of tea manuring, it would appear that Indian planters, as well as those in Ceylon, are beginning to recognize the future importance of really suitable fertilizers.

JOHN HUGHES, F.R.S.

A LOCAL SULPHURIC ACID FACTORY.

For some years past we have written very freely respecting the great advantages of a local factory for the extraction of the valuable alkaloids from cinchona bark, and how by selecting on the spot the best qualities, we might produce a febrifuge that would compete with that prepared by the best makers in Europe. The difficulties in the way seemed to us latterly to be considerable, in view of local depression and scarcity of capital; but we have printed several letters from a correspondent who has studied the subject, full of confidence in the success of the project. Whether such a factory would answer or not would, we are assured, depend chiefly upon the management rather than upon any question of local climate; and having regard to the course of the market there can be little doubt that the present practice of sending large quantities of bark at a considerable cost for freight into the home market is not likely to continue long, especially as the price of the pure sulphate of quinine has become so very much reduced during the past few years. There is, however, one indispensable preliminary before quinine can be extracted on a commercial scale in Ceylon. It is absolutely necessary that sulphuric acid, commonly called oil of vitriol, should be locally manufactured; for, the high freight of this article would be fatal to the profitable manufacture of quinine. And even, if hydrochloric (muriatic) acid should be found superior to sulphuric for quinine manufacture, still the latter acid is necessary to the manufacture of the former on the spot, such local manufacture being in either case deemed indispensable.

It is therefore quite time to consider seriously the establishment of a local factory for the manufacture of sulphuric acid, which shall be available not simply in the interests of cinchona but also for the manufacture of a cheap supply of aerated waters so largely required both for local consumption and for the supply of calling steamers of the different Companies. The one previous attempt to establish a local Acid factory failed, because in reality the project was not taken up by men having a practical knowledge of the business. At any rate it certainly did not fail because such a factory was not required—for in good hands the results would have been a decided success. So far, we have said nothing in reference to the value of acid for what was the main purpose in view ten years ago, namely, the manufacture of really cheap and useful manures for tea, cacao, cinchona and coffee plantations; but in this respect alone a ready supply of acid for dissolving bones—as well as for saturating fish manures and castor-cake with acid sulphate of lime so as to prevent these materials being eaten by grubs instead of nourishing the tree—is a matter of great local importance.

A gentleman who has by a recent mail communicated with us is in constant communication with Acid Factories at home, and he has taken the trouble to make some enquiries relative to the actual cost for a small factory, and in order to be able to give us reliable figures he has communicated with the authority who prepared the plans and specifications for a small Acid work recently erected in Barbados, West Indies, which has given most satisfactory results to the proprietor. We learn that a factory capable of producing 500 tons of sulphuric acid of specific gravity 1.560 would not cost more than £1,200 to be erected complete, and the plans and full particulars of construction could be obtained for the sum of £50 sterling, so that it is open

to any one in business in Colombo to calculate whether such a factory would prove remunerative or not. The daily cost for labour, we were told, would be very small: one man to look after the chambers by day and another by night, being really all that is required. Our authority says that a good man could be readily secured to put up the works if desired and see to the working for one year. The necessary sulphur could be obtained from Sicily, and the nitrate of soda either from Europe or Chili direct as most economical. The sulphur which is daily removed from the gas as an impurity might be utilized in Colombo for the manufacture of acid in the same way as it is employed in Europe—and the acid so made could be used in the subbers for removing the valuable ammonia compound.

So fully convinced is the gentleman who supplies this interesting practical information of the great use, indeed of the ultimate necessity, of an Acid Factory in Colombo, that provided Government would grant a monopoly for ten years, and the undertaking were taken up by good hands, he would be quite willing to invest two or three hundred pounds sterling himself in the establishment of a small Works on the most recent and economical principles. This offer of one-fourth of the capital from a gentleman who, though not unacquainted with Ceylon, has no personal stake in the island is a strong proof of the success which can be achieved in the establishment of a Sulphuric Acid Manufactory, and we commend the subject to the attention of the parties interested in local quinine preparation, and indeed to the Chairman and Committee of the Planters' Association as most interested of all in the question. We saw the other day that a Sulphuric Acid Factory in Japan was a success; and it is evident that the aid of the working chemist must be called in, in several directions, if our planting industries are to be maintained in a satisfactory and progressive condition. The degree of civilization of a country is said to be proportionate to its consumption of sulphuric acid. Ceylon has surely reached the stage when it can afford to manufacture its own article. The preparation of cinchona alkaloids and of artificial manures on a large scale and the aid of practical chemists in many ways to planters would inevitably follow. There can be no hesitation, therefore, in supporting a movement for the establishment of a Sulphuric Acid Factory; and if there is one direction more than another, in which we should be inclined to make an exception to our *Observer* editorial rule of holding no shares in local Companies, it would be in favour of an attempt to give our Planting Enterprise the benefit of a Chemical Works and Establishment on a scale such as is here described by our London authority.

DISYNTERY AND THE BELL OR WOODAPPLE FRUIT.—Two instances have lately come under our notice of planters who attribute their recovery from dysentery which had become almost chronic, to the use of the well-known "bael" or woodapple, a time-honored remedy, but one which apparently has been falling out of notice, seeing that in one case of a gentleman who has been for some years a sufferer, it was only very recently this remedy was mentioned to him. This is not our fault; for if planters consulted the Medical Hints for Planters published at this office, a copy of which used to be in every upcountry bungalow, they would find a small quantity of the quince apple (delisted or narmel) morning and evening, recommended when an attack was subdued in a dysenteric patient.

CEYLON TEA GARDENS.

From I. A. Rucker & Bancraft's first list of Ceylon Tea "Gardens" or Estates.

Annexed is a List of Ceylon Tea "Gardens," so far as our present information goes. For the benefit of those interested in the Planting, Shipment, or Importation of Ceylon Tea, we purpose adding to this List from time to time, so as to show the growth of Tea Cultivation in the Island. We take this opportunity of asking those friends who are aware of our long connection with Ceylon Produce, and our deep and sterling interest in the Prosperity of the Colony, to enable us to make these tables as full as possible, by sending for publication the names of any New Plantations that they become aware have been put under Tea, and if they will add estimates of the acreage present and prospective, we shall be able to give Planters and Importers valuable information as to possible extent of yield, course of markets, &c. &c. Roughly speaking, we may look for about 6,000,000 lb. from Ceylon during the twelve months commencing 1st October, last season's shipments having reached 3,800,000. From the greater number of the Gardens, whose names we append, we have not seen any samples as yet. Those plantations yielding more or less during the past season, the produce of which has passed under the hammer, are marked with an asterisk. The other names are those of Gardens or Estates, we understand are in course of cultivation of "The Leaf." We have to acknowledge our indebtedness to Messrs. A. M. & J. Ferguson, whose able and most comprehensive "Handbook" of 1883-4, we have laid under heavy contributions. Where marks are given we do not know the District or Plantation, and any information on this head would be gratefully received. It would be a great convenience to the trade if Planters would adopt Mr. Armstrong's suggestion, and simply mark the packages with the name of the Garden or Estate. We do not mean that it is any comfort to anyone to have to say "Gikiyankanda" instead of "D in a diamond" but at any rate the name of one Garden is not likely to be confounded with that of another, while for purposes of tracing sales and following country orders, marks are likely to confuse both Dealers and Brokers. When figures are subject to immediate correction and alteration by those to whom we address this very imperfect list, it would obviously be futile to give exact additions or to base any nice calculations on the results of our work. Suffice it to say that there were apparently some 43,000 acres set aside in 1883-84 for the cultivation of tea in Ceylon. To bring next season's (1885-86) shipments up to $\frac{1}{2}$ million pounds, we should only require 150 lb. from each acre. As many of our readers are aware, it is by no means unusual to get 500 to 800, and even in favourable circumstances 1,000 lb. of tea per acre, so it will be seen that *without* for the adding to the area of cultivation the acreage comprised in our list is capable of sending forward at 500 lb. per acre, at least 21,500,000 lb. of tea. Since Messrs. Ferguson's estimates were made, planting has been rapidly pushed forward, and private advices are to the effect that something like 70,000 acres are in cultivation. This would point to an ultimate export of from 50 to 65 million pounds. This, however, is not in the near future, and at present the data we have to go upon only warrant the assumption that the Ceylon tea business will increase with a rapidity that may early introduce a change in the standard of values of tea generally. It would be well to bear in mind that the great bulk of tea consumed is purchased from the Grocer's "2s cister," and that this means a Mincing Lane basis of not over 1s per lb. We are not of those who think China teas are to be ousted from this market. In fact it is quite conceivable that there might be even a partial reversal of public taste from the strong and pungent Indian tea in favour of the lighter and more delicate China. Should this come about Ceylon would hold their position in the consumption, being to our taste more like a blending of the better classes of Indian and China.

[It is a pity that our London friends should not have waited for our Directory list now printing.—Ed.]

PLANTING IN BURMA, AND WAR ON THE FRONTIER.

(From an ex-Ceylon Planter.)

THE WAR WITH BURMA—UPPER BURMA LIKE LOWER EGYPT—THE IRAWADDY—UPPER BURMA: ITS PEOPLE AND NATURAL WEALTH—COAL—GOLD AND RUBBER—WASTE LAND FIT FOR TROPICAL AGRICULTURE—LABOUR—EXPERIMENTAL CULTURES—MUNICIPALITY—THE ANNEXATION OF UPPER BURMA—MR. C. E. BERNARD.

Tavoy, British Burma, 6th Nov. 1885.

I am sending you a bulget of information by this mail for the T. A.—all the different experiments in new products and also silos and ensilage in all parts of the world.

War to the knife sure enough. The Indian soldiers have now arrived, and will be on the borders of Upper Burma by tomorrow and ready to strike. What a splendid country U. Burma is. When I first arrived in Burma, I took up a trip to within 30 miles of U. Burma. It reminds one of Lower Egypt 20 years ago. The magnificent Irrawaddy reminds you of the Nile, and the great expanse of land is exactly like the cultivated land in Egypt. The Irrawaddy at some places is several miles in width and the climate is a nice dry bracing one.

The natives of the country themselves seemed to be in good health, but, poor creatures, to see them huddled together like so many animals in their villages would make anyone sorry, and the small pieces of ground cultivated; in fact, the whole of this people's energy is lost to this fine country. By the time you get this letter the people will be freed from the tyrant-murderer, and we will be in Mandalay and we shall be in possession of one of the richest countries to England in the wide world. You will be saying: "Hold a bit." No, not one inch will I hold, but rattle on, and I am able to inform you that I have seen the trees growing with their roots entwined in pure carbonized coal, coal that burnt down to pure carbon almost. Now, can you tell me of a greater wealth to the energy of England than coal? Coal is one of the greatest energies of the world, and it has been predicted by experts that we have not coal in England to last more than forty years. In Burma there are whole forests growing on coal, with no mining required—only to go up a creek with your boats and fill them with pure carbonized coal. When I went up to U. Burma, I brought down with me a great lump of pure coal from "Cala Creek" and presented it to the Chief Commissioner, and you could see the roots entwined in the veins of coal. I also brought down a splendid specimen of petrified wood; I saw the stumps of trees turned into stone. Of course, there is gold in any quantity and ruby mines; but I look upon the coal in U. Burma as of more importance to England than all the other things put together.

Then there is the great expanse of "waste land" ready for the steam plough and grubber. There is a chance for those who may try their hand at wheat-farming and raising of stock. Buy a few thousand acres and import a few good bulls and stallions, also the best varieties of seeds of kinds, and a man is bound to get on.

The great ranges of hills are suitable for tea and coffee, cacao, cinchona, cardamoms, and in fact all tropical fruit, grapes and mulberries. Silk is now manufactured to a certain extent. There is also a field for the indigo plant, jute and fibres. I think I hear you say: "Oh, but where is your labour?" Mr. Editor, would you believe me when I now inform you that I am only paying six annas (about 37 cents) for able-bodied men, and they are coming now to Burma by the thousand monthly. The chetties of Madras have bought a

steamer, the "Madras," and she runs between Negapatam and Rangoon regularly, and also the B. I. S. N. Company and the A. C. C. 4,000 coolies arrived last month; when they come to Burma they seldom leave it now.

I am getting on very well, and now my success is an established fact. Coffee in perfect health, no leaf-disease, and I shall have a crop this coming year. Cacao doing well since I got up the shade. Tea growing nicely; also divi-divi and croton-oil trees. Liberian coffee simply splendid. Coffee now beginning to cover the ground and showing bud already. I have three acres of paddy and about five acres of maize (American maize). The paddy takes me up to the neck, a fine crop now showing seed. The maize is only just sown, it is a cold weather crop here. I am to sow a few acres in hemp, and am to put down about 20,000 betel-nuts, Tongoo variety, that fetches R40 per cwt. I have betel-nuts now growing first-rate; also *Bica Orelana*, oranges and limes, doorians and guavas. Plantains for shade, splendid plantains. Chestnuts grow well; also gamboge of two kinds. I have sown three maunds of best indigenous and hybrid tea seed; also six lb. of croton-oil trees sent from William of Henaratgoda. I am to put in more cacao; am only waiting for the seed. I am exceedingly well pleased with myself and am in excellent health. I am a brave Volunteer, have put in my 29 drills already. We are about 39 strong, a spirited little band, commanded by Lieut. Palmer and Capt. Duke; Duke is Commander-in-Chief, and we have sworn that we will defend our beloved Queen and country even to death.

I trust by the time you get this letter that Upper Burma may be annexed and that the well-deserving Chief Commissioner, Mr. Bernard, may be elected as Lieut.-Governor of British Burma, a better man could not be appointed; he is a regular go-ahead man, all energy and perseverance.

THE MACHINERY.

We would draw attention to an advertisement in another column to a new patent tea sifting and sorting machine, the invention of Mr. Mudge, a tea planter of long experience, it is styled the "Hinge and Lever," which is most appropriate as it carries with it an idea of its construction; we have seen specification and drawings of the machine, and, so far as we are able to judge from these, it appears to us to be a very good thing in every way, being simple in design and offering altogether many advantages. Not the least of its recommendations is the variety of ways it may be employed for sorting tea so as to suit individual taste or circumstances, for in consequence of it being a double row of trays, each two deep, with removable sieves, it becomes apparent that any size mesh of netting may be placed and used as desired, so that no hard-and-fast line assortment is laid down. One row used in conjunction with the other it is capable of giving five grades of tea at one and the same time or the rough bulk tea fed at upper tray on either side, it will give three classes of the same from each. The trays, which are three-sided, work on a level, having all their four sides shut in. This the patentee claims will ensure a thorough sieving of each class of tea, and we should be inclined to think so too. When the trays have become fairly full of well assorted teas, they are easily and rapidly discharged of their contents by the very simple operation of unhooking a lever, which causes them to fall to a slant, being secured on hinges (inside a suspended frame) at the back end, and the front ends drop in front, and this is so ingeniously contrived that the lever does not go to and fro with the quick reciprocating motion of the sifter at work, so that it does not become necessary, or even desirable to throw the belt on to the loose pulley and so stop the machine for this purpose. There is ample space between the trays for cleaning the netting, and the

tea on each and all of the sieves is open to manipulation, neither for feeding, discharging, or cleaning the netting need the machine be stopped. The "Hinge and Lever" sorter is designed to do a large amount of work per diem and is well adapted for big gardens. We believe it will do its work well and that without having first to pass the tea through a breaking machine, as a man is able to stand alongside, crossing the tea on the trays as much, or as little, as need be. We understand that arrangements have been made with a well known firm of engineers to make these machines, and are also informed that one will shortly be on view in Calcutta. Planters and all others interested in the manufacture of tea having the opportunity of seeing it would do well not to lose the chance of doing so.

There are sifters with the trays on a fixed incline, and probably sifters also with the trays or sieves that work on a level, but a machine such as Mr. Mudge's, with the trays working horizontally combining the power to bring them to a slant at pleasure for purpose of discharge is quite a new idea, and a capital one. The price, all things considered, is very moderate. Messrs. Mitchell, Reid & Co., are the Calcutta Agents.

With regard to an advertisement which appears on another page a correspondent from Ceylon writes us:—"I have had the pleasure of seeing another of Mr. W. Jackson's new machines at work, namely his Venetian Dryer. Like many others in the island I have hitherto had implicit faith in the Siroccos, believing that in simplicity and efficiency of working they could hardly be surpassed, but I now say the Venetian certainly carries the palm. It would do you good to see how well this neat little machine goes through its work. The cooler pulls forward a drawer-shaped sort of feeding and drying surface and on this he spreads a charge of leaf and pushes the drawer back again, and waits for about 2½ minutes (during which he can stoke or take away the dry tea). Then he begins near the bottom of the machine by pulling a handle which, by an ingenious arrangement, working similar to the action of the venetian blind of a window, the drying surface is opened up, and the dry tea is delivered down into a trolley, which, when full, is withdrawn just like a charge of leaf from the well-known Excelsior Roller. Having shut this handle he moves the one next above it, causing the tea nearly dry to descend on to the surface just emptied, and in succession he moves the next one higher up, and so on till the charge he put in 2½ minutes before is delivered down one surface, when a fresh one is inserted. All this is done in much less time than it takes me to describe it, and the perfect way the tea is turned over on these surfaces, can only be well understood by those who have seen it at work. A No. 3 Sirocco stands idle beside this Venetian, and, if I mistake not, is likely to remain so. Mr. Jackson has been long in coming forward with his driers, but the opinion here is, he has at last made a leap past everybody else."—H. J. C. Mail.

Mesmoons. A correspondent asks:—"Could you tell me if there is any easy way of distinguishing edible mushrooms from the poisonous ones? I have mushroom beds where the mushrooms have just started, and, though it seems pretty certain they are the real ones, yet it is just as well to be perfectly certain." The article "Mushroom" in the *Encyclopedia Britannica* gives details regarding the differences between edible and poisonous mushrooms, which are too lengthy for us to quote, but the following may help our correspondent:—

To summarize the characters of a true mushroom:—it grows only in pastures; it is of small size, dry, and with unchangeable flesh; the cap has a frill; the gills are free from the stem, the spores brown-black or deep purple-black in colour, and the stem solid or slightly pithy. When all these characters are taken together no other mushroom like fungus—and nearly a thousand species grow in Britain—can be confounded with it. (See page 472.)

TEA AND COFFEE IN CEYLON.

The utmost activity continues to prevail among our tea-planters, and machinists are very busy over the needful preparing machinery for the tea factories, in all its varied forms of rollers, driers, withers, sifters, &c. Planters whose gardens are just coming into bearing are glad to be able to sell their leaf at remunerative prices to their more advanced neighbours, and we hear that as much as 12 cents per lb. is being paid in Maskeliya for newly plucked leaf, at a rate equal to 9d a lb. for the dry leaf. But, after all, the ambition of estate proprietors is each to have his own set of machinery and factory as soon as possible. This may be all right where there is a considerable area under tea, but the convenience of central well-equipped factories where their leaf is bought (or even prepared on account) must be more and more appreciated by smaller gardens. One proposal mooted which deserves serious consideration from the owners of tea-gardens around Kandy is to attach a tea-factory to the well-known Bogambra Mills of Messrs. John Walker & Co. where there is plenty of power in water and steam to drive the requisite machinery. By-and-by we may expect to have similar favourable central positions in the lowcountry taken advantage of, for the benefit more particularly of native growers of tea.

There is another department in which a renewal of activity may be anticipated with progress in tea, namely in the import and local preparation of suitable manures. And as the foundation for any such work and indeed for many more useful operations (more especially the establishment of a local manufactory of cinchona alkaloids if not of quinine itself) we have had a proposal laid before our readers by a London correspondent of practical experience for the establishment of a Sulphuric Acid Manufactory in Colombo. A pattern one has already been set a-going with success in the little island of Barbados in the West Indies, and there is abundance of room for one in Ceylon, so that the project is likely to take shape ere long and directly and indirectly to afford the aid of the chemist to the planting community.

That new life is springing up in the community is evidenced by the sales of tea property and forest-land—the latter by private parties at Rs 30 per acre, while a share in the Kandaloya tea estate has been disposed of for £7,500 cash. The tea-plant in Ceylon certainly assumes old coffee plants by its ready adaptation to climate and soil: a report on tea at an altitude of from 6,000 to 6,800 feet in Udapussellawa stated that the growth and flushing were almost a good as in the lowcountry! From sea-level to the top of Pidurutalagala even, the tea plant in its several varieties will apparently flourish. The hardy variety of the Assam "Indigenous" has given very good results at an elevation of from 2,000 to 3,000 feet in Ceylon where there is shelter, abundance of rainfall and fairly good soil. There are some, too who have planted "Indigenes" lower down who are satisfied; but, as a rule, those who have tried or watched both, much prefer a good Hybrid as the hardier and generally more satisfactory plant. This opinion an old Assam planter and practical planter passing through Colombo the other day fully endorsed to us. The "Indigenes," which came from R129 upwards on the estate in Assam, is too delicate a plant in our climate at a rule, while the kind which succeeds is that sold in Colombo at from

R70 to R80 under the name of 'Indigenous,' but which is probably more a high-class Hybrid.

From tea we may turn for a moment to coffee to mention, that, while, taking the country as a whole and especially the old districts, there is scarcely any crop to gather, yet in some plantations we hear of wonderfully good pickings which is the rule in the fine Udapussellawa district where also the promise is very favourable. Over 270 acres of comparatively young coffee on Peacock, Pussellawa, Mr. Wm. Smith who has recently gone there from Dimbula, has got such a crop as has kept him as busy as in the palmey crop days of the years ago. Pulping by lantern light to a late hour, picking against time to save crop from dropping, and even gathering coffee from under the trees are all novel experiences of late years, and yet we cannot help hoping that where good coffee is kept up in cultivation and surrounded with other products, old diseased trees being pulled out, there may be profitable crops gathered for many years to come. In the midst of his hurry in crop, Mr. Wm. Smith found the greatest possible help and satisfaction in Mr. Westland's recent invention, the sieve-plate for preventing good coffee beans dropping among the rubbish from the pulper. It is simply perfect as a labour-saver and ought to have made the fortune of the inventor most simple as it is had he only appeared with it 20 or 30 years ago in Ceylon. As it is, Mr. Westland ought to be able to get "royalty" from Java, Brazil and Central American planters for a contrivance which cannot help being greatly appreciated wherever coffee is "pulped."

PHYLOXERA LAWS.—The kingdom of Greece is the last which has found it imperative in the interests of the vineyard culture—an important one indeed for the miniature monarchy—to forbid all trade with North and South America, Australia, Africa, the coast of Asia Minor, and the whole of Europe, with the exception of Holland, Belgium, Denmark, and the Scandinavian kingdom, in trees and plants of every kind, fresh fruits and their foliage, fruit juice, in natural or mixed state; flowering bulbs, and fresh fleshy roots of every description. Vine stakes which have been used in vineyards; and, lastly, hay in bundles. The regulation dates from July 5, 1885. As usual the restrictions are for the most part absurd and unnecessary.—*Gardener's Chronicle*.

LOCAL SALES OF CINCHONA BARK.—In a letter from Mr. M. A. Lawton, Director of Government Cinchona Plantation, Parks and Gardens, Nilgiris, to the Government, reporting the result of the auction sale of Cinchona bark on behalf of Government, on the 5th October, he says: "It will be observed that the Root Crown bark sold very well (R125 against R112 at the auction of September 1885) but that the price realized for the Renewed and Mossed Crown viz., R121 and R122, respectively, is somewhat below that obtained at the February and March sales, viz., R130 and R128. This is due to the comparatively low price which the Nativatum Mossed Crown fetched (R113) compared with that of Dolabertia (R132). This latter has sold better than any of those in February or March. The rate per pound, however, (1s 11½d) compares favorably with the last London quotation for the same kind of bark (3s 6d), that is after making a due allowance for freight, insurance and other charges; and on the whole, I think, that the results of the sale may be considered fairly satisfactory. Messrs. Oake & Co. mention that a Bombay Firm of Chemists was among the purchasers, while heretofore, houses of agency in Madras have been the only purchasers. This is an evident sign that competition for the bark in Madras is on the increase.—*Madras Mail*.

DIBRUGARH—Considerable dissatisfaction is very generally expressed at the remarks of the Chief Commissioner on the official report by our divisional officer in which he averaged the yield per acre of bearing plant throughout the district to be over four hundred pounds. This amount that revolving diktary regards as fabulous. He is not perhaps aware that this large average is decided by the enormous outturn of the large Upper Sadiya road gardens. Roughly speaking there are here about six thousand acres of mature tea, between the Chota Hajianj and Dholla. Of this, two thousand five hundred yield at the rate of no less than eight hundred pounds per acre, and the remainder, with the exception of two insignificant gardens—Dholla and Mesai—average between six hundred and thirty and seven hundred and fifty. The two gardens which promise to lead the list this year are Besakopie (Doom-Dooma) and Hiliha (R. G. S. estates). Up to date their outturn has been at the rate of eight maunds per acre, and they hope to make eleven before they have done. The manager of Talup, who used to show us all the way, has decided to stop at ten maunds per acre, and go in for quality more than he has done. To give those of your readers, who do not know our district, an idea what work on these gardens means, when the manufacturing season is at its height, I may mention that most of our tea here is made in July, August and September, and that Talup and Hiliha are a thousand acres each and Besakopie nearly six hundred.—*Indian Planter's Gazette*.

CEYLONESE AGRICULTURAL STUDENTS—It may interest Mr. Green and other friends of agriculture to know that a Ceylonese is now prosecuting his studies at Cirencester. In a private letter he writes:—"Though I was a week late in entering, I have almost got into the swing of work. It is all very novel. The theoretical part, in which we have lectures, is of course altogether scientific. It includes geology, physics, chemistry, agriculture, Veterinary and book-keeping. Then there is a farm and hospital class, which is novel in the extreme. The farm class is a "locomotive one," and it is a thing one has to get used to, to walk 2 or 3 miles over fields through slushy soil (leather gaiters are of course indispensable) to examine crops and soils and animals, I doubt not this will be pleasant in other weather, but it is horribly cold now. We have about 180 students, from nearly every part of the world—even from Burmah—but the bulk are sons of English farmers. We have even farmers themselves of 30 and 40 who came down to attend the lectures. The vacation commences about the 15th December and lasts six weeks at least, possibly eight; and we cannot remain at Cirencester at all. It will make three weeks next Saturday that I have been here. I stay in town in a licensed house, the College being situated about a mile or more from the town. I am up at 7 every morning, and after breakfast start out for the College where work begins at 9 sharp. Mondays and Tuesdays keep me there till 4, and then I am obliged to lunch at College, but on other days I am back for dinner. The theoretical work takes us 2 or 3 hours, and there is one practical class each day in analysis of soils, plan-drawing, and the farm class—the latter in the open air where we discuss crops, soils, manures, dairies, sheep, beasts of the field generally, and watch the different processes in the different departments. The College is beautifully situated, and the country about is very lovely just at this time. We have a delightful park, the grounds of the Earl of Bathurst, open to the public, through which I return from College. It extends seven miles. The central road is lined on either side with regularly planted elms, and the view of these stretching as far as the eye could reach, with their various shades of green, yellow, brown and red, is very pretty. Cirencester is a neat little town, the only exciting times being the hunting season, the Fairs, and the "Mop" when the hiring of farm-labourers takes place. There has been a good deal of excitement lately over the election. This is a fearfully Conservative old place, (for all it is, since you will be shown a Roman arch in every kitchen) and when a liberal candidate called Winterbotham came with Mr. Broadhurst, M.

P., to address us at the Corn Hall—our great public building!—there was a free fight and a smash up." We trust the writer of the above will prosecute his studies so as to prove an acquisition to the island on his return, whether to put into practice on his own land the knowledge he has acquired, or to be the head of an enlarged and flourishing Agricultural College.—"Examiner."

INDIAN PLOUGHING.—The improvements introduced by civilisation in every industry and every occupation of life seem to reach agriculture last of all. This is so in England, and in Europe and also in India, as we read in an interesting paper on "Punjab Ploughing" by Mr. Kennedy in the current number of the *Calcutta Review*. "Looking at the actual state of tillage in India," says Mr. Kennedy, "a scientific agriculturist will be perhaps, inclined to think that the Indian peasant has made but little advance upon the primitive tillage which yokes a bullock to the branch of a tree for a plough and a thorn bush for a harrow, and with these rude appliances roughly scratches and harrows the soil. He may be inclined to think that under British rule, agriculture alone of all the arts has not progressed, and still remains in the state it was before European skill and energy were brought to bear upon the industries of the East." But if we examine more closely into the subject and compare the efforts of the agriculturist with those of his ancestors, there may be found signs that the influence of scientific improvements has not been entirely unfelt. Too much must not be expected. In Europe, and especially in England, labour is dear, and every invention of machinery which can perform the work of men or horses, and every extension of the application of steam to drive such machinery proves effectual from the cheapness of fuel and the dearth of labour. But "in India labour is still cheap, and labour-saving machines have not hitherto proved a success. Machines, on the other hand, to increase the agricultural output, such as the India Sugar Mill, oil-expressing machines, etc., have probably a great future before them. But until we thoroughly understand the conditions under which native husbandry is carried on, the merits or demerits of the various operations of tillage the farmer practises, and of the various implements and tools he uses, and thoroughly understand the general principles which guide his practice—and such knowledge is still in its infancy—it would be unsafe to too rashly condemn his methods, or to ask him to forego the use of appliances which he understands, and adopt others of which he is ignorant, and the advantages of which are still problematical." And Mr. Kennedy does a service in pointing out that improvements which work well in England may not do so in India and ought not in such cases to be forced upon the acceptance of the agriculturist, who is almost of necessity conservative in his habits and of a low intellectual development. An instance is quoted from the Punjab Famine Report, which is very instructive. Mr. Hume, the writer, says:—"I remember once seeing a practical English ploughman plough up a piece of land on the English system, that is, throwing the soil inland; the operation was beautifully performed, the crop germinated well, but when the time came for it to be watered, it naturally preferred to remain in the furrows between the land; the result was, the crop came to nothing. This system of ploughing in lands in England is employed on purpose to cause a surface drainage: in the Punjab we do all we can to keep moisture in the soil."—*Times of India*.

Correspondence.

To the Editor of the "Ceylon Observer."

TEA IN BADULLA.

Dotland Estate, Badulla, 21st Nov. 1885.

DEAR SIR,—By this day's tappal I send you samples of tea made here from two-year old trees, rolled by Prater's new tea roller, and fired on estate.

If you will give me an opinion on it, as to whether the same would find a market in Colombo, I would esteem it a favor. I have already some 15 acre planted, but before extending the acreage would like to arrive at what price this class of tea is likely to be worth. Being so heavily hand-capped in Badulla in the way of transport and fuel likewise will be a serious item to cost of production (especially should we have to use coal or coke for our machinery) compared to the more favored districts south of Nuwara Eliya, where the principal estates (giving large returns) are very near the Government cart-road or alongside of a railway station.

The present season is and has been all one could wish for planting and a large acreage has been put in with many thousands of cinchona.

Coffee is looking very well, and very little leaf-disease to be seen, but no doubt it is there, but nothing like in the form it was two years back.—I am, dear sir, yours truly, T. J. E. JOHNSON.

The tea is certainly marketable and very good in make for first samples.—Ed.

FLORAL:

THE HORSE-TAIL CREEPER, PORANA VOLUBILIS, BURM., AND THE GOAT-FOOT IPOMOEA.

DEAR SIR,—In my notes on "Hints on Gardening specially adapted for Ceylon, by W. Caneron," which appeared in your Directory for 1863, pp. 205-221, I made the following note at p. 212 in reference to the Convolvulus family:—"A member of this order called the horse-tail creeper, *Porana rotundifolia*, sent to me by Mr. Dyke from Jaffna some time ago is now, Dec. 1862, in full flower in the Fort Garden, and with its hundreds of small white flowers which hang down in festoons, in the shape of horse-tails, is a fine plant and will soon be a great acquisition for trellises in Colombo"; and the magnificent sight of this plant in full flower all over Colombo during the last few days confirms the truthfulness of my assertion made 22 years ago.

The addition of this splendid creeper to others now in Colombo deserves a few notes respecting its introduction, and others which may be of interest to the readers of the *Ceylon Observer* and *Tropical Agriculturist*.

When passing through Jaffna to or from Madras in 1849, I saw this plant for the first time in full flower in the garden of the late Mr. Minor of the American Mission at Manipalay, and it was then called the Pulney or horse-tail creeper as it was brought by one of the missionaries from the Pulney hills in the Madras districts, Southern India. Cuttings of it which I got from Mr. Minor then failed to grow. In 1859 Government very kindly gave me a free passage in the steamer "Pearl," then bound to inspect the Pearl Banks off Arippa, with Mr. Vauz, Inspector of the Banks, and Mr. Dyke, Government Agent of Jaffna, as a passenger, Captain Donnan in command. The "Pearl" set out direct to Jaffna to land Mr. Dyke, and then came back to the Pearl Bank, which were inspected and surveyed, and plans made of them. On our return to Colombo

the "Pearl" encountered a cyclone in the Gulf of Manar, and my belief is that we passed through the centre of it; an account of this would be interesting, and Captain Donnan has no doubt correct notes of it, but suffice it to say that during four voyages round the Cape and three by the overland route I never encountered such a storm as went through on that occasion. We did not remain long enough at Jaffna to enable us to get another supply of the horse-tail creeper but the late Mr. Dyke promised to send me some rooted plants, and two of these in separate flowerpots came shortly afterwards, but the plants were eaten down to the surface of the soil by goats which were on board the vessel that brought the flowers. On examination, however, it was found that the plants were still alive, and one of them was planted by me about 1860 in the centre of what was then called the Fort Garden, the space now bounded on four sides by the Government Offices, St. Peter's Church, the Grand Oriental Hotel, and the Scotch Church, &c. and from this plant all those now growing in Colombo are offshoots. It appears from Moon's Cat. p. 13, that this plant and another, *P. paniculata*, were introduced into Ceylon before 1824, and I believe these are still growing in the Royal Gardens at Peradeniya, but they do not flower so well there as in the low hot part of the island, and no attempt has been made that I am aware of to cultivate them until those from Jaffna were brought to Colombo as stated above.

The genus *Porana* (probably *porona*, to extend, or journey, from the rambling branches) was established by N. L. Burman (son of J. Burman, author of the *Thesaurus Zeylanicus*) in his "Flora Indica" in 1768, the present plant being the type of the genus. It is described on p. 51 and figured in table 21*, figure 1, but universally quoted as tab. 21 f. 1 which is an error, as there are two tables, viz., 21 and 21*.

The above notes were written exactly this time last year, and the free flowering of the horse-tail creeper now makes them as applicable as they were then. These flowers in many respects remind one of the hawthorn or may flowers of old England, and if "a thing of beauty is a joy for ever" surely the "horse-tail creeper," now in flower all over Colombo, is a joy to the lovers of flowers of many lands.—Yours faithfully, W. F.

P.S.—And this reminds me that another plant with an appropriate common English name, the Goat-foot Ipomoea is now in full flower, and remarkable for its large purple-colored flowers, and two-lobed leaves resembling a goat's foot, close to the Fort of Colombo. Some years ago the seashore from the Fort to Mount Lavinia was lined with this beautiful plant, patches of which occupied the roadside on the Galle Face parade ground, the branches of those on the shore spreading till they were dashed back by the waves, thus proving that it is one of the best sand binding plants in Ceylon. The plant is such a favorite as food for rabbits that the owner of these, almost entirely rooted out the Goat-foot Ipomoea in this place with the exception of some enclosed in the compound of Aloe Avenue, but even here it is an eternal struggle to keep the plant from being taken. Provisions having been put on the Superintendent of Works of the Colombo Municipality to plant some ornamental trees, in the triangular piece of ground in front of the police station on Galle Face, he had some certainties of this plant removed from the bed of the Kalmi river, which were planted here and along the seashore at Galle Face, at a beginning, and before the last rain he took the liberty to plant the open

space between Norris Road and the breakwater railway, opposite to the guard-room, without asking for or receiving the consent of the Brigade-Major, and if that functionary will have the patience to wait a short time, he will find a display of these large purple flowers where erst the grass-cutters constantly cut up the sward, and whose occupation will soon be gone here if the goat-foot *Ipomoea* is allowed to remain. This plant used to be the very familiar *Ipomoea pes-caprae* of botanists, but it was first described as the *I. biloba* by Popskal in his "Flora of Egypt and Arabia," and this name now takes precedence of almost half-a-dozen others, some of which, such as *Ipomoea maritima*, are equally applicable to it, which surrounds the earth within the tropics and some places a little beyond them as a seashore plant.

May I express a hope that the police will protect these plants from destruction.

W. F.

THE AFRICAN OIL-PALM IN CEYLON. 26th November 1885.

DEAR SIR,—There are a number of African oil-palms that were remarkably healthy and have grown with apparently the greatest luxuriance here, though in habit almost more resembling a cardamom-stool than a tree—the blossoms forming at the foot from the ground upwards. These were planted about four years ago, and with a good show of nuts at present, as far as yield goes, seem to promise success for the cultivation with little or no trouble, or heavy expense. If not going over old ground, can you or any of your readers kindly give any information, as to when the plant may be supposed to be in full bearing, the correct distance to plant, the yield and gross return per tree per acre that is considered fair, what has to be set against this for crop expenses, and how the nuts are collected, &c.?

If the tree is as a heavy bearer as the coconut and the oil as valuable, from what I can judge of the appearance of the trees on Udagama estate next this, it seems to me as an industry it promises well, and worth collecting data. This is what struck me on walking through them lately.

UDAGAMA.

A CURIOUS CATERPILLAR.

"Lodge Harmony," Bambalapitiya, 26th Nov. 1885.

DEAR SIR,—I beg to forward under separate cover a caterpillar found by me on a croton plant. Several of my friends have seen it and showed great delight at its beauty, but no one could tell me the name or the order to which it belongs in the insect family. Will you therefore be good enough to forward the caterpillar to your natural history referee and obtain full particulars? You will please observe with what fineness the feet are formed and the very pretty moss covering all over them.—Yours faithfully,

DARLEY ALTENDORFF.

Our entomological referee writes:—"The larva of a butterfly, *Adolus casanta*, Moore, common about mango and cashew trees. Has a sharp rapid flight, settling on the ground and on leaves of trees with its wings open. The male is a glossy blackish brown on the upper side, the female chocolate brown with a white discal band on the upper wing; underside of both sexes ochreous gray. The larva feeds on mango. The laterally projecting finely branched spines, of which there are ten pairs, are not feet, and are of no assistance in progression. I should say it probably dropped or was blown from a mango tree on to the croton plant on which it was found."—E.S.]

HOW TO TEST MUSHROOMS.

Kandy, 1st Dec. 1885.

DEAR SIR,—The simplest and surest way of ascertaining if the mushrooms be edible, is to put a silver spoon in the saucepan or pan with them while they are cooking; should the spoon turn colour, beware of the fungus in your pan; should it retain its colour you may be sure your mushrooms are good.—Yours faithfully,

E. N.

THE "WOODAPPLE" AND DYSENTERY.—A writer in the local "Examiner," with a wondrous assumption of superior knowledge, is anxious to correct the *Observer* as to the value of the "woodapple" in cases of dysentery. The position taken up is that by the popular term "woodapple" applied to two fruits, alike only in having a hard shell, the acid "Indian quince," *Feronia elephantum*, would be understood and not *Aegle Marmelos*, the *bael* of India, *beli* of Ceylon. The latter is immensely more common than the former, and is the fruit any Englishman would understand by the term "woodapple." Its curative properties are due to the principle of opium which its mucilaginous pulp contains. In cases where the pulp may be deemed too coarse, it is made into a strained jelly. The acid "woodapple" may be a favourite with people of this country, but, we believe, not one Englishman in a hundred has ever tasted it,—certainly not a second time. Its odour is generally sufficient. As to the *beli* tree said to grow in swamps, we have not the remotest idea of what the "wondrous wise" writer meant. Here, however, is what a competent authority says in the *Treasury of Botany* of both trees:—

Aegle. The name of a genus of plants belonging to the Orange family (*Aurantaceae*). The fruit known in India as the *Bhel* fruit, is the product of *A. Marmelos*. In appearance it is much like the orange. The thick rind of the unripe fruit possesses astringent properties on which account it is used in India in cases of dysentery and diarrhoea. The ripe fruit has an exquisite flavour and perfume. Not only the fruit, but other portions of the plant are used for medicinal purposes; and a yellow dye is prepared from the rind of the fruit. The genus is distinguished by its numerous disunited stamens from the Orange (*Citrus*), to which, in other particulars, it is closely allied.

Feronia. The Wood-apple or Elephant-apple tree of India, *F. elephantum*, is the only species of this genus of *Aurantaceae*. It is common throughout India, Burmah, Ceylon, and Java, and forms a large tree, yielding a hard, heavy wood, of great strength but not durable. When wounded, there flows from it a transparent gum, which is mixed with other gums and sent to this country under the name of East India Gum Arabic. The tree has pinnate leaves composed of shining stalkless leaflets, and the flowers are arranged in racemes containing a mixture of male, female, and perfect blossoms; these have a flat five-toothed calyx, five (occasionally four or six) white spreading petals, ten stamens and five-celled ovary. The fruit, which is about the size of an apple, has a very hard, rough, woody rind, and contains a pulpy flesh with numerous seeds imbedded in it. This pulp is eatable, and like that of the Bengal quince, which is the fruit of a closely allied tree, it exerts a beneficial action in cases of dysentery and diarrhoea; a jelly resembling black currant jelly is also prepared from it. The leaves have an odour like that of anise, and the native Indian doctors employ them as a stomachic and carminative.

BUCHU-PAIBA,

Quick, complete cure, all annoying Kidney, Bladder and Urinary Diseases. Druggists.

W. E. Smith & Co., Madras, Sole Agents.

THE COLONY OF NATAL.

TO THE EDITOR OF THE "AUSTRALASIAN."

Sir,—Mr. Litton complains of my strictures being uncalled for. I respectfully ask Mr. Litton for an explicit reply to the following questions:—

Second.—Have you ever drank a cup of coffee made from Natal-grown berries? If so, how does it compare with the Java or Ceylon article?

Third.—Can you certify to the fact that a single bag of Natal-grown coffee, or 20 lb. weight collectively of nutmegs, mace, cloves, cinnamon, cassia or pimento, also the product of that colony, has been at any time exported thence?—P. L.

SUGAR FROM THE DATE PALM.

TO THE EDITOR OF THE "AUSTRALASIAN."

Sir,—I was most amused by a paragraph in the scientific column of your paper, mentioning as a new discovery that sugar was to be obtained from the date palm.

It is now quite forty-three years since I, then a lad studying engineering, was gaining practical experience and at the same time acting as inspector of works on a large sugar factory in course of erection in the Jessore Zillah in Lower Bengal, during which time I also learned something of sugar work, and I can safely say that most of the sugar made in that part of Jessore and adjoining zillahs was from the date palm, the sugar being quite equal to cane sugar, the only objection to the use of palm-juice being that the molasses was at that time considered unfit for distillation, therefore cane was preferred as it gave a better return.

For how many hundreds of years the date-sugar industry of Lower Bengal had been in existence, I being, as I said, a lad, never thought of inquiring; I only know that it was no novelty then, so far as my memory serves.—I am, &c., Old Quoi Hy.

COFFEE LEAF DISEASE.

TO THE EDITOR OF THE "MADRAS MAIL."

Sir,—With reference to your article on *Hemileia vastatrix*, let me say that the various members of the vegetable kingdom—like those of the animal kingdom—are, in a minor degree of course, endowed by nature with certain functions, upon the due exercise of which the health and (eventually) the life of plants depend. So long as (what man chooses to term) nature holds the reins, these functions will ever be exercised in their proper order and degree. When man, however, steps in and—for the furtherance of some special purpose—takes upon himself to control or arrest any one of these functions, he thereby runs the risk of ultimately causing great mischief to the health of the plant unless he possesses a most thorough, intimate acquaintance with all the laws of plant life.

Suppose a man, in the exercise of his own personal functions, devotes his entire energy to the exclusive exercise of (say) the function of brain power. Unless that man be careful to preserve a balance between this and his other functions, Nature will sooner or later remonstrate, and, if the remonstrance be unheeded, will directly interfere to prevent such abuse, and to restore the deranged balance of functional energy. This intervention will probably be manifested in the form of disease (in the case in question of mental disease probably); and that man will continue prostrated thereby until the disturbed balance of functional energies be restored to their normal state. Inspired truth teaches us that if one member of our body suffers all our members suffer with it. In like manner, if one function suffer from abuse or excessive exercise, all the functions will suffer because Nature's even balance will be upset. One of the main functions of plant life is that of reproducing its kind, and this function the coffee-bush, with its clusters of bright berries, performs very freely at Nature's own command. But man comes along, and

virtually says to the unfortunate coffee bush, "Let all your functions be held in abeyance, as far as possible, to the furtherance of the utmost possible exercise of your function of seed-bearing, and to that end off with all that redundant foliage which, if retained, would, whilst tending to preserve the balance of the normal exercise of all your healthy functions greatly curtail my bumper crops! Nature is, on the whole, very patient and long-suffering under abuse, but sooner or later she is bound to protest. At last Nature—addressing those who perhaps have not ears to hear her silent warning—indicates that the function of seed-bearing having been forced to the highest possible pitch, to the exclusion more or less of the exercise of other functions, man must either allow the exhausted tree to revert to its normal condition, and rest, or otherwise Nature will be under the necessity of suspending the functions of the tree (which have all suffered) and compel an enforced period of rest until the balance of functional energies be restored to the normal condition. Hence leaf disease and red spider, which are but symptoms of the disease of functional derangement and exhaustion. You, sir, rightly remark that coffee grown under shade enjoyed immunity from leaf disease. And why? Because under shade the coffee bush preserves its functions in a normal condition for a longer period of time, its environment being unfavourable to excessive forcing on any one function. When I hear of Ceylon tea estates yielding 1,000 lb. of tea per acre, I know that means a steady advance towards functional exhaustion and derangement, and that by and bye red spider will denote the arresting of the functions of the exhausted tea bushes. NOVICE.

THE USES OF COTTON-SEED IN AMERICA.

It is well known that Cotton-seed is, as an article of commerce, a comparatively modern introduction. Not many years since the seed, which was produced in such abundance in the Cotton plantations of America was, not only a waste product, but one which the growers scarcely knew what to do with. Of late years the oil has been expressed in continually increasing quantities, and applied to a variety of useful purposes, not the least important of which is its substitution for Olive oil, for Cotton-seed is now purified so carefully that the result is a clear bright limpid oil, equal in appearance if not in taste to the best oil obtained from Olives. Mills for the expression of Cotton-seed oil have been erected in America in increasing numbers of late years. In 1870 there were only twenty-six mills, and in 1880 forty-seven, six of them in New Orleans. At the present time these mills are scattered throughout the South in all the important Cotton centres on the rivers and on the railways, and number 108 in all. The average yield of seed is about 3½ lb. to every pound of lint. The amount of seed annually crushed in the United States averages about 420,000 tons, a ton of Cotton-seed yields 35 gals. of crude oil, 22 lb. of cotton, 750 lb. of cake of average value of 19 dols., making the total value of the Cotton-seed product of the South 8,000,000 dols., or 3 per cent. of that of the Cotton crop.

Cotton-seed cake—the residue of the seed after the expression of the oil—is used chiefly for stock feeding and for fertilizing purposes for this purpose; it is generally ground into a meal known as Cotton-seed meal. Most of that used for feeding purposes is shipped to this country, where it is extensively used for fattening stock; it is also said to be a splendid food for cows, causing a rich and plentiful flow of milk. The cake is shipped from America in sacks containing 200 lb. each; it is of a rich golden colour when fresh, and has a sweet, nutty, oleaginous taste. It is a very valuable fertilizer for a large number of plants.

The oil from the Cotton seeds has been applied to a variety of uses in America, such as the manufacture of the finer kinds of soap, also for mixing with paint, and for lubricating purposes; it, however,

dries too slowly to be valuable for the first purpose, and is too gummy or sticky for the second. Another product is glycerine, but this manufacture has been but little attended to as yet. One gallon of crude oil will make 3½ lb. of glycerine. Its chief use, as before stated, is as a substitute for Olive oil, and the following extract will show the state of perfection in which the oil is now prepared:—"It is nearly impossible to detect good Cotton-seed oil from the best brands of Olive oil by taste, smell, or any other process; this the Olive growers of Italy have been unwillingly compelled to acknowledge. An instrument called the oleometer has been invented to distinguish between the two oils by means of their different specific gravity; but this is confessedly an uncertain and unreliable test."

The hulls or shells of the seed are used as fuel to drive the oil-expressing machinery, and containing some oil, they burn well and produce a good heat, and are used exclusively without any other fuel. It was recently stated in America that before long Cotton-seed would yield all the Grape sugar demanded by the commerce of the world. It is estimated that, "if all the seed produced was used and crushed this little article, once despised and deemed of no value, would be worth between 80,000,000 and 100,000,000 dol. annually."—*Gardener's Chronicle.*

WILD MANGOES.

The Jungli An, which is the original stock of all the fine Mangoes, is not often met with in its native habitat, and less frequently in fruit. I have just received a few fine specimens of several varieties of Jungli Mangoes. From the fruits it appears they vary quite as much as our cultivated ones; and as to shape, they are the exact counterpart in miniature of many of our best varieties. My specimens came from the Kangra Valley, and were collected by a gentleman much interested in the fruit. I once saw the true Jungli Mango in the Dooars, and again afterwards growing at an elevation of about 2,000 feet in Sikkim. It is very unlike the cultivated sort, having generally a straight trunk, whitish smooth bark, and thin leaves, forming a fine round-headed tree. The fruit rarely weighs 2 oz., often only 1 oz. The common country Mango, called "Deju," or "Desi," in Tirhoot, is really an inferior kind of cultivated Mango, and not the proper wild Mango of the forests.

Wild Mangoes are found from India through Malay to Manila, and some of the Pacific islands, and it is not really known if there is more than one species. The wild and cultivated sorts are so widely different in shape of fruit that they could almost be called distinct species, but every intermediate connecting stage may be found to bring them under one head. The flowers of the wild and cultivated Mango are exactly the same in structure, except that in the wild one there are often more stamens fertile.

It may not be known to most people that generally in a Mango flower there is only one stamen out of the lot fertile; this one is curved round just over the pistil in a peculiar way, to facilitate the fertilisation. The so-called "nak," or nose of the Mango, is the place the pistil adhered to in the flower. All this can be plainly seen with a moderately powerful reading-glass or lens when the Mangos are in flower.

PROTECTING MANGO FRUIT.

A very good way to protect Mangoes from the attacks of birds and insects is to get a lot of very finely-woven, round, Bamboo baskets made, say 4 inches wide at top, 5 inches at the bottom, and as long as may be required for the fruit. See that there is no room for a fly to get in through the basket-work. Then put the Mango inside as it hangs on the tree, push a long thin peg through the top of the basket by side of the stalk of the fruit on one side, and another similar peg on the other side, and the Mango will hold the basket up itself; then tie a little calico over the top of the basket, taking care not to tie the Mango stalk, and also to completely shut up the top of the basket. The Mango

stalk must be quite free, because when the fruit is ripe, or nearly so, it will fall of its own accord, and will be found to be just fit to gather. If a net be suspended under the tree then all danger of bruising the fruit will be avoided. Then shake the tree, to gather only the ripe ones. These should be kept on a "machau" for a few days till quite ripe, as all Mangoes improve by keeping a little, and should never be eaten perfectly fresh from the tree.—O. MARIES, in *Indian Agriculturist.*

THE COCHINEAL INDUSTRY IN GUATEMALA.

The following paragraphs describing a visit to a "cochineal range" in Guatemala are taken from the *Montreal Daily Star*:—

"In this queer country the raising of hemipterous insects of the bark-lice family—especially the *Coccus cactus* or Spanish cochineal—is a profitable if not a pleasant industry. In this portion of Guatemala vast plantations are given up entirely to the cultivation of the "Indian fig," or nopal, of the genus *Cacti* (*Opuntia cochinchinifera*), upon which these bark-lice feed.

"Señor Espanosa's plantation of *Opuntia cochinchinifera* which was the one we visited, includes nearly a thousand acres, and the *modus operandi* of cultivating the insect is most curious. They require about the same care that is ordinarily bestowed upon silk-worms and the occupation is not more disagreeable among crawling bugs than wriggling worms. Immediately before the annual time of violent rains, great branches of the nopal, covered with insects, are cut off and stored in a building erected for the purpose, to protect them from the weather. At the close of the wet season, four or five months later (about the middle of October), the plantations are again stocked from these supplies, by suspending little nests made of henequin, maguey, jute or any sort of woody fibre, upon the spines of the growing cacti, each nest containing about a dozen females. Warmed by the tropic sun, the insects soon emerge from their semi-comatose condition, and begin to lay eggs with marvellous rapidity, each female producing more than a thousand young. These spread over the plants with marvellous celerity, the young females attaching themselves to the leaves and immediately swelling to incredible size, adhering so closely to the nopal as to become almost a part of it, resembling vegetable excrescences rather than animated creatures.

"In this condition they are gathered for cochineal, none but the pregnant females being valuable for commercial purposes. The males are comparatively few in number—not more than one to two hundred and fifty females—and are of no use for colouring purposes; but, as in the higher orders of existence, escape most of the pains and perils of life. While the male are thus left to disport themselves undisturbed, the females are picked off with a blunt knife, collected into baskets and killed by dipping them into boiling water, or baking them in a heated oven, or on plates of hot iron. The first crop is gathered about the middle of December, and subsequently several more of as many successive generations—the last for the year being late in May. These tiny insects, of the family *Coccidae*, are in the form of rounded scales, the body covered with deep, transverse wrinkles, abdomen of dark mulberry colour, with short, black legs, and bristly on the posterior part. The male has two great wings, the female none.

"A labourer of ordinary skill can pick only about two ounces of cochineal bugs in a day. These lose at least two-thirds of their weight in the process of drying. As it requires no less than seventy thousand insects to weigh a pound, and the average retail price of cochineal is only sixty cents per pound, it may be inferred that the business is by no means a sinecure. By the method of immersing the insects in boiling water they turn to a reddish-brown hue, losing much of the white powder with which the wrinkles of their bodies are loaded. When dried in an oven they retain this, and then their colour is grey, and when killed on hot iron they become black. This is the cause of the varieties known in the market as 'silver

grains, 'black graius,' and 'foxy,' the latter (killed by the first plan) being preferred. When dried, the cochineal presents the form of convex grains, each about an eighth of an inch in diameter, with the transverse wrinkles still visible.

"An inferior quality of insects, called *sylvestre*, which is indigenous to a wild species of cactus, is frequently gathered and sold for the better variety, and sometimes the species become mixed without design on the part of the planter. Occasionally a bug distemper breaks out and devastates entire plantations, as in Guacamalá a few years ago, when the hacienalados were obliged to clean out the old stock, root and branch, and begin anew. The *Coccus ciliatus* are also fed upon by birds, mice and the larvae of other insects—the latter destroyers sacking out their bodies and leaving only the empty skins."

A LICORICE PLANTATION.

Several days ago, while at the ranch of Isaac Lea, some two miles north of Florin, in this country, a representative of the 'Bea' had his attention called to a field covered with what appeared to be alfalfa, but which he was assured by Mr. Lea was licorice, and any doubts were speedily dispelled when a piece of the root was dug up and sampled. Mr. Lea has three acres covered with this valuable root, will plant another acre this Winter, and contemplates adding to his field every year. This is certainly the only licorice plantation this side of the Rocky Mountains, and so far as known, the only one in the United States. The following interesting information in regard to the matter was gathered in conversation with Mr. Lea. It seems that twenty years ago he had a package of roots sent out to him from England by mail for planting, but they failed to reach him, and three times since he has had cuttings mailed which invariably were lost in transit.

About seven years ago he prevailed on a friend to bring some of the root from England in his trunk. It waten weeks before it reached Mr. Lea's hands, and in that time had grown several inches in its wrappings of moistened paper. It was successfully planted, however, and from it has come not only the three acres seen by the writer, but a considerable quantity which has been sold and sent to different sections for planting.

The plant, as it grows in the field, so much resembles alfalfa that only close inspection will detect the difference. A single green stalk grows above the ground about the size and general appearance of an alfalfa stalk, with similar little green leaves. There are two systems of roots to each plant—first, the tap root, of a chocolate color, which is sometimes as much as three inches in diameter, and will run down as much as six feet. In soils of this depth there will be but one such root, while in shallow soils there will be three or four. A little below the crown of the tap root grow out the lateral roots in all directions. They are of a lighter color and much smaller than the tap root, increase in diameter as they go away from it, and bear numerous buds about an inch apart. The tap root has no such buds. Every year the end of each lateral root buds and sends out five or six shoots, which will attain a length of about eight feet in the season, and then the end of each one buds and sends out more shoots until the ground is a perfect network of roots. The top lies down in the Autumn and comes up again from the root in the Spring. The plant is very tenacious of life and spreads and multiplies as rapidly as morning glory. The fibre of the root is very tough and would make a excellent ties for hoppers, if it were not more valuable for other purposes. The plant matures in three years, and the crop is then harvested—in England by digging by hand, but here where labor is high it is found better to use a plow which penetrates about fifteen inches. The lateral roots are more juicy and valuable than the tap roots, though both are utilized. As soon as a field is

cleared it is replanted, and of course a succession of crops should be provided for by planting a field each season.

For planting, the small ends of the lateral roots are used, cut into pieces of about three inches in length, that securing several buds on each. These cuttings are planted one every ten inches in rows four feet apart, and then cultivated between until the growth of the roots interferes with cultivation. Mr. Lea has given but little care to his crop. It might be added that the soil on his place is a red clay, not more than from fifteen to thirty inches deep, with the rock immediately below it. Licorice is valuable, not only for medicinal purposes, but for other and widely different ones as well. In England the green root is kept for sale in every candy store, and the children purchase and enjoy it as they would candy. To retain its juice for this and other purposes it is packed in sand immediately after being dug and kept there till needed. The green root is also used in the manufacture of porter, being boiled in the malt; and doubtless one reason that we import all our porter is because we do not grow licorice. The dried root is used in medicine and extensively chewed by the American youngster because the luxury of the green root is unknown to him. Mr. Lea states that the yield per acre is between 30 and 40 tons of the green root. Taking the lowest figures he will have from an acre 60,000 pounds green or 20,000 pounds dried licorice, which, at 15 cents, would bring \$2,600. Allowing \$200 for planting, cultivation and gathering of crop and sending it to market, he would have \$2,400 net return from one acre in three years. Eight hundred dollars per acre is not at all bad.—SACRAMENTO BEE.—*Madras Mail.*

NORTH-WEST NEW ZEALAND AND SUB-TROPICAL CULTIVATION.

Mr. Alfred Yarborough, an old resident in New Zealand, has published an interesting little pamphlet, entitled, "A New Field for Emigration—the North-West of New Zealand." As he truly says, the North-Western corner of New Zealand has not hitherto received that attention at the hands of the English public that its capabilities merit. Whether because the climate partakes of a sub-tropical nature, or because the fear of native difficulties has kept the emigrant away, or because the nature of the soil is not the same as that to which the English farmer is accustomed, is not clear; but the fact remains that there exists here a fairly extensive field for European emigrants who have the courage and the technical knowledge to go a little out of the beaten tracks. If English emigrants do not care to venture upon silkworm culture, or wine and olive growing, or on the other similar industries for which this district is admirably suited, Italian emigrants, whose eyes seem turned more towards South America than any other part of the world, would find a country here after their own heart, with opportunities for self-advancement denied to them in their own country. A few Italians have already settled there. Mr. Yarborough states that an Italian Colonist, Federli by name, has given a great deal of his time to the rearing of silkworms and the culture of sub-tropical fruits, and has now settled down with some friends in Hokitanga, with the intention of throwing his whole attention into the subject. It is quite clear, from his experiments, that so far as climate and other natural conditions are concerned, the north-west of New Zealand is exceedingly well adapted for the industry, but it will be necessary to grow the white mulberry to an extensive degree before this industry can be greatly developed. The land is well suited for the growth of this tree, as well as of the olive and orange, and many other fruit-growing plants. Vines, especially the more hardy descriptions, such as the Isabella, grow in the greatest profusion, and bear remarkably good crops, the soil, which is volcanic, being admirably adapted for the cultivation of the plant. The majority of English settlers, however, have not the requisite knowledge to bring the fruit-

bearing qualities of the vine into full perfection. In 1872 an Italian priest put a few acres into cultivation as a vineyard, and had splendid results. He made an excellent wine, some of which he sold, "but," adds Mr. Yarborough, "he left the district shortly afterwards, and his vineyard became completely neglected, and has now, I believe, disappeared. In other places I know of the Isabella vine growing perfectly wild, the branches trailing over the grass, and bearing the finest bunches of grapes in great quantities. Three of these vines in their wild state, gave $\frac{1}{2}$ ton of grapes, saleable in Auckland at least 3d. per lb. A German, near the Kohu Kohu, has now planted a few acres of vineyard, which look exceedingly flourishing, and, as he understands his business, he will no doubt do well. Last year he made a large quantity of wine from the Isabella grape, and sold a portion of it at a fair price. The remainder is being kept for a few years." Concerning the cultivation of other plants Mr. Yarborough gives some interesting information, which holds out most hopeful prospects to the right class of settlers. As lemons, oranges, date palms, citrons, figs, olives, loquats, bananas, Cape gooseberries, mulberries, peanuts, tobacco, guavas, maize, ginger, vine, castor oil, Manila hemp, peaches, plums, &c., grow more or less in wild profusion, it is reasonable to suppose that they are capable of a high cultivation. Lemons are common; a few orange trees planted by early settlers are luxuriant in their foliage and fruit, and thousands are now being planted; date palms grow readily; bananas require warm and sheltered spots to do well, but all the other plants or trees mentioned appear to enjoy the climate and soil. It is a curious fact that wherever a patch of brush or fern land has been burnt off for sowing, there the Cape gooseberry may be found during the course of the following few years bearing in quantities. Quinces do remarkably well, and bear in a wild state, while apple, pear, and other trees common to both England and the Colonies, are excellent bearers in the district. Strawberries and cherries are produced in abundance, but gooseberries and currants are hard to rear; melons of all sorts, and all vegetables commonly placed under glass in England, are easily reared. Some portions of the district are better adapted than others for orchard and fruit produce, but it is not difficult to select land of which at least parts are eminently suited, owing to their sheltered position and northern aspect, for the culture of the more delicate descriptions of fruits. Peach trees grow wild in great numbers, and the fruit is produced in such abundance that the pigs frowl fat on them in autumn. In some places you may almost walk ankle deep in peaches; they are not the luscious fruit which is obtained from greenhouses in England, but are very palatable, and make excellent preserve, or may be dried and sold to advantage. The peach tree, properly cultivated and attended to, produces a fruit very little, if at all, inferior to the dessert peach in England, while the quince in its wild state gives enormous crops of excellent fruit.—*European Mail*.

CUSCUTA CREEPER.

Woods and Forests Board,
15th January 1885,

The Honourable the Colonial Secretary,

Sir,—I have the honor to enclose copy of a report from the Acting Director of Woods and Forests, on the "cuscuta" creeper, and on the steps taken in view of its destruction—which was read and considered at a meeting of the Woods and Forests Board held on the 12th instant.

The Board requested Mr. Scott to use his best endeavours to destroy the "cuscuta" as fast as he can on Crown Lands, taking if necessary some additional men to help the present members of the staff so as to secure their more rapid destruction. And, whereas, according to Mr. Scott's report, the proprietors of "Alma" and "Bar-le-Duc," which now form one and the same estate, are the only proprietors who seem to have taken steps for its destruction on private property. The Board further suggests that His Excellency the Governor be pleased to consider

whether it would not be desirable to enact an Ordinance directing private proprietors to destroy the "cuscuta" creeper on their property, and in case of default by them so to do—within a reasonable delay—authorizing the officers of the Woods and Forests Department to enter their property, except private dwelling-houses, and to destroy the creepers at the proprietor's expense.

I have the honor to submit these recommendations for His Excellency's favourable consideration.

I have, &c.,
V. Naz,
Chairman.

Enclosure

A/12 12th January 1885.

The Chairman of the Woods and Forests Board. As you requested, I beg to submit for the information of the Board a report on the Cuscuta creeper.

This parasitical creeper belongs to the Convolvulus family (*Convolvulaceae*) and is known by the common name of Dodder. There are seven or eight different species, but as I have not as yet examined the flower I am unable to say at present what species we have in Mauritius, and I have been informed that there is more than one. There are three or four different species indigenous to Europe and the temperate parts of Asia. It is also found in Russia where it does great damage to the Flax crop.

It is difficult to say in what way it was introduced into Mauritius, but most likely with foreign seeds. I have not found, I believe it was seen at Quartier Militaire in 1852, and the rapidity of its growth accounts for its now being so abundant. It has been found in the Districts of Moka, Plaines Wilhems and Grand Port.

Here is an extract which throws some light on the method by which the Cuscuta first becomes attached to the plant on which it grows. "The seed germinates in the soil in the usual way, and by the long spiral like germ makes one or two tight coils around its future support, and during the time these coils are progressing the toster parent is increasing in size. The compressing of the former around the latter becomes tightened, thus causing the bark of the foster-parent to become more delicate, while the parasite is preparing a series of seral roots to penetrate it. It having done this, its position is firmly established. Its own natural root dies away and thenceforward its true parasitic growth is astonishingly rapid."

It will thus be seen the great difficulty there is in exterminating it, for, should even half an inch of the stem be left on the branch of a tree it will again grow and increase; therefore the only plan to adopt is to cut down the branches and burn or bury the whole.

No trees have as yet been seen killed by it, but I saw on the Reserves of River Moka some *Francoisias Marrounies* which appeared to have been killed by it. It has been proved that it has been spread to a great extent by the Indians carrying it from one locality and throwing it on to trees in another, under the false idea that it was the "*Jiane sans fin*" (*Cassia filiformis*) which they use as a medicine in certain cases.

There are at present three forest keepers employed in clearing it out where it is most abundant. It is intended to send six other keepers to assist in exterminating it.

The only Estates that are clearing it from private forests as yet are "Alma" and "Bar-le-Duc," and I should suggest that a Forest keeper be sent to work along with the men sent for the purpose of clearing it away.

WILLIAM SCOTT,
Acting Director, Woods & Forests,

I would add that the Cuscuta is not without its medicinal qualities, and the juice of the fresh plant is prescribed in sub-inflammatory complaints, and the powder of the dried plant is strewn on fresh wounds, the healing of which it is said to promote.—W. S.

The above Minute was referred to the Law Committee.—*Mauritius Mercantile Record*.

LETTUCE GROWING: A THING WORTH KNOWING.

TO THE EDITOR OF THE "PIONEER."

Sir.—In the Lucknow Horticultural Garden is grown an acclimated cos lettuce, with a selected pedigree of upwards of 15 years. No newly-imported kinds come up to it, as far as suitability to this climate is concerned, yet it is hardly known beyond the sphere of official reports. It is a large and tall cos variety; the tips of the leaves cabbage or fold over each other, so as to blanch the inner leaves without the bother of swathing. Please note what those who have tried it have said about it. Some years back a trial of the Lucknow cos lettuce seed was made at the Saharnpore Botanic Garden, which resulted in the following report:—"A splendid variety; three sowings were made, and all made heads superior to any imported variety we had. Enquiries were made by parties who received it in *dahles*, where the seeds were obtained." (!) In 1883 I sowed some seed of this superb cos lettuce in Etawah, and sent some heads of it to friends. They said they never saw anything like it for size, whiteness, sweetness, and crispness. Last year I grew it again. I sent a few heads of it to a lady who had come to Etawah. She said she never saw anything so good. On returning to Agra she asked me to send her some heads of this lettuce, that she might show the residents of Agra what fine lettuce ought to be like in India. Later on she did not forget to write for some of its seed. Now there is a little secret about growing lettuce for seed, which may not be generally known, and which the sooner it is learnt the more easily will the grower be able to improve his seed for future sowings. First, always get hold of the best acclimated strain possible. Second, sow the seed, *not too thickly*, in well-prepared beds of rich soil, in October (in the N. W. P. and Oudh). Third, when big enough to handle, prick out the young plants carefully, 12 or 14 inches apart, in rich soil of the best quality, where they can get plenty of air and sun. Water at once with a rose, and then irrigate the beds regularly at intervals and watch the result. The growing lettuce should never want water, that is, it should never be checked in growing; being a leaf-vegetable, it should have the richest possible soil. Of course weeding and other culture must be attended to. *Choola* ashes appear to suit lettuce, but of course it is possible to give too much of a good thing. When the heads are coming on towards being fit for the table you will find that most of them will fold the tips of their inner leaves one over the other, that is, they *cabbage*. These are the ones you should select for seed. Do not fancy for a moment, however, that you lose the heads for the table by keeping seed from these plants. Not a bit. When the head is ready for use, *cut it off* close to the ground, leaving only three or four leaves on the stump. Plunge the head in clean fresh water at once, and use it afterwards as required for salad. Within a week or so you will see little sprouts coming up from the stump. These are the *side shoots* of the lettuce, and it is *from these only* that good seed for the next generation can be obtained, that is, if you wish to have lettuce that will grow slowly and cabbage, and will not "run off into flower like rockets." Please note also the following:—Any lettuce heads which do *not* cabbage and remain open like an olive, take up scrupulously *by the roots* and do what you like with them. This you must see done yourself, as your man will not do it, but will leave the stumps of the open-headed lettuces *also* in the ground, the shoots of which would seed like the rest and leaven and spoil your stock with lettuces fit only for cows and goats. The stumps with their flowering stems should be irrigated regularly as before until you gather all the seed you want. Remember the seeds, when ripe, are attached to little tufts of cotton, and will be soon blown away anywhere after expanding. They should therefore be collected

daily, after the sun has dried off any dew. A second selection may be made while the flower stems are growing. The fewer stems you leave on each stump, the more nourishment will they get and the stronger will the seed ultimately be. The stumps of the earliest heads taken off *corticis paribus* are likely to give better seed than the latest. The former will have a good bit of the cold weather to grow and perfect themselves in, while the latter will have the beginning of the hot weather to do it in. Yet a third selection may be made. By winnowing the seed, after sowing it, in a gentle breeze, over an extended sheet, you will be able to separate the lightest, and therefore the soundest and heaviest seeds from the chaffy, light ones; the former is what you should keep for stock. If you follow this advice strictly, and see to it now and again yourself, you will not be disappointed with your acclimated seed. Moreover, by growing already acclimated seed and keeping your own every year, this lettuce will adapt itself, with a little intelligent modification in the treatment, to all the climates of the N., S., E., W., and centre of India. One word more about the seed. As it would be useless to go to war without keeping your powder dry, so would it be useless to take all the foregoing trouble about nursing and selecting it, after all, you do *not keep your seed dry*. Baskets well curked or tin boxes with tightly fitting covers—never too full—are the best for keeping seeds in. Take advantage of dry bright sunny days to air and sun your seeds on a blanket spread on a charpoy (not on the ground), with a boy to watch the squirrels. Now there is a reason for most things in this world, and the reason why the side shoots of the lettuce plant are better than the main shoots for keeping seeds from in India is this: the main stem tends to shoot up *quickly*, and its seeds will produce plants with the *soma* tendency. Therefore lettuces from the main stem seeds would disappoint you by flying off like rockets into flowering stems before you would have time to consume them, and on the slightest provocation from warm weather and dryness at the root, while your object should be to make them grow slowly, and have them fit for the table throughout a longer period. This you can bring about by keeping seeds from the side shoots only, which will give plants that will grow more slowly. Remember that the winter in India is very short; no sooner are you rid of the rains and their hot-house atmosphere than the coldest part of the winter is upon you (when most vegetables are at their best), and the next warm weather soon following up. Curiously enough, natives do not care about lettuce, although they who are fond of eating raw vegetables might eat the raw blanched and sweet leaves with advantage, especially if they first dipped them in lemon juice and then in salt. I use this fine cos lettuce, however, every winter for prisoners, while I keep the stumps of the prime ones for seed. In the prison the lettuces are chopped up and boiled as other vegetables, and a fine thing they make when properly done up. For soldiers nothing could be better than this fine vegetable. Last of all it is not impossible that this lettuce grown largely without much richness of soil would yield an opium called *Lactuosinum*, which is useful in medicine. It is collected from incisions in the flower stalk, and the root is said to yield an extract which is stronger than that made from the leaves. The medicinal properties of *Lactuosinum*, or the extract, are said to be sedative, narcotic, gently laxative, and powerfully diuretic. Whether the cultivated kind can be made to yield this apparently useful drug is, however, a matter for experiment.

AGRICULTURE IN BRITISH BURMA.

We have received a mass of papers from Mr. Watson, who himself obtained them from the Government of British Burma, from which we extract the Chief Commissioner's order on two reports on experimental cultivation at Paletwa and Kyaukpandaung in the Arakan Hill Tracts during the past year. The Chief Commissioner has read the reports with interest, and I am to ask you to convey Mr. Bernard's thanks to Mr. Fanshawe for the care and trouble he has taken to make this experimental cultivation successful. At Kyaukpandaung the cultivation of tea has been successful, but coffee, potatoes, and the English fruit trees do not appear to thrive, with the exception of the raspberry trees. At Paletwa the cultivation of tea, pepper-vine, cinnamon, Liberian coffee, Mauilla hemp has been successful; potatoes, however, have failed here as well as at Kyaukpandaung, and it would appear useless to plant again potatoes with which the climate or the soil does not agree. Mr. Fanshawe's suggestion that sugarcane-cultivation should be attempted may be adopted, and cane-cuttings from Bilin can be sent for experiment during the present rainy season. Tobacco seed of different kinds, as well as cotton seed, will also be supplied immediately. The experimental cultivation has shown that it is possible to grow varied products in the Hill Tracts, but there is no hope of attracting there for the present European settlers, as the labour difficulty and the climate are obstacles to any successful planting enterprise; the hillmen may, however, be induced to grow staples which are useful and necessary to them, such as sugarcane, tobacco, and cotton; and if the result of these experiments is to introduce the permanent cultivation of these products among the wild tribes of these hills, the money expended on these grants will not have been uselessly spent. The Chief Commissioner agrees to continue for another year the grant of £1,000 for experimental cultivation on the Kyaukpandaung and Paletwa gardens, but he trusts that the grant will be expended on the introduction of products which are of immediate use to the hill people.

From Col. Sladen's report we take the following extracts:—At Kyaukpandaung, or rather the spot known as Alicetaung, it may be generally taken for granted that tea and cinchona thrive well, and may be cultivated with success. The tea-garden is already assuming large proportions, and the time is coming when, with a little skilled labour for curing processes, the trees will yield a return which ought to make the garden more than self-supporting. The number of trees and young plants exceeds 12,000, and this number is capable of large extension, so as to form the nucleus of a fairly good tea-estate, which would pay well in any part of the country where labour was procurable at ordinary low rates. The fact, too, that we have over 100 cinchona plants or trees at Kyaukpandaung, all doing well, particularly the larger ones, seems to prove that the locality is favourable to the growth of this very important vegetable product. I am not in favour of spending money on an English vegetable garden, or on coffee, but I shall ask the Deputy Commissioner, after tea and cinchona, to give his attention more to the cultivation of hot-pains and pepper-vines, both of which should grow abundantly and, possibly, in time yield good results. I will also endorse Mr. Fanshawe's suggestion that he may be supplied with varieties of tobacco and cotton seed. The tobacco already produced is very good of its kind and fetches a good price in the local market. But unfortunately, owing to sparsity of population, the production both of cotton and tobacco is very limited, and there is none available for foreign export, for which, otherwise, these products are well suited.

Mr. F. C. Fanshawe reported:—The cinnamon trees are getting on excellently. Any number could be brought down from Kyaukpandaung, where there is a small forest of them. The young coffee plants put in last year are doing fairly well. About half of them were put in under the shade of plantain trees and about half near, and partly shaded by a kamaung

tree; about half of the latter and about three-fourths of the former are living and seem to be getting on well. The old trees have grown and look healthy. The experimental cultivation in the Arakan Hill Tracts has done little or nothing, I am sorry to say, to induce the peasantry to try new products, and I am afraid that, as long as they live the life that they do at present, they will never attempt anything new. Their staple products are of course rice and sossamum for home consumption, and tobacco and cotton for both home consumption and export. Their time is pretty well taken up in their taungyas and tobacco fields, and the month or two in which they have nothing to do they spend in a series of feasts. The ground used for the cultivation of tobacco could not be used for permanent garden land as it is all under water during the rains; and if taungyas were cut far from the water, the labour would be immense to keep the ground properly watered during the hot weather, and that is just the time that they are all hard at work cutting their taungyas for planting paddy, &c. They are too lazy and indolent to put themselves out in any way, and as long as they have enough to eat and drink, with a few rupees to spend yearly, they are quite contented. Different kinds of tobacco and cotton they would willingly sow I think; and if Mr. Bridges supplies seeds next year as he has very kindly offered to do, I have no doubt that the experiment will be a success. Even if planters were induced to settle up here, I do not think they would find cultivation profitable as the great difficulty of course would be cool labour. The peasantry here simply would not work regularly, and all the labour would have to be imported; and even then I am afraid the coolies would be constantly down with fever, for the first year or two at any rate, and unless they were paid at ruinously high rates, they would desert whenever they got a chance. At Kyaukpandaung the scarcity of water would be a great drawback; but coolies, if well paid, might be induced to live there, as the climate is good all the year round, and the policemen there keep wonderfully free from fever.

It is curious to find Mr. Fanshawe desiderating a fuller work on Cinchona than Dr. King's Manual. He should get Owu's, and as he says he knows nothing of tea, there is the *Vade Mecum* recently published.

C. W. Palmer, Esq., Deputy Conservator of Forests, South Tenasserim Division, reported on the Mergui Plantation for the year 1881-85, dated the 22nd June 1885, as follows:—

There are 1,350 bearing Liberian trees, 708 young trees, and 2,244 seedlings. The growth of this coffee has been very fine; the bearing trees are 8 to 12 feet in height, age $3\frac{1}{2}$ years, and gave last season a heavy crop. It is not possible to give any definite quantity of coffee produced as the whole amount was collected by the plantation gang.

2. I gave Mr. Watson, the planter at Tavoy, $1\frac{1}{2}$ cwt., and some seeds (a note of the quantity was not taken by plantation gang), have been sown in the plantation. The trees have flowered very well this year, and I expect a bumper crop next season. Some arrangement for pulping the coffee must be made next year, as there was great difficulty in getting this done this season. I am sorry to say that white ants are beginning to attack the coffee, though they have as yet done very little harm, nor do I think they will ever do much. This coffee wants shade, though too dense a shade seems to draw it up too quickly. I should give it shade for the first year or two fairly thick and then thin out heavily.

3. There are 920 bearing trees and 1,268 seedlings. The produce from these trees this last season was very small and has all been sown in the plantation. No definite idea of the amount of seed produced can be given as the plantation gang did not take the trouble to measure the quantity. This coffee does not succeed nearly as well as the Liberian. It is, however, only 2½ years old, and perhaps in another two years the results may be better.

4. There are 22 trees altogether. Several of the trees

are flowering, and will, I hope, form pods. This tree will, I think, succeed exceedingly well at Mergui, provided it is kept under shade. I have had them all fenced in to protect the pods from the monkeys, which are very troublesome at times.

5. There are 120 young trees in the plantation, all growing admirably. There can be no doubt as to the success of this tree; the only difficulty is in getting the seeds to germinate. I shall try some experiments this year with the seed, as the percentage of seed which do not germinate under our present system of sowing is very large.

6. Two hundred and fifty-one creepers altogether. Two of these flowered this year and formed 30 flowers. I tried my hand on fecundating these, but am afraid I have not succeeded. I cannot understand Mr. Connor's mode of fecundation. I intend starting a vanillery this year, so as to get the creepers all close together.

7. During this next year I hope to distribute a large number of coffee seedlings amongst the Burmans and Kareos of the Mergui district. I believe thoroughly that if once these men see that coffee-planting pays, they will go in for it heavily, especially if Government will undertake to purchase the produce of their gardens at the market rates.

POTATO CELLULOSE.—According to a Vienna journal a substance may be produced from potatoes possessing the properties of celluloid. For this purpose the peeled potatoes are boiled for thirty-six hours in a fluid consisting of eight parts sulphuric acid and 100 parts water, then dried through blotting paper, and relieved of the superfluous water by pressing. Pipe bowls are at present made therefrom in France that can barely be distinguished from real meerschaum, and billiard balls are likewise made from it by strongly pressing.—*Electrical Trades Journal*.

SWEET TEA OF SZE-CH'UAN.—In a report of a journey through Central Sze-ch'uan in June and July last, Mr. Alexander Hossie mentions the discovery by Mr. Barber of a peculiar kind of Tea, in the following words:—"If my memory is not at fault, he [Mr. Barber] was regaled by a priest on mount O-mei with Tea possessing both the flavour of milk and sugar. It may have been in the very temple on the mountain-side in which I am now writing that Mr. Barber was agreeably surprised. At any rate, I am sipping an infusion which is, without doubt, sweet, and which is declared by the priest to be brewed from a naturally prepared Tea leaf. It is a large, dark brown leaf, and is very sweet when chewed. The people at the bottom of the mountain, whom I first questioned regarding this Tea, asserted that the leaves were sweet because they were first steeped in molasses; but the balance of evidence, as I have since found from extensive inquiry, is against any such artificial preparation. The tree is said to grow in only one gorge in the mountain, whence the leaves are brought for sale." We are indebted to Mr. Hossie for a sample of this Tea, which consists of the entire leaf rolled up loosely into little balls, and almost black in colour. Upon chewing a portion of a leaf it is found to be decidedly sweet, with a strong suspicion of liquorice rather than molasses, as stated by Mr. Hossie. Upon soaking the leaves and flattening them out they were found to be those of *Viburnum dilatatum*, Thunberg. To prove that the leaves of this plant possessed no natural sweetness, we obtained a few leaves from a growing plant and dried them, and found that neither in their fresh, and still less in their dried state, have they any marked flavour. Moreover, the leaves of the Mount O-mei Tea are transparent, as if they had been steeped in some solution, while those which I gathered and dried are opaque, and yet retain their green colour. It seems certain, then, that this singular Tea owes its sweetness to some foreign substance as stated by the people at the bottom of the mountain, and that substance may be molasses, but is in all probability liquorice.—*Gardener's Chronicle*.

THE PRODUCTION OF HEAT in flowers has often been observed and measured, and the general chemical explanation given of the phenomenon is no doubt true in the main. It depends upon oxidation or the union of oxygen gas with the tissues of plants or their contents, and to the "combustion" or destruction that goes on in consequence, accompanied by the emission of carbonic acid gas. In an earlier stage of the plant's life the process is just the reverse. The leaves and green portions of the plant when exposed to sunlight give out oxygen gas; the process is one of deoxidation, and with it occurs a process of evaporation of moist vapour from the surface, both cooling processes; so that while on the one hand during the flowering period and during the ripening of fruits and the germination of seed we may expect the temperature of the plant to rise; on the other, all the time assimilation of carbon is going on in tissues still green and exposed to light the temperature may be expected to be no higher than that of the surrounding air.—*Gardener's Chronicle*.

THORIUM BENZOATE AND ITS THERAPEUTIC VALUE.—Among the botanical products of New Zealand there is one item for the *Materia Medica* that will prove a valuable auxiliary to the surgeon as soon as its therapeutical effects have become generally known. From 1869, when the properties of the plant were first made known, till the present, I have used it in hundreds of cases, including lacerations and amputations of every description, and I have no hesitation in saying that there is nothing known in the old country that can equal it in producing healthy granulations. I use a strong decoction—the stronger the better—made from the roots and the buds of the leaves, boiled for twelve hours. At one time I had to make it fresh every second day, as it readily ferments and deteriorates, but since carbolic acid came into vogue, I keep it for any length of time by adding about an ounce of equal parts of carbolic acid and glycerine to every quart. I require no other antiseptic precautions, but simply syringe the lesions occasionally with it, and maintain cotton wool or lint, soaked in it, constantly to the parts affected. If there are no foreign matters to be discharged there will be no discharge, in support of which I will instance the case of an Austrian, named Louis Lourich, whose forearm I lately amputated, after it had been shattered through dynamite. The flaps were thirty days in coming away, and the amount of pus from the operation up to that time would not altogether amount to a table-spoonful. The same patient had the soft parts of the other forearm torn and blown into such a mass of shreds that the members of the staff thought it was hopelessly beyond repair. I need only say that with the same treatment it became as sound and useful as before, and exhibits only scars showing where new skin had been formed. Some time ago a navy on the Winton Railway works had a loaded truck go over his foot, doubling it on the sole, bursting the integuments and leaving the os calcis nearly bare and the flexor tendons dipping loosely with bits of skin and fascia under the sole of the foot. The man lived in a tent near the works. I instructed one of his mates how to boil down a billy of Flax every day, and suspend it with a drip-rag over the injury, and the case recovered perfectly, with no appearance of pus, except on one occasion for twenty-four hours, through his mates leaving him for some sports or races with an insufficient supply of decoction, which compelled him to use water instead. In this case no carbolic acid, or anything, was used but the decoction of Flax by itself. I might adduce proofs by scores of its efficacy, but if, owing to these facts being made prominently known through the *Australasian Medical Gazette*, medical men can be induced to test the remedy for themselves, it will require no assertions from me to cause the Pharmaceutical Society to enter the positive list of its *Standard Dispensary*.—FRANCIS A. MONKTON, M.R.C.S.E., Surgeon Superintendent, Kumara Hospital.—*Gardener's Chronicle*.

CAMPHOR IN CHINA.—Reporting on the trade for Tamsin, China, the Commissioner of Customs says that the trade in camphor is represented in the returns by such an insignificant figure, that there is great fear of its total extinction in the near future. The immediate cause of its rapid collapse may be traced to the eagerness of the Chinese to acquire, by all possible means, as much territory as possible. During the last three years, hills thickly wooded with camphor trees have been burned over by the Chinese, in order to compel the savages to withdraw. Destruction on so large a scale naturally tells on the camphor trade. Forests of camphor trees do still exist further inland, but the absence of all beaten tracks across the mountains render them difficult of access.—*Journal of the Society of Arts.*

ORCHID PRUNING.—A good deal of information is likely to be gained incidentally by the discussion of this subject. Some people ask whether the old pseudobulbs are of any use; because, if not, they ought to be cut away. At Mr. Lee's the other day we saw the use to which they, or some of them, are put in that establishment, where the requirements and peculiarities of Orchids are so thoroughly met and understood. The bulbs of *Dendrobium nobile nobiliss* are tied down horizontally to a board just as babies are in some countries still, and bung up near the glass, kept in suitable temperature, and with sufficient moisture, when, after a little, buds present themselves at the nodes, by which the plant may be propagated. It is clear, then, that the reserve food and growing power of the old bulbs are not exhausted.—*Gardener's Chronicle.*

THE SMALL-LEAVED LIME.—Where a neat, somewhat low-growing shade tree is required, *Tilia cordata* is preferable to either *T. platyphyllos* or *T. vulgaris*. At Metz, and elsewhere in western Germany, and also in eastern France, &c., where the three species were often growing in close proximity, the contrast between the bright, cheerful, fresh appearance of the first-named and the parched-up, almost leafless state of the two latter was very marked last month. In some towns the street arcades, and the trees planted thickly in the squares for shade purposes, were almost all *T. cordata*, which seems rarely planted in Britain. It may be as well to remark that *T. cordata* is the correct name of the species generally mentioned in works on British botany as *T. parvifolia*, *T. platyphyllos* and *T. vulgaris* are both included under the old name, *T. europea*; the two species are, however, thoroughly distinct, and in most cases can be readily recognized by the leaves alone. The first has soft leaves, more or less hairy on both surfaces, and flowers earlier than *T. vulgaris*, which has leaves glabrous except in the axils of the principal veins.—*Gardener's Chronicle.*

NOTES BY THE WAY.—Just at a time when coffee planters and importers have their cups full if one may use such a figure of speech, some ingenious botanist has discovered a substitute for coffee. At the Commercial Exchange, Cape Town, there were exhibited recently some specimens of a root, *Umpimysia*, which has much in common with *Chery*. The following letter from Mr. Hamdoun-Willis, Under Colonial Secretary, accompanied the exhibits:—"With reference to a letter from the Civil Commissioner of Peddie, under date 14th ult., I am directed to forward, per separate parcels, some specimens of a root known by the name of 'umpimysia,' viz., a piece cut off the root, some pieces roasted after being passed through a mincing machine, and two packets of the ground material. The root is largely used by farmers and others, who make a beverage from it resembling coffee in flavour, but sweetish. The process employed in preparing it is to pass it through a mincing machine, roast, and grind it. Some farmers also make a syrup from it, by cutting up the root, boiling and skimming it. This resembles golden syrup, with a slight cinnamon flavour. It is thought that with proper machinery this root could be utilized as a substitute for coffee as an article of commerce."—*Home and Colonial Mail.*

WYNAAD, Nov. 11th.—The weather with us of late has been most unusual. October we generally expect to be showery, but not a succession of storms and heavy rains. November, as a rule, is dry, with land winds. We are now having heavy showers almost every afternoon, the rest of the day being still and hot. It is "fine growing weather" at any rate, and the cinchonas, both *Ledgeriana* and *Succirubra*, show their appreciation of it by looking most luxuriant, our coffee crop is pretty fairly on taking the estates "en bloc," the crops appear to be very irregular—good in some places, and sadly indifferent in other. Today a meeting is being held for the especial consideration of the great question of the day, *i. e.*, the discoloration of coffee, its causes and possible prevention. It is a subject of very particular interest to us, as Indian coffee appeared to be so seriously depreciated last season on this account. Of course opinions differ considerably in the matter; but we must hope that a satisfactory discussion may be arrived at in today's council, on the principle of many heads being better than one, where so vexed a question is under consideration. In my next, therefore, I hope to be able to write more fully upon this (to planters) most interesting topic. I hear that those concerned are still very sanguine as to the results of the experiments in fibre cultivation which are being carried on at Devala under the direction of Mr. Mutchin. Those also who have gone in for cardamoms seem very hopeful of their future. Tea, the little we have of it in the district, looks well, and has cropped very satisfactorily; so that, taking a general view of Wynaad affairs, I think I am safe in saying that a more hopeful spirit is rising amongst us. It will, however, be many a long year before we can wholly recover from the terrible depression of the hard times with which we have of late been so sadly acquainted.—*Madras Mail.*

PROTECTING RIVER BANKS FROM CAVING.—A novel system of protecting river banks against the consuming action of an ever-flowing current is being applied near Memphis, Tennessee, along the Mississippi, where a caving bank rises straight up from the water's edge from 10 to 50 feet. There is an incessant lapping and chafing by which the bank is slowly worn away and undermined, and, as a consequence, it breaks down piece by piece, and is dissolved and carried away by the river. To check this steady but slow disintegration is the problem which United States engineers are trying to solve satisfactorily. The idea of a blanket placed along the slope of the bank from high-water mark to the bed of the river naturally suggested itself, and the contrivance adopted, a willow and pole mattress, represents the blanket theory. The woven webs are some 50 feet wide and from 200 to 1,000 feet in length, with flexible willows worked in for woof and poles and wire for warp. These are made on boats having a length equal to the width of the mattress, and as the mattresses are completed they slide away into the water. The sunken mattresses, it is said, prevent undermining below the low-water line, and the grading down of the overhanging bank stops the undermining above that line. The space between the upper edge of the mattresses and the top of the bank is protected with willows and stone. All this mattress-grading and stone-covering is embraced in the term revetment. The work already done by the American engineers and the staff of workmen under them is described as being of the most substantial character. The appropriation of 200,000 dol., secured from the last Congress for this work will, it is estimated, be sufficient to place mattresses along the river front from Wolf River to the foot of Beal or Linden Streets. The work will probably be completed before the next rise of the river. It remains to be seen whether it will hold the bank and prevent it from further caving. Next spring, when the floods turn the Mississippi into an inland sea, the practical test will be made, and, if the mattresses hold the banks successfully against the impinging and undermining current, the mattress-revetment theory will be sustained.—*Iron quoted in Public Opinion.*

THE PRUNING OF TEA IN CEYLON.

Mr. Logan of Assam and Mr. Teare of the Nilgiris—gentlemen who are largely interested in tea and who, between them, make up about fifty years' experience of planting,—have just made a round of some of the principal Ceylon districts. They first visited Udagama, in the Galle district, and neither with the tea nor the soil there, were they much impressed, and they began to think that they had made a mistake in intermitting their voyage to Madras and Calcutta, for all that Ceylon had to show them. But the trip to the Central Province altered this opinion. They travelled up by railway to Nanuoya, and making Nuwara Eliya their headquarters for a few days, they visited all the tea and cinchona plantations available in the neighbourhood, being much pleased on the whole with what they saw. Separating here, one visitor travelled down by way of Udupussellawa, Maturata and Deltota, while the other took Dimbula, Ambagamuwa and the famed Mariawatte plantation more at leisure. Mariawatte would undoubtedly be considered an exceptionally fine tea-garden anywhere; but Messrs. Teare and Logan have some home truths to tell us which it is well we and Ceylon tea cultivators generally should examine. They do not consider that as respects economy of labour Ceylon has any advantage to show over the average Indian tea districts. Mr. Logan gives Rs5 a head as the first price paid for coolies indentured for five years, and who if well treated usually go on for another five years, their wages being Rs5 a month or say with bounty Rs5½ to Rs6; while in Ceylon our average must be nearer Rs8 to Rs10 for monthly wages. So in respect of cost of transport, our visitors will not admit we have an advantage considering the greater cheapness of railway and river transport in India, while freights to London positively average less from Calcutta, than from Colombo. The only admitted gain of Ceylon is in respect of a fortnight in time. But we should scarcely mention in this prominent way the visit of the above two experienced Indian tea planters, were it not for the serious warning they have tendered to us as respects the system of pruning they found almost universally observed during their trip. Messrs. Teare and Logan call it destruction, and ruinous to the tea bush, and that a very few years will afford sufficient proof. The Luckinporc Company was instanced as one case where tea gardens had been pruned after the present Ceylon fashion up to about the time the late "Mr. W. Cameron" came to Ceylon, with the result that for five or six years heavy crops and splendid dividends were realized; but then came the reaction and a blank with a debit account for several years, and only after very careful nursing did the trees come round. The strange part is that while Messrs. Teare and Logan condemn nearly all the pruning they saw, they both declare that nothing can be better than the advice and instruction given on this subject by Mr. C. S. Armstrong in the pamphlet republished at this office. Can it be true that our tea-planters, as a rule, refuse to follow Mr. Armstrong's teaching as regards the pruning of their tea bushes?

JOTTINGS OF A JOURNEY UPCOUNTRY, CEYLON.

The tea in Ambagamuwa being now planted will no doubt do well, but at present, in passing through, many places look red and bare through the rooting out of the coffee ere the tea is planted. This may be the better way, but is it a shock to see the tea 18 months old and gradually prune down the coffee, and only remove altogether when the tea again make the hillsides green, and it is a shock where you knew good-looking coffee had been of old now to see bare acres. Coffee up to Dimbula through the Kotagaloya valley seems wretched, but some estates with tea growing well underneath looks like business still. On Craigie Lea a lot of fine young tea is coming on round and above where the resthouse was, and it is being extended; and on Forest Creek there is good young tea among the coffee in the field by the church, and many acres being planted. At that end of the valley Mount Vernon tops the coffee in look and crop *facile princeps*. St. Andrew's has a lot of good young tea also, and a coffee crop. As one ascends the valleys coffee improves towards Lindula and Agras, though crops don't seem too abundant; and at the farthest point reached that way the coffee looked really good. Tea of about the same age seemed to be on every estate, but men there seem loath to prune and shape extremely big bushes; why, can't tell! Up to the end of railway coffee looks seedy, although the best crop I saw anywhere was on Louisa I think, at any rate, under Mr. Mackie's charge, and the portion I saw had really a fine crop.—*Kelani Valley K. C. B.*

EXPERIMENTAL CULTIVATION OF PEARL OYSTERS.

Captain Donnan's report is to the following effect:—

"I regret to say that out of 12,000 oysters placed in the experimental tank on the reef off Silavatturai in March last, I found only 21 remaining alive. Some of the oysters may have been washed out of the tank by the S.W. monsoon sea, as it was not completely sheltered from the wash of the waves, but the bulk of them have, I believe, died off and been destroyed by some fish preying upon them. About 100 dead shells were found in the bottom of the tank, many of which bore evidence of having been bored through and nibbled away. It is just possible that some fish may have got into the tank and preyed upon the oysters either by getting over the coral barrier around it, which would be slightly under water at high-water, or through the interstices of the coral underneath.

"The experiment so far has been a failure, which may be attributable to four causes: 1st, overcrowding the oysters in the tank; 2nd, deficiency of nourishment in water so near the surface; 3rd, destruction by fish which had got into the tank and preyed upon them; 4th, by excessive agitation of the water in the tank during the S.W. monsoon sea; or probably to all these causes combined.

"I shall try the experiment again in March next in a tank to be made on a more sheltered part of the reef, with the embankments raised above water and fewer oysters placed on it." We are glad to see that Capt. Donnan means to persevere in experiments which, notwithstanding previous failures here and off the coast of Southern India, are, we cannot doubt, destined in the end to be successful. There are many appliances of modern science, such as the electric light which could be applied and which it would pay

to apply so as to secure success in the culture of the pearl-bearing bivalve. Besides the reasons for failure adduced by Capt. Donnan, it seems quite possible that the higher temperature of comparatively shallow water may have had an injurious effect. Unlike the edible oyster, the pearl mussel seems to flourish best in comparatively deep water, from four to seven fathoms. Not only is the sea-water still at such depths, but it is quite possible that many of the predatory fish, which are so destructive to the shells, do not exist at, or but rarely visit, such deep floors of the sea as constitute the habitat of the "pearl oysters." The results of successful culture in converting a capricious but welcome source of revenue into constant productiveness would be so important to the colony and all its interests, that we cannot doubt Government will afford Capt. Donnan all possible aid as well as encouragement in his interesting and intelligent efforts to cultivate the pearl oyster.

TEA IN THE LOWCOUNTRY OF CEYLON.

COLOMBO, 5th Dec. 1885.

The land actually under tea in the lowcountry districts, principally in the Kelani Valley and Kalutara or Kaluganga Valley with outlying estates, cannot be less than 14,000 acres, which is being added to every day; the greater portion of this is not yet in full bearing, but, as low tea gives a good return within two years, the whole of this large acreage will be in full crop within the next two years. That the cultivation of tea in the lowcountry of Ceylon is an unqualified success, no one can doubt who has seen the estates. A good deal of poor land has been planted which will probably run down unless manured, but the greater portion of the land under cultivation or about to be planted is good tea soil, and the low lands where not too frequently flooded both in the valley of the Kaluganga and Kelani rivers are admirably adapted for the cultivation, whilst the high land even on steep slopes of the lower ranges of the hills is not only far superior to what I expected but there is an even regularity in the fields which is very beautiful and very pleasing to the eye, and what is of much greater importance to the planter the yield from the hill or steep land though inferior to the heavy soil of the flats is very satisfactory. It is difficult to arrive at anything like a true average of the yield from the low districts as the tea is of all ages and much of it has been planted to replace Liberian coffee or cacao, and the tea has not had a fair chance whilst some of the fields have been planted as wide as 6 x 6 and others are as close as 3 x 3. I saw one field five years old planted 6 x 5 which gave 700 lb. cured tea to the acre. I consider 100 lb. a fair but safe average to look for from the Kelani and Kaluganga valleys.

The acreage of available land adapted for tea cultivation within a radius of fifty miles of Colombo is practically unlimited, but the manner in which the land is being blocked out and sold seems to me to be without system, and at present the estates are detached or in small groups, making them more or less difficult of access and difficult to road systematically. Why there should be any objection to opening up, say, the whole of the Kelani Valley from Awisawella to Gimigathena with the various affluents and valleys of the Kelani river, I cannot see: the rainfall is not only ample but superabundant, and the climate even for tea would be greatly better if the rainfall was not quite so much. There is very little virgin forest left, but the

wilderness of bamboo and thorny chena makes the country almost impenetrable, cattle cannot graze, and the land is at present not only utterly useless but it harbours all manner of vermin destructive to poultry and everything, and the damp rank vegetation and decaying matter renders the country during the dry months fever-stricken and unhealthy. Some 200,000 or 300,000 rupees have already passed into the hands of the villagers for felling and roading, and every acre felled means one cooly to feed and his pay mostly spent amongst the villages. This being the case, why there should be any desire on the part of Government not to allow the country to be opened up, I cannot conceive. At present everything away from the tea estates is in a state of stagnation. I have never at any time known the road between Colombo and Awisawella so bad as it is now apart altogether from the flooding of the low places; and as for the road from Awisawella to Yatijantota it is simply a wilderness, the drains are overgrown with lantana and the middle of the road is a grazing ground for cattle, whilst the minor roads are unbridged and dangerous. It is fortunate for the tea-planter that the river affords good and cheap transport, or he would be utterly at a loss to get his crop away.

The District Association should take up the matter of transport and road extension and improvement. The proposed new road from the 27th milepost near Awisawella to Labugama, if opened up, will prove not only a very valuable and useful road, but will open up a large tract of valuable tea land at present useless and waste and enable the proprietors to get out much timber fit for staves and tea boxes.

JAMES IRVINE.

FOR PLANTERS AND CULTIVATORS GENERALLY:—ONE OR TWO THINGS WORTH KNOWING:

TREES FOR SHADE—A MARKET FOR ORANGES AND LEMONS FROM CEYLON—MEDICAL USES OF CITRUS FRUIT—CULTIVATED FRUITS.

Kandy, 29th Nov. 1885.

Sir,—I understand that in some plantations trees are grown, such as the jak and others, for shading coffee, cacao, &c. On the way up from Colombo, I have seen jak so grown. This, however, is a tree that will go on growing and extending its roots, to the probable disadvantage of the shrubs in the plantation. I would suggest the trial of the *Agati grandiflora*. I have been making experiments with it in the N.-W. P. of India, where it grows very well. For shading plants, I think there is nothing like it. Its leaves are pinnate, and its foliage of the proper density, so that the rays of the sun are broken up into light and shade, which cross each other below, and make a delightful half-shade of the strength needed by plants that suffer by direct sunlight. It grows so rapidly from seed, if sown at the commencement of the rains, that in one year, in Upper India, it attains the height of 20 feet. In Ceylon its growth might be still more rapid. The stem in one year is three inches in diameter. It grows straight and has a head about 10 feet across. Up to the height of a man or more it can with the greatest ease be kept to one clean stem, so that it offers facilities for weeding, &c. The height to which the lower branches can be stripped off can be suited to the needs of the plantation. Should it be found that it takes too much out of the soil when full-grown, a succession of trees can be kept up, and the older ones cut down. Finally the *Agati* is not at all a useless tree in other respects. Every part of it is fit for food. The leaves make good soup, and are eaten by natives as vegetables. The flowers make a good curry and mixed with butter or whipped eggs make good fritters; the young pods can be eaten boiled, as French beans; and I have no doubt (though this I have not tried) the seeds might be eaten as 'dal,' or roasted and eaten as parched gram, so that the lower branches, as the tree grows, would

furnish vegetables for the coolies, so would its large pea-shaped flowers and its long slender pods. I feel certain that a trial of it would meet with approval, as far as the proper amount of shading for plantations is concerned. In Upper India, it is called 'Agast'; in Tamil, 'Agati' (and probably from this its botanical generic name has been taken); and in Sinhalese, 'Katuru Muringa.'

A few words now about Oranges and Lemons. In the *Ceylon Observer* of the 18th November I see that someone has been energetic enough to send Ceylon oranges to England, and that they reach there in good condition. I think there is an opening for the orange trade nearer Ceylon than England. In the Bombay market, oranges, lemons, and limes sell at a high price. It may not perhaps be generally known that Bombay imports oranges all the way from Zanzibar (called Mozambique oranges), and sweet lemons (called limes) all the way from Muscat in Arabia. Bombay in addition imports oranges from Poona and the surrounding country and all the way from Nagpore, in the Central Provinces of India. The P. & O. steamer takes about four days from Colombo to Bombay, and about a week to Calcutta, another good market for Ceylon oranges. To Calcutta, oranges (called 'Kambala Nimboo') are brought all the way from Sylhet to Goalundo by country boats, and thence to the capital probably by rail. Oranges fetch a high price in Calcutta. A writer in the *Indian Agriculturist* of the 10th October last, signing himself 'Old Mallee,' says that "he realizes 8 annas a score for the Sylhet oranges he grows in Bengal; that his income from orange growing is Rs700 per acre at 10 feet apart (he says this is too close), which only costs him Rs190 in expenses, so that he nets Rs500 per acre. He considers well decayed night-soil, cow-dung, and black tank soil, with an admixture of slaked lime, or old mortar finely powdered, the best for oranges. He buds on the 'khatta' or sour orange. He grows the Sylhet variety principally.

The commercial value of the ordinary products of the orange and lemon tribe are too well-known to need mention here, but the medicinal value of the fruit of the citrus has only lately been brought prominently before the medical profession. I mean Dr. Maglieri's "decoction of lemon." I will here give the result of my experiments with the decoction of lemon, which will sufficiently indicate its value, as a remedial agent. The experiments in each class are not solitary but many.

A.—In simple quotidian fever (that is without any other complication), even if it is of some days' standing, the decoction of lemon, given only once a day, acts like cinchona febrifuge.

B.—In enlarged spleen of recent occurrence (that is of some months' standing, not years), there is only one remedy I know which equals the decoction of lemon in power, and that is "fluoride of ammonium." In many cases this decoction has removed enlarged spleen of some months' standing, even when the spleen reached within an inch of the middle line of the abdomen, in less than one month, sometimes much more rapidly.

C.—In loss of appetite and weakness after fever, or other debilitating ailments, I am not acquainted with any drug or remedy that picks one up so quickly. After the second or third dose, the appetite not only becomes normal, but the digestive powers keep pace with the improved appetite, and vigor pervades the body.

It will be seen that the lemon contains a drug of no mean value. To planters in districts subject to fever, the lemon would be a cheap and most efficient remedy always close at hand. I have tried experiments with the decoction of the Malta lemon, which is the same as the Italian, Sicilian, and Portuguese lemon, the identical one sold in the London fruit shops. I have also tried the common small sour lime, which is found all over Ceylon, and all over India. I have also tried a third kind, the 'khatta' or 'karns' of India. All appeared to be equally valuable as remedial agents in the above-mentioned ailments. The choice, I think, lies between the more or less pleasant flavor of the decoction, and I think the best flavored one is that of the Malta lemon. I believe that this important remedial property is contained in all the sour fruit of the citrus, even in the urripe orange, but of this I cannot yet speak with

certainty. It is not improbable that at no distant period the active medicinal principle of the citrus will be isolated and then orange and lemon plantations would probably become more valuable, but in the meantime the result of the foregoing experiments, and the value of the decoction of the fresh fruit may be worth knowing. As everyone may not have read how this decoction is made, I give it here. Take one Malta lemon, or a sour orange or three sour limes, cut them into thin slices, rind, pulp and all, add three breakfast cupsful of water, and boil in a glazed pot, or enamelled saucepan, until the liquid is reduced to about one cupful. Then leave it exposed all night to the air, and next morning strain and squeeze through a rag, and drink the liquid early, on an empty stomach. My experiments have all been made with one dose a day, but there is no reason why, in urgent cases, two doses a day should not be given, one in the morning and one after midday. In that case a double quantity of everything should be used and boiled down to one-third and after straining divided into the two doses. In Kandy I have found two kinds of citrus which would be invaluable for this preparation: one the 'cidrang,' a large round lemon, which would do for two doses with double the amount of water; the other is the 'natrum,' an oblong, warty, sour citron, which would be enough for one decoction.

I think the way to set about making orange plantations, for commercial purposes, is not to plant any kind on a large scale, but to try all the good kinds on a small scale—first (it is only the choice kinds that will bear the cost of transport, in competition with those already in the market), and ascertain which variety does best in any particular locality. I think nothing is more certain than the fact that all varieties do not thrive equally well in all localities. For instance, the Sylhet and Nagpore oranges do well in Lucknow, while the Delhi Situtara does badly, and the Mandarin is quite unsuited to the climate of Oudh and the N. W. P. I think the best kinds for experimenting with are the following:—The Sylhet, the Nagpore, the Delhi Situtara, the real Mandarin (totally different from those called so in Colombo and Kandy), obtainable from Lucknow or Malta; the Malta blood and egg oranges (these might be more readily and cheaply obtained from Malta, but the egg orange is also obtainable in Lucknow, and the blood orange in Gujerat, Punjab); finally the Zanzibar orange. Those who know the latter state that it is even better than Malta or Spanish oranges. Government might introduce the plants, but then on common kinds, and distribute them. Experiments might be made also by seed, obtained from Calcutta, Bombay, Zanzibar and other places.

Finally it should not be forgotten that choice fruit is only to be had by cultivation, especially where the climate and soil are not exactly what is needed by the orange and lemon trees. Besides ordinary manures the citrus are benefited by wood-ashes and leaf-mould, and in particular want lime in the soil, as it is a large ingredient in the ashes of the orange wood. Iron in the soil is, I think, of great importance. It probably gives flavour and juiciness. This latter ingredient however is not wanting in many soils of Ceylon, as Sir Emerson Tennent says the 'patana' lands are impregnated with iron. The annual fall of orange leaves should on no account be removed from an orange plantation; when they decay, they form the best manure for the orange and lemon trees. The packing for exportation should present no difficulty in dry weather, the orange being ripe in December and January. Each orange should be wrapped in a bit of tough tissue-paper and twirled at both ends (hair-curling paper, or tough bamboo paper, would answer). Then the oranges so wrapped should be packed closely in dry boxes (about 2 feet x 1 foot x 1 foot). The object of the paper is to absorb any moisture and the close packing to prevent wabbling and bruising. Before packing the oranges should be aired for a few days on lofts or shelves to rid them of excess of moisture, and, most important, should be handled carefully at all times to prevent bruising.

E. DONAVIA, M.D.,
Brigade Surgeon, I. M. D.

No. 3 AND T SIROCCOS.

Palman qui meruit ferat.

To the Editor "Indian Planter's Gazette."

In your issue of 6th October your correspondent "Arid" made a vehement attack on Mr. Davidson's No. 3 Sirocco, and with a wrong interpretation of the cause that led Mr. D. to give the alteration pieces gratis to all, clenches his reasoning by adding "this is equivalent to an open avowal that the other is a failure." I too was much disappointed by the *time* the No. 3 required to turn out one mound of dry tea, and in face of the statements made by many Ceylon planters and others I could not get it to surpass the useful and compact No. 1 in the matter of time; I tried many experiments and got satisfactory tea out of it, but it utterly failed to "turn out our mound of dry tea in an hour" as advertised.

But to "Arid" and all others who have No. 3's, it is well to know that "balm in Gilead" still remains and, if disappointed, they should lose no time in having their Siroccos altered to the T-shape.

I have had mine altered, and for the first time tried it yesterday with the following satisfactory result. Having the thermometer up to 28° I had the first tray charged and placed at 2 p.m., which was taken out quite dry in twenty-one minutes. The last tray was taken out at 5-21 and the tea dried in that time (3 hours) weighed 3 mounds 5 seers.

The tea was rather full-fired—*not burnt*; and I am of opinion that, with a lower temperature—say, 27° to 26°—it will give fully dried fine aroma'd tea with as little trouble as the No. 1 gives. CRAIG PHADRIK. Eastern Doars, 4th November 1885.

BAMBOO.—There is nothing like science for enlarging the mind. Take bamboo for instance, which most people would define as a hollow, jointed stick of varying size with lance-head-shaped leaves. Bamboo, we all know, is one of the most useful productions of nature. But we can scarcely recognize our old friend, when described as a plant the leaves of which "are said to be tussic, tonic, antelmintic, stomachic and carminative, and the root 'cooling, tonic, and alexipharmic.'" Another species "is prescribed in the form of a decoction of the leaves or root in diseases of the head, chest, &c." A wash of the leaves in certain other diseases. "Bamboo juice is prescribed in catarrh, fever, acute cerebral, spinal, and bronchial affections," and so on. But this really quite carries our familiar acquaintance into another world. I knew that the use of the bamboo stick frequently caused "acute cerebral affections" (vide police reports *passim*). It is news to learn that its juice taken internally provides a cure!—*Singapore Free Press*.

INDIAN MILLS.—We notice that while in the twenty-one years the number of the local mills has increased from ten to forty-nine, the upcountry ones have increased from three to nineteen, the total advancing from thirteen to sixty-eight. The number of spindles have increased locally in round numbers from 250,000 to 1,347,000 and upcountry from 36,000 to 303,000. Total increase from 286,000 to 1,650,000. The number of looms has increased locally from 3,400 to 12,000, and upcountry from 200 to 2,600. Total from 3,600 to 14,600. In 1865, but 7,400 persons—6,600 in Bombay and 800 upcountry—were daily engaged in the mills of the Presidency. This year over 51,000 were similarly occupied, of which nearly 12,000 were employed in the city and suburbs. A record of the consumption of cotton previous to 1873 is not obtainable, but in that year we see the local consumption is given as over 67,000 bales (of 392 pounds each), and the upcountry has 7,500 bales, a total of close on 75,000 bales. Twelve years later—30th June this year—the local consumption is stated as over 392,000 bales and the upcountry as over 73,000 bales a total of nearly 466,000 bales.—*Times of India*.

WATER-WHEELS.—In reply to "Sentifer," it is generally admitted among engineers that turbines give a better result than the best vertical water-wheels. They also run much more quietly, and less gearing, shafting or belting is required to connect them with their work. The power may be conveyed twenty yards or upwards by means of a wire rope with very little loss of power. Mr. Mann's assertion that a turbine requires "a greater and more concentrated fall than a water-wheel" does not agree with my experience. If "Sentifer" will state his county, I shall probably be able to mention an application of a turbine in his neighbourhood. For very small water supplies a water-wheel is sometimes preferred on the score of economy in prime cost.—CHAS. LOUIS HETT. (Exchange Club, Brigg, Oct. 24th.)—Seeing an inquiry in your columns as to water-wheels and turbines, I may state that Messrs. A. H. Williams, Worthy, Winchester, are at present erecting a turbine here, to drive my saw mill. There are about 220 yards of 8in. iron piping let up the side of a pretty steep hill into a reservoir, giving a fall of 70ft., which is to give off 37 h. p. indicated, at the turbine. The diameter of the wheel is, I think, 14in. I have formerly driven the saw mill by steam, and I anticipate a great saving in fuel, absence of engine driver, &c. The turbine will be at work in about a fortnight, and I shall be glad to furnish further particulars if wanted.—C. H. DURRANT STEGART. (Dalguise, N. B.)—*Field*.

MUSK RATS AND TAINTED WINES.—In the *Field* of Sept. 12th, I see two notices of the supposed power of the Indian musk rat or shrew (*Sorex coruiscens*) to taint wine by the simple process of running over the bottles. The explanation is simple enough. The shrew, which lives on cockroaches, scorpions, small lizards, snakes, and the like, runs round the edges and corners of rooms to hunt them, chiefly at night and by day, if possible, finds a soft nest far from his hunting ground. I do not think that he often burrows, or even uses the burrows of true rats; but on this point I stand open to correction. I do know that he will willingly take up his quarters in any basket, box, or other nook where he has a soft bed. Now, his neighbour, the native "khitnudgar," "boy," "bearer," or other servant, is very much given to wiping glasses with any rag handy; and, as the "Sahib" and "Madam Sahib" very seldom intrude on the "dispense khana" or pantry, the same rag does duty for many days on end, and, after use, is not hung up or washed, but thrown down into any corner, and used again next day, or, perhaps, after several days. In the meanwhile it has very likely been the bed of the musk shrew, and acquired enough of his flavour to communicate it to the glass and to any wine poured into it. I have known the same thing to happen with kerosine oil, the same rag having been used first to a lamp and then for a wineglass; yet no one attributes mystical powers to kerosine. I was once in the habit of keeping wine, soda water, &c., in a basket in a room off my office, with glasses and other necessaries for luncheon. A musk rat established himself on some folded napkins among the bottles, and I, to try the matter, left the contents of the basket untouched for a fortnight, merely opening it daily to make sure that he was still using the nest. They are gentle creatures, and not timid unless bullied, and he soon found that I meant him no harm, and treated his daily inspection as a mere form. At the end of the fortnight I asked several friends to taste the liquor and tell me if they could detect any flavour of musk rat in it, but neither they nor I could find it in either the wine, which had foil capsules over the cork, or the soda water which had the common wired corks. But the napkins were "fit to kill at forty rods," and communicated their flavour, when damped, to glasses: they were useless till thoroughly washed. If Anglo-Indians generally knew the true habits of the poor musk shrew I hope they would stop persecuting that humble guardian of their stores, and lay the blame on the dingy shoulders of their dirty servants, where it is due.—KFWALA.—*Field*.

Correspondence.

To the Editor of the "Ceylon Observer."

LOSS IN WEIGHT ON TEA.

Colombo, 29th Nov. 1885.

DEAR SIR.—I am constantly receiving complaints from constituents in London as to the heavy loss in weight on shipments of tea from Ceylon.

My attention was drawn to a case the other day where the tares of teas from a certain well-known estate were 1 oz. over the pound—incurring a loss of 1 lb. per package.

I will instance an extreme case to show your planting readers what can be lost by not seeing that the gross weights of their packages are rather over the pound, with tares slightly under the lb.

Suppose a half-chest 66 lb. 15 oz. gross, 16 lb. 1 oz. tare. The Customs in London would return this package as 66 gross, 17 tare, or net 49 lb., whereas the package actually contained 50 lb. 14 oz. of tea. Had the package weighed 67. lb 1 oz. or even 67 lb. gross, tare 16 lb. or under, the Customs would have returned the weight as 51 lb. nett (gross 67, tare 16), making a difference of 2 lb. per half-chest or 4 per cent. Add to this the loss incurred by the trade allowance of 1 lb. per package draft and you have a loss in weight of 6 per cent. whereas by a little care it would have been reduced to 2 per cent (draft allowance).

It appears to me so easy for a planter, especially if he used a lever scale, to make his packages up to within, say, 2 oz. of the lb. by adding sheet or lumps of lead, and then packing $\frac{1}{4}$ of a lb. of tea over and above what he invoices and marks his packages. This $\frac{1}{4}$ of a lb. could save, in the case given above, 1 lb. 11 oz. in London.

TEA BUYER.

JAPANWOOD TEA BOXES.

Colombo, 30th Nov. 1885.

DEAR SIR.—At the request of Mr. H. D. Deane we have the pleasure to send you herewith 3 samples of Japan tea chests made of the following woods half-an-inch thick:—

(1) Cedar wood, which, though objected to by some on account of the smell, has been pronounced by undoubted authorities in London not to taint the tea.

(2) Mome wood.

(3) Matsui wood.

The names of the respective woods will be found marked on one side of the chests, and on the lid the weight of each. We may also mention that each chest will contain about 70 lb. nett of tea. —Yours faithfully, J. M. ROBERTSON & Co.

The specimens referred to can be seen at Observer Office: Mr. Deane has decided to have no more boxes under $\frac{1}{2}$ inch thickness. The cedar wood box only weigh 11 $\frac{1}{2}$ lb.; the other two, 18 $\frac{1}{2}$ and 21 lb. lb.)

TEA-BOXES AND SEASONED TIMBER AND THE "TARE" RECKONING.

Dumbara, 2nd Dec. 1885.

DEAR SIR.—"Tea Buyer"’s dodge with the bits of lead will not quite get us out of the difficulty. The wood of a half-chest, and a portion, therefore, of a full chest (in Ceylon, whatever may be the case elsewhere) will take up or lose, in proportion to its condition as to seasoning, and according to the weather it meets with, much more than 2 oz. So that a well-seasoned package weighing 1 oz. under the pound in the factory, might weigh 1 oz. over the pound in Colombo, and Heaven knows what it might weigh in London! I believe well-seasoned wood shows the least vari-

ation. A full chest made of half-seasoned wood will lose a pound in a very short time in the temperature of an ordinary tea-house. For which reasons I have long ago given up marking the tare on my packages, as the weights marked cannot be correct when the chests reached their destination. Well-seasoned chests (which are very hard to come by, however) will do something to mitigate the evil, and so will the bit of lead dodge, which I have tried, but the real remedy would be in inducing the gentlemen of the Customs to take the trouble to weigh correctly. But this is of course out of the question. TEA MAKER.

TEA.—Efforts to cultivate the tea plant are now being extensively made in several parts of Europe. In France, on the Loire, the plants have been extensively set, but it is still a question whether the leaves will retain their characteristic aroma on a foreign soil. In Sicily, the plants set three years ago at Messina are strong and healthy, and have flourished in leaf and seed. Russia has also made the attempt, the first planting being at 10 versts from Aleschbri, on the Dnieper, and proving satisfactory; and plants have also been sent from Odessa to Suchum. In Germany, the Silesian Committee of Agriculture have received seed and directions from Professor Goppert, of Breslau, with a recommendation to attempt their cultivation.—*Penny Pictorial Views.*

EAST INDIA GUMS are of dark and light mixture, being in fact a conglomeration of rubber, leaves, dirt, and bark. This is also true of African rubber. The presence of so much foreign matter in the East India rubber has ever been a great drawback to its successful use in manufacture. The difficulty is, however, obviated in part, by running the "mats" when in process of washing through a machine which both crushes the foreign element and, by stretching the sheet, liberates it, the particles flying in every direction. From 30 to 48 per cent. of the original bulk is lost by this process of thorough washing, before the gum is sufficiently pure for use. African rubber, unless kept from the sunlight in time, decomposes, and becomes like tar in appearance, and is entirely useless.—*Electrical Trades Journal.*

DR. BONAVIA'S letter (page 183) has, we regret to find, been rather too long delayed. He gives us some useful practical information about citrons and oranges which we commend to the attention of growers of these fruits, and the advice tendered to parties attempting the systematic cultivation of the orange tree is manifestly sensible and useful. We are not, however, quite with Dr. Bonavia about the *Agati grandiflora* as a shade tree for estate products, for, although a quick grower, it is also of but short duration. "W. F."’s notes written in the *Observer* on the subject are not at hand, but we quote from the *Treasury of Botany* as follows:—

AGATI. A genus of the Pea family (*Leguminosae*). *A. grandiflora* is the only species. It is a native of the East Indies and tropical of Australia, but is commonly cultivated in tropical countries for the beauty of its flowers. It is a small slender tree twenty or thirty feet high, of rapid growth and short duration; its leaves alternate, abruptly-pinnate, with from eight to ten pairs of small leaflets. Flower stalks axillary, bearing from two to four large pea-like red or white flowers. The pods are about eighteen inches long, and as thick as a common quill. In India the flowers, pods and young leaves are used by the natives in their curries; a juice is pressed from the flowers and used in curing dimness of vision; and the seed are eagerly sought after by birds. The bark is powerfully tonic and bitter, and considered effective in smallpox. The wood is useless except for fuel. The tree being a fast grower and sparingly clad with leaves is used for the purpose of training the Betel (*Piper Betle*).

TORREYA CALIFORNICA :

THE STINKING CEDAR OR CALIFORNIAN NUTMEG.

This is described as a tree 60 to 80 feet high, with a trunk attaining 3 feet in diameter, and inhabiting the western slopes of the Sierra Nevada of California, from the Mendocino County to Zulare County. During my visit to California I had not the good fortune to see a good specimen of this most interesting tree. The only place in which I remember to have met with it was in the gorge of the Yosemite Valley by the rocky stream, some miles below the hotels, where it formed a seraggy tree 20 feet high, or thereabouts, growing interspersed with *Pinus contorta* and various deciduous shrubs. The colour of the foliage was bright green, and the large green Plum-like fruits, produced in abundance, had a very singular appearance. The wood is described as light, soft, not very strong, very close grained, compact, susceptible of a fine polish, and very durable in contact with the soil. It had all the appearance of a slow growing tree, and this is its character in cultivation at Kew. The genus is one of the most interesting amongst Conifers, on account of the rarity and remarkable distribution of the few species it is known to contain. There are, besides the Californian, the *T. taxifolia*, Arnot (Savin or Stinking Cedar of Florida), confined to swamps in the neighbourhood of Bristol in Western Florida, and very rare there; *T. Grandis*, Fortune, of North China; and *T. nucifera*, Seibold and Zuccarini, of Japan.—J. D. HOOKER.—*Gardeners' Chronicle*.

SOIL FERTILISERS.

The following is the summing up of the main points in a lecture upon this subject delivered by Professor G. C. Caldwell, Ithaca, New York, before the Massachusetts Horticultural Society:—

1. That if the elements needed for the food of the gardener's or horticulturist's crops cannot be obtained in sufficient quantity from stable manure, or other animal waste, they can be procured in the trade in unlimited quantity, and in every degree of availability depending on different grades of solubility, and in the greatest variety of mixtures, so as to suit any whim or fancy of crop or crop grower.

2. That profitable crop-growing can be carried on for many years at least, with these commercial fertilisers alone.

3. That the most evident distinction between stable manure and commercial fertilisers, and the distinction upon which we should, therefore, naturally base an explanation of the greater reliability of the former, is its large proportion of vegetable matter, or humus-forming material, of which commercial fertilisers contain practically none.

4. That soils contain, in a difficulty soluble condition, and therefore not easily fed upon by the crops, large supplies of all the needed elements of plant food.

5. That humus, through its decay in the soil, furnishes carbonic acid among other solvent agents; and this carbonic acid appears to play an important part in the nourishment of crops by bringing the native, insoluble stock of plant food within their easy reach.

6. That even if we add water-soluble plant food to the soil it becomes largely insoluble before the crop can feed upon it, or needs it; therefore soluble plant food added to the soil in commercial fertilisers needs also the help of the humus, finally, for its solution.

7. That plant food in most animal and vegetable residues used as manures costs much less than in commercial manures.

8. That, in spite of the disadvantages which, under some conditions, attend the use of commercial fertilisers, they are, nevertheless, a very important and necessary help in crop growing.

9. That in using these fertilisers the wisest course appears to be to make one's own mixtures of the raw materials, as well for securing a better manure as for economy in first cost.—*Gardeners' Chronicle*.

PLANTING IN SOUTHERN PROVINCE, CEYLON.

For many years an industry has materially contributed to the welfare of the inhabitants, but this too, as with other products, is gradually feeling the effects of over-production. More than a score of years ago we are told of citronella oil fetching 2½ per ounce in the London markets. The same substance now realises under 3d. and this lowness of price has naturally resulted in less care in production and consequent falling-off in prosperity among all employed in its manufacture.

The citronella is to all appearances like *mana grass*, growing just in the same manner. It is not indigenous, is planted upon forest land and should be weeded after each cutting, which should take place twice a year. Now, however, less care is observed in its production. I have even heard of kerosine being added to increase its bulk. One travels very few miles in this province without coming upon land which was once a prosperous garden of citronella, the cultivation of which is now restricted to a few acres of badly-kept grass. The oil is what is called an essential oil, and is extracted from the grass by distillation, the grass being steamed, which forces the volatile oil with a certain quantity of pungent vapor through the still, from which it falls in a small stream of green water and oil. It soon, however, comes to the surface, is skimmed off and put in handy bottles, and in this form shipped to Europe. Its chief uses are in scenting soap.

It is not generally known that the hog-deer in this part of the island is more common than the sambar axis, or munt-jac, and can be easily shot by anyone so disposed. It is in size almost as large as the axis or spotted deer. Snipe are at times very plentiful in the swamps and paddy fields and quail abound on the *orittas*. Teal too abound upon the lakes which are not unfrequented.

Tea is being tried in various parts and is so far a success; indeed those who are searching for land would not go far wrong in having a look at the Southern Province before they finally decide where they will plant. Sinhalese labour with some care can be procured in plenty, both cheaply and in quality. Most places are healthy and the province is not by any means badly roaded, having in addition river and lake navigation to assist transport.—*Local "Times."*

RECENT RESEARCHES ON OAK-GALLS AND THEIR MAKERS.

The oak has always been a favourite in this country. The ancient Britons worshipped under it, and held even its parasitic mistletoe sacred; their successors for centuries built their "wooden walls" of it; and once a year at least the mistletoe is still a thing of consequence, although it is from the apple and not the oak that it is now chiefly obtained. Valued by man as the oak has been, it is much more essential to another and lower order of living creatures. It is both nursery and foster-parent to the gall-dies, whose eggs it envelops in its own substance, and whose young are reared to maturity on the same juices with which it feeds and ripens its own acorns. The most casual observer of oak trees cannot have failed to notice the numerous excrescences which occur on different parts of their surface. These are oak-galls, the hatcheries and nurseries of a family of hymenopterous insects. They are found on every part of the tree: its roots, bark, leaves, twigs, and flowers; and show a great variety in form, size, and colour—a variety roughly corresponding to the number of kinds of gall-dies which form them. On the under surface of the leaves there occur, for example, the "cherry-galls," of a bright scarlet colour, or a mixture of white, orange, and red, like the colours of a Newton pippin; also the "oak-spangle" galls—button-like disks of russet brown; and the "currant galls of the oak," yellow or red, that hang from the leaves like bunches of berries. The "oak-apples" grow from the smaller branches, and justify

their name by their appearance; while the "artichoke gall," resembling a miniature artichoke, takes its rise from a bud, less known forms grow on the roots and bark. Of foreign oak-galls the most important are those known to commerce as "Aleppo galls," which grew on a species of oak common in the Levant. Galls are imported into Britain in considerable quantities, the imports for 1883 having amounted to 39,500 cwt., valued at £18,400. It ought to be stated, however, that more than half of that quantity came from China, and that the Chinese gall of commerce is the work of a plant-louse on a different tree from the oak. Galls are used in the manufacture of ink, that useful material being a mixture usually of green vitriol, a decoction of oak-galls and some gum arabic. Their value for this purpose is due to the abundant tannin they contain—as much sometimes as 77 per cent. The British forms are comparatively poor in this constituent, although the "Devonshire marble gall," now one of the most abundant in Britain, yields 17 per cent of tannin, and is said to make excellent ink. The Dead Sea Fruit or Apples of Sodom, described by Josephus and others as lovely to the eye, but nauseous to the palate as bitter ashes, are generally identified with the larger Mecca galls which grow on a species of oak in the neighbourhood of the Dead Sea. Among the most curious of oak-galls are those known in California as "flea-seed." They grow on the leaves of an oak, from which in August they get detached and fall to the ground. So exceedingly lively, in this instance, is the living kernel, that its jerking movements within the thin-walled cavity cause the entire gall to skip about.

What is the history of the growth of these vegetable excrescences? The gall-flies are small insects with bodies seldom bigger than garden ants, but with four large clear wings. They belong to the same order as bees and wasps, and when the time has come for depositing their eggs, the female selects a spot on leaf, bud, or bark of the oak, and pierces it with her ovipositor. This is a slender organ projecting from the creature's abdomen, and is but a slightly modified form of the wasp's sting. After piercing a hole, the blades of the ovipositor open, and an egg passes down between them into the place prepared for it. There is then injected into the aperture a small quantity of an irritating fluid, and the work of the parent insect is completed. This fluid, which is at least suggestive of the poison of the hymenopterous sting, has a remarkable effect on the tissues of the plant, causing them to swell into those globose knobs known as galls. In due time the egg of the insect becomes a grub, which finds its proper nourishment in the abundant juices of the gall. When its transformations are over and its natural term of imprisonment expired, the gall-fly tunnels its way through the enclosing tissues and emerges into daylight. How such puny insects can make their way, for example, through a Hungarian gall, which is as hard as the most seasoned oak, is altogether mysterious. That they do tunnel their way through is evidenced by the little hole on the surface which marks their points of exit. Where no such aperture occurs in a sufficiently mature gall, the insect has failed to make its way out; and thus, no doubt, the strongest gall-flies are "naturally selected" before they ever see the light. Sometimes, however, the strongest may fail, as in the case mentioned by the Rev. J. G. Wood in which two galls had united. The insect in the one gall escaped, but that in the other unfortunately bored into the part joining the two, and being unable to tunnel farther than the distance which under ordinary circumstances would have brought it to the outside, it died. In order to secure the insect reared within the gall, it is necessary to place the branch in a bottle of water and cover it over with gauze. A difficulty, however, occurs here from the fact that a considerable variety of insect-species usually emerge from a single gall. Some of these are closely allied forms that do not grow galls for themselves, but

which, like the cuckoo among birds, drop their eggs into the nests of others. These are lodgers or guests of the true gall-flies. Others, again, are parasitic on the latter, and these, feeding on the juices of its body, ultimately destroy it. It is only the entomologist who has specially devoted himself to the study of this family of insects that can readily identify the fly that has emerged from a particular gall. It might be supposed that, in securing this fly, the observer had got an insect similar in every respect—supposing it to be a female—to the one which had placed its egg in the juices of the oak-leaf. In some species at least this is not the case, and the probability now is that it is seldom, if ever, so.

The recent researches of Mr. B. Walsh in America, and still more of Dr. Adler in Germany—an excellent summary of which is given by Prof. Trail, of Aberdeen, in a paper recently communicated to the Perthshire Natural History Society—show that the gall-flies exhibit *Dimorphism*, or "alternation of generations." Dimorphism, according to Professor Trail, consists essentially in this, "that there are in the full life history of any species in which it occurs two forms of the insect, or, as it is at times expressed, two generations, of which the one possesses both males and females and produces offspring in the usual way, while the other consists of so-called females alone, and reproduction is effected by what we may regard as a process of budding from a part of the body of the parent, not by the true sexual method." Before dimorphism was thought of in the case of gall-flies, there were mysteries in the life history of these insects which no fellow (of the Entomological Society) could understand. For example, there is no reason to believe that the life of the particular fly which emerges from the "currant-gall" of the oak in June is prolonged beyond the autumn of the same year. How comes it, then, that in the following spring a new crop of those oak-galls appears on the young leaves and male catkins, seeing that the gall-makers have been all dead months before the appearance either of leaves or catkins? The answer, according to Dr. Adler, is, that the fly producing the "currant-gall" has existed through the winter in a totally different oak-gall; that the fly itself differs so entirely in form from the insect into which its eggs develop—i. e., its own offspring—a to have been hitherto regarded as belonging to a totally distinct genus, but that these offspring deposit eggs which, after surviving the winter as grubs emerge in spring in the likeness of their grand parents. This cycle of generations will appear more clearly if we trace in detail the life history of this currant-gall fly. As already stated, it emerges from its gall in the month of June, and the brood contains both males and females. In July the impregnated eggs of the female are deposited usually on the lower surfaces of oak leaves, and soon after they give rise to what are known as "spangle-galls." Of a russet brown colour and flat lens-like form, they are totally unlike the "currant-galls." The spangle-galls fall to the ground shortly before the leaves, and there lie concealed among the fallen foliage during winter. In this position they enlarge and become much more convex, while within the insect is undergoing its metamorphoses. In spring it emerges, but the form that now appears is never male, but always what Professor Trail terms *asexual*. It is what the boy said his canary was when asked by a possible purchaser as to its sex. Not wishing to commit himself before he knew what was wanted, he replied, "It's a kind o' she, and not a she either." The spangle-gall fly is a kind of female in so far as it deposits eggs, but inasmuch as these eggs are not produced by the true sexual method, the creature is in reality sexless. It is these unimpregnated eggs deposited by the spangle-gall fly in spring that give rise to the "currant-galls" in May, and to the male and female currant-gall flies in June. This dimorphism has been traced through a considerable number of species; and in the list of Scottish gall-flies given by Professor Trail, nine species, belonging to four genera, are

regarded as merely dimorphic forms of nine other species belonging to four totally different genera. Of several others, only the one form is as yet known in Scotland, although both forms have been determined by Dr. Adler in Germany; while there are a few British galls, such as the "Deronsire Marble," common also on the Continent, of which no one seems yet to have found the alternate generation. In seeking for these missing forms, an interesting pursuit is opened up to Scottish entomologists.—*Scotsman*.

THE ADIRONDACK FORESTS.—A report has been presented to the State of New York, dealing with the present condition of the forests of the Adirondack plateau, a region ill-adapted for agricultural operations. The forests have been, as elsewhere, recklessly destroyed, but what remain are considered as essential to the continued prosperity of the State, and their destruction must be followed by widespread commercial disasters. The Commissioners have obtained proof that the flow of the rivers has decreased within the memory of living men from 30 to 50 per cent, while the damage from spring floods and summer droughts is increasing. The report ends with a series of practical suggestions applicable to the particular case drawn up by the Commissioners, among whom is Professor Sargent, of Harvard University.—*Gardeners' Chronicle*.

MILDEW.—The *Journal Officiel* publishes a report addressed to the Minister of Agriculture by M. Prillieux, Inspector-General of Agricultural Instruction, as to the results obtained by the use of a mixture of lime and sulphate of copper in counteracting mildew. It has long been the custom in some parts of the Medoc to sprinkle the Vines bordering roads with lime-water, to which a salt of copper was added. At one time verdigris was used, but it was expensive, and so sulphate of copper was substituted. The purpose of using it was to prevent children and depredators from pulling the ripe Grapes which were within their reach. They were afraid to eat the sprinkled bunches. A belt five or six stocks wide was treated in this way along the sides of the thoroughfares. When mildew spread to a serious extent in the Medoc it was remarked that the Vines which had been sprinkled with the mixture suffered less from the disease than the others. The leaves attacked by the *Peronospora* withered and fell off prematurely everywhere except along the roads, where they remained green, and where the Grapes ripened. At Danzae, the property of M. Johnston, the stocks had been carefully sprinkled by M. Millardet, Professor of the Faculty of Sciences, and M. Gayon, Professor of Chemistry at Bordeaux. After studying the results in this and a large number of other places, it was discovered that the sprinkling of Vines with a liquid containing about 8 per cent of sulphate of copper mixed with lime-water checked the progress of mildew, and enabled the Vine which had been attacked to ripen its fruit. The treatment is easily applied, and cheap. The earliest application gives the best result. The action of the mixture is not yet understood, but MM. Millardet and Gayon hope soon to be able to throw light on it. It seems to M. Prillieux that this unexpected remedy may prove useful to Northern agriculturists. The *Peronospora* of the Vine is closely related to that of the Potato, and it seems not improbable that if it is an efficacious remedy in the one case it may be so in the other. The hypothesis has already been supported. At Obateau Laogou, belonging to Messrs. Barton, Tomatos were attacked by a disease to all appearance due to the development of the *Peronospora* of the Potato, which is known to attack also the Tomato. M. Jouet, the steward on the estate, who is a scientific agriculturist, treated the Tomatos like the Vines, and succeeded in destroying the disease. Isolated as this fact is, M. Prillieux thinks it should be made known, so that Potato growers may make in their fields, from the first appearance of the disease, attempts similar to those which have been carried out with such success this year as regards the Vine in the Medoc.—*Gardeners' Chronicle*.

TEA IN CALIFORNIA.—A Californian paper thus refers to Californian tea:—"About four years ago Mr. Gould received from the Agricultural Department a package of Japanese tea-seed. He planted and carefully cultivated it, and now at his ranch can be seen what is a curiosity in this country—a large plot of tea plants. They have done remarkably well, and he has raised quite a quantity of superior tea. Some years ago the experiment was tried in El Dorado County without success, but Mr. Gould has accidentally or otherwise hit upon the right method of raising the plant, and his success is a pointer for other farmers to provide themselves with this luxury. More than that, the fine growth and excellent quality of this tea looks as if its culture might be engaged in as a profitable business. There is apparently no limit to the possibilities of Placer country if she tries."—*Indian Tea Gazette*. [Tea may grow well, but where is the cheap labour to be found?—Eo.]

ORANGES IN DOMINICA.—The weather has again become excessively dry. Rain is much wanted for the crops, especially for the lime and orange, which are estimated as likely to fall short of even last year's small harvests. In consequence of the past drought a blight has fallen on the fruit of the orange trees in certain localities. In others the fruit promises to be of fine size and flavour though small in quantity. Buyers for the American markets have commenced operations, but there is no reason why freight to London or Liverpool should not be so much lowered as to tempt large shipments of fruit at this season of the year, when neither St. Michael's nor Mediterranean consignments are to be found in English centres of consumption, and when the Royal Mail steamers return home half full and the Direct Line has to seek elsewhere a homeward cargo.—*Dominica Dial*.

COCAINE.—The *Sethia indica* having been sent to me under the name of *Erythroxyton monogyuum*, is found upon examination to contain a certain amount of alkaloid. The *Sethia acuminata*, which has also been sent to me as a variety of *Erythroxyton*, is a drug that has long been in use in Ceylon as a vermifuge, and I have for some time distributed it in the form of a fluid extract. At that time I was not aware that it had passed under the name of *Erythroxyton*. As soon as further supplies of these two drugs arrive a therapeutic examination will be carefully made with the alkaloids. I am glad to be able to record some further valuable information of general interest respecting *Erythroxyton* (Coca. Dr. Manassein, of St. Petersburg, gives an interesting account of the employment of the drug in sea-sickness. Dr. G. H. A. Dabbs reports this week in the *British Medical Journal* (p. 473) that he has used cocaine most successfully in four consecutive cases of childbirth, and that it is his intention to use it in future cases. I can only add that in one American journal that reached me last week there were twelve notices of the employment of cocaine, and in no one instance have I as yet been able to trace any ill effects from its use. The employment of the *Erythroxyton* Coca has now gone from the barbaric stage of depending for the effect by chewing the leaves (which might be fresh or stale; this means that they might contain hardly any percentage of cocaine, or, on the other hand, they might contain 0.55 per cent), to the employment of the alkaloid where the doses can be most accurately apportioned. The solution of hydrochlorate of cocaine with water is always better when made fresh, and it is safe to apply it in any case of pain, even with children, by rubbing it in. It is most easily mixed with vaseline, and rapidly allays pain in the joints. A small quantity of the alkaloid may be put with water and then placed on sugar, and it has a marked effect upon any one suffering with a sore throat. The price having fallen to about 4d. per grain, it is quite within the reach of any one.—T. CHRISTY.—*Gardeners' Chronicle*.

SUGAR PRODUCTION IN RUSSIA.

The recently issued report of the Russian Department of Indirect Taxation for 1883 contains some useful statistics regarding the progress of the sugar industry in the Czar's dominions. For several years past the volume of manufactured sugar turned out of the Russian refineries has increased so rapidly that the production in 1882-1883 was more than double that of 1872-73, as may be seen from the following table:—

Year.	Number of Factories.	Sugar produced Poods.
1872-73	235	8,479,187
1873-74	249	9,133,389
1874-75	249	8,660,853
1875-76	254	9,507,015
1876-77	260	12,669,594
1877-78	245	10,602,918
1878-79	240	11,101,063
1879-80	239	12,544,628
1880-81	236	12,369,597
1881-82	235	15,936,714
1882-83	237	17,537,890

These figures have been compiled from the manufacturers' returns, but it is believed a close investigation would show that the output for the last three years has averaged annually 15,600,000 poods. The duty has, of course, increased in proportion. Since 1881 the duties upon sugar have been twice raised without, however, any evil effect upon the production. In 1883-84 an additional area of 41,706 *desjatines* was devoted to the growing of beetroot, but the result was not very satisfactory, though the twelve months' production did not fall below that of 1882-1883. In the latter year the 20 refineries in Russia—mainly scattered about the Governments of Moscow, Kieff, Charkoff, and St. Petersburg—turned out 9,150,701 poods. Since 1882 the Governments of Pultava, Kieff, and one or two other provinces have grown sorghum. The Department of Imperial Dominions has also tried this experiment, and for the encouragement of sorghum growing the duty has been remitted.—*Financial News*.

OPENING OF SILO IN SUJAN NIWAS GARDENS, OODEYPORE.

Mr. Thomas H. Storey, formerly of Madras, and now Superintendent of Sujan Niwas Gardens, Oodeypore, writes to us as follows:—

We had a splendid crop of Hurialce grass (Dube) which enabled me to carry out the experiment. I first intended packing the grass in pucker-bait tank, but owing to the unusual heavy fall of rain, I was unable to make it water-tight, and so gave it up, and dug a pit on the side of a little hill, about 10 feet above water level. I dug the pit 32 feet long, 16 feet wide, and 8 feet deep. I had no idea the quantity of grass a pit of this dimensions would hold until I began to fill it. I had 217 men cutting for two days, 16th and 17th of October, and on the 18th carried the grass up, weighed one maund, and put it in a box cart with both ends out. It held a maund exactly, and I then bulked the remainder. When the two days' cutting was packed in, it looked very little when tramped down, so I covered the grass with mats, and had to begin to cut again on the 19th with 96 men, so the total number of hands cutting was 313 for three days. The mats were lifted and the grass carried up on the 20th morning, and packed in. I had the grass well shaken quite even all over the place, from the very bottom, and continued till filled, with as many men as could conveniently stand in the pit tramping it, so that they could not press it any more. I sent up to the palace for an elephant to give it a finishing touch. The huge animal almost sunk a foot in it and kept walking round, amusing himself, by throwing the grass at the men, till he could not press it any tighter. I had bamboo mats placed on the top of the grass and put a layer of perfectly dry soil, sifted fine, on the top to a depth of two feet. I

have read of plastering the top with wet soil, which I consider does not answer the purpose so well as the dry earth. For this season, that should a crack open the dry soil would fill it up of its own accord and exclude air, whereas a plaster of wet soil is almost sure to open and remain so. On the whole I put four feet of soil and had it well beaten. I visited the pit daily for a month, but not a crack was to be seen. I may mention that the grass was cut after the rains, and was packed quite green, containing all its own natural sap, and on the 21st it was completely finished and sealed up. It remained so in the 21st October till 21st of February, so that it was sealed up for exactly four months. I opened it in the presence of Colonel Walter, the British Resident, A. Wingate, Esq., revenue settlement officer, and a few other gentlemen who take an interest in silos. The grass had a very alcoholic smell, and was very brown to the depth of an inch on the top, but when shaken up to the sun and air for a little, it soon lost most of its strong smell. The grass under was very fine, and pronounced by all the gentlemen present to be one of the most successful silos that they had heard of. I may mention that our garden bullocks are in fine condition and they eat the ensilage in preference to the jungle grass they have been used to get. The quantity of grass placed in the silo was 567 maunds. I am feeding all our bullocks on the ensilage, except one that is getting the usual jungle grass, giving each animal six seers per diem; the reserved bullock is getting seven seers every day, and I shall be able, in the course of a month or so, to see which of the animals are in best condition.—*Madras Mail*.

MEXICAN SANDAL WOOD BARK.

BY H. STIREN, M.D.

In Mexico and some of the Central American Republics, where it is indigenous, there is used, no doubt from reasons of economy, for fumigating purposes in churches, in the place of frankincense, the bark of a tree, particulars of which I have been unable to obtain, but which I am strongly inclined to consider as some species of *Myrciophylon* or *Myrcospermum*, leguminous plants.

This bark occurs in irregular, more or less smooth or unevenly corrugated pieces, of a light whitish cinnamon colour, with dark, hard epidermis, and of an agreeable, eustard-like smell, and aromatic, slightly acid, balsamic bitterish taste. A small quantity, coarsely powdered and sprinkled over burning coals, emitted a balsamic, mixed aromatic odour, devoid of the pungency of burned frankincense.

A thin cross-section manifested, at about 75 diameters linear, in the microscope, oil cells interstratified with apparently semi-viscid, resinous matter.

Nine hundred and sixty grains of the bruised bark, including about one-sixth its weight of the dark-colored epidermis, were exhausted with alcohol, and yielded, after removal of most of the alcohol by slow distillation on the water-bath and final spontaneous evaporation to syrup-consistence, 95 grams, equal to 146.5 grains, or about 15.25 per cent of a clear, rich brown, sweet-scented balsam-like substance, not dissimilar to Peruvian balsam in appearance. In the process of final condensation of the alcoholic extract, something like an ethereal oil partly separated to the surface in oily drops, but afterwards reunited with the denser parts.

A sample of this alcoholic extract yielded, with potassium hydrate, crystalline, quadrangular tablets of a yellowish colour and of the flavoured emanation, which, distilled with water and a little alcohol, gave a milky product of insipid, indifferent taste and smell, while the residue re-assumed, after a few days' standing in the retort, the previous camarin odour, indicating no essential change by distillation. This residue, treated with sulphuric acid to slight acidity, yielded a viscid, brown mass, of the exact smell of Storax, while the liquid, which deposited a slight amount of cinnamic acid, was of cinnamon odour. The alcoholic extract is soluble in caustic alkali.

A small amount of the bruised bark was distilled with water, when a slightly milky distillate was obtained, of faint cinnamon smell, with a very slight oily surface, the phlegma being of a muddy brown colour.

Another quantity of the bruised bark was macerated for a few days with water, with the addition of a small quantity of caustic potash to slightly alkaline reaction, the result, after expression and filtration, being a yellowish-brown liquid of same flavour as the bark. Sulphuric acid caused in the liquid a whitish turbidity with subsequent yellowish, crystalline precipitate; with hydrochloric acid also a whitish turbidity with subsequent brownish crystalline, precipitate; both liquids, after addition of the acids, separating also on the walls of the precipitating vessels resinous matter as a flocculent, brownish mass. The yellowish, as well as brownish precipitates mentioned proved to be cinamic acid, more or less contaminated with precipitated resinous matter.

Continued experiments proved that the odorous principles rest in an oily substance, cinamic acid and its combinations, and resinous matter. Benzoic acid, as a proximate principle, could not be identified, neither is there an alkaloid present in the bark. The peculiar action of potassic hydrate on the alcoholic extract, producing the exact coumarin flavour, deserves continued attention, which I shall give it in due time.

Although, as a rule, not comparable to frankincense, which is a pure resin, and of a pronounced, strong and penetrating smell upon ignition, this bark, from its milder, but more aromatic odour, may be considered a good substitute for fumigation in churches, and the oleobalsamic constituent, being contained in the bark to the extent of 15 per cent, will, no doubt, be found adaptable to many uses, and many eventually replace Peruvian balsam, than which it is much finer and more delicate.—*American Druggist*.

DIGGING AMONGST SHRUBS.

Opinions about the advantages or the disadvantages of digging amongst shrubs are not all on one side, as, although the practice is not favourably looked on by the majority of cultivators, on account of the injury more or less done to the roots that lie near the top, especially when the work is carried out thoughtlessly, still, there are those who contend that by the loosening of the surface soil the rain is enabled to descend more readily, and thus convey to the roots the requisite moisture, much of which, if the top crust were left undisturbed, would run off to a distance beyond the reach of such roots as most need it. In this, as in most other things connected with gardening, soil and situation make a difference in the course best to pursue. On open or fairly porous soils, especially where the annual rainfall is above the average, or where the shrubs are for the most part young, and have not to struggle for sustenance against the moisture-exhausting influence of the roots of large trees, there can be little question that even shallow digging—as amongst shrubs it ever should be—is so far a mistake: that there is no need for it on the score of enabling the winter rains to soak down and sufficiently moisten the subsoil, on which in a great measure the roots have to depend during the summer. But where, in addition to the rainfall being light, the soil is of a character that causes it, during the dry season, to form a close, impervious crust, the greater part of the much-needed autumn and winter rains run away, leaving the under stratum continuously in a semi-dry condition from one year's end to another, so as to make healthy growth impossible. This state of matters is most apparent amongst old shrubs that are more or less overhung with the branches of trees, and equally under the moisture-robbing influence of their roots. After the past very dry summer, the state of the large quantities of shrubs that exist under such conditions requires consideration, as regards the moisture in the soil indispensable for their future well-being. The mode for loosening the soil—digging amongst roots

has an ugly sound for persons who fully realise the importance of their not being injured—is at hand; and, taking into account the still unusually dry state of the subsoil in many localities, there is little doubt but loosening a few inches of the surface will help the much-needed water to get down. An important matter bearing on this subject is the proportion of trees allowed to remain where the joint occupancy exists. To keep the surface of the ground, when interspersed with old trees, fairly clothed with shrubs is often indispensable, and it is only by judicious management in retaining no more trees than will admit of the undergrowth of evergreen shrubs growing fairly, that the surface covering can be kept in a satisfactory state. How often may be seen unsightly objects, such as buildings that would have been better hidden, standing exposed through the undergrowth of shrubs not being able to thrive, on account of the trees above being so much too close together, that the combined shade of their branches, and the impoverished, moistureless state of the soil caused by their roots, reduce the growth of the shrubs to a bare existence. Nor is the condition of the trees when under such joint possession calculated to prolong their existence, especially if they have reached maturity and are in a dry locality; as the roots of the shrubs inflict only somewhat less injury on the trees than those of the trees do on the shrubs, the difference being that the tree roots stretch out further in search of food and moisture than those of the shrubs are capable of doing. As may be seen in places innumerable, the joint occupancy of trees overhead and shrubs below can be satisfactorily managed, even up to the time when both have reached what may be termed old age; but only by keeping a fair balance between the top and the undergrowth can this be secured.—*Friedl*.

AMERICAN FLORICULTURE.

There are, it was stated by the President at the recent convention of the Society of American Florists, not fewer than 8,000 florists engaged in the business, either growing plants or raising cut flowers for sale. Allowing 400 feet of glass-covered surface to each florist, gives us a total of 3,000,000 square feet; in other words, 630 acres. Calculating that half of the glass structures are used for growing plants, and that one-third of the space is actually covered with them, and averaging the size of pots used at 3 inches diameter, and allowing two crops each year, the number of plants would be about 40,000,000.

The remaining half of the glass structures are used for the purpose of growing cut flowers; the actual number produced is almost incredible. I can state, however, that during the past season—beginning with November and ending with April—nine large growers of Roses sent into the New York market close upon 4,000,000 of flowers, and when I state that this was not 50 per cent of the Roses sent to New York alone, the magnitude of Rose growing will be imagined. The Roses grown around Boston, Philadelphia, Pittsburg, Cleveland, Chicago, Washington, and all other places, could not be less than twice as many as were produced for the New York market. This would bring up the number of cut Roses produced during the past season to 21,000,000. It would be very safe to multiply the number of Carnation flowers produced in the same time from all sources by at least five; this would give 125,000,000. Fabulous as this may seem, I feel that my calculations are rather under than over the actual number placed in the market. It would, moreover, be very safe to state that at least one-fourth as many Roses and Carnations are annually raised by gentlemen for their own enjoyment, which represents as much value as if thrown on the market and sold over the counter. Of various other flowers, though not in the same proportion, there are produced many millions.

The bulb trade, the bulk of which is represented by importation, has grown to be a source of great value to the business, and as there is a duty of 20

per cent on all bulbs imported, it is a source of revenue to the country also; and, while I have no actual data to make a close estimate of the value imported last season, it is safe to say that not less than 200,000 dollars' worth were actually imported in the last twelve months—the bulk of these being Hyacinths and Tulips, more than one-half being used to force for cut flowers: this does not include more than 5,000,000 of Lilies of the Valley, which are not dutiable.

Thus far I have not said anything about a very important branch of the business, or those engaged in it. I refer to that branch known as the florists' supplies and requisites, which has grown to be a most important factor in the trade. The number engaged is estimated at 700. The most important articles are shapes for floral designs, such as ornamental baskets, vases in glass and porcelain, and other wares; wire work, holders for bouquets, tinfoil, wire for stemming, different papers for packing and wrapping flowers, and other articles used in the business. The actual amount of capital invested in this branch of our business is in the aggregate many hundreds of thousands of dollars, employing more labour in proportion than does the florist proper, paying in many cases enormous rents for their accommodation. Most of those engaged in this branch have other business relations, either as seedsmen or dealers in bulbs or cut-flowers. Then we have the army of cut-flower men, those who are not producers, but make a business entirely of selling flowers, either made into shapes or loosely. This is a growing branch, and to-day there are not less than 2,000 employed in it.

The land occupied with flowering plants and bulbs of all kinds scattered over the country must aggregate at least 12,000 acres, in addition to several thousand acres used for growing flower-seeds. This is accounting only for land so occupied in America. It would not be too much to say that fully half as much land in Europe is also used in the same manner for the American trade. In addition to this there is nearly as much area of land, and as much glass, and more than half as much labour devoted to the cultivation of flowers by gentlemen who can make a pleasure of so doing; yet, with all this, the florists and gentlemen growers of America have been unrepresented by any organisation until the Society of American Florists was established. Just think of an industry of such magnitude without a voice or a word in its own interest!—*Gardeners' Chronicle*.

NOTES ON SOME JAPANESE OILS.*

BY E. M. HOLMES, F.R.S.,

Curator of the Museum of the Pharmaceutical Society.

At the close of the International Health Exhibition at South Kensington, some specimens of the fixed oils used in Japan were presented by the Japanese Commissioner to this Society. These seemed to be of sufficient interest to demand a short notice in the columns of our Journal. This I had intended to have given later on, but my attention having been called by Mr. R. H. Davies to some oils imported from China, very similar in character to some of these Japanese oils, the present moment seemed to be the fitting one to notice such of the latter as appeared to resemble the Chinese oils, reserving a notice of the remainder to a future date.

BRASSICA OIL.—Two qualities of this oil were exhibited at the International Health Exhibition, one of a yellow colour and of "superior quality" and closely resembling European colza oil in appearance and odour, and without any pungent taste; the other similar in colour to linseed oil. The former is probably obtained from the seeds of the *Abraxa* of the Japanese (*Brassica campestris*, L.), of which three varieties,—early, common and late,—appear to be cultivated to a considerable extent in Japan. The oil is used for culinary and lighting purposes. Accord-

ing to Dr. E. Mene it is also used in tobacco manufacture to prevent the leaves falling to powder after rapid drying. Lampblack for use in making Chinese ink is also made by burning the oil under conical receptacles pierced with holes in the upper part. The residue after the expression of the oil is used for manuring plantations of *Camellia japonica* and other plants.

The dark coloured oil is probably obtained from the seeds of the *Petsai* (*Brassica sinensis*) and is used for similar purposes. It is also employed in medicine as a purgative, and as an external application in certain diseases of the skin. *Brassica sinensis* is also grown in immense quantities in China especially in the Yangtse-kiang and Hankiang valleys, in the province of Hupeh and to some extent also in the provinces of Kiangsu and Chikyang. The seed is ripe in May. It probably this kind of oil that has recently been sent to the London market, and which Mr. Davies has now examined and reported upon.

CAMELLIA OIL.—The specimen exhibited at the International Health Exhibition was labelled oil of *Camellia japonica*. It is of the colour and consistency of olive oil, and in consequence of its containing very little solid fat, and not yielding a deposit when exposed to considerable cold, it is employed by watchmakers in Japan, according to Mr. Murai. In Siebold and Zuccarini's "Flora Japonica" (p. 157) it is stated that the oil obtained from the seed is mixed with Japanese wax (*Alnus succolarum*) and perfumed with oil of cloves and other essential oils to form a pomade which is in common use in Japan. A similar oil is obtained in China from *C. oleifera*, according to Mr. C. Ford,* who observed the shrub in cultivation in the neighbourhood of the West River.

In that district it is used to supply the growers with oil for culinary purposes and for anointing their heads, but is not grown in sufficient quantities for export. It must, however, be largely cultivated in other parts of China, since I find, from a statement in Spou's Encyclopædia (p. 411), it forms an important article of trade, having been exported from Hankow to the extent of 3,610½ piculs (of 133½ lb.) in 1873, and 5,826 piculs in 1879; Shanghai also imported 5,792½ piculs in 1879 and exported 2,991½. The oil is obtained by crushing the seed to a coarse powder, boiling, and then pressing. The seeds of *Camellia japonica* are ripe in September. It may be mentioned here that the seeds of *Thea sinensis* (*Camellia Thea*) were recently offered in the London market under the name of "tame" seeds ("tame" meaning seeds according to Mr. Murai). The seeds are capable of yielding one-third of their weight of oil,† and according to a recent examination by Peckolt yield also 13·8 per cent of starch and 1 per cent of theine.‡

The camellia oil is non-drying, very fluid, of pale colour and free from unpleasant odour, and doubtless if prepared by cold pressure would compare very favourably with the best olive oil, and judging from the price in China (about 4d. to 6d. per lb.) could certainly compete with almond oil for many uses in this country, if not with olive oil.

WOOD OIL.—The Japanese oil exhibited under this name is stated on the label to be the product of *Elaeococcus cordata*.§ It must not be confounded with the oleoresin known as wood oil or gurjun balsam, obtained in India and Malaya from *Dipterocarpus turbinatus* and other species. The Japanese wood oil is a fatty oil, obtained from a euphorbiaceous tree called "shura giri" i.e., oil tree, and "yani kiri," i.e., mountain or wild kiri,—"kiri" being the Japanese name for *Parlownia superciliosa*, whose leaves are very similar in appearance. The tree grows wild

* *Journ. Soc. Arts*, 1883, p. 513.

† Spou's Encyclopædia, p. 1411.

‡ *Pharm. Journ.*, [3], xv., 508.

§ I am reminded by Mr. W. T. T. Dyer that the genus *Elaeococcus* has been sunk by Bentham in *Alseodora*. The name should therefore be *Alseodora cordata*.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, February 4, 1885.

in the warmer parts of Japan, and is also cultivated in mountainous places and woods, as well as by roadsides, chiefly in the provinces of Homolakei and Figo, in the central parts of the Isle of Nippon and in the provinces of Suruga, Sagami, Muzasi and Idzu.

The seeds yield 35 per cent of oil by cold expression, but the specimen presented to the Museum of the Society has probably been made by boiling the crushed kernels previous to expression, since the cold drawn oil is colourless, inodorous, and nearly tasteless, and according to Cloez* has a sp. gr. of 0.9362, moreover it solidifies rapidly when exposed to light in a closed vessel filled so as to exclude air. The Japanese oil, on the contrary, has a brownish colour and a higher specific gravity, as has been shown by Mr. Davies; it remains perfectly fluid when exposed to light. The wood oil, or "doucoum," as it is called in Japan, is employed to fill the pores of wood before applying lacquer; it is also used, like tar, to render wood impermeable to moisture. It is stated by Cloez to be the most drying oil known. In medicine the oil is used in skin diseases, and mixed with other ingredients to make an application for ulcerated wounds and carbuncle. The cold-drawn, pale-coloured oil is, according to Dr. E. Mene, used for varnishing furniture, umbrellas, paper, and paper leather.

In China the oil is one of the principal articles of native manufacture; in the provinces of Kyaugsi, Chikyang, and Szechuen it is universally employed for painting and caulking junks and varnishing and preserving all kinds of woodwork. Hankow is the chief market for the outward trade, and exported in 1878 as much as 336,053 piculs (133½ lb.) and 203,820½ piculs in 1879. The importance of this commercial product has already attracted the attention of the Director of Kew Gardens, for it is stated in the Kew Report for 1880, p. 11, that seeds of the tree had been obtained from Szechuen and distributed to Ceylon, Demerara, Dominica, Jamaica, Zanzibar, and the United States. An attempt to naturalize the tree in Algeria has also been made by the French.

In view of the frequent adulteration of linseed oil with resin oil, etc., the appearance in the market of an oil possessing still greater drying properties may be hailed as a circumstance likely to lead to the production of a purer and equally valuable drying oil by our colonial possessions.

Mr. Naylor said that the meeting was very much indebted to Mr. Davies for the information which he had given upon the chemistry of these oils, and also to Mr. Holmes for giving them some particulars respecting their history and commercial uses. He had been particularly struck with the sample of tea oil which had been handed round. Some time ago a sample of oil had been placed in his hands along with several samples of olive oil. It was a kind of oil which could not be well identified with olive, and he rather gathered from the observations which he had just heard and from the examination which he had made that the oil of which he spoke must have been either tea oil or a product very closely related to it. He was a little surprised that the sample of lead plaster had not come out somewhat better. It appeared to be rather greasy. Perhaps if different proportions of litharge and oil had been used and the mode of preparation somewhat altered, a very fair emplastrum plumbi might have been obtained. The drying oil was really a very remarkable body. He did not think that it was approached in its drying qualities by any oil met with in this country. There was a large demand for an oil which would possess drying powers superior to those of linseed for the preparation of gutta percha and rubber compounds. Some further information as to the commercial value of these new oils might be interesting.

Mr. Groves said that a great amount of interest attached to this new drying oil. He had been won-

dering whether it had any purgative effect like that of castor oil and similar oils. If it could be obtained at anything like the price of linseed oil it would be extremely valuable, for linseed oil frequently was contaminated by products derived from cruciferous seeds.

Mr. Tanner said he had been more especially interested with the tea oil. He did not quite join in the condemnation of the lead plaster. He wished to know whether Mr. Davies used the proportions of oil and litharge ordered by the Pharmacopœia, and whether he followed the instructions as to the boiling. The soft condition of the plaster would, he thought, tend to show that a larger proportion of litharge was requisite.

Mr. Allen said he had always heard that a certain fortune awaited the man who could introduce an oil which would dry quickly and not deteriorate paintings. The drying oil which had been described seemed to be of such a remarkable nature that Mr. Davies would do well to investigate it further. The camellia oil which had been spoken of was another example of an oil which might become remarkably useful. Watchmakers had the greatest difficulty in finding an oil which would not dry, and as many clocks were placed in elevated positions in a heated atmosphere, especially in pharmacies, perhaps the oil could be advantageously used in connection with such clocks. The pharmacist's clock exercised a great deal of the watchmaker's ingenuity.

Mr. Chubb said he should like to know whether Mr. Davies had tried the effect of sulphuric acid upon the oil in respect to the heat that was produced by the action of the acid upon the oil. That heat must of course be tremendous. He should also like to know whether Mr. Davies had tried the effect of solvents upon wood oil in order to see whether alcohol, for instance, would extract anything from the oil. As to the other two oils, he understood that the amount of acid in them was practically nothing. A short time ago he examined a whole stock of oils for a large manufacturer in Liverpool, and after that he obtained about thirty samples from different brokers in Liverpool, and out of the whole of the samples there was not a single specimen of fatty oil which contained less than ½ per cent of free fatty acid. He had understood that in a very large stock of oils examined in France the average was about 3 per cent of free fatty acid.

Mr. Watson Will said that the tea oil had been stated to be closely allied to olive oil. He wished to know whether it contained the same amount of fatty acid. If it contained a larger amount of free fatty acid, that fact would explain the reason why the lead plaster was greasy. He should like to know the specific gravity of the brassica oil.

The Vice-President said that he hoped Mr. Davies would prosecute his inquiries upon the chemical side of this research. He thought that it would be right for the meeting to recognize distinctly the value of the work which had been done in that direction. As Mr. Davies had told them, the work in that direction was not complete. That seemed to be the case with nearly all chemical research. Investigators never seemed to approach finality, even with regard to those substances which were the very alphabet of their pharmaceutical existence. Looking commercially at the subject which had been brought before the meeting, his own impression was that there was a vast future in the direction of the exports from those comparatively unknown countries, China and Japan. Japan was a most interesting country, with a civilization strangely antique and strangely new, and at present we had access to the country only through the Treaty Ports. Mr. Holmes, in his paper, referred to the fact that one of the oils was used for cooking purposes. He (the Vice-President), confessed that though the oils exhibited very elegant pharmacy in respect to their colour and the handsome bottles which contained them, he should not like either of them to be used for cooking his omelette.

* *Comptes Rendus*, vol. lxxxii., 1875, pp. 469.

Mr. Davies, in reply, said that he was very much gratified at the interest which had been manifested with respect to those oils. As regarded the emplastrum plumbi, he must say that it was not at present satisfactory. But he was not at all prepared to say that a good plaster could not be made with the oil. The Pharmacopœia proportion of litharge had been used in this case, and the time of boiling had been about four or five hours. In such matters "rule of thumb" was bound to obtain to a certain extent. As to the fatty acids, he had given in each case the amount produced by a given weight of the oil, and the proportion dissolved by the washing water, and of what they might call insoluble fatty acids. He had not compared the percentages of the fatty acids with those of olive and almond oils, but he had compared the new oils with olive and almond oil in respect to the amount of potash required to saponify a given amount of oil, or the saturation equivalent, as it was called. This comparison pointed to the similarity which he had indicated being very great. In this respect the tea oil very closely resembled olive oil, and there was a resemblance also with regard to the specific gravities of the two oils. The cabbage oil bore a resemblance to rapo oil in respect to the saturation equivalent. The wood oil, however, did not resemble any other oil with which he had compared it, and therefore probably it would be found that in the case of the wood oil there was a distinct acid, different from anything else which had been previously discovered. While speaking of the drying oil he might mention that its drying character was exceedingly apparent. He had not been aware that anyone else had worked at these oils until he saw the statement in Mr. Holmes's paper, but it appeared that Cloez published, in the *Comptes Rendus* for 1875, an account of a seed yielding one of these oils. But the oil which Cloez described differed from the oil he (Mr. Davies) had found, inasmuch as it was of a lighter colour. With regard to the action of solvents, he had found that alcohol effected a considerable difference in the appearance of the oil. When the oil was boiled with alcohol a portion appeared to dissolve, and it was difficult to tell while the liquid was hot whether the oil was all dissolved or not, but when the liquid was allowed to cool, the oil commenced to deposit, and when it was collected it was found to be much lighter in colour. It would appear that at any rate one constituent of the oil was soluble in alcohol, though as a whole the oil was not soluble. With regard to the commercial aspect of the question, he had done his best to obtain information, but he had altogether failed in that respect. Respecting the internal administration of the oil, about which Mr. Groves had asked, he was not aware that any experiment had been tried. He should feel much diffidence in taking himself any oil derived from the Euphorbiaceæ, but he was quite willing to supply oil for the purpose of the experiment. The lubricating quality of the camellia oil had been alluded to in the paper. Whether the oil would refuse to dry under the action of a warm atmosphere he did not know. He had exposed some of the oil upon filter papers in the tolerably warm temperature of the laboratory without any perceptible drying. He had not ascertained the amount of heat developed by any of the oils under the action of sulphuric acid. He did not see what useful end would be served by such an experiment.

Mr. Holmes said that he could add nothing with regard to the medicinal properties of the wood oil. He could only suggest that as the oil was used for application to ulcerated sores, he should think that it might be used with comparative safety internally. As to the adulteration of the wood oil, the Chinese had an excellent character for imitation and adulteration, and unless the oil could be obtained through an English factory or an English firm, he should very much doubt whether it would always be exported pure. The camellia oil which had been exhibited was not obtained from the *Camellia thoa*, but from the *Camellia japonica*, and as far as he had observed, the latter

did not possess any perfume. The camellia oil which was exhibited was not derived from the seeds of the tea tree (from which indeed it seemed to differ, since a specimen of oil in the museum, and which was labelled oil of the seeds of the tea tree, had become semi-solid), but was obtained from the plant known in this country as the camellia (*Camellia japonica*), the flowers of which were so commonly worn in button-holes. The Chinese oil was apparently obtained from another species, *Camellia oleifera*. In speaking of the uses of these oils in Japan he did not intend to point out that they might be so used in this country. It was quite possible that the Japanese and Chinese might not object to the flavour of mustard or cabbage in the oils used for culinary purposes—tastes differed in such matters. The camellia oil moreover might in some samples have a acrid taste, which was very perceptible in the seeds, and might easily be communicated to the oil if it were obtained by hot pressure.

A vote of thanks to the authors having been passed, at the request of the Vice-President—

Mr. HOLMES called attention to various pharmaceutical specimens which were exhibited on the table. Among these were specimens of various salts of cocaine presented by Mr. Merck, an alkaloid which, as they all knew, in a very short time had obtained a great reputation as an anæsthetic. There was also a series of specimens of medicinal products from Jamaica, received from the Director of the Botanical Department at Gordon Town. The Director had paid great attention to the cultivation of the various drugs, as cinchona, jalap, etc., in the island, and recently he had turned his attention to the preparation of Barbadoes aloes, a specimen of which was on the table, while a small duplicate was at the disposal of any member who would be willing to examine and report upon it. Some leaves of the *Eucalyptus citriodora* had been sent by the same donor. These had exactly the odour of citronelle oil, and would probably yield an oil that might compete with it in fragrance. A specimen of the stem of the *Camellia alba* with the outer bark attached also came from Jamaica. The bark being dried on the stem did not possess the white colour which was generally seen in the commercial article, but showed the outer bark, which is removed in its preparation for the market. The Curator also directed attention to a specimen of a bark which had been recently recommended for use in diabetes, *Syngonium jambolanum*. A specimen of spurious musk pod, sent by Mr. H. A. Woolnough, of Hong-Kong, consisted of a piece of the skin of the musk deer with the hair attached, and was very nearly sewn up so as to resemble a true pod, but the contents were worthless. There were two very fine specimens of pip-menthol prepared from the true peppermint by Mr. A. Tod, of Michigan. It was proposed to introduce this into commerce to compete with the Japanese method. It appeared drier than the Japanese drug, but opinions seemed to differ as to its superiority for use in medicine. A cluster of pods of the Mexican vanilla, growing on the original stalk, had been presented to the Museum by Mr. H. Cocksedge. It was very rare to see it in commerce in this form. He should like to know whether the vanillin existed from the fruits in the form of vapour and then crystallized, as the crystals extended in some cases to fully half an inch beyond the pod, and as these were formed at the ordinary temperature it would seem as though it was volatile at about that of the air. A large specimen of "mandrake root" had been sent for exhibition by Mr. C. O'Sullivan, of Sutton. It might not be known to all pharmaceutical students that white bryony root (*Dryas alba*) was sold under this name; it should not be confounded with the plant called mandrake in the United States (*Poleophyllum peltatum*), nor with the true mandrake (*Atropa mandragora*). A specimen of the false cubebs which had been mentioned in the Journal had been placed upon the table for examination by the members present, since it was possible it might come into commerce. This was the article that had

been offered recently as cubebs in the London market, and might serve as a warning to chemists to be on the look out for adulteration whenever a drug goes up in price. A very interesting specimen of the Chinese insect wax *in situ* on one of the plants, *Fraxinus chinensis*, on which the insect feeds, had been received that day from the Director of Kew Gardens. Also a specimen in fruit of another plant, *Ligustrum lucidum*, upon which the same insect feeds.—*Pharmaceutical Journal*.

NEW TEA MACHINERY.

From information supplied by Mr. Rutherford to a local contemporary, it would appear that Messrs. A. J. Main & Co. are in the field with "Dick's patent mechanical tea packer." It is claimed for this machine that it will compress into 800 boxes a quantity of tea, which, by the usual methods of packing, requires 1,000. There would be thus not only a saving of 20 per cent on boxes, nails, &c., but a corresponding saving in land carriage and sea freight. The cost of this wonderful compressor is stated to be so high as £147 10s (note the odd 10s) f.o.b. at Glasgow. This is a heavy sum when charges to the estates are added, and the whole converted into rupees, but it would doubtless pay large estates to use the machine, if, besides compressing the tea, it fulfilled the further claim made on its behalf, "without breaking the tea, or other injury occurring." It seems to us impossible that, with the pressure applied, the leaves should not be broken, and more than this converted into a solid mass. The tea, in fact, would be compressed tea, such as some years ago was widely advertised as especially convenient for travellers. We tasted the compressed tea, and found that the crushing process had developed tannin at the expense of theine, and that the infusion tasted strong and coarse. It was a modified brick tea, in truth. Until, therefore, the owners of very large estates, such gentlemen as Mr. Rutherford, have adopted and reported on the work of this automatic packer, we fancy tea factories in Ceylon will continue to pack tea after the fashion now in vogue, viz., that of a cooly treading on a clean cloth spread over the tea in each box, half-chest, or chest, until the package is full or contains the regulated quantity in proportion to size.

Mr. Rutherford, it seems, is about to give a trial to another invention by the Messrs. Main, the importance of which, if it achieves the success claimed for it, cannot be overrated. The difference between high quality and low quality outturn of tea depends largely on the proper withering of the green leaf. But the success of this process depends largely, almost entirely, on the state of the proverbially fickle atmosphere which surrounds our earth, and which in a climate good for the culture of tea is for a considerable portion of the year saturated with moisture. Now one of our highest, if not the highest authority on tea manufacture in Ceylon desiderates a warm moist atmosphere for the proper withering of green tea leaves. If such an atmosphere is necessary, then grave doubts must arise, whether the principle of Main's appliances for withering tea leaves is correct. It is thus described:—

Messrs. A. & J. Main & Co., after having made careful and elaborate experiments for the last two years, seem to be confident they have at last solved the problem, and state they can effectually wither green leaf in from 1½ to 2 hours, while all "stewing," "scorch-

ing," or other deleterious effects are avoided. The fundamental principle of their patented appliances is to desiccate or dry the air before it is allowed to operate on the leaf. This is done by an absorbent, perfectly innocuous, cheap at first cost, and which does not require renewal beyond the evaporation of the moisture absorbed. The desiccated air is then applied to the leaf in a simple, but effective, manner at the normal temperature of the atmosphere, or about 85° to 90°, while light is freely admitted.

This sounds well, but the idea of the application of desiccated air is certainly a new one, and our fear would be that the leaves would be left, not soft and satiny, but hard and crisp, semi-desiccated themselves by the desiccated air, which, of course, would keep absorbing moisture as long as any remained in the soft vegetable substance with which it was brought in contact. This is certainly not the orthodox tea-house idea of *withering*. It is a drying process, rather, in anticipation of the final drying by fire heat. Either the experienced tea-planter, Mr. Armstrong, is wrong in his philosophy, or Messrs. Main & Co. in the principle of their invention. But we may hope soon to learn the result of a practical test. The same firm have invented a drier, which is thus described:—

The next invention is by the same makers, and is a "Tea Firing Machine," for which they claim that it has the power to "fire" at any desired temperature at the option and under the control of the operator; and that it will fire its charge at 200° in 15 minutes. One size of dryer takes 200 lb. at one charge, and the other 80 lb.—or equivalent to about 800 lb. and 320 lb. per hour respectively. We are not informed if this quantity refers to green leaf, fermented leaf, or made tea.

Then Mr. Kimmond, Mr. Jackson's rival in rollers, but unsuccessfully so in Ceylon, has, in conjunction with a Mr. Richardson, invented a new roller which is thus described:—

This machine is described as differing from all other tea-rolling machines, in that, at each stroke or revolution of the rolling surfaces, the tea leaf is presented to the rolling surfaces at a different angle, and no two points in the rolling surface give the same rolling action to the leaf, which is subjected to a multiple action, the consequence being a harder twisted leaf and a total absence of flat leaves.

The motive power required is 3 h. p., and it is stated to be capable of rolling 900 lb. of green leaf per hour. The price in England is £100, and the makers are Messrs. Robey & Co., Globe Works, Lincoln.

SEEDLING FRUIT TREES.—Seedling Apples, Pears, and possibly other fruits, may under the conditions of the soil and climate, &c., of the districts in which they have originated be found to be possessed of qualities which they will not retain when transferred to other localities where similar conditions do not exist; while on the other hand, varieties may have been discarded on being found of little value in the locality where they originated, but which might, under the influences of other soil and climate, be found to be possessed of desirable qualities.—*Gardeners' Chronicle*.

EUCALYPTS.—At the Linnean Society on November 5, there was shown for the Baron von Mueller a characteristic collection of skeleton leaves of species of Eucalyptus prepared by Mrs. Lewellin, of Melbourne. These confirm Baron von Mueller's observations as to definite layers and the relation of these to the skeletonising process. The leaves in decaying produce no bad odour. Mueller's observations do not support Mr. Riviere's statement that the bamboo is as good as Eucalypts to subdue malaria; the former dry up, but do not exhale the volatile oil, as do the latter, and the Eucalypts, moreover, absorb moisture as quickly as Willows, Poplars, and Bamboos.—*Gardeners' Chronicle*.

Correspondence.

To the Editor of the "Ceylon Observer."

CURE FOR DYSENTERY; TEA AND FIBRES
IN SOUTHERN INDIA.

2nd Dec. 1885.

DEAR SIR,—Your note on the value of the bael fruit as a remedy for dysentery reminds me to send you the enclosed extract from a letter lately received from a gentleman, deservedly an authority on planting matters, in South India, that may otherwise be read with interest:—

"Ootacamund, 17th Nov. 1885.

"I heard of a man at Coonor who gave R90,000 for 50 acres of tea and 50 acres of scrub. The bushes give 400 lb. an acre, and they say they make 7 per cent on the purchase, but matters here just now are not looking up, as there have been many failures, especially of a large firm that did business in coffee and tea plantations. There is no doubt that any plantation of tea that gives 500 lb. an acre must pay well, specially with the price of silver falling. If you would avoid too much blossom at that low elevation plant nothing but the best sort of Assam, no suspicion of China about them. Did you ever try the Maseekoy nut for dysentery? It acts like a charm. It can be bought in the bazaar. One nut ground down with water is generally enough. The rhea here under Mr. Minchin is doing well, and likely to be a success. I know him very well, and he told me that he had 250 acres planted, and was going to adopt a process for cleaning that was certain to succeed. But the plant requires high cultivation to yield well; plenty of irrigation and manure."

Unfortunately the name of the nut is rather indistinctly written. It looks to me like "Maseekoy" nut. Perhaps you can identify it—with further particulars—and say if procurable locally? R90,000 sounds a good selling figure for 50 acres of tea giving only a third the crop average of Mariawatte, and, say, half of our less sanguine hopes elsewhere here; and 7 per cent rather a more modest interest than men in Ceylon, I expect, would care to calculate on as their *maximum* from an agricultural investment, with its hard work, anxiety, and many uncertainties. A pity a few more of these less avaricious investors from India don't come over here with their pockets full: little doubt but they would find themselves met in a friendly and fair spirit?

It would be interesting to have fuller particulars of this new fibre-cleaning process, and I hope to get them later on. I expect it has reference to the use of a cheap chemical, lately discovered, that I read somewhere had been found to answer. The only thing necessary was to boil rhea ribbons for a short time in a solution, with no further "plant" than a few inexpensive boilers—and I suppose a baling press—required to produce a sample, perfect under every test! From what I could make out from a friend who has recently visited Mr. Minchin's estate, with the idea of cultivating fibre here, we are out of the running as regards richness of soil, but our climate and facilities for irrigation and manuring sufficiently greater to more than make up for this! Rupees one hundred per acre seems to be the annual profit anticipated in India. E.

[Mr. Minchin has written twice to us explaining his fibre work: his letters will be found in the *Tropical Agriculturist*; the R100 per acre have not yet been made.—Ed.]

TEA PLANTING IN UVA.

Badulla, 5th Dec. 1885.

DEAR SIR.—A great deal of valuable, if not practical, information regarding the progress of cultivation of tea in the Uva districts ought now to be reaching you, but it is not nearly so full as it might be, and, considering the great importance of the subject, any special effort made by you to furnish us more frequently, and with fuller information, would, I feel sure, be greatly appreciated by all who have (and who has not?) the success of the enterprise at heart. The figures of the area under tea in Uva in your new Directory will prove very interesting, and doubtless the information will be as complete as possible up to the date of publication, but the aspect of things is changing with us every day, and so much is being done in a quiet determined fashion, which is only known to those immediately connected with the carrying out of the work, that many of your readers would be glad to see a larger space in the *Observer* under the heading of "Planting Notes" devoted to "Tea in Uva." In this connection Mr. Johnson's letter in your issue of the 2nd inst. is of considerable interest, but not of much value. It is interesting to know that a marketable tea can be grown on an estate situated as Dotlands is, in the midst of a large tract of pataua, and a rainfall which does not compare very favorably with the returns published from other properties in the district where tea is being planted on a very extensive scale, and if it can only be shown that tea will grow and pay on Dotlands, it would prove a source of great comfort to some of us. If the only thing which stands in the way of Mr. Johnson's extending his area is the price which his tea is likely to fetch in the local market, his doubts on this point would be most effectually solved by his sending a sample for report and valuation, accompanied by the small sum of R3, to one of the many experienced tasters now resident in Colombo. But I fear that something more than this is required, for, until his tea is a good deal older, he will not be able to say whether Dotlands is capable of producing the article at a figure which will show a balance on the right side.

It is true we have to pay somewhat heavily for the transport of our produce and supplies, but the difference on this item will not be found so much in favour of districts served by the railway, as Mr. Johnson's remarks would lead one to suppose. Were the profits on the cultivation of tea in Uva to be calculated on so fine a scale as the difference in cost 'twixt road and rail transport, the prospect would not be a bright one. The reasons that might be urged in favor of railway extension to Badulla are legion, and I must say that you have consistently and persistently brought forward the whole array on every possible occasion when their recapitulation could be of any service to us, but perish the thought that the absence of a railway should stand between us and the successful and profitable cultivation of tea. The question of transport and almost every other item which is likely to crop up in connection with tea has already received most careful consideration at the hands of some of those who are foremost in the enterprise, and it should be encouraging to those who hold suitable land in this district to know that one of its earliest pioneers (Mr. John Brown) is now one of the strongest advocates for the extension of tea on the large properties in which he is still interested, and with whose management he has for so many years been closely connected. The rate of transport has not been prohibitive in the case of coffee, neither will it be so with tea. Indeed the benefits of quick transport as regards coffee are of vastly more im-

portance than they are in the case of tea, for my Colombo Agents have repeatedly told me that ten shillings a hundredweight was no overestimate of the extent to which my coffee was depreciated by the long transport via Ratanapura. Just think, Mr. Editor, what a huge sum of money ten shillings a hundredweight on the crops of Uva from its palmy days down the present day of small things would amount to. It would almost pay for the construction of a railway, I should think. On most of the estates, both here and in Madulima, where tea is being largely planted, there are considerable reserves of forest available as fuel, and, in addition to this, large numbers of fast-growing trees are being planted, so that for a time at least we shall not all have to depend on rail-carried fuel, but when we do have to indent for tons of coke and coal, I hope the means of transport, in the shape of a railway right into Badulla, will be there to meet our wants.

I believe I am right in stating that some thousands of acres are already under tea in Uva, and if the men who have borne the burden and heat of the day, and are pegging away at it still, would tell us occasionally something of the progress of the young plants, it would add greatly to the interest and value of your paper. If you would just give a hint to the effect that those planting tea in Uva might be a little more communicative of their doings, I feel sure it would have the desired effect.

ICH DIEN.

Our Directory figures show some 4,500 acres of tea planted within the Principality, and they are certain, as our correspondent says, to attract attention. We shall be happy to receive and publish communications of the nature desiderated. We have ever believed in the suitability of Uva for tea culture, and a new and strong argument for railway extension lies in this fact, of which we have not failed to make use.—ED.]

THE PACKING OF TEA.

Dinbula, 10th Dec. 1885.

DEAR SIR,—There is an error in your printer's rendering of my letter. I said "a fortiori" and not "a portion of." As I am again on this subject I may point out how much more profitable it is to employ full chests rather than half-chests or still smaller packages. For the extraordinary arithmetical manoeuvre described by "Tea Buyer" can of course be practised on each package, and I have seen an account sale of tea shipped in small packages in which 15 per cent loss in weight was incurred. This most objectionable weighing trick and the 1 lb. draft are public scandals, and should both be abolished.—Yours truly,

TEA MAKER.

SULPHURIC ACID: LOCAL MANUFACTURE.—A planter writes:—"I don't quite agree with your views about that SO₂ Company. The loss of the Ceylon custom would not reduce the home price by a cent. The local Company would of course want to make as much profit as it could, and so the public would merely in all probability gain but a very slight reduction in price, say just something under what the acid could be imported. A ten years' monopoly would be bad. Let Government however offer a handsome bonus on the first 10 tons acid made and remit duty on its imported machinery and material." The proof of the pudding is in the eating: if a success in the Barbados, why not in Ceylon? With abundance of sulphuric acid locally available, there is no saying what can be done!

IVY FOR SCREENS.—I have from time to time travelled a good deal abroad. Recently, when at Darmstadt, I noticed a very good plan of ivy for screens, which was the growing of ivy against wooden uprights painted green, stuck in long, narrow, but deep wooden boxes, also painted green. These boxes could be easily moved about as required, and a screen some three yards or more in height, as required, could thus at once be produced.—C.W. (Pau. Besses Pyrenées, France).—*Fruit.*

A METHOD OF WATERING PLANTS IN INDIA.—At a meeting of the committee of the Agri-Horticultural Society of Madras, Deputy-Surgeon-General John Shortt, concerning watering in India (on the Shaverooy Hills) said:—"I also resort to the *Girrah* mode of watering plants, that is, the common water-pot styled *colaba* on the Madras side, having a small mouth. It has a small hole knocked into the bottom, and the pot is buried to a depth of one-third its size, as near to the stem of the plant as possible, and it is kept constantly filled with water, which very gradually oozes into the soil through the minute opening at the bottom, giving moisture to the roots of the plants without causing waste by spilling or evaporation. I find this method a great success."—*Gardener's Chronicle.*

WONDERFUL CATERPILLARS.—A Demerara contemporary says:—"A country correspondent has been good enough to send us a bottle containing a number of caterpillars, about 6 inches long and about a quarter of an inch thick. They are round in the body, the back being a glossy black, and the under side a marled white with vermilion spots; the head is a bright vermilion. Our correspondent says:—"These worms are destroying all the sweet cassava in Sisters Village; they are so numerous that some of the people cannot get into their beds to work or reap their crop. Fields of cassava are destroyed by them; they are also interfering with the coffee trees. The farmers in Good Intent, Sisters, and La Re-traite have suffered much. It is something wonderful to bear them feeding." It is to be hoped that Demerara will send specimens of this scourge to the Colonial and Indian Exhibition.—*Colonies and India.*

TEA IN PERSIA.—The *Pioneer*, commenting on the re-export trade from Bombay to Persia, says:—"No fewer than 985,000 lb. of Chinese tea were sent from India to Persia, and only 40,000 lb. of Indian tea. We have often reminded our tea-planters of the neglect of their own interests shown by them in not cultivating the Asiatic market, but these figures place that neglect in a striking light. India, which affects to be a tea-producing country, actually sends to Persia 25 lb. of Chinese tea for every pound of Indian tea. This evidence of want of enterprise among our tea-growers is perhaps the most discouraging feature in the whole prospect of Indian industries." These are hard words, but we are afraid they are deserved. Why should not the Tea Syndicate exploit Persia.—*Indian Tea Gazette.* [We learned in Java that a good deal of the tea of that country is sent to Persia.—*Ed.*]

WHEN TO EAT FRUIT.—Fruits, to do their best work, should be eaten either on an empty stomach or simply with bread—never with vegetables. In the morning, before the fast of the night has been broken, they are not only exceedingly refreshing, but they serve as a natural stimulus to the digestive organs. And to produce their fullest, finest effect, they should be ripe, sound, and every way of good quality; moreover, they should be eaten raw. What is better than a bunch of luscious Grape or a plate of berries or Cherries on a summer morning, the first thing on sitting down to breakfast? Or a fine ripe Apple, rich and juicy, eaten in the same way? In our climate Apples should constitute not the finishing, but the beginning of the meal, particularly the breakfast, for at least four months in the year; and fruits, raw or cooked, should make a part of the morning and evening meal provided suppers are eaten during the entire year.—*Fruit and Wine, quoted in Gardener's Chronicle.*

BAT GUANO.

TO THE EDITOR OF THE "MADRAS MAIL."

Sir,—In reply to the letter of your correspondent "Amateur," which appeared in your issue of the and instant, relative to the use of Bat Guano as a manure for flower gardens, I beg to state that the guano in question is extensively used by farmers for the rapid and luxuriant growth, and rich produce of certain vegetables, such as the Snake Gourd, *Trichosanthes Anguina* (Linn), Cucurbitaceae, known as Poodalagai in Tamil, Brinjal, or egg plant, Katherai, Tamil, Solanum Melanera (Linn), common chilly, Mollagah, Solanum Auum, Solanaceae and some others. The guano is employed as a top dressing to plants before they begin to flower, by powdering the dung, and mixing it with cattle or vegetable manure, but not by itself. I have seen the guano from bats very largely used by gardeners at Manargudi, where it is procured in abundance from the Hindu temples, at a very little cost. The interior contain thousands of these nocturnal animals, which have been their dwelling for ages; hence it gives a strong and offensive, or unpleasant smell to people visiting these temples. I have ever seen bat guano resorted to as a manure for flower gardens, but a trial of it can be made, mixed in the same way as described above. It should be watered regularly and plentifully, otherwise the plants will die. I find in the 2nd volume of the "Pharmaceutical Times and Journal of Chemistry," 1867, one Mr. Thomas Dickson, of Lincolnshire, an eminent farmer, speaks of the extraordinary supply and use of the guano from bats, and states that when he was employed as a manager of an extensive estate in Jamaica, a considerable increase of sugar was being procured there by applying a new guano as tillage. Dr. J. H. Balfour, of Edinburgh, speaks very highly of guano or the dung of sea fowl as a special manure, its value depending partly on ammoniacal salts and partly on phosphates. The special manures may be called "rapidly acting manures." They are composed of ingredients which are intended for the special benefit of the crop to which they are applied, while comparatively little effect is produced on those that succeed it.

TANJORE.

BOHEA TEA.

(From the "Indian Review's" *Cream of Monthlies*.)
Extract from an article in *Cornhill Magazine*, entitled "Some Recollection of Buddhist Monasteries."

Following the course of the river Miu at about eighty to one hundred miles above Foechow, the traveller comes to a region of most beautiful scenery where the mountains tower to a height of from six to eight thousand feet, and the river winds amid majestic crags, all broken up into fantastic forms, gigantic towers, Cyclopean columns, an majestic ramparts. This is the celebrated Bohoa tea country; the cultivators are Buddhist monks, whose very numerous monasteries nestle among the huge rock, or are perched on the summits of perpendicular precipices, which, seen from the river, appear to be wholly inaccessible.

The tea fields where these agricultural brethren toil so diligently are most irregular patches of ground of every size and shape, scattered here, there, and everywhere among these rocky mountains; but, like all Chinese gardening, the tea cultivation is exquisitely neat, and the multitude of carefully clipped little bushes have a curiously formal appearance, in contrast with the reckless manner in which Nature has tossed about the fragments of her shattered mountains.

From these strange fields the carefully gathered leaves are carried in large basket-work trays of split bamboo to the monasteries, there to be spread on mats and left in the sun till they are partially dry, after which they are placed in very large flat circular trays, and barefooted brethren proceed to use their feet as rollers, and twirl the leaves round and round till each has acquired an individual curl. (This does not sound very nice, does it?) Then the whole

process is repeated a second time; the leaves have another turn in the sun, another foot-curling, and a more elaborate hand-rubbing. Then once more they are exposed to the sun, till they are so thoroughly dried that no trace of green remains. They are then packed in bags, each weighing about sixty lb., and despatched from the monasteries on the shoulders of tea-coolies, each of whom carries two bags slung from the ends of a bamboo which rests on his shoulder. Thus they are consigned to the foreign tea-merchants, to be fired under their own supervision in the great tea-hongs, where the hitherto unadulterated leaf receives that coating of indigo and gypsum which imparts the bloom so highly prized in the European market, to which it is shipped in boxes labelled "pure uncoloured tea," greatly to the edification of the heathen Chinese, who is not so much astonished at the fraud as at the singular taste which is said to necessitate its practice. It is needless to remark that the Chinese merchants have themselves taken the hint, and prepare specially coloured tea for foreigners.

THE MANURIAL VALUE OF FRESHLY FALLEN LEAVES.

Our knowledge regarding the manorial value of fallen leaves has recently been added to by Professor Emmering and others, in a communication contributed to the current number of the *Bied. Centr.*, 1885.

The results are given in the following tables:—

	PERCENTAGE COMPOSITION.										PRINCIPAL CONSTITUENTS IN THE ASH—PER CENT.													
	Water	Dry matter	Albuminoids	Fat	Carbo-hydrates	Fibres...	Mineral matter (ash)	Water	Potash	Soda	Lime	Magnesia	Phosphoric acid	Sulphuric acid	Shilica	Water	Potash	Soda	Lime	Magnesia	Phosphoric acid	Sulphuric acid	Shilica	
Grey Poplar (Populus carolinensis)	50.88	48.44	20.44	7.51	29.44	7.51	29.44	1.84	14.79	7.98	24.69	9.89	4.87	5.07	23.96	1.84	14.79	7.98	24.69	9.89	4.87	5.07	23.96

Common Alder (Alnus glutinosa)	17.06	82.94	18.71	7.07	57.3	30.66	24.83	3.40	14.79	7.98	24.69	9.89	4.87	5.07	23.96	1.84	14.79	7.98	24.69	9.89	4.87	5.07	23.96	
Do Platanus (Acer Pycnanthum)	17.74	82.26	18.71	6.57	57.3	30.66	24.83	3.40	14.79	7.98	24.69	9.89	4.87	5.07	23.96	1.84	14.79	7.98	24.69	9.89	4.87	5.07	23.96	
Sycamore (Acer Pycnanthum)	17.74	82.26	18.71	6.57	57.3	30.66	24.83	3.40	14.79	7.98	24.69	9.89	4.87	5.07	23.96	1.84	14.79	7.98	24.69	9.89	4.87	5.07	23.96	
Horbeam (Carpinus betulus)	17.03	82.97	18.05	6.57	57.3	30.66	24.83	3.40	14.79	7.98	24.69	9.89	4.87	5.07	23.96	1.84	14.79	7.98	24.69	9.89	4.87	5.07	23.96	
Beech (Fagus sylvatica)	15.35	84.65	18.71	6.57	57.3	30.66	24.83	3.40	14.79	7.98	24.69	9.89	4.87	5.07	23.96	1.84	14.79	7.98	24.69	9.89	4.87	5.07	23.96	
Oak (Quercus robur)	17.73	82.27	18.71	7.07	57.3	30.66	24.83	3.40	14.79	7.98	24.69	9.89	4.87	5.07	23.96	1.84	14.79	7.98	24.69	9.89	4.87	5.07	23.96	

A glance at these figures will show the immense variation in the constituents, and consequently in the manorial value, of different plant leaves, but it must be remembered that a few analyses of plants or their separate organs do not suffice to decide what kind and what amount of plant food a crop needs, and still less in what combination they produce the best effect; they simply tell what kind and amount the plant

under examination contains at that particular moment. It is a well established fact that the same variety of plants, whether raised upon different kinds of soil or upon the same soil of a varying degree of richness, may contain a widely differing absolute amount of the same kind of organic "volatile" and organic "fixed" constituents.

It appears that about 3,000 lb. of perfectly dry Fine timber are produced with a consumption of only 2½ lb. of potash and 1 lb. of phosphoric acid per acre per annum: with Birch trees the quantities required are rather larger. The growth of trees and shrubs, therefore, plainly less exhaustive to the soil than ordinary garden culture. The demand on the soil becomes, moreover, considerably greater if all the fallen leaves are removed.—J. J. W.—*Gardener's Chronicle*.

CARRAWAY SEED.

We have received from Messrs. Praschkauer & Co., of 12, Savage-gardens, London, a diagram illustrative of the fluctuations in the price of carraway seed from 1875 to 1884 inclusive, which show a maximum of 49s. a cwt. in 1877, down to 23s. in 1882, the closing price at the end 1884 being 33s. It would appear from statistics furnished that the supplies are very short, and that something like scarcity is anticipated. Holland is the principal producer, and a succession of low prices has caused a considerable reduction of acreage. It is suggested that, as the crop can be successfully grown in the southern counties of England, its extended cultivation is deserving of attention. It requires two years to come to maturity, and can be sown with some other crops, such as beans and peas.

We are quite of Messrs. Prashkauer's opinion, that any crop that offers a fair prospect of remunerative growth deserves careful attention at the present time. It is said that carraway seed can be grown on strong land, so it might be taken in place of wheat. The following details given by Messrs. Prashkauer to cultivation in Holland may therefore prove useful and interesting:—

In Holland the carraway seed is sown mostly for its seed-crop only; in other parts, principally in Germany, it is treated more like a fodder-plant, which, with its exquisite properties and its delicious aroma, forms a valuable green food, to be either grazed off or made into hay, the second cut being allowed to run to seed; in this respect it is similar to clover. Most of the English farmers will be familiar with the various preparations of cattle-lice, which they use either to sweeten musty hay, damaged grain, or other food for cattle not palatable enough by itself. In all these preparations ground carraway forms a chief ingredient, and it stands to reason that it would be just as well to grow the seed sprinkled amongst vother pasture seeds, in the meadows. This is done very extensively on stock farms in Germany. There is also the additional advantage that it would sweeten the hay, particularly that drawn from silos, which is more or less liable to lose its aroma through its long confinement.

We may mention that in Holland the mode of cultivation deviates from that of similar grains only in so far that in the first year it is sometimes sown together with mustard seed, sometimes with peas or beans. In those parts of Germany where the agricultural system is nearer like the English, there are two modes of cultivation as a rule. We will first mention that the quantity of seed required is 12 lb. per acre.

First System.—Sow barley or other cereals in drills, then crossways, also in drills carraway seed, best in March or April, then hoe the barley only, and take no notice of the carraway seed, which, when the barley is ripe, is only about 1 in. to 2 in. above the ground. When the barley is cut hoe the carraway, and remove the plants that have sprung up irregularly, so as to give full scope to the plants in the regular drills. In the late summer cut the carraways, making an excellent hay of it, or turn your sheep on the

field to graze off the plant. The latter is best where applicable, as the sheep loosen the soil, and by leaving behind their manure give to the plant fresh vigour. The plant then gradually makes way again, winters through, and produces a crop of seed next June or July. Before that, in spring, liberal hoeing is requisite, so as to keep the ground clean.

After the seed is cut in July, the stems are left as plants, and produce then another crop in the following year.

Second System.—Use land that is going to be in fallow according to the usual system of rotation; plant carraway seedlings (young shoots) on this land, which, will produce a crop of seed next year without in any way interfering with the rest the ground required, for instance from a cereal crop.—*Field*.

PHORMIUM TENAX: N. ZEALAND FLAX.

This liliaceous plant is indigenous to New Zealand, and may frequently be seen in this country, where it is cultivated for ornamental purposes. To call it flax is a misnomer, but it contains a fibre which endures a great strain, and is valuable as a rope-making material. In its native habitat it is found almost everywhere—thickly clustered in huge swamps, sometimes on hillsides, but more commonly scattered in the vicinity of streams, and it is in the richest soil that it attains its most luxuriant growth, frequently reaching a height of 6 feet and upwards. In its natural condition it is a most serviceable plant, and may be described as the twine of the country, being used for a variety of purposes—from tying up, a horse or repairing a fence to replacing a broken girth or a missing saddle strap. From the earliest days of European settlement, the Maoris have been accustomed to trade in the fibre, which they extract by a wasteful and laborious manual process, and use for making ornamental mats.

How to utilise the fibre on a large scale for industrial purposes, is a problem that has long engaged the attention of scientific men; and large sums have been expended in experiments with a view to its solution. Having closely studied the question—both in England and in New Zealand—my experience may perhaps be deemed of interest to Colonists and others.

In 1874 a series of careful and patient experiments on leaves which were grown in this country or brought from a distance resulted in an ingenious invention known as Andrews' patent, by which the fibre was efficiently cleansed by a hammering process without its strength being impaired, and the gummy or resinous matter removed by jets of water which played under pressure during the operation. It was confidently believed that the fibre which resulted from this process would prove suitable for textile fabrics, and some bolts of excellent canvas were produced at Dundee and Belfast. The manufacturers found, however, that to work it up on a large scale would necessitate considerable modifications in the jute and flax machinery, and this they were not prepared to face unless it could be incontrovertibly shown that a regular supply of material equal to sample could be guaranteed.

With a view to ascertaining this point I consented to visit New Zealand, and traversed the principal phormium-growing districts in both islands, from Invercargill to Auckland. I found that a rough-and-ready process of preparing the fibre by the use of revolving beaters and scutchers was extensively in operation, and large quantities were being shipped to the London market. As a result of my investigations I emphatically pronounced against the commencement of operations in New Zealand on several grounds. Firstly, the leaf, as procurable in the Colony, was of varying size and tenacity, owing to the action of high winds and of fires, and it was all but hopeless to count on a uniform crop. In this respect it was found to differ materially from the home-grown or imported specimens which had been used for experimental purposes, and, consequently, the machinery dealt less efficiently with the natural leaf. Secondly, the *Phormium tenax* was most abundant

in fertile tracts which only required draining to adapt them to the prolific growth of English grasses and a variety of paying crops, to make way for which the most eligible "flax fields" were doomed to extinction at no distant date. Nor could I recommend the cultivation of the plant in view of the time required to mature a crop and the high price of labour, which then amounted to 8s. a day. Consequently on these representations the project was abandoned as regards New Zealand, and wisely so. It may, however, be mentioned that the plant has been cultivated with marked success at St. Helena, and considerable shipments of fibre were at one time made from that island, but the cost of freight and charges, coupled with the depressed condition of the English market, soon killed the industry. The conclusions I have arrived at, after careful observations, are that the phormium fibre is unsuitable for the manufacture of textile fabrics in this country in competition with flax and jute; that the price it commands in the London market in comparison with Manila hemp is not such as to enable its shipment from New Zealand at a profit; but that it is admirably adapted for ropemakers to utilise on the spot. I believe I am correct in stating the bulk of the rope used in New Zealand is made either from phormium fibre pure and simple, or else in combination with the well-known product of the *Musa textilis*.

It should be mentioned that the mills and ropewalks in the Colony afford employment to upwards of 400 persons. The exports of phormium in 1870 were valued at 132,578*l.*; in 1871, 90,617*l.*; in 1872, 99,405*l.*; and in 1873 the amount reached 143,799*l.* Then there was a falling off until 1879, in which year the exports represented only 7,874*l.*; but in 1882 they rose to 41,955*l.*—J. S. O'H.—*Colomes and India.*

THE BEETROOT SUGAR QUESTION.

TO THE EDITOR OF THE "GLASGOW HERALD."
Greenock, 26th February 1885.

Sir,—I have delayed replying to yours of the 28th ult. in order that I might complete some inquiries I had set on foot anent the cost of beet sugar production in Germany. I am inclined to believe the following to be facts—i.e., to represent a fair average condition of the elements of cost in ordinary years:—

1st. Roots cannot be grown with even the slightest profit under 90 pfgs.—=18s per ton delivered at factory, the pulp being returned free to the farmer.

2nd. That even the best factories cannot work—pay wear and tear and 5 per cent on capital—under 10s per ton of roots worked.

3rd. Taking an average of the last five years, it requires (in districts of average fertility) 1033 cwt. of roots to make 1 cwt. of sugar of 95.5 polarisation—(say) 89.5 net analysis. In this calculation after-products and molasses are reduced to the standard of 95.5, and included in the weight.

Now let us calculate on this basis:—
Roots cost 18s per ton
Working expenses 10s "

Therefore 1033 cwt. of roots and expenses... £0 14 6

Root duty, 1033 x 80 pfgs ... 9.25

Drawback, 1 cwt. 9.00

Gain or bounty on export ... 74 pfgs— 0 0 9

Deducted 1½ degrees @ 3*l.* calculation being 0 13 9

I cwt. at 89½ 0 0 4½

Cost of 88 P cent delivered loose on factory floor 0 13 4½

Add—For discounts and loss of interest,)

Bags,)

Transit to Hamburg,)

6 months' loss of interest on drawback,) ... 0 1 6

Shipping expenses,)

Insurance,)

2 months' interest at 5 per cent,)

Cost price on English conditions, f.o.b. Hamburg .. £0 14 10½

In reference to the cost of roots, I may say that in the Danzic districts, where rents are low roots can be grown 10 pfgs. to 15 pfgs. per ton below this price calculated, but then there are some disadvantages also in those districts, and owing to the position of the factories the whole production has to be sold for export, and the fabricant gets a lower price for his sugar f.o.b. Danzic than f.o.b. Hamburg. Some factories work below 10s per ton of roots, but the average is right. The yield of 1 cwt. of sugar from 1033 cwt of roots must not be taken as applying to this year or to the most fortunate fabricants. A yield of 1 cwt. from 831 cwt. of roots has not been uncommon, but the past two years have been of such an exceptional character both as regards weight of roots and richness that it would be unfair and imprudent to reckon on their repetition. By the employment of the villmorin seed and high manuring, yields of 14 per cent to 15 per cent have been reached, but always with a diminution of weight per acre, and at a heavy expense. At present prices there is not a sufficient premium to pay for this "forcing" of richness. Many competent agriculturists and fabricants consider that, counting the cost, it is more profitable to cultivate the kinds giving a large yield per acre and a moderate richness. I think that cultivators who are not fabricants (about 20 per cent of the whole in Germany, about 20 per cent in Austria, and about 50 per cent in France and Belgium) will not sow soot unless they can make contracts for roots at above the prices offered by fabricants, and I think the latter won't see their way to bid higher and will not be sorry to see less sown. If the bills now being discussed in Germany and France become law promptly, then I feel certain that the average diminution of sowings will be 25 per cent. Another point to be considered is that farmers generally in Germany and Austria have not done well lately. They are in many cases economising their labour and manure expenses—just letting the land produce what it will by its unexhausted fertility. This I hear from several people who supply the German farmer with manure. The results will surely be that the yield per acre, and possibly the richness, will fall below average instead of being, as it has been for two seasons past, above average.—I am, &c., II.

THE REGENERATION OF THE POTATO.

There seems to be good ground for the theory that the cultivated potato is to a certain extent "run out," and that its increased susceptibility to disease in these latter days is partially, if not entirely, due to this diminished vigor or vitality. This has led to the suggestion that the plant may be regenerated or re-vigorated by judicious "crossing" of varieties that seem to resist disease better than others, and more recently it has been proposed to cross the cultivated potato with some other species. Some interesting experiments have been made in England during the past year in the way of this; introducing "new blood" into the worn-out and degenerate tuber. Mr. J. G. Baker, the eminent botanist connected with Kew Gardens, was led to make a careful investigation of the history of the potato, its geographical range, and the differential character of its varieties, or their relationship to each other. He made his report in the form of a "Review of the Tuber-bearing Species of Solanum," from which we learn that all the cultivated species of potatoes consist solely of one species, *Solanum tuberosum*; that there are six species of potatoes which produce tubers; and that some of these seem to be worthless, while others yield good crops of tubers under cultivation. Mr. Baker fixed upon *Solanum Maytia* as the best species for the purpose of hybridizing with the cultivated potato for the purpose of invigorating the breed. He selected it partly on account of its large production of tubers, and partly for its vigorous growth, and its habit as a native of a moist and cool climate on the coast of South America; while our cultivated plant is a native of the mountains of Chili, growing at an altitude of

eight thousand or nine thousand feet, in a dry atmosphere. It is not surprising that our potato does best in a dry, hot season. Dr. Lindley, who himself recorded so many improvements in fruits, flowers, and vegetables as the result of hybridizing, used to say, "Hybridizing is a game of chance played between man and plants." He added that a good player can judge of the issue with tolerable confidence, and that skill and judgment have all their customary value. It is too early, perhaps, to estimate the probable results of this new experiment in hybridizing the potato; but it is something, that hybridized potato-seed has been raised in England for the first time, after many futile attempts. An English journal explains in detail how this was accomplished, and we condense the account for the benefit of our readers.

At the request of Lord Cathcart, Mr. A. W. Sutton of Reading undertook to experiment with some tubers of *Solanum Maglia* and *Solanum Jamesii* sent him by the former. Of the tubers so received, only three of *Solanum Jamesii* and forty of *Solanum Maglia* were raised, although they were carefully treated in pots under glass. The plants were put out in the first week of June in a carefully selected plot of ground, and were accompanied by two specimens of *Solanum Commersonii*. The three species made rapid growth, but *Solanum Jamesii* and *Solanum Commersonii* showed signs of ripening off about the middle of August. *Solanum Maglia*, which continued growing, resembled, in its habit and general character, an ordinary variety of *Solanum tuberosum*; and, when a portion of the crop was lifted, it was found that the majority of the tubers were of a deep-red color, with here and there a few pale, almost white, specimens. The sets had been carefully divided into two sections: the pale and those distinctly red; but the produce as well as the growth was practically identical. *Solanum Jamesii* was totally different in every respect, and to an ordinary observer would not have been considered a potato at all. The height was only about eight to ten inches, and the leaves excessively small. The *Solanum Commersonii* somewhat resembled the *Solanum Jamesii*, although it was more robust, and in every way more nearly approaching the type of an ordinary potato-plant. Each of the three species produced an abundance of flowers, the corolla in each case being white. As the flowers appeared, every possible care was taken to fertilize them with pollen from some of our best disease-resisting potatoes; and Mr. Sutton, in the case of *Solanum Maglia*, obtained three fully developed berries well filled with seed. These he hopes to sow next year, watching with great interest the development of the seedlings, and noting what practical result has been obtained by thus hybridizing the two species. Both *Solanum Jamesii* and *Solanum Commersonii* resisted every effort at fertilization.

It was found that the tubers of these species had not been materially altered by cultivation, either in form or size. In the *Solanum Maglia*, however, the effect of cultivation was most marked. The tubers, as received from Lord Cathcart, were about the size of a pigeon's egg; but the produce consisted of tubers quite as large as an ordinary potato, and as many as eight to twelve tubers to each plant. A few specimens were cooked, and proved to be of fair quality for table. As the *Solanum Maglia* has not hitherto been known to bear a seed-berry, there is reason to believe that the three berries which Mr. Sutton has obtained are the result of the impregnation with pollen of *Solanum tuberosum*; and there is, consequently, every ground to hope that the new seed may be the origin of a race of potatoes more suitable to the climate of the British Isles than the varieties we have at present.—*Popular Science News*.

SUGAR IN GERMANY AND THE UNITED STATES.

The German statistical returns for December furnish the result of the past Beet season between August 1st, 1883, and July 31st, 1884. The *Frager Zuckermarkt* publishes from this volume the following interesting particulars, in which the comparison is, of course, made with the previous season, namely, that ending on July 31st, 1883.—

There were 376 Beet Sugar factories at work, with 3,715 steam engines, of 46,158 horse power, against 358 factories (against 15) extracted the juice by other means than diffusion. The quantity of beet-root worked up was 4,459,065 tons (against 4,373,576 tons), and 47.2 per cent was grown by the fabricators themselves on 352,100 acres. The average crop obtained was 6 tons to the acre, against 6 tons 18 cwt. The Beetroot crops of 1883 and 1883 were, each in its own way, unprecedented, the former in respect of its immense quantity, and the latter owing to the extraordinary saccharine richness of the Beet. A total of 608,440 tons of saccharine matter was obtained, against 546,778 tons, from which were made 470,055 tons of raw Sugar, and 103,989 tons of Molasses, against 415,998 tons and 98,652 tons respectively. This result includes the Sugar extracted from Molasses, as far as that process was conducted in conjunction with the working up of the Beet; and 37,100 tons of Molasses, against 34,902 tons, were carried over from the previous season, or were drawn from other factories. The quantity of Beetroot required to produce 1 cwt. of raw Sugar, if the Sugar obtained from Molasses be reckoned, was 4.79 cwt., against 5.25 cwt. The duty on the home-grown Beet amounted to £7,270,000, against £7,000,000, and the import duty on foreign Sugar to £70,000, against £85,000. The repayments for drawback reached £4,815,000, against £3,720,000. The consumption of Sugar per head of the population is estimated at 16.94 lb. raw Sugar, against 17.82 lb., and against an average of 14.96 lb. in the thirteen seasons, 1871-2 to 1883-4. The quantity of Beetroot to be worked up during the present season of 1884-5 by the 408 factories which have commenced operations, is estimated at nearly 5,000,000 tons, against 4,459,065 tons worked up in 1883-4 by 376 factories.

We abridge from the Berlin *Deutsche Zucker Industrie*, a communication from a Louisiana Sugar-planter, who is stated to be well acquainted with the conditions of the German Sugar industry. His remarks are worth the careful attention of those who imagine that a reciprocity treaty and the admission of West Indian Sugar duty-free would restore the prosperity of our islands. Doubtless freight from the West Indies to New York would be less than from New Orleans to New York, but there is a great western and local market where freights would be immensely in favour of Louisiana. If, therefore, with no duty and with freights in their favour the Louisiana planters cannot hold their own, how could the miserably made Sugar of the West Indies do so? Premising that in his opinion the time is approaching when either Cane or Beet Sugar must assert its supremacy in the world's market, and force its rival from our field, the Louisiana Sugar-planter, whose letter suggests these reflections, proceeds to examine the influence which the United States is likely to exert on this contest:—

The question of Beet Sugar production in the United States and in Canada may be regarded as settled. The solitary Californian Sugar factory in Alvarado must cease work directly Claus Spreckels loses the monopoly of the Pacific coast, and prices in that district fall from their artificial height to the normal level of the New York Sugar market, plus the usual freight. Sorghum or Amber Cane has not fulfilled the hopes of the late Commissioner of the Department of Agriculture; and although some Sugar is produced under the stimulus of heavy State bounties on the cultivation of and manufacture of Sorghum, the absence of any practical result has

proved that this section of the Sugar question must also be regarded as disposed of. It therefore only remains to consider the Louisiana Cane Sugar production, in order to arrive at a conclusion whether the 60,000,000 people in the United States can in any way reckon on a supply of home-grown Sugar, or whether they will not rather be compelled to import the whole of the Sugar they require. A few years before the Civil War broke out, the production of Sugar in Louisiana increased at an important rate, so that in 1850 and 1861 it was at the height of prosperity. In those days the Louisiana Sugar-planters—nicknamed the "Slave Lords"—were considered to be the richest, most independent, and most to be envied caste of the American people. But an avenging Nemesis has overtaken them, and with a terrible power. The former slave lord is today himself a slave; not just as the slaves of those days had no hope of liberty, the Louisiana Planter now despairs of freeing himself from his chains; he works with a millstone round his neck; he is the slave of the commission merchant. If in former days the Sugar-planter wielded his slave-whip only under exceptional circumstances, and then mildly, the commission merchant flourishes his moral lash with pitiless cruelty. Of 1,100 planters in Louisiana, at most 50 are able to exist, or, rather, to vegetate, without advances from the commission merchant; the other 1,050, however, obtain advances under the most oppressive conditions, and in the most humiliating fashion, and must then pay 25 to 45 per cent interest. Nominally the rate is less, but only nominally! They pay 8 per cent actual interest, and 2½ per cent commission; 2½ per cent for buying, 2½ per cent for selling. Then come brokerage, insurance, cooerage, weighing charges, and whatever else each lengthy Charges Account includes. The contracts which must be entered into to obtain advances, and in which a mortgage is given on the whole plantation, with everything upon it moveable and stationary, dead and alive, are usually so formed that the planter not only loses all control over the Sugar, but over the growing crops as well. Many planters worked up all their Cane last season, retaining no seed for a fresh crop; and numerous fields, formerly cultivated with Cane, will this year be sown with rice. Thereby the planter is rendered less dependent on the commission merchant and on low Sugar prices, but the extension of rice-growing fearfully aggravates the already existing malaria; still he seems to prefer to fall a victim to malarial fever rather than to the commission merchant. Unless, therefore, some miraculous and prompt intervention should prolong the existence of the Louisiana Sugar-planter, this once so prosperous branch of the United States Sugar industry must be looked upon as a relic of the past. Then it will only remain for the German Fabricants to take steps to secure the market of these 60,000,000 people. Cuba and Porto Rico resemble Louisiana, and their situation is not much better. Let nobody suppose that this sketch is exaggerated; on the contrary, it does not come up to the reality. The German Sugar Fabricant may, therefore, be of good hope, especially when he recognises how vastly better is his position than that of his unfortunate Cane Sugar brethren.—*Produce Markets' Review.*

A POLICE FORCE OF ANTS.—A queer way of employing ants is reported by an English gentleman who has been travelling through one of the provinces of China. It appears, that, in many parts of the province of Canton, the orange-trees are infested by worms; and, to rid themselves of these pests, the natives bring ants into the orangeries from the neighboring hills. The ants are trapped by holding the mouth of a hard bladder to their nests. They are then placed among the branches of the orange-trees, where they form colonies; and bamboo rods are laid from tree to tree, to enable the ants to move throughout the orangery.—*Popular Science News.*

PEPPER VINE.

Colonel E. B. Sladen, Commissioner of Aracan, has very courteously placed at our disposal the following report from Captain C. A. Cresswell, Deputy Commissioner, Sandoway, on the results attending the experimental cultivation of the Pepper Vine, in the neighbourhood of the town of Sandoway. Before making any remarks on the cultivation of the pepper vine and its probable success, it would be as well perhaps, as this is the fourth year of the experiment, to give the actual position as regards number and size of plants as actually counted about the 14th February 1885, and which will be entered as 1884 and compared with those of 1883 counted in March 1884 and entered as 1883.

Under 1 ft.	From 1 to 2 ft.	From 2 to 4 ft.	Above 4 ft.
188	73	30	289

A great part of the Dodauing cultivation is now, I find, not fitted for the pepper vine. The original acreage taken up was 105 acres. The decrease in the number of plants is due to the fact that in March 1884, over 400 plants were destroyed by fire in Block 2, and further from Blocks 1, 2, and 3. I have now thrown out about 40 acres as ground upon which the vine is not likely to succeed. The ground will not be given up but will be simply left to take care of itself; if the young cuttings at present existing struggle up, they can be looked after hereafter. The acreage, as at present looked after by the two gardeners in Dodauing, is 62 acres only, and in April and May I shall again inspect the whole of this ground, and finally decide what is worth keeping up.

Block (4) I intend to devote special attention to as the ground is good and the trees are doing capitally. I have taken on to Block (4) at the cost of five rupees, an old sugar-cane plantation of over 3 acres, and there I have put down one hundred cuttings of the *Erythrina Indica*, most of which have struck, and will be ready for the young vines to be planted at their feet next June. This is the method adopted on the Malabar coast, and is, I think, a far better plan than planting the trees in a jungle, where the ground is not of uniform quality, and the vines of course have to be spread over a large area. By this method (the Malabar plan), about 225 trees can be planted to an acre, and after four years an average crop of one lb. a tree might be expected. The yield in Sumatra is however very different; there an acre of first class vines will yield from 1,161 pounds of pepper. In Malabar the average yield from 1,000 plants is only put down at 450 lb. or less than ½ lb. a tree. From which is actually gathered from trees in Sandoway, I think I am justified in putting down 1 lb. for each tree. Seven pounds is looked upon in Malabar as a very high yield for one tree. Seven pounds is sometimes realized from the old and uncared for trees round Sandoway. The price at present here is £1-12-0 a viss. A valuable product in comparatively small bulk, and one which will bear the expenses of transport which paddy rarely does in the Sandoway District. In Dodauing I expect from 50 to 100 trees to fruit next year, in February 1886. In Kyaundauing from 200 to 250 in February, 1886, or say a total in the two plantations of 300 trees and a produce of say 300 lb. of pepper, and taking the

produce of the year at 8 annas a pound, 150 rupees ought to be realised to March 1885.

The allotment was in—

1882-83	R500
1883-84	500
1884-85	500
1885-86	200 (proposed)

For 1885-86 I only propose to keep one gardener, and I propose to limit the expenditure to 200 rupees. This would give the receipts as 150 rupees on an expenditure of 1,500 rupees, or say roughly 10 per cent. In 1886-87 a far larger yield might be looked for, and the gardens should be not only self-supporting, but should give a surplus over the expenditure for that year. I do hope that the gardens will be kept up till April 1886, and then Government will be fairly able to form an opinion whether the experiment has been a practical success or not. Of course in an undertaking of this sort I had at first no practical experience. My first idea was that deep shade was necessary, and that the soil was, comparatively speaking, a secondary consideration. The first place I fixed upon was Dodaung. This had been frequently worked as taungya, and consequently large shady trees were only to be found here and there. This led to the work being scattered over a large area. By the second and third year from the undergrowth being cleared away, &c., the trees had sprung up considerably, and more shade was obtained and more trees fit for planting. But still the vines only flourished in certain places, and that was in places where there was the best soil. Given good soil, shade seems to be an unimportant factor. In Malabar alluvial soil is said to be the best. As I have already said, I think the Malabar method is likely to be the most successful.

Cuttings of *Erythrina Indica* (Penli Kathet) are put down 14 feet apart in the dry weather, and by June next are ready for the pepper vine plants or cuttings. They are all planted in straight lines, and a plantation is easily watched and inspected. In four years the vines begin to fruit and last for 25 years in the case of cuttings; 40 in the case of seedlings. One of each is usually planted at the foot of each tree. This method of cultivation is somewhat similar to that adopted by the people for the betel vine, so that they will be more likely to take it up. There is no difficulty attached to the cultivation of the pepper vine. Cattle will not touch it nor even goats. In a healthy state, the vine has few enemies. I have only found two—snails and a long thin brown caterpillar-like grub, with a horny head. Will the people take it up? I think they will; already it is being tried by them in different villages on a small scale, but not on any systematic plan. I am inducing people to visit the Government Plantations, and see for themselves. People are beginning to talk about it, and from what I can hear, a good many attempts will be made next rains. As regards Dodaung I have not gone into calculations, nor mentioned the percentage of deaths, and number of plants put down, simply because a great many were planted under conditions which, as we now know, were hopeless. Further, a good deal of ground, viz., about 43 acres, has been thrown out. In March 1884 there were in four blocks of Dodaung (105 acres) 3,709 plants alive, of which only 52 were over two feet high, and 400 of these were destroyed by fire in May. During the rains of 1884, 1,700 plants were put down in the reduced acreage of 63 acres, and now there are 3,030 plants alive, of which 236 are over two feet high (62 of them are over 4 feet high). I have also put down cuttings of *Erythrina Indica*, of which 100 are alive, and will be planted with vines in June 1885, and before the end of April, I hope to have another hundred down.

KYAUNG-DAUNG.

In March 1884 there were 430 plants alive in this small plantation of 3 acres; 250 plants were put down in the rains of 1881; and in February 1885, 580 were alive, showing a percentage of deaths of cuttings amounting to 33 per cent as against 36 per cent last year. No record of the height of these trees was made in March 1884; but in February 1885, out of a total of

580, over 289 were more than four feet, and 103 other^a between one and four feet high. Here the soil is remarkably good; more trees are springing up fit for planting, and next year probably 150 more plants can be put down, bringing up the total to 730 trees, which gives about 243 vines to the acre—rather more than the number per acre on the Malabar method of planting. Supposing all these vines in fruit, and allowing 1 lb. a tree, these three acres would give a production of 730 lb. of pepper, worth at least 365 rupees for three acres, or an average of say 120 rupees per acre. No comparison exists between this and the production of paddy, either as regards labor or profits. To any one, who can afford to wait and work up his ground, fruit trees can be used for growing the pepper vine with just as much success as any other tree, and with the double result of fruit from the tree and the vine. An easier or more paying cultivation does not exist. I think Kyaung-daung may be considered a thorough success. It is not as if the fruiting of the vine were doubtful; that is an ascertained fact. From some trees in Sandaway 5 to 7 lb. of pepper are gathered annually. I have done my best in travelling about the district to explain the advantages, method of culture, &c. As I have already noted, its cultivation is here and there being attempted. On the arrival of the Thugyis with the land Revenue rolls, I took the whole of them to visit the gardens and explained the principal points. A number of the inhabitants of Sandaway have also visited the spot.

Sandaway, with its network of creeks from Sandaway to Mlai, wants nothing but a valuable production of this sort to bring it forward from its present backward position. Boat or canoe transport would cheaply bring the pepper to any central point at very little cost, and we might then hope to see a little more trade in the district. If Government should feel inclined to sell or lease Kyaung-daung now that the vines are well established there, I think there would be plenty of applicants. I should then simply continue the experiment on the best part of Dodaung, at the same time testing the Malabar method of planting in straight lines on cuttings of the *Erythrina Indica*.
—*Indian Agriculturist*.

THE INDIAN CORAL TREE.—The enquiry instituted by the Department of Revenue Settlement and Agriculture, last month, regarding the alleged influence of the *Erythrina Indica* (Dadap or Indian coral tree) in producing leaf disease when planted for shade among coffee trees has, according to Mr. W. Wilson, the Director of the Department, elicited replies from several gentlemen well qualified by their practical knowledge to speak with authority on the subject to the effect that there has not been observed in Southern India any connection between the presence of *Erythrina* trees and the production of leaf disease, but that on the contrary the effect of planting *Erythrina* has been distinctly beneficial, not hurtful to the coffee trees which it is planted to shade. The replies given are in complete accord on the point.
—*Madras Mail*.

ESPARTO IN TUNIS.—Reports from Tunis state that the Esparto-grass trade is now carried on there on a large scale, and large tracts of Esparto-producing fields have been bought by speculators. The Anglo-French Esparto Fibre Company are developing their trade at Abouhedma, and a tramway is now being laid down by the same to carry the Esparto fibre to the coast. But export duty is very heavy on this article, and competition by Tripoli and Algeria, where Esparto pays no export duty, is telling much on the trade. This trade is said to be amongst the very foremost resources of the Lous district. "Through good and bad, dry or rainy years, there is always a crop of it. The Arabs fall back on it chiefly in times of scarcity, when successive years have brought them deficient crops. But the duty on this article, especially at Lousa, is so heavy as to deter the Arabs from pulling and bringing it to the market, except when they feel the pinch of poverty."—*Gardeners' Chronicle*.

HOW TO MAKE BELTS RUN ON THE CENTRE OF PULLEYS.—It is a common occurrence of belts to run on one side of the pulley. This arises from one of two causes:—1st. One or both of the pulleys may be conical, and of course the belt will run on the highest side. The most effectual remedy for this would be to straighten the face of the pulleys. 2nd. The shafts may not be parallel, or exactly in line. In this case the belt would incline off to the side where the ends of the shafts come the nearest together. The remedy in this case would be to slacken the hanger-belts, and drive the hangers out or in, as the case may be, until both ends of the shafts become parallel. This can be determined by getting the centres of the shafts at both ends by means of a long lath, or a light strip of board.—*Electrical Trades Journal.*

FRATER'S ROLLER AND OTHER MATTERS.—Badulla, if it has lost some of its ancient "prestige" as the land of coffee, is likely to come very prominently into notice as having produced one of the best mechanical appliances used in the manufacture of tea. It is now about 18 years since Mr. John Walker of Kandy started the Bon Accord Iron Works in Badulla, the firm being Messrs. Walker & Wilson, afterwards changed to Walker & Greig. From a small beginning these works soon increased so as to be a rival to Kandy. Notwithstanding the great difficulty of transport on iron and heavy goods. With the decadence of coffee the workshops became almost silent, and no longer were heard the busy hum of machinery driven at speed and the noisy steam-engine; but this is not to last long, for has not the Bon Accord Works or rather Mr. Frater their manager turned out a machine which, with the rapid increase of tea cultivation in Uva, will test the capacity of the works to the fullest to keep pace with the demand which is sure to arise? I have already frequently expressed my views as to Uva tea proving not only successful, but I still maintain that Uva will produce both the maximum yield and a quality of tea second to no district in the island. I consider the Railway Extension as good as sanctioned to Haputale, and if to Haputale certainly it will go on to Badulla; for if the Legislative Council sanction the loan for railway purposes it is not likely to be rejected at home, and at last the long and bitter cry of neglected Uva is to be partially answered by giving the much-needed relief of a Government Agency separated from Kandy, it immediately becomes all the more necessary that the local Government be placed in more rapid and easy communication with Colombo and the Executive.—J. IRVINE.

SUGAR GROWING IN NEW ZEALAND.—Although little is being done at present to carry out the proposals of the association recently formed in Christchurch to establish a farm for silk and fruit culture at Hokiaanga, other industrial undertakings are being considered which, if given effect to, cannot fail to exercise a beneficial influence upon this part of the colony. During the last session of Parliament encouragement was given for the production of sugar from plants grown within this colony. A bonus of £1,000 was offered for the production of the first 1,000 tons of sugar of either beet, sorghum, or any other sugar-producing plant grown in the colony, and the produce prepared for market by machinery permanently fitted up in the colony. The settlers in the Waikato district are at present considering the advisability of securing this handsome bonus offered. Several meetings have been held, and to some extent an agreement has been come to with the farmers and the capitalists who would provide the manufactory plant. It is suggested that the manufactory should be erected in the neighbourhood of Hamilton, and a number of farmers are willing to grow the beet at 16s. per ton. The capital required is estimated at about £25,000, and should

the enterprise be put fairly afloat, it cannot fail to have a most beneficial effect upon the Waikato district generally, and indeed upon the colony as a whole. At the present time about £700,000 is sent out of the colony for sugar, in its various forms, every year; and if a portion of this drainage of capital could be stopped by the production within the colony of the sugar required, the additional capital in circulation will produce a vivifying effect wherever it is felt. Years ago the experiments carried on in various parts of the Waikato district showed that sugar-beet could be grown well there, and the content of sugar was large, ranging up to upwards of 14 per cent. With one manufactory in successful operation others would soon follow—thus, not only saving the outflow of capital, but providing a large amount of profitable labour for our people, and the employment of our spare capital.—*Anglo-New-Zealander.*

INSECT WHITE WAX.—There could not be a prettier illustration of human labour as consisting only in moving matter from one place to another than the account of the "insect white wax" trade in China given in a Parliamentary Report by Mr. Hosie, a member of our consular staff at Peking. In the west of the province of Ssu-chuan (the province bordering on Thibet) grows the insect tree, an evergreen with thick, dark leaves. In March and April peashaped excrescences or galls are found attached to the bark of the boughs, and in each of these galls there is a swarm of brown creatures, each with six legs and a pair of club antennae. In the east of the province, on the other hand, grows the wax tree—usually a stump about six feet high, with numerous sprouts rising from the gnarled top. In the early part of May the insect carriers are busy carrying the insects from the insect trees in the west to the wax trees in the east. Packets of galls are suspended close to the branches, a few holes are pricked with a needle in the packets, and the insects creep rapidly up the branches to the leaves, and excrete the wax. After ninety or a hundred days the wax is about a quarter of an inch thick; the branches are lopped off and the wax removed by hand. The Chinese then place the insects themselves in a bag, squeeze them until they have rendered their last drop of wax, and finally throw them to the pigs—a depth of ingratitude in which, alas! "that Heathen Chinese is not peculiar." The account of the journey through Central Ssu-chuan which Mr. Hosie undertook in order to forward specimens of the insect wax trees to Kew is very readable, and if the libraries were in the way of subscribing to Parliamentary Papers would be widely read. Mr. Hosie and his party struck westward to the city of Chiating, on the right bank of the Min river; visited the famous Mount O-mei, and did not see the "Glory of Buddha" (they "viewed the mist, but missed the view"); and then went southward to the highest navigable point of "the River of Golden Sand." All along they journeyed through fertile country, bathed in happy sunshine and smiling industry, passing here a potter by the roadside shaping his clay, there a herd of swine, all carefully shod with hempen shoes. Some native verses which Mr. Hosie found scribbled on the wall of an inn, and of which he gives a translation, have a more European, not to say Cockney, ring in them:—

Within this room you'll find the rats,
At least a goodly score,
Three catties each they're bound to weigh,
Or e'en a little more.
At night you'll feel a myriad bugs,
That stink, and crawl, and bite;
If doubtful of the truth of this,
Get up and strike a light.

"Catties," it should perhaps be explained for the uninitiated, are not animals, but weights, a "catty" being equivalent to 1½ lb.—*Fall Mall Budget.*

THE PEARL FISHERIES IN WESTERN AUSTRALIA.

The *Standard* of Nov. 23rd has an interesting article on the discovery of pearl banks in King Sound, Western Australia. "The locality," it says, "is just the spot in which one would expect the gem-bearing oyster to breed. It is a deep and comparatively quiet inlet of the warm sea which leaves the shores of Western Australia, and therefore in every way suited for a mollusc which loves quietness, and has an insuperable objection to cool currents. The chances are all in favour of the pearl oyster being found in greater or less abundance in the majority of the bays and gulfs around the coast. Nickel Bay has long been a famous 'fishing' station; the oyster abounds in nearly every suitable lagoon of the Pacific Islands; and for many years past the 'fishery' has formed an important industry off the shores of Queensland and North Australia. It is true that neither in size nor in water can the pearls of Torres Strait and Western Australia compare with those of Ceylon, Panama, the West Indies, or the Persian Gulf. Yet the shells within which they grow are much more valuable for the cabinet and button makers than those which yield the finer gems of the Orient and Tropical America. Indeed, the Australian and Polynesian pearl oyster is 'fished' not so much for the pearls which they may or may not contain as for the shells. Hence, though the occasional profits of the business may not be so great as those of the industry as pursued in Ceylon, yet the returns are steadier. For, gem or no gem, every oyster brought to the surface represents so much money. There is—as there must always be in any trade pursued under the surface of the sea—a certain gambling element in it. But the risks are infinitely less than those attending the work of men who depend on pearls alone for their reward. Until lately the 'fishers' have, for the most part, confined their operations to the strait between Queensland and New Guinea. They have, however, for some time stretched along the entire extent of coast likely to yield the object they are in search of, and we may be certain that before long we shall hear of fine hauls being made in some of the half-explored or wholly unvisited bays and gulfs of Papua. Hitherto it has only been the extreme risk run by the fishers which has prevented the extension of their operations in that direction. Still, if the necessities of the Colonists demand it, we cannot doubt but that a gun-boat will be sent to protect the divers, just as, at intervals, the Navy has extended protection to the establishments which pursue their calling in the islands in Torres Strait, which, for this very reason, we permitted the Queenslanders to annex some six years ago."

Mr. E. W. Streeter, of Holborn Viaduct, writes to our contemporary to say that, being largely interested in the pearling industries of Australia and Ceylon, he has read the article with much attention, and adds:—"The so-called new pearling ground at King's Sound has been known for some time, but owing to the depth of water there, varying from 15 to 20 fathoms, it could never be worked by naked divers, and it is only lately since apparatus divers have been introduced along the coast that the ground has had a fair chance of being properly tried, and you know with what success; but even now its depth is detrimental to the health of the men and also to the amount of work they can do per day. The Western Australian fisheries, however, have produced pearls which in size and quality can compare with the finest the world has ever seen. One pearl which was found along that coast last Boxing Day by one

of our boats was as large and round as an ordinary marble, and for it the present owner has refused over 1,800*l*. We have visited some of the half-explored bays and gulfs in New Guinea, and discovered fine shell there, but the unhealthiness of the climate was found to be a far greater drawback to work than the hostility of the natives. In fact, so many divers died of that peculiar disease known as Beri-Beri that few care to go again. Those engaged in shelling have to undergo many hardships caused by the scarcity of fresh water, the frequency of hurricanes, and the dangers of navigation in close waters, of which only incomplete charts have been made; but though fortunes have never been won at this industry, the better class of shellers have conferred many benefits on the natives belonging to the different coasts where they have worked."—*European Mail*.

COOL-DRY-AIR: A REMARKABLE DISCOVERY.

An American inventor, Mr. Jennings, of Boston, has discovered a method of drying quickly, and without injury to the material, such substances as green mahogany, slabs of English oak or elm, corn harvested in wet seasons, hides and skins, wool and various descriptions of fibres when thoroughly saturated with moisture. No problem ever seemed simpler than the mere extraction of moisture from the substances we have enumerated, and yet few have more obstinately baffled human ingenuity. A solution has now been found to this problem in the "Cool Dry-Air Process." The name indicates the whole secret of its success. Materials to be dried are placed in a chamber through which a current of moderately warm dry air is passed continuously, and the test of experience shows that air so deprived of moisture acts as an absorbent in a manner that without such a test would have been deemed impossible. In the first instance, the current is drawn through a small furnace, in which it is heated to about 600 deg. F. At this temperature the atmosphere is, of course, without trace of vapour. After being thus heated, it is cooled by a vigorous circulation of external air, which lowers the temperature to between 80 deg. and 90 deg., and in this condition is propelled by fans, driven by steam, through the drying chambers. Within these chambers the temperature is that of a hot summer's day, but the air is so "greedy" of moisture that everything within its wonderfully penetrative influence is desiccated. A machine just erected on this principle shows the practical operation of the system, and gives some results that are equally remarkable from a scientific as from a commercial point of view. A package of wool, 1 lb. in weight, was saturated with water; it then weighed 3½ lb., and in this condition was placed in the drying-room. In twenty-eight minutes the moisture was almost wholly evaporated. Timber, as is well known, takes years to season. It has a perfectly surprising power of absorbing and retaining moisture. Thus 41 cwt. 2 qrs. of birch were subjected to this process for ninety-four hours, and then examined, when it was found to be completely "seasoned, free from checking, rents, or warping," and it had given out in the operation 10 cwt. 2 qrs. 2½ lb. weight of water. The industrial value of this important discovery can scarcely be overestimated. The scientific and social interest is not less significant. It appears that fish, fresh provisions, and fruit may be preserved for an indefinite time after being subjected to this mode of treatment. It is stated that "a beef-steak cut from the loin a year ago, and dried at 75 degrees F. in one hour, is as sweet today as when cut, and would keep for years; its moisture having been removed, decay is impossible."—*Echo*.

ANTIPIRYN IN SUNSTROKE.

(Extract from the *German-American Pharmaceutical Gazette*, Vol. VI. No. 10.)

Dr. Westbrook, chief medical officer of St. Mary's General Hospital, Brooklyn, publishes in the *New York Medical Journal* a report on the treatment by antipyrin, and with favourable results, of two men suffering from sunstroke. The remedy was injected subcutaneously, in the form of a 50 per cent solution, in doses of one drachm. In the first case, which was the most severe of the kind which the author ever met with, enemata of chloral hydrate and whiskey were administered; at the same time bleeding and leeches were resorted to, and for some time compresses of iced water also. In the second case no blood-letting took place, nor were any cold compresses applied except that ice was placed on the head. The favourable result obtained in both cases is remarkable, the author says, as the cases were characterised by high fever and signs of profound vital disorder. The first case was probably somewhat influenced by the continuous application of the cold water compresses. The successful issue of the second case appears to prove that the outward application of cold becomes unnecessary where antipyrin is used. Another interesting observation was that even after the temperature had decreased the vital symptoms continued, which seems to show that even a short period of intense heat and arterial excitement may paralyse the vascular system to such an extent that several hours are required for its recovery. A remedy which rapidly lowers the temperature like antipyrin may therefore prove most valuable. Further observations are requisite, however, but from experience thus far, Dr. Westbrook considers half-a-drachm sufficient to attain the object in view. A solution of 50 per cent can be easily made, and causes only slight excitement when injected subcutaneously.

INDIAN FIBROUS PRODUCTIONS SUITABLE FOR ROPES.

Among the various firms in India who deal extensively in coir-ropes and cables, those who have made the most out of the fibres which are largely found all over India, seem to be Messrs Ahmuty and Co. of Calcutta. We are partly indebted to that firm for the following interesting particulars in regard to the Indian fibres. Coir, or the fibre from coconuts, has deservedly earned the foremost place among the Indian fibres. It is very valuable for its extremely elastic qualities, and in cases where "give and take" is required, no other known rope-fibre, except hair, we know, can equal it. As coconut trees do not thrive beyond the influence of sea-air and salt, good coir is produced only from trees on the coast and in the islands such as the Laccadives, etc. Nothing has yet been done with the coir produced from trees cultivated in the inland parts of the country. True to the agencies under which the coconut tree thrives, its coir cannot be preserved for any great length of time without the influence of salt water. Immersion in fresh water without immediate drainage results in deterioration and ultimate rot, while constant or occasional immersion in salt water will, with fair wear and tear, preserve it for probably three or four times as long as a rope of any other fibre would last under the same conditions. Where a dead strain or heavy lift is required, coir is not recommended as a safe or reliable rope, the fibre being too short and elastic. In Bengal, coir is very largely used by Marine Department for riding cables and springs for the Light Vessels and for towing-hawsers, warps and running-gear for the Marine Service. The coir trade seems to have declined somewhat on the West Coast. Not many years ago a good deal of coir yarn was shipped from Calicut, but now the trade seems to be centred at Cochin. There is at present little or nothing done in the coir business in North Malabar, where the coconut husks which contain coir is now largely used for fuel. The coir trade in North Malabar

has therefore still to be developed. But in South Malabar with the exception of Calicut, the coir trade presents quite a different aspect. The increasing tap which in some months proceeds from both the banks of the Ponnani canal and backwater, and which a traveller hears as he skims along in a boat to or from Cochin, is indicative of the brisk trade that is now done in coir yarn with Cochin as the port of preparation and export. To express in a condensed form the uses of coir, we may say that it serves for various marine uses including its extensive if not sole use in native crafts for light work and rough usage, and for matting. There is yet another fibrous production grown on the Malabar Coast and known as Calicut-hemp. It is of great strength and fineness, and is especially suited for small ropes and lines. It is very little inferior to the best Russian hemp, and is a most reliable rope, second only to Manila-hemp. Considering the valuable properties which experts attach to the Calicut hemp, we see no reason why with proper cultivation, curing and preparation of it, we should not dispense altogether with the Russian hemp. Considering its value as an article of trade, we are surprised that Calicut hemp is not more largely cultivated in Malabar. Sernad is the only place in the district where *yakku nira*, as the Calicut hemp is termed in Malayalam, is grown to any extent. There are extensive tracts of land in the Kurumbanad Taluk for example, which are excellently adapted for the Calicut hemp.

Another species of Indian hemp, which is much coarser than the Calicut hemp, is the *Jubbulpore hemp*, which is in general use for heavy cordage. In utilizing this material there is much wastage, but it turns out a very satisfactory and reliable rope, is tough and strong, and will stand much rough usage. Hemp ropes are largely used by the Marine, Ordnance, Commissariat and Public Work Departments.—*Malabar Spectator*.

◆

MANAGEMENT OF FRUIT TREES.

Complaints are commonly made by gardeners of fruit trees not coming into bearing so early as they desire. Complaints of that kind are not altogether reasonable, for though some varieties are naturally less precocious than others, whoever plants them, knowing their natures, should wait with patience till fruit comes in the natural course. But if it is really necessary that fruit of these particular varieties should be had, then we maintain that it is the defect of the gardener if he does not obtain it when required, and not that of the trees. For although the most profitable mode of treatment of a fruit tree is to allow it to continue to grow without check till it naturally commences to bear, it may be forced into bearing by artificial means. It may be taken as an axiom that strong wood-growth is incompatible with fruit-bearing, so that if we have one we cannot have the other. It is, however, generally the case that a capable gardener can have which of the two he chooses; if he wishes his trees to make wood, he feels them, and checks their fruit-bearing propensities, but if fruit is the desideratum, then he checks production of wood and thereby encourages that of fruit, to effect which he has a plurality of means at his command. It may be accomplished by means of pruning the branches, and more effectually and rapidly by root-pruning. But whether pruning the branches produces the desired effect or the contrary depends entirely upon the season in which it is performed. Pruning in winter tends to the production of further wood-growth while summer pruning produces an opposite effect. Properly practised summer pruning is simply placing fertile power where it will be found next year in a plentiful crop of fruit.

A tree must have attained a certain stage of maturity before fruit-bearing commences; the growth, instead of being vigorous and gross, as is generally

the case with healthy young trees, assumes the stunted or stocky appearance so well known to the practical grower as being indicative of a disposition to produce flowers and fruit. This condition may be brought on prematurely by repeated checking of the young shoots while they are making growth. By this means the flow of the sap is checked, and instead of continuing the development of leaves and shoots, it is thrown with greater force into the remaining bud, and, if the work has been judiciously performed, and not carried to an extreme, organises them for a future year; but if the stopping is overdone, the whole of the buds may break, and thus the object of the operator is defeated. It is evident, then, that summer pruning with the object of inducing a fruitful habit, requires some amount of observation and experience to ensure a successful result. If commenced early in the season, the stopping of a shoot does not produce any great or lasting effect, and the process may be repeated again and again, perhaps three or four times before the desired object is attained. We have seen trees, not of extreme luxuriance, brought from a state of barrenness into one of fertility in a single season by pinching the tops of the shoots towards the end of the summer, after the season for exuberant growth was past while the sap still flowed with considerable vigor, though not so much as to cause the buds, or at most only a few of them, to start into growth, but still sufficient to fill and cause them to swell into fruit buds, instead of remaining as wood buds, which they would had the sap been allowed to flow past them and expend itself in the formation of more leaves and wood. It is, however, a very nice point to time the operation of stopping the shoots so as to produce the desired effect, for by the weather or other causes, the process might be spoiled either by inducing too large or too small a flow of sap; in the first case causing the buds to break at once, and in the other preventing them from swelling owing to the deficiency of sap. Under some conditions, trees may be brought into a fruitful state by leaving them altogether unpruned; for, as a rule, the more a tree is pruned the more wood it makes, but if left alone its superfluous energies become exhausted in course of time and fruitfulness supervenes. A similar effect may be produced by ringing the branches, by which means a check is given to the sap that almost invariably throws them into a bearing state. The sap may be also checked by bending the tops of the branches towards the ground, by which means fertility can be generally produced in the course of one or two years.

Root pruning is, however, the most rapid as well as certain method of inducing fertility in a vigorous tree; by this means the flow of sap can be checked to such an extent that growth may almost entirely cease and the whole of the leaf buds be transformed into fruit buds the following year. And it has this advantage, that by the time the fruit buds are formed the young roots, if properly fed, are ready to supply an amount of nourishment sufficient to bring the crop to perfection. This process also requires a large share of skill and experience to enable the operator to carry it out to the proper extent so that, while the vigor of the tree is sufficiently reduced, the pruning may not be so severe as to cause it to be starved and rendered incapable of producing either leaves or fruit. The pruning must, therefore, be in exact proportion to the vigor of the tree. As a rule, it is best not to overdo it, for, if it is found in the ensuing season that it has not been severe enough a few more roots can at any time be cut through. The common practice is to cut only a portion of the roots at one operation, leaving the remainder until a further check is required. Root pruning gives the grower great command of the vital energies of a tree; he can, at any time, by lessening the supply of sap, stop the too vigorous growth, while it is also in his power to increase the vigor by extra feed-

ing of the young roots that are quickly formed in place of those cut off. Thus the process may be even made use of for the renovation of partially worn out trees. For when a tree has got into a stunted condition its roots become almost inactive and incapable of furnishing sap in sufficient quantity to maintain a state of vigor in the tree. But if the roots, or a portion of them, are cut through they presently send out young fibres, and if these are supplied with rich food and plenty of moisture they increase rapidly in strength and vigor, and are presently able to impart new life into the parent tree, bringing it back to a state of growth and fruitfulness, which may be maintained for an almost unlimited period by periodical root pruning, first one side of the tree and then the other.—*Leader.*

SOILS.

Lime is one of the most important ingredients of the soil. 1st, lime is in constant requisition for building up the framework of plants and animals; 2ndly, it absorbs moisture and carbonic acid gas from the atmosphere and from the minerals which surround it in the soil, and, owing to its great affinity to acids, it facilitates several chemical changes that take place within the soil (decomposition of vegetable and animal matter, &c.). In combination with clay or alumina, lime forms a mixture called marl. It has been pointed out that we cannot form a lump of marl by simply mixing up, ever so intimately, different proportions of clay and lime; a piece of such substance as would appear to be perfect marl, put into water, is separated again into clay and lime, which form distinct sediments at the bottom of the vessel. We have found also that a piece of clay soaked in lime water changes into true marl, and we may thus presume that the enormous layers of that substance which we occasionally find have been formed in nature by a similar process of infiltration of lime water into clay. Marl is easily distinguished from clay by its containing lime. On application of hydrochloric acid the lime will testify its presence by causing an effervescence; the lime takes up the hydrochloric acid and gives off its carbonic acid. Pure clay shows no effervescence. The different kinds of marl may be classified according to the quantities of clay, lime, magnesia, and sand which they contain. There is—

1. Marly clay; it contains 5-10 per cent of lime and 90-95 of clay.
2. Clay-marl; it contains 15-28 per cent of lime and 75-85 of clay.
3. Common marl; it contains 25-50 per cent of lime and 50-80 of clay.
4. Loam marl; it contains 15-25 per cent of lime and 20-25 of clay; the remaining portions being sand or silica.
5. Chalk marl contains 50-90 per cent of lime; 10-25 per cent of clay or silica. It effervesces in nitric acid.
6. Magnesia marl, 10-30 per cent chalk; 20-50 clay; 10-40 per cent magnesia. It effervesces with hydrochloric acid.
7. Clayey marl, 90 per cent lime and 10 per clay— which may always be called chalk soil.

There are also marls containing gypsum, &c. The important feature of the marl family is their tendency to lose all coherence when they are exposed to the influence of the atmosphere. For this reason they are more easily cultivated than stiff clay soils. This property, as well as the power of marl to absorb moisture and gases as clay does, greatly depends upon the proportion of the clay or the magnesia to the lime in the marl; the greater the proportion of clay the greater is that power of absorbing, and of retaining also what has been absorbed. Greater percentages of lime, on the contrary, interfere with the absorbing power of the clay and more readily give up again the water under the influence of heat. The capacity of clay of holding back greater quantities of water than lime does is the cause that clayey marls generally form cold soils; they require greater heat to act upon them so as to infuse the warmth necessary for the process of vegetation

throughout their whole substance; but they also retain better stores of heat thus accumulated than chalky marls do.

If lime is predominant water is not readily absorbed. The substance of the marl absorbs heat quicker because there is no water to monopolise the heat for itself; heat is therefore easier imparted to chalky marl, but it also loses that heat more readily by radiation.

Amongst the other minerals that constitute the chief ingredients of a good soil are potash and soda. They are likewise derived from rocks. Their importance in agriculture will be discussed on a later occasion.

Ordinary soil is chiefly composed of clay, lime, or clay-lime (marl), sand (minute particles of silica), potash, and soda. There is another substance generally found in good soil which is not of mineral origin but which is a modification of carbon called humus.

Humus is a substance formed out of vegetable matter in a state of decomposition. Taking a dead leaf as an instance, we notice that its natural green colour gradually changes into yellow, from yellow into brown. When dead leaves, chips, sawdust, or other vegetable offal, are exposed to the influence of the atmosphere, they gradually change into a dark brown substance not unlike peat. In fact, peat is vegetable matter not perfectly decomposed. The beginning of the decay of dead leaves, &c., is chiefly due to the influence of light, moisture, and other atmospheric agencies. The process of decomposition, however, is greatly promoted by certain threadlike microscopic fungi called bacteria. How quickly decomposition will spread if the bacteria have once got hold of vegetable substance is easily seen in a case of fruit; if one apple or orange begins to decay many others are also very quickly infected. During this process of decomposition of vegetable matter several chemical changes take place, which, owing to their subtle nature, we cannot well describe here. Several acids are formed in succession—ulmic, humic, crenic, apocrenic, and finally carbonic acid. This formation of vegetable matter into carbonic acid gas alone is of great interest to the farmer. This process may go on very gradually, and humus, in its first state of decomposition, may remain a long time in the soil before the chemical changes to which I have alluded actually take place. Humus, when dry, is an earthy powdery mass which does not dissolve in water, but which absorbs it readily, and forms a spongy muddy substance; it gradually breaks up into a perfectly disintegrated state, forming a soft mud which, along with water, can be so perfectly absorbed into clay or marl, and in such quantities, that it serves as a store of vegetable food for any plants that may grow on that soil in the course of time. The several acids (ulmic, humic, crenic, &c.) into which humus successively changes have the remarkable property of rendering soluble, in the water in which they themselves are dissolved, mineral substances which cannot be dissolved in ordinary water. These acids facilitate thus the absorption of mineral matter by the plants. Humus is therefore not only vegetable food for the young plant itself by being gradually changed into carbonic acid, but it is the mediator for the digestion of mineral matter for the plant.

There is another substance of interest to the farmer which, however, we can in this place only briefly mention. It is geine. Like humus it is the result of decomposition of vegetable matter, and it is found at the bottom of ponds, lakes, and other stagnant waters. Brought into contact with carbonates, geine changes into geinic acid, a substance which, owing to its corrosive nature, is highly detrimental to plants. Exposed to the influence of the atmosphere, geine is gradually changed into crenic and a porcenic acid, a subject to which further reference will be made on a later occasion; likewise to the substance called peat.—J. S. HERMANN SCHMIDT.—*Queenslander*.

TO PREVENT MUSTARD-PLASTER from blistering, mix with the white of an egg.—*Southern Planter*.

TO KEEP INSECTS out of bird cages, tie up a little sulphur in a bag and suspend it in the cage. Red ants will never be found in a close or drawer, if a small bag of sulphur be kept constantly in these places.—*Southern Planter*.

SIR WILLIAM HOOKER AND KEW.

The announcement that at the end of this month Kew Gardens will be without a Hooker at their head will be read not only with regret, but with something approaching to consternation. Kew and Hooker, Hooker and Kew, were, as it seemed, so inseparably combined that no severance could take place. If a Hooker did not plant the seed he transplanted it from the seed-bed and nursed it till it became a goodly tree, while another Hooker still further developed the tree till it bore abundantly of flower and fruit and seed. In paper I. viii., Sir William Hooker found the garden at its lowest ebb. Shortly before his accession to the office of Director, to such a state of degradation had the garden arrived that it was seriously proposed to hand over the collections to the Horticultural Society. In consequence of the report and recommendation of the former Editor of this journal, Sir William (then Dr.) Hooker removed from Glasgow, where he had already done wonders in establishing and maintaining a botanical correspondence and interchange of plants with all parts of the world, and assumed the post of Director of the Royal Gardens, Kew. Those who remember the old state of things, speak of Hooker's transforming touch as something magical. By his clear-headedness, his unswerving diligence and zeal, his extensive knowledge, his stately courtesy, and the encouragement he extended to all occupied in horticulture and botany, he raised Kew in a very short time from its low estate, and with the assistance of the ex-Curator, who still survives, made it the botanic garden of Europe. Actually dying in harness, at a ripe old age, just twenty years ago, Sir William was succeeded in the directorate by Dr. (now Sir Joseph) Hooker. The career of the son is well known, at least its main features, to every botanist, and to most gardeners. His early travels in the antarctic regions with Sir James Ross, his adventurous wanderings in Sikkim Himalaya, whence he introduced so many of the glorious Rhododendrons, gave him fame, if not fortune, and on his return from India he occupied himself with the determination and distribution of the immense collections made by himself and Dr. Thomson, and shortly after became Assistant-Director of the Gardens under his father, so that on the decease of Sir William in 1865 it was universally felt that he, and he alone, was a fit successor.

During the twenty years that have elapsed, the record of Kew is one that the proudest administrator might envy; the area has been greatly extended, the succulent-houses, the T-range, have been erected, old houses have been removed, the herbaceous ground remodelled, the fruticetum and rock garden constructed, the arboretum vastly extended, the museums (three in number) greatly enlarged and improved, the new herbarium built, the "Noth" gallery installed, the Laboratory erected. The two latter establishments testify to the confidence reposed in the Director. Such magnificent gifts would never have been made to the public had there not been a general admiration of the administrative ability and competence of the Director. While all this new work has been undertaken and carried to a successful issue, the maintenance and improvement of the old have been such as to elicit admiration; and herein the chief has been well seconded by the Assistant-Director, Mr. Dyer, Mr. John Smith (who occupies the same position that his nameake did under the directorate of Sir William), and the other officers of the establishment.

So far we have alluded to results which all can see for themselves, but on the time that this work of extension, provision, and maintenance has been going on a vast amount of work has been thrown upon Sir Joseph, or rather he has himself developed it in connection with India and our colonies. The latter, Sir William early endeavoured to make Kew the great centre of reference of the English-speaking world, and this he has done by developing the son. Kew is now the real centre of a series of botanic gardens and similar establishments through-

out the empire. The diffusion of information, the interchange of plants has been most beneficial, but it has entailed on the directorate at Kew a vast amount of correspondence on all matters connected not only with scientific botany but with practical or economic botany, and with methods of cultivation. In this way Kew has taken a large share in the collection and dispersal of the Cinchonas in India and elsewhere, which is of untold and ever-increasing value. A similar statement may be made with reference to Tea, to Gutta-percha, and Caoutchouc yielding trees, and to very many more useful plants distributed mainly through the agency of Kew. This is, indeed, a vast work, but one of which but few of the hundreds of thousands of annual visitors to Kew know anything. While all these labours have been carried out unintermittingly, Sir Joseph has found time to undertake and carry through an amount of purely scientific work which if he had done nothing else would have of itself been considered remarkable. We have not space to do more than mention his many classical papers, on systematic Botany and Botanical Geography, his Floras of the antarctic regions, of New Zealand, of Tasmania, and his co-operation with the late Mr. Bentham in the elaboration of the *Genera Plantarum*. When one calls to mind the amount of detail and drudgery which must have been encountered to bring such works to a conclusion it becomes a matter of astonishment how in the midst of the official duties of administration so much can have been achieved. But this is not all. While all this was in progress Sir Joseph, abandoning the traditions of his early education, warmly adopted the now generally accepted Darwinian views of evolution, took his share in the government of the Linnean, the Geographical, the Geological, the Royal, and of other Societies. For a few years he filled the chair of Newton at the Royal Society; he has presided over the British Association, and taken much active interest in the Royal Horticultural Society, over the Scientific Committee of which he has presided for some years.

It is no matter for wonder that Sir Joseph should, after twenty years' such labour, varied by travel in Western America, and in Syria, and in the far less accessible Morocco, desire to be relieved from the strain and responsibility of official duties, but his reasons are characteristic. The *Flora of British India* has occupied several years to bring it to its present state, with the assistance of several collaborators; at least a third remains to be accomplished. Apart from his pre-eminence capabilities as a botanist, Sir Joseph has a knowledge of local and special matters relating to Indian botany that no one else possesses, or is likely to possess. To obtain leisure to complete the *Flora of India* is, then, one of the main reasons which have induced Sir Joseph to tender his resignation. It is some satisfaction to know that the completion of this work will necessitate his frequent presence at Kew (though in an unofficial capacity). There, in the noble herbarium originally formed by his father, so largely extended by himself, and in which so much of his own life and work has been spent, Sir Joseph will, it is to be hoped, find leisure to complete these works which heretofore must have been sadly hampered by administrative duties.—*Gardener's Chronicle*.

INDIARUBBER IN NICARAGUA.—Reports from Nicaragua on the rubber trade continue to refer to the falling off in the supply. The rubber trees, it is stated, along the banks of the river San Juan and the neighbourhood of Greytown have been almost entirely destroyed by the short-sighted policy of the rubber cutters, and the entire want of efficient police supervision. The men who formerly worked in these forests, who bought their provisions and sold their indiarubber in Greytown, are now dispersed along the Mosquito coast.—*Gardener's Chronicle*.

BEE-CULTURE IN INDIA.

I have read with interest the articles under the above title that have appeared from time to time in the *British Bee Journal*, especially those of Mr. J. O. Douglas in the number for Dec. 1st. Did time permit, I would gladly detail a number of my observations and experience in connexion with the bees, bee-hunting, and bee-keeping in India while on a journey there during the winter of 1880-81 after new races of bees, more especially the great *Apis dorsata*. However, though the greater number of these observations have not been printed, on account of my ill-health as well as lack of leisure to put them in shape for publication, I cannot forbear a word or two regarding a few of the points and allusions made in Mr. Douglas's article.

Mr. Douglas speaks of the unicombed bees, *A. dorsata* and *A. florea*, and the 'multicombed' bee, *A. Indica*. It is very probable that each swarm of *Apis florea* only build one comb, as all that I saw had but a single comb, and I was repeatedly told that they did not build more. Moreover, as these tiny bees do not frequent the forests as much as they do the more open country where shrubs and bushes form the greater part of the vegetation, it is reasonable to suppose that they choose the latter, so as to find near the ground suitable twigs upon which to build; and, in fact, all that I found were in such locations. The pasturage of the open country may very likely suit them better, yet as there are always some large trees among the bushes, they might choose elevated places if they wished. As, however, the single comb is generally attached to a small branch or twig, there is room for but one. This at the top is built around the twig so as to envelope it, the cells being deep for storing honey, the thickness of the comb at the top often reaching two or three inches. Below, where the brood is reared, the comb is, however, but three-eighths of an inch thick. The tiny hexagonal wax-cells, of which there are eighty-one on each side of a square inch of surface (100 on both sides), are very beautiful. Of course it is easy to imagine that a swarm constructing a single comb not much larger than a man's hand can never be made very available, even if it can be kept in hives. I succeeded in taking one hive of these bees from Ceylon to Cyprus, and they behaved much better than hives of the two larger species. An accident resulting in the death of the queen at a time when no brood was present in the hive was, of course, the virtual extinction of the stock.

Most of the *A. dorsata* stocks which I saw consisted of but one huge comb attached to a large branch, or to some overhanging ledge of rocks. But this giant honey-bee (it surely deserves the name 'honey-bee,' although it is not cultivated) does sometimes build several combs side by side, for when in Ceylon I transferred into a mammoth moveable frame-hive a stock which had built three parallel combs in a cavity of the rocks. I found these bees in the Kurungala district at a place known to the natives as Bambera-galla (*A. dorsata* rock). It was a wild forest region, some miles from any habitation, rarely visited, so that I had much difficulty in transporting my hives and implements to the place, and getting up to the top of the rock, which, perched on the side of a mountain, towered up nearly a hundred feet from the lower side, as near as I could judge. The walls on all sides were either perpendicular or overhanging; and I was at first at much loss to know how we were to get up to the dozen or more huge stocks of *A. dorsata*, whose combs depended from two to four feet from one of the overhanging ledges near the summit. But the natives, of whom there were a dozen present, led me by a crevice just large enough to admit a man's body into the interior of the rock, and, by building a ladder of poles and rattans, we reached a sloping ledge some forty feet up; thence winding around we came near the summit, and at last found a dark passage leading right up through the centre

of the rock. The top was nearly level, and about ten feet square. A cavity enclosed on all sides but one, and partially roofed over, contained a large stock of *A. dorsata*, which of course I had not been able to see from below. The bees dove us down in the daytime, but at night with the aid of a torch and smoke I cut out the combs and lifted them into frames which were placed into a hive hauled up over the side of the rock. I had learned that the best time to approach these bees in their forest lodgment is at night, as they do not fly much then. The frames of my hives were about 12 m. deep by 18 in. long, and so the combs were cut accordingly. I think larger frames would have been better, but not so easy to transport. As the *A. dorsata* comb is one and three eighths inches thick, the bars of my frames had been made of that width. There were some fifty to sixty pounds of honey in the combs of this stock, and after I had given the bees a fair supply, the natives had a nice feast, and some was left over; besides, they eagerly devoured the bits of brood which did not find place in the hive.

As this was towards the close of the season when the bees find little honey, just before the swarming season, it is fair to presume that the amount of honey would be much greater at most any other time, and the huge combs would have made a nice lump of wax. We secured but one other stock of the dozen that were on the overhanging ledge of rock; the risk to limb and life being too great to try for any more there, so we moved on to other localities. Once in moveable-comb hives, I did not find *A. dorsata* intractable, but there are other reasons why its culture may never prove successful, although it is an experiment worth trying.

The little *A. Indica* builds its parallel combs (five-eighths of an inch thick; thirty-six cells on each side of a square inch) in hollow trees, rock cavities, etc., and is cultivated to a certain extent in earthen pots, wooden skeps, etc., yet I do not believe with much profit. The queens are prolific, and the workers industrious, but it is what the Germans would surely call a *swarm-bee*. And if kept in moveable-frame hives, the great difficulty, as Mr. Douglas well remarks, would be the absconding of the bees at nearly every manipulation, notwithstanding the presence of brood and honey. I have lively recollections of getting the bees of a recently transferred stock whose combs I was fixing a little, back into their hive six times in succession one morning, performing in these processes a good many gymnastics on the roofs and trees in the vicinity of my apiary. Before I learned of this peculiarity of *Apis Indica* I formed quite a favourable opinion of it, though, from all that I saw, I should think 24 lb. reported as its yield in the Wynad rather high, though, of course, I judge merely by the amounts I saw in the combs of the stock I captured. As the cause for absconding seems to lie in the very excitable nature of these bees, I would recommend the use of smoke only when absolutely necessary. They can generally be driven from combs by blowing them strongly, and become less excited than when smoked. They can be brushed or shaken from the combs easily. As the worker brood-combs are but five-eighths of an inch thick, the bars of frame-hives intended for these bees should be but five-eighths wide instead of seven-eighths to one inch, as for *Apis Mellifica*, and the spacing but one-quarter in. to three-eighths at the most.

In Ceylon I found two parties who had got out hives from England, which, of course, were adapted to *Apis Mellifica*; and had frames whose bars were seven-eighths of an inch wide, and spaced so as to remain three-eighths of an inch apart. Of course, these parties could not understand why their bees would not do the way the backs of other people's bees were accustomed to do, that is, build their cells regularly and put on in a line, never once absconding that, and only were they not of the same race, but, even more, they belonged to quite distinct species.

Whatever may be the result of any attempt to cultivate the honey-producing bees native to East India, I still feel sure that, in the hands of a bee-master of sufficient experience and knowledge of principles to enable him to adapt himself, or rather his management, to circumstances, any of the races of the species *Apis mellifica* can be made to thrive in India. Certain I am that those stocks of *Apis mellifica* which I took to Ceylon thrived very well indeed during the time I had them under my observation.

I look forward to the time when bee-culture in India will be a source of no inconsiderable revenue; in fact, I fear the time will yet come when 'Brother Jonathan' across the water will find that his tons of delicious nectar will have to compete in the English market with tons of sweats gathered on 'India's coral strand.'—FRANK BENTON, *Munich, Germany.*

THE EUCALYPTUS IN ARRAN, SCOTLAND.

No tree so fully realises the beautiful saying of Scripture, 'The leaves of the tree were for the healing of the nations,' as the Gum Trees of Australia. They heal the land by drying the poisonous marsh. They heal the air by emitting quantities of ozone to purify it, by removing injurious organic matter. They heal man himself by preventing the spread of disease; by arresting the violence of fever; by allaying the irritation of cough, and by giving sleep to the sleepless.

We rejoice to be able to report that many species of this tree grow in Arran. They are as follows:—

1. The Blue Gum (*Eucalyptus globulus*).—This is the best known, and the most extensively planted of all the Gums. It germinates freely, grows rapidly, and attains a great height—as high as 330 feet. When young its leaves are soft, and covered with a fine bloom, and diffuse abundantly a camphoraceous odour. It also abounds in that oil which has been found so beneficial as a medicine. Like most of the Gums, its appearance in the earlier years of its growth is very different from what it becomes when the tree is more advanced. Then the leaves acquire a scimitar shape, become leathery, diffuse less perfume, and the tree is altogether much less attractive. In this country it has also the disadvantage of being delicate—no tree in Scotland, growing in the open air, having survived the severe winter of 1860-61, except the one at Captain Brown's, Craigyard, Lamnish. It is now about 30 feet in height, and is 1 foot 10½ inches in girth. Another plant grows at Strabane, Brodie's. The species is named from the form of the leaves when the plant is young. It has not yet bloomed in Arran, nor any of the others.

2. The Twiggy or Manna Gum (*E. viminalis*).—This may be called the Weeping Blue Gum, for while it differs from the Blue Gum in the leaves being small and roundish, and in the branches being very slender, the leaves much resemble the Blue Gum in perfume, bloom, and also in hue, though this is somewhat more of a plum colour. This species is very hardy. A large tree grows at Whittinghame, East Lothian. One has been planted this year at Lamnish. It is named *E. viminalis*, from the slenderness of its branches—Manna Gum from manna being obtained from it.

3. The Almond-leaved Gum (*E. amygdalina*).—This and *Eucalyptus colosa* are the tallest trees in the world, growing, in some instances, to the height of nearly 500 feet. A tree of this species has grown at Omana, Orie, for about ten years. It is somewhat slow in growth, being only about 25 feet in height and 13 inches in girth. This Gum is more hardy than the Blue Gum, but not so common as some other species. It is not from the leaves of this tree that the Almond tree and the Blue Gum are the species from which the oil of eucalyptus is principally obtained.

4. The White Gum *E. pauciflora* syn. *arabica*.—In 1879 I received seed of this species from Mr. Bailey, Government Botanist, Queensland, and had them gathered on the Blue Mountains, New South Wales.

I sowed it at once. The following year (1880) it was planted at Craiggard, Lamash. It is already 18½ feet in height, and 7½ inches in girth, and probably will one day be the tallest tree of any kind in Scotland, and probably in Britain. It is so hardy that not even a leaf was browned in the severe winter of 1880-81. Its leaves are very large, approaching the size of those of the Blue Gum. They are covered with a whitish bloom. It is called the White Gum because of the whiteness of the trunk after the annual shedding of the bark. It is a native of Tasmania, and its white trunks give a peculiar character to the forests of that great island. Plants of it grow also at Brodick and Corrie.

5. The Alpine Gum (*E. alpina*).—This tree is a very interesting and important addition to the forestry of Arran, as it is altogether diverse in habit from any of the Gums formerly introduced. Its leaf is large, thick, and remarkably broad, 9 inches by 4½. It is specially illustrative of that feature in the trees of Australia which enables them to expose themselves edgewise, instead of horizontally, to the sun, for the development of one side of the leaf is almost twice that of the other, and thus the superior weight of the one side causes it to hang down, and to make the opposite side stand erect. The habit of the tree also corresponds to the shape of the leaf, being broad and close. This tree also illustrates the well-known fact that some alpine plants grow well in the vicinity of the sea. This tree, which, as its name denotes, is a native of the alpine regions of Australia, is at Corrie Hotel, Arran, growing in fullest luxuriance within 35 yards of the sea, at high water. It was planted last year, and is now 3½ feet in height. I send a leaf.

6. The Cider Gum or Mountain White Gum (*E. Gunnii*).—The leaves of this Gum are small, of a light green colour, and are highly odiferous. It is very hardy, and grows in the open air at Kew. A plant 6 feet 5 inches in height grows at Craiggard, Lamash; a smaller one at the Free Church Manse, Whitingbay. It receives the name Cider Gum from the liquid that flows from it when the bark is pierced.

7. The Urn-bearing Gum (*E. uruigera*).—The leaves of this species are of medium size and of a dark green colour. It grows at Strabane, Brodick, and is very hardy. It receives its name from the shape of the vessel containing its seed.

8. The Coccus-bearing Gum (*E. coccifera*).—This differs from most of the Gums in the leaves being leathery, even when the plant is very young. They are small and of a dark bluish colour, and look as if covered with bloom. This species is very hardy. A tree of it grows at Powderham Castle, Kenton, Devonshire, more than 60 feet in height and more than a foot in diameter. A tree of what I consider this species, though the authorities at Kew have pronounced it to be *E. amygdalina*, grows at Castle Kennedy, Wigtonshire. It grows at several places in Arran.

In addition to the above mentioned Gums already in Arran, through the kindness of friends allowing me to plant them in their gardens, I may mention that I have specimens of the Fig-leaved Gum (*E. ficifolia*), from Broken Inlet, Western Australia, the leaves of which, as its name denotes, resemble those of a species of Fig. It is also remarkable for flowering when comparatively young, and from the flowers being of a crimson colour; I have also a plant of the crimson-flowered Iron-Bark (*E. leucocylon* var. *coecinea*), whose flowers are magenta-crimson in colour. Its leaves are small and narrow, and the branches slender, so that it much resembles a Babylonian Willow. Its wood is said to excel that of all other trees in hardness. I have also the red Iron-Bark, *E. siderophila*, the bark of which, as its name tells, is almost iron-like in hardness. Its leaves much resemble those of the Turkey Oak, the veins are red, on account of which it is named the red Iron-Bark.

This summer I have further, through William Stewart, Esq., been favoured by receiving from Sir F. Mueller, Government Botanist, Victoria, seeds of

E. conifera—these have just germinated; also of *E. pauciflora*, the White Gum already mentioned, as growing so well in Arran. I have also received a similar favour from Mr. Bailey, Government Botanist, Queensland, who has sent the seeds of 'a rare and most valuable Lemon-scented Iron-Bark' (*E. staigeriana*) from the Palmer River, Queensland. It also has germinated under the kind care of my friend Mr. Gray, gardener, Newshill.

I only add that plants of several of the most hardy Gums, such as *E. pauciflora*, *E. Gunnii*, *E. uruigera*, and *E. coccifera*, are now growing at various places of the west coast of Scotland—at Knockdoan and Anehearne, near Balantrae; at the Established Manse, Rosneath; and at Ballinakill, Cantyre.—*Gardeners' Chronicle*.

REST ON TOOLS.—The *Farmer's Advocate* says there are several easy ways to prevent rusting of ploughs and cultivators, and to keep the teeth bright. One is to give them a coat of thick linewash as soon as they are brought in from the field; another is to dissolve an ounce of rosin in four ounces of linseed oil and while hot mix this with a quart of kerosene and stir well. This is laid on to smooth iron with a paint brush. Another way is to dissolve an ounce of camphor in some turpentine and add this to four ounces of lard and one ounce of pulverized black-lead or stove polish, and mix well. This may be rubbed on with a rag. To remove rust from ploughs or tools nothing is better than a mixture of a half pint of oil of vitriol poured slowly into a quart of water, and apply this to the rusted metal. Wash off with water.—*Florida Dispatch*.

FIRE-PROOF PAINT FOR ROOFS.—A correspondent of the *N. Y. World*, writes:—I send my receipt for fire-proof paint, which I like for many reasons. Slack stone-lime by putting it into a tub, to be covered to keep in the steam. When slacked pass the powder through a fine sieve, and to each six quarts of it add one quart of rock salt and water one gallon; then boil and skim clean. To each five gallons of this add pulverized alum one pound, pulverized coppers one-half pound and still slowly add powdered potash, three-quarters of a pound; then fine sand or hickory ashes, four pounds. Now add any desired color and apply with a brush. In my opinion this looks better than paint and is as durable as slate. It stops small leaks in roofs, prevents moss and makes it incombustible.—*Florida Dispatch*.

THE MANGO IN QUEENSLAND.—The present season has proved to be a non-bearing one for the mango. More particularly is this the case in the Northern districts. Last year enormous crops were gathered; the trees being loaded to their utmost. It is evident from this experience that the mango does not differ from other fruits in requiring a year of rest after one of great productiveness. The extraordinary growth of these trees anywhere on the coast line of this colony, their productiveness, and freedom from disease point to the fact that before long they will be the common fruit tree of Queensland. As the mango is a fruit that can be exported to such distances as the southern colonies and New Zealand, and also cannot be grown to perfection in those parts, there is no reason why a profitable export trade should not spring up. The peculiarity of the mango is that although almost everyone dislikes it upon first tasting the fruit, yet it does not take many trials before the singular flavour becomes most fascinating to the palate; therefore the sale for them, when once the large markets of the southern cities are reached, will be very great. Selectors could not do better than plant. The trees grow readily from seed, and as long as due care is taken to plant only good seeds from good mangoes they will come tolerably true to variety. Otherwise, if the exact variety is desired to be maintained, then grafting on seedling stocks must be resorted to; and grafting of the mango is difficult—in fact, it can only be done by inarching.—*Queenslander*.

THE HOMING PIGEON.

It would be difficult to say how early in the history of mankind pigeons were domesticated. The dog has been the friend and companion of man since long before the dawn of historic times; and his bones now lie with those of his pre-historic master in the cave dwellings of a race that left no record of its existence but its bones, a few flint arrow heads, stone hammers and stone hatchets. The horse, like the dog, has followed the fortunes of man from a very early period and ranks in fidelity and courage with its humbler four-footed companion. The pigeon may not claim so long a friendship with man as either of these two faithful servants and friends, but it was domesticated very early in the history of the civilization of most races of men, and probably it is the smallest of its bones alone which prevents its being identified as the companion of that race of cave dwellers whose lives are much closer linked with the geologic past than they are with the dawn of mythic history. We do not maintain that fossils and relics of smaller boned animals are not preserved in the earth's crust. Whoever knows anything of say, the carboniferous system knows the delicate tracery of fronds and fragile shells to be found in shale, but our contention is that the bones of the pigeon were crunched up and eaten by his master the cave dweller, and thus left no trace behind. There are sound evolutionary reasons for believing that, without exception, the whole of the present existing perplexing varieties of the pigeon, domesticated and wild, are traceable to the common blue rock pigeon. At all events that is Professor Huxley's opinion and we do not feel disposed to differ from him. The pigeon is the most plastic of creatures, and every pigeon fancier knows what beautiful results can be obtained by careful selection, breeding and crossing. Of all the varieties of pigeon, the one we desire to deal with at present is, what old-fashioned people used to call, the "Carrier," but which in these latter days is known as the Racing Pigeon or the Homing Pigeon. Some variety or other of the homing pigeon is to be found in almost every country in the world, and probably the Belgium bird is regarded as the highest trained. All homing pigeons possess the same qualities. Let loose, after training, long distances from home, they fly with incredible speed in a straight line for home, far outstripping, in many instances, the steam engine. It would be an easy matter to give records of distances, but what we are at present immediately concerned with is the uses to which homing pigeons could be turned in India. Every frontier station in India could easily have a few trained birds which, should ever an emergency arise, could carry messages with a speed and certainty which no contrivance of man could attain. The news of an outbreak of the Nagas or any of the other hill tribes bordering Assam could by means of homing pigeons be communicated to the authorities within a few hours of the occurrence and immediate steps could be taken. On the North-Western frontier a regular pigeon post across Afghanistan will one day, sooner or later, be found invaluable. Simla, the seat of the Imperial Government for eight months of the year, is liable to be cut off from all communication with the plains by heavy rains.

Here, too, homing pigeons would be invaluable. Planters in the Mofussil might train a few birds for their own purposes, and they would find that some day, sooner or later, their care would be rewarded. In a case of sudden and serious illness the arrival of a medical man a few hours earlier than ordinary could carry the message, might mean a great deal, and there are dozens of instances where the service of a pigeon post in the Mofussil would be highly advantageous. Pigeon posts are not unknown in India. In the Bombay and Madras Presidencies as well as in the Upper Provinces racing pigeons are not uncommon. Some years ago a regular pigeon post was worked between Nagpore and Hyderabad, some 270 miles. Some 200 birds were kept for this purpose at Nagpore and were cared for by fakirs. Racing or homing pigeons scattered the seeds of rebellion all over India before the outbreak of the Mutiny, and at the present day their use for various pur-

poses by natives is not unknown. Before the Crimean War, Mr. Ferguson, of the *Ceylon Observer*, established a pigeon post between Point de Galle and Colombo, a distance of 72 miles and pigeons did the distance invariably within an hour.* This pigeon post brought the first news of the fall of Sebastopol to Colombo. With favourable conditions of weather and wind, homing pigeons can fly with ease 60 miles an hour, and 45 miles an hour for eight hours on end has been accomplished by pigeons. There is a case on record in which in a race between the Crystal Palace and Brussels, the winning bird beat the telegraph by ten minutes. We are glad to say that the Government of India have, during the last three years, given some attention to the breeding and training of homing pigeons for military purposes, and it would be well, if the great value of trained pigeons was more practically realized than it apparently is. No contrivance of man, not even the steam engine or the telegraph, can equal, on emergency, the speed and certainty of the homing pigeon, and its advantages for military purposes are obvious.—*Indian Planters' Gazette*.

PLANTING PROSPECTS IN CEYLON.

A gentleman with considerable interests in Ceylon, writing from London under date Nov. 16th, is good enough to state:—

"I am pleased to notice from time to time in the *Overland Observer*, which I receive regularly, your continued satisfactory reports regarding the tea enterprise in the Colony. Since my retirement from the life of coffee planter in your island, I have increased my stake considerably in the colony, and naturally read your reports with interest. On my last visit I found a very favourable view in regard to the ultimate success of this product, so much so that I at once commenced operations on ——— properties which I trust may prove a lucrative concern, but in these days of blights and pests it is as well not to be too sanguine; so far however I have cause to be satisfied with a large acreage planted up, a portion of which is already producing 500 lb. per acre, and I hope to extend still further before many months are over, but proprietors must look ere long to a substantial fall in prices: they are good at present and perhaps may continue so for another year, after that we must be prepared, I think, to content ourselves with 1s, which price, there are reasonable grounds for believing, should be realized, by fair average qualities of Ceylon teas. It is wonderful to notice how these teas have risen in favor with the British public during even the past nine months. A year ago, I had considerable difficulties in persuading people to drink them: now I am pestered from all quarters for supplies. There is little doubt in my mind that proprietors are making a fatal error in sacrificing such large quantities of cinchona bark at the present time. A decided upward tendency has set in in the value of this article in the London market, and before long, in my opinion, we shall see a further rise of 40 to 50 per cent. My advice to those who have bark and can keep it, is most decidedly to do so: they will reap a golden harvest by-and-by. Poor King Coffee in some districts doubtless is a thing of bygone days, but it is not true to say that 'no more coffee is to come from Ceylon' as I have heard remarked from time to time. As an instance I may quote a property in Haputalewhicht this past season has yielded a crop of over 7 cw per acre on the fully bearing coffee. It is hard enough to fight for the credit of the island on

* Not quiet this: good birds in favourable weather have been known to fly the distance of 72 miles in 1 1/2 hour, or about a mile a minute. "Generally within two hours" would be about correct.—Ed,

this side, without receiving damaging reports of such a nature emanating from men who are supposed to have a knowledge of such things but who though perhaps hard hit themselves, ought to be more moderate in their remarks, if only for the present and future welfare of 'old Lanka.' On commencing this letter it was not my intention to have enlarged so freely, but when one begins talking on the subject of Ceylon interests it is a tempting topic."

FOR CATARRHAL COLDS.—One drachm of camphor, coarsely powdered or shredded, is stirred into a vessel containing very hot water. A paper cone, placed large end downward over the dish, is the means by which the camphorated steam is inhaled through the nose. Dr. G. E. Dobson asserts positively, through the *Lancet*, that if this treatment is continued for twenty minutes, and repeated three or four times in as many hours, great and usually permanent relief follows.—*Popular Science News*.

TEA IN CEYLON.—Many absentee proprietors are now in such haste to hurry into Tea, that the necessary instructions are being conveyed to their Managers—net by means of letters but by telegrams. Kalutara—the youngest of our Tea districts—has just received its second Tea Roller—intended for Torwood Estate under the Superintendence of Mr. J. A. Cochar. The first Sirocco will also soon be on its way to the same district. It has been remarked that many of the Dimbula and Lindula Teas are below the average standard of Tea from other districts, notwithstanding the use of the most approved Machinery. The Teas are said to be thin and weak in the cup. It must be remembered that in the districts referred to much of the Tea is planted in with the Coffee, and we think this fact alone is sufficient to account for the complaint. When the Coffee is eradicated the quality may improve.—*Ceylon Advertiser*.

ORCHID EXPORTATION FROM BRAZIL.—We confess to a certain feeling of satisfaction at reading the following extract from a letter written by one of the Compagnie Continentale:—"The Municipal Council (of the island of St. Catharine) has also imposed a tax of 500,000 reis (=2,500 francs), on each individual leaving the island with plants, and an additional tax of 5 per cent provincial dues; and all this because a collector last year boasted to have taken from the island more than 100,000 francs worth of Orchids, saying that the Brazilians were simpletons who did not know the value of their weeds, as they call the Orchids. I force the time when, all the countries acting in the same way, Orchids will become very rare in Europe, and where it will not be easy in future to introduce them in large masses. It is alleged that certain districts formerly rich in Orchids are no longer so now. The great fault does not, however, depend on an excessive quantity of Orchids sent to Europe, but on collectors, who after having obtained the desired numbers, set the forests on fire and thus destroy the plants and prevent them from being collected by others." If this be true, hanging is too good for such murderers.—*Gardener's Chronicle*.

OIL MILLS.—The Pondicherry Steam Oil Mills Company, which was formed in Pondicherry about a year ago, for the purpose of extracting oil from seeds and groundnuts by means of improved machinery, worked by steam power, has just completed the factory and buildings, and the erection of the machinery, and crushing operations will, it is expected, commence some time this month. The machinery was officially tested last week, and its working sanctioned by Monsieur Jemeau, the Chief Engineer of the colony, assisted by the Chief Engineer of the Messageries Maritimes Company's steamer "Tibre." The promoters of the undertaking base their claims to success, firstly, on account of the greatly reduced cost at which oil can be produced by machinery as compared with native country presses, and, secondly, by reason of the larger output, and saving from waste. The Company seems to have secured

a good bargain in the press and steam engine, which were bought second hand equal to new, and, which with the buildings, works, offices and preliminary charges, complete, will represent a total capital outlay of under R10,000. The share capital of the Company is R50,000, so that there will be a working cash balance available of R10,000. It is intended, for some time to come, to confine the crushing to ground-nuts, the product of which is mostly shipped to Barmah and Mauritius.* The chief drawback against cheap working will be the cost of fuel; in other respects the Company's arrangements appear to be such as to insure economy. The shares are held by a few of the leading residents of Pondicherry, mostly merchants, a committee of whom control the management gratuitously. An artesian well has been successfully sunk in the factory compound, the water from which being pure, is well adapted for steam purposes.—*Madras Weekly Mail*.

LABOR IN TRINIDAD.—*Public Opinion*, a paper published at Port-of-Spain, Trinidad, in its issue of Oct. 20th laments over the customs returns for September, which show a decrease of £15,000 for imports and £2,300 for duty paid, the total decrease for the nine months being £740,670 for imports and £17,100 for duty. On this our contemporary remarks:

Would we could say that a considerable part of this decrease was due to increased production of native provisions to replace foreign imports, but no such solace is admissible. The decrease simply means the pauperization of our population and their consequent inability to purchase. Years before this great crisis the present writer, and others who had the real interest of the country at heart had raised a warning voice that the abandonment of the liberal policy of Sir Arthur Gordon would sooner or later, bring forth its bitter fruits. All our laws have tended to foster the preponderance of one industry to the exclusion of other, and, at the first crisis, we are all prostrate. Foster the sugar industry by all means, but do so in an intelligent and broad spirit. It is our mainstay, therefore does it require to be propped up by minor industries.

The writer then goes on to compare Trinidad with the sister colony Barbados, and states that the depression in the latter is caused by the high price of landed property having bartered estates with a load of interest. The writer then proceeds:

In Trinidad we have many advantages which do not exist in Barbados. In the first place we have other industries, other products which, on the whole, almost equal in gross value our sugar crop, and, at the present moment, especially, far surpasses it in nett profits. Our cocoa crop alone is equally in gross value to fully two-thirds of our sugar crop. Next, in regard to sugar, our lands are more fertile and do not require the heavy expenditure in artificial manure, without which no result can be obtained from the inferior and exhausted lands of Barbados. But against those advantages, we have the terrible drawback of dear labour. It is calculated that the indentured cooly, if all the expenses of his introduction into the colony and those which bear exclusively on the planter, such as indenture fee, hospital and other expenses are added up, cost about 50 cents for a full day's work. This is enormous.

We should think so. The creole laborer earns 20 to 25 cents per task, but he cannot live on this, so supplements it by other means; in Barbados the laborers receive about 6d a day, but they work only four or five days in the week, the rest of the time being occupied in the cultivation of ground provisions: this system, the writer in *Public Opinion* considers should be introduced into Trinidad.

* What product? The oil, we understand, sent to Marseilles to take the place of olive oil. We presume it is the oil cake which is sent to Burma and Mauritius.—Ed.

HOW TO MAKE POTASH.

Baron Ferd. von Mueller, K.C.M.G., of Victoria, writes as follows how to make potash:—The wood, bark, branches, and foliage are burnt in pits sunk 3 feet or 4 feet in the ground; the incineration is continued until the pit is almost filled with ashes. Young branches and leaves are usually much richer in potash than the stem-wood, hence they should not be rejected. The ashes thus obtained are placed in tubs or casks on straw over a false bottom. Cold water, in moderate quantities, is poured over the ashes, and the first strong potash liquid removed for evaporation in flat iron vessels, while the weaker fluid is used for the lixiviation of fresh ashes. While the evaporation proceeds, fresh portions of strong liquid are added until the concentrated boiling fluid assumes a rather thick consistence. At last, with mild heat and final constant stirring, the whole is evaporated to dryness. This dried mass represents crude potash, more or less impure, according to the nature of the wood employed. A final heating in rough furnaces is needed to expel sulphur combinations, water, and empyreumatic substances; also to decompose colouring principles. Thus pearl ash is obtained. Pure carbonate of potassa in crude potash varies from 10 to 80 per cent. Experiments, so far as they were instituted in the laboratory, have given the following approximate result with respect to the contents of potash in some of our most common trees. The woods of the Casuarinas, or She-Oaks, as well as that of the black or silver Wattle, are somewhat richer than the wood of the British Oak, but far richer than the ordinary Pine woods. The stems of the Victorian Blue Gum and the so-called Swamp Tea-tree (*Melaleuca ericifolia*) yield about as much potash as European Beech. The foliage of the Blue Gum proved particularly rich in this alkali, and as it is heavy and easily collected at the sawmills, it might be turned there to auxiliary profitable account, and, indeed, in many other spots of the ranges. In the Queensland coast country the Mangrove could be made to yield potash in immense quantities, as it is richer in this alkali than almost any other native tree or shrub; and even if the Mangrove were not used for the manufacture of potash, the Ash being rich in this valuable fertiliser, could be easily and economically applied for manurial purposes. Of course British woodmen are aware that it is hopeless to compete with the extensive mineral deposits in Germany, whence most of the potash of commerce is now made.—*Forestry.*

GINSENG IN THE COREA.*

The most important product of this part of Corea, (Sonedo) is the drug known as ginseng, so highly prized as a tonic by the Chinese. I visited several of the numerous ginseng gardens in this neighbourhood, and saw the plant at various stages of its growth. It is grown from seed which is sown in March. The seedlings are planted out in beds raised a foot above the level of the surrounding soil, bordered with upright slates and covered in from sun and rain by sheds of reeds three or four feet high, well closed in except towards the north side, where they are left more or less open, according to the weather. These sheds are placed in rows with just room enough to walk between them. In the first or second years the ginseng plant is only two or three inches high, and has only two leaves. It is transplanted frequently during this period. In the fourth year the stem is about six inches high, with four horizontal leaves standing out from it at right angles, and in fifth year a strong healthy plant has reached maturity, though it is more usual not to take it up until it has reached the sixth season. Mould containing plenty of rotten leaves is the only manure used. It has to be carefully guarded against thieves, especially in the late stages of its growth, and in every ginseng garden there is a shed raised high on poles, where a watchman sits night and day.

The ordinary ginseng is prepared by simply drying the root in the sun, or, when the weather is unfavourable, over a charcoal fire. To make the red or clarified ginseng, the root is placed in wicker baskets, which are put in a large earthenware vessel with a closely-fitting cover, and pierced at the bottom with holes. It is then placed over boiling water and steamed for a longer or shorter time, according to the age of the plant, four hours being an average time.

The export of this quality of ginseng is a strict monopoly, which affords a considerable revenue, and is said to be the king's personal prerogative. Death is the punishment for smuggling it out of the country; but in spite of prohibition, considerable quantities find their way abroad by illicit channels.

The annual amount exported to China is 202 piculs, which is valued at forty nyang a catty, or, say, forty dollars a picul (133½ lb.). The white ginseng is worth about half as much. It is the wild ginseng for which enormous prices are sometimes paid. Ginseng is also grown at Yong-san, in the Province of Kyong-sangdo.—*Pharmaceutical Journal.*

TOBACCO IN BURMA.

That the soil and climate of Burma are admirably suited for the cultivation and curing of tobacco has long been admitted, and it is very satisfactory to learn that there are now good reasons to hope that the cultivation of tobacco is beginning to be popular and to take root in the Province. The farm at Kyauktan in the Hanthiawadi district has been of special benefit in this respect. The cultivators, both Burman and Karen, had free access at all times to the plantation. Several cultivators in the immediate vicinity took to the cultivation. They were presented with seed and seedlings, and their plots were visited by the Assistant Director of Agriculture, who afforded them both advice and assistance. The result was highly satisfactory; all got good crops, and one or two succeeded in raising excellent tobacco. They were shown how to dry and cure the tobacco. A large number of people flocked in to verify what they had heard about the successful cultivation of tobacco, and, after judging for themselves, no less than 500 or 600 landholders have since started tobacco cultivation. It is believed that, by this new impetus, an additional area of something like 500 acres has been brought under cultivation. In other parts of the Province much is also being done. In the Ma-ubin Island, grants of land aggregating about 10,000 acres have been made to cultivators, a considerable number of whom have agreed to start tobacco cultivation. A small farm has also been started on the Island; and the cultivation and curing will be carried on, as at Kyauktan, under the eyes of the people, and it is hoped that results similar to those obtained at Kyauktan may be achieved. In addition to the above measures, steps have been taken to revive the cultivation and proper curing of tobacco in Arakan. Mr. Roberts, formerly a tobacco and cigar manufacturer in Koonadi, was deputed to Palewa in July 1882, to start a small plantation of the indigenous tobacco and prepare as large a supply of leaf as possible for trial in the local and home markets. The object was to ascertain what were the real quality and value of the Kaladan tobacco under proper treatment. The experiment was successful. Samples of this tobacco dried and cured at Paletwa, and samples of American tobacco grown and cured at the Kyauktan farm, have been sent to two large London tobacco importers and manufacturers for valuation and report, and a sample of both the Kaladan and Kyauktan leaf has been sent to the French Government at the request of the French Consul at Rangoon. The London tobacco manufacturers are, it appears, keen to find new sources of tobacco supply; and the French Government is the largest single purchaser of foreign tobacco in the world. It is hoped that, if the reports from these sources are satisfactory, a favourable outlet for the tobacco of Burma may be obtained.—*Calcutta Englishman.*

* From a Report by Consul-General Aston.

TORENIAS.

The next plants to which I wish to draw attention are the *Torenia*s, and all those who admire the perennial *Torenia Asiatica* will also appreciate the equally beautiful annual species *T. Bailonii* and *T. Fournieri*. The flowers of the former are yellow with a purple centre, and those of the latter species are a blue, somewhat resembling *T. Asiatica*. The genus belongs to the natural order Scrophulariaceæ, and consequently is allied to many of popular garden flowers, such as the Foxglove, Snapdragon, Toadflax, Mimulus, and Calceolaria. Like *T. asiatica* the species under notice are as well adapted for culture in baskets as for pots, being of a pendant habit. The leaves are small, and produced in pairs, the flowers springing from the axils of the leaves. All the species in cultivation are impatient of stagnant moisture at the roots, but at the same time they all require abundant supplies of water, consequently it is necessary, in order to achieve even a moderate share of success, to secure perfect drainage and use an open soil. The seed, which is very small, should be sown early in spring in pots or pans that are well drained, and containing 2 or 3 inches depth of fine soil made level, and watered through a fine rose previous to sowing the seed. If it is decided to cover the seed with soil great care must be exercised in doing so, but anyone who is accustomed to raising *Lobelias*, *Celery*, and herbaceous *Calceolarias* from seed will not be likely to err on that score. In my own practice I find it the best to never cover very small seeds with soil, but after sowing I cut a piece of newspaper to fit the outside diameter of the seed pan, and then press it gently down on to the surface of the soil, and thus leave a margin standing up all round and close to the sides of the pan, and if the pan is stood level, as it ought to be in any case, the water which is poured on the paper remains thereon and keeps the soil underneath constantly moist, and not a seed is disturbed. As the seedlings appear the paper can be removed at will, and replaced to shade from the sun or too strong a diffused light. Water the young *Torenia*s previous to transplanting them, and, as with *Thubergias* during growth, frequent syringings will be beneficial, and will keep red spider in check. Should black thrips appear, light and frequent fumigations will destroy them, but an extra strong dose of tobacco smoke would, in all probability, be as fatal to the *Torenia*s as the thrips. The annual *Torenia*s are the most difficult plants to rear and cultivate of all that I shall mention in this paper; and if amongst my readers there are any amateurs who can boast of never having failed with any plant they have yet taken in hand—and I know one or two who can truthfully say as much so far—to them I heartily commend for their culture, and if they only succeed in raising and flowering 10 per cent of the seeds sown, they will be amply repaid for their trouble.—*J. W. S.—Journal of Horticulture.*

[These are very beautiful plants and suitable for terrandabs, but like many other things here, the seeds are generally covered deep, and they never come up.—*Ed.*]

GUTTAPERCHA.

Now and Boolongan, Ssaxap and Sambakong' and the intermediate rivers, produce all sorts of guttapercha, that of the latter port being chiefly "mixed qualities," i.e., the different varieties mixed. Longmassing produces guttapercha as well as other ports on the south and west of Borneo, but the rivers extending north into the interior accounts for the exports at these southern ports. There is also a large quantity of common sorts of guttapercha obtained on the north-east coast of Borneo, viz., at Sarawak and Bruni, and is exported from Labuan. Within a recent period guttapercha trees have been discovered towards the east end of the Celebes (still within the limits). Guttapercha has been exported from this region, but it is not quite apparent as to what quality, it is simply described as "fair quality."

The second and third sorts or classes of guttapercha, viz., Gutta Mookas and Gutta Kapur grow within ten miles of the sea coast, and on low, but not swampy land. They grow, too, on some of the islands such as Trakkan and Boneyoet, but the best kind, viz., Getah Lanyüt, is seldom obtained at less than thirty miles from the sea coast, and at an elevation of 100 feet from the sea level; and it is worthy of remark, that the inferior kinds all disappear 100 miles from the coast, and the best kind only is found at that distance. These trees are found growing in groves, each variety being in separate groves. These groves number from 100 to 500 trees in each, and grow on the hill slopes, with higher forest trees surrounding them. The natives affirm that at times guttapercha trees are found at an elevation of 600 feet above the sea level, and where so found yield a better and more abundant supply of gutta. The soil in which they grow is rich, and with a rocky subsoil. The rainfall is greater than in Singapore, and the driest months of the year are November and December; the rest of the year is always moist.

The average temperature (in the shade) for the year may be stated thus:—

	Day	Night	3 a. m.
May to October	{ Highest range	90°	Fabr. —
	{ Average	75°	... 66° Fabr.
Nov. to April	{ Highest range	95°	... —
	{ Average	84°	... 70° "

All accounts seem to agree that guttapercha trees flourish best in a moist temperature, in light loamy soil at the foot or slopes of hills, thus having plenty of drainage and also surrounded by primitive (not secondary) jungle.

As guttapercha trees are indigenous to Singapore, although only now seen as curiosities, its climate, although somewhat modified by the denudation of its own forest trees and from the adjacent peninsula, will give the best index to the requirements of these trees. The Singapore year may be divided into three periods of four months each; 1st, from January to April, during which the rainfall is very variable and uncertain; 2nd, from May to August, which may be called the dry season, in which period as a rule the rainfall is least; and 3rd, from September to December, which may be called the wet season, during which the rainfall is greatest. The yearly rainfall in inches in 1869 was 90.63, in 1870 123.24, in 1871 109.45, in 1872 75.90, and in 1873 85.60. The following was the temperature for the same period:—

	1869	1870	1871	1872	1873
Highest temperature	92°	93°	91°5	92°	92°5
Lowest	69°	69°	60°	67°	68°5

—*Indiarubber and Guttapercha Journn.*

MANGABEIRA RUBBER.

This rubber is likely to attract considerable notice in consequence of a recent favourable development in the manipulation of the raw material. When first imported, owing to the careless way in which it was collected and prepared, it only fetched about sixpence a pound. But it has recently been imported by a Brazilian merchant in very fine condition, and the article when submitted to some of the best London firms, has been declared to be worth three and four-pence a pound. The rubber is especially suited for springs of railway and tram cars, and for similar purposes.

Through the kindness of Messrs. Christy, we are enabled to present our readers with some information concerning this rubber, as well as with a picture of the plant from which it is produced. The Mangabira, Mangaba, or Mangabira Tree, as it is called in Brazil, is a small tree belonging to the *Apocyna* æ— with an elegant mode of growth, like a weeping birch, having drooping branches and small oblong leaves, sharp at the base, but with a short rounded point at the apex. The tree yields an excellent rubber, but is more frequently grown for its fruit, which has a most delicious taste, and is a great favourite with the Brazilians. It is about the size

of a plain, of a yellow colour, and marked with red spots or streaks. It is only fit to eat when perfectly ripe, or after being kept for a short time. Hence the tree has the double advantage of bearing fruit which will bear exportation, and of yielding a valuable rubber. The tree is now attracting attention in its native country, having been undeservingly neglected, as may be seen from the following note, taken from the *Journal of the Society of Arts*, June 4th, 1880, p. 631.—

"The inhabitants of Pernambuco are beginning to realize the vast stores of undeveloped wealth existing in their virgin forests, and rubber is being exported from that province, which may soon rival Pará in the extent of its exports of the article. Recently Senhor José Fernandez Lopes issued a circular, April 20th, 1880, calling attention to this important source of wealth, and giving practical instructions for the collection and preparation of the rubber, from which the following is extracted.—'The process of extracting the milk from the Mangabeira is very simple and easy. Each person must be supplied with fifty or more small tin basins and a small axe. He should make oblique cuts sloping downwards at a little distance from each other, all round the trunk of the Mangabeira, cutting only the bark, and placing immediately below each cut one of the basins, securing these either with adhesive clay or nails. These small basins will collect the milk that exudes from the cuts, and when full they must be emptied into a larger vessel. This process should be continued during the whole day, and thus three or four bottles of milk may be collected, according to the fertility of the trees. The cuts should not be deep and a great number of incisions should not be made on each tree, as these may weaken or kill the trees, which has been the case in some instances with the Seringueira, the tree from which the Pará rubber is obtained.'

"The rubber is prepared from the juice as follows:—Put a little powdered alum into a teacupful of water, mixing it well, then put a few spoonfuls of this solution into a vessel in which three bottles of the milk have been placed, properly strained to clear it from any extraneous matter. Immediately the milk coagulates, which will be in two or three minutes, the rubber must be exposed to the air on sticks, and allowed to drain for eight days. After thirty days it is ready to send to market in cases or barrels."

To the above it may be added that in incising the trees it would be better to use a guarded axe, i. e., one thickened in the upper part of the blade to prevent its penetrating the bark beyond a certain distance, so as not to injure the cambium or juicy layer, for if this be pierced the tree is likely to decay.

The use of alum or salt, or any such substance, to coagulate the rubber, is liable to render it wet and spongy, unless it be prepared in sheets and subjected to strong pressure. The best plan is to evaporate the milk in thin layers, over smoke-basins as done in Pará, in shallow pans in a current of hot air.—*Indian Rubber and its Cultivation*.

PLANTERS IN FIJI.

(From the *Times* of 17th July 1885.)

Natalia, being the present holder of Mataiva, is the proprietor of the plantation on that island, which he has bought from the Government of Fiji, and is now cultivating it in a most successful manner. He has planted about 1000 acres of sugar-cane, and is now harvesting it. He has also planted a large quantity of rubber-trees, and is now harvesting the milk from them. He has also planted a large quantity of coconuts, and is now harvesting them. He has also planted a large quantity of other crops, and is now harvesting them. He has also planted a large quantity of other crops, and is now harvesting them. He has also planted a large quantity of other crops, and is now harvesting them.

the north by Malaisi. When the present proprietor came to it not an acre was cleared. It was bush and jungle from high water mark to the highest hill; now 250 acres are cleared and planted with coconuts, coffee, tobacco, corn, yams, &c. The major portion of this area is planted with coconuts, and 170 acres are bearing fruit. Coffee was grown on the hills, and the area would have been extended but for the coffee leaf disease which turned a paying industry into a losing one, and the cultivation of the berry was abandoned. The soil and general features of the estate are similar to those already described—an extended notice is therefore unnecessary.

Considerable attention has been given to pastoral pursuits. The estate is partly fenced and divided into paddocks to facilitate the breeding and fattening of stock. There are 25 head of cattle and 250 sheep running under the coconuts and doing the work of cultivation. Both cattle and sheep do remarkably well. These sheep are fanned, on Taviuni, or the very excellent and full flavoured mutton which they make. Mr. Rannie has been trying to improve the carrying capacity of his run by planting an imported grass from the Southern States of America named *alfafa*. This is said to be a species of clover which makes splendid feed. It grows most luxuriantly in a warm climate and is most suitable for cattle, being very nutritious and very fattening. It is said to be in great favor and demand on all cattle runs in South America.

There is every convenience on this estate for pulping and drying coffee as well as for curing copra. There are 30 running *vatas* for sun drying the copra and a house under which they can be placed for shelter in a few seconds. There is also a large drying house, with pipes and furnace, &c., where the copra can be dried during the wet season. This house is also a great convenience for drying coffee and copra as the temperature can be regulated. There is also a large two story building used for storing the produce awaiting shipment. Another two strong buildings fitted up with sleeping *vatas* is used for labourers' quarters. There is a detached kitchen for cooking the labourers food. A little further away is a very neat weather-board cottage where the Indian overseer lives. All these buildings are on the beach facing the main road. They are all very well placed and built of hardwood frames weather-boards or iron and all covered with iron roofs.

The dwelling house is situated on a hill, and is reached by what appears an endless flight of steps up an almost perpendicular hill. * * *

The dwelling house is a weather-board building with a flower garden in front, in which crotons, roses, &c., were growing. The situation was beautiful and the outlook was magnificent. Mr. Rannie is too well known to need an introduction to your readers. When he was introduced to me for the first time it was as one of the successful planters of Taviuni. Here was a *bona fide*, for I had not met many successful planters before in Fiji, and I was glad to meet even one. Mr. Rannie is what some people would call a lucky fellow (many people regard success in life as an evidence of luck rather than of ability or good management). Most of the things he had taken in hand have prospered, and generally speaking he has handled these things that require paying for in a most judicious manner, and he has not only paid for them, but has also made a profit out of them. When he was first introduced to me he was in the midst of a most successful business, and he was in the midst of a most successful business, and he was in the midst of a most successful business.

The plantation is situated on a hill, and is reached by what appears an endless flight of steps up an almost perpendicular hill. * * * The dwelling house is a weather-board building with a flower garden in front, in which crotons, roses, &c., were growing. yams, pines, peanuts, and bananas. It was purchased with the special object of growing pines and bananas for exportation to the Australian colonies and New Zealand. With the S. S. "Suva" running regularly, as she does, to catch the outgoing steamers, special facilities are offered to fruit growers on Taviuni. The fear that the steamer may be taken off the line has, perhaps, somewhat retarded cultivation in the fruit district. But a pushing energetic company like the U. S. S. Co. of New Zealand is not likely to abandon a trade if it gives any promise of future success. Before I close I may say there is a plentiful supply of water on this estate.

FRUIT PRESERVES.

The past season has been in many respects an exceptionally good one for the manufacturer of fruit preserves. This industry is increasing yearly in importance, and seems likely, before long, as in the case of many other industries, to fall almost entirely into the hands of the larger houses who have the command of sufficient capital to bring the resources of machinery to bear upon the different processes employed.

During the height of the preserving season we had an opportunity of visiting the London factory of Messrs. J. Moir & Sons, where fruit of all descriptions is preserved on a large scale. The raw material, consisting of baskets of strawberries, currants, gooseberries, &c., is gathered in the market gardens which surround the metropolis at the earliest hours in the morning, it being a point with this firm that all fruit should be converted into jam before the evening of the day on which it is plucked. In the boiling room there are long rows of jacketted copper pans each of about 60 gallons capacity. Steam at a pressure of about 50 lb. to the square inch is admitted into the jacket and the fruit is poured into the pan. Each pan is served from above by a trough through which the loaf sugar, having been previously crushed in a mill and weighed by an automatic apparatus, is shot on to the fruit and the whole is boiled for a sufficient time. Some of the pans are made to swing on trunnions, the steam passing through the latter as in an oscillating engine, whilst others are provided with an ingenious valve arrangement for emptying, in which case the necessary operations can be performed without tilting at all. The latter arrangement is found a great convenience in practical work, as it takes less time and occupies less space. In order to preserve the flavour of the fruit it is necessary that no water should be used in cleansing it, and consequently many ingenious devices have to be introduced for the purpose. In the case of red currants, for instance, which seem somehow to possess a special power for attracting "matter out of place," a cylindrical sieve containing revolving brushes of a peculiar description is used. This runs at a speed of 1,200 revolutions per minute. The fruit passes through the sieve, whilst the stalks and other refuse are discharged at the lower end perfectly dry.

For making fruit jellies the fruit is boiled and the first of the juice separated by means of open straining bags. The fruit is then placed in a centrifugal separator, consisting of an open-work basket rotated by a vertical shaft. This runs at a great speed and almost instantaneously separates the fluid parts of the fruit from the skins and seeds. There is also a somewhat extensive hydraulic plant, consisting of pumping engines and presses, which is used with some fruits in place of the centrifugal machine for making jellies. As these jellies are slightly acid carbonaceous vessels, pipes, and taps are used in their preparation.

It is said by those interested in this trade, that through the excessive competition of the present day in the jam-making industry, firms that manufacture a good article from sound fruit can only manage to exist by means of the closest attention to economy in production. However this may be, Messrs. Moir & Sons appear to have brought their labour-saving appliances to a high degree of perfection, and this most noticeably in the "filling room." The material is here carried in copper pans with wheels running on a tramway, and

passes by gravity on to a hydraulic lift which raises it to an overhead gantry. Beneath the latter is a range of filling vessels, and the pan, which is fitted with a valve at the bottom, stops over each vessel and delivers the exact quantity of material required. Beneath the filling vessels the jampots (which have been previously washed in a steam-driven machine) are brought up by an automatic arrangement, each pot stopping in turn until it receives its full complement of preserve, when it passes on to make room for the next. In this way thirty to forty thousand pots of jam are filled in an ordinary day's work, the attention of one man or boy to each set of apparatus being alone required. It is the fashion now to pack a good deal of the best quality of jam in glass bottles, and these are filled in the same way. No machinery has, we believe, yet been devised by which the ordinary cover can be stretched and tied over a jampot, but the bottles have long been closed by an automatic arrangement. The stopper consists of a stout tin capsule, inside which is a thin disc of cork provided for the purpose of preventing contact between the fruit and the meta. The cork and capsule having been put in position, the bottle is held firmly in a revolving holder by means of a weight. A pair of rollers are brought up to the capsule and close it under the projecting flange on the neck of the bottle. Each machine will turn out about 300 bottles per hour in ordinary work. The quickness and precision with which the jampots and bottles are automatically taken from the stacks and marshalled into rows, and are then brought up to be filled by the various machines, is not a little comical at first sight. In another department of this factory pickles are made by the ordinary process, or rather what should be the ordinary process, only distilled vinegar being used in place of the coarser acids which are employed by less scrupulous manufacturers.

There is a building set apart for making the tins used on the premises. Here there are power presses and stamps driven by a separate engine. We understand that over 2000 packages an hour are sometimes turned out from this department. Steam machinery is also used for stamping the circular pieces of paper which are used for covering the jampots. Although the machinery here in use for making tin packages is comparatively new, it will shortly be superseded by an entirely fresh plant of novel design by which the labour will be still further reduced. The machines have been especially designed for the firm, and we hope to be able to publish particulars of them at a future time. This firm has other factories at Aberdeen, Wilmington, Delaware, and Seville. At the latter establishment orange marmalade alone is made. The works of Messrs. Moir & Sons are instructive if only for the purpose of showing how largely machinery is now used in every branch of industry, even in one so apparently simple as making jam.—*Engineering.*

SOOT-WATER FOR PLANTS.—The London *Garden* says: "If you merely make a mixture of soot and water, you have a crude and dirty thing to deal with; and the right way is to put a bushel of soot into a well-made canvas bag, into which a heavy piece of old iron has previously been thrown as a sinker; then tie up the bag tightly, and throw it into a tank or large butt of pure rain or river water. None of the crude carbon makes its escape; but you have all the ammonia and other essential component parts of the soot, which are really soluble; and, either for syringing or watering, it is of the utmost value."—*Popular Science News.*

QUININE MANUFACTURED IN CEYLON BY MESSRS. SYMONS AND COCHRAN.—We have had the opportunity of inspecting about a pound of Sulphate of Quinine locally manufactured by Messrs. Symons and Cochran at their laboratory. The quinine is a beautifully white color but is not so flaky as Howard's quinine. We do not suppose that quinine will ever be locally manufactured for the market, for it is not a mercantile speculation which many men would care to embark in, but the sample of quinine made by the two above-named gentlemen is worthy of inspection for all that.—*Local "Times."*

PLANTING IN SUMATRA.

(By an ex-Ceylon Planter.)

CEYLON TEA F. SUMATRAN TOBACCO.

It is with the greatest pleasure I read both these publications (the *Weekly Ceylon Observer* and *Tropical Agriculturist*), the former for news concerning my old home and the latter for information on all sorts of agriculture. It is certainly a most invaluable magazine, shall I call it, and on any of the questions I am able to solve by reference to it.

I am glad to see that Ceylon is again coming to the front with its tea, and have no doubt it will regain its former proud position. Commend me to the Ceylon planters for pluck, but they must keep their eyes open, as there will soon be plenty of keen competition, though I do not apprehend they have much to fear either from this part of the world or the Straits Settlements, as these Settlements must long suffer from want of a sufficient and cheap supply of labour.

Here we are wholly engrossed in tobacco, and it is impossible to get planters to look at anything else so long as it pays handsomely. Cent per cent is nothing unusual, and many are the fortunes that have been made within the last few years.

Things progress very slowly under the Dutch Government; or rather want of Government (but it is very good, however, at collecting taxes); and it is only the occasional murder of a European by Chinese coolies that rouses the apathy of the official mind, and if the murderers are caught and hanged two years afterwards, we are apt to cry out, "Well done the Government," though I doubt if such tardy justice conveys to the native and Chinese minds that sense of might which is supposed to appertain to a civilized power; but rather that the Government have suddenly discovered in their jails some criminals who deserved to be hanged (and there are always plenty of them unchanged), and it would be better to get rid of them.
