Step after step the ladder is ascended."—GEORGE HERBERT, *Jacula Prudentum*.

THE
TROPICAL AGRICULTURIST:
A
MONTHLY RECORD OF INFORMATION
FOR
PLANTERS
OF
Tea, Coffee, Cacao, Cinchona, Sugar, Rubber, Tobacco, Palms, Spices, Rice,
AND OTHER PRODUCTS,
SUITED FOR CULTIVATION IN THE TROPICS.
[ISSUED ON OR ABOUT THE 1ST OF EACH MONTH.]

COMPILED BY

A. M. & J. FERGUSON

of the "Ceylon Observer," &c.

LIBRARY
NEW YORK
BOTANICAL
GARDEN.

"It is both the duty and interest of every owner and cultivator of the soil to study the best means of rendering that soil subservient to his own and the general wants of the community; and he who introduces, beneficially, a new and useful *Seed, Plant, or Shrub* into his district, is a blessing and an honour to his country."—SIR J. SINCLAIR.

A. M. & J. FERGUSON: COLOMBO, CEYLON.

The "TROPICAL AGRICULTURIST" can be obtained from, or advertisements for it sent to, the following agents:—

London:—Messrs. TRIBNER & Co., 57 & 59, Ludgate Hill; JOHN HADDON & Co., 3, Bouverie St., Fleet St.; GEO. STREET & Co., 30, Coruhill; F. PRINTED AT THE "CEYLON OBSERVER" PRESS: COLOMBO, CEYLON: 1886.

TO OUR READERS.

LIBRARY
NEW YORK
BOTANICAL
GARDEN.

In closing the Fifth Volume of the "TROPICAL AGRICULTURIST," we have but to repeat what we have said on similar previous occasions, in directing attention to the large amount of useful information afforded, and to the great variety of topics treated in our pages. From month to month, we have endeavoured to lay before our readers the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make this periodical not only indispensable to the planter, but of service to business men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge and science, besides being the basis of human wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have never omitted to notice minor industries likely to fit in with tropical conditions; and our readers have an ample guarantee in the pages before them that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of commonsense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

The official Reports on the Royal Botanic and Economic Gardens in Ceylon are republished in full in a separate form, in the present volume and throughout our pages will be found reviews of, and extracts from the Reports of other Botanic Gardens situated in or near the tropics. We are ready to give copious extracts from, if not to reprint *in extenso*, the Reports of all other sub-tropical Public Botanic Gardens which may reach us. Most of these Reports we already receive and utilize as above-mentioned for the benefit of our planting readers.

A full and accurate Index affords the means of ready reference to every subject treated in this fifth volume which we now place in our subscribers' hands, in full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

In conclusion, we must tender our thanks to readers and contributors, and our wish that all friends may continue to write instructively and read with approval: for then indeed must the "TROPICAL AGRICULTURIST" continue to do well.

A. M. & J. FERGUSON.

COLOMBO: 15th June, 1886.

SEEING THE TEA GROW IN THE CENTRAL PROVINCE OF CEYLON. WITH A GLANCE AT CACAO, CARDAMOMS AND OTHER NEW PRODUCTS.

VICTORIA AVERAGE LOSS OF WEIGHT IN DRYING TEA LEAVES—JACKSON'S AND KINMOND'S DRIERS COMPARED—PROTECTION AGAINST LOSS OF SMALL TEA—DRYING LARGE AND SMALL TEA—THE PROCESSES OF THE VICTORIA DRIER—TEA NOT TOUCHED BY THE HUMAN HAND IN MANUFACTURE—A SUBSTANTIAL PIECE OF WORK—GREAT HEAT—SMALL AMOUNT OF LABOR REQUIRED—THE A AND B MACHINES—JACKSON'S DRIER AND THE SIROCCO USED TOGETHER—OUTPUT OF MADE TEA—TIME NECESSARY FOR ROLLING—QUICK ROLLING IN ASSAM—CEYLON TEA PLANTERS PROFITING BY THE EXPERIENCE OF THEIR INDIAN BRETHERN.

All familiar with the processes of tea-making are aware that the loss of weight in tea leaves, in passing from green to dry, is on an average 75 per cent. Mr. Armstrong in a recent letter to our columns, gave the actual weight of rolled tea as compared with the finally dried article, and I am sorry I cannot refer to the statement as I write, but I do not suppose I shall be far from an approximation when I attribute two-thirds of the whole loss of 75 per cent to evaporation in the "withering," the other third disappearing in the roasting or "drying" process. In very wet weather, probably the proportions are altered so that the rolled leaf contains considerably more moisture than one half of its weight. The weather during the trials at Carolina was mild, although occasionally showery: good withering weather on the whole. The amount of moisture in the rolled leaf, therefore, which had to be carried away by the heated air and which reduced that air, in its transit, from 28° to 115° Fahrenheit, may, I suppose, be considered the fair normal proportion. I suppose most readers familiar with the processes of tea-making will agree with me that the principle of Jackson's machine, by which the hot air is continuously exhausted and expelled as it becomes laden with moisture and as continuously renewed, is superior to what I was told was the principle of Kinmond's, by which the moisture-laden air was repeatedly made to traverse the same tea. What is certain is, that, while the exhaust fan in Jackson's machine draws out at the top the hot-air which has imbibed moisture in its passage through the tea leaves, those leaves are delivered below in a perfectly dry state. At present the tea is received in boxes, but Mr. Megginson, I understood, was meditating an appliance by which the roasted tea would be conveyed directly from the drier to the sifter. The word appliance reminds me that what I telegraphed was that there is an appliance to prevent small tea being drawn up by the exhaust fan in Jackson's drier, so that only a medium, not worth mention, goes on to the slanting board up which the exhausted air travels to the withering loft. A small quantity of tea, I believe, falls down to the bottom of the machine, which can easily be taken out in a finished state. Of course Mr. Megginson's plan of separating the smaller tea from the larger and drying it on the Sirocco reduces the chances of any possible loss of small tea in this drier. In my notice of Mr. Megginson's processes, for which he has no doubt good reasons, the want of punctuation and capitals created some confusion. The statement was meant

to run thus:—"Mr. Megginson takes out the leaf from the roller at the end of the half-hour, sifts out the small leaf on a pulper-sieve No. 3 mesh, and, when this small tea is fermented, he dries it on the Sirocco. The larger tea is again put back into the roller and operated on for a quarter-of-an-hour further before being fermented and dried on Jackson's machine." With these corrections we trust our descriptions of the various processes is clear. The rolled tea is fed in at an orifice in the top and is automatically spread successively on three travelling webs composed of plates of perforated lead-covered iron, the tea falling from the first web, down to the second and then the third, while the hot-air, is in the process of rising through the series. By this arrangement, it will be seen, the tea finally comes in contact with the pure hot-air unmixed with moisture, parting before being ejected with the last traces of moisture in its own substance. The tea leaves are not touched by the human hand from the time they are fed in as "roll" until they emerge as finished tea, and, if Mr. Megginson's design is carried out, the tea on emerging will be conveyed without man's intervention to the sifter or, if more convenient, the bin. The machine is, as we stated in our telegram, a solid mass of metal equal to 13 tons, and Mr. Jackson assured us that the pipes in the multi-tubular arrangement are so substantial, that he does not anticipate that even with constant working it will be necessary to replace any of the lower tier of six pipes in less than five years at the earliest. Of course the heating of the great (although most compact) mass of metal we have described tells powerfully on the surrounding atmosphere which is proportionally raised in temperature (our weight while note-taking was reduced by at least the equivalent of a five-catty box of tea); but our readers will observe that the machine is so constructed and does its work after such a fashion, that the European superintendent need merely occasionally see that the rolled tea is properly fed and the finished tea properly received, a stoker being held responsible for keeping up the furnace to the proper mark. To do this, we suspect 2 lb. of fuel to 1 lb. of dry tea will be needed. But even so the drier is just the machine for a respectably sized estate, where motive power, of which the drier demands but a moderate portion is available. In places where the withering lofts are over the tea-house and the climate renders artificial warmth desirable, we should think two of the B machines such as that exhibited at Carolina, price £270, would be preferable to one of the A kind costing £370, although the latter is said to turn out 240 lb. of tea per hour against 160 lb. promised, and about 170 lb. accomplished by the former. Probably most planters (who can afford to do so), will follow Mr. Megginson's example by using Jackson's Drier and Davidson's Sirocco, in combination. We noticed that Mr. Jackson did not depreciate the Belfast machine, the chief fault of which is the amount of handling and friction of the tea needed. Mr. Megginson stated that 70 lb. as a maximum per hour was prepared by the No. 3 Sirocco, but this was when pushed to its utmost capacity. When we stated that only 64 lb. an hour could, as yet, be got at Abbotford, Mr. Megginson stated that about 55 lb. an hour was the real average. For reasons which we doubt not are good, Mr. Megginson, as we have stated, rolls his small tea for half-an-hour and the larger leaf for three-quarters of an hour, but Mr. Armstrong, whom we had the pleasure of meeting at the station, reminded us that he and others find twenty minutes sufficient, for tea of all sizes understood. But we have never heard of Ceylon leaf being rolled in ten minutes as Mr. Jackson said was done in Assam. We regret we did

not think of asking Mr. Megginson whether his prolonged rolling was a necessity, from the use of Excelsiors, or the result of experience which proved the benefit of the longer period, but we have no doubt that courteous gentleman will kindly afford this information as he so readily did on all other points referred to him. We have endeavoured to give a popular notice of Jackson's Drier, which, supplementing his Excelsior Roller, places Ceylon planters, at the commencement of their enterprise, in possession of the best machinery, the result of extended and costly experience in India, giving them thus great and important advantages, of which they and the colony are to be congratulated. We meant to refer to the technical descriptions of the Victoria and Venetian driers and to deal with other topics suggested by our visit to Carolina. But we must, for today, hold our hand.

HIGH PRICES FOR TEA MACHINERY—JACKSON'S VICTORIA DRIER—GOOD SOLID WORK—SAVING OF LABOR AND FUEL—DESCRIPTION OF THE MACHINE—THE AMERICAN PATENT CHAIN—A TEST OF THE TEA PREPARED BY JACKSON'S DRIER AND THE SIROCCO—THE VENETIAN DRIER—TEA WITHERING—MANURING TEA—ASSAM IN DIGENOUS—MOSS ON TEA; CAUSE AND REMEDY.

We suspect that many of our planter readers will draw a long breath as they scan the symbols £270, representing the price at the English works of Jackson's Victoria Drier, Class B. "Where are we to obtain £4,000, which the machine will cost by the time it is erected in a Ceylon Tea Factory, even if motive power already exists?" will be the question asked and difficult to answer. And, of course, neither Excelsior Rollers nor Victoria Driers are within the reach of beginners. These must content themselves with cheaper machines, until tracts of 100 acres or over come into full bearing with a rush, the tea crop providing the means for obtaining the requisite machinery for preparing it. Such great central factories as that on Carolina solve the difficulty in a still better manner, the green leaf being purchased by the owners of such factories from the proprietors of neighbouring estates at remunerative prices, and so enabling the latter to save the cost of buildings and machinery, until the extent of tea in bearing justifies a separate establishment. There can be no question that for the preparation of tea more costly machinery is required and more unremitting labour and attention demanded than was the case in regard to coffee. But arrangements can be made to give superintendents much needed holidays, and as regards cost of machinery, which we trust will be soon reduced, it must not be forgotten that in the case of tea all the requisite machinery and operations are concentrated on the estate. The Colombo agent, if one is employed, merely receives and ships the already hermetically closed boxes which are ready for the market. But, to show how persons differ in their estimates of costliness, we may say that Mr. Jackson, in conversing with us about his machine, dwelt on its comparative cheapness when its merits were considered. He said:—"My endeavour has been to provide the tea planters, especially those of Ceylon, with the best possible drier at the cheapest possible price, and I believe this machine meets those conditions." We have already mentioned that the weight of metal in the structure, including framework, furnace, pipes, lead-covered drying webs and gearing of all kinds, is no less than 13 tons, while the fact that the manufacturers are Messrs. Marshall, Sons & Co. of Gainsborough is a guarantee for the honest, solid, lasting character of the work. Then, let us hear Mr. Jackson state both what can be saved and gained by the use of his hot air exhaust, automatic feeding and discharging drier. It is well to be reminded

that 90 per cent of labour and an enormous saving in charcoal, fuel, costly and troublesome to obtain, are secured by the supersession of the old "chulaha" or "dholes." The time had arrived, indeed, when over wide areas the kinds of timber alone suitable for charcoal had become exhausted. The same may be said of timber generally, and the next great discovery desiderated in the interests of steam navigation and railway travelling as well as tea manufacture, is that of a fuel small in bulk, cheap in price and rich in clean and concentrated caloric. The small dimensions of the drier are contrasted with the immense area occupied by the "chulaha." But let us quote the patentee's description:—

The utilization of all the heat generated by its stove, as no trays have to be drawn out to turn the tea, no heat is lost and all risk of smoking is avoided by using surface heated air.

Wood, coal, or grass fuel can be used, by this means a continuous supply of hot air is generated in a multi-tubular cast-iron stove; this stove being of such a nature that no fumes, smoke, or gases from the combustion chamber can come in contact with the drying tea.

Steaming is impossible, as a very powerful exhaust fan is placed on the top of the Machine, and the moist air is instantly drawn off the drying tea, and is followed up by fresh and pure hot air drawn through the tubes of the furnace from the surrounding atmosphere, thus retaining the original aroma of the out-turn, and giving it that malty flavour so highly prized in the market.

The risk of burning is reduced to a minimum by a peculiar arrangement of air ducts, the leaves during the process of drying are submitted to a temperature of 300° when at first fed into the Machine, then the drying is completed in a temperature of about 200°. The Machine also being on the exhaust principle makes it favorable for adjustment, and doors are placed in it which if opened will reduce the working temperature over 100° in the course of a few minutes.

Fermentation is instantly checked, and the color may be fixed or decided upon before the leaf is put in the machine without any fear of its becoming more fermented, and no time has to be allowed for that purpose, as in some Drying Machines.

The color or bloom of out-turn is improved, and is of a beautiful glossy black, from the fact that the tea lies perfectly still on the moving trays and is not handled. Mostly all who are acquainted with tea manufacturers know that handling is very injurious to the color of tea, and this is a most important advantage gained over tray driers.

The action of the machine is perfectly automatic, and the leaf to be dried is placed in a mechanical feeding hopper, the bottom of which consists of a solid travelling web or band, composed of corrugated lead-coated iron plates. Over the top of this band a reciprocating plate moves for the purpose of equalizing the feed, which it does with great regularity. The feeding hopper is sufficiently large to hold about two or three maunds of fermented leaf. When the leaf is carried in by the automatic feeder it falls on to an endless travelling web of perforated plates, (also of lead-coated iron) which overlap each other somewhat like Venetian blinds when closed.

These are carried round on the chain wheels at ends by means of pitch chain of a disconnecting and interchangeable form. The web has a slow motion imparted to it by means of gearing, and it carries the tea along while the exhaust fan is drawing the hot air rapidly through it. When it reaches the end it is tipped over and falls on a second web of the same kind. It is thus returned and tipped on to a third, and so on till it passes over three travelling webs, and is then discharged. It is thus turned several times in the course of drying, and those travelling webs can be adjusted in a few seconds to run at different speeds, allowing the tea from 10 to 25 minutes in the machine. One boy is required to supply the hopper with leaf, another to carry away the dried tea, and another to attend to the fire. The motive power to drive the machine is fractional. The consumption of fuel varies of course with its conditions, but it will generally be found that from one-and-a-half to two maunds of fairly good timber will give a

maund of tea perfectly dried. The out-turn, when a steady temperature and speed are kept up, will be about two maunds per hour of dry tea.

And then follows the price, in the case of machine B, £270, with "packing for shipment and delivery to London or Liverpool extra." We presume the price in rupees, laid down in Colombo, can be ascertained from the Ceylon agents, Messrs. John Walker & Co. of Colombo, whose fame in connection with coffee machinery is worldwide. The chain alluded to in the description of the machine is worthy of special notice. It is an American patented invention and ought to be useful for a vast variety of purposes. It is composed of a series of solid but separate links, so that, combined with extreme strength, there is the convenience of being able, at any moment and at any portion of the chain, to abstract or supply any number of links deemed necessary. In our popular description we have spoken of three drying webs, but in reality the web is endless, the leaf being tipped from one portion to another as it travels until the dry tea is discharged at the base. The speed at which the tea-laden perforated webs travel through the heated air can be elowed or expedited as the condition and appearance of the tea leaf may seem to demand, while a regulating apparatus spreads the tea over the webs at a uniform thickness. Readers acquainted with the effect of iron on tea when the two come in contact will understand the reason why the webs and all other portions of the machine which the leaf touches are coated with lead. The final test of the merits of this as of all other machines of the kind is, of course, the quality of the tea it turns out, and to meet this test effectually (apart from the judgment of planters and others present at the trials), two separate invoices are to be sent simultaneously, from Carolina for sale in the London market—one of tea dried on the Sirocco and one of leaf prepared by Jackson's machine. The results will, of course, be published and will guide planters who have not satisfied themselves by the results of the trials still going on. In the description of the travelling web, it is said to be composed of iron plates which fold over each other somewhat after the fashion of a venetian blind. And this brings us to the fact that Mr. Jackson has invented a Venetian Drier, the cost of which is only £100. It does not seem to have been introduced into Ceylon, and, therefore, we cannot speak of its performances or merits. What Mr. Jackson claims for it is thus stated:—

This machine embodies a convenient and handy arrangement for turning over and passing the tea leaves down from one drying surface to another, without having to take such leaves out of the drying chamber till the operation is completed. The drying surfaces are composed of a series of perforated lead-coated iron strips or flaps, which are arranged together somewhat after the style of the laths, of what are known as "Venetian" blinds. Every flap is provided at each end with a pivot or bearing, on which it can turn in suitable supports in the sides of the drying chamber, and the flaps are placed side by side, so that when all are in a horizontal position, they will overlap each other a little, and form an unbroken drying surface. Each flap is also provided with a crank, which projects outside the casing, and all the cranks of each series of flaps constituting one drying surface, are coupled together by a connecting rod or bar, which, on being pulled the one way or the other, either opens or shuts all the flaps. On the top, or feeding surface, which can be withdrawn from the drying chamber, is spread the leaf to be dried, and when pushed back in position the connecting rod or bar is pulled, and the whole of the flaps are turned, so that the leaf is caused to fall therefrom on to the next lower surface. The top surface is then withdrawn, re-charged and inserted. The connecting rod of the next lower surface is now pulled, which projects the leaf down a surface further, and so on, down from surface to surface, until each charge ultimately arrives upon the lowest, from which it is dis-

charged in a proper dry condition into a suitable receiver.

The quick tilting of the flaps turns over the tea in a perfect manner, and obviates breakage of the fine leaves, and injury to the bloom, that must accrue from tossing and turning the tea by hand on wire mesh trays. This change, therefore, from the use of hand mesh wire trays will be admitted and received as a very desirable one.

Labor will be saved in working, and as the tea is not withdrawn at all from the machine till the process is completed, not only is much time saved, but the leaf will give out a more brisk and malty liquor on infusion. An Exhaust Fan, of very simple construction, provided at the top, to draw off the moist air, which is followed up by a continuous supply of pure hot air from the multitubular air heater below.

Wood, grass, coal or other fuel may be used. The drying appliances in this case, it will be observed, are not automatic. An exhaust fan carries up the hot air, but a series of cranks must be adjusted, so as to give the tea layers in succession the benefit of the heat. With reference to the venetian principle, we may mention that Mr. Fleming of Messrs. John Walker & Co., Kandy, who was our fellow-traveller from Wstawala downwards, pressed on us, as he had done on others, the adaptability of the principle of the well-known venetian to the process of tea withering, the laths being, of course, cut to the proper width. The appliances at present in use, next to the surfaces of floors and lofts, are trays of Hessian or other cloth, narrow and wooden-framed. A series of knots on a rope hanging from above, sustains a considerable number of these trays superimposed. When the leaf spread on these trays is sufficiently withered, it is either gathered up, or the rope is withdrawn and all the trays fall from the horizontal to the perpendicular, depositing their loads in long rows on the floor. Mr. Fleming pointed out, that, if venetian platforms were adopted, they could be of any length desired. When the leaf spread on them was withered, a spring at one end could be let go, and then the venetian would be retracted to the opposite end, folding from above downwards over a roller and depositing its charge of leaf in a heap on the floor or in a box below. We cannot doubt that our ingenious and enterprising planters will give practical effect to this idea, and we should be glad to be able to report the result. And while on the topic of new ideas, we may, say that, instead of teak wood (liable to wear) for the table and iron for the top of his roller, Mr. Jackson is meditating the employment of marble (in sections) for the former and granite (in mass) for the latter. Of many inventions under the sun there is thus no end, and those who devote ingenuity and skill, industry and perseverance to providing substitutes for human toil and additions to the comfort, well-being, power and prosperity of their fellow-men are justly entitled to due reward, which we trust Mr. Jackson will receive for his unremitting and useful efforts to facilitate the operations of that industry to which humanity owes its most innocent, beneficial and cheering beverage.

Visitors to Carolina Factory cannot help noticing, (any more than they can help observing the rush of the waterfall, unhappily hidden from the railway traveller.) the fact that tea is here being cultivated on a typical specimen of the numerous estates on which coffee has been grown for a third of a century or so and which the tropic sun and rains have deprived of humus and top surface. It is clear that on such places tea will absolutely require manuring, and the proprietors of Carolina are evidently alive to the fact. A portion to which cattle manure has been applied has responded wonderfully, so that we were not surprised to hear of a 50-acre grass-field and increased cattle establishments being meditated. Coconut peonac in addition to cattle manure, good fertilizers, applied to good jat (indigenous) tea, growing on good soil

and in a good tea climate, have resulted in a luxuriant shew of heavy flushing bushes on Kadawella, than which Mr. Jackson said he had seen none finer in Assam. Nothing can be better than Assam indigenous in a suitable climate, but we suspect its zone in Ceylon ends nearer 3,000 than 5,000 feet. It is curious how a thing will come to the front all at once. Until recently and in our own experience we had never heard of moss on the stems of tea bushes, and we have searched Money's Essay and the Tea Cyclopaedia in vain for any notice of moss, lichen or fungus on the bark. But one of the first things we heard on reaching Carolina was that Mr. Dalgarno, whose experience had been obtained in Darjeeling, had uttered the warning: "In a few years the growth of moss on the tea bushes will lessen flush in Ceylon," while Mr. Jackson in answer to our questioning told us that moss on tea stems is well known in Assam. Such being the case, it is surely curious that in books and essays on tea, nothing or so little should have been said of a form of "blight," which certainly requires the attention of planters. The growth of the moss is probably promoted by the dense shade produced by wide surfaces of flush-yielding wood and foliage, and pruning in the dry season, December and January, was mentioned to us as a remedy. Until better advised, we shall continue to believe in the necessity of occasional rubbing of badly affected stems and dusting with lime. But the prominent impression created by a visit to Kadawella is that of truly luxuriant and magnificent tea, while we learned that, if a recently purchased block of forest is cleared and planted, the total area under tea belonging to the owners of the great Factory will be 2,000 acres.

BANANA PLANTING AND TRADE IN WEST INDIES.

Jamaica, June 17th, 1884.

Four people supervising the work of about 300 or 400 coolies and coolies seemed too absurd, and particularly unpleasant for me who formerly accustomed to 400 and 500 people without anyone to dictate to me as to the *modus operandi*. Bananas, forsooth! People here make as much fuss about them as though they were coffee, or tea, or cinchona. Why, in Ceylon, we gave the bananas to the coolies, and they grew at their "own sweet will" better than "cultivated." The present rush into bananas has resulted in a fall in price: fancy, a fall of 50 per cent from 2s to 1s 6d and is local prices paid at the wharf for eight-hand bunches only. My first "banana" savings were expended in buying a snuff-coloured suit and half-a-dozen new shirts, a pair of elastic-sided boots and pair of slippers, oh, and a brown felt hat to match the clothes: fancy my new outfit coming out of "banana savings." I was as proud of my banana suit as old Goldsmith when he bought a new suit out of his advances for the MS. of the "Vicar of Wakefield." Bananas have done more for some people: one man bought a "carriage and pair" and another bought two old sugar estates, all out of the profits of a good season. I feel sorry to leave Port Antonio. Captain Baker said I might please myself, go or stay at Bog or Bound Brook, but I told him, there were too many people overlooking the works there and that I wanted to be "boss" myself. "All right," said Captain Baker, "go and look after the 'heathen Chinee.'" He kindly gave me a free passage in the "Flying Cloud" schooner just getting under weigh and bound for Annatto Bay. One last long gaze at pretty little Port Antonio and the "Flying Cloud" was making tracks along the east coast of Jamaica. The sun set and moon rose, and the captain and his mate entered into an animating conversation on nautical subjects in which I took part.

"Yes, sir," said the Captain, "as I just remarked to my mate, 'Starboard your helm.'" "Starboard it is, sir." — "Damn that boy! he is asleep on his look-out again! Ho! 'a' 'useless creature for true.'" Whack, whack, with

a rope's end. "Who dat knock me? me not asleep, captain, me nebbber sleep on my look-out." By-and-by the captain went to sleep, and the mate steered the "Flying Cloud." I had some hard boiled eggs, cold fish and bread for supper and smoked a cigar, the "Flying Cloud" rolled very much and rocked in the cradle of the deep I rolled myself up in the main sail and was soon in the arms of Morpheus. Anchored in Annatto Bay at 2 a.m. When the captain awoke he hammered his boy as most captains of small crafts do. "I shall be the death of that boy yet! Fancy his not turning out when the watch is called and me and my mate got to shorten sail. Never heard of such a thing ever since I've been at sea, my king! Boys are men in these days. Now be quick and make the coffee or look out for squalls." It did rain during the night and blow hard, and I went below, but the rats and cockroaches ran over my face and the fleas in the banana trash prevented sleep down below, therefore anyone taking passage in a Jamaica drogher should stick to the deck, if weather permits, for there are too many cabin passengers in the form of natural history specimens. A night in a Jamaica fruit boat is not a thing one would care to experience twice, if it could be helped. Anyhow the writer cannot count the number of times he has spent miserable nights at sea in all sorts of crafts.

I landed in Annatto Bay on the 30th July 1884. Met Mr. Broughton, drove out with him to Iter Boreale estate, and had a nice breakfast with Mr. Manahan, the manager of the property. The Chinese had arrived, but done no work from date of arrival; they look a good-looking gang and may turn out well. The worst of it is, we have got to weigh out rations to them, and they are always complaining of quantity and quality of the provisions when they are all of the very best obtainable, much better than we use ourselves sometimes. It is hard lines for me after trudging up and down the hill and working all day in the sun to be obliged to weigh out their meat, rice, coco, sugar, salt-fish, &c., &c., until dark, our dinner getting spoiled, and pitch dark before time to bathe or wash and dress for dinner. The worst of it is, the Chinese are not likely to improve, their motto being to get as much out of the estate and their employers as they can for the least labour. Iter Boreale estate is a sugar plantation with extensive fields of cane, sugar-house, distillery, &c., &c. Mr. Manahan and two book-keepers are in charge of the property. Mr. Broughton visits once a fortnight or so for a Mrs. Hossack, resident in England. The estate gives about 180 hogheads of sugar and eighty or ninety puncheons of rum per annum. It is situated on the sea coast between Annatto Bay and Port Stewart. Banana cultivation is carried on up the hill near "Prospect," a property occupied by the Westmoreland family, also owners of sugar estates, "Gibraltar" and others.

There are several produce brokers in Annatto Bay who send out their waggons to the estates and buy up the bananas by the hundred. The price is at present low, about 4s per 100 bunches. Mr. Benbow is agent for Messrs. Baker & Co. of Port Antonio; and, when the "Flying Cloud" landed me in the Bay, Mr. Benbow kindly took charge of my baggage and sent it up to me by the Iter Boreale cart. Mr. Benbow had no bananas ready for the "Flying Cloud" and telegraphed to Baker for orders. She was sent to "Port Maria" higher up the coast for a load of coconuts. Mr. Benbow and his brother are descendants of the brave Admiral Benbow, who fought the French off Port Royal and had both his legs shot off before sinking the French frigate Admiral Benbow was buried in Kingston, Jamaica.

Store-keeping appears to pay in Annatto Bay, to judge from the number of stores and shops. Wednesdays and Saturdays are the market days. There is a market for the sale of fresh beef twice a week, a post office, telegraph office, court-house and a church of the Church of England. A little out of the Bay there are churches of other denominations including a Baptist and Wesleyan. The roads are fairly good and bridged over for somewhat distance from town, and all along the public road is a succession of fruit gardens, coconut palms bearing well, breadfruit, oranges, limes, &c.

Iter Boreale is only two-and-a-half miles from the town

and convenient for obtaining provisions fresh from market. Sugar growing has received a severe check from the fall in prices, and Iter Boreale estate is to be abandoned as the cane is removed and bananas planted instead. It is a great pity, as the sugar-house, machinery and distillery, boiling appliances, &c., are all in good working order. It is an animating sight to see the sturdy Jamaica cattle dragging the wains of sugarcane into the yard where it is conveyed to the crusher and converted into barrels of sugar. All this bustle and life will be soon still, the doors of the mills closed, the people marching off to the Isthmus of Panama and everything brought to a dead standstill. The main cause of all this trouble is similar to the crisis in coffee and cacao and perhaps tea in its turn, "over-production," the bounty on beetroot and the increased quantity last year by 200,000 tons.

Stock-farming and pen-keeping in Jamaica is a fairly good living, especially if a large pen-keeper gets a military contract to supply the troops with beef, perhaps half-a-dozen beasts killed weekly. In the country parts of Jamaica the breed of horses is improved, and a great number of mules are raised.

With a good rainfall of about 120 inches this part of Jamaica is well-watered and grazing grounds or pasture lands very rich. There are no leeches to bother sheep and cattle, and no snakes to speak of,—the writer has not seen a Jamaica snake yet. Mongoose are as common as rats and may be seen crossing one's path at all hours of the day and play old gooseberry in fowl-houses, amongst the chickens at night-time.

The Chinese having given a lot of trouble to the Government and the planters, and their striking work on Iter Boreale for six weeks made me lose money, being paid only for the days they turned out to work at 6s per day. My mess money was paid by the estate during the strike, in consideration of having the trouble of serving out their daily rations. We could not stop their food-supply because the Government paper were not signed, and each Chinaman cost £17 a head passage money from Hongkong. They ask a dollar a day, and my gang are afraid to work because the Chinese on the other estates have struck work and threaten to beat those inclined to go to work.

H. COTTAM.

SANDAKAN, NORTH BORNEO: EXTRACTS FROM RESIDENT PRYER'S REPORT ON THE YEAR 1884.

(From the *British North Borneo Herald*, May 1st.)

"Gutta percha and Indian rubber show an increase of \$13,000 over last year, the Dyaks are the principal collectors of these products, they report that up the Kina Batangan and Labuk rivers there is very little more left now, and they have mostly left those rivers and gone up the Segama for which river during the quarter this office granted passes to 87 people. Rattans on the Kina Batangan also have been mostly cleared off for the present, those at all events near the river's banks; there are however plenty, but a few hundred yards in, our principal supplies now are coming from the Sugut and Labuk. Bees-wax and camphor show an increase; these products are more particularly collected by our own villagers and not by aliens, as most of our other forest produce to a great extent is, and the increase in their value is therefore a very good sign. Sea produce shows a considerable increase in the quantity of seed pearls exported, but these are chiefly understood to be some that have been for a considerable length of time in the country, though some have been collected principally at the mouth of the Morap, a few have come from Labuk Bay also, but scarcely any from Sandakan Bay; both these latter localities seem never to have properly recovered from the destruction of seed pearl oysters caused by very heavy rain in 1873.

"Timber this year first figures to any extent, the value put down is just the bare amount spent on its collection and gives but a small idea of its true value in an ordinary market, there is every appearance of timber figuring more and more largely in our export sheet in the future as it gets better known in the Australian, China and Singapore markets."

We may add now that it may almost be looked upon as a certainty that there will be a great expansion of the

timber trade during the present year. Mr. de Lissa's first shipment of scrayah and other woods to Melbourne per S.S. "Woosung" proved a decided success and it is reported that the North Borneo Trading Company have taken over his Sigaliud estate for a sum of over £6,000, principally for the sake of the valuable timbers it contains. Captain Beeston, as agent for the North Borneo Trading Syndicate of Melbourne, has provisionally accepted terms offered by the Government for the right of cutting timber over about 11,000 acres of land. A summary of these terms will be found in our present issue.

REPORT ON THE GERMAN BORNEO COMPANY'S ESTATE, BANQUEY ISLAND.

The Estate.—About 12 acres of land have been cleared and while I was there the sound of falling trees was going on all day long. The jungle is very heavy, I have never seen finer timber anywhere. The coolies' sheds are all up and Mr. Lindt has bought a Dusun house, and finished it for himself.

Soil.—I can only say the same as Mr. Parry (formerly a Ceylon coffee planter) namely that I never saw such soil before. In the wells for 6 feet from the surface there is a rich chocolate soil, below this about 5 feet of clay mixed with sand, and under this if near a water course gravel, if not old mangrove swamp, which plainly shows that the 11 to 12 feet above is all alluvial deposit and proves Banquey to be far older than any of the mainland near, except Silimpuden and Marasing in Marudu Bay. I asked Mr. Lindt how long it was necessary to leave land that had been planted with Tobacco before it would grow it again, he replied—"That depends, if the land is very good I could return to it in five years." "This land" pointing to what he is now clearing "I can return to in five years."

General.—Mr. Lindt appears to be getting on well, he has certainly got through much work, and he has had a good deal to contend with, owing to this having found it desirable to move from Pangkalau. Having also lost his "tongkong" he has had to carry all his goods and material overland. Mr. Lindt means to plant fifty fields this year, and he talks quite confidently of the number of fields he is going to clear at the end of this year for next year's crop. Mr. Parry thinks he will be able to get from 5,000 to 7,000 acres in one block near Limbak and the S. E. corner of the block will be from a mile and a half to two miles from the settlement at Timbang Dian. The remaining 3,000 to 5,000 acres taken up by the Company will be taken near the head of the Spuruk river which runs into the harbour. Some of the Chinese coolies complained of the darkness of the goods at the estate shop, therefore the sooner the road to Timbang Dian is made the better, as then the coolies will be able to come and buy there. To make a cart road to where Mr. Lindt is now planting would cost about \$1,500, but to make a road to the corner of the block only would cost about \$600. To make a jungle road all the way would cost about \$300, to the corner of the block only about \$120. I may also mention that the head mandor and the Chinese coolies (old tobacco planters from Deli) are quite satisfied with the soil and as they are all working on contract and depend on the goodness of the crop for their wages, I think this a very good sign for Banquey.

As I expected the centre of the island appears flat. Mr. Parry who I may mention is surveying the German Borneo Company's Land, said he thought he could get one block of 30,000 acres in the middle of the island, 20,000 acres of which would be flat and the other 10,000 flat enough for Tobacco. This block would be entered from the Spuruk river which runs into the Harbour. Probably Banquey contains about 40,000 acres of land suitable for tobacco but we shall be in a better position to say how much there really is when Mr. Parry has finished his survey. From the top of the "Peak" Mr. Parry pointed to a valley below us and said. "If it was not for leaf disease I should say, there is my idea of a site for a coffee plantation."

NORTH BORNEO.

FOREIGN IMPORTS.—Into British North Borneo during the year, 1884.—Total value, \$485,895. Exports from

British North Borneo during the year, 1884:—Camphor, 8,575; dammar, 4,120; gutta-percha, 34,697; Indian rubber, 22,924; rattans, 31,575; sago, 11,125; timber, 9,756; tobacco, 2,112; trepang, 8,020. Grand total \$267,240.

We learn that the following terms for timber cutting have been provisionally accepted by the agent of the North Borneo Trading Syndicate, Captain Beeston, subject to confirmation by his directors.—The Syndicate to have the right for three years of cutting and exporting timber only, from 11,000 acres of Government land situated in large blocks on the Tolibas and Sagayan rivers, in the Unsang Peninsula, in the Benkoka river, and in Marudu Bay; paying the Government for this privilege a quit rent of 25 cents an acre in advance per annum and an export royalty of \$1 per ton of 40 cubic feet. The rights of the natives in the matter of timber for domestic purposes are conserved.

GOLD IN NORTH BORNEO.—The following letter addressed to the Government by Captain Beeston regarding gold in North Borneo, cannot fail to be of interest at the present moment, when the question of gold is exciting so much interest. Captain Beeston, whose opinion is valuable owing to his possessing practical knowledge on the subject, appears to be very favorably impressed with the metalliferous characteristics of the northern and Eastern portion of the Territory. We may state that since the date of his letter information has been received from London to the effect that rock sent by Resident Davies from the Sugut-Paitan district yielded gold on analysis. It would seem that gold exists in an extensive district comprising the North and East of North Borneo from Marudu Bay to Silam.

Sir,—As promised I have the honor herewith to forward you such information regarding gold in North Borneo as I procured during my visit to the country in 1883.

While the whole of the East Coast from Silam to the Segama river is from its formation undoubtedly auriferous I actually got gold in the following places:—

Silam; the Segama River; Lahadata, in Darvel Bay; Banguey Island.

SILAM.—At Silam the gold was found in a small stream or creek that runs past the experimental gardens. The wash is principally quartz gravel mixed with ironstone cubes and stanniferous sand. The hill above the creek bordering the gardens also contains quartz and I shall not be surprised if a reef were found in the locality carrying gold.

SEGAMA RIVER.—On the Segama River the country in which I found gold is micaceous granite and sandstone with serpentine outcropping not far off. I found it in a small creek on the left bank of the river not far from a high conical hill at the foot of which there is a large outcrop of serpentine. I am pretty certain that the whole of the country up this river is auriferous and it greatly resembles that of the Palmer River country in North Queensland. Besides the gold I obtained a small quantity of stream tin in this river, and I am also of opinion that Uinabar exists in large quantities as I found one or two pieces in the creeks, but they had evidently "travelled" some distance as they were much water worn.

LAHADATA.—The Lahadata country in Darvel Bay resembles that at Silam with the exception that slate outcrops slightly here and there. The wash in the creek exactly resembles that at Silam, and the country abounds in quartz. This place is well worth thoroughly prospecting, as the country is easy to get over, and should payable gold be found, it could be very easily worked.

BANGUEY.—On Banguey island the gold I obtained was on the right bank of the Pangkalan river about two miles from its mouth. I like the look of the country here very much but had no time to prospect it properly. In addition to the gold here I found asbestos in the creek. As Banguey is now inhabited and work being carried on there, it is quite possible an important discovery might be made at any time. Mr. G. L. Davies, Resident of the West Coast informed me that he had tried the river with no result and I gave him on the chart the exact locality where I obtained the gold.

In addition to the above places I should consider the country in the neighbourhood of the Selimpadan River running into Marudu Bay would be well worth prospecting, as from the wash and the look of the beaches it appears very likely to contain minerals of any sort.

In conclusion I would record my opinion that a systematic prospecting of the East Coast would not fail to bring about valuable results.—I am, Sir, your obedient servant,
R. D. BEESTON.

The Hon'ble W. H. Treacher.

THE NO. 1 SIROCCO: MR. C. S. ARMSTRONG'S AND MR. C. A. HAY'S EXPERIMENTS DISCUSSED BY THE PATENTEES, AND THE DIFFERENCE IN OUTURNS EXPLAINED: INTERESTING INFORMATION.

Messrs. Davidson & Co. write as follows:—"We have received the copies of the 'Times' and *Observer* with both Mr. Armstrong's and Mr. Hay's reports on working the No. 1 Siroccos. We notice that Mr. Hay cannot understand how Mr. Armstrong manages to get 45 to 48 lb. of dried tea from a No. 1 Sirocco, against his own 30½ lb., but we can see that their work is about equal.

"Mr. Armstrong puts 13 trays of 9 lb. charges equal to 117 lb. leaf, into his Sirocco in the hour and gets ... 48 diy tea,

which gives an evaporation of 69 lb. water or moisture in the hour.

"Mr. Hay gets 10 trays in with 9 lb. on each equal to 90 lb. and has, an outturn of 30½ lb. dried tea,

which indicates an evaporation of... 59½ lb. of water in the hour, and you will admit that it is not far wide of Mr. Armstrong's results. It is Mr. Davidson's experience of some estates in India, growing indigenous leaf on low flat soil that 2 to 2½ lb. sap has to be evaporated to give 1 lb. of dried tea, while others working hard China leaf on sloping hilly and dry soil nearly get a lb. of dried leaf to every lb. sap evaporated. In like manner Mr. Armstrong may have a naturally less amount of sap in his roll, or may wither it a little better than Mr. Hay's, and in this way may have a larger outturn per hour of dried leaf. Of course you will readily see that it is the amount of moisture driven off that regulates the outturn, and if there was hardly any moisture to evaporate there would be a very fire rate outturn. The best evaporation ever done by us with a No. 1 was 80 lb. of water per hour against Mr. Armstrong's 69 lb., but of course it is to be expected we would get fullest possible results with our experience and European workmen. With a No. 3 L shape we have got 180 to 195 lb. and once 200 lb. (this is a remarkable advance on the No. 1), and with our new T-shaped Sirocco 216 to 220 lb. per hour. The results obtained by Messrs. Hay and Armstrong are very fair indeed for practical working with coolies. Of course when our men do a day's experimenting they have a certain advantage over ordinary labourers at a tea garden, for we work carefully and with all the knowledge of a long experience, and could hardly expect an estate to get quite our results, but they should get within a few lb. (6 or 10) of what we get."

Note by W. H. Davies & Co.—As Mr. T. J. Grigg of Theberton also sent to the papers the result of his working the Sirocco No. 1, we give below the three experiments for comparison:—

C. S. ARMSTRONG.	C. A. HAY.	T. J. GRIGG.
13 trays of 9 lb. each,	10 trays of 9 lb. each,	11 trays of 7 lb. each.
117 lb. leaf	90 lb. leaf	77 lb. leaf
48 lb. made tea	30½ lb. made tea	34 lb. made tea
69 lb. water evaporated.	59½ lb. water evaporated.	45 lb. water evaporated.

Note by Editor C. O.—It would thus appear that the average proportion of moisture in rolled tea which has to be dissipated by driers, ranges from 53 to 66 per cent. The latter figure is so much higher than the other two, that we believe we may safely take it for granted that the general average is as nearly as possible 60 per cent, somewhat more than one-half of the roll. Taking the fact that 4 lb. of green flush yield 1 lb. of dry tea, we should like now to know the proportion of moisture dissipated in withering? Apparently only 15 per cent?

INDIAN, CEYLON, AND JAVA TEAS.

SIR,—I have noticed from time to time in your issues remarks about China tea, and, as these were evidently written by some one who knows the subject thoroughly, I am in hopes you will allow me to give you some information about Indian, Ceylon, and Java teas, feeling assured it will be of equal interest to your readers. I am indebted for most of the information I give you below to Messrs. George White and Co., the well known tea-brokers of this city. There is very little doubt in the minds of importers like myself that if the Chinese levy an extra local tax (lekin tax)—perfectly distinct, it must be understood, from the export duty charged by the Imperial Chinese Government—on all teas exported by foreigners from China, the benefit will be great to those interested in Indian, Ceylon, and Java teas in the coming tea season.

Ceylon and Java are expected to produce about four and a half millions each during the coming season. Planters in the former island appear determined not to be left behind in the race, which they have been carrying on so well for the past two years, while the produce of the latter has shown a great improvement, some of the teas having full rich flavour like hill-grown Indians or Ceylons.

"Regarding Indian teas," to quote my authority, "prospects for the coming season seem favourable, though a higher average price than last year's should not be depended on with an increased yield. The stimulus given to the market by the duty scare may cause a reaction after the budget is announced, whether an alteration takes place or not. If an addition is made it will tend to increase the demand for teas for price, and if no change is made things will probably settle down as before. Fine to finest will in all probability be much wanted until September or October, and high prices may be obtained for them until buyers have replenished their stocks. During the past season a few fine, pungent, lightly fermented teas have sold well, partly owing to their scarcity, but the demand for these is rather limited. It has now been pretty clearly shown that, with a few exceptions, a large quantity does not pay so well as a smaller amount of better quality. The temptation to swell their out-turn per acre should not be yielded to by managers, for, although the figures may look well on paper as regards the total of tea manufactured, the pecuniary result often proves anything but satisfactory. The different stages of manufacture have of late engaged the attention of planters in India and Ceylon, and a great deal of correspondence has been carried on with regard to it, both privately and in the different journals connected with tea. Some advocate fully withered leaf, as it produces teas with fine rich flavour, which the same leaf less withered does not possess. Rolling by machinery is almost general, though owing to the leaf being sometimes submitted to too much pressure the juice is partly lost. Fermentation, one of the most important processes, does not appear to be thoroughly understood by the majority of planters, and is a subject which would well repay scientific investigation. The cause of the poorness of a larger portion of this season's crop has

been shifted from 'climatic influence' on to the shoulders of the drying-machines. As, however, it is a well-known fact that good and bad teas have been produced by the same machines, and even from the same gardens, it would appear that sufficient experience in the use of them has hardly yet been attained. Firing at a very high temperature and briskly is advocated by a few, but it is generally considered that tea fired at a moderate heat is usually the best. To obtain a good name for a garden should be one of the chief aims, as many buyers will give pence per pound more for a mark which they have become used to, and of which they can depend upon obtaining a regular supply." Then again: "The total estimated crop for the season 1884-85 amounted to 68,000,000 lb., from which deduct say one-and-a-half million for local consumption, and two-and-a-half millions for shipment to the colonies, America, and the Continent, which will leave about sixty-four millions available for Great Britain."

Let me add that, if Ceylon growers of tea wish to maintain for their teas the high prices that have been ruling in the London market, they must keep a standard quality, otherwise their teas will fall to the level of the low prices ruling for all China teas and for large quantities of Indian and Java sorts.

Apologizing for the length of my letter, but trusting its subject may be of sufficient interest to excuse the trespass on your valuable space, I am, your obedient servant,

ASRAM.

London: April 1885.

—Whitehall Review.

NOTES ON TEA.

By PERCY SWINBURNE, late of Sylhet and Cachar.

The following "notes" are the outcome of many years practical experience in India in the cultivation and manufacture of tea, and were made from time to time with the idea of placing on record the results of actual observation on a subject in which hitherto the planter's only guide has been his own experience. Of course the experience however varied of no individual planter would be anything like adequate to the purpose of giving a full history of so vast a subject, and it is with the hope of obtaining the opinions of others that I venture to publish the following. Although the strides made during the last ten years in the scientific cultivation of tea have been enormous, yet it may still be considered in its infancy, nearly every planter having some special opinion of his own differing from others on even the most elementary and vital subjects, and it can only be by massing together the observations of a number of men, that proper deductions can be drawn which may act as a serviceable and reliable guide to planters present and to come. Year by year, the extension of the area of cultivation, the introduction of machinery, and the increased competition render the economic, or what is the same thing, the scientific cultivation of India tea all the more necessary, and the only road to success will be the carefully studying and taking advantage of the observation of others. Some of my deductions will doubtless be canvassed. Indeed, I do not profess to speak *ex cathedra* on any subject which may be open to question, but only to claim attention to the facts to which I have noted down in the hope of obtaining the mere valuable experience of others, as in no other way can a proper knowledge of the subject be advanced. These observations are necessary to account for the form in which the notes are written, and if other planters can be induced to record their observations, the results in combination would be invaluable. I may add that I have thought it advisable to "begin with the beginning."

Choice of Land.—An experienced and careful planter will probably be successful on almost any site of land he may choose, yet the measure of his success will depend in the first place on the quality and lay of his land. If possible the services of a surveyor should be secured, and the proposed land should be demarcated, and diagonal furrows cut in a perfectly straight line through the jungle. The sur-

veyor should also mark out the ground, showing which part would be most suitable for tea cultivation, cattle ground, and timber reserve—giving the area of each. In order properly to examine a piece of jungle land, it is necessary to cut paths or farries through the dense undergrowth; and if this work is not carefully supervised, the natives invariably follow any old tracks which may happen to run in the required direction. If there are no tracks they will choose out the lightest jungle, and as in land consisting of chains of hills and valleys, the lightest jungle as well as the old jungle paths generally run along the top of the hill ranges, a false notion will be given to any one passing along a farrie thus cut of the area of the land; and it continually happens that gardens are opened up on undesirable hill land under the impression that the site chosen is a large flat with a few low hills. On elevations of 2,000 feet or higher, the forest is generally old and the ground light, and in these places the difficulty of seeing the land would not be so great.

Soils.—Nearly all soils appear suitable for tea, stiff clay, well drained and cultivated being well adapted for it, as well as the lightest sandy soils on which bamboo jungle grows. Light sandy soil heavily manured appears to give the largest crop, but it is impracticable to manure a large area. Bamboo land is enriched by the large quantity of leaves which fall every year, and also by the network of fine roots which spread for some distance near the surface of the ground. These roots thoroughly disintegrate the soil and serve to manure on the death of the tree. In some places the soil contain large quantities of slate-like stones, or is full of "Kunker," or is hard and gravelly. These places should be avoided, but a mixture of kunker and soil a few feet below the surface, and where the kunker only occasionally appears on the surface, is desirable on account of the natural drainage it affords, and also on account of some property in kunker soil, probably some mineral which is much appreciated by the tea plant. There are some estates below the hills containing some stretches of fine tea growing among large stones which are so thick as to prevent any cultivation except an occasional picking and forking between the stones, but these are exceptions to the general rule. When land prospecting, holes should be dug at short intervals two feet deep, and the soil carefully examined. At every four or five inch depth, the hole should be cleaned out, and the soil placed in a heap on one side. In this way there would be six heaps, showing the variation of the soil at various depths. The best soil for the tea in hill or plateau land is generally black or dark leaf-mould near the surface, with a rich yellow red subsoil. If the soil on examination prove satisfactory, the prospector may rest assured as to its quality—of bamboo, virgin forest, or very luxuriant sun-grass, or if in the case of low land, ekur or huldie is growing on it. But the soil still better suited for tea, or indeed for any other crop which requires much manure as tobacco or sugar is to be found in narrow strips of low swampy land between tea-hills. The heavy rains rush down the teelchs, carrying with them a small quantity of "wash," and, in the course of centuries, hollows which were below the flood level of the country are raised above it. In these places tall grasses grow—ekur, null, huldio, cane, and cralce grass. Large quantities rot yearly, and new shoots springing up, the result is that the surface soil becomes a mass of decayed vegetation to a depth sometimes of thirty six feet or even more. In the higher parts where the swamp rises, trees grow with a dense undergrowth. Sometimes this "tal" or chel land is coated with a deep surface soil of sand, and in this case it is not so valuable as sand, or sandy soil does not contain much plant food unless under exceptional circumstances. At other times it consists of blue clay, in which case if heavily drained and thoroughly cultivated, the clay turns into soil full of nourishment. If the clay is dark coloured and full of decaying vegetable matter, the result of cultivation is still more satisfactory, and the value of the soil increases with the amount of decayed vegetation it contains. Sometimes the soil on teelch or hill land although containing a large proportion of sand is good for tea, and this is specially the case when it has previously grown bamboo. The root

of the tea plant finds its way readily through the light surface soil, and penetrates deep down into the subsoil which is generally more consistent. The rain also percolates readily through the sandy surface, and the plant is enabled to absorb some of the mineral matter of the soil below. In some parts of Assam stretches of low lying land are covered with little mounds three to four feet high called kooka. It is supposed that the mounds are thrown up by worms. This kind of land is generally drainable, and well suited for tea. Small patches are sometimes seen in Sylhet and Caubar, where the hills fall away into the dhan khets.

Labour.—Having found the proper site, the next great question is how to get the very best result at the least possible cost. It is of course impossible to make the cheapest and also the best garden at the same time, and it is still a matter of dispute as to how far it is advisable to increase expenditure to improve results, and what ratio one should bear to the other. Putting the average yield of the bearing tea at 34 maunds, and the working expenditure at 130s to 150s per acre, and the average price of the tea at 45s per maund, the annual produce of the acre would realize R157-8 at an annual cost of 130s to 150s, or R17-8 yearly profit. The average price and yield have perhaps been fixed a little too low, but the average profit is probably not more than 5 to 6 per cent, while the cost of opening out the gardens as well as working them is yearly decreasing and though the yield is increasing, the market is falling in the same ratio—if not faster. Now, as the manufacture of tea, is a delicate operation, and the quality of a crop may easily deteriorate to the extent of 2 annas per lb., it is evident that a certainty of profit can only be secured on gardens which give a yield considerably above the average, while their working expenses are comparatively low. It costs proportionately far less to turn out six maunds an acre off a fine garden, than three maunds off a poor one. Planters now understand that a 200 acre garden yielding 1,200 maunds is much more valuable than a 100 acre yielding the same.

In three estates equally well worked, and in which the same quantity of leaf was plucked, and the same quantity of tea produced, the result might be roughly estimated as follows:—

Estate.	Yield per Acre Maunds.	Expenditure there. Per Acre.	Value of Produce Per maund.	Profit Per Acre.	Capital Per Acre.	Percentage of Profit.
		R.	R.	R.	R.	Per cent.
A	9	250	45	155	700	22
B	6	190	45	80	500	16
C	3	120	45	5*	200	24*

A estate with a fall of 2 annas per lb. or realizing 35 rs. per maund for its tea, would still show 9 per cent profit, while C estate under the same circumstances would show a loss of 7½ per cent, consequently an investor with 700 rs. (per acre) would be in a better position with an acre of A estate than with 10 acres of C estate.

These figures are given to show that it is more important to make a good garden than a cheap one, and if the difficulties are not positively insurmountable, it is better to choose the soil which gives a high yield even if it should be disadvantageously situated and costly to operate upon.—*Planters' Gazette.*

SOME EXPERIMENTS OF CONSIDERABLE IMPORTANCE, so far as irrigation is concerned, were made during last year at the agricultural farm at Sailapet, in Madras, with the view of ascertaining what quantity of water produced the best returns from soils such as those in the farm. The experiments tended to show that the smaller quantities of water representing a rainfall of 1, 2, and 3 inches respectively produced the best return, and that a much smaller quantity of water than is commonly used by rayats would suffice to produce very good crops. No comparison, however, is given of the results of these experiments with the results of irrigation on any land of similar quality by ordinary rayats, or of the quality of water usually made use of by the rayats.—*Calcutta Englishman.*

* The profit per acre should be R15. Surely equal to 7½ per cwt.—Ed.

* Kunker is an impure limestone.—Ed.

Correspondence.

To the Editor of the "Ceylon Observer."

THE CULTIVATION AND PREPARATION OF JUTE.

Tavoy, British Burma, 16th April 1885.

DEAR SIR,—I see by the *Observer* that a Queensland man is in quest of instructions for jute cultivation: so here goes.

INSTRUCTIONS FOR JUTE CULTIVATION.—*Soil and Climate.*—Jute thrives best on loamy soil, rich clay and sand, or sand combined with alluvial deposit, and on land which is neither inundated nor dry. A clayey soil and a ferruginous soil are not unfavourable to the growth of the plant. But laterite and gravelly soil are unsuitable. A hot, damp atmosphere is most favourable to the growth of the plant. Alternate rain and sunshine are most congenial. The plant suffers less injury from excess of rainfall than from the entire want of it. Too much rain at the beginning of the season and early floods, however, are injurious and destructive to the young plants. Drought stunts their growth and very often even destroys them, if not sufficiently developed. But heavy rains have no such destructive effect on the plants, so long as they do not drown the plants and there is sufficient sunshine to afford the warmth necessary to strengthen the plant so that it will not fall to the ground.

Modes of Cultivation.—The preparation of the soil should be commenced early in low lands where there is considerable risk of water rising very high early, but deferred to a later period in high lands when no such apprehension is entertained. Friable, sandy soils are ploughed as early as in March, but when there is much clay and the soil is hard, tillage is deferred till after the first showers of rain in April. The number of ploughings required is dependent entirely on the nature of the soil: a clayey, hard soil requires a greater number of ploughings than a light sandy or loamy soil. Under any circumstances the land should be so ploughed as to render the soil finely pulverulent and to expose every part of it repeatedly to the sun. The oftener and the more thoroughly the land is ploughed the larger is the yield. The seeds should be sown about the middle of May as the first showers have fallen; they are sown broadcast on a clear, sunny day and harrowed over twice, that is, a double stroke of the harrow. Except in low situations, seeds are never sown until after a shower of rain to help germination. On germination, which takes place within four to eight days after sowing, the fields are again harrowed, and all the weeds removed. Overcrowding should be avoided. It checks the full development of the plant. About 12 lb. (twelve pounds) of seed should be sown to the acre "Imperial." The crop should be thinned wherever it becomes too thick, by the removal of the more backward plants. Ordinarily the space left between the plants is six inches, and the thinning is carried to that extent, but sometimes the plants are left wider apart: this must be decided by the quality of your land.

Cutting.—The plant is cut generally near the root, unless the lower end is overrun with suckers. The time considered best for cutting is when the plant is in flower and just before the appearance of the pods. The fibre of the plants then cut is of superior quality. The fibre of the plants which have not flowered is weak, while the fibre from plants in seed is harsh and wanting in gloss, though it is heavier and stronger than the fibre of the plants cut in flower. Whenever practicable the plant should be cut either when flowering or when the flowering is just completed.

Preparation of Fibre.—The stalks when cut should be made up in bundles according to size—long, middling or short—and allowed to remain few days in the field and then thrown into water and there steeped. In steeping the stalks are covered with a layer of refuse, tops of the jute plant or other jungle plants, or with clods of earth, or cording, trunks of plantain trees, or with straw smeared with mud in order partly to protect the upper part of the bundles from the action of the sun and partly to keep the stalks sufficiently below the surface of the water, and to hasten the process of rotting. There are two ways: the bundles are either first sunk by the root end, which is harder, leaving the upper end exposed above the water, and then after 10 or 12 days the upper end is pressed down to the same level with the root ends, so that the whole length of the stalks may rot uniformly, or the bundles are turned over while steeping. The duration of steeping is regulated partly by the condition of the plant at the reaping time, that is, whether it was in flower or in seed. Much also depends upon the temperature of water while the steeping lasts. Understeeping has the effect of leaving runners and pieces of bark adhering to the fibre, causing it to separate unequally and stopping chiefly at the small knots which appear on the stem, and thus causing the black specks so often seen in jute. On the other hand, oversteeping impairs the strength and flexibility of the jute fibre and imparts to it a dull, muddy colour. While the bundles are under water they should be examined from time to time to see how far the rotting has progressed, and when the rotting has so far gone on that the fibre peels off readily, the bundles should be taken out of the water and at once put in hand for the separation of the fibre.

This separation process may be done thus:—The operator, standing up to his middle in water, takes as many of the stalks in his hands as he can grasp, and removing a small portion of the bark from the ends next the roots and grasping them together, strips off the whole from end to end without breaking either stem or fibre. Having prepared a certain quantity into this half state, he next proceeds to wash off, which he does by taking a large handful and swinging it round his head; he dashes it repeatedly against the surface of the water, drawing it through towards him so as to wash off the impurities; then, with a dexterous throw, he fans it out on the surface of the water, and carefully picks off all remaining black spots. This done, he wrings out the water and hangs the fibre out to dry. The cleaner the water in which it is washed and the more frequent the washing, the cleaner and more whiter becomes the fibre. Whenever readily accessible, running water is therefore preferred for this process. After washing, the fibre is dried in the sun from one to five days. When dry the fibre is made up into bundles and is then ready for the market.

The quantity will depend upon the quality of the soil and the cultivator; the value, upon the quality of the article produced, and the great secret is in giving attention, "strict attention," to the preparation of the fibre.—I remain, dear sir, yours faithfully,
JAMES D. WATSON.

THE CONSUMPTION OF CROTON OIL.

DEAR SIR,—There was an article in the *Tropical Agriculturist* referring to the consumption of oils, and "croton oil" was put down at 14,000 tons annually for wool-dressing. Now I can't find any statistics to back up this statement: can you? It is a mistake surely for cotton oil! If not, it is a fine thing to go in

or, specially with cacao, the latter requiring shade, the former supplying both shade and produce of a remunerative kind especially as the consumption is so great. I would not have troubled you but that a general opinion prevails that the thing will be overdone as it is only used medicinally, and, knowing your proverbial good-nature, I am writing to ask you if you can put my mind at rest, as, if so, I intend putting down a good acreage.—Yours truly, PLANTER.

[There must certainly have been some mistake: where did our correspondent see the article in the *T. A.*?—we cannot lay our hands on it for the moment.* But a reference to the latest edition of MacCulloch shows that the imports into the United Kingdom of all the "seed" oils put together do not average more than from 12,000 to 14,000 tons. We cannot find croton specified separately. The following reference is the only one of consequence in the *Encyclopædia Britannica*:—

CROTON OIL (*Crotonis Oleum*) is prepared from the seeds of *Croton Tiglium*, a euphorbiaceous tree indigenous to the Malabar coast and Tavoy, and grown in many parts of the East Indies. The tree is from 15 to 20 feet in height, and has few and spreading branches; alternate, oval-oblong leaves, acuminate at the point, and covered when young with stellate hairs and small, downy, greenish-yellow, monoecious flowers. The male blossoms have five petals and fifteen stamens; the females are apetalous, but bear three bifid styles. The fruit or capsule is obtusely three-crested, and $\frac{1}{3}$ of an inch long; it consists of three carpels each inclosing a seed. The seeds resemble those of the castor-oil plant; they are about half an inch long, and 2-5ths of an inch broad, and have a cinnamon-brown, brittle integument; between the two halves of the kernel lie the large cotyledons and radicle. The kernels contain from 50 to 60 per cent. of oil, which is obtained by pressing them, when bruised to a pulp, between hot plates. Croton oil has long been known in India as a medicine, and has been in use in England since 1813. Seeds for manufacturing it are imported mostly from Cochinchina and Bombay. It is occasionally adulterated with olive, castor and nut oil.

From Simmond's Commercial Products we get some interesting particulars:—

Croton oil is obtained by expression from the seed or nuts of *Croton Tiglium*, an evergreen tree, 15 to 20 feet in height, belonging to the same order as the castor oil plant, producing whitish green flowers, and seeds resembling a tick in appearance, whence its generic name. It is a native of the East Indies, 100 parts of seeds afford about 64 of kernel. 50 quarters of croton nuts for expressing oil were imported into Liverpool from the Cape Verde Islands, in 1849.

The *Croton Tiglium* grows plentifully in Ceylon, and the oil if properly expressed, might be made an article of trade. The best mode of preparing it is by grinding the seeds, placing the powder in bags, and pressing between plates of iron; allow the oil to stand for fifteen days, then filter. The residue of the expression is triturated with twice its weight of alcohol, and heated on the sand-bath from 120 to 140 deg. Fahrenheit, and the mixture pressed again. In this step the utmost caution is necessary in avoiding the acrid fumes. One seer of seed furnishes by this process rather more than eleven fluid ounces of oil, six by the first step, and five by alcohol. The oil acts as an irritant purgative in the dose of one drop. In large doses it is a dangerous poison. When applied externally it produces pustules. In 1845, eight cases of croton oil and six cases of the seed were exported from Ceylon. Other species of croton, as *C. Pavana*, a native of Ava and the north-eastern parts of Bengal, and *C. Rozburghii*, yield a purgative oil. The bark of *C. Eleuteria*, *C. Cascarilla* and other species is aromatic, and acts as a tonic and stimulant. It forms the cascarilla bark of commerce already spoken

of. When bruised, it gives out a musky odor and is often used in pastilles.

Oil is also obtained from the seeds of *Jatropha curcas*, a native of South America and Asia, is purgative and astringent, and analogous in its properties to croton oil. It is said to be a valuable external application in itch. In India it is used for lamps. Then of the "*Jatropha*" we read in Simmond's tropical work:—

PHYSIC NUT (*Cucurus purgans*, Lindl.; *Jatropha Curcas*, Lin.)—This small tree or shrub is grown in Brazil, the East and West Indies, and West Africa; but the principal seat of production is the Cape Verde Islands. In the tropics, hedges and enclosures are made with this shrub, as cattle will not touch the leaves. The seeds are excessively drastic, hence their general name of purging nuts. This plant grows in abundance at Casamansa, and Gaboon and other parts of the African coast could supply this oil seed. The bush from which the seed is obtained is readily increased by cuttings, which rapidly take root. The seeds are three or four, contained in a thin skin, which is black; the seed is of the same colour, and grows in bunches; the stems of the bushes are not strong, but they answer excellently for fences, with split bamboo tied on each side to keep them straight and together, and the great advantage is that no kind of cattle eat them. The seeds are collected and the oil expressed in the usual way. The oil obtained from the seeds is chiefly used for lamps, and also in cutaneous diseases and chronic rheumatism. The Chinese boil the oil with oxide of iron to make the black varnish used for coating boxes, &c. The oil is viscous, of a deep yellow, with a density of 0.918.

This oil has been frequently imported into England as a substitute for linseed oil. The colour is somewhat paler; it answers equally well. Quantities of the seeds are shipped from the archipelago of the Cape Verde Islands; the average export from thence is about 100,000 hectolitres annually; they are sold at the port for 5 francs the hectolitre. The seeds are known under the name of Pignons d'Inde by the French, and Purqueira by the Portuguese.

The following shows the quantity of these seeds raised in 1869 in the Cape Verde Islands, the chief locality of production:

	Tons.
St. Jago	15,750
Fogo	900
Bona Vista	22
	16,672

An oil obtained from another species in India (*Jatropha glauca*, Vahl) is also used locally in medicine and for lamps. In appearance and consistence it resembles castor oil. The seeds of other species, *J. multifida* and *J. gossypifolia*, are also purgative.

CROTON OIL.—The oil is obtained by grinding the seeds, placing the powder in bags, and pressing them between plates of iron. The oil is then allowed to stand fifteen days, and afterwards filtered. The residue after expression is saturated with twice its weight of alcohol, heated on the sand bath from 120° to 140° Fahr., and the mixture pressed again. The alcohol is distilled off, the oil allowed to settle, and filtered after a fortnight. One seer (2 lb.) of seed furnishes 11 fluid ounces of oil; 6 oz. by the first process, 5 oz. by the second. Sometimes the seeds are roasted before they are compressed. The seeds of *C. Rozburghii*, *C. Pavana*, and *C. oblongifolius* have similar purgative properties.

We suspect that a profitable market will be found (for other than physic purposes) for all the croton oil seeds our Ceylon planters can produce for some time to come. All we can learn from the India Customs Returns is that the export of "seeds" in 1883-4 was equal to 17,357,884 cwt. valued at R10,086,009, but in the term "seeds" the following are included:—"Castor, coriander, casuarina, jinjili, ortil, ground-nuts, linseed, methic, mustard, poppy, rape or sarson, and others."—Ed.]

* We have since found the passage: it is in an article from a Demerara paper and we should like much to have some light thrown upon the statement which is as follows:—"About 14,000 tons Croton oil are annually imported for the use of the wool-dressers of Britain."—Ed.

A CONSPICUOUS ORNAMENTAL JUNGLE TREE IN THE FORESTS ABOUT DIMBULA.

"The Governor was also struck with a tree in our forests which for some time back has shown masses of white flowers over its top."—Extract from letter "From the Hills" in *Observer* of 13th May 1885, p. 3, top of col. 2.

15th May 1885.

DEAR SIR,—I feel almost certain that this refers to an abundant and very conspicuous tree in the forests in Dimbula and I notice in my copy of the "Flora of British India," (vol. 2 p. 6) that I procured and identified specimens of it at Lower Abbotsford on the 13th of February 1881, from trees 60 to 70 feet high and at an elevation of 5,800 feet. The trees were very conspicuous from the large panicles of white flowers on the tops of the branches then, and no doubt at other times. It has no native name that I am aware of in Ceylon.

It is the *Meliosma arnottiana*, WIGHT, and the following remarks from Colonel Boddome's "Flora Sylvatica" (t. 160) are very applicable to our Ceylon tree:—"A very common tree in Southern India and Ceylon at 4,000 feet and upwards; it is very abundant at Oconoor on the Nilgiris, and is a most beautiful sight in June when in full blossom, its whitish panicles forming a perfect sheet of flowers over the top of the tree; it is also a very conspicuous tree when in flower in the mountain sholas of the Annamallays. It is called by the Burghers on the Nilgiris 'Huli makay' (tiger-like), the heart-wood of very old trees being striped reddish and white; the timber is worthless, being spongy and light, but is occasionally used for rafters and as firewood." This genus is the last one in *Sapindaceae* in Th. En. p. 59, but it is now included in an order called *Subiacceae* and is the first one in the 2nd volume of the "Flora of British India."

We have the following three species of *Meliosma* in Ceylon:—

1. *Meliosma Wightii*, PLANCH.—A tree with simple leaves found at the same elevation as *M. arnottiana*, and Col. Boddome's remarks in the Forester's Manual, p. 77, equally apply to this tree also:—"A most common tree in the shola forests about Ootacamund and other mountain tracts on the west side of this presidency and in Ceylon, at and about 5,000 feet elevation. The tree is called by Europeans on the Nilgiris the hill mango and at the distance it has somewhat the appearance of a mango tree when in blossom; it is called Tode by the Burghers. The wood is useless and not even cut as firewood, as it burns very badly. The tree is said to be held sacred by the Todas."—It is given as *M. pungens*, WALP., in Thw. 59.

2. *Meliosma simplicifolia*, ROX.—This also as its specific name implies is a simple-leaved plant. It is very common about Kandy especially on the banks of streams, and is very conspicuous from its long panicles of flowers and fruits about the size of red currants. "A very common tree in the moist subalpine forests on the western side of the Malras Presidency at 2,000 to 3,000 feet elevation, also in Ceylon and Bengal, I have not seen it above the latter elevation, its place being then taken by *Pungens* Wighti."—Ed. l. c. The Sinhalese name for this small tree is Elbedda, and I wonder if the famous Elbedda plains derive their name from this tree, but I fear not, as it is scarcely likely to be found at that elevation.

3. *Meliosma arnottiana*, WIGHT.—With large pinna'ed leaves, the very conspicuous tree already referred to.

I trust these notes will enable your readers to identify this latter tree at least.—Yours, W. F.

P.S.—Moon, pt. 2, p. 27, gives "El-Bedda" to mean cold jungle or bush,

THE SIROCCO:—A CORRECTION.

The Ceylon Purchase Hire Company,
Colombo, May 20th, 1885.

DEAR SIR,—Will you kindly permit us to correct a statement in your issue of the 18th instant re tea drivers. You say that the No. 3 Sirocco on Abbotsford estate only gave an outturn of 64 lb. per hour.

As a matter of fact the Sirocco on Abbotsford is not a No. 3, but a converted No. 1, in which form Messrs. Davidson & Co. claim "it is capable of doing about two-thirds more work per hour" than the original No. 1. If therefore it does turn out the quantity you mention (64 lb.) it fulfils the promise of the patentees, as do the No. 3's with an outturn of 80 lb. per hour obtained by Mr. Jas. Wight of Kandaloya from his two machines, of Mr. Blackett of Deteloya and Pen-y-lan with his machines, and Mr. J. M. Boustead with two of his machines.—Yours faithfully,

W. H. DAVIES & Co.

[We stand corrected in this matter, and if we have fallen into any other mistake we shall be glad to know. Our sole object is to state the exact truth about the various machines competing for public favour.—ED.]

AN INSECT PEST.

The Wharf and Warehouse Company, Colombo,
20th May 1885.

DEAR SIR,—I send you three branches from a suriya tree cut in these premises today. You will please observe that they are infested with some poochies resembling very much those found on drift timber in the sea. The tree from which these branches were cut is nearly dying. I would therefore feel obliged if you will be good enough to forward these branches to your usual botanical referee and find out the name and origin of the poochie.—Yours faithfully,

DARLEY ALTENORFF.

[Our entomological referee reports as follows:—"The shell like tubes on the branches from the suriya tree are the abodes of the larvae of a small homopterous insect belonging to the Cercopidae family, of which *Aphrophora spinularia* is a member. The latter insect is commonly known in England as the cuckoo-spit and frog-hopper. The tubes in question seem to have been constructed by the insects from matter secreted within them. This must harden at once, and a full-sized tube is probably the work of many days, as the insect grows and feeds upon the sap of the tree. Its body is so soft, that, without some kind of protection from the heat of the sun, it would be speedily dried up and killed, but in its tube it can feed in safety, and is also protected from the attacks of other insects. It is the first time that these tubes have been brought to my notice, and I intend to send some of them to Professor Westwood, as they may also prove new to him."—ED.]

TEA BROKERS' ADVICE ON FERMENTATION AND FIRING,

23rd May 1885.

DEAR SIR,—In reply to your query in the brokers' advice as to "fermentation" and brisk firing, consider full fermentation as explained to mean a fermentation carried only to that point which while it secures a deep color does not produce a weak, insipid, pointless liquor. In overfermented teas, though pungency is lost, color of liquor may still remain; but the chemical changes (regarding which see Tea Cyclopaedia, discussion between C. H. Lepper, Chs. Russel, M.R.A.C., and others) are indicated by certain unmistakable tests,

For practical purposes, however, in a factory the following tests may suffice:—

1. The outturn of over-fermented tea will more or less approach in color an old penny, rather than the new penny,—“THE DESIRABLE LIGHT SALMON COLOUR.”

2. In the liquor, the grip, like taking alum water for a gargle (especially in the case of a well-fermented pekoe or broken pekoe), will have disappeared.

3. A sweet smell, the result of the change from the incipient stage of fermentation to the stage of true fermentation, will emanate from the testing cup and follow the tasting.

4. The liquor on being cooled will not cloud, as will the correctly fermented tea from the broken pekoe down to the pekoe souchong in good teas.—Yours truly,
AGRICOLA.

P.S.—You have disposed of the question of firing briskly. A Sirocco at 300 or even 275 is brisk enough, and the Ceylon men do not burn, as a rule, by any means. As regards underfermenting, there is always a market for underfermented teas. Overfermented teas are valueless, according to their degree of weakness.

VOLCANIC ROCK (?) AND TEA PRODUCTION.

Onoonagalla, 23rd May 1885.

DEAR SIR,—I am sending you to lay as promised a specimen of the rocks in the Galleluca tea-field. The formation is in places very similar to that of a field of lava having all the appearance of being a surface deposit filling up the bottoms of two ravines.

I annex particulars of leaf gathered during the last four flushes from the field above referred to. The whole extent is 100 acres, but as the tea has been planted (chiefly at stake) at different periods during the last five years, as cinchona died out, it is very irregular and the number of trees in bearing cannot be estimated correctly. I may mention, however, that I put out nearly 120,000 supplies last season. The result is I think satisfactory as showing regular yield and cost of plucking; and as there is very little tea yet in bearing out of the considerable area planted in this district the figures may prove of interest to some of your readers.—Yours faithfully,
M. H. THOMAS.

[We shall take measures to ascertain the true character of the rock, which is evidently exceedingly fertile, judging by the returns of tea growing on it.—Ed.]

TEA DRYING BY “JACKSON’S PATENT

VICTORIA DRIER.”

Carolina, Ambagsnuwa, 25th May 1885.

DEAR SIR,—A break-down in gearing prevented the use of the turbine for three days. The Victoria drier was worked by hand, on cooly driving the webs, but the fan was not used. The amount of dry tea turned out was 80 lb. per hour. The Challenge roller came in very usefully, 120 lb. of withered leaf per hour being rolled by it.—Yours faithfully,

W. MEGGINSON.

CINCHONA BARK: A MANUFACTORY AT NUWARA ELIYA.

SIR,—In 1833-34 about 40 per cent East Indian and 60 per cent South American barks were imported into Europe: last year 75 per cent East Indian and 25 per cent South American. Soon manufacturers will have to rely entirely on East Indian bark. At the same time production of bark has so increased that prices must and will fall from their present low ruling rates. Even now it does not pay to export any bark containing less than 1 per cent quinine sulphate. When one thinks of the expense of exporting to Europe and America a raw material, which only contains from ½ to 6 per cent of the manufactured commodity, one feels staggered to think that the few capitalists of Ceylon have not ere this established a factory in Nuwara Eliya.

The climate is suitable, so is the water, and an article could be produced of the first quality at a price which would simply cut all others out of the market. This question is of more importance to us as an agricultural colony than that of the Graving Dock in Colombo. About £8,000 would build and stock the factory, besides providing a working capital. A factory at the fountain-head of bark would be the most successful speculation of the day.

Kindly take this up.—Yours,

G. A. D.

[We have urged the matter on quinine makers and bark dealers in New York and England, but without avail. There are secrets in the manufacture, too.—Ed.]

LOCAL MANUFACTURE OF QUININE.

Bowhill, 28th May 1885.

DEAR SIR,—Referring to “G. A. D.”’s letter and your footnote—the subject has engaged my attention for some time—it has always seemed to me to be as reasonable for the Jamaica planters to send home their cane, as for us to send our bark.

All that is wanted is the capital. Success is certain. The “secrets” of the manufacture are known to me, and I am at the present moment in correspondence with a practical quinine manufacturer of long experience, who, I have no doubt, would come to Ceylon at once were the capital available. The “plant” &c. would cost at £5,000, and a working capital would be necessary to keep such a factory going at the rate of at least 500 ounces of made quinine daily.—Yours truly,
R. W. JENKINS.

[Supposing half the capital in cash (or say £5,000) were invested in England, how would it do for the Ceylon plantation to be contributed in “bark” by planters willing to wait for their returns till the quinine was tested and sold?—Ed.]

“BUCHU-PAIBA.”

Quick, complete cure, all annoying Kidney, Bladder and Urinary Diseases. Druggists. W. E. Smith & Co., Madras, Sole Agents.

THE KANDY (CEYLON) AGRI-HORTICULTURAL SHOW.

(May 20th, 1885.)

The exhibits were all arranged on tables running down the centre of each court and passage and were divided into 10 classes as follows:—Class I. Garden Perennials in pots; Class II. Garden Annuals in pots; Class III. Ferns in pots; Class IV. Foliage Plants in pots; Class V. Cut Flowers; Class VI. Vegetables; Class VII. Fruit; Class VIII. Native Products; Class IX. Estate Products; Class X. Arts and Manufactures. In addition to these and not classified were the machinery and other miscellaneous exhibits.

Class I., Garden Perennials, was on the whole very creditably represented, Mr. J. V. H. Owen's pot plants being specially worthy of mention. The roses were a very poor show, and the judges decided that no awards should be given for them.

Class II., Garden Annuals.—These were not very largely represented.

Class III., Ferns in Pots.—This was one of the best filled classes in the Show, and one of the finest. Mr. Pate of Colombo sent a magnificent collection of ferns which excited universal admiration and took the first prize. Mr. Jonklaas was also an extensive and a successful contributor to this class.

Class IV., Foliage Plants in Pots, was very largely represented and a very good show.

Class V., Cut Flowers.—This was a very good show indeed. S. Jayetilleke Mandaliyar took the first prize, and silver medal for the best collection of roses. The exhibits in this class—of Mr. Barber, Nuwara Eliya, Mr. Wingate, Maurata, and Mr. J. V. H. Owen—were specially good.

Class VI., Vegetables.—A very extensive collection of vegetables was on show, and some really fine exhibits were very much admired, reminding one as they did of similar shows in the old country. Mr. J. Alexander of Udapussellawa was the most successful contributor in this class and took the Silver Medal for the best collection of English vegetables and the prizes for potatoes and tomatoes. Mr. Whyte's collection of English vegetables grown in Kandy was a very good show, but the judges decided it was worth a Bronze Medal and not the silver medal offered.

Class VII., Fruit, was not extensively represented, but what there was exceedingly good. The principal exhibits in this class were those sent by Mr. W. I. Cotton of New Galway. The peaches and plums were exceptionally good and looked very tempting.

Class VIII., Native Products, deserves a special word of commendation. The collection of paddy was most extensive and the samples really splendid. Yatawara Ratemahatmaya well deserved the gold medal given by the Society for the best general collection of native products, and for the best collection of paddy the gold medal given by His Excellency the Governor was well bestowed on Palipane Ratemahatmaya. Tennekoon Ratemahatmaya's collection of paddy was a beautiful show and was accompanied by a capital catalogue. His collection he presented to Dr. Trimen for the museum at Peradeniya Gardens. Fibres and jungle ropes were very well represented, and the cotton shown was of good quality.

Class IX., Estate Products, was of course the principal collection in the Show. The class may be summed up on the whole as not numerous but very good. A finer sample of coffee than that shown by Mr. G. H. D. Eppinstone and which took the Gold Medal could not be wished for, and the other samples shown were not far behind in quality. The pty of it is that there is so little of it now in the island Tea was certainly disappointing, not in quality shown, but in the paucity of *bona fide*

commercial samples. It was all "too good to be true": in fact the judges declared that they were all fancy teas and that there was scarcely a commercial tea in the collection. It is not pleasant to have to say so, but they undoubtedly all were "doctored" as it was expressed by more than one planter. Of one sample sent it was stated that the souchong, broken pekoe and pekoe were all nothing more or less than threegrades of pekoe. Perhaps it would have been more satisfactory had the teas been sent in bulk and sorted by the judges with the assistance of one of the numerous tea sifters now in the market. Some samples of tea which would otherwise have got prizes were badly packed and were tainted by the wood or paint of the boxes. Gallebodde tea would probably have taken the prize for "fancy" tea had three qualities instead of two been sent. For the best set of samples of *bona fide* commercial tea, the Gold Medal was awarded to Blackstone, the judges believing this to have been a genuine sample of a break, but they declined to give the silver and bronze medals offered for the second and third best samples. For "fancy" tea, under which name nearly all samples should have been entered, Lauderdale took the palm though that estate was closely run by Blackstone and Gallebodde, the latter as stated as above losing it by not complying with regulations; these two latter were awarded Bronze Medals. Cacao was extensively represented, and some beautiful samples were shown. Pallekelly took the lead in this product and the sample winning the Gold Medal was undoubtedly the finest there. Cardamoms were extensively shown and all the samples were first-class. Cinchona too was a very fine collection. Mr. J. Alexander of Kirklees took the palm in this product, his collection being a really first-class lot of barks. In cinnamon the well-known mark of Mr. J. F. Drieberg's estate took first place for a capital collection. Vanilla was fairly well represented, Mr. S. Jayetilleke of Kurunegala showing the best and winning a Bronze Medal with a very fine sample.

Class X., Arts and Manufactures, was a very interesting show and included Dumbara nuts, inlaid tables, fret-work, carving in wood and ivory, pottery, silver-work &c. &c. Mr. W. G. Wood showed a large number of fret-work texts and mottoes which were splendidly carved. Mr. G. A. Cherrington of Colombo had some very excellent models of ships. Mr. A. K. Ashton had a model of a 40-pounder field gun and also a model of H. M. S. "Invincible." The silver and ivory work was remarkably fine, and a special Silver Medal was awarded for the former besides the one offered. The awards in this class have not yet all been made.

PRIZE LIST.

CLASS I.—GARDEN PERENNIALS (in pots).

Begonias. Best collection of not less than 6 different varieties	Silver Medal	Hon J F Dickson
do do 3 do	Bronze Medal	J de Livera
Best Geraniums	do	H S Saunders
Pelargoniums	do	J Alexander
Carnations and Pinks	do	J F Wingate
Gloxinia and Achimenes	Silver Medal	J V H Owen
Anthriscums	Bronze Mdl	H S Saunders
Gladioli	do	H S Saunders
Orchids in flower	Silver Medal	H M Lewis
Tuberous-rooted Begonias	Bronze Mdl	J V H Owen

CLASS II.—GARDEN ANNUALS (in pots).

Best Balsams	Silver Medal	A Whyte
Petunias	Bronze Medl	W D Bosanquet
Phlox	do	W. D. Bosanquet
Zinnias	do	A Whyte
Asters	do	J V H Owen
Penstemons	do	G H Ashton
Calceolarius	do	E J Thwaites
Cinerarias	do	do
Friarulas	do	J V H Owen

Basket	C of Merit	Tennhook R M
Mats	Bronze Mdl	Jayetlicke Mdl
Spinning wheels	Cut Merit	Huingalla R M
Textile Fabrics	Bronze Mdl	Rambukwalle R M
Embroidery	do	J Awtis Mdl.
Extra Prize Model of Bridge	Silver Mdl	C E Spooner
Extra Stuffed animals	do	S Bligh
For design of building	Silver Mdl	C E Spooner

SCIENTIFIC AGRICULTURE IN NEW ZEALAND.

By R. W. EMERSON MACIVOR, F. I. C., F. C. S., & c.

The Agricultural School at Lincoln, New Zealand, is the only well-organized institution of the kind in this hemisphere, and the manner in which it has been conducted from the outset says much for the practical ability and perseverance of Professor W. E. Ivey. In addition to class teaching and the general routine work of the farm, experiments and investigations of one description and another have been carried out with eminently valuable results.

The course of study extends over three years, and includes agriculture, dairy work, chemistry, natural science, mathematics, survey and plan drawing, book-keeping, veterinary science, meteorology, blacksmithing, carpentry, and field work. Last year the students numbered 36, and obtained their final certificate of competency. Speaking of his students, Professor Ivey says:—"There are always a few students to whom work of all kind is irksome, and who are discontented at its being enforced. These do their best to make others dissatisfied. I am strongly of opinion that it is essential that farm students should go through the drudgery of the farm, and I therefore object to doing the unpleasant part of the work by hired labour. The few students have an objection to such work as carting dung and similarly confessedly unpleasant parts of the farm routine; and, unfortunately, some parents think their sons should not be required to do such unintellectual work. I think the school is far better without such students; and that for its future credit no hesitation should be displayed in weeding out and requiring the removal of those who do not enter with the bona fide intention of becoming farmers, or, at least, of thoroughly learning the farmer's business. I think the labor test of considerable value to this end." It will thus be seen that Professor Ivey has made up his mind to drill those put under his charge in such a way as to make them sound practical farmers. Agricultural education on any other basis must end in worse than failure.

The extent of the farm in connection with the school is about 661 acres. Of this area 126 acres are sown with 10 different varieties of wheat, 69 acres are planted with five kinds of oats, 21 acres under barley, 25 acres under beans, and 24 acres under peas of different sorts. Some 157 acres are in rotation of grasses, 115 in permanent pasture, 24 acres under mustard, rye, and vetches for spring keep, to be followed by roots, and 50 acres are in fallow for roots. The total productive area is about 616 acres. The live stock on the farm are 1,262 sheep, 69 cattle, 60 pigs and 15 horses. The yield of grains for last year was 7,500 bushels, or an average of 35 1-3 bushels per acre.

In the dairying department of the farm large returns were obtained last season. No less than 16,649 gallons of milk were purchased, and 16,294 lb. or over 7 tons of cheese manufactured. Ivey has made some interesting and important observations on the loss in weight experienced by cheeses which are kept for six months. He finds that those weighing about 75 lb. each lose 8 per cent, whilst those of about 37 lb. each lose nearly 9 per cent. Small cheeses, 12 lb. to 18 lb., lose as much as 10 per cent. The cheese made in 1883 sold at 7 1-16d. per lb. and had been kept until it was well matured, when it had shrunk so much in

weight that 1 lb. of the cheese represented 12 lb. of milk. The yield of new cheese averages practically 1 lb. to one gallon of milk and the shrinkage is about the same each year, the loss in weight being about 9 per cent, in the six months.

Much valuable analytical work has been done in the laboratory during the past three years. This part of the institution is under the care of Mr. Gray, the lecturer on chemistry, who has devoted much of his time to the analysis of farm produce, soils, and manures. With regard to the latter Professor Ivey has endeavoured to check the sale of adulterated manures by announcing that farmers may have samples analyzed free of cost. This has already led to the exposure of fraud. A sample of bonedust recently examined by Mr. Gray contained no less than 17.72 per cent. of sand, or over 34 cwt. per ton. Another specimen contained 12.7 per cent, or over 2 1/2 cwt. per ton. Besides thus aiding the agriculturist, Mr. Gray also examines soils and waters without making any charge. The composition of the wheats of the various colonies has been under investigation for some years and the results obtained are most interesting. The well-known "weakness" of New Zealand and some Australian flours has been shown to be due to their containing less gluten and more starch than either Russian, Hungarian, or American flours.

In the natural science section Mr. Kirk, F. L. S., has conducted important researches in regard to insect and other farm pests, the germination of seeds, the cultivation of indigenous and exotic grasses, and the destruction of weeds. This gentleman has recently made a useful contribution to our knowledge of smut in wheat. It having been found that dressing with a strong solution of bluestone had a very prejudicial effect upon some varieties of wheat—particularly Tuscan—experiments were undertaken to discover what strength of solution would effectually destroy the smut spores adhering to the seed without damaging the grain. It was ascertained that where Tuscan wheat was treated to a solution of two ounces to one quart of water, which is equal to one pound of bluestone to the bag of wheat more than one half the seed was killed, germination of the other half being delayed some 11 days. With a solution half this strength one-fourth of the dressed seed was killed. For this reason, and because carbolic acid was being advertised as a certain preventive of smut, an extensive investigation was made, and the following conclusions arrived at:—1. That sulphate of copper (bluestone) is the only substance effective in killing smut spores. 2. That with adulterated bluestone the effects are relative according to the copper sulphate present. 3. That carbolic acid is useless. 4. That bluestone retards germination, weakens the young wheat plant, and in strong solutions even kills a large proportion of some kinds of wheat. 5. That solutions containing one ounce of bluestone to two quarts of water or two ounces per bushel of seed, are strong enough to kill the smut spores. 6. That it is probable that by damping the wheat a few hours before dressing it so that the smut spores are swelled up and made more susceptible, a much weaker solution of bluestone may be used. This investigation is not yet finished, and we may look forward to even more useful results.

It will be seen from what has been said that the school at Lincoln is doing much good, and the sooner New South Wales provides itself with a similar institution the better it will be for our farmers.—*Sydney Mail*.

THE "T. A."—Mr. Merriis of Jamaica writes:—"I trust the *Tropical Agriculturist* is extending its operations and becoming still more widely known in all tropical countries. We require its powerful aid everywhere here, and I wish it every success."

COFFEE IN COORG.

MERCARA, May 10th.—In the year 1876, the prospects of coffee planters were at their best, a magnificent crop had been gathered, and above a hundred pounds nett had been realized, which placed planters as a rule free of their London firm, or advancing agents; coffee then was realizing 30 per cent upon the money invested. A pack of fox hounds was imported, more land was recklessly taken up, loans were pressed upon borrowers: in fact at that moment coffee was lord of all things. In the August of that year, the coffee trees presented a superb appearance, with their healthy look and vigorous show of crop, but when they ripened in November, a terrible crisis was at hand, which changed the aspect of affairs, as completely, as a sudden equal obscures a placid sky—upon the unmanured, and unskillfully worked estates lying west of Mercara and which then were the bulk of the whole, a terrible reckoning was at hand—the whole of the crop failed, in so far that outwardly it was perfect to the vision, but there were no berries or beans inside, it was all light, one of the planters, clever and practical, who had then 800 acres in full bearing, assured me on one occasion in that terrible year, he permitted 700 bushels of ripe berries, (that would have given him 4½ tons of coffee ordinarily) to pass unpulped away to his manure heap. Then, he amongst others, who had reckoned upon retiring, said that prospects were blasted: money had to be borrowed, estates mortgaged; whilst others, the blow struck so grievously, that they never recovered, but sunk under it, notably our two 'coffee kings' who at one time owned between them nearly all the best estates. Since then, no man has been able to stand in their shoes. In south Coorg, or the Bamboo as it is locally termed, matters had turned out most favorably, there was nothing wrong with the crops: low-lying, feverish, impure water, shortness of labor, it offered few inducements for planters, as long as the healthy European climate of the ghat paid so handsomely—it was now that covetous eyes were turned upon this rich bamboo land, with its thick black soil, on gentle slopes; and coffee estates sprang up upon all sides, worked in many cases with money borrowed from the old ghat estates which in 1877 was a year of plenty.—*Madras Standard*, May 15th.

A CURIOUS phenomenon is reported from some of the vineyards in the province of Malaga. According to Spanish papers, plants attacked by the phylloxera and given up as practically dead have begun to show marked symptoms of vitality, due, it is believed in the localities, to the destruction of the insect by gases, or electrical conditions consequent upon the earthquakes in that district.—*Overland Mail*.

MARKET GARDENING ON THE HILLS.—A correspondent writes:—"I thought of 'market gardening' long before your other correspondent did, but the fact is as most of the gardeners here will tell you it does not pay to send vegetables to Colombo. Perera, the most extensive market gardener, has told me even although he had a contract to supply the P. & O. steamers, it nearly ruined him, and he had to give it up. Now that there is a railway from Nannuwa, it might pay: the difficulty is the getting in the money, so many of the natives are such rascals in their dealings with each other. It might pay one European to send to another European in Colombo, but the Government would require to carry vegetables at very low rates, and return the hampers free of charge, and I am not aware that they have even thought as yet of doing so. The Colombo market always seems to me to be full of locally grown vegetables of good kinds, only the servants won't apparently buy them for their masters or cannot cook them so as to please European palates when they get them." If such tomatoes as those a friend has sent us from a Ud pussellawa could be regularly supplied to Colombo, there ought to be a good demand, as also for cabbages, peas, &c. The way would be to register so many regular customers among Steam Companies and Colombo householders.

COFFEE IN MID-DIMBULA.—An old planter writes:—"Do you recollect criticizing this place unfavourably in your paper in 1879? I think you rather made a mistake then, and, if you could see this year's crop (in spite of leaf-disease and grub) on the old place I almost believe you would think so too! According to Mr. Hughes' analysis of soil, this place was to 'go out' or something of that kind and other places were to flourish, some of them even without manure; but, alas, for the frailty of these scientific cards—exactly the reverse has been the case. Trusting we will yet have the pleasure of seeing the Railway (for which you have fought so long and so well) advancing towards Uva." We are very glad indeed to hear such good accounts now of Mousa Ella, and hope it may flourish for a hundred years. Would that many more or all Dimbula planters could say the same of a good prospect of fine crops.

MOISTURE IN TEA.—The percentages given in connection with tea-drying were a little mixed. Taking the fact that 4 lb. of green leaf yield 1 lb. of dry tea, we would put the ratio as follows:—WEIGHTS: Green leaf, 4 lb.; after rolling, 2½ lb.; dried, 1 lb. This is based on the assumption that on an average 60 per cent of the weight of rolled tea is dissipated as moisture in drying, so that on an average a rolling which weighs 2½ lb. gives 1 lb. dry tea; but 1 lb. dry tea on the average requires 4 lb. green leaf, and therefore 4 lb. green leaf after being withered and rolled, on an average gives a weight of 2½ lb. The percentage of the green leaf, therefore, which is dissipated, on the average, is as nearly as possible 40 per cent. But direct experiments ought to be made in order to settle all doubt: it would certainly seem that more moisture ought to be dissipated in the drying than in the withering and rolling; and therefore probably Mr. Armstrong's estimate of 66 per cent of the roll being moisture may be the nearest. This would give nearly 3 lb. as the weight of the roll making the proportional weights:—

Green leaf.	After withering on the roll.	After drying.
4 lb.	3 lb.	1 lb.
(25 p. c. dissipated.)	(66½ p. c. dissipated.)	

RHEA FIBRE.—Even as the nearly ruined coffee-planters of Ceylon found salvation at the last moment in cinchona and tea cultivation, so, perhaps, may the unfortunate gold-seekers of South of India save something by growing rhea grass on their estates. Owing to recent improvements in the machinery for separating the fibre, this industry promises to prove very remunerative. The main difficulty, indeed, is in finding localities where the soil and climate suit the plant. A supply of cheap labour is also necessary, and as all these requisites exist in the Wynaad and adjacent districts, it requires nothing but capital and enterprise to make a start. According to the calculations of Mr. W. G. Kemp, each properly cultivated acre should yield a net profit of £8 3s. 1d. per annum. This includes all working charges from planting until the prepared fibre is placed on board ship. A farm of 1,000 acres would, therefore, return £8,154 3s. 4d. as interest on the capital sunk in buildings and machinery. These estimates are made on the assumption that each acre would yield 10 cwt. of the fibre per annum, but Mr. Kemp is of opinion that the out-turn might be doubled by careful planting and manipulation. Even, however, as matters stand it would appear that a handsome profit awaits those who are the first to enter this promising field of industry. The pioneers in cinchona cultivation realized huge profits before the market value of the article was depreciated by augmented production.—*Globe*,

WORKING CHINESE LABOUR IN JAMAICA.

THE HEATHEN CHINEE—TRIAL OF THE CHINESE—RIOT ON GRAY'S INN SUGAR ESTATE—A CHINAMAN KILLED—COURT OF INQUIRY—OUR GANG ON ITER BOREALE TRIED AND THE RINGLEADERS ARRESTED—STRIKE AGAIN—MY GANG WORKING AT THE SUGAR MILLS—PROSPECTS OF THE SUGAR TRADE IN JAMAICA—WONG SEO AND LEE LOO IN JAIL.

August 9th.—On Saturday night we issued fresh beef, salt-fish, coco yams, rice and sugar to the Chinamen: they kept Mr. Manahan and self until dark pottering over their confounded rations. Our dinner was waiting and the soup got cold—my bathing towel was on my arm waiting to bathe, and when I got down to the sugar mills the mosquitoes attacked me in millions, therefore I dressed quicker than ever before. It is enough to vex a saint the ingratitude of these Chinese beggars, they live like fighting-cocks, and their food of the very best quality and yet they grumble. The work done during the week past, though little, is done well, the timber heaped up for burning in a clearing intended for bananas.

August 11th, Monday.—The Chinese struck work this morning and said they had no money and that we ought to pay them for 5½ days' work since arrival. Mr. Manahan sent for them and was witness to their each and all refusing to take sixpence balance due. Their rate of pay is fixed by the Jamaica Government at one shilling for nine hours' work daily. They worked four days only last week and 1½ previously for the past week; 3s 6d only was charged for good rations, leaving those who had worked four days at 1s only 6d balance. The sixpence they refused and each and all of the 11 men refused to go up the hill to work. Wong Seo was their spokesman and said the pay was "not enough," rice not enough, and oil was wanted for lamps at night. Mr. Manahan wrote off by special messenger to Mr. Pegue, the immigration agent residing in Port Maria 15 miles from here, he will come with the Chinese interpreter and will, no doubt, run the heathen Chinese into "chokie," or as the creoles call it, "The Work-house." At any rate Wong Seo and another must go as an example, the position is not a pleasant one, considering the risk run for small pay, fancy a fellow coming out of jail, full of evil intentions towards those who put him in. My berth is as unstable as the wind and my only chance is to be patient and wait until another berth is offered me elsewhere. Probably the British Honduras Government will reply favourably to an application made to them and backed up by Mr. Morris of the Botanical Department or the Tropical Products Company of Livingston, Guatemala. (Since writing in my diary as above, replies came from both quarters, the British Honduras Government not being able to employ me at present and the manager of the Tropical Products Company saying he had no berth with a salary attached thereto, but could employ superintendents to overlook labour in the field at \$25 and a furnished house, "but this would probably not fill up the bill.")—I cannot quite fathom the meaning of the last expression used, perhaps it is an Americanism. Perhaps it means the game is not worth the candle. There is a far "better scheme" on the board and that is to join Mr. D. Morris, the Director of Government Plantations, as Assistant Commissioner with the Jamaica exhibits to New Orleans. Mr. Morris writes me officially to the effect that the Jamaica exhibits will not be extensive and not beyond his own resources, but, as he has not engaged anyone to assist him, he will write me again. There is not much time to spare, for the "big show" at New Orleans comes off soon and Mr. Morris has only got a week to spare, I believe. The Government has sanctioned £600, and another two or three hundred will by this time be raised by private subscription. The Yanks will muster strong at the Grand International Exhibition, as they generally come down south to cheat the winter.)

August 14th, 1884.—We gave out rations again this morning to the Chinese and enough beef fresh from the butcher at 11-30 a. m.

RATIONS TO CHINESE.

Rice	Coco Yams	Sugar	Beef
1½ lb	... 1 lb	... 2 oz	... 8 oz.

An order for ...

- { 1 keg salt beef
- { 1 keg salt pork
- { 2 boxes salt fish
- { 3 boxes of best rice
- { 1 cask of split peas

is a sample of how the "heathen chinee is fed in Jamaica. It is hard lines we should be obliged to feed them so well, when they are on strike. The Agent of Coolies and Mr. Broughton will be here today. Meantime, "Wong Seo," acting as spokesman for the others, says that, if they work here, the other Chinese will beat them, they refused the 6d balance of pay due for four days work last week at 1s per day; 3s 6d charged weekly for the above rations.

August 15th.—Received a letter from Mr. Broughton of Low Layton Estate informing me that "owing to the ruinous prices of all produce" he cannot afford to pay me at the rate of 6s (six shillings) per day (working day) and that I am to "please understand" that only on looking after the Chinese on working days can I draw my "full pay"—6s. Now this is rather rough on rats and cockroaches, considering I carry my life in my trousers pocket working them. Moreover, I have to serve out the beef, the rice, the coco yams, the sugar, the salt fish! by the powers I might as well turn storekeeper and have a little bell on the door like the "sweet-stuff shops" in the old country. What a fortune I might have made as a general storekeeper out in the East Indies, yet stuck to planting and planting ruined me with hundreds more who had spent their lives growing the fragrant bean. Why, it would have been better to turn newspaper man and sit in the editorial chair! Even a catsmeat-shop would be a "better scheme" than planting anything.

August 16th.—The Chinese are still on strike, and drawing their rations regular as clock work, the beef, rice, coco yams, sugar, carefully weighed to an oz. in the spring balance. When I got up in the morning there is the "heathen Chinese" peeping in at the window and asking for "chow chow!" I went to their lines yesterday and tried to get them to turn out to work, but they one and all refused stoutly to budge an inch without the consent of the other Chinese in the district. "The strike" is general throughout Jamaica I believe; and know it to be so in Metcalfe and Portland districts. In spite of my explaining to them that my pay is stopped every day they won't turn out, they still refuse to do anything but eat, drink, and be merry. Solomon Simpson from "Boa" accompanied me to their quarters, two lines of huts or rooms; they have rigged up bed and mosquito nets, and we provided each room with lock and key, even gave them lamps and kerosine oil and yet they won't "turn to." In one room, four Chinamen were tailoring, they had made splendid jackets and trousers. Fancy the joke of paying £ 5 to £17 per head for these gay and festive cusses and feeding them up like fighting-cocks for nothing in return. If we stop the prescribed rations, they might abscond, and let the planter in for the passage money from Hongkong and overland in Jamaica. As it is, the poor planter is let in for streams of rations and the Government for the passage, the planters have not yet signed the indentures for 7 years' service in exchange for all charges. So the "heathen Chinese" has sold us all including the Governor! During the week, very great excitement has prevailed owing to a big fight between the Chinese of Gray's Inn sugar estate and the Inspector of Police, Captain Coward and his men, and the planters with their creoles and coolies. It appears that the police had arrived to arrest those Chinamen who refused to turn out to work and were answered by a shower of big stones, wounding Captain Coward and his officers and men of the police and one of the bankkeepers of Gray's Inn estate very severely on their heads, the cuts being deep. It is said the creoles and coolies, when called to rescue, fought like demons with their sticks and a free fight resulting in the death of one Chinaman and severe wounding of five others carried to the Government hospital. It is unknown up to date (13th September 1884) who killed Johnny, but suffice it to say he was as "dead as a herring." We intend to turn our gang out on Monday and if they refuse go through the same ceremony of arresting them and "running them all in to chokie." Meantime Mr. Broughton of Iter Boreale estate has

sanctioned my expenditure. The Chinese strike, however, has made me lose about £10, as I agreed to be paid for working days only, though I have to weigh out their rations every morning including Sunday. Times are hard in the West Indies just now, and the failure of sugar will be the straw that breaks the camel's back. Well, one fine morning a lot of mounted police with swords and pistols and their best uniform on rode up to our "great house" and the chief immigration agent Mr. Cork and assistant Mr. Pegue arrived and tried our gang, finding them all guilty and asking for the ringleaders. Wong Seo was pointed out as one and Lee Loo the other. The latter had politely told me he would cut us down with his cutlass if the police came, and on the spur of the moment, your correspondent thought Lee Loo very impudent and hit out with the right, catching him fairly on the nose. We confessed this to the Justice of the Peace and handed over Mr. Lee Loo over to the police as an improper person and suitable example to the other Chinamen.

Thursday, 18th September 1881.—Yesterday we made the Chinese in the barracks surrender their cutlasses. Wong Seo's gang refused to work unless the others were liberated from jail. I then told them they would be arrested and sent to Port Maria prison unless they turned out at once. *It was very hard lines that the police left me to go by myself to the Chinese barracks when they were excited.* I sent a messenger to call the police, but she returned and said they had gone into the Bay and that the cool agents had gone too. So much for our trial, the two ring-leaders got a month each at Port Maria State prison. What with women crying and the excitement of the trial, everything was upset for that day, and I think after this I shall not trouble you about the "Heathen Chinese." There was a strict court of inquiry held at the Court-house in Annotto Bay which resulted in the verdict that Johnny was killed by some person or persons unknown. Since the grand row, my Chinese worked steadily, sometimes working at the sugar mills, heading cane for the crusher, and clearing away the trash from the sugar machinery; they afterwards went on lopping forest in the banana clearing near "Lady Hole," a piece of forest below "Prospect" and above "Gibraltar."

CEYLON UP-COUNTRY PLANTING REPORT.

25th May 1885.

The monsoon still keeps off, but the variable winds—now S. W. now N. E.—tell us that the change is near. Most of us are like regiments which have been warned, and may expect to go into active service ere many days are past, for there are acres upon acres holed and filled, nurseries more than ready for putting out, and seed in germinating beds for planting at stake, if we had but the needed rain to enable us to go on. The slight showers which we do get only trouble us with the problem, as to whether it is safe yet to begin, and we sigh for the good honest burst, which puts reasoning to the wall and clears the mind of doubt. At this season of the year when no particular monsoon has the ascendancy it is very trying for those who are indoors, as well as for those whose duties take them out: all alike grumble, and all desire change. Headaches, fever, liver and many of the other ills which flesh is heir to under an Eastern sun crop up at the end of the hot season, and add their worries to the muggy heat. If we could, like our Aryan forefathers, look upon the contending monsoons as a great battle being fought for our special benefit and in which our champion Indra, the rain-giver, was sure to be successful, there would be comfort and balm in the thought for many of our minor miseries. But we can't. Indra has long since been relegated to the limbo of the defunct gods; the "darksome spirits" which he assailed have followed in his train; and now we have to turn our eyes to the Himalayas, and mark the snow line there ere we can form an

approximate opinion as to what the S. W. monsoon will do for us.

The disappearance of coffee is being hurried again this year by bug. It was very bad last season, but this one bids fair not to be a whit behind. One thing, it somewhat mitigates the pain in cutting an old friend—the fact that he has developed such low tastes—that no other way will do with him. But you do grieve that a product which might have helped to have carried the estate over the hiatus of the last lean years and the coming plenty is turning out so valueless. Bug is said to be very bad in all the low districts, and it is to be hoped that the higher ones may be spared. A more sickening sight than a field of coffee badly stricken with bug I hardly know.

By the way, while speaking of coffee, I am reminded that one of our firms the other day enclosed in their account to me a circular entitled "Particulars of Improved sieve-plates," and quoted prices! I read this precious missive very carefully, but it was like a message from the dead, a thing that ought to have been in my hands ten years ago. When tempted, as I was the other day, to accept R50 for a pulper which not so very long ago cost R700, to be now offered improved sieve-plates for the same kind of machine at R125 per square foot, seems very like joking on sacred subjects.

PEPPERCOIN.

PLANTING IN MANILA.

(Translated for the "Straits Times.")

Model Farm.—A telegram from the Colonial Minister has been received announcing that the royal sanction had been given to the preliminary operations following the choice of a site for the establishment of a model farm in the island of Luzon, within the province of Pampanga, at the village of Magalang. Within a few days, preparations will be made for starting this important agricultural undertaking.

Leaf Tobacco for Government.—The official Gazette has published the conditions under which tenders are invited for supplying Government with Philippine leaf tobacco, applications to be forwarded to Madrid. This notification bears out what we have asserted so many times, namely, that the Government has no intention to neglect a produce article of such importance, and that hence growers should not become discouraged, but on the contrary ought to set about, with greater confidence, planting operations to secure abundance of leaf tobacco of good quality. The 200,000 quintals, tenders as to which have been called for by Government, even through the price brought be only \$10 per quintal on the average, will when exported leave two millions of dollars in this country chiefly in the hands of growers, who can now, if they choose, freely part with their produce without the interference of intermediate dealers.

The Government hence protects its own work, that is, the beneficent work resulting in the abolition of the tobacco monopoly. The people of these islands should be very grateful to it therefore. It is notorious and well known to the public that discouragement has set in among those engaged in the tobacco business. But a calling for tenders of such importance as that we have announced will revive the market, and it may be said that the leaf tobacco shortly to be gathered in will not be sufficient for Government requirements, local consumption, and private exportation. Hence, then, it is necessary for growers here who may have land enough for the purpose, not to lose heart, but to sow their fields and look well after the plants, for the better the quality of their return the higher will be the market quotations. The abolition of the tobacco monopoly will, without fail, prove beneficial, unless growers here slumber while those elsewhere

keep awake. It will be inexcusable were the cultivation of this valuable product neglected in the Philippines, famed as they are from of old for producing tobacco of the best quality in the Far East, and were the Government and mercantile community obliged in consequence to have recourse to foreign ports in search of what should be available at home.

THE LABOURING CLASSES IN BRITAIN AND IN CEYLON.

(By an ex-Ceylon Coffee Planter.)

How often do we hear old Indians inveigh against the coolies and servant boys whom they were accustomed to have in the East? Their stealing propensities, their want of gratitude and their general behaviour, are sources of unending conversation for them, and I have oftentimes found myself in a woeful minority, when I have taken up the cudgels in defence of the absent Hindu. It is now my purpose to compare the working classes of Great Britain with those dark-skinned workers of India, and try to prove from my personal knowledge of the two classes, that the latter is the better after all. No doubt, every coffee planter has had his troubles with regard to labour-supply, and the petty jealousies and quarrels which went on amongst his coolies were, doubtless, sources of great annoyance to him: but we all have our little troubles of this kind, in whatever sphere of life we have a part, and the settling of disturbances in the cooly lines or smoothing down of jealous feelings are scarcely sufficient cause for a sweeping denunciation of a whole class. But it is the incorrigible wickedness of the Hindu that is always spoken about, and first and foremost of all their vices comes the one of kleptomania,—a vice that is supposed to reign paramount in a coolie's breast. I have known of many cases of coolies having committed theft, and I have taken evidence down in my judicial capacity, which would have been counted as conclusive by many, but, when the poor half-starved and shivering creatures, who as a rule represented the accused, pleaded hunger as a reason for their crime, I always felt inclined to lean to the side of mercy. I have been told of bungalows being broken into and robbed of parchment coffee taken from stores, and of many other instances of petty larceny, but I have never had my bungalow or store broken into, and so I can only speak of these things from hearsay. The bungalows of some planters are in a chronic state of being broken into, and it is possible that this may be accounted for by the fact that the planter is not altogether a favourite with his coolies and they do it for revenge. At one time, the district in which I was residing was visited by a gang of thieves, and one bungalow after another fell a prey to their marauding propensities. I daily expected that it would be my turn next, but, although I made no difference in the way of watching, I was never interfered with. However, before I had been long away from that estate, I heard that both the bungalow and the store had been visited by light-fingered gentlemen. This gang, however,—and indeed, I may say, a very well-organized gang,—of robbers in Ceylon consisted of Sinhalese, whose lazy habits have been so fostered by Government that they prefer stealing to working, and living in gaol to life in their own villages, for, in gaol, they have better food and a greater selection to choose from than they could possibly have in the villages.

Robberies that have come to my knowledge, and which had been committed by coolies, have as a

rule been very trifling and were evidently perpetrated more for the sake of supplying themselves with food than anything else. Their want of gratitude I admit to a certain extent only. They are always grateful to the hand that supplies them with rice, but, when the donor goes elsewhere, their gratitude is promptly transferred to his successor, and the former "durai" is blotted from their memory so far as gratitude is concerned. Yet I have met with many coolies who were grateful for any little attention I had bestowed on them during sickness, that I am fain to believe that theirs is a grateful nature if one can touch the right chord, and I have never yet known a coolie return a kind action by an ungrateful one.

Now compare this with the manners and customs of the working classes in the country at home. As a rule, the lairds and large farmers are a warm-hearted race, and ever ready to put their hands in their pockets to relieve their poorer brethren; in return for this, they are abused in public as well as private, and are spoken of as if they were grinding the working classes under their heels. In Scotland, there is, of course, no such thing as politeness amongst the labourers: they think that rudeness shows a fine, free and independent spirit; but in England one does find a trifling display of polish in the manners of the country labourers. As there is an exception to every rule, it would be unjust of me if I neglected to mention that, when travelling in one part of Scotland, in a parish called Huntly in Aberdeenshire, I conversed with every labourer that I chanced to come across, and met only with politeness, and a quiet yet straightforward manner. I mentioned the fact to a clergyman there, and asked him how he could account for it, and was told that it was all due to the schoolmaster, who was a gentleman and had inculcated his manner into his pupils, and that under the present school-board system the teachers often sprang from the lowest rung of the village ladder, and therefore failed to have and to hold the respect which they were entitled to from their pupils. Whether this is the case or not I am not in a position to say, but I give the illustration as I got it. One thing I do know, is that the child is father to the man, and that both child and man of the labouring classes here show a want of gratitude and a total ignorance of the distinction between *meum* and *tuum* that far outstrips the coolies on the estates of Ceylon. Both boy and man consider that they have a perfect right to go into private plantations and steal firewood or pull up young trees for decorating the halls of their Mutual Improvement Associations without leave from the proprietors. For the same reason, flowers growing in gardens easy of access are considered as public property, and the poultry fancier is lucky indeed who can bring up chickens or ducklings for his own table, they generally being confiscated by lads who, having passed the necessary standards at school, are free to apply their education to such noble ends. In my younger days, taking a turnip out of a field was considered a sin, but we now live in an age, when one's turnips seem to be public property, and when not only is it apparently thought to be perfectly legitimate to take turnips to eat, but also to throw them over the dykes for sheep travelling along the road to partake of, these sheep not being the property of the grower of the turnips!

My shooting extends to about 1,000 acres and my fishing to about two miles of river frontage, and, during the season, scarcely a day passes that I do not order poachers off the river, who know they are trespassing, and chief amongst these is our district constable, whose arduous duties seem to consist of poaching on my fishing ground and spooning on the post office girl! Poaching game was much indulged in before I came here, but I have an awkward

habit of getting up early in the morning, at the very time when the game poacher is busiest, and this has driven them to "fresh fields and pastures new": indeed, during the last three years, I have only twice seen evidence of the presence of poachers. A large farmer in Scotland, and father of a worthy Kandy citizen, told me that the Ground Game Act had been a curse to farmers, as it granted leave to their sons to shoot hares and rabbits, and they would do nothing else now, and this just led to worse, as the carts belonging to game-dealers went round the country and bought the game from these boys. Since I was told this, I have seen this evil in full swing, and I agree with what the old gentleman said, that a plague of rabbits is pretty bad, but a plague of no'er-do-weel boys would be much worse.

How often have I heard old planters—now farmers at home—say, that if they only had a gang of coolies, how differently would they get on with their work, and how much more pleasantly than with the stupid bumpkins that are nowadays turned out by the school-boards as farm servants—louts that have just been taught enough to make them believe that they are very clever, but have not received sufficient education to let them understand what utter idiots they are. There are still many of the old race of farm-servants to be met with, shrewd and hard-headed, but who have not been educated to any great extent beyond the three r's and it is a real pleasure to speak with any one of these, as they are so superior to the rising generation. When that old race of farm-servants dies out, it will be almost impossible to get their places filled as grieves, cattlemen, &c., the rising generation being quite unsuited for such work, they having never learned to supervise men, nor caring to make themselves acquainted with every work belonging to a farm. A coolie learns every variety of work connected with a coffee estate, but a farm servant only learns a few of the duties on a farm; he may attend to a pair of horses, plough with them or drive a reaping-machine with them, but could he reap with a scythe, shear a sheep, or milk a cow? Certainly not: he leaves the general knowledge of farming to the old school of labourers, and he is content with having passed the school-board standards and been shown the way to look after a pair of horses. These are the men who, going out to the colonies with large ideas of their own abilities, find themselves snubbed by the colonials, who are obliged to learn how to do everything for themselves, and who don't understand a man who can't put his hand to anything and everything, and so the deluded farm-labourer of the present day comes home again, and seeks to forget his colonial career in the more congenial work of acting the part of a machine, without any idea of why he is ordered at one time of year to take his horses and plough, and at another time to cart out manure: it is nothing to him the why or the wherefore, so long as he gets his pay, and that it is sufficient for him to indulge in a periodical spree. That is the farm-servant of nowadays at home, and any old Ceylon man that ever I met has agreed with me in thinking, that, for working, intelligence and gratitude, the Malabar coolie is decidedly the superior of the two.

COSMOPOLITE.

THE CEYLON BOTANICAL GARDENS: DR. TRIMEN'S REPORT FOR 1884.

Although in Dr. Trimen's latest report, there is nothing sensational, the contents show that good and useful work has been done, not only at Peradeniya, but at Hakgala, Henaragoda and away near the site of the ancient capital of Ceylon at Anuradhapura. Although the rapid rise of tea and cacao is recorded, and the bright hopes founded on "new products" indicated, yet reference has had to be made to the decadence of coffee under the accumulated ravages of fungus, grub and bug. The effect of the consequent prevailing depression is shown in the lessened sales of plants generally, while it is complained that at Hakgala extra expense is incurred from the necessity of renewing supplies of plants for which demand has ceased, but which may again be called for. Ceylon is now in the transition period from coffee to tea as the staple production of the island, and the sudden and complete giving-out of the old product over large areas in the Kandy and Matale districts, is this year a sore trial to many who hoped with the proceeds of sales of coffee to "plant up" their land with tea. Dr. Trimen's notices of the Morada and Verde Calisayas, as well of cinchonas generally, will be read with interest, while cacao in its varieties is exhaustively treated. If the enterprize of Ceylon planters has resulted in low prices for bark, such as in many cases cannot possibly remunerate the growers, there is such comfort as is available from the fact that humanity is the gainer by the large supply of quinine available at very cheap rates. The danger is that Ceylon planters will go ahead so rapidly as to bring about similar results with tea. Tea, however, is not a medicine, but a most useful and acceptable article of food, so that the danger will probably be averted: at any rate it is far distant. The meteorological returns from the gardens below the vast brow of Hakgala are very interesting, and, unless 1884 was an exceptional year as regards temperature as well as rainfall, we have strong proof of the superior geniality of the climate on the eastern side of the Nuwara Eliya table-land, as compared with the region to the west. As the result of very careful observations taken by the late Mr. Edward Hellic, a mean temperature of 65° was established at 4,600 feet altitude in Dimbula. Hakgala is nearly 1,000 feet higher (the difference between 4,600 and 5,581 feet being exactly 981), but the mean temperature of the loftier position for last year was only one degree lower than the mean of the Dimbula station. Between Dimbula at 4,600 feet with 65° mean temperature and Nuwara Eliya at 6,200 with 57° mean temperature, the fall is 8°, or at the rate of 1° for every 200 feet ascent. Or, to take the reverse: in going down from Nuwara Eliya to Langdale in Dimbula, a warmer climate is gained only at the rate of 1° for every 200 feet descent; but in going down from Nuwara Eliya to Hakgala a degree of heat is actually gained for every 90 feet of descent! The difference is very great, and no doubt it largely accounts for the success with which peaches and plums are grown by Mr. Cotton in New Galway, a district which lies close to Hakgala, but at a lower level and therefore still warmer. It would seem, however, that Dimbula has the more equable climate, in being less liable to extreme cold. In ten years in Dimbula,

TEA DRIERS: "THE CRY IS STILL THEY COME!"

We were one of a party who inspected an invention by Mr. Charles Shand for drying tea, which we agreed in terming an improved "Chulah," a horizontal flue being the equivalent of the numerous charcoal fires of former times. We intended to have written a full notice of the apparatus, but we must give the precedence to the details of mail news. One great merit of the new drier is its cheapness.

the thermometer only once went down lower than 45°, and then it was over 44°, in the month of March. But in February last year, Mr. Nock at Hakgala, recorded 43.5° in the shade and 34° on the grass in the same month. The maximum in the shade was 78.5° and in the sun 147°. The first portion of the year being droughty, the rainfall for the year was 75.24 inches on 196 days. We should think that when the weather of 1855 has been carefully recorded, fair averages for temperature, rainfall, &c., at Hakgala can be computed. The conditions of climate are very different to those at Peradeniya even, and certainly the opposite of those which prevail at Henaragododa and Anuradhapura. It is specially pleasing to hear of the success of the latter Garden, as persons condemned to live in the climate of the ancient city used every possible alleviation of their lot, such as the sight of luxuriant plants and beautiful flowers can supply. The rainfall at Peradeniya was only a few cents below that which fell at Hakgala, but the rainy days at the 1,600 feet station were only 115 against 196 on the mountain plateau. The Hakgala Gardens, which command so grand a view of the Valley of Uva, will, now that the railway has been opened to near Nuwara Eliya, be more than ever the resort of visitors, and we are glad to be assured, and indeed to know, that, under Mr. Nock's energetic management, the place is a credit to the colony, in degree only behind the romantic scene near Kandy of which Dr. Trimen is the presiding genius. Our readers will see that interchanges of plants and seeds have gone on briskly and that to the list of plants at Peradeniya large additions have been made, while the volumes in the Library have also been increased. We now know why the Ceylon *Helopeltis* has the distinguishing name of *Antonii*. It is named after Dr. Anton Dohrn, but why the first instead of the second name of that gentleman was chosen, except for reasons of euphony, we cannot say. We are also informed that cacao was grown at the Botanic Gardens at Kalutara in 1819 and that in 1834-35 Sir Robert Wilmot Horton (who had just declared the Indian rupee to be the equivalent of two shillings) obtained a consignment of the plants from Trinidad. Of course there is reference to the old narcotic and new anæsthetic coca or cuca, and it is shown that specimens of *Strychnos nuxvomica* growing in Ceylon are especially rich in the alkaloids from which the valuable medicine but deadly poison, strychnine, is obtained. Fruit trees are not forgotten, and altogether Dr. Trimen's Report will well repay perusal. We hope his next will announce a revived demand for trees, plants and seeds; and the establishment of a Garden at Badulla which the Government has too long delayed.

GOOD COFFEE CROPS IN UVA.

BADULLA, 30th May.—You will, no doubt, be glad and perhaps also surprised to hear that almost everybody in these parts is getting a great deal more than his estimate of coffee crop: in some instances indeed nearly double the estimate has already been attained and there is a lot more to pick. If coffee quotations were only at a decent figure, we might well exclaim: "What a day we're having." Many of the oldest and most experienced planters here have been altogether out in their calculations this season; the very severe attack of leaf-disease we had making it extremely doubtful if half the crop would ever arrive at maturity. The mistakes in estimates being on the right side, however, one is likely to raise an outcry about the error. Agents and proprietors might object to a superintendent estimating 10,000 of parchment and getting 5,000, whereas they would not be likely to

make any unpleasant remarks if the superintendent estimated 10,000 and cured 15,000; and yet he would be equally wrong in the latter case as in the former and quite as deserving of censure. I wonder what the feelings of those people are now who have been cutting down good bearing coffee to make room for tea. "Coffee ain't dead yet, and so I tells yer." Afternoon showers have been prevalent during the last fortnight, and one day recently a rather severe thunderstorm was experienced, which, however, was only of very short duration.

HOW LIBERIAN COFFEE WAS FIRST INTRODUCED INTO CEYLON.

[From a letter addressed to a London correspondent by the late Mr. John Gordon.]

London, 27th November 1878.

You may have been reading in the papers from time to time the history of the Liberian coffee without perhaps being aware of the trivial circumstances which first led to its introduction into Ceylon: it may not therefore be out of place if we give it now.

In 1866 there was a ship captain who had been on a trading voyage along the West Coast of Africa, who thought if he had some copper coins to trade with he could do so much better than by barter. He therefore called on Mr. Gordon (late of Ceylon) and spoke to him with reference to having some copper coined. While in Mr. Gordon's office the captain saw there a number of small sample bottles of coffee, when he remarked that at one place where he had gone ashore he had seen two coffee trees growing side by side, in the jungle, one of which was a large tree with the berries on it like small English plums. The other tree was entirely different and grew smaller berries. Gordon asked the captain for a few berries of both sorts, which he gave him. Mr. Gordon was greatly surprised at the large-sized beans; the other coffee was about the usual Ceylon size, but different in this respect that about seven-tenths of the berries had three beans in each cherry, in place of the usual two.

Gordon did not think much of this latter coffee, but sent some of the large beans to Mr. Massey in Kandy and set about obtaining a quantity of the coffee seed from Liberia to forward to Ceylon, but, owing to the Civil War and President Ray's death, the seed was not obtained for some years. When Gordon succeeded in getting eight bushels of parchment coffee, he packed it in powdered charcoal in old flour barrels and sent it out to Mr. Tottenham, who unfortunately had just left Ceylon for a trip to Borneo. The casks lay for several months in the Customs House at Colombo until his return, when he had it plauted. Owing, however, to the coffee having become too much dried from the absorbing nature of the charcoal, not a single seed of it grew.

President Roberts brought him an open box of coffee plants which he presented to Mr. Gordon, who sent them to Mr. Tottenham. The weather being rather cold at the time of the plants' arrival, and the steamer for Ceylon not sailing for ten days, Mr. Tottenham took the box of plants in a cab to Mr. Bull's hot-house where they remained until the departure of the vessel. (Two leaves from the plants in this box are still pasted against the wall in Mr. Gordon's office.) This was the first time Mr. Bull had seen the coffee. In 1872 Gordon had two warlike cases with plants, and cherries, in the earth, and these were also sent to Mr. Bull's conservatory until the steamer was ready. These plants were all sent to Mr. L. St. George Carey to whom Mr. Tottenham had sold his estates.

Although Mr. Tottenham paid the greater part of the actual expenses, Gordon states that he is still out of pocket by the introduction, and, as the Government

has had a good pull out of the sale of otherwise useless land, it would seem fair that they should give the introducers of this new product some compensation, as an encouragement to others to introduce plants.

Mr. Massey has stated that he had sent the editor of the *Observer* some of the first beans, so he, and Mr. Massey could prove the introduction years before Mr. Bull or Kew Gardens knew anything about the coffee. Mr. Bull considered each of the wardian cases and plants worth over £100. Mr. Gordon had about £6 for them, which was the bare cost of charges. Mr. Gordon was not charged for the plants, nor did he make a claim for them on Mr. Tottenham.

[John Gordon is now no more, and we believe he left his widow and family well off, the foundation of his competency having been laid in Ceylon.—Ed.]

CINCHONA SUCCIRUBRA IN UVA. TEA GROWING SPACE IN MADULSIMA.

31st May 1885.

CINCHONA.—Five acres one rood 20 poles planted in 1878-79 and 1879 80:—

June 1883.—The clearing was shaved and gave 1,536 lb. of original bark which sold locally at 51 cents per lb.; analysis being 1.65 C. S. of Q.

February, March and April 1884.—The clearing was shaved and gave 1,851 lb. renewed bark and 390 lb. original bark. Renewed sold locally at R1.0261 cent, and original at 25 cents per unit, analysis being 3.31 and 1.11 respectively. The drop in the analysis of the original is owing to the fact that some very young trees were shaved this year and the bark from the clearing not kept apart.

In 1884-85 (season current) the clearing has been coppiced leaving sufficient trees standing to make a good cover to the ground and the result is

Quill	2,659 lb. wet.
O. chips	3,283 " "
R. chips	8,679 " "
Twig	4,353 " "
O. shvgs.	520 " "
R. shvgs.	639 " "
Twigs	52 " "

20,235

At 33 per cent 6,743 lb. dry bark.

33 per cent is the actual output of all bark dried at this date. Sales and analysis of this season will be sent on completion of the necessary statistics.

[The correspondent who sends us the above, remarks:—"I send you some particulars of cinchona succirubra in MadulSIMA. I think the result is satisfactory, to say the least. I hope my tea will some day do as well. I am certain that we can grow very fine tea in Uva, and have seen some very lately 2' 6" high at one year old planted on patana soil. If we had been sending our produce to Colombo by rail for the last five years, we should never have heard the name of distress in Uva, and the whole district would have been a monument to the man who had given the word to extend to Badulla. Would that it could have been said of the Governor of that year: "*Si monumentum queris circumspice!*""]

REPORT ON THE GOVERNMENT CINCHONA ENTERPRIZE IN JAVA FOR THE 1ST QUARTER OF 1885.

(Translated for the "Ceylon Observer.")

The past quarter was marked by much heavy rain. Whilst as a consequence of this planting could be carried on without cessation, in respect of other branches of work some delay was experienced on account of the

continuous wet weather. At the beginning of March several storms were experienced, which caused a little damage to plants and nursery-houses, especially at Nagrak. The product of the harvest of 1884 was dispatched to Batavia in bales and chests at the end of the quarter. A total of 400,236 half-kilograms was gathered, of which 394,663 half-kilos were reserved for sale in the Netherlands and 5,573 pounds for the local military medical service. On account of the continuous wet weather a very small quantity of bark was gathered during the past quarter, which still lies stored in the packing-houses. The supply of labour was very large, so much so, that in conjunction with the managers of private estates in the Bandoeng and Tjitjalengka divisions the wages were reduced 20 per cent. The diminution of wages was applied only in the case of coolies and newly engaged fixed bondjangs, and was not attended with the slightest difficulty afterwards. On 18th Feb. a sale of cinchona seed took place under the Government order. The prices obtained were on the whole pretty high: for a small lot of Ledgeriana seed from the plantation of grafts and cuttings at Tirtasari as much as J750 per gram was paid. The total netted was f1,463.75. A portion of the 1884 crop, viz. 1,112 bales containing 78,725 kilograms, was sold on 4th March by public auction at Amsterdam, realizing an average of J064 per half-kilo. The markedly low price given for the portion sold is to be referred to the large proportion of inferior bark of which the 1884 crop consisted. Now that the bark of young branches and twigs is no longer gathered, it is to be expected that the average prices will gradually rise in a corresponding degree. The plantations from which in 1884 and 1885 inferior varieties like *C. Josephiana* and *C. Calisaya* have been rooted out were during the late west monsoon planted with *C. Ledgeriana* and partly with *C. succirubra*, whilst the graft plantation at Tirtasari was largely extended. The plantation now consists of about 78,000 grafts and 7,000 cuttings, occupying an extent of about 40 bouws. In the nurseries at Tjijirocan are about 25,000 more grafts, a portion of which are to be planted out during the prevalent rain in the second quarter of this year. The plants have during the last three months made a vigorous growth chiefly as a result of the thorough working of the soil carried out last year, and promise to yield a large harvest in 1885.

VAN ROMUNDE,

Director Government Cinchona Enterprise.

Bandoeng, 7th April 1885.

THE INDIAN TEA CROPS, ESTIMATED AND ACTUAL: OUTTURN FOR 1885-86.

From the interesting report by William Moran & Co., which we reproduce in our commercial column, it will be seen that for 1884-85 the estimated outturn of tea for all India, was 66,664,000 lb.; the revised estimate reduced this quantity to 62,514,000 lb.; while the actual outturn was 63,414,000 lb.

The estimate for 1885-86 is more than five millions of pounds in excess of these figures; but the requirements of India and exports to Australia and other places will reduce the supply for Britain to about 65,000,000, a quantity which, judging from the increased figures for monthly consumption and the lowness of stocks, is certain to be readily absorbed. There had been an increase of more than a million of pounds in the average monthly deliveries for 1884 against those for 1882, the comparative figures for three years being

1882	...	4,322,000 lb.
1883	...	4,538,000 "
1884	...	5,444,000 "

An average not higher than these last figures would more than exhaust the 65,000,000 lb. So that all Ceylon can add to the production of India is likely to go to a good market. An improvement in prices

is needed, the averages per lb. for the three years being, for

1882 ...	annas	8 7
1883 ...	"	9 11
1884 ...	"	8 6

An average of a little over 8 annas, or considerably under one shilling per pound is certainly the reverse of remunerative. It depends, of course, on the cost at which tea can be produced. We in Ceylon have many advantages, over the remoter districts in India, but we suspect very little of our tea is sent to market at a cost of less than 30 cents or a little under 8d per lb. There is talk of 25 cents, but few and far between are the cases where that sum has sufficed. There is a good margin, however, between 8d and 1s per lb.

If Ceylon planters do not make the very best possible tea, it will not be for want of good advice. But can any reader tell us what Messrs. Moran & Co. really advise as to the process popularly known as "fermenting"? First they say "a full fermentation should be given," but they add "it is safer to under than over-ferment." "Brisk but thorough firing is recommended," and yet Ceylon planters are charged with burning their teas. The cases, however, in which the brokers report "leaf burnt" are very rare.

SUGAR PLANTING IN MAURITIUS.

(From the *Mercantile Record and Commercial Gazette*, May 11th.)

THE WEATHER AND THE CROP.—Since our last, the weather has continued favourable in certain parts of the island, to the young plantations. But there is every reason to suppose, as we already stated, that the out turn of the crop 1885 to 1886, will not be equivalent in quantities to the one of last year. The depression on our sugar rates is always causing great anxiety, if the market does not improve, the cost price of our staple will no doubt leave a serious loss. It is high time that Government should take in hand the interests of our planters, nothing has yet been done in that respect, if our authorities are really desirous of helping the planters to get out of the present crisis, they must, at once, improve the labour law in order to put a stop to vagrancy and more particularly to absenteeism on sugar estates.

THE GOLDEN FRUIT.

(*Reis and Rayget.*)

In a pleasant article, to which an appropriate adaptation from (if we mistake not) Herrick gives a delicacy of literary flavour, the "Ceylon Patriot" exposes the myth of the Coffee *Eldorado* in the Island, and anticipates the same collapse for the tea mania. The account of Great Expectations and their discredit—of the facilities for extravagance from blessed Paper Credit and the consequent demoralization—have more than a passing local interest. The following is the way of all money-making mania, with the necessary variations from the nature of each industry:—

"When the Central Province became known as adapted for coffee, and when a few, as planters and superintendents, lived as if money was of no consideration, drawing their income from their agents, King Coffee was thought to be a fairly Sovereign who was willing to use his wand, at the beck and command of every man, who called himself his subject. So gorgeous was the picture of future wealth, that even the natives thought, that to be conductor on an estate was to be on the high road to wealth. The kangani also when he went to his country told his friends, how they could gather rupees under the coffee bushes, and as a tangible proof of his assertion he freely distributed a few rupees out of the heavy advances he received from

this master. Now while conductors have earned a competency, and kanganies and coolies could boast of lands and fields in their own country, while carpenters from Moratuwa have been able, by working on estates to become well-to-do, and while Chetties have grown fat on rupees, it is a fact, which cannot be denied, that take it all in all, on an average, very few of the planters have been able to feather their nests, and retire from business with something substantial. The reason is not far to seek. Paper money and the facility of obtaining things on credit have been the bane of the coffee planters. A *thandu* to the Chetty, an order on the shop, and a promissory note at the bank, made him think that money was cheap as pebbles, and luxuries as the *sine qua non* of every day life. This was not found fault with, because there was the prospect of future bumper crops; and for the time being King Coffee yielded quite enough to keep a man out of the bankruptcy court, and enable him to make a flash in the pan, which maintained his credit abroad. If he returned to England he lived for the six or seven months he was out on an holiday, as he was an Eastern Prince. So glowing was the picture he drew of fortunes to be realized by investment in coffee, that there was no difficulty in persuading those who were looking for good investment to launch out in lending money on mortgage of coffee property. He then returned to Ceylon, with another feather in his cap, with greater facility of raising money, and what he counted upon as resources was paper credit: and that did not trouble his mind: for he had nothing to pay with; nothing to lose: but if king coffee was generous as good dame Fortune he had every thing to win. Then followed the gradual decrease of crop. We say gradual, advisedly. This induced the use of various kinds of manure, which made the trees precocious, and brought about for the time being a large produce to stave off heavy losses and insolvency. Till at present coffee is well nigh dethroned, and his greatness is the memory of the past and a matter of history."

The above ought to act as a general warning to planters and speculators on both the Continent and the Island. The same cause is at work in many of our Indigo concerns, specially since the protection to the peasantry has dried up the former illicit sources of profit of planters. The same acting doubtless with other circumstances, has been the ruin of the tea industry in Bengal and Assam. It would appear that the same path is being pursued in Ceylon with respect to tea, which has there taken the place of coffee. The result may be easily predicted.

Our contemporary seeks to create a diversion. It depreciates the prevailing devotion to the ambitious culture of coffee and tea, and offers a sober yet far from unpromising alternative. It recommends a falling back on a cultivation to which the soil is adapted and for which the island has been famous from of old namely, coconut. Our insular brethren should seriously consider the suggestion. Coconut is a tedious cultivation, but it is easier and less costly than tea or coffee and its ultimate success is not so problematical. The soil suitable to it is, of course, different from coffee or tea soil, but probably many estates have both kinds and in that case it might be worth the while of the owner, to grow both sorts of produce, so that the uncertainties of coffee or tea might be balanced by the tolerable certainty and moderate profitableness of the cocoa palm. Whatever the vicissitudes of the more ambitious culture, an estate with a goodly plantation of young coconut trees would always command a good price.

We would make the same suggestion for India. In fact we notice this extra-Indian subject so prominently at this length, in order to direct our readers' attention to the advisableness of promoting this substantial culture. Coconut is out of the question for the

hills and highlands where tea is grown. But many of the Indigo concerns in Lower Bengal are within the coco palm belt. The ambitious planter may deride it as a poor idea, but there may be prudent and astute men who might seriously consider the profitableness of having coconut nurseries in the neighbourhood of their factories and plantations on their estates. We especially commend the culture to natives to whom it is in every respect better suited. It is most lamentable to see this fine productive resource of the country unutilized. While so many of the respectable classes are pining in want, while our educated young men are crowding the professions and the ordinary spheres of employment to the detriment of those already in them and to their own disappointment, while multitudes besiege a single vacancy, here is actually a royal road to riches absolutely neglected. We say royal road, because success is certain and on the easiest terms imaginable. Wealth perhaps may not be open to all, being a question of capital, but with ordinary outlay and skill and industry, such as most may command, a more than fair return and even competence may be assured. We pretend to no discovery, the thing ought to be well known. The coconut is one of the oldest of indigenous plants. It is everywhere about us, specially in the maritime fringe. It is, within its sphere, found in numbers in every homestead—its most striking object and cherished monument. It is, on the face of it, a substantial valuable tree. For that matter, it is unique. It is invaluable—absolutely and entirely valuable—useful in the highest degree in every feature and belonging of it. It does not very much trouble, scarcely ever deceives, the loyal cultivator, for on the right soil it is sure to grow without solicitation and does not want delicate nursing, and it almost never disappoints the merchant or tradesman, as it keeps for ever and a satisfactory sale is only a question of time. In fine, it is the best provision for a rainy day in the agricultural career. Our unemployed youth without professional training could not do better than beg, borrow, or steal some little capital, and plant a few acres of coconut.*

PLANTING IN DELI.

(Translated for the "Straits Times.")

Sprcad of Plantation enterprise.—A few years ago plantations in the Battack country inland were only few in number, but the tale of them both in Deli and Langkat has now greatly increased, there being every prospect that further advance by Europeans in that direction is only a question of time, and that the opening of tobacco estates in the Battack country will take place in all directions wherever the soil is in any way suitable for it. By comparing previous surveys of the Deli district with those lately carried through by the topographical office as set out in a map now readily obtainable by the public, this forward movement becomes more evident. This peaceable annexation goes on so slowly but surely that probably, before ten years shall have elapsed, the green mountains at which we had so longingly gazed from the coast will no longer be a closed book. By that time, European cultivation will have reached them, and a fertile country will in a lawful manner be brought under the Netherlands' sceptre. Already at various places the so-called independent Battack boundaries have been, if not crossed, at least reached, though the authorities *pro forma* have only granted sanction to land contracts bearing upon districts where the Sultan of Deli or the Pangeran of Langkat

enforce claims or exercise dominion. Soon, however, this will no longer prove sufficient, and then the turn will come for contracts with which the Malay rulers have nothing at all to do. The Government may now look upon this as undesirable, and withhold as long as possible its sanction to such contracts, but even this reluctance cannot be carried beyond certain bounds; and, when once the inclination and the need for extending colonization become too great, it must give way. Difficulties and differences between the natives and European settlers will not be wanting at the outset (such things have taken place everywhere); but in this case they might be greatly obviated by Government taking action in time to favour settlement."—*Deli Courant*.

The European residents in Deli are 500 in number, many of whom are planters.

At a meeting of the Deli, Serdang, and Langkat Planters' Association held at Medan, on the 23rd March, it was decided to fix by way of trial from the 1st June to the 1st November this year, the fee for Sinkeh coolies delivered on the estates at \$50 each owing to its having risen so enormously of late from competition among planters when the labour market was badly supplied, as to bid fair, unless checked, to amount to \$100 per coolie.

"We may add to our previous statement about a German Consulate in Deli, the intelligence that, yesterday, by French mail, Mr. F. Keding received a notification of his appointment to fill it, so that he only awaits the *executur* of the Netherlands Government in order to enter upon the duties of his office.

"The severe drought which has been experienced here also for a couple of months, which has hindered the putting out of young tobacco plants on many estates and also did great havoc among the seedlings, appears to prevail along the whole coasts and more severely even than here. In Assahan, the patty crop has proved a total failure, so that the exportation of grain has been forbidden, a striking contrast to former years when Assahan exported sometimes ten thousand gantangs to Penang, contrary, however, to the rumours current thereabout in the Straits, the state of health here generally is satisfactory, and there is not the least truth in the assertion that cholera is prevailing epidemically."

The running away of coolies from estates is becoming unusually frequent this year. Both in Deli and Langkat, several planters are complaining heavily of it, without any of them being able to find out what the true cause is. The blame may partly be laid on the continually dry weather, for having made the Chinese in consequence sick at heart and impatient; but this cannot be the only cause, because absconding takes place on estates where field work is not in such an advanced stage that the continuous drought need cause uneasiness. We rather prefer to account for it by what we lately heard brought forward, namely, that the runaways are helped to abscond by confederates of the Penang brokers. The excessively high fees paid of late for coolies at Penang naturally tends to encourage kidnapping. We moreover believe that supervision over departing Penang steamers is not so strict as the Planters' Committee fancy. During the illness of the Captain in China and his stay at Medan, his sons of it repaired upon country. In our opinion, their absence resulted in supervision becoming slack. It would also be desirable were the planters to pay greater heed to the returning of the discharge passes of those coolies who leave the country. A regular trade in these passes is carried on in Labuan Deli.

* See "All about the Coconut Palm," published at the Office of this periodical.—En,

THE PROSPECTS OF TEA.—An old planter writes:—"There is no doubt about one thing, and that is that there are thousands of acres of tea being planted in Ceylon quite equal to if not superior to show-places, Mariawatte. Another fact is that tea is most remunerative at 1s sterling per lb. all round in London with a good margin for a fall in price."

THE CINCHONA ENTERPRISE IN JAVA.—The latest report (translated for our planting column) is a great contrast to the *couleur de rose* statements of former years, the twig bark even of Ledgeriana sharing in the general depression and selling at a price unprecedented for lowness. Hard times in Java, it will be seen, had had the effect of rendering labour plentiful and cheap.

COCONUT PLANTERS are bewailing the shortness of their crops this year as well as the bad prospects for next year that they have to look forward to. Two successive years have told heavily on the trees in the Western Province, and old and experienced coconut planters tell me that they do not expect to get $\frac{1}{2}$ the crop that they have hitherto picked from their respective estates. On some estates no rain fell for fully four months, thus causing all the blossom to fall and not allowing the same to mature.—*Cor.*

MARIAWAITE NEW TEA FACTORY is like'y, when ready, to be the most complete in the island if not in the world. The machinery (all Jackson's Patents, Rollers, Drier, Sifter, &c.) is to be driven by a 12 horse-power Marshall's steam engine, now on the way out. There is no lack of fuel for machinery or drying, around Gampola, but it is pointed out that where timber is scarce in Ceylon, dried grass can be readily got as in many districts in India where grass is regularly used for the driers. Our manna grass dried and stacked ought to be very useful for tea-drying.

RORAIMA "THE MYSTERIOUS," which has at length been fully explored by Mr. Im Thurn, is the subject of an interesting paper by Mr. H. J. Perkins (who accompanied the explorer) noticed in *Nature*. The falls must be magnificent, the Kerkenan river, which rises in the mountain of the same name descending from the summit in a splendid fall of 1,300 feet. The rain water on the top of Roraima rushes over the side of the enormous cliff in magnificent "cascades" some of which have a clear fall of 1,500 feet! Roraima plateau was found to be 8,600 feet above sea-level.

BRITISH COLUMBIA.—What traffic will the Canada Pacific line have in this country? In the opinion of many who know the country there are few—if, indeed, any—districts of the size of British Columbia for which the amount and diversity of its natural resources promise a more prosperous future. Its coal-beds produce fuel that is generally acknowledged to be the best on the whole Pacific slope, a circumstance amply corroborated by its large export to San Francisco and other American ports. Of the timber wealth it is not necessary to speak, for British Columbia has today by far the largest and by far the finest forests in the world. Its fisheries are finer than anything on the east coast of America or in Europe, while what good judges pronounce to be perhaps the most important of its resources—that is, its minerals—deserves very much more attention by capitalists than it has hitherto received. The extent of its agricultural land is limited, but what there is is usually of the most productive alluvial character. Its grazing areas are limited to certain districts, where excellent bunch grass and a mild winter climate prevail. In a few valleys, such as the Upper Kootenay valley in the attractive Kootenay district, through which the Canada Pacific is now being built, there is a rare combination of both these kinds of lands. And withal the whole country is one where life is not made unpleasant by extremes of temperature.—*Pall Mall Budget.*

SALE OF A COFFEE ESTATE.—Sir James Gordon, your late Resident, has at last found a purchaser for his coffee estate on the Nilgiris, known as Glenburn. The estate is 91 acres in extent, all coffee in full bearing and realized 20,000 rupees, a third of the price asked a year ago for the property, and a little more than a half of what was wanted a few months back. The average crops were given at 16 tons, which was the estimated outturn of the crop for 1884-85, but up to the end of April the coffee didn't ripen, and was not off the trees when the estate changed hands. The industry all over the District is greatly depressed and the agencies refuse advances. It is not surprising therefore to find that properties quoted at high prices a short time ago are going a begging.—Ootacamund correspondent of *Bangalore Spectator.*

MR. ARNOLD WHITE ON ADULTERATION AND EMIGRATION.—This versatile ex-Ceylon planter whose name is not unknown in the Rakwana and Balangoda districts, after being Secretary to an Electric Light Company in London, has now developed a new career as a social philanthropist—a seeker-out of the nomad poor in the East of London and a controversialist with Socialists. In the former capacity, Mr. White has contributed an article to *May's Contemporary* in which the planter comes out in his demonstration of adulteration, thus:—"To take but a few instances: legalizing the sale of a mixture of coffee and chicory has not reduced adulteration of these commodities, for the coffee is half-ripe or insect-eaten, 'tails' blended with 'finings,' and the chicory is fortified with beans, lupin seeds, acorns, 'lambro' powder, mangel-wurzel, and spent tan; and the most obvious proof of adulteration is, that the coffee is sold retail in London at a price at which it cannot be produced on his estate by the coffee-planter. A pennyworth of tea, as purchased by the poor in many small East-end shops, does not contain one leaf. It consists of floorstuf, the sweepings of inferior teas, China clay, fine sand, and spurious leaves of 'Ma-loo' mixture. Bread in the East-end has some peculiar characteristic well worth the notice of a philanthropist."

TEA WITHIN 25 MILES OF COLOMBO.—I visited Dumbarton estate, Henaragoda, some weeks back (I think it was about a fortnight back) with two friends and was most courteously received by the resident superintendent and his son. I had not seen this place for some time, and was simply astonished at the marvellous change that has taken place in the aspect not only of the estate itself but its bungalow and its surroundings. Liberian and cacao were rapidly giving place to tea, and tea was actually being manufactured on the estate. I did not like to enquire, but I certainly think it must be from trees under two years in growth, as I have visited the estate before and my visit previous to the last could not have been so far back as two years ago. One of my companions is one of the most fastidious gents I ever came across as regards what he eats and what he drinks. He had long since eschewed tea, has become a great coffee drinker, is a great authority on the best mode of grinding coffee, has his own opinion of Dr. S.'s ground coffee as sold by a leading Company, carries a patent coffee pot, one of Walker's best, his own coffee, and lastly makes his own coffee. He had not tasted tea it appears for years. We reached the estate at about 10 a.m. having started from Henaragoda rest-house, and after a walk round the estate went into the bungalow and were there given a cup of tea made out of the estate produce, and I can assure you each and all of us, including our "fastidious" friend, the great coffee-drinker, pronounced the tea really good. We felt so refreshed after it that we walked a good distance back on our return to the resthouse and each and all made up our mind to buy nothing but "Dumbarton" tea in the future. So, not informing you as to the proprietorship of the estate, I beg you will be so good as to inform me where "Dumbarton Tea" is to be got.—*Cor.*

THE "TROPICAL AGRICULTURIST" in all its volumes has been added to the College Library of the Royal Agricultural College, Cirencester.

"THE FERMENTATION OF TEA," writes Mr. John Hughes, "is indeed a most important subject, but I think, like the analysis of *Silage* (which is attracting so much attention in this country), it should be investigated locally. Fermentation in hot climates proceeds so much more rapidly than in temperate zones."

CEYLON TEAS IN LONDON.—A gentleman in the Tea Trade writes from the Lane:—"London, 8th May.—Since my last letter to you a large quantity of Ceylon Tea has been brought to auction and mostly sold. Our market still remains in a firm condition, especially for the finer grades, which have been well competed for. An invoice from the Hardenhuish estate has shown decided improvement both in style and liquor, the teas being something similar to those from the Loolcondra estate. A shipment from the Oliphant estate (which I gather from the *T. A.* to be one of the most elevated in Ceylon) was sold this week, but the teas were greatly deteriorated in value by their being over-fired; this over-firing is still to be noticed in a large quantity of Ceylon Tea."

THE DEATH AND ELLWOOD MACHINE IN JAMAICA.—The trials of fibre cleaning machines, conducted by a committee appointed by the Government of Jamaica have concluded, and in a recent number of the *Official Gazette*, we find a copy of the committee's report on the working of the machine. It differs from that of the Calcutta committee, and this is doubtless due to the presence of Mr. Death himself in the one case, and the want of anyone expert in the use of the machine in the other, for this Jamaica record is by no means satisfactory. Thus we find that from 310 lb. of green pineapple leaves, only 25 lb. of wet fibre, or 8 lb. of dry fibre were obtained in 7 hours 20 minutes; from 488 lb. banana stems, only 34 lb. of wet fibres, or 6½ lb. dry in 2 hours 20 minutes; from 247½ lb. rhea stems, 13½ lb. wet, or 4½ lb. dry in 4 hours 12 minutes. Similar results were obtained in the case of other fibres, and the committee express their regret that they are so far below what they had been led to expect. We understand, however, that the General Fibre Company will shortly send out a representative to the West Indies to demonstrate what the machine can do when properly handled.—*Planters' Gazette*.

PLANTING IN TAVOY, BRITISH BURMA.—Mr. Jas. D. Watson writes:—"I am quite well and jolly, and products are flourishing nicely. I send you a photograph of my estate taken by Mr. A. H. Loansdale, head-master of the Tavoy school; also one small photo of a coffee tree in full bloom taken by our energetic Deputy Commissioner, Mr. C. J. A. Dube: it will remind you of the good old times in your lovely island, Ceylon. I am now busy felling again for cocoa, tea and Liberian coffee. Have fine nurseries, and plants splendid, rank and vigorous. Fine rains this season: January rain, February rain, March rain, and we expect in April about middle." The photographs have duly come to hand and that of the coffee tree in flower should be a cure for "sore eyes" to an old coffee planter, so grand is the display of blossom. The view of the "Model Duke Estate" gives us a glimpse of Liberian coffee and other products backed by abundance of vegetation with buildings peeping out at one or two points. The worthy manager and a kangani come out all. We have a long report in the printer's hands from Mr. Watson, who, as the planting pioneer of Tavoy, is practically demonstrating how model estates should be formed.

JAMAICA AT THE NEW ORLEANS EXHIBITION.—We learn from Mr. Morris, that, besides making a large and attractive exhibit, Jamaica bids fair to open large trade relations with New Orleans, and one of his chief duties, successfully accomplished, was to get the quarantine regulations against Jamaica which have been in existence for nearly 30 years removed. Mr. Morris adds:—"We have vindicated the climate and sanitary conditions of our island as being the best in the West Indies, and hence we shall have unrestricted trade with the Southern States of America all the year round. This will have a great effect upon our fruit trade and smaller industries, and it is really in these just now (in the universal depression which has overcomes our larger industry) that our true safety lies."

TEA BOXES FROM JAPAN.—Mr. H. D. Desane of Maskeliya has made good use of his time in a holiday-trip to the Far East, to judge by the following extract from a letter received from him:—"Yokohama, 23rd April.—Of our travels, I have but little time to write, but you may be sure we are having a very jolly time of it. We stayed a fortnight at Hongkong, two days at Canton, a week at Kobe and Hiogo, two days at Osaka, a week at Kioto, doing from there Lake Bewa-ko and the rapids, and we shall stay here and at Tokio &c. until the mail after this, when we return to Ceylon. I believe I have been able to be of use to Ceylon tea-planters in that I have managed after a lot of trouble to arrange for an unlimited supply of well-seasoned tea boxes of cedar and pine-wood: the rates at which I can place them in Colombo I enclose on a separate memo:—
Cost of 1,000 tea boxes 19 × 16½ × 16½, to hold 60 lbs.,
to 70 lb delivered in Colombo at ... R555 00
Plus Colombo charges and duty, say 5 per cent 2 75
Plus, say lauding and brokers' charges 5 per cent 2 75

Boxes about ¾-inch thick dove-tailed and packed
in shoeks, of best seasoned wood ... R560 50

Cost of 1,000 tea boxes 17 × 14 × 15, to hold 35
to 45 lb delivered at Colombo at ... R500 00
Plus Colombo charges and duty, say 5 per cent 2 50
Plus, say lauding and brokers' charges 5 per cent 2 50

Boxes above ¾-inch thick dove-tailed and packed
in shoeks, of best seasoned wood ... R565 00
I will bring samples with me by next mail. The quality of the boxes is A1, better than ones in Ceylon in every way: they are dove-tailed by machinery by a system called the "lock-hook," which is so much stronger than our old system that no nails except those used for hoopironing will be required, and they are so beautifully made that no planing is required on the estate, both the sides, tops and bottoms fitting together exactly. I cannot tell you what the lauding charges will be in Colombo, but I have in my enclosed estimate allowed 10 per cent for duty (?) and landing and brokers' charges. [The Government might well forego duty on an article calculated to benefit a rising agricultural industry.—E.D.] The larger boxes measure about 7½ tons of 40 cubic feet to 1,000 boxes and the smaller about 6½ tons; but in any case the charges on this side as far as Colombo are correct, and I shall be able to deliver the boxes at Colombo (the purchaser to pay lauding charges) at R555 00 per 1,000 on the larger sizes or 55½ cents per box, and R500 per 1,000 on the smaller size or 50½ cents per box, provided each order be not less than 50 tons, for which measurement I have obtained special rates of freight—the sizes of course can be altered if desired. I at present give the sizes for which the machine is set to cut." [We give Mr. Deane's experiment the advantage of an advertisement because he has personally visited Japan and taken trouble to bring a new article to aid our planters. As in the

case of the "jinrickshaws," we do not see why local makers should not copy this Japanese pattern when it is fully introduced, that is if generally approved of. We hear deplorable accounts of the state of the carpenters of the Moratwa district for want of work. Have they begun to try their hands at "jinrickshaws," the use of which is extending upcountry, or at tea boxes?—Ed.]

NEW ZEALAND FLAX.—It will interest colonial botanists to know, that a very fine specimen of the plant *Phormium tenax variegata* is blooming in the conservatory at Castle Hill House, Huntingdon, the residence of the Ven. Archdeacon Vesey. The specimen is in a No. 2 pot (15½ inches in diameter). The flower-spike is already 12 feet high, and seems likely to reach another 2 feet. The spread of the beautifully-striped leaves is 13 feet, and altogether the plant forms a striking object in an angle at the garden entrance to the conservatory.—*European Mail*.

TEA PROSPECTS.—Commenting on the future of the tea market, the *Grocers' Chronicle* says:—"We have examined into the prospective supply and carefully considered the figures as far as they are known, and our investigation leads us to the conclusion that the total crop of the year is about four millions of pounds in excess of last year. New Zealand, Australia, and America have taken about one million in excess of last season; and the S. S. "Justitia," which was lost had about three quarters of a million on board. So that as nearly as possible the excess to be expected in London over last year is about 2,250,000 lb. The deliveries have been 8,000,000 lb. greater than last year, and the good pieces ruling here for the last two months have tempted importers to put up every chest they had for sale. So that the unsold part of the crop now in dock is only about 4,000,000 lb. against 14,000,000 lb. this time last year. Some authorities say that at this time last year there was not so much as 14,000,000 lb. remaining; but from the 15th April, 1884, to the end of the season, 160,000 packages were catalogued for sale; and allowing each package to average 90 lb., we incline to regard our statement as quite within the mark. Of course, as long as the market is so well supplied as it has been for the last ten weeks (during which time 40,000 chests more than last year have been sold in sale), no scarcity is felt, but as soon as the four millions yet to be sold are cleared off, there will be rather a want of occupation for the noble army of tea-tasters in Mincing Lane. Perhaps, therefore, the active desire to get hold of as much tea as possible is, after all, not far wrong, although the prices paid for some lots this week in our judgment could scarcely be justified on any other grounds.—*Home and Colonial Mail*.

TEA TAXATION.—Nearly simultaneously, at both ends of the longline over which it travels, tea has been threatened with increased taxation, owing to financial exigencies caused by war. The alarm has proved a false one, so far as London is concerned. The protests of teetotalism and the free breakfast table have prevailed; and Mr. Childers has sought other sources of revenue, and those interested in the leaf are quit from the excitement and the temporary spurt which it caused. It is, however, not so certain that it will be equally fortunate in China. Though stronger in a military sense than before the French war broke out, China has without doubt been subjected to a severe financial strain; and the necessity for some additional taxation may well remain, even now peace has been declared. The financial scheme lately drawn up by the Board of Revenue and Taungli-Yamen seems to have contemplated an addition of from 25 to 40 per cent. to existing dues on the common and medium teas; and though that increase is not greater probably, than would have been imposed here, if tea had been selected for additional taxation, the

effect would be vastly different on the China trade. An additional tax at this end would affect Indian and China teas alike, and place the latter therefore at no relative disadvantage; while an additional tax in China would give an impulse to the cultivation in India and elsewhere that would probably affect permanently both the selling value and the demand for the Chinese produce. As we have said before, however, the new scheme was drawn up before preliminaries of peace had been settled, and will hardly be maintained in its integrity under the altered conditions. The Imperial approval was provisionally accorded, subject to the advice of the provincial authorities; but we can hardly doubt that the alarm of the Chinese dealers, who fully appreciate the situation, will communicate itself to the latter, and lead at least to a modification of the plan. If additional revenue must still be had, the Chinese Government will be wise to follow the English example, and leave tea alone—visiting its difficulties upon the other articles in its programme. In opium alone it has a rich mine, if it would frankly recognize the squeeze which are actually levied on the native drug, but whose quasi illegality enables the diversion of the greater portion into the official pocket. China tea is already taxed heavily enough, at either end; and any modification should be rather in the direction of easing than lightening the burden, if it is to keep its place in the market; whereas it has had a narrow escape of incurring a double mulct. The escape is complete so far as the threatened 3d at this end is concerned; and we hope it may escape the greater portion, if not all, of the threatened increase in China. Chinese mandarins are not the most skillful or most moral of financiers, but they have a crude idea of the folly of quite killing the goose that lays the golden egg; and the danger in this case is likely to be borne in upon them from many sources. They cannot afford to injure severely a large and important industry; so we may probably take it for granted that, if there be an increase, it will be a more moderate one than the memorial proposes.

In the tea market, operators are relieved from further uncertainty as regards the duty, in which no alteration has been made. By an increase in the tax on beer and spirits it is not improbable a further stimulus will be given to the consumption of the leaf, and which is undoubtedly the cheapest beverage that is sold. The consumer has now been educated to a preference for Indian grown, but there is no doubt, if teas from China showed improvement in quality they would quickly regain the lost ground. An effort was made by the Foochow teamen by an "edict," strongly urging the growers in the different districts of the Foh-Kien province to devote greater care in the cultivation &c., and so compete with the teas grown in India. The Chinese now seem fairly aroused to the necessity of arresting the declining trade, the total export for the season being only 145,000,000 lb., against 153,000,000 lb. As regards Indian tea, consumption goes on rapidly increasing, and this has been helped by low prices. The accounts from India, however, are not satisfactory, as planters have done no good at the prices current during the greater part of this season. The firm belief that the duty would be increased on tea continued up to the time of the Chancellor of the Exchequer making his statement last night. Yesterday two firms alone paid as much as £24,000 in duty, representing nearly a million pounds of Tea. During last month advances have been made to a considerable extent by the banks against the amounts cleared by the dealers. A quiet market may now be expected, unless war breaks out which would create a reaction.—*London and China Express*, May 1st.

MR. J. B. MOENS ON THE POSITION OF THE CINCHONA BARK MARKET.

From an elaborate article headed "THE CINCHONA MARKET IN 1884," which has appeared in the *Indian Mercury*, a Dutch publication, we are glad to observe that our good and valued friend, the Director of the Java cinchona plantations, is still to the fore and resident, during his well-earned furlough, at Haarlem. We are the better pleased to receive this information because several books and periodicals which we forwarded to Mr. Moens, "care of the Dutch Minister of the Colonies," were returned to us, with the intimation that Mr. Moens was "not to be found"! That one of the greatest benefactors of the chief colony of Holland, of Holland herself, and of the human race, should be so little known or held in so little esteem by his countrymen, is, we conceive, greatly to their disgrace. In connection with the history of the very king of the fever-plants Mr. Moens's name will be honourably remembered ages after the names of the leading statesmen and warriors of the Netherlands will have sunk into oblivion. We are glad to notice, that, while absent from this scene of his honourable and useful labours, Mr. Moens is not forgetful of the product with which his name is so intimately associated. The paper to which we have referred, and which we shall transfer in full to the columns of the *Tropical Agriculturist*, gives good and clear résumé of the circumstances which have brought the market for quinine-yielding bark and quinine sulphate to its present low estate. In less than a quarter of a century since first the South American plants were introduced into Asia, the experiment has been so successful, that the Eastern bark, chiefly the product of Ceylon, has almost closed the market to the product of which the Western world, for many centuries after the discovery of the virtues of "Peruvian Bark," was made, had the monopoly. As is our fashion in Ceylon, we have disregarded the maxim *festina lente*, and, commercially speaking, we have, by going ahead too fast, injured our own interests only less than those of the bark-gatherers of the Andean forests. But, as we said, in reviewing Dr. Trimeu's report, humanity is the gainer in having available in plenty the most valuable febrifuge in the world at a price unprecedentedly moderate. We only wish we saw consumption advancing more in proportion to plenty and cheapness. But all in good time.

Mr. Moens commences his paper by adverting to the unfavourable influence exerted on the bark market at the commencement of 1884, by the operation of an agreement by a syndicate of European and American quinine manufacturers to limit the manufacture of the sulphate,—of all the alkaloids, in truth. The result for a time was that the proportions of value between bark and quinine were entirely destroyed. Mr. Moens uses the Dutch florin to indicate prices, and the difference in value between this coin and the rupee is so small that they are practically the same. Early in 1884, while the price of manufactured quinine was kept up at f145 per kilogr., the sulphate in the bark went down to f60. The just proportions would have been f112 to f122. But rings of this kind contain within them the principle of destruction. Had the syndicate persevered, Mr. Moens is of opinion that the result would have been the establishment of manufactories in Java, India or elsewhere from which quinine could have been turned out at f50 per kilogr. But dissensions broke up the ring, mainly from the action of one of its members, who in October 1883 had entered into a contract with the Netherlands Government. It

was also discovered that the high profit on such sales of quinine as took place did not compensate for the low limit to which sales were reduced. Consequently, instead of lasting till May, the compact came to an end early in January. The manufacturers had done no real good to themselves, while they had caused larger losses to those interested in the sale of bark. The immediate effect of the break-up of the ring was not a rise in the price of bark, but a very considerable fall in quinine. This fall was only temporarily arrested by the destruction by fire in February of a quinine manufactory in Philadelphia. The speculative operations of the notorious Milan Manufactory in purchases of bark, chiefly cuprea, continued and by October bark and quinine both went down until Howard's quinine was quoted at f7 and German at f6'50, while bark went down in London to 4½d per lb. unit. In August the Milan Company and Meyer & Co., of London went down, but the banks interested prevented a crash by disposing gradually of 30,000 bales of cuprea bark and 21,000 kilogr. of quinine. The Milan concern had been long in financial difficulties; the shareholders lost all their capital and the creditors are not likely to receive more than 45 per cent of their claims. The Italian Factory is still at work, but, as only 25 kilogr. of sulphate of quinine per diem are turned out, the expenses are not covered.

No. II.

Mr. Moens writes in regard to the Milan Factory that it must have been in difficulties for some time, the liabilities having been stated at f5,000,000 against assets f2,280,000. Amongst the assets were cinchona plantations in Bolivia valued at f50,000, but of which no title-deeds had been found! The price of cinchona bark continued to fall until the end of November 1884, but then, and all through December, there was a great demand for quinine and the unit in bark went up from 25 cents (of a florin) in October to 30 cents at the end of the year. Mr. Moens, in giving the range of prices for English, German and French quinine in 1884, states his opinion that Howard's sulphate has no superiority over the others in proportion to the higher price, but we suspect purchasers have more confidence in the English drug as unadulterated, the very name of the Howard's being a guarantee of genuineness. Whatever the reason, the range for English quinine was from 82 to 150 florins or guilders per kilogram; for French from 67 to 149; German 66'50 to 145. The contract rates for the Dutch Colonial Department were from 65 to 108'87. As illustrating the great fall in the value of bark between May 1883 and September 1884, Mr. Moens mentions the case of a parcel of bark from Java, which was sold in the former month, stored, and then resold in the latter month. Stem bark went down from 40 cents per English pound to 17½ cents, branch from 50 to 22½, and shavings from 90 to 40. Low quality barks were almost unsaleable, and most of the South American kinds were held for better times. The imports of this kind of bark dropped from 163,000 bales in 1882 to 37,000 in 1884! About 80,000 bales of the 1882 imports were cuprea bark, of which description England and France in 1884 took only 12,000 bales. As our readers are aware, the cuprea bark is not cinchona bark at all, although possessing similar qualities, and we have seen it stated that it was easier for the chemist to deal with. Speculative storing up of this pseudo-bark ended in heavy losses when sales were necessitated by the continued and heavy influx of the superior Asiatic barks, "Cey-

lon" writes Mr. Moens, "bears the palm amongst Asiatic possessions for quantity of the product." We should think so, indeed. Mr. Moens gives figures in kilogrs. showing a more than nine-fold increase in the supply from our island in four years, the rise being from 541,000 kilograms in 1881 to 5,215,000 in 1884.* No wonder if prices of bark and quinine went down in sympathy in the face of an increase so enormous and so rapid. But there will, infallibly, be lessened exports from Ceylon as the process goes on of ousting cinchonas as well as coffee to make room for tea. This year, however, and perhaps next, we suspect there will be a still further increase rather than a diminution. Mr. Moens states that the percentage of quinine in Ceylon barks is estimated at an average of $1\frac{1}{2}$ or 2 per cent, while Java bark (a large proportion of which is Ledgeriana) averages from 2.22 to 3.5. The highest percentage was 9.5 in the air-dried bark of government Ledgeriana, the produce of private plantations competing closely. For instance, Ledger stem bark from Soekenagara gave 8 per cent; and the lowest from other estates was 5.3. Official barks from estates also ranged high, from 4.3 to 5.8. As regards Ledgeriana, Mr. Moens deduces the result that the successive generations of trees have improved upon those derived from American seed. As far as high quality is concerned it seems certain that Java will be the leading cinchona country of the future. As a result of heavy sales of Ceylon in consequence of low prices, we suppose, as well as checked supplies from South America, stocks of bark in London, France and North America went down from 129,000 bales in 1883 to 96,900 in 1884. Mr. Moens calculates that of the bark in stock over one-third is of poor quality or useless. Counting by bales is deceptive, for while the American packages average only 60 kilogrs. each, those from Ceylon were 110 in 1883 and 112 in 1884. The stocks in London at end of 1884 consisted mainly of South American, of which 64,000 bales were cuprea, only 5,800 bales being East Indian. The prospects for 1885 seem better than those for 1884, but Mr. Moens, taking our figures that 128 millions of cinchonas must have been planted in Ceylon, of which 22 millions were 2 years old and upwards, in 1881 gives a needed warning that Ceylon is not likely soon to be an insignificant factor as bark-producing country. Our own opinion is, that, after 1887, Ceylon will decrease as Java increases in the production of the fever bark. There has not been and there does not seem likely to be any sacrifice of cinchonas to tea in Java, while in Ceylon the giant "GHA" demands and receives his holocausts of cinchona and coffee victims, even young cinchonas being immolated. A good deal of cinchona exists in Travancore and Wynaad, which tea will not, probably, supersede. Java sent 453,000 kilogrs. into the market in 1884, of which only 27,000 were from the Government gardens, and the quantity from the Dutch colony will speedily increase, although it will be long before it overtakes the astounding Ceylon figures—figures which have taken producers and consumers equally by surprise. Mr. Moens enters into a laboured argument to prove that Amsterdam is as good a market for Java bark as London can be, but he mentions the one great attraction of sales in London being for cash, while 1 per cent is deducted for cash at Amsterdam. The auction charges are "very heavy" at both places, being more onerous the lower the prices obtained. Direct sale by analysis to manufacturers exists in some cases. Mr. Moens dwells on variations in analyses, owing largely to the differing qualities of bark in the same bale. Besides the cash principle, London has the advantage of frequent

auctions, once a fortnight, while at Amsterdam only eight were held in 1884. Mr. Moens dissuades from any attempt at sorting quills of Ledgeriana and other "chemist's bark," which sells on its merits as shown by analysis, in whatever form it is received. Such bark should be broken into small pieces and thoroughly mixed. Indeed, to save a multitude of analyses, he advises the thorough mixing up of bark of all qualities and all ages, root, stem, branch and twig of the various kinds. Wood should not exist in parcels of bark, and succirubra bark (for druggists, of course) should be from trees at least seven years old, or rather older, so as to have the white silvery appearance outside and reddish brown inside, so much desiderated. Then he tells the Java planters to mark the tare of their boxes, and after alluding to two so-called substitutes for quinine which reduce the heat of the system but are not febrifuges, the writer brings his able and interesting paper on the present condition and future prospects of the cinchona market to a close. The details which will appear in the *Tropical Agriculturist* will well repay perusal and be useful for reference.

MR. JAMES IRVINE ON TEA.

TEA AND COFFEE TOGETHER NOT A SUCCESS—TEA AT LOW AND HIGH ELEVATIONS—TEA PREPARATION—OVER-PRODUCTION—THE FUEL QUESTION AND RAILWAY EXTENSION TO HAPUTALE—THE HAPUTALE-BADULLA TRACE—SUITABILITY OF UVA FOR TEA.

(Extract from letter)

Nuwara Eliya, 25th May 1885.

* * * There is no doubt, tea is now the great planting industry of Ceylon, and where it is planted coffee must come out. You will see lots of tea and coffee growing together, but I am convinced that wherever tea has been planted in coffee, not only must the coffee come out ultimately, but it is in my opinion best that the coffee come out at once, as the growth of the tea is greatly retarded. Tea grows freely from Nuwara Eliya to Avisawella. I do not yet feel inclined to give a hard and fast opinion as to elevation, but will probably adhere to my original opinion that an elevation of from 1,500 to 2,000 feet will be most productive when climate and rainfall are suitable. On the other hand, I was greatly pleased and I may also say surprised at what I saw on Abbotsford: not so much with the large "Giant Trees" as with the new fields at the top of the estate at an elevation of say 6,000 feet. They are far more rapid in growth than I expected: the bushes flush freely and have stood close plucking as no low-grown tea would do. I fully believe that the figures for Abbotsford manufacturing tea per acre, if not exceeded, will at least be realized on many high estates. I am also confirmed in my opinion as to the durability of tea under cultivation, more especially at high elevations. As to the preparation of tea by machinery it is only in its infancy as yet and will gradually be improved: the "revolving web" for drying is one step forward, but the whole work of the tea-house may be so systematized as not only to lessen the cost of production but to do away with much night-work. What we Ceylon planters have most to fear is over-production. We will certainly send into the London market within the next five or six years not less than fifty million pounds of good tea. I was of opinion that 300 lb. good tea per acre would be a fair average for the Island, admitting that exceptionally good estates will give a very large yield: there will also doubtless be failures perhaps many, but the acreage of really good tea land is so large that I feel convinced a larger yield than 300 lb. per acre will be got as an average for tea land in full bearing. The fuel difficulty has practi-

* All continental India added less than 5,000 bales,

ally no existence on the Kandyan estates with the opening of the railway, but as for Uva, you must have a railway not only to Haputale but to Badulla. It is a very great mistake to suppose that the trace from Haputale to Badulla is either costly or difficult to construct: on the contrary, it is by far the easiest portion of the line, the difficulty was in getting a trace to meet the requirements of the consulting engineer as to curves and gradients; the sudden drop from Baudarawela to Kumbalwella between the 17th and 19th mile-posts on the Badulla and Haputale road was the real difficulty, but I pointed out to Mr. Ferrar that by keeping well behind the resthouse he would probably find a good enough trace with a little cutting and the whole line to Badulla has been pegged out and there is hardly a piece of rock cutting on the line. The difficulty, if difficulty it can be called, will be to get good stone for the few culverts on the line: so soft and yielding is the whole country here, that Mr. Ferrar's fear was that constant slips would add much to the cost of upkeep for some time after opening, and, in order to avoid this, the trace has followed the bed of the Baduluoya as closely as possible, where the bed of the road would be sounder and stone and lime available for building; this necessitates crossing the stream several times, and the bridging of the Baduluoya will be one of the most costly items in the construction. This trace will take all the coffee from Lunugalla, Ampitikanle, Leangahawelle, Craig and the whole group of estates near Bandarawela; the whole of the Kandapala estates will also find their nearest outlet at Bandarawela, but a cart road must be cut from Koslanda to the Bandarawela station. The large group of Badulla estates from Ravenswood through Gowrakelle to Poptogashena will find their outlet at a station near Demodara, their present place of dispatch, Keenakelle, Naraangalla and probably the Gampaha group of estates in Udapussellawa will find their outlet at Dikwella station, as the nearest point on the railway line. Badulla station will serve the whole of the Badulla, Passara and Madulsima estates and probably Meouragala as being nearer than Haputale to the unhealthy country of Wellawaya. When the railway is completed, then may the Badulla planters hope to compete with the Kandyan districts in the cultivation of tea. I still adhere to my previously expressed opinion, that the soil and climate of Uva are capable of producing alike the maximum yield with the finest quality of any tea grown in Ceylon, but, still you have got a railway, you will labour under far greater disadvantages in tea cultivation than you have ever done with coffee. * * * JAMES IRVINE.

[If Sir Arthur Gordon brings back sanction for the Haputale section we and the Uva men will be well-pleased; but should he overcome all objection to go on to Badulla at once we should indeed be delighted!—Ed.]

BURNING OF ANOTHER TEA FACTORY:

THE NEED OF SPECIAL PRECAUTIONS: ASBESTOS PAINT—IRON STORES—FIRE INSURANCE.

The report that Mr. W. I. Cotton, of Warwick estate, New Galway, has sustained the loss, by fire, of his tea-house and a considerable quantity of produce, more or less prepared, is, we much regret to say, confirmed. This occurred on the evening of Friday, May 23th, and so sudden was the seizure, about 7 p. m. that although the alarm was at once given and all possible steps taken, almost nothing was saved: the tea-house with the furnishing,

the bins full of tea (2,500 lb.) and 50 boxes of tea ready for dispatch; all were lost. There was some danger at one time of the fire spreading to the bugalow and outhouses; but, fortunately, this was prevented. As it stands, the loss is a heavy one for Mr. Cotton, and much sympathy is due to an honorable, industrious and (like so many more in these days,) struggling planter.

This is the second case of the burning of a tea-house in the neighbourhood of Nuwara Eira where, no doubt, the cooler temperature and occasional strong winds increase the risk. A third and even more important case was that of Campden Hill. It is no wonder therefore though the agents of Fire Insurance Companies should expect to do considerable business in Ceylon. But insurance at best can ill compensate for all the loss and inconvenience sustained on such occasions—the stoppage of work for instance. And therefore it will become a question whether iron stores should not become the rule in the future. In the meantime those with timber exposed to the risk of catching fire should at once consider the importance of applying this new fireproof asbestos paint, which, we understand, is not much dearer than ordinary paint and which has stood so severe a test that a log painted with it and thrown into a furnace resisted the action of the flames!

CEYLON UP-COUNTRY PLANTING REPORT.

THE WANT OF REVERENCE OF THE PRESENT AGE: AN INSTANCE—A TEA "AUTHORITY"—LOSS OF FLUSHES FROM *helopeltis*—A CACAO ESTATE PLANTED UP WITH *ARECA PALMIS*—A REAL OLD-FASHIONED SOUTH-WEST MONSOON, BUT WITH VERY LITTLE WIND.

8th June 1885.

Want of reverence is said to be one of the crying sins of the age; it affects things sacred and secular, theology and tea. I had a sad example of its intrusion into the region of our promising new product the other day. One who ought to have known better come up to me with a broad grin on his face, and said: "Did you hear that good joke?" and not having heard it he peared it out then and there, adding as his moral to the tale: "These fellows who give themselves airs as authorities on tea seem to me to know very little about it." The irreverence displayed was shocking,—but I will tell the story that was told to me, so that my readers may judge for themselves how far my indignation is righteous. On an estate about to be turned into a tea garden a report was called for as to suitability for the new enterprise, and special reference was made to some tea bushes then growing, as to what they were, and whether it would be worth while preserving them for seed. The "authority" came, saw, and delivered as his verdict that the tea was a very poor *jât*, and ought to be rooted out. The superintendent on the estate was not an authority, and did not pretend to have that nice perception which distinguishes the knowing ones; but for all that he was practical, gathered the seeds of the doomed plants, and put them out in a nursery. In due time the nursery flourished, and specimens from it were forwarded to "the authority" and advice asked as to whether it would be safe to buy similar plants for planting. The answer returned was to the effect that they were of a very fair *jât* indeed, and a recommendation that they should be bought! Now I don't pretend to understand what my friend had got to laugh at. You remember—in "Don Quixote" was it?—the perplexity caused by the different verdicts on a pipe of wine by the two famed connoisseurs. One said it had a taste of iron, and the other that it had a flavour of leather, and how their skill was established by the discovery when the pipe of wine

was empty that a key with a leathern thong was found at the bottom of the cask! I admit at once that it is a hard problem, how an authority in tea can recommend, as a good jät, plants grown from seed of trees so very worthless as to be worthy only of being rooted out: still, I'm "agin" all irreverence, and on the side of authority.

I was sorry to hear the other day that on one tea place two flushes had been lost by *helopeltis*.* It is to be hoped that this sort of thing won't go on. It is bad enough in cacao, giving no end of trouble, and it is much to be desired that the multitudinous duties of the tea planter there won't be added the hunting-down of this fly.

I heard of one man, who ought to know what he is about in regard to cacao cultivation, having gone in for planting his young cacao place with areca palms. Wind and *helopeltis* were the reasons given.

So far we are having a real honest old-fashioned S. W. monsoon, minus the wind. The absence—or rather comparative absence—of the latter is very marked, and few I think will regret it. Such a spell of planting weather we have not had for long, and if the tea plants don't come on which are being put out by the thousand now, it will be through "sheer cussedness." I take it that every planter does his honest best to have this work carefully looked to.

PEPPERCORN.

THE NEGROES AND PLANTING IN JAMAICA.

Iter Boreale estate is a famous place for good water for drinking and good bathing places. A favourite place of mine was under a culvert on the cart-road where the old millrace for driving an undershot water-wheel used to be. The wheel is still there about 40 feet in diameter or 120 in circumference, but it is rotting with the roof over it, and would be better used for firewood; in parts of the dam there are good bathing holes, and Mr. Forrest and self go down nearly every evening and bathe in a shaded place, where fastoons of hanging climbers touch the water, and the wall of the dam protects us from the view of the public road. There are a great number of rock strams and springs gushing out along the boundary of Iter Boreale. The Mills and Trash Houses on Iter Boreale estate cover an area of about three acres. Six buildings in all:

- 1st.—The Boiling House.
- 2d.—Sugar House and Store.
- 3d.—Distillery and Fermenting House, Rum Store.
- 4th.—Trash House.
- 5th.—Do. do.
- 6th.—Carpenter, Wheelwright, and Cooper's Shed.

The machinery of a sugar-house is very interesting. Three heavy cylinders or crushers driven by a steam-engine draw in the cane as it is placed on the table to feed the crushers and the creole man employed passing the cane is called "the feeder." He generally has an old woman to help him "feed," and on the off side another couple of hands are necessary to clear away the "trash" quick enough so that the machinery may not be impeded, pressure being put on of 66", and the machinery should be kept regular, without blocking the "trash." A heavy cog-wheel revolving steadily and regulated by a large fly-wheel not only turns the shaft of the connecting crushers but pumps the cane liquor (flowing from the gutters into a cistern) up into the boiling pan, receiving boiler or vat. A small quantity of lime is mixed with the cane juice in No. 2 cistern or vat and then it is let off into the boiling coppers below, five of which are kept boiling and a staff of men under a "chief boiler" employed skimming off the froth and refuse floating on the surface of the boiler. They are wide-shouldered pieces of wood used for this purpose, like canne paddles; for manipulating the sugar other men are armed with heavy ladles.

* Is this hearsay? In two cases, we know, of alleged *helopeltis*, it has been proved that this insect was not to blame.—Ed.

After the sugar is pressed out of the cane trash it is dried in the sun and used for fuel for the engines. The pressure of steam was 51, and there is disconnecting gear to use at times of block. Old Brown has been engineer for 22 years on Iter Boreale; he is fifty years old and son of the old lady working at the "Great House." Heading out cane in the cane-field ready for the wains requires supervision, and the wainmen come along at a good rate with their teams of cattle, calling them by their respective names, such as "Prince," "Dashwood," "Rover," &c. One has got to look out in the cane yard when four wains are dragged in with a rush drawn by sixteen heavy steers. In the distillery there are eight large vats for fermentation and a syphon worm would need a cistern filled with water. Sugar boiling and rum distilling are not learned by a day any more than tea manufacture, and your correspondent is rather "fuddled" with the rum business, and considerably mixed up with the "dunder" and the "lees" and the "high wines" the saccharometer and the "beads" to test the "above proof." It appears to me that a "Doctor" or still-house book-keeper is indispensable, and yet ours was discharged shortly after the "field book-keeper," and now "Busha Jim" is discharged to reduce the expenditure and left me "the Chinese book-keeper" to look after the bananas until Mr. Broughton took charge of over the whole estate and is about to hand over to Mr. Ed. Forrest (late of Dimbula); so that like the Government of Jamaica we are to have a "new departure." Meantime Mr. Forrest is to be "Busha" field book-keeper, stillhouse book-keeper or "doctor" banana cultivator and penu-keeper all rolled into one. My "new departure" will probably be to the City of New Orleans in the Southern States of America. Since writing to you, I visited the great Gray's Inn sugar estate in Annatto Bay. The day was Saturday, the creole market day so there was no work going on. There is a manager or "Busha" (sometimes called overseer) a field bookkeeper and stillhouse book-keeper, also a "boiling house book-keeper" on Gray's Inn sugar estate. The fields of cane stretch along both sides of the cart-road and even the low hill land is under cane. The outcrop of sugar last year was between 500 and 600 hogsheds of sugar! What a pity such fine properties should be at a discount just now through the Frenchmen and Germans growing so much beetroot. (Gosh! Why don't John Bull "beet" them with his "cane"?)

That bounty business is ruining all the West Indies and some want to go over to the United States and others to the Dominion Government of Canada. The Yankees say the West Indies are no good and call the negroes lazy and good for nothing. Meanwhile off goes "Quashee" to cut the Panama Canal and leaves all the creoles to shift for themselves. This is another view of the "new departure." Lord Derby promised the West Indians! The new members of the Legislative Council at Kingston have tried to reduce the expenditure but failed to do so, to any extent, without disorganizing some of the departments. The new railway extension will soon be opened to the public and when the country is more opened up, by roads and railways and the Panama Canal is in working order, Jamaica will stand a good chance as a coaling-station and place of call convenient to vessels plying the Canal. People in Jamaica are too fond of saying everything is "going to the dogs." Now why don't they go in for all kinds of new products suitable to the climate and soil of the country. You may depend upon it Ceylon will come off with flying colours by and by, when the Tea boxes are shipped, and cardamoms, cinchona, coffee, cacao, tobacco, &c. are all up again, fetching high prices. I read your speech in the Colonial Institute and glad to hear the new products are putting old Ceylon on her feet again. As far as I can see you will not have the competition in the future you have had in the past, and borne so patiently.

What is the use of repining?

For where there's a will there's a way.

Tomorrow the sun may be shining

Although it is cloudy today.

H. C.

BRAZIL SLAVES AND COFFEE CROPS.

The *Gazeta de Noticias* has collected and printed some very interesting statistics in relation to the slave population of the empire. From these we beg to ex-

tract some figures. The slave population of the empire is estimated at 1,177,022, of which 623,274 are males and 553,748 females. As to ages:—

14 to 20 years	...	323,868
21 to 30 "	...	497,725
40 to 50 "	...	267,487
Over 60 "	...	87,942

1,177,022

This table is claimed to be based on actual figures from 14 provinces and estimates in the case of 5; 2 provinces are said to be freed. The disproportion of the slaves over 60 years old to those younger, arises from the non-registration of such of them as are yearly becoming superannuated. ▲

Beyond the emancipated provinces, Amazonas and Ceará, Rio Grande do Sul has made large strides towards the same goal. Our colleague goes on to show that the freedom of the slaves over 60 years, will not disorganize agriculture, for this is already disorganized. In the provinces of Rio de Janeiro, Minas, S. Paulo and Espirito Santo there are 726 plantations with 34,548 slaves mortgaged; these represent a value of \$41,459,705 and the real estate etc. \$53,551,901. The greater part of the mortgages were made over 20 years ago, which goes to prove that neither the Rio Branco law, nor the abolitionist propaganda have produced the straits of planters. The figures given show that of 348 plantations in the province of Rio 326 are mortgaged; of 266 in S. Paulo 251; of 150 in Minas 140 are mortgaged. The coffee crop of 1868-69 is estimated at 116,420 metrical tons against 272,382 in 1882-83 and 188,323 in 1883-84. The figures should serve the purpose of refuting the constant complaints of the agricultural interest that they are badly treated and need every kind of Governmental coddling. It is not agriculture that is benefited at the expense of commerce and industry, but the holders of these mortgages, for the great majority of the planters are little more than tenants, and to a large extent dependent on their respective mortgagees. There is no question that agriculture will always be compelled to raise money on its lands, where large properties are concentrated in few hands, and this is a serious matter at the present moment. The mortgagees are in a position to bring pressure to bear on the planters, that the land may be subdivided into such moderate sized farms as will suit freedmen or immigrants, and this in their own interest they should do. We do not lose sight of the antiquated and anomalous mortgage law, by which a debtor may become his mortgagee's creditor, but the matter should be tested and if practicable, the results would be advantageous to both parties; for the mortgagee could spread his investment over various families of labouring people and the planter would have no object in retaining any more land than he might be able to properly cultivate on some *mitatic*, or similar, system, with such immigrants as are not in a position to assume the responsibility of a farm of their own. There can be no satisfactory influx of immigration, until some means are secured for placing the immigrant in a position to immediately gain his living. Dropping him down in the virgin forest to contend with all the difficulties of sub-tropical vegetation will not prove an attraction, and the division of the large plantations seems the only solution of the question. As to the figures in reference to the slave population, there seems no reason to concede that the liberty of some 85,000 sexagenarian slaves, out of a population of 1,177,000 could seriously affect the agricultural interests of the country. Then the figures of the increase in the coffee crops, even with the reduction of labour by death and emancipation, are further proofs that so far the coffee planting interest has little cause to complain as to production, although prices are so much lower; an increase of 72,000 tons in 15 years should be considered satis-

factory and contradict the demands for more favours from the planters. Let the large planters, or their masters, the mortgagees, declare their willingness to divide their lands among immigrants, and let this decision become generally known abroad, and we are of opinion that immigrants of a good quality would be attracted to this country.—*Rio News*.

THE AVERAGE PRICE OF WHEAT in England for last year was 35s 8d. In 1883 it was 41s 7d per quarter. The former is the lowest average for upwards of a century. In 1780 the annual average was the same, viz. 35s 8d.—*Planter and Farmer*.

A VALUABLE FIBRE.—The Trinidad Agricultural Society were about to bring the following resolution to the notice of the Governor:—"That this society petitions His Excellency the Governor and Council for the introduction and distribution in this island, at the Botanical Gardens, of seeds or plants of the '*Bomera nivea*,' the Chinese grass-cloth plant of English writers (Tchou-ma of China and Rhee-a of Assam), a plant well adapted for cultivation here, the fibre of which (Ramie fibre of commerce) is of great commercial value."—*Colonies and India*.

TEA.—DARJILING, May 15th.—There has been a great deal of rain, and no day has passed for the past fortnight without a good fall. However, although it has shut us indoors a bit, it has done much good in cleansing the town and putting fresh life into the tea trees that had been nearly annihilated by the hail storms. It also holds out the pleasant prospect of less moisture and no landslip when the regular rains set in a month or so hence. It has otherwise benefited tea generally, and, as the weather has been altogether just what suited to the tea bush, viz., alternate sun and rain, most gardens have made a good start, and the reason promises to be better than usual.—*Calcutta Englishman*.

THE ANNUAL EXHIBITION OF SILK COCOONS was held at Murshidabad from the 19th to the 24th of January, and appears to have been, on the whole, a success. There were no less than 448 exhibits this year as compared with 181 in the previous year, the districts exhibiting being Murshidabad, Birbhum, Malda and Nadia. Prizes to the value of £2,067 were awarded. The cocoons are described as far superior to those of last year, although not better than, or even so good as those of 1883. This is accounted for by the fact that there was a large crop of mulberry which was sold at a very cheap rate, and so enabled the rearers to feed their worms better and at a cheaper cost, whilst obtaining an increase of from 15 to 20 per cent in the produce. It is said to be nearly always the case that when the mulberry crop is large and cheap, the cocoons are good and more productive. A few attempts to cheat on the part of the exhibitors were discovered, some of the rearers having borrowed good cocoons from others and exhibited them as their own. In every case where this could be proved the prizes were withheld, but still the Collector considers it probable that many prizes were dishonestly obtained. The Government of Bengal displayed its interest in the exhibition by sending a special officer to see it, but the Collector anticipates that the public would take more interest in the exhibition if it was extended so as to show the process by which silk is made, and the final products woven. Already the cultivation of the mulberry and the rearing of the silk worm have added much to the prosperity of the Murshidabad district, and silk piece-goods manufactured there by the natives are purchased and exported. If the European silk merchants would encourage the trade, and if the exhibition were extended also to tasar, silk, there can be little doubt that it would become much more important.—*Calcutta Englishman*.

TEA: NEWS FROM THE INDIAN DISTRICTS.

SPLENDID weather for tea is reported from Julpigoree, very hot and moist and the *chota bursat* over. Unfortunately, however, tea and human beings are differently constituted, and fever has been sadly prevalent, as also cholera in a lesser degree.

OUR Tezpur correspondent writes:—The past week has been a favourable one for tea; but excessive rain has made it too cold for good leaf, and red spider is spreading. A few sunny days will, however, improve matters, and, generally speaking, prospects for the season are good.

DARJEELING.—The *chota bursat* has not quite taken its departure, as showers have fallen in the station almost every day recently. The temperature has gone up a good deal within the last few days throughout the district and there has been a fine, bright sun out when rain was not falling. To show your readers how very partial the rainfall is in these hills, it may be mentioned that at the Darjeeling Observatory over 22 inches of rain have been registered already this year, while at a place nearly due east from here and about six miles distant as the crow flies, the rainfall since the beginning of January has not quite reached 11 inches. Here is a fact connected with red spider which is of interest. A small patch of a garden which had been infested by this blight for several years was deep hoed early last October, pruned at the usual time, and then not hoed again until the rain had begun. The result has been that spider has completely disappeared from this patch. The experiment is of course, on far too small a scale to build any theory on, but it might be worth while to try this plan on other gardens and watch the result. Mr. Blandford's theory that heavy snow in the interior of the Himalayas meant a short rainfall certainly held good in this district last year. Snow was unusually heavy in the interior last winter, and snow fell unusually low and late. It remains, of course, to be seen whether the same rule will hold good in this year of grace.

ASSAM.—Here we are sitting with the thermometer at 75° in the shade at 3 p.m., and the first quarter of the month of May is gone astern. It is difficult to realize that the year is so far advanced. Most of us have only just commenced punkahs; but it is more with a view to driving away mosquitoes than in order to cool the air. Everybody has been crying out about the weather, and with good reason; for we have had an exceptionally damp April. Rain fell on nineteen out of the thirty days and the remaining eleven were mostly cloudy and dull. 10.73 inches of rain fell during the month, against 5.82 in April 1884, 4.27 in 1883 and 3.39 in 1882. The thermometer ranged between 84° and 60°. The average highest temperature being 78° and average lowest 67°. There was a violent gale on the 9th which did some damage to buildings and stopped the traffic on several of the roads, by blowing down trees. One planter had an exceedingly narrow escape: he was driving along in his buggy when a large tree was blown over and came down with a tremendous crash on the road immediately behind him. The horse took fright and bolted for some distance. There were also several hailstorms which knocked off some of the young tea shoots in several gardens. On the second of this month the weather cleared and we had two glorious days, all the weather prophets (and their name is legion) declaring that we were to have a prolonged spell of scorching accompanied by blights and pests. On the night of the 4th, however, it clouded over and, by the 9th, 3.30 inches had been added to the rainfall. Although we have had so little sun during the last six weeks, and the occasional stiff breezes have opened up the leaf, making it *banji*, nearly all the gardens about here are considerably ahead of last year and, should the weather be favourable, ought to make a good May also.

TEZPUR.—Again I have to chronicle a week of very favorable weather for tea—the little rain we have had has fallen at night and the days have been bright and warm. The month promises to be a very good one as compared with May last year and most gardens are getting well ahead. Red spider is unfortunately still spreading, but that seems to be the normal state of affairs for this time of the year and need not perhaps be remarked upon. The season is exceptionally cool and healthy so far.

MESSRS. GOW, WILSON AND STANTON, Tea Brokers, have published a diagram "showing the quarterly import and delivery of Java tea, with the price of the leading descriptions for the past five years," the chief features of interest being distinguished by lines printed in green and in red. As they remark—"The trade in Java tea has exhibited a steady increase in both the imports and deliveries during the above period, which is shown by the total annual figures, herewith subjoined:—

	1880.	1881.	1882.	1883.	1884.
Imports	2,019,000	1,217,000	1,759,000	3,056,000	3,589,000
Deliveries	2,612,000	1,314,000	1,786,000	2,893,000	2,709,000

These statistics prove that Java teas have been gradually gaining favour in the London market, for the deliveries have continued to increase equally with the imports, while in some years they considerably exceeded them." Prices during the five years have varied as follows:—"Fair" Pekoe started in 1880 at about 1s 6d., and soon fell to 1s. 4d., but in the subsequent year the value rose to 1s. 8d., after which it gradually descended to 1s 4d., and again touching 1s 6d in 1883, it dropped to 1s 3d per lb. by the close of 1884. "Medium" Pekoe similarly varied; commencing at 1s 2d in 1880, falling to 10½d before the expiration of that year, rising to 1s 4d at the end of 1881 and the opening of 1882, and, after many short ups and downs, closing last year at 1s per lb. Pekoe Souchong of medium to fair quality ranged from 1s 0½d in 1880 down to 9½d early in 1881, and only once more advancing to 1s., in the first quarter of 1882 almost continually declined in price until the end of 1884, when it was only 8½d. Souchong has followed the same downward course, selling in 1880 at 1s, being worth only 9d later in the same year, and though realizing 11d in the last quarter of 1881, this kind of tea has since fallen by degrees to the low level of 7d per lb. Messrs. Gow, Wilson, and Stanton observe that—"The gradual fall of prices must, however, be disappointing to importers, but this has not been in any way peculiar to Java teas, and applies equally to all other tea industries, many of which suffered to an even more serious extent. Some consolation may, nevertheless, be drawn from the fact that those gardens, both in India or Ceylon, and in Java, have suffered least which have sent home the best liquoring teas; and we may add that more attention is now being paid by buyers to the quality of the liquor than has ever before been the case, while teas for mere appearance—that is, with handsome leaf and poor cup—are every year being looked upon with less favour. Many of the best gardens in Java have recognized this fact, and turned their attention to producing teas with fine flavour and useful strength, in which endeavour they have met with considerable success; such invoices always command the attention of the trade, and meet with the best reception, averaging naturally the highest prices." Altogether the diagram is well worth studying by that branch of the trade most interested in Java tea, and both planters and manufacturers may also glean, from the remarks which accompany it, some useful hints as to the best modes of preparing and "firing" the teas for the English market.—*Indian Planter's Gazette.*

KANGRA VALLEY TEA PROSPECTS.—The tea manufacturing season is now well on. Till within the last day or two the weather has been most unfavourable, three or four hailstorms having cut up some of the gardens, and there having been constant falls of snow on the hills, which rear themselves up just behind the valley, the snow itself being only about four miles distant as the crow flies. The appearance of the upper range is wintry, and it has not been so white at this month of the year within memory of man. The consequence of this unseasonable weather is that the first flush has nearly all gone *banji*, and as in the Kangra Valley this crop represents fully a third, and often a larger percentage, of the year's output, the damage done by the cold can be estimated. The more hopeful planters look forward to a bumper May and June crop, but close plucking and *banji* heads on the bushes are but a poor preface to a big second flush. Gardens will probably all come round in the rains, which is a consolation for those who still regard last year's 'output to date' with eyes of fond but foiled admiration. Personally, however, it is satisfactory to note the vacillating thermometer doing its little constitutional

between 47° and 50°. Desperate as this may be for flushes and liquor sellers, it affords a pleasing sense of coolness which you must envy in the plains. —*Calcutta Englishman.*

TEA IN JAPAN.

(From the *Japan Weekly Mail*, May 2nd.)

New season's tea has arrived in small quantities at Kobe from Tosa during the week. Tea men at that port expected to ship to Yokohama on the 8th of May, but the condition of the crop makes it now apparent that the first batch will not be ready before the 15th.

The yield of tea throughout Yamato is expected to be forty per cent. below the average, and the Izumi crop twenty per cent.

The Central Tea Industry Association having determined to establish the sale of Japanese tea in the Russian territories in Asia. Mr. Matsudaira Taro is now travelling through Manchuria and investigating the requirements of the tea trade in that region.

A change in the weather in Kishiu has favorably affected the tea crop, and the plants are reported to present a promising appearance.

Two hundred and forty-five *me* of new tea from Suruga were sold at Yokohama, at the rate of 85 *yen* per 1,000 *me*, on the 11th instant. The local buyers distributed the fresh leaves among the foreign tea merchants of the port in the shape of presents.

THE KANGAEAN ISLANDS: NETHERLANDS INDIA.

(Translated for the "*Straits Times*.")

From a private letter written by an official who has been visiting the Kangean islands, the following particulars are taken:—The Kangean islands are well worth a visit. They lie at about equal distances from Madura, Java, the smaller Sunda island and Celebes.

There are also found there Madurese, Malays, Bugis, Mandarese, people from Sumbawa, and emigrants from Celebes, who all live in a very primitive style. Money is seldom used. In the markets different products are simply bartered. Sugar and petroleum, articles found in the smallest village in Java, are seldom obtainable at the chief town of these islands. A short time ago a fowl could be got here in barter for an empty wine bottle. The people seem to be of a very mild disposition, and are particularly honest. Theft is almost unknown here. Horses are allowed to run about uncaired for day and night in the villages and in the bush, yet not one of them is ever stolen. The islanders are, however, very lazy, and refuse to work for others even when paid. The coolies whom I make use of here are compelled by the authorities to come along with me at high wages. The above details bear chiefly upon the Kangeanese properly so called, who are mainly descendants of Madurese banished hither in former times. The remaining population, who are mostly found on the coasts and with whom I have had very little to do, are quite a different sort of people. Kangean is a fine island. The soil is derived from coral rocks, which had been upheaved by volcanic action to a height of one thousand feet at several places. In the hills there are several stanniferous grooves of jungle, of which a comparatively small portion consists of teak. The flora, and fauna present many features of great interest, and bear a strong resemblance to Australian forms, though the island belongs geologically to the same limestone formation as Madura, North Sourabaya, and Roméling. The only European who resides permanently on Kangean is the controller. The sea around the island is notoriously unsafe.

BEES.—It is said that there are in America no less than three million stocks of bees, producing an annual yield of 20,000,000 lbs. of honey. —*Flourist and Farmer.*

CINCHONA PLANTATIONS.—We learn that Mr. J. W. Ryan has been selected, among other applicants, to fill an important appointment in connection with the Neddittvattam cinchona plantations, and we cannot refrain from congratulating Mr. Lawson on this nomination, which we have not the slightest doubt will in every way prove a great gain to the department so ably supervised by him. —*S. I. Observer.*

DIVIDENDS OF TEA COMPANIES FOR 1884.—We have pleasure to announce that at the annual meeting of the shareholders of the Berokai Tea Company, Limited, held yesterday, (April 30th) a final dividend of 10 per cent, making fifteen per cent, for the year was declared; and at a similar meeting of the shareholders of the Tea Company of Cachar, Limited, a dividend at the rate of 3½ per cent, for the year was declared. We hope to give the reports in full in our next issue. —*Home and Colonial Mail.*

A SUBSTITUTE FOR COFFEE.—Ground nuts are being successfully substituted for coffee in Pondicherry. The nuts are roasted and ground, and prepared in the same way as the coffee berry, and when properly manipulated a pleasant and refreshing drink is the result. Ground nuts have been used in America for many years as a substitute, and very largely for adulterating coffee, but the Yankees mix the nuts with horse beans into a paste from which they turn out the berry in perfect shape and with a greenish colour and an aroma. —*Madras Mail*, May 28th.

TEA IN THE LOWCOUNTRY OF CEYLON.—Ilenaratgod, 8th June.—The monsoon rains began here at 4 a.m. on the morning of 2nd June, and the first spell lasted six hours; the rain has kept up pretty constantly till the end of the week, though, after a spell of from five to ten hours, it would pretend to have done its worst, and let the sun shine out for an hour or so in an unclouded sky, when it would suddenly pull itself together, and break out more fiercely than ever. I might easily have put out all my available plants in the two first wet days, but I lost so many plants in 1883-84 from the lack of planting weather that I can now put no faith whatever in any appearance or promise of the clerk of that ilk, that I this season decided to give each plant put out in the field the additional chance of a special shade, without reference to the weather, which I dare not depend on. This business of shading was a much more laborious and protracted affair than the mere planting, and as things have turned out was an unnecessary work, for there has hardly been enough sun to make the tender leaf droop since the ball opened. Well in five days, with a good deal of broken time, I have planted out 30,000 tea plants, and shaded them with a total day's labour, of men, women and children, of 104, and I do not think I will lose 2 per cent. When the sun shone out at 8 a.m. today, I said the blushing hembug was at his old tricks; he had cheated me many times during last week, and I would on this occasion pay no attention to him, so I went on planting, and did not stay, while I had a plant left. The sun was however in earnest, and shone at intervals during the day, and there was no more rain till late at night. I have plenty more plauting to do, but must wait till the plants grow large enough, which will take a month at least. The most forward of the tea bushes are beginning to flush, since the rain came, and there will now be nearly constant plucking, for a limited force of women and children. I fancied I had got the weeding well in hand before the rains came on, but on some spots the grass is more flourishing than ever. Verily there are worse things to deal with than ageratum. The vast rainfall we have had during the past week has done its work very quietly; we have had very little wind.—10th May, The weather seems settled for the last two days; we have only had slight showers at thine.

APPROPOS, of the planter in S. Paulo, who placed some Italians in the stocks. The *ju z municipal* of the nearest town makes a very lame excuse, for he says he only heard of the occurrence through the S. Paulo papers. And they want immigrants?—*Rio News*.

A MINAS GERAES paper says that a larva has been discovered in a district there, that feeds on the leaves of the coffee-trees. It is of a green colour and difficult to detach from the branches. Over 50 were found on a twig. Whether this will affect consuming markets is questionable, but in any case it should be looked into.—*Rio News*.

DUMBARA: THE MONSOON, &c.—3rd JUNE.—It certainly looks like the S. W. this morning. If it is the S. W., it has come in very quietly. On the 1st and 2nd we had over 3 inches of rain, bringing our rainfall at date up to 13.91: so we are better off than we were last year. The cacao crop came in with a rush. It will be all in by the end of June. Estimates are turning out short, doubtless owing to the pods being ripened before attaining their full size. *Helopeltis* is extending its ravages. Catching the insects is very expensive work and does not have any effect apparently. The only thing I can see for it is shade, and under shade we will not get nearly as much crop as we do in the open, but "half a loaf is better than no bread," which will be the case whenever shade is not resorted to. The Coorg fig (or "attimaram" of the coolies) makes a fine shade tree—it always did for coffee. I have often seen a patch of coffee, green and flourishing under one of these trees when all around it was dead. I believe the splendid crops that we hear of their getting in Coorg are all due to the shade of this tree. It grows easily and quickly, and is not a deuse shade, and it is the very thing for cacao where the cacao has been established.

OLD CEYLON COFFEE PLANTERS ON TEA.—Both Messrs. MacLeod and Sinclair have returned to Ceylon more than ever impressed by what they have seen and heard at home regarding the good prospects for our tea. The former has a hundred acres of tea on Donside, a half of which is already giving leaf, and two hundred acres to be added, making 300 acres in all. It is not his intention to put up machinery just yet, but in the meantime he will dispose of his green leaf to neighbors. He continues to have an interest in Belgravia, which has thus far done well for him, whilst Mr. Sinclair is equally fortunate with the coffee crops from Bearwell, of which he continues to have excellent accounts. It is evident from the information gathered in the Lane by these friends that the feeling in favor of the Ceylon tea enterprise has taken a firm hold of the London financial mind. Public sales and brokers' reports are so unanimously in favor of the article that it is impossible any longer to resist the inference that the industry must be remunerative and the demand for Ceylon leaf is now on a thoroughly established basis. Brokers declare that, even with 200,000 acres of land under tea and in full bearing, giving say, 300 lb. an acre, or a total yield of 60,000,000 lb. of such tea as we are now sending home, we need be under no apprehension about finding a demand for it all at fairly remunerative prices, having regard to the extremely low rate at which it can be produced in Ceylon. But there is only one opinion in the Lane as to plucking. They say "Do not go in for coarse plucking, but produce an article with which China cannot compete and you will always obtain your price for it." Five hundred lb. an acre of really good leaf will find a better and readier market and pay better in the long run than 800 lb. or 1,000 lb. an acre of coarse leaf. It may suit Assam, Chittagong, and Dooras planters to go in for quantity in competition with China tea, but not Ceylon or Darjeeling. Mr. D. Reid is doing the colony a service by exposing for public examination the accounts of his Mariawatte estate in the reading-room of the Westminster Palace Rooms. A sale of extraordinarily fine Blackstone tea had been made just before the mail left and had been noticed and commented upon in the "City" article of the London *Times*.—Local "Times."

THE "TROPICAL AGRICULTURIST."—A home subscriber writes:—

"It is an excellent magazine for those who are actively and practically engaged in tropical agriculture, and I wish you every success with it."

A HINT TO THE CEYLON AUTHORITIES.—The Director of Agriculture in Madras has made a suggestion with regard to the prizes to be given at Agricultural Shows which is certainly worth a trial, and has met with the approval of the local Board of Revenue. Instead of giving the whole of the prizes in money to successful competitors at Agricultural Exhibitions, it is proposed that presentations of good specimens of stock, of agricultural implements and of selected seeds, should be made. The nature and kind of the stock and seeds, as well as of the implements, would of course be determined according to the agricultural conditions of the district in which each exhibition was held. It is thought that, by the adoption of this suggestion, the improved stock would get into the hands most likely to make the best use of it, whilst at the same time it would lead to a general improvement amongst the cattle.—*Calcutta Englishman*.

"THAT MISERABLE ASSISTANT."—A tea planter, writing to the *Calcutta Englishman*, says:—I feel like a Soudan special correspondent writing in a zareeba under a hail of bullets. Only my zareeba is a corner verandah of the factory, where my simple-minded manager (who imagines I am inspecting the roll) can't see me, and the hail of bullets is hail—imminent hail, from some exceedingly disgusting looking clouds which are sweeping up from south-south-west. Why hail should so frequently come from the south I do not know, unless it is because that is a pleasant quarter to reside in:

When Economising Agents are not writing,
When Directors leave the Board Room (with their feet),
You'd think they were not capable of blighting
Or smashing up a Manager with ease.
The hail may come and all the bushes smother,
Still it melts away quite sweetly in the sun;
Oh! take one consideration with another,
The tea planter's life is not a happy one.

Except when he can lay all the blame on that miserable assistant.

MARKING FRUIT (*C. L. R.*).—This is the produce of *Semecarpus anacardium*, is a large tree, 50 feet high, a native of the mountains of the East Indies, and is called Marking Fruit. What constitutes the fruit is the swollen receptacle, which, when ripe, is yellow, and is roasted in ashes and eaten by the natives. They have the flavour of roasted in ashes and eaten by the natives. They have the flavour of roasted apples; but when unroasted they taste astringent and acrid, leaving a painful sensation on the tongue for some time. When unripe it may be made into good bird-lime by pounding it. The nut is heart-shaped and seated on the receptacle, black, and consists of a cover or shell composed of two skins—an outer and an inner—and a kernel. Between the two skins is contained a black, acrid, resinous juice, which, before it is ripe, is of a pale milk colour. This black acrid juice of the shell is by the natives applied externally to remove rheumatic pains, aches, and strains. In tender constitutions it often causes inflammations and swelling but where it does not produce these effects it is an efficacious remedy. It is in general use for making cotton cloths, and the colour is improved and prevented from running by a little mixture of quicklime and water. The juice is not soluble in water, and is only diffusible in spirits of wine, for it soon falls to the bottom unless the menstrum be previously alkalisied, but then the solution is pretty complete, and of a black colour. It sinks in fixed oils and unites perfectly with them, but the alkaline solution acts upon it with no better success than plain water. The kernels are rarely eaten. The wood is reckoned of no use, not only on account of its softness but also because it contains much acrid juice, which makes it dangerous to cut down and work upon.—*Journal of Horticulture*.

SALT FOR CURING FISH.—On reconsideration of the subject, the Government of Madras is of opinion that it would be better to forego all duty on salt used for curing fish, having regard to the advantages to the public which will accrue therefrom. The present system of supply at cost price will be continued, and it will be the object of the Department to suggest measures for extending the benefits of the system.—*Madras Mail.*

CATTLE BREEDING.—As a step towards improving the live stock of the country by the influence of example, the Director of Revenue Settlement and Agriculture recently proposed to encourage land owners and Mofussil stock-traders by substituting presentations of live and dead stock for the money prizes which it is now the custom to distribute at Agricultural Exhibitions. These proposals had the concurrence of the Board of Revenue, and have now received the entire approval of the Government.—*Madras Mail, June 5th.*

A PANACEA FOR ALCOHOLISM.—Dr. Fleischl, of Vienna, declares that morphiism, alcoholism and similar habits can now be cured rapidly and painlessly by means of cocain chloride. The method is very simple—a withdrawal, either gradual or abrupt and complete, of the habitual intoxicant, and treatment of the nervous and other symptoms which arise therefrom by means of hypodermic injections of the cocain. He claims that in ten days a cure may be effected in any case. The dose of cocain chloride, hypodermically, is from one-twelfth to one-fourth of a grain, dissolved in water, repeated as necessary.—*Morning News.*

BLACKSTONE TEA up to 2s 8½d with an average for 35 packages of 1s 10d per lb. is the best report on Ceylon Teas by this mail, and is another feather in the cap of the spirited, careful and intelligent Ceylonese proprietor and manager of the estate. All honour to Mr. Barber, gold medallist, and may his success lead many of his countrymen to follow his example by turning tea planters. A London Correspondent sends us the following series of capital averages just realized:—

	TEA.	
	AVERAGES.	
Blackstone	35	pkgs. averaged 1/10
Gallehoddoo	116	" " 1/7
Rookwood	99	" " 1/5½
Windsor Forest	158	" " 1/4½
Letcheme	24	" " 1/3½
KAW	112	" " 1/2½
Ovoea	45	" " 1/2½

MOSS AND LICHENS ON TEA TREES.—In the proceedings of the Agricultural and Horticultural Society of India, we find the following under Communications:—"From Messrs. Maeneil & Co., enquiring if any preparation suitable for removing moss and lichens from the stems of tea bushes can be recommended, as one of the gardens in their agency is much affected, and a remedy would be useful. Messrs. Maeneil & Co. were informed that a saturated solution of soft soap and common salt, applied with a painter's brush, is used for removing moss from fruit trees, and is also said to destroy eggs of insects; lime, either dusted on while the trees are wet or applied in the form of whitewash, is also used. It would be interesting to note the effects of these remedies on red spider." We understand that iron-wire gloves are used to remove moss from forest trees in Britain. Can any reader who has seen such gloves used say if they would be likely to answer for tea bushes? We should fear decortication unless the wire were very fine. But we suppose coir is as good as anything which can be used? We fancy the moss ought to be rubbed off as a preliminary to any application, although, no doubt, a liberal application of caustic lime would kill the moss on the stems

THE OUTWARD AND VISIBLE SIGNS OF TEA JAT are so uncertain, especially in the case of old trees allowed to grow up in a state of neglect, that the "tea authority" alluded to by the author of "gup" is not so much to blame as might be imagined. Tea planters are familiar with the process by which hybrids with leaves as large, bright-coloured and serrated as those of pure indigenous, show smaller and more slender leaves as they increase in years, whether left as seed-bearers, or cultivated for leaf. But if a shoot springs up from the root of such a tree the leaves of such shoot revert to the original fine type. In our own experience the best flush-yielders amongst hybrids are those with long but narrow leaves. We are speaking of tea at high elevations, where even China bushes well cultivated yield wonderful returns.

MATERIAL FOR PAPER MAKING.—It seems that at the Lucknow paper mills a kind of Indian esparto is used, which is thus noticed in the *Madras Mail*:—"We quote the passage because the plant may, possibly exist in Ceylon:—The materials employed for the production of paper in the Lucknow Mills are rags of all sorts; rope and gunny (jute) refuse and vegetable substances, including rice-straw, 'moonj' and 'bed or baid,' otherwise locally known as 'Khabar or banks. The scientific name is—Major Pitcher informs me—*Pollinia Ariopoda*. It is found all along the Himalayas. This last plant is a sort of esparto which is collected in Shahjehanpur and Philibet, through the Forest Department, and locally purchased at from 11 to 1½ a maund. It is said to grow at the foot of, or on the lower ranges of the hills, and as it is considered the best known raw material for paper making in this part of India I have sent Dr. Bidie a small bundle for the Madras Central Museum, as I believe that it, or something like it, is common in the Madras Presidency. The proved good qualities of this grass makes it desirable that it should be utilized on a much larger scale than at present. Paddy straw is much the cheapest material, and answers the purpose fairly well. All the other substances used for the same purpose in the mill, and already enumerated, cost about the same price as beh.

PRODUCTS FOR THE NORTH OF CEYLON.—We have in Ceylon a closely allied species *E. monogynum*, which is common in the hot dry districts, and called in Tamil "Tevadaram." The wood is slightly fragrant, and Dr. Ondaatjie has recorded the preparation from it at Puttalam of a creosotic oil. The leaves are strikingly like those of *E. Coca*, and it is interesting to note that in South India, they were largely used as food by the poor during one of the late famines, as recorded by Dr. Bidie. They may possibly contain cocaine.—*Dr. Trimen.*—There are, we ["Jaffna Catholic Guardian"] believe, two kinds of trees going by the name of Tevadaram in the North. One is largely used in native medicine, so much so, that trees of this kind, which no one takes the trouble of cultivating, are getting very scarce in Jaffna. They extract a kind of oil out of the wood, or use it in the form of powder; the wood is of light brown colour and fragrant. We think the gardens should not be all confined to the limits of one or two provinces. The North does not lack industry or soil; all it wants is means of turning these to account; we think that nowhere could a botanic garden prove more useful than in Jaffna. To mention only one or two items: cotton, if attended to, could very soon become an important produce, and the source of a no less important industry in Jaffna. It grows wild in our gardens; but, as old wild plants, is of poor quality, though it must not have always been so, as the native names of Point Pedro (Parutti-turrai, cotton-harbour) shows that there was formerly a trade in that branch in the Peninsula. Jaffna fruits are of superior quality, and its grapes and plantains are famous all over the island. What could not be achieved in this respect with the care and learning of a Dr. Trimen? We just mention this as a specimen of what could be done.—"Jaffna Catholic Guardian."

RHEA FIBRE: CULTURE AND PREPARATION.

RHEA CULTIVATION—PROPOSED COMPANY—USES OF RHEA FIBRE—A HINT TO CEYLON—SIMPLE PREPARATION.

It is now nearly eighteen months since Mr. Edwin Watson of Johore entered into an agreement with Mr. G. W. H. Brogden & Co. of Gresham House, London, to sell to a Company 20,000 acres of land selected by him for the cultivation of rhea in Johore, and to act as local manager of the property, but up to present time the Company has not been floated. Mr. Watson has however since his return to Johore about a year ago planted out a considerable area of land with rhea, and has already demonstrated the suitability of the soil and climate for its culture; not that there could ever have been any doubt on this point, as the plant is indigenous all over the southern portion of the Malay Peninsula. A determined effort is now being made by the London firm above-named to establish a company to promote the production of the fibre, and to purchase from it the rights to use the Favier-Frémy processes, and in furtherance of this object Mr. Edward Caspar, one of the partners, went down to Manchester a few days ago, and held a meeting at the Town Hall, under the presidency of Mr. James H. Hutton, the Chairman of the Chamber of Commerce, who is by the way the brother of the late Mr. T. O. Hutton, formerly of Kandy, and son-in-law of Mr. John Capper. Sir Joseph Lee, and some other prominent Manchester men have lately manifested a keen interest in the question of utilizing rhea, and extending its supply, and Mr. Caspar's purpose was to enlist the sympathy and support of Lancashire mill-owners for his project, which is now called the China Grass Supply Company. His efforts seem to have been very successful, if one may judge from the attention that has been attracted to the subject in the Manchester papers, and the large number of influential men who took part in the proceedings, but whether when it comes to the practical test of subscribing the requisite capital, they will be found equally eager, I cannot of course pretend to say. Mr. Caspar exhibited a great variety of materials made from rhea, extending from fire hose and machinery belting to beautiful velvet goods, towellings, table covers, and other articles; yards of all counts up to 20's (French); and samples of the fibre in every stage of manufacture, and of the chief shades of dye. It was conclusively demonstrated that entire success has been gained, and that the material has been proved applicable to a very wide range of goods: indeed, it is claimed for it that it stands at the head of all vegetable fibres. There is in it a hairiness of texture which permits of it being worked up into resemblance of wool; and it has also a gloss and lustre which assimilates it to the most delicate of animal fibres, namely, silk. For rough goods it is particularly valuable. Although it can be sold at half the price of flax, it is six times as strong. Made into fire hose, and tested against ordinary material, it has been found that whereas the latter commenced to "weep" at a pressure of 100 lb. the rhea hose would stand a pressure of 600 lb. As machinery belting, the results of experiments by Messrs. D. Kirkaldy & Sons prove its high superiority to leather in respect of tensile strength and rates of extension: leather broke at 600 lb. mean stress, China grass fabric held out until 1,400 lb. had been reached. It works up admirably in furniture fabrics, taking the place of spun silks, in giving all the silky appearance with the advantage of greater strength.

Mr. Caspar explained to the meeting the nature of rhea cultivation, pointing out that it was both easy and profitable, and announced that large blocks of land had been secured by the Company in Johore and Venezuela. A large portion of the land in Johore lay on both sides of a river navigable to the ports of Johore and Singapore at all seasons, and there were six crops a year. The delay which had taken place in the popularizing of the fibre arose from the difficulties and expense attendant on its treatment to prepare it for use, but processes had somewhat recently been discovered, which removed this difficulty, and now the fibre could be delivered chemically pure, ready for spinning and dyeing. From the date the plant was cut off until it was delivered to the manufacturer a week need not elapse, and the Company, if

formed, would insure a supply of at least one thousand tons a month. The material could be laid down cheaper than any present one,—flax, cotton or hemp, and it had qualities infinitely superior to any of them. Those who were moving in the matter had secured some thirty square miles of land, and had acquired very valuable concessions and privileges. What they wanted now was money to enable them to cultivate the plant, and to the Company which it was proposed to form Sir Joseph Lee had promised to subscribe.

One of the Manchester papers in discussing Rhea Culture remarks as follows:—"Even as the nearly-ruined coffee-planters of Ceylon found salvation at the last moment in cinchona and tea cultivation, so, perhaps, may the unfortunate gold-seekers of South India save something by growing rhea grass on their estates. Owing to recent improvements in the machinery for separating the fibre, this industry promises to prove very remunerative. The main difficulty, indeed, is in finding localities where the soil and climate suit the plant. A supply of cheap labour is also necessary, and as all these requisites exist in the Wynaad and adjacent districts, it requires nothing but capital and enterprise to make a start. According to the calculations of Mr. W. G. Kemp, each properly-cultivated acre should yield a net profit of £8 3s 1d per annum. This includes all working charges from planting until the prepared fibre is placed on board ship. A farm of 1,000 acres would, therefore, return £8,164 3s 4s as interest on the capital sunk in buildings and machinery. The estimates are made on the assumption that each acre would yield 10 cwt. of the fibre per annum, but Mr. Kemp is of opinion that the out-turn might be doubled by careful planting and manipulation. Even, however, as matters stand, it would appear that a handsome profit awaits those who are the first to enter this promising field of industry. The pioneers in cinchona cultivation realized huge profits before the market value of the article was depreciated by augmented production."

I may add that Mr. Kemp's calculations are purely theoretical, since he has never planted, or even seen, a single acre of cultivated rhea in his life, but Mr. Fenings, the Secretary of the Glenrock Co., assures me that under Mr. Minchin's management the industry has been most successfully introduced on the Company's estates in the Wynaad. Starting in May last year with about 2,000 plants which he brought with him from Algeria, Mr. Minchin had in December succeeded in establishing no less than 300,000 healthy plants, and during the monsoon rains this year he hoped to complete the planting up of 200 acres. Of course, in order to produce such a result as this everything was sacrificed to propagation; no plants were allowed to mature; as soon as possible they were taken up and divided, and in this way a single plant in five months had produced thirteen strong-growing cuttings. The soil and climate, he said, are evidently most suitable, and before the close of the present year it is expected that a portion of the mature stems will be cut and decorticated, so as to test the commercial value of the industry. He reports too, that the natives in the neighbourhood of the estate are manifesting a lively interest in the subject, and eagerly enquiring for seeds and plants to put into their own gardens, so that, if any one of the processes now available for extracting the fibre should prove really satisfactory, it is pretty certain that the rhea industry will soon become a very important one, both to Europeans and natives.

I have gone at some length into this matter because I am convinced that it is one which must at no distant date receive serious and practical consideration in Ceylon, where there are thousands, I might almost say millions, of acres of land now lying waste, which might profitably be occupied with this product. It has the great advantage over most others now in vogue, that, where plants are available, the first crop may be cut within twelve months. During the last few days, moreover, I have received information which lends much additional importance to the question of rhea culture, and the accuracy of part of it can easily be tested in Ceylon as there is plenty of wild rhea growing in the jungles. I am told that there is really no necessity for the Favier steaming process in order to decorticate the stems, for if the thumb nail be inserted in the soft bark and fleshy matter contained in the fibre

at the thick end of the stem, so as to loosen it from the woody pipe which runs up the centre, the whole can be stripped off by the hand with the greatest ease, provided this is done very soon after the stems have been cut, and when there has not been a long-continued drought. The "ribbons" thus stripped off, and containing the outer bark and the fibre embedded in the gums lying beneath it, are said to be much more amenable to subsequent treatment, than if steam had been applied, because they are in a perfectly natural state. They can be easily dried in the sun, and baled for export. If this be true, and I have been shown some "ribbons" said to have been obtained in this way in Egypt, it would surely be possible to start the industry at once, by employing men to go into the jungle and operate there and then upon such stems as they might find sufficiently matured. But more important than this is the discovery of a more simple, economical and efficacious method of subsequent treatment. A French chemist claims to have found a chemical, a solution of which in boiling water will dissolve all the gums surrounding the fibre and attaching it to the bark, and will leave the fibre itself perfectly clean and ready for the spinner. The ribbons need not be boiled under pressure as in the Frémy process, but, as I understand it, they are simply steeped for a short time in the boiling solution, and the fibre which then comes away need only be washed in cold water and dried. The chemical is not costly as you may judge from the fact that the whole process will, it is estimated, be completed in quantity for less than a halfpenny per lb. I have seen the cleaned fibre and have heard the opinion of experts to the effect that it is even better for the spinners' and dyers' purposes than that prepared by M. Frémy. No machinery or elaborate plant is necessary, nothing but an ordinary cauldron or boiler, and a supply of the chemical, so that it would be easy enough to carry out the process on any estate or even native garden, and ship home stuff which would be worth at least 1s per lb. making a liberal reduction for the influence of increased supplies. You will at once appreciate the immense importance of such a discovery, if the brief description I have given of it be accurate, but I wish you to understand that I am only repeating what has been told me by the London agents of the French chemist alluded to, who is engaged in negotiations for a sale of the secret.—*London Cor.*

THE SOIL SUITED TO THE ORANGE.

Analysis of some soil taken from Mr. Pye's celebrated Rocky Hill orangery, Paramatta, New South Wales, as published in *Orange Culture in Auckland*, shows that silica is its principal component. Mr. Pye was one of those who believe that the orange does not want much manure, but well-worked soil, and plenty of heat and moisture. The analysis belows shows that he was right:—

I.—SOIL.

Water	1.21
Organic matter	1.41
Substances soluble in dilute acid (a)	0.61
Clay	0.22
Fine sand (b)	21.69
Coarse sand	78.83
			100.00

(a.) Composition of part soluble in acid.

Silica	0.154
Iron sesquioxide	0.298
Alumina	0.114
Lime	0.021
Magnesia	0.010
Phosphoric acid	traces
Alkalies	0.011
			0.611

(b.) The sand is principally quartz.

II.—SUBSOIL.

Is very similar to the soil, except that it is a little coarser.

W. SKEE,

N. Z. Geological Survey Laboratory.

11th December, 1881.—*Queenstown.*

CINCHONA LEDGERIANA.

Mr. E. M. Holmes states that the name *Cinchona Ledgeriana* was first used in the East Indies to distinguish the trees grown from seed collected in the northern portion of Bolivia by an Indian servant of Mr. Ledger, and which was subsequently distributed to Java, various plantations in India and Ceylon. Mr. J. E. Howard figured three forms he had received from Java as the produce of Ledger's seedlings, under the name of "*Cinchona Calisaya*," variety *Ledgeriana*. Doubts, notwithstanding have existed among planters as to the exact characters of recognition. Mr. Holmes is of opinion, finding marked differences in the external characteristics of specimens submitted to his notice, that several different varieties or forms, one or more of which are probably hybrids, are now grown in plantations under the name of "*Cinchona Ledgeriana*"; and that there is not sufficient evidence to support the conclusion of Dr. Trimen that he had determined the typical plant, which, having figured and described, he had erected into a species.

Mr. Holmes suggests, therefore, to planters that herbarium specimens, gathered when in fully-formed fruit, and accompanied by a characteristic portion of bark, should be kept for reference of all forms that present a recognizable difference in habit of growth, appearance of bark, typical form of leaf, size and structure of flower, and shape and size of fruit. In this way only can the tangle be unravelled into which a mixture of a variety of seeds supplied by Mr. Ledger has led botanists.—*Chemist and Druggist*. [Dr. Trimen will, doubtless, have something to say to this, but why does Mr. Holmes ignore the portraits and descriptions of *Ledgeriana* varieties by Moens? Equally with Dr. Trimen, the eminent Dutch botanist separates *Ledgeriana* from the *Calisaya*.—Ed.]

"CRYPTOMERIA JAPONICA" AS A TIMBER FOR TEA BOXES.

Some eight years ago, Mr. Gammie sent us, from Darjiling, a quantity of seeds of this tree, but they did not succeed at Abbotsford, probably from loss of vitality in the long carriage and perhaps from want of knowledge how best to germinate the seeds. As the tree has been naturalized in the Darjiling hills, growing readily at elevations of 5,500 to 7,000 feet, we cannot doubt that it would succeed on the mountains of Ceylon. Provided the seeds are in good condition, they seem to be easily germinated. Our authority is Mr. Gamble, in whose valuable Manual the tree is ranked with the conifers and specifically with the cypresses. Such being the case, the terebinthine odour so strong in many of the true pines is probably absent from the timber. In any case, whatever odour there may be is dispelled by the artificial seasoning to which the wood is subjected by the sawing and box-making establishment in Japan. When we come to think of it, surely a prominent place in the romance of commerce must be found for the connection which Mr. Deane of Kintyre estate, Maskelyne has been the means of establishing between the enterprise of the tea planters of Ceylon and the forest wealth of the Far East of the globe as utilized by the ingenuity and scientific appliances of men from that Far West which has been defined as "a little on this side of sunset." The Japanese call their country again, "the land of the rising sun." Ceylon lies merely midway between the regions of sunrise and sunset, profiting by the resources of each. And let us not forget that, but for the wonderful progress of steam navigation and the competition which has so largely cheapened freight, we could not possibly be receiving tea boxes manufactured by American machinery from timber grown in Japan, at prices below those at which the locally-manufactured articles can be supplied. While not only timber suitable for tea boxes and building purposes but even firewood is becoming scarce in Ceylon, let us be thankful that so large a proportion of the Japanese archipelago is clothed with luxuriant

forest, much of it close to the seashore. The gentleman who recently left Ceylon for Europe with the purpose of getting tea boxes manufactured from the pines of Scandinavia, may find his plans affected by this sudden opening of imports of boxes in shooks from Yokohama. But as neither the forests of Northern Europe nor those of Eastern Asia are inexhaustible, it may be well for Ceylon tea planters to devote some portions of their estates to the cultivation of trees which in the minimum of time will supply useful timber from their trunks and firewood from their branches. Next to the Australian blue gum in rapidity of growth and perhaps the superior of the eucalypt in available timber seems to be this Japan cypress (it grows also in China) which the botanists call *Cryptomeria japonica*. Mr. Gamble describes it as of excessively rapid growth in Darjiling, where it is largely cultivated. He says it is a large tree of China and Japan, the seeds of which were originally brought to India by Mr. Fortune. It grows best at 3,000 to 6,000 feet, say 4,000 to 7,000 in Ceylon, and probably seeds could be more easily obtained from Japan than from Darjiling. It seeds abundantly, and the seedlings are, according to Mr. Gamble, very easily raised in boxes and sheltered beds. He describes the tree as brittle, the tops and branches being easily broken by high winds. Thickly planted we should think the trees would shelter one another. We quote what follows from Mr. Gamble:—"Bark brown, fibrous, peeling off in narrow strips. Wood soft, white, with a brown, often almost black, heartwood, very uniform, with narrow bands of darker and firmer tissue at the end of each annual ring. Medullary rays short, fine and very fine, extremely numerous."

DIVERSIFIED AGRICULTURE IN THE MADRAS PRESIDENCY.

We attract the attention of Sir Arthur Gordon, his Executive Council and Revenue Officers to the following letter from the Director of Agriculture to the Madras Board of Revenue, dated 26th March last. We now merely add that the Madras Government, on the 2nd May, passed an order approving of the Director's proposals. The system which prevails in India, of the Board of Revenue publicly dealing with administration proposals laid before them by the Civil Officers, so encouraging a general and progressive interest, is much superior to our Ceylon mode of managing provincial and district affairs. It is time too, that the Ceylon Government and revenue officers did much more than they are doing to promote a *diversified Agriculture*. We quote as follows:—

The Government Farm at Saldapet is to be closed, and direct agricultural operations on the part of Government are for a time therefore at an end. I do not, however, think that agricultural experiments need on this account be abandoned, but I propose that they should now be undertaken in a new direction. There are two objects which I consider worthy of the consideration of Government in this connection—one of a purely agricultural nature, the other intimately connected indeed with agriculture, but of a more commercial and speculative nature. The former relates to the introduction of a more diversified agriculture in irrigated tracts that are now almost exclusively devoted to the production of rice; the latter to improvements in the curing of country tobacco, so as to make it a more marketable and commercially more valuable article than it now is. The introduction of a more diversified agriculture in tracts where rice is now the sole or chief product is intimately connected with the more economic use of water provided for irrigation, so as to make the same quantity available for wider areas by the growth of crops which are either not generally irrigated or do not require such an abundance of water

as rice does. Such crops often suffer much from the failure of rain, and would often be saved altogether or greatly benefited by partial flooding from artificial irrigation. If this end can be secured by the contraction of the area of rice cultivation, a largely-increased area of land would be perfectly protected, which, at present, is only partially and intermittently protected, and the area and volume of production largely increased to the great advantage both of the cultivating classes and of the public generally. I propose, therefore, that with the permission of Government, this department should enter into an arrangement with some substantial cultivator for the cultivation on a block of land, say, of 50 to 100 acres in extent in one of the delta tracts, which ordinarily is cultivated with rice only, of a diversity of crops, one only of which shall be rice and the other crops that are not usually classed as irrigated, the cultivator being guaranteed against loss by a covenant on the part of Government to make good to him the loss, if any, incurred by him in making the experiment. The question of loss or no loss would be determined by the relative value of the products other than rice with that of rice grown on the same area; this again being determined by reference to the value of the produce raised on the rice-cultivated area of the block or by consideration of what, in ordinary years, the same land can be shown to have produced when cultivated with rice. For an experiment of this kind, Mr. Kistnasawmi Mudali of Shiyali would, if he can be induced to undertake it, be admirably fitted, and I have to request the sanction of Government to my negotiating with him on the matter. There is another point of view from which the introduction of a diversified agriculture in irrigated tracts of wide area is desirable. The losses sustained every year by cultivators in these tracts from the attacks of insects, from fungoid diseases and from closed ear-shoots (*kodu*) and deaf ears may not impossibly, be due, in a great measure to the exclusive cultivation, for a long period of years, of a single product, and the introduction of new and varied products might not impossibly have a considerable effect in mitigating, if not removing, the evils from which the single product at present suffers so seriously.

CINCHONA BARK IN EUROPE AND AMERICA.

The past year has brought occurrences of wide significance, which have put an end to the unnatural situation that has existed so long. On January 21st, 1884, the "ring" of quinine-makers broke up, and during the first half of August came the failure of the great quinine factory of Milan and of the largest London holder of bark. It is known that the "ring" was the work of the former director of the *Fabbrica Lombarda*. From the reports subsequently published of the rash engagements of this establishment it appears clearly that the situation, from the very formation of the "ring," was quite hopeless, and that this last anchor of salvation was also deceptive. The loss of the subscribed capital of 6,000,000*fr.*, with a further deficit of 5,000,000*fr.* due to creditors, could only be the result of several years of excessive speculation. In the first half of the past year attempts were made from Milan to bring about a new turn. In May and June, with the co-operation of the London speculator, bark was artificially raised to 8*l* and 9*l* per unit. But in July the bark market became more and more uncontrollable, and in August, after the catastrophe, Ceylon bark reached 5*l* and 6*l* per unit. That a complete panic was avoided was due to the fact that the stocks of quinine and bark were in the hands of powerful banks, and have come on the market only by degrees, and perhaps not even yet. The reduction in the price of manufacturing barks was, therefore, slow, and when 5*l* per unit, the lowest point, was reached in November the Ceylon planters affirmed that the collection of bark would no longer pay. By withholding their stocks they were able to secure in December not only a better tone, but high prices, for in January 6*l* and 8*l* per unit was regained. The cause of this recovery is to be sought in a combination of circumstances. First, the London holders of South American barks continued to make such high demands that the buyers at the auctions confined themselves almost entirely to East Indian. Then in January came the report of revolutions in Columbia. The statistical position at the end of December

also appeared favourable to a rise. During 1884 in England the imports were 59,287 bales against 90,608 and 110,517 bales in the two preceding years; the deliveries were 78,532, 67,340 and 88,717 in 1884, 1883 and 1882 respectively; and the stocks remaining were 80,500, 99,667 and 70,676. The stocks in France in the same years were 11,205, 18,282 and 15,776 bales; and in New York 2,600, 6,200 and 15,900 bales respectively. Thus in 1884 the total imports were 76,708, deliveries 106,630, and stocks reduced from 124,149 bales in the preceding year to 94,305. The London imports included 10,000 bales of Cuprea. This statistics are not to be accepted without examination, as the greater part of the imports and a large percentage of what was worked up was of Asiatic origin, that is to say, the bales were nearly double the size of those from South America. The English imports and exports stated in hundredweights give a different appearance:—

	1884.	1883.	1882.
	Cwt.	Cwt.	Cwt.
Imports	105,957	117,825	138,763
Exports	102,853	69,370	80,014

The stocks in 1884, although reduced by 19,107 bales, are only 3,104 cwt. less. The shipments from Ceylon have been as follows, the year dating from October 1st to September 30th:—

	Lb.	Lb.
1880-81... ..	1,208,518	6,925,598
1881-82... ..	3,009,893	11,492,947

It was estimated that the shipments for 1884-85 would be between 5,000,000 and 8,000,000 lb., or about 6,500,000 lb. But this amount is almost certain to be exceeded, as up to February 19th 678,183 lb. of twig and 3,053,579 lb. of stem bark had already been embarked, against 240,836 lb. and 2,177,018 lb. in the same part of the previous season. The imports of South American bark into London were—in 1882, 95,930 bales; 1883, 53,780 bales; 1884, 20,070 bales. The high prices of bark at the beginning of the year were partly influenced by sudden large purchases for North America, which possessed only small stocks of bark, and where the newly-erected factory in Philadelphia, as well as a further establishment in New York, will soon commence operations, or have already done so. Their object is to make the importation of European quinine into the United States unnecessary and impossible. Here are the imports of quinine (in ounces) into the States from June 30th to end of the fiscal year:—

1877 (duty 20 per cent.)	75,804	1880 (duty free)	416,968
1878	17,549	1881	408,851
1879	228,348	1882	794,495
		1883	1,055,764

The guiding spirit in the new American factory is the speculator formerly of Milan, who desires to influence the London auctions as was attempted to a small extent in January, or by purchases in Ceylon to lessen the arrivals in London, and so pave the way for a fresh rise in prices. Against this stands the magnitude of the stocks in London, amounting to 76,561 bales on March 1st, mostly in strong hands, and consisting to a large extent of valuable Cuprea, Tocima, and Calisaya. Nothing but a considerable reduction in the arrivals from the East Indies, with stagnation in the exports from South America, could favour a fresh and permanent arrangement.—*Chemist and Druggist*, May 15th.

TEA IN LONDON: THE SECRETS OF THE SALES-ROOM: REFORM NEEDED.

With the increase in the public sales of tea some years back, the system of offering parcels in lots of six, nine, or ten packages, which was well adapted to a small trade, was felt to be totally inapplicable to a large one, while the waste of time to which it led was intolerable. It was therefore suggested to the importers and brokers that the size of the lots should be increased, and that not less than thirty or fifty packages should be offered at one time. Instead of this reasonable solution of the difficulty, a far more drastic remedy was adopted, and the importers decided to offer entire parcels in single lots. This certainly had the effect of saving much more time than the trade had desired, but it has led to much greater evils than the former state of things. The China teas chiefly offered

at public sale are of the commoner qualities, where the trade are more closely agreed as to value than with other sorts. On 6d. or 7d. Congou, for instance, the general valuations would not differ more than about a farthing. When a parcel of tea is offered there is at once a wild shout from perhaps twenty or thirty voices, and the auctioneer is more often than not at a loss whom to knock down the tea to, so that the most clamorous and persistent individual has the best chance of being named the buyer. The public sale-room for China tea has long become a sort of bear garden, and everyone is agreed that some change in the method of conducting the sales is an absolute necessity. It is not, however, the question of maintaining better order in a place supposed to be frequented for business purposes, which it is proposed to discuss here, but the point that full competition, under the present circumstances, is rendered practically impossible. On entire breaks of common descriptions offered in one lot, buyers cannot afford an extra farthing, as it will render the teas dear. If, on the other hand, there were several lots, for instance four of twenty-five packages instead of one of a hundred, there would be an opening for competition, and other buyers, by giving the extra farthing for a few packages, which would not materially raise the average cost, would have a chance of securing some of the tea they wanted. For instance, a further farthing on twenty-five packages would represent only 1-16d per lb. on 100 packages, which would be a trifling matter, even on low-priced tea. With the finer China teas or with the more expensive Indian sorts another set of considerations arises. It is only the larger buyers who are prepared to take entire parcels of costly teas, and, by offering them in one lot, competition is materially diminished. The general results of this state of things are most injurious both to the sellers and to the real buyers of tea, because they have had for their inevitable result the revival of the "buying-over" broker, and the handing over of the Tea sales, which were thrown open with so much trouble and at so great a cost a few years ago, as a close monopoly to a small clique of operators, whose voices are almost the only ones heard in the auction rooms. This return to old and evil conditions of trade is distinctly injurious to the importers, to the first-hand brokers, and to the dealers, by limiting competition and by introducing a totally unnecessary element of cost into the purchase of tea. The importers, if they sell to two or three people instead of to twenty or thirty, place themselves in an unfavourable position, and undoubtedly get less for their tea than if they appealed to the whole trade. Unless they take active measures in time they may see their property sacrificed to a virtual "knock-out," such as they formerly so loudly complained of, and they will have the mortification of knowing that the spoil is divided afterwards. The first-hand, or Importers' Brokers, do not in any way benefit by the change that has taken place, unless it be that when they have orders to buy a parcel of tea they are offering, they can generally knock it down to themselves. To the dealers the alteration is anything but satisfactory. The benefit of the abolition of the buying brokerages is gone, so far as public sales are concerned, because the "buying-over" brokers assume the mastery of the auction-room. If a whole parcel of common tea is wanted, which is not always the case, except among eight or ten of the larger houses, it is out of the question for a dealer to bid a farthing beyond the buying broker, as the brokerage paid for taking the tea from him after the sale is very small, compared with 3d per lb. With finer teas the old bad practice is revived, and a dealer who bids on his own account at sale is tacitly let know that he will be what is called "run" for the tea—that is, he made to pay more for it than if he took it through a buying broker. The evils of the present state of the public sales must be patent to anyone who will look through the catalogues, though they are still more obvious to those who attend the rooms. The remedies, also, are simple. First, not more than twenty to fifty packages should be offered in a lot; second, the leading dealers should agree among themselves that for a time they will refuse to purchase any "bought-over" parcels, but only buy their public sale teas either in their own names, or through instructions given to a broker by themselves.—*Produce Markets' Review*.

Correspondence.

To the Editor of the "Ceylon Observer."

BREWING IN CEYLON AND INDIA.

Oldbury, 20th May.

DEAR SIR,—I was asked the other day for some information respecting the brewing process as carried on in India and Ceylon. A brewery was started in Ceylon at Nuwara Eliya just before I left the country in 1883, but I have heard nothing of its ultimate success or failure. If the Brewery is still carrying on business, could you obtain from the managers an article on the "process they adopt," "water," "yeast," and general means of overcoming the climatic difficulties, which must be great? I should esteem it a great favour if you could oblige me in this matter, and I think if you had no objection the article could very likely be published in the *Brewers' Journal*.

With every good wish for the success of yourself and paper, I am, yours very sincerely,

C. W. BARTON.

[This letter speaks for itself, and perhaps someone who knows may send information on the subject of Brewing in the East. The last time we saw Mr. Whymper, he stated to us that his chief obstacle in Nuwara Eliya to successful brewing lay in the prohibitory railway traffic rates for malt and other requisites: costing him as much for a hundred miles here, as for a thousand miles in India. We hope a concession has since been made.—In vol. I, of *Typical Agriculturist*, pages 690 and 718, and again on page 655 of vol. II, we gave some information which should be of service to Mr. Barton's friend who is interested in the *Brewers' Journal*. It is therefore from a literary point of view that information is wanted. Can Mr. Barton in return tell us of the prospect of an increasing demand for cinchona bark on the part of brewers either in England or on the Continent of Europe?—ED.]

TEA SIEVES.

Bunyan, 30th May 1885.

DEAR SIR,—Reading the local papers some days ago, I noticed some tea-men found it a difficulty to separate the large from the small leaves, I mean the pekoe from souchong ones. I got my carpenter to make two large sieves (one for each of my estates) 8' by 3' with a depth of say six inches, meshes $\frac{1}{2}$ of an inch square made out of the strands of an old wire rope, a simple contrivance. So I suppose many tea planters have the same sort of a thing, *cheap but not nasty*. The sieve is slung from the four corners with a wire from the floor alone. One man can sift 300 lb. leaf per hour just as it arrives from the field. Pekoe leaves of course go through leaving souchong ones in the sieve. Leaves being thus separated enables me to get even withering: as the small leaves will be ready before the large, if put together to wither, I do not see how a man can get even or proper withering. Leaves will be ready for rolling, and will have more white tips of course than if the large and small ones were all rolled of a heap; tips will not be discoloured by the juice from the large leaves. Common sense tells us all that. My sieves have been in use with me between two and three years, and they are a great help indeed. 60 to 70 per cent of pekoe leaves pass through. When leaf comes in wet, several of the leaves will be found clinging together; the sieve shakes them adrift. Of course this sort of a sieve may have been in use for many years. I hope so.—Yours truly,

THOMAS GRAY.

TEA FROM SMAEL GARDENS: HOW CAN IT BE BEST SORTED AND DISPOSED OF.

Madulkele, 31st May 1885.

DEAR SIR,—Having a small acreage of tea, "say from 15 to 20 acres," and from which I hope to get about 150 to 170 lb. of made tea per m uth, could you or any of your numerous correspondents, inform me as to the best mode of sending this small quantity home—whether it should be assorted into two or three classes or dispatched unsorted?—Yours truly,

ENQUIRER.

OLD COFFEE PULPERS CONVERTED INTO TEA SIFTING MACHINES.

Blackwater, 4th June 1885.

DEAR SIR,—Now that so many coffee estates are being planted up with tea, planters must be asking the question, "What are we to do with our pulpers?" I can tell them: Do as I have done with an ancient one I found on this estate—convert the sieve attachment into a tea-sifting machine. I have had one working for some months, and it does all my work and quite as well as the most expensive patent. I made a set of sliding sieves, Nos. 8 10, 12, and 14, and whichever I require can at once be adjusted. The tea is put in a hopper at top and falls on the sieve, through that on to a galvaniz'd plate, Pekoe, Souchong unqualified passing off the top at one end whilst Broken Pekoe and Pekoe mixed pass out at the other. Two men can easily sort in a day 300 3 400 lb. Pekoe and Broken Pekoe mixed together with one man to equalize the Pekoe Souchong; these 3 men can finish off 400 lb. of bulk into Broken Pekoe, Pekoe, Pekoe Souchong and Dust for a day's work. Messrs W. H. Davies & Co. can supply the wire mesh, a piece of which 3' 6" x 3' costs about R5'25, and to make each sieve with wood, nails and labour another R2; so that they are very little over the price paid for one of the round ones which cost R6'50 and has only half the sifting surface. I am making on an average 400 lb. tea a day, and these men keep up with the manufacture easily. Anyone wishing can send his carpenter and get the plan of the whole affair.—Yours faithfully,

C. A. HAY.

TOBACCO-LOVING INSECTS: A CURE WANTED.

DEAR SIR,—Could any of your numerous correspondents inform me what can be done to keep insects from cigars? They make a small hole in the cigar and pierce it through and through. If you could be the means of informing me what could be done to prevent the ravages of these beasts, you would much oblige

VINO.

THE SOUTH-WEST MONSOON: INTERESTING DEDUCTIONS.

DEAR SIR,—Weather science, as it affects any particular locality, is an impossibility. The result depends upon so many circumstances spread over such a vast area where observation is impracticable, that the event must ever remain uncertain at any given time and place. By the leading astronomers in Europe it is now relegated to the columns of *Zodick* and such like publications; together with "Sun-spotty" and the South Kensington clique of office-seekers, who still humbug Government and the public with that myth. The swaying of the tropical monsoons, however, is another matter, but the quantity and frequency of the rains which accompany them belong to weather science. The *burst* of the monsoon should surely always be according to your own definition and not according to those marked A, B and C.

But what strikes me forcibly in regard to the chief question under discussion, namely, "the average

period required for the travelling, of monsoon rains from Colombo to Bombay," was the 35 days average therein arrived at, because observation here appears to agree with theory.

The monsoon follows the sun in theory, so Mr. Pearson's table shows that it does in fact. Taking the latitude of Colombo at 7° and that of Bombay at 18° (?)* we have a difference of 11°. According to Whitaker the sun this year was vertical at Colombo on April 8th and at Bombay on May 12th, or 34 days later!

The question to be solved appears to be: "How many days is the monsoon on an average later than the sun?" under any agreed definition. Take definition A, for instance: we can then construct the following table:—

N. Lat.	Sun Vertical	Add Monsoon due.
Colombo..... 7°	8th April (?)	12 days
Bombay..... 18°	12th May	12 days
		24th May

METALLIC VEINS IN THE ROCKS OF CEYLON.

SIR,—There has been much learned speculation about the age of the rocks in Ceylon, but it seems to me of very little importance what place they occupy seeing that they are old and crystalline enough to make it highly probable that they contain something of more value than fossils. I mean metallic veins, the search for which seems to me to have been sadly neglected, for it is hardly possible that rocks so crystalline could prevail over such a large extent of country and not have some payable fissures in them. I have only heard of one case where any real prospecting was done, and, I believe, some silver found, but the work was not carried out sufficiently to prove whether the vein was a paying one or not. Some good however was done by the attempt, as it showed that veins may be looked to run from about E. N. E. to W. S. W., same as they do in Wales.

Many erratic attempts have been made to find gold in bedded quartz when the strata chanced to be sufficiently on edge to give it the appearance of a fissure vein; but nothing was examined that did not show quartz, as only gold was hoped for. The only reason I have heard given, against the chance of finding metals in Ceylon, is that no trace, may be said, is to be found of them on the surface; but this is hardly any reason, in my opinion, against them in a country that has not been knocked about by earthquakes and volcanic disturbances. Except silver, very few metals are to be found quite up at the surface, and copper is usually from 80 to 100 feet down.

M.
[Our correspondent, in a private note, tells of "prospecting" in Pussollawa, and sends the following from Mr. A. Dixon:—

"Normal School, Colombo, 13th August 1884.

I am sorry I have kept you waiting so long, but I have been very ill under the doctor, who would not allow me to do any work. I have assayed your quartz. It is of a far superior quality to the last you sent, being much more compact. It contains the minerals hornblende and epidote in layers, and at the junction of these with the quartz there is metal. Silver is present at the rate of 113.5 dw. per ton. There are also traces of gold, titanium, iron and manganese, and other less important metals.—Yours sincerely,

ALEXANDER C. DIXON."

We quite agree with our correspondent that a thorough geological and mineralogical survey of our formations should be made. There have been some pretty deep cuttings on our mountain railways, and an examination of the debris might reveal something valuable. Mr. Blakett, who brought knowledge and testing material from Ballarat, is sanguine that gold will be found in

Dolosbage, Mr. Blakett, in fact, had specimens of his rock assayed at the School of Mines, Victoria with the result of gold being found at a rate which would pay under favourable circumstances.—Ed.]

COOLIES PER ACRE FOR PLUCKING TEA?

10th June 1885.

DEAR SIR,—I should like to know if you or some of our leading tea men would inform me what they consider a fair number of coolies per acre for tea picking. We hear a lot about coolies picking an average of 15 to 20 lb. or more. What I want to find out is what extent of ground a cooly ought to be able to pick over, say for a field giving sometimes 30 lb. green leaf per acre, sometimes 40, 50, up to nearly 100 lb. per acre or more.

The only letter that I have seen that bears on the subject is Mr. M. H. Thomas's of May 23rd published by you on May 27th. There he states he is picking off 100 acres: I see he averages from 27½ to 34½ coolias, or say 2½ coolies to 3½ per acre, and the former picked the best round of the lot, viz., average of 17.2 per cooly. Abbotsford ought to be able to give us a good idea on the subject. I should like to know what difference is experienced in picking Assam hybrid and China hybrid: as the latter is much smaller leaf, it is, I suppose, more expensive picking; at any rate I find it so.—Yours truly,

B. S.

[A "V. A." gives 1½ to 2 coolies per acre as his idea of an annual average for tea plucking.—Ed.]

NEW TIN AND TAINTED TEAS.

Rangala, 11th June 1885.

DEAR SIR,—I shall be very much obliged if you will obtain me an answer to the following through your paper:—The way to remove the smell of new tin canisters, which taint the tea if it is packed in them.

PLANTER.

[Keep the canisters open to the air for some time, or, query, burn a little charcoal over them.—Ed.]

TEA IN JOHORE.

SIR,—I beg to send you copy of a letter I wrote to a friend of mine the other day who was in communication with me, as to whether Johore would answer as a profitable tea-producing country. If you think the letter worth publishing by all means do so, as I think it may be the means of preventing tea planters coming here from Ceylon and elsewhere to meet with nothing but (as the most have done) disappointment.—I remain, dear sir, yours faithfully,

W. H. G.

DEAR SIR,—In reply to your query of the 5th inst as to whether tea would pay in Johore or not, I beg to submit the following as my candid opinion, and which is supported with the opinion of other tea planters that I have met here and been in communication with: gentlemen and planters of experience that have given the country of Johore a more lengthened and as some of them are sorry to say to their cost a determined trial (more than I care to do now), which proved unsatisfactory and unprofitable without an exception.

TEA CULTIVATION IN JOHORE.

Climate.—A good tea climate as a rule is not a healthy one. Johore and Singapore are boasted of by the European community here as the healthiest places in the tropics. This fact I candidly admit and coincide with them in. It has not the hot damp mucky climate we have in Assam and which is an indispensable point with regard to profitable tea cultivation. Therefore the great desideratum Johore possesses, sufficient rainfall, but suffers from lengthened and severe drought in the early part of the year; in fact rain throughout the year is very irregular, so much so that I have seen rents or cracks all over a tea plantation called—(that I resided on some time) so bad and the soil actually baked as hard as a brick. I began to think that this evil

* Bombay is in 19 degrees N. Lat. exactly.—Ed.

alone would be against the profitable introduction of the tea plant, which I have no doubt it will be as any drought is prejudicial to tea. Without continual moisture, the tea plant will not luxuriate to satisfy the wants of the European system of plucking, and what we prune for, i. e., plenty of young and healthy growth which cannot but give plenty of leaf if the climate is suitable. Every leaf or half-leaf left on the shoot plucked to send from the axis of that leaf a bud which should develop in 36 to 42 days into healthy and large vigorous shoots now ready for plucking, and which ought to be a shade harder plucked than its parent, and so on in succession with every new flush until the flushes begin to get stunted which will then necessitate pruning. A Ceylon coffee planter now residing here asked me not long since, why it was the tea plant did not flush in Johore so regular and so continuous as he had seen it do in Ceylon? I told him I thought it was because the interval between the rains was by far too long, &c., and when it did rain it came down in such torrents and lasted such a short time, the soil which is very stiff and hard had not time to benefit from the showers; being mostly hilly here, such heavy showers run off as fast as it rained, and from its hard dry state through continuous dry weather and nature of the soil sudden showers had not time to percolate. A really pleasant climate cannot be a good one for tea—Indian experience. [Contradicted by Ceylon experience!—Ed.]

Soil.—I have visited several estates in this neighbourhood, coffee &c., and I find there is a great sameness throughout, too much of this red stiff soil and too much inclined to cake and split. What little good soil there is I find very shallow, so much so in some places that after holing land on a moderate slope a few of the showers were accustomed to here and the sub-soil (i. e., clay) is laid bare exposing a stiff hard clay almost impenetrable, where I found instead of the taproot of some tea plants going straight down they went straight along its surface, a circumstance I never saw happen to a tea plant root all the time I have been in India. Tea thrives best in a light loose friable soil: the spongioles or ends of the feeding roots are very tender and cannot penetrate any other. It is a well known fact there is more nourishment in stiffer soils, but for this reason the tea plant cannot take advantage of it. It was long believed that tea would thrive best on poor soil, but thank goodness that idea has long been exploded but not before thousands of pounds had been wasted. The growth of the tea plant here as far as a good is concerned, is, I must say, very rapid in Johore. A three-year old plant has a stem as thick and in every way equally as large as a five-year old plant grown in Assam; but this system of judging tea plants, as is generally known amongst tea planters, is a very fallacious test.

Tea.—As regards the quality of tea manufactured in Johore there is no disputing the fact good tea can be made. As a convincing proof, I manufactured quantities of tea at different times and sent samples to tea-tasters in Calcutta; better reports and valuations I could not have expected; much better in every respect than what we usually get on teas I have sent at times from Assam. I shall be happy to show you the valuations when I next visit Singapore. Unfortunately that is no criterion to go by. The tea-plant will not flush the same as it does in Assam or Ceylon. I thought it was simply sulking (a term we use in Assam very much when a flush is long in growing), but no, it is worse than that. A week or two after the first plucking what appears to be a nice flush from the axis of each leaf left on the stem that has had the tip and one-and-half or two leaves taken from it I found at nearly every axis seed developing not only that but the old leaves to start growing afresh. I felt quite mystified: it such a freak and could not determine the cause as yet: on asking the conductor if ever he saw that happen before he said 'yes'; such being the case tea-planting in Johore is, I may say, not worth the candle. What is wanted before tea can pay in Johore is a rapid succession of healthy flushes, and from my experience and that of others to get this, the long and the short of it is, it is simply a moral impossibility.

Labour.—When we come to consider the large amount of labour required to work a tea plantation, it is certain facilities for it are a *sine qua non* to success. With the present state of affairs the labour of Johore i. e., Chinese and Javaneses with one or two Malays

now and again, really cannot be depended on, and the class of Chinese to be picked up are of the very worst kind. At the most they will only work 20 days each man per month. If a manager says too much to them to spite him they will wait until he gets a flush of leaf that he wants to take off quick, then in a body they will refuse to work unless they get an increase of pay, making this the would-be reason and leave the garden leaving the mandoro to receive their pay for the days worked. This actually happened to two estate managers here. They tried this game on with me, but I soon put a stop to it. I took the two ringleaders before the police authorities and put a stop to this nonsense. I am glad to say it had the desired effect. I did not punish them, but simply showed them I could. After that I had more coolies than I wanted and in consequence had to refuse many work. Coolies are not to be had under 25 cents (equal to about 1s) per day for Chinese, 20 cents (or about 10d) per day for Java-coolies, Malays \$6 (American dollars) per month, very scarce. They cannot be got to engage for more than a month, and in consequence every month coolies are changing more or less. This constant changing is the source of great annoyance and inconvenience which the planter of Johore (tea as well as coffee) knows to their very great cost and trouble. More in my next.—
Yours truly,
W. H. G.

TEA DRYING AND NO. 3 SIROCCO.

DAVIDSON'S No. 3 SIROCCO.—Mr. James Blackett of Deteloya, Dolobago, recently reported to Messrs. W. H. Davies & Co. as follows:—"The two No. 3 Siroccos that I have at work on Pen-y-lan and Deteloya estates, turn out 80 lb of dry tea per hour without any difficulty whatever. Both of them are in pits and the heat not allowed to come quite up to 270 degrees."

15th June 1885.

DEAR SIR.—Referring to Mr. James Blackett's note to Messrs. W. H. Davies & Co. about the No. 3 Sirocco, it strikes me there is something very ambiguous in the wording of it. Messrs. Davies & Co. contend that the No. 3 Sirocco will fire properly 80 lb. of made tea per hour, and looking casually at what Mr. Blackett writes, a person would think that he confirms this; but what I wish to know is, does Mr. Blackett get each of his No. 3 Siroccos to turn out 80 lb. of dry tea per hour working at 270°? or does he mean that the output of the two Siroccos combined is 80 lb. per hour? I have a No. 3 Sirocco and working it at 260°, it burns my tea. I have heard of the same happening on two other estates where the No. 3 Sirocco is used. I suppose in my case it may be attributed to my ignorance as to the proper way to work the Sirocco; up to date my results with the No. 3 have been unsatisfactory. I am making some changes in my way of working the machine and am hopeful of better results.—Yours faithfully,
R.

TEA-PREPARATION: A WITHERING REBUKE,

Ambagamuwa, 16th June 1885.

DEAR SIR,—The remarks of "A Practical Proprietor" (p. 44) appear to me far from practical. He is clearly discovered for this once in a somewhat steamy atmosphere of speculation, when he goes floundering about among pails and pans of hot-water, calico (l) trays and Turkish baths, in a dense vapour of theoretical tea-making.

In solemnly and decisively pronouncing his opinion against withering by hot-air, it is stated that he has the high sanction of "commonsense and scientific grounds." The latter has been however studiously withheld from us and the former does not appear to me to correspond with that of tea-makers in general, who take advantage of their Sirocco heat, and influence heat, day after day, for the purpose of withering their leaf. The objection to hot-air is stated as follows:—"Because, in drying this way the juices of the leaves are extracted,"—this is one objection; "the juices are extracted,"—what next?—"and the leaf would become harsh and would not roll well." Did ever a tea-man hear of anything like this? A heightened temper-

ature in a tea room, just enough to secure a wither, "extracting" the "juices?"—theine and tannin, I suppose, are meant. Pray what does the Sirocco do with the juicy roll put into it, when it is fired at from 275 to 300 degrees, when its 40 feet chimney is spreading far and wide the fragrance of the drying tea? Is the hot dry air rising from the stove and going through the trays guaranteed to spare the "juices" referred to? or is it only the moisture that is dispelled? Any way, it leaves enough behind to give practical proprietors at least an average of 1s 3d a lb. for the residuum. Why run the gauntlet then, with a claim for "commonsense and scientific grounds" in the case of withering? Does "Practical Proprietor" profess not to know that from 25 to 50 per cent of moisture is expelled in ordinary withering? and if this process which is indispensable in tea-making does not "extract" the "juice!" any more than the Sirocco does at a fierce "dry" heat of 300 degrees, wherein lies the "scientific" or "commonsense" difference which has caused so much alarm and anxiety in the proprietary bosom?

The next objection is: "And the leaf would become harsh and would not roll." I don't think even "commonsense" and "scientific grounds" can be accepted as an excuse for the charming heterodoxy of this proposition. It is so well established that an over-withered leaf makes invariably a better twisted tea, that one does not know by what subtle reasoning the writer arrived at his conclusions. No matter how harsh the withered leaf may be, if well plucked, I'll venture to back a Jackson's "Excelsior," ay! even a Thompson's "Challenger" for harshness to set against harshness. You have seen a corkscrew. That's the association in the mind, at the end of the conflict, as far as the leaf goes.

It is consoling to our ruffled feelings however to know that "A Practical Proprietor" has not left us and his superintendents without a hope at this critical juncture of his reflections and speculations. He has "thought the subject out" and told us what he thought. Yet he premises to "consider the question further and let you know the result." India has worked out a great deal and Ceylon is working it out now in her numerous tea factories. Let us by all means add to our experience the speculations in Turkish baths if they will stand criticism and practical experiments. —Yours truly,
AGRICOLA.

ROSE CULTIVATION.

DEAR SIR,—Will any of your readers be so good as to inform me the best method of growing roses in Colombo? What manure to be applied and in what proportion? Are wood-ashes as gathered in the kitchen mixed with manure any good? Also the best way of removing black bug, which infest the trees and kill them ultimately. Information on these points will be gratefully received by, yours faithfully,
RESIDENT IN COLOMBO.

No. II.

D. Itota, 21st June 1885.

SIR,—The best method I found of striking slips was to put them in almost pure sand kept moist all the time, for about two weeks, giving them a little of the morning sun. By that time they will have struck root, when they could be transferred to a bed or pots having equal portions of rotted cow-dung and sand. Charcoal applied to the plant's wings out the color of the flowers better. A small amount of ashes is good, but it must be known that ash is caustic, and without the aid of manure is inert, or rather harmful. For black bug try a dusting of sulphur, a branch from the ornate placed in the plant, or an infusion of tobacco d tomato leaves; any of these is said to be efficacious.

If your correspondent has the *Tropical Agriculturist* with him, he will read about the best way to cultivate roses and keep off insects from them. I gained most of my experience from reading it, and was successful in growing roses.

I forgot to mention that roses thrive well on cabook soil, but the ground must be well forked and a little lime or ashes applied to make the soil porous.—Yours faithfully,
B. E.

P. S.—I have seen a lot of people unsuccessful in growing roses; they manure them too often, and fork them too often and thereby damage the rootlets formed by the previous application of manure.

TEA BOXES.—Messrs. W. H. Davies & Co. send us a sample of a box made by the Patent American dovetailing machinery. The box is of American pine well seasoned and very strongly dovetailed together. Messrs. Davies, we understand, are importing these boxes in the following sizes:—16×16×16 (¾ in. thick) for 40 lb. and 24×19×19 (½ in. thick) for 50 lb. tea. If they can be supplied cheaply, there should be a good demand for them.

TEA LEAF WITHERING.—Here are hints from practical proprietor to his superintendent in reference to "withering" which are worth reading:—

"— is in trouble about the accumulation of unwithered leaf he has, in consequence of the rainy weather. I wrote to him yesterday, suggesting experiments in withering, by means of heat from the vapour of boiling water, i.e. steam. I told him the result of an experiment I made, and suggested further trials. Since then I have thought the subject out, and I now tell you, for your guidance, what I think.—It is quite clear that tea should not be artificially withered by means of dry hot-air; because in drying this way the juices of the leaves are extracted and the leaf would become harsh, and would not roll well; but if the leaf is withered by moist hot-air, the result would be different. I remember well, that in offices and buildings heated by stoves and hot-air; there was invariably placed, or should have been placed, large tins containing water on the top of the stove, so that the air to be inhaled should have a sufficient quantity of moisture. If you heat your tea-house up to 120 degrees with hot-air, you would soon knock your coolies and yourself up; but if you put tins of boiling-water and make your air moist, you and they could stand 120 or 140 degrees without inconvenience. Anyone who has been in a Turkish bath knows all about this. I say then, on commonsense as well as scientific grounds, that, if tea leaves are to be withered properly by artificial means, it must be air heated by the vapour from boiling-water. Fortunately nothing can be easier than doing this: a dozen ways at once present themselves to me. You can try the experiment in the easiest and most inexpensive way, and with very little trouble. Place on your tea-drier tins (as large as possible) containing water; over this put your calico trays, on which spread your leaf. The water will soon boil, and, what with the heat from your drier, and the boiling-water, you will soon raise the general temperature to 120 degrees (not enough for withering), and the heat under your calico trays to 140 or 150 degrees, which will wither your leaf in a few minutes if thickly spread. The best vapour for heating a withering room would be that from pouring water on a surface of red-hot iron: the steam would be superheated. The chief object of my writing this letter to you is to say, after thinking the matter over, that there is one way of artificially withering leaf without extracting the juices, which can be carried out at a very small expense in a variety of ways, viz., by heating the air in your withering-room to the necessary degree of heat by means of the vapour from boiling-water, that is by moist heat in contradistinction to dry heat. After reading this letter send it over to —, and, I ask you both not only to experiment but think the subject out. I will consider the question further and let you know the result."

A FRENCH SCIENTIST has been studying the effects of altitude upon vegetation, and concludes that for each augmentation of about 100 yards there will be, as a general average, a retardation of four days; that is, other circumstances being equal, a crop planted at the sea level will appear above ground four days before a similar crop planted 300 feet above it.—*American Grocer*.

"HELOPELTIS" AND TEA.—We have heard from "Peppercora" about the case he referred to, which is one previously reported to us, and in which we believe the injury done to the tea bushes was due to some other and temporary cause rather than *helopeltis*. "Not Proven" seems to be the verdict so far in respect to every instance in which *helopeltis* is alleged to have damaged tea in Ceylon.

IN A recent letter I mentioned that a parcel of COCA LEAVES was on its way from Bolivia, and last week it was disposed of at the handsome price of 7s per lb at public sale, the buyers being Messrs. Howard & Sons of Stratford, the well-known quinine makers. They have gone in for the manufacture of the muriate of cocaine and of some other out-of-the-way extracts and alkaloids which have hitherto been almost exclusively in the hands of American and German chemists.—*London Cor.*

TEA-PREPARING INVENTIONS.—We are glad to learn that the experiments made with Mr. C. Shand's new tea drier are pronounced very favorable in the results: the tea so prepared being valued above average. We have no doubt that Ceylon men, are to do much for the simplifying and improving of tea-preparing machinery, unless they should happen to be pulled up by patentees. One such case is now in the Courts and on its decision a good deal may turn.

CINCHONA AND TEA.—The Dimbula Coffee Company is entering on a new lease of life, and we trust it will prove one of uninterrupted prosperity. Mr. Dick-Lauder, who has so well done his work in the past, remains as Resident Manager, and between coffee and bark there are receipts to come in for the new shareholders more than enough to cover expenditure, while the planting of tea is being so actively carried out that already this season 450 acres have been covered—350 with fine plants and 100 planted with germinated tea seed.

TEA PLUCKING CONTRACTS WITH SINHALESE ON LOWCOUNTRY ESTATES.—An estate proprietor writes:—"It occurs to me to suggest that it would be a good plan to institute a system of plucking contracts, similar to weeding contracts: for outlying fields on estates it would be invaluable. The plucking of coarse leaf could be easily guarded against by severe fines. Assuming that when tea is in full-bearing about 18 lb. of green leaf per diem would be a good day's work, and this at 26 cents would be 2 cents per pound of green leaf. I am sure if this system was established there would never be any labor difficulty in Ceylon. The Sinhalese could easily be taught to pluck properly, and they would willingly do contract work."

COFFEE MOVEMENT IN AMERICA.—The consumption last month was unusually heavy, it reaching 22,345 tons, being larger than for any month in the record of several years. In 1884 the average per month was 17,833 tons; in 1883, 16,391 tons, which indicates the gain made this year despite dull times. The consumption for the first quarter of 1885 was 61,980 tons, against 49,225 tons and 53,594 tons in 1884, and 1883 respectively. Undoubtedly a decline of over two cents per pound has done much to improve the deliveries. The increasing distribution in a roasted state steadily tends to increase the consumption. The roasters are educating the people to believe that coffee fresh roasted, fresh ground, and fresh made is a cheap luxury and a delightful stimulant. In fact, coffee is fast becoming the most popular beverage of the day.—*American Grocer*,

COFFEE IN JAVA.—A *satisfactory prospect*.—We understand that the coffee crop in the Residency of Samarang promises to be overflowing this year. The trees are now laden with berries which are almost ripe, and of leaf disease there is hardly any trace. Barring accidents, there are good grounds for expecting an abundant crop.—*Locomotif*.

THE PROSPECTS OF TRADE ON THE CONGO.—Mr. Stanley speaks in one chapter on "The Kernel of the Argument." The Congo River is three thousand miles in length, and the regions on either side are densely populated, some of the villages being miles in length. Palm oil, timber of various kinds, cotton, orchilla weed, indiarubber, copal, spices, these and an immense variety of their merchandise awaits exportation, and a railway 235 miles long, as Mr. Stanley shows, would be able, in export and import freights, to earn a gross revenue of 300,000l per annum.—*Colonies and India*.

TEA BOXES FROM JAPAN.—Mr. H. Drummond Deane has returned after his pleasant Far Eastern trip, not so strong in health as we should like to see him. His tea boxes from Japan from what we have seen and learned are, undoubtedly, to be a great success. Their manufacture is by means of American patent machinery and has only been lately commenced, so that the question is if the demand for Japan itself (with exports reaching to 40 million lb. per annum), tea for Ceylon and India can be kept pace with. An Assam planter who travelled with Mr. Deane was so pleased with the sample boxes that he at once gave a big order. One of the largest boxes without hoop-iron has been tested by Mr. Deane with a full packing of dust, and has come in such good order notwithstanding transhipment at Hongkong from hold to hold, as to give a good guarantee for the strength of the boxes. Mr. Creasy has been appointed Mr. Deane's Agent here and at his office, the samples can be seen: the timber is good and thoroughly seasoned (kiln-dried), the workmanship perfect, and the boxes strong though light, while the prices range from 50 cents for a box to hold 20 lb. (weighing itself 5 lb.) to 80 cents for a 13 lb. box to hold 100 lb. There are three intermediate sizes to hold 45, 70, 90 lb. and to cost 55, 60, 75 cents. Altogether Mr. Deane has made a happy hit and done good service to his brother-planters.

TEA-BOXES FROM JAPAN.—The firm manufacturing the boxes brought by Mr. Deane from Japan have obtained a private concession for the cutting of timber over 20 square miles of forest, covered with the trees so peculiar to Japan, the *Cryptomeria Japonica*, of which the following account is from the *Treasury of Botany*:—

CRYPTOMERIA. A lofty evergreen tree, forming a genus of *Coniferae* of the tribe or suborder *Cupressinae*. The leaves are shortly linear, falcate, rigid and acute, crowded but spreading. The flowers are monocious, the males in axillary catkins, the petalate scales bearing five anther-cells at their base. The fruits are in small terminal globular cones, with palmately-lobed imbricate scales, each one covering four to six winged seeds. *C. Japonica*, the only species known, is a native of North China and Japan, and being hardy enough to sustain our [English] climate without injury, is now very generally planted in collections of Conifers. It is not, however, suited to heavy soil.

Messrs. Fraser, Farley, Varnum & Co., have only recently begun manufacturing the boxes by machinery.—Mr. Deane in fact taking away the first samples. They use 40,000 chests a year on their own account, and as all the tea from Japan has been sent away in similar boxes—hand-made, hitherto, and therefore 30 to 40 per cent dearer—the machine-made boxes are likely to secure the home market for the forty millions lb. of tea exported; besides being in demand for India and Ceylon,

SQUIRRELS AND THEIR HABITS.

A correspondent sends us an interesting account of the doings of one of our small Ceylon squirrels. He saw it ripping up the long foxglove-like flowers of a foreign but now common climber in Ceylon, and supposed by Mr. W. Ferguson to be the *Lophospermum erubescens*, in order to get at the nectar they contained, whilst our correspondent at first imagined the tiny rodent was eating his peaches. Here in Colombo the three-striped "ground" squirrel, so-called, but which affects our palm trees and houses, is constantly seen eating seeds, nibbling at flowers, &c. It is one of our most familiar and bold little mammals. By a curious coincidence we heard recently about a fight between one of them and a blood-sucker, *Calotes versicolor*, but which of them was the aggressor we do not know. We have seen the palm squirrels at Colombo not only pilfering gram meant for poultry but actually feeding on white-ants which had climbed up the root step of coconut trees, so that this amusing little creature seems to be omnivorous.

HABITS OF THE COMMON SQUIRREL.

"Yesterday, I witnessed to me a new and most interesting habit of the common striped ground squirrel, which may interest you. I saw a little fellow on a large peach tree, which was festooned with a common but beautiful creeper. I do not know its name. Naturally thinking the 'beautiful wretch' was after my peaches.—I like the birds and little beasts to have a share of my fruit, but really sometimes they do not seem to think that I want any!—Just to see what it was up to I watched its movements a few feet over my head and quite undisturbed. It seemed so busy that it had not noticed me. It was evidently 'on the feed,' but seeing it pass a good fat peach at once attracted my attention, and it was evidently busy in some way with the foxglove-like flowers of the creeping plant. I saw it visit several before I could make out what it was doing. Turning a small telescope on it, I saw that each time it went to the base of a blossom its little head gave a quick jerk upwards, and then was quite motionless to all appearance for a few seconds. A blossom falling near me, after it was operated on, I quietly picked it up. It was not a fully expanded one; there clearly enough was to be seen marks which fully explained the intelligent little creature's movements to get at the nectar at the base of the flower. It had seized the calyx with its sharp cutting teeth and deep enough to catch hold of a portion of the blossom, and with the jerk noticed laid open the base of the blossom, sufficiently to insert its tongue and suck the honey out. I watched it operate on 30 or 40 blossoms in a very few minutes, and saw, with the help of the glass, its tongue inserted quite clearly. It was so expert at the work that it never missed laying the base of the flower open at first shot. About a third of the blossoms fell: the older blossoms had a piece bitten quite out near the calyx, the latter sometimes not injured; younger blossoms invariably had more or less of the calyx cut up. I enclose you a specimen of each, and no doubt you can tell me the name of the plant, which is like a weed here, but I expect not a native. I enclose three mature blossoms to show how clearly each blossom is bitten exactly in the same way. The wretch is at it again this morning, throwing scores of blossoms down."

PLANTING NOTES FROM UVA.

Haputale, 12th June 1885.

The last month was a busy one up here from all accounts, crop gathering being in full swing during my absence in Colombo; the final rounds of picking are now progressing, and I am happy to be able to report the most cheering accounts of estimates being realized and in many cases being greatly exceeded, not by hundreds but by thousands of bushels of parchment, which most satisfactory result is said especially to have been experienced on all the higher estates above the Pass, and I am also glad to learn that those who had sprung crop to gather on estates below the Pass have been equally fortunate; so that my earlier predictions when drought and leaf-disease were prevalent and threatened the loss of much crop, especially on estates below the Pass, have most happily been disappointed and estimates are said to have been gathered in full. That some crop was lost from drought and leaf-disease cannot be denied, and it has been mentioned to me that but for these unforeseen calamities estimates in many cases would have been doubled, and twice the quantity estimated would have been gathered this season. From the Badulla side I have heard that one estate has actually gathered double its estimate, and others have got from 2,000 to 4,000 bushels parchment over estimate, whilst in some of the public papers I saw it recently stated that the Uva Company's estates were this season giving 1,000 cwt. of crop over estimate. How much more crop they would have given if they had not destroyed some 200 acres or more of fine bearing coffee, to make room for tea, I leave you, Mr. Editor, to guess.

The "tea mania" has now fairly set in here, and many estates have extensive tea nurseries and some are planting tea under the coffee and cinchona trees. Oh! ye gods of agriculture, how in the name of commonsense do you expect all three products to thrive in the same six feet square of soil? If you are in a hurry to get rich I will also suggest your sticking in the same plot a plantain tree, a few brinjals, tomatoes, *et hoc genus omne!* If a word of warning from an old stager would be acceptable to my brother-planters, I would say: "Don't plant tea amongst your good coffee, but stick to the old and generous King. Treat him kindly and regally and he will respond to your affection by good crops for a good many years yet to come. If you want to plant tea, do so on your spare land or buy patana or chena lands, of which there are thousands and thousands of acres all around you in Uva, with soil quite as good as on most of the tea clearings I saw in my travels through the Kelani Valley, Yakkessa, Ambagamawa, Kotmale and Dimbula. After a residence of nearly 30 years in Uva I can say that the rainfall here is ample. The present season's weather is more like the good old times when I commenced planting here early in the fifties. Last month the rainfall was 12.21 inches distributed over 20 days, and since 1st June to 10th inst. there have been 7 wet days totalling 3.06 inches.

HOW TO PLANT AND PREPARE TEA;
THE FATHERS OF THE INDIAN TEA INDUSTRY
INTERVIEWED: II. MR. WM. ROBERTS.

Mr. Wm. Roberts, who has for many years so successfully steered the affairs of the Jorahaut Tea Company, Limited, into its present eminently satisfactory position, first entered on his Indian experiences in the year 1811. "The question of sending out a really properly qualified chemist to analyse the tea under various stages of manufacture is a very important one. Our experience of experts in connection with investigations relating to tea-blights has not been satisfactory, in fact, very much the reverse, but that is a totally different branch of science, as you know. Yes; and their failure might have been foretold, as it is a question affecting the most fundamental laws of nature; as we know that in nature, given the requisite conditions of life in sufficiently attractive quantity and quality and 'pest' life will be developed in proportion to the extent of the attraction offered to it. Having planted large tracts with tea, where hitherto only odd bushes existed, we had but to expect that those forms of life which are specially attracted by tea bushes would multiply under

the thriving conditions supplied to them, just as happened in the Straits Settlement to the spice cultivation, in Ceylon to the coffee, in Ireland to the potatoes, in France, to the vines, &c.

"Quite so, and the particular form the tea-pests took rendered their partial extermination extremely difficult; though special meteorological conditions varying in different seasons, appear to affect, sometimes favourably, sometimes the reverse, the propagation of the pests. Coming back to the question of the chemist, I think that it is quite probable that he would be able, after discovering the essentials upon which depend the manufacture of good tea to point out how the weather affects the manufacture; and thus we might have indicated to us the means of modifying atmospheric conditions where we could almost say that tea manufacture had been reduced to an exact science, and independent, so far as the manufacture of good *cutcha* leaf goes, of all conditions of weather. Tea companies and estates would probably be found quite ready to supply the necessary funds for such a very desirable purpose. Tea planters need not be alarmed at the prospect. A knowledge of chemistry would not be required of them. General principles would merely have to be placed on a basis of scientific fact in the first place, then rules for guidance, to be followed according to the varying conditions, based upon those principles, would prove as simple as present rules, only they would be based on reason in the place of rule of thumb."

"What are your views as to a return to panning?"

"Panning was a dirty, troublesome, dangerous process, but it is quite possible we may have to return to a modified form of panning, under which, by the assistance of mechanical appliances, the old disadvantages of the process may be overcome. In any case, I should very much like to see 50 maunds of tea manufactured under the panning system alongside of 50 maunds under the present system, sent home as a trial; as upon these reports could be obtained which would do much to assist us in forming an initial opinion as to the desirability of further experiments in that direction. For myself I think that many advantages resulted from panning, which we have lost by discontinuing the process. The leaf was made more pliant, and the essentials were more fixed—by a partial evaporation of the moisture—before the rolling, and thus less of these were lost by excessive expression of juice in the rolling; further, the dried half was blacker and more glossy, and many other advantages might be credited to the panning process."

"Care would have to be taken to select an old planter to try the above experiment, one who remembers all the details of the obsolete process, as except those planters in Dehra Dun, and Kangra, for example, who manufacture green tea for Afghanistan, and the two or three in Assam who still occasionally make "Namouna," the present generation of planters, as a rule, would regard a "carol" as a curiosity well qualified for a museum of antiquities."

"To what, if I may ask the question, do you attribute the success of the Jorabant Tea Company?"

"That is a short question, but the answer to be complete would be voluminous. Briefly, we have experience, and a system based upon experience, and we do not change our managers if they happen to have had an occasional unsatisfactory season. Then we select good men as managers, provide them with every requisite and of the most improved and perfect kind procurable, and treat them well, insisting in return upon their treating the Company to the best of their abilities. We have a complete system of printed forms, each a report on some head in itself, and these keep us at head-quarters thoroughly posted in all that goes on or does not go on. We have all along seen the economy of putting up comfortable, substantial buildings to start with, and thus the constant drain for repairs to *cutcha* buildings has been avoided, and our people have healthy dwellings and proper weather-tight accommodation for the manufacture of tea under the most favourable conditions in consequence. Even the coolies' huts are iron-roofed and have brick walls. The mortality has, therefore, naturally been immensely reduced. Every attention possible has been paid to sanitation on all hands. We have supplied aerated water machinery, and an ice machine driven by steam, thus adding greatly to the comfort of our Europeans and hastening their convalescence from fever. Large iron filters have also been supplied for the

coolies, and our doctors have to report periodically upon the quality of the water. Our managers' bungalows are well built, commodious, and healthy. There are photographs of some of our buildings on that wall, you will allow they are very superior. If the Europeans like to come home to recruit their energies during the cold weather after October, they are permitted to do so occasionally, and they receive full pay and their commission on the previous season, as though they had remained on duty. If they come home during the manufacturing season, the man who does their duty receives the commission of the season, as only fair. As regards cultivation, we insist upon this being thoroughly well done, overdone rather than underdone. Then as to pluckings; each factor has to submit a ten-day return to the superintendent, and if the leaf of each "flush" is not shown as all gathered within that limited period, enquiries as to the reason take place, as it is one of our maxims that to make good tea the "flush" must be gathered at the right moment. As few supply sufficient labour for that purpose this condition of good tea-making is rendered possible, as well as essential. Finally, we carry nothing to capital account, all charges for buildings and even extensions, are met out of revenue, and notwithstanding this our Revenue Fund is a large one."

Truly an excellent example this of the happy results of a correct realization of the responsibilities of capital towards labour.—*Home and Colonial Mail.*

NEW PRODUCTS IN SOUTHERN INDIA.

Barks.—A most important bark is that of the *Cassia auriculata*. This shrub, which grows in great quantities in certain districts, is extensively used both for tanning purposes and for manure, and the rates at present in force vary very considerably. The Board of Revenue propose that the levy of seigniorage should be discontinued, that the tracts on which the plant is found in abundance should be taken up as reserved lands and worked departmentally, and that on other tracts the cutting of the plant should be permitted free of charge. If this course were adopted, the tracts outside the reserves would speedily be exhausted. As for the wants of the ryots for agricultural purposes, the case is to a great extent met by recent orders which will allow of their cutting the shrub for manure within the limits of their own villages. The best policy seems to be to impose a moderate seigniorage everywhere, and at the same time to form departmental reserves in places where the demand is unusually great. There should ordinarily be two scales of seigniorage, based on charges of 1½ and 3 rupees respectively per cart-load, and it will be for the Collectors of the districts concerned to adopt either the one or the other according to local circumstances of demand and supply. In tracts bordering on Mysore it will be necessary to maintain a high rate as heretofore.

Fruits, Leaves, &c.—In some districts it is proposed to levy seigniorage rates on fruits, gums, roots, medicinal plants and leaves for manure. The levy of these rates should be confined to areas under special protection and reserved forests. Minerals also should be charged for only in reserved areas.—*Orders of Madras Government*

THE CHINA TEA TRADE.

(From the *North-China Herald*, May 29th.)

Twenty-five years ago, dating, I believe, from this very month, Hankow was opened with "great expectations" to foreign trade. Its history has been one of a few successes and many bitter disappointments, and the semi-jubilee we are celebrating at this time gives little promise of better things to come.

The future of the tea trade of this port is as difficult of divination as ever, and on the true *lucus a non lucendo* principle only those who know nothing of heartle and the conduct of riverine affairs, who watch in calm ease at Shanghai our wearying labour here, are fit to sit in judgment upon us.

"Suave mari magno turbantibus æquora ventis
E terra magnum alterius spectare laborem,"

In passing in review some of the more prominent features of seasons 1885-86, one fact stands pre-eminent, viz: the status of the native teaman today. Six short weeks ago, only a limited amount of sycee had been sent into the country, a small quantity of tea made, and a very gloomy prospect of outlet. Today, fickle fortune, ever Celestially sympathetic, comes to his aid with the glad tidings of peace, backed up by the appreciable gifts of cheap exchange and cheaper carriage. The result of these kindly favours will be a very full supply of tea and assured large profits to the natives. Truly if ever fortune's favoured nation clause were extended on behalf of any race, it has been stretched to its utmost limit in the interest of these long-tailed, long-nailed, long-headed middlemen who batten upon the profits of this vexatious trade.

Now as regards the produce itself. *Inferiority* is its characteristic. The teas of nine districts out of ten are poorer in leaf and poorer in cup, and super-add to these misfortunes the ever present objectionable tarry or burnt flavours. It would appear that the three great tea-producing provinces of Kiangsi, Hubei and Hunan had all done a thriving trade with Stockholm. Taking the Kiukiang teas in their order:

1.—The Ningchows are tarry, burnt, mouldy or weathery.

2.—The Keemuns, if not tarry, are for the most part burnt. These classes of tea have been bought by the great judges, and are out and out the best teas of the year.

3.—Hohows generally quite enough baked. The Oopack teas, Sungyangs, Yung-low-tungs, Tongans, &c. are a jejuue lot; all thin, dry and hungry. They lost a great deal of money last year for shippers, and will probably repeat the performance this.

The Onahm teas are a motley crew. They are all touched with the tar brush.

In the first rank as regards quality are the Tonyuens. They are well made, powerful teas, possessing any amount of brute force.

The Onafas are soft, tarry things, fit for the eighteen penny canister.

The Kokens are few in number and of fair quality.

The Lilings, Shun-fas, Fa-tams, and Shun-tams beggar description.

FOOCHOW.

CONSULAR NOTIFICATION.

To the British mercantile community of Foochow.

British Consulate, Foochowfoo, 14th May 1885.

The undersigned begs to circulate for the information of the British mercantile community the annexed translation of an address that has been made to him by the native tea firms and brokers of this port.

They therein represent that certain abuses have grown into existence in the conduct of the tea business of Foochow and that through these abuses they have suffered serious losses; they refer in particular, firstly, to the overplus of weight taken from them in the process of weighing; and secondly to the long delays in settling up accounts.

It would then appear to be their fixed purpose to endeavour to place the tea trade on a fair and uniform basis; with this end in view, a set of Trade Rules has been drawn up, and a copy been submitted to the undersigned with a request that they may be notified to the British Merchants at the port for their observance and guidance.

In compliance with that request, a translation of the said rules is herewith published, and to them the attention of the British Mercantile Community is now kindly invited.

H. M.'s Consul nowise pretends to dictate the form in which business should be conducted with the native Tea Firms; he may, nevertheless, be allowed to give expression to an opinion in regard to these Trade Rules, namely, that they appear to him to contain not only nothing illiberal and unreasonable, but much, on the contrary, that is likely to conduce to a healthy and mutually profitable trade, if carried out in their integrity, and he hails the introduction of such rules with pleasure.

He may add, that in this view of the subject he shall feel disposed to guide his decisions by these Rules, in those cases which might come before him judicially, where it should be shown that no special contract had been made on the part of the buyer.

CHARLES A. SINCLAIR,
Her Majesty's Consul.

PETITION OF THE FOOCHOW TEA GUILD TO CONSUL SINCLAIR.

Petitioners, the Committee of the Foochow Tea Guild, beg to state that in consequence of the heavy losses they have sustained from the system of giving over-weight and taking credit, they have held a meeting, and framed an agreement of which they beg you will cause the observance.

Having invested their capital and opened Tea Honges in Foochow, they beg to point out that trade between Chinese and Foreigners is entirely dependent on good faith, and if it is carried on without dispute, it may be expected to be permanent.

Now of late years Foreign merchants when purchasing tea have adopted methods of weighing and making payment which have been very detrimental to Chinese teamen and brokers; for 2 or 3 catties a chest overweight have in some instances been given, in others 3 or 4 catties; sometimes 5 or 6 months' credit has been taken, and occasionally over a 12 months'; and cases have even occurred where firms who have first taken long credit have eventually suspended business, and have paid only a composition, or not even a cash, thus involving petitioners in serious loss. As a result, of late years many of the native tea firms have had to close their establishments, and have been plunged in the deepest distress. Now the merchants at all the Treaty Ports ought to deal fairly. If they take overweight, then their estimate does not tally with that of the seller, and all the tea firms alike suffer; if long credit be taken, then the latter have to bear a further and considerable loss of interest. Moreover the tea ought to be weighed without delay immediately the order is entered in the books.

Petitioners have been compelled by the great difficulties under which the trade labours, to hold a meeting and pass resolutions that in future in all transactions the true weight be adhered to, that payment be made at the stipulated time, and that no one be allowed to reduce the weight at pleasure or to take credit at will. These rules will, it is hoped, prove beneficial to the Tea Trade in the South-East of China. Buyer and seller should treat each other in a reasonable and considerate manner, so that henceforward their good faith may be manifest to all. They must not take an unfair advantage of each other.

Petitioners enclose the rules framed by the Guild, the terms of which they beg you will view without prejudice and be good enough to make known to all Foreign merchants, that trade may be carried on in accordance therewith. Compliments.

RULES FROMED BY THE TEA GUILD.

May 1885.

1.—All Foreign merchants buying tea must pay ready money; or, where this is impracticable, within three days after clearance at the Custom House; or,

if press of business prevents this, payment in full must be made at the latest within seven days. No credit will be given in any case.

II.—Should, as may happen now and again, the purchaser not have taken delivery owing to the non-arrival of the steamer, or should the tea, though delivered, not have been weighed; in any case, at the expiration of four weeks after the entry of the transaction in the books, the tea shall be immediately weighed and payment made in full, whether the steamer has arrived or not. No further credit will be given. Tea that has already paid duty at the Custom House does not come under this rule.

III.—In weighing tea, the exact weight must be adhered to. A tare of 2 lb. will be allowed on every large chest, and of 1 lb. on every 25 lb. chest: $\frac{1}{2}$ lb. only will be allowed on small boxes. On 25 lb. boxes of Oolong $\frac{1}{2}$ lb. only; on large boxes of Pekoe 1 lb. All we require is fair dealing at the time of weighing.

IV.—When the tea is weighed after purchase a memorandum of the weight must be sent without delay to the Chinese tea firm, who will forward it to the seller for his information. Should any discrepancy be reported by the firm, it must not be shipped till it has been re-examined. The tea must not first be shipped under the pretext that otherwise it would miss the steamer.

V.—In all transactions these rules must be in every respect strictly observed. Should any person infringe them, our Guild will cease to send him musters, and will refuse to deal with him.

Translated by R. W. HURST.

NORTH BORNEO.

SIR WALTER MEDHURST'S PAPER BEFORE THE
R. COLONIAL INSTITUTE.

North Borneo will rank as one of the dependencies of the Crown, and the Royal Colonial Institute is therefore to be commended for departing somewhat from its "Colonial programme" in order to enlighten the world upon a territory which, from all accounts, has a very successful if not a most brilliant future before it. Sir Walter H. Medhurst, who was deputed by the company to proceed to Borneo in 1882 for the purpose of organizing a suitable system of Chinese immigration, was the reader of the paper, and he described in much detail the success which has so far attended the efforts of the enterprising gentlemen who have taken upon themselves the arduous task of building up a new State in the Eastern Seas. It appears that the company owns a coast line of not less than 600 miles, and that the total area of the country ceded is computed roughly at 24,000 miles. When we are told that the land is indented at various points by bays and harbours, some of them scarcely to be equalled by any in the world; that the soil, whilst specially adapted for tobacco and pepper cultivation, is pronounced as being most favourable for cultivation in general; that the climate, a tropical one, is at the same time a grand one, the temperature being pretty even all the year round; that the timber is of the very finest; that the supply of guano deposited by the bats and the birds is enormous beyond calculation, and that the flowers are pronounced by competent authorities to be as numerous, delicate, and beautiful as the forests are grand and imposing, the company may well be congratulated upon obtaining such a valuable acquisition upon very favourable terms, and we are sure that as soon as the richness and fertility of the country becomes more generally known, private enterprise will not be backward in seconding the strenuous efforts which the company are making towards preparing the country for colonization. So successful has the company been in this respect, that the inhabitants of other parts are said to be clamouring to be placed under the company's rule. This shows that the natives are beginning to appreciate fully the advantages attending a life of peace and security at home, combined with a lucrative trade abroad,

as compared with the fitful and hazardous existence they once led as pirates and head-hunters, with the war cry of tribal dispute perpetually ringing in their ears. As another and satisfactory evidence of the hold upon the confidence of their own people, as well as the neighbouring tribes which the company have succeeded in securing, it may be mentioned that they have introduced a one cent copper coinage, which has become a monetary medium both in North Borneo and beyond its limits. They have, moreover, established a paper currency of \$1, \$5, and \$25 notes, which pass current even as far as Sarawak, Singapore, and Hongkong; and they have set up their own postage-stamps, and opened a money-order communication with Great Britain and foreign countries. Sir Walter Medhurst certainly said enough to convince anyone that all that British North Borneo needs is capital, enterprise, and judicious working to be developed successfully. The principal centre of trade at the present time is Sandakan, which, lying in a position relatively to the route of steamers running between Australia and China, must have a commanding commercial influence, whenever North Borneo becomes sufficiently developed to take a place amongst the producing districts of the world. The site of the settlement comprises a frontage of about 5,000 feet, with water deep enough to admit of large vessels being laid alongside its future wharves, which are at this moment represented by one well-built wooden pier, 450 feet in length, and enabling vessels drawing 20 feet of water to go alongside. Although private enterprise does not appear to have effected much as yet, still it is gratifying to observe that over 260,000 acres had been taken up to the end of 1883, in the East Coast Residency, and 1,000 acres in the West Coast Residency. Of the first-named quantity, 100,000 acres were applied for by the Australian Borneo Company, and there is every reason to believe that other companies will follow suit in the same direction, as soon as the promising results of the efforts of that association become generally known. It is certainly not a little singular that, although the existence of a pearl oyster of the same variety as that fished up with such good results off Thursday Island, has been conclusively proved, the opportunity, for some unexplained reason, has not yet been taken advantage of. The introduction of Chinese is looked upon as absolutely necessary for the development of the country. It has been suggested that an offer of free passages to Borneo, say for twelve months, would have the effect of bringing into the country hundreds of Chinese of all classes, the poorer ones of whom, already accustomed to jungle life in the Straits, would find the means of living in various ways, as collectors of jungle produce, charcoal burners, gambier and pepper planters, gardeners, plank sawyers, &c.; but Sir Walter is of opinion that a still stronger incentive to respectable Chinese settlers would be an offer of plots of land free for a certain term of years, in self-selected localities, subject to subsequent assessment of value whenever the productiveness of the soil has been sufficiently established. In the discussion which followed the reading of the Paper, Mr. A. Dent, the originator of the British North Borneo Company, gave some rather later statistics regarding the progress of the country than those submitted by Sir Walter. Mr. Dent admitted that much had been done, but he confessed that he anticipated the advancement would have been in a much greater ratio. The revenue fiscal of 1884 showed an increase of 60 per cent. over that of 1883, but the land sales exhibited a decrease of 39 per cent., so that there was a surplus of 21 per cent., which, considering the state of trade all over the world, was not wholly unsatisfactory. He wished to correct an impression that the company received its powers from Her Majesty's Government. They derived all their powers from the Sultans of Brunei and Sulu Sea, the English Government merely allowing them to incorporate themselves as a company. General Lowry pointed out that the country, being halfway between China and Australia, it must be most valuable from a strategic point of view, and he hoped the time was not far distant when its importance as a coaling station would be recognized by the English Government. Mr. Myburg, Q. C., one of the directors of the company, thanked Sir Walter for his Paper, and for introducing Chinese immigration into Borneo. The Chinese would never have gone back to their

homes if the sugar-planting interest had not turned out a failure, owing to the depression existing in the various markets of the world. Before long, he had no doubt, the position of the company would be altered, and that British North Borneo would be incorporated in the British Empire. Sir Richard Temple, in a long speech, urged the development of the country by Chinese labour, which, he said, was 50 per cent. better than Indian labour, and expressed a hope that at no distant date the country would become a dependency of the Crown. Admiral Mayne, Mr. de Müller, who has recently returned from Borneo, and Mr. J. Beaumont followed, and the discussion, after lasting over one hour and a-quarter, was brought to a close by a few remarks from the chairman—the Duke of Manchester—who expressed his gratification at the advance the colonial question had made during his absence in Australia. This was the first appearance of His Grace at the Instituto since his return, and we need hardly say that he met with a most enthusiastic reception.—*European Mail*.

QUEENSLAND SUGAR PLANTERS AND THE POLYNESIAN ISLANDERS.

BRISBANE, May 31st.—The steamer "Victoria," which probably leaves on Tuesday, will take back to their homes the islanders who were declared by the Polynesian Commission to have been illegally recruited. Mr. A. Musgrave, jun., goes with the steamer as acting deputy commissioner for the Pacific. The Queensland Government will be represented by Mr. H. M. Chester, Mr. M. C. Lawrie, and Dr. Smith. The northern planters are, however, taking steps to prevent, if possible, the removal of the islanders. Formal protests have been entered with the immigration agents at Mackay and elsewhere, and also with the Government. One planter at Mackay is said to have flatly refused to give up his labourers at present, and an injunction to restrain the Government from removing them will be applied for, at the instance of some of the Mackay planters, in the Supreme Court tomorrow. The three Mackay firms who are understood to be taking the chief action in the matter are Messrs. Sloane and Co., the Colonial Sugar Company, and Messrs. Fanning, Nankivell, and Co. One of the chief reasons given is that if the labourers are removed at the present time the sugar crop will be completely ruined.

INDIARUBBER AND GUTTAPERCHA IN THE DUTCH EAST INDIES.

We have received a separate reprint of a paper from the February number of the *Tijdschrift van Nijverheid en Landbouw* (Journal of Industry and Agriculture) published in Batavia, the title of the paper being "Over de Toekomst der Caoutchouc-cultuur in Oost-Indië" (On the Future of Caoutchouc Culture in [Dutch] East India), being a notice of a "report on planting experiments with caoutchouc-yielding trees during the first quarter of 1884, carried out by the forester of the forest district of East Preanger, A. H. Berkhout." The review is dated "Batavia 19th December 1884," but there is no signature, so that we cannot tell who the writer is. He commences by briefly sketching the history of indiarubber and detailing the uses to which it is put, and then deals separately with the three commercial varieties of East Indian, Sumatran, and American. Under the first, he speaks of *Urosigma elasticum* and *Urosigma karet*, but belonging to the family of the *Artocarpææ*. It seems that Java has the oldest plantation in the world of karet trees, Messrs. Holland having in 1866 formed an extensive plantation in the neighbourhood of Sobang. The writer goes on to

refer to the wasteful method of gathering the rubber, and quotes from the *Tropical Agriculturist* for Nov. 1884, p. 361, an extract on this subject, the statements in which, he says, are borne out by experience in Java, and he quotes from Mr. Berkhout's report an instance of this, and then mentions the regulations which are being enforced in Assam for the protection of rubber trees. Details are given of experiments by Mr. Berkhout with karet trees, which seem to promise success. The usual method of propagating this tree is by cuttings, but the writer thinks that the use of seed would be cheaper and more efficacious. Proceeding to speak of Ceará rubber (*Manihot glazovii*), the writer quotes from Mr. Berkhout's report details of experiments with seed obtained from Ceylon in Dec. 1883 through Messrs. John Pryce & Co. Two different methods were employed. A portion was simply put out in the open air between gunny bags and kept constantly moist. To guard against the attacks of ants, which are very fond of the kernels, the bags were placed on rough trestles, the legs of which were put into tins of earth and these into kerosene tins filled with water. Three days afterwards some of the seeds had sprouted, but a large portion after the expiry of a month showed no signs of germination: recourse was therefore had to filing, and the seeds were once more placed between the gunny bags. Many then showed that they possessed the power of germination, but, Mr. Berkhout adds, filing is a difficult operation and if not done carefully causes harm instead of good: if the gerin is injured the cotyledons swell but soon rot and no roots are produced. Mr. Berkhout adds that as soon as the seeds begin to germinate they should be planted with the root downwards 1 centimeter (say $\frac{1}{2}$ inch) deep. Seedlings should not be planted out directly in nursery beds, as many would fall a prey to ants, but should be put into pots filled with sand and placed on trestles. When the plumule begins to develop the plant can be placed with the ball of earth in the nursery bed, and for the first few days shaded. The differences in the growth of the plants Mr. Berkhout thinks are to be explained by a portion of the seed being from young trees. Figures are then given of the growth made by plants at different elevations. Experiments were to be tried with cuttings, but Mr. Berkhout considers these doubtful of success, judging by experience with cassava, which is closely allied to Ceará. The writer of the review then quotes from the *T. A.* for last Nov., p. 354, an extract from the report of the Agricultural Society of Madras, giving part of a letter from Messrs. J. P. William & Bros. of Honaratgoda on Ceará cultivation, and directions for the germination of the seed, which he compares with those given by Mr. Berkhout. Passing on to speak of *Castilloa elastica* the reviewer gives an extract from Mr. Berkhout's Report relating to the planting of seeds from a tree in Java all of which germinated, the plants growing well. Mr. Berkhout adds:—"The statement of Dr. Trimen, that the *Castilloa elastica* is destined, under careful culture, to be a source of revenue, appears to me, in view of what I have stated, perfectly correct." Information on the subject is again quoted from the *T. A.*, and then the reviewer proceeds to notice certain indigenous caoutchouc yielding trees, viz. *Leuconites eugenifolia*, *Beaumontia grandiflora* Wall., *B. multijlora* F. & B., *B. spec. jav.*, and *Yalua gummifera*, and finally Pará rubber. Figures for rainfall at various places in Java are then given, and a table showing the growth of the various varieties of caoutchouc planted. The last plant referred to in the Report is a tree called by the Malays *hambarang* (*Ficus sulva*), which yields

a vegetable wax, used in the coloring of cloth. The Report concludes by pointing out the importance of an extended cultivation of caoutchouc-yielding plants, now that the price of cinchona bark has so decreased and the coffee crops have fallen off to such an extent. The writer points out that there is no fear of over-production, as in the case of quinine, the uses to which caoutchouc can be put being almost endless. He calls upon the Government to send a botanist to South America to procure plants and seeds of the best varieties; while at the same time there should be a thorough investigation into the varieties growing in the Dutch East Indies, especially Borneo. So far Mr. Berkhout's Report, and the reviewer concludes his remarks by pointing out the difference between caoutchouc and guttapercha, which two substances are popularly confounded together, though entirely distinct in origin, chemical composition and uses. His final words are:—"If, however, the reader wishes to get further information on this subject he should buy the following"—and then come the entire title and list of contents of the book on indiarubber and guttapercha compiled and published by us. For this gratis advertisement and testimonial to the value of our publication we tender our thanks to the anonymous writer.

COFFEE AND LEAF DISEASE IN CEYLON.

Guided by the experience of the last two years, I have all along assumed that coffee is doomed, that "le roi est mort," and that tea everywhere is taking its place. But we read this year of a wonderful revival of coffee in all Uva. What does this mean? Is it likely to last? Their last year's season must have been more than usually propitious, and the great depth of soil in Badulla enables the coffee to send down its roots to depths far below the deepest diving grub. But what about leaf-disease? Let us see. Dr. Thwaites asserted that "leaf-disease would last as long as there was coffee to nourish it." The fight then is between the two, and to judge of the future we must look at the past. Has the fungus asserted its supremacy in the past in such a degree as to make us fear—bearing Dr. Thwaites's dictum in mind—that it will finally triumph everywhere? Or are there some favoured spots where coffee and fungus have arrived at a sort of equilibrium, one making up its strength, as the other periodically falls off, and *vice versa*? This seems to be the condition of things in Uva just now. But as the fungus has even there brought crops down from, say, 7 cwt. an acre to 2 cwt., it has, so far, proved its baneful power over coffee. Having thus reduced coffee from its previous state of vigor, is it likely that coffee can now—in its weakened condition—resist and survive, so long as the fungus exists and attacks? If it can, then must it necessarily be in consequence of some falling-off of virulence in the fungus itself—a happy omen for the many patches of good coffee still existing all over the country. But I fear this is not a reasonable expectation. If it has taken fifteen years to reduce coffee from its best condition to a mean crop of 2 cwt. an acre, how long will it take to finish it off from 2 cwt. an acre to nothing?

Since the "fifties" too, and before the end of the 'eighties," the island will have passed through two great extremes, testing in the one the sweets of prosperity, and in the other the dregs of misfortune. To the credit of the good old coffee days must be ascribed the material advantages the country now enjoys in railways, roads, bridges, &c., and also the still unexhausted wealth in native hands, and the many civilizing

institutions within their reach. Europeans reaped a rich harvest also, but with few exceptions these disappeared from the scene. So that the residue of former prosperity is chiefly now seen in material improvements, and amongst the natives.—*Old Planter.*

VENEZUELA: ITS CLIMATE AND PRODUCTS.—There are three zones, three climates, within the limits of Venezuela, from cold too intense to be endured by man, to the greatest degree of heat known on the earth's surface. The Alpine zone lies to the west among the snow clad summits of the Andes, where are plains swept by blasts which chill the blood. The next zone is from from 5,000 to 8,000 feet above the sea, covered with forests of timber and nutritious grasses. The third zone is the tropical, where fruits of all sorts are produced in the greatest abundance. The Venezuelans claim that theirs is the only land where coffee and corn, sugar and apples, bananas and wheat grow in the same soil.—*American Grocer.*

DIAMONDS AND GOLD IN MADAGASCAR!—So runs the news in a private letter from Antananarivo published in a Cape newspaper. But the difficulty is to get at these precious gems. The law of the country says twenty years in chains against the digging minerals. The writer describes the country as really marvellously rich in diamonds, gold, silver, copper, lead, tin, graphite, and specimens of ruby and sapphire. But he complains that he has utterly failed in getting a concession out of the Hova Government. This information may be especially commended to the attention of a gentleman at present doing duty as a war correspondent in the Soudan. He was successful in getting a concession for sugar plantations in Madagascar from the Malagasy euevys when they were in this country, and ought to be able to secure a digging concession for an English company.—*Fall Mall Enlygt.*

THE DIMBULA ASSOCIATION ON TEA CULTIVATION.—We call attention to the Report of a Sub-Committee of the Dimbula Planters' Association, given on page 66, as a model of the good and useful work which all District Associations might set themselves to do with more or less success. The interchange of the results of experience, observation or even reading in this way is calculated to be of very great service in connection with our new industries, both in supplying the information most in request with young planters and in dealing with the various disputed points constantly raised about the treatment of new products. What is said about tea in the present report may be open to criticism on some points; but no one can dispute the general advantage of bringing together a variety of opinions in this way. We may refer to the report in an early issue.

CINCHONA ALKALOIDS.—We are glad to learn that the Madras Government has directed a new departure in the matter of cinchona alkaloids. Mr. Hooper, the oenologist to that Government, has found that the Madras Medical Store Depot possesses a laboratory with appliances that can readily be adopted to the manufacture of liquid cinchona on a large scale, and he has accordingly obtained permission to manufacture liquid extract of cinchona alkaloids to the extent of 1,000 lb. . . . At all events the experiment is a most valuable one, and if it succeeds must necessarily give an enormous impetus to the cultivation of cinchona for it will supply a local market for the bark, thus doing away with all charges for home export, agent's commission, &c., &c. Mr. Grant Duff certainly deserves commendation for the persevering manner in which he has pushed on the question of practicability of the local manufacture of cinchona alkaloids, and if Mr. Hooper's anticipations are realized, a grand future of prosperity will be opened to the Wynaud planters, who have been sorely tried since coffee began to fall.—*Times of India.*

A BOTANIC STATION FOR ST. LUCIA.—A contemporary, discussing the proposal of Mr. Morris to establish a botanic station at St. Lucia in connection with the Jamaica Gardens, says:—"Without wishing, in any way, to forestall the judgment of the committee, we would at once state that a botanic station on the very limited scale suggested by Mr. Morris would be perfectly useless in St. Lucia. That we want information respecting the profitable culture of industrial plants is quite certain. But we want that information to be, not merely mechanical, but intelligently reasoned. We could not look for this from a gardener at 15s to 18s a week, as recommended by Mr. Morris. If we could get a good man, loving his work, who could teach us how to make two pods of cacao grow where one only is growing now, who could show us how to get 7 tons of sugar from the land that now produces only two, and who could direct our industry into new and paying channels, we could well afford to cheerfully pay him a liberal salary."—*Colonies and India.*

A TEA FAMINE PROBABLE.—The supply in this country decreasing, and nothing coming from China. *New York World*: The war between China and France creates great uneasiness among the importers of tea. By reason of the blockade of Chinese ports the supply in this market is becoming limited, and fears are entertained that this country will be affected with a tea famine." A member of the firm of A. Colburn & Co., No. 110 Wall street, said yesterday:—"The Island of Formosa, upon which we depend largely for our supply of black teas, has been blockaded by the French since September. As a natural consequence we have been unable to communicate any orders we might see fit to make to shippers at that point. Therefore, we have received no invoices since the war began." "For how long a period will the supply we now possess last?" "I fear we shall be very short of tea before August unless the blockade is raised. It is to be supposed that the planters in Formosa are now sowing their crop. In June they will reap it. If by that time the French vacate Chinese waters we shall have an abundant supply. Should France, on the other hand, decide not only to continue the blockade of Formosa but to cut off all communication with Shanghai, Foo Chow and other tea ports, we shall be forced to call upon Japan." "Could Japan be depended upon to furnish us an adequate supply?" This country consumes annually in round figures 100,000,000 pounds of tea. The vast majority of this we have heretofore received from China. Possibly Japan sends us between 20,000,000 and 30,000,000 pounds. I doubt if we could depend on her for more than 50,000,000 pounds a year in the aggregate. You can readily see then that should our Chinese supply be taken from us we should be put on half rations. Tea parties would then be rather expensive luxuries and indigent persons would be compelled to forego the pleasure of partaking of the delicious drink. Our advices today say that as yet there is no reason for believing that the blockade at Formosa will be raised for sometime to come. The other tea ports have not yet been compelled to sever communication with us. What may happen in a week's time we are too far from the scene of conflict to predict. Strange idea of the agents sewing—quite as good as some of the Directors of the Ceylon Company, Limited, who proposed at a meeting of the shareholders:—"That all their estates should be planted with the seed of 'Orange Pekoe' tree—and none of the coarser kinds planted." And another one who wrote to a friend and asked him "to send a pinch of tea seed in his next letter." But perhaps these are old. Our cart road is getting very nasty, not at all like our "Spooner" days. It is not the man that is to blame. More improvement in machinery one notices in every paper: yes, in two years' time most of our present will compare with our future as "Alleck's rattle T. traps" (1855) to J. Walker & Co.'s, (1876) "improved gearless double pulpers." Sell your leaf to a central "Factory" and wait a little is my advice to Ks. T. B. (Knights of the Tea Bushes).

THE PROGRESS OF TEA CULTIVATION AND MANUFACTURE IN CEYLON.

In a speech made by Mr. John Ferguson at the Colonial Institute very recently, it was shown, that, though coffee had fallen off in quantity through leaf-disease, the new products were likely ere long to balance the deficiency. We have now arrived at the period of the new products passing coffee, tea taking the lead by several lengths, cinchona a good third and other products bringing up the rear with more or less success. Allowing then that tea will soon be the staple product of Ceylon, coffee second, and cinchona third, with a railway running through the heart of the Central Province and region of tropical products, *Ceylon must regain a firm footing and confidence in commercial circles.*

A Visiting Agent of long experience remarked a few days ago that the traffic on the railway would soon be greater than ever known before since the advent of the "iron horse" into our mountain ranges. It is refreshing to hear the whistle of the steam engine under the Great Western. Capitalists and others who come up into the mountains simply to satisfy their curiosity and breathe the mountain air will be so delighted with the scenery and struck so much by surprise at seeing such a vast area under cultivation that the fame of Ceylon will soon spread far and wide, capital will be restored, and speculative merchants and brokers out do each other in giving the highest prices for produce.

Let us now glance at the rapid progress tea cultivation has made during the past four or five years. Another Visiting Agent anxious to glean statistics of tea for the information of people at home made a rough estimate of the area now under tea, and, although he omitted Kotmale and other districts likely to produce tea largely, the total acreage arrived at was no less than 85,000 acres "with power to add," say 100,000 acres or half the cultivated area of the Central Province under coffee, tea and cinchona.

It is true much of the above tea is under coffee and cinchona, and on this important subject of whether it is economical in the long run to grow all three products grouped together much may be written at some future time in this series of letters to the *Observer*.

No old planter, experienced in the fluctuation of prices and disappointments in relying on one product, would advocate the wholesale rooting-up of old King Coffee or cinchona as long as prices are low. There is a very good prospect of both coffee and cinchona rising in price at an early date. The reason for thinking so, in the case of both products, "the rush" has subsided and leaf-disease has shaken confidence is, that thereby diminishing extended cultivation; but the best of all reasons is the prospect of emancipation of slavery in Brazil. As soon as the four millions of ewt. cease to pour into the American and European markets and the other coffee-producing countries all more or less suffering from leaf-disease and indifferent cultivation, coffee will rise steadily and so will cinchona. As people cease to cultivate this product and the market is not glutted with the article, prices will rise for a certainty.

It is therefore extremely difficult to give any advice as to the prudence or otherwise of rooting up coffee and cinchona to replace them with tea. There is no question about the benefit tea would derive by being released from the shade and drip of cinchona succumbra with its large cabbage-shaped leaves, and as tea requires loose soil, well opened to receive moisture, the network of roots must of

necessity be injurious. Pickaxing, forking, or digging of any kind would hurry on the growth of tea, and pruning should be early attended to. But on these subjects we will devote separate articles and revise the pamphlet on tea cultivation and manufacture in Assam in a series of new letters on a subject now interesting all classes of our Ceylon community and brother planters in Southern India. When in Assam in 1876 the tea planters said it was no use our attempting to grow tea in Ceylon, that tea would not thrive inside 15° lat. N. of the equator, and they forgot that the elevation of our Ceylon mountains compensated for deficiency of the North latitude.

In fact without mincing matters with our friends in Assam and other tea-producing parts of India we in Ceylon are likely to profit by their experience, especially in the perfection reached in tea machinery. The tea planter of the old school was of opinion that tea could only be made with the aid of charcoal and heavy reserves of forest were left to provide wood for charcoal burning. "What will you do for wood?" said a tea planter of Assam. The quantity required is enormous! What have we now? "The Sirocco" and other improved tea-driers exploding the idea of charcoal and its fumes as an actual necessity for tea manufacture. Improvement in tea machinery is reaching such a pitch, that by and bye we shall probably see the green leaf going in at one end and coming out *made* pekoe sonchong at the other, like the pigs at Chicago having their respective throats cut at one end and coming out bacon and hams! Fancy the pleading Assam tea planter with his chulahs and charcoal ever dreaming of Ceylon competing with him with all the means and appliances of modern mechanical improvements. We must not crow over the success of Ceylon as a tea-producing country on a large scale unless care be taken to make our tea *as well* to compete with India and China. There is danger of overproduction in this article the same as in coffee and cinchona, and to protect ourselves from future loss, the quality of Ceylon tea must eclipse the "Indian make" and the cunning manipulation of the "heathen Chinese" It is gratifying to know that Chinese supplies have fallen off about 50,000,000 lb. corresponding with the steady increase of Indian tea which rose from 1876 to 1884, say in eight years, to *more than double!* Ceylon in the same way will gradually increase year by year until we catch up to India's supply.

The capabilities of Ceylon as a tea-growing country are long past the experimental stage, and a taste for Ceylon tea has sprung up in all parts of the United Kingdom. We must watch jealously that inferior teas are not palmed off on the English public as *Ceylon-grown teas*. It was whispered to me on the way out from England that a certain individual in London had been victimizing Ceylon's reputation by selling rubbish from India as a Ceylon-made tea. If this sort of thing is persisted in, Ceylon will not hold her own, and I would suggest that an agent be appointed to watch the interests of Ceylon planters and merchants, and if necessary prosecute an offender of the kind above described—perhaps a warning would be sufficient. Meanwhile Ceylon tea bears a high character and is now sold all over London—wholesale and retail.

Now comes the question of how much tea we can produce. One hundred thousand acres at three hundred pounds per acre will be no less a quantity than thirty millions of pounds within the next three or four years. Now double the area, and say 200,000 acres. We find we can produce sixty millions of tea in about six years' time. What a prospect if the prices *keep up!* The estimate is reasonable enough.* We shall be running neck and neck with all India; and

* Too sanguine, in our opinion.—Ed.

when the worn out Assam planter comes to see how we are getting on, he will in all probability transfer his capital to Ceylon, where we possess climate, suitable soil, elevation to 7,000 feet railway transport to the sea-board, and all improvements in tea machinery.

Why is Ceylon tea preferred to China and Indian teas? The reason given is before it combines the two in flavour and strength, and *does away with blending China and Indian*.

The great district of Dimbula including the Agras and Lindula promises to contribute largely with thirteen thousand acres already planted. Machinery has already been introduced into this district, rolling machines, "Siroccos" and sifting apparatus. We enter an old coffee store and find it converted into a tea-house, with fixtures for the withering trays, shelves for the tasting cups, large bins for storing the different qualities of tea from "pekoe" down to "fannings," Peeping into a side room, we find a lot of happy-looking podiyans using No. 8, No. 10 and No. 12 sieves, and down below we find carpenters making tea boxes. On one estate here may be seen tea making, coffee curing, and cinchona baling all going on at one and the same time!

"Things are looking up" (as an old Uva planter used to remark), and we are glad to hear that Uva is commencing to grow the coming product tea, and 500 acres are planted at Spring Valley.

Abbotsford takes the lead and was lately making one thousand pounds of tea a day. Anyone who has had the advantage of a visit to Abbotsford estate and seen the giant growth of tea leaf as seed-bearers would at once proclaim Ceylon the home of the tea plant. The tea factory at Abbotsford is supplied with rollers, Siroccos and sifters, and it is a pleasure to see how quickly our Southern Indian coolies have grasped the *modus operandi*: they seem to like it better than exposure to all weathers in the coffee field, though perhaps the stupid ones will have to work outside as usual gathering the leaf. Mr. A. M. Ferguson junior is willing and obliging in giving his visitors all information regarding tea cultivation and manufacturing on Abbotsford estate, and Mr. A. M. Ferguson, C. M. G., the proprietor of the property, deserves all the success of being first in the field in Dimbula with large returns. The editors of the *Ceylon Observer* advocated new products and railway extension, and, now that the former are being harvested and the railway is opened, things will daily improve and more than thanks are due to the Messrs. Ferguson of the *Ceylon Observer* standing to their guns under a heavy fire of *stinking fish*, for everybody knows that there were more people ready to say Ceylon was hopelessly ruined than the far-seeing few who predicted "a good time coming boys, wait a little longer." There is a marked improvement in the people of England, *less heavy drinking*, and, if the Government reduce instead of increase the duty on tea, the consumption of the article will greatly increase. Our Australian colonies will doubtless in time discontinue importing Chinese teas.

Next to the operations on Abbotsford estate, Lindoola estate is well-known as a progressing factory where everything is carried on in a business-like manner: leaf purchased from adjoining estates, and upwards of one thousand pounds of leaf manufactured daily. Then comes Calsay estate under the supervision of Mr. Scott, who received his training as a tea maker under Mr. Taylor of Looloondura in Hewaheta, I intend to visit that estate soon and report progress with Mr. Scott's permission.

Much can be written on the subject of jats. Neatly every estate has got a mixture of jats &c., and we are

not quite sure which quality to select as a "good working jat." Some are in favour of as nearly approaching the indigenous as possible. In this case, Mr. Ashton of Torrington possesses a nursery of indigenous plants &c., and he is willing to exchange in proportion to value with his neighbours, or sell by the thousand. Mr. Ashton's nursery is a success, and the plants are of a uniform quality, very light in colour and no doubt the real article. Another gentleman in the Agras who pushed forward the coffee enterprise in his time has made extensive tea nurseries. Mr. Johnston, the gentleman referred to, has been selling plants at Thornfield estate and made nurseries for others. His nurseries are well made, and the plants good and in a hardy condition and ready for planting. A central factory will be required for the Agras. Mr. Jackson of St. George's has planted tea on parts of that estate, and informed me that Messrs. Carey, Strachan & Co. have already upwards of two thousand acres of tea put down in different districts.

Great Western is not behind in the tea enterprise. The manager of Scalpa estate will gather from 500 acres and have a proper tea house fitted up with all requisite machinery. Messrs. Tilly and Murray are also planting tea on Louisa estate and Galkandawatte.

I have not seen Glasshaugh estate operations where machinery is working. The general appearance of the districts of Dikoya and Dimbula promises well. Some planters are cutting away the lower primaries of their coffee to give light and sun to their young tea plants, and from the railway track between Nawalpitiya and Talawakele several glimpses of tea estates may be obtained from the carriage-window. Gallehodie estate with an even sheet of tea. Blackwater estate on the righthand side coming up, Carolina store which has been often written about in the *Observer*, large nurseries at Kotiyagalla, and Hatton estate being cleared up for tea. Plucking has been commenced at Middleton, and all the estates in these districts are doing something or intend commencing soon. It is very encouraging that old districts in coffee should be doing so well with tea. I hear the Brothers Scovell are doing wonders at Strathellie and in Maskeliya district. Mariawatte must have astonished disbelievers in the theory that tea can be cultivated to pay where coffee failed, and the district of Dolosbage, always a struggling district, will now reward the labours of Messrs. Blackett, Drummond and others who have toiled so many years. Yatiyanota, Awisawella, and other hot places where there is a good average rainfall is the perfection of climate for the growth of the tea bush, and heavy crops of leaf can be expected from that quarter in a short time.

HENRY COTTAM.

WYNAAD PLANTERS' ASSOCIATION.

The monthly general meeting was held at Pookete club, Vythery, on the 3rd June:—

COFFEE CURING.—Mr. Jowitt asked if any member could give a reason why Wynaad coffee is deficient in colour and also in size, and invariably fetches a lower price compared with that of other districts than it did in former years. Mr. Walker and others attributed this to the deterioration of the coffee trees from the effects of leaf disease which could only be overcome by growing them under heavy shade such as exists in Mysore and Oorg, but not in Wynaad. After considerable discussion it was resolved that the Honorary Secretary should address the various Planters' Associations of Southern India, asking information on the following points:—1. How does the bean of coffee grown under shade compare in colour with that grown in the open? 2. Is there any proved system of estate curing that will affect the colour of the bean? 3. Is there any marked difference in the colour

of the beans cured at the West Coast, East Coast, and inland coffee works? 4. How do manures affect the colour? 5. Have the different modes of packing any influence on the colour? The W. P. A. will be glad to receive the opinions of any persons interested in this matter. Resolved that those questions be circulated separately as well as in the Report of proceedings.—*Madras Mail*, June 20th.

COORG PLANTERS' ASSOCIATION.

(From *Hon. Secretary's Annual Report for 1884-85.*)

I think you will agree with me that this past year has been a very trying one to us all, and the severe crisis we are now passing through, owing to the heavy fall in the price of coffee, has told hardly upon a good many of us; but let us hope that the experience we have gained has taught us a lesson that we shall few of us forget, and that by reducing our expenditure within reasonable limits we may yet again make coffee pay even at the present reduced values. **Labour Question.**—The first and most important matter that occupied our attention was the endeavour to induce the other Associations in Southern India to join us in reducing the wages for labour, and doing away with advances to Maistries. This is a question that has occupied the attention of this Association for some time, and as we did not come to any unanimous decision amongst ourselves, it was unlikely that where so many different districts were concerned with altogether separate interests that any one united action would be evolved. The replies from the different Associations were laid before you at the time, and although they could not come to any definite agreement to reduce their present rates of pay; or promise to give no advances in future to Maistries, still they were one and all unanimously of opinion that it behoved each district for itself to reduce its wages for labour, and advances to Maistries, as much as possible according as circumstances permitted. Thus although no definite agreement has been come to, still the question has been well ventilated, and is bearing fruit already. We in this district have already reduced the wages of all Coast labour from 5 annas to 4 annas a day, and the pay of all locals to the same level as Canarese. The question of advances to Maistries has, I consider, solved itself, as owing to the tightness of money I believe that few or no fresh advances have been given out this year, but on the contrary, large sums have been recovered from the Maistries. This is a step in the right direction, and if we will only persevere in the same course next season, I feel confident that we shall have given the death-blow to advances to Maistries, and to the heavy losses that planters annually sustain therefrom, not to mention the release of a large amount of capital hitherto locked up in these advances, and which will now be profitably employed in the cultivation of our estates.

Adulteration of Coffee.—We in company with other Associations of Southern India agreed to refer this question to the Ceylon Central Association, and it was understood that they were to draw up a Memorial on the subject for presentation to the Home Government; but as over a year has now passed, and nothing has been done, I think it behoves us to act for ourselves, unless we wish the matter to drop altogether, which I think would be unwise considering the present depressed state of the coffee enterprise.

Curing Charges.—Our representations to all the Coast Curing Firms and Agencies on the subject of a reduction of their charges during the present depressed state of coffee did not meet with the favourable reply that we could have wished, but did not in the least expect; and they one and all politely but firmly declined to meet our views.

THE TEA-ROLLER PATENT CASE.

The case of Jackson v. Kerr, was argued in the District Court on Saturday last, upon the plaintiff's motion for an interim injunction restraining the defendant from making, selling and using the machines known as Kerr's Tea-Rollers, the plaintiff alleging that such machines involved infringement of his patent rights in respect of Jackson's Tea-Roller.

Mr. Advocate Layard, for the plaintiff, explained to the Court with help of working models, the two peculiar fea-

ures of the plaintiff's machine which were alleged to be improperly embodied in the defendant's Roller viz., (1) free and automatic vertical movement of the top rolling-surface which is loosely enclosed in a jacket or box, which imparts motion to it; and (2) an arrangement for turning over on hinges the jacket or box together with the upper rolling-surface, for purposes of cleaning out, &c. Mr. Layard relied on *Canington v. Nuttall* (L. R. 5 H. L. 205) to show that a patent might be sustained through each principle or process was previously wellknown to all persons engaged in the trade to which the patent related, provided the mode of combining such processes was new and produced a beneficial result. He also cited Lord Ellenborough's words in *Huddart v. Grimshaw* (Dav. Pat. cases 265). He claimed the plaintiff's machine to be an entirely new combination never previously applied to any purpose. Even the first importer into this Island of a new machine might properly patent it. *Minter v. Wells* (1 Webs. R. 131). Even a colourable title in the plaintiff is sufficient to entitle plaintiff to an interim injunction. *Oxford and Cambridge Universities v. Richardson* (6 Ves. jr. 706). Even the use of part only of plaintiff's combination would constitute an infringement. *Sellers v. Dickinson* (5 Ex. 325).—A discussion here took place as to whether defendant should be ordered to keep an account pending trial. Mr. Layard contending that all proceeds realized should be paid into Court or into a separate banking account, and Mr. Browne opposing this as quite unusual, but being quite willing to keep an account of the machines sold by the defendant with the prices realized for them. Ultimately the matter dropped, no agreement being come to on the point. —Mr. Advocate Browne (Mr. de Vos with him) opposed the motion on behalf of the defendant. The plaintiff was wrong in proceeding against the defendant as though he were an imputent pirate, whereas he had as good *prima facie* title in virtue of the patent that he too held. Where the parties have obtained patents for the same invention, the Court of Chancery will not interfere by an interlocutory injunction, but leave them to try the legal right by *scire facias*, as questions might be raised also as to the validity of plaintiff's patent. *Copeland v. Webb* (11 W. R. 134) where *Kindersley, V.-C.*, merely put the defendant upon an undertaking to keep an account of the articles sold. The plaintiff was also not entitled to the injunction by reason of his *laches* in coming forward. The defendant's patent was taken out at the latter end of 1853, and a full account of it was given in the *Ceylon Observer* of 8th December 1853, and plaintiff in his affidavit merely said that he heard in 1854 (without mentioning the date) of the alleged infringement. *Goodeve's Abstract of Patent Cases*, p. 58; *Bridson v. Benecke* (12 Deav. 1) where a delay of 11 months was held fatal notwithstanding the Court had a strong impression in favour of plaintiff's right. Mr. *Browne* put in the affidavit of Mr. Aitken to show that one of Jackson's machines, made in accordance with the patent now in question, had been used in Ceylon at the latter end of 1851, long before plaintiff's grant of letters patent. This would be a good defence. *Stead v. Anderson* (11 Jur. 1877). Again, plaintiff's patent is recent, there has not been exclusive possession of it for any length of time, and defendant contends that it should never have been granted in view of the facts stated in Mr. Aitken's affidavit: under these circumstances no interlocutory injunction should be granted. *Hilt v. Thompson* (3 Mer. 622); *Renard v. Levenstein* (10 L. T., N. S. 94, 177). At the conclusion of the argument, the Court intimated that it was inclined in plaintiff's favour, but would carefully consider the matter before making its order.

A question was started yesterday by the Secretary of the Court, whether the pleadings in the case should not bear the usual *ad valorem* stamps, not being especially exempted by the Stamp Ordinance. This point still remains to be decided.—“*Examiner*,” June 23rd.

JAPANESE PEPPERMINT is rapidly increasing in value owing to the large demand from the United States. A few years ago, its price, as stated in a Tokyo paper, was four *yen* per pound, whereas it is now fourteen *yen*. Its quality is highly praised by the foreign consumers.—*Japan Weekly Mail*.

THE CEYLON PLANTING INDUSTRY AND THE “ADVANCE” SYSTEM.

Under the *nom-de-plume* of “An ex-Coffee Agent,” a gentleman who is well entitled to write on the subject with authority sends us the following interesting and timely communication:—

London, 22nd May 1885.

Coffee planting in Ceylon may almost be said to be the child of the advance system. Nurtured on advances, the cultivation grew with promising, not to say astonishing, rapidity. And in the hey-day of its success it was the basis of a well-known Colombo merchant, that to him was due the prosperity of Ceylon in that he was the first to induce London capitalists to make large advances in anticipation of securing the sale of coffee crops in Mincing Lane. But there was death in the cup. One need not insist on the debatable point whether leaf-disease and other pests were directly produced by the over-haste to be rich. This at least is certain, that when the storm burst the consequent ruin was greatly intensified by the existing financial position; and the same cause, which had in previous days accelerated the rise of our late King, now in a much greater degree accelerated his fall.

In the old days, when, barring exceptions just numerous enough to prove the rule, every local merchant or agent was heavily indebted to London merchants or banking companies, every estate proprietor similarly indebted to local agents, every company to his estate proprietor, every cooly to his kangani it was idle to hope for a fair and full discussion on its merits of the system in vogue. The evidences of a present prosperity on which all, from the merchant prince of the capital to the humble and hardworking cooly of Southern India, were undoubtedly thriving, were too strong to be assailed by abstract arguments based only on general principles however sound.

The case is now altered, and at the present juncture when the advance system is for the time in abeyance it may well be profitable to raise an academic discussion on its merits and shortcomings, not only as being highly interesting in regard to the past, but also as a guide and warning for the future.

To begin in true academic fashion let us try to define the system of advances. The essence of the matter, apart from any special arrangements for attaining the end in view, will be found on consideration to lie in the application of the accumulated capital of one country to the development of the resources of another.

Given that coffee-planting in Ceylon offered a reasonable prospect of success, it would seem, at all events in its first beginnings, to be especially adapted to be the subject of advances from without. Indeed looking at the time and cost necessary to bring coffee trees to maturity, it is difficult to see how the first coffee estates could have been opened without extraneous capital.

It is true that Mr. Henry George boldly asserts that labour is altogether independent of capital and is in every case self-sufficient. But even he would, it may be presumed, be puzzled to get a force of coolies to come over from the Coast of India and plant up an estate in Ceylon with no means of feeding them the while, beyond the hopes of some coffee berries at the end of three years.

Again even when the estate is in bearing a large expenditure is necessary each year in anticipation of the harvesting of the crop. And the problem is still further complicated by the fact that the labour force has to be continuously imported and that not a cooly can do a stroke of work till a certain limited

sum at least has been expended in bringing him from his native village in India to the scene for his future labours.

It is obvious then that without extraneous capital the earlier coffee estates of Ceylon could never have been planted. And as capitalists were hardly likely themselves to come and open estates, it may be freely admitted with the abovementioned Colombo merchant that the man who first induced London capitalists to make advances to Ceylon may be considered in some sort a benefactor to the colony.

Once let the cultivation be fairly established, however, and the case would seem to be greatly changed. Then the enterprise is thriving, a sound and healthy development will certainly take place, though no further capital be introduced from without. But such development will in that case clearly be dependent on actual attained results. And here one sees at once wherein may lie the risk of a continued inflow of capital from abroad. Extension being no longer controlled by the results of previous adventures may take place in any direction or to any extent that the most sanguine hopes of the future may suggest.

And so indeed it happened in the case of the Ceylon Coffee Enterprise. Somewhere between fifteen and twenty years ago, it had become evident to those who were most widely interested in the cultivation, that there was difficulty in keeping up the yield, that crops did not as previously increase in proportion to the increase of acreage. In the face of that experience it was yet found expedient to begin about the same date the opening of new districts on a scale beyond all precedent, and, as if to prevent any chance of prudent hesitation, about the same date bankers rushed in where agents were fearing to tread and under the name of cash-credits, did in effect place capital in the hands of any, be he novice or not, who wished to speculate in coffee planting. It is needless to dwell on the result, which is only too well-known to all.

It may be said that this is but *ex post facto* criticism and that it is easy to be wise after the event. But it is the case that there were some who steadfastly refused to join in the rush into the new districts though pressed to do so, and who later when the great rise in coffee caused a temporary and delusive flush of prosperity were seriously blamed for their inaction. It is the case also, that, before a cash-credit was signed, the proposed system was denounced without hesitation by one at least as "a dangerous trap."

How different would be the position of Ceylon planters today, if, say from the year 1870, instead of the wild rush into tens of thousands of acres of coffee in the new districts, steady progress had been made with the cultivation of tea, cinchona and other new products, and if the great Bank, in place of joining in the race to make advances, had confined its operations to the very lucrative business legitimately open to it!

But it is idle to cry over spilt milk. And the only value to us of recalling the mistakes of the past lies in their bearing on the future.

Tea is the future King. Will it be prudent that the system of advances, which was first so useful and then so disastrous in the case of coffee cultivation, should be extended to that of tea?

It would undoubtedly be safest as far as possible to restrict advances. The conditions under which the planting of tea estates is taking place, differ widely from those attending the opening of the coffee estates. The land is in most cases already cleared and in many cases actually giving some return, so that the necessary first outlay is comparatively small; and again as soon as the plant is in bearing, the crops

comes in continuously so that the necessity for yearly crop advances does not exist.

Moreover, Ceylon is now comparatively well-known and accessible, and capitalists in England will now certainly come themselves in sufficient numbers to carry forward tea cultivation so long as it offers reasonable hopes of good returns. Indeed the greater fear is that, even without any revival of the old system of advances, means will be found for the rapid extension of cultivation beyond the limits of prudence.

To end this prolix essay: On this as on every subject our great poet has written not for an age, but for all time. Were Polonius now starting off Laertes as a Tea-planter to Ceylon, how could he better advise him than in those well-known words of old?

Neither a borrower nor a lender be,
For loan oft loses both itself and friend;
And borrowing dulls the edge of husbandry.

SAN DOMINGO.—Transportation is still in its primitive condition in San Domingo. There is not a single wagon road penetrating more than three or four leagues into the interior. All of the inland traffic is carried on by means of animals. A railroad is being built from Samana Bay to Santiago, and if completed will open up rich tracts of lands capable of producing great crops of sugar, tobacco, coffee, cocoa, and other tropical articles.—*Chamber of Commerce Journal.*

COPRA.—*Philadelphia Press*: One of the leading articles which the Polynesian Islands send to this country is copra, which is simply the dried meat of coconuts. The natives break the nut into small pieces, which, after exposure to the tropical sun, turn to a dark brown color. Copra is used in the manufacture of candles to a large extent. Besides pomade and coconut oil, copra furnishes a volatile oil which is used in the manufacture of perfumery. The importation of copra into the United States is yearly increasing.—*American Grocer.* [The "volatile oil" is new to us.—Ed.]

A CHANCE FOR INVENTORS.—The Government of the State of Yucatan, Mexico, offer a prize of \$20,000 to the inventor of a machine which shall successfully extract the fibre from henequen, under the following conditions: It must be automatic and not require skilled and experienced workmen to manage it; it must be entirely free from danger to the operatives; it must require less motive force than the machines now in use with relation to its producing power; it must increase the production or extraction of the fibre within a given time, diminishing its loss compared with the various machines in use. The reward is to remain open for three years, and is without prejudice to the right of proprietorship and of patent.—*P. T. Journal.*

SAWDUST PAPER.—Paper made of sawdust is among the latest achievements in wood pulp and paper making inventions. The Rutland (Vt.) *Herald* comes to us printed on paper made exclusively of sawdust. It is a product of a roller pulp machine invented by G. H. Pond of Glens Falls, N. Y. There is no grinding in the process, the material is pressed into pulp by iron rollers working inside an iron cylinder, and is bleached by a new process devised by the same inventor. In his machine, shavings, chips, sawdust, and refuse of saw mills generally, as well as bagasse—the refuse of sugar cane—are converted into pulp which the maker claims is superior to the pulp of wood and rags. It does seem to be in one respect, it possesses the important advantage of being strong—tough. The tensile strength per square inch is about double that of paper used by most newspapers, which bears a breaking strain of only about eight pounds in the tester, while this marks seventeen to the square inch. It is, however, rather hard, harsh, and "rattly."—*P. T. Journal.*

LEAF DISEASE, NEW PRODUCTS, &c., No. VII.

To "running brooks and sermons on stones," Shakespeare might have added "and wealth in the woods." Besides timber and wild fruits, there are a great deal of materials in the woods to engage the energy and industry of man. The supply of fibres, and their uses, obtained from the aloe plant, the wild hemp (the mudur, and vara of the Sinhalese, erukelam of the Tamils), the suria Thepesia (puvaresi of the Tamils) and others have been already adverted to; I would now invite attention of the industrious and enterprising to fibres obtainable from wild trees and vines or creepers: of these—the ittie tree yields, it is said, fibres of the strongest quality (although not equal in strength to the mudur, *erukelam*) from its bark. This tree is nearly allied to the bayuan (Ficus), with beautiful green foliage; it loves to cling round other trees; the stem is smooth and almost glossy, of a pale green colour, abounds in milk. The next fibre tree is the thegulum of the Tamils; it is a vine with soft obovate pale green leaves; the flowers are in large clusters, but small, corolla white with dark red calyx, resembles the flowers of the margosa; the bark of the vine yields fine pink fibres, and is made into twine of a fine quality (specimen is enclosed); it is useful for ordinary bindings, but is liable to break on much exposure to the sun; the fibres are also useful for making gunny bags. The natives detach the fibres and go on twisting into twine or rope, by the hand; with a machine a large quantity might be made. Then there is the *aethee naor*. The *aethee* is a leguminous tree, grows to a height of ten or twelve feet with spreading branches and thorny, the leaves are bifid at the termination of a dark green colour, the flowers are solitary, of a yellow colour, the pod is beane. The fibres are obtained in the same way as the last, the cordage is much stronger, is used for a variety of purposes. There is another vine which is used entire for tying fences, and roofs of thatched houses is called *maang code*. I could not get the leaves and flowers. The above are however sufficiently numerous varieties of materials for cordage, and if the manufacture is carried on extensively, I have no doubt of its yielding a profit to speculators. The long pods of the Cassia fistula (*terocandel*) of the Tamils is, I think, already an article of trade and is exported. The covering of the seeds is a soft blackish pulp, possesses laxative properties and enters into the composition of the confection of senna. The *Cayan memo* Ceylon Tinctoria is a beautiful tree when in full flower, which adhere to the branches of the tree, and present the appearance of small bushes, stuck on the tree, of a beautiful blue colour, slightly fragrant, but soon fades on removing from the tree; it yields, I think, a beautiful blue dye. Specimen will be sent, but they are to be seen in the jungles about Maradana.

SILEX.

THE CINCHONA MARKET IN 1884 IN EUROPE AND AMERICA.

(See page 28 for remarks on this paper.)

In the commencement of 1881 the condition of the Cinchona market was highly unfavourable for the producers of Cinchona bark.

The quinine manufacturers, both European and American, had formed a convention in 1883, which had for object to limit the manufacture of sulphate of quinine, but to maintain the price of this medicine at a fixed height. Although it was not the direct intention of the manufacturers to depress the price of barks, yet the natural consequence of the combination was, that very soon there was more bark on hand, than could be made use of by the limited manufacture of quinine, and so the proper proportion between the value of the quinine in the bark and that of the prepared sulphate of quinine, was entirely disturbed. Whilst the price of the sulphate of quinine was kept at about £145 per kilogr, the value of the quinine (calculated as sulphate of quinine) in the bark, fell to about £60, while the just proportion would have required it to have been £112 to £122. By the convention it had been stipulated how much every manufactory might produce per month,

The unavoidable consequence of this convention, if it^s continuance could have been possible, would have been, that here or there—probably in Java, or British India, or elsewhere—one or more new quinine factories would have arisen, which, not bound by the convention, would have been able to sell their product at a much lower price, about £80 per kilogr.

But discussions soon arose in the bosom of the convention itself. One of the members contracted 1st October 1883 for the furnishing of 100 kilogr. of sulphate of quinine for the use of the Colonial Department in Netherlands, at the price of £127 per kilogr. The supposition is authorized that, where this could happen in a public tender, it would not be unlikely that, in direct sales from the factories, some of the manufacturers would not keep strictly to the stipulated price. The manufacturers soon discerned that the sales became limited to the smallest extent, since, by the too high prices of the sulphate of quinine, only so much was purchased as was required for immediate use, while the stimulus was wanting to take much trouble to increase the consumption.

There were great profits on what was sold, but so little was sold, that the factories who kept honestly to the agreement, made a bad business of it, whilst the benefits of the convention were only conferred on a few.

The convention was to have lasted till May 1884; but, fortunately, the condition had become so untenable, that it fell asunder as early as the latter part of January.

It is to be hoped that the experience gained by the quinine manufacturers while this convention lasted will prevent them from ever again proceeding to such a measure. To the producers of cinchona bark it was highly injurious, as they obtained a very low price for their product, without the advantage of the consumption increasing by reason of this low price.

So in the beginning of the year a healthier state of things set in. The 24th of January 10,000 oz. (321.4 kilos) of sulphate of quinine were sold in London, at £3075 per oz. or £99 per kilogr., and Howard & Sou soon followed by reducing the price from £150 per kilogr. to £120. The price of the bark did not rise to any importance, but that of the sulphate of quinine was lowered more and more, and so came more in agreement with that of the bark.

In February the news came that a fire had broken out in the quinine factory of Powers and Weightman at Philadelphia, which destroyed part of the stock, and would also entail a temporary stoppage of the manufacture. This intelligence occasioned for some days an increased demand for quinine, but soon it became evident that the reports had been exaggerated, and that the loss did not amount to more than 500 bales of bark.

In March the price of sulphate of quinine fell to £110 per kilogr. and in April a very large quantity—11,000 a 15,000 bales—of Cuprea bark, with a proportion about $\frac{2}{3}$ p. Ct. of sulphate of quinine, was sold to the factory at Milan, at a price which was kept secret, but thought to be too high in proportion to the value of the sulphate. In May, too, the price of the bark was somewhat forced up, especially by the instrumentality of the Milan manufactory, which seemed then to intend some new speculation. However, this did not succeed, and an attempt to dispose of another 14,000 bales of Cuprea by auction, on 20th May, failed likewise, as only about 500 bales found purchasers. In June the prices remained the same as in the preceding two months, but since July they constantly declined, till at the latter end of October the price of the sulphate of quinine for Howard's was quoted at £77, and for German manufacture at £67.50.

The bark prices followed this movement, and the unit per half kilogram fell for barks of 2-4 p. Ct. to 26 cents, in London to 45d. per pound unit.

In August the failure of the Milan Factory became known, and shortly after, that of the firm Meyer & Co. at London, the principal importers of barks from South America. It was first feared that these failures would have a very injurious influence, because by it the market was threatened with about 30,000 bales of Cuprea bark, besides 21,000 kilogr. of sulphate of quinine. But fortunately neither contingencies occurred, and it appears that the stock was gradually disposed of by the banks who had lent money upon it.

The Milan factory must have been in financial difficulties for a considerable time. The liabilities were stated at £5,000,000, the assets at £2,280,000. The shareholders have entirely lost their capital, while the creditors will receive about 45 p. Ct. The value of the factory is estimated at £975,000, the stock of sulphate of quinine, etc. at £1,940,000. The factory possesses also Cinchona plantations in Bolivia, which are valued at £50,000, but of which no title deeds have been found. The manufacture is still continued, but as only 25 kilogram of sulphate of quinine per day are prepared now, it does not cover the expenses.

The demand for sulphate of quinine remained very trifling up to November, and the stock of barks could only be disposed of by constant lowering of the price. But against the end of that month, and in December, a greater demand for this salt arose, and prices improved somewhat, so that also the unit, which had fallen in October to a mean of 25 cents, improved by ultimo December to 30 cents.

The range of prices for sulphate of quinine during the year 1884 is given here for every month.

As is known, Howard's sulphate of quinine commands higher prices than either the French or the German. In general there exist no other reason for this, than that Howard's salt is preferred in England and part of the British Colonies to the exclusion of all other marks.

The purity and the appearance of the salt do not differ so much as to authorize the higher price

The price of the various marks were, per kilogram, in guilders:—

	English.	French.	German.
January	150	149	145
February	120	96-106	91-101
March	111	106-110	101-106
April	101	96-101	86-91
May	101	96-101	91
June	101	101-106	91-96
July	96-101	101-106	86-96
August	87	77-86	82-87
September... ..	82-87	77-82	72-77
October	82-87	72-82	67-50
November... ..	82-87	67-80	66-50-72
December	87-90	77-86	72-77

For the Department of Colonies in Netherlands, the furnishing of sulphate of quinine was contracted: the 5th March for £108'87, 9th April £95'97, 13th May £91'40, 5th November £65, 20th December £76'63 per kilogram. These prices agree pretty well with the market value, whilst the contract for 5th November only was in fact below the market price.

The price of bark declined with that of the sulphate of quinine, but the difference is not so great, because the January price of £145 & £150 for quinine was an artificial one. However, on comparing the prices of bark in May 1883 and in September 1884, it will become evident what a great diminution in value has taken place within that period. An excellent instance to corroborate this, is the history of a parcel of bark from the Tjomas plantation, which after being sold in London, in May 1883, was stored by the purchaser, and offered by him again for sale in September 1884 in the same place. The prices were per English pound:—

	In 1883.	In 1884.
146 bales stem-bark	40 cents	17 ⁹ / ₁₀ cents
28 " branch-bark	50 " "	22 ⁵ / ₁₀ " "
8 " shavings	90 " "	40 " "

The unit for barks containing of 24 p Ct. sulphate of quinine varied from 25 to 45 cents. For barks of very low percentage, below 1 p Ct., however, this was not the case, and the unit for these descriptions has fallen as low as 18 cents, while buyers neglected those barks, giving more attention to material of a higher percentage.

A circumstance, observed during the whole course of the preceding year, was, that the American barks were only sold and supplied in small quantities. The rate to which the bark prices had declined, left no margin for profit for these barks. There were still some supplies, for which modest advances had been paid, but the importers, who would have had to lose upon their supplies have generally preferred to withhold their bark, hoping for better times.

The following statement shows how much the imports of American barks have decreased, compared with former

years. These figures are the totals of imports from S. America to England, N. America and France in bales:—

1878 1879 1880 1881 1882 1883 1884
91,990, 107,900, 110,530, 157,805, 163,587, 104,690, 37,490.

A great part of these supplies of the years from 1881 to 1884 consisted of Cuprea-barks; in 1882 about 80,000 bales of this description were imported to England and France together, in 1884, only about 12,000 bales.

As has been said above, in May about 15,000 bales of cuprea bark had been taken by the Milan factory. But save this larger sale, only about 20,000 bales of S. American bark were sold during the whole first half-year of 1884, which figure fell in the second half-year to 6,000 bales. So only 21,000 bales were sold, out of more than 89,500 bales that had been put for auction.

Among the Cuprea barks sold this year, there were thousands of bales which had lain for to or three years in London, and with which a speculation had been attempted in hopes of engrossing all the bark, and so force up the prices. Fortunately this speculation miscarried, and the figure expressing the losses in that speculation must needs be very high.

Especially the great supplies of cultivated barks from Asia have tended to frustrate the attempts to force up the prices.

Ceylon bears the palm among the Asiatic possessions, as to quantity of the product. The quantity has increased there with astonishing rapidity, as will appear from the following table. The total imports from Ceylon were in kilograms, during the years:—

	1881	1882	1883	1884
	544,200	1,405,850	3,174,500	5,215,250

The other parts of British India, Madras, and Bengal, brought to market in London during 1884 only a quantity of a little more than 5,000 bales.

In 1884 Java furnished 453,700 kilograms of bark. Of this quantity 323,500 kilograms were sold by auction at Amsterdam, in London 50,000 kilograms by auction, and 80,200 kilograms were sold direct to quinine fabricants.

The percentage of the Ceylon barks is at present estimated at an average of $\frac{1}{3}$ or 2 p Ct. sulphate of quinine. That of the Javan barks sold by auction amounted to 2.22 p Ct., while those sold direct to the factories held on an average 3.5 p Ct. On the whole, all the cinchona barks imported from Java in 1884 and sold in Europe, contained about 10,000 kilograms of sulphate of quinine.

The highest percentage was found in the Ledgeriana barks of the Government's Cinchona plantations (9.3 p Ct. sulphate of quinine in the air-dried bark), but also among the private supplies, stem-barks are constantly met with, which, though mostly younger than the Government barks, excel for high contents.

From auction notes and direct sales to factories known to me, I here give the highest contents of parcels of barks of some estates in Java, which were sold during 1884.

The percentage is: sulphate of quinine in air dry bark:

Djoengo (East Java) Ledgeriana stem-bark	6.3 p Ct.
Pringombo (Pekalongan) "	7.5 "
Pagilaran "	6.7 "
Karang Mego "	7.3 "
Pamanoean & Tjiasem Krawang Ledgeriana stem-bark	6.4 "
Soekaneagara (Preanger Reg.) Ledg. stem-b.	8.0 "
Paujairan "	6.9 "
Tjiseureuh "	5.2 "
Bojabang "	5.1 "
Pasir Ipies "	6.2 "
Waspada "	5.0 "
Tandjoeng laect "	5.7 "
Djajagiri "	5.6 "
Soekawana "	5.7 "
Telaga Patengan "	5.1 "
Tjitrapp (Buitenzorg) "	5.3 "

The officialis bark, too, often showed a high percentage of sulphate of quinine. The following Cinchona concerns, for instance, sold:—

Pasir Ipies officialis	stem-bark	5.8 p Ct.
Waspada "	"	4.7 "
Pamanoean & Tjiasem officialis	"	5.1 "
Djajagiri "	"	5.1 "
Soekawana "	"	5.1 "
Djoengo "	"	4.3 "

This shows how, in various parts of Java and in different plantations, the percentage of the *Ledgeriana* bark is very high. We might hence deduce that this generation of *C. Ledgeriana*, reared from seed gained in Java, has not deteriorated, that the percentage may be at least equal, and sometimes superior, to the average percentage of the original *C. Ledgeriana* of the same age, reared from *S. American* seed. The first harvest of these, in 1872, when the trees were six years old, had a proportion of 6.2 p. ct. of sulphate of quinine, just as much as the average of the above stated contents, which for the most part relate to bark of four or five years old. As the quantity of *Ledgeriana* seed, that could be placed at the disposal of private persons, was not abundant, and the trees of inferior quality flourished first, the consequence was that at first seeds were given from trees of inferior percentage. As the richest barks from *S. America* contained only 3 p. ct. sulphate as maximum, it was thought at the onset very fair if seeds were distributed to the planters from trees with 3.5 and 4 p. ct. of quinine sulphate. So from the older gardens of the oldest private *cinchona* plantations, we often find supplies of *Ledgeriana* bark not exceeding in contents 3.5 to 3.8 p. ct. sulphate,—while the richest barks come from the plantations. Those of Soekanegara, Pringombo, Karang Mego, Pagilaran, mostly derive from the year 1879, when there was an abundance of superior *Ledgeriana* seed from the harvest of 1878.

The stock of *Cinchona* bark was, at the end of 1884, considerably less than at the commencement of that year. On the last of December of the years 1878—84 there were in stock, bales:—

	1878	1879	1880	1881	1882	1883	1884
In London ...	9,000	14,205	28,170	39,200	72,300	100,470	79,300
.. France	1,370	8,400	8,040	15,780	18,280	11,200
.. North America	17,400	29,900	11,800	12,500	15,000	10,400	5,700

Total ... 26,490 44,575 48,370 59,740 104,080 129,150 96,200
So there was during 1884 a considerable reduction in the stock, with as much as 32,800 bales; but still it remains very considerable. However the stock on hand is not all good bark. It can be taken for granted that among the remaining 96,000 bales, a great part, probably as much as one-third or one-half, does not average more than 1 p. ct. and often less than that, of sulphate, so that these barks are mostly of very little value, and even quite worthless for the manufacturers. So, for instance, it is stated of North America that among the 5,700 bales in stock as many as 3,100 are as good as unfit for use.

In Amsterdam the stock amounted on the last of December, to 2,000 bales, for the greater part Government barks.

It is a pity that for all countries the returns of supplies and stock are not given in weight, as the expression bales or chests is so vague as to the quantity. The South American bales are estimated on an average at 60 kilos, but the Ceylon bales are much heavier; in 1883 these contained on an average 100 kilograms, and in 1884, 112 kilograms each.

In London the stock at the end of 1884, consisted of 64,500 bales of Cuprea, Pitayo, Columbia and North Granada barks;

3,545	Calisaya;
1,010	Carthagena;
1,175	Officialis and Mierantha;
65	South American Succubra;
5,835	East Indian bark.

The prospects for 1885 seemed rather better at the end of 1884. The barks from *S. America* will be no longer imported in any quantity, as at the heavy reduction in value, they can no longer make good the costs of harvesting and transport.

It is moreover thought, and this opinion is confirmed on many sides,—that during 1884, by various circumstances, and especially owing to financial position, more was harvested than was necessary or good for the plantations, and that in many places the harvest was a forced one, because the *cinchona* trees began to die off.

The opinion has been expressed that the soil of Ceylon, which is not very rich in the mountain districts, and which, in many places, has grown much worse by the manner of cultivation, will not in the long run be able to produce annually such great *cinchona* harvests. Dr.

Trimen, the Director of the Botanical Gardens at Peradeniya, says in his report of 1883, that, according to the planters, the young plants and seedlings die away much more than they did formerly, and he himself experienced this in the Botanical Garden at Hakgalla. Yet 128 millions of *Cinchona* trees must have been planted in Ceylon, of which about 22 millions were still alive in 1884. How many of these will henceforth remain alive, cannot be said with any certainty, but it seems only prudent not to found the supposition on these reports that Ceylon will soon be an insignificant factor as a bark-producing country.

In Bengal and Madras the *cinchona* cultivation seems not to attain much larger proportions. In the western parts of Madras,—Wynaad and Travancore,—a great deal of *Cinchona* has been planted for some years too, which can be harvested two or three years hence.

In 1884 Java brought about 453,700 kilos of bark to the market. Of these about 207,000 kilos were from the Government gardens. The production now increases year by year, but will not for the first years equal that of Ceylon in 1884.

The London brokers are doing all they can to attract the Java *Cinchona* bark, which, in general, surpasses all other *cinchona* barks in quality, to their market, and boast of the high prices which are obtained at London more than any where else.

On looking more closely into the matter, it will be seen that in general quite as good prices are obtained at Amsterdam as in London. For the continental factories Amsterdam is better situated than London, and for barks of high quality the English fabricants also come to make their purchases at Amsterdam.

It is a difficult thing to make out for certain whether the prices are as high at Amsterdam as in London; only the manufacturers, who examine all the barks, and can thus constantly compare the analysis with the prices would be able to do this. At first sight, however, it may be thought impossible that in the long run any important difference can remain in favour of either market; for if really the prices at either place were constantly lower, this would very certainly attract the buyers, thus causing that great competition by which, according to the London brokers, their market deserves the preference.

It is a fact, that often German manufacturers come to the *Cinchona* bark sales at Amsterdam with the intention of buying large quantities but who quit the auction as owners of only a dozen bales, because they found prices run too high and as they could obtain their supplies cheaper in London. Though orders are often given by English manufacturers for the auctions at Amsterdam yet they are seldom effected, because the limits are mostly too low; whence it may be concluded that in London such purchases can be effected at that lower price.

As far as is known, the following Java barks were sold in London during 1884:—

			SULPHATE OF QUININE.	PRICE p. ct.	UNIT OF p. 1 kilo IN QUININE.	IN cents.
Febr. 26th.	Ledgeriana	A 19 b.	6	pCt.	206	34 ⁵

Now, if the unit is taken of the auctions held at about the same time at Amsterdam, we find:—
London.

Feb. 26th. 32^s—44 ct. Feb. 29th 31—45 ct.

N.B.—The barks with more than 4 p. ct. sulphate were paid at London with 32^s—36^s per unit, at Amsterdam with 36—45.

April 9th. 32^s—41 ct. April 18th. 32—43 ct.

N.B.—During the month of April the prices remained unaltered.

July 30th. 23^s ct. July 25th. 31—32 ct.
N.B.—For Amsterdam I have purposely taken only the unit of barks which obtained about 2 p. ct. like those of London.

Dec. 2nd. 27—32 ct. Nov. 25th. 31—36 ct.
N.B.—The market had a rising tendency, so that the date of Dec. 2nd must have been in favour of London.

It is evident,—at least as far as these few comparative data go to prove,—that the advantage was not on the side of the London market. I must, however, observe that in London the payments are cash without deduction, while at Amsterdam 1 p. ct. is given for ready money. We shall then do wisely to take for granted that the business takes its natural course, and that, at the same periods, the same price is paid at Amsterdam and London for the same manufacturer's bark.

The comparison of druggist bark is even more difficult. In the reports of sales we only see noted of Dutch barks: *stanbost 1ste soort* or *1ste soort in lange pijpen*,—of English barks: *long* or *bold silvery druggist quill*, etc.—but the particulars—fair, sound appearance, the being well covered with lichens, the silvery coating, and other details that determine the high value, are not learnt from such a description. It is therefore difficult to say: succirubra has fetched at London so much, and at Amsterdam so much, and thus compare them, because those succirubra barks may differ immensely in the eyes of a druggist.

That sometimes very high prices are given for such barks at Amsterdam was evident from the auction of 29th February, when very young succirubra bark in long quills was sold on appearance for 192 à 204 cts, and the 19th of June, when long quills of Calisaya Schuhkraft fetched 302 cts. per $\frac{1}{2}$ kilogram.

As there is not so much wanted of this sort of barks, it may easily happen, that at one time there is more demand in London, and at another in Amsterdam, and that the prices in proportion may vary in favour of either market. Dealers of druggist-barks in Netherland assure that the prices of this article are better at Amsterdam, but I believe that their colleagues in London find the prices better there.

The costs of sale in London are not less than those of the auctions at Amsterdam; the contrary is even averred. The planters who have sold in both places, would be able to give information about this point, which would certainly not be to the detriment of the Dutch market. The charges of auction are very high in both places, and they weigh heaviest the lower the prices, the less good the bark, and smaller the parcels are. If, for example, very young succirubra quills are packed in chests, and if the whole lot must be sold at 30 or 40 cts. per half kilogram, then freight and insurance run away with the greater part of the produce, and it may occur that as much as 40 pCt and even more of the gross produce is lost for charges, while the seller in Amsterdam is after all ill-paid for his trouble.

Direct sale, by contract, to manufactories, under control of the analysis from the side of the sellers,

has for a couple of years been practised to satisfaction by some planters. The payment is regulated according to the average price of the sulphate of quinine during one half-year. This system of sale entails very small charges. The chance of deriving eventual profit from the inclination for speculation of some buyer who pays higher prices at the auction than the price of the sulphate of quinine at the moment of the auction would authorize, is then disregarded; but then there is the advantage of being always sure of an immediate sale at the average value sulphate of quinine during one half-year.

The brokers, both at London and Amsterdam must be directed by analysis of the barks. For the factory-barks especially, these are quite indispensable for valuation. The analyses for this purpose must often be made in great numbers and very expeditiously, and it frequently occurs that an exact determination of quinine sulphate is required within two or three days.

I found that my method of analysis, which I constantly followed in Java, though it gives exact results, did not answer under these conditions, because it required too much time and labour. I was therefore obliged to adopt another method, and at first this gave some trouble, and I could not be always satisfied with the results obtained. But at present this difficulty is surmounted, and while using the same method of analysis followed in many quinine factories, the figures in general agree with those of the manufacturers.

Differences in the analyses constantly occur, and the more so in proportion as the barks are badly mixed, or appear in quills, which makes it difficult to take a good average sample. If several persons take samples from one and the same parcel of bark in quills, it is very likely that their analyses will diverge more or less considerably, and it often occurs by this reason that the limits of the manufacturers for one and the same parcel of bark greatly differ. Thence follows that units obtained by dividing the amount of quinine sulphate upon the prices per $\frac{1}{2}$ kilo, diverge sometimes considerably from each other, which difference is increased by the unit's being in proportion to the contents, a little higher or lower, because the manufacturers pay more for the best barks of 4 p. ct. sulphate of quinine than for that of lower percentage.

Hitherto we did not find the London market to excel by any particular advantages. Yet there is one, and that is that in London cinchona sales are held regularly, every fortnight, about 25 per annum; while at Amsterdam the auctions are not so regular, and last year only 8 were held. This may sometimes occasion some delay for small parcels, but, in proportion as greater supplies come from Java, and the planters send their barks less frequently to London, this difficulty will diminish. It is probable that in 1885 one sale per month can be held. Besides, the way is always open to dispose quickly of fit parcels by privately selling them to the manufactories.

The arrivals in Amsterdam in 1884 consisted for a great part of manufacturer's barks. We cannot recommend the planters too strongly, in the case of typical Ledgeriana, not to apply themselves to obtain more or less fair bark quills. As soon as the contents exceed 3 à 4 p. ct. of sulphate of quinine, the bark is not bought as druggist-bark, and so the form gives no advantage; indeed it is a disadvantage, because the bark takes up more room, requires more costs of package and freight, and the exact valuation is rendered more difficult. Such barks should be broken up in small pieces a couple of centimetres long, and be thoroughly mixed. It is no use whatever to do, as is so often done with Ledgeriana barks of more than 6 p. ct. sulphate—to separate them in quills of 3, 4, 5, 6 decimetres in length, and thus sorting several small parcels, instead of breaking them all up into small pieces and mixing them up to one good large parcel.

The manufacturers have at present an immense deal of work. In the first two months of the present year 8,072 halves of Ceylon cinchona bark were set up for auction in London, besides the 8. American barks. If now we assume that all this consisted on an average of parcels

of 10 bales, then every factory that wishes to be properly enlightened had, only for these barks, to make 807 tests. Add to this the S. American and Javan barks. It is obvious that the consequence will be, that small parcels of 1 à 2 bales are neglected, that the manufacturers examine no samples, or at least not all the manufacturers, and that the true value is obtained with difficulty for such parcels. By mixing several small parcels, for instance, *Ledgeriana* and *officialis* root-bark in powder, *Ledgeriana* and *officialis* stem-bark of equal contents, also in powder—young plantations, which otherwise would have to supply too many small bulks of various sorts, can thus make up one parcel important enough to attract the attention of buyers.

If there is enough of each sort to make up 5 or 6 bales—about 500 kilograms—then it is not necessary to mix them. For manufacturers bark the name of the bark is not of the least consequence, the only factor that regulates the prices is the proportion of sulphate of quinine it contains.

I also observed that the harvesting of the bark—especially of the branch bark—was performed rather rudely, and that a good deal of wood was taken along with the bark. In some samples I have found as much as 10 à 15 p. ct. of wood. This ought to be looked to, for it acts very prejudicially for the seller because the buyers will deduct a very full percentage for wood.

In general the *succubra*, offered by private planters, was too young. There is a good demand for these barks, but they must be at least 7 years old, or rather older, and have the white silvery appearance on the outside and the reddish brown colour inside, that are required of this sort, and if these conditions are not complied with, it is of no use cutting the bark in long quills.

Nor do the shippers in Java usually set the tare of the chests in which the barks are packed on the outside of the chest. This causes much trouble at Amsterdam, because the chests must then be unpacked there, weighed and be repacked, to state the tare to the buyers. The barks suffer under the treatment, and for all these small operations the charges are relatively high. I therefore advise planters to mark the tare as accurately as possible on the outside of the chests.

As substitutes for the quinine-salts, during 1884, antipyrine, a derivative of chinoline, and thalline were recommended.

Anti-pyrine is a greyish-white, crystalline body, smelling of tar, and having an acrid bitter taste. It possesses absolutely no febrifugal quality, but lowers the temperature of the body two or three degrees Celsiusus. The dose is one gramme, and must be repeated from 2 to 5 times, at intervals of one hour. The great quantities required to be taken, render the antipyrine, which costs about 750 per kilo, very dear.

Thalline (tetrahydroprachinaminis) has been prepared by Skraup. With sulphuric and tartaric-acid it yields crystalline salts, which taste acrid and bitter. This new remedy, which has also the quality of lowering the temperature, is now being made the object of experiments.

J. C. B. MOENS.

Haarlem, April 1st, 1885.

MANURING AND CULTIVATION: PRACTICE WITH SCIENCE.

FINE v. COARSE SUPERPHOSPHATES.—The controverted point as to the relative effects of very finely divided manures and coarsely powdered fertilizers has received some illustration in recent experiments of P. Wagner. He finds that the degree of fineness of a manure really is of great importance as regards its action in the soil, but that its activity does not necessarily increase with the degree of fineness. As a case in point, he maintains that on soils rich in lime it is preferable to use finely divided superphosphate, while on soils poor in lime coarsely broken superphosphates give better results.

THE FUNCTION OF SILICA IN PLANT GROWTH.—Experiments by Dr. Emil Wolf on this subject may possibly lead to important results, for he has been endeavouring to ascertain how far it would be practicable in the culti-

ation of grain crops to substitute for the expensive phosphoric acid the far cheaper silica. The experiment, were made on oats grown by means of water culture that is, in nutrient solutions the compositions of which is known and may be modified at pleasure. There were three sets of experiments arranged respectively to include no silica, very little silica, and much silica. It may here be observed that although silica is commonly found in the ash of plants, particularly of grasses and cereals, yet healthy vegetation may be produced in the absence of silica, so that this ingredient cannot be regarded as essential to plant growth in the same way as nitrogen, potash, and phosphorus are known to be. Wolf's results indicate that the absorption of silica greatly assists the assimilation of other plant foods, and that plants to which silica is supplied show a decidedly better development of grain and straw than do others not so treated. Previous experiments had shown that phosphoric acid similarly acted in facilitating the assimilation of ordinary plant foods, and hence it is suggested whether it would not be possible to replace phosphoric acid by silica, acid (silica) in the composition of artificial manures. As a matter of fact, manure manufacturers have attempted to achieve this result, and their failure is attributed to using silica in an unsuitable form. Further experiments are needed, especially by ordinary methods of cultivation, as under-water culture plants absorb more nutriment than when grown in the soil. It is doubtful whether phosphoric acid in manures could be successfully replaced by silicic acid, but it is not unlikely that a combination of both may be obtained, which would yield excellent results in the cultivation of cereal crops.

INFLUENCE OF SHELTER ON SOIL TEMPERATURE.—Observations by E. Wolny on the temperature of soils under various circumstances show that during the warm season bare soil is much warmer than sheltered soil, and soil sheltered by straw manure warmer than that covered by grass. At the hour of greatest daily temperature the difference between the temperature of the shaded and exposed soil is greatest, while at the lowest temperature of the twenty-four hours the exposed soil is generally cooler than the sheltered soil. Perfectly analogous results obtain, as is well known, in the case of a sandy desert as compared with a grassy plain. The daily variations of temperature are greatest in exposed soil and least in grass-covered. Soil covered by vegetation or dead vegetable matter, such as stubble or manure, is considerably warmer in summer at some distance below the surface and cooler in winter than a fallow, but when a warm period in winter or a cold period in summer intervenes the influence of the covering makes itself felt in the opposite direction. Bare soil is in spring more rapidly heated, and in winter more rapidly cooled. A crop exerts a decided influence on the temperature of the soil, the thickness of sowing and the age and character of the crop being all effective, though it is uncertain whether the plant itself has any influence. Soils are found to warm more rapidly when the crop is drilled than when it is sown broadcast, and a further advantage is gained if the drills are wider apart and if they run north and south. In the case of perennials, as meadow grass, the temperature rises after mowing.—*Adelaide Observer.*

SIR J. B. LAWES ON THE CULTIVATION OF POTATOS.

Although I consider that the use of complete artificial manures involves too great a cost for their employment in the growth of ordinary farm crops, perhaps an exception may be made in regard to Potatos, a crop which requires a large supply both of potash and nitrogen.

At Rothamsted we have grown nine crops of potatoes in succession upon land which for fifteen years previously had received no yard manure, and the average yield of the last three crops has been 400 bushels per acre, calculating the bushel to weigh 50 lb. The manure used each year has been 300 lb. of sulphate of potash, 350 lb. of superphosphate of lime, and 400 lb. of salts of ammonia; while in another experiment, instead of the salts of ammonia, 540 lb. of nitrate of soda were applied. The produce from both manures has been almost identical.

The sulphate of potash supplies about 130 lb. of potash—

and we find very nearly the same amount in the crop. The phosphoric acid, on the other hand, is much in excess of the requirements of the crop, and it might be reduced one-half. The salts of ammonia and the nitrate each supply about the same amount of nitrogen—57 lb.; and of this the crop does not take up more than 50 lb.; there is, apparently, therefore, a considerable loss of this substance; but at the same time, any reduction in the amount of these manures would be followed by a reduction in the crop. The loss of this costly manure ingredient is a most serious matter, as unfortunately there is but little prospect of recovering, in succeeding crops, any appreciable amount of the 37 lb. not taken up by the first. By means of the same mineral manures alone we have grown—over the same period—one-half the crop we obtained by the application of minerals with nitrogen, the soil having supplied a sufficient amount of that substance to give a product of 200 bushels; but one-half of the minerals applied remained inactive in the soil; these, however, might be made available to the crop by an application of nitrogen.

The quantity of potash removed in potatoes is very large. In the 400 bushels it amounts to about 130 lb. Compare this with the amount removed by animals. An ox, weighing 1,400 lb., which was killed for the purpose of analysis, contained only 2½ lb. in the whole carcass and offal. Hay is another crop which takes a good deal of potash from the soil, and farmers in England rarely grow either hay or potatoes for sale unless there are facilities for the purchase of town dung. Artificial manures are certainly not used alone by practical farmers in the growth of their crops.

In our experimental field, the character of the manure is represented in the stem and leaves of the plant. Ammonia and nitrate without minerals give a low stem and greenish-brown leaves, which in the evening appear almost black. Minerals without nitrogen give a thin, low stem and yellowish-green leaves; while mineral and nitrogen together give a luxuriant, and sometimes an over-luxuriant, stem, with leaves of a bright green. There is no difficulty in accounting for these peculiarities. A plant takes up whatever food is most abundant in the soil, with the hope, as I sometimes put it, that sooner or later it may find the food which suits it best. In the dark-green leaves the nitrogen is in excess; but starch cannot be formed without potash, and the supplies of potash are not sufficient to use up the nitrogen. It is far more easy to change the yellowish-green of the mineral-manured potatoes into a dark green than it is to lighten the colour of potatoes which receive nitrogen; a solution of nitrate of soda will effect the one in a very few days, but as both potash and phosphoric acid form the insoluble compounds with the soil, they are much more slowly taken up by plants.

We always, however, obtain a larger crop of potatoes where we apply the mineral manures alone, than where we apply the nitrogen without the minerals, though in the next field, salts of ammonia applied without minerals for thirty-nine years in succession, have grown larger crops of wheat over the whole period than mineral manures without ammonia. To explain this apparent inconsistency we must consider the great difference in the character of the two crops.

Wheat in England is sown in the autumn, and being a deep-rooted plant, it has a greater range of soil to obtain a supply of mineral food than the spring-sown potato. The relation between the potash and the phosphoric acid and nitrogen in the two crops is also very different. In the wheat crops grown by salts of ammonia alone, mixed samples, taken over a period of ten years, give the products per acre of the total crop—straw and grain—as follows: nitrogen, 36 lb.; potash, 23 lb.; phosphoric acid, 13 lb. The relation, therefore, between these two important minerals and nitrogen is as one to one.

In the potato crop, on the other hand, the proportion of nitrogen to the minerals is nearer one of nitrogen to three of minerals, the demand upon the soil for potash being much greater in the case of potatoes than where wheat or barley is grown. It must be a very large wheat crop indeed which removes 50 lb. of nitrogen from the soil; but in some of our potato crops we carry off more than 100 lb. of that substance per acre.

As very few soils could furnish so large an amount as this from their own resources, when potatoes are continuously grown, it becomes necessary to furnish a supply of potash either in dung or chemical salts. The following table gives the products of the crop grown in 1883, being the ninth in succession without any change in the manures.

	Potatos per Acre in Long Tons,	Cwt.
1. 14 tons of dung	6	...
2. Minerals without nitrogen ...	5	...
3. Nitrogen without minerals ...	3	3
4. Minerals and ammonia	8	19
5. Minerals and nitrates	8	2

amount of mineral matter and nitrogen per cent. in dry tubers:—

	Mineral Matter.	Nitrogen.
1.	3.5	1.09
2.	3.86	0.73
3.	2.64	1.47
4.	3.67	1.08
5.	3.86	1.37

The character of the manure is most clearly shown in the composition of the crop. In No. 2, manured with minerals, the minerals are five times as high as the nitrogen; while in No. 3, where ammonia or nitrates are used, the minerals are considerably less than double the amount of nitrogen. In both cases there is a waste of power, shown by small crops, and unused manures. The loss, however, is not equal in both cases, as the minerals remain in the soil to be taken up at some future time, while the nitrogen is probably lost.—SIR JOHN LAWES, in "*Rural New Yorker*."—*Gardeners' Chronicle*.

INJURIES TO CULTIVATORS BY IMPORTED PESTS.

A circular has been issued and widely circulated from the office of the *Adelaide Observer* upon the subject of injuries done to crops, fruit, and farmers' produce generally, by imported pests of all kinds including the Colorado beetle, the Oidium Tuckerii, and the Aphis lainger or American Blight for which reductive if not entirely obliterative remedies have already been discovered. The author refers to the excessive danger done by the shot hole fungus—*Helminthosporium rhabdiiferum*—of which Mr. Frazer S. Crawford has recently discovered the fruiting spores. This destructive fungoid pest attacks the almond, apricot, and peach crops, eating innumerable circular holes in the leaves of trees, affecting the tender branches by absorbing their juices, and disfiguring and dwarfing the fruits. At one time this fungus was unknown in the colony, and our apricot, peach and almond trees used to be loaded with fruit of the largest size and finest flavour. Now it is a very rare thing to see a good peach or almond, except at American River, Kangaroo Island, where the disease has not yet been introduced. An acre of apricots would contain about one hundred trees, and it would be an exceedingly mean estimate at present to put the value of the yield of a good tree at twenty shillings. We have seen hundreds of dozens of fruit upon the trees at the island, and at fourpence a dozen that sum would be realized over and over again. What, then, would be the value of a remedy by which the grower could secure the proper and healthy crops—as of old—from the apricot and peach trees? For years it has existed amongst us, and until now not one in a hundred growers knew what it was that was injuring him, and not one at all knew the remedy. It is very simple, and credit is due to Mr. Crawford for his enquiry into the life history of the pest, as well as his suggestion of a remedy—which is simply soft soap. Probably the kerosine emulsion would answer equally as well, and as it is also destructive of scale and aphid it might answer better

The farmer and the gardener have to fight innumerable noxious weeds that have been imported from various countries without the natural enemies that keep them in check in their own countries. Some, perhaps all, have their redeeming qualities, but when they get mixed up with the farmers' crops or the gardeners' grasses they destroy the average product of the field in which they grow to just the extent that they cover and rob it. Whether the "takcall" fungus was imported or not we cannot say, but it most probably found an entrance by way of one of our ports. However, it is idle to speculate whether this and red rust came that way or not. We know that the list of introduced noxious weeds is very numerous, and that it is increasing very rapidly. We have had scale insects innumerable introduced on various plants; we know of, certain snails that were let loose purposely by a man who brought them from England, and now they are a great nuisance. A number of specimens of aphids have been brought here, and the phylloxera aphid is waiting just outside our doors, having been brought from France to Geelong, and our jammakers and even our nurserymen are importing fruit and fruit-trees in quantities from Geelong, quite careless whether or not they introduce it to our vineyards. It is well known that the Codlin moth has caused the loss of millions of pounds to orchard-owners in America and in Tasmania, as well as many other places, and yet we are taking absolutely no steps to prevent the importation of fruit and fruit-trees from those countries, or even to inspect and disinfect the boxes or trees upon landing.

The apple blight is rampant in our orchards, and no one can even estimate what its introduction has cost the colony. The potato moth (*Leda solandrella*) eats tons of potatoes occasionally, and causes the rest to rot wholesale; we have the curculio beetle, also imported from the Mediterranean, whence we get the stinkwort (*Luula graveolens*), and a few more pests; and we might enumerate a number of borers, coccidæ, sawflies, slugs, beetles, &c., but we have said enough to prove that the enemies against which our cultivators have to contend are neither few in number nor mean in power to hurt them.

The question is, can they successfully cope with their enemies? We say most decidedly they can in some cases, and could in others if they knew more about them and with what weapons to resist their attacks. They want a good practical knowledge of their enemies in all stages and particularly of these periods in their life history when they are weakest and most defenceless, and then they want unanimity of purpose. Thus the locusts in Russia, Syria, and other places used to descend upon the country in thousands of tons and eat every green herb, causing famines and deaths to thousands of human beings. It would be useless to attempt to destroy them at this time, but the armies of the different Governments were sent out when the locusts had just emerged from their egg-cases in the soil, and, besides, every soul that could work was impressed into the duty, so that before they were able to fly the whole lot were killed, and thus a catastrophe was prevented. How often do we hear from our country correspondents that "the whole place is alive with young grasshoppers, and fears are entertained that the crops will suffer by and by," or "that the grubs or the caterpillars are crawling in procession over the newly sown wheatfields, clearing them as they go." Surely the whole neighbourhood should turn out in such cases as these and by means of landrollers, or even of masses of bushes drawn across the living masses of soft defenceless locusts or grubs, they could kill them wholesale, and, by preventing them coming to maturity would stop an indefinite multiplication of these pests.

Upon the subject of education into the origin and destructiveness of such pests the circular goes on to say and wisely too. "Everything concerning insects injurious or beneficial is taught in all the schools on the Continent, and particularly in Germany where beautifully prepared specimens and plates of the insects, their larvae, their eggs, and the work done by each are illustrated. Great attempts are being made in England to establish a similar practice, and Miss Eleanor A. Ormerod, whose work is often referred to in the proceedings of our Royal Agricultural Society, has done very much towards disseminating a knowledge of insects injurious and beneficial to

cultivators, besides enlisting the sympathies and the assistance of numbers of cultivators. But it is in America that the greatest attention has been paid to farm and garden pests, and the funds of the States have been expended with no parsimonious hand in endeavouring to find out all about the farm and orchard pests as well as to devise means for their extirpation. We cannot hope that an Australian Government will establish any such complete organization as exists in the American States but a great deal might be done to gather particulars and disseminate information concerning insect and fungoid pests with a very small expenditure of money. Those who have had the opportunity of inspecting the two cases of insects prepared by Mr. F. S. Crawford, and placed in the room of the Royal Agricultural Society, can easily see how valuable and instructive a work could be done by only one person during each year were his whole attention put into the work. When once an institution for examination into the character of insects and fungi affecting agriculture has been established, there will arise hundreds of willing workers, who will send in specimens, observe their habits *in situ*, and try experiments either under direction or voluntarily, and communicate every particular to the central authority. By these means a great deal of valuable information would soon be got together, and doubtless simple and inexpensive means for combating the various enemies to cultivation would be devised."

In conclusion, although we have not said half of what could be urged in the interests of the various cultural industries, we may point out that in the public Museum there is already the room where the centre of operations could be located; and as the Museum already employs a collector in the entomological department and also a highly skilled preparator, there would only be needed a small additional expenditure for cases, &c., in which to exhibit the specimens. The Director, or other officers, would find no difficulty in publishing all information concerning his department, for each newspaper in the colony would only be too pleased to convey information for the benefit of those important classes—the cultivator of the soil and breeders of live stock.

It is sincerely to be hoped the Government of South Australia will not hesitate in incurring the expenditure necessary to ensure a prompt and searching investigation into the origin and best means of eradicating all pests above and under the soil from which agriculturists of all kinds have suffered and will continue to suffer still more severely if not to a disastrous extent, unless provision for their discovery and total eradication be made in time.—*Agriculturist and Review.*

AMERICAN EXPERIMENTS ON ORANGE SCALE.

Equally with the orange growers of Australia, those of southern California, and the southern states of America, especially Florida, are frequently subjected to losses through the ravages of the orange scale insect, and much attention has been devoted by the central Department of Agriculture in the way of experiments having for their object the finding of an effective remedy for the plague. The latest experiments that have taken place in Florida form the subject of a report submitted to the Commissioner of Agriculture at Washington. Mr. Geo. B. Loring, who forwards us a copy, and from it we gather that the greatest amount of success has been obtained by the use of emulsions composed of 67 per cent. of kerosene and 33 per cent. of soap and water. The experiments with kerosene emulsions have proved that various soaps can be readily made to combine with the oil, and that the soap and kerosene emulsions are as effective as those formed with milk. The use of soap materially reduces the cost, except where milk is abundant as cheap, as is very seldom the case in Florida. Common bar soap, soft soap, and whale oil soap have been tried and found to be almost equally good. Whale oil soap, when of good quality, is preferred, as it is stronger, and adds to the insecticidal properties of the emulsion. The following formula is one which has proved in practice useful where a moderate quantity of emulsion is required, and is said to give a wash of sufficient strength to kill the eggs of the scale insects commonly found in Florida; kerosene

2 gallons; common soap or whale oil soap, $\frac{1}{2}$ lb.; water, 1 gallon. "Heat the solution of soap," the directions state, "and add it boiling hot to the kerosene. Churn the mixture by means of a force pump and spray nozzle for five or ten minutes. The emulsion, if perfect, forms a cream, which thickens on cooling, and should adhere without oiliness to the surface of glass. Dilute, before using, one part of the emulsion with nine parts of cold water. The above formula gives 30 gallons of emulsion and makes when diluted, thirty (30) gallons of wash. The percentage of oil can be increased considerably without danger to the plant, and a stronger emulsion, may, in fact, be required in coping with some of the *Aspidiotus* scales, but the amount of kerosene in the emulsion cannot be greatly reduced without weakening too much its power as an insecticide. The amount of soap may also be varied, but less than $\frac{1}{2}$ lb. to the gallon of water forms an unstable emulsion."

The distrust of kerosene felt at the outset, it is stated has now given place to confidence, and the emulsions are now widely used by orange growers in eastern Florida. Want of thoroughness in applying the wash, however, is found to render repeated applications necessary. The invention and introduction of what is called the cyclone nozzle by the Department of Agriculture greatly diminishes the labour of applying the liquid to orange trees and insures success with ordinary care and attention, at the same time reducing to a minimum the amount of liquid required and the expense of an application, and there is no report of any case of loss or permanent injury resulting from the use of kerosene emulsions, although the reckless use of emulsions imperfectly formed, or of unnecessary strength, it is noted, may be expected to cause defoliation and a temporary shock of greater or less severity. It is indeed the opinion of a majority of the Florida growers that in kerosene properly emulsified and diluted they have a nearly perfect remedy, more effective than any other insecticide in destroying scale insects and having as slight an effect upon the plant as can probably be expected from any remedy with sufficient penetrating power to reach and kill the eggs of these insects.

In regard to the physiological action of kerosene upon the orange, careful observations are reported as having been made during the year, and the following conclusions arrived at:—1st. That kerosene differs from most other remedial agents in being entirely harmless to tender young growth, blossom buds, and young fruit. It may, therefore be applied to bearing trees at seasons when other insecticides would cause more or less loss of growth or of fruit. 2nd. That the shock produced by an overdose is felt more severely upon devitalized portions of the plant, and is not appreciable where there is full vigor. This shock is quickly followed by a healthful reaction, and is not ordinarily attended with any serious consequences, such as hardening of the bark. 3rd. That extremes of heat and cold increase, sometimes to an injurious extent, its action upon the plant. Applications made in the hot sun, during the middle of the day, are observed to cause a greater amount of defoliation than would result from the same application made at evening or in the shade. In winter, when the air is charged with moisture and the nights are cold, with frost or heavy dews, it is found that the oil does not evaporate as rapidly as in warm or dry weather. Applications made under such atmospheric conditions sometimes prove unexpectedly severe and cause the tree to shed all its leaves or even kill a portion of its branches. The most favorable season for applying kerosene washes is agreed upon as being early in spring or as soon as all danger of frost is past. The shedding of the last year's leaves, which takes place naturally after the orange tree has renewed its foliage in spring, is often accelerated by the action of the oil, which is thus made to appear very severe, but the loss of old and devitalized leaves is regarded of slight consequence, and in the case of badly infested trees is a positive advantage, as the leaves in falling carry with them the scales most difficult to reach with insecticides.

In dealing with an enemy so thoroughly protected as are many of the bark lice, the liquid insecticides, it is recommended, should be applied in as fine a spray as possible, or at least in moderately fine spray, driven with considerable force in order to increase to the utmost

their penetrating power. The aim should also be to reach and thoroughly wet every portion of an infested tree, so that no individual scale insect shall escape the action of the liquid. This result was not found attainable by the old method of sending a jet from a distance into the tops of the trees, and an ordinary garden syringe is practically useless. There is needed a force pump and a nozzle giving a finely atomised spray. This nozzle, it is noted, should be attached to a sufficient length of flexible hose, to allow it to be introduced into the top of the tree. The orifice of the nozzle, it is explained, should be directed at a right angle to the hose, and not in line with it, so that the jet of spray may thus by a turn of the wrist be directed upward or downward, and brought into contact with all parts of the foliage and branches, from beneath as well as from the upper side.

The Cyclone nozzle, which answers the above conditions and is easily attached to any force pump, is described as consisting of a "shallow, circular, metal chamber soldered to a short piece of metal tubing as an inlet. The inlet passage penetrates the wall of the chamber tangentially, admitting the fluid eccentrically, and causing it to rotate rapidly in the chamber. The outlet consists of a very small hole drilled in the exact centre of one face of the chamber. The orifice should not be larger than will admit the shaft of an ordinary pin. Through this outlet the fluid is driven perpendicularly to the plane of rotation in the chamber. Its whirling motion disperses it broadly from the orifice, and produces a very fine spray, which may be converted into a cloud of mist by increasing the pressure in the pump. The perforated face of the nozzle chamber is removable for convenience in clearing the orifice when it clogs. The diameter of the chamber inside need not exceed $\frac{3}{4}$ inch, and its depth $\frac{1}{4}$ inch. A nozzle of these dimensions attached to an Aquapump covers $1\frac{1}{2}$ square yards of surface at a distance of 4 or 5 feet from the orifice. The amount of dispersion depends somewhat upon the thickness of the perforated face of chamber. The diameter of the cone of spray may be increased by countersinking the exit hole and making its edges thin. Half inch gum tubing is sufficiently large to supply one or a gang of several nozzles. The tubing must be strengthened with one ply of cloth." In use, the end of the hose is supported by being fastened to a light rod of wood, which forms a handle, by means of which the nozzle may be applied to all parts of the tree. For full sized trees a rod long enough to reach nearly to their tops must be used. For this purpose, a convenient device, it is explained, may be made by passing the small rubber hose through a hollow bamboo rod of the required length, and a three-sixteenth brass tube inserted in a bamboo rod has also been used.

The following is the estimated cost for a standard wash^h of whale oil soap and kerosene emulsion containing 67 per cent. of oil, and diluted 1 to 9: Kerosene, 2 gallons, retail at 20 cents, 40 cents; soap, $\frac{1}{2}$ lb., retail at 10 cents, 5 cents; water, 1 gallon; emulsion, 3 gallons: total cost, 45 cents, or 15 cents per gallon. One gallon of emulsion will make 10 gallons of diluted wash; cost 15 cents. Cost of wash per gallon, $1\frac{1}{2}$ cents. With the Aquapump and Cyclone nozzle, 4 gallons of wash is sufficient for thirty nursery trees of one and two years from the bud. Cost per tree, two-tenths cent. Trees which have been transplanted and have made two years' average growth in the grove (three or four years from the bud), it is stated, require about two-thirds of a gallon of wash, Cost, 1 cent per tree. Bearing trees of full size will require from 5 to 10 gallons of wash. Cost, 7 to 15 cents average about 10 cents per tree.—Melbourne Leader.

CRANBERRIES.—Although much of this fruit is imported into this country, notably from America, its culture might be profitably undertaken in naturally suitable places at home. Much swampy land still exists that might be turned to such a use. Where the soil is naturally damp and rests on a bed of porous material and there is free circulation of air, the American Cranberry (*Oxycoccus macrocarpa*) grows quite luxuriantly.—Gardener's Chronicle.

TRIMEN'S CATALOGUE OF CEYLON PLANTS.*

(Communicated.)

If brevity be the soul of wit and the expression be akin to "*multum in parvo*," seldom could either be more appropriately quoted than on the present occasion respecting this Catalogue of Ceylon Plants. The well-known apology of a Frenchman to a correspondent for the length of his epistle on the ground that he had no time to write a shorter, can scarcely be quoted by Dr. Trimen in respect to the matter contained in this list of Ceylon plants; but, on the other hand, it is difficult to calculate what portion of Dr. Trimen's fully occupied time has been devoted to the preparation of this catalogue, and the boiling down of the scattered and heterogeneous mass of matter from which he has had to compile it during his short residence amongst us. To be able to do this correctly implies a peculiar training and practical knowledge of botanical literature, but when the careful examination of several thousand specimens of dried and living plants has to be added to Dr. Trimen's labours, the value of this list can be fully appreciated by brother-botanists interested in the plants growing in Ceylon. But to non-botanists truly the list is strongly recommended on the ground that a more full and correct list of the botanical, Sinhalese and Tamil names of our Ceylon plants has not before been made in accordance with the recognized and proper arrangement of the several families of plants. Dr. Trimen's list forms a complete index to Thwaites's "*Enumeratio Plantarum Zeylanica*"; but in the sequence of the families or natural orders it differs very materially from Thwaites's work. Dr. Trimen's list is really a catalogue of the botanical names of the plants of Ceylon generally derived from Latin and occasionally Greek terms; and it may be safely stated that nearly all the English names of plants in this list of some 3,000 to 4,000 individuals can be counted on the fingers of one's hands.

To save ladies and others from making dry faces by attempting to commit to memory and pronounce the Latino-Greek names of plants, would-be popular writers have attempted to give them fictitious English names in every case, but in this respect the ever courteous Director of the Royal Botanic Gardens, Peradeniya, always so ready to impart useful and popular information on plants to every one visiting the classical gardens of Peradeniya or applying to him for information, thus disposes of the English names of Ceylon plants:—"English names have been added to the few plants which have acquired them," thus clearly trampling under foot the admitted fact by all nations, including Russia, "that we (English) are the people, and that wisdom will die with us!" But to make up for this fact Dr. Trimen has given more than his titlepage indicates, for in addition to the "flowering plants and ferns" he has added five natural orders, viz., Rhizocarpacee, Lycopodiacee, Isoetee, Selaginellacee, and Characee, not bargained for.

The catalogue consists of two pages of an "Explanatory Note" (which is quoted after this notice) and 137 pages of the list of plants divided as follows:—pp. 1 to 86 include DICOTYLEDONS; pp. 86 to 110 MONOCOTYLEDONS; and pp. 111 to 119 VASCULAR CRYPTOGAMS; whilst pp. 121 to 137 are occupied with the indices of the botanical names of the

natural orders and genera, and the Sinhalese and Tamil names of the plants.

The catalogue includes 156 natural orders, 1,071 genera, and 3,249 regular species, with 408 varieties, some of which may prove to be distinct species. The catalogue is issued as a number of the "*Journal of the Ceylon Branch of the Royal Asiatic Society for 1885*," and has been printed by Mr. George J. A. Skeen, Government Printer, Ceylon, to whom the author and the members of the Asiatic Society owe a debt of gratitude for the neat and careful way in which the book has been issued. It may be safely stated that this catalogue of the plants of Ceylon by Dr. Trimen is the most valuable work ever contributed to the Society in strict accordance with its objects in connection with the several branches of the natural history of Ceylon forming its programme.

The following specimens of the catalogue are given: On page 36 and under Natural Order 54, "*LYTHRACEE*; genus 309 *Lagerstromia Flos-reginae*, Retz. 122. *Murata*, S. *Kadalipava*, T.," and on page 55, under Natural Order "85, *ASCLEPIADEE* and Genus 486, *Hemidesmus indicus*, BROWN. 195. *Iranusol*, S. *Nannari*, T. *Indian Sarsaparilla*," which means that these plants are to be found on pages 122 and 195 respectively of Thwaites's *Enum. Plant. Zeyl.*, and that the letters S. and T. stand for Sinhalese and Tamil. All the members of the Ceylon Branch of the Royal Asiatic Society will be entitled to a free copy of this valuable catalogue, and there need be no hesitation in recommending it to all others interested in the Botany of Ceylon. W. F.

Of the scientific value of the list, there can be no question, but we (Ed.) trust it will be speedily followed by the long-promised, long-looked-for popular work on the Botany of Ceylon.—Dr. Trimen's Explanatory Note is as follows:—

EXPLANATORY NOTE.

The *Natural Orders* and the *Genera* in this Catalogue are each numbered consecutively throughout, the sequence followed being that of the "*Genera Plantarum*" by Bentham and Hooker. The *Species* are generally named in accordance with the "*Flora of British India*," so far as that work has yet been published (to end of Genus 594, p. 67).

Names of species or varieties printed in SMALL CAPITALS are believed to be *endemic* (i.e., found in Ceylon only, or peculiar to the Island).

Names with an asterisk (*) prefixed are exotic species which have become more or less *naturalized*, usually as weeds in cultivated or wasteland. Many are thoroughly established and very common; others merely casual and rarely found. A dagger (†) prefixed to a name indicates a suspicion of exotic origin or a doubt as to true nativity.

Names enclosed in round brackets () are exotic species which, being largely *cultivated* for use or ornament, are often found apparently wild, but are not really naturalized here.

A query (?) prefixed to a name indicates doubt as to the occurrence of the plant in Ceylon; placed *after* a name it means doubt as to the correctness of the determination.

Names enclosed in square brackets [] are species which have been recorded for Ceylon, but the occurrence of which is a matter of grave doubt or requires verification. Most of them are, in all probability, *errors*; but as they are given in books of more or less authority, it is thought well to include them, thus clearly distinguished from the others.

The additional names (synonyms) in *Italics* are those of Thwaites's "*Enumeratio Plantarum Zeylanica*," (1858-64) when different from the ones here adopted. The numbers following the names refer to the pages of the same book, to which this Catalogue forms a complete classified index.

In the case of a few species of which I have not seen Ceylon specimens—and for the most part not included in

* A Systematic Catalogue of the Flowering Plants and Ferns Indigenous to or Growing in Ceylon. With the Vernacular Names, and with References to Thwaites's *Enumeratio*. Compiled by Henry Trimen, M.B., F.L.S., Director of the Royal Botanic Gardens, Ceylon, 1885.

the "Enumeratio"—I have quoted the names of the collector given by the author recording the species as Ceylonese, thus ("Walker"). Most of them, it will be seen, were collected by Col. or Mrs. Walker (in 1830-40), and many, it seems, have not been again found.

"C. P." refers to the distributed sets of dried specimens of *Ceylon Plants*. The numbers given here are the whole of those subsequent to the ones quoted in the "Enumeratio," which terminated with C. P. 3860. A few of the earlier numbers however are occasionally quoted in this Catalogue; when necessary to secure precision in nomenclature.

New Species.—There are a few MS. names here printed for the first time. It is my intention to publish descriptions of these supposed new species in the "Journal of Botany" (London) without delay.

Vernacular Names.—The letters "S." and "T." after these signify *Sinhalese* and *Tamil* respectively. With regard to the former, it is believed that a fair amount of accuracy has been attained, and that the spelling is in accordance with the rules for transliteration prescribed by the Ceylon Government. In the case of the Tamil names, however, it is to be feared that but a small number of those in use in the North and East of the Colony have been obtained, and that these are not always rightly determined or properly transliterated. But it may be hoped that the publication of this list will serve as a basis for a more systematic and accurate collection.

English names have been added to the few plants which have acquired them. H. T.

Peradeniya, February, 1885.

We may add to this an extract from the *Journal of Botany* for May 1885, which contains among other contents, the following paper:—

NOTES ON THE FLORA OF CEYLON.

BY HENRY TRIMEN, M.B., F.L.S.

The last part of the late Dr. Thwaites' 'Enumeratio Plant. Zeylanicæ' was published in 1864, and, besides completing the systematic enumeration of the plants of Ceylon to the end of the Vascular Cryptogams, contained two appendices (extending to 43 pages) of Addenda and Corrigenda, thus bringing the earlier portions of the book (which began to appear in 1858) up to the date of its conclusion.

The numbered series of *exsiccati*, well known as "C. P.," had been previously made up and widely distributed by Thwaites; their numbers are systematically quoted throughout the book, and are, in the supplements above mentioned, carried on up to C. P. 3860 inclusive.

After the completion of the 'Enumeratio' the C. P. numeration was still kept on, as new species or varieties were detected in the Island, or as further research showed the necessity of breaking up some of the previously recorded ones into two. In this way 164 additional C. P. numbers were given, and the series was extended from C. P. 3861 to 4024, which number is absolutely the last.

Many of these additional numbers have been sent out from Peradeniya to the public herbaria of Europe and Asia and to private collections, and not a few have been quoted by authors of recent monographs and descriptive treatises. It will therefore, I believe, be of use to give a list of them with their determinations, as represented in the Peradeniya herbarium, which in any case of doubt must be considered as the type series.

I may note that very nearly all these additional numbers refer to plants collected between 1864 and 1869. After this latter year Dr. Thwaites turned his attention, so far as Botany is concerned, almost exclusively to the Lower Cryptogams, and although his collectors brought in a few additional Flowering Plants, only two or three C. P. numbers refer to any year after 1879.

In the following determinations I have been often assisted by the staff of the herbariums at Kew and at the Natural History (British) Museum and have especially to thank Mr. Hensley of the former establishment, and Mr. H. N. Ridley of the latter, for their prompt attention to my enquiries.

[Then follows Botanical list.—Ed.]

In addition to the plants in the above list, a considerable number of species has been recorded from Ceylon in various systematic treatises (and especially in the 'Flora of British India,' now in course of publication), which were

not included in the 'Enumeratio.' Of these most were collected by Col. and Mrs. Walker, in the years 1830-1840, entirely in the south-western and southern parts of the Island, and have not been met with by subsequent collectors. Some of their gatherings were garden plants however. Another collector was MacRae, who had charge of Peradeniya Gardens from 1827 to 1830; many of the plants sent home by him as natives of Ceylon were evidently gathered in the gardens, and are nowhere wild in the colony; whilst others are from N. W. India, where he also collected for the Horticultural Society. Some of Gardner's plants, collected by him in company with Wight in the Nilgiris in 1845, have also been erroneously given for Ceylon; and altogether there is a rather large number of names to be deleted in the list of recorded Ceylonese plants. A corrected and revised catalogue of the whole flora is now being printed at Colombo for the Asiatic Society's (Ceylon Branch) 'Proceedings,' in which I have taken care to distinguish all doubtful natives and erroneous records.

During the five years I have been in Ceylon, a good many species (chiefly Indian) have been detected, especially in the less-known portions of the Island, which have not, so far as I know, been previously recorded. The greater part of these have been met with in my own excursions through the country, but many have been detected by my friend Mr. W. Ferguson, F.L.S., of Colombo, an excellent field botanist, who during the long residence of 45 years in the Colony has lost no opportunity of acquiring and adding to his extensive acquaintance with its vegetation. Mr. H. Nevill, of the Ceylon Civil Service, has also availed himself of his residence and travels in unfrequented districts to collect rare plants, and has thus added several species to our flora.

The following is a list with notes of these additions. The few new or undescribed species it contains, as well as those mentioned under Ms. names in the above list, and a few others, will be described at the end of this paper.

[The list referred to must be very interesting to Botanists, and we see it is "to be continued"—Ed.]

DIMBULA PLANTERS' ASSOCIATION : TEA SUB-COMMITTEE REPORT.

It is with some diffidence that the Sub-Committee have undertaken to draw out this report, feeling, as they do, that they have not sufficient experience of the subject. Owing to the courtesy however of some of the most experienced tea planters in the country, amongst whom are Messrs. A. E. Soovell, W. Forsythe, T. Gray, C. E. Weldon and C. S. Armstrong, who have kindly given their opinions on questions submitted to them, the Sub-Committee venture to issue their report to the district, confident that the information contained in it, will be useful and as reliable as can be at present obtained.

The first part of the report has been compiled from the answers given by residents in the district to questions A, treating chiefly of seed, nurseries and planting, branches of the subject in which members of the Association have had some experience. The second part has been drawn up from the answers given by the experienced tea planters outside the district to questions B.

Part I.—NURSERIES.

In answer to question I the majority are decidedly in favour of a high-class Assam hybrid, as most suitable to the district, while some are in favour of local seed when a good jāt is obtainable, others Indian. The plan of packing recommended by most is in charcoal (though some have found burnt clay or earth answer) with layers of paper between each layer of seed.

Dry sand in lead-lined cases has also done well. With regard to germinating the seed before sowing it, 9 are against doing so and 5 in favour of germinating by different methods. By most 4 feet wide beds are recommended, dug from 8" to 12" deep, the seed being sown 3" apart and 1½" to 2" below

the surface. With regard to shading for the beds 5 recommended ferns, 5 mana grass, 3 jungle shading, dan 1 dried pulp.

PLANTING.

In 7 papers 4×4 is considered the best distance apart to plant in a new clearing, 3 considered 4×3 best, and 3 say 5×3 or 4. So in coffee, 9 recommend 4×4 . Four by four is therefore the most popular distance to plant in Dimbula. Heligi is considered by nearly all as the best means of preparing to ground. Some consider forking to answer in free or cultivated land. Plants, except in one case, are universally prepared to stake planting for old land. In 2 cases only is germinated seed at stake preferred to plants, for new clearings. There appears to be no doubt that the early part of the south-west monsoon is the best season for planting in, and plants from 8 to 10 inches high are most popular. Most are in favour of cutting the thin end of the taproot before planting, though some would not do so unless the roots are long.

In only one case are cuttings favourably reported on.

TOPPING.

The majority are in favour of topping at from 15 to 18 inches at 18 months old, and of plucking 8 inches above the topping-level, though nearly as many say 6 inches. Six have found grub attack their nurseries, while 4 have not. The majority have not found this pest injure the plants in the field.

Part 2.—JAT, &c.

Beginning with the all-important question of jat, the experienced tea planters who have been good enough to give us their opinion are almost all in favour of a high-class hybrid, closely approaching indigenous, i.e., either one or two removes from indigenous, for elevations up to 3,000 and 4,000 feet. The majority (amongst whom are Messrs. Scovell and Armstrong) recommend a medium hybrid, for yield from 4,000 to 6,000 feet.

For strength, a high-class hybrid is universally considered the best.

As to distances, at which tea should be planted, $3 \times 3\frac{1}{2}$ or 4 is said to be the best for steep land, while $4 \times 3\frac{1}{2}$ or 4 is the best for flat land and high elevation, 4×3 or 4 being recommended generally for low elevations.

The majority recommend 15" as the height to top, some saying "when the plant has reached 4' to 5 feet high," and some, "when it is a year old." Mr. Armstrong says "when the greatest diameter is at 18 inches in red wood." He also recommends that single stem plants should be stumped to 9 inches before this.

Nearly all say the first pluckings should be done with a stick 5 to 6 inches above the topping level, provided that $2\frac{1}{2}$ leaves are left on the shoot above topping level.

With regard to pruning most recommend the S. W. monsoon, that is from June to August, as the best season, though a few say October and November, and some say all the year round chiefly on account of their labour force. Digging young tea is generally approved of, especially when the prunings can be buried. By some it is thought unnecessary (especially in free soil) until the bushes are 4 years old. Pruning the sides of young bushes below the topping level is not approved of. Some recommend plucking below that level for the last two months before pruning.

G. A. TALBOT; J. A. CAMPBELL; W. B. JACKSON; JOHN CLARK; THOMAS MACKIE; JNO. MARTIN; G. H. D. ELPHINSTONE; W. SANDYS THOMAS; WM. CAMERON; GEO. BECK,

Questions A.

I.—What class of plant do you consider most suitable for Dimbula? and give your reasons.

II.—Do you prefer local-grown seed or Indian? Give reasons.

III.—With regard to imported seed, what method of packing has answered best with you?

IV.—Do you prefer to germinate your seed before sowing it, to putting straight out? If the former, what mode of germinating do you find answer best?

V.—Give your ideas as to the best style of nursery.

VI.—If you shade your nurseries, what mode of covering do you consider best?

PLANTING.

VII.—What do you consider the best distance for planting tea?

(a) In the new clearing. (b) In the new coffee.

VIII.—Which of the many methods now in vogue do you consider best for preparing the ground for planting, hoeing, forking, alavanga planting, &c.? and give particulars.

IX.—Do you prefer planting at stake germinated or ungerminated seed or plants?

X.—What sized plant do you prefer? and what do you consider the best season of the year for planting?

XI.—Do you consider it advantageous or the reverse to cut the taproot before planting out?

XII.—Have you tried cuttings? and with what result?

TOPPING.

XIII.—Do you prefer to top by cutting down, and if so at what age and to what height from the ground? Or do you prefer to form your bush by plucking? and if so at what height?

XIV.—What growth do you give to your bushes after topping before you commence plucking?

XV.—Have you found your tea plants eaten by grub?

(a) In the nurseries. (b) In the field.

Questions B.

1.—What do you consider the best jat of tea (a) for yield and (b) for strength at the following elevations:—2,000 feet; 3,000 feet; 4,000 feet; 6,000?

2.—What do you consider the best distance to plant at the above elevations?

(a) In steep land. (b) In flat land.

3.—At what height and age do you consider it best to top?

4.—Does, in your opinion, delaying the topping benefit the bush eventually?

5.—Should the first pluckings be done with a measuring stick? and, if so, at what height above the topping.

6.—What season or seasons do you consider best for pruning (at the above elevations), having regard to exposure?

7.—Do you consider it advantageous to dig young tea? If so, at what age and season?

8.—Do you consider it advisable to pluck the sides of young bushes? If so, at what period after topping?

MINING OPERATIONS in China do not seem to have been much affected by an unsettled condition of affairs in that country, for we learn that during the recent Franco-Chinese war, the opening of the Tamechow silver mines in Kwangtung went on uninterrupted. The mines are under English management, and the results obtained are very satisfactory. Altogether, there would seem to be a bright future for the last outcome of Anglo-Chinese enterprise.—*Indian Agriculturist*.

"THE NEW TEA No. 3 Sirocco," writes an up-country correspondent, "has been much improved by Mr. Bentley. He has shortened the height of the horizontal arm about a foot, thus bringing it practically nearer the fire, and with an alteration in the plates, has vastly improved the machine in every respect. To prevent the spilling complained of in a large hopper should be constructed into which the cooles can shake the trays, so that not one pound of tea is lost. With these improvements, to my mind, the No. 3 Sirocco is quite equal to any other drier.—*Local Times*."

COFFEE LEAF DISEASE.

The *Tropical Agriculturist* accuses us of sneering at Ceylon Planters, because we wrote:—"There is one thing should strike Planters, that is, if the trees on a Coffee Estate have once yielded good crops, why they should not do it again. The climate has not changed; the tree demands nourishment which it does not get; the result is, short crops and disease." Now, we never sneered at Ceylon Planters, but we certainly pointed out that their trees have never been properly manured, nor have they been in Wyeinal. The writer goes on to say:—"that a fair degree of success rewarded their efforts (?) as well as those of Southern India, until the calamitous advent of the debilitating leaf disease. Even after its appearance manures were liberally applied until many planters found that they were merely feeding the fungus." We know that liberal manuring means about one bullock an acre, we have hardly heard of one case of scientific manuring, and not one of draining. We think, that if a really good case could be produced of the above remedies having been carried out and failed to afford relief, then would owners of coffee plantations have been justified in abandoning coffee and taking to tea; but until we know of a really well authenticated case, we must adhere to our original opinion. With borer it was different; estates went out because they were too dry; fungus has laid hold of coffee because the ground is too damp, and it is easier to remedy that, than where it is too dry. We have seen how Cinchonas in Ceylon have to be cut out when their roots get down into the damp impervious subsoil, and we have a shrewd suspicion, that undrained damp subsoil in Ceylon, has a good deal to do with leaf disease. We have not heard of draining having been resorted to for Cinchonas any more than for leaf disease, and yet, very probably, it will be found a cure for both Cinchonas and Coffee. [The above is from the Nilgiri *Planters' Review*. We have simply to repeat that never in the world's history were more scientific culture, careful and thorough manuring applied to coffee and cinchonas more than in Ceylon. But leaf-disease proved fatal to the highest cultivated estates, as much as to those left uncared for. Let the writer in this *Review* practically establish his theories and then blame planters if they do not follow his example.—Ed.]

MADRAS: THE ORGANIZATION OF A BOTANICAL DEPARTMENT.

We recently referred in our columns to the creation of a new appointment—a Mineralogist to the Madras Government, for which Mr. Bosworth Smith was selected. We now learn that the local Government have in view the organization of a Botanical Department for this Presidency—a measure which will, it is thought, besides subserving the interests of science, be of great and immediate practical utility, while it can, in present circumstances, be carried into effect at a very small cost to Provincial Funds, and to which it is hoped the sanction of the Government of India and of Her Majesty's Secretary of State will be readily accorded. With this object in view, the local Government invited Professor Thibouton Dyer, c.s., of Kew Gardens, to offer, in consultation with Professor Sir Joseph Hooker, another eminent Botanist, suggestions with regard to the constitution of the department. This he has done, and the Government have much to be indebted to that gentleman for the valuable opinions he has given on the question. There is in all India only one Botanical institution which, though technically provincial, must, at any rate, in external estimation, from its size—it has nearly attained its centenary—from its scientific traditions, and from the splendour of its maintenance, rank as imperial. Whatever be now or in the future the exact official status of the Royal Botanical Gardens at Calcutta, it must always be regarded as standing at the head of the Botanical institution of the Empire. India, however, possesses only one such Botanical institution of a second order, and that is the gardens at Saharunpore; but from its vast size and resources India needs more than one such localized institution. Not that its want has not been felt, but that

it has been provided for, at the best, imperfectly and in a tentative and uncoordinated manner. What has been done seems to have produced only moderately useful results, with undoubtedly much expenditure. Thus India owes in great part to the Calcutta Botanic Gardens, its great Cinchona enterprise, and to Saharunpore the practical inception of tea cultivation, though the initiatory stages must be credited to the Calcutta Botanists.

There is nothing precisely and collectively answering to a Botanical Department fulfilling the functions required of it in this Presidency. There is, however, the Agri-Horticultural Society's Garden, which, though subsidized by the Government, is not under its control. Founded in 1835, its establishment and early management owed every thing to its first Secretary, Dr. Wight. It has not been barren of results. To its experiments in 1840 may be attributed the introduction of coffee cultivation; and it has in no small measure encouraged the cultivation of European vegetables and indigenous and naturalized fruits. But it is much to be regretted that in more recent years the more scientific aspects of the garden seem to have been sacrificed with little consideration. That a really scientific Botanical Department, on the basis of the one at Calcutta, was needed, has long been apparent at Kew, from the numerous communications, both public and private, relating to the practical as well as the scientific side of botanical business. The materials for such a department are, however, all to hand, and a little organization would practically effect all that is needed. There is Mr. Lawson, late Professor of Botany in the University of Oxford, now in charge of the Government Cinchona Plantation, Parks and Gardens, Nilgiris; as regards the head of the proposed department a very slight extension of his duties is all that is required. He now draws £600 per mensem, and it is proposed to raise it to Rs80 per mensem rising to £1,000 in five years. He is serving at present under no definite conditions, and the Government consider that his service from the commencement should be declared to count for leave and pension, and that he should be admitted to the more favourable leave rules. Application will be made in the Financial Department for sanction to these proposals.

The situation is not complicated by the existence of any Government Botanical Garden at Madras. The existing Government garden at Ootacamund seems in every way the proper seat of the Botanical Department. Its remoteness from the capital may be objectionable, but the planting industries of Southern India gravitate to its Western side, and the Botanical head-quarters should be in the nearest feasible proximity to them. The detailed administration of the Botanical gardens will require a Curator, subordinate to the Director. Mr. Lawson has the advantage of the cordial co-operation of Mr. Jamieson, who has long efficiently filled this position.

In order to extract the maximum of usefulness from a tropical Botanical Department, it is found necessary that it should comprise a chair of gardens at different elevations, as in Ceylon and Jamaica. Ootacamund, therefore, will require to be supplemented by an Intermediata Garden and a tropical garden. Besides, the department will require the maintenance of a well-arranged Herbarium, a Museum wherein a collection of wood, fruits, seeds and other vegetable products of economic interest might be stored, a small but carefully selected library, and all other paraphernalia of an Administrative Department. Under the new arrangement Mr. Lawson will retain charge of the Cinchona plantation and the superintendence of the Botanical Garden and Parks on the Nilgiris, as at present. His official designation will be "Government Botanist and Director of Cinchona Plantation." On receipt of sanction orders will issue on the minor points of organization.—*Madras Standard*.

[While the step proposed is, no doubt, in the right direction, let us not forget that the Government of Madras and Mr. Thibouton Dyer have both recently borne high and well merited testimony to the excellent work done during its fifty years' existence by the Madras Agri-Horticultural Society. Government gave a sum of £1,000 which has been used to add to an already rich botanical library.—Ed.]

HIDE-BOUND PLANTS AND TREES.

An experienced eye will soon detect a hide-bound plant from its weakly growth and sickly appearance; but it is amongst hard-wooded subjects that we must look chiefly for this condition. Plants in pots, such as cypripis, pineleas, acacias, chorozemas, and subjects of that class, are too often found to be hide-bound, and an experienced grower will avoid purchasing them when it is possible. Of one thing they may be certain, viz., that if they get held of hide-bound plants, the most skilful treatment will not convert them afterward into satisfactory specimens. Only those who have watched the behaviour of hide-bound plants can realize the disappointment attending their culture. The hard dry bark seems to encircle them like a band of iron, and as the roots have been so long crippled from want of food and space, it is a long time before they regain sufficient activity to burst through the bonds of inaction to which they have been subjected.

How many cases of failure those who are much engaged in planting forest trees meet with, it may perhaps be difficult to tell; but we may be sure they are not a few, especially in the case of those who buy in the cheapest market, without any guarantee as to quality. However that may be, the selection of trees for forest planting is one in which good judgment is necessary; and only those who are practically acquainted with the characters that constitute a young and healthy tree should be engaged in the business. When young trees make growth after the first year of planting in nursery quarters of only a few inches in length, it may be safely concluded that the soil is either too poor or badly drained. Either of these conditions will produce hide-bound trees, and it will take several years of patient cultivation in a good soil to restore them to health. It does not follow that a hide-bound tree is diseased; for that matter, the tree may be perfectly healthy; but early crippling engenders a sort of inherent weakness that only time and a total change from a poor soil to a rich one will restore. I have good reasons for remembering a case that has a direct bearing on the subject under notice; it occurred when I was a junior in a large garden. An order came one morning that all hands were to assist at once in planting several thousand young larches. We had proceeded with the work for several hours before the manager came to inspect the trees. On his arrival he instantly gave the order to stop planting. It appeared he had not seen the trees before then and had no idea as to their condition. However, he at once condemned them as hide-bound, and therefore would not plant another tree of the number then on hand, but had them returned to the person who had supplied them. In a few days another lot of trees arrived, and so great was the difference between the two samples that, even as a young hand, the case made an impression on me. I saw at once the difference between a hide-bound tree and one that had been liberally grown. The longest leaders on the former did not exceed seven inches, while those on the latter had reached twelve inches and sixteen inches in length, with proportionate side shoots. The side shoots on the stunted trees were mere sprays, and a grey kind of lichen had extended a good way over the stems; the colour of the growth, too, was a dull, rusty brown; while the colour of the stem, and especially the young growth on the properly grown trees, was bright, and free from all kinds of parasitic growth. The difference of behaviour in the two lots of trees was equally marked for several years afterwards. As a matter of fact, the hide-bound ones never overtook those that were healthy. This was my first experience with hide-bound trees; but I have dealt with many cases since, though of less magnitude, and the result has always been the same. If the subjects whatever they were, regained a vigorous state of growth it was at the expense of much patience, coupled with a direct loss of time.

In the case of fruit trees, especially plums and pears, examples of hide-bound trees frequently occur, particularly if sorts are wanted for sale in a regular demand, and growers for sale must necessarily keep a large number of varieties of all kinds in stock,

Those for which there is a constant demand are regularly renewed; but in the case of less popular varieties they do not receive the same attention. Plants are repeatedly cut back to keep them within salable dimensions; the consequence is they exhaust the soil in which they are growing; and, what with hard cutting back and poor soil, the plants become weakened. But this is not the only cause of hide-bound plants. The worst cases come off naturally poor ground—land that will take four years to produce a tree of a salable size; while in properly manured ground only two years should be occupied.

Regarding conifers the fact that the plants are hide-bound when received causes more disappointment than is attributed to that cause. I do not wish to imply in regard to these trees that they are all hide-bound, but I do say that in cases of unsatisfactory growth the blame is often laid upon indifferent planting or unsuitable soil, when they have nothing to do with it, and that the real cause is in the condition of the tree at the time of planting; yet there is no class of plants that sooner reveal that condition to a practised eye. When the plants have leaders only three or four inches long, and the side branches show still less vigour, with lichen in various stages of growth establishing itself upon the stem it is quite safe to conclude that such examples have been stunted in growth; and that although under changed and favourable conditions they may ultimately recover, their behaviour for the first four or five years after planting will not be satisfactory to persons under the impression that the specimens at planting time were suitable for the purpose. I have no hesitation in saying that purchasers of conifers exceed prudent bounds when they insist on securing plants that have been frequently removed while in nursery quarters. To the frequent transplanting of young trees there is a limit, exceeding which is advantageous neither to the seller nor to the purchaser. Frequent removal means a check to all the functions of the plant, and, if repeated so often as to cause a serious loss of vigour (which it certainly does under such circumstance), all the energies of the plant get enfeebled—it is hide-bound, in fact—and, therefore, not in a condition to give satisfaction to anyone.—J. C. C., *Field*.

THE VINE IN INDIA.

It is a singular fact that in an Empire once famous for its wine there is not a drop to be had today for love or money. The grape, although it grows luxuriantly in various parts of Hindostan, has no association whatever with the bottle; for one reason, perhaps, because wine from the palm, *Indice*, "toddy," is so much the more easily made of the two. Bait is not always so. Tavernier, Captain Hamilton, and other early travellers in India speak of native wines, and of one especially of such potency that it floored the Great Mogul himself. And another emperor—Baber—tells us in his memoirs how he used to drink freely in his younger days of the wine of Lud, and commit mad pranks thereafter, such as practical jokes—on horseback—with his boon companions. These monarchs doubtless were of the Chiuaman's taste, who made "drinkee for drunkee, rot for dry," but at all events the generous juice of the grape was there, however much the potentates in question thought fit to abuse it. Where the wine was made it is difficult to say now. Baber's wine perhaps came from Cabul, where wine is still found, but where did Aurungzebe get his? Possibly in the Deccan, where grapes grow magnificently; one town—Aurangabad—being famous for its eating grapes to this day. Later still we find the early English merchants of Calcutta drinking Shiraz wine, but this must have been an importation from Persia. The wine of Shiraz is also praised by Hafiz the poet, and it must have been fairly good tittle, to judge from the postprandial gambols of old Job Charuock and the men with the pigtails and nankeen small cloths. In *Hickey's Gazette* we read how these old Anglo-Indian worthies drank the toast of the day—probably some native belle—in bumpers filled with the wine of the country, and how later on they thrust at each other with their swords over the prostrate palanquin of the dusky one. The fumes of Shiraz were evidently provocative of midnight brawls and street rows, and perhaps it was this

heady Persian liquor which caused Sir Philip Francis and Warren Hastings to have their memorable meeting on the *Maidan* of Calcutta. But by and by, when easier communication with Europe brought European wines into the Indian markets, the Nabobs took to Sneyd's claret in preference to Shiraz and very much it would appear, to the improvement of their morals and their tempers. What has become of the wine Shiraz now, it would be hard to say. Perhaps it goes, with wines from all countries, to Oette, there to be manufactured into something that is the fashionable drink of the moment.

In India they grow the vine chiefly on trellises. I have seen a charming effect produced by trellised vines extending over an alley of a hundred yards or so. Underneath the canopy of vine leaves and purple, red, and white clusters of grapes, were ferns, tastefully arranged in ornamental pots and baskets. Every fern, from the tree fern to the maiden's hair, was there in profusion, and the happy combination of shade and chequered light from above was enchanting. But although wine is made from trellised vines in Italy, it is not the proper way of growing the vine for wine. However, the little stunted bush with which Continental travel has made every one familiar are absent in India, though one need not know as much about wine, as Cyrus Redding or Vitzetelli to see that certain soils in India must be admirably adapted for the vine, and perhaps for wine. The Maharajah of Cashmere has thought so well of the capacities of his dominions in this direction that he has imported vines and vine-dressers from France, and proposes entering the market as a rival of *Yeuve Clicquot* and *Pol Roger*; but the Maharajah's experiments are being conducted out of British territory, so have not the same interest as if conducted in our own. There is plenty of soil (and proper climate) however in Northern India that could grow the grape just as well as Cashmere, and it seems a pity that British India, which now produces corn and oil in the greatest abundance, should not have the conventional third type of a land's fertility added to the other two. There is a diamondiferous district in Southern India, bordering the Kistna and Toonga Woomdra districts that might perhaps produce a good wine. There are diamond fields there which were once very productive, and they are now being reopened. But the grapes of Cuddaph, and those parts, are better than the diamonds—at least than any I have seen. And if there were no difficulty about irrigation—for Cuddaph is a frightfully hot place—vines—and wine—should succeed there with care. But it is easy, of course, to get any climate almost one pleases in India by simply ascending the plateaus and mountains that are to be found everywhere; thus the Mysore plateau 3,000 feet high, would seem in parts to be favourable to the cultivation of the vine. The natives of the present day, however seem to have lost all knowledge of the vine. They scarcely know what the plant is, they see it so seldom. And yet there was a time when wine was sold in the bazaars, and when, no doubt, large tracts of country were planted thickly with the vine. The value and importance of a local wine, whether it was made in the North, the South, the East, or West of the Peninsula of India, may be guessed by the enormous figures which represent the importation of wines and spirits to India. It is a curious fact, borne out by those figures, that while Europeans in India are becoming more temperate, natives of India are growing more and more bibulous. Europeans now mostly content themselves with a little whisky—adulterated wines being more poisonous in India than elsewhere; but to the native tippler all is good liquor that is bottled, so much so that kerosene oil has been quaffed under that delusion. And the imports through the Bombay Custom House represent a total of gin, and of other cheap spirits, that is awful enough to make Sir W. Lawson's hair stand on end. Gin seems the peculiar vanity of the lower class of Hindu; his superiors get drunk on cherry brandy, port wine and champagne—perhaps all mixed together. But it is a noteworthy circumstance that while this import of foreign spirit is steadily flowing into Hindostan, there is another alcoholic current flowing out of it. Of late years the exportation of arrack has been very considerable, though what becomes of this rice spirits after it leaves India no one knows. There is no vanxhall now, where rick-punch would be in demand, and if there was, sensible people would take Joe Sedley's example as a warning, and avoid the "hot coppers" produced by it.

But toddy, or the juice of the palmyra, or the date palm, is unquestionably the national drink, the wine of India at the present day. And in taste it somewhat resembles ballroom gooseberry, miscalled champagne. Toddy, nevertheless is a poisonous drink, and it is an argument in favour of the restoration of the vine that a liquor so demoralizing should be the wine, so to speak of an enormous part of the population of India. Toddy has the curious property of being non-intoxicating, and therefore harmless, before the sun is risen and it has had time to ferment, but toddy in the day time is to be avoided, of which an instance you point. In my griffinish, or salad days, I used to drink a tumbler of palmyra juice in the early morning before it had fermented, and found it acid and refreshing. But one day, about 11 a.m., being fagged and heated in pursuit of antelope, I had a hearty pull at a toddy-pot in a village I passed through, and the result is never to be forgotten. My horse went home by himself, and I awoke, at three o'clock, from a sound sleep in the middle of the public road. The stuff is as quick in intoxicating as good champagne, and exposure to the sun intensifies and quickens its effects. The confirmed toddy drinker's appearance is a caution. His eyes are the colour of rubies, or of coals of fire, in his head, reminding one of those lines in *Bon Gaultier*, slightly transposed:—

What is this, his eyes are pinky,
Was it his toddy? oh, no, no,
Bless your heart, it was his curry,
Curry always makes them so.

And I have heard that excessive indulgence in toddy produces a number of bodily ailments besides those common to the abuse of any intoxicating liquor.

Unquestionably the vine is the least hurtful of all the plants that give an intoxicant to the human race, and I am sanguine enough to think that if the vine and vineyards were revived in India we should have a remedy for the drunkenness that threatens the Indian population of the future. The destruction of the vineyards of India I attribute to the Mahomedan conquerors of the country; men who would have rooted up the vine wherever found as an unmitigated evil. But even the Mahomedans with civilization and unbelief are becoming free livers, while the educated Hindus notoriously drink like fishes. There is no hope for such a people if they once take to drink, and what?—the cheap spirits imported from abroad! But if India grew—as I make no doubt she could grow—a cheap and pure *vin de pays*, such as the temperate peoples of wine countries use, the 250 millions might drink as they pleased, their drinking could do them little harm.—*F. E. W.—Graphic.*

PRACTICAL RESULTS OF RAMIE (OR RHEA) CULTURE.

By HENRY SANFORD BEIGMAN.

CULTIVATION, DECORTICATING, BLEACHING AND SPINNING.

For several years the farmers in the northern part of France have raised ramie as a better paying culture than that of wine. Three crops can be raised on a hectare equal to two acres, viz., in the middle of the months of June, August, and October. One crop will yield 60,000 kilograms, per hectare, or 180,000 kilograms, in all, which can be sold at 8 francs per kilogram, thus giving a crop valued at 4,800 frs. (\$9 0 per year). The total cost of roots, planting and labor amounts to 1,200 frs. per hectare in the first year; in the following years no cost except for labor are to be incurred, as the ramie plant is a perennial plant. The culture of ramie on a large scale is more remunerative, as the cost of labour is thus gradually diminished. The decortiating and baling of the fibres is generally done on the spot under a shed; the stalks bring a price of 8 frs. per 100 kilograms.—The difference between raising ramie on a small and large scale is illustrated thus:—A small grower sells his stalks at 8 frs. per 100 kilograms, receiving 4,800 frs. per hectare; a large grower, who decorticates the fibre, sells it 1 fr. per kilogram, receiving 12,000 frs. per hectare, or at a difference of, 7,200 frs. per hectare. A decortiating machine, system

Berthet, costs 5,000 frs. and is sufficient for 10 hectares or 20 acres. One machine will clean 1,200 kilogs. dry stalks per day, which yield from 23 to 25 per cent., or 270 kilogs. clean stalks. According to this, a yearly crop of 180,000 kilogs. ramie will yield 54,000 kilogs. dry stalks per hectare. The bleaching and preparing processes produce 80 per cent. of clean white fibres, free from gum or 9,600 kilogs. of a silk-like fibre. After these processes the fibre is combed by which process 80 per cent., of 7,680 kilogs. silk floss and 1,920 kilogs. noils are obtained. These products command a price of 4 frs. and 1½ frs. per kilog. respectively.

The yield is as follows:—

	Frances.
7,680 kilogs. floss, at 4 frs.....	30,720
1,920 " noils, at 1½ frs.....	2,880
Total frs...	33,600=£1,344

The expenses will amount to 14,000 frs., leaving a balance of 196,000 frs. (£784).

The loss and waste in spinning the yarn amounts to 7 per cent. Thus from 7,680 kilogs. floss, 7,000 kilogs. yarn can be obtained in Nos. 50, 60, and 80 at a selling price of 8, 9, and 12 francs respectively. According to the size of yarn spun, a clear profit of from 56,000 to 84,000 frs. can be made, after all the wages for labor for cultivation, decorticating, bleaching, combing, and spinning have been paid. A plant of 5,000 spindles will produce 500 kilogs. yarn per day, or 150,000 kilogs. per year of 300 days. The consumption would be 251,000 kilogs. bleached fibre, equal to 1,100,000 kilogs. decorticated stalks, and 3,600,000 kilogs. green ramie. Such a production would require a farm of 20 hectares, or 40 acres, at three crops per year. with four decorticating machines.

The cost of a plant of 5,000 spindles, including buildings and other machinery, would amount to 700,000 frs (£28,000); further, a cash capital of 300,000 frs (£12,000) for buying, &c., would be required, or a total of 1,000,000 frs. The following is an estimate of expenses:—

	Frances.
Wages, at 400 frs. per day, 300 days ...	120,000
Coal, Engine, &c. ...	30,000
Management and office expenses ...	85,000
Total ...	235,000
Raw material—3,600,000 kilogs. green stalks at 8 frs. per 100 kilogs. ...	288,000
Total per year ...	523,000
Production—150,000 kilos. yarn. Nos. 30 to 40, 7 frs. ...	1,050,000
50,000 kilogs noils at 1.50 frs. ...	75,000
Deduct expenses and raw material ...	523,000
Leaving a profit of ...	602,000 or £24,080

The above calculations will amply demonstrate the importance of so remunerative a cultivation of this plant.

SPINNING AND MANUFACTURING OF RAMIE CLOTH.—American hosiery manufacturers are using ramie yarns for imitating hosiery which was imported as a silk mixture. In Europe ramie is employed for making saddles, and shoemakers' twist for fancy sewing silks, being lustrous like silk and having twice the strength of the best silk or linen thread. Fine ramie yarns are used in silk manufacturing as filling; the noils are bought by woollen manufacturers for so-called silk-mixed goods.—Of late fine guipure laces and lace curtains were manufactured by Seidel and Richter, at Zittan; the same yarns and articles are also made in France by a large company who bought the patents for France from F. E. Seidel and Co. This company is also notable for its enormous demand for yarn. The latest product from ramie is sealskin plush, which is equal to silk-seal plush, and is sold in large New York dry goods stores at from \$12 to \$18 per yard, being the most perfect imitation of seal.—At the Industrial Exhibition at Rouen, in 1884, the

ramie industry was represented by a new decorticating machine of the system Berthet, and a collection of samples of ramie in the various degrees of the process, of manufacturing, and its application, as decorticated, bleached, combed, spun, dyed, and woven; these samples have been sent partly from Algeria, by M. Ferray d'Es-souves, by M. Wallon, foisher, and by Caron and Miray, dyers. In the south of France and in Algeria four crops can be obtained per year. For this decorticating machine, which works other fibres as well as ramie, a gold medal has been awarded to M. Barchet, and the results obtained by it fully correspond with figures above mentioned. M. Barchet, who is director of spinning and weaving, has been in Louisiana to organize a cotton spinning and weaving mill. While sojourning there and in Mexico he conceived the idea of his decorticating machine, which has given such satisfactory results.—English manufacturers are using ramie for making alpaca, by mixing wool and ramie, which gives a superior article to cotton and wool.—Introducing the ramie culture in the United States is principally due to the efforts of the *Dry Goods Bulletin*, which for years acted as the pioneer of this industry, by publishing leading articles on the merits and advantages of this culture. It has received samples of fibres, yarns, and fabrics from its foreign correspondents, and has called the attention of its readers to the mixture of silk goods with ramie. Beautiful laces and lace curtains are being made from ramie, samples of which are open for inspection. Of late the majority of the American and foreign textile papers have taken up the subject of ramie culture. There was no profit made yet in this country by planting ramie, as most of the culturists merely have grown it for a pasture or for experimenting, and no proper machine for decorticating the fibre built.—Mr. David S. Ogden, founder of the Hyde Park at Chicago and general agent of Illinois Railroad Land Office, a gentleman full of life and enterprise, started with the writer of this for the United States of Columbia, to explore the pita ramie and other fibrous plant. After a difficult travel of eight months, mostly on mules, we returned, having achieved splendid results, and then we sailed for Europe, to find the most appropriate machinery for decorticating and spinning ramie. We travelled through England, Scotland, Ireland, France, and Germany for eight months, we visited machine builders and yarn spinners, and had the intention to go to work on a large scale. Mr. Ogden, previous to going to Europe, secured a contract with Mexican and New York capitalists, with power of attorney authorizing him to use his own judgment in selecting and buying machinery, we to furnish our experience and the bankers the capital for this enterprise.—After having returned to this country. Mr. Ogden died three weeks afterward, which unfortunate event left the matter in the same state as two years ago. Later the writer made the acquaintance of Mr. Jagerhuber, editor of the *Dry Goods Bulletin*, who had devoted many years' study to the vegetable fibres.—A large collection of samples of yarns and fabrics are to be found at the office of the *Dry Goods Bulletin*, which consists of specimens of ramie, in all the degrees of the process of manufacturing, and serve to demonstrate the importance of the cultivation of the ramie plant, its preparation for the use of yarn and textile manufacturers in the United States.—The time is near at hand when every manufacturer of textile fabrics must calculate with ramie, if he wants to keep alive.—Thus far the practical results achieved are a *complete triumph*, and, in my opinion, the American people, from the farmer and mechanic up to the merchant and manufacturer, will soon have occasion to express their gratitude to the pioneers of this great industry, but above all to the unselfish and persistent labour of the editor of this paper, Mr. Jagerhuber, who has helped us more than all European agitators.—*New York Dry Goods Bulletin*.

JAPAN GREEN TEAS: THE CULTURE AND PREPARATION OF TEA IN JAPAN.

We have received from Mr. H. D. Deane of Kintyre estate, Maskeliya, Ceylon, two specimens of Japan teas, the one simply fired by the Japanese themselves and uncoloured, the other re-fired and coloured for the American market by foreign merchants. This out-turn of both shows a strong and peculiar light-orange liquor, which may, no doubt, be acceptable to some palates, but which tastes very poorly against our fine pungent Ceylon liquors. The leaf, after infusion, shows quite green in both cases, proving that it had been withered by steaming and had been rolled the same day as it was plucked. The dried leaf is not rounded and twisted like China and Indian black tea, but looks like long chips of green wood. The type of a Japan tea-bush is the very smallest China variety, and these teas show in addition very fine plucking. The coloured tea appears to have passed through a cutting machine. The samples can be seen at our office.

From Mr. Deane we have received a number of the "Transactions of the Asiatic Society of Japan," consisting entirely of an illustrated paper by Mr. Henry Gribble on the preparation of Japan tea. We are thus enabled to appreciate the peculiarities which distinguish the culture and preparation of the fragrant leaf in "the land of the rising sun."

At the outset we are struck with the extreme disparity between the size of good Assam hybrid leaves and those of the varieties of tea cultivated in Japan. The former produces leaves varying from five to ten inches long, but the larger-leaved variety of tea cultivated in Japan, *mé cha*, is only two inches long, while the smaller variety, *o cha*, has leaves, the largest of which is little more than an inch, the flush is, of course, small in proportion. Besides pictures of the two varieties of tea bushes, showing flowers, fruits and leaves, natural size, Mr. Gribble's paper is illustrated with representations of the larva and larva case of the *mino mushi* (Psyche sp.), the only pest, and that not a formidable one, to which tea grown in Japan is liable. The insect would do considerable damage if let alone, but it is easily detected and removed, while tea bug, red spider and other plagues of Indian plantations do not trouble the Japan tea-grower. There may be something in climate and a good deal in the system of culture in detached patches.

Besides the three illustrations referred to, there are no fewer than twenty-one engravings from representations by native artists of the various processes of preparation, from picking to roping and finishing, the various implements and appliances being also depicted up to a foreign firing godown and its fittings. The picking of the flush seems to be done entirely by young girls (well-clothed and their heads covered by wide round hats, the picture shows them), and, unless a very serious printer's error has been allowed to pass in Mr. Gribble's paper, the average day's gathering is only 3½ lb. ! As this could not possibly pay, even where wages are so low as in Japan, we suspect that the equivalent of 3½ lb. of made tea must have been meant, in which case the quantity of green leaf would be 14 lb., a fair average, considering the extreme minuteness of Japan tea flush. Following "picking" we have a representation of the processes of "collecting and carrying to market." In this case two girls are pouring the green leaves out of their small

field baskets into a large one, with a fellow of which a man is walking off. His feet are clad with sandals, and he carries his burden on his back, the universal pingo not being in this case brought into requisition. Then comes the peculiar process of steaming the green leaves, on which, evidently, the main peculiarity of the Japan tea depends. In this process which a recent correspondent wanted Ceylon planters to adopt, only men seem to be employed. The steaming pan and the oven on which it is set are fully shown, and there are enlarged designs of the carrying basket, *cha maké*, and the small basket used in the fields, *cha biki*. Both baskets seem nicely finished and are more elongated in form than those we have observed in use in Ceylon. We next get pictures of the small hand-broom, *mygohoki* in use, as also a small hand-basket for sorting, *mi* a steaming tray with wire bottom, fitting top of oven, *fukashi shero*, and a lid for the same, *futa*. If the steaming of tea is really tried in Ceylon, a set of the necessary appliances, and good drawings of the oven, ought to be procured from Japan.

"Preparatory to Firing" represents two girls on their knees apparently rolling balls of the leaves, but Mr. Gribble's paper represents the rolling and firing as taking place simultaneously. A man is taking away the slightly rolled leaf on a sieve. We then see "The First Firing," over "chookag," two girls taking up the leaf, rolling it between their hands and spreading it again over the trays "The Final Firing" seems to be done by men. One is pouring leaf from a sieve on to the trays; another is rolling and spreading the leaf on the trays. Then we get separate representations of "the firing box" "*horo*" "waxed firing tray, fitting top of firing box," "*shiat no joto*," and "papered tray for final firing," "*shiang no joto*." As our readers will learn when we come to notice Mr. Gribble's description of the process of firing they manufacture a paper in Japan (some of which might be turned to good account in Ceylon?), strong enough for a long period to resist great heat and the pressure of rolling at the same time.

"Sorting" represents only two men with basket sieves (not perforated), some tea on the floor and three boxes. There are large size pictures of the "square basket," "*kakuhara*," and the "basket for sorting," "*shida-chi mi*." Now comes "Sifting," apparently out of place (after Sorting?). There is one sieve with a perforated bottom hung by ropes and a second man is at work with the ordinary basket sieve. The large perforated sieve "*furu*" is shown enlarged size, as also the round basket, "*maru boro*." We now come to "Hand-picking," in which four girls are represented picking out what we take to be stalks, red leaves and foreign substances from the tea. Separate pictures follow of the "picking table," "*yooi da*"; "trays for rejected leaves," "*cha suté hako*"; "platter for yellow leaves," "*kiba ire*"; and "bag for yellow leaves," "*kiba bukuro*." As we look at the engravings of all these ingenious and neatly finished contrivances, we cannot help wishing that to all the other obligations conferred by him on Ceylon in connection with Japan, Mr. Deane would, through his friends at Yokohama, now obtain sets of all the implements and appliances connected with tea culture and tea preparation. We feel sure the Chamber of Commerce and Planters' Association would gladly defray the cost. The articles could be first displayed at Colombo and then at Kandy, being finally placed in the permanent keeping of the De Souza Museum, as the big institution can only receive articles of Ceylon origin. Many useful hints might be obtained from the tea making appliances used in Japan. "Weighing and Packing" are well represented, men alone being employed in these processes, and then comes a quaint and amusing picture of Packing (soldering and nailing

up the boxes) and marking. Now come "Roping and Finishing." "A Foreign Tea Firing Godown," interior view presents a busy and animated scene, with its long rows of furnaces, pans and freres. There are separate representations of "the firing pan in brick work and plaster"; "carrying basket for taking tea to the pans"; "hand-scoop for removing the tea from the pans"; and a longitudinal perforated "sieve." Finally we have, in this curious and instructive set of native drawings a representation of "basket firing," the baskets looking like Indian drums. There are a "general view and section of basket, centre tray for receiving the tea, small broom and fan." In the sectional view of the basket (wide at both ends and narrow in the middle), we see that the fire is beneath the basket and that the drying tray laden with leaf is in the centre, the heat and vapour passing up through the top part of the basket. This, we suppose, is about the simplest form of firing which can well be adopted.

Having thus noticed the interesting illustrations to Mr. Gribble's paper, we shall now give our readers an abstract of the valuable information embodied in the elaborate paper itself, "On the Preparation of Tea in Japan," preparation which, like culture in Japan, differs essentially from what is familiar to planters in India and Ceylon.

At the commencement we have a good story from Kaempfer's History of Japan, about a woman who, being desirous of getting rid of her husband, was advised to feed him entirely on pork and other fat things. Wish-ing to expedite the desired event, however, she took further advice, pursuant to which she gave her husband, now reduced to a skeleton, large drafts of tea. The result was his perfect restoration to health! After quoting many absurd denunciations of tea, and Dr. Johnson's apology for his own love of the infusion, Mr. Gribble characterizes tea as giving the Yokohama merchants their occupation (he purposely avoided saying profit) by supplying some 35 millions of pounds weight to the thirsty inhabitants of the United States. This was in October 1883, and, we believe, that 40 millions is now nearer the mark, the United States being almost the sole market for Japan green teas, the revelations about faking and adulteration having almost annihilated the trade in green tea for Britain. The more is the pity, for pure green tea are easily made and could be more cheaply supplied than black. Tea seems to have found its way from Assam to China about the fifth century of the Christian era, and from China seeds were brought to Japan in 805 A.D. It was not, however, until the twelfth century that a Buddhist priest succeeded in getting the Japanese properly to appreciate the virtues of the tea-plant, and it would seem that, until quite recently, only nobles and rich people indulged in the luxury of the leaf infusion. It is curious to see Kaempfer quoted to the effect that Buddha was an Indian and a negro, born 1028 B.C.! The Japanese tradition is that Dharma, who introduced the tea-plant to China, crossed to Japan riding on a tea-leaf, an original parachute truly! We quote a couple of paragraphs:—

Probably the earliest mention of Japan Tea by an Englishman is to be found in the "Diary of Richard Cocks," the Agent of the Hon'ble East India Company at Hirado (Hirado), 1615-1622, lately published by the Hakuyt Society, in which more than one reference is made to "cups for *chau*," and where one entry records the receipt from Misco (Kiyoto) of "iij jars of *cao*" for Mr. Wickham, who had been the company's resident at Osaka. It is noticeable that Cocks throughout his diary makes no mention of tea drinking, an omission which would hardly have taken place if the custom had been at all prevalent there in Hirado, or indeed if he had at any time partaken beverage there on his several trips to the north. For a

long time Tea was too expensive a luxury even to the Japanese themselves to be indulged in by any but the nobles, and Kaempfer, writing in 1692, describes how the tea used at the Imperial court was then grown and prepared at Uji under the care of the chief purveyor of Tea; how, for at least two or three weeks before the gathering of the leaves the persons who were to pick them were prohibited from eating fish or any unclean food, lest their breath should contaminate the leaves; how, during the gathering season they had to wash themselves twice or three times a day; nor were they allowed to touch the leaves except with gloved hands. When finally prepared, the Tea was sent up to court under a good guard; sometimes a simple pot of this tea, containing no more than three or four catties, being attended by nearly two hundred people. This Imperial tea cost thirty or forty Taels for one catty, and when receiving a cup at his audience at court, Kaempfer was told by the attendant that the single cupful cost one *ichibu*.

Mr. Gribble gives a botanical description of the tea-plants, and states that the large and small leaves (one inch and two inches long) are found growing on the same bush, the native planters stating that they cannot tell beforehand which variety will be germinated from any given seed. In some districts the different kinds are called male (*otoko*) and female (*ona*). The chemistry of tea is added, but for this detail we wait until we come to a very able paper by Dr. Divers, which embodies the most correct and fullest information. We quote what is said about planting and growing, directing the particular attention of our readers to the extraordinary system of cramming 30 seeds into a circle of 2 feet diameter, the centre of each circle being 5 feet distant from its neighbour. The result must be that the ground is completely covered, for, although there is a distance of 3 feet between the rims of the circles, on the surface, yet the branches from the outside plants of each circle must nearly meet. No wonder, though seed thus sown should develop into "a compact bush," the 30 plants, or all that result from the 30 seeds put into each circle of 2 feet diameter, becoming, in fact, one mass of stems and twigs. It is hedge-planting, after a fashion. This is what Mr. Gribble writes:—

Planting.—The tea plant requires a well-drained soil; it grows well on level ground with well-kept drains, but is more often seen on gentle hill-slopes and again on steep inclines, where terraces are cut to maintain small level patches and to prevent too violent rushes of water during heavy rains. These terraces on the hill-sides, when covered with plants, look very picturesque; but they are only selected as being the cheapest ground procurable, and not because the tea requires any such elevation. A new plantation is started from seed, planted in circles of about two feet diameter; each circle receives about 30 seeds and its centre is placed at a distance of about five feet from its neighbour.

Growing.—The circle of seed develops into a compact bush, some shoots of which will be found to bear leaves of a darker colour and of harder texture than the others and also much smaller. This difference in the leaf on the same tea bush is one of the difficulties of the tea-farmer and tea-picker, and it seems difficult to believe that with more care this trouble cannot be avoided. In the third year of its growth the tea plant bears leaves ready for picking, and it is considered at its best from the fifth to the tenth year. But age does not deteriorate the plant, the only difference being that with years it requires more manure. The shrub is not allowed to grow beyond a height of three or four feet, necessary both for the convenience of picking and for the strength of the new shoots.

Picking.—As the season is early or late, the first picking commences at the latter end of April or beginning of May, and lasts about twenty days or a month. The second crop is gathered in June and July, and sometimes a third one later on. This work is performed almost entirely by girls, who deftly pick off the new leaves, but very often also the whole of a new shoot, so that long stems are frequently met with in their

baskets, where leaves only should be seen. The shrub, being an evergreen, has still many of its last year's leaves, so that some skill is necessary to fill a basket quickly without also including some of the old growth. A girl will pick, at the beginning of the season, about one *kwan-me* of leaves (3½ lb.) in a day, for which, this year, her wages were 15 *sen*.

We have already stated our belief that Mr. Gribble must have meant not 3½ lb. of green leaf gathered daily, but green leaf equivalent to 3½ lb. made tea. The average Indian task or "nerrick" of green leaves being 16 lb., a gathering of 14 lb. comes pretty close to the average. But our readers will notice the long intervals indicated between the picking or plucking seasons. We now come to the "country preparation," which is very curious and largely opposed to the processes by which black tea is made in India and Ceylon. Mr. Gribble writes:—

The following notes on the country preparation were made during a few days stay at Shizuoka (the capital of Suruga) early in May this year, at the time when the first pickings were being made and when the whole district was alive with the industry of a new tea crop. Suruga and the adjoining province of Totomi are two of the principal tea producing districts of Japan, and at the time of my visit the tea gardens on the plain, on the hill-slopes and on the terraces up the hill-sides were dotted with the figures and large sun-hats of the girls picking the leaves. The roads leading to the town were seldom free from men carrying baskets full of green leaves to be fired; others dragging to the port of loading, cart-loads of the finished tea for shipment to Yokohama. In the town itself dealers bargain for each small lot of tea brought in from the fields and the carriers either stay to sell their baskets-full, or pass on with a word of chaff if their load has already been bespoken, or if it has to go direct to the firing place of the owner of the plantation where the tea has been picked. As a rule the tea belongs to very small proprietors, who fire their few cattie a day, generally in the entrance of their only apartment, and then sell the fired leaf to larger dealers who, as principals or go-betweens, mix their various purchases together and then send twenty or more boxes of similar tea for sale at the treaty ports. But the process of preparing the green leaf is the same whether done in a small shanty or in the godowns of a well-to-do merchant. It is as follows:—

Steaming.—As soon as possible after the leaves have been picked they are steamed by being placed in a round wooden tray, with a brass wire bottom, over boiling water; the tray filling up the mouth of an iron cauldron set in plaster over a wood fire. The tray is about 18 inches diameter, and receives about a couple of hand-fuls of green leaf; the lid is put on to confine the steam, and the process is complete in about half a minute; the attendant taking one look at the leaves and stirring before removing them. The water in the cauldron showed 210° Fahrenheit and the bottom of the tray 185°. The moist leaves, with their natural oil now brought to the surface, are then tumbled on to a wooden table for a few minutes, and then taken into the firing room, where the principal manipulation has now to be performed.

Firing.—A box-shaped wooden frame about 4 feet long by 2½ feet broad, coated with plaster, forms the oven. Charcoal (well covered with charcoal ash) is alight in the bottom of the oven, and about a foot and a half above the charcoal rests the wooden frame with tough Japanese paper stretched across it. This paper gets darkly tanned by the oil from the leaves, but below it shows no signs of getting burnt, and one such paper tray will often do more than a whole season's work without being renewed. The heat of the paper at the time of firing is about 120°.

About 800 *me** (6½ lb.) of green leaves are thrown on to one of these paper trays and a man (for the work can only be done by men †) now proceeds to fire this quantity, which by the time it is finished becomes reduced to about 170 *me* (1½ lb.). At first he throws up the soft, moist leaves in quick succession and keeps the whole mass moving

without any attempt at rolling or twisting. Gradually the leaves assume a darker colour, and gradually he works them up into balls, rolling the balls between his hands, separating the leaves again, rolling them on the hot surface of the paper, again collecting them into balls, which he will now roll backwards and forwards on the paper, and finally do so with considerable strength and pressure, occasionally resting one elbow on the edge of the tray and rolling the tea between the palms of both hands with all his might. After some hours work (depending upon the quality of the tea) the leaves have all become separately twisted, and have changed their colour to dark olive purple. They are now crisp, long, thin wiry "spills," and, in the case of the best leaf, look more like slender tooth-picks than the leaves of a shrub. When finished, the tea is strewn on a similar firing tray, but at a lower temperature (about 110°), and is there allowed to dry until it becomes quite brittle. The heat is then further reduced to about 95°, and the tea left for 4 to 6 hours, even longer if it is intended to keep it in stock for many months. Tea well fired in this manner and afterwards packed in earthenware jars will keep for a whole year without spoiling.

Sorting.—After leaving the firing room the tea passes to the hands of a man who sorts the leaves by jerking them up and down in a bamboo hand tray, by which he separates a large proportion of the light from the heavy leaf.

Sifting.—The tea is then passed to a sieve suspended from the roof and swung backwards and forwards with a circular motion, allowing all the fine thin leaves to collect in a heap on the ground and retaining the large and coarser ones to be thrown into a separate heap.

Hand Picking.—The completing process of the country preparation is to distribute the tea to girls, seated on the mats in front of a picking table, who sort out all the seeds, stalks and rubbish that may still be mixed with the tea. The tea, thus finished as far as the country process is concerned, is packed into wooden boxes, nailed, corded and marked, and then sent to the treaty port for sale, each box containing about half a picul.

Before following the tea into the foreigner's godown, where it has again to be fired and packed for shipment over sea, I give the result of my enquiries as to the country cost of its growth and manipulation.

Level ground, within easy distance of Shizuoka, suitable for a tea plantation, is now said to be worth about 100 *yen* for 100 *tsabo* (3,600 square feet); ten years ago it was worth about 25 *yen*, and twenty years ago only half the latter sum. On the hills equally good ground is said to be worth an average of 30 *yen* per 100 *tsabo*.

Tea shrubs covering 100 *tsabo* will produce in their third year about 30 *kwan-me* (250 lb.) of green leaves at the first picking and about 15 *kwan-me* at the second picking. According to this year's scale of wages (about 25 per cent. cheaper than last season's) the cost of picking 30 *kwan-me* was *yen* 4.50.

The cost of labour in firing, of packing boxes and of freight to Yokohama was given to me as *yen* 7, and the charges for selling in Yokohama 5 per cent. We thus have as the cost of the first crop from 100 *tsabo* of land under cultivation:—

Picking 30 <i>kwan-me</i> (250 lb.) ...	<i>yen</i> 4.50
Firing, packing and freight to Yokohama ...	7.00
Agency charges in Yokohama, 5 per cent60
	<i>yen</i> 12.10

at exchange of 1.50 *yen* per dollar the equivalent of \$9.31 for a net weight of 6 *kwan-me* (50 lb.) of fired tea (the loss in weight thus amounting to 30 per cent). This is equal to about \$25 per picul without any allowance for profit to the planter or for rental of his plantation. Of course if the whole of his crop were of the "Choiceest" quality, this cost would leave him a large profit, but whether his tea sells as "Choiceest," or as "common" the average cost of production is not far different.

At the time of my visit to Shizuoka the best tea, already fired and picked, was being bought by the large dealers at *yen* 270 per *kwan-me*, the equivalent of *yen* 43.20 per picul. The cost of boxes and expenses to Yokohama amounted to *yen* 2 per picul, making the total cost here, with selling charges, *yen* 47.46 per picul or \$38.50. Similar tea was then selling in Yokohama at a little over this price. The value in Shizuoka of similar tea at the same time in

* 120 *me*—one pound.

† Their wages this year were 50 *sen* per day, during which they would finish about 700 *me* of fired tea about (6 lb.).

the previous season, was *yen* 4 per *kwan-me*, and the tea men were all loud in their complaints that, although the cost of labour was so much cheaper this year, the present would be a losing season to them, and that it would not pay to gather the second crop. This, however, has not proved the case, and, contrary to many expectations, the total yield this year of Japan tea seems likely to be little short of last season's supply. I am, therefore, inclined to think that the figures of cost as given to me at Shidzuoka were excessive, and we must probably wait for that long-hoped for period of the opening of the country to foreign enterprise before this Society can be correctly informed of the cost of producing tea in Japan.

Note.—120 *me* = 1 lb. 1 *isubo* = 36 square ft.
 1 *kwan-me* = 133 $\frac{1}{3}$ lb. 1,210 " = 1 acre.
 16 " = 133 $\frac{1}{3}$ lb. 1 acre = 43,500 sq. ft.
 1 picul = 133 $\frac{1}{3}$ lb.

At the date of writing these notes one dollar was equal to 130 *yen* (paper) and the sterling exchange was 3s 8d. per dollar, thus making the pound sterling equal to 7.09 *yen*.

The further manipulation that Japan tea has to undergo before it can be exported to America or Canada (its only markets) is familiar to most of us who reside at the treaty ports. During the season we have daily experience of the aroma issuing from the open windows of the tea-firing godowns, of the troops of tea-firing men, women and children who clatter past our windows at an unearthly hour in the morning, and who make day hideous with their noise, singing and crying. Probably most of us have also been inside these godowns and seen these women at work, stirring the tea in iron pans with unceasing vigour and song, only interrupted by the occasional shouts of the overlookers or by the motherly attentions required by the children slung on their backs or tugging at their skirts. There are two systems of finally firing Japan tea: Pan firing and basket firing.

Pan Firing.—This is done in rows of iron pans (21 inches diameter by 13 inches deep) set in brick work and heated by charcoal. The tea which has been bought probably in small lots of different qualities has been bulked into large enough quantities of the same description and is then carried by the women in baskets to the firing godown. At a given signal all the baskets are emptied into the pans (about 5 lb. weight into each), and the fires being well lit and afterwards constantly attended to, the stirring of the leaves continues until the overseer (generally a Chinaman) considers the tea sufficiently fired, when the signal is given to take out the tea and carry it back to the packing godown, or put it through a second process of stirring in cold pans. According to the quality of the tea and the ideas of the tea-taster, the pan firing of one lot of tea may last from 40 to 65 minutes in the hot and from 25 to 60 minutes in the cold pans. When finished it is taken into the packing godown, where it is sifted to remove the dust, and then packed while still warm, into the half-chests lined with leads, which are to convey it to the grocers and tea-drinkers of America.

Colouring.—When colouring matter has to be used it is thrown into the pans at the proper moment by the Chinese overseer and quickly gets absorbed by all the tea. The use of colouring matter has lately given rise to considerable discussion, and there can be no doubt that, as far as it goes, it is a species of adulteration—just as much adulteration as the use of colour to make some sugar plums white, others pink or other salmon colour. Certain tastes for colour are developed in the consumers of tea as in the consumers of sugared almonds, and it becomes the necessity of the manufacturer to meet the requirements of his customers. The American dealers have called for more or less coloured tea, and their demand has been met here by those who prepare it. That demand is now undergoing some change, and tea merchants in Japan will be only too glad when it has ceased altogether. A large quantity of tea is now sent without any colouring matter whatever, and even where it is still used it cannot be condemned as being in any way injurious to health, in the infinitesimal quantities in which it is mixed with the tea. The outcry against colouring matter has been principally caused by the excessive colour and actual weight-adulterations of the lower grades of China green tea; also by the re-manufacture in London or New

York of teas shipped from the East—a process for which merchants here are not responsible. Dr. Divers, Principal of the Kohn-Dai-Gaku, has kindly contributed a special report upon this part of the manipulation of tea, which will be found attached to this paper and will be read with interest as representing the opinion of an able and independent expert.

Basket Firing.—Basket firing consists in simply refiring the tea without any of the stirring process as gone through in the pans. A bamboo basket, shaped like a dice box, but open at both ends, is placed over a large iron brazier containing lighted charcoal (well covered with ashes) and the tea is strewed, about an inch in thickness, on a close woven bamboo tray which fits the neck of the dice box. The baskets are occasionally removed from the brazier and the tea turned over by hand in order that all may be equally fired; they are carefully replaced on the brazier, without allowing any dust or leaves to fall through the tray on to the charcoal, and in the course of 40 to 60 minutes the tea is ready for packing.

Congou.—The foregoing description applies to the preparation of ordinary Japan tea, during which no fermentation of the leaf has been allowed to take place. But in the preparation of Black Tea (*Congou*), of which a considerable quantity was made some seasons ago, fermentation has to occur and the process deserves special notice. The financial result of Japan-made *congous* has not hitherto been a success, but there is no reason why further perseverance should not make it so; and it is in every way desirable that the Japanese should continue this industry, and thus limit the constantly increasing supply of green tea, which year by year is found to be in excess of its demand in America and Canada. These now are the only markets for the Japan green tea; but they would also absorb a certain quantity of Japan-made *congou*, whilst the latter would find an outlet in Europe and Australia, where the Japan greens are not now appreciated.

To anyone reading this account it would occur, that, surely, instead of final-firing factories in the towns, there ought to be central factories in the districts. The objection, no doubt, is, that the patches of tea are not only too small but too widely scattered to enable such country factories to be worked with a profit. Mr. Gribble speaks of no rolling before steaming, but the pictures we previously noticed would seem to indicate that the leaves are rolled to some extent before they are steamed. The process of withering is nowhere indicated, either in the native pictures or in Mr. Gribble's descriptions.

If Mr. Gribble's figures for yield are correct, the result would seem to be 4,500 lb. green tea, or 1,125 lb. dry per acre; but, even with constant manuring and the system of small husbandry adopted, this figure seems very high. It may probably bear reduction by one-fourth. The figures for cost would seem to prove that tea laid down at Yokohama cost about 50 cents per lb. of our money, but Mr. Gribble indicates that the native information is untrustworthy. If the tea did not yield some profit, the landholders would surely cease to grow and prepare it. Our readers will observe that the final processes in the European godowns include manipulation in cold pans, as a sequel to firing in hot pans. What can be the philosophy of the cold pan process, unless it be to give a polish to the leaves or rather "spills"? Refiring with baskets, it will be observed, dispenses altogether with pans, just as the mode adopted by the vast majority of Indian and Ceylon planters now does. The last paragraph quoted shows the vast difference between Japan green and black tea to be that the former undergo no process of fermentation. The steaming process is represented as evolving a "natural oil" from the leaves. Is there any such oil as can be appreciably noticed? There is, no doubt, an essential oil, but it could scarcely act as represented?

Black tea as well as green is made in Japan, a deputation of Japanese having been sent a few years ago to India to collect information as to the process pursued there. Mr. James Green of Kobe, who, we

believe, travelled with Mr. Deane, furnished Mr. Gribble with a description of the native manufacture of black tea. The opening paragraph reveals the grand mistake of wasting the juice exuded in rolling, a practice, we believe, followed largely if not generally in China, while Indian and Ceylon planters are careful that the juice is absorbed by the rolled leaf before it is fermented. We quote as follows:—

"The great objection to Japanese made congo is that it is too skinny in leaf and lacks strength in cup. The first crop produces the most attractive tea, but the leaf is too succulent, and nearly all its good qualities are lost when being rolled. I have often seen a heap of green foamy juice, rolled out of the leaf, lying on the ground beneath the rolling tables, and as a natural result the infused tea much resembled 'toast water.' The third crop produces the best tea, as the sun is then powerful and the shoots are strong and hard. The greater part of the congo made in Japan is shipped to England, where it is mixed with Indian teas, the former most effectually toning the latter, and thus forming an excellent combination.

"*Drying.*—The young pickings are spread out in thin layers on bamboo or straw mats in a sunny place till they are quite soft. Care must be taken not to wilt them too much; in fact extremes should be avoided, for if the leaf is either not sufficiently soft or wilted too much, broken or dead leaves will become visible and spoil the appearance of the tea when made up. When then the leaf is as soft as untanned leather it is fit for rolling. In wet weather or when it is cold, or in the early morning, the leaf may be rendered sufficiently pliable by wilting on iron plates or ordinary firing pans over charcoal fires. Steaming, as in the 'Uji sei' or green tea process, must be avoided, as it takes too much vitality out of what is naturally a weak tea.

"*Rolling.*—The wilted leaf is gathered up in baskets and taken to the rolling room, where it is turned out on a long table, on either side of which stand the rolling coolies. Each coolie takes a double handful and rolls it, as a baker kneads dough, for thirty minutes, after which it is packed tightly in large round baskets (*obote*) and covered over with a cloth for an hour or so to allow it to ferment, at the expiration of which time it attains a reddish-brownish tint. To assist the process of fermentation, the baskets containing the rolled leaf should be placed in the firing-room. The leaf is then tipped out on to the rolling tables, well shaken out and rolled for fifteen minutes more and fired on iron gauze sieves or in *tsuyuni kago*, drum baskets, over charcoal fires. The first mentioned and best process takes forty-five, and the drum baskets seventy minutes. There is a saving of charcoal in the latter, a small item, however, when the difference in quality is taken into consideration, for sieve-fired teas always command a better price on the London market.

"*Sifting.*—Ten men stand in a row, the first having a large-sized sieve, the mesh of the others decreasing in rotation, and the tea is passed from one to the other; the last sifting being dust. As all the tea must pass through No. 5 sieve, the larger siftings are broken by the hand and then winnowed to take out all flakey leaf. The bulk is at last reduced to five siftings, viz., large and small congo, large and small pekoe, and dust.

"*Sorting.* is generally performed by women, who sit down before long, low, black tables and take out the stalks and discoloured flat leaves, either with chopsticks or their fingers.

"*Making a Chop.*—A layer of large tea is first put into the bulking recess and carefully levelled; then a layer of small congo, then pekoe, then a small amount of dust, followed by another layer of large leaf, and so on. The No. 5 sieve teas are fired once more in drum-baskets and put into the chop quite hot. When thoroughly warmed through, the bulk is broken with iron rakes in a most careful manner, so that the tea shall be all alike. It is then packed into leaded half-chests ready for shipment.

"*Another Method.*—Some tea producers in Omi and Mino, acting upon instructions given them by the *Kowan no Kiyoku* (department for the advancement of husbandry) about five years ago made at congo after what they called the 'Indian method' (*Indau sei*), but the demand for their production was not at all up to their expectations, and they

were forced to abandon an enterprize that cost them a lot of money in plant and buildings.

"*Preparation.*—Wilt the leaf on white calico sheets in the sun, and when sufficiently soft roll on cross-plated or ribbed tables for twenty minutes. The rolled leaf is then placed on shelves in a hot-house (*uro*), bearing a temperature of 160°, where it remains till it assumes a reddish colour. It is then rolled again for ten minutes to give it a twist, and fired on thin iron plates over slow charcoal fires. After the first rolling the leaf is sifted so as to separate the pekoe from the congo.

"A very attractive tea can also be made by steaming the green leaf and then rolling it for thirty minutes, after which it is fired for forty minutes in a hot Fyehow pan. The tea then somewhat resembles a Hysou, and has the advantage of being a natural green leaf, but in cup it has what the Japanese call *no kusai*, or raw taste."

Information is given respecting 'brick tea' in which none of our readers are practically interested. We need only mention the curious fact that in certain parts of Mongolia the people will only purchase bricks which have been cut in half, so as to show the stalks. Mr. Gribble indicates that the foreign merchant are making experiments with machinery and improved modes of preparation, the results of which are likely to be apparent in the future. The trade in Japan teas has grown up within the score of years or so since the Perry and Elgin treaties. It is practically confined to the United States and Canada, and production has now outstripped demand. Prices have gone down from \$56 per picul in 1872 to \$33 in 1883 for choice, and for lower grades the fall has been heavier in proportion. The export in 1863-64 was only 4½ millions of lb. against an average of 40 millions now. Mr. Gribble produced specimens of teas, from \$350 per picul down to 88. The latter was an uncoloured common tea. Finally the author of the paper said:—

Allow me, in conclusion, to thank you for your kind attention and to offer you a cup of the Powdered Tea (*Hikicha*), such as delights the heart of the most aesthetic and extravagant member of the *Cha no Iu*. Its value is only about \$100 per picul, and you will please imagine that the three or more hours necessary ceremonies have been gone through elsewhere, before it has become *comme il faut* to drink this tea.

The value of this exceptional tea would be about 12s per lb.

The paper by Dr. Diver on "The Chemical Composition of Japan and Other Tea" is one of the best and most discriminative we have met with, and our readers will thank us for extracting it:—

The following analyses of Japanese tea, made in the laboratory of the Imperial College of Agriculture, Tokiyo, were published in 1879 by Mr. Edward Kiuch, then Professor of Chemistry there, and now in the same position in the Royal Agricultural College of England:—

	I.	II.	III.
Water	6.74	6.10	8.92
Fibre	11.20	11.70	...
Ash	6.53	6.10	5.26
Soluble in water ...	43.26	52.55	36.50
Tannin	12.50	12.10	13.19
Nitrogen	5.79	6.33	3.18

These quantities refer to 100 parts, and are not to be added together, because the matters enumerated are not exclusive of each other, part of the ash, part of the nitrogen, and all the tannin being contained in the matter soluble in water. No. I. is *hiki-cha* or ground-tea, from Uji, for eating with its infusion in the form of a broth. No. II. is *sen-cha* or leaf tea for infusing in the ordinary way, also from Uji. No. III. is tea made by the Chinese method, at the Experimental Section of the Agricultural Bureau, Naito Sijuku Gardeus, Tokiyo. I have myself had examined tea sent me by Mr. Gribble, and found it to contain moisture varying from 2 to 3½ per cent, and in the dry state, 5.73-5.8 per cent, ash or mineral matter. Eder in *Donglers polytechnisches Journal*, vol. 231, has reported upon 'yellow' or Japanese tea, so called because although it is nearly black in its dry state, it differs from true

black teas in becoming yellow coloured in hot water. He has found:—

Ash	5½
Tannin	13
Insoluble part	60
Water	10

The same analyst gives a summary of his examination of various teas, Chinese, Japanese, and Indian, of which the following is an abstract:—

Water	...	10
Soluble matters	...	30
Tannin	...	2
Theine	...	10
Tea-oil	...	0.6
Legumin (albumenoids)	...	12
Mineral	...	1.7
Other substances	...	3.7
Insoluble matters	...	60
Albumenoids	...	12
Wax	...	0.2
Resin	...	3
Cellulose	...	20
Mineral	...	4
Others	...	20.8

REMARKS ON THE COMPOSITION OF TEA.

Tables of chemical composition, such as those of tea, are generally for the most part unintelligible and therefore without interest to others than the initiated; and even to the latter, I may add, they are often indefinite and unsatisfactory from the contradictions, real or apparent, which occur in them. A few words in addition to those of Mr. Gribble, descriptive of the composition of tea and of the applications of our present knowledge of it, may perhaps be here acceptable. The desired effects of tea-drinking are almost certainly due to the hot-drink in the first place, and then to the tannin, the theine or caffeine, and the fragrant oil and resin in the tea. When, further, the entire tea is consumed, as in the use of *hiki-cha* in this country, tea also serves as common food. This use of tea as *food* may almost shock those keenly sensitive to the exquisite delicate flavour and the intellectualizing effects of a cup of choice tea, and it will therefore be noticed first, so as to get done with it. Attention then is called to the fact shown by the analysis by Eder and other chemists, that tea, with even as much as 10 per cent of water, contains about *one-quarter of its weight of albumenoids*, the so-called 'flesh-formers.' It is consequently of but little less value than beans. The nitrogen mentioned in Professor Kineh's analysis of Japanese tea is an important chemical element of these flesh-formers, being found in them to the extent of 16 per cent of their weight. Hence after deducting some nitrogen for theine, we can calculate from the remainder the amount of these albumenoids. *Nitrogen*, 3.4 per cent.—Mr. Kineh's analysis III.—indicating in the presence of 2 per cent of theine about 25 per cent albumenoids, is the usual quantity in tea cured for the foreign market. The much larger quantities of nitrogen in teas I. and II., cured by the Japanese method, are interesting and need chemical investigation. Now to notice the *water or moisture* mentioned as present in tea. When the tea comes hot from the firing operation it is without any water and, if at once packed in really air-tight cases, will remain so. Even by some exposure, as on keeping in common tins, it may remain a long time with only 2-4 per cent moisture absorbed, as my own analyses show. But analyses of tea in Europe have been published, giving as much as 16-17 per cent of water; and 10 per cent is regarded there as the normal content. Thus, it will be seen that every nine pounds of tea put up in Japan or China, will on retailing in the United States or Europe, run to ten pounds. The tea containing this water remains dry to the touch. Another point of interest attaching to this water, is that in its absence, the spores of *mould* and *mould* are inactive, while they at once find a congenial seat of growth when they fall in with tea containing a tolerable quantity of moisture, especially when the tea has been lightly fired as by the Japanese method only. With regard to the *theine*, and *volatile oil* and *resin*, it is certainly of interest to note that while these are very active physiological agents, and undoubtedly give to tea much of its esteemed qualities, the quantities of these

constituents—of the theine at least—have not been found to be at all in any direct relation to the recognized value or appreciation of the tea. Theine is also found in coffee, and as far as the possession of this substance is measured it may be said that one ounce of tea is equal to at least two ounces and a half of coffee. Two per cent is the usual proportion of theine in tea. *Tea-oil* does not exist in the fresh leaves of tea, but is developed by a species of fermentation after they are gathered. The *resin* appears to be the substance into which the oil changes by time. When this change is complete the tea has lost its aroma.

Tannin, so-called because it is that which when it occurs in oak-bark serves to tan skins in leather-making, is found to be a useful and pleasant component of tonic and refreshing draughts. It is to it that the roughness of the taste of tea is due. Many persons prefer to remove much of this roughness by the addition of milk, the albumenoids of which render the tannin insoluble and therefore tasteless. On the other hand, a pinch of soda, or of wood ashes in the water brings more of it and other matters out of the leaf, as most housekeepers have learned by experience, but only at the cost of the more delicate flavour of the tea. The amount of tannin is sufficiently constant in tea to be trusted by the chemist, when taken with other points, in detecting that form of spurious tea consisting of spent or once used leaves rolled and dried again for sale. Tannin from other sources is sometimes added to poor tea to give it a fictitious strength, an addition which also occupies the chemist's attention. Japanese tea yields about 13 per cent or *one-eighth of its weight of tannin*, a quantity a little higher than that of Chinese tea. Firing and fermentation seem to destroy tannin, so that in black teas less tannin is found than in green. In the analysis of Indian tea, taken by Mr. Gribble from the *Indian Tea Gazette*, it can be nothing else than a mistake to have made the tannin so much more than a quarter of the weight of the tea. Indian tea is, however, a little richer in tannin than Japanese tea, and would be more so if the cultivation of *Thea Assamica* had not largely or entirely been replaced by that of *T. Hybrid*. Indeed an extract of coarse Indian tea is prepared as a substitute for catechu.

The *resin* mentioned in Eder's analysis comes from the surface of the fresh leaves, where in a delicately thin layer it protects the living leaves from undue loss of moisture. The bruised leaf withers in consequence of the breaking of this coating. Of the *fat* mentioned in the analysis taken from the *Indian Gazette*, I know nothing. The *sugar* mentioned is not common sugar; it is in very small quantity only, and does not exist ready formed in the fresh leaf.

The *ash* or *mineral part* of tea remains to be noticed. Hitherto the use of the fertilizers has been but little practised with tea. Experiments in India do not appear to have had very promising results, although the effects of the use of these agents have been quite evident upon the crops of leaves got. Now any experiments in this direction can only be properly carried out under the guidance of a knowledge of the composition of the ash of tea. This ash has been repeatedly analysed, but in the present state of the matter, it would be probably of little use to reproduce the published results here. The ash of tea is slightly under 6 per cent of the tea, of which a little more than half is soluble in water when in the state of ash. In the tea itself less than a third of the mineral matter is soluble in its infusion, the rest remaining in the exhausted leaves, as will be seen on looking at Eder's general analysis. In determining the degree of adulteration of tea, the chemist depends largely upon these facts.

This ends the account of the constituents of tea. But a word should be said as to the use of the hot infusion, namely, that Europeans seem to be largely indebted to the Chinese and Japanese for a knowledge of the pleasure, if not advantage, of hot beverages, as such in hot weather as in cold.

It will be seen that tea leaves properly dressed and eaten form a nutritious diet! As to the colouring of teas, Dr. Diver shows that the quantity of colouring matter used by foreign merchants can do little, if any harm.

BOWEN'S REVOLVING TEA TOASTER—RE-FIRING TEA—CULTIVATION IN JAPAN—A NOVEL PROPOSAL—TEA FANS.

In connection with the above, we may notice an article headed "Japan Tea and Bowen's Revolving Tea Toaster." Mr. Bowen's account of the culture and manufacture of tea in Japan is almost entirely borrowed from Mr. Gribble's paper, but he is more detailed in his notice of the final firing in the foreign factories. The introduction of some disgusting and very improbable details of children carried by their mothers becoming sick amidst the tea, looks as if it was done to further Mr. Bowen's design of giving employment in America to a tea-toaster he has invented. As our readers are aware, no degree of heat to which tea can be safely exposed will succeed in dispelling all the moisture. About 5 per cent remains in the best fired teas, and to tea packed in hermetically closed boxes this percentage can do no harm. The harm is done, if people in America or Europe open the boxes and leave them open, so that the tea should imbibe further moisture and get spoiled or even mouldy. The teas imperfectly fired in Japanese houses or huts, however, contain an appreciable quantity of moisture, which is expelled in the final firing. Mr. Bowen's contention is that a revolution ought to take place in the tea trade of Japan, in order that employment may be given to a tea toaster which he has invented. He holds that the teas as fired by the Chinese middlemen, could safely bear the comparatively short voyage to America via San Francisco, and could, after arrival, be kept in the original packages, until taken out to be toasted as coffee is, when required. The quality of the tea, he believes, would thus be superior. An engineering authority, to whom we submitted the number of the *Indian Mercury* in which the article occurs, gave his opinion thus:—

I have read the article carefully, and am inclined to be very sceptical: (1) because the writer is cracking up his own machine and (2) because of the nonsense he writes in the paragraphs I have marked.

We suspect this will be the general feeling amongst experts. No doubt it might seem desirable to friends in America and Europe, that the final firing or toasting of tea should be relegated to them, but producers cannot be expected to see it, or to give up their belief that the very perfection of a manufacture is that the leaf when *picka battied*, as they say in India, and finally fired, as people say where "the English she is spoken," should be packed and soldered up when dry and hot. But we shall allow the ingenious American speak for himself. We ought to say that the *Indian Mercury* quotes Mr. Bowen's article from the *Grocer*. Mr. Bowen states that the mode of planting adopted resembles that pursued in Californian vineyards and that the separate circles of plants are better than the hedge system, inasmuch as an opportunity is thus given to more thoroughly fertilize and cultivate, which is conscientiously done. He states:—

In the third year of its growth the plant bears leaves ready for picking, and from its fifth to tenth year is considered at its best, although with proper cultivation from this time on it deteriorates but little. The shrub, for convenience of picking and for the strength and development of the new shoots, is kept trimmed to a height of three or four feet.

Mr. Bowen repeats Mr. Gribble's statement as to girls gathering $3\frac{1}{2}$ lb. per diem but "the tender leaves" follow, and that they gather a greater weight as the leaves develop in size. The wages for a day's work is said to be 124 cents of American money, which would be about 25 cents of a rupee. Twenty-five cents per diem for less than of a equivalent of a lb. of dried tea could never pay; so we suspect Mr. Bowen.

copied Mr. Gribble, and that the latter referred to lb. of dried tea. Mr. Bowen talks of a first crop in April or May; a second in June or July; and sometimes, with a favourable season and high prices, another crop is gathered still later on. It is clear that plucking flush is generally confined to the period extending from April to July. Bowen says distinctly that the first process after plucking is steaming. And now for Mr. Bowen's proposal:—

Before following the tea into the godown or warehouse of European exporter, I desire to call the reader's attention to the basis of the writer's idea in shipping thoroughly cured tea, and freshly firing or toasting (I use the word *toast* as being, perhaps, more generally expressive) it in America as soon preceding its actual consumption as possible.

The position, I assume, is that it is possible and practical to ship to America properly cured tea, direct from the plantation, free from all coloring matter, and in its natural state, and toast it as it is consumed.

In all my experiments I have met with only one expression of doubt, and that is that the "tea won't keep," but when showing samples that have been in stock *eighteen months*, and perfectly sound and sweet, the regulation reply has been, "I did not think it possible."

The climate of America is noted for its tea-keeping qualities, and with the ocean voyages reduced to fifteen or eighteen days, the risk is much less than when shipments were made by the Cape or Horn.

Unfortunately the manipulation of tea, unlike its active competitor, coffee, is but little known, but for the purpose of an illustration, I may compare them. Every child knows that coffee comes to America in what is commonly called the "green" state, and that before it can be used it must be toasted, or roasted; but how many children, or, for that matter, how many adults generally speaking, ever heard of tea being toasted?

Not one, I will venture, in a hundred! and yet, every pound of tea, that is or ever has been exported, has undergone this final toasting process before leaving these shores. It is acknowledged by all coffee drinkers that coffee, when used immediately after toasting, is better than it ever will be by subsequent keeping. This is identically so with tea.

But I am asked, what is the use of toasting tea? The best reply to that is by asking, what is the use of toasting coffee?

Whatever the chemical action of heat upon the combined or individual properties of tea or coffee may be, one fact remains fixed, and that is for centuries no other treatment has been devised that will develop the body, bouquet and flavor as the toast does.

Naturally, then, if our tea is treated one day or one week before using, it will possess more flavor, aroma and "snap" than if bought as it is now, with the toast from six months to three years old.

To carefully toast tea by what is known as the basket system, without having skilled labor, is the problem the writer after three years of experimenting in Japan claims to have deciphered in the completion of what is known as "Bowen's Patent Automatic Tea Firing." This machine consists of a cast iron box, dividing into three equal sized compartments, over and partially in which on suitable journals, revolve three nickel-plated wire baskets. The baskets are revolved by an endless screw, which is propelled by a small ingenious water wheel of recent design. On one end of each basket is fastened another screw of corresponding thread, which meshes into the driving screw, and this is connected by a light running rubber belt to the driving wheel of the water motors. These motors are very simple, and screw on to the same sized nut as an ordinary garden hose, and therefore do not require any expensive pipe connections. By the arrangement of the screw, the baskets work entirely independent of each other, thus enabling a person to toast at one time three separate grades of tea. Under each basket is placed a pan of fine charcoal after the smoke and gas have been burnt off. This furnishes the necessary peculiar steady heat, which in about twenty minutes will give the tea a most even and thorough, quick toast. At this moment your tea is at it

best, and like coffee, the sooner thereafter it is consumed, the more delicious it is.

The machine is in working order on tea that has been expressly cured for it this season, and to those who may be interested, a practical demonstration will at any time gladly be made.

That is Mr. Bowen's scheme, and, if it has real merit to recommend it, we ought to hear of further progress. Mr. Bowen gives a full account of the firing process in the foreign godowns, from which we gather that the pans employed are not copper, as we imagined pans for preparing tea always were, but cast-iron. They are described as thin and about 2 feet in diameter and 13 inches in depth. Many godowns contain 500, 700, or even 1,000 such pans, two persons operating on each. We need not quote disgusting details thrown in as regards perspiration, &c. Mr. Bowen concludes thus:—

As soon as the tea is sufficiently toasted, it is immediately packed in lead lined chests or jars and shipped on its journey, with the hope that the toast may remain till it is opened.

Of course, the inference desired to be conveyed is that the toast will not remain, and that Bowen's toaster ought always to be brought into requisition. Purchasers and consumers may be left to settle that point. In any case our properly rolled and fermented teas, will not need re-firing in the consuming country.

THE CHINA TEA TRADE:

(From the *North-China Herald*, June 5th.)

THE DISPUTE IN THE TEA MARKET AT FOOCHOW.

The disputed matters between the foreign buyers and the teamen in Foochow remain unsettled, and the market has consequently not yet been opened. The Chinese case was stated in the document presented by the Tea Guild to the English Consul, which we published some days ago. The English Consul, in a manner which ought to be fully reprobated by his superiors, intimated his intention of adopting the rules propounded by the Chinese, and of guiding his opinion by them in any case that might be brought before him judicially. He did not wait to learn whether his countrymen had anything to urge against the demands of the Chinese, but, with that indiscretion which has often marked his official proceedings, at once ranged himself on the side of the natives. The Chinese Guild complains of the "cuts" which have often been made in the weights of teas. These seem to be pretty much the same as, but on a smaller scale than the malpractices we exposed in the Hankow trade about two years ago. They are the growth of an unhealthy competition on the part of foreigners, and have no doubt been encouraged by the desire of native dealers and brokers to sell their teas at nominally high prices. The Guild required that a certain scale of allowances should be adopted, and the Chamber of Commerce has proposed another more favourable to buyers. The dispute as to the allowances resembles that which occurred here in 1880, and which was settled by a compromise which has worked satisfactorily. Now that both sides have fully expressed their views we have little doubt that a similar compromise will be adopted by the trade in Foochow. Practically it does not matter in the long run on what conditions the tea trade is carried on, if these are faithfully observed. But there is great reason to fear that the Chinese dealers have no intention of considering themselves bound to apply the rules of the Guild to their dealings under all circumstances and to all people. No security that the rules will be adhered to by the Chinese is offered by the Guild, and foreigners cannot trust them to resist the temptation of selling contrary to the rules, and thus in an underhand way injuring the fair dealer who adhered to the regulations approved

by the Chamber of Commerce. This is so obvious that the Chamber of Commerce, in the resolutions adopted by them, require that a substantial guarantee or an approved security be given to their Committee that the tea hong's will adhere to the rules which they proposed. And for what the Tea Guild says about the long credit taken by foreigners, that is a peculiarly Chinese way of stating matters. Long credit has more or less a characteristic of the trade since the opening of the port, and was introduced by the first Cantonese teamen who established themselves there. These men were wealthy, but they and their wealth have given way to a new and by no means rich class.

The tea trade at Foochow has been for a long time conducted generally on peculiar principles. The Chinese dealers were mostly wealthy Cantonese who did everything they could to encourage speculation on the part of foreigners. Long credit was given; sometimes the teas or at all events a portion of their value was not paid for until they had been sold in London and returns received back. This accommodation was paid for by considerably higher prices being given for the teas than prudent shippers offered. Thus the market was sustained in Foochow above its proper level, to the detriment of the general body of foreign traders. The teamen ran some risk by this kind of business, but on the other hand they secured higher prices for the bulk of the crops than they would otherwise have done. From time to time they made severe losses, but it may be inferred from the style of business having continued so long, that, upon the whole, it was profitable to the Chinese. In other cases foreigners did not pay for the teas they purchased until it suited them to sell their exchange, which might be weeks, or even months, after the teas sailed for England. Sometimes foreigners kept running accounts with the teamen, to which payments were made from time to time, and a settlement nominally made once a year. At no other port in China were such facilities for reckless speculation offered by the Chinese. This system of credit-business was probably introduced when the port was first opened some forty years ago, and was no doubt the same as that on which the tea trade had been conducted at Canton from the time when the East India Company closed its factories. The Cantonese teamen had always a strongly speculative element in them. They liked to do things on a great scale, and they ran considerable risks in order to make large profits; and under the régime of the East India Company they could only try to get these by demanding high prices. They could not increase their gains by giving credit, as the Company paid cash at once. But as soon as an opportunity presented itself the Cantonese availed themselves of it, and more than seventy years ago several of the Hong merchants impoverished themselves by giving long credit to American merchants, who were thereby induced to overstock the New York market. Teas, we are told, fell in prices there to much below the actual cost of such teas in Canton, and the Continental markets, from which a large part of the teas used in England were then obtained by smuggling, were also seriously depressed. It would appear that the shippers who thus obtained credit in Canton were, at least in many cases, unable to make good the losses, and, the Hong merchants having been trading on borrowed capital, some of them were brought to ruin, and the remainder more or less embarrassed. Again we find the same thing occurring in Canton some thirty years ago, when an American firm failed owing large sums of money to the teamen, and a few years later an English house suspended payment here, to which large credit had been given by the Chinese. In this latter case, the only one of any consequence which has occurred here, the teamen had given credit in the Canton way, but they did

not bear their losses with the equanimity which has often characterized their brethren in the south under similar circumstances. Readers of Laurence Oliphant's account of Lord Elgin's mission will remember how the natives here persecuted the foreign merchant to whom they had given the most lavish credit. Since that time there have been some instances in Foochow in which the teamen have made serious losses, but they are not entitled to claim sympathy for these, or to make them reasons for bringing charges against foreign merchants, as they catered on a dangerous business with their eyes open, and ran considerable risk for the sake of a larger nominal gain than they could have obtained from selling their teas to responsible firms. The sooner this sort of business is put an end to the better for all parties. It was never a healthy one, and the rapidity with which business is carried on nowadays has probably increased its dangers. We believe the system of giving long credit to foreign buyers is now almost confined to Foochow; at all events there is nothing of the kind in the northern tea markets. Had there been, the bad condition of the trade in late years would undoubtedly have been even worse than has unfortunately been the case.

FOOCHOW.

THE DISPUTE IN THE TEA TRADE.

At the annual general meeting of the Chamber of Commerce held on the 20th May, the following resolution was unanimously adopted:—

1.—That the following regulations be made for the payment for teas.

(a).—In all cases payment to be made within seven days after the examination of the teas by the Custom House.

(b).—A discount of 1% (one per cent) to be allowed on all such payments.

(c).—No discount to be allowed on teas not shipped off or not paid for within one month of date of purchase.

2.—For the regulation of weights.

(a).—The turn of the scale and fractions of a lb. to be in favour of buyer.

(b).—With the following allowances;

Per Chest of Congou	3 lb. each.
" Half-chest Congou	2 "
" Box of all descriptions of tea	$\frac{1}{2}$ "
" Half-chest Oolong	1 "
" Chest Flowery Pekoe	2 "

Note.—Boxes to be weighed one at a time. No contract need be accepted when boxes are over 27 lb. gross and no allowance will be made for any excess.

(c). Notice to be given of the time for weighing teas, which can be shipped off, if a complaint is made, at once. If the teamen or his representative does not attend at the weighing, no complaint will be entertained.

A substantial guarantee or an approved security be handed to the Committee of the Chamber of Commerce that the various tea hong on their side will adhere to the above rules.

JOHN ODELL, Chairman.

20th May.

THE TEA DISPUTE AT FOOCHOW.

Foochow, June 8th.—The dispute with the teamen still continues. On the 4th, a special general meeting of the Chamber of Commerce was held at the Club, when the following memorandum from the Tea Guild's Committee was presented for consideration:—

CONGOU.—Two half chests of Congou or Souchong to be weighed together. Teas to be weighed exactly and fractions not up to half-pound to be in favour of buyers.

TARING.—Half-chests to be tared singly. The

fractions not up to a quarter pound shall be calculated as a quarter pound and to be in favour of buyers. An allowance of 2 lb. per half-chest in the case of Congou; 2 lb. per half-chest in Souchong, and 3 lb. per chest to be made.

BOXES.—Boxes to be weighed exactly in two together at a time (sic). Fractions not up to half a pound to be in favour of buyers.

TARING.—Each box to be weighed at a time (sic). Fractions not up to a quarter pound to be in favour of buyers. No other allowance to be made besides this.

OOLONGS.—Two half-chests of Oolong to be weighed together. Half-chests to be tared singly. An allowance of 1 lb. per half-chest (Oolong) to be made.

FLOWERY PEKOE.—In Flowery Pekoes an allowance of 1 lb. per chest to be made.

Teas must be weighed within a fortnight of date of purchase. Teas must be paid for within seven days of their being examined by the Custom House. In all cases they must be paid for within 6 weeks of date of purchase, whether the teas be shipped or not.

A properly adjusted scale to be kept at one of the foreign tea hong, so that any dispute in weight may be compared by it.

In case of infringement of the foregoing terms on the part of foreign buyers their masters to be at once stopped, and in the meantime no business will be done with them. In case of infringement on the part of tea-men, a fine of 1,000 taels to be imposed by the Tea Guild, and as a guarantee of good faith a signed document to be lodged at the British Consulate stating that the above fine will be paid by any teamen so offending.

Further, a memo. of weights in all cases will be at once sent to the tea hong concerned, and the same may be shipped when no error is detected; furthermore, that in the absence of an answer from the tea hong they cannot be shipped under plea of quick despatch, as also allowances shall be deducted out of the weights mentioned in said memo.—Foochow, 2nd June 1885.

As compared with the rules originally put forward by the Tea Guild, this document shows a considerable diminution in their demands. The allowances of weight are increased so as to correspond, excepting in the case of flowery pekoe, with the resolution of the Chamber of Commerce. The period within which payment must in all cases be made is extended from four to six weeks. The guarantee demanded by the Chamber is also provided for. But the points at issue remain numerous and important. A fixed time for payment, irrespective of the examination of teas by the Custom House, is still demanded. Only $\frac{1}{2}$ lb. instead of 1 lb. is conceded for the turn of the scale. Boxes and half-chests are to be weighed two at a time, thus lessening the allowances for fractions of weight. And the buyer is still left to wait the convenience of the teamen as to the time for making complaints about the weighing.

The meeting adjourned till next day in order that the memorandum might be printed and circulated among the members of the Chamber of Commerce. At the adjourned meeting, further proposals were presented to maintaining the necessity of the rule that the turn of the scale and fractions of a lb. are to be in favor of the buyer, and generally the adoption of the Chamber's motion as to the regulation of weights, but passing over the claim for discount of one per cent. The teamen, however after much discussion with the committee appointed to treat with them, found themselves unable to accept the proposal and so things continue at a deadlock. Many people, however, express confidence in the acceptance of the proposals of the Chamber by the teamen within a short period.

The claim of the foreign buyer to have given in his favor all fractions of a lb. is necessitated by the custom

of the London market and should be agreed to. The reason for weighing boxes singly I have explained in my last. As to the disputes about weight, the propositions of both sides might be slightly modified. The foreign merchant can hardly consent to wait an indefinite time for a reply from the teaman and so possibly lose a chance of shipping his teas, while it may be seriously inconvenient to the teaman to 'at once' compare the weights and forthwith send in his protest. Perhaps the best course for the Chinese would be to appoint a special agent or agents to be present at the weighing of all teas, and to make protest on their behalf, if necessary.—*China Mail.*

The controversy between the Foreign and Chinese Tea Merchants has been finally settled between themselves, and the revised propositions made by the Chinese Tea Merchants' Association have been accepted by the Foochow General Chamber of Commerce. The following is a copy of them:—

REGULATIONS

FOR THE CONDUCT OF THE TEA TRADE AT FOOCHOW, SUBMITTED BY THE CHINESE TEA MERCHANTS' ASSOCIATION COMMONLY CALLED THE TEA GUILD.

1.—Teas to be paid for within 7 days of their being examined by Custom House.

Teas to be weighed within 14 days of contract, unless special arrangement to the contrary be made and stated on the contract.

In all cases Teas to be paid for within 7 weeks of date of contract.

2.—For the regulation of weights.

(a)—The exact scale, and fractions of $\frac{1}{2}$ lb. to be in favour of buyer.

(b)—With the following allowances, viz:—

Per chest of Congou	3 lb. each.
Per half-chest of Congou	2 lb. "
Per chest of Souehong	2½ lb. "
Per half-chest of Souehong	1½ lb. "
Per box of all descriptions	0½ lb. "
Per half-chest Oolong	1 lb. "
Per chest Flowery Pekos	1½ lb. "

TARIFF.

All packages to be tared singly. Fraction of $\frac{1}{2}$ lb. to be in favour of buyer.

All packages to be weighed one at a time. No contract need be accepted when boxes are over 27 lb. gross, and no allowance will be made for any excess.

(c)—Memo. of weight to be at once given, and the teas can be shipped off if no complaint be made within 3 hours after receipt of such notice.

NOTE.—In order to avoid any misunderstanding in the matter an example is subjoined of what is considered a fair method of weighing, viz:—

If the gross weight of half-chest is, say,

71½ lb. it shall be called	71 lb.
71¼ lb. " " " " " " " " " "	71½ lb.
71¼ lb. " " " " " " " " " "	71¾ lb.
72 lb. " " " " " " " " " "	72 lb.

TARIFF.

If the half-chest weighs

15 lb. it shall be called	15 lb.
15¼ lb. " " " " " " " " " "	15½ lb.
15¼ lb. " " " " " " " " " "	16 lb.
16 lb. " " " " " " " " " "	16 lb.

If the gross weight of the boxes be more than

27 lb. it shall be called	27 lb.
26¾ lb. " " " " " " " " " "	27½ lb.
26¾ lb. " " " " " " " " " "	26¾ lb.
26¾ lb. " " " " " " " " " "	26 lb.

TARIFF.

If the boxes weigh

7½ lb. each they shall be called	7½ lb.
7¼ lb. " " " " " " " " " "	7¼ lb.
6¾ lb. " " " " " " " " " "	7 lb.
7 lb. " " " " " " " " " "	7 lb.

Foochow, 13th June, 1885.

Foochow, 19th June.—An agreement was come to between the foreign tea merchants and the Chinese

tea-men on the 12th; and, the document having been signed by all the foreign firms, musters were sent in at the beginning of the week. We are now looking forward to the opening of the market in another ten days or so. This final agreement is to the following effect:—Teas are to be paid for within a week after examination by the Custom House. Teas are to be weighed within fourteen days after the contract is made, in the absence of special arrangements entered in the contract. Payment is in all cases to be made within seven weeks from the date of the contract.

As to weights, fractions of $\frac{1}{2}$ a pound are to be in favour of the buyers; with the following allowances, viz:—

Per chest of Congou	3 lb. each
" half-chest " " " " " " " "	2 lb. "
" chest of Souehong,	2½ lb. "
" half-chest " " " " " " " "	1½ lb. "
" boxes of all descriptions,	½ lb. "
" half-chest of Oolong,	1 lb. "
" chest of Flowery Pekos,	1½ lb. "

All packages are to be tared singly, the fractions of $\frac{1}{2}$ lb. being in favour of the buyer.

All packages are to be weighed one at a time.

Notice is to be given of the time of weighing and any complaint must be made within three hours, otherwise the tea can be shipped off.

The above terms, when compared with the rules originally put forward by the Tea Guild, shew an extension in the time for payment from 4 weeks after contract to 7 weeks; the allowances granted are to be weighed singly. As compared with the unanimous resolution passed by the Chamber of Commerce, the chief concessions to the teamen are no claim for discount, fractions of $\frac{1}{2}$ lb. instead of 1 lb. to be in favour of the buyer, and a slight diminution in the allowances made. A fixed time for making complaint as to weight is laid down and the teaman is not required to be present at the weighing.

Possibly the offer of the above terms made by the Guild was accelerated by the discontent of the smaller Chinese tea-hongs, shewn in a placard full of virulent abuse of the richest compradores, which was posted on the walls on Saturday.

Foochow, 19th June.—The dispute between the Teamen and Foreign Merchants has at last been satisfactorily settled, and seemingly in a way fair to both parties.

The origin of the dispute arose from a circular issued by Tea Guild, in which they asked or insisted that business this season should be carried on terms which were a little too much for the "haughty Foreigner," so the reply was a counter demand very much against the "poor ill-used Native Trader."

The real cause of the whole thing was this. Several firms who annually purchase a great quantity of tea had taken advantage of the old style of doing business to weigh in a manner so as to give them a clear gain of 4, 5, and even 6 per cent. in weight, and at this the Chinese winked, as it kept up the nominal price of the article. For instance, a small buyer wishing to have a chop or two, just to look in, finds the price of Panyongs Tls. 14; and after bidding Tls. 13, Tls. 13½, and Tls. 13¾ in vain, sees them all slipping away at a reported price of Tls. 14, and so gives that price, thus paying unwittingly 4, 5, or 6 per cent. more than his neighbour. At last this came out and everyone in his own defence merrily bumped the scale so at last to claim the attention of honest John Chinaman.

The new system of weights is calculated to put all on the same footing and to save the loss in weight on shipments to London, calculated in the old tables at 3 per cent, and caused by the manner

in which teas are weighed by the Customs in London and the allowance of 1lb. draft per package to the trade.

The present agreement has not been arrived at without considerable opposition from native (i. e. Fokien) teamen, and the walls of the Canton Joss House were for a day or two embellished with some of the choicest abuse the Chinese language allows of, some epithets being quite original and ingenious and well worthy of the attention of any of our anglers who are compiling a Chinese slang dictionary.

Our tea market was opened yesterday, and prices seem to suit the weather, as they are passing sales. —*Hongkong Daily Press.*

**INSECT PESTS AND INSECTIVOROUS BIRDS :
A WILD BIRDS PROTECTION ORDINANCE WANTED IN
CEYLON.**

We commend Mr. A. Whyte's letter (page 93) to the attention of all connected with gardens or plantations. The statistics given as to the insect-destroying powers of even a few birds are marvellous. As faras cacao is concerned, we should think insectivorous birds would do well, if properly provided for and conserved, up to the limit of the zone in which the plant grows, and a very large proportion of the tea culture of Ceylon will be in this same zone, from sea-level to 2,000 or, at the utmost, 3,000 feet.

The difficulty will be with tea grown above 3,000 feet, for nothing is more striking than the paucity of bird-life as higher and higher elevations are attained in Ceylon, the substitution of plantations for the original forest having seemingly banished a large proportion even of the birds whose habitat is in the elevated regions. No doubt, something could be done by growing groves of trees around bungalows and elsewhere on estates, but, unless abundance of *Holoptelis* (which we all deprecate) attracted insectivorous birds, we scarcely see how they are to exist in any numbers on hill and mountain properties. When first cinchona officials seeded, numbers of small birds came to the trees, but evidently the seed was not acceptable as food, for the birds gradually disappeared. Still, around Nuwara Eliya where the forest is untouched, the birds continue plentiful. Perhaps some of our planter-friends may have experienced to record or suggestions to offer.

"The Need for a Wild Birds' Protection Act for India" was the subject of a paper read before the East India Association by Mr. Robert H. Elliot ("the Mysore Planter") about a year ago. We quote a few passages in order to strengthen our position in calling for some legislation in Ceylon. The paper, in its entirety, now in our possession, will be at the service of the Government or any legislator who may wish to take up the subject during the session of Council. Mr. Elliot mentioned, among other insectivorous birds that ought to be protected, the following:—

The Jay, Kingfisher, many kinds of Woodpeckers, Thrushes, and Titmice. All these are sought in India for their plumage, and there can be no doubt of their use as insect-eaters. The value of such birds to the planter and the agriculturist has been fully recognized by the Government of Madras, which, some years ago, applied to the Supreme Government for a Preservation Act. After a long delay, there descended from Simla a single sentence, declaring that the Viceroy in Council was not prepared to legislate in order "to prevent the indiscriminate destruction of wild birds for the sake of their plumage." In the case of Mysore, I am happy to say, we have been more fortunate. The Planters' Association of that State lately asked for an Act. A petition was also signed by native farmers and coffee-garden owners who, I need hardly say,

are fully aware of the value of birds. The Prime Minister promptly requested the planters to submit a measure for consideration, and we hope, before long, to have our beautiful and valuable birds efficiently protected.

About the way in which destruction is proceeding, we read:—

As the most convenient season for the destruction of birds is during the fine weather that succeeds the heavy rains of the monsoons, and as this season is also the breeding season, the destruction of birds proceeds at such a rate as must soon lead to almost absolute extermination, unless preservative measures are immediately adopted. And the rapid progress towards extermination is clearly shown by last year's export returns from the port of Madras.

I have obtained the following return, which exhibits the shipments from the port of Madras alone:—

Birds' Feathers.		Birds' Skins.	
Quantity.	Value.	Quantity.	Value.
1881...122,175	16,625	82,400	18,880
1882...105,513	19,950	98,300	20,553
1883...167,750	20,960	11,275	1,760

As most of these exports go to Hongkong and Singapore it is fair to conclude that Asia East of India has already become exhausted of bright-plumaged birds. It would be interesting to ascertain the exports from the numerous ports on the Western side of India, which, from the quantity of woodland towards the West, probably far exceed the exports from Madras.

That birds can be very rapidly exterminated we know from experience in other countries. From Bogota in South America, large supplies of skins and feathers once come. Now none come. The Quetzal, or Trogon of Guatemala, has been exterminated in the districts where once it was common, and is now only to be found from three to four hundred miles inland. My own experience too has shown me how rapidly the process of extermination proceeds. In 1879, when I visited my plantations in Mysore, bright-plumaged birds were numerous. When I returned in 1881 their numbers had perceptibly diminished. Towards the close of last year, when I again visited my estates, the decrease of birds was so marked, that I instituted inquiries, and soon found the cause, which I had not previously suspected, and you will not wonder at their rapid diminution when I tell you that, quite early in a recent season, a single bird-catcher in my district had secured four hundred skins.

Mr. Elliot goes further than prevention:—

To promote the increase of birds, and spread them throughout the length and breadth of the land, is not less important than to prevent their destruction, and in order to effect this, plantations should be formed on the waste lands of every village. Such plantations would at once shelter the birds, provide fuel (to the saving of the manure now used for that purpose), wood for building and agricultural purposes, shelter for grass and crops, promote the conservation of water and effect a general amelioration of the climate.

Finally, let me remark on the need for establishing a close-time for the protection of game-birds. Every civilized Government preserves them, with the exception of that of India, which, with two unimportant exceptions, allows them to be destroyed in any way, and at any season of the year. To act thus, is of course, simply to extinguish a valuable source of food. The almost absolute extermination of game-birds, (which live largely on insects, it may be observed) has already been accomplished in many parts of India. As to the rapidity of this extermination, I can myself bear witness, as Pea-Fowl, Jungle-Fowl, Spur-Fowl and the Imperial Pigeon, have been almost exterminated along the Western districts of Mysore. When last in India, I saw during a three months' visit one specimen of the Imperial Pigeon, which I regarded as a curiosity. The shrill call of the Jungle-Cock, once such a familiar sound, is no longer to be heard, and the extermination of this bird has been accomplished with a completeness I could never have credited had I not had ample opportunities of observing the fact.

In conclusion, permit me to point out that legislation as between man and nature is of far more urgent importance than as between man and man, because, whatever the laws may be which affect our relations with

each other, there is an accommodating power always at work which answers fairly well for the existing needs and circumstances of the times, and which largely modifies the worst evils that society is liable to suffer from.

While man is always represented in some form or other, and while, therefore, in his case, legislation may for long be delayed, nature, being unrepresented, ever needs the vigilance and timely action of the legislator. Prompt attention, then, is needed in order to extend throughout the length and breadth of India those woods which are necessary for the use of man, and birds and the amelioration of the climate. Not less attention is required to preserve and promote the increase of those birds which so largely aid in preventing an injurious increase of insect-life. Let us, then, do what we can to represent the cause of nature, and endeavour, on behalf of the beautiful and useful wild birds of India, to bring about a measure for the restoration and preservation, of that balance of nature which has been, and is now being, so grievously injured by the negligence of the Indian Government.

We trust Mr. Elliot's eloquent words will move the Ceylon Government to follow the example of that of Mysore: a copy of the Act passed there can easily be procured. We may mention that although the export trade in birds' feathers and skins from Ceylon is not so extensive as that from Madras, still it is large enough as the following figures show, to indicate a very considerable destruction of birds for the sake of their plumage:—

BIRDS' FEATHERS EXPORTED FROM CEYLON TO BRITISH INDIA AND STRAITS SETTLEMENTS.

Value...	1884.	1883.	1882.	1881.	1880.
	Rl,034	3,350	4,255	5,160	4,912

We cannot tell the value of birds' skins exported, because in our Customs accounts there is but the one heading "Skins of sorts" for the skins of all animals. But the above figures are sufficient to show that a large annual destruction of birds for their plumage takes place in Ceylon and to justify the call, at this time, for a "WILD BIRDS PROTECTION ORDINANCE." The object is one peculiarly within the scope of our Planters' Associations; but perhaps before they move, our present Acting Colonial Secretary may fortify himself with the Mysore Act and issue circulars for information to the Government Agents.

PROGRESS OF PERAK AND MALACCA.

The report for 1885 of Mr. Swettenham, the Acting Resident of Perak, is noticed in the *Straits Times*, and we learn that

while ten years ago, in 1874, the revenue was only \$226,233, against an expenditure of \$256,831, the deficiencies doubtless being made up by loans from this Government, the revenue has risen steadily year by year, until in 1884 it reached \$1,532,497, against an expenditure of \$1,481,470. During these ten years, the State has entirely cleared itself of debt, including the loans from the Colony's Treasury and the whole of the war debt, so that its finances are now in a thoroughly sound condition—having a credit balance of \$310,000; and Mr. Swettenham advocates the abolition of some unimportant but annoying taxes which are regarded rather in the nature of a poll-tax.

The chief source of revenue of the State is the tin mining industry, and in spite of the low price ruling for this metal, inducing the Government to reduce the royalty from \$12 to \$10 per buhar in Larut and to \$9 in Selama district, the output was larger than ever and the customs receipts exceeded the estimates by nearly \$75,000, being \$4,000 more than in 1883. Some of the tin deposits, however, are almost worked out, so the Government are opening up the country by means of roads, the most important being that now under construction from Kwala Kangea to Ulu Bernam to meet the road recently made by the Selangor Government.

This, Mr. Swettenham says, will be the main trunk road of the State, and when completed "there will be an uninterrupted highway from Malacca to Province Wellesley, i.e., a distance of about 365 miles from Malacca town to Butterworth."

This road, however, it seems,

is not to be a metalled cart road, which the State could not now afford,—but a first-class bridle road, graded to nothing steeper than 1 in 20, and any section of it can be altered into a cart-road as the necessity arises. The Perak portion of this road is about 150 miles in length, and passes over the Meru range at a height of 1,300 feet, but there are two branch roads, one 24 miles, and the other 50 miles in length, already under construction and forming part of this scheme.

The railway from Port Weld has been completed since Mr. Swettenham's report was published.

The Port Weld wharf, has proved a white elephant to the State, and though \$20,000 were placed on the estimates for dredging, piling, and building the wharf, and \$100,000 for the railway, the wharf swallowed \$34,800 and the railway \$168,000. The railway alone, with rolling-stock, was estimated by the State Engineer to cost about £8,000 per mile, or, as it is only 8 miles long, \$357,000 for the whole. The work on the wharf at Port Weld has been stopped, as the original plan is not likely to succeed. Temporary landing stages were therefore being erected, and the Hon. Major McCallum had reported on the work and prepared detailed plans and estimates, but Mr. Swettenham has no idea what the cost of completing the wharf will be; and probably the original scheme will never be carried out.

A commencement has been made with the surveying and mapping of the State, and it is to be hoped this will be carried to completion. Chinese immigration has fallen off greatly, owing no doubt to the low price of tin. Mr. Swettenham gives his opinion on the subject of European tin-mining companies, and thinks that the Rev. Mr. Tenison-Woods was rather premature in stating that Europeans cannot make tin-mining in Perak a success. He says:—

The advice I would offer to European miners is *festina lente*, and reduce as far as possible the risk, whether as to nature of ground or amount of money sunk in the venture. If the investment of a small capital proves successful operations can gradually be extended; if it fail, there is a possibility of withdrawal without much loss. Companies, however, do not usually care to prove the ground by a small expenditure and one pump, and it is only operations on a very large scale indeed, something I fancy as yet untired and for which the character of the Malay tin deposits may be unsuited, that can support a numerous highly-paid European staff and a quantity of powerful machinery and still show a fair margin for dividends.

Mr. Swettenham concludes his report by contrasting the state of Perak as it was when he first visited it more than eleven years ago, narrowly escaping sharing the fate of Mr. Birch, with its present condition.

The *Straits Times* also notices the administration report of the Resident Councillor of Malacca (Hon. D. F. A. Hervey) for 1884, from which we learn that the revenue for last year was \$35,000 less than the expenditure, but was \$2,000 over the 1883 revenue, so that it is hoped that ere long there will be a balance to the good. We read that

The tapioea planting has been to a great extent given up owing to the great fall in price of the manufactured article but the extension of frontier roads, and the opening of roads through the assistance of this Government in the Native States, must eventually tend to make Malacca an important and prosperous country. The Report states that

There is plenty of tin near Kuala Pilah and also in Gemenech, and it is to be hoped that the opening up of communications will be the means of attracting capital to work it.

Tin-working has already been taken up in two places in Rembau.

There is plenty of fine hill country in Johol, Rembau, Sri Menanti, and Jelai, which it would be worth planters' while to inspect.

On this our Straits contemporary remarks:—

Now, the fact that the people of Rembau have allowed minerals to be worked in their territory, against which they are said to have entertained a superstitious dread, shows the advantage that will be derived from closer and easier communication with the more prosperous coast states. The working of tin is the direct result of the opening up of the country by roads, which must also give an impetus to agriculture and by affording ready outlets for the products. As to Malacca itself, Mr. Hervey concludes by hinting at the possible production of tea, coffee, and sugarcane, and remarks that if all the available padi land in the Settlement were taken up, and cultivated as the Chinese know how to do it, Malacca might be the granary of the Straits. He says nothing, however, about the difficulty of export, owing to the shoal state of Malacca harbour and the want of facilities for shipping grain, and it is to be feared that unless these are improved the produce of Malacca and of the adjoining states will find readier outlets by the Muar river or by way of Sungai Ujong, and that the neglect that has been shown by Government of the interests of the ancient and interesting Settlement will unless speedily remedied eventually hasten its decadence.

PLANTING IN CEYLON AND SOUTHERN INDIA.

(Notes by "Aberdonensis.")

CEYLON AND SOUTHERN INDIA COMPARED—CHANGES IN CEYLON—TEA 'S THE WORD—CEYLON A FRUIT-BEARING AS WELL AS LEAF-BEARING COUNTRY—THE CEYLON GM AND THE MYSORE MAN ON WEEDS—COST OF WEEDING IN MYSORE—SHADE—LEAF-DISEASE A RESULT RATHER THAN A CAUSE—ASSAM PROPHETS OF EVIL ON TEA IN CEYLON—HELOPELITIS—A WARNING—COFFEE IN CEYLON AND SOUTHERN INDIA—PROFITS FROM CARDAMOMS IN CEYLON—CARDAMOMS IN MYSORE.

A most interesting time is before me. A few months' holiday has afforded me the opportunity of confirming comparisons already noted and considered between Ceylon and Southern India. Before saying anything further, I wish to emphatically assert that as there are intelligent Britons in both countries all striving after the main chance, spending their lives in closely studying the characteristics of the climate and requirements of the plant from which they hope to make a competency,—I say it follows that it would be dogmatic and unfair to institute close comparisons which are proverbially odious. At the same time it is interesting to compare the two countries in a harmless way, and so I make use of some spare leisure in writing down my humble ideas.

In three years there have been great changes in Ceylon. The talk everywhere is tea. In bungalows, in hotels, in railway carriages—everywhere the talk is about tea. I can't say I am interested. I have seen great talk about many things, but lasting results have not been so apparent. When I go farther upcountry tea may impress me, but I am sceptical, and I resist "gush" as far as I can.

Ceylon may be, and is, a leaf-growing country, but it is eminently a fruit-bearing country too. Fruit, being the result of reproductive efforts of the plant of course differs in its effects on that plants from leaves which support its life. "Magnesia and silicic acid are the principal conditions for the formation of roots and leaves" (Liebig) and are favourable for the cultivation of tea and weeds. Weeds rob the soil of potash, but promote nitrification and so on. These facts are applicable to cereals more than to fruit-trees. Now for a local application. The Ceylon man's first dogma is: "Ceylon soil being too poor to grow both weeds and a particular product, the weeds must be kept down as cheaply as possible. We have arrived at the nearest point of perfection in working out this principle." And the Ceylon man shoves his hands into his

pockets and looks as if he wished to hear no more on the subject. Very well. Now the Mysore man says: "We like weeds: they save wash in the monsoon, they continually furnish a ready substance to dig into our soil, they do not get much beyond control because we have shade, and they sweeten and nitrify the soil." I needn't enlarge on the Ceylon system, which is known to your readers. I may merely state that a weedy estate is a blot on a man's escutcheon in Ceylon, a stain on his fame as a planter. How do they then combat with weeds in Mysore save at a ruinous cost? Well, I would like first to ask would a V. A. or Colombo agent allow you to charge the eradication of weeds as *digging* if *digging* were the process? or what would you call renovation—pitting and top-dressing the soil with the earth out of the hole? You would n't charge it to *weeding*? All right." Then Mysore weeding beats you as regards cost. A dry-digging at the commencement of four months drought is pretty rough on weeds for some time, you'll admit; and, besides the renovation-pits, the sickle is used to mow down all weedy growth in the rains, the stubble of which forms a splendid protection against wash. Add to this the effect of digging in every year a great deal of green vegetable matter, and you will see the system is not altogether "happy-go-lucky," or "rule-of-thumb." But before we can be on even ground on the subject of weeds we must look at *shade*. It is no use to roll scientific jaw-breakers on our tongue and say that *Hemelia vastatrix* ruined coffee therefore coffee should be given up; that *Helopeltis Antonii* has played havoc with cacao therefore away with cacao. I once very foolishly tried to break a lance with "W." and I see my folly, I think, now. I now agree with him that leaf-disease is a result rather than a cause, and I include *helopeltis* and borer in the same category. If you outrage nature a punishment is sure to come. Is there a punishment in store for the forlorn hope tea? Now shade has been proved in India to be a specific against borer. Twenty-five years have clearly proved this: I find cacao planters acknowledge this to be true with regard to *helopeltis*. Too thick shade may be modified, but once removed it is hard to re-establish it. This question applies perfectly to the districts where cacao has flourished. But higher up men of experience say they want all the sun they can get. It is truly to be hoped that the Ceylon men have found a door of hope now in tea. Assam men ask: "How long will it last? You can't have flushes all the year round. No plant will stand it. You have no droughts to check *vegetation* and afford a rest to your tea estates. Financial considerations are forcing you on." The Ceylon man answers: "The oldest tea is the island is just as good as ever, even better. There is no sign that any harm is accruing; and at the present rates we will be out of the wood long before the tea will absolutely require to be maintained by manure." Then he soars away into arithmetical flights—*so much per acre so much per pound*, and the bitter part and the trying present are for the nonce forgotten. My sympathies are with thee, oh sorely tried planter of Ceylon! Surely success will come before the old veterans are all laid beneath the sod. It is coming, they say. Let it come speedily. I will have more to say after I have seen more. I often think that Ceylon being at the apex of the triangle gets the full evil of blights that are carried on the wings of the wind. This *helopeltis* has declared itself in Ceylon in cacao, in Assam in tea, in Java in cinchona. It may creep into your grand tea expanses. Look the thing in the face, for, behold it is within your borders. Gently does it. Draw the line in dipping too deeply in the usurper's and money-lender's purse. Guard against the spider's net.

I have seen Courg coffee in Ceylon today sappy and

croppy as is its wout. There is no argument against it here.

I hear Udspussellawa is asserting herself. Poor coffee! art thou altogether rejected?

In Mysore, looking across the Maidan, you can make out the locality of the coffee estates by stretches of what appears to be jungle, so thick is the shade. And if the coffee appears to have heavy shade what would be said of cardamoms where the covering is much heavier?

Talking of cardamoms, I have to retract my chaff about "orchards." The figures are startling. Forty acres in Ceylon give about the same yield as three thousand acres in the Mysore Ghâts. This will give a profit of over twenty thousand rupees. How about the Ceylon forty acres? This is another example of stuffing a market. The Ceylon men are again responsible. They are not blessed in India, especially in Assam!

The difference in yield and prices since both have had the cream skimmed off, say on 3,000 acres, is the difference between a profit of £100,000 annually and one-fifth of that sum. The prices have been lowered by the Ceylon buccaniers!

I referred above to the Mysore Ghâts. In the Mysore Ghâts the cardamoms reach the height say of eight feet and about the same number of shoots in the stool. In favoured spots the growth exceeds that, and in large areas less favoured the stools are very poor. Now in the Maidan, just on the boundary zone out of the Ghâts and out of the true Maidan—between the two where the coffee thrives—you find cardamoms in ravines assume the thick luxuriant appearance of the Malabar cardamom in Ceylon, and bearing heavily. They fear however to plant it up the hillsides on account of the drought and because they are pleased with the coffee. But why enlarge on this subject? You get 25,000 pounds weight from forty acres and you have brought the market down about our ears. I want to see how you are working tea, and I will send you my ideas if they are acceptable.

ABERDONENSIS.

PROGRESS IN TEA MANUFACTURE.

(To the Editor of the "Home and Colonial Mail.")

All folly and injustices will be minimised when thorough and official investigation shall have not only formulated rules for manufacture but scales of requisites, also standards for out-turn per 1,000 bushes of the various *ghats* for various sub-districts. I say per 1,000 bushes as acreage too often tells against the planter where vacancies are of abnormal number. A planter can then before taking over the management of a garden, form his own estimate, and compare it with that expected of him by the proprietors, and at once protest on the grounds of officially sanctioned scale, against any improper entry in the proprietors' estimate. Thus it would not be a case of his opinion against that of his predecessor, but that of his predecessor against the scale. Of course, such scale could only be approximate and must be subject to the average effect of each season's weather over the sub-district in which the garden is situated, but it would be far nearer a true criterion of a manager's merit than anything we at present have, and some little safeguard to his reputation. I have said sub-districts because there are too great differences in "lay" and soil in whole districts to allow of one scale being fair to all the gardens in it.

DARJEELING.

"TEA NOTES."

[We shall shortly publish a review of our own of this book.—Ed.]

Mr. D. M. Traill, of the *Calcutta Advertiser* Press, has just published "Tea Notes" compiled by A. F. Dowling, of the Kornafuli Association, Chittagong. The book is a very useful *Omnium gatherum* on every conceivable subject connected with tea-plants. It deals

with the chemistry of tea and the advantages of wire netting; the forest trees of Chittagong and Screw threads and shingles; foreign rate of postage and prescriptions of all sorts; tables of wages, tea returns, waste land lot, in short something is said about everything. The subjects are arranged alphabetically and the book is interleaved, so that notes may be added from time to time as may be found needful. Mr. Dowling's Tea Notes should certainly prove a success. Here is what is said regarding soils and manure:—

We have to consider first, what *Soils* consist of; second, what the plant takes out of the Soil; third, what are the constituents of Tea leaves, manufactured tea, tea extracts, spent leaves, and tea ashes; fourth, what should be done to replace the substances removed from the soil? All soils consist of organic and inorganic bodies; the latter, the earthy and stony substances; the former, animal and vegetable matters.

As a rule, soils contain but a small percentage of vegetable or other organic matter, from three to ten per cent only,—the proportion being easily ascertained by placing a sample of soil over a strong fire, when the organic portion will be more or less readily burnt away, while the residue will represent the inorganic percentage, which remains fixed and permanent in the fire.

The best soil for tea is a strong humus soil, full of organic matter, provided it be friable, that is to say, contain thirty per cent or so of sand. Such soils, however, are scarce, and the bulk of land taken up now-a-days for tea is a light loam, containing plenty of sand, with more or less of clay, carbonate of lime, potash, magnesia, and oxide of iron; while the richer it is in organic matter the better for the growth of the plant. Clayey soils, containing little or no lime, and marly or calcareous soils, containing lime in excess, are unsuitable for tea. Clay can with difficulty, and only at heavy expense, be brought to grow tea. Sand, on the other hand, with but moderate manuring can be made a fair yielding soil. Animal manure, however, is now very scarce; in fact it can hardly be obtained.

To know what our bushes extract from the soil, it is necessary to be acquainted with the constituents of green tea leaves, manufactured tea, tea extract, the spent leaves, and tea ashes.

The leaves of the teabush are all that is actually removed from the land provided that weeds are buried, which in every case should be returned to the soil to keep up its fertility. The leaves contain a large proportion of water which is taken back by the soil from natural sources. All but about 5 per cent of this water is driven off in the process of firing the leaf, the residue, or manufactured tea, consisting of the following substance:—

In the extract or soluble part, or Liquor:—

Dextrine, glucose, gum, principally carbon ...	per cent. 17.55
Tannin ...	11.00
Theine (the Alkaloid of tea, 23 per cent of which is nitrogen) ...	2.00
Nitrogen ...	6.00
Potash ...	2.75
Ammonia70
Chlorine and Sulphuric Acid ...	a trace
Essential Oil ...	Do.
And in the spent leaves, or insoluble part or outturn:—	per cent.
Water ...	5.00
Woody fibre principally carbon ...	27.00
Legumen, a nitrogenous protein substance, sometimes called vegetable casein ...	15.00
Other protein albuminous compounds ...	10.00
Insoluble tannin and insoluble ash...	3.00
	60.00
Total ...	100.00

Tea, it will thus be observed, is extraordinarily rich in nitrogen, so much so that the fresh leaves contain

more nourishing protein compounds than beans and peas; and were it possible to render the coarse leaves palatable, they might be used as a nourishing article of food.

The whole percentage of the leaf need not necessarily be returned to the soil, as we have already seen that part of it is derived from the air. To determine approximately the substances actually extracted and which cannot be restored from natural sources, we must pay attention to the ash of manufactured tea, the analysis of which is:—

	per cent.
Potash	3.00
Soda10
Magnesia30
Lime25
Oxide of Iron25
Protoxide of Manganese... ..	.05
Phosphoric Acid80
Sulphuric Acid	a trace
Chlorine25
Silica25
Carbonic Acid	1.00
While the combustible or gaseous portions of the manufactured leaf are :	per cent.
Water	5.10
Nitrogen in tea extract	6.00
Do insoluble spent leaf	6.00
Do Theine50
Carbon	40.00
Oxygen	30.00
Hydrogen	5.00
Sulphur	1.50
Total	100.00

The bulk of the carbon, oxygen, and hydrogen of the above being supplied by the air, and existing so plentifully in good tea soils; and the quantity of soda, magnesia, lime, oxide of iron, and manganese extracted being comparatively insignificant, we need only pay attention to a resupply of the other substances, nitrogen, potash, sulphur, and phosphoric acid; the two former, nitrogen and potash, being those of most importance. There being 12½ lb. of the former and 3 lb. of the latter in each 100 lb., it therefore follows that a yearly produce of 400 lb. removes from the soil 50 lb. of nitrogen and 12 lb. of potash per acre. Cow-dung and linseed, or castor cakes, are the only manures which so far have been used to any extent by tea planters, and with considerable success so far as a resupply of nitrogen and some of the soluble salts is concerned; but neither of these manures contains potash. It will be an assistance to have a simple test for this last named valuable ingredient. Chemical text books may be sought in vain for any but the most elaborate means of detecting its presence; but I find that for a rough test it is sufficient to stir into the tea infusion (in a wine glass) as much tartaric acid as will cover the point of a pen knife (part of the contents of the white packet of a selditz powder will do,) when a slight cloud will indicate a trace, and precipitate an abundance of potash.

With reference to the Saw Tree Mr. Dowling says:—From close observation it would seem that tea generally is better (at any rate greener) under the shade of the Acacias. At Agonea there is some very good tea near Korais, while at Waga Surrah the best tea in the garden is shaded by an unusually large Chukwa. The peculiarity of the Saw, I understand it, is that it has a beneficial effect on the soil, and I can well imagine this chemical action is possible, for in Chittagong we know to our cost what a baneful influence some trees have on the soil. The Assur injures tea near its base. The Banian, though innocuous to plants round the stem, yellows the bushes many yards off. The Gurjon, Hoojia, Chamlash and Mango weaken

the soil. The Badhi Pecaala exudes an odour from its roots which poisons the plant for some distance round, while the Doomir (fortunately rare) kills the plant outright at the time when it bears figs on the bark of its stem in February and March. It is only reasonable to suppose then that some of the Albizzias, apart from any benefit desired from their light shade, have the capability of impressing the soil. If there are trees which deteriorate the land, we may naturally look for others which better it, and the thanks of the planting community are certainly due to Mr. Buckingham for making generally known the advantages and beneficial influences of Albizzia Stipulata.—*Indian Planter's Gazette.*

THE FATHERS OF THE INDIAN TEA INDUSTRY INTERVIEWED.—III. MR. W. HAWORTH.

Mr. Haworth, the subject of this interview, is probably the *Doyen* of the class representing Anglo-Saxon enterprise in India. He first left England for India in the last week of 1827, arriving in India in the middle of the following year after one of those protracted voyages long since relegated to the limbo of the past. Thus every railway in the world, with the exception of that short initial line between Stockton and Darlington, has been commenced since Mr. Haworth first left home to become—as it turned out—the father of various enterprises in the land of his exile. His object in first going out to India was to superintend the building of the Straud Flour Mills in Calcutta which, for a long time, were the largest mills of the kind. His energies were absorbed by this venture till 1832 when he returned home, but soon left again for India to take out the machinery for and establish the Cossipore rice and flour mills on his own account. These were afterwards converted into a sugar refinery, in which, by introducing “centrifugals,” he soon produced unprecedentedly large crystals, these becoming known as “Haworth’s paving stones.” It was as a member of the Agricultural Society of India, of which he afterwards became vice-president, that tea was discovered in Assam. Its gradual extension and establishment as an industry thus came prominently under his notice. He was, it may be mentioned, in passing, a member of the committee, who received from the Viceroy, and tasted the first small package of tea which was made and sent down to Calcutta as a sample. How little could he have anticipated on examining, as a curiosity, those few ounces, that he would not only become one of the benefactors of the new industry which was about to take the lead of all others in India, but that he should see the day when that industry should have absorbed close upon 16 millions sterling, and have produced over 67 million pounds of tea in one season, yielding about 1½ million sterling to the English Exchequer as revenue. Since his position in the Agricultural Society thus first brought tea before him, his connection with the industry which immediately sprang up has been continuous. His special training naturally enlisted his energies on the side of mechanical innovations in the process of manufacture. Up to 1867-68 tea was rolled by hand, and—*horrible dictu*—sometimes by the feet, after the fashion taught by the Chinese tea makers who were imported to supervise the manufacture on approved Chinese principles. These principles, though still adhered to in China with that tenacity to “old custom” so peculiarly dear to the Celestial mind, presented many objections to the more go-ahead Europeans who controlled the tea estates in India. In 1867-68, two or three gentlemen commenced experimenting with machines, of more or less crude design, in the hopes of replacing the costly and dirty manipulation by means of a machine which should be both more economic and cleanly in use. From one of these Mr. Haworth received

the inspiration which led to the production of his first rolling machine. The first of these machines was sent to Tarrapore Estate in Cachar, in 1865. This original design has since been completely remodelled and vastly improved. The original model, however, may be said to have been the first rolling machine introduced which succeeded in competing sufficiently favourably with hand-labour to merit adoption by planters, though there are now several well-known rolling machines very efficient, of which it is not on this occasion the place to speak. Coming to the views now entertained by Mr. Haworth on the subject of manufacture, it is to be confessed that that gentleman's modesty militates somewhat against the duties of an interviewer. His distaste against "appearing in print" is marked when it is a question of advancing opinions, or the chronicling of his experiences. The years during which he has been connected with the industry he ignores when it is proposed that he should pose as an authority; "I don't see that I can add much to what everybody who is intimately acquainted with tea must already know."

"Granted, for the sake of argument, but under great reservation, it is, none the less, of considerable interest just now to many, that views should be discussed, and to be discussed they must be known. Perhaps your views may help enquirers on a point or two in that search for more light, which is the acknowledged duty of the hour?"

"Well then, to take up one point in manufacture only; we need a thorough sifting of the question of the temperature at which tea should be dried. This, in my mind, is the crux of the whole position. I am convinced that very excessive temperatures have, in many cases been adopted, and I have reason to believe that even the chief advocates of high temperatures are now becoming converted and are realising the fallacy of their former creed. The true temperature will probably be found to lie under 250°. At that temperature or under it, air can be more evenly and regularly heated over a large surface, and also more economically probably by using steam as the heating medium, than in the case where high temperatures are employed, apart from the most vital consideration of all, the chemical effect upon leaf."

"This means that time which has hitherto been such an object to save is to be sacrificed?"

"Not necessarily so; as with slight modification the work can be done as quickly as it is now by using additional apparatus; but if Indian tea is to maintain its reputation for quality we must make the latter more of an object than we have done of late; though I think it is quite possible that machine may be produced or adapted from present forms by which the quantity turned out need not be reduced though the temperature should be."

"Are you in favour of a return to panning?"

"I think it is very probable that we shall find that if our quality is to be improved it will be necessary to re-establish, not panning after the old-fashioned *caro* plan, but a mechanical substitute for that plan whereby the action produced by the old process of panning shall be revived. I think an appliance could be constructed without much difficulty in which all the action produced on the leaf by panning could be produced without the old risk of burning from the pans being overheated, and without the costly employment of manual labour in the working entailed by the old system. Such an appliance is already under consideration in certain quarters. You see there is about 75 per cent. of water in the *cutecha* leaf, of this about 25 per cent. is extracted during the withering, roughly speaking, then 25 per cent. should be extracted during the panning, and this would only leave 25 per cent. to be extracted during the final drying, instead of about 50 per cent. less juices crushed out during the rolling, often to a fatal excess by

planters, as at present. Thus the lower temperature would then have less moisture to dry off, and this would compensate in a measure for the decrease in temperature, though at the cost of an additional process, that of panning, it is true. If the quality demands it, however, that additional process must be accepted as a necessary inconvenience, and in this way the whole process might be done as quickly as it is at present."

"What would then be your complete ideal system of manufacturing?"

"Firstly, I should of course wither; secondly, roll slightly; thirdly, pan mechanically; fourthly, ferment, or, more properly, oxidize; fifthly, finish the rolling; sixthly, final fire, and at this final firing I should, as already explained, have only 25 per cent. instead of 50 per cent. of water to evaporate—i.e., one-half of what now has to be evaporated."—*Home and Colonial Mail*.

LONDON (INDIAN) TEA COMPANIES.

THE BOROKAI TEA COMPANY, LIMITED—Capital £43,560 in 4,356 shares of £10 each. Area under cultivation, 910 acres. Directors, Messrs. William Duncan, C. A. Duncan, T. W. Powell, and W. H. Simpson.

The twenty-first annual meeting of the share-holders of this Company was held on the 30th ult. at the Company's office, when the following report was represented to them by the directors:—

The directors have to report that the crop of tea from the company's gardens in 1884 was 2,980 maunds, and that the quality of the tea was satisfactory.

The gardens were well cultivated and 54 acres of new garden planted, the area now under plant being 910 acres, of which 802 are in bearing. It is intended to plant an additional 50 acres, or more, in 1885, and a supply of the best tea seed has been bought to raise seedlings for that purpose, and for filling in vacancies in the gardens.

The coolies worked well during the year, and the number on the garden on Dec. 31st last was 781. Mere labor will be required for the increasing area of garden and the manager states that if his recruits are as successful as they were last year, the requisite number of coolies will be obtained through them.

The gardens were visited and inspected in January last by a member of the firm of Messrs. Jardine, Skinner, & Co., the Company's agent in Calcutta, who was much pleased with the appearance of the gardens, which he found in good order. The whole of the crop has been sold with the exception of 118 maunds, and estimating these to realize £678 10s or £5 15s per maund, the total revenue for the year, as shown in the annexed accounts, amounts to £19,536 12s 5d against a total expenditure of £11,654 10s 1d, leaving a profit of £7,882 2s 4d, to which has to be added a balance of £399 14s 6d brought forward from the previous year, making the total amount available, £8,281 16s 10d. An interim dividend of 5 per cent has already been paid, and the directors have now the pleasure to recommend a further distribution of 10 per cent making 15 per cent for the year, which together will absorb £6,534. They further recommend that £1,000 be added to the reserve fund, raising it to £4,750; and that the balance remaining at the credit of the profit and loss account be carried forward.

Results seem to show that these estates are among the finest, if not actually the finest in the district of Cachar.—The returns given by the area in full bearing appear to us to be quite as encouraging as any we have heard of, even in Ceylon, so far as the value of the produce goes. The yield per acre of bearing plant is close upon four maunds, and the net result is a profit of 49 8s per acre.

We congratulate the fortunate shareholders on the substantial proofs they receive of the good management of their gardens—15 per cent. dividends for the past two years may well make the mouths of shareholders in the older companies water!

The Company's crop of tea was, we notice, 321 maunds above the out-turn of 1883.

THE INDIAN TEA COMPANY OF CALCUTTA, LIMITED.

Capital, £94,060, in 9,406 shares of £10 each. Area under cultivation, 796 acres. Directors: Messrs. William Duncan, C. A. Duncan, T. W. Powell, and W. H. Simpson.

The twenty-second annual meeting of the shareholders in this company was held on the 28th ultimo at the Company's office, when the following report was presented to them by the Directors:—

The Company's gardens yielded, in 1884, a crop of 2,592 maunds of tea. The season commenced well; but in April there were several hail-storms, which cut up the bushes badly, and for a short time plucking had to be altogether stopped. For a month or two afterwards the yield was small, but with favourable weather, and less blight than usual, it improved later on, and the season closed with an out-turn of 154 maunds more than in 1883. The progress of cultivation continues to show the propriety of gradually abandoning the steeper parts of the "teelah" land of the old garden, and bestowing more labour on, the planting and cultivation of flat land, which is much more productive. During the year 64 acres of new garden were planted on flat land, and the total area now under plant in 796 acres, of which about 700 acres are in bearing. The machinery in the garden continues to give satisfaction, and the supply of labour is sufficient for the area under cultivation. The gardens were inspected in January last by a member of the firm of Messrs. Jardine, Skinner & Co., the Company's agents in Calcutta, and he reports an improvement in the flat portions of the garden since his former visit, the bushes having increased in height as well as in breadth. As shown in the annexed accounts 2,516 maunds of tea have been sold, leaving unsold 76 maunds, and estimating these to realize £380, at £5 per maund, the total revenue for the year amounts to £13,773 11s. 8d., against a total outlay of £9,814 7s. 5d., leaving a profit of £3,959 4s. 3d., to which has to be added £501 14s. 7d., brought forward from last year, making an available balance of £4,460 18s. 10d. The directors recommend that a dividend of 3½ per cent. be declared free of income tax: that £750 be added to the reserve fund and that the balance remaining at the credit of profit and loss be carried forward.

DARJEELING COMPANY, LIMITED.

The following is the report of the Directors to be made at the meeting held on May 11th:—

The Directors beg leave to submit their Twentieth Annual Report on the operations of the Company during the past year.

The weather during the manufacturing season of 1884 was most variable and unfavourable for the production of large quantities of fine leaf, and consequently the tea made was far below the amount expected by the manager at Darjeeling when he prepared his estimate of the crop. For the same reason the quality of the tea at times was rather disappointing; some invoices were, however, received possessing fine flavour, and realized excellent prices.

The average rainfall on the plantation during the past three seasons, up to November 9th in each year, was 113 inches in 1882, 91 inches in 1883, and only 73 inches in 1884.

The great depression in the value of all colonial produce that has existed so long, has also been keenly

felt in the tea market, and, under such adverse circumstances, the results that have been realized, as indicated below, must be considered to be of a satisfactory character to all parties interested in the Company's affairs.

The Directors would desire especially to draw attention to the large savings effected in the expenditure in 1884, as compared with that in 1883, and this was accomplished without in any way diminishing the efficiency of the labour staff, or curtailing the necessary operations on the plantations; on the contrary, the plantations and everything connected with them have been maintained in the highest state of efficiency and many important improvements of a permanent character have been carried out.

The cash receipts in 1884 have fallen short of those in 1883 by about £2,734, but, on the other hand the general expenditure in 1884, as mentioned above, was less than that in 1883 by £2,259, so that the gross profits realized in 1884 have been only £475 less than in 1883.

The particulars are given as follows, viz.:

The crop of tea of 1883 was	473,810 lb.	
" " " 1881 "	473,206 "	
Decrease in 1884	604 lb.
The average price for 1883 crop	...	1s 6-50d	
" " " 1884 "	...	1s 5-11d	
Decrease in 1884...	1-18d.
The crop of tea, 1883, realized	...	£35,927	
" " " 1884, "	...	£33,975	
Decrease in 1884	£1,952
Exchange account in 1883 was	...	£3,791	
" " " 1884 "	...	£3,292	
Decrease in 1884	£400
Cinchoua bark in 1883 realized	...	£392	
" " 1884 "	...	Nil.	
Decrease in 1884	£292
			£2,753
Less, extra receipts for sales of tea and seed in 1884	£19
Total decrease in receipts in 1884	£2,734
Outlay in Darjeeling in 1884	...	£18,296	
" " " 1883 "	...	£17,493	
Saving in 1884	£803
General outlay in 1883	...	£1,803	
" " 1884 "	...	£3,755	
Saving in 1884	£1,918
Insurance and charges on tea in 1883	...	£4,657	
In urance and charges on tea in 1884	...	£4,249	
Saving in 1884	£408
Total savings effected in 1884	£2,259
Showing a balance against 1884 of only	...	£475	
The gross profits in 1883 were	...	£12,299	
" " " 1884 "	...	£11,824	
Decrease in 1884	£475

The following comparative statements show at a glance the operations of the Company during the past three years:—

TOTAL OUT-TURN OF TEA AND COST AT PLANTATIONS.		
In 1882, 1,531 acres, 566,102 lb. at 360 lb.		R.
per acre	...	195,336
In 1883, 1,562 acres, 473,810 lb. at 306 lb. per acre		182,965
In 1884, 1,586 acres, 473,206 lb. at 298 lb. per acre		174,932

GROSS EXPENDITURE AND COST PER POUND OF TEA, AFTER DEDUCTING THE DIFFERENCE IN THE RATES OF EXCHANGE.

In 1882, £27,256 ...	cost per lb.	Os. 11:82d.
" 1883, £25,461 ...	"	1s 1:17d.
" 1884, £23,767 ...	"	1s 0:18d.

ACCOUNT SALES WRIGHT OF TEA, AVERAGE PRICES, AND

PROCEEDS.	
In 1882, 553,027lb. at 1s 3:34d	£35,336
" 1883, 463,681lb. at 1s 6:9d	35,927
" 1884, 468,239lb. at 1s 5:41d	33,975

DIVIDEND.

The Directors beg leave to recommend to the members the declaration of a dividend at the rate of 7 per cent, free of income tax, payable on and after May 11th, 1885.

After providing for this dividend a balance will remain on the profit and loss statement for 1884 of £782 16s 3d, which will be carried to the credit of the reserve fund.

DIVIDENDS DECLARED.

On 1882 crop of tea, 6 per cent.	
" 1883 do	7½ "
" 1884 do	7 "

RESERVED PROFITS.

The following sums have been set aside from the profits as a reserve fund, viz. —

From profit and loss account, 1880...	£1,073 10 11
Do do 1881...	1,312 14 6
Do do 1882...	199 10 4
Do do 1883...	683 16 2
Do do 1884...	782 16 3
Total...	£4,057 17 2

TEA SEASON, 1885.

The manager at Darjeeling has prepared his estimates for 1885 on the basis that fair average weather will prevail throughout the season; a diminished rainfall, similar to that experienced during the past season, must necessarily upset an estimate prepared in this way, but under favourable conditions and estimated quantity of tea ought to be produced.

ESTIMATED CROP OF TEA AND EXPENDITURE IN 1885.

Amboitia Plantation, ...	208,000 lb.	£59,208
Ging do	132,000 "	43,434
Tukdah do	108,000 "	38,660
Phoosering do	72,000 "	24,568
Sudder charges	—	13,834

Totals...520,000 lb. R179,694

DIRECTORS.

Mr. John Farley Leith and Mr. Henry Smith retire from the direction by rotation on this occasion, and, being eligible, they beg to offer themselves for re-election as Directors of the Company.

AUDITOR.

Mr. John W. Roberts, the auditor of the Company, begs to offer himself for re-election for the ensuing year.—*Home and Colonial Mail*.

(From the *Planter and Farmer*.)

BEES.—It is said that there are in America no less than three million stocks of bees, producing an annual yield of 120,000,000 lb. of honey.

It is said by an American contemporary that a good sprinkling of a pint of sulphuric acid, diluted with a pail of water will effectually purify poultry yards if sprinkled in thin. Disease will be eradicated and noxious gases destroyed. It effectually keeps cholera away.

THE PRODUCTION OF MAIZE in the United States during 1884 is said to have been greater than in any previous year. It is estimated to have amounted to 1,975,000,000 bushels.

THE AVERAGE PRICE of wheat in England for last year was 35s 8d. In 1883 it was 41s 7d per quarter. The former is the lowest average for upwards of a century. In 1780 the annual average was the same, viz., 35s 8d.

THE EGG TRADE of Great Britain is simply enormous. In 1833 the return show that the importation of eggs amounted to 7,836,963 great hundreds of 120 eggs each, valued at £2,732,055.

SWEET POTATOES IN JAPAN.—Seventeen square miles in Kagoshima prefecture are devoted to the cultivation of sweet potatoes.—*Japan Weekly Mail*.

COCOA LEAVES are thus referred to in the proceedings of the Agri-Horticultural Society of Madras:—Read letter from the Honorary Secretary, dated 4th February 1885, to Messrs. Thomas Christy & Co., London, enquiring what preparations the leaves of *Erythroxylon coca* require to fit them for the market? Read the following letter from Messrs. Thomas Christy & Co., dated London, 27th February 1885, in reply:—“Your favour of the 4th inst. is to hand. I very much regret you did not act, if it was only to send home 10 to 20 lb. of the coca leaves which are worth here today 10s per lb., when dried in the shade and received green, whereas by your delay of only sending perhaps in the course of a month or so, the new leaves will be in from Bolivia, Chili and Brazil, and the price is very likely to fall down to 2s to 3s per lb. We have had to empty all our show bottles so great is the demand for even a few ounces of the leaves for medicinal purposes. The extract from the green leaves has been selling as high as 10s an oz. and the alkaloid has been as high as 22s 6d the gramme. A pound of leaves when well prepared yields a gramme of alkaloid. If you can send us over a supply of the seed in bags by post, we shall be very grateful for it. They only want tying up in bags and directing here. Your earliest attention will much oblige.”

GAMBIER AND PEPPER PLANTATIONS IN NORTH BORNEO.—In addition to the ordinary regulations under which lands are leased it has been thought desirable to issue special regulations having reference to the cultivation of Gambier and Pepper, and with this view the court have ordered as follows viz. —that upon an application for land being approved for the purposes named a permit will be granted to the applicant to occupy such land rent free for three years, at the expiration of which period a rough survey of the land will be made and a lease will be issued for 99 years for so much of the land as shall have been under cultivation, and for the remaining acreage an extent not exceeding two thirds of the cultivated portion the whole being subject to an annual quit rent of 44d per acre. The Company reserve the right to impose an export duty on the produce of such lands. The sale of lands fell short of the estimate for 1884, principally in consequence of the nonpayment of certain large tracts alienated to Australian firms who however are expected to make good their liabilities during the current year (1885).—*North Borneo Herald*.

AGRICULTURE FOR NATIVES.—Mr. S. Weerackody, Interpreter Mudaliyar of the Kegalla District Court, and a member of the Ceylon Agricultural Association, sends us Part I of “Wawunwidi Sangarāwa, or a Treatise on Planting.” “This work,” the writer says, “is especially intended for the information of the large class of Sinhalese landowners and cultivators who are unable to derive much benefit from books on scientific and practical agriculture, published in English both in Ceylon and elsewhere.” The book will be completed in two parts, each containing sixteen pages. The price in advance for the whole book for registered subscribers is R2, and each part is sold at 25 cents. Mr. Weerackody, in a letter accompanying this part, says:—“I have acknowledged in the introduction my deep indebtedness to your valuable journal, and other publications on agriculture issued from the Observer Office, without the aid of which, I must say, it could hardly have been possible for me to complete my book.” This first part contains an Introduction and deals with the Plant, the Soil, and Manure, vegetable, animal and mineral. The work is dedicated by permission to Sir Arthur Gordon. Mr. Weerackody deserves well of his fellow-countrymen and we hope his venture will be a success.

Correspondence.

To the Editor of the "Ceylon Observer."

BLACK-BUG ON COFFEE.

Agra Store, 22nd June 1885.

DEAR SIR,—One of your correspondents wishes to know the best remedy for the cure of black-bug in coffee. If you think the enclosed is worth your notice, you might advise him to try it, and kindly publish it in your next.—Yours faithfully,

WILLIAM JUDD.

CURE FOR BLACK BUG ON COFFEE.—First cut down all guava trees in the field near the buggy coffee and bury or burn all branches and leaves. Spread a thick covering of pig manure on the surface 18 inches wide all round the tree, taking care that the manure is direct from the sty without any mixture of cattle-manure, and I have not the least doubt you will soon see a favorable change in the coffee.

MOIST VS. DRY HEAT FOR TEA

WITHERING.

Kelani Valley, 24th June 1885.

DEAR SIR,—“Agricola”'s Withering Rebuke to a practical proprietor is amusing, if not instructive. “P. P.,” however, is not far wrong in his theory, though (probably owing to the steamy atmosphere in which his speculations were carried on) his ideas of cause and effect are less clear than might have been, had they been formed under more favourable circumstances. During many years of tea planting both in cold and hot climates, I have had my full share of the difficulties a planter has to contend with in the matter of withering, and have made many (I confess futile) attempts to overcome them by artificial means. To sum up the results of years of experience in a few words, I find:—

(1st) That really good tea cannot be made from leaf that has been subjected to a higher temperature than 90° during the withering.

(2nd) That the cause lies not in any waste of juices, but from the action of extreme heat rendering the leaf unfit for (or incapable of) undergoing the chemical changes necessary to produce what we call fermentation: the result of forced withering being an uneven greenish outturn, a thin pale liquor and a harsh unpleasant flavour not unlike a weak cup of bad green tea. To illustrate the effect of the heat by an extreme case: if the leaf be subjected to a temperature that would fit it for rolling within an hour after plucking, the result would be a perfectly green outturn, a pale straw-coloured liquor and almost as bitter as an infusion of cinchona bark.

(3rd) That, up to 80° or 85° a perfectly dry atmosphere is best for withering, but above 90° moist heat affects the fermentation far less than dry heat; so much is this the case, that I believe 110° would not injure the leaf if the atmosphere were charged with moisture—at the same time, be it remembered that 110° of moist air would take as long to wither the leaf as 85° of dry. Never having studied science, I cannot tell “Agricola” why moist heat has less injurious effect on the leaf than dry heat, but that it is so, I know from

EXPERIENCE.

PLANTING NOTES FROM TAVOY, BRITISH BURMA:

THE VALUE OF A GOOD JAT OF TEA.

SIR,—I see “Lindula Proprietor” complains of want of information about indigenous tea. Can't find it in the *T. A.* Dear me. Lindula, Esq., put on your specs and look up July number, pp. 13 and 39, year 1883, and you will find information as far back as 1874, some years ago, Mr. Editor; and one can have ocular demonstration of results in Seaford, Horagalla, Windsor Forest and St. Rumbold, not a long distance from Lindula. There you will find the oldest indigenous and the best hybrid that is to be found in Ceylon, distinction easily perceived by an experienced eye: colour of leaf and bark of tree quite different, of a much lighter pale-green leaf, and the bark of the indigenous tree of a much lighter colour than either China or hybrid.

Those seeds of indigenous and high-class hybrid are the first of the kind turned to good practical account. And it does a poor fellow's heart good (in this lonely spot) to read the grand account of those estates still holding their own, and to think of the “senior editor” looking down upon them with admiration when he surmises that they must surely have been planted with indigenous or near the real Simon pure. Quite right, indigenous and No. 1 hybrid!

Indigenous. Hybrid.

5 maunds to 60

I may be able to further enlighten some of you, on the value of a good jat of tea. I remember some of you poor-poohed Owen's quotations on the value of a maund of tea-seed. I have now in my possession replies from four different firms in Calcutta and prices of tea-seed from Rs25 to Rs150 per maund.

I had the pleasure of seeing Mr. Ward here when he came to Tavoy; although he had little time, he came to see me here. Mr. Ward is now Chief Commissioner of Assam, was formerly Judicial Commissioner there, and, as he is a man of observation and takes a great interest in tea cultivation, he gave me sterling good advice. He said: “If you plant tea, put in the best hybrid and indigenous that you can secure; plants of an inferior kind will thrive well for a time, better even than indigenous or A1 hybrid, as they feed for a time on the surface soil, but they have not got strength to penetrate some sub-soils, and all inferior jats after a time do not pay to keep up.”

Indigenous will make way with its roots through rotten rocks, but indigenous should not be planted alone. From all information I have got, the best flavoured tea and greatest quantity for an average yield is from tea planted with indigenous and hybrid mixed. In the tea districts now, inferior tea is being pulled up, and the best kinds being planted instead. I trust this information may be of some use to your lovely island.—Yours faithfully,

JAMES D. WATSON.

P.S.—Can you give me any information on the value of annatto seed?—J. D. W. [Let “J. D. W.” refer to page 656, vol. 1883-84 of *T. A.*—Ed.]

TAVOY SIAM ROAD.

The scenery down the river is intensely pretty. High hills averaging 800 to 1,000 feet, running along on either side and thickly wooded to their very summits. It certainly is not child's play for the Assistant Engineers to trace the road, for in many places the hills seem to be literally almost perpendicular, and it is a case of holding on by one's eyelids, while the brushwood is so dense and tangled that in many places one has to actually crawl through it to get to an opening when tracing. Plenty of game abounds in the shape of sambar and barking deer, wild pigs, deer, rhinoceroses, jungle fowls, peacocks

&c., and make a welcome addition to the larder of one's camp, and a pleasant variety to the tinned meats which is all we can manage to get here. Fish too is very plentiful, and there being no devotees to hold them sacred dynamite is used to procure the same. They are very fair eating, but are terribly bony and remind one considerably of the Hilsa, only the flavour is not so delicate. We have had the Chief Commissioner at Myitta, and he went down the river as far as Woodwin, and from all I can learn enjoyed the fun greatly of shooting the rapids. As far as he went he made a pretty keen inspection of the work done, and one of the results of his investigation has been that the Executive Engineer will also come down the Tennasserim and take charge of a division so as to be in the centre of the work and push on the same as fast as possible. The Chief Commissioner has also written a pretty lengthy minute on the subject, but this I have not as yet seen. There is evidently a thorough determination to have the path made as far as Ponséke before the monsoon breaks, but I am of opinion that it will be a near piece of work, and that it will be pretty tough work to get it finished. Now that all the officers and men are in their places the work will of course go on far more quickly than hitherto, but still it will take them all their time to have the road made. Now too that the transport of stores is almost at an end many coolies can be utilized on the road and this will also tend to hurry on the work, for many hands make light work, and if the men can be kept well, as it is to be hoped they will, the 6-foot road may be a *fait accompli* by the end of March. In the meantime the Chief Commissioner has promised a fair inducement for the work to be completed and there is little doubt but that all will put forth every endeavour to finish the road in the given time. Owing to indisposition I believe, Colonel Lang did not accompany Mr. Bernard, but he is expected down in these parts in a fortnight or three weeks, and by the time he comes I fancy there will be a substantial amount of work for him to inspect. The Telegraph meantime are also pushing steadily on, Mr. Pittman's headquarters being at Tsindoung at present. There is a temporary office at Kyoukh-toune, but it will not be long before the line will be fixed up as far as Tsindoung, and then I presume the Camp's headquarters will be shifted on to Simbading. There was some talk of the Siamese Government meeting us at Simbading or a little way over the frontier and fixing the telegraph line thence to Bangkok, but somehow it has come to nothing. At all events the original programme both as to the telegraph, and P. W. D. road is to be carried out to Ponséke via Amya, though may be next season a diversion may be made.

When the road is finally completed it is an open question as to whether it will tend to serve as an inducement for people to settle, and populate the land. Were the country cleared somewhat of the dense jungle I cannot but think that it would prove healthy and as far as cultivation is concerned the soil seems pretty rich and well adapted for crops. I should fancy too that a good trade might be done all along the banks of the Tennasserim in cutting down the huge trees and floating the same down to Mergui, where the river discharges itself into the sea. Burmans, however, would, I am afraid, be too apathetic for the latter work, and I very much question if Europeans could do it on account of the climate though I don't suppose it is worse here in the rains than up in the Chindwin forests. Of course not being a forester I do not know the value of the trees here but judging from the specimens of those cut down which I have seen all along the route the wood appears to be of a very hard quality and well adapted for building purposes. Time, however, works wonders and it may be that some day this desolate region may become populated, and where all is silent and still, civilization may step in and change this howling wilderness into cultivated acres and open out fresh fields and pastures new to many to whom civilized Burma is played out.—*Rangoon Gazette.*

CIGARS IN TEA: A WEEDY SUBJECT.

Dadulla, 25th June 1885.

SIR,—In your issue of the 22nd instant "A Lover of the Weed," makes rather a sweeping assertion in stating that cigars are utterly ruined by being kept in tea longer than a week! I have brought many thousand cigars packed in tea and in a tin-lined case to Eng-

land from both India and Australia, the former via the Cape of Good Hope, and the latter by way of Cape Horn and on their arrival in England, after a three and even four months' voyage, have been pronounced excellent in condition, flavour and quality, by my friends, who, I dare say, are quite as *choicé* with their cigars as "A Lover of the Weed."

Many people with whom I am acquainted have shipped quantities of cigars and cheroots from India to England packed in a similar manner, and on no occasion do I remember having heard a single complaint as to the cigars becoming deteriorated or affected in any way, by being in contact with tea during the time which elapsed in their transport from port to port. I would recommend "A Lover of the Weed" to try packing his cigars in *old* and thoroughly *dried* tea; and he may then find he will have good reason to alter his opinion.

GLOBE-TROTTER.

ROSES IN CEYLON.

Deltota, 25th June 1885.

DEAR SIR,—Can you or any of your readers let me know if anyone has compiled a pamphlet on the roses of Ceylon? I have before me the book prepared by Morris, Assistant Director, on the forest trees, fruit trees, &c. &c., in which he gives 27 roses. There are at least 100 varieties in Ceylon, and someone (Mr. Nock I think the most competent, as he has the greatest variety) should give the names of roses, with a description of each, intelligible to everyone. Did you see the large rose exhibited by the Hakgala Gardens? One who is something of a botanist called it "Mrs. Williams," while another "Paul Neron." Morris in his book gives *Rosa centifolia* as the cabbage rose, and further on "Souvenir de la Malmaison" as the Malale rose. Now I have heard almost everyone call the "Souvenir de la Malmaison" the Hundred-petal or *Rosa centifolia*. Then there is the beautiful cream rose with a salmon centre called the "Gloire de Dijon." Mr. Whyte, the naturalist, says that everyone is wrong, and calls what everyone calls the Victor Verdier (a creeping light-brown rose) the "Gloire de Dijon," while to the "G. de Dijon," he gives another name ("Margotin"). Then again there is the sweet-smelling pink rose, very large, called by some "Baroness Rothschild" and by others "La France."

Again what in Ceylon is called the "Field of the Cloth of Gold" is also named "Lamarque," while a small book I have gives the name "Lamarque" to a pale straw-colored rose, and "Cloth of Gold" or "Chromatella" to a creamy white with a yellow centre. This shows the necessity for a book on roses, giving the name, color, size, and a description of the rose, and whether it will flourish at low altitudes or not. A great variety of roses, I am sure might be got from Calcutta &c., for the Botanical Gardens, *i. e.*, if they are likely to blossom in Ceylon: *e. g.*, "Madame Laffray"; "Madame Desprez"; "Mrs. Bousquet"; "Keen," crimson scarlet shading into purple; "Grandissima," rosy crimson; "Safraon," pale yellowish buff; "Barbot," cream, suffused with rose and salmon; "Luxembourg," deep crimson; and other varieties. Roses cool well in the hill-country, and hybrids might be obtained from them by fertilizing in the following manner: the petals to be opened quietly with the fingers and the anthers removed with a pair of pointed scissors, and fertilized with a flower of another variety. In this way we might raise any number of hybrids of different varieties.

B. E.

HARVESTING CINCHONA.

Hewa Eliya, 27th June 1885.

DEAR SIR,—I have read in the June number of the *Tropical Agriculturist* a letter from "B. E.," Deltota, in which he enquires "if an average of 130 lb. of green bark shavings from cinchona succubra trees of from 2 to 5 years of age is a fair amount (quantity)." I guess it is! I have never heard of such a quantity of shavings being obtained; to get this average, some of the shavers probably harvested as much as 160 lb.! Does "B. E." measure twice a-day?

I think some reliable figures could be obtained from several men in Madulsa, which would show that your correspondent "B. E." ought to be well satisfied with the task done by his truly wonderful coolies.

On a certain well-known estate up here, with very fine large succirubra trees from 6 to 7 years of age, the average quantity harvested was about 73 lb. per cooly after having been at the work for some time; a few of the men would bring as much as 80 to 90 lb., but they were exceptionally good coolies. The work was most carefully done, and on the slightest signs of bad or careless work the coolies were checked.

"B. E." should most certainly cover the trees after being shaved; it is now generally believed that "covering" pays well in every way. Will "B. E." kindly let us know what force he employs "shaving"?

It will be a bad look-out for this and other cinchona districts, if he has a large force and can employ them for some months shaving at his present average rate of 13½ lb.

I will be glad to know if, before he comes to an end of his harvesting operations, he gets the average up to 150 lb.—Yours truly,
ENVIUS.

COCA SEED: THE DIFFICULTY IN GROWING PLANTS;—THE LOCAL ALLIED SPECIES—WHAT ARE ITS PROPERTIES?

27th June 1885.

DEAR SIR,—Your correspondent "Peppercorn" notices the general failure of the coca seed from Persleniya, at least, in hands less capable than the Assistant there; and this has certainly been my own experience, for, out of 100 seeds kindly sent me by the Director, not one has come up. The fact, that at the Gardens it has grown, is a proof that the fault is not in the seed. But wherein lies the secret of success? Is it that it should be sown at once on being gathered? In South America they seem to have no difficulty—the plants being, I believe, invariably raised from seed sown in shaded or roofed beds—very much in the style of our cinchona nurseries, though probably less carefully constructed. But is it not premature to run wild after coca, till the comparative merit of our own nearly allied species of *Erythroxylon* has been determined? Is this not desirable in view of the large demand opening out for coca leaves? That its leaves do contain the active principle of the latter in some proportion would seem evident, or at least probable, from the effects their use is said to have had with the natives during the last famine in India. Surely it is a point that some of our local experts could at once decide, if a sample for analysis were sent them? Would Dr. Trimn or your correspondent "W. F." kindly mention whether it belongs to the moister parts of the lowcountry or where chiefly abundant, and by what names it is known, in Sinhalese and Tamil?—R.

[Dr. Trimn's remarks in his last report may be repeated with advantage:—

"I may add that we have in Ceylon a closely allied species, *E. monogynum*, which is common in the hot dry districts, and called in Tamil 'Tevedarana.' The wood is slightly fragrant, and Dr. Ondaatje has recorded the preparation from it at Puttalam of a cresotic oil. The leaves are strikingly like those of *E. Coca*, and it is interesting to note that in South India, they were largely used as food by the poor during one of the late famines as recorded by Dr. Lidie. They may possibly contain Cocaine."

Some leaves ought certainly to go to Mr. T. Christy to get tested by a chemist: he is so keen about a supply of the commercial product that he would gladly attend to this, we have no doubt.—Ed.]

INSECT PESTS, AND INSECTIVOROUS BIRDS, "HELOPELIS" AND RED ANTS.

Kandy, 27th June 1885.

DEAR SIR,—On several previous occasions, some of my experiences of the value of insectivorous birds, in clearing our cultivated plants of their insect pests, have appeared in your columns, and I now send you a few statistics, which, I trust, may prove of some interest.

It is impossible to overestimate the importance of this subject, in a climate such as ours, teeming with insect life. The more I have investigated the question, the more I have had impressed on me the great value of insect-feeding birds, in assisting us in our garden and in fact general plantation operations.

We have tried to reduce the rearing and fostering of these useful little creatures to something like a system, and, though this is a very difficult and uphill task, we think we can say, our efforts have been attended with some degree of success, in the case of at least one species, our common "Magpie Robin" or "Dialbird" (*Copsychus saularis*, LINS.) He is to be found in the compound of almost every bungalow, in and out of town, and he awakes us at early dawn of day, with his clear, rich and joyous notes, long ere old Sol has passed the horizon. There are several pairs, which now breed regularly in our compound, and which we may term semi-domesticated.

Our plan is this: we attach chatties or flower-pots, with suitable holes in them, to the wall, in places where no cat can reach them, and so arranged that the crows cannot get at the eggs or young ones. These are intended as breeding-places, and in most cases, instinct tells cock-robin and his mate, that they are safe harbours of refuge. After due inspection—for he is a knowing and cunning little dodger—he will hop in, hop out, hop on to the top of his chatty, and pour forth his long shrill notes of love and approval. In a day or two the materials for the nest begin to arrive, and one then knows all is right, and we bid betide the impudent crow, whose curiosity may lead him to be too inquisitive. In due course the period of incubation is completed, and the process of grubbing commences, the two parents incessantly bringing caterpillars for the young.

When the little ones are nearly fledged, we remove them from the nest, and place them in a good roomy wicker cage, outside, but protected from rain. The parent birds now get very excited, and express their disapproval of these proceedings in harsh screeches, and cock-robin is no doubt highly indignant at the liberties taken with his offspring. Gradually, however, he and mother-robin get reconciled, and go on assiduously stuffing the young with caterpillars or larvae through the bars of their cage. In this cage the young undergo an imprisonment of six weeks, during which time the dietary arrangements are entirely left for the parents to settle. At the expiry of their term of servitude, the youngsters are liberated. They are, of course, delighted, overjoyed, and show their gratitude, by still remaining near the compound, to which they have become attached, and by regularly visiting our pot plants, and rose trees, till not a vestige of a poechie can be found.

We were very anxious to get at some reliable statistics as to the number of larvae a family of robins would destroy in a day, and had a careful hand told off, to take tally of the number of trips the male and female each made to their young with food, during the entire day. He was furnished with a pencil and a board, and stationed close to the cage, and whenever cock-robin arrived with a mouthful of caterpillars, down went a x; and whenever old mother-robin came, down went a l. On reckoning up the crosses and strokes, for three successive days, we arrived at

* Water being, of course, plentifully provided.—Ed.

the following average result, viz. :—

	Per day.	
Cock Robin 92 trips a day } Mother Robin 121 " " }	=213 trips.	
Take the average to be two larvæ at each trip (a low estimate); then larvæ=double the number of trips or=426 larvæ.		

As the cage on this occasion contained two young ones, the allowance for each bird was 213 larvæ.

Now, even say the adults will not require more larvæ than the number they give their young, viz. 213 each, we arrive at 852 larvæ per day, for the four birds, or 35,784 for the six weeks the young were in confinement.

Again, at and in the neighbourhood of the nursery grounds and garden, we have at least five families of say six each, including the adult birds, i.e. 30 birds, each capturing 213 larvæ daily: then for the year of 365 days we arrive at the enormous number of 2,332,350 destructive larvæ captured by the five families of robins.

In this calculation, you will see, we have not allowed more food for the adult birds, than was sufficient for the young in confinement, and we think $\frac{1}{2}$ more might, with safety, be added to the number of larvæ destroyed. It is better, however, to be on the safe side, and these figures as they stand, are sufficiently startling.

We have not yet got any data to give you, as to the destruction of larvæ by the "Warblers," (*Sylviadae*) and "Bush-creepers" (*Leiotrichinae*), and other small fry; but we are positive that these are more useful to us than the "Robins" (*Saxicolinae*), the "Bulbuls" (*Pycnonotinae*) and even the "Flycatchers" (*Muscicapinae*). Little "Snips," the "Tailor Bird" (*O. longicauda*) warbler, has an insatiable appetite and is actively personified, or we should perhaps say *ornithoid* (to coin a word).

These smaller insect-feeders are the very birds our cacao planters should show the utmost attention to, and encourage in every way. Why, little Snips and his nimble confreres are a match for *Helopeltis* any day, if you can only get them to locate and pay their addresses to that vile little pest. We'll back a dozen tailor-birds or other warblers against the entire coolly population of the estate, at *Helopeltis* catching. The plan would be to plant up any waste patches or swampy ravines between the cacao fields or even the road-sides, with thick clumps or belts of wild cane, or other sort of tall reed, in which they delight, and where they would soon make their home. These of themselves would form a sort of shelter for the cacao, and, as they do not throw down seed, would do no mischief, if the roots were kept from trespassing by means of trenches.

To all lovers of horticulture, I would respectfully say, try and rear your robins regularly, and other species of insectivorous birds if you can, and attach them to your gardens and compound. We all know how trying it is to one's equanimity of a morning, to discover that that grand bloom of *Capt. Christy, La France*, or *Gloire Duchess* rose, which we were looking forward to feast our eyes on, has been half-devoured during the night by a wretched larva of one of the *Geometridae* moths.

Watch over and foster your robins, and no such catastrophes will occur.

WHY? *Naturalist and Florist.*

P. S.—On the question, as to how *Helopeltis* can be kept in subjection, I feel more and more convinced that it can be vanquished by the steady and persevering introduction and application of its natural enemies. We have no mysterious and insidious fungus to deal with here; nature has provided the cure, if we can only apply it. I mentioned in my last letter, that I thought (and in fact I feel sure) that lizards would be most destructive, and I now see that some planters are introducing *red ants*, a capital move I

think. They are the veritable tigers of the insect world, and cannot fail to be most beneficial. Hunting down such small insects with coolies seems an expensive, clumsy and slow operation. I believe thoroughly in the smaller insect-feeding birds, as the most efficacious cure. No coast advances, no check-roll or monthly pay required for them. We could not even purchase their services; they are given without money and without price; are in fact, in a twofold sense of the word, *priceless*.

INVESTIGATION OF COFFEE LEAF-DISEASE: AN APPARENT REMEDY BY AN UVA PLANTER.

SIR,—I have never seen the report made by Mr. Marshall Ward regarding the result of his investigations into the nature of our coffee leaf-disease nor the report of anyone else, and I am altogether ignorant as to the conclusions which have been come to in the matter. My own observations and investigations, which have extended over a period of nearly nine months, have therefore been entirely independent of the opinions of others. Like a great many other planters, I believe I have hitherto been led to regard the pest as a *parasitical fungus*, and even now I am not prepared to deny that the saffron-coloured spots which appear on the underside of coffee leaves are a fungus, but, if it is, it appears to me to be one which derives its nourishment from the air and not from the substance or juices of the leaf. I have never yet seen a leaf change its healthy-looking aspect until the development of the insect which is inseparably connected with the so-called fungus. I have therefore been led to the conclusion, after long and patient investigation, that the evil effects are due to this insect and not to the fungus, if it be a fungus. That the maggot or larva is produced from zoospores there can be no doubt. The question therefore comes to be: What relation do living zoospores or germ cells, ova or spawn bear to the spores of the supposed fungus? For the one does not exist without the other, and it is only after the maggot is developed that the leaves change their color, blacken and die. This creature, although it is very minute, is not so microscopic that when it is full-grown it cannot be perceived by the unaided eye, for it is then about the sixteenth of an inch in length, and it is surprising to me that I have heard nothing of it before. My microscope is unfortunately not a very powerful one, so that probably several hours must elapse before the newly-hatched larva becomes recognizable within the range of my optics. It is then a mere speck, like a *molecule* of shining silver. Within 36 hours however it is a perfectly-formed maggot, of a red blood color, cylindrical in form, no feet, body consisting of ten segments counting the head and tail two, which are both white; back and abdomen red blood colour with two white longitudinal lines along the underside. The periphery of the segment rings are also tipped with white on the lower sides. But the head is armed with a most formidable, horny-looking *proboscis*, long enough to pierce the scarf skin of the leaf and penetrate the *pulp*. For three days after it makes its appearance it does not move much from its original position but appears to feed upon the yellow-coloured *vesicles* which were previously broken up by the female insect and now assume a moist, semi-fluid appearance, adhering together in masses. About the fourth day of its existence it begins to show active signs of life, moving freely amongst the accumulated masses of *fovilla*, and in nine or ten days' time it has attained its full size, being, as I have said, about the sixteenth of an inch in length, and is then quite perceptible to the naked eye. It now quits its native spot in search of "fresh

fields and pastures new" over the surface of the leaf, leaving the patch on which it previously existed quite dead. Having no feet, it makes use of its strong proboscis for the purpose of locomotion as well as to perform the functions of a mouth, for it appears to be purely suctorial in its larva state. Into the portions of the leaf which remain fresh, this maggot thrusts its proboscis deep into its substance, and, holding on to it as a sheet anchor, drags along its body, covering about the sixteenth of an inch of surface at every pull, and so great is the power which the creature exercises over its proboscis, that on a cardboard surface which it could not penetrate, when the point of the weapon suddenly slipped, the force which was being exerted would roll the maggot clean over on its back. An insect armed with such an instrument as this was not made to live a harmless or innocent life, and during each insertion of its proboscis into the leaf it is doubtless at the same time pumping up the sap for its nourishment, and it may therefore be readily imagined how soon after the maggot has begun to crawl the whole surface of the leaf becomes deeply punctured. The juice (or whatever may remain of it) is shortly evaporated, and the leaf blackens all over and drops off. When the larva is full fed, which it is in about fourteen days, it becomes inactive and enters on the pupa stage, but before this it frequently drops off from the leaf or falls with it to the ground at the roots of the tree where the larva shelter themselves until they throw off the chrysalis.

The perfect insect as it emerges from its chrysalis is extremely minute but can be perceived by a good eye unaided. It is oblong, cylindrical, with three legs on each side of the body and a very long pair of antennæ, the only ovipositor on the females sharply defined. Body, head, legs and antennæ all of a bright silvery lustre. It proceeds at once to attack the young leaves by puncturing a minute hole at the junction of the midrib and primary veins, and upon any tree which has been badly attacked, to find a single leaf that has not been thus punctured at the root of every vein, is the rule and not the exception. It is now at this stage of my observations where I fail for want of a powerful enough microscope. Do the insects on entering these holes tunnel underneath the scarf skin of the leaf? If they do, then I have great doubts of the so-called fungus being a fungus at all, but that the yellow-coloured vesicles are the *spermatozoids* or sperm cells of the male insect which emerge through the pores of the leaf, among which the female deposits her eggs and which she breaks open to fertilize her spawn. On removing the skin of the leaf round these orifices they are also found to contain numerous insects of somewhat smaller size and shape than the full-grown insects, but they possess the same color, the same number of legs and long antennæ, and I am under the impression that the insect is at a certain season of the year oviparous and at another viviparous.

Whenever a sufficient quantity of *spermatozoids* or *spermatogones* have become developed, the female insects may be seen issuing from the holes and proceed direct to one or more of the powder spots where they soon get so completely covered with the yellow dust that it is impossible to see more of them than the action of their legs, but they can be perceived to be engaged turning over and bursting open the yellow-coloured vesicles which very shortly assume a different appearance from what they did before the insect operates upon them. They now become moist-looking and adhere together in detached masses. Amongst these masses I have observed the female to continue for three days without leaving the spot, dropping eggs at the rate of three or four per day, covering them over at the same time with

the yellow-coloured matter. The newly-laid egg is dark brown, oval in shape, with a tail or filament resembling the sperm cells contained within the *antheridia* of *cryptogamia*. They appear to consist of a lymphatic substance, firmly pasted to the surface of the leaf to which the *foveola* of the yellow vesicles instantly adheres, so that, if the egg is not observed just as it is excluded, it is impossible to distinguish it from the general mass, and might possibly be taken at first for a spore of fungi.

Such is a brief account of the life-history of this insect so far as I have been able to trace it with the appliances at my command. In the hands of a skilled entomologist doubtless much more light is capable of being thrown upon the subject.

As a body of planters, however, we care little for the life history of the insect: our object is to get rid of it, and a remedy is in this case probably more readily found than for many other kinds of pests. It would be much easier to root out the scourge from a whole district than from an individual estate, as, although I do not think that the germ cells can be borne on the wind—they are much too firmly glued to the leaf for that—still the perfect insect can be carried on coolies' clothes from one estate to another. The best thing to do is to destroy the eggs by an acid or boiling water and remove the medium of the insects' existence for a season. As a trial, I selected some time ago, one or two trees the leaves of which were completely covered with larva and full-grown insects and had everything in the shape of a leaf snipped off without injuring the buds: in fact, put them under a complete wintering. I then had the stem and branches of the trees as well as the ground round the roots well souced with fresh cattle urine, so that the caustic ammonia might kill any larvæ or insects concealed amongst the crevices of the bark and keep off the small black ants which are often seen covered with the yellow dust. Now a fine flush of new shoots and fresh leaves have sprung forth on which there is as yet no trace of yellow spots or punctured leaves.

On any estate the coffee of which has been badly attacked, snipping off the leaves will not be a very difficult matter; but in order that this proposed remedy should prove thoroughly effectual, it is essentially necessary that an estate should be literally swept of dead leaves, weeds and rotten branches. These all harbor the larvæ in the pupa state and should be carefully collected in bags and destroyed. All moss that sticks to the stem or grows in the ground should be effectually decomposed. Nothing will do this better than caustic lime or caustic ammonia arising from fresh cattle urine. In fact I believe the latter is capable of destroying every kind of living vermin which prey on coffee trees.

In a letter which I wrote you a short time ago upon the benefits of liquid manure which I intended as a prelude to this, I sent you a plan of a simple method of applying cattle urine or liquid manure on a large scale, but on which you were good enough, Mr. Editor, to throw a cold blanket by saying that the cost would be excessive, whereas I believe Messrs. Walker & Greig of Badulla could lay the whole thing down for less than £20 per acre. But in order to convert everything into liquid manure it is necessary to have a supply of sulphuric acid, and I have no hesitation in saying that it would pay a district like Haputale to have its own sulphuric acid manufactory, and, if such an idea should be contemplated, I should be happy to furnish Messrs. Walker & Greig with drawings of the necessary apparatus which they could construct perhaps with the exception of the leaden chambers which could be got from home.

My own impression with regard to this insect is, that, until the matter is set at rest, the planters of Uva should hesitate before they root out their coffee or plant tea amongst it. I have no faith at all in Uva as a profitable tea-producing district unless on paddy land having the benefit of irrigation. I have a very intimate knowledge of the geological formation of this large district, and I fear the sub-soil is of much too porous a nature to yield sufficient flushes of leaf, especially when prices decline as they are inevitably bound to do before long.

[The coffee leaf-disease is due to a fungus, and no authority, from Thwaites to Marshall Ward, ever mentioned an insect in connection with it, except one which it was hoped (a hope not fulfilled) might prey on the fungus. Perhaps it is this insect which this correspondent professes in his extraordinary letter to have discovered. As a preliminary to discussing such a question, surely he ought to have read at least Marshall Ward's reports. There are insect pests which affect coffee: grub at the roots and black bug on the leaves and stems. But it is the fungus *Hemileia vastatrix* which enters the stomata and feeds on the life juices of the plant contained in the leaf-cells.—Ed.]

CEYLON PLANTING: PAST, PRESENT, AND FUTURE.

DEAR SIR,—The writer of "Ceylon in the Fifties and the Eighties," refers to visiting agents in a somewhat humorous vein, and mentions that, in his early planting career, estates were inspected by the chiefs of the agency houses or the proprietor, whilst now "an organized army of V.A.'s traverse the country, add beauty to the scenery, and make life and work pleasant to the superintendents whom they visit." This remark, I thought, would have reminded some of the "inflationists" of a few years ago to say something about their old remarks on the "detractors," or on that one who was said by them to be the exponent of the class, W. McK. Although I never had a V. A. over me, I happened to be acquainted with one and all the members of the "army," and still take a sort of interest in them: therefore I would be glad to see some of those who wrote against them acknowledge themselves in the wrong. And to take poor W. McK. as an example: one of the inflationists wrote of him that he had done more to destroy the credit of the colony than any leaf-disease could have done, and that his shadow was dreaded by every proprietor—especially in Maskeliya. It is some four years ago since that was written, and the writer has never yet thought proper to send a second letter to the paper, pointing out that W. McK. was the strongest advocate for the planting of tea in Maskeliya, and it has proved a success there, as far as one can gather from the newspapers, whilst we find no reports proving that he was wrong when he said that coffee was doomed in Maskeliya, and the sooner tea took its place the better.

Some years before Morris of sulphur and lime fame startled the world with an unpublished life history of the *Hemileia vastatrix*, W. McK. stayed at my bungalow, and I showed him some trees which I had tried with sulphur and lime applied to them in every conceivable way, even to the extent of boring a hole down the centre of the stump, filling it with the two ingredients and plugging it, but, it is scarcely necessary for me to add, without any good effect taking place. I dressay I tried more novel and heroic ways to cure coffee of *H. V.* than any other planter in the island, but the only one that gave any good results was rubbing the whole stems of the trees with kerosine oil, and this had the effect of

keeping off the attack of *H. V.* for about a year, but of course the costliness of the cure made it prohibitive. After seeing the various trees on which I had been operating, W. McK. seemed only more convinced in his opinion than ever that coffee was doomed, an opinion in which I quite agreed with him, but his strong advocacy of tea, as a means of restoring prosperity to the island, my belief being, that, although tea growing may be a very good profession for John Chinaman, it is not for a *pukka* white man. I have not changed my views on this subject, although I am pleased to see that tea is doing so much good for Ceylon. Having been accused of being a pessimist myself, because I chose to think coffee doomed, I naturally feel that justice has not been done W. McK. and others who were, in the columns of the local papers, abused for giving their honest convictions, when asked for an opinion. So far back as 1874 I wrote in your paper:—"No! Dimbula, you have disappointed me, although you did make the fortunes of so many young fellows, who were, luckily for them, obliged to buy land here, or else go without any at all. How little did they think that they were being forced into a fortune. I hope those who bought second-hand will manage to get their money out of you again." To this sentence Ed. C. O. put the following footnote:—"Mr. George Smith for instance, who, knowing all the faults as well as all the merits of Dimbula, has paid £11,500 cash for 275 acres of coffee." If Mr. George Smith has got his money out of his investment again I must acknowledge myself wrong, but, if not, perhaps you will add a P. S. to your former footnote, bearing in mind that, however successful Mr. Smith may have been with regard to tea and cinchona, it was with reference to coffee that I wrote. Although W. McK. was singled out as the V. A. upon whom the inflationists chose to pour the vials of their wrath, he was not the only V. A. that held pessimistic views on the subject of coffee, and several others openly confessed their want of confidence in the revival of the old staple of the island, and, in some cases, this opinion cost them their billets. I could mention the names of many old and experienced planters who held just as pessimistic views as W. McK., but, not being V. A.'s, their opinions were not circulated, and so they escaped the odium of the inflationists. These men all believed in the new product theory, and those have nearly all turned out fairly successful undertakings; and yet I see no signs of the inflationists making any favourable comments on the views which the hated W. McK. & Co. entertained in days gone by, and which have turned out so well. I might give numerous quotations, which appeared in the columns of your paper, against the views of W. McK. & Co., all of which have been proved wrong, but no note of admission that such is the case has come from the writers, and I could give as many quotations from the pens of pessimists, myself amongst the number, all of which have come right, or nearly so; but these require no comment, they speak for themselves. Perhaps none of these has proved more correct than the prophecy of mine, which was published about 10 years ago—when coffee was king indeed and everything connected with it stood at a premium. In that article I foreshadowed the future of the planting industry, and placed the products in the following order as likely to be remunerative to the growers: viz. cacao, cinchona, cardamoms, tea, coffee, cinnamon, and Liberian coffee. I placed absolutely last. I was laughed at for holding such views, at the time, but I leave it to the present race of planters to say whether I was very far out after all. The old V. A. was not such a villain as the inflationists would fain have painted him, he believed

in himself and, as he believed, he spoke,—but, alas for him, his belief was detrimental to his opponents' interests. It is pleasing therefore for me to see that the views of planting in general, which my old friends entertained, have to a great extent come true, and I only wish that the inflationist faction would be as honest in according praise which is due to those that they chose to call "detractors," as these men were honest in upholding their opinions, even when prejudicial to their own welfare.—Yours truly,

LANG, LANG IST'S HER!

[Our correspondent will certainly deserve credit for his opinion of Dimbula and coffee in 1874, provided he is able to say that he foresaw then the ruin which the leaf fungus was to work. We, most certainly did not then foresee that result; nor did "W. McK." nor any of the other V. A.'s. On the other hand, had it not been for H. F., we believe it will be admitted, that both Geo. and Wm. Smith and many other Dimbula men would have got the handsome coffee returns they expected. Our advice to young investors in the palmiest days of inflation, when coffee was 100s and over, was to count on 3 cwt. an acre and 80s a cwt., but, of course, leaf-disease was not then thought of as a serious evil. The fault found with "W. McK." was, we understood, not so much for running down coffee as for prescribing all barren from 'Dan to Beersheba' and his only advice to Ceylon planters' seemed to be to 'clear out.' The *Observer* long before W. McK., preached "new products" in cinchona, tea and cacao, in season and out of season. In the case of Maskeliya, the same gentleman led more men to follow his example and plant coffee than any other pioneer; and only yesterday we had occasion to recall a visit W. McK. paid to us in 1879 or early in 1880 when he described in the most glowing terms the appearance of the Liberian coffee on Putupaulakande and spoke of this new product as an assured success. "Lang, Lang" naively confesses that he put tea after cacao, cinchona, and cardamoms, in the order of probable remunerativeness and success, showing how he also was wrong. There is therefore scarcely room for any one (unless it be the shade of G. H. K. Thwaites) in connection with the past history of planting in Ceylon, to stand up and say:—"I was right and you were all wrong." Our correspondent "Lang" &c. says he has seen no notes of "confession of error" in our columns: he has certainly like Rip Van Winkle been asleep and suddenly revived. What, for seven years back, has been the burden of our planting correspondence, reports, reviews and of our own articles and writings in the *London Times*, before the Colonial Institute, in "Ceylon in 1831," but one long confession of past errors, a bewailing of the mistake made in putting all the eggs in one basket, in sticking with the Irishman to one product, and so forth? But, in our so confessing, we should like to see the Ceylon planter of 15 years' standing who can honestly say: "I have nothing to confess." As for "W. McK." we believe him to have been as big a sinner as any of the planters up till 1878-9, the year when nearly everybody's eyes were opened; and we began our crusade in favour of clochona and tea some time before then.—Ed.]

A GOOD WORD FOR JACKALS, CIVET CATS AND CROWS.

Madulima, June 1885.

DEAR SIR,—After an hour and 15 minutes with Lord Forrest Hill's hounds, a "who-whoop!" in the open proved to me, during a punishing worry, a matter I had long been in doubt about, whether or no jackals eat cinchona poochies; for a hearty early tea of this delicacy had been partaken of. This accounts for the enormous visitation of jackals yearly at this season

when poochies are in. I have dogs that will take a poochie off any branch within reach and demolish it with relish.* A jackal has been seen performing the same feat on this estate. But unfortunately they don't stick to one diet, having also a taste for the "Chins Kauley." So six more have fallen to this gallant little pack since above kill, and contents of all examined contained cinchonapoochies and their cocoons which predominated amongst the debris that would probably be as puzzling to analyze as some samples of bark from this district were lately shown to be. Noticing my hands smelt strong of civet after suckering in cinchona clearings, I examined contents of stomach of next "Poonapu Poonie" "rolled o'er by the menel" and found again cinchona poochies swallowed whole which were doubtless gathered off the suckers. Ocular demonstration is afforded daily of the amount of these poochies crows polish off: especially the wild crow, with its peculiar way of hopping in and out of thick branches, is particularly well adapted for this work.† I have seen them over and over again secure a fine prize and fly off with it to their habitation in any adjacent thorny scrub, be it ever so small, whilst the ordinary village crows only visit high estates in fine weather, and are not therefore quite so valuable, though they also clear a considerable quantity. As coolies of almost every caste readily eat the red wild crow, I trust all in authority will do their best to prevent the destruction of these useful agents. A few years ago when first poochies appeared on our cinchonas great damage was done, and £150 to £300 were spent by many in coolies' wages collecting them: now it is the exception to find any coolies thus employed, due to our friends the jackals, civet cats and crows, which also destroy and principally live upon beetles, cockroaches and grub of all sorts.‡ So I trust you will find space in your valuable journal for a good word for these creatures, the usefulness of which has often doubtless perplexed many, including, yours faithfully,

BILL THE WHIP.

GIGANTIC SECTIONS OF CINCHONA SUCCIRUBRA AT THE KANDY EXHIBITION.

SIR,—All reports of the Kandy Exhibition have omitted to mention the two fine sections of wood of Cinchona Succirubra grown on Sherwood estate, Haputale. They were the finest I have ever seen, and I am certain better specimens cannot be produced in the East. They are spoiled and almost beyond identification, besmeared with dirty varnish. They are to be sent to England and may pass for the section of a pear tree sooner than anything else, having that irregular form of trunk. I did not take the dimensions of the blocks, but I dare say Messrs. Alstons, Scott & Co. will be pleased to make that public.

J. A.

ROSES IN CEYLON.—As a contribution to the discussion which has arisen, we suppose, Mr. Archibald Fernando, of El Eza Villa, Kolupitiya, sent us this morning half-a-dozen bouquets of the most exquisitely beautiful roses we have ever seen in Ceylon. Every possible shade of pink is represented, and there is one wonderful yellow rose which seems to settle the problem of "gold in Ceylon." The roses were tasteful y wrapped in maiden hair and silver ferns.

* At Siogear in Java Mr. Kerhoven's dogs greedily ate the bruised masses of *Helopeltis* collected from the tea bushes, but they never foraged for themselves. That dogs should be insectivorous is certainly a revelation in natural history.—Ed.

† The species of Indian cuckoo called "the jungle crow" is, apparently, meant.—Ed.

‡ That crows should feed on such insects we can understand, but we fancy our correspondent is the first to notice that jackals and civet cats feed on such "small deer" as poochies.—Ed.

TO TEST BUTTER.—The *Scientific American* recommends this simple test for oleomargarine:—Stir a little—half a teaspoonful or less—of the suspected butter in enough sulphuric ether to dissolve it. By the time the grease is dissolved the ether will have been evaporated, and the residuum will show, to smell or taste, whether it is butter, lard, or tallow. Five cents' worth of ether will suffice for several tests.—*Chemist and Druggist*.

A QUICK FILTER.—Take a clear piece of chamois-skin, free from thin places; cut it of the desired size; wash it in a weak solution of sal soda, or any alkali, to remove the grease; and rinse thoroughly in cold water before using. Tinctures, elixirs, syrups, and even mucilages are filtered rapidly. A pint of the thickest syrup will run through in four or five minutes. By washing thoroughly after each time of using it will last a long time.—O. F. Nixon, in *Druggists' Circular*.

SUGAR CANE.—For the past three years the cane crop in the Province, except in well favored localities has been a poor one, owing to insufficient falls of rain while last year it may be said to have proved a failure. The seasonable rains this year however will make the crop, if all goes well, a good one. In many parts sugar cane cultivation is being carried on vigorously and as it is usual to manure the cane with oil cake, the hongay seed cake being especially used, the price of this cake, or hendi as it is locally called, has risen considerably.

TEA PLANTING IN CEYLON.—Messrs. A. M. and J. Ferguson have just issued a little work of about 100 pages entitled "Tea and other Planting Industries in Ceylon in 1885. A good field for Investment;" a copy of which they have been kind enough to send us. This work has been produced with the object of showing what a magnificent field the isle of spicy breezes offers for the employment of British capital and energy, and the compiler has executed his task with an enthusiasm and vigour which will convince every reader of it that the author has the fullest confidence and belief in the truth of his statements. The claims of Ceylon to consideration from enterprising capitalists are set forth in such a forcible manner that we are surprised they have not commended more general attention earlier. The first part of the book consists of a letter written by Mr. J. Ferguson, who has had an experience in Ceylon of more than a quarter of a century, to the *London Times* on the 24th August last year. * * * It is estimated that eventually Ceylon should have 150,000 acres under tea, which should yield, calculated on the basis of the amount realized from the present cultivation, about 43,000,000 lb. At the same time the planters are carefully mixing the products in order to avoid a revisit from the dreadful fungus or any other equally deadly pest. All that is wanted are young men of energy and intelligence with capital to restore to Ceylon the prosperity she enjoyed some years ago. Cheap free labour there is in abundance. The book under notice contains, besides Mr. Ferguson's able statement of the case, a number of papers written by planters of experience, fully discussing the question of tea cultivation, giving rules for the guidance of any one embarking in the enterprise, and a quantity of valuable figures showing the cost of working estates and the results obtained. It goes without saying that the Chinese trade will be seriously affected if the projects which are bidding fair to be realized in Ceylon for the growth of tea succeed. It has already suffered heavily by the competition of the Indian planters, who are bestowing on their products an intelligence which has already gained for Indian teas a reputation second to none. The same intelligent cultivation will no doubt take place in Ceylon, and there is, therefore, every probability that Chinese teas will be less required and less thought of. For a glowing though unvarnished picture of the brilliant possibilities of the tea industry in Ceylon, we would commend our readers to Messrs. Ferguson's little work.—*China Mail*.

TOOTHACHE REMEDIES.—Dr. J. R. Irwin writes to the *North Carolina Medical Journal* that one of the most pleasant remedies for toothache is chewing cinnamon bark. It destroys the sensibility of the nerves and suspends the pain immediately, if the bark is of good quality. The editor of the *American Druggist*, quoting this, adds that in many cases a teaspoonful of bicarbonate of sodium in half a glassful of water, to be used at short intervals as a mouth-wash, is equally serviceable in relieving the sensitiveness of the teeth and gums.—*Chemist and Druggist*.

BLISTER BLIGHT.—A planter in the Dibrugarh district, writing on 7th instant, says:—*Blister blight* has made its appearance here. I have not seen any of it since 1871 or 1872, when we were severely punished in the Jorchant district. It used to be put down to shade, want of draining, heavy wet alternating with excessive heat. It so happens that I have removed all shade from the garden this year; one plot attacked would be the better of draining, but another plot is very well drained. We have certainly had a very wet spring, 35.89 inches of rain in April, but we have had no heat, in fact, blankets are still in use at night. Doubtless the blight is a fungus and possibly there is no remedy. I just mention the facts in case the disease should be general this year, and other of your correspondents should note their observations.—*Indian Planters' Gazette*.

TEA DRYING.—Owing to excuses having been made that the teas from certain gardens under one agency had "gone off," because Gibbs and Barry's dryers were used, the following test was applied. A certain taster, who had purchased for the above agency a considerable quantity of teas of various outside marks in Calcutta, having recently arrived in London, was requested to re-taste and report upon these purchases on their arrival in London, and to be particular to note any signs of their having "gone off." He did as instructed with the result that he could find no such signs, yet the gardens of the marks represented are known to employ the Gibbs and Barry dryers. There is such a thing as use, and there is also abuse. If people are told that a horse can drag safely 25 cwt. and they thereupon compel him to drag 35 cwt. they must blame themselves if the result is fatal. Mr. Gibbs is against the excessive temperature used by many in the G. and B. dryer, as also, I believe, Mr. Barry. Mr. Gibbs is showing a new model at No. 1-A, Paternoster Row, in which it is said numerous radical improvements will be found. I have yet to see this latest model.—*London Cor., Indian Planters' Gazette*.

TOBACCO PAPER.—The *American Tobacco Leaf* says that paper made of tobacco stalk is one of the latest claimants for public attention. Tobacco paper produces a stronger paper than wood, at a much smaller cost. Samples made under unfavourable circumstances show comparatively few defects. A great point in the manufacture is the fact that only the ordinary machinery found in every paper mill is required. Tobacco stalks reduced to a bone-dry pulp show a waste of only five per cent. The paper produced is similar to that found on every grocer's counter. There is no taste or smell of tobacco left to show the raw material. A year ago an experiment was made at the Jordan paper mill. A case of about 400 pounds of leaf tobacco, minus the "backbone," was put through the regular treatment of straw. A fine pulp was the result, but owing to the lack of fibre the pulp was crumbly and stuck obstinately to the roller. However, several small pieces were removed, and after becoming dry presented every appearance of straw paper, besides being a more pronounced brown. The idea of converting the cuttings and stems that accumulate in cigar factories into paper has occupied the mental capacity of not a few. The latest result is a smooth surfaced, fine textured, tough sheet, from a pulp produced from the stems or "backbone" of leaf tobacco, and presenting artificial minute veins all over the surface. The only defect now left is the slight papery taste and smell, with which defect the inventor is at present labouring, with every indication of overcoming the drawback.—*P. T. Journal*.

CULTIVATION OF CHINA GRASS IN BRAZIL.—According to the *Central Blatt für Textil Industrie* a concession has been granted to a German firm securing to them various rights as to the treatment of the fibre for paper-making purposes. Scientific researches have resulted in fully establishing the climatic advantages of Brazil with reference to China grass cultivation.—*P. T. Journal*.

COCONUTS SHIPPED TO ENGLAND.—I understand that there is no demand now for coconuts to be shipped to England which was done to a great extent last year, and the reason given is, I believe, a true one: that the brokers receiving short notice of extensive orders used to buy up immature nuts from the different gardens in the vicinity of Colombo, which, when shipped to England, and received there, are principally found to be spoilt and unfit for the purpose required; hence there is an extensive falling-off in the shipping of nuts this year.—*Cor.*

GAMPOLA DISTRICT has not experienced such a fine planting season for many years. Today it has been raining very heavily, preventing outdoor work. The tea on old Sianapittia is fast covering the ground and in a year or two will be upside with Mariawatte. Black-bug very bad and is killing out the few coffee trees left. Cacao, I fear, will be a failure in this district unless shade is planted amongst it. There was a good blossom out six weeks ago, but hardly any of it set. Helopeltis is blamed for doing more harm than it really does. *Thrips* is the worst enemy the cacao tree has got, and if anyone will take the trouble to examine the insect under a microscope, they will find it full of green juice sucked from the young leaves. On more than one estate in this district they have done a great deal of harm.

CINCHONA.—In former years when the Cinchona industry was in its infancy, and a larger number of plantations were being opened out by private growers at Ootacamund and other places, there was necessarily a very large demand for cinchona seed and cinchona young plants; and as the Government plantations were the oldest and most noted in the districts, the growers naturally applied to Government to supply their needs. This went on for several years, until the new plantations were able to supply their owners, with what Government before had only been able to produce. Again, these new plantations are now able to compete with the Government in the sale of seed and plants. Owing to the great depreciation which has recently occurred in the value of cinchona bark, the public have been deterred from increasing their plantations, or from opening new ones. The miscellaneous receipts of the Ooty plantations from 1877-78 to 1884-85 aggregated Rs2,562.—*Indian Agriculturist*.

RAMPODA: DISTRICT AND WEATHER REPORT: 30th June.—The monsoon set in mildly about the end of May; and up to within the last few days we have had most perfect planting weather. Since the middle of last week however—with the exception of one fine day (Saturday)—the rainfall has been so heavy and persistent as to put a stop to all work. It is still raining heavily, and we may expect to hear of floods in the lowcountry and more slips on the railway, traffic on which no doubt interrupted, as Monday's *Observer* has not yet come to hand. Tea is being extensively planted on many estates; in some cases amongst the coffee—in others the coffee is being removed and a fresh start made with the new product. The latter plan will doubtless prove the most satisfactory in the end, as the lining, hoeing and planting can all be done much better with a clear field to work on. Still one can quite understand a planter's reluctance to uproot coffee that has given good crops in times past, and may—so many think—do so again if it only goes fair play. Labour is fairly abundant for present requirements, though some not overpopular employers find it necessary to give advances to obtain coolies.

BAUHINIA VAHLLII, A GIGANTIC CREEPER, the stem of which sometimes attains a circumference of five feet (!) is thus noticed in the proceedings of the *Horticultural Society of India*:—From Captain Pogson, enclosing a letter to him, from Mr. Smythies, Deputy Conservator of Forests, Dehra Doon, and forwarding a parcel of *Bauhinia Vahllii* seeds: Mr. Smythies says "this is one of the commonest climbers in India, and has a wide range. I should be glad if the natives would eat the seeds, pluck all the leaves, and cut down all the stems of this climber in our forests. We wage war against it, and have already cleared a considerable tract in Ranghar of this weed. The stem is sometimes five feet in girth, and the leaves range up to 18 inches diameter. We annually grant a large sum for the destruction of this climber, and eventually shall exterminate it; but it will be a work of time. In the open forests, I am afraid, it will remain for ever." Captain Pogson remarks that it is a pity such quantities of this superior fibre should not be utilized.

TEA PLANTING IN DARJELING: No. 3 SIROCCO.—No rain, and a high, parching drying wind every afternoon have been the characteristics of the weather during the last fortnight. I am sorry to say that our *chula bursat* has been a failure and a humbug, with the natural result that tea planters are beginning to feel decidedly anxious at the prospect before them. As it is the commencement of the manufacturing season was later than usual, and so far as I can gather the quality of tea made in the hills to date is less than last year, while the quality is by no means an improvement on last April's; and, yet, the "experts" who sit "at home at ease" will not believe that weather can have anything to do with the quality of the crop. It is now certain that the second flush, owing to drought, will not be ready for plucking as soon as in ordinary years. However, "care killed the cat" and all planters can do is to hope for more favorable weather later on, and make the best of what has been a bad business so far this season. One gleam of comfort is that labor is very plentiful, so that there will be no difficulty in taking the leaf off when it is fit to pluck. You asked me the other day to let you know what I thought of the No. 3 Sirocco. I give you my opinion in full. I am afraid it is not altogether favorable. In the first place, it is easy to put up, and when up is neat and clean and has one very great advantage, and that is you can see and handle the leaf throughout the whole process, and that there is no fear of burning at any time, it dries tea quicker than the old way, and the teas certainly have a flavor of their own. Getting up heat is much more expensive than is represented by the inventor, for with *dry wood* we use from 19 to 25 maunds in a day; that is, of course, going up to 9 p.m., and the result is only 7 maunds of *pucca* tea. Another point is that it is said only to take a man and a boy to attend to it; whereas when we work for 14 hours, or even 10, it takes at least 3, sometimes 4, hill men. But, of course, all these drawbacks will be more than compensated for should the Sirocco dried teas get half more per pound than the *chula* dried teas. I do not think that at the best of times we shall be able to do more than 7 to 8 maunds of *pucca* tea, though the inventor says, I believe, 13½. The great test of the drier will be as to whether its teas fetch a higher price. If they do that then we may overlook its other defects, at present they value it a little higher in Calcutta. Your readers will see that in this opinion nothing is extenuated and naught "set down to malice," and I am sure both the public and the inventor will be glad of an honest opinion on the drier. I will have more to say about the Sirocco as the season goes on, as there is no doubt that a really perfect tea drier has a great and useful future before it, and would be a fortune to the inventor as well as an immense saving in the production of tea.—*Indian Planter's Gazette*, April 25th.

DARJEELING TEA.—There is little doubt but the quality of tea made in the hills this year is better than up to the same date last season, but one must always take the opinions of Calcutta experts *cum grano salis*, as they always report more favourably on the quality of samples when the market is rising, as is the case this year; and besides, and to say, experts are not quite infallible.—*Darjeeling Cor., Indian Planter's Gazette.*

THE NEW TEA EVAPORATOR.—A correspondent from Assam writes us that he was the first person to introduce, or at any rate use, anything of this kind in Assam. He says he made one himself from designs which he saw in the *Scientific American*, but he attached a fan to the far end, so as to draw the heat through the tea. At this time the Evaporator had not been thought of in America for tea, but only for desiccating fruit and the like; and our correspondent thinks that some one who knew the experiment he had made as to adapting the Evaporator for tea has appropriated his ideas. Our correspondent says, however, that he only used the Evaporator for ficial firing, for which it answered very well, burning either coke or charcoal, and with less than 3 maunds of the latter he could finish 20 to 30 maunds of tea a day. He does not believe the American Evaporator will answer for first firing.—*Indian Tea Gazette.*

REFORM OF LONDON TEA SALES.—The manner in which the tea sales are conducted has caused much dissatisfaction for some time past, for the reasons given last week, and a private meeting of a few of the aggrieved brokers has recently been held to discuss the subject. In fact, this question is in many respects even of more importance to the buying brokers than to the dealers, as is shown by the meeting referred to. The present system culminated last week in the purchase of an entire catalogue of congous by one broker, a circumstance which, of course, attracted the serious attention of other brokers, many of whom were anxious to buy at the sale. What took place at the meeting of brokers which this occurrence led to has of course not been published in detail, but one of the leading firms of brokers this week announced a slight alteration in the terms on which they would offer tea. Hitherto, the buyer of one lot has had the option of taking the following lot, even when he was not the first bidder of the price at which it was sold. Under the system of offering entire parcels in one lot, this has increased the tendency to give a monopoly to a few buyers at public sale. The change announced this week was that the "last year" should not have the succeeding lot knocked down to him at the sale, unless he was the first to bid the price at which it was sold. This does not meet the difficulty that when a parcel of common tea is offered at the sale there is a simultaneous and deafening shout of the same price from seven or eight people. In this case the "last buyer" would still claim to have the lot knocked down to him. Further, the firm of brokers in question propose to withdraw the remaining privilege of the "last buyer" in case the latter buys more than two lots in succession. This will, in some degree, reduce the advantage enjoyed by the buyers of a previous lot, and may thus be a slight palliative to the evils of the present system, but it is not backed up by a general agreement, so that it is simply an arrangement made by an individual firm who hold some of the most important China tea sales. No alteration, short of the sub-division of parcels into lots of 25 or 50 packages, can replace the public sales of tea on a proper basis. Without this sub-division there cannot be efficient and free competition, purchases must tend to drift into a few hands, and importers, brokers, and dealers alike must in time suffer from the creation of a buying monopoly. Apart from this question the great disorder which prevails in the public sale-rooms certainly calls for immediate reform.—*Produce Markets' Review*, May 23rd.

FINANCIAL CRISIS IN BRAZIL.—Customs, almost the only source of revenue in Brazil, had fallen off greatly under an almost prohibitive import tariff. The position of commerce and finance may be judged by the following extract from proceedings of Parliament, reported in the *Rio News*:—In the Senate, Sr. Correia read an extract from the *Diario do Brazil* from which it appears that one of our principal banks will shortly commence its liquidation and that 200 commercial houses here are bankrupt. The Senator then referred to the increased charge on the Treasury through the lower rate of exchange and wished to know what was the floating debt, including that to the savings banks.

INSECT PESTS.—From Bucharest it is announced that locusts have invaded the Dobruddacha in such quantities that the military have been sent out to destroy them. We have plenty of plagues here in England, but, thank goodness, our English pests do not do things on such a magnificent scale as the Dobruddacha locusts. If our peaceful countrymen were to read something like the following in their daily paper, they would think the editor, staff and compositors were all under the spell of madness:—

"The common or garden-slug has appeared in such numbers in Hyde-park, that the Guards are under orders to commence a campaign against them."

"Rats having infested the banks of the Thames in such numbers, the Channel Fleet has been ordered to Mouleyse to bombard the banks."

"The Government purposes calling out Her Majesty's Reserve Forces to wage war against the army of cockroaches which has seized upon the Tower and the Houses of Parliament."—*Weekly Echo.*

FLAX FIRRE.—Attention is being given in the United States to flax fibre as a material for paper making. In southern Dakota flax is grown for the seed, the fibre going mainly to waste. Last year 1,000,000 bushels of flax seed were sent out of the territory. The fibre is sold for \$2 to \$2.50 per ton, a price that would seem to offer an opportunity for a paper manufacturing experiment. It is stated that the proprietors of the London Telegraph, who own a large paper mill at Dartford, England, have purchased a large tract of railroad land in the Mojave Desert for the purpose of using the yucca plant which grows on it for the manufacture of paper. The plant will be ground into pulp at a point on the Colorado river, and shipped by rail to New Orleans, thence by sea to Liverpool. Apropos of paper making from moss, the *Pensacola Commercial* says that the moss crop of Florida is worth more than the cotton, and can be put on the market at less expense. The demand exceeds the supply, and there is not a county in the State in which this product is not going to waste.—*P. T. Journal.*

RESULTS OF GOLD MINING IN MYSORE AND AUSTRALIA.—Captain Plummer indulges in no prediction, but there is a tone of confidence in the outlook of the mines that he is exploiting, which should be encouraging to shareholders in his Company, and should stimulate the enterprise of other companies on the Mysore field. It will be observed that the assay of the stone at 173 feet level gave 2 oz. 10 dwt. 22 gr. per ton; at 233 feet it gave 3 oz. 1 dwt. 6 gr. to 4 oz. 1 dwt. 6 gr.; and at 236 feet 7 oz. 18 dwt. 10 gr. to 9 oz. 1 dwt. 7 gr. The deeper the shaft is sunk the better is the result, and at the lowermost point, "very rich stone" has been found. The depths of the shafts are particularly noticeable. Here is Captain Plummer at Mysore winning \$ to 9 oz. of gold per ton of quartz at a depth of only 236 feet, while at Sandhurst, the shafts go down as deep as 1,760 feet, and a return of 673 oz. of gold from 628 tons of stone, or but little more than 1 oz. per ton, is characterised as a "grand yield."—*Madras Mail.*

COCA SEED.—A correspondent writes from up country:—"Have you any idea where I could buy some coca (Erythroxylon) seed? What is Mr. Blacklaw's address in Brazil? Could he procure it, do you think? Would he do so, or would he be angry at my remitting money to him for the purchase and despatch of some? Everyone who has got seed from Peradeniya has failed in raising plants." Mr. Blacklaw will certainly not be offended at our correspondent's request should it reach him; but he may not be able to procure the seed. His address is:—"A. S. Blacklaw, Esq., Mangaratiba, Province of Rio de Janeiro, Brazil." But what are the enterprising J. P. Williams & Bros. of Henaratgoda about? As the seeds are successfully raised at the Peradeniya Gardens, may it not be possible to procure plants there very shortly?

TELEGRAPH POLES.—Mr. George Simpson writes to us on the subject of telegraph poles:—"There is one wood and one only which unites in itself all the qualities requisite for the purpose, and that wood is the product of our colony of Western Australia. It is the wood known as "jarrah," a species of eucalyptus, whose special qualities are that it is absolutely impervious to atmospheric influences, it cannot be acted upon adversely by sea water or sea insects, is non-inflammable, and having been tested for shipbuilding purposes for over forty years, and also as piles for Jocks, is found practically indestructible. M. de Lesseps, no mean authority, has testified through his engineer-in-chief that after a test of seven years the jarrah used for piles in the Suez Canal showed no signs of deterioration, and adds that apparently it does not allow of decomposition or of being deeply affected by rot. Why, then, not try jarrah? The wood is abundant, and can be readily delivered in this market at about half the price of teak, and in lengths considerably exceeding those of the average telegraph poles.—*Pull Mall Budget.*

ERYTHRINAS AND LEAF-DISEASE.—As *dadaps* have never been planted as shade trees for coffee in Ceylon, and as we have always regarded as absurd the idea that the *erythrinus* were in any degree responsible for leaf-disease, we feel rather sore that in the following proceedings of the Madras Agri-Horticultural Society the *Ceylon Observer* should seem to be connected with so unfounded a theory. It was in Java the idea originated, which is thus disposed of:—Read letter from the Director of Revenue Settlement and Agriculture, dated 29th January, 1885, forwarding for information an extract from a letter published in the *Weekly Ceylon Observer* for 27th November 1884, which states that the writer was told as far back as 1840, that coffee leaf-disease was caused by planting "Dadap" trees between the coffee plants for shade, and that his experience since has convinced him that this is the case; for, wherever coffee is planted on forest land, or where no "Dadap" trees are used for shade, there is no sign of leaf-disease; and requesting to be informed whether from knowledge and experience of the subject the statement that planting *Erythrina* trees for shade causes coffee leaf-disease. Read also communication from the Director of Revenue Settlement and Agriculture, dated 4th March 1885, No. 388-A, informing that the enquiry regarding the alleged influence of *Erythrina indica* (Dadap or Indian Coral Tree) in producing leaf-disease when planted for shade among coffee trees has elicited replies from several gentlemen well qualified by their practical knowledge to speak with authority on the subject to the effect that there has not been observed in Southern India any connection between the presence of *Erythrina* trees and the production of leaf-disease, but that, on the contrary, the effect of planting *Erythrina* has been distinctly beneficial, not hurtful to the coffee trees which it is planted to shade; and that the replies given are in complete accord on the point.

THE DUTCH AND ENGLISH LABOUR SYSTEMS COMPARED.—The Melbourne *Leader*, reviewing a work on New Guinea, states:—"Mr. Chalmers is an admirer of the system pursued by the Dutch in Java, but he has had no personal experience of the working of that system, so that his opinion does not carry much weight. Perhaps he is not aware that even now there is such a thing as forced labour on the coffee and sugar plantations. There is a Dutch law in force which provides that the forced cultivation of the sugarcane is to be totally abolished in 1890, but there is no such limitation in respect to the forced cultivation of coffee. The prosperity of Java has ensued from the continuation of a policy which is virtually a modification of slavery. It was not until 1860 that the slaves were nominally set free, and they then fell under the "culture system." The event was also followed by the introduction of large numbers of Chinese. It should, besides, be remembered that the Dutch system has not been a success elsewhere. In Java there are 400 inhabitants to the square mile, while in the remainder of the Dutch Indies there are only 13. Mr. Chalmers might have asked himself this question: If the Dutch system is so excellent, how is it that there are no fruits of it visible in the western half of New Guinea? It would, perhaps, be hardly fair to ask what the Dutch are doing in Sumatra. It is certain, however, that, looking all round the globe, the English system works better than the Dutch. Ceylon will bear favourable comparison with Java; and if we look to another quarter of the globe, we see British Guiana showing much more satisfactory progress than Dutch Guiana. The English system, when allowed free scope, is entirely successful.

CEYLON TEA WANTED IN CHINA.—A merchant writes:—"What do you think of foreigners writing from China for Ceylon tea? You will be interested in reading the enclosed from ——. Some friends at home actually sent him a sample of Ceylon tea, and so pleased is he with it that he wants to get supplied direct from Ceylon. This is praise, indeed." Yes, for the correspondent, a married resident at Swatow, has been accustomed to get his tea from Foochow, and "though in some seasons we can get it very good, we recently enjoyed the change to a sample of Ceylon." Hence the present enquiry, which may lead to many more foreign residents in the Far East going in for boxes of our product. What a change since the time, a few years ago, when 5-catty boxes from Hongkong sold by Messrs. Geo. Wall & Co. nearly supplied the whole Ceylon market.

Mr. MYLNE, of the firm of Messrs. Mylne and Thomson, of Bechea, recently visited British Burma with the object of introducing the Beehea sugarcane mill into the province. The experiments conducted by him with a Beehea double-squeeze mill were generally satisfactory, as far as they went. But it appears that, owing to the large size of the cane grown and the draught power of the cattle, which is great, something more than the mill experimented with is required for Burma. The difficulty, it is thought, will be solved by the construction of a double-squeeze mill with a large leak-roller, and Mr. Mylne is going to have such a mill made in England and sent out to Burma. The several methods of boiling cane juice adopted in South Behar were also shown the Burmese cultivators, and the methods were admitted by them to be superior to their own. Mr. Mylne, a contemporary says, intends sending a small party of Indian agriculturists to Burma to try the cultivation of various Indian crops on a limited scale. The men will be selected from Shahalad. Sugarcane, peas, wheat, Indian corn, and gram are among the crops with which it is proposed to experiment.—*Bombay Gazette.*

COFFEE.—By last official advices from Bali the coffee plantations there present every prospect of a shorter yield than in previous years, owing to a disease breaking out among the coffee trees.—*Locomotief*.

THE SUPPLY OF TEA (Japan) has thus far been limited, but the quality is pronounced superior to the early products of last year. Prices have been high, and will probably be higher as the season advances, an unusually small crop being expected.—*Japan Weekly Mail*.

MULBERRY TREES have been injured by frosts in various parts of the country, and growers of silk-worms are apprehensive that the usual supply cannot be reared this year. For this, and also for reasons connected with the general distress among the labouring classes, a bad silk season is predicted by native newspapers.—*Japan Weekly Mail*.

JAVA TEA IN BRITAIN AND IN HOLLAND.—A tea planter, calling attention in the *Dayblad* of the 27th May to a report on the trade in Java tea in England during the last five years, which showed that the importation of that article there increased from 1,216,000 lb. in 1881, to 3,536,000 lb. in 1884, in spite of a steady fall in prices, thus comments thereon:—

“The gradual decline in prices, though disappointing to importers, has not affected Java tea alone, but has taken effect also upon other teas sometimes even in a greater degree. Nowadays, attention is paid to good aroma and flavour more than to the quantity of the leaf, and several Java planters who set to work supplying strong and fragrant tea found a ready sale for their produce at good prices under the circumstances. Messrs. Gow, Wilson & Stanton, the tea brokers who drew up the said report, give in conclusion a few hints about the preparation of tea. Hence not only do British brokers shew their kindly feelings for Java tea planters by yearly bestowing a splendid cup to be run for yearly at the Buitenzorg races, but their interest shows itself still more by suggesting improvements in the article produced and by the valuable and reliable information which they always furnish to planters here in their tea trade reports, accompanied by tabular commercial statements. Also as to expenses, above all in these times of such great importance to growers, these brokers more than once have shown an inclination to render them as little burdensome as possible upon growers. How unfavourably does the routine policy and the indifference of the brokers in Holland (a few only excepted) contrast with the helpful and judicious conduct of their British fellows! Hence it is no wonder that a large number of Java tea planters shun our markets, where expenses are heavier, and a good brand finds much less recognition than in foreign lands. However patriotic people may be, saving expenses—especially in such times as these when prices hardly yield any profits—is the main consideration, and self preservation enjoins that a foreigner's hand should be accepted when that of one's countryman offers less support. Instead of taking this amiss of the Java tea planters and showing it now and then, our brokers would do better to follow the example of their British fellows in order by so doing not only to keep what little tea now goes to the Dutch market, but also draw thither the larger portion of the consignments, so that, in the long run, the strange fact should not become manifest that consumers of Java tea in Holland have to supply themselves for home consumption at the London market. We do not keep pace with the times owing to the old colonial commercial ideas not being yet rooted out. It should not be forgotten that a grasping policy always proves unwise, or in fact that clinging to old ways of transacting business no longer suits these times of keen competition.”—*Netherlands Indian News*. Translated for the *Straits Times*.

WILLOW-LEAF TEA.—It is announced on excellent authority that more than half a million poundsof willow leaf were made up at Shanghai last season and palmed off as green tea.—*Madras Mail*, June 30th.

MR. DESPERRIS ON TEA.—Mr. Desperis, our intelligent Royal Society member, gave us on the 22nd ult., a remarkable lecture on the subject of tea going through its whole history in a most lucid manner. The Society of Arts and Sciences ordered it to be printed and deposited among its records. It will be a valuable guide to those who undertake tea cultivation in Mauritius.—*Mauritius R. & M. Gazette*.

GOLD ON THE SEGAMA RIVER.—The Commissioner of Lands, Mr. Henry Walker, returned from the Segama River on the 16th May, after an absence of 52 days. We have not seen his detailed report but the summary of his investigations is, that in old beds of gravel in the lands on each side of the river gold has been found in sufficient quantity to be remunerative if worked by sluicing, as at present done by the Chinese in Sarawak. The gold obtained is fine, of good quality, and would probably have been found to exist in large sizes had time admitted of the bottom being examined. There are reports of large pieces of gold being taken from the Sabosow, a tributary on the right bank, three days' journey above Mr. Walker's limit if made at high water. Mr. Walker's notes on the geological strata show it to run at an angle of 120° from the meridian or nearly S. E. by S. and N. W. by N. which lines produced on the chart will lead to the supposition that gold may exist at Silam and the East shores of Darvel Bay, and on the higher waters of the Kinabatangan, the Labuk, and Sugut Rivers, all of which is borne out by native reports, and latterly, been proved by observations made by Captain Beeston and Mr. Davies, the Resident of the West coast. This represents an immense area and we may fairly hope it will yield such profitable returns as may lead to the influx of a very large Chinese population.—*North Borneo Herald*.

MONSOON IN MERCARA.—June 12th.—Thunder and lightning are rare things after the monsoon has fairly set in and indicate, so say the natives a light monsoon. There was very vivid lightning accompanied by thunder the other night, and I thought the natives had made a very fair hit when the stars were visible for a little last night, and the day today was partially fair; because we generally have a spell of 15 days' rain after the burst; during which the sun is almost entirely veiled before a “break” sets in. But it is far too early to decide whether it will be a light or a heavy monsoon. The monsoon is a rather gloomy time of year, but the most healthful. It is well that it brings much employment in its train for planters, or else we should inevitably fall victims to *ennui*; and I don't know if very many of us can escape it now, for the coolies have not come in as yet, and we have very little to attend to, I suppose this is owing to the lateness of the rains in Mysore. But I think planters are rather glad of it, as we can well do without them for the next month or so, and it will help to keep down expenses. Many perhaps would rate this a false economy—allowing estates to be overrun with weeds and supplying vacancies late. A few coolies should always be at hand very desirable for supplying vacancies as it is to put the young plants out early in the season. As to estates being allowed to be overrun with weeds, I have seen no permanent evil produced by allowing weeds to remain even as late as August. May it not be possible that weeds are a natural provision against “wash” from which coffee lands deteriorate so rapidly? But enough of this. I leave it to the wiser heads to propound. The blossom showers in March had been so seasonable that planters are elated at the prospect of a heavy crop this year and if prices would only improve!—*SPECTATOR*.—*Madras Mail*.

FIBROUS PLANTS AND THEIR PERCENTAGES OF FIBRE.

We, in common with our readers, are very much indebted to Mr. J. W. Minchin of South-East. Wynaad for his correction of an astounding error made by a Mr. Halcombe in regard to the proportion of clean fibre to bulk in New Zealand hemp or flax, and for showing that in reality the best fibre-yielding plants have not a greater percentage of useful and marketable material than from 2½ to 10 per cent—the higher percentage being rare. The stems of plantains and bananas contain very little more than 1 per cent of fibre, even the best Manila plants not excepted. New Zealand flax, when reduced to its proper proportions, shows a much better result than this; but, if the enormous proportion of water in plantain stems renders fibre-extracting from them unprofitable, the difficulty, on the other hand is almost as great in consequence of the small quantity of moisture, in the New Zealand plant. Besides the difficulties connected with too much and too little water, and great bulk and weight in proportion to fibre, additional impediments to profitable working are offered by obstinate bark and woody matter and sticky gum. To clean fibres thoroughly a combination of mechanical forces and chemical agencies are required, and, when these can be and are thoroughly applied, the cost in labour and money is too often far more than the market price of the resulting fibre. For paper-making, generally fibre at a very low price is desiderated, and even for textile purposes a high price is only rarely given. We have seen so many sanguine statements ending only in disappointment and loss, that we are inclined to advise great caution in regard to experiments. That in which Mr. Minchin is engaged, of growing rhea over an appreciable area, is one of the most promising we know of, and we sincerely trust it may be successful. The chances in its favour include the fact that the stems yield fibres of such varying qualities that while part is used for ship's cables and cordage the finer fibres are suitable for replacing or being mixed with the most lustrous silks and the most superior merino wools. There can be no doubt as regards demand, if only cheap as well as thorough processes of preparation could be discovered and adopted. If these desiderata are met, we cannot help thinking, that, next to rhea, attention ought to be paid to the leaves of pineapples, grown as these plants generally are by the natives of Ceylon in shady places so as to develop leaf to the utmost. Pineapples have a great advantage over green leaves apparently in not being so exhaustive of the soil. In our recent travels through the tea regions of Ceylon, we found the proprietor of lands in the Kelebookka Valley (a valley destined to be even more famous for tea than it once deservedly was for coffee) waging relentless war with alien hedges, on the ground of experience obtained, that they were fatal to all other growth within fifteen feet on either side of them. As a general rule, therefore, fibre-yielding plants cannot be grown as subsidiary cultivation, but must have special areas of ground devoted to them. And not only so, but, as crops in succession are taken away, fertilizing matter must be supplied. Rhea certainly requires rich soil and copious manuring. The question of "Will it pay?" under such circumstances becomes urgent, and certainly as far as Ceylon is concerned we have not yet heard of successful experiments with fibres, if we except the black bristly substance found on the kital palm

(*Caryota urens*) and the fibre of the coconut (coir), from the manufacture and export of which certainly fortunes are not made. Mr. Minchin will, no doubt, continue to report progress in regard to the rhea experiment under his charge, and we shall be always glad to hear from him;—especially if, as we trust, the experiment results in success.

PERCENTAGES OF FIBRE IN VARIOUS PLANTS.

The Glenrock Company, Limited, Pondalour,
S. E. Wynaad, 22nd May 1885.

(To the Editor of the "Tropical Agriculturist.")

DEAR SIR,—With reference to your article on Fibre Cultivation in the May number of the *Tropics Agriculturist*, vol. iv. page 866, and your remarks on the percentage of fibre in different plants, read Mr. A. T. Halcombe's statement that *Phormium tenax* gives one ton of fibre to three tons of leaves with great surprise, and at first thought it must be some error in printing, but I see that the figures are repeated at the end of his letter. The weight of green leaves of *Phormium tenax* to the ton of fibre is stated by various authorities at 5½, 6, 6½, 6¾, 7, and 7½ tons, and is taken at 15 per cent. (See Spon's Encyc. Commercial Products, div. iii., page 985.)

Dr. Sutherland, in his answers to the Fibre Committee at Natal (see *Tropical Agriculturist*, vol. iii., page 461), gives 10 per cent as the yield of fibre from *Phormium tenax*. I think there must be some error in the statement made by Mr. Halcombe which would show that the New Zealand flax, *Phormium tenax*, would give tenfold more fibre, in proportion to the green stuff treated, than *Boehmeria nivea* or rhea.

The percentage of fibre to the weight of green material depends mainly on the percentage of water it contains. Succulent plants such as Manila hemp and plantain contain as much as 90 per cent of water. When first cut, rhea contains from 70 to 80 per cent of water, according to the age of the stems and the season of the year. Young succulent stems contain more water than the ripened stem which has begun to brown at the butt, and there is more moisture in the ripened stem during the rains than in the dry weather even under irrigation. It is undoubtedly the case that fibre plants growing in dry and arid ground will contain a larger percentage of fibre to their green weight than succulent plants grown in a moist climate. The leaf blades of the *Phormium tenax* contain very little moisture, and this is partly the cause of the difficulty experienced in the preparation and extraction of the fibre.

The yucca, which you kindly inform me has been found to yield 12½ per cent of fibre under Mr. Charles Shand's experiments, grows in very dry sandy soil, and would not suit the moist soil and climate of Wynaad. Its principal use at present is for paper making, and its commercial value is small.

I gather that the percentage of fibre from the following plants is found to be as follows:—

COTTON.—*Gossypium*.—15 to 20 per cent of the unginned seed.—Spon's Encyc. div. iii., page 957.

HEMP.—*Canabis sativa*.—9 to 12 per cent raw fibre, of which 25 per cent is gum soluble in water, 25 per cent is gum soluble in alkalies. Say 5 to 6 per cent of clean ultimate fibre. The green stems contain 50 per cent of water.—Dr. Forbes Watson's Report on Rhea, 1875, pages 16 to 17.

FLAX.—*Linum usitatissimum*.—60 per cent water, 5 to 7 per cent raw fibre, of which 35 per cent is gum, half soluble in water, half soluble in alkalies. Say 4 per cent clean ultimate fibre.—Dr. Forbes Watson on Rhea, 1875, page 16 to 17.

RHEA.—*Boehmeria nivea*.—80 per cent water, 4 to 6 per cent raw fibre, prepared by hand as China grass, of which 30 per cent is gum not soluble in water. Say, 2½ to

4 per cent clean ultimate fibre.—Dr. Forbes Watson on Rhea, page 15 to 17.

YACUM.—*Catropis gigantea*.—10 tons green stems will give 582 lb. fibre. Say 2½ per cent.—Strettel's New Sources of Revenue for India, 1875.

ALOE.—*Agave Americana*.—6 to 10 per cent fibre from leaves 8 to 10 feet long and 1 foot wide.—Spon's Encyc., div. iii., page 912. But in a report to the Bengal Government published in the *Tropical Agriculturist*, vol. ii. page 655, it is stated that it requires as much as forty mannds of aloe leaves to make one maund of fibre. Say 2½ per cent of fibre.

MANILA HEMP.—*Musa textilis*.—Average weight of tree 50 lb. 1-4 per cent of fibre. 3,200 trees may give one ton of fibre.—Spon's Encyc. div. iii. page 981.

MARUL.—*Sansevieria Zeylanica*.—Full-grown leaves 3 to 3½ feet long, yield at the rate of one pound clean fibre for every forty pounds leaves. Say 2½ per cent.—Spon's Encyc., div. iii., page 995.

I have not been able to ascertain the percentage of fibre from green jute stems.—I am, dear sir, yours faithfully,
J. W. MINCHIN.

IRRIGATION IN INDIA.

Mr. A. B. Fforde, of the Settlement Department, has addressed a valuable letter, on "Irrigation Works," to the *Times of India*; and as we agree generally in the views expressed by Mr. Fforde, we reproduce the letter below:—I have read with interest your leading article on irrigation. The ryot is, as you say, in the habit of declaring that canal irrigation is not so fertilizing as well irrigation. He says that the canal water is too "cold," requires more manure than that from wells. He does not say this of canals, from small streams made by himself but only of Government canals. The reason for his objection lies, I think, in the fact which I have often noticed, that he uses too much water when he takes it from Government canals, and waterlogs his soils. Where the small village canals are used, he is restricted to a very limited supply of water, and gets no more than is absolutely necessary. His neighbours watch carefully to see that he takes no more than his proper share. Where the supply is practically unrestrained, as in the case of large Government canals, he keeps the water going all day and drowns out his crops. Again, since he can get much more land under water, he is tempted to spread his available manure over a large area, and compared with land under wells the crop is poorer in consequence. In the Deccan the ryot will often leave his well unused if he can get water from a local canal, because the labour is so much less. I imagine that, all expenses considered, canal irrigation, even if showing a poorer out-turn, is cheaper than that from wells—gives a larger profit. As to deterioration of soil by canal water, that applies equally to wells. I have seen soil, formerly of the best, so ruined by well-water as to be perfectly barren. In the famine year I saw crops killed by water from wells. The smaller quantity of water probably caused concentration of the salts in the water-bearing stratum. If canal water caused the salts to rise from the lower strata where they generally lie, so does well-water, and in such strata the latter is even worse, because the water is drawn direct from the underlying strata and is not surface water like that from canals. Where canal irrigation is impracticable, well construction would be of great value. Seven years ago I advocated, in one of the Bombay papers, the construction of wells by private capitalists in such districts. There is no doubt that wells could be constructed and hired to the ryots at rates which would pay very largely indeed. Such wells would be a most valuable property. The comparative failure of Government canals to return large profits is, I think due to the fact that many of them are not perennial. The people will not pay high rates for water, unless

they can get it during the summer months, and some large canals are, as I know, unable to give water all the year round. That the people are willing to use canal water is beyond doubt. In one taluk alone in the Deccan there are upwards of 800 small canals from rocky streams. None of these can carry down anything but sand or stones on to the soil, but they are used wherever there is the slightest chance of making them. Well-water may be more fertilizing, but very slightly so. It would naturally contain more earthy and vegetable matter from infiltration.—*Indian Agriculturist*.

WHOLESALE TEA DEALERS IN COUNCIL.

At the annual general meeting of the members of the Wholesale Tea Dealers' Association several matters of interest to tea-planters were discussed. The report was read by the Secretary.

The Chairman in moving the adoption of the report congratulated the trade on the point which the Association had carried, which had put a stop to the short weight delivery of teas to their customers. For, as they were aware since October last, the system of reweighing had been carried out with most satisfactory results. The next question referred to in the report was that of Indian tea, and he was glad to say that by the action of their Association it had been arranged that when there was any difference beyond the net weight in Assams, the Customs authorities turned them out and the tare was properly calculated. One or two cases had come under his own notice in which customers had not had the weight they were entitled to, but he hoped that by the new regulation this would be remedied.

Mr. John Harrison then referred to the heavy charges on the handling of teas in the warehouses, and believed that if they took united action, they would be able to get a reduction of them. He would move therefore, "That this meeting is desirous of entering a strong protest against the exorbitant and very unjust charges made in connection with warehouse rent, and the handling of teas, and undertakes to support the committee in any action they may take, for the purpose of securing their reduction."

The resolution was unanimously agreed to.

Mr. Oglesby referred to the question of sampling. They might legislate but they could not make the brokers sample in the same way as the leaders, but if it was discussed with the former he thought they would be very likely to consent to some mutual arrangement. He thought the present mode of inspection was very far from what it ought to be. He had recently had a case in which the inspection was most outrageous, the lid had only been lifted, and the inspector took out a fair sample only stating that the surface was slightly damaged, whereas when the box was turned out the back was in a bad condition, fortunately the box was kept, and he was able to show it to the broker, but it was only after a great deal of correspondence that he got the amount which he claimed. He considered it most unjust that they should have such insufficient inspection. He hoped they would be able to get it reformed, for he believed by so doing they would benefit merchants as well as dealers.—*Home and Colonial Mail*.

AN OPENING FOR CEYLON TEA IN CANADA.

With very much information laid aside to be dealt with at a convenient season are papers connected with a brief visit we paid to Canada in passing through America last year. It will be remembered that Mr. Stimson visited Australia, Ceylon and India in 1883, in connection with a proposed Exhibition at Boston. He took back with him a con-

siderable number of exhibits destined eventually to be displayed not in New England, but in Ontario. In passing through Toronto in March 1884, we attended a meeting of some of the leading citizens at Mr. Stimson's request, in connection with the purposes of his intended Oriental Exposition, and also to give and gather information as to the best means of promoting a trade, especially in our planting products between Ceylon and Canada. We may quote a few sentences from the report which appeared in *The Canadian* of March 17th:—

A meeting of a few gentlemen interested in the promotion of an "Oriental International Exposition," took place at the Rossin House last evening, Ald. Lobb, being moved into the chair. The Rev. E. R. Stimson, who has travelled very extensively in the east and other quarters of the globe, stated the object of the exhibit, which was to promote the intercourse between the eastern and western hemispheres. Mr. Stimson has but recently returned from Ceylon, bringing with him a large collection of specimens of the products of the east in general, and of Ceylon in particular, such as tea, coffee, precious stones, cinchona, etc. Such an exhibition as that proposed, will be a very gratifying and instructive one, and will enlighten the people of this country on some subjects connected with the Orient, of which at present they are lamentably ignorant.

Mr. Ferguson was then asked to speak and gave a brief but very interesting sketch of Ceylon. The coffee estates of that island are, at present, attacked by a disease to the trees which is of so serious a nature that the cultivation of coffee in the island will probably soon be a thing of the past, tea supplanting coffee and being found to thrive excellently and produce a very fine article. Mr. Ferguson dwelt on the various Ceylon products more especially tea, which might be sent to the Canadian market and trusted that Mr. Stimson's exhibit would prove to be as great a success as it deserved to be, concluding his address by paying a very high compliment to Toronto, stating that, from what he saw of it at this season of the year, he was certain it must be a very beautiful city in the summer.

The Assistant Editor of *The Canadian*—an ex-Ceylon planter, well-known in Kelebocka and Deltota for his powers as a cricketer—rather over-coloured our remarks about coffee, the total extinction of which culture we certainly did not consider a foregone conclusion a year ago. But it is with reference to tea we have now to call attention to the Canadian market. The Toronto Exposition came off in due course some time towards the end of the year, and, while exciting a great deal of interest and bringing to many of the Ceylon Exhibitors, Diplomas of Merit issued under the sanction of the Canadian Dominion Government, we regret to learn from Mr. Stimson that, pecuniarily, he and his colleagues have been heavy losers. The exhibits of Ceylon tea and other products—coconut oil, Liberian coffee, &c.—sent by Messrs. Leechman & Co., attracted much attention, we are told, at the Exhibition, and led to enquiries on the part of local dealers, who, however, in most cases, consider London far enough to look to for the supply of their requirements. One gentleman of extensive business connections throughout Canada and who is especially interested in tea has however sent enquiries to us in Ceylon. From this letter (from Mr. Alderman Lobb of Toronto) we quote as follows:—

Referring to our conversation at the "Rossin House" here, where I had the pleasure of meeting you, I recently received samples of teas (duplicates of which I forward per this mail) from Mr. Stimson, who would have handed them to me earlier but for some difficulty which he got into with the Custom authorities. I have submitted them to some of our leading merchants and they have been very highly approved, some of them remarking: "They were the finest black teas they ever put the water on." They are undoubtedly a high grade of teas and could be sold here, if price would not be an obstacle. Having no idea of your valuation, I can give no definite opinion, but, if

any of your friends would like to consign an assorted parcel of, say, 100 half-chests, I could test the market here and elsewhere and should hope to make satisfactory returns.

Then follow business and banking references which will no doubt be deemed satisfactory. The duplicate samples returned are of the well-known "K. A. W." and "Cullocen" marks, and the fact that these are among the finest black teas ever seen in Canada ought to encourage the testing of that market by consignments. Of course, the market in Canada, as well as the United States, has attracted the attention of Indian tea-planters, and the Calcutta Syndicate have done a considerable business through New York, although the impression we got from leading tea-men there, was that it would take a considerable time to win the American tea-drinkers from their fondness for the artificially-prepared Japanese green teas. Nevertheless, the process is going on and the value of a pure unadulterated article is being surely, if slowly, appreciated. The following letter on the Canadian market appeared in the *Indian Tea Gazette* a short time ago:—

THE CANADIAN TEA MARKET—A NEW MARKET FOR INDIAN TEA.

SIR,—The tea-planters of India are sufficiently alive to the necessity of opening up fresh markets for the produce of their gardens, but the persistence with which they adhere to the original method of making up all their tea on the model of China black teas, would almost leave it to be inferred that either they are wanting in enterprise to push their teas beyond the English market, or they know nothing of the state of the tea trade in the other great markets of the world.

Surely if it were known in India that of the sixty-three million pounds of tea imported into Canada in the first seven months of the current year, only about one-tenth was black tea, and that the other nine-tenths consisted of Chinese green tea and natural leaf Japan tea, the planters would make some effort to adapt at least a portion of their output to this market, and to enter into competition for the supply of the United States,—the greatest tea-consuming country in the world, and equally with Canada, a green-tea drinking country.* A certain measure of satisfactory, and presumably permanent, trade in Indian teas has been created with England, but the demand is almost limited to pekoes and the finer class of pekoe souchongs suitable for flavoring up Chinese congous, which have had their pekoe leaf carefully sorted out for Chinese home consumption; but the grades of Indian teas below these qualities give no promise of growing into favor in England, while the very fine quality of the green teas manufactured in Upper India for the Central Asian trade, lead me to infer that the Indian leaf is especially adapted to the preparation of green teas, which even in the lower grades would command satisfactory prices on this side the Atlantic.

I have placed myself in personal communication with several of my acquaintances among the planters of Upper India on this subject, and having established an Agency in Montreal, have every facility for placing suitable Indian teas upon the Canadian market, and I hope to pave the way to a considerable development of the Indian tea trade in this direction; being perfectly satisfied that if the Indian planter will give practical effect to my suggestion, there is an ample market for the whole Indian output on this side the Atlantic.

In the Canadian customs returns Japan and green teas are grouped together, so that it is impossible to determine the exact proportion of each; but from my knowledge of the trade, I should say that the Japan teas constitute considerably more than half our total imports.

These Japan teas owe little to appearance; they have apparently been subjected but to little firing, and the leaf, which is in various shades of dull olive green, is not rolled up compactly, but just folded once upon itself as if sun-dried. The mode of preparation could probably be ascertained through the agency of our consuls, but the subject is of sufficient interest to Indian planters to warrant the deputation of a competent man to familiarize himself with the method of preparation.

* Absurd nonsense and greatly exaggerated statistics.—Ed.

Some few years since Japan shewed sufficient enterprize to make up a lot of pekee for this market in imitation of Indian pekoes. These teas look well, are fully up to the standard for strength, but they are overfired, and want the aroma of the Assam pekee; and failing to command good prices, are no more imported. This is an instructive lesson; the same tea which, fired and got up as a pekee, scarcely saleable at sixteen pence in this market, is worth two shillings prepared as *natural leaf* or *basket fired*.

The one lesson which I wish to convey to the Indian planter is, that here is a market large enough to absorb the whole Indian output,* but that if India thinks seriously of competing for a share of the trade, she must adapt her teas to the market.

The Canadian demand for Indian pekoes and pekee souchongs is limited by the consumption of congous; the trade at present is small, but ruling prices are approximately ten per cent better than in England, and the trade is susceptible of some development.

The following are the current prices of teas in Montreal:—

Japans ...	1 0 to 2 2	} The bulk of business done is in the medium grades.
Young Hysons ...	1 4 " 2 8	
Gunpowders ...	1 4 " 3 0	
Imperials ...	1 4 " 2 8	
Congous ...	1 1 " 2 0	
Indian Pekoes ...	2 0 " 2 6	
Pekoe Souchongs ...	1 3 " 1 9	
Upper Indian Souchongs...	1 3 " 1 6	

These prices include the duty paid, ten per cent *ad valorem*, with an additional penny per lb. on black, and 1½ per pound on green teas.—I am, yours faithfully,

C. F. ANERY, Tea Agency, 487, St. Paul Street, Montreal. There are some absurd errors in the above, more especially in referring to the United States as the greatest tea-consuming country in the world. The United Kingdom is far in advance, the comparison being somewhat as follows:—

	Total annual Consumption.	Per head.
United Kingdom	170,000,000	5 (about)
United States with Pacific Coast	60,000,000	1 1-5th "
Canadian Dominion	12,000,000	2½ "

The sources whence the States and Canada receive their principal supply of tea are approximately as follows:—

China	30,000,000
Japan	40,000,000
India	2,000,000
United Kingdom	

We hope that, before many years elapse, Ceylon may figure for an appreciable quantity in this return.

LETTERS FROM JAMAICA:—No. VI.

CROP TIME ON THE BLUE MOUNTAINS—SHORT CROPS—A VISIT TO THE GOVERNMENT CINCHONA GARDENS—A LOVELY VIEW—GROWTH OF CINCHONA—AN UNWISE POLICY—PROFITS FROM CINCHONA—MR. MORRIS—A SANATORIUM WANTED—PUBLIC OPENING OF A BRIDGE—RAIN IN JAMAICA—A GOOD STORY.

BLUE MOUNTAIN DISTRICT, May 1885.

DEAR SIR,—This is now crop time in the Blue Mountains, for, as in Hapitala, Ceylon, most of our crop is picked during March, April, May and June. The high picking lasts for fully nine months of the year. The present season is very backward; this has no doubt been caused by colder and more showery weather, which has prevailed since January, though, lower down the want of rain is much felt. As a rule crops will not be as large as last year; this should help to keep up prices, as there is now much less good colony coffee in the European markets than in former years when Ceylon and South India were free of leaf-diseases.

Since I last wrote you, I have paid my third visit (since 1882) to "Cinchona," the Government plantation, where the old coffee estate of Belle Vue formerly existed. Each time I have visited Cinchona, I have

noticed an improvement in the appearances as the cinchona fields advance in age, the grass lands and pastures improve, the many variegated trees and shrubs grow up, and the lovely flower beds decked out in their gay array flourish from seeds sent from Kew of all the new varieties; indeed nothing reminds me more of "Home, sweet home," than Cinchona. It is a pity this old Belle Vue is not more accessible, but it is fully twenty-three miles from Kingston only nine miles of which are cart-road to Gordon Town, thence steep bridle-path to Gnava Ridge, down to the Yallahs, and then the last tug of all, a rise of, I suppose, quite 3,000 feet in five miles. But the traveller is rewarded by a most glorious view extending southward to Port Royal and the Manchester Mountains far westward; to the sea at Annotto Bay on the north side; to Morant Point to the eastward; embracing a view most lovely, grand and extensive, of sea, hill and valley, precipice and virgin forest with the Blue Mountain 7,350 feet above the sea as a summit, and Kingston Port Royal, and the Pallisades, at the foot, looking as if one could almost throw a biscuit and land it in King Street, for it cannot be more than 10 miles distant as the crow flies. Words fail me to describe with full justice this most lovely and extensive prospect, which I consider quite equal to many of the best views I have seen in my various wanderings and travels. As to the cinchona itself there is no doubt as to its success, and consequently it is a pity for Jamaica, that prices have fallen so low. There may now be seen succubra trees fully ten to twelve years old (or even older) which have been shaved and mised and are looking none the worse; an official field, which has yielded three or four coppiced crops and is now mainly composed of self-sown trees; very beautiful patches of hybrid and officialis of younger growth, and all the newer sorts, such as Ledger, Calaya Verle, etc., all well represented and making good progress. In addition plantations of forest trees and shrubs, specimens from all lands, are being termed, so that in a few years it will indeed be a show place, and well worthy of Jamaica. So that it seems a pity the Commissioner recommended the sale of the larger part of the plantation on the plea that Government should not compete with private individuals in the Produce Market, and even Mr. Morris himself is of the same opinion, but I have always thought this admitted maxim might be waived in the case of Jamaica, as the produce of 150 acres cannot make much difference in the markets, whereas it would enable the department to become self-supporting, and no longer a charge on the revenue. If Government can without prejudice, and for the general public good, own and work a Government Railway as in Ceylon and Jamaica, I can't see why it should not also own a cinchona plantation to enable the Department of Public Gardens and Plantations to be beneficial to the public without causing a charge on the revenue, thus enabling duties to be diminished on other imported goods which are now taxed at the rate of 12½ per cent *ad valorem* duty. Prices of cinchona are certainly very low, but there are those here who, notwithstanding, still believe that will pay, and say that in 9 years old it may be worth one shilling a tree; so, with 8,000 trees to the acre, that would mean a value of £160 an acre, on which sum a very fair profit should be obtained. Mr. Morris is a most zealous and hardworking public servant; he has lately rendered immense service to the island as Commissioner at the New Orleans Exposition in bringing Jamaica prominently before the American public, and was instrumental in getting quarantine removed from vessels sailing from Jamaica, so opening up the fruit trade for the supply of the vast region of the Mississippi Valley.

* Absurd nonsense; and greatly exaggerated statistics.—E

It has always been a surprise to me that there is no public sanatorium in Jamaica, as there is at Nuwara Eliya in Ceylon, for the climate is simply perfect from November (after the rains) to April and May, but Newcastle at 4,000 to 5,000 feet above the sea is a purely military cantonment, only accessible to the favoured few who know the officers, so that a large hotel on the American principle would, I am sure, pay well, if but some enterprising New Englander would find the capital, or get up a company to carry out such a desideratum. There are many sites at 4,000 to 5,000 feet above the sea, which would suit admirably, and even ready-built houses for a commencement: the difficulties in the way are lack of cart-roads to get up supplies easily and cheaply, and the lack of good servants, but these no doubt could be got from the States, and I feel sure it would pay, as not only would Jamaicans who live in the hot lowcountry gladly avail themselves of such a good chance for change of air, but visitors from America and even from Europe would be attracted to the place if they could be assured of being comfortably housed and well fed. I know of two places such as Belle Vue and Flamahead on the Port Royal range, not much more than four or five miles from Gordon Town, which would suit for the purpose; the present good bridle-road might be widened here and there, so as to make it passable for those Chinese conveyances called "juriksha," so that aged visitors who could not ride could be wheeled up to their mountain hotel.

I was lately present, as one of the Commissioners of Roads for this parish, at the public opening of a bridge over the Yallahs river connecting the parishes of St. Andrew's and St. Thomas's. There was a large assemblage of buckra's brown folk and creoles to witness the ceremony, which was made quite a gala day in the district. The Member of Council for Portland and St. Thomas, the Hon. George Henderson, performed the ceremony in the absence of Major-General Mann, R.E., Director of Public Works, breaking a bottle of champagne over the rail, named the structure "Mahogany Vale Bridge." It spans the river close by that old coffee property, and is a strong, well-built iron-girder bridge. It will confer an immense benefit on the travelling public and inhabitants of the district, for, when the rains are on, and the river as they say in Jamaica "comes down," it is a wide and most formidable current. Many, I am told, have been the deaths caused by people endeavouring to ford it when in flood; at present, after two or three dry seasons, it is but an ordinary stream, but in flood expands some 200 to 300 feet, which proves that when it does rain in Jamaica it comes down with a vengeance.

I may as well conclude my letter by relating a good story I heard some time ago. A gent man and his friend, having gone to Kingston, brought home a block of ice and ordered the old negro woman who was in charge of the house to stow it away in the "drip," which is the term used here for a large earthenware water-cooler and filter, but was obliged to leave home again at once. On his return shortly afterwards he asked the old woman for some ice, when on going to look for it, she found none, it having melted; so she came back in a great state of mind, saying:—"Hi! my massa, him no dere, somebody hav' t'ief him fa' true." W. S.

PROGRESS OF THE CEYLON TEA ENTER-PRIZE IN THE FIVE YEARS BETWEEN 1880 AND 1885.

Messrs. Gow, Wilson & Stauton have, in a very interesting and useful paper, summed up the progress of the Ceylon Tea enterprize from the second quarter

of 1880 to the second quarter of the present year. The main facts and statistics are graphically described in a series of diagrams. First are shown the variations of prices. Commencing with 11d per lb. average in the second quarter of 1880 the course was regularly downwards to 9d in the first quarter of 1881. Our teas have never gone so low as this again. From 9d as recorded, the rise was regular and rapid until 1s 2d was reached in the first quarter of 1882. Then came a fall to 11½d in the fourth quarter of 1882, followed by a steady and rapid rise to 1s 5½d in the last quarter of 1883. This was the highest average. Then there came a fall to about 1s 2½d in the third quarter of 1884, with a rise to 1s 2½d in the fourth quarter, and a fall to 1s 2½d in the first quarter of the present year, followed by a recovery in the second quarter to 1s 3½d, with which the record of 5 years ends. The second diagram shows the shipments in each quarter from Ceylon, and a third gives the annual shipments. We give the figures in a combined form:—

1880	1st qr.	8,000 lb.	} 114,845 lb.
	2nd "	36,000 "	
	3rd "	54,000 "	
	4th "	17,000 "	
1881	1st qr.	54,000 lb.	} 311,145 lb.
	2nd "	68,000 "	
	3rd "	111,000 "	
	4th "	78,000 "	
1882	1st qr.	139,000 lb.	} 621,068 lb.
	2nd "	195,000 "	
	3rd "	179,000 "	
	4th "	108,000 "	
1883	1st qr.	385,000 lb.	} 1,599,687 lb.
	2nd "	548,000 "	
	3rd "	462,000 "	
	4th "	204,000 "	
1884	1st qr.	408,000 lb.	} 2,285,294 lb.
	2nd "	656,000 "	
	3rd "	882,000 "	
	4th "	339,000 "	

The shipments for the first quarter of the present year were 671,000 lb. Our readers will see that, so far, the bulk of the crop has gone forward in the second and third quarters of each year. In each of the years given, in order to find the entire production of tea in Ceylon, figures gradually increasing as China tea was displaced, ought to be added for local consumption. The average home consumption of tea in Ceylon in 1875-76 was 86,000 lb. and probably a higher figure should be added to tea exported, as the local consumption of tea must have increased since ten years ago. Let us say 120,000 lb. for home consumption, and then we get 2,513,000 lb. for the total production of 1884, adding exports to other places than Britain.

Having thus disposed of the diagrams, we give the brokers' remarks in full below.

The statement is altogether encouraging, not only as regards the quality of Ceylon tea but as to the prospect of the market generally. With few variations prices have advanced with advancing exports, the estates sending produce having risen from 20 in 1880 to 185 at the beginning of 1885. It will be seen that the consumption of tea in Britain has doubled in twenty years and that the proportion of Indian (including Ceylon) is rapidly increasing, being already not far from 49 per cent.

The continental demand for the better teas is also increasing. It seems time that steps were taken to follow the advice given from so many quarters to call in the aid of the analytical chemists, to test the quality of the tea leaf, as well as to give judgment on the constituents of soil and the manurial substances which can with best results be applied. As regards the hints at the end, we should like to know the secret of making tea without dust? Some exporters certainly seem to have discovered it. To us it is a mystery equally with the alleged superiority of large

breaks. In our own case our London agents have recently combined several invoices at one sale, not certainly to our advantage, however much it may have been to the convenience of the big brokers.

CEYLON TEA.

(Report by Messrs. Gow, Wilson & Stanton, Tea Brokers.)

We beg to submit for your consideration a few facts bearing on the statistical position of Ceylon Tea, which may be of interest to you.

The rapid increase in the production of Ceylon Tea, and the universal favor with which it has been received, attract attention to the growing importance of this island as a field of production. In order to convey graphically the progress made, we give, in diagram* form, a comparison both of the quarterly and yearly increases, together with a line tracing the course of price averaged in the London public sales during the period under review.

The blocks representing the production speak for themselves, but a few words in reference to the "price line" will be of interest to all concerned in the industry. It generally happens with articles of consumption that increased production leads to reduced values, but in this instance it will be seen that the reverse has taken place. Now, we would ask, to what cause this enhanced value is to be attributed? Is it that the price of Tea generally has improved during the past five years? This is decidedly not the case, and we can see no other cause than that the efforts of planters, favored by a climate suited to the production of Tea, have been successful, and that this success has so far been appreciated by the consumer.

Referring to the second diagram we observe that the amount shipped in 1884 is twenty times as great as in 1880; and if we examine the number of gardens represented in the London auctions, as stated below, the result is exceedingly striking, for while in 1880 the number was under 20, it has risen in 1884 to 135.

	1880.	1881.	1882.	1883.	1884
Gardens ...	13	15	56	111	135
Chests ...	855	705	3,806	11,080	15,139
Half-Chests	334	1,612	4,852	10,280	16,728
Boxes ...	40	13	1,071	857	710

Total Pkgs. ...
Catalogued 1,229 2,330 9,229 22,217 32,577
and the present year has already contributed nearly 50 new names.

Large tracts of land recently devoted to the cultivation of Coffee are now being planted with Tea. As an instance of this, it is said that in the district of Dickoya alone which lately contained 27,500 acres of Coffee, the Tea shrub now covers 11,000 acres, and it is expected that before the end of the current year these figures will be nearly doubled. We may therefore assume that the rapid development of the Tea industry is likely to continue, and as the out-turn from India is certain to increase, we are compelled to ask ourselves whether the supply of Tea will not soon exceed the demand, and become too great to admit of a profit to the planter.

In considering this important matter let us glance over the last 45 years, and observe the annual quantity of Tea consumed per head of the population of the United Kingdom in each decade, viz.—

1840.	1850.	1860.	1870.	1880.	1884.
1½ lb.	1¾ lb.	2½ lb.	3½ lb.	4½ lb.	4½ lb.

The home consumption in 1864 was 88,500,000 lb. and in 1884 175,092,000 lb. and had, therefore, almost exactly doubled itself in twenty years. Here, then, we notice a steady advance; and we are led to infer that the gradual cheapening of the commodity, together with the ameliorated condition of the working classes, the spread of temperance amongst the masses, and the modified social habits of the people, have largely contributed to a more general use of the article. There is, therefore, substantial reason for believing that the demand will continue to increase.

With this augmented consumption has come a demand for improved quality and flavor; and as these characteristics are especially combined in Indian and Ceylon descriptions, it is evidently on this account that these teas have grown so much in favor with the public; we find that whereas in 1864 only *three* per cent of all the tea consumed was Indian, in 1884 the percentage had risen to *thirty-seven*. Considering the great similarity existing between Ceylon and Indian teas, we may almost treat them as one article; and there is no doubt that by the combined efforts of the two sister countries the percentage of their teas consumed will year by year increase; and that the consumption of China tea will be proportionately reduced on account of its general deficiency in strength, pungency, and flavor, while it seems probable that before many years are passed, the staple tea of the London market will be Indian and Ceylon, and that only such amount as these countries are unable to produce will be drawn from China. We may add that the exportation of Indian and Ceylon tea to the Continent shows a gradual increase, and that there is every probability of this branch of the trade becoming largely developed.

In furtherance of these ends we would impress upon planters the paramount importance of keeping up the quality. Let them never rest until they have succeeded in producing a "perfect tea"; until they have exhausted every virtue which the plant possesses. Do they fully comprehend the nature of the plant with which they have to deal; the soils which are best suited to its development, and the situations which are most conducive to its growth? Do they understand how to utilize its various properties for their own purpose, and what qualities they should strive to foster in their plants; can they account for "delicate flavor" "peculiar pungency" or "unusual strength"; in short, do they understand that which chemically constitutes "tea"?

They have already pressed into their service the engineer, who has shown them how to cheapen their manufacture, and at the same time to improve their produce by the judicious use of machinery. It is now time that they proceeded a step further, and learned from the chemist the nature of a "true" tea, and the agricultural requirements necessary to obtain it—whether by manuring the soil so as to supply the plants with those particular ingredients in which they might be individually lacking, or in so manipulating the leaves in the process of manufacture as most effectively to preserve the active principle contained in them. As soil has much to do with flavor, an analysis of portions of it might in some cases prove an advantage.

From our own personal knowledge of tea planting, we venture to ask planters when dealing with "Green" leaf, to keep the following facts before them, viz.:

1st. Starch is universally diffused throughout the vegetable economy, especially in leaves.

2nd. The absorption of oxygen from the air converts the starch into sugar.

3rd. The green resinous principle of the leaf diminishes in quantity while oxygen is absorbed.

The excellence of black tea depends upon the management of the leaves in such a way that the above noted chemical changes may take place.

The following suggestions regarding Sorting, Packing, &c., may be of use:—

Sorting.—It is the custom in the London market to postpone the sale of Breaks, under eight chests, eight half-chests, or twenty boxes until the conclusion of the general sales, when the majority of buyers have already left the sale-room. In addition to this objection the trade have not the same facilities for obtaining samples of these "small breaks." We would therefore impress on managers, especially of smaller gardens, the desirability of sorting into as few grades as possible. In our opinion four grades are sufficient, viz., One fine tea, two mediums, and one lower class, and, when necessary, an occasional Dust.

BULKING.—By the new Custom's Regulations for weighing net, the old system of turning out and repacking each chest in London, by which the tea was frequently injured, can be avoided, when the bulking has been effectively performed upon the garden. We give these regulations as published by the Tea District Association, which must be strictly adhered to.

* We regret we cannot reproduce the diagrams, but the letterpress is sufficiently explanatory.—[En.]

1. The packages on arrival to be weighed to ascertain the gross weight of each package.

2. With each entry the importer to give an endorsement or statement of the net contents of each package.

3. To test the accuracy of the endorsement of the net contents, ten per cent of each break to be turned out and weighed net, but in no case should less than three chests be turned out.

4. If the variation in weight of the test packages be found to exceed one lb. the whole parcel to be weighed out; when the averages of the packages weighed net, amount to so many pounds, and a half or more, the half or more will be charged as a full pound; when the fraction is less than half a pound, it is to be rejected and disregarded.

PACKAGES AND MARKS.—Owing to the convenient size and weight of the usual "half-chest" for carrying from the garden, this particular package is in favor with growers but for estates which are near a means of transport, we certainly recommend full-sized "chests" of from 80 to 100 lb. nett, as they are more liked by London dealers for home trade: some of the choicest kinds might be packed in "half-chests" or even "boxes." When packed in the latter, care should be taken not to let the gross exceed 25 lb. otherwise a loss equivalent to five per cent in weight will result, owing to the trade custom of allowing 1 lb. draft on all packages over that weight. The only marks requisite on the packages are—the description of contents, garden numbers, and the name of garden in preference to any elaborate device.

Gow, WILSON & STANTON, Tea Brokers, 13, Rood Lane.

INDIAN TEA: ANNUAL REVIEW.

38, MINING LANE, LONDON, June 1885.

The publication of the Statistics on the 1st June completes the record of another season.

There have been few events in the history of the market which call for special notice, the feature of most interest and importance being the large increase in Consumption.

The Deliveries (including Ceylon Tea) have reached a total of 71,000,000 lb.; after deducting from this some 2½ million lb.—the probable excess in clearances due to the apprehensions respecting the duty—the increase amounts to 8,000,000 lb. while supply has only increased 1,000,000 lb.

It is most satisfactory to find that this has been attained without any considerable reduction of the average price—for although at one time values for certain kinds touched a low point, the depression did not last long enough, nor was it sufficiently general, to materially affect results as a whole.

It must be remarked that the growth of Consumption has not been due so much as in former years to the inferiority of the China Teas, for Indian Tea has had to compete with a good average China crop selling at a low range of price. Writing a year ago, we drew attention to what we felt was evidence of a growing demand from consumers for a better article than that with which they were formerly satisfied; and this we believe to be steadily operating in favour of Indian and Ceylon Tea. The sustained competition for the finer qualities confirms this view; for although low-priced tea undoubtedly still forms the bulk of the Trade requirements, the comparatively high prices maintained throughout for fine teas are proof of the demand for "quality"—and probably in no season has the contrast been more marked between the dead level of rates ruling for common and medium grades (as in the China market) and the higher range and elasticity of values for fine descriptions.

The lowest point was reached during November and December, under pressure of heavy imports, and large supplies of tea of inferior character: medium kinds showed the chief depreciation; common, by comparison, being little affected; while fine sorts scarcely gave way at all. At that time the short-fall in the crop was not fully realized, nor had the expansion in Consumption reached its maximum. The recovery which has since taken place has been a very slow movement, seeing how unusually strong the statistical position has become. The Dealers, however, are working from hand to mouth, on very small stocks, relying upon the receipt of fresh supplies as soon as they are wanted.

Anticipations of the future, when so many of its factors are unknown, are of little practical value; still, experience

of the past justifies a somewhat hopeful view of prospects for the coming season. The import of China Tea fell off 9 million lb. last year, and was 21 million lb. less than it was three years ago; it is, therefore, not unreasonable to assume that, owing to the competition of India a range of price has been reached which checks immoderate shipments. Estimating the supply from India at 66 millions, and from Ceylon at 4 millions, we get a total of 70 million lb., which will not more than suffice for our wants, assuming that Consumption continues gradually to expand as it has done year after year. In the estimate of requirements we have not taken into account any material increase in the demand from other markets; progress, however, is being steadily, if slowly, made with the sale of Indian tea to the Canadian, American, and Russian buyers through the agency of London Dealers and Exporters.

It is well to consider how the policy of producers should be influenced by the added experience of another year. Speaking broadly, results of 1884 have been satisfactory to those who made fine tea, and to those whose yield was so large as to bring down cost to a minimum,—but it has not been equally profitable to those who realized only a moderate yield and made only medium quality; the reason being, that prices for "medium" have year by year been receding nearer to the range for "common," until the difference has become very slight; while difference between "medium" and "fine" has become wider. The conclusion is that those who cannot confidently rely upon such a yield as will reduce cost to between 9d. and 10d. per lb. in London, should devote all their energies to improvement of quality.

It is often asked, "What is the most suitable class of tea to make?" In reply we would say that the taste of the Trade does not alter, as is sometimes assumed, the demand from different parts of England, Scotland and Ireland for different types of tea—which has been so largely instrumental in the past in promoting consumption—continues; and what is required is, that the distinctive variety should be maintained and that each tea should be as good of its kind as it can be made. We think that an undue proportion of lightly-fermented tea has recently been made, especially in Assam; many gardens whose produce was formerly distinguished for richness and strength in cup, having lost these characteristics without having gained pungency and flavour.

It is also certain that closer attention must be paid to the important matter of firing—upon which so much has already been written—in order to discover how to utilize machinery, which has many advantages and has become almost indispensable for heavy crops, without imparting to liquor, leaf, and aroma characteristics which lower the value. This, however, is a subject for experiment rather than for theory, and is a question for the tea-maker to solve, clear and definite expression having been given to the opinion and requirements of the Trade.

Referring to the course which the market has taken during the past year in order to find what light may be thrown upon the future, it is again to be noticed that prices have been less subject than formerly to sudden fluctuations. We referred last year to the causes which contribute to this, and expressed an opinion that it would be a future of the future. The main reasons are that the opening quotations for the new teas are not so high as they used to be, leaving less room for decline; while at the present scale of values there are now large operators, with sufficient means and confidence to hold stocks, who come in whenever supplies are heaviest and prices presumably at the lowest point; which has a healthful and steady influence upon the market. This greater evenness in price and absence of excitement over first arrivals is likely to be more marked in the future, when the large planted area in Ceylon—estimated at 80,000 acres—is yielding: for the heaviest shipments from Ceylon arrive between April and August; so that in a few years the interval between the Indian crops will be filled up, and there will be continuous supplies all the year round.

About 2,500,000 lb. of Ceylon Tea have been received, as compared with 1,500,000 last year. With larger supplies the premium paid for a time in 1883 has disappeared, and values are now adjusted to those of Indian Tea. In point of quality, the average has been maintained, some that were poor having been improved, while a few gardens

have not made quite such fine tea as before. The average price of the year's sales is 1s 3d per lb.

The import from Java shows no increase. These teas do not yet sufficiently resemble Indian in liquor to compete with any but low qualities, notwithstanding their fine appearance; and their value has been but little affected by the recent advance in the Indian market.

The following are the statistics for the past three seasons:—

	IMPORT.		
	1884-85.	1883-84.	1882-83.
India	61,472,000	61,535,000	56,760,000
Ceylon	2,482,000	1,500,000	1,500,000
China and Java	142,476,000	152,222,000	148,635,000

	DELIVERY.		
	1884-85.	1883-84.	1882-83.
India	69,109,000	60,469,000	56,621,000
Ceylon	2,047,000	1,500,000	1,500,000
China and Java	169,918,000	155,261,000	158,407,000

	STOCK 1st JUNE.		
	1884-85.	1883-84.	1882-83.
India	13,548,000	21,179,000	19,069,000
Ceylon	738,000	303,000	303,000
China and Java	36,279,000	54,717,000	57,765,000

Proportion of Indian and Ceylon taken for Home Consumption

...about 40 p. c. a' out 35 p. c. a' out 33 p. c.

We append a table showing the results obtained during the past season for some of the crops sold in London, which we have received permission to print. The returns comprize the produce of 49,283 acres, amounting to 17 million lb, the average of the whole working out at 1s 1-4-7d per lb. The quantity sold in Calcutta, according to circulars, was about 23 million lb, the average realized being 8 as, 9, of which the equivalent to the planter is 1s 0-3d per lb in London, at current rates of Exchange and Freight.

CEYLON UPCOUNTRY PLANTING REPORT.

WHAT IS TO BE DONE WITH CINCHONAS AMONG TEA—PRICES FOR BARK—A POOR COMFORT—SLANG EXPRESSIONS—EFFECT OF DROUGHT ON CACAO—BENEFIT OF SHADE—*Heloptilis* IN WATAGAMA—ROOT SHADING—TOO MUCH OF THE RAIN.

6th July 1885.

One of the problems of problems which is before most of us is that of knowing what to do with our cinchona which is growing among the tea. That it very much checks the growth of the latter, is too manifest to all of us, but to take it out now is such a sacrifice, that the pleasure of seeing the two grow afterwards will hardly compensate for the loss which we have all totted up in our sanguine moments, when we made our cinchona assets look,—well perhaps "too handsome by half." And yet what is to be done? I went over a place just lately with a friend, and found he was engulding his brains on the same problem. No one doubts that the tea in the open is ever so much better; that under cinchona it won't do any good; but when to cut it out is the question? and how long can they be allowed to grow with safety side by side? As for the cinchona market, I have heard by the mail now in, that several of the shipments of branch and twig, sold just before the mail left, had not realized the amount of freight and charges! We have had that sort of thing before, and there is this comfort that when things get to their worst they mend, still it's poor comfort after all. It is like Carlyle's definition of despair—a "kind of hope."

Is the word "shuck" an exclusively slang expression of Ceylon? I have not got the Slang Dictionary beside me to refer to, so as to see if it has been netted there; but I certainly never heard nor saw it anywhere else than in this island and its literature. Now that tea has become our mainstay, and its nomenclature an everyday word with us, I hear that there is a new slang phrase trying to warm itself into life, borrowed

* We believe it is a Yankeeism (or an Irishism from "Shekin")—ED.

from one of its classes. "He has a good deal of broken pekoe about him," remarked someone to me the other day, and I found that what was meant was "side." Perhaps when one hears it the second time and without the explanation, it may have more force in it than it has now.

The want of shade for cacao, is being seriously felt where there is none, and there is a considerable rush to plant it up. To see how the drought in the early parts of the year has affected some trees is very grievous and makes one appreciate the planter's remark that while cacao was a food for the body, it was also clearly becoming a food for the mind. One is never done with cacao scares of some kind or another, and it is too evident that in very few places indeed will it be grown with success. The yellow variety is however holding its ground well, and stands in unaffected grandeur alongside the badly-stricken Trinidad species which is a heart-break to see. Wind, drought, *helopeltis*, and root-disease—are a few of the abominations with which the cacao planter has to contend.

Some of the places about Kandy, and in Dumbara, are looking bad enough from want of shade, and the fly besides. I hear that some who have got cacao growing under fair-sized trees say that they do not suffer from the fly very much, that it goes up to the leaves of the trees above, and neglects the cacao pods and shoots. The man who gave that opinion ought to know something about it, and if it be verified it is not without some comfort in it.

At Watagama, where cacao grows particularly well and which has been free from *helopeltis*, it is not always to escape. The fly, I understand, has begun to appear there, not as yet in any great numbers or with any deadly effect, but it is unpleasant to hear that it is about.

The following hint comes from a London broker:—"He was told lately by a reliable party that keeping the roots of the trees shaded very much improved the quality of the cacao, and that this was not generally known." This, I suppose, must mean littering the surface around the stem of the tree, although it is not very clear. That that treatment has a good effect is not unknown here.

The long-continued rain has not a little worried the cacao-curer as well as the tea-maker. Indeed most of us are getting a little tired of the constant drip, and especially the high winds which of late have been so general. The Irishman who was green mouldy for want of a "bating," had been in the Central Province for the last fortnight, might have got his hiding and not had his condition improved.

PEPPER CORN.

A HINT TO PROPRIETORS AND SHAREHOLDERS OF TEA GARDENS.

TO THE EDITOR OF THE "ENGLISHMAN."

Sir,—Now that managers of tea gardens are vying with one another as to which shall land his teas in the market at the lowest figure, it may not be out of place to remind both proprietors and shareholders that, much as agents are to be congratulated on bringing about this very gratifying rivalry between managers, it would be well if agents on their part would look into their own charges, and satisfy their proprietors or shareholders that these are legitimate ones. It cannot be denied that, in gardens in which the mufsal outlay has been reduced to the lowest figure, Calcutta charges stand out, in a most unproportioned manner, and do not appear to ever lessen, but on the contrary seem to be on the increase. In the present state of the tea market, to make tea properties pay a reduction all round must be made. I now propose to give a few suggestions as to how this is to be done.

I take an agent of a tea estate to be a paid person, or persons, employed to represent the proprietors or shareholders' interest, to enable him to work the estate to the best advantage, and not, as it would appear to be in many cases

a person who, after having secured the keep of a garden, imposes as many charges on that estate, both directly and indirectly, as the proprietors or shareholders wish in their good nature, or ignorance, allow. I admit that, for tea agents to exist and to be dependable, the business must be a remunerative one, and therefore must be well paid. A good article is never cheap. They should, however, only be allowed to make one charge, and that charge should be a commission on the gross proceeds. Of course, when funds are required, the rate of interest should be agreed upon. When once this has been settled between both parties, no other profits should be allowed to be made, such as on coolies, stores, or machinery sent up to the gardens, but the full benefit of buying stores cheap, by purchasing them in large quantities and getting the trade discount, should go to the garden. I take it to be incontestably a breach of confidence on the part of the agent to make a profit on coolies, stores, &c., sent up to gardens. Shareholders should insist on their agents only charging the estate the net price on all stores, coolies, &c.

Many proprietors of gardens find, when they go home, or even to Calcutta, that they can purchase stores at a much lower rate than their agents charge! I know of several instances of this being the case. I will mention one, to put the matter vividly before shareholders. A proprietor had asked his agents to ascertain the cost of an iron roof, sufficient to cover his tea-house. In due course of time an estimate was sent up. In the meantime this owner went down to Calcutta, and whilst there ascertained for himself, from different firms, the cost of such a roof. The result of his enquiries was that, by buying the iron roof direct, the material for such would have cost very much less, I believe 40 per cent less. Now, is this a legitimate profit on the part of the agents? I say decidedly not. Yet many agents do not scruple to make large profits on stores, &c., sent up to gardens. They possess their own store godowns, which they fill with stores purchased at the very lowest trade prices, and distribute them to gardens, guiding themselves in their charge for these from the prices put down in the different lists of stores published by the trade. If proprietors and shareholders followed the following suggestions before they appointed agents, I feel confident that they would soon see Calcutta charges very much reduced:—Firstly: Agents to only receive a fixed commission on gross proceeds. Secondly: A fixed rate of interest on advances required. Thirdly: Only net outlay to be charged on coolies, stores, &c. Fourthly: No tea agent to be also agent for garden stores, &c.

At present Calcutta charges are divided over so many items that it is impossible to put a finger on any as being excessive. Until the advice I give above is followed, Calcutta charges will always remain an unguessed conundrum.

A POOR SHAREHOLDER.

LEMONS IN INDIA.

Dr. Bonavia, of Etawali, writes to the Agri-Horticultural Society of India in reference to this subject as follows:—

"I wish to bring to the notice of your Society a most important tree, viz, the Malta lemon tree, which I imported from the Mediterranean many years ago for the Horticultural Garden of Lucknow. I lately sent four plants from here to Dr. King to ascertain how it would stand the moist climate of Bengal. I wish your Society would take it up also and make some experiments to ascertain its value in that climate. The facility with which it can be propagated is simply marvellous. It stands the climate here with the greatest ease, and I believe would do everywhere in India, where oranges and lemons can be grown, Sylhet, Nagpore, Delhi, Nepal Valley, Kangra, &c., &c. If we could obtain citric acid easily in India and cheaply, there is no reason why citrate of iron and quinine could not be manufactured. It is the next important tonic to quinine, and would be invaluable for picking up the strength of the people recovering from fever. The commercial products of the lemon tree are many. Could you kindly help me in obtaining the statistics of imports into India through Calcutta, Bombay and Madras of the following commercial products of the lemon and orange, viz:—

1. Citrate of iron and quinine.
2. Citrate of iron and ammonia; there are other citrate drugs, but I think these are most important, but some of the Calcutta chemists may mention others.

3. Citric acid for pharmaceutical purposes, and for aerated waters, (tartaric and sulphuric acids are often used now for *lemonades*, because citric acid is dearer).

4. Essential oil of lemons (of the rinds) used in pharmacy, confectionery, and flavoring lemonades. The lemonades are now very important that most of the army, railway employes, &c., &c., are becoming teetotalers.

5. Lemon drops and other confectionery where this essential oil and citric acid are used.

6. Candied lemon and orange peel.

Oil of neroli (essential oil of flowers of Citrus Bigaradia and others. The C. Bigaradia, or Seville orange, grows here just as well) for confectionery, perfumery, pharmacy, &c.

8. Pottis grain for scenting soaps and perfumery. This is the essential oil of the 'leaves' of C. Bigaradia.

9. Marmalade.—Of this, there ought to be great consumption in India in tins.

I have been experimenting with this 'citrus lemonum vulgare' of Risso for nearly 25 years, and the more I see of it, the more highly I think of it as an industrial plant for India."—*Madras Mail*.

COCONUT OIL, TEA, AND COIR YARN.

I was talking yesterday with a merchant who had been for 25 years in the Australian trade, and who happened to mention that he was open to buy a parcel of Coconut Oil of July shipment, but that in response to the request for a quotation which he had wired to a Colombo house he was told the price would be £30 in pipes, cost, freight and insurance; whereas the present nominal value in London is £28, at which there are sellers but no buyers. There is therefore a difference of fully £2 per ton, and my informant said that this was commonly the case also with Australian tallow, prices on the other side being almost invariably £1 to £2 higher relatively than the current quotations in London. Another notable instance of this kind of thing is to be found in pepper, which can always be bought cheaper here than in Singapore, Penang, or Cochin. The mention of these facts and others having the same drift naturally led me to ask my friend how he accounted for what seemed such an anomalous state of things, and also for the glut of produce in the consuming markets of the world, and his answer as that of a man of long experience is at all events worth discussing. He attributed the relatively high value of produce on the other side to the excessive competition for it there arising out of two causes. 1st, that, by the opening of the Suez Canal and other improvements in the means of intercommunication, the consuming markets had been multiplied and many of the smaller ones now found it advantageous to send orders direct instead of buying in London. Everyone in Ceylon knows of course that the has been true as regards coffee, and orders for Trieste, Venice and Marseilles were filled at figures considerably above the parity of London quotations, so that it was always more advantageous to sell on the spot than to ship to London, as those under block loans were generally obliged to do. But my friend went on to say that there was another source of excessive competition which had of late years played an important part, not only in the Australian but also in the Indian and China trade, and indeed to a greater extent in the two latter than in the first named. It arose out of the necessity imposed upon merchants of employing their clean credits. Mercantile bankers like Barings, Matheson, Huth, etc., grant clean credits on condition that the bills drawn on them shall be covered by documents before maturity, and of course if these were not used they would speedily be cancelled. Hence merchants in India and the Colonies are induced to speculate in produce even against their better judgment as to the probable results. In certain trades as we know the result of such ventures has been consistently disastrous for years past, but still the shipments go on simply because the shippers cannot afford to stop, as this would be to commit the "happy dispatch." In too many cases fresh bills have to be drawn on London houses, not so much to purchase produce, which is likely to realize a profit on realization in London, as to meet reclamations from London upon previous consignments, and hence the wheel is kept rolling as long as credit can anyhow be maintained. I

have here given the bare outline of my friend's argument, but it must be for you and your readers to say whether it is at all applicable to the Colombo markets, and Colombo firms. It is easy to see, however, that such a system would give an unhealthy stimulus to prices in the places of production and tend to that accumulation of stocks in the consuming markets which has been so disastrous during the last few years.

Fresh evidence has been afforded of the importance attached to Ceylon TEA in Mincing Lane by the publication of a valuable paper on the subject under today's date by Messrs. Gow, Wilson & Stanton, the Indian tea brokers of Rood Lane. Mr. Gow was himself for many years a tea planter in Assam and Cachar, and still owns gardens there, so that he can speak with considerable authority on questions connected with the cultivation and manufacture. They have gone very thoroughly into the statistics of Ceylon tea, and include diagrams showing comparatively the quarterly and yearly increases in production together with a line tracing the course of prices averaged in the London public sales during the last five years. They point out that "it generally happens with articles of consumption that increased production leads to reduced values, but in this instance the reverse has taken place." Now, we would ask, to what cause this enhanced value is to be attributed? Is it that the price of tea generally has improved during the last five years? This is decidedly not the case, and we can see no other cause than that the efforts of planters, favored by a climate suited to the production of tea, have been successful, and that this success has so far been appreciated by the consumer." After mentioning the rapid expansion of the tea industry in Ceylon and glancing at its probable development in the near future, Messrs. Gow, Wilson & Stanton proceed to discuss the very important question whether in view of what is going on in Ceylon and also in India the production of these teas will not very speedily outrun consumption. This same question must often have occurred to the minds of the more cautious Ceylon planters, and it is satisfactory to find that there are solid reasons given in the paper before me for the conclusion that for many a year such teas as Ceylon produces will find a ready sale at remunerative prices, provided always that the quality is maintained. I am however sending you a copy of the paper itself, and I do not doubt that you will quote largely from it. There is one recommendation which will, I am sure, commend itself heartily to Ceylon planters who have so long been distinguished as the most progressive of their class; I mean that the aid of the chemist as well as of the engineer should be invoked in order to insure the nearest approach to perfection both in cultivation and manufacture. Mr. Gow is himself the inventor of a new wither and drier, which he claims to be superior to anything previously in use, and the experimental trials with these appliances were most successful; but whether they stood the test of actual work on a tea-garden I am not in a position to say.

I have just had an interview with the biggest broker in the COIR YARN trade, and he describes the market as completely demoralized owing to excessive supplies chiefly from Cochin. There are at present no less than 6,400 tons of yarn in stock, including Ceylon, and 2,000 tons on the way, making a total visible supply of over 8,000 tons, or a quantity altogether unprecedented and far beyond the requirements of the market. Under these circumstances it is not surprising to learn that the value of medium yarns has declined fully £5 per ton since the beginning of the present year, and that today, for instance, my informant was utterly unable to sell a large parcel of Ceylon yarn though the importers had instructed him to let it go for what it would fetch. Six months ago it was well worth 18s, and a month or so ago full 14s per cwt., and so he put it up at 9s, but failed to get a bid of even 3d beyond that, nor in fact would anyone take it even at 9s. The finer sorts of Ceylon yarn from 22s upwards, are somewhat steadier as being of course in smaller supply, but even these must leave a terrible loss to the exporters. The worst of it is that my informant could see no prospect of any improvement unless the Ceylon and Cochin merchants would cease to ship for some time and let the stock go down a bit. There were 22 catalogues advertised for today, some of them postponed from a month ago, but not half of them were got through, and it is needless to say that the tendency is all in favor of buyers.—*London Cor.*

SUGAR IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

BATAVIA, May 27th.—(From a correspondent.) There is not much news regarding industrial and plantation enterprises. One result of the sugar crisis is that investigations are being made as to how far sugar can be turned to advantage for other purposes than those for which it has been hitherto used. The result is that in Britain, Germany, and Austria, sugar is coming into use as an article of food for fattening stock. As a matter of course, only cheapest kinds are availed of for this purpose. The results gained thereby may really be termed brilliant, so much so even that animals fattened on sugar exhibited at the last Berlin Cattle Show surpassed all those on view which had been fattened on other foods. Another item of sugar news is that Mr. Eydmann, a Java planter, has been experimenting on the extraction of sugar from megass and molasses with Steffen's diffusion apparatus so satisfactorily that the experiments have proved a thorough success. In Europe sugar is rising in value. This year's crop is, however, not expected to be large, owing, in all likelihood, to the depressed condition of the sugar interest last year. Should, however, prices continue improving, the ambition to have heavy crops will no doubt gain the upper hand once more.

COFFEE IN AMERICA AND TOBACCO IN THE PHILIPPINES.

(Translated for the "Straits Times.")

COFFEE GROWING.—We deem interesting the following particulars with respect to the cultivation of this produce article given by a South American Journal:—Statistics bring out the fact that the coffee plant can bear great extremes of temperature, and that differences of even between 20 and 30 degrees do not harm it. The most favorable ground for its cultivation is hilly tracts lying from 1,500 to 4,500 feet above the sea-level in the torrid zone, and these between 25° and 30° south of the equator. In Brazil 16 varieties of this plant are growing without any cultivation whatever, but though coffee was not known as an article of commerce in Brazil until 1722, the exports of it from there reached fourteen millions of pounds in 1780, those from Cuba during the same year being twenty-six millions. Towards the close of the last century, extensive sugar plantations in Brazil were turned into coffee estates. The exports of that product therefrom increased in consequence till they amounted to 98,207 tons in 1850, decline setting in after that date. Coffee from the State of Colima, in Mexico, where it is grown on a large scale, enjoys high repute. That from Cordoba and Orizaba in the same country is deemed equal to the Cuban article, but the Colima product is regarded as superior to the highly famed Mocha coffee. In Mexico, great improvements have been made in the cultivation of the berry, and there is every prospect that, in years to come, coffee will become one of the principal articles exported from that country. At present, coffee growing is in a somewhat depressed condition in Honduras and Guatemala. Wages elsewhere have fallen considerably, and should the fall prove of long duration, it may be anticipated on good grounds that growers in the republic of Colombia, Venezuela, Costa Rica and Nicaragua will be ruined, while the luckier ones in the republics of Mexico, Guatemala and Honduras will realize productive yields.

A correspondent in the *Comercio* of the 21st May, takes up the subject of the disappointment to growers and cigar dealers alike resulting from the abolition of the tobacco monopoly, that measures, so he says, not having met with fair play at the outset, from the Treasury authorities having then on hand large

stocks of Government tobacco which, coming into competition, with the first free crop brought to market, so lowered prices that growers frequently had to dispense of their produce of what it would fetch, which too often meant at heavy losses, to their grievous discouragement. The area under cultivation, notwithstanding this, increased so greatly in 1883 that there was every prospect of a yield amounting to twice that of the previous year had not growers, disheartened by low prices, left a portion of the crop to rot on the fields, what was gathered in barely paying working expenses. These tidings spread with lightning-like rapidity with the result that in all the provinces, even in those most suitable for tobacco growing, the cultivation of that article has since fallen off considerably, the area under crop decreasing about one-third. A large number of cigar factories have besides stopped work. The remedies suggested are State aid in pushing on the state of Philippine tobacco and cigars in foreign markets, and the abolition of the import duties on these articles in Spain, besides opening up the producing districts by roads and readier means of communication.

THE MANUFACTURE OF QUININE AT CALICUT, INDIA.

On the 28th March last Messrs. Arbutnot and Co. wrote to the Chief Secretary to the Madras Government:—

We have the honor to report that Dr. E. L. Cleaver, who has been, since December last, at Calicut conducting experiments as to the practicability of making quinine in India, has arrived at the conclusion that there are no insuperable difficulties to the success of such manufacture. We enclose, for the information of Government, copy of his letter dated 13th instant, and we also send the three samples to which he refers. It is to be borne in mind that Dr. Cleaver's experiments have been conducted under somewhat adverse circumstances, it being impossible for him to obtain some of the chemicals that he deems essential to the complete success of his process. He is now about to return to England to lay before the gentlemen who have found the £1,500 required for the experiments an account of his mission, and we have every reason to believe that the next step will be the formation of a company to manufacture quinine on a commercial scale. We bespeak the favorable consideration of Government for such a company, and we will be glad to know whether we could rely on obtaining Government bark on terms somewhat similar to those indicated in Dr. Cleaver's letter of 13th March, or if, in any other way, Government can see their way to encourage an enterprise which, if as successful as it promises to be, will be a boon alike to the growers of cinchona bark and to the users of febrifuge of all kinds.

Enclosure.—Letter from E. L. Cleaver, Esquire, to Messrs. Arbutnot & Co., Calicut, 13th March 1885.

I send you by this post samples as follows:—No. 1 Sulphate of quinine, No. 2 Febrifuge, No. 3 Crystalline febrifuge. Sample of quinine is not quite as white or as silky crystals as Howard's, but is quite equal to many commercial specimens; and considering the very limited resources I have at my disposal, and the small scale in which it is prepared, it is I think a proof that it could be made commercially. It is prepared from red bark, and it is as pure as could be obtained from that kind. The febrifuge, although similar in color to Government preparation, is different in composition. The whole of the alkaloid in it is easily crystallisable while it is a most difficult matter to crystallise much from the Government febrifuge. The crystalline febrifuge is prepared by simply crystallising No. 2. I have forwarded samples to London similar to those sent you. As regards the percentage of alkaloids obtained from working the barks, I am of course not able yet to say; but the following facts may be of some service to you in your negotiation with the Government. The bark sent by the Government weighed 2,000 lb. and should yield, according to the analyses sent by them at the same time, about 100 lb. of alkaloids; these analyses, however, I consider too high, are not similar to analyses as would be given by Dr. Paul of London. From the Government paper issued on the subject of the amount of alkali-

oids obtained from bark sent to England for manufacture, I see that the average loss on red bark is about 1 per cent. of the total alkaloids; therefore the 2,000 lb. would yield to Government if sent to England 80 lb. of mixed alkaloids obtained of course by a far better process than I am working, but also more expensive. The cost charged to Government of working quinine barks in England comes to about 1 shilling per pound on the bark used exclusive of the freight and other charges. The following is drawn up by me from the Government papers of the 18th October 1881—

Cost of bark to Government as per return of Plantations, 9 annas 6 pies per pound.	£ s. d.
Cost of 5,104 lb bark	259 10 8
Freight charges, &c.	30 6 8
Return Freight	27 4 8
Manufacture charges	272 18 0
Total	590 0 0

from which 295 lb of mixed crystallized alkaloids were obtained, that showing the cost of crystalline febrifuge to them at 40s per pound, of which cost the expenses alone were about 22s 5d per pound. The 2,000 lb of bark sent to us would, therefore, if sent to England, have produced to the Government about 80 lb but I think less of mixed crystalline alkaloids at a total cost of about £200, of which 120 would be expenses. If the Government therefore would make any arrangement by which they let us have a definite supply of certain barks we could undertake to supply a definite proportion of alkaloids, and charge them much less than the price they at present pay. The percentage of alkaloids obtained by the Bengal Government is about 2½ per cent, and I expect the proportion of alkaloids in the bark used is 5½ per cent on the average. This febrifuge does not contain more than 7 per cent of quinine, and also contains about 16 per cent of various impurities. We could do better than this and, I think, might undertake to give about 3½ to 4 per cent of mixed alkaloids and charge them either so much a pound on the bark worked, or so much a pound on the alkaloid delivered. In the above calculations I have left out the question of amorphous liquors, which would be handed over to the Government when produced as done by the English manufacturers. In the above I have calculated on employing a different process from that used in England but from my experience of the climate I see no reason why the same process as used at home could not be worked here if required. At present I am working up all the bark I have in hand by the old soda process, and the amount of alkaloid I shall obtain will be much less than by the process originally intended to be used, but still will be a guide.

The letter from Messrs. Arbuthnot & Co, with the enclosures and the samples of quinine were forwarded to the Director of the Government Cinchona Plantations for full report, that the latter might be carefully examined by Mr. Hooper.

Mr. M. A. Lawson, Director of Government Cinchona Plantations, Parks, and Gardens, Nilgiris, reported to Government, on 1st May:—

With respect to G. O., Mis. No. 1,716 dated 1st April 1885, I have the honor to inform you that the three samples of cinchona alkaloids, which were sent by Dr. Cleaver to Messrs. Arbuthnot & Co., have been carefully examined by Mr. Hooper, and I forward, herewith, a copy of his report on their analyses. From this report it will be seen that sample No. 1, which was forwarded by Dr. Cleaver as being sulphate of quinine, contains no less than 37.90 parts of sulphate of cinchonidine out of 102.07 parts. This large amount of cinchonidine would, in the present legitimate state of the market, greatly impair the commercial value of this preparation, though, as Mr. Hooper very accurately points out, its medicinal excellence would not be interfered with. Analyses of Dr. Cleaver's sample No. 2 are compared by Mr. Hooper with analyses which he has recently made of samples of febrifuge obtained from the Government laboratory in Sikkim; and from this comparison it will be seen that while Dr. Cleaver's febrifuge contains no quinine, that from the Sikkim laboratory contained 6.97 per cent. On the other hand, Dr. Cleaver's febrifuge contains 35.62 per cent of cinchonidine, while that from the Sikkim laboratory contained only 15.78 per cent. Therapeutically considered the two febrifuges are probably

of equal value. Of Dr. Cleaver's third sample Mr. Hooper says that, "although labelled crystalline febrifuge, it is really nothing more than an unbleached preparation of quinine and cinchonidine sulphates, almost identical in composition with sample No. 1." Dr. Cleaver, in his letter to Messrs. Arbuthnot & Co., and also in a letter to myself states that he has labored under considerable difficulties in manufacturing these febrifuges owing to his not having received certain necessary chemicals and apparatus. It is therefore to be presumed that, under more favorable circumstances his account of the composition of the samples which he has sent would have been more exact; and I have no doubt that, if a factory were to be established under his direction a febrifuge of a high character might be turned out at a reasonable cost. In an interview which I had with you the other day, I told you that Government had in stock a large quantity of "red bark," which, though low in the amount of sulphate of quinine, contained a large amount of "total," and I pointed out that the prices offered for these barks were wholly unremunerative; and I urged that Government should not sell these barks, but undertake the manufacture of a febrifuge from them. This manufacture might be carried on by Government themselves, or it might be entrusted (under agreement) to some such firm as that which it is proposed to establish at Calicut. If Mr. Hooper goes to Madras and superintends the manufacture of 1,000 lb. of bark into liquid extract, he will be in a position to inform Government very exactly as to the cost of its production, and Government would afterwards be able to negotiate equitably as to the terms they would concede to private enterprise.

ENCLOSURE.

Extract from letter from D. Hooper, Esq., Government Quinologist, to the Director of Government Cinchona Plantations, Parks, and Gardens, Ootacamund, dated Ootacamund 1st May, 1885:—The Director of the Cinchona Plantations has handed me three samples of cinchona alkaloids prepared by Dr. E. Cleaver at Calicut. In accordance with instructions contained in G. O. Mis. No. 1,716, I have submitted them to a thorough examination, and have the honor to report upon as follows:—No. 1 sample was labelled "sulphate of quinine" and was of good appearance, white and crystalline. It had the following composition:—

Sulphate of quinine	64.17
Sulphate of cinchonidine	37.90

102.07

The quantity of cinchonidine present is comparatively large, but it should be pointed out that all commercial samples of sulphate of quinine invariably contain some amount of this other alkaloid, which has similar medical properties. Sample No. 2 was "febrifuge," the dried and powdered alkaloids of red cinchona bark. The color compares favorably with that of other makers, and it is almost entirely soluble in dilute acids. The analysis is quoted below, and, for comparison, the analysis of some Sikkim febrifuge, received last month from Calcutta, is also given—

	Calicut	Sikkim
Quinine	None	6.97
Cinchonidine	35.62	15.78
Quinidine	Trace	1.24
Cinchonine	44.29	60.63
Amorphous alkaloids	10.82	8.12
Moisture, ash and coloring matter	9.27	7.26
	100.00	100.00

This febrifuge, Mr. Cleaver states, is made from branch bark, which is usually poor. The process, however, for its manufacture is cheap, and it contains a fair quantity of crystallisable alkaloids equally valuable in fever with quinine itself. Sample No. 3, although labelled "crystalline febrifuge," is an unbleached preparation of quinine and cinchonidine sulphates, almost identical in composition with sample "No. 1"

On the 2nd May Mr. M. A. Lawson forwarded a copy of the analysis of the twenty bales, or 2,000 lb., of bark supplied to Dr. Cleaver on the 2nd December 1884.

ENCLOSURE.

N. B.—Results expressed in percentage on the air-dried bark.

(Signed) D. HOOPER.

Order of Government dated 6th June 1855.—The report of the Government Quinologist on the samples furnished by Dr. Cleaver will be communicated to Messrs. Arbuthnot & Co., who will be requested to forward the whole of the products to the Government Medical Stores, Madras. It is observed that Dr. Cleaver's letter contains no information as to the total quantity of bark supplied to him, information on this point is, of course, essential to any final judgment on his results. The Government note that Dr. Cleaver's calculations in regard to cost are open to criticism in several respects. The percentage assumed as the average loss in the process of manufacture in England is incorrect, as appears from the official papers quoted by Dr. Cleaver, and this percentage has been applied by him to the total quantity of raw bark instead of to the quantity of alkaloids contained therein. Further the calculation proceeds on the assumption that the cost of extracting a febrifuge in the form of mixed alkaloids is the same as that of extracting from an equal quantity of bark sulphate of quinine, sulphate of cinchonidine, and cinchonidine alkaloid in their separate states. The opinion expressed by Dr. Cleaver that the Darjeeling febrifuge contains about 16 per cent of various impurities is also believed to be incorrect. The Government understand, on the contrary, from their Quinologist that it is almost entirely free from impurity. The cost price of this febrifuge according to the reports of the Bengal Government Quinologist, was in 1882-83 Rs. 8-10 per lb. and in 1883-84 Rs. 10-4-5 per lb. Dr. Cleaver on the other hand, would apparently undertake to convert 2,000 lb. of bark into 80 lb. of febrifuge (mixed alkaloids) for something less than £120. At this rate his febrifuge would cost something under Rs. 18 per lb. for manufacturing alone, to say nothing of the value of bark consumed in the process. With reference to the report contained in the conclusion of their letter, Messrs. Arbuthnot & Co. will be furnished with a copy of G. O., dated 20th Oct. 1884, No. 1,154 Revenue, containing the despatch of the Secretary of State on the subject of concession to the proprietors of local factories, and they will be informed that the Government are not at present prepared to make any such arrangement as is suggested in Dr. Cleaver's letter. The object the Government have in view is the production of an efficient febrifuge at such a cost as will be within the reach of all classes, and they have recently issued orders for the conduct of experiments on a large scale in the manufacture of a liquid solution of cinchona under the superintendence of the Government Quinologist. The question of employing this or that agency on behalf of Government must depend upon many considerations, and of course, amongst others, on its ability to turn out what is wanted as or more economically than can be done by Government agency.—*Madras Mail*, July 1st.

DISINFECTANTS.—Experiments have lately been made by the Government experts, aided by other scientists, with all the known disinfectants, for the purpose of determining the efficacy and value of each as germ destroyers. By actual trial it was found that corrosive sublimate in the proportion of one part to 1,000 parts of water is found to destroy all known germs. A solution of chloride of lime in the proportion of one part to 100 parts of water is equally effective. Many of the commercial disinfectants in common use were found to be untrustworthy.—*American Cultivator*.

PLANTING IN CEYLON 30 YEARS AGO

AND NOW: CHAPTER XII.

COFFEE CULTIVATION TO DIMINISH YEARLY IN CEYLON—CEYLON AS A FIELD FOR THE INVESTMENT OF CAPITAL—IS TEA LIKELY TO BE OVERPRODUCED IN CEYLON?—ADVANTAGES OF CEYLON OVER OTHER TEA GROWING COUNTRIES—CEYLON IN LONDON—MERCING LANE—MARK LANE—PRODUCE SALES—MESSRS. L. S. D. & CO.—ONE'S "OWN LITTLE BUSINESS"—TEA IN LONDON—THE FUTURE OF CEYLON.

Coffee having now lost its pre-eminence as the staple of Ceylon, each succeeding year will see the area under its cultivation smaller and smaller, as field after field dies out, or is uprooted to make room for the tea planted in its old rows. For home readers a few words may here fitly be said about Ceylon as a field for the investment of capital. Only one thing now ails Ceylon, the lingering effects of the recent coffee and cinchona crisis, viz., want of confidence and of capital. The former (coffee) has succumbed under a providential visitation, but its downward progress was slow, the disease being gentle; and it afforded all interested ample time and opportunity to ward off its threatening consequences. Coffee pays even now where there is no debt and where working capital is available. It was not the fault of coffee if the rush was into the wrong new product. Surely it might have been foreseen that a drug like quinine could easily be overproduced, and it is not long ago since the editor of the *Observer* wrote that "he shuddered to think of the position of cinchona if all the seed planted had matured into tea." It is easy to be wise after the event, but it is nevertheless true that the best business men in London, as well as in Ceylon, lost their heads over cinchona, and its present position is only what might easily have been foreseen.

Now tea is the rage, and the same question arises: "Is it likely to be overproduced by the sole action of Ceylon as was the case with cinchona?" The writer is not going to presume to answer this question dogmatically. But he believes that not only is the world's consumption likely to steadily advance but that Ceylon will ever be the country most suited for its economic production and manufacture; and that, however other countries may suffer and collapse, Ceylon will always keep its place as the most profitable tea-producing country in the world. We owe this position (1) to our situation for cheap and ready transport from the garden to London, and *vice versa* for the cheap and ready importation of all the requisites for its production, manufacture and packing; (2) to our geographical position giving us an equatorial sun together with regular monsoon rains, ensuring constant flushes of new leaf limited only to the natural powers of the soil and plant, which here, can be worked up to exert themselves to their very utmost; (3) to the inherent advantages of the island, its railways, roads, harbour and active Sinhalese army of cartmen and artificers, and peace-loving people; (4) its proximity to the Tamil country whence unlimited labor can be drawn; and last, though not least, to its unrivalled healthy and pleasant climate. At the present moment I consider Ceylon to stand at the very top of the list as the best of all fields for the employment of capital, and of the energies of that ever-rising army of young Englishmen looking beyond their own shores for these desiderata. At home, everywhere, they hear of the recent troubles of Ceylon, but these things belong to the past, and only still cling to those, belonging to the past, who still struggle with their old debts or with the unnatural absence of the breath of all trade and enterprise, confidence and credit. At the present moment

estates can still be bought for a fraction of their real value, and a few thousand pounds of capital judiciously invested here, now, would most certainly ensure a large fortune in a very few years. Existing estates can be converted into paying tea-gardens very cheaply, and new land can be purchased and be brought into bearing for only a very little more. But it is not to be supposed that this condition of things will last much longer: the turn will be sharp and complete when it does come, and those who now have the means, and employ those means judiciously in Ceylon, will reap a rich harvest in a very short time. There are plenty of men who know this, but scarcely one who can turn the opportunity to account because there is yet absolutely no money in the country. Those who write of Ceylon in the nineties will have a very different tale to tell.

Having had much experience of London as well as of Ceylon during the period of which these papers have treated, I may, perhaps, refer also to it, so far as concerns

CEYLON IN LONDON.

In order to find Ceylon in modern Babylon, one's steps are naturally directed, in the first instance, to that mart of the world's produce, *Mincing Lane*. Having but little throughwheeled traffic, it is one of the quiet thoroughfares of the great City, joining at its top and bottom two of the noisiest in the world. How many times a day is not Fenchurch Street blacked by drays, omnibuses, cabs and carts? all indiscriminately wedged together in one immovable mass until some fallen horse is got up, or the cross-traffic up and down Gracechurch Street is made to wait while the jam in Fenchurch Street is relieved. Having steered safely through all this, we turn down the quieter lane, where the subdued hum of men's voices and the tripping of their rapid steps is all we hear. A stranger wonders where all the business is done, for externally there is to him absolutely no signs of it, except in the quick rushes of black-coated business-men in tall hats, up and down, in and out of the various long passages leading to private offices and to sales-rooms up and down stairs, from basements to fourth and fifth floors of the various hives. In the next thoroughfare, *Mark Lane*, we do, indeed, find a couple of large buildings of the true market type, where, inside a large open hall fit up with stalls, samples of wheat and grain are displayed. These are the "new and old Coin Exchanges," but we search in vain for anything of the kind in the lane so well-known by name to all the producing colonies of the world. Suppose you are a "colonial" at home, and you know that a large quantity of your own produce is to be sold that day, you would like to see how it is done. You have the address of the selling broker, and you ferret his private office out. On several of the doors nearest to the spot in the passage on which you stand, you see his name painted up with the addition of the word "Private" on one, "Clerks" on another, and "Sales-room" on a third. You notice that this last is kept ever on the swing by men rushing in and rushing out with curious long blue papers in their hands. You enter, but your produce is not sold in this "sales-room": only small samples of it are here, ranged round and up and down the room in trays of small square boxes, each bearing a number. You obtain one of the said blue catalogues, or lists of lots, with particulars of them all: name, mark, ship, description, number and quantity. Besides your own you probably find fifty other parcels perhaps far larger, which knocks just a little bit of the conceit out of you to begin with. You then notice that these men move rapidly from sample to sample, and that each makes a private mark against the lot he quickly examines, passing on (no loitering there) to make

room for the next pressing behind. Suddenly the room is deserted, but if your coffee (say) has not yet actually passed the hammer its fate as to price has already been sealed in that room on those blue papers. If you wish to see it actually sold, you must be quick and find the particular auction-room indicated, in another building higher up or lower down the street. The *Mincing Lane Sales-rooms* are a collection of such auction-rooms in one building, where, simultaneously, by different brokers, tea, coffee, cocoa, bark, spices, &c., &c. are being rapidly sold. Having found No. 7, say, you enter and find business has already begun. At the end is a high rostrum where the selling broker and his clerk stand, the rest of the room being filled with benches and narrow desks crowded with the men you have already met before. Your biggest lot comes in its turn according to number in the list. "Lot No. 20," shouts the broker, "a thousand hundredweights"—but his further words are drowned by a hideous babel of shouts, yells, catcalls, squeals, grunts and other noises followed by only a second's silence when the fall of the hammer is heard; and if you don't know the last and highest bid and who made it the selling broker does from long experience. "The next lot," calls the broker, and so on rapidly through the list. There is no dawdling or no coaxing, the broker knows that every buyer's mind has been made up before he entered that room to give only so much and to get it cheaper if he can; but a hundred others ear as sharp as he is, so it's soon all over and the parcel not likely to go either above or below its value, though you may think so. The last lot through, either the room rapidly empties, or another broker mounts the desk to go through another catalogue in the same way.

Well, here, with the exception of very small samples, you have not seen much of the produce or many of the people of Ceylon; but you have seen where and how it is all sold; and it is possible you may go away with a feeling that you have seen nothing of Ceylon there, for, probably at the same time and in the same catalogue, more coffee from Rio, and Costa Rica was sold than from Ceylon.

If you further search for Ceylon in London you will find its interests represented by Messrs. L. S. D. & Co., who will accord you a few minutes' interview to discuss its present condition and future prospects, theirs being one of the mercantile houses doing chiefly with Ceylon produce, and who found the advances you used to draw through your Colombo agents against your crops. In other parts of the City are the offices of various Limited Companies of Ceylon, whose managers are usually old Ceylon men, with whom you may also have a talk. Another centre is your Bank, where you are most likely to run up against old acquaintances, but Ceylon business is only a fraction of the whole there, and nowhere can you find much of Ceylon. So vast is the business of the City, and so small a fraction of it belongs to Ceylon, that it and you are lost and become only microscopical objects. You follow your own little business, and you find out and consort with old friends and neighbours and talk shop, and that's all.

But the most important to you is always your "own said little business," and, in pursuing that from morning till night, you and the people with whom you deal become for you the true centre of Ceylon in London. So unfortunately I have had occasion to feel very frequently. For some years there have been in London private businesses dealing only in Ceylon produce, the success of which shows that the proprietors struck out a very good line for their own advantage, not the least amusing feature being the struggle of one or other of them to keep the field to themselves against all comers. Many broken Ceylon men could not do better than start tea-houses in London, rather than go to the Congo: i. e. Congo in

London is a better spec for such than the Congo in Africa. Remember there are 5,000,000 people in and about London, who all drink tea, and that the majority of them can get only poor, adulterated rubbish from China! It will be to the interest of the aforesaid established businesses to ridicule this advice; but it is sound. It only wants the right men, with sufficient capital to begin in a small way, to work up s eadily to an ever-expanding trade. It also requires a knowledge of London itself which perhaps few possess; but the key to this knowledge, for trading purposes, lies in the fact that "London" is an agglomeration of a hundred different towns in one. That is, it has (within the postal districts say) a hundred different centres, around each of which, in circular areas of vast extent, reside an immense population, which has so little in common with its neighbours, that many thousands of people almost live their lives and die without seeing any other part of "London" but their own. Even busy City men seldom visit the West-end, but for pleasure occasionally; and Westenders may be rarely seen in the City oftener than twice a year, when dividends are due at the Bank of England. London is an inexhaustible subject, and Ceylon an infinitesimal one in comparison.

These Ceylon men who have left the country and are successful at home or in new fields will not regret having done so—but doubtless a few years hence will see many others of them return to their old haunts, where their local experience and knowledge will yet be in great demand. Ceylon has a great and immediate "future" before it, undoubtedly. And I hope and trust that all who are here now, without exception, but especially the much-tried, older residents, will have their fullshare in the coming prosperity.

BRAZIL AND JAVA:

REPORT ON THE COFFEE CULTURE IN AMERICA, ASIA AND AFRICA,

BY

K. F. VAN DELDEN LAERNE.

It is a well-known fact that the coffee grown in Brazil represents one-half of all the coffee produced in the whole world: therefore Brazil may be considered to rule the whole market. As it is for our Government, who derive a great part of the revenue from this source, of paramount importance to be thoroughly acquainted with the conditions of this culture elsewhere, especially when such a serious rival as Brazil interferes, it was resolved in 1883 to send out an authorized and qualified person, to examine into the state of the coffee culture in Brazil in order to study it in connection with the interests of our coffee culture in Java.

Our readers may remember that accordingly in 1883 Mr. K. F. Van Delden Laerne was charged with this delicate mission. This gentleman was, by his position as Referendary at the Department of the Interior at Batavia, and his known abilities, eminently qualified for this mission. Accordingly he left the port of Lisbon Sept. 9th, 1883, and on the 6th of April 1884 he returned to Europe with a store of materials carefully collected for his report; these he worked up with surprising diligence; for, in the short space of six months after his return to Europe, his report was ready and delivered to the minister of Colonies. This report, a voluminous octavo volume of 600 pages, was published in December of last year, and a splendid specimen of industry and perseverance it is, besides being provided with maps, views and a number of statistical tables of great value.

We hear now, that to render the contents more universally known, an Edition in French is almost completed, and one in English is in course of publication. The interest of the matter deserves this distinction. The book is full of carefully collected facts with many useful and practical suggestions concerning our own tropical cultures.

Thus we find the vital question of labour, the great stumbling block in Brazil, slave-labour or government cult-

ure, fully discussed. The financial system in Brazil has also been an object of close scrutiny; the overproduction and consequently low prices, which latter consideration has led the Centro da Lavoura e Commercio to look out for new *debouchés* for their coffee.

We have further a chapter on immigration which would be so necessary to replace slave labour in case of complete emancipation, the agrarian and economical conditions of the country, the means of communication especially Railways, Commerce and Banking business, and then more especially the Coffee culture as is it practised in that country.

The writer concludes his most interesting report with a review of the coffee culture in Netherland India, expressing it as his conviction, that by better pluck and better preparation the Dutch Government could derive much more advantage from the culture, without oppressing the native population.

To give the reader a specimen of the work, we will extract the conclusion of the Chapter Slavery and Emancipation.

"The new settlement of the emancipation question will not, I fear, be effected without a violent struggle, and even then we shall have to ask ourselves, how it is to be carried out.

By the proposed bill of the Minister Dantas, which if it passes will render the above mentioned motion of De Bulhoes null and void,—freedom is desired for all slaves:

- a. That have attained their sixtieth year.
- b. That have not been registered previously.
- c. That have been removed from their legal domicile.

It is further enacted:

d. That all liberated slaves of sixty years of age and upwards have a claim to board and lodging as long as they remain with their former masters; but cannot insist on payment for work performed: this is left to the good will of the master.

e. That, if liberated slaves leave the service of their masters, they shall be maintained by the State.

f. That within a year after the passing of this Bill, there shall be a new registration of slaves—based on that of 1817-73 stating name, age, colour, size, nationality, percentage, physical capabilities, calling and value. All slaves not registered are free.

g. That the registration fee shall be one milreis per head.

h. That the value of the slaves be estimated according to age, and must not exceed:

800 milreis for those under	30
700 " " " "	between 30—40
600 " " " "	40—50
400 " " " "	50—60

j. That the compensation paid out of the Emancipation-Fund shall be calculated according to that standard, with this understanding, that the slaves valued lowest shall be the first to be bought out.

k. That a tax shall be paid of 5 per cent in Rio de Janeiro and the seven largest provincial capitals, 3 per cent in the other towns, and 1 per cent in the interior.

l. That from this time forward there shall be levied a tax of from 10 to 25 per cent on slaves changing hands by inheritance; 5 to 25 per cent on legacies *INTER VIVOS*; and 10 per cent on sales.

m. That the ecclesiastical orders, after the conversion of their lands into Government bonds or "apolicies" shall have to pay a duty of 20 per cent on the interest of these apolicies.

n. That the slaves legal domicile shall be considered to be the Province where he is on the day the Bill becomes law, always excepting such as are attending their masters on a journey.

o. That all slaves whose liberty has been bought out of the Fund, shall be required to continue work for five years in the district they are in, on pain of fine, forced labour on public works, or imprisonment.

p. That all work agreements, which must not be entered into for more than three years, shall be registered.

q. That the minimum wages to be paid to the emancipated slave shall be determined annually by specially appointed judges and arbiters.

r. That no traffic in slaves shall be carried on on pain of a fine of 5,000 milreis for each offence.

s. And lastly, that all existing state taxes on slave-property, transport, etc. are repealed on the day this law comes into operation.

It is alleged that, if this motion should be adopted, a very great portion of the present slave-population will be able to claim their liberty by reason of the following fact:—

At the registration of 1871-73, the slaves imported after 1831 were represented by their owners as older than they really were, for fear they should, as emancipados, be declared free.

It seems now that thousands of slaves who have not actually attained 60 years, are according to the old registers officially above that age, and consequently have a right to claim their freedom.

Owing to the reasons mentioned, the exact number of slaves in Brazil cannot be ascertained within a few tens of thousands.—*Indian Mercury*.

COFFEE IN THE PARCHMENT OR IN THE CHERRY.

We copy from the report of Messrs. Chabot & Andres at Rotterdam, the following:—

The imports of coffee in the parchment in Netherland were in this season only:—

About 190,000	bags, against:
306,621	in 1883-84
188,005	in 1882-83
150,000	in 1881-82

and show thus a considerable decrease.

This decrease can be accounted for by various causes:

- 1°. by the smaller crop in general.
- 2°. by the inferior quality of the coffee itself,
- 3°. by the constant expectation of higher prices.

The crop was decidedly less than had been anticipated, and the leaf blight has, in several places, acted very injuriously on the quality. This year in general there were very few especially good qualities; the colour was flat and mostly dull and pale; the berry not large and shrivelled. This we attribute to the blight already mentioned and to the difficulty of drying through a protracted rainy season. In our account of January 1884 we mentioned that a great part of coffee in the parchment was held back, to be disposed of later on by eventual improvement of the market. Instead of improvement there came a decline, and at every transaction the prices frittered away. In July, September the remnants were disposed of before the beginning of the campaign, and the results could not but be very disappointing. Indeed, the decline was more than 8 cents per $\frac{1}{2}$ kilo. Mainly to the impression this caused, and to the existing low prices not giving occasion to expeditious deliveries, it must be attributed that in this campaign more coffee had been peeled in Java. The crop was gathered timely, but on account of the rains the drying did not proceed expeditiously, and as after the gathering the planters had hands unemployed, he resolved to proceed at once to peeling and sorting. We see that crops small in quantity and inferior in quality at low prices, which hardly remunerate the planter for costs of production, counteract the treatment in Netherland; as, under these circumstances, it is not advisable to make expenses that would on an average render the product $\frac{3}{2}$ cent per $\frac{1}{2}$ kilo, dearer. Having considered what were the causes of the smaller supplies of coffee in the parchment this year, we believe we may also state that, in general, with very special expectations, the results have been in favour of treatment in Netherland.

In July 1882 we wrote:—

"To resume, we think we have hereby adduced the reasons on which we believe that for all superior W. I. crops, and we repeat, especially for coarser coffees, the peeling in Netherland will find more and more encouragement, because it will prove the most profitable, while for small-berried medium coloured coffee the result will always remain doubtful, and will be much more subject to all possible vicissitudes of the market, whether favourable or unfavourable. "We can now, after later experience, perfectly confirm this.

One example will suffice:

At the Rotterdam market the following parcels of one and the same crop and from one and the same plantations sold.

		peeled in this country.	
8	October	1884 349 bags ...	46 $\frac{1}{2}$ cts.
5	November	" 427 " ...	44 "
14	"	" 434 " ...	44 "
25	"	" 526 " ...	44 $\frac{1}{2}$ "
6	December	" 344 " ...	44 $\frac{1}{2}$ "
16	"	" 405 " price unknown tax. 38 "	
19	January	1885	

		peeled in India.	
8	October	1884	
5	November	"	
14	"	"	
25	"	"	
6	December	" 896 bags price unknown tax. 39 cts.	
16	"	"	
19	January	1885 256 " ...	35 "
19	"	" 602 " ...	33 $\frac{1}{2}$ "

These prices require no comment.

To the question whether coffee in parchment can be stored here for some length of time without detriment to the quality, the trials made lead to the following answer: "Well dried parcels after 6 months' and longer warehousing, showed no diminution of colour of any consequence whatever, while coffee less well dried could be observed to grow gradually paler from month to month. Coffees from different plantations furnished in this respect different results." "Whether a parcel, brought over here in the parchment is dried in such a manner that it will not suffer by lying in store, can be determined with sufficient certainty." Yet it is decidedly injurious to the quality for the coffee to lie in the parchment for any length of time in Java before being expedited. We could observe this by comparing various lots.—*Indian Mercury*

APPLICATION OF ELECTRICITY TO THE PLOUGHING OF RICE AND SUGARCANE FIELDS IN JAVA.

The firm Siemens & Halske, Berlin, have for several years been making a series of experiments with an Electric Plough invented by them, and made accurate observations concerning the labour, traction-power and speed, at which different species of soils could be most profitably ploughed, and compared these results with the labour obtained in Java with buffaloes.

The results of these trials, which were all made on a large scale and with great care, are very favourable, and prove not only the practical feasibility, but also the advantage that may be derived from introducing Electric Ploughs in Java.

The plough which Dr. Siemens has had constructed for this purpose, is a so-called *double or balance-plough*, consisting of two equal halves, that can swivel on the axle of the wheels like a hinge. By this arrangement it is unnecessary to turn the plough, and you can plough forwards or backwards, by letting down either the back or the front half.

The ploughs in Java have one plough-share 26 cm. broad, and go 13 cm. deep; for an electric plough, however, 3 plough-shares of the same breadth might be used and the ploughing would be as deep, and according to the trials made 1 Hectare of land might be ploughed in 7 hours and 6 minutes.

For the same work, the Javanese yokes two buffaloes to his plough, and with a working time of six hours per day, he would require 26 hours.

Therefore the same labour is done by the Electric Plough $\frac{26}{7.1} = 3.66$ times quicker than by the yoke of buffaloes.

Besides this the buffaloes work only 6 hours per day, while the Electric Plough can be made to work with advantage during 10 hours per day. If we take this into consideration the difference becomes much greater, for the Electric Plough does in $\frac{7.1}{10} = 0.71$ day as much as 3 buffaloes do in $\frac{26}{6} = 4.33$ days, or $\frac{4.33}{0.71} = 6$ times as much.

The driving power serving as standard for these experiments, was 5 H. P. In actual practice, however, by making

use of newer and better electric machines, an available power of $7\frac{1}{2}$ H. P. would have to be reckoned upon, and the work performed by such an arrangement would be much greater in proportion, so that $6.1 \times \frac{75}{5} = 9.15$ times the work of 2 buffaloes can be done, that is the work of 18 buffaloes.

The advantages, then of electric ploughing appears clearly from these results. We have now only to answer the question: How to apply it while observing the claims of the Indian soils. If we consult the latest inventions on agricultural appliances, then no doubt (leaving the costs of purchase out of account) the two-machine system introduced by John Fowler deserves the preference by far chiefly by the light and easily moveable portable engine. Yet this system has a drawback that must not be left out of account, namely the alternate inactivity of one of the boilers. The two-engine system is also applied by Siemens and Halske, but without this drawback, as the power developed in one engine is alternately transmitted to one of the ploughing machines. These ploughing-machines consist each of an electric machine with coil, etc., and are fit to be moved along or over the field; their weight is therefore as little as possible, the electric connections are partly stationary, partly easily removable.

The primary electric machine, through which the fore-mentioned electric ploughing machines receive their motive force, can be moved either by steam or water, according to circumstances. The motive power, with the primary electric machine, driven by it, may be quite stationary, and derived from an existing steam-engine or from a water-wheel; it can also consist of a portable engine, remaining on the road, so that its transport, as also the supply of fuel and water, can be effected with the utmost ease. The wagons for the electric ploughing-machine are entirely constructed of iron, therefore very durable, and do not weigh much more than 3,000 kilogr. against 7-8,000 kilogr. of a portable engine with appliances filled with water. So here, too, there is a great economy of weight. Regarding the costs of arrangement as described above, we can give the following notes. They consist:

1st. In 2 vehicles with electric machines, coils etc. complete, arranged for ploughing a furrow 200 M. long and provided with gear to move on so constructed, that according to the desired horsepower to be evolved, they may be removed to a distance of 1,000 Metres from the primary engine.

2^d. In a primary electric machine with, which 900 revolutions evolves 10 H. P. of which, after deduction of 2.5 H. P. to surmount all resistances, $7\frac{1}{2}$ H. P. remains for the plough-labour.

The electric steering arrangement, coils with isolated conducting wire for connection with the machine, all other conductors and appurtenances.

3^d. The balance-plough with four shares, each 29.5 c.M. suitable for the available labour of $7\frac{1}{2}$ H. P.

4^d. 400 Metres of conducting-material, for connecting the two vehicles.

5^d. Belts and appurtenances, small material, instruments etc.

The cost of this complete is estimated at f 15,000, the expense of transport to Java included.

If then you have, at a distance of about 1,000 M. from the land to be ploughed, an available force of 20 à 25 H. P., you would, with a direct outlay of f 15,000 at once, and a constant expense of about 10 per cent. for interest and amortisation, besides occasional expenses, not here to be specified, for wages, fuel, etc., obtain the same result as by purchasing 18 buffaloes with 9 ploughs including interest and amortisation, maintenance, food and wages.

We hear that the "Nederlandsche Maatschappij voor Electriciteit en Metallurgie" at the Hague who represent the firm Siemens & Halske for Netherland and the Colonies, are willing to furnish any further details that may be desired.—*Indian Mercury*.

FLIES AND BUGS.

Beetles, insects, roaches, ants, bed-bugs, rats, mice, gophers, chipmunks, cleared out by "Rough on Rats,"

W. E. Smith & Co., Madras, Sole Agents.

TEA AT HANKOW.

There are some things which improve upon a fuller acquaintance. The first crop teas of this season are not amongst those things. Never, perhaps, were first impressions more correct than they have proved themselves to be this year as regards the leaf: for no one will question the inferiority of the crop. Nevertheless it is by no means the worst crop we have seen of late years. It is not a pleasant thing to have to admit that samples of one's earlier purchases are not today as good as they were a fortnight ago; still, such is the fact. The Ning-chows have not improved in canister; or rather, with very few exceptions, they have palpably deteriorated. The "weatheriness" before alluded to has developed. The teas, in fact, are going through "no slow gradations of decay," and some shippers will soon have an experience of what is known as the "calamitous invoice."

The Hohows are tender plauts, and will bear no handling. In cup they are very "curio," and it is difficult to understand what virtue that enlightened American cousin finds in these most unsatisfactory of teas. The Kernans alone maintain their "pride of place." *Inter eccos monoculus rex est*. In other words these teas "star away" from the vulgar crowd. They are the finest teas of the year, as regards "head chops," and the upper medium class is ripening up. But nothing good can be said of the lower grades, which are skippy, choppy, dusty, and often sour. Red leaf Twankays they have been called.

Amongst the Hankow district teas, Towyuens alone are fit to be placed in class A. The head chops are very pretty to look at, and full, strong, tarry teas besides. But the later packs are already deteriorating in canister; sure herald of coming grief. There are some shippers who have taken a "view" in the Omfu department, and who, in some instances, have obtained good value for their money; but it is scarcely necessary to refer to the other already too numerous classes of Oonahm tea who hide the wolf, the irrepressible *Shuntam*, in the sheep's clothing of pretty names like Lowyong, Li-ling, Wing-fung, Kokew, and a crowd of others. If it were not for the Russian buyers, Oopack teas would be nobody's children. They are a hard lot, and demand a very appreciative palate. Regarding prospects, the early shipments ought to pay, because:

1st.—They were not dear.

2^d.—They go to a bare market in London.

3^d.—They will arrive at home shortly after the trade has proof that the first crop from Hankow is nearly 5,00,000 lbs. short. The total settlements to date are 713,236 half-chests or 81,000 half-chests less than at same time last year; a difference which it seems now impossible to reduce.

The purchases for England are 540,000 half-chests or about 47,000 tons; not quite enough to satisfy the tonnage supply of the season.—*Shanghai Courier*.

TEA, CHARCOAL & C. IN NORTH FORMOSA.

18th May.—Queer weather; quite cool again; ther. 71 to 75; wind, strange to say, is north-east still; generally calm in the mornings, and a breeze about 10 a.m. Two steamers outside: the "Welle" from the north and the "Inguban" from the south. No lead on board these ships. Some 70,000 half-chests of tea down and only lead for about 4,000 half-chests. Chinese packers are buying up leaden joss candlesticks, etc., to make leaden hangings to tea-chests, and fishermen are said to be parting with the leaden weights attached to their nets for same purpose. Lead last season was sold at about \$5 per picul; at the beginning of the present season sales were made at \$9 \$10 per picul. In the beginning of the present month \$16 per picul might have been obtained. Today packers are willing to pay, people say, \$20 per picul.

Charcoal, which is an important article in the manufacture of tea, is also a scarce commodity just at present. Some years ago you could buy it at the rate of \$1 for 3 piculs; now you can only get 80 catties for a dollar. A very large quantity of charcoal is used in all the large towns of Formosa for cooking purposes, but an enormous quantity is also required at Twaatia and elsewhere for firing tea. Each tea packing hong has a large firing room attached. Small hongs have 50 to 100 fires and large hongs have about 200 to 300 fires and even more. The fire places are simply circular holes, about two feet in diameter, surrounded by brick facings. They are arranged in rows, and are not much more than eighteen inches above the floor of the room. The fire holes are apart about half a foot and on the top of these circular holes or receptacles for live charcoals are placed the baskets containing tea. The fires are prepared in a simple way; a large pile of charcoal is lighted and allowed to burn till all the combustible matter contained therein has disappeared, and then the red hot particles are piled by the firing men in the circular fire-places. For several hours the fires are allowed to flare up and cast forth a flame and glow that few men can stand for any length of time. If you enter a large firing room at the time the fires are being lighted it is like going into an oven, and the return to the open air reminds you forcibly of the heated atmosphere of Montreal hotels, where inside the temperature is perhaps over 70° and on going out of the front door you suddenly find yourself in an atmosphere several degrees below zero. This is putting it very mildly, for in a room with 300 fires the heat is far more intense. It takes time for the fires to settle down, and the red hot charcoal has to be broken up with iron implements; the red heat has to penetrate to the very core of the charred branches or portions of trees, and when no smoke whatever issues from the fire holes, the firing men place on top of the embers a thick covering of ashes of paddy husk, which deadens and tempers the heat to such an extent that in the course of 12 or 15 hours from the time the blazing lumps of charcoal were placed in the fire holes it is safe to place the baskets containing tea leaves over them. The baskets are cylindrical in shape, about 2 feet in diameter and about 3 feet high; they are divided in two by a sieve partition, and on top of this sieve the tea is placed. The teas brought down from the hills and tea districts have undergone the sun-drying and absorbing process, have been fired in an iron pan, have been twisted by hand or passing through the rapid frying process, and on occasions are basket-fired up country. But the up-country process of preparation is insufficient to permit of the leaf being shipped away to a foreign country; it has, therefore, after you have purchased it, to be "cured" properly and finally at Twaatia. Every particle of moisture has to be extracted in the final process, previous to packing the leaf in lead-lined chests.

Wherever Chinese colonists are sent to—and it is always inland towards the savage frontier or border land—their first idea is to make a clearing, build shanties, plant a few sweet potato fields, &c. Then after squatting and settling down, they turn their attention to the hills in neighbourhood, which are covered from bottom to top with trees of all kinds and their jungle. Without entering deeply into border life, we may mention that these pioneers are for the most part Hakkas, in fact our old friends the hillmen. They become squatters—rampor producers or charcoal burners according to circumstances. They enter into the business, whatever it may be with zest, whether wood clearing or hunting, and in a generation or two become semisavage in their ways and habits. They have to deal with savages,

and in course of time they out-savage them, having a poorer idea of honour than the aborigines. They commit treacherous acts on occasions, and feuds arise, lasting often for years. These borderers or hillmen come in contact with the savages daily, and they act as a sort of buffer between the quiet farmers and villagers in the valleys and plains and the noble owners of the hilly country. They are therefore looked upon as protectors and are often paid by the people and the Government to check the savages when making raids into Chinese territory, perhaps only lately acquired.—*Daily Press Cor.*

IMPROVED PLOUGHS.—It is now some nine months ago since the Director of Public Instruction experimented in several districts with some of Messrs. J. & F. Howard's English Ploughs. The results of the various trials have been satisfactory, judging by the number of natives who have now adopted the modern implement. Several native cultivators have been very successful with them, and later on we hope to be able to give some tabulated returns from different provinces. The ploughs can be drawn by the ordinary country buffalo, and their great merit is that they thoroughly turn over the soil, thus exposing it to the fertilizing influence of the atmosphere, while the native ploughs is really only a one-pronged harrow, simply scratching the soil without turning it over. The ploughs are equally suitable for coconut and other gardens, and to paddy land. In the case of paddy fields the improved plough should be used about six weeks before the ordinary native ploughing time. After the ground has been well turned over by the new plough the old native plough should be used to mix up the soil, like a harrow, and then the cultivation should proceed in the usual native manner. Some of the ploughs may be seen in use at the School of Agriculture, Cinnamon Gardens.—*Ceylon Advertiser.*

JAFFNA NATIVE RESOURCES.—Take care of your pence, and your pounds will take care of themselves, is a trite old adage, and yet contains the very essence of practical wisdom, holding good under all circumstances, and worthy to be remembered by all classes of our community. We wish to direct the attention of our readers, and of those in authority to the gradual failure of our smaller sources of income which at one time in the Province went along way to increase our revenue. Thus the export of chanks, palmyra-timber, fish fins, hides, and ghee, honey, horns, bones and oils of sorts were at one time a brisk and profitable trade in the Province. In preparation of these articles, and in sorting them some have been so careless and others have been scamping and adulterating them that importers have sought other places to get the genuine article, and thus our traders have been penny wise and pound foolish. It is painful to observe how the export of most of these articles in the Province is left in the hands of Chetties and Moormen, while our countrymen fold their hands, and cry that all the money goes into the hands of strangers. The fact is our young people feel ashamed to be seen as they think dirtying their fingers with fish fins and beech-de-mar and think such occupation must be left either to their aged relatives or to the Chinese who come and settle in the Province derive a profitable trade, and go back to their country and settle themselves there as merchants, while a poorer relative is sent to take his place. The preparation of beech-de-mar is so simple and the catching of the fish is such an easy task and requires not a large outlay of money that we are surprised that the trade is left entirely to the Chinese; more especially as the article at Colombo commands a good price. Such localities as Kalmuui and Ariallai, so very close to the town are the fishing ponds where the Chinese settle themselves. And yet very few of our young people know anything of their doings or can speak with certainty of the manner in which the fish is cured and the habits of their life. The desire for Government employment even on five or ten Rupees to prove that they know English and are anglicized is the secret of the reluctance for anything like labor though that labor is certain to give independence and be a blessing to others whom we could comply.—*Jaffna "Patriot."*

AGRICULTURAL EXHIBITS AT THE INVENTIONS EXHIBITION.

Messrs. E. Packard & Co., of Ipswich and London, show under Group 14 the following:—

Phosphoric acid, concentrated superphosphate of very high quality, phosphates of soda, potash and ammonia and other compounds manufactured under processes which comprise the use of a particular form of mixing apparatus for dissolving phosphates; the mode of separating the gypsum and solid mass from the liquid to phosphoric acid by means of filtering presses, particularly woollen filtering presses; the mode of concentrating phosphoric acid solution so obtained; and several other processes connected with the manufacture of superphosphate, &c. The chief point of novelty is the practical and cheap method of manufacturing phosphoric acid from which can be produced superphosphate and other compounds of high concentration, and, if necessary, of great purity.

Under Group 17 they exhibit:—

(1) A number of samples of sugar manufactured in Mauritius under the new process invented by Messrs. Icery, Bernard and Ehrmann. By this process a great economy is effected in the manufacture of cane sugar, and the following are the advantages that this process offers:—1. Increased yield of sugar. 2.—Improved quality of sugar. 3.—Proportion of molasses reduced. 4.—Great economy effected. 5.—Necessity for charcoal filters obviated. 6.—Superior clarification obtained. 7.—More time may be employed in defecation. 8.—The evils of overtempering counteracted. 9.—The cost of the reagents recovered in its value for manuring the next crop. 10.—Greater proportion of first quality sugar produced.

(2) Various reagents used in the above process, including a particular form of phosphoric acid to which the name of "Ehrmannite" has been given, and which is entirely soluble in water and manufactured by the exhibitors under patents invented by them.

INSECTS ON ROSES.

At this season, when rose shoots are young and tender, they are very apt to be attacked by green fly and other insects, which cover the points of the shoots and injure or destroy the flower buds. I have known many roses, especially in unfavourable situations, ruined by insects when the shoots were young; the buds which formed never opened properly. When insects are allowed to increase and overrun the shoots, imperfect development is sure to happen, and no after-cleaning will rectify the damage. The only way to succeed is to check them from the first, and get them cleared as soon as possible. It may be no easy matter to keep the plants perfectly clean, but all who care to try may save their crop of flowers. Dryness at the root will always cause insects to take possession; therefore roses thoroughly watered will stand a good chance of escaping. Cold winds and general starvation of root and branch will induce hosts of insects; and in order to reduce their numbers, the first thing to do is to have the plants in a free-growing and healthy condition at the root. Tobacco powder is excellent for clearing insects off roses; aphides cannot withstand it. It should be put inside a fine muslin bag and dusted on the shoots affected. If put on at night and syringed off in the morning, nearly every insect will be washed off at the same time. When the shoots are dry, and much of the powder is likely to fall to the ground or be blown off as soon as put on, the best way is to damp the shoots first and then put on the powder, which may thus be made to stick. Soap suds, if applied by a syringe freely, will clear roses of most kinds of insects, and one wine-glassful of petroleum to a gallon of water and a small piece of washing soda, mixed up together, will take off every living thing, but this must not be allowed to stay long on the trees; it should, indeed, be syringed off after being on, say, five minutes. Evening is the best time to do all this kind of work, and it should be done before the buds are far advanced, or the crop of blooms may be injured or lost.—CAMBERIAN.—*Field.*

EXPERIMENTS IN AGRICULTURE.

Dr. Home, writing in 1759, says "Agriculture does not take its rise originally from reason, but from fact and experience. It is a branch of natural philosophy, and can only be improved from the knowledge of facts, as they happen in nature. It is by attending to these facts that the other branches of natural philosophy have been so much advanced during these two last ages. Medicine has attained its present perfection only from the history of diseases and cases delivered down. Chemistry is now reduced to a regular system by the means of experiments made either by chance or design. But where are the experiments in agriculture to answer this purpose? When I look around for such, I can find few or none." Where are the experiments? We repeat in these enlightened times. To experiments we undoubtedly owe many of the improvements that have been introduced. To experiments that have been carried out by aid of the acquired knowledge of chemistry we are indebted in the largest degree. With further study, and experiments I doubt not but that we shall see "Agriculture" still further improved from this one motive power alone. But when this is done, all will not be accomplished. We have seen how Blythe suggested that new species of produce, those of foreign growth, might be with advantage grown here. The ascertaining that the foreign husbandman did grow these cost money. For either actual observation was made of the parts where they were grown, or knowledge was acquired of the same from book learning. Today we have as much need to find some new species of produce as had the farmer who lived in the last century; aye, we have more. Establish your seminaries with sufficient funds, and your teachers will make it their business to discover the way that husbandmen in other countries carry on their business, and will thus be able to instruct the farmers of the future. I fear that experiments made without the founding of seminaries are liable to be confined too much to the scientific class.—S.—*Field.*

ORANGE GROWING IN FLORIDA.

Sir,—A friend at home in London sends me the *Field* weekly, and, having noticed a good deal asked lately about Florida in reference to orange culture, I take the liberty to write you this letter. I came out here thirteen months ago through the advice of a friend, and threw up a very good berth at home to do so, with the intention of following out my friend's advice, and starting a 10-acre orange grove. As far as I have gone, I am well satisfied with the results; but my expenses have been a great deal heavier than I anticipated, and one should take many things into consideration before coming out here to make a grove. For the first year it is very disheartening work, and a man must have energy, patience, and perseverance to succeed in this undertaking.

It is no good for young fellows to come out without capital, say £300 or £400, to start a 10-acre grove of 600 trees, and they must not expect any return to speak of for six years; so they should have sufficient means to keep themselves and a horse for a period. I am making a grove on good pine land, but I should advise those with the means to buy hammock, which, with the expense of clearing, costs nearly double the amount in the first instance that pine land does. We have not many settlers in this vicinity as yet, but the few young groves round here cannot be beaten for the time they have been set out.

A good many young fellows from home go a little further south to settle, viz., to Orlando and Orange County, where land is high, owing to its being more settled up, and they get nearer town, and have more chances of spending their money; but let me advise those coming here with the idea of starting a grove with a small capital to take a look round here and Crescent City. The latter place is six miles on the main road from here, and is rapidly settling up. There are several Englishmen, who are starting like myself, who would be glad to give sound advice to new comers

from the old country. The pine land in this vicinity is supposed to be as good as any in Florida, and is owned by private individuals, most of whom started groves about five years ago, so that it is not advertised up in any way. Fruitland is 125 miles from Jacksonville on the St. John river, or twenty-five miles from Palatka.—JOHN E. D. KING, Fruitland, Putnam County, Florida, U. S. A., March 22.—*Field*.

BÊCHE-DE-MER FISHING IN JAPAN.

Sir,—Having just read the very interesting article by Mr. Wilford Powell on bêche-de-mer fishing in your issue of Dec. 27, 1884, it has occurred to me that a few particulars about the same industry, as carried on in Japan, would not be unacceptable to some of your readers.

Bêche-de-mer (called by the Japanese "irico"), although found more or less all round the islands which compose Japan, is only obtained in any quantity on the island of Yezo and on the N. E. coast of Nippon. From these places it is sent to Hakodati, the only treaty port in Yezo, and is shipped thence to Shanghai by the foreign merchants.

The mode of capturing the fish is different from that described by Mr. Powell. They are caught here from small boats, manned by two men; a small trawl net is used. The process of preparing, also, differs from that employed in Australia, and is as follows:—The fish, having been caught, are thrown, as soon as the boats return to the shore, into large boiling pots, and boiled for about one hour. They are then taken out and spread on straw mats to dry in the sun. Before boiling, the fish spoil if kept for a longer period than twenty-four hours; but after having been boiled and dried once, they may be kept for some time without any danger of their going bad. When thoroughly dry, the fish are again boiled for about one hour, and then dried as before. At this stage they should be hard; if soft, it is a sure sign that they are not sufficiently boiled.

In this state it is bought by the merchants at Hakodati, where it undergoes the process of being doctored for the Chinese market. The bêche-de-mer most in demand is the prickly black kind, and the more spines it has, and the blacker it is, the better price it fetches. Now, although known as black bêche-de-mer, yet it is of a dirty brown colour by the time it arrives at Hakodati, after having undergone the processes of preparing. As this dingy appearance would depreciate its value if sold in this state, it is subjected to the operation of colouring. This is done by plunging the fish into a cauldron of boiling water, in which Indian ink has previously been dissolved, for about half a minute. When taken out and dried in the sun, the fish should be hard, and of a dull black colour. It is then sorted and put up in boxes holding one picul (133½ lb.), to be shipped to Shanghai.—H.—*Field*.

FUEL FOR TEA ESTATES IN THE NEW DISTRICTS OF CEYLON.

Anyone passing through those districts through which the newly opened line of railway has been constructed cannot help being struck with the great extension of tea planting now in progress. At the same time, the question naturally arises how will the fuel be obtained necessary for the manufacture of leaf from such immense areas of tea? Coal or wood will have to be found and transported up to these districts. If wood, it may have either to come from Kurunegala or Matale. If coal, from Colombo. This naturally opens up the question as to whether some of the forests which exist beyond Matale could not be utilized for the purpose, and so contribute further towards the maintenance of the Matale railway line. It may be of course that wood will be found much nearer upon some of the dividing ranges; indeed it is to be expected that it will.

Whatever it is to be the material used, whether wood, coal, or coke, it will not be long before the demand comes, and I look upon it as a question that should be brought before the public. To utilize the long and costly piece of new railway recently constructed, rather than

that it should be left solely for the running of a train or two up and down its length daily, surely fuel might be carried upon it at rates so low as to look for a profit upon the consequent down traffic it would augment. It is time too the question arose, as, thereby, by the time everyone is ready for it, some cheap and certain source may be found. The question too is one which may take our rulers some time to decide upon, but, if there is wanted an incentive to the extension of tea in the so-called new districts, some safe figures as to the cost of the fuel necessary for the manufacture of tea would greatly increase it. Now, it is a great and moot question, which no one can satisfactorily answer; consequently few people care to ask it; yet, it is of immense importance to all interested in tea in these districts, for the time is not far off when fuel will have to be purchased for the factory, bungalow and cooly lines, and the only way it could be cheaply supplied is either from the forest reserves on the Uva side of the range or the lowcountry. In either case it should be carried at exceptional rates.

The nearest spot is the forest along the route to Haputale, along the new trace, and this may form another claim for the extension of the railway to Haputale.—WM. FORBES LAURIE.—Local "Times."

TEA PRUNING.

I have just read Mr. A. E. Wright's letter upon the very interesting and important question of tea-pruning; referring specially to the two opposed systems most in vogue among tea-planters.

The one, as he clearly explains, keeps the single stem of the plant intact and its shape like a small tree with a flat top, without allowing young wood to grow from the bottom upwards within a distance of six inches from the ground. The other system is opposed to this, inasmuch as it, if anything, encourages the growth of young shoots from the ground, and, as they grow and occupy the space of the original tree, are allowed to take its place; a gradual removal of the original tree by pruning from the top downwards follows until in a year or two the whole, except a foot or so, has disappeared in the process; fine red young wood taking the place of white. At one period in India, I believe, the first of these two methods had the larger number of votaries; but of late, upon lowlands as well as upon hill gardens, where it has ever been popular, the second system has gradually grown into favor. For my part, I am inclined to believe that the tree-system (in contradistinction to the bush) has arisen out of the idea of cultivating fruit and other trees, where matured wood is necessary for flowering and fruiting, and that the second has, as a rule, proved with tea the most profitable. Owing to the short period that tea has been cultivated in Ceylon, I am not prepared definitely to urge the advantages of either, but as far as my experience goes, I am inclined to believe a better class of wood results after the centres of bushes have been cut out, the shoots ensuing after them being both stronger and stouter and more evenly distributed over the bush. I would, however, in explanation add that I do not oppose the removal from the tree-stem within 6 inches of the ground of all weakly branches and shoots; and also that I am not advocating carpet bushes which should only be grown where larger ones, owing to wind or general exposure, are impracticable. As unnecessary height is not desirable I do not quite see the use of the wasted six inches at the stems of the trees being kept absolutely free of young shoots, for, practically, it only adds six inches of unnecessary height to their stature which may make them just too high to allow children to pluck them well; or it may afford so much more unnecessary wind exposure. Of the two, the single trees afford by far the prettier appearance, reminding us of our coffee of former years; the shorter bushes (to me) appear, however, closer to their work and have less white wood upon them.

Some discussion, however, upon this subject before the pruning season, would, as Mr. Wright says, be generally beneficial.—W. F. L.—*Ibid*.

THE CAROB TREE.

We have received from the Hon. R. A. Tarlton, of South Australia, some seeds of the Carob, or Locust tree, accompanied by a copy of a letter from that gentleman to the *N. A. Advertiser*, and the comments of that journal on the cultivation of this useful and valuable tree. He writes as follows:—"I am informed that the Hon. G. C. Hawker has a tree that has yielded 8 cwt. of carob pods in one season. Here then is food for one horse for 149 days at the rate of 6 lb. per day. It is said that Thorley's food for cattle consists largely of these pods. Baron Von Mueller, in his book on extra-tropical plants, readily eligible for industrial culture, has the following—"The carob attains a height of 30 feet, and resists drought well; succeeds best in a calcareous subsoil. The saccharine pods, algaroba, or St. John's Bread, is of value for domestic animals. The seeds germinate readily. The exportation of pods for cattle food from Creta alone is now about 180,000 tons annually. The fruit serves for a medicinal syrup, caramel, an imitation of chocolate, and a liqueur. In some of the Mediterranean countries horses and stable fed cattle are almost exclusively fed upon the pods. The meat of sheep and pigs is greatly improved in flavor by this food, the fattening properties being twice that of oil cake. The pods contain 55 per cent of sugar and gum. To horses and cattle 6 lb. a day are given of the crushed pods, raw or boiled, with or without chaff." I have been informed that the Hon. G. C. Hawker has been using this food for stud sheep. No wonder he turns out such magnificent animals. Froun beans supplied by Mr. Hodgkiss I have already about three dozen young trees planted out. I purpose putting in a bean wherever I have a vacant spot. Last week I put in beans around all my unplanted fences up at Stirling East. The beans were first put in hot water, and were allowed to remain soaking for three or four days. The bean is then planted half an inch deep in the spot where the tree is intended to grow, as it sends down a long tap root. As the season is late, put in only so many as you can manage to water occasionally through the dry summer. Let me urge upon every farmer to go to work earnestly in May of 1885 in surrounding his homestead with the living green of the carob tree. It is easily grown. It is beautiful." This tree would grow on the Sandpatch, and why should not the Government spend a little money in procuring seeds and planting them so that the apparently sterile hill which is blowing into the harbor may yield a useful product? The seeds received we have distributed to several gentlemen to plant.—*Albany Mail*.

NEW COMMERCIAL PLANTS AND DRUGS.

Mr. T. Christy has published the eighth part of his publication on these subjects, comprising a history of the Kola Nut, together with remarks on gatta percha, the tuberos Solanum, the genus Myristica, Caca (Erythroxylon Caca), Cuprea barks, and other matters. A paste made from the seeds of Kola acuminata, it appears, can be used with advantage to mix with inferior cocoa. "Chocolate made with Kola paste is ten times more nutritious than chocolate made with cocoa..... and a workman can, on a single cup taken at breakfast time, go on with his work through the day without feeling fatigued." Such statements are likely to be received with incredulity save by travellers and botanists who have long been aware of the composition and effect of these seeds, though it is only now that public attention is being drawn to them. It is many years since Dr. Daniell published an account of the plant, and his statements have formed the staple of what has been given to the world since up to quite recent times. The good effects of the Kola appear to depend upon the large amount of proteid (nitrogenous matter) and of caffeine. The fatty matter of cocoa is here replaced by a large quantity of starchy material, which, of course, adds to its nutritive properties. The male or Bitter Kola is a seed produced from a species of *Garcinia* or some allied genus, of which a figure and description were given

by Dr. Masters in the *Journal of Botany* for March, 1875. The description given by Messrs. Heeckel and Schlagdenhauffen adds nothing to the account given in the work cited, which appears to have been overlooked by the two writers cited by Mr. Christy. The planting of the true Kola tree in low damp situations in the Tropics is counselled by Mr. Christy, and doubtless he has good reasons for so doing, for the good qualities attributable to the true Kola are by no means mythical. We say the true Kola (Kola acuminata, R. Brown, Masters in *Oliver, Flora Trop. Africa*, i., 220), because the Bitter Kola is probably less valuable and devoid of the caffeine which renders the true sterculiaceus Kola so valuable. Mr. Christy also recommends the planting in our colonies of the Caca (Erythroxylon Caca), which in addition to its properties as a stimulant and restorative has lately come into use as a local anæsthetic. It may be well to say that the name Caca has been proposed and adopted to avoid the confusion arising between Caca, Cocoa, and Cocus-nut, all three referring to different things. The Papaw and its derivative papaine, also comes under notice, and here again the valuable results already obtained suggest the culture of the plant on an extensive scale in suitable localities. A similar remark may be made about the Simaba cedron, the seed of which is useful in the treatment of fevers. It will be seen from these remarks that Mr. Christy is doing good service in introducing to the knowledge of commercial men and practical cultivators a number of plants whose good qualities have, at least in many cases, been well known to and published by botanists. But practical men would no more think of looking into such books as the *Flora of Tropical Africa* for the special information they required than botanists would consult the trade lists of the merchants to ascertain the names and descriptions of commercial plants. Mr. Christy's publication is a medium between the two, and a very serviceable one.—*Gardeners' Chronicle*.

SOME WEST INDIAN FIBRE PLANTS.

In the celebrated Lace-bark of Jamaica (*Lagetta lintearia*), an arborescent Daphne, we have a bast or inner bark-fibre which is found enclosing the stem, and consisting of numerous concentric layers, which interlace in all directions, presenting in a great degree, and especially when well prepared, a resemblance to the finest lace.

The purposes to which this lace is applied in the island—for the manufacture of doyleys and light fancy articles—are well known. Formerly, when more abundant than it is now, it was manufactured into ropes, whips, and other articles. It can however, even at the best, be hardly included amongst fire-plants likely to be useful on a commercial scale. A similar remark would apply to the bast or inner bark fibre of the Mahoe (*Paritium elatum*), known in commerce—from the fact of its having been exported from the neighbouring island—as Cuba bast; as also fibres yielded by such trees, as Spanish Elm (*Cordia gerascanthus*), the Down Tree (*Ochroea lagopus*), the Trumpet Tree (*Cecropia peltata*), the Burn-nose Tree (*Daphne tinifolia*), the Screw Tree (*Illicites jamaicensis*). All these fibre fibres of certain qualities, samples of which, prepared by the late Mr. Nathaniel Wilson, are still to be seen in the Museum of the Institute of Jamaica.

Of plants belonging to the natural order Malvaceæ there are numerous species besides the Mahoe belonging to the genera *Paritium*, *Sida*, *Abutilon*, *Hibiscus*, and *Pavonia*, which are remarkable as affording the everyday fibre-plants of the West Indies used by Europeans and natives alike for tying up produce, and indeed for all purposes when a convenient and cheap material is required for securing and binding.

The fibre contained in the Sugar-bark of the mountains (*Malvaviscus arborescens*) possesses wonderful strength and tenacity, and probably ranks next in these respects to the bast fibre of the Lace-bark Tree (*Lagetta lintearia*).

Amongst obscure and little known plants which yield fibrous material, mention might be made of *Anthurium* (*Potlios violaceum*, which is described by Mr. Wilson in the following words:—"Where strength and lustre of appearance is an object, this plant will be found equal, if not superior, to the best Lignhorn plant I have ever produced. This plant, though an epiphyte, and growing plentifully

at the roots and on the tops of the highest trees, at an elevation not under 1000 feet, may readily be cultivated in woodland and moist places to any extent. The part of the plant made use of is the petiole, or foot-stalk of the leaf, which grows from 18 inches to 2 feet long, and is readily divided into strips of any dimensions, and contains a strong fibre not existing in the common plant of the Fan-Palm. It has a durable colour."

Remarkable and valuable, however, as the fibre yielded by these plants may be in a rural sense, they are not likely, at least at present, to be rendered of commercial value; and I refer to them only for the purpose of supplying a general review of plants capable at all of yielding fibre and for the purpose of bringing into notice what may be termed the possible ultimate resources of the West Indies as regards fibre-plants.—From a lecture by D. Morris, M. A., Director of Public Gardens and Plantations, Jamaica.—Gardeners' Chronicle.

TREES ESPECIALLY SUITED FOR AVENUES

Mr. J. S. Gamble, Conservator of Forests, Northern Circle, has reported to the Board of Revenue as follows:—The question of what is the best tree to plant for avenues is entirely one of (1) climate and (2) soil. The same trees which would form magnificent avenues along the roads in Malabar would most of them fail altogether along those of Bellary or Vizagapatam. So far as the Northern Circle is concerned, omitting Nilgiris, the climate is dry, with the few exceptions of the hill tracts of the Circars or the Nallamalai hills. Scarcely anywhere does the rainfall exceed 50 inches. On the other hand, the soil varies extremely from the alluvial plains of the Godavari delta to the nearly bare metamorphic plateaux of Cuddapah and Bellary. Roughly speaking, however, we may classify the soils as follows:—(1) Rice lands on alluvium, (2) Laterite and the red soil which is produced by its decomposition, (3) Decomposed metamorphic soils—sand, gravel or sand and boulders, (4) Black cotton soil, (5) Riversand. Along roads passing through the great low country like the coast from the Godavari delta down to Pulicat, probably no better trees can be formed than the figs, viz. the Banyan (*Ficus bengalensis*), the Pipal (*Ficus religiosa*), and the Pekar (*Ficus infectoria*), with its allies (*Ficus benjamina* and *Ficus tictala*). Of these, the first is the best, though to avoid the damage referred to in the Board's paragraph 2 it might be kept away from bridges or culverts. There is probably no tree which so quickly reaches a size fit to give shade as the banyan, and it is easily propagated by cuttings consisting of stout poles, perhaps even 6 to 12 inches in girth and 10 to 12 feet high. They must, of course, be planted during the rainy season and fructed, and if the rains fall afterwards, they may require watering. In such places also the mango does well on ground slightly raised above the level of rice fields, and the Margosa (*Melia azadirachta*) and Jaman (*Eugenia Jambolana*) will also thrive. Another good tree for such places is the 'Kadam' (*Anthocephalus Cadamba*) which is very fast grown and easily raised. Near the foot of the hills, *Pterocarpus marsupium* might perhaps be grown with advantage. On laterite and lateritic soils the mango generally thrives well, and the jaman will also grow; but the figs should be avoided. Teak may be grown, but is a very bad avenue tree as it is leafless when shade is most wanted, and the shedding of its large leaves is probably bad for the roads. But whatever is planted, care must be taken to dig the holes deeply and to provide good soil to fill them when the planting takes place. On high level sandy soils, the result of decomposed gneiss and schists, figs may be grown if the soil is fairly good and the holes are well dug. So may the mango, but the best trees are the tamarind, the margosa and the sankesula (*Telugu*) *Poinciana elata*. Good avenues of these may be seen in various parts of the Cuddapah plateau, in Karnool, Bellary and Anantapur. Another very good tree is the Kanuga (*Pongamia glabra*), which gives a good shade, and has a fruit which is valuable for its oil. The Duisaia (*Albizia lebbek*) is much grown in such places, but is untidy and by no means so useful as the margosa, which has the valuable property of being in full flower and

young leaf in the hot season when its shade is most necessary. On black cotton soil there are only a few trees which thrive. The tamarind and margosa are perhaps the best, but a good plan is to grow the Babul (*Acacia arabica*) rather thickly by sowing in large patches protected by thorns and then thinning out to one or two good stems. Other, but smaller, trees which will grow are the *Parkinsonia aculeata*, *Albizia lebbek* and *Balanites aegyptiaca*. When river sand has to be planted—which occasionally happens—probably the best tree is the palmyra palm (*Borassus flabelliformis*), but the jamao, margosa and babul may also be grown, while near the sea there are few kinds so useful as *Calophyllum inophyllum* and *Terminalia catappa*. In some places the casuarina may be grown, but it is often untidy and does not give a good shade in avenues. There are many other trees which are occasionally planted in this Presidency. There is the *Cassia siania* to which His Excellency the Governor referred as being so common round Madanapalle, though, as remarked by him, it rarely makes a good avenue tree. There is the Deodum or Asoka (*Polyalthia longifolia*), which makes a beautiful avenue tree when it thrives, as it does in places along the coast. The Cork-tree (*Millintonia hortensis*) is often planted and is very pretty and sweet-scented but brittle, and so is the gold mohur tree, the brilliant *Poinciana regia*. Near canals where the soil is not salt, *Sissu* (*Dalbergia sissoo*) is useful, and as along the Kendrapara canal, in Orissa, the cocoon and *Calophyllum* may usefully be grown where there is some salt in the soil. To sum up, for general purposes, the best trees are the banyan, mango and margosa, but where special circumstance make others necessary, some of those I have mentioned will probably be best to use. On the subject of avenue planting, I would recommend the consultation of Ribbentrop's 'Arboriculture in the Punjab' and Sineair's 'Notes on Arboriculture in the Bombay Presidency,' a little book lately published by the Bombay Agricultural Department. Before concluding, I would beg to offer a few remarks regarding roads on the Niigiri plateau, where the presence of avenue trees or an avenue belt is so valuable as a protection against the cold bleak winds of their monsoon. The value of the belt of Blue gum (*Eucalyptus globulus*) and Wattle (*Acacia melanoxylon* and *Dealbat*) along the road from Oonoor to Ootacamund is obvious to all who travel along it in bad weather, and this belt should be continued along all public roads. The best tree to use is undoubtedly the *Acacia melanoxylon*, which is stronger and more shady than the others, and not troublesome like the silver wattle; but some conifers and specially (*Cupressus macrocarpa*) should also be grown. Where such roads cross swampy land, Willow (*Salix tetrasperma*) which grows most readily from cuttings should be planted.—*Madras Mail*.

THE CULTIVATION OF THE ERI SILKWORM.

The following letter has been forwarded from the Director of Agriculture, Assam, to the Hon. R. D. Ross, M.P.:—

"Camp Rangia, December 4, 1884. Sir.—In reply to your letter dated July 16 to the address of Mr. Stack, late Director of Agriculture in Assam, I have the honour to state that Messrs. C. H. B. Forbes & Co., Bombay, have informed me of the arrival of a case of wheat and other seeds intended for this department. I beg to thank you for forwarding the seeds, and to enquire whether you wish for any report as to the result of an experimental trial with it in this country. If quite convenient to you I should be glad to be favoured with an account of any experiment made with the sample of rice forwarded last June. A statement in the *Adelaide Observer* was brought under my notice a short time ago, in which the castor-oil plant was stated to grow luxuriantly in South Australia. If this be the case, it might perhaps be worth while to try if the Eri silkworm will not flourish there. This worm, as you will see by the accompanying note on the subject by Mr. Stack, is largely produced in Assam. It is exceedingly prolific, and if its cultivation were carried on upon commercial principles it might prove a source of considerable profit. But the Assamese peasant cares for ease and personal comfort much more than for wealth, and a

long as the valley is thinly populated and fertile land obtainable in any quantity, there is no chance of a large trade arising in Eri silk. The condition of things is different in your colony, and it may be that the cultivation of the worm could be carried on successfully in Australia. The two essential advantages the Eri worm possesses over the Mulberry worm are—that it gives four to six broods in the year; that it feeds on an annual plant, which is cheaply and easily grown, and whose leaves (now wasted) can be largely utilized without materially impairing the produce in seed. Its disadvantages are—that it must be spun, not reeled, and that the silk is not of as fine a quality as that produced by the Mulberry worm. Should you be disposed to try the experiment, I shall be happy to forward you eggs. There may be a difficulty in sending these without their hatching on the way, but I could make more than one consignment, some of which ought to be successful.—I have, &c., H. Q. DARRAH, Officiating Director of Agriculture."

A lengthy report on the different species of silkworm is attached to the letter, and from it we make the following extracts, which refer particularly to the Eri worm:—"We have three kinds of domesticated worms in Assam, or rather it may be said in Brahmaputra Valley, for the Surma Valley is not generally a country of silk cultivation. These are the Pát or Mulberry worm (*bombyx textor*), the Muga or sum-feeding worm (*Antherocœ Assama*), whose cocoon like that of the Pát can be reeled, and the castor-oil worm (*Attacus ricini*), yielding a silk which is never reeled, but spun by the hand. Looking simply to their commercial potentialities these three species of silkworm may be at once reduced to two by striking out the Mulberry worm (Pát), on account alike of the costliness of its silk, the scantiness of the present supply, and the difficulty of extending its cultivation. The two remaining species—the Muga and Eri—present a much more hopeful field of enterprise. They are produced in considerable quantity already, they are thoroughly adapted to the climatic conditions of Assam (being indeed probably indigenous to this part of India), and there is no obvious condition why their cultivation should not be capable of immense development. The Eri is the more promising of the two, both because it is cheaper and more abundant, and also because being reared entirely indoors its cultivation does not entail that troublesome necessity of watching by night and day which is imposed upon the Muga-breeder during the period that his worms are on the trees. The Muga, indeed, yields the finer silk, but as it is only in the roughest shape that Assam silk can hope to become an article of demand in the English market, the difference of quality will perhaps prove to be a matter of secondary importance. . . . The manufacture of silk plushes and similar fabrics out of waste cocoons imported from India and China is a flourishing branch of the silk industry in England, and although China has hitherto been the principal source of supply, there is no reason why Assam should not contribute large quantities of an article which is produced with so much ease in the valley of the Brahmaputra. The kind of thing that is wanted is described in the following words by one of the English gentlemen engaged in its manufacture:—"The class of silk called spun silk is made by a combing and carding process out of the refuse of the thrown silk and out of the cocoons that are damaged and not windable, and out of pierced cocoons, as we name those from which the moth in the order of nature has escaped. It is in this latter condition that I think wild silks should be found somewhere in India, and this is what I principally want. I do not wish to windsuch silk, but to spin it into fine thread. It is no matter how broken and rough it may look, or how much it is knocked about, torn, or crushed. I only want it as free as possible from the dead bodies of the worms, and of such foreign matter as sand or branches. It will not look like silk at all till the gum and dirt are boiled and washed out of it. You observe I ask nothing from India that requires skilled labour or machinery, only to collect the raw material in a state in which it must be almost valueless in India, and let us by our superior mechanical appliances make something of it here. Eri I like best for its whiteness. I believe it breeds frequently, but I do not believe any amount of cultivation could get thorough silk out of it, I mean, of course, to be of any commercial

value. Muga is darker than Eri, but has some other properties, and are valuable principally as spun silk. No Eri or Muga waste cocoons have, as far as I know, ever been sold in the London market. I only knew of trifling samples having been tried, too small to base any value upon. Tusser waste silk, however, is regularly sold in London. It comes both from India and China; the price is about 1s. 6d. per lb., and it is very dirty; I should say the Eri and Muga would be much more valuable. In a letter from another firm engaged in the same business I find the raw material described as pierced or spoilt cocoons—cocoons from which the moth has worked itself out and escaped, while cocoons with the chrysalis inside them are not wanted at all."—*South Australian Register*.

THE CHINESE SABAH LAND Co.

Report of Mr. Ernest Major, Chairman of the Chinese Sabah Land Farming Company, on the Sandakan Estate dated the 1st February, 1885. I have to report having arrived in Sandakan on the 12th ult. *Sabooqa Estate*.—I visited this estate on the 13th January. It consists of a felling of about 70 acres, of which about 25 a 30 acres are planted, principally with Liberian Coffee. There is also a little Cocoa, Laroot hemp, Bananas and Pepper. Liberian Coffee looks remarkably strong and healthy. Cocoa looks well when protected from wind. Hemp is planted too close, and looks weedy. Bananas look well. Pepper—This is very young, but looks very healthy. By calculations made on particulars given to me, I am of opinion that Hemp and Bananas will not pay in a foreign plantation, and the future value of this block of land will be its adaptability for Coffee and Pepper. It has also the advantage of being within walking distance (about ten miles) of Sandakan. The present opening will facilitate the future sale of the land. It will show the capabilities of the land; will form a healthy place of residence for planters beginning in the neighbourhood, as also a nursery from which to obtain plants and seeds. If the uncultivated land be divided in blocks of 50 to 100 acres, there seems a fair probability in my mind of being able to sell the blocks to Chinese planters in a year or two at \$5 a \$10 per acre; such sales would be also the more readily made if time, say one to two years, was given for payment conditional on planting being commenced at once. Clearing, etc., are finished for some 20 a 30 acres more, which will be planted over with Coffee, leaving a surplus of plants from the nurseries. In view of the cleared vacant ground to be left annually on the Suanlamber suitable for being planted over with trees, it would be unwise on the part of the Company to continue extending on the Sabooqa. A staff of 4 or 5 men will therefore only be kept on the estate, sufficient to plant out the 20 a 30 acres of clearing referred to, and to keep up what has been done.

Suanlamber Estate.—I resided with Mr. Gibson on the estate for three days. The buildings consist of three large drying sheds, the Manager's residence, an Assistant Manager's residence, a house for Malays, and various smaller buildings. The opening for last year's Tobacco, some 60 acres, is now overgrown with grass. Roads and new fellings have now been completed for 220 fields of about 1½ acres each, and fellings for 30 fields more are to be completed in about a fortnight more. There are on the estate some 260 Chinese labourers and 50 Labonan Malays; also 20 Sulus, temporarily. The programme to be now carried out is:—*Fields* to be allotted over to each man on 1st February, and barring and clearing to be made separately by each allottee. *Nurseries* to be sown out individually by each man on his own field, a little seed at a time each week from 1st March till planting finished. *Planting out* from middle of April till end of July, or, if season bad, to end of August. *Gathering* begins end of June. *Drying* takes about 20 days. *Fomenting* begins when sufficient dried plants are in hand; time required depends on quality. *Sorting* after fomenting begins about November. *Packing* begins end of December, finishes end of February.

1st Shipment: about end of January. *2nd Shipment*: about end of February. This programme, Mr. Gibson says, will be carried out in due course. The 50 labourers will finish the remaining 30 fields of fellings in about a fort-

night, and will then be put on to building drying sheds—some twenty in number. Mr. Gibson is sending by today's steamer for forty more Chinese coolies as a provision against sickness and death, so as to ensure the entire planting of the 280 fields. Everything therefore seems in order for the coming tobacco season. The abandoned fields of last year Mr. Gibson has promised to plant at an early date with coffee and cocoa trees, and he is at present sending to Singapore for sufficient seed to form a nursery with which to plant on the 250 fields of this year when the tobacco is gathered. This he considers he can accomplish with his present men. The Company will then, by this arrangement, have a very valuable plantation of coffee and cocoa—some 300 acres, if matters are carried out as arranged. The small patch of sugar-cane planted by the Company as a test of the power of the land for sugar cultivation, and which was done at considerable cost, was, I regret, but money wasted. We are as ignorant of the capabilities of the soil for this cultivation as before. The cane was uncareed for, and I can get no report whatever as to quality and yield per acre. It is now all finished.

The *Demondong*, as you are aware, has been abandoned. In *Sandakan* we have the office. There is also the private residence for the agent. This is a nice house, and can probably be let for \$30 a \$35 per month.

Failure of 1884 Tobacco Crop.—The estimate of the year's crop, as you will have already heard, is reduced to 65 piculs. The reason for this, as alleged by Mr. Gibson, is that he had hoped for a continuation of fine weather for a fortnight more, but the season suddenly broke up, and the growing crops, then very late, came to nothing.

Liberian Coffee.—I am of opinion that this will be one of the most paying articles of production (during the next five or six years). I went to see this plant growing on Chasaros Estate, Singapore. Trees 26 months planted only were loaded with berries. The estate has been just converted into a Company at a capital of \$250,000 on the strength of the great promise of L. Coffee. The estimate per acre of return is thus made:—

5 catties coffee per tree, which seemed reasonable by appearance, say 1 ton per acre (over 400 trees per acre), or pel. 16 @ \$10 per acre per annum ...	\$160
One man, including all work, can care for 2 acres, say	60
expense per acre	—

leaves \$100
per acre.

Liberian Coffee seems quite equal in taste to *Coffee Arabica*. You will then see that if we can plant this year 300 acres of *Coffee* on the *Suanlamber*, in 2½ years' time we shall stand fair to get an income of \$50,000 per annum. The matter thus becomes one of considerable importance. Tobacco being only a superficial plant will not interfere with *Coffee*. Mr. Gibson thinks as well of cocoa, but the plant is a very delicate one, and not so reliable to my mind as *Coffee*. I arranged at *Sandakan* as to sending seed at once to *Sandakan* of the best kind to put into the nurseries immediately. The seeds take 6 or 8 months to produce plants large enough for transplanting.—*N. C. Herald*.

SWEET MANIOC.

The attention of both Europeans and Fijians should be drawn to this new species of what is more popularly known in Fiji as the *tapioea* plant. The bitter or poisonous variety of manioc (*Manihot utillissima*) and which may be distinguished by its purple stems and leaves has been long ago introduced into Fiji; it is known by the natives as *yabia kau*, and is cultivated and used by them in the manufacture of two or more kinds of their *madriri*, or native bread. The new species, the sweet or non-poisonous cassava (*manihot aipi*) and which may be at once recognised by its green stems and leaves, is a native of tropical South America, and has only been introduced into Fiji within the last ten year (presumably having been first imported by Mr. Ephinstone).

This most valuable plant has now become well known in *Savusavu Bay*, where attention was first drawn to it by the late Mr. Towson, thence it has spread to other parts of *Vanna Levu*, and it has been carried by the Fijians, who have designated it the *yabia valu*, to the

Ra Coast, whence it is slowly spreading and has already reached *Ba*, and doubtless it will gradually take its place among the most valuable food plants that has yet been introduced into the colony. Like the species already well known in Fiji, the new species, or sweet cassava, is propagated from sets or cuttings of the woody portions of its stems, the vitality of which is so great that the cuttings can be carried long distances at sea, or may be left neglected on the ground for weeks, and when planted scarce one will miss or be found to have lost its vitality, and consequently after the first cost of introduction the sets may be taken to cost nothing but the labor involved in procuring them. Planting can take place from December to May inclusive. The plant will grow in any dry soil, and assuredly it will grow and give a return in soil so poor that in it nothing else will grow, but the largest returns are obtained when it is planted in loose dry sandy loam. It should be planted in rows 6 x 6 feet, and in richer soil 7 x 6 feet, and in very rich and suitable soil the plant will require 8 x 6 feet.

The labor required for its cultivation is comparatively small and of the simplest kind, clearing and weeding the soil followed by a burn off, lying the rows as for cotton, and planting with a *doko*, or Fijian digging stick, and precisely as a Fijian plants his sugar cane; using three sets or cuttings of 18 inches in length, inserting them each one foot in the soil at an angle of about 45° and in the form of a triangle, the sides of which are each one foot in length, this forms a hill, and when planted 6 x 6 feet, 1,225 of such hills will be found in one acre; and as a yield 10 lb. per hill may be calculated upon for a certainty, in even poor soil, after nine months, it will readily be perceived that five tons of tubers may be obtained from an acre of inferior soil, whilst from better and richer soils ten tons and even heavier crops may be obtained.

The tubers are edible from the 9th to the 12th month after planting, they continue to increase in size until the 18th month, but after the 12th month the tubers gradually become fibrous and fit only for the manufacture of its farina, from which is made the *tapioea* of commerce. Not only is the sweet cassava thus planted at no other cost but the labour, but its subsequent cultivation demands less labor than any other of the food crops, for, if the ground be kept weeded during the first three or four months, the shade of the plants will thereafter prevent any after growth of weeds. Whilst the cultivation of the yam is so precarious that few Europeans succeed in cultivating this crop to profit, and even amongst the natives two good yam seasons rarely follow consecutively, no such difficulty attends the cultivation of the sweet cassava, and its yield can be calculated upon with unflinching certainty; nor is the sweet cassava liable to that total destruction which occasionally a yam crop sustains from a hurricane. Hence for the districts of *Ra* and *Ba*; and the *Ysawa*, *Nadroga*, and *Lau* the introduction of the *yabia valu* will be an inestimable boon to the people.

The sugar companies and planters, employers of labour, will find the sweet cassava plant to furnish the solution of the food difficulty, more especially those companies situated in the dry climates of the group, such as *Ellington*, *Penang*, and *Rarawai* estates, and the different island properties of the *Mango Island Company*. To their managers the sweet cassava plant will provide a large supply of wholesome and nourishing food. And although this food is not to be found on the ration lists of the Ordinances, it is yet hardly to be entertained that an article which is known to be the staple food in *Brazil* and many other countries will be condemned in Fiji.

At nine months and until twelve months old the tubers of the sweet cassava very much resemble the yam, and perhaps more closely the *tikan* or wild yam, and like them can be either boiled, roasted or baked. Moreover, the sweet cassava is the only food that a Fijian admits to be upon a par with a yam, and he testifies his predilection by frequent petitions from his European neighbor's cassava field. When once the attention of the Europeans is fully drawn to the sweet cassava, its great value will then be soon conceded, and as they instruct their Polynesian laborers in the many methods of preparing the root for food, so the Fijian,

although somewhat deaf to instructions upon anything new, is yet prone to imitation and will soon pick up the method he sees the Polynesian adopting.

If a column of the "Na Mata" could be devoted to spread the information abroad in the group concerning the advantages of planting the *yobia vata*, a couple of years would find the whole native population in possession of one of the most valuable food plants in the world, and for which it is claimed that it is the food crop which can be cultivated at the minimum of cost for seed, at the minimum of labour required for its cultivation, and that it will produce the maximum of return and with the greatest certainty of any other food crop known in Fiji, and that is adaptable to both Polynesians and Fijians. It may be added that as the tubers when dug do not keep good for any length of time, the sweet cassava cannot be looked upon as likely to supplant the cultivation of the yam, but it may either be viewed as a great addition to the food crops of the natives, and likely to prove of the greatest value in those years when the yam crop is ruined by hurricanes or droughts, and when the cassava crop may still be relied upon. It should be added that goats and cattle and pigs will eat both the leaves and the tubers of the sweet cassava greedily. Outtings of the sweet cassava can be obtained from Mrs. Towson, of Savusavu Bay.—*Fiji Times*.

MANURES.

The following, for which we are indebted to our correspondent, Mr. De Mar, is a paper which was read at a meeting of the Massachusetts Horticultural Society, and will be of interest to many of our readers resident near the great fishing stations and fish markets of this country.

The Hon. James J. H. Gregory was introduced to the meeting, and read a paper on "Nitrogen." After an introduction, showing the very small quantity of mineral matter in plants—a cord of wood, that might require two yoke of oxen to draw it and would be of the bulk of 100 bushels, yielding but a bushels of ashes, which the driver might carry on his shoulder—and the sources of this matter, he passed to the consideration of nitrogen, which makes up about four-fifths of the air mass that surrounds the earth for a depth of about 50 miles, the other fifth being oxygen. This gives unnumbered thousands of tons of nitrogen, right at hand, but never available, for human knowledge has not yet discovered a way by which nitrogen can be economically got from it for plant food. We have to depend for our supply wholly on what plants and animals have incorporated into their structure, using their waste in the form of manure, dead remains, either from land or sea, for our supply. The ammoniated liquor from the gasworks is but the waste produced from the remains of ancient forests which we burn as coal.

When nitrogen is combined with hydrogen in the proportion of three parts of hydrogen to fourteen parts of nitrogen, we have ammonia, one of the most common forms, in which forms the waste of both animals and plants, nitrogen is fed to our crops.

The other most important source of nitrogen is nitric acid. This is a combination of nitrogen with oxygen; and nitrates, of which we see frequent mention in all works on manures, are a combination of nitric acid with soda, potash, and other materials called bases. It is well to fix in the mind that, in changing nitrogen to ammonia in any manure analysis, we must add about one-fifth to the quantity given. It appears to be the settled conviction among men of science, as the result of many experiments, that plants cannot take up pure nitrogen directly from the air. The theory is that they are able, in a greater or less degree, to get their supply through the water that carries it in some form in solution into the soil, and also from the air indirectly by the soil first separating it from the air that permeates it. Still another source of natural supply for plant growth is nitrogen in a latent condition, that has accumulated in the soil, set free by the action of such substances as lime and plaster. There is a general belief among agriculturists that plants have ways of collecting still but little known, while some extremists have gone

so far as to declare that there is no necessity of feeding nitrogen to our crops, for they can of themselves collect from natural sources all they require. There is a growing belief that their power to supply their wants from natural sources is greater than has hitherto been credited to them. It is found also that different kinds of plants have different capacities for taking up nitrogen. Clover is an example, for though nitrogen enters largely into its composition, it has such a capacity to help itself to the good things which surround it, that it needs but very little artificial help from the manure pile, while wheat, though it needs but little nitrogen, is so dainty a feeder that it insists on a large artificial supply from which it may pick out that little.

In regard to the sources from which the practical gardener can obtain nitrogen, Mr. Gregory first considered hen manure which has by some been compared in value to guano, but he regarded this as overestimated. He laid down a grand principle, that no more nitrogen, phosphoric acid, or potash can be obtained from the manure of any animal than is contained in its food. An ordinary hen will eat about 2 bushels of maize a year, and the larger breeds about one-half more. From this they must take the material for about 125 eggs annually, a change of feathers, keep up the animal heat, and make up the growth of the body, besides performing the various functions on which life depends. Now, subtracting what is required for these purposes, the waste element in our 2 bushels of maize shrinks to very small proportions. We must also take into account the fact that the dropping which we save are confined almost wholly to those made during half of the twenty-four hours. By analysis 2 bushels of maize contain, in nitrogen, potash and phosphates, 46 cents in value. From this standpoint it will be seen that the droppings of a hen for a year cannot contain nearly the value sometimes claimed for them. For many years the essayist collected hen manure at a cost of 1 dol. per barrel, but afterwards reduced the price to 75 cents, and thought it at the latter price a cheap manure until he tested it side by side with an equal value of guano. Moreover, it is a sticky mass difficult to handle, and it is worth any one's while to experiment, if it were only to realise the advantage in the handling of any commercial fertiliser over hen manure even in its finest state. It is generally composted with muck or dryish soil—three parts of muck to one of manure—and the compost should be made as fine as possible. A rake is the best tool to do this with if it is sticky, and it should be turned over in three or four days, and a six-tined fork is a good implement for this purpose.

Sulphate of ammonia, a by-product where coal is used for the manufacture of gas, is one of the principal sources of nitrogen. It looks like rather coarse salt, and is often sold in huge casks weighing 1000 lb. or 1500 lb. It is readily soluble in water, but does not waste in the air. Nitrate of potash (saltpetre) is usually too costly a source of nitrogen to make it available. Nitrate of soda is a remarkably stimulating fertiliser, but if there is much rain it will waste before plants can take it up. In dry seasons, however, it is better and cheaper than sulphate of ammonia, as the latter needs a degree of moisture to make plant food; yet, on the whole, the latter is considered the better investment, for, first, it is not likely to be lost in the atmosphere; second, it is not too soluble; and third, it has the power of clinging to the ingredients of the soil. Clay will hold it persistently, and even pure sand, when washed with water, will retain a large portion of it. Its ammonia is easily changed into nitric acid by ingredients in the soil. Nitrate of soda is very liable to be adulterated with white sand or broken quartz, and with common salt or the cheap potash salts. The purchaser should see that it dissolves entirely in water and does not taste distinctly of salt. Castor oil pomace affords a supply of nitrogen, but it must be kept from animals, as it is poisonous, and in spreading it care must be taken to go with the wind, as it is very disagreeable to the eyes or mouth. Cotton seed meal is better fed to stock, and the manure used, which will be nearly as rich as the meal before feeding. Occasionally spoiled meal can be found in the market, and this as good for manure as the best, and is a very cheap source of nitrogen and phosphoric acid. Wood and horn

havings and leather are very rich in nitrogen, but they are not readily available, and therefore they have a low value as market articles. The last is excellent for mulching, and in time will decay and fertilise the ground, but if worked into tillage land it becomes a nuisance.

The waste of the fisheries is one of the principal source from which manufacturers obtain the ammonia in their fertilisers. The largest portion is from the fish called menhaden, hardheads, moss bunkers or fat backs. They are caught in immense quantities in nets, and boiled to secure the oil, in which they are rich. After pressing, the pomace or chum is packed in barrels or dried ground. When a surplus of fish is caught they are sold to farmers, who put them directly on the grass land where the effect is very stimulating for a few years, but the final result is that the soil becomes hard and the fish have less and less effect, and finally the crop is almost nothing. The fish are deficient in potash, and the result is what always comes from continuous manuring with any substance that deficient in any one of the three essentials of plant food. The land can be restored by using potash. Other fish wastes are found in the form of spoiled fish, and the heads, sound bones, and entrails of fish which accumulate at fishing ports. So immense was the waste of heads, bones, &c., of fish at Isles of shoals that the harbour had to be cleared twice by dredging them out. The essayist left a standing offer with a fisherman, a few years ago, of 25 cents per 100 lb. for his surplus pollock; the result was that 20,000 lb. of fine large fish, weighing from 8 lb. to 15 lb. each, just out of the water, was hauled to his manure heaps. All these substances are, however, very disagreeable and difficult to handle, requiring a vast quantity of soil to compost them. Where bay fishing is carried on on a large scale, liver or blubber chum can sometimes be found, and furnishes a very cheap source of nitrogen. It should be cut with sharp sand before composting, to make it fairly fine. Halibut chum is the refuse from the heads of halibut, which are cooked under high pressure to extract the oil, and the bones are left in such a state that they can easily be crumbled. It is especially rich in phosphoric acid. The skin, bones, and fins of salted fish, stripped and sold free of bone, are another form of fish waste, and the waste of herring mackerel at the fishing stations is sometimes made up into chum. Dogfish, a small species of shark, are caught in immense quantities, and are very rich as manure, their muscles being very firm. The shells and other refuse of lobsters at canning factories are ground up and sold as plant food, and are especially rich in nitrogen.

All fish waste must be composted with a large quantity of soil, or the crops will be burned; and the compost, owing to its great richness, should be spread broadcast rather than used in the hill. Fish chum may be used broadcast or composted with poor manure to enrich it, or with soil, muck, or sawdust. It is surprising how penetrating is the ammonia from fish compost, and, therefore, in making a heap, the bottom layer of soil should be a foot or more in thickness. Cases have been seen when the fish was mixed liberally where the soil was full of ammonia for several feet below the surface. The layer of fish should be thick enough to just hide the soil, and the next layer of soil about 3 inches, and so on, scattering raw ground plaster over each layer of fish before covering with soil, at the rate of 50 lb. of plaster to 300 lb. of fish. The heap should be on level ground, with a little embankment around to catch the liquid that sometimes runs from it when the fish begin to decompose, or may be washed out by heavy rains, and it will be handy to fill up the holes that are apt to show on top as decomposition progresses, letting out bad odours unless closed. Fish containing much oil are better composted with stable manure, and plaster should be scattered as before directed. If decomposition is slow to start, unleached ashes or lime may be mixed with the mass; but be sure to cover the heap with several inches of soil.—*Gardeners' Chronicle.*

★ CATARRH OF THE BLADDER.

Stinging irritation, inflammation, all Kindey and similar Complaints, cured by "Euchu-paiba." W. E. Smith & Co., Madras, Sole Agents,

EUCALYPTUS CULTURE.

The following communication, forwarded to Mr. A. H. Smece by a correspondent in Chili, will be found of value, especially to our numerous Indian and colonial readers:—

It is not necessary to enter with great minuteness into those matters on which all are agreed, but rather to accentuate the points regarding which my personal experience partially diverges from, or is found in open conflict with, the current instructions supplied by accepted authorities. These points are:—

1. The preparation of the seed-bed.
2. The advisability of rooting the seedlings in pots previously to planting them out definitely.
3. The use of stakes for propping the recently planted trees.

4. The space to be allotted to each tree.

5. The suitability of marsh land for large plantations.

1. THE SEED-BED.—The plants are raised from a small and exceedingly hard black seed, which should be thoroughly soaked before being sown. As the seed germinates with great difficulty, and seems unable to overcome the resistance of a soil even slightly compact or tenacious, it is usually recommended to form the bed of coarse sand or other very light earth; this plan is, however, attended with the disadvantages consequent on the general porousness of such soils, and the still greater one of the difficulty of removing the seedlings from the bed without detaching the sand adherent to their roots, which is fatal to their life if immediately transported to the plantation, and causes loss even if potted at the edge of the bed. After experiencing these evils, I ultimately prepared seed-beds some six months before sowing, composed of some garden earth and a large proportion of leaves (those of the Fig and of the Eucalyptus itself are very good) and of sheep's dung, which I had continually watered and dug over until completely incorporated and rotted. The decayed leaves impart to the composition a peculiar mellowness, and, while the bed is kept damp, that softness so necessary to the successful germination of this delicate seed, as well as a fertility far superior to that of the sand usually recommended; while by leaving the bed completely dry and exposed to the sun for a few days previously to transplanting the seedlings the dung causes it to become hard and tenacious, so that each separate plant may be cut out with a knife, remain firmly embedded in its surrounded earth, and, being as easily transported on trays or in carts as little bricks, thus rendering unnecessary the use of the often costly and always pernicious pot. All depends in this plan on the proper proportions of the ingredients. Should the leaves be deficient or clay be present in the earth, the surface of the bed will be sticky and the seed will not come up; while, should there not be during enough (it must be sheep's) the bed when dry will not be sufficiently compact to cling to the roots of the little trees when removed for transplantation. Above all, both leaves and dung must be thoroughly rotten, or larvae may appear from the latter, and all operations may have to be postponed for a year by the complete ruin of the young plants.

I quite agree with the received opinions that the seed should be sown very light, and rather thin, that the bed should be kept damp by frequent though not too copious waterings, that the young plants should be continually guarding against the small birds which pursue with passion the young plants in their early stage, that they should be protected by mats from the chance of a frosty night and from excessive sunshine. As they may all be lost by the slightest accident, a fresh lot of seed should be sown every fourteen days during the season (which lasts, I should imagine, everywhere more or less from midwinter till the end of spring), which plan also ensures a succession of suitable plants, as the work of plantation on a large scale progresses.

2. SEED PANS.—Should the sand-bed plan be adopted pots are necessary as a means of transportation to the plantation of the young plants, since the attempt to carry them loose would entail the detachment of their adherent soil and their consequent certain loss. They should, however, be left only a few days in the pots under the penalty of incurring a misfortune gravely compromising to the whole future of the plantation. The

roots rapidly developing, fill up the entire pot with a contorted and interlaced mass, and the taproot, twisting round like a corkscrew, often assumes an upward direction, with usually causes lingering the death, roots being unable to disentangle themselves and assume their natural direction and relative position; the surviving plants obtain merely a rachitical existence, and very rarely become healthy, and never really fine trees. In large operations any unforeseen delay in carrying on the planting with sufficient rapidity may compel the use of "pot-bound" plants, with all the explained disadvantages, and I therefore declare myself hostile to the pots, and in favour of the direct removal of the seedlings to their plantation; from a series of beds prepared as related in the first section, so as to secure by their softness the certain germination of the seed, while assuming, when thoroughly dried, the tenacity of sun-dried brick, thus facilitating the removal of the seedlings without disturbance of their roots. In cutting out the seedlings from the beds, the severance of many ends of roots is unavoidable, but occasions no injury whatever, since their general relative disposition and direction (especially important in the tap-root) are preserved, and they have to undergo no struggle to rectify distortions such as they suffer in the pots. Many large plants have failed completely, from the plants having been pot-bound, and the failure is attributed to every cause but the true one. I know, for instance, of a municipality having expended a large sum on the formation of miles of avenues of Eucalyptus, all of which have turned out small, unhealthy, and distorted trees, and which will never be any better. The people themselves blame the trees, and denounce them as unsuitable to the climate and ugly in themselves; but an expert can see evidently that the cause lies in their having been grown in sand and pots, according to the instructions of the local sages.

3. STAKING THE TREES.—It is generally recommended that seedlings should on transplantation be tied to a stake, to prevent their being overthrown by the wind. I think this practice generally mischievous.

The Gum tree, when healthy—i.e., in favourable soil, and starting with sound and contorted roots—is quite as able to resist wind as any other tree, in spite of its slender superficial roots, since, armed with the whiles of Nature, they immediately build up a mass of filamentous roots, extending like a net in every direction, and throw out numerous boughs, heavily loaded with foliage of graduated length, from the ground upwards; thus presenting the aspect of a broad-based cone with its centre of gravity in the lower third of its height, so that when agitated by wind they not only hold on by their reticulated surface-roots but are also sustained by the actual contact of their lower boughs with the soil. Relieved by the props of the necessity of those precautions, they develop fewer roots and lower boughs, and running too soon to height, and shifting upwards their centre of weight, become top-heavy, and can only be saved by substituting longer and longer props, from friction with which they often sustain damage, and rarely turn out quite satisfactory, in spite of the trouble they cause. At the same time it is doubtless necessary to continually examine the young trees, and to prop those partially uprooted, or which, having failed to protect themselves by proper boughs and foliage, have a spindly growth. I may mention that in plantations the trees greatly protect one another by intercepting the wind.

4. DISTANCE AT WHICH THE TREES SHOULD BE PLANTED.—Influenced by the analogy of European plantations many persons have wasted large sums in planting these trees in thick clumps, thinking that as their growth progresses they may be thinned out advantageously, and that those spared will attain the same development as if originally planted at suitable distances, only suffering the usual retardation. Convinced of the necessity of testing this before undertaking an industrial plantation, I planted half an acre favourably situated at distances of 2 metres apart (that often recommended), and a part even closer together, with the bad result which immediately became apparent. Unable to obtain sufficient air and sun, they entered into a frantic struggle to overtop one another; those which were distanced in the race were completely deprived of leaves and eventually died, the remainder could only maintain a scanty foliage at the top, and when already 60 feet

high (their growth was rapid enough in height) were not more than 8 inches in diameter, and their wood was nearly worthless. By thinning they were not restored to prosperity; as they had formed no matted surface roots they were most of them blown down, and those which escaped this fate showed no sign, when I last saw them, of any serious increase of girth.

The planter should never lose sight of the main peculiarity of the Blue Gum, viz., that its whole future is irrevocably fixed in early youth, i.e., before it exchanges (at from two to three years old) its abundant boughs, loaded with luxuriant dark blue foliage, for the sparse ramifications, and dark, narrow, and almost shadeless leaf, of its second stage of vegetation. Should its early roots have been unhealthy; if on transplantation it has failed to develop a large crop of inferior boughs and of healthy leaves; if these inferior boughs have been stripped of foliage,* or have been only clothed at their extremities with leaves; or should the leaves, instead of presenting their healthy tint of glossy dark blue, become clouded with greyish bloom, be red or yellowish, a perfect development will rarely be realized, and I should recommend removal and replacement as a saving of time. I may remark in this connection that a premature change of leaf is a sure indication of ill-health.

I ultimately made the large plantation at the distance of 5 metres, or with 25 square metres to each tree, but on their arriving at four years old, I was convinced that even this distance was not sufficient; as, however, they would not have incommoded one another till long after the change of leaf they might perhaps have been thinned at about ten years old without damage, i.e., obtaining useful timber from those alternately cut down before any appreciable injury would have been incurred by those remaining. I think, however, that the best plan is to plant them at 7 metres apart (if not a little more), utilising the enclosures after a few years where possible for pasturage, since the matured Gum at this distance with its comparatively scanty crown and obliquely set foliage would not prevent the growth of coarse herbage, if soil and moisture were suitable.

The whole beauty and much of the success of the plantation depends on the exact collocation of each tree in its place, so as to form to the eye avenues in every direction; the ground should, therefore, be previously laid out with a theodolite, or it may even be done by a skillful and careful operator with a large compass by the well-known methods employed in such cases. When the inestimable advantage of artificial irrigation exists, the gutters should be equidistant and parallel, and the trees placed in them, or at their edge. I must not forget to mention that the young trees at the moment of planting must be watered, as they are always quite dry when planted, whether from pots, or according to my plan, in little bricks, in order to avoid detachment of the soil from their roots; when there is no irrigation, and rain should be inconveniently delayed, they would doubtless again shortly require to be watered by hand, which is a costly and troublesome proceeding on a large scale. When once rooted they can exist an almost indefinite time without rain, though they will not thrive until they get access to subsoil moisture.

5. PLANTING IN MARSH LAND.—The strangest peculiarity of the Gum is its combination of the greatest avidity for water, which it contains in the form of sap, and throws off from its leaves in almost incredible quantities, with the capacity of surviving prolonged drought, and of thriving fairly in very dry places when once developed to a certain point by a sufficient supply of moisture. It is, however, my opinion that the customary statement, that the Gum tree will grow in rank marshes, i.e., in land completely saturated to the surface with stagnant water, is very extravagant; and I may boldly state that this tree will not grow in waterlogged soil, although it feels much less aversion to running than to stagnant water; enduring, for instance, for a long time complete immersion of its roots in the flood water of a river, while dying rapidly under the influence of the casual elevation of the level

* I need only mention the madness of those persons who recommend the removal of the lower branches to strengthen the growth.

of stagnant subsoil water. It will, however, thrive admirably in the ordinary marshy ground, where it enjoys a space of free soil of from 2 to 4 feet deep before reaching the level of the subsoil water, the amount of free soil required apparently depending chiefly on the aeration of the water; if this should be absolutely motionless and charged with salt the Gums are much less tolerant of its proximity than when pure and moved by a slight drainage current.

I think the truth to be that this tree will not endure that its surface roots should be permanently immersed in stagnant water, whatever statements may have been made to the contrary, but that it thrives admirably, although its tap-root (which is virtually a continuation downwards of the trunk) should descend vertically into the same; in other words, it can and will imbibe enormous quantities of water voluntarily, but dies if the water be administered by force. I feel no doubt that marshes fulfilling this condition of the existence of a certain depth of unsaturated superficial soil may be completely drained and sanitated by extensive plantations, provided the subsoil-water should arise from the imperfect removal by drainage filtration of the merely local accumulation of rainfall; but I utterly refuse to believe that huge spongy plains completely saturated, not only with their own rainfall, but, further absorbing whole rivers discharged from neighbouring hills, can be restored to human habitation and commerce by any such insufficient device. It requires no argument to show that while each tree can pump and discharge into the atmosphere a quantity of water far exceeding the rainfall of the space it occupies, the trees cannot deal with an unlimited quantity of extraneous moisture, and the less so that only the more elevated spots in such plains are at all suitable for their cultivation.

I find I have omitted to mention in its place an interesting experience illustrating the bad effect of superficial stagnant water on Gum trees. I had a flourishing row of large trees growing on the very edge of a permanently flowing irrigation ditch; there occurring a scarcity of water, the ditch was left dry for six days out of seven, and when dry there remained a pool behind a sluice at the foot of one of the trees, which suddenly died. On repeating the experiments with another tree it also died.

SEASONING.—The recently felled timber is so charged with sap that in drying it becomes much warped and cracked, and there is no doubt that seasoning it is most difficult and troublesome. I am assured that the Australians immediately strip the trunks, and then keep them for a long time in water—sea-water by preference. On a large scale this difficulty, as well as that of preparing the wood for market, could be easily dealt with by making the requisite pools and constructing saw-mills.

When we consider that the Blue Gum averages a growth of 10 feet a year, that it possesses a bark admirable for tanning purposes, that the east bark serves for firewood, and that its timber endures a crushing or longitudinal strain greater than Oak, and is unsurpassed by any for ship-building and for timbering mines, and is capable of developing heat fierce enough to smelt sulphurets of copper in a reverberatory furnace, and that this wood can be grown in soils often useless for many other purpose, we can find no difficulty in believing that a large business might be made by industrial plantations in selected localities, of which there must exist many in all the subtropical countries, either in dry sandy plains accessible to irrigation, or on the wet marshlands above described. I need not, however, insist on the necessity of careful study and experiment before embarking definitively in such a venture, both as regards the chance of the tree itself thriving, as well as of the economical conditions relating to expense and final disposal of the timber. My own experience is limited to Chit, in the north of which country I made the plantations alluded to, but they may perhaps be of some use to your friends.—*Gardeners' Chronicle*.

TREE FUNGUS IN RUSSIA.—According to the *Bulletin* of the Society of Naturalists of Moscow, the hitherto unaccountable destruction of Pine forests is caused by the ravages of a species of Mushroom which takes growth on the surface of the wood, and afterwards penetrates and destroys the tree. Maps are given in which the path of the destroying fungus is traced through the Pine woods of Russia.—*Gardeners' Chronicle*.

CINCHONA, TEA AND COFFEE CULTIVATION IN INDIA.

(From Official Reports published in 1885.)

CINCHONA CULTIVATION.

In the Government plantation in Sikkim there was an area of 2,269 acres under cultivation, containing nearly 4½ millions of trees, and there was in addition a stock of over half a million of seedlings and rooted cuttings in the nurseries available to be planted out. The output of bark collected during the year amounted to 306,160 lb this quantity being much below the average output of the four previous years. With the stock in hand at the commencement of the year there were 469,963 lb of bark available for manufacture during the year, of which 320,320 lb were issued to the Quinologist for manufacture, the rest being stored. Of the febrifuge, 8,464 lb were produced at a cost of £10-4-7 per lb, and 250 lb of the superior crystalline febrifuge at a cost of £15-6-11 per lb.

Of the trees in the plantation, much the largest proportion (3,532,000) still consists of *Cinchona Succirubra*; but these are gradually giving place to the more valuable *C. calisaya leleperiana*, of which there are now 554,218 trees permanently planted out. The hybrid cinchona numbers 354,378 trees. The other descriptions exist in small numbers only.

The Nilgiri Government plantations contained an area of 847 acres planted out with cinchona trees, the number of these at the end of 1883-84 amounting to 1,315,444. The bark collected during the year amounted to 183,765 lb of which 30,510 were shipped to England for sale and 62,616 lb sold at auction in Madras, while 1,000 lb were issued to the Bombay Medical Department, a stock of 62,526 lb being left at the end of the year.

In these plantations the principal kind cultivated is *C. officinalis* (964,000 trees out of a total of 1,315,444).

There is one other Government plantation at Thandonyuee in British Burma—a small one containing under 90,000 trees, seedlings, and cuttings.

In regard to private cinchona plantations the information accessible is defective. What is known of them is that at the end of 1884 there were in—

	Ares.	Plants.	Yield of bark.
Bengal ...	680	1,116,778	4,806 lb
Mysore ...	23	22,940	3,472
Coorg ...	1,868	1,494,385	(Not known.)

The small yield of bark in the Bengal plantation is accounted for by the fact that the plants to a large extent are quite young.

TEA CULTIVATION.

In giving the figures relating to tea cultivation in India for 1883, it will be interesting to compare them with those for 1875-76, the first year of the series entered in this volume:—

	1875-76.		1883.	
	Ares.	Yield in lb	Ares	Yield in lb
Assam and Cachar ...	87,307	20,028,800	180,453	52,171,207
Bengal ...	26,378	4,941,226	40,753	10,703,139
North-Western Provinces ...	4,363	631,182	7,819	1,202,147
Punjab ...	4,246	679,949	7,061	1,300,010
Madras ...	2,392	220,070	5,423	529,190
British Burma ...	150	25,000	159	706
Total ...	124,836	26,526,317	260,571	65,903,009

Thus within these nine years the acreage under tea increased by 109 per cent nearly and the whole output increased by 149 per cent nearly.

In the Province of Assam the principal planting districts are:—

Cachar ...	40,901 acres.
Sibsagar ...	40,532 "
Lakhimpur ...	36,873 "
Sylhet ...	28,085 "
Darrang ...	16,601 "
Nowgong ...	10,786 "
Kamrup ...	6,220 "

In Bengal about three-fourths of the cultivation are found in the Darjeeling district, which had 33,817 acres under tea in 1883; Jalpaiguri had 9,220 acres; Chittagong 2,909; Lohardugga 2,752, and Hazaribagh 1,023 acres.

In the North-Western Provinces there were 4,775 acres in the Din, the rest being in Kumaon and Garhwal (3,043 acres).

In the Punjab no tea is grown except in Kangra (7,964 acres). There was a small plantation at Kotgarh in the Simla district, but no information has been received concerning it, and it is understood that it is not now working.

In Madras there were 4,772 acres on the Nilgiris and 580 acres in Travancore. Elsewhere in that Presidency the industry is unimportant.

In Burma there is very little tea planting. There is one plantation of 150 acres at Akyab and another of 9 acres in Touhoo.

COFFEE CULTIVATION.

The figures are so defective that it is not possible to make any useful comparison with former years. In 1883 the whole area under mature plants was 185,839 acres and the entire yield 30½ million pounds, a greatly diminished yield even as compared with the imperfect returns of previous years. The causes which have injuriously affected the coffee industry in recent years are well known, and as the subject has been fully discussed in the reviews of the sea-borne trade of the country it is not necessary to return to it here. The acreage under mature coffee plant was thus distributed in 1883:—

Mysore	82,108	acres.
Madras	53,917	"
Coorg	41,600	"
Travancore	6,268	"
Cochin	1,938	"
Bengal	8	"

MANGOES.—There has been a large crop of these fruits, which means that the poorer people will make an extraordinary day. But, however large, fine and sweet the mangoes be in Jaffna, they have, unlike the mangoes of the Western Province, somewhat of an acid taste. This is true in Jaffna of most of our fruits. The jak in size will beat out any in the Sinhalese country, but those nice bags of honey, when the fruit is ripe, combining all the delicacies of the honeycomb and the essence of the sugarcane, you do not taste in Jaffna. Our soil perhaps contain too much of saline matter; and our fruit-trees, instead of being left to grow as well as they can, require a lot of cattle-manure. But this is just what is not done. The fact is, the working people do not care for the exquisite delicacy of garden cultivations, but only seek something to satisfy hunger if only the article be not absolutely nauseating.—“Ceylon Patriot.”

USEFUL PLANTS IN THE ISLAND OF ST. THOMAS.—In a recently issued report on the Island of St. Thomas, Danish West Indies, it is stated that attention has recently been drawn to the possibility of utilising the soil of the island and making it productive. An attempt was made some two years since to revive the cultivation of the Sugar-cane, but it has resulted in heavy losses, and now that the price of sugar is so ruinously low, this branch of industry will probably be entirely abandoned. The cultivation of Aloes (Agaves) and other fibre-producing plants is now being tried. The climate and soil seem well adapted to such plants, the hills are thickly strewn with them, and if the leaves were collected, many hundred tons of fibre could be annually exported without an acre of land being planted. Actual trial, it is said, has, however, demonstrated that 6s. a ton for the crude leaves is the highest price that can be paid, but as this price does not appear to offer any inducement to the peasants to collect the wild leaves which are so numerous, they remain untouched. It remains to be seen whether cultivation will reduce the cost of collection by localising plants, and thus rendering the gathering of the useful portions easy, rapid, and economical.—*Gardeners' Chronicle*.

COLORLESS CEMENT.—The following recipe is said to produce a perfectly colorless cement:—“In an airtight bottle 75 grama of indiarubber cut into little pieces, are mixed with 60 grama chloroform. After complete solution of india rubber, 15 grama of mastic are added, and the mixture warmed for eight days till the latter is dissolved also.—*Queensland Planter and Farmer*.”

SEEDS AS WEIGHTS.—In many provinces of India the seeds of *Abrus precatorius* are used as weights, the unit of weight or seed being called the “retti,” the latter term applying especially to the weight. The weight, as appears from an article by Mr. Chubb in the *Pharmaceutical Journal*, varies from 1.92 grains to 1.979 grains. *Mucuna capitata* is the seed which is the origin of the “massa” = 8 “retti.”—*Gardeners' Chronicle*.

CEYLON TEA IN LIVERPOOL.—A correspondent writes:—“It is only just getting to be known here. As yet not much comes into the northern markets, but it is likely that in due course it will force its way. The brands ‘Blackstone,’ ‘Rookwood,’ and others have come to this market. What we want is leaf of the full drinking kind; you know in the colder northern climes they say we like a good, strong cup of tea.”—*Ceylon Advertiser*.”

LIQUID MANURE.—Probably nothing conduces more to the success of the majority of vegetables than being liberally supplied with liquid manure. It is far more stimulating and quicker in its effect than heavy dressings of dry manure. The reason for this is obvious, as it is supplied in such a way that the plants are able to absorb it at once. It may be made from fresh droppings of the cow, horse, sheep, goat—in fact nearly any animal. All that is required is to allow the water to remain on it for four or six days, so that, when it is used, it may be perfectly clear. Its strength, of course, must be regulated according to the requirements of the crops for which it is intended.—*Queensland Planter and Farmer*.

THE ENSILAGE COMMISSION.—An inquiry was commenced last week at the Agricultural Department of the Privy Council which promises to have an important bearing on the future of agriculture in this country. Lord Walsingham presided over a commission of agriculturists, who will take evidence as to the best means of preserving green crops by the ensilage process for the use of stock in the winter. It is beyond a doubt that the British farmer's best chance of competing with the foreigner is in the rearing of cattle, and some of the witnesses who have been examined state that they can keep more than double the stock by using ensilage, which has other advantages, such as making sure of securing a crop by harvesting it in all weathers and enabling an extra crop to be had. Some witnesses spoke of substances that were regarded as waste products of the land being greedily devoured by animals, Mr. Harris, M. P., mentioning that the rushes grown in the Devonshire valleys, and used for bedding, were actually eaten after acting as a covering for the ensilage and getting its flavour. The silos for preserving the green crops spoken to by the witnesses ranged from structures specially made to digging a hole in the ground and merely stacking it, sufficiently weighted to extract and exclude the air. Lord Walsingham's agent (Mr. Woods) spoke to ensilage being a valuable auxiliary to dairymen, as it could be sent by rail in casks, and it had actually become an article of commerce, and was sold at Maldon, in Essex, for 50s. a ton. The general scope of the evidence so far as it has gone, is that the process only requires to be known to be generally adopted. Mr. Moffat, agent of the United States Department of Agriculture, referred to the reports to the American Government in the matter, and to a tour in France with Mr. Kains-Jackson, the promoter of the ensilage competition at the Smithfield Club. The Commissioners will recommence their sittings tomorrow, and evidence will be taken at intervals during the Parliamentary session.—*London Times*.

Correspondence.

To the Editor of the "Ceylon Observer."

MR. JOHN HUGHES ON BATS' DUNG, &c.

London, E.C., 8th May 1885.

DEAR SIR,—I send you an article on *Bats' Dung Guano* from this week's *Mark Lane Express*, which gives some new interesting information about a natural deposit likely to be most valuable as manure. You will notice that reference is made to some analyses by myself, but the details are not given; so I enclose the full results of one sample, as your readers may know of similar deposits in the caves of Ceylon.

At present most of this bats' guano has been found in Texas, but I have had samples sent to me from Jamaica, and doubtless wherever there are large caves in a country with a hot climate, we may expect to find these valuable accumulations of bats' dung.

I have received your interesting book on "Ceylon in 1884." It should be in the libraries of all the Indian passenger steamers, for Ceylon is now becoming of general interest to travellers from its central situation, beautiful scenery and varied productions.

JOHN HUGHES, F.C.S.

[The Sinhalese are aware of the value of bats' dung and use it to fertilize their paddy-fields. If obtainable in quantity and cheaply, it would be valuable as an application to fields of tea. The long article sent by Mr. Hughes from the *Express* is given in full below.—ED.]

BATS' GUANO.

That the excrement from such small animals as bats should accumulate in sufficient quantity to be workable as a source of agricultural fertilisers may no doubt be a surprising fact to those who learn it for the first time. The well-known deposits of guano in Peru, formed chiefly by marine birds, have long constituted a material source of wealth, and the substance called, but hardly correctly, "fish guano" is also a familiar article of commerce. But bats' guano is a comparatively new candidate in the now extensive field of artificial fertilisers, and a few words as to its composition and mode of occurrence may be of interest. Although a perfectly natural product, it, of course, comes under the head of "artificial" fertilisers, inasmuch as it is purchased and brought on to the farm, instead of being produced on the homestead in the ordinary routine of farm practice as is the case with farmyard manure.

The bat, as everybody knows, is a little mouselike animal, provided with a lateral extension of its integument by means of which it propels itself bird-fashion through the air. It is a true mammal—that is, it brings forth its young alive and suckles its offspring, differing in these respects from birds. Its nearest allies are to

be seen, not in rats and mice, which are true rodents furnished with well-developed incisor teeth, but in the moles and hedgehogs, which feed chiefly on insects and grubs, and are therefore called insectivores. However similar a bat may appear to be to a mouse, an examination of its teeth—always a safe zoological test—will at once reveal its affinities to such insectivorous animals as the mole and the hedgehog. The bats that may be seen flitting about in the twilight in country districts are roaming the air in search of insects for food, and any one who has handled a live bat has probably not been long in discovering that the fur of these little creatures is abundantly infested with objectionable insects. Some exotic species of bats are fruit-eaters, and others, like the vampires of South America, are bloodsuckers, frequently inflicting cruel wounds on the hides of horses, cattle, and other animals in their quest for nutriment.

In this country bats dwell under the eaves of barns and other outhouses, or in some similar dark or poorly-lighted nook, their nocturnal habits, no doubt, impelling them to seek such spots where they may slumber securely during daylight. In a country not much opened up, underground caves would naturally offer to bats such accommodation as they seem to require, and it is from such bat-haunted caves in the State of Texas that bats' guano is now beginning to find its way in to the English market. Texas is one of the most south-western of the United States, its southern boundary being washed by the warm waters of the Gulf of Mexico. Here, in the counties of Uvalde and Comal, are two immense caves known as the Uvalde cave and the Cibolo cave. Underground caves of this kind are not uncommon in the States one of the most celebrated being the mammoth cave of Kentucky, which extends for more than two hundred miles underground. Such caves have usually been formed by the dissolving away of the rock by subterranean water-courses, which have eventually disappeared, leaving a record of their work in a tunnel-like excavation beneath the earth's surface. The river Miami in Derbyshire pursues its course for some distance underground, and if from some geological change this river were to dry up, and underground cave would be seen to be scooped out. The Uvalde and Cibolo caves, however, are remarkable for the rich deposits of bats' guano they contain, which have been accumulated by myriads of bats over an unknown period. Their depth has been tested by boring, and in some cases has been found to be as much as 25 feet, while the average depth is believed to be not less than six feet. In the Uvalde cave the deposits are estimated to cover an area of at least one square mile. Mr. Moreton Frewen, who has visited these caves, states the daily deposits from the myriads of bats which still haunt them must at least run into tons.

The official report of the Commissioner of Statistics of the State of Texas says, with reference to these deposits:—"In the mountains there are several large caves, in which are enormous quantities of the richest guano, the droppings through untold years of vast numbers of bats. The guano is of a dark brown colour, about the consistence of finely-ground coffee, and is as strongly impregnated with ammonia as the best Peruvian guano. Chemical tests have established its great value as a fertiliser, and it is being removed in large quantities and shipped to Europe by a company organized for the purpose." The caves are about eight miles from the railway leading to Galveston and New Orleans, at either of which ports shipment may be effected for transport across the ocean.

Bats' guano possesses little or no odour, and it has a peculiar felt-like softness when passed between the fingers. A cubic foot of it weighs about 73 lb., so that a ton of it would occupy rather more than one cubic yard.

As Peruvian guano is so well established, bats' guano must stand or fall entirely on its merits, and it appears that the few parcels which have yet found their way into this country have been disposed of, after analysis at an average price of £9 per ton, which compares favourably with the price of Peruvian guano, provided the two fertilisers are equally efficacious. A well-known firm of guano merchants values it at £3 10s. per ton

in bags on the London wharves. With regard to its composition, analyses have been made by Messrs. Bernard Dyer, John Hughes, C. Dixon, and the late and present Drs. Voelcker. Glancing over the results of these analyses, it is seen that the total nitrogen equal to ammonia varies between 9.25 per cent. (Mr. John Hughes) and 11.39 per cent. (Dr. Voelcker and Dr. John Voelcker), while the percentage of tribasic phosphate of lime represented by the phosphoric acid present ranges between 14.43 and 16.74. Judging from these figures it is likely that bats' guano will become no unworthy rival of Peruvian guano.

Field experiments made during the last year or two in England have yielded highly satisfactory results, and it is proposed to repeat these on a large scale during the coming summer. The Texas Guano Company, by whom the deposits are now to be worked, find that there is a local demand for between 2,000 and 3,000 tons per annum, but it is to be hoped that the output will be sufficiently large to meet the demand which should arise in this country providing the fertilizer continues equal in quality to the shipments that have already been made to England, and there is no apparent reason why this should not be so. A fair estimate places the total quantity of bats' guano in the Texas caves of Uvalde and Cibola at not less than half a million tons. The experience of any farmers who have made use of this new fertilizer—for it is practically new—would be of interest.—*Mark Lane Express.*

CHINA GRASS AND KOLA PASTE.

155, Finchurch Street, London, E. C., 5th June 1885.
DEAR SIR,—You will no doubt hear about a new process of treating China-grass. The fact is that it is now suggested to revert to the plan in use in China, namely, of stripping with the nail the skin of the reed stem, then drying it and sending it over to this country here to be treated by an alkali to dissolve the gum. The beauty of the Smith process was that the product should be treated directly it was cut and while in its soft gummy state on the plant. These straps—as they are called—come at the present time surrounding the cotton and fibre bales and are largely sold in the Liverpool market to paper manufacturers to improve their paper. They have also been sold to the fibre producers and prepared for spinning. This shows that the "new process," as it is called, has really no value because it is an old process, and every detail in the operation is now practised commercially.

I am sending by this mail a sample of the kola paste to Dr. Trimen. If examined under the microscope it will be found to correspond exactly with chocolate paste and has much the same flavour of the raw product as sold preparatory to its being flavoured and sold as chocolate.—I am, yours obediently,

THOS. CHRISTY.

TEA IN JAPAN AND CEYLON.

DEAR SIR,—Your extracts from Mr. Gribble's book about tea in Japan are very interesting, but what strikes me as the most wonderful thing about it is the enormous yield they get at three years—viz. 375 lb. of green leaf from 100 *tauho*—100 *tauho* are stated to be equal to 3,600 square feet, which is about a twelfth of an acre. So they get over eleven hundred pounds of made tea per acre at three years old! I presume this is due to their manner of planting, and I believe the yield to be possible considering that they have circles of about 30 plants at distances of five feet apart. It would be worth while trying an acre on the same system. I am of opinion that Mr. Gribble meant 3½ lb. of leaves as he has written it, and not 3½ lb. of made tea or its equivalent in leaves as you take it to be. Look at the cost of plucking given! It is over a halfpenny per lb. of green leaf, and this for the year in which as he states wages were 25 per cent below the rates ruling in the previous year. Now I shall suppose labour to be very

cheap in Japan, and I would not consider it very cheap if girls get more than 2d to 3d per day. The wages for girls is stated to be 15 sen per day and men get 50 sen per day. As the men get nearly 3½ times the wages of the pluckers, I would suppose that the pluckers are quite small children. I would think that tea planted as the Japanese plant it would be more difficult to pluck carefully than tea planted on the Indian system. R.

[Wages (of adults, we suppose) being, according to Mr. Bowen, about 25 cents of a rupee per diem, probably this correspondent is correct about the plucking by young girls and the proportionate wages. But what have experts to say to the use of cast-iron pans in the final drying of tea in Japan? and how is it that the leaf retains its green colour after such intimate contact with iron?—Ed.]

CEARÁ RUBBER TREES.

Matang, Sarawak, 13th June 1885.

DEAR SIR,—I have a few hundred Ceará rubber trees about three years old, and am desirous to procure a sample of rubber from them. I therefore write, asking if you will kindly tell me the best means of doing so.—Yours truly,
LOYALTY PEAKE,
[Our correspondent should apply to Messrs. John Walker & Co. for one of Mr. R. S. Fraser's rubber collectors.—Ed.]

JUNGLE AND PLANTATION TEA SEED HYBRIDIZING?

Blackwater, Galboda, 1st July 1885.

DEAR SIR,—Under separate cover I send some leaves. The dark bronze ones I know to be tea, but the pale red ones are so much like the jungle tea that I am in doubt, though they came off a bush at least seven years old, which has been pruned and plucked for years. A large number of the jungle tea plants were put out by mistake on this estate, the seed having blown into the tea nurseries. Is it possible for the jungle tea to hybridize with tea? There are so many bushes on this estate so like the jungle tea, there is no telling the difference. I have never in all my experience seen leaves so red, though bronze is quite a common color.—Yours faithfully,
C. A. HAY.

[Every person connected with tea in Ceylon must be aware that when nurseries are formed plants of what is known as "wild tea" spring up simultaneously with the true tea seedlings. It is now nearly ten years since we drew the attention of the late Dr. Thwaites of the Peradeniya Royal Botanic Gardens to this fact. From him we then learned, that, except similarity of leaf, the so-called "wild tea," a very common jungle tree, has no affinity to true tea. The idea of hybridizing may therefore, we suppose, be dismissed, even if both trees have been in blossom in close contiguity. There remains the idea which the late Mr. Howard propounded in regard to cinchona, the insensible influence, short of hybridizing, produced by plants on each other when growing in close neighbourhood. The leaves sent by Mr. Hay are certainly very peculiar, but we think they are the leaves of a variety of China plant. We would suggest, however, that leaves be sent for Dr. Trimen's opinion.—Ed.]

HARVESTING CINCHONA.

Deltota, July 2nd 1885.

DEAR SIR,—Christie, in his Prize Essay on Cinchona Cultivation, states: "From 4 year old trees at a medium distance apart, I think 80 lb. nett bark per cooly is a good average; and from old trees 100 or even 120 lb. can be brought in"; so that the 73 lb. from trees 6 to 7 years in Hewa Etiya is after all not a very good average.

In May 127 coolies harvested 18,435 lb. nett bark, the average for each cooly being 145 $\frac{1}{2}$ lb.; in June 67

coolies harvested 10,196 lb., the average being 152 $\frac{3}{4}$ lb.; so for the two months May and June 28,631 lb. were harvested by 194 coolies, the average being 147 $\frac{1}{4}$ lb.

I may here mention that I obtained an average of 197 lb. one day last month, my best cooly bringing in 231 lb. nett bark.

I weigh my bark once a day, as so much time will be wasted in weighing twice. One cooly cannot carry all the bark he shaves for a day; so on striking work another man employed at some other work is put on for carrying the extra bag. The force I employ for shaving is very small, 6 or 7, and the best men are put on to it. The work was carefully done, because the V. A. after examining many of the trees found no fault with me for overshaving or damaging the trees in any way. I can account for getting such a large quantity of bark per man easily. I have a small force of coolies, and about the only work I have to do is to look after the shaving and thatching of the trees, so that I can devote more time to my coolies than other superintendents who have to look after tea or coffee, or both products, as well as cinchona. B. E.

P. S.—I think there are many estates here that get above 100 lb. per cooly.

WHAT ARE THE PROSPECTS OF CEYLON TEA?

3rd July 1885.

DEAR SIR,—Now that what may be truly called "the rush into tea" has got well under weigh, it is not out of place to take a glance into the future and ask ourselves:—

1st. What effect on the London market will 60,000,000 lb. of Ceylon tea have five or six years hence?

2nd. What profit per acre should we have if tea fell to an average price of 8d per lb. with a yield of 400 lb?

3rd. Would China exports fall off? or stop entirely, supposing such a limit (81) to be reached?

4th. Would Indian exports fall off? or would they abandon their land as so many estates have been in Ceylon lately? the answerer should bear in mind that a very large part of the Indian tea estates are the property of companies who probably have capital.

5th. Has the production of any tropical product been known to suddenly cease through a fall in price? Vide Brazil, Java, Ceylon and India. I except South American bark because that is not a cultivated product and no money is invested in the growing it.

6th. What is the probable fall in the price of tea, consequent on the future export from Ceylon likely to be?

These questions are what every man should ask himself now, and the answers, though they may cause a good deal of disappointment, will save far more by and bye.

I am not a pessimist by any means, though some might infer it from my questions. What I aim at is some forecast of the future. Tea is going in everywhere and any how in all sorts of land and in every district; with 400 lb. an acre at 1s it is *couleur de rose* of course, and so all the planting world would have it not only now but for all time. How it would be at 81 is the reason of my being

A QUESTIONER.

[With reference to the letter of "A Questioner" which appears above, the same was no doubt written before we published Messrs. Gow, Wilson & Stantoo's and W. J. and H. Thompson's latest reports which afford the best answers at present available to most of the questions asked. The comfort which many Ceylon tea planters take about tea prospects is that they are toned to beat both China and India out of competition should the prices fall for good teas. At the same time no words of warning can be too weighty in reference to the evils of hasty reckless planting of bad seed or miserably poor jāt of tea-plants on poor land.—ED.]

JUNGLE AND PLANTATION TEA SEED HYBRIDIZING.

Colombo, 7th July 1885.

DEAR SIR,—With reference to a letter from Mr. C. A. Hay, and your editorial note on the above subject in your issue of this date, you will perhaps allow me to state that the family to which the tea-plant belongs is called *TERNSTROMIACEÆ* from the genus *Ternstroemia*, so named by the younger Linnaeus in honor of Ternström, a Swedish naturalist and traveller in China, who died in Policandre in 1745, and the Ceylon jungle tea-plants and the cultivated ones are both members of this family, but I do not think they can possibly hybridize, and their progeny be confounded with the real tea-plant when they are in flower or fruit. This family was elaborately worked out by Mr. W. T. Thiselton Dyer, c. m. c., Assistant Director of the Royal Gardens, Kew, in pp. 279-294 of volume 1 of the Flora of British India, by Sir Joseph Hooker, and others, and in which 14 different genera are given, whilst only four of them occur in Ceylon, viz., *Ternstroemia*, *Adinandra*, *Eurya*, and *Gordonia*.

The cultivated tea-plants were described by Linnaeus under the genus *Thea*, but it is found that this genus does not differ essentially from that of *Camellia*, and, as this latter is the older name of the two, the tea-plant and its varieties take their place as *Camellia theifera*, not of Linnaeus, but of Griffith, a modern Indian botanist (Fl. Brit. Ind. 1, p. 292). The jungle tea-plant of Ceylon belongs to the genus *Eurya*, and the leaves are so like those of the real tea-plant that they are very likely to be confounded, and what adds to the confusion is the fact that the *Euryas* spring up in all new clearings and nurseries in the higher elevations of Ceylon, and these are no doubt the jungle tea-plants referred to by Mr. C. A. Hay and yourself, though it is to be hoped that it was not one of them that was pruned and plucked for years. In this respect there is surely "a confusion of epithets" on the part of Mr. Hay, because the ubiquitous *Euryas* after all differ so much from the real tea-plants that a practical tea-planter should be able to distinguish them at once.

In Trimen's List of Ceylon Plants, p. 8, Natural Order 20 and Genera 74 to 77, you have the four genera I have mentioned above, and of the *Euryas* there are two good species, and two varieties which may also be good species; but, though their leaves resemble those of the real tea, their flowers are very small, and their small so-called berries are many-seeded, whilst the capsules of the tea-plant have from one to three large seeds in them, and the flowers are large and conspicuous. The most common *Eurya japonica* is the "Naya-dasse" of the Sinhalese.—Yours, W. F.

COFFEE LEAF-DISEASE.

Kandy, 8th July 1885.

DEAR SIR,—I have no doubt many persons must, like myself, have read with interest "Oberon's" researches in re leaf-disease. I fear it is not within human ken to give a satisfactory reply to "Oberon's" question, "What relation do living zoospores or germ cells, ova or spawn, bear to the spores of the supposed fungus?" "Oberon" is not correct in saying the "maggot" he refers to has no legs. With the aid of a Coddington lens of high power I have discovered legs resembling those of an ordinary caterpillar, and I may add that the insect progresses rather rapidly, moving its head from side to side in the manner of a cow when in the act of grazing. The spores are filled with an orange-coloured substance resembling crystallized honey, and the maggot* moves freely among the spores emptying each and leaving behind him the despoiled

* More correctly caterpillar.

receptacle, or shell, which is of a whitish colour. A large portion, however, of the shell or skin is devoured with the contents. If the orange-coloured spores are the means of propagating leaf-disease (?) we ought to be very thankful that there is such a voracious little animal as our friend the maggot to render so many of them innocuous.

I think "Oberon" is again mistaken in saying that the larva is armed with a sharp proboscis with which he pierces the skin of the leaf. I find many of these larvae lying in chrysalis form and perfectly quiescent among the spores. The supposed proboscis may possibly be the integument wherewith the larvae are attached to the leaf. The "maggots," I observed, were certainly not indebted to the juices of the leaf for their sustenance; their attention was directed solely to the spores. But I can support "Oberon" in his statement that the larvae lie in their larva state on the dried blackened portion of the leaf, originally a pin-spot, which fact goes to strengthen the supposition that a living organism and not a fungus is the origin of the fell disease which has blighted so many hopes and expectations.

I am aware, Mr. Editor, that I shall be deemed foolhardy to appear to question the received opinion that the propagation of leaf-disease is by means of the spores, but you may remember that General Braybrooke, years back, was not afraid to propound the theory that the origin of the disease was in the sap of the trees, and now "Oberon" is bold enough to come forward to support that theory; and, if I mistake not, Captain Rayley carried on some experiments at Galle which went far to show that it was possible the disease was propagated by some means other than the orange spores, so that the spores may be the effect and not the cause of the disease; and is not this more probable than its propagation by a fungus which being without the power of locomotion is yet supposed to be able to find its way through the stomata into the interior of the leaf?

If the propagation of the pest is due to the spore substance, may we not look hopefully for a rapid diminution of its effects from the wholesale destruction of all the "shuck" coffee which is being carried out in every district in the island? For not only will there be fewer spores to convey the disease, but the strong healthy trees may be expected to, in a measure, resist contamination.

Though plucky enough to send you this, I should be glad if I could, like the schoolboy, prepare for my castigation by inserting a copybook inside the seat of my inexpressibles. PUCK.

P.S.—Can any of your readers say whether the scale-insect, and *H. P.* are to be found on the same leaf? I have examined many leaves suffering from the latter, but in one instance alone did I discover scale-insect and then there was only one, and he did not appear to be at all in a flourishing state. P.

[Mr. Dick of Udapusellawa some months ago expressed the opinion that the coffee leaf fungus was, itself, in a diseased or dying condition, and that he could not get a healthy, full-developed specimen such as filled the back of every leaf some years ago. It is possible therefore that the epidemic may be dying out, leaving life in the coffee-trees in certain districts still. So note it be.—ED.]

CAN THE CHEMIST PRACTICALLY AID THE PLANTER IN PREPARING TEA?

DEAR SIR,—In your leader on the increase of Ceylon teas, you remark that it may now be time to take the advice given in several quarters to call in the aid of analytical chemists.

I think it would be as well to consider what aid they could afford us in the direction of perfect tea,

If, for instance, they could establish a test to enable us to tell when leaf was properly withered: that is, let us say, by taking a pound or so of leaf and mashing in a mortar, by adding certain chemicals, we could be sure we had withered up to the necessary point, then the capacity of the ordinary planter would be equal to the occasion and chemists would be a decided boon. But if the necessary process demanded either difficult calculation or delicate filtration, then, I think, the majority of planters would fight shy of the method.

Practically, too, would such tests tell us more than our senses of sight and touch do at present! The same remarks apply to fermenting and firing.

Of course, chemists could tell us whether teas are good or bad when they are made, but so can planters; and if we can tell what prices our teas will fetch within a penny or so, we ought to be able to spot anything seriously wrong with our method of manufacture. Supposing the above remarks are correct, then the benefit which would accrue to us by the introduction of professional analysts reduces itself to the question of soil and manure. On these points, of course, they could give us most valuable information, but, at the same time, such proved of but little practical value in the case of coffee, and it's doubtful whether it would be of more use in tea—in both cases the opinion of experienced planters seems to have the happiest commercial result.

Then, as to making perfect tea, I am convinced that what we require is not so much experiments in chemistry as better arrangements for the withering and further manipulation of the leaf. I am not competent to say whether this can be done by Clerihew's, Blackman's, or any of the air-exhaust patents, but this I am sure of, that withering is the point on which attention is needed.

I am talking of estates that are sending home good teas at present and under competent management, not of places where tea is just coming into bearing and the superintendent has had no experience. There, of course, much improvement may be needed in the whole operation of making (*vide* the case of —, whose teas doubled in value after the superintendent had had lessons from a man who knew something about tea), but the good places in Ceylon at present, if they have to show much improvement on their present make, will do it only by more extended withering arrangements, possibly assisted by hot-air machinery. It may be going too far to say that a good wither ensures a good tea, but most manufacturers will agree with me that a bad one generally has most unhappy results.

The most useful idea in regard to the improvement in teas and spread of information as to manufacture, &c., seems to me to be a series of questions in your planting columns, answers being solicited from correspondents in all districts, at all elevations, &c.—each estate to state its method of plucking, average age of flush, age of tea, and other particulars,

WITHERING.

1. What percentage do you wither down to?
 2. Have you tried stroccons or tulias as aids to withering? and with what results?
 3. Is your withering house enclosed or open?—state average temperature.
 4. Is tossing the leaf in the air, in your opinion, conducive to rapid withering? have you found it blackens the leaf?
 5. State your opinion as to the most rapid withers you have had, with notes on the tea made from the same, &c. Soon, through rolling, firing, fermenting, bulking, packing.
- The notes as to plucking should be full and explicit, as, of course, fine leaf will wither better than coarse or mixed. You will easily find experienced planters

to give you the necessary questions, and I doubt not you would receive useful and plentiful answers.—
Yours,
X. Y. Z.

[Tea-making is a chemical process, and every tea-maker is more or less a chemist, but the professional, analytical chemist might aid planters greatly by testing for strength and aroma and suggesting the substances to be applied to the soil, and probably changes and improvements in manufacture. To be fully able to do this, the chemist should first make himself familiar with all the processes of culture and manufacture, analyzing soils and leaves in various stages.—Ed.]

HARVESTING CINCHONA.

10th July 1885.

DEAR SIR,—The figures given by "B. E." on page 134 are in accordance with my experience. But where I obtained 100 lb. per cooly in shaving 5-year old cinchona trees when shaved all round the stem, I found difficulty in exceeding 80 lb. when taking off half the quantity per tree in two strips. There is of course loss of time when the cooly has to narrowly watch where he is shaving so as not to encroach upon the two strips to be left. Will "B. E." kindly give his experience on this point? Including lopping I cannot get more than 45 lb. branch and twig per cooly; nor thatch my trees for less than $\frac{1}{2}$ cent per tree, including cutting grass, which is close.
B.

THE ANOMALOUS LEAVES FROM BLACK-WATER.

Blackwater, Galbode, July 10th, 1885.

DEAR SIR,—It is evident from "W. F."s letter that the leaves I sent you were never examined by anyone competent to say what they really were.

I was perfectly aware that they were tea leaves, though I expressed my doubt from their color being of a kind that I have never before seen, though I have been wandering up and down lines of pluckers for many many years. What I would like to know is, if the true tree will not hybridize with the jungle kind, how is it that the true tree on this occasion has attained the exact appearance? is it diseased?

I quite agree with "W. F." that a practical planter should be able to distinguish the difference between the two kinds, but, when Assam hybrids take to copying their jungle friends in color of leaf, it is time to enquire into the matter. I will send you some more leaves, merely marking A, B, &c., and if you will kindly get "W. F." to look at them I shall be obliged.—Yours faithfully,
C. A. HAY.

P.S.—If "W. F." has only seen the jungle tree growing in the forest, he would be astonished at the change that takes place when the plant is pruned and kept as a bush; it loses a great deal of the jungle appearance and its pink color tones down; in fact it is only in the young plants that the difference is seen, as the stem bark is quite a different color though it becomes very much like tea proper when it grows older.

C. A. H.

[The leaves will be submitted to "W. F." and Dr. Trimen. As for ourselves, we may be as incompetent to pronounce on them as Mr. Hay imagines, but we retain our opinion that they were leaves of a peculiar China jāt.—Ed.]

TEA CULTURE IN JAPAN.

DEAR SIR,—In reply to "R."s letter in which he wonders at the large yield of Japan tea bushes, I may here mention that I was informed by a gentleman of great experience in the Japan tea trade, that the plucking with the exception of the first spring months

is of the coarsest description, and also that before the winter came on the bushes were absolutely stripped of leaves, all of which being rendered pliable by the steaming process are converted into tea and mixed with better grades, and then sent as fourth crop to the European firms, who mix them again and break them up and color them. The loss on weight between the green leaf and the made tea as fired by the Japanese in the first place is only from 10 to 15 per cent; of course after the refining process in the European hongs there is another considerable loss in weight, but this latter is to a certain extent made up for by the weight of the coloring matter. The bushes or clumps of shrubs resulting from the 20 to 30 seeds sown in a circle are very similar in size and appearance to our own bushes, and are in no ways remarkable for their circumference, and they are kept cut at a height of about 2 feet 6 inches to 3 feet; in no case did I see any higher, and only that height where the tea was evidently pretty old. As to the wages in the factories I was shown over, I noticed only about 10 per cent of men, the balance of those employed being women and girls. 50 sen is the equivalent of 1 rupee and 12½ cents, and, though it is the ordinary wage of skilled workmen in the hongs, I doubt very much if anything like that is paid for work in the gardens, few of which exceed five or six acres, and the majority of which are small patches of land surrounded with wheat, rape, radish or paddy and probably worked by the peasant proprietor and his family. The cultivation of land, whether it be of crops or of tea, is most liberal, manure being used generally, and whether in towns or villages every pound of refuse of any kind is bought by contract by the surrounding peasant farmers and applied to the soil.—Yours faithfully,

H. D. DEANE.

TEA FROM AGAR'S LAND, BALANGODA, TOPPING THE LOCAL MARKET.

Kandy, 13th July 1885.

DEAR SIR,—Your issue of the 11th instant contains a "Local and General" statement to the effect that "Kelani Valley" tea has topped the local market at 84 cents. "Agar's Land" has recently twice averaged 87 cents. My attention has been called recently by a "tea-man" to the poor prices "Agar's Land" tea has been selling at; hence my bringing the matter before the public.—Yours faithfully,
SHELTON AGAR.

TEA IN JAPAN.—A report published by the Kiyoto Tea Guild shows that the tea plants in the neighbouring districts have suffered considerably owing to the cold, wet weather; but, up to the present, nothing of this has been discernible in the arrivals of tea at the open ports.—*Japan Weekly Mail.*

COPRA.—There appears likely to be an increasing demand for copra, so that our northern settlers may plant coconut palms with a liberal hand. The Demerara *Argosy* advertises, as "a new colonial product," "coconut oil meal," which is sold in Demerara for 2½ cents a pound and is fed to stock. The advertisement says that "this oil is made from the kernel of the coconut, after the oil has been extracted; but considerable oily and other nutritious matter still remains in the product, and consequently makes it one of the most nutritious and fattening feeds that can be got for stock of every kind, especially for fowls. Stock of every kind, which have been fed on this meal, when cooked have a delicious flavor, an immense improvement on the tough tasteless things we have hitherto been accustomed to. We can quite believe that this article would be all that is claimed for it in feeding poultry at any rate.—*Queensland Planter and Farmer.*

"TEA, CACAO, CINCHONA, ARECA AND OTHER PLANTING INDUSTRIES IN CEYLON."*

(A REVIEW.)

As one who has spent over twenty years in different parts of the world, I have often been applied to for advice as to which was the most promising place for a young man to go to, and as to the sort of life which he would have to lead there. With regard to the Australian settlements, my advice has always been easily given, and the sort of life and prospects there have been as easily understood, but, when I came to describe the life of a Ceylon planter, and the chances of success in the accumulation of money in that island, I have had far greater difficulty in making myself intelligible to those desiring to emigrate, from the fact that tropical agriculture is not understood by these at all. In a small pamphlet entitled "Tea and Other Planting Industries in Ceylon in 1885," I have found a ready solution to the difficulty, for that work tells as clearly and concisely as it is possible, what the prospects are for a young man, with a little capital and plenty of energy. The work is published with the express purpose of pointing out that Ceylon is a good field for investment, and, I think, it has made a very good case, without being too optimistic in its arguments, for "Moderation" steps in with a very wholesome letter of advice, which, so far from damaging the case by the suspicions which he ventures to express, actually leaves the reader with a more favourable opinion of the field for investment, by the very clearing away of those suspicions by the encouraging reports which come in answer to "Moderation's" letter. Of course, Tea is held up as the means by which a young man is to increase his capital; but other products, such as cacao, cinchona, spices and even the nearly defunct "King Coffee," are not forgotten, but are all spoken of favourably; and when I remember the splendid fields of cacao in Dumbara and Malale, I think it well deserves to be classed well to the front. Philosophers speak about a wave of depression, which is sweeping over all parts of the world at present, and, without going into the reason why this is so, I think the pamphlet under notice has proved that Ceylon is no worse off than other countries, but it need may be said to be in a more favorable way, as the "wave" seems to have swept past its shores, and it is once more on the fair road to repay those who have stuck to the ship when supposed to be in a sinking state. The compiler modestly says that he will be repaid any trouble it may have cost him if the pages serve to interest even a few young men in the industries of Ceylon. I think I may safely say that not one single reader will lay down the work without having had his interest thoroughly awakened in the subject.

A RETIRED PLANTER.

In the Old Country, June 16th.

THE GREAT BARK COUNTRY OF AMERICA is thus described in a recent account:—The Roman Catholic religion is the prevailing one in Bolivia. Any other form of faith is merely tolerated, and general education is much neglected. The leading society is largely composed of military adventurers and men of the bar. The backwardness of the people at large, and the miserable tea ons which ever and anon are committed by Government officials, continually throwing the country into a dreadful state of anarchy and guaranteeing no security for investments, have hitherto been the stumbling-block on the road of progressive life in Bolivia.—*South American Journal*, May 16th.

COFFEE ADULTERATION.

Kandy, 10th July 1885.

To the Editor of the *Tropical Agriculturist*, Colombo.
SIR,—In reference to page 54 of the issue of the *Tropical Agriculturist* for July, just received, I observe an extract from the Annual Report for 1884-85 of the Coorg Planters' Association, and think it right to prevent any misapprehension regarding the paragraph on the adulteration of coffee to annex a copy of the letter, which I had addressed to the Honorary Secretary of the Coorg Planters' Association on the subject.—I am, sir, your obedient servant.

A. PHILIP, Secretary.

(Letter referred to.)

Planters' Association of Ceylon, Kandy, 30th June 1885.
G. R. Evans, Esq., Hon. Secretary, the Coorg Planters' Association, Mercara.—Dear Sir,—I observe from the report of the proceedings of your Association in the *Madras Weekly Mail* of the 13th instant that reference is made to this Association in connection with the steps to be taken in regard to the admixture and adulteration of coffee. As you may not be aware of the decision come to sometime ago, I beg to transmit by book-post a copy of proceedings of this Association 1883-84, and to refer you to pages 218-221, &c. The book of proceedings for the year ending February 1885 will be issued soon when I hope to have the pleasure of sending you a copy. I shall be glad if you will reciprocate with copies of your proceedings etc. from time to time.—I am, dear sir, yours faithfully, (Signed) A. PHILIP, Secretary.

THE TEA INDUSTRY IN INDIA:

By COLONEL MONEY.

(Written specially for the "Ceylon Observer.")

THE RAPID GROWTH OF THE INDIAN TEA INDUSTRY—THE HISTORY OF TEA PLANTING IN INDIA—MISTAKES MADE BY THE GOVERNMENT IN THE SELECTION OF LAND AT HIGH ELEVATIONS—THE INDIAN TEA DISTRICTS—MONEY LOST BY MISTAKES—IRREPARABLE MISCHIEF DONE BY THE IMPORTATION OF CHINA SEED—THE DISCOVERY OF THE ASSAM INDIGENOUS TEA—HIGH AND LOW GROWN TEAS—INDIAN AND CHINESE TEA MIXTURES—PURE TEA THE EXCEPTION—INCREASE IN THE IMPORTS FROM INDIA AND DECREASE IN THOSE FROM CHINA—THE TEA OF THE FUTURE—INDIAN TEA NOT A FINANCIAL SUCCESS—SUPPLY EXCEEDING DEMAND AND CONSEQUENT FALL IN PRICES—A WARNING TO CEYLON PLANTERS—NEW MARKETS—ADVANTAGES OF INDIA AND CEYLON OVER CHINA—TEA FIRING—MACHINERY.
East India Club, St. James' Square, S.W., 12th June 1885.

Perhaps no great undertaking of any kind has ever assumed larger proportions in a comparatively short time than the tea industry in India, which boasts today of nearly 300,000 acres under plant. Fifteen years ago tea from Hindustan was virtually unknown in England. The imports did not then exceed 13 million pounds in the year. They are now 61 million, or above one-third of the whole consumption of Great Britain.

The history of the tea industry in India is a very remarkable and curious one. The possibility of growing tea there was first mooted in 1836, and the Indian Government started an experimental garden at Lukimpore (Assam) at that time. It is perhaps strange this was not done before, for, as early as 1780 some tea plants had been brought from China by a Colonel Kyd, and were cultivated in Calcutta. As Calcutta is not a good climate for tea, the chances are, the plants did not thrive well. However that may be, it is certain nothing was done with a view of growing tea in India till 1836. From 1836 till 1845 again little or nothing was done. Assam is a long way from the seat of Government in Calcutta. As regards time, it was much farther in those days than England is now. There are no records to show how the said experimental garden in Assam flourished; it failed eventually; but in 1845 and following years the Indian Government awoke to the fact that tea could be grown in India, and large quantities of China seed were imported.

The first mistake was then made. Because, presumably

India is better than China, localities were sought which, owing to elevation, had more or less of a temperate climate, and thus the first nurseries established were on the Himalayas. This was a mistake, because, though some of the best Indian tea is produced in those elevated regions, the growth of the plant is very slow there, and the yield less than half what it is in moist climates on the plains. The Indian Government was generous in those days. Land, to grow tea in those mountains, was offered on easy terms to any individuals who would essay the cultivation, and seedlings from the said Government nurseries were offered gratis. For five years, viz., up to 1850, however, Government were the only cultivators, and then private individuals, seeing it was a success, commenced plantations in Kumaon and Gurwhal, which are districts in the Himalayan range.

While this was being done in the north-west of India, the Assam Company, as early as 1810, had commenced cultivation in the south-east, viz., in Assam. There are now no less than 13 tea districts in India, and the cultivation in each was commenced in the following years:—Assam 1840, Kumaon and Gurwhal 1850, Cachar 1855, Dehra Dhoon 1855, Sylhet 1857, Kangra 1858, Darjeeling 1860, Terai 1860, Chittagong 1860, Neilgherries 1862, Chota Nagpore 1872 and Douars 1875. Thus, with one exception, it may be said tea planting in India dates from 1850, or only a little more than 30 years back. What wonderful strides it has made in that time: wonderful in the quantity now produced, more wonderful still the improvements in manufacture over the old Chinese method.

Mistakes are certain to be made in new fields of enterprise. With all its wonderful success, with all the perseverance and energy which have made the Indian tea industry what it is today, the mistakes made, looked at with the knowledge experts have now, seem as wonderful as the results achieved. It is very certain that had a tithe of the knowledge existing now, been available in the early days, many millions sterling wasted, owing to ignorance, would have been saved; the area under cultivation in India would not have cost half what it has; and perhaps, more important than all, good as Indian teas are, they would then have been far better.

The last shall be the first explained. A Committee was appointed in 1834 to report on the possibility of cultivating tea in India, and, strange as the delay seems, it was not till 1845 the Government took the first steps, and for some years continued to import China seed. When the said Committee was first formed (and strange to say it was possible), had an individual stepped forward and said, "No such Committee is necessary, the question you are asked to solve was settled by nature some hundreds of years ago," he would have been esteemed mad; but it was no less true. Again when, in 1845, the Government began importing China seed, had they been told they were injuring what was destined to be one of India's great industries, they would only have been told the truth. At that time, and for hundreds of years previously, many square miles of tea trees, the indigenous plant of India, existed in the sombre, deep and damp forests of Assam and a part of Cachar. There was seed enough at hand for all the requirements of India, and seed of a very superior kind, many degrees better than the China tea seed! The most valuable tea received now from India is the product of this indigenous seed. The best gardens are those in which the tea plants, mostly now hybrids, assimilate nearest to the indigenous nature. Thus, when India was flooded with China tea seed, irreparable mischief was done to the cultivation. † The indigenous tea of India was first discovered in Assam, about 1830, by a Mr. C. A. Bruce, to whom was granted a medal for the discovery. But it was not till years after that it became known, as a certain fact, the trees, alleged to be tea by Mr. Bruce were really so. ‡ Our

* "Some hundreds of years ago" If, as is generally believed, tea is indigenous to Assam, it must have existed far back in time.—Ed.

† Colonel Money has constantly repeated this statement, but the vast majority of Indian planters hold that good hybrids are preferable in many cases to pure Assam, being less delicate.—Ed.

‡ Dr. Wallich delayed the utilizing of the indigenous plant for several years, by insisting that it was a camellia and not tea.—Ed.

knowledge of the tea plant was, at that time, confined to the China bush which is say 3 or 4 feet in height. The trees, said to be tea, found in Assam were 30 feet high! But, little by little, the fact became patent. The trees were cut down to 3 or 4 feet from the ground, new branches and leaves sprouted, tea was made from the latter, sent home, and pronounced by the brokers to be wonderfully good. Then came a great rush for the forests where those trees were, others were removed, the indigenous seed was sown in the vacant spaces, and many of those gardens are the best and most valuable today. The indigenous plant of India is far the better, but it lacks the hardihood of the China bush. Had the knowledge we have now been available then, a little China seed of the best kind should have been imported, and hybrids carefully reared with a dash alone of the China in them. We should then have had a very perfect plant for India, whereas now the plant most common, in the Himalayas at least, is much more Chinese than indigenous, some of it entirely Chinese.

Two distinct teas, the produce of high and low elevations, or in other words of tropical and temperate climates, are received from India. They vary much. The high tea is the more delicate in flavour, but much weaker than the low kind. In case of those essaying Indian teas for the first time, the former is preferable; but the latter, owing to its greater strength, goes much farther, and is the more economical to use. After a time it is preferred by many to the hill teas. Until quite lately the only use in England made of Indian tea was to mix it with Chinese, to give the latter the strength in which some kinds were deficient. Now, of the 64 million pounds imported, certainly not more than the odd 4 million are retailed pure. But the taste for Indian teas grows apace, and yearly more and more will be used unmixed with the produce of the flowery land. Because Indian is dearer than Chinese tea, the more of the latter there is in any blend or mixture retailed, the larger the profit of the vendor. Pure Chinese or pure Indian tea today is quite the exception: the former simply because the public won't have it, as lacking the body the partial use of the latter has lately accustomed them to. Pure Indian tea is the exception, partly because the education of the public in that way is not yet complete, partly owing to its higher cost. The mass of the tea consumed in Great Britain, today, is a mixture of about two-thirds Chinese and one-third Indian.

In 1830 the first of the Indian teas were sold in London. The quantity was small, and fancy prices, 15 to 35 shillings a pound, were paid! Not before 1855 had it come home in sufficient quantities to attract much attention, but after that year it increased quickly, till in 1870 thirteen million pounds were imported, four years after, viz. 1874, the imports rose to seventeen million; again 4 years, 1878, they had more than doubled being thirty-six million; and they went on increasing until last year, when they stood at sixty-four million, or above one-third of the total tea imports. While India has been thus advancing, the imports from China have been actually decreasing. The yearly large increase in the consumption is more than supplied by India alone, as the following figures (pounds) show:—

Years,	China,	Indian.	To al.	Chins.	Indian, ¹
1804	85,704,000	2,796,000	88,500,000	97	3
1874	118,896,000	18,528,000	137,424,000	87	13
1881	110,880,000	61,212,000	175,092,000	63	37

The above shows at a glance, that, while the consumption of China is steadily decreasing, Indian tea is advancing with giant strides, for, whereas twenty years ago India only supplied 3 per cent of the tea consumed in the United Kingdom, last year her proportion was 37 per cent, that is more than one-third of the whole. The above figures are also interesting as showing the enormous increase in the tea consumption each decade, and that during the last, while the said total increase was 38 million, the increase of Indian tea was 46 million. Thus there is some ground for saying, as some do, that Indian tea will be the tea of the future.

As regards financial results to the growers, Indian tea has been scarcely a success. When the industry first started, both the cultivation and the manufacture were

unknown, and everything was done expensively. There were generally two or three Chinamen to be found, in those early days, on every garden, and in many cases they taught us wrong. There are very few now. The Indian planter thinks, and the result shows he is right, he knows more about tea than his Chinese brother. Gradually, as knowledge increased, economy was studied, but an element, not foreseen, had slipped in. Supply began to exceed demand, both as regards Chinese and Indian teas, and prices fell. A few years back Indian planters easily realized two shillings and upwards for their teas all round, they get not much more than half that now. Some fortunes were doubtless made by the lucky ones in the first good days, some even with the present low prices manage to make tea pay still, but the days of large profits are gone. Take it all in all, from the first up to this time, quite as much money has been lost as made by Indian tea.

Still, in spite of the above, there is probably a fair future in store for the Indian tea-planter, that is for those who *have* good gardens. But, with the market as it is now, it is no less than folly to invest in new cultivation. The hindrance to success has been that too many embarked in the industry. Too much tea is already grown in India and she has now a very formidable rival in Ceylon, where the cultivation is extending greatly, and whence tea, quite equal to Indian, is sent home. But the planters in Ceylon should be warned by the experience of those in India, for it is very possible they are rushing too much ahead. The question of new markets for tea is an all-important one to the producer. The taste for Indian tea is spreading in Australia, somewhat also in America, and the demand from those countries may be eventually enormous. But that will not be yet. Shortly, if supply does not increase much, demand will probably overtake it, and better prices result. Let it do so before the tea area is widened. Some thought, some still think, the war in China will raise prices: it has not done so yet.

How far Indian tea will eventually supersede China is of course a question. The figures of the last two years certainly lead to the belief, that, in the near future, the imports will be at least equal. There is no doubt the teas of India and Ceylon have some advantages. They are much stronger, and therefore, though much dearer, more economical. It is said, that, while many desert Chinese for Indian teas, the converse is very rare. Some China tea has been now and then condemned as adulterated, but in no one instance has any foreign substance been found in Indian tea. The fact that Indian tea is all manufactured by machinery, instead of by hand as in China (tea manufacture by the hand is not a nice process) ensures its cleanliness. When we consider that tea has been cultivated and manufactured in China more than a thousand years, in India some thirty only, it is almost incredible, but no less a fact, that in point of manufacture the Indian planter is far ahead of the Chinaman.

One proof may be given. In Chioa (it is so still) tea has always been fired with charcoal. The Chinese imported in the early days to teach us tea manufacture in India, said this was necessary, and that the fumes of charcoal had some beneficial chemical effect on the tea. We did as we were taught for some years, for, though charcoal was a very expensive and inconvenient agent, we then knew no better. After a time a series of experiments, carefully conducted by me, showed that heat from any fuel, if the products of combustion did not mingle with it, was equally efficacious, may make better tea, but it took a long time ere my convictions were accepted. Not likely, planters said, the Chinese would have used charcoal for centuries had it not been necessary! The result proved however I was right. The first crude machine I designed for the operation, at the Soom Tea Plantation in Darjeeling in 1871, established the fact. (See page 239 of my Tea Book, 4th edition.) It was soon superseded by more perfect ones, and very nearly all Ceylon and Indian tea is now fired by the agency of coal, wood, or any fuel. Economy in manufacture is the result. The comparative immunity of the forests in India is another advantage, and it is now an accepted fact that superior teas are thus made, that is always supposing it is not, by excessive heat, done too quickly, which seems to be the error planters are falling into now. Whereas in India each and every process in manufacture is done by machinery, the Chinese still make their tea by

hand as their forefathers did before them. A well set up tea factory in India is a wonderful sight, when the infancy of the industry is considered. Machines are there present for each and every process, and they are many. Much labour is saved thereby, and improved tea is the result.

If ever Indian supersedes Chinese tea in England, the result will be due, in a great measure, to the use of machinery * in its manufacture.

EDWARD MONEY.

THE NORTH BRITISH BORNEO COMPANY.

The progress of the North British Borneo Company has always been so interestingly followed in Ceylon, and so many of those who have, during the late years of misfortune, failed to make their way in your colony have proceeded to try their luck in Borneo, that the following report of what transpired at a meeting of the Company's shareholders this week cannot fail to be of interest to your readers:—

The fifth half-yearly general meeting of the British North Borneo Company was held yesterday, at the City Terminus Hotel. Sir Rutherford Alcock, K. C. B., presided, and in moving the adoption of the report observed that they had now been at work for three years, and it might be desirable that he should make a brief review of the progress which had been made by them. The total receipts for the year ended December 31st last had been £20,043, being an increase, as compared with the previous year, of 60 per cent, while the expenditure of 1884 showed a decrease of 30 per cent as compared with 1883. Their receipts were made up of three different items—£15,238, the revenue proper—rents, rates, taxes, &c.; £2,898, which had been received from land sales, and £1,717 from interest on investments. He thought with these results before them they would see that they were in a fair way to attaining the end they were seeking; but to understand thoroughly the significance of the progress of the company they must remember the very adverse circumstances in which they had been working. Almost immediately after taking over the country there was an unexampled depression. There had been great speculation among the Chinese, both at Shanghai and Hongkong in various companies, which had ended more or less disastrously, and quickly following on that state of things there were the hostilities with the French, which had destroyed all trade on the coast, and all trading intercourse among Chinese and foreigners in the treaty ports. A comparative statement of revenue and expenditure for 1883 and 1884 was given in the report, and it would be seen that the increase in the revenue had been under every head with only two or three exceptions, and the same remark applied to the reduction in the expenditure. They had followed the example of Singapore and Hongkong, and they now had no import duties. They had received the most favourable reports from Governor Treacher of the prospect of an increase in nearly all the items which had been already continually increasing, and now that there was a cessation of the war with China, and more capital would be liberated, they might hope that a considerable extent of land, which had been allowed to lie fallow from want of enterprise, would come speedily into cultivation. Timber, tobacco, and minerals had hardly appeared in their returns yet, but they now offered very great promise. Beyond this there was certain jungle produce—sago, pepper, hemp. Of timber they had practically an inexhaustible supply; tobacco was one of the most fruitful of their prospects; and, with regard to minerals, without wishing to raise any over- sanguine expectations of immediate wealth, he might say that they had ascertained, certainly, that gold was in two of their rivers. As to their new territory, they had every reason to believe that this acquisition would prove very advantageous to them. It had given them an addition of 60 miles of coast, and it took them down to Brunai Bay. They had obtained this territory on what they conceived to be very advantageous terms, and great credit was due to Governor Treacher for the successful manner in which he had negotiated its acquisition. The territory possessed a large population—which of itself was a great advantage—and it was covered with produce, sago, rice, and other articles, which were immediately salable. With regard to their financial position, they had some £16,000 available, in addition to

* With skill and conscientious care.—E. D.

the £18,000 which was out in advances, and cash balances in Borneo, part of which were held in reserve against the treasury notes they had issued. From this it would be seen that further funds would be required, but not more than £10,000, only half of which would be immediately wanted. The directors had therefore decided to call up £1 a share, which would be sufficient until about that time next year, when another call of the same amount might be necessary. Within the year 1886 it might be reasonably hoped, having regard to the progress which they had already made, under most unfavourable conditions, that an equilibrium would be established between revenue and expenditure, unless some wholly unforeseen circumstances should occur. Rear-Admiral R. C. Mayne, C. B., seconded the motion. In reply to Mr. Dence, the chairman stated that the convention which had been made between England, Spain and Germany with regard to the Sulu Archipelago and British Borneo was entirely to the company's advantage, for until it was signed there was just a possibility of some question being raised by Spain about their trade and position and their immunity as to the Archipelago. With respect to the duties, there was to be no monopoly, and Spain was to be on the same footing with Germany and England. The motion was unanimously adopted, and the retiring directors and auditors were afterwards re-elected. In reply to a vote of thanks, the chairman stated that they were founding a great colony, which he was satisfied would sooner or later become of immense value to the nation as well as to those who were now concerned in developing its resources.

I cannot refrain from telling you how one of your oldest planters recently expressed himself with reference to your *Tropical Agriculturist* to a friend of my own. He said it was to him, now that he had quitted Ceylon, one of his greatest pleasures and resources. That he industriously read every word of it, and never failed to find in each number much that was new and instructive. He further said he could not conceive that any man actually engaged in planting work in any part of the world could do without it. This private opinion is but confirmatory of that expressed by every journal by which your useful monthly has been reviewed or noticed.*

◆
"TEA NOTES": BY MR. A. F. DOWLING,
OF THE KORNAFULI ASSOCIATION, LIMITED,
CHITTAGONG.

In noticing this work we commence by publishing a letter which has reached us from the author. Mr. Dowling writes:—

"At page 822 of your May number of the *Tropical Agriculturist*, I find some 'Generally-admitted Facts with regard to the Manufacture of Tea' attributed to the 'late Mr. Camerou.' They were written by Mr. A. F. Bruce and myself in May 1881. It would scarcely be necessary to mention this, were it not for the circumstance that I have embodied such of the facts as are not considered antiquated now in my 'Tea Notes,' page 31, of which I recently sent you a copy.

"The 'Facts' were freely circulated, and Mr. Camerou (or Campbell) must have taken his copy from this to Ceylon."

We copied the matter from the local "Times," to which it seems to have been sent by a correspondent. In the preface to his work Mr. Dowling states:—

These notes were originally compiled for the use of the Kornafuli Association. Mr. A. F. Bruce supplied the greater part of "Forest Trees," Mr. A. Watson the "Vernacular," the rest of the collection consisting of extracts from the several Note Books at the Association's gardens.

In the copies offered for sale the pages of Areas, Crops, expenditure, &c., are left blank, while the book has been interplaved throughout to admit of additions and corrections.

There will naturally be found much to alter in a compila-

* And yet, many proprietors of large estates make no provision for the supply and filing of this periodical (costing a few pence or shillings per annum) on their properties.—Ed.

tion of this sort. The book does not claim to be an authority: it is merely a collection of Notes subject to correction. A better edition may be issued later on, if those who have occasion to refer to the pages will be kind enough to point out any errors they may come across, and will offer suggestions for subsequent improvement.

The "Notes" form a curiously mixed collection of matter, commencing with a Calendar extending from May 1885, the date of publication, to December 1886. There is an almanac and the names of the months in English and Bengalee, with the Bengalee alphabet. Then come pages with headings for filling in areas plauted at different dates; averages and outturns of tea with garden cost and freight per lb.; expenditure under different headings per acre, such as European and native establishments, old and new cultivation, buildings, cooly expenses, manufacture per lb., freight to Calcutta and carriage and boat-hire per maund, and general charges; with total garden cost and freight per lb. deducted. The book was primarily designed for the superintendents of estates connected with the Company for which Mr. Dowling is manager, but it will afford useful hints to tea cultivators everywhere. No fewer than nine kinds of bamboo are named in the Notes as applied to various purposes, amongst which we find "slings and binding purposes." The best time for cutting bamboo is said to be December, when there is a decided wintering in Northern India, the foliage of bamboo being white. Then as regards "belt lacings" we get some curious information as to eel skins:—

The strain on belts is always in the direction of their length and therefore holes cut for the reception of lacing should be oval. Eel skins, when procurable, make the best lacing belts. Raw hide lacings are useless, and indents should express dressed leather.

Figures for the dimensions of tea boxes are given which we need not quote, but we notice that between 40 lb. boxes (recommended by the Tea Syndicate for Australia) and the 80 lb. chest there is a difference of cost of £1 10 annas per maund in favour of the larger package. Information is given about bricks and buildings which shows that the cost of the latter at Chittagong is very moderate. The position is laid down that garden rates should be one-third to a half less than those paid by Government. Of rattan cane there are six kinds which are applied to various purposes, including "staking." There is quite a chapter on "the Chemistry of Tea," from which we quote as follows:—

From the moment pressure is brought to bear on the succulent leaves in the Rolling Machines through the silent process of fermentation or coloring, to the time when the fragrant smelling tea leaves the fires, a variety of chemical changes occur in the Dextrine, Glucose, Gum, the Tannin, Nitrogen, Potash, Ammonia, Chlorine and Sulphuric Acid and Essential Oil, which are found in the extract or "Liquor." Is it too much to expect that, in the course of time, or the monotonous report of "greyish, fair tip, brisk, little flavor," may be added the more desirable information of "fairly gummy, potash 2-13 per cent only, good trace of Essential Oil"? We could then, with our knowledge of manures, supply after a while the lacking Potash, and do our best to keep up the desired proportion of Essential Oil.

Referring to "Soils and Manures" for the constituents of tea leaves and manufactured tea, I add the following particulars from my note-book:—

Acids redien lime litmus paper.

Alkalies or bases give a blue color to red paper.

Acids and *Alkalies* have thus a kind of antagonistic function, and neutralize one another.

Acids acting on *bases* from *salts* which commonly have no action on either blue or red litmus paper.

Theine gives Tea its bitter taste—it is very nitrogenous; although a base, it does not, as other bases, neutralize an acid. It does not exist in the leaf in a free state, but as *Tannate of Theine*.

Tannin gives astringency and color to the tea—it is partially destroyed during fermentation.

Tannin consists of nitric acid and resins. It can be manufactured from nitric acid and charcoal. A solution of *Gelatin* gives a white flocculent precipitate, showing the tannin in tea, and ferric acid, which can be made from iron filings dissolved in warm dilute nitric acid, gives a blue-black precipitate.

Certain combinations of Tannin absorb oxygen from the air and turn black and all substances containing tannic acid turn black when brought in contact with iron.

The following experiments may be of interest:—

	Adds to Roll.	Makes the Outturn and the Liqueur.
Chlorate of Potash	...dulls the tips,	bright, pungent;
Carbonate of Ammonia	...improves "	dark green, soft;
Tannic Acid	... "	dirty, thin;
Carbonate of Soda	...dulls "	fair, dark;
Hydrochloric Acid	...ordinary "	ordinary, weak;
Gum Arabic	... " "	good, thick;
Hydrochloric Acid and Gum	... " "	" " weak;
Nitrate of Soda	... " "	" " full;
Tincture of Steel	...dulls the tips,	black, very bad;
Nitrate of Potash	...ordinary tips,	good, cloudy;

the taste of the liquor being injured in every instance.

The last experiment but one shows how necessary it is to ensure that no iron comes in contact with the moist roll, or the appearance of leaf, color of outturn, and the liquor will be prejudicially affected.

What is said about iron is the general belief of planters everywhere, and yet it has been stated that a planter who turns out some of the best teas that go from Ceylon lures the iron in his roller so as to let the tea come in direct contact with it! There is information about chaukidars or village watchmen, which is not applicable to Ceylon. Damp coal is said at pack in less space than charcoal, 10 clamps go to a full chest, and choolas or drying furnaces, where used, should be

25' from ground to top of brick work, and 2'8" square inside top. This takes a tray of 2' 10" x 2' 9" x 3" deep. Our iron ovens are of a size to fit the choola top of the particular garden where they are used, but are always 21 inches to admit 5 trays, and a lower zinc slide.

We naturally pass over a couple of strangely interjected paragraphs about Liberian and Arabian coffee, and as to colour contrasts in the case of paint for machinery, we content ourselves with quoting the opinion that "a good cheap contrast, serviceable and clean, is the old-fashioned stone colour and black." Contract rates for masonry, brickmaking, sawyers, tanks and excavations are given, and we learn as regards tea boxes that

Carpenter should put together 4 chests from shooks and 3 chests from planks per diem. Tin-smith should line 15 boxes.

The notices regarding stakes for planting, bamboos, withering trays, dallas and baskets are scarcely applicable to Ceylon. As regards the manufacture of all these appliances, Mr. Dowling says:—"The work done by garden coolies is invariably better than contract work, but usually more costly." Figures as to weight and dimensions of sheets of corrugated iron and information as to the quality of cotton need not be quoted. Crop figures state that 85 maunds of leaf were gathered on an estate under Mr. Dowling's charge on 4th August 1883, and it is shown that the period for gathering half the crop extends from June to September, picking being commenced in March, we presume. Mr. Dowling states:—

The average of 1882, in which year we got fair October showers, was 6th July quarter and 27th August half crop date. The average half crop date of the district for a number of years is generally accepted as 24th August.

There are useful tables

Showing cost, in Shillings and Pence, laid down in London, of Indian Tea, at Exchange from 1s. 7d to 1s 10d, per rupee; Freight at £3 10s.

There are hints on Gardening, which, being short, we quote:—

A good mould for seeds sown in pots is:—Half leaf mould, half common loamy earth with a little sand. A little pounded charcoal should be mixed with the covering soil.

Coal ashes mixed with dry horse manure is an excellent fertilizer for flower beds. Red and violet flowers are benefited by covering the earth in their pots with about an inch of pulverized charcoal. The colors are intensified. White flowers or roses will be greatly improved in brilliancy by mixing iron filings and ashes with the soil. A dressing of quicklime also improves the color of flowers.

All creeping plants, such as Verbena and Lobelia, should have the first bloom picked off before being pegged down to the surface of the mould. This will hasten the spreading.

Weeds on paths can generally be destroyed by watering with a very dilute solution of carbolic acid.

Plant Fertilizer.—Ammonium sulphate, 4 troy ozs; potassium nitrate, 2 troy ozs.; white sugar, 1 troy oz. Powder, mix and dissolve in 1 quart of water. One tablespoonful of this mixture added to one gallon of water, and sprinkled on the plants once or twice a week, enriches the soil, and imparts health and vigor to the plants.

Under the heading "Indents" is shown what should be specified in ordering adzes, anvils, augers, &c. It seems from a paragraph on Marine Insurance that in India tea leaf can be insured from date of plucking to 30th day after arrival in Calcutta. The recipe for kerosene as an insecticide may be useful where pochies are prevalent:—

Kerosene oil 1 gallon, milk 1 quart, water 1 quart, Mix intimately, and dilute with 12 volumes of water.

Weights of bar iron are given, and regarding hoop iron we learn that

Of $\frac{1}{2}$ " size, 8 oz. or 10 feet to a tea chest when clamps are employed. 1 bundle of 56lb. thus goes to 112 chests. Of $\frac{3}{8}$ " size " " " " 100 "

But if the Japan dove-tailed boxes are generally used in Ceylon, hoop iron can be saved. "Kodales" our planters know all about. We pass over Government returns, which are far more onerous in India than in Ceylon. Under "Land Measurement" it is gravely asserted that

In measuring Hill lands, the Surveyor takes from top to top of the Hill. The gain in sloping land, such as the Tbandachiri Bungalow Teelash, is seven per cent. by actual measurement.

What have scientific men to say to this? The book is written for Indian planters, who, doubtless, will appreciate the information that "the *chuckbund* of a *sunnud* is the boundary of a *mehal*!" "Land Tenures" have no direct applicability to Ceylon, where all plantations are held on a peppercorn tenure. A specimen, in Bengalee and Roman characters, of a letter from a Native Mohurrir to an estate superintendent is given, and immediately following is an extract from the *Tropical Agriculturist* on China "he" tea. We quote thus from "Machinery":—

Jackson's Standard Roller gives its best twist with the Machine worked at 83 revolutions per minute. 130 lb. of withered leaf can be completed in 12 minutes.

Jackson's Excelsior with 76 revolutions and 110 lb. withered leaf turns out a good roll in 10 minutes.

Kimmond's Dryer No. 2 at Fenoa consumes 1½ maund wood per maund of Tea.

The Sirocco at Raungona finishes 23 lb. Tea in one hour, and burns about 2 maunds wood to 1 maund of Tea.

Jackson's Hand Roller takes 4 men at the handles and 20 lb. withered leaf at a fill. It will turn out a maund and a half in an hour, and eight men will finish off 7 to 8 Mds. within ordinary working hours.

According to this Jackson's Standard Roller, of which nothing seems to be known in Ceylon, turns out 650 lb. withered leaf (equivalent to 162 lb. made tea) per hour, and the Excelsior 660 green or 165 lb. dry per hour. The Sirocco employed on the estate referred to by Mr. Dowling uses up 2 maunds of wood to 1 maund of tea. The capacity of Jackson's

hand roller used in India is so low that it takes in only 20 lb. of leaf at a fill, and yet it is said to turn out 120 lb. an hour. The rolling must, therefore, be completed in ten minutes, instead of over fifteen minutes to half-an-hour, as is, we believe, generally the case in Ceylon.* Full instructions for working steam-engines are given.

The Notes on "Manufacture" we quote :—

1. Leaf is best withered when there is free supply of light and cool air. Withering space of 600 square feet to the maund is required to dry leaf in perforated Bamboo trays in damp weather, or say 67 trays of 3×3 with a spread of 1½ lb. per tray. In dry weather a seer of leaf per tray, or 40 trays per maund, will be found sufficient.

2. Withering in the sun is objectionable, but in bad weather wet leaf is better withered in the sun or in the wind than by artificial heat. The operation should not be hurried as dried leaf is not necessarily withered leaf.

3. Under-withered leaf breaks in the roll and gives a green outturn. Over-withered leaf gives tips, but a dark outturn. Leaf withered in the sun gives a reddish tea. A bright coppery outturn can only be obtained from properly withered leaf.

4. The leaf gets broken when low rolling tables are employed, anything under 3 feet high would seem to be objectionable. If sap comes quickly in the roll, it shows that the leaf has not been properly withered, and too much sap will cause a knobby or lumpy roll. Heavy rolling destroys the tip and flavour of the small leaf, but improves the strength of the large leaf. Were it possible to treat the small apart from the coarse leaf the quality of both would be bettered.

5. Contact with iron blackens the roll, and all iron surfaces in the Rolling Machines should be changed for wood or brass. Tannic Acid gives a black precipitate with iron.

6. Coloring in balls is uneven. The roll spread out over 3 inches thick has a tendency to get hot and mawkish. A spread of 1½ inch covered with a white cloth, in a cool place, takes a good and equal color. There is no fixed time for this coloring or oxidation. The point at which to stop can only be determined by the eye. The color of the roll just before brisk firing is mere or less the color which will be found in the outturn.

7. Pungency or rasp and a light liquor accompany a green outturn; thickness and a dull liquor a dark outturn. Over-colored roll produces a soft tea. Care given to the withering ensures good color; care given to the roll ensures strength, but it will not ensure flavour. There is as yet no known method by which flavour can be fixed.

8. Leaf opened out to color requires a light re-rolling. If too heavy, this second roll will discolor the tips. A seetul pattee mat gives gloss and bloom.

9. Drying in the sun gives a black and tipsy tea but the liquor has a metallic objectionable taste.

10. Quick firing over all glow fires gives a brisker Tea than slow firing. The teas get softened over slow fires. The roll spread thick on firing trays gets stewed and dull:—it has been spread too thickly when the fires cannot be seen through contents of tray. When three quarters dried the trays can be safely, and with advantage to quality, piled up five deep in iron oven frames and the curing finished over slow fires. The risk of burning is thus avoided.

11. One and a quarter maunds of charcoal to one maund of Tea is ample for Teas cured as above.

12. Pucka battying develops nose or aroma. Drying in the sun before packing completely desiccates the Tea, but gives it a peculiar and dangerous flavour.

13. Bulking is better before than after pucka battying to ensure the Teas being packed hot.

14. Tea rubbed over and through iron or brass sieves becomes nearly white. Grey leaf is caused by smashing through the sieves instead of breaking with the fingers. Bamboo sieves preserve the bloom but the process is slow and costly.

Of course our readers are aware that "pucka battying" means final firing, and as regards what is said about treating large and small leaves separately, we may remind planters, that, while Mr. Megginson of Carolina separates the partially-rolled leaf in a coffee

* Leaf grown at high altitudes seems to require longer rolling.

pulper sieve, Mr. T. Gray of Maskeliya sifts the leaf when green and professes to be successful in the operation. Which is the preferable process? or are there any objections to both? or either? Mr. Dowling, it will be seen, did not believe either possible. We need not copy what is said about "Mensuration" and "Nails," but we may say that for Nurseries Mr. Dowling states, that, if the seeds are 3 inches apart, 12 maunds per acre of nursery ground will be required; while, if 1½ inch is the distance, 18 maunda will go in an acre of nursery. No preference is expressed, at which we are naturally surprised. In "Paints and Oils" we notice that for an engine 1 pint coconut oil is equal to 1 quart of castor. Portland Cement, Polish, and Postage Rates we may pass over, but we quote what is said of pots for transplants:—

To prepare earth for making pots for transplants, add half a maund of fresh manure (½ maund if dry) to a maund of sticky mud, a quarter maund of charcoal dust, and five seers hay straw or doop grass chopped fine.

"Doop" is, no doubt, the doob grass, so plentiful in Ceylon. Prescriptions for fever and other diseases are given, some of which, for instance "Liq. Areen," ought certainly not to be administered except on the advice of a medical man. The story in Ceylon was that a former superintendent in Dumbura put an end to 30 coolies before discovering the proper dose of areenic! Amongst the miscellaneous information in this extraordinary book are illustrations of "Proof corrections." The rainfall for Rangonea estate for the months and years from 1875 to 1884 is given, from which we find, that, as in most other parts of Northern India, practically the whole of the rain is concentrated into the five months, May to September, much the greater portion indeed falling in June, July and August. Where rainfall is so unequally distributed the climate is generally insalubrious. The annual falls varied from a minimum of 73 inches in 1878 to 125 maximum in 1883. The average for nine years we make to be somewhat over 103 inches. There are useful recipes for a planter's everyday life quoted, such as to uncrow tight-fitting nuts and so forth. From the paragraph on Roads we see that the estates in Chittagong are assessed for roads at over half-a-rupee per acre. There is information about Shingles, Solder and Soldering Fluid, and also about tea seed which we quote:—

16,000 seedlings raised from the 30,000 seeds which a maund is supposed to contain, is a fair average to expect. Planting 4 feet by 4 feet, 2,722 seedlings fill one acre, and a maund of seed is thus about enough for 5½ acres of new land. There is an elaborate chapter on Soils and Manures from which we extract as follows:—

To know what our bushes extract from the soil, it is necessary to be acquainted with the constituents of green tea leaves, manufactured tea, tea extract, the spent leaves and tea ashes.

The leaves of the tea bush are all that are actually removed from the land, provided that weeds are buried, which in every case should be returned to the soil to keep up its fertility. The leaves contain a large proportion of water,* which is taken back by the soil from natural sources. All but about 5 per cent of this water is driven off in the process of firing the leaf, the residue, or manufactured tea, consisting of the following substances:—

In the extract or soluble part, or Liquor :—	Per cent.
Dextrine, glucose, gum, principally carbon	...17.55
Tannin	...11.00
Theine (the alkaloid of Tea, 28 per cent of which is nitrogen)	... 2.00
Nitrogen	... 6.00
Potash	... 2.75
Ammonia70
Chlorine and Sulphuric Acid	... a trace.
Essential Oil	... do.

* 75 per cent, or 3-4ths total weight, in case of tea flush indeed 80 per cent, if we count moisture which finally remains; in finished tea.—Ed.

And in the spent leaves, or insoluble part or outturn :—	
Water	5 00 per cent.
Woody fibre principally carbon	27 00 "
Legumen, a nitrogenous protein substance, sometimes called vegetable casein	15 00 "
Other protein albuminous compounds	10 00 "
Insoluble tannin and insoluble ash	3 00 "
	60 00

100 00 p. c.

Tea, it will thus be observed, is extraordinarily rich in nitrogen, so much so that the fresh leaves contain more nourishing protein compounds than beans and peas; and were it possible to render the coarse leaves palatable, they might be used as a nourishing article of food.

The whole percentage of the leaf need not necessarily be returned to the soil, as we have already seen that part of it is derived from the air. To determine approximately the substances actually extracted and which cannot be restored from natural sources, we must pay attention to the ash of manufactured tea, the analysis of which is :—

	Per cent.
Potash	3 00
Soda	10
Magnesia	30
Lime	25
Oxide of Iron	25
Protoxide of Manganese	05
Phosphoric Acid	80
Sulphuric Acid	a trace.
Chlorine	do.
Silica	25
Carbonic Acid	1 00

While the combustible or gaseous portions of the manufactured leaf are :—

Water	5 00
Nitrogen in the tea extract	6 00
" " insoluble spent leaf	6 00
" " Theine	50
Carbon	40 00
Oxygen	30 00
Hydrogen	5 00
Sulphur	1 50
	94 00

100 00 p. c.

The bulk of the carbon, oxygen and hydrogen of the above being supplied by the air, and existing so plentifully in good tea soils; and the quantity of soda, magnesia, lime, oxide of iron, and manganese extracted being comparatively insignificant, we need only pay attention to a re-supply of the other substances, nitrogen, potash, sulphur and phosphoric acid; the two former, nitrogen and potash, being those of most importance. There being 12½ lb. of the former and 3 lb. of the latter in each 100 lb., it therefore follows that a yearly produce of 400 lb.* removes from the soil 50 lb. of nitrogen and 12 lb. of potash per acre. Cowdung and lised, or castor cakes are the only manures which so far have been used to any extent by tea planters, and with considerable success so far, as a re-supply of nitrogen and some of the soluble salts is concerned; but neither of these manures contains potash.† It will be an assistance to have a simple test for this last named valuable ingredient. Chemical text books may be sought in vain for any but the most elaborate means of detecting its presence; but I find that for a rough test it is sufficient to stir into the tea infusion (in a wine glass) as much tartaric acid as will cover the point of a pen knife (part of the contents of the white packet of a seidlitz powder will do), when a slight cloud will indicate a trace, and a precipitate an abundance of potash.

Were sea weed available in any quantity, it might pay to produce a manure from its ashes, rich in both nitrogen and potash. Such a manure, mixed with a small propor-

tion of bone ash and sulphate of soda, would be an efficient food for the tea plant, and would need to be applied in moderate quantities only, to keep the soil in condition. It would seem that tea leaves remove from the soil only about one-third or one-fourth the potash which coffee beans take away, the potash in high-class Ceylon plantations being so high as 50 and even 52 per cent. What was good for coffee, we may rely on it, will be good for tea: superphosphate, bone dust or steamed bones, castor cake, and especially cattle manure. If cow-dung cannot be cheaply produced, then we should think ammoniacal, substances, such as dissolved guano, or nitrate of soda, could be substituted. But the effect of returning all prunings and weeds to the stirred soil is wonderful.

We pass over Telegrams and Telegram Rules, with rules about Tea in Bond, Tea Consumption and Tea Lead. From a table showing working of tea companies in 1883, we find that production per acre varied from 231 lb. lowest to 617 highest. The profits were not, however, in proportion to yield. The tea in the case of the large yield cost 10½d per lb. and sold at only 11½d. In the case of the highest profit £9 3s 7d per acre, the cost of production was 1s 1d, but the tea sold for 1s 8d. Of 23 Companies included, four made no profit, while only five realized between £5 and £9 per acre. The others were below £5, down to £1. But in many cases the profit was calculated upon excessive capital expenditure per acre, so high in one case as £143 per acre. There is an interesting notice of the rise of the Indian tea industry, which we need not repeat. But it is well to recall the fact that the Committee of eleven Europeans and two natives appointed by Lord Wm. Bentinck in 1834 ascertained that tea was indigenous from Suddia in Assam to Yinnau on the border of China. The first public Company, the Assam Company, was formed in 1839, so that really it is not yet half-a-century since private enterprise engaged fully in tea culture in India. But nearly 70 millions of pounds will be produced in 1885. Mr. Dowling's article concludes thus :—

The future of tea is a subject to be approached with diffidence. Prices have fallen to a figure at which only the best concerns can work with profit, and, if the lowest point has not yet been reached, there is a bad time ahead uncomfortable to contemplate. There is room for any amount more of Indian and Ceylon teas in the consuming markets from the circumstance of their being of better quality than their China rival, but the question is, will the consumer, accustomed to cheap China mixtures, give a price to pay the grower of the pure Indian article? In the meantime there is the consoling fact that the consumption of tea is increasing and that of intoxicating liquors decreasing. Poor China stuff held its own fairly well in the good days of pure malt; there need be no fear then of wholesome Indian tea competing successfully with the mixtures of distilled rice, strychnine, juniperberries, turnips and petroleum which now-a-days are sold in fancy labelled bottles under the delusive name of "wines and spirits."

The question of the abolition of the exorbitant duty of 6d a lb. has never yet been taken in hand in earnest, and probably will rest till it is realized that the only effective blow to strike at the root of intemperance is the introduction of a "free breakfast table."

Production will no doubt right itself like every thing else. If gardens producing 3 maunds of tea an acre find it hard to pay their way, those turning out less than that quantity must close sooner or later unless very favorably situated as regards labor and transport. It is a question of soil, and, as we all know, there are thousands of acres, which some day, when shareholders have had enough of them will revert to jungles unremunerative and worthless. In a description of brick tea, it is stated that the mæs is sprinkled with *françes pane!* The temperature of the Agonea estate is given new, instead of in connection with rainfall, and we find that the extremes are 46° at 7 a. m. in January to 91° at noon in July. From April to August the

* Dry tea no doubt.—Ed.

† Castor cake contains a good deal of potash.—Ed.

temperature is never below 80°, so that this must be the great flush season, the rains and the hot weather being nearly coincident. The extremes of temperature are about the same as those obtained at 4,600 feet in Dimbula, Ceylon, only Mr. Heelis observed cold once below 45° and no heat higher than 89°. The mean temperature of the estate in Chittagong must however, be at least 5° higher than the 65° obtained at 4,600 in Dimbula. The difference between the two districts we have mentioned (the one in Northern India, the other in Ceylon) may be imagined from the fact that Mr. Dowling quotes a tide table as useful to planters in Chittagong. A Bengalee table of divisions of time is also given, from which we gather that a week is *hopta*, a month *mahina*, and a year *butsur* or *sal*. We now come to the notices of forest trees, the greater part of which, according to the introduction, were mainly supplied by Mr. A. F. Bruce, in connection with *Mimosa stipulacea* (*Albizia stipulata* or Assam sau) it is stated:—

I have not been able to identify with any native of Chittagong the tree recently described by Mr. Buckingham in his paper regarding "The Sau Tree, and its remarkable influence on the tea bush." I thought at first that this tree (*Albizia stipulata*) was our koral (*Albizia procera*), but the leaf is entirely different, nor is it our Chukwa (*Anogeissum Acuminata*), the latter being a soft, while the Sau (or Sow)* of Assam is described as a hard wood. There is a Sau in the Botanical Gardens at Calcutta (Roxburgh Flora Indica 419) which it would be worth the while of visitors from Chittagong to examine to see if we have the tree here. It may possibly be the *Tettooya* which is a scarce *Albizia* seldom found in the gardens. At any rate there will be no difficulty in identifying it in a year or two, as there is a good show of young seedlings at Kodala and Agonea raised from seed supplied from Assam, and I may mention that they are growing up remarkably like the *Dividivi* seedlings grown from seed supplied to me by Mr. T. G. Burnell of Oodaleah about the same time. From close observation it would seem that tea generally is better (at any rate greener) under the shade of the *Acacia*. At Agonea there is some very good tea near Korais, while at Waga Surrah the best tea in the garden is shaded by an unusually large Chukwa. The peculiarity of the Sau, as I understand it, is that it has a beneficial effect on the soil, and I can well imagine this chemical action is possible, for in Chittagong we know to our cost what a baneful influence some trees have on the soil. The Assur injures tea near its base. The banyan, though innocuous to plant round the stem, yellows the bushes many yards off. The Gurjon, Hoojia, Chamlash and Mango weaken the soil. The Badhi Pecala exudes an odour from its roots which poisons the plant for some distance round, while the Doomir (fortunately rare) kills the plant outright at the time when it bears figs on the bark of its stem in February-March. It is only reasonable to suppose then that some of the *Albizzias*, apart from any benefit derived from their light shade, have the capability of improving the soil. If there are trees which deteriorate the land, we may naturally look for others which better it, and the thanks of the planting community are certainly due to Mr. Buckingham for making generally known the advantages and beneficial influences of *Albizia Stipulata*.

Then comes a long list from which we gather that a tree called "Assur" injures tea bushes; that "Pecala" has poisonous roots; that the banyan, although soft and useless and injurious to tea, makes good ash for manure. Toon timber is, of course ranked as good for tea boxes, but *Ficus glomerata*, while it can be converted into charcoal, is bad for tea; another fig is simply dismissed as useless. Some trees yield sweet berries, others dyes or tanin, and "fribi-fige bark" is against a number. Hocjia, like the banyan, makes charcoal but injures tea. The name "*Cassia fistula*" is, in this list, applied to a red-blossomed tree as well as to the yellow-flowered. *Lagerstromia regina* is described as good for "ships and piles."

* A wretched punster insists that the value of the sow tree is due to its litter.—Ed.

It is an important forest tree in Northern India. *Gloditschia sinensis* is hard, makes planks and charcoal, and is "good for engine firewood." Opposite *Sterculia villosa* is the warning "avoid for charcoal," but rope is made from the bark. *Amoora roh-tuka* (?) must be a marvel of a tree, yielding posts, planks, canoes, boxes, and illuminating oil. It is new to us to learn that the leaves and bark of *Ficus religiosa* (the bo-tree) are medicinal. The palmyra is "used for drain pipes," not a word about raffers or reppers. We learn that the wood of a guttapercha tree *Dichopsis polyantha*, (?) is "appreciated in England." The cotton tree, *Bombax Malabaricum*, is soft but makes planks and tea boxes. "Avoid for charcoal" is opposite wild mango, but the berries are eaten by deer. There is actually a gigantic mango-creper.

The peculiarities of the Chittagong vernacular, a dialect of Bengalee, are set forth, and a vocabulary by Mr. Watson follows, from which we gather that "You will start the tea-house work" runs: "Tu'i cha gharer khas doro." "When the dak wallah comes, tell him to leave the newspapers at the bungalow, and bring all the letters to me wherever I may be": "Dak wallah aile khabbarer (news) kaghun buglat raitke rho, aur beg chitti ar kasti an ja jaibo." Children are "fooaal," while a good English equivalent for bones is given in the word "hardi." There seems to be no objection to mention a mother-in-law, for we get "How is your wife's mother?" in the shape of "Tur sasuri kemas asi?" Mouth is "mukh," the original of the slang "ugly mug." A maternal uncle is "mama"! wife is "bo"! and grandmother is "dadi"! There is an elaborate table of wages for a month of 23, 29, 30, and 31 days in rupees and their parts in Indian money. At Chittagong, we are told under "Waste Land Lots," the "Pioneer" garden under the auspices of Government was opened in 1840, but Mr. D. Fuller is held to have really started the tea enterprise in the district in July 1864. Tea planting in Chittagong is, therefore, just of age. It is complained that planters are excluded from the hill tracts, English and Indian weights and measures are given, and it is stated that "galvanized wire-netting No. 12, of 33 inches, has proved the best for firing trays, brass wire being too expensive and bamboo work being rapidly charred." Firing over charcoal in choolas is, of course, referred to. So ends the printed information of the "Notes," some fifty leaves of good blank paper being added for each planter to enter his own notes as they occur to him, a good idea, as is the book altogether, which planters would do well to have on their shelves or table.

INSECT DESTROYERS.—A correspondent to the *San Francisco Call*, quoted in the *Oil and Drug Reporter*, says, that "after a long series of experiments, I have at last practically confined myself to the one cheap article that seems to be absolutely effectual." Concentrated lye is efficacious, but too expensive; whale-oil soap has also good effect, but a decoction of tobacco is simple, inexpensive, and, if properly applied, an effectual remedy for every class of insect-pests. Forty pounds of good strong leaf tobacco, thoroughly boiled in water, will make about eighty gallons. This can be thrown upon the trees with a powerful garden syringe. It should be kept at the uniform temperature of 130° to 140° F., while it is being used; hotter than this would be injurious to the plants. The cost, however, of this insecticide here, prepared from the duty-paid tobacco, would be much greater than in countries where the tobacco is grown. The same writer observes that every keeper of an orchard must grow his own tobacco, which he can do, in a small way, at a cost of two cents per pound. One acre will produce 4,000 lb., if properly attended to.

ANALYSIS OF RAINWATER FROM DIKOYA
BY MR. JOHN HUGHES, F. C. S.
Planters' Association of Ceylon, Kandy,
10th July 1885.

SIR,—I beg to enclose for publication corresponding with Mr. John Hughes, F. C. S., with his interesting report of the analysis of a sample of rainwater collected by Mr. Giles F. Walker of Dikoya during the south-west monsoon of 1884.—I am, sir, yours faithfully,
A. PHILIP, Secretary.

Planters' Association of Ceylon, Kandy, 15th April 1885.
John Hughes, Esq., F.C.S., Analytical Laboratory, 79, Mark Lane, London.

Dear Sir,—Referring to your letter of the 9th May last, I beg to enclose steamer receipt for a case containing rainwater collected by Mr. Giles F. Walker of Dikoya during the south-west monsoon of 1884.

Mr. Walker remarks, that, as this monsoon was so very mild compared with what the south-west generally is, the analysis of this water, he fears, will not fairly show the amount of salts we get when we have persistent heavy winds from off the sea for days together. But, as, owing to the unusually light rainfall, it has taken a great many days to give the amount of water required the analysis will be useful for comparison with that of the rainwater last sent by him, which was collected on only eighteen days as against fifty-seven this time. I annex table of rainfall during the period in which the water was collected for your information, should you consider the analysis of the sample of practical value for the purposes in view.—I am, dear sir, yours faithfully,
(Signed) A. PHILIP.

Rain-water 6 bottles—about 1 gallon, collected at St. John Del Rey, Bogawantalawa, Ceylon, by Giles F. Walker. Elevation about 4,300 feet above sea-level.

The water was collected during the S. W. monsoon between 15th July and 2nd Oct. the rainfall being as follows:—

1884.—July 15th .44 inches, 16th .05, 17th .17, 18th .03, 23rd .25, 24th .07, 25th .03, 26th .04, 28th .05, 29th .06, and 30th .02 inches; August 2nd .40, 3rd .50, 4th .29, 5th .10, 6th .38, 7th .30, 8th .53, 9th .36, 10th .10, 11th .26, 12th .07, 19th .05, 20th .24, 21st .11, 22nd .25, 23rd .15, 24th .23, 25th .50, 26th 1.14, 27th .60, 28th .30, 29th .12, 30th 1.9 and 31st .04 inches; September 1st .52, 2nd .08, 3rd .14, 7th .06, 8th .47, 9th .24, 10th .10, 11th .04, 14th .08, 15th .05, 17th .56, 18th .60, 19th 1.82, 20th .12, 21st .12, 22nd .18, 23rd .02, 25th .07, 28th .05 and 29th .02 inches; October 1st 11, and 2nd .07 inches. Total 13.97 inches.

Remarks.—The S. W. monsoon during 1884 has been exceptionally mild, the rainfall having been much below the average, and high strong winds only occasionally prevailing, and then but for short period. (Signed) GILES F. WALKER.

To the Secretary of the Ceylon Planters' Association.

Analytical Laboratory, 79 Mark Lane, London, E. C.
June 12th, 1885.

A. Philip, Esq. Kandy.—Dear Sir,—I have much pleasure in sending you the results of my analysis of the six bottles of rainwater sent by Mr. G. Walker and referred to in your letter of the 15th April.

From the interesting particulars of the daily rainfall which you have forwarded, it appears that the sample analysed represents the rain registered between the 15th July and 2nd of October a period of 79 days and amounting in all to 13.97 inches. Of this the greater portion was made up of small showers varying from .02 of an inch to .60 except on August 20th when 1.14 was recorded, and on September 19th when 1.82 was registered. The analysis shows that the water so collected was not specially rich in ammonia compounds, while the mineral salts, usually brought by the bursts of the S. W. monsoon, are not at all considerable, as indicated by the small quantity of chloride of sodium. Indeed most of the mineral matter consisted of finely divided earthy matters which in the form of dust naturally must get into the receiving vessels during so long a period as 79 days. I should like to know whether Mr. Walker has made any notes respecting the prevalence of thunder during the time this sample was being collected.

From the absence of nitric acid in appreciable quantities, I am led to conclude that there was not much thunder between the dates of collection named above, but I should be glad of information on this point. The question of how

far leaves have the power of absorbing nitrogen from the atmosphere has recently had some new light contributed through the valuable researches of Mr. W. O. Atwater of Middletown, Connecticut, who maintains that some experiments made by himself clearly prove that electricity exercises a most important effect in promoting the assimilation of free nitrogen by plants. I may add that if further experiments confirm Mr. Atwater's results, we may assume that the absence of electricity in the experiments of Boussingault, Pugh and others may probably explain their failure to solve this important problem, and to fully understand how the atmosphere which consists of 4-5ths of nitrogen should be the original source of supply to the whole vegetable world of the most important element of food.—Believe me, yours faithfully, (Signed) JOHN HUGHES.

Analysis of a Sample of Rain Water sent by Mr. Giles Walker of Del Rey Estate, Bogawantalawa, Ceylon. Elevation about 4,300 feet above sea level collected during the S. W. monsoon between 15th July 1884, and 2nd Oct. Total rainfall 13.97 inches.

An Imperial Gallon contains on evaporation solid residue dried at	110 at = 2.89 grains.
Consisting of	Per gallon. Per acre per every inch of rain
Organic and Volatile matters 1.63	= 5.264 lb.
Mineral matters	1.26 = 4.069 "
	Grains 2.89 = 0.333 "

Also by direct determination:—
Containing Free Ammonia .001 grains = .003 lb.
Albuminoid Ammonia009 " = .029 "
Chloride of Sodium217 " = .700 "

This water appears to have been most carefully collected and preserved for analysis free from any large quantity of extraneous matters. It contains very little ammonia and no appreciable quantity of nitric acid. The proportion of mineral salts is also very small, though somewhat more than in the sample reported in November 1883.

(Signed) JOHN HUGHES.

PLANTING IN NETHERLANDS INDIA ;
DELI, BORNEO, MACASSAR.

By last advices from Macassar coffee leaf-disease has appeared in the northern districts of that province which had been hitherto almost exempt from it.

Messrs. Van den Bossche, Menten and De Meyer, as well as the N. I. S. N. Company and the Factory of the Netherlands Trading Company have, on application, been granted leave by Government to secure concessions from the native authorities in East Borneo for working coal mines, without having to refund to Government the expenses attending official survey of the mining selections, and with permission to stipulate with the native chiefs for exemption from import and export duties. No limit is even fixed to the area of land selected, provided it be proved that extension of the boundaries of the selections is called for to further mining operations, the limit hitherto being 2,000 hectares or 4,940 acres. These unusually favourable conditions are ascribed to powerful influence having been brought to bear at the Hague in favour of the concessionaries.

Mr. J. T. Cremer, in an article in a Dutch Magazine on Kling coolie immigration into Deli, thus points out how it is that the abovementioned class of labour is in demand there:—For tobacco growing, properly so called, Chinese coolies are unsurpassed. Their wages are in a great measure dependant on their zeal and care which can only be gauged after the crop has been gathered in. Their calculating turn of mind prompts them in hope of high pay to bring under cultivation as much land as possible, for this purpose to work at the land in the cool of the night by moonlight, to lay their nurseries carefully out, and put the young plants out judiciously, to clear the growing crops of caterpillars and suckers, in short to do everything in their power to turn out as high a yield as possible of the best quality. Ex-

periments made to bring Javanese, Klings and Battaks, to plant tobacco in the same way, have all failed owing to these people looking no further than meeting their daily wants, and troubling themselves less about the future than their fellow coolies from the North. There is every reason for deeming that had the planters no Chinese coolies available for their tobacco estates, Sumatra tobacco would soon lose its high reputation or become a thing of the past. But it is just because the Chinese are so exactly suited for this kind of cultivation that it is of the utmost importance that their energies should be as much as possible exclusively directed hitherto, and not to be largely wasted in many secondary operations inseparable from the work in hand, such as roadmaking, drain digging, jungle felling, housebuilding, carriage of budding materials and tobacco in bullock carts, &c. For such kind of work, labourers of other races are more suitable. But Klings are also particularly required on the East Coast of Sumatra for other kinds of crops than tobacco, it being hard to get Chinese to grow them. As it were from of old, the Chinese are in Deli inseparably bound up with tobacco growing. The more they earn by it, the better for the planters. They understand full well that no other branch of cultivation can yield them such advantages. Tobacco is what draws them from China. Were Kling immigration in the East Coast of Sumatra to be secured, and were it to result in colonization by great numbers of that useful race settling down with their wives and children, coffee cultivation would be as practicable as in Ceylon, and sugar growing as easy as in Province Wellesley, to say nothing of many other industrial and planting pursuits. Hence what Deli planters want is the importation of as many labourers as possible of different races so as to give each race a sphere of work suiting it in particular, to bring out as much as possible the inexhaustible productive wealth of their estates, and to settle a permanent population on the land alongside a population which though steadily keeping up in number is still a floating one.

CEYLON TEA.

(Written for the "Grocer," by Mr. John Hughes, Chemist.)

Of late years Ceylon Tea has attracted so much attention, and the competition at the Mincing Lane sales for specially favoured brands has been so keen, that the eye of the capitalist, as well as that of the struggling planter, has been directed to Ceylon with a view of obtaining a profitable investment. To all such, as well as those interested in the production and manufacture of tea we would recommend the careful perusal of a little pamphlet on *Ceylon Tea* published by A. M. & J. Ferguson, Colombo, and which may be obtained of Messrs. Haddon, Bouverie Street, E. C.

The book contains valuable information respecting the most suitable soil, the selection of seed, the preparation of the land and the cost of same; also details respecting the enormous yield obtained on certain estates amounting to as much as 800 to 1,000 lb. of made tea per acre.

But side by side with this, we find words of warning to the young and inexperienced and a caution to those new to the island which will be doubtless fully appreciated by all who may be thinking of going to Ceylon with a view of trying their fortune. The healthiness of the tea gardens on the Ceylon hills at an elevation of 4,000 to 5,000 feet is proverbial and much in favour of the young planters as opposed to Assam.

Special attention appears to be paid to the process of preparing the tea leaf for market, the fermentation of the leaf, withering and firing being carried on with every attention to scientific accuracy and with the aid of the most improved machinery. At the present time there is a demand for experienced men who can super-

* Nothing in our brochure indicates this: we said there was room for capitalists. Ceylon has abundance of superintendents for all "tea" work at present: later on the case will be different.—ED.

intend the manufacture, and take charge of depôts on the main roads where the green leaf is purchased from neighbouring planters day by day; for it is an advantage that tea should be made on a large scale, the various qualities being sorted out as soon as received for special subsequent treatment.

Time and space prevent us from going more fully into a review of this little pamphlet, but to all those who may think of embarking in the Ceylon Tea trade either as planters or merchants we would recommend a perusal.

CACAO AND CINCHONA BARK IN CEYLON.

Our plantations of Cocoa have undoubtedly suffered greatly in some places—notably Dumbara—from *Helopeltis*. The preventive, it is now indisputably demonstrated, is to supply shade which at once stops the insect ravages. An interesting experiment is mentioned to us where a planter erected a temporary pandal over some rows of his cacao trees in an almost leafless field. So soon as the bare trees began to throw out shoots or fresh leaves, in the open, the *Helopeltis* at once disposed of them; but, under the artificial shade even, the trees soon became green and vigorous and untouched by the pest. In some cases where Ceará rubber has grown up into large forest trees, the cacao under the same flourishes untouched. Cacao-planters in Ceylon have therefore practically settled the question, and their cultivated fields will soon be all under shade; but the same amount of crop cannot be expected from the trees shaded as was got from the trees in the open before *Helopeltis* appeared: one-half last year's crops is the estimate, and yet the cultivation should pay well. From Malala and Western Dolosbage we have favourable accounts of the cacao; in the latter, it is being in some parts interspersed with tea which in that climate is regarded as the great staple of the future. As regards cinchona, we have the opinion of a planter who has been keeping his eyes open while travelling all over the country, to the effect that Ceylon can supply all the demands of the European and American cinchona bark market for many—perhaps 20—years to come, from the trees now growing on our plantations! This, however, is contrary to other opinions which indicate that with no fresh plantings, our exports must run down ere long. We suppose that if prices prove remunerative, Ceylon can continue to send, at least, 10 million lb. of bark for a number of years to come.—A good deal of interest is excited by the satisfactory coffee crops gathered this year not only in Uva, but in isolated cases in the Dimbula and Dikoya districts. A crop of 4,000 bushels (800 cwt.) from 200 acres of coffee in Dimbula is very satisfactory, and it is asserted that with proper attention to cultivation, this may be continued over many fields, especially if they have an eastern exposure. At the same time everything seems to have taken a turn of late: even the grass, which could not be got to grow satisfactorily of late years, has been flourishing this season.—Tea is, of course, growing everywhere, and although there is a check in the shipments for the present, any deficiency will soon be made up.

TEA.—Some idea of the extent of the competition in the retail tea trade may be gathered from the following announcement displayed in the window of a Glasgow tea shop:—"Tea for Nothing! One Pound of Tea for Nothing!—We are now selling this very fine blend of Indian and China tea at 2s per lb. In every fifth pound parcel there is enclosed 2s; every fifth half pound parcel 1s; and every fifth quarter-pound parcel 6d. The fortunate purchasers of these particular parcels shall have their pound of tea for nothing."—H. & C. Mail.

COCAINE, the new anæsthetic, is a colorless fluid not unlike glycerine. Under its effects a patient at a hospital the other day submitted to the ball of his eye being punctured by a delicate spear-head knife, and in its place a small suction pump inserted, which brought out some pus from a sac which the knife had punctured, and all the while the patient, mentally conscious, chatted pleasantly with the operator, as inensible of the operation as though it were being performed on his hat band.—*American Cultivator*.

TEA.—The report of the Central Tea Industry's Association indicates a disastrous diminution of the product, this year, and announces that the total yield will not exceed one-half the amount of ordinary seasons. The chief causes of the decline are said to be the exceptionally severe winter and spring, and the inability of the tea-growers,—through poverty,—to provide manure and proper protection for the plants.—*Japan Weekly Mail*.

The experiment of Mr. J. C. Douglas, the naturalist, with imported Italian bees, has been crowned with complete success. The bees seem to thrive perfectly in Calcutta, and have yielded during the season, up to date, eighty pounds of splendid honey. The honey is taken straight from the centrifugal extractor, and without being strained or manipulated in any way, is pure, clear, fragrant and delightful to the taste.—*Madras Mail*.

MEXICAN COFFEE.—In Mexico, in the isthmus, on the Banks of the Coatzacoalcos, wild coffee is found in great abundance, the quality of which is said to be superior. It is claimed by a writer for the Mexican press that the actual cost of raising coffee under favourable circumstances is not less than \$5 per one hundred pounds. Adding \$2 for interest on capital invested, the outlay will be \$8. The inaccessibility to market makes the general cost of production average from \$10 to \$16 to place one hundred pounds in market.—*American Grocer*.

JUNGLE TEA AND THE TRUE TEA: DIFFERENCE IN SERIATURE OF LEAF.—Mask-lyja, 9th July.—Agent Mr. Hay's letter on "Jungie Tea," the difference between it and the real Simon Pure is that the jungle tea leaf is "serrated" from top to bottom and the real article stops about $\frac{2}{3}$ of an inch from the bottom of the leaf. This was pointed out to me by a friend who knows a little about plants and their habits. He also told me the two could not hybridize: their seeds are so different. By the bye I see in your London Letter of a Mr. Gow bringing out a tea wither and drier, and I see in a home paper a Mr. Dick has taken a patent out of a machine for withering and drying tea leaf, and some one or two planters here are off their food and sleep inventing a wither; so we will be well to the front by-and-bye.—*Cor.*

SQUIRRELS AND HELOPETS IN CACAO.—Rangala, 10th July.—In the *T. A.* for July, page 46, you make the following remarks on "Squirrels and their Habits":—"We have seen the palm squirrels at Colombo not only pilfering grain meant for poultry but actually feeding on white-ants which had climbed up the root stem of coconut trees, so that the amusing little creature seems to be omnivorous." Now, is it not just possible that cacao planters have been doing harm by destroying the pretty little things? Perhaps the squirrels were the means of keeping down helopets, gobbling up the horrid insects as they gambolled from twig to twig. I would suggest that a few squirrels be shot near spots where helopets is bad and the contents of their stomachs be carefully examined to find out if they preyed on the insects. I believe immense numbers of squirrels have been destroyed on cacao plantations.*

* We fear it is beyond question that they are very destructive to young nuts.—*Ed.*

TEA.—A Company has been started in London for the sale of Indian tea, a fact, says a London correspondent, which will rejoice all those who know how thoroughly superior Indian tea is to Chinese or at least to the Chinese tea that we get in England, and who have experienced the usual difficulty in obtaining pure Indian tea. "Nearly all that is imported has hitherto been bought up by dealers to mix with the Chinese and give it flavour. Most of the persons with whom one talks on the subject will say: 'Oh! but Indian tea requires to be mixed with Chinese before it is drinkable.' There never, of course, was a greater mistake. Had they reversed the proposition, it would have been true enough, for Chinese tea is hardly drinkable without a certain admixture of Indian. The new company hails from Keymer's in Whitefriars-street. They receive their teas direct from the Kangra Valley, Darjeeling, Assam, Kumaon, Noilgherries, and Cachar. They are sold here in tins containing five pounds and upwards, at 3s and 2s 6d per lb.—*Madras Times*, June 10th.

MANUFACTURE OF CINCHONA ALKALOIDS IN MADRAS.—Hitherto Madras was dependent upon Bengal for its supply of cinchona alkaloids; but since the appointment of Mr. Hooper, as Government Quinologist in Madras, it has been considered desirable that the manufacture should be carried out in the Medical Store Depot. For that purpose Mr. Hooper recently visited the Medical Store Depot, and, after an inspection of the laboratories, found that the appliances there could be adapted to the manufacture of the liquid cinchona on a large scale. The cost of the manufacture, taking the bark at the rate of the recent sales at Madras, and allowing the usual percentage for fuel, labor, &c., was estimated at Rs 0-9, per fluid pound. This will enable it to be issued at a price some 30 per cent. lower than the feebleness now obtained from the Government factory in Bengal for use in hospitals and dispensaries at this Presidency. Government, we learn, have now directed Mr. Hooper to arrange at once for the manufacture in Madras of 1,000 lb. of the fluid extract at 40 grs. to the ounce, and to personally superintend the operations. He has been asked to arrange, in communication with the Medical Storekeeper, for the association with himself and instruction of a competent person for the immediate superintendence of all future operations in Madras.—*Madras Times*, June 10th.

THE SILHET TEA DISTRICT.—Arrived at Silhet the visitor from Calcutta or Dacca will notice a diminished temperature. The hot westerly winds have given place to cool moisture-laden breezes, whilst the mercury stands at a figure some ten degrees less than that he has been accustomed to in Bengal. The approach to Silhet, as seen from the river on a fine day, is striking and pretty. With the great blue barrier of the Khasia Hills looming in the distance, groups of low jungle-clad hills in the foreground and near at hand, clusters of the beautiful feathery foliaged bamboo, mingled with the tall slender stems and swaying crests of the graceful betel-nut palm, combine with the bright green stretches of the rice fields and sheets of sun lit water, to form a picture worthy of the artist. But to the outer world, Silhet will be known not so much for the picturesqueness of its scenery as for the fact of its being a district in which the cultivation of tea is extending more rapidly, probably, than in any other part of the Indian Empire. Year by year there is an increase of the European community engaged in the industry; year by year large tracts of virgin forests give place to the neat rows upon rows of tea bushes, and if, as appears to be the case, the cultivation can be carried on at a cost with which less favourably situated districts cannot compete, then its future should be indeed a prosperous one.—*Calcutta Englishman*.

THE LARGEST MAT in the world covers the circus ring of the Covent Garden Theatre. It is made of unbleached coconut fibre, and has a soft pile four inches thick. Its weight is more than two tons.—*American Grocer.*

THE SWEET-SCENTED VERBENA.—The lemon-plant, or sweet-scented verbena of our garden (*Aloysia citrifolia*) holds a foremost place among Spanish herbs. Every leaf of it is treasured and dried for winter use, and it is regarded as the finest cordial and stomachic in the world. It is taken in two ways—either made into a decoction with hot water and sugar and drunk cold as a *refresco* and tonic, or, better still, with the morning and evening cup of tea. Put a sprig of lemon verbena, say five or six leaves, into the tea-cup, and pour the tea upon it; you will never suffer from flatulence, never be made nervous, never have cholera, diarrhoea or loss of appetite. Besides, the flavour is simply delicious; and one who has once drunk their pekoe with it will ever again drink it without a sprig of lemon verbena.—*Gardener's Chronicle.*

OUR PRODUCE IN THE LONDON MARKET.—A well-informed London correspondent writes to us by this mail:—"It is not supposed that prices for Bark will fall much lower than they are now in spite of the fall in the price of quinine recorded yesterday, namely 3s 6d for Howard's in oz. bottles. The supply from South America has entirely ceased, and the trade are now prepared to receive some 12- to 13,000,000 lb. from Ceylon by 30th September. Ceylon Cocoa is again realizing enhanced prices, while prices for good colour plantation Coffee have risen some 10s per cwt. in the last month. Common kinds about 3s to 5s during same period. The Cardamom market is a shade steadier."

THE KEELING ISLANDS.—"A Naturalist's Wanderings in the Eastern Archipelago." By H. O. Forbes, F. R. G. S. The first place visited by our traveller in his long circular tour was that extraordinary little coral archipelago, the Keeling Islands, long since made famous in scientific literature by Mr. Darwin. As no other tourist had visited the atoll for purposes other than those of strict business or by stress of weather since 1836, Mr. G. C. Ross, the king of the islands, was naturally gratified at receiving in fulness of time his first genuine morning caller. Mr. Forbes's account of this narrow ribbon of land, enclosing with a palisade of palm trees its calm lagoon, and thundered upon from without by the ceaseless rattling of an entire ocean, is one of the most interesting portions of a most interesting and valuable book. So tiny is this precarious wall of coral, rising sheer from the bed of the ocean, that as Mr. Forbes sat talking with his host on his first night far into the small hours of the morning, he could feel the very foundation of the land thrill under his feet at every dull boom of the surf upon the outward barrier. Yet wee as the islets are, they have none the less a romantic history of their own; rival dynasties have ruled over cookeys and cocoa nuts on their coral shores, and a glorified beech-comber has collected a harem of all mingled Oriental nationalities under the friendly shade of their remote palm trees. Mr. Ross himself, the survivor of the better line, has raised the Keelings into a little model patriarchal community, judiciously tempered with lathes and steam mills, and parentally overlooked by the benevolent proprietor and his wife and family. The purpose of Mr. Forbes's visit to this remote spot was of course to test the truth of the rival theories as to the origin of coral islands; and the result of his researches tend to show that the Keeling reef foundation has arisen in the manner engegeted by Murray, Somper, and Agassiz, but that the islets themselves are due to the combined action of storms, and the slow elevation of the volcanically upheaved ocean flooring.—*Fall Mall Budget.*

RICE CULTIVATION AND MANURE.—Mr. John Hughes, Analytical Chemist, writing on June 19th, says:—"With attention to irrigation works, Ceylon should produce more rice and a new industry be called into existence in the low country. Some thousands of tons of manure are sent from England to Spain annually for the growth of rice where irrigation is in full force."

THE LABOUR TRAFFIC IN THE SOUTHERN PACIFIC.—"Great excitement has been caused throughout Queensland," says the Brisbane correspondent of the London *Times*, "by the publication of the Report of the Royal Commission appointed to inquire into the conduct of the labour trade in New Guinea and the adjacent islands." The Report reveals awful iniquities: there is no question that South Sea labour traffic must be stopped, and as coolly immigration is not allowed, the Queensland sugar enterprizes, in which 5 millions sterling are embarked, will be ruined. As for coffee, tea, cacao, &c., these are all out of the question. If sugar kept up in price, however, white men might possibly do the work. The one thing that seems too much for them is the cutting and trashing of the canes under a tropic sun.

TEA PROSPECTS IN JAPAN are very poor, to judge by the *Japan Mail*:—"At this moment dollar prices seem to be about on the level of those of 1884 at the same period, but there, too, the loss of 10 per cent. on the exchange into *Kinsatsu* must be severely felt. The tea men also speak of a shorter crop than the last, owing to the damage done by late frosts, and to the poor yield of the shrubs in consequence of a deficiency of manure. And tea, no less than silk, has to contend with low prices in foreign countries. At last dates from New York, good Japanese tea was selling at 20 cents per pound, owing to small demand and the prospect of abundant supplies of Oolooongs from Formosa. If from this price he deducted the export duty, the packing and curing expenses, the freight, insurance and other charges, and the cost of manipulating the leaf, it is impossible that anything whatever should be left for the grower of the tea. Altogether it must be confessed that the outlook for 1885 is peculiarly dismal, and we heartily pity the poor cultivators who have to face it.

JAVA TEAS.—The aim of the tea planters of Java has been almost exclusively to secure a large out-turn per acre and a beautiful leaf: in both these they have succeeded, the produce per acre being nearly double that of the Indian gardens, and their finest teas being the most beautiful the world produces; unfortunately, however, quality in the cup has been almost entirely neglected, consequently, their teas enjoy and evil reputation with blenders, the general run being thin, oaky and earthy, and some of the lowest kinds are so sour and nasty as to ruin any blend however sparingly introduced. Of late years, however, some estate managers appear to have realized the wisdom of aiming at a higher standard of quality; seed has been imported from India, and improvements in cultivation and manufacture have been introduced with most beneficial results; but for some years to come Java teas will have to be very cautiously handled by blenders, and probably the wiser and safer course is to let them entirely alone, as the common grades are worse than useless, and, as a rule, even the better kinds rapidly "go off" if kept.

The classes of Java Tea are as follows:—

Whole leaf kinds.	Broken kinds.
Flowerly pekoe	Broken flowerly pekoe
Pekoe	Broken pekoe
Pekoe souehong	Pekoe dust
Souehong	Fannings
Congou	Broken tea
Bohea	Dust.

The chests used to be papered in a somewhat similar manner to Chinese packages, but from many estates they are now sent plain to resemble Indian chests, and some are so sufficiently unprincipled to actually mark the chest as containing Indian teas.—*Lewis & Co.'s Tea Circular.*

THE FUTURE OF TEA IN CEYLON.—The *Indian Tea Gazette* writes:—Very sanguine expectations are being formed as to this matter, which, for the sake of Ceylon itself, even, it is to be hoped may not be realized. We read as follows:—"The chairman of the Ceylon Chamber of Commerce, at the recent half-yearly meeting, dealt with the prospects of the staple products of the Colony, and went into a calculation showing that in a few years' time Ceylon would be exporting 52½ million pounds of tea." The "Chairman" is cautious in saying *how many* years he means by "a few." Ceylon, it is true, is going ahead in tea cultivation, but the anticipated leap up to 52½ millions in a presumably short space of time is rather too much, we should think, even for Ceylon ambition. Colonel Money has already sounded a note of warning as to over extension of tea cultivation in the Island, and we may trust to the common sense of Ceylon planters for restraining them from overdoing an Industry which, if limited to due bounds, may do much to recompense them for the failure of coffee. All extremes are bad, and a departure from reasonable caution, in the case of tea extension, would be attended by a collapse more serious even than that which the Island has suffered from coffee,—albeit the collapse might result from different causes. [The *Tea Gazette* should impress caution on tea-planters near home.—Ed.]

TEA AND FIBRES.—Maskeliya, 13th July.—We have had a very smart dose of the monsoon, but evidently not as much as down the valley: June measured only 33.43 here against Theberton 49 odd, and they must have had more wind. The early tea planting is coming on very, very well. The cold weather is against the old tea flushing now. In August, September and October it will come out; then prune. Our tea "boes," says, now is the time to prune, and also that tea bushes "should be plucked once a week." Surely this sounds too much. Will some of your experienced correspondents kindly answer this? I say old tea once 10 days; young tea (up to 3½ years) twice a month. To add to the general grumble on state of roads, you may now see the cartmen driving in a zigzag fashion actually allowing one wheel go on the grass, so as to keep the bullocks' feet on the smooth road and avoid the darned patches. It is cruelty to force any beast with cloven foot to pull a weight having loose, broken, sharpedged stone as a "footing." "Shuck" is a very common expression in the South of Ireland, and is applied to animals, cattle, horses, &c.; very lean or worn-out animals, "tinklers' donkeys," and horses; or more commonly to animals that have not been housed during the winter, only getting a little hay near a sheltered fence, are called "shuck" cattle.—Any fibre-yielding stuff must be very exhausting to land, and would require manuring in bulk heavily, would not pay out here I fear. Against the growing of flax on most properties in Ireland, there is a prohibitory clause in the lease as a rule, so much does it injure land, and *always* after such a crop the farmer *must* till the land again (take a crop of roots) before laying it down with grass seeds. Leaf-disease showing on our coffee again on some patches badly. I have found in planting at stake several of the 2nd plants a wild sort of tea, not in the very least like a *tea*, and on two occasions the kernel of the seed was still adhering to the plant when taken up; and when I mentioned it to another planter he declared it to be impossible, so there I let it rest. It was not a case of nursery plants, but planting at stake two seeds in each hole, the one a good jāt tea and the other a jungle or wild plant. If I can find any more, I will send them down to you. I am afraid, in supplying they have been removed. I am now convinced it was a cross of some jungle tree. Raining still—not heavy, and this year no great flood as yet.

COCONUT AND ITS USES.—Britannia needs no bulwarks," says the old song, and we shall need a new version for old Lanka, if her coconut palms should be found to yield a product so valuable for the defence of the British Navy as that referred to in the following extract. It is sent to us by a correspondent who believes it to be taken from the *Daily Telegraph*:—

It has been discovered in France that a composition obtained from pulverised coconut cellulose has the remarkable property, when penetrated by shot or shell, of closing up instantaneously, so as to prevent the influx of water into a ship's hold. The name of "cofferdam" has been given to this preparation, for which it is claimed that not only will it render harmless the perforation of a ship's sides by any projectile which strikes them above water, but that it will also disarm the torpedo of its submarine powers of mischief. For the present, it will perhaps be enough to watch whether the French have in reality made such a discovery as will enable them to line the armour-plates of their men-of-war with a preparation which is at once light and elastic, and also of a nature to forbid the admission of water into a ship's sides when riddled by shot and shell. If all that is reported of the Toulon experiments with "cofferdam" be true, the compound seems destined to solve the armour-plate controversy by turning the scale once more in favour of the swift or thinly-plated vessel. Having built up a target of cofferdam, made of a mixture of fourteen parts of pulverised cellulose, and of one part of cellulose in fibre compressed into a felt-like mass, the French inventor, lined the side of an iron-plated ship with a layer of the new compound two feet in thickness. Against this strange target a solid shot, seven and a half inches in diameter, was launched, with the highly-satisfactory result that the projectile carried away with it one-fifth of a cubic foot of the composition, and that, no sooner had the shot passed through the target, than the cellulose closed up so firmly that a strong man was unable to thrust his arm through the hole. A box or tank filled with water was then hung against the aperture; and after the lapse of fifteen minutes a few drops of the liquid began to trickle through the hole in the cofferdam. When the composition had been thoroughly saturated, not more than from three to five pints of water made their escape inwards in a minute, when they were intercepted without difficulty by a man armed with a pail. As soon as the cellulose had become completely soaked, it offered greater resistance to the percolation of fluid, which finally ceased almost entirely to flow. The spongelike texture of the target resisted the leakage of water through the hole so effectually that the breach closed up automatically. The results were the same whether shot or shell was employed against the target; and it was also discovered that, in addition to excluding water, the cofferdam was proof against ignition by fire. Red-hot coals were heaped upon the cellulose without setting it alight, and thus far appearances seem to warrant the conclusion that an iron-plated ship, lined with two feet of cofferdam, has nothing to fear, when perforated with shot, from either water or fire. "The experiments," says our contemporary, "seem to prove that the material in question possesses the property of closing automatically a leak caused by shot or shell, and of protecting a ship to a certain extent against fire." It will thus be seen that all maritime nations are vitally interested in ascertaining whether a backing of coconut cellulose is really calculated to render ironclad ships impervious to water when penetrated by a projectile launched against her by an enemy. Upon the importance attaching to this discovery it would be idle to expatiate, although we must be permitted to express the gravest doubts whether a cofferdam will ever be able to resist the fatal effects of a torpedo exploded under a ship's hull. In order to investigate this point thoroughly, we understand that fresh experiments are about to be tried at Toulon; but enough, and more than enough, has already been said to show that it would be the height of folly for the British Admiralty to close their eyes to the possible value of a discovery which may add enormously to the defensive efficiency of such a magnificent fleet of ironclad vessels as that with which Admiral Sir Geoffrey Horby is about put to sea.

"COPRA CAKE," says our Paris Agricultural Correspondent (in his monthly letter for the *Tropical Agriculturist* received by this mail), "is becoming a necessity for cattle feeding on the Continent, and two Companies are in course of formation to make plantations in Belgian and French Congo for the culture of the coconut palm."

TEA PLANTS IN BOMBAY.—Messrs. J. M. Mody & Co., the local agents of the Nassau Tea Estate, Kangra Valley, have recently imported into Bombay, at considerable expense a number of tea plants from the estate. The plants are, of course, of no practical use in this climate, but they are of interest to those who have never seen the tea plant growing.—*Times of India*.

HIGH YIELD OF TEA PER ACRE.—Unless there is some mistake in the figures the average yield obtained by the Doom Dooma Tea Company is almost twice the general Indian average. The statement is:—"The crop amounted to 925,147 lb., and average yield of the Company's plucking area of plants (viz., 1,450 acres) was 638 lb. per acre. The superintendent's estimate of the outturn for the current year, inclusive of the yield from the newly acquired Moiragorie garden, is 960,000 lb. of tea, with an outlay in Assam of 2s. 6p., or about 5d per lb., as compared with 6d per lb. the past season, and it is hoped that the total cost will be reduced to 10d per lb.—*Indian Tea Gazette*.

PLANTING IN NORTHERN AUSTRALIA.—The end of the venture of Messrs. Poett and Mackinnon and their supporters in the Northern Territory of Australia may be gathered from the following paragraph from the *South Australian Register*:—"Sale of Property in the Northern Territory.—Mr. W. B. Wilkinson has sold privately, to a small company of gentlemen interested in the Northern Territory, the estate in the Hundred of Goyder, County of Palmerston, known as Poett's Plantation. The property comprises 1,000 acres of freehold land, 82,793 acres of leasehold land. In addition to the bungalows, fencing and other improvements, there are nurseries containing 500,000 coffee plants and 70,000 cinchona plants in good forward condition. The whole of the property realized £1,220."

AGRICULTURE IN THE NORTHERN PROVINCE OF CEYLON.—Says the Jaffna "Patriot":—"Our Botanic Garden. We have none; and we cry shame on those who have not taken the trouble of establishing such an institution. The fact is we do not shout so lustily, as our friends in the Central Province; we do not grumble and kick up a dust, as our planters; and we meekly take whatever dole is meted out to us, so that we are left out in the cold and Government takes in our fat revenue and a very small proportion of it is spent in the Province. Barbarous Anuradhapura, just out of the shell, quite a weak chick in comparison to our Province, has its botanic garden. It makes us almost angry when we read the following in the report of Dr. H. Trimen, and see how Anuradhapura takes the shine out of us.*** Now the above is a downright outrage of all our rights and privileges. Taking our palmfruits to decorate Anuradhapura, and stocking it with flowers and ferns, and speaking of it as if it was the Northern Province, make us long to fight a duel with any one who would stand up for Anuradhapura, the bastard child of the Central Province, potted and spoiled with a lavish expenditure. Our late Government Agent Mr. Dyke in his broad views of the resources of the Province had a Botanic garden attached to his residence, and hence it is called the old Park. Trees of all sorts were planted in it. Fruits and flowers in abundance and by the ingenious contrivance of digging broad pits to the very level of water, English vegetables, as beet root, carrots, turnips, watercress &c., were all successfully cultivated. The gardens were open to visitors, and at the season all were welcome to partake the nectarine fruits, provided they carried none away. Our present Agent has endeavoured to keep up the grounds to the best of his resources, and without respect of persons all have received, for the asking, cuttings of flowers and

ornamental trees. Yet it is not to be expected that a private individual, having the claims of a family, can be expected to keep up a garden in such a way as to deserve the name of our Botanic Garden. A few acres of land in the interior where sweet water is in abundance, could be put in charge of our Forester, and a Native assistant, and the beginning of our Botanic Garden could be inaugurated. We have often wondered why under the head of Administration reports we do not see the reports of our Foresters. They seem to be all in the shade. The fact is, you have only to show yourself fond of out-door exercise, and have some influence with those in authority, then when they cannot do anything for you they will make you a Forester. An apprenticeship at least for a year under Dr. Trimen, Government might require, just to let the public, who pay them know that they are at least receiving somewhat of a qualification to be able to discharge their duties with efficiency. Of late we have heard very frequently of the scarcity of jack-wood, teak and mahogany, while ebony is nowhere in the province; and this too to such an extent, that our carpenters refuse to undertake work on contract with such wood, as their rarity and high price prevent them to execute the work with anything like profit. The natives of Jaffna delight in getting up Botanic Gardens. We know men who are extremely clever in grafting. We have seen the common cabbage rose trees grafted with tea rose, the common white rose and the pride of Franco. A single shoe flower tree has been grafted with a variety of the species in all kinds and shades of their colour. A garden of roses in Jaffna, where they grow so well, and give a sweeter odour than roses in the Central Province would heat out anything Dr. Trimen can attempt in Anuradhapura, or accomplish in Peradeniya. Give us the chance, and we will beat you hollow. If ever a Governor desires his memory to be preserved in attar of roses let him give us a Botanic garden. Sir James gave us a Town-clock, which as the Psalmist says of dumb idols, they have tongues and speak not; they have hands and handle not, feet have they and walk not; neither speak they through their throat. It is only a mass of dead machinery for which we have erected a long den in a cylindrical form, erect and tall costing us no end of money."

TEA IN CEYLON.—The *Standard* of Monday last contained an advertisement for an Assistant Superintendent on a Ceylon Tea Garden which was described as being 4,000 feet above sea-level, and in a delightful climate, etc., etc. The proprietor undertook to teach his assistant all that appertains to the cultivation and manufacture of tea, and to pay him R100 per month for the first year, R125 per month for the second and R150 for the third year, after which he was to have the management of the garden, and all these advantages were to be secured by payment of a premium of £200. My attention was called to this advertisement by a young fellow who thought it presented a favourable opening in life and whose parents were quite willing to find the required premium. He asked my advice as to the advisability of closing with the offer, and I felt bound to tell him that it was not the custom of Ceylon planters to require a premium with their assistants, and that I thought it probable the advertiser wanted the money, rather than the man; but one could better judge of this when he had found out who it was and what were the circumstances of the property. My friend argued that in every business or profession a premium had to be paid by the artful pupil, or apprentice, and he did not see why a tea planter should be an exception to the rule. This is sound reasoning, and I do not see why an experienced and efficient planter should not get a premium with his assistant on the lines laid down in this advertisement, provided, of course, he is prepared to give full value for the money and is certain of being able to carry out his part of the bargain; but I think you will agree with me that great caution should be exercised by parents or guardians before closing with such offers in the present circumstances of the planting enterprise. I am told that in this case the advertiser received nearly 100 replies, all relating to young men who were at all events ready with the money. It is evident, therefore, that the premium would not stand in the way, if the planter can show a fair *quid pro quo*.

INSECTS AND AGRICULTURE.

In the primitive condition of the country, as the white man found it, insects, doubtless, took their proper place in Nature's economy, and rarely preponderated in any direction to the injury of the wild plants, scattered, for the most part, sparsely throughout their range. Harmony between organisms, in the sense of the widest inter-relation and inter-dependence, had resulted in the long course of ages. But civilised man violated this primitive harmony. His agriculture, which is essentially the encouragement and cultivation, in large tracts of one species of plant to the exclusion of others which he denominates weeds, gave exceptional facilities for the multiplication of such insects as naturally fed on such plants. In addition to this inevitable increase of species thus encouraged, many others have been unwittingly imported from other countries, chiefly through the instrumentality of commerce with those countries; for it is a most significant fact that the worst weeds and the worst insect pests of American agriculture are importations from Europe. Thus, in addition to the undue increase in our native species, as above noted, we have to contend with these introduced foreigners, and it is no wonder that Dr. Fitch declared America to be the land of insects, for, as compared to Europe, we are truly bug-ridden. As I have stated (*Encyclopedia Americana*, "Agricultural Entomology"):—"The losses occasioned by insects injurious to agriculture in the United States, are, in the aggregate, enormous, and have been variously estimated at from 300,000,000 dols. to 400,000,000 dols. annually. It will never be possible to fully protect our crops from the ravages of the many species that injuriously affect them; but it is the aim of the economic entomologist to prevent as much of the loss as possible, and at the very least expense. To do so effectually the chief knowledge required is of an entomological nature, i.e., the full life-history and habits of the different species; and this implies a great deal of close and accurate work in field and laboratory. By means of it we learn which species are beneficial, and which injurious; and the ability to distinguish between friend and foe is of the first importance in coping with the latter, for it is a notorious fact that the farmer often does more harm than good by destroying the former in his blind efforts to save his crops."

The economic entomologist, to do effectual work, must possess, not merely a knowledge of the particular injurious species and its habits with which he wishes to deal, but must study its relations to wild plants as well as to the particular cultivated crops it affects. He must also study it in its relations to other animals. Indeed, its whole environment must be considered, especially in connection with the farmer's wants, the natural checks which surround it, and the methods of culture that most affect it. The habits of birds, the nature and development of minute parasitic organisms, such as fungi, the bearing of meteorology, must all be considered, and yet, with the knowledge that a study of all these bearings implies, he will frequently fail of practical results without experiment and mechanical ingenuity."

... Mere study of [insects], however, while essential, is not often productive of those important practical results which follow when it is combined with field work and experiment by competent persons and upon scientific principles. Many of the remedies proposed and recommended in the agricultural Press are either ridiculous or else based on misleading empiricism; and economic entomology, as a science, is of comparatively recent date.

Insects probably outnumber in species all other animals combined, some 350,000 having already been described, and fully as many more remaining yet to be characterised. The proper and conscientious characterisation of a genus or species of some microscopic creature involves as much labour as that of one of the higher animals. Of the above number a goodly proportion are injurious to cultivated crops. Lintner recently records no less than 176 affecting the Apple.

INSECTICIDES.—Of insecticides any number of substances have been recommended, and many of them tried with more or less satisfaction. Of these may be mentioned

lime, sulphur, soot, salt, wood-ashes, corrosive sublimate, naphtha, naphthaline, turpentine, alum, carbolic acid, phenyle, cyanide of potassium, blue vitriol, ammonia, alkalis, benzine, vinegar, sulphuric acid, quassia, vitriol (the sulphate of copper), hot water, &c. Most of these may be safely used for specific purposes, either dry, in liquid, or in vapour; but the three most useful insecticides of general application in use during the early days of economic entomology in this country and up to within a few years, were undoubtedly tobacco, white Hellebore, and soap. Tobacco-water and tobacco-smoke have long been employed against aphides and other delicate insects, and are most useful. A quite recent advance in its use is by vapourising. The vapour of nicotine is most effectual in destroying insects wherever it can be confined, as in greenhouses. Thus the boiling of tobacco in such a greenhouse is as effectual as, and less injurious to the plants than, the older methods of syringing with a decoction, or of fumigating by burning; while experience by Mr. William Saunders at the Department of Agriculture during the past two summers shows that the vapour gradually arising from tobacco-stems strewn on the ground and regularly moistened is likewise effectual. White Hellebore, either dry or in liquid, has long been one of the most satisfactory insecticides against Tenthredinid larvae, otherwise known as false-caterpillars, of which the imported Currant-worm (*Nematus ventricosus*) is a familiar type; while soap, syringed in strong suds, will kill some soft-bodied plant-destroyers, and when used as a paint on the trunks of trees is an excellent repellent against the parents of different borers. Transcending in importance, however, any of these older insecticides are the three now most commonly used because most satisfactory. They are:—(1) arsenical compounds, (2) petroleum, and (3) Pyrethrum. The first act through the stomach, and are effectual chiefly against mandibular insects; the second and third act by contact, and are, therefore, of more general application, affecting both mandibular and haustellate species.—*Gardeners' Chronicle*.

CALOTROPIS GIGANTEA.—Two out of the three known species of this genus are flowering for the first time at Kow.—*Gardeners' Chronicle*.

PRICKLY PEAR IN AMERICA.—In some recently published Consular reports of the United States, the following interesting paragraph on the Nopal, or Prickly Pear (*Opuntia cochinitifera*) occurs:—"The plant abounds in the whole territory of Mexico, Texas, New Mexico, Arizona, and California, and extends much farther north. It has flat oval leaves, about 6 inches long and nearly half an inch thick, covered by long sharp thorns, and bears a fruit of purple colour resembling a Pear, filled with numerous small seeds. The plant grows from 3 to 6 feet high. Its fruit is eaten freely by cattle, and the leaves, after having been burnt in a fire to get rid of the thorns, are thrown by the cartmen in place of fodder to their oxen by means of a long sharp-pointed stick, especially when on the road where there is no grass. It also makes an excellent hedge, and once planted will last for ever. There is another species of Nopal called Nopal de Castilla, which has no thorns, and which is cultivated for the sake of its fruit. This Nopal has much larger leaves than the wild species, and grows to the height of 10 and 20 feet, and the fruit is much larger. Of this species there are a great many different kinds, each having its distinct name. They are of different colours—green, red, yellow, white, and purple. The fruit is delicious, and in the interior of Mexico forms one of the principal means of sustenance for the inhabitants. From the purple Tuna a liquor is made called *Coloche*, and a sort of sweet cheese (*Queso de Tuna*). There is a small red Tuna growing wild in the mountains near to Zacatecas, called Cardona, which is highly prized on account of its fine flavour and digestible qualities, and several cartloads of which are sold daily in Zacatecas. They are sold at 6 cents for four dozen. Besides serving as food for men and beasts, its leaves form the food of the cochineal insect."—*Gardeners' Chronicle*.

MARKET RATES FOR OLD AND NEW PRODUCTS.

"THE TEA ENTERPRISE IN CEYLON":

REMINISCENCES OF THE VERY BEGINNING OF TEA-PLANTING HERE BY "W. M. L."—MR. ARTHUR MORICE'S MISSION TO INDIA—THE ROCK AHEAD: "OVERPRODUCTION."

London, 26th June 1885.

DEAR SIR,—I am much obliged for the little books you send me on the cultivation and preparation of tea, &c. in Ceylon.

Old associations make me keenly interested in all that pertains to the tea enterprise in Ceylon, though my interest is almost altogether sentimental.

It may have chanced to one to have loved in its earliest infancy some bonnie babe, to have played with the engaging sprite, to have dandled it on one's knee, to have tossed it in the air. The chances of life part one from the pet. Years pass by and anon one hears of the lusty young school boy and his famous deeds, may be with bat or oar, may be with pen or book. How strong is the interest one feels in the opening career of the once loved infant! How benevolent, tinged not with the slightest touch of sordid considerations, but with hopeful anxiety alone, how so much vital power may develop itself in the future!

Such is my interest in the Ceylon tea enterprise. Nineteen years have passed since, as Secretary of the Planters' Association, I took an active part in promoting the mission of Mr. Arthur Morice to report on the cultivation and preparation of tea in India. That mission, if it had no other result, caused me in the following year on behalf of my firm to order from Calcutta a consignment of seed of the hybrid Assam plant, and these seeds committed to the care of that ever watchful nurse, Mr. James Taylor (who had already by his success with cinchona, and more recently with China tea earned the complete confidence of his employers for experimental work), formed the beginning of the now famous Looecondura estate. In due course (I think in 1872) I found myself selling in Kandy to all-comers the produce of our little garden, and therewith my direct connection with the cultivation and preparation of tea in Ceylon ceased probably for ever.

Such being my experience, it gives me unmixed pleasure to read now, after so many years, that cultivation is at last being taken up in good earnest and how, be it for good or for evil, Ceylon is now surely growing into a great tea-producing country. It is pleasant too and encouraging to learn from the divers writings that you have brought together that all possible care and intelligence are being used to secure the utmost economy and efficiency in the various operations.

That hopes should be high is only natural. Looking to all the discouragements of the past, to forbid hope would be cruel; but as I have hinted above, hope must needs be mixed with some anxiety, and this for several reasons.

The first reason that I should give (a very general one, which applies to any enterprise equally with that of tea-planting), is set forth in the late Lord Beaconsfield's dictum: "It is always the unexpected that happens." In a business career extending now over 30 years, during which many speculations of many different kinds have been tried, I have been much struck with the truth of this saying. Schemes of the greatest promise as judged by all past experience have proved the most complete failures owing to some new factors in the problem of which no human foresight could possibly take cognizance; and *vice versa*, in cases where hope had died away, success has been achieved

contrary to all expectation. To illustrate my meaning: I remember having heard one of the shrewdest and most experienced of Colombo agents say that he would value coffee property only on secured results, that is on the actual crops for previous years. A valuation of any of the famous Haputale estates made on this principle before the year 1870 would have given as the full value of the property probably a less amount than a single year's profits in subsequent years. And there is no need to point out how misleading, though in the opposite direction, would be any valuation of coffee estates of late years based on previous crops.

In all mundane affairs it is unsafe to judge confidently of the future by the past, and tropical agriculture certainly forms no exception to this rule. Having thus sweepingly disposed of all hopes based on the facts and figures which are set forth in your little publication, it may seem superfluous to consider any particular reasons why hopes should be moderate. And one only shall be mentioned.

The one rock ahead, which in the impenetrable haze of the future stands out in unmistakable clearness, is the so-called "overproduction": overproduction that is for the interests of the producers, though not for those of the consumers. It is stated that tea will grow and flourish in Ceylon from the sea-level to 5,000 feet above the sea. Given that the cultivation prove as successful as is now hoped on the agricultural side, we may expect from Ceylon alone an astounding addition to the imports into Europe within the next ten years. In a much more limited zone of elevation the extent under coffee some years back exceeded 200,000 acres. The acreage of tea may easily be half as great again, yielding yearly 100,000,000 lb. annually. We have lately seen both in corn and sugar, and indeed also in nearly every branch of manufacture, the result of the extraordinary powers of production developed of late years. Even those who produce most cheaply have had to sell at a loss. Under the inexorable laws of supply and demand, which not even the most advanced Radical has yet attempted to abolish by Act of Parliament, the consumer calmly takes, not only all the hoped-for profits, but confiscates also a good slice of the actual cost of production. But someone will be saying "that can only be temporary; see how sugar has already gone up again with a bound." Tea and sugar are not in like case. But is a yearly crop, and beet-growers having lost very heavily last year, do not sow it again this year. Tea gardens can only be allowed to cease learning under pain of loss of the whole capital invested, both in the ground and in plant, and they will in no case succumb to the low prices due to increased production without a long and stern struggle for life.

It is the old, old story of *sic vos, non vobis*. The tea planters of Ceylon will surely do good service to the tea-drinkers of the world. But whether they will earn the hoped-for abundance of gold for themselves is matter of doubt. An ominous sign to me is the cry raised by some for more capital. It is quite certain that very moderate realized profits will draw at least as much capital as is necessary for sound development of the tea industry. Within the last ten years we have seen the effect of an influx of capital. My best prayer for Ceylon is that it may be spared another similar flood.

This is a letter of a pessimist, your readers will say. Not so. Were I young and with some small capital at my disposal, I would be ready willingly to cast in my lot in Ceylon as a tea-planter. It is a fine, healthy, beneficent employment, and offers as fair chances of success as any other similar work that I know of. But unless I wished to be disappointed I should not fix my hopes on high profits which it is

almost certain will be realized only in exceptional instances. Moreover, the extravagances of hope will almost surely again, as already often in the past, destroy all chance that otherwise might exist of its own fulfilment.

"*Nil desperandum*" is an excellent motto; but "*nil minimum sperandum*" is its logical supplement. The infancy and childhood of Ceylon tea-growing have been singularly free from drawbacks arising from the greedy hopes of man. While coffee and cinchona have both been the subject of overhaste to be rich, tea seems to have been left at all events till lately to those who have studied solely how best to grow and manufacture it. May its adolescence and maturity be as healthy as its childhood and youth! And may the day come when, both in quantity and quality, Ceylon will stand first among the countries of the world as an exporter of tea!—Yours faithfully,

W. M. L.

THE CULTIVATION of the pearls of fresh water mussels has become an industry of considerable importance in Saxony and other parts of Germany. The pearls are generally inferior to those of the genuine pearl oysters, but occasionally a gem of real excellence is produced.—*American Grocer*.

DIKOYA, July 18th.—We are having what is a most welcome change: from constant rain to bright and warm sunshine. The rain has lasted long enough to enable everybody who desired to plant out tea to do so to his heart's content; and now the warmth of the sun will enable the plants to put out their first rootlets and lay well hold of the ground, besides giving the older tea a chance of flushing, which it has not had for ever so long. As for the effect of the weather on the coffee up here, there is not much to be said about that as there will be so little left for crop yielding in the future—the more 's the pity as some think. I know of at least one substantial proprietor not long out from the old country who is convinced that there is a great mistake being made in the too general uprooting of coffee. His argument is that, although it is quite true that some estates give but 1 cwt. the acre taking the entire acreage of the estate, and that, therefore, it is not worth while to keep up the whole estate; but that in reality the crop comes off a very limited area, equal in fact, to perhaps 3 cwt. an acre, and that it is well worth keeping up the portion giving that amount of crop, replacing the rest with tea. He is confident that it will be a great mistake for planters to once again cultivate only one product: the lessons of the past should teach us the unwisdom of this course in the future; and, if for no other purpose it will be prudent to maintain a certain extent of land under cinchona, even through the returns yielded be not great.—*Local "Times."*

EFFICIENCY OF SULPHUR.—We take the following information from an Italian newspaper. Dr. Vergani of Naples has just discovered an effective protection against croup and diphtheria. The abovementioned physician happened to notice that, in villages where water charged with sulphur is continually used for drinking in default of better, these dreadful diseases are unknown, the result being that he was led to try experiments on the subject. To one of his sons, three years old, during eight days, he gave nothing but sulphured water to drink and, at the end of that period, took him to a children's hospital where he allowed him several times to play with others of his age suffering from diphtheria without the lad catching it. From the results proving so satisfactory, Dr. Vergani prescribed sulphured water to his children. For them, it was sufficient to put a cylindrical piece of sulphur in a bottle and fill it every night for use, the sulphur remaining serviceable for an indefinite period. It may be substituted by lozenges of sulphur to be taken by children every morning on rising from bed and whenever the abovementioned diseases were rife, each taking another lozenge in the evening. Sulphur is besides a powerful means to deliver children from many kind of diseases.—*Straits Times*.

THE "CAROLINE ISLANDS." A NEW FIELD FOR ENTERPRISE.

Spain has joined in the colony grabbing race, and proposes at once to acquire the Caroline and Mariana islands which are situated about 700 miles to the eastward of the Philippines.

They may be said to be contained between the 7th and 10th parallel of North Latitude and extend from 134 degrees to 160 degrees East Longitude, and to put it roughly, about 1,600 miles distant from this.

The northern part of the Pellew Islands from Corror upwards, is moderately high, and could with a more industrious class of inhabitants be made very productive, as the soil is extremely fertile. The southern portion of the group, with the exception of the Pillelew and Ngour, is uninhabited. The islands are small and of basaltic formation, densely covered with hardwood trees, the cabbage palm, etc. Pillelew has a fine taro land, but the root is small, and the natives of this island are dependent in a great measure on the northern islands for their food during certain seasons of the year. The bread fruit, however, is more plentiful here than in the other parts of the group. The cocoanut is also abundant, and from its fruit the Pillelew people made oil and molasses which they exchange with the northern people. The Pellew Islands produce *bêche-de-mer*, tortoise-shell and pearl-shell, the latter however of inferior quality and known in commerce as the "black lipped." The soil from Corror northwards is rich and produces a great many tropical fruits (most of which were introduced by Cap. Cheyne) in abundance and without any cultivation. Tobacco of a superior quality is grown by the natives, and coffee could be raised with very little trouble.

The Uap group, lying between the *Matelots* and the *Mackenzies*, consist of three principal islands, which are comparatively high, and are thickly inhabited by a people similar in appearance to those of the Pellews; their manners and customs also in a great measure resemble those of the Pellew natives, but they are however, a superior class of men and far more industrious. They cultivate large quantities of yams and sweet potatoes, tobacco and some of the tropical fruits. The whole of the coast is thickly planted with cocoanut palms and a large quantity of copra is produced annually; copra being, I may mention, the dried fruit of the cocoanut. The reefs surrounding the group formerly furnished *bêche-de-mer*, but at present only a very little can be procured. Pigs are plentiful, and there is also a kind of half domesticated fowl which can be procured cheaply. Deer and goats are seen, but the natives do not protect them as they destroy their plantations. The rat appears to be the only indigenous animal, and the large edible iguana is found in the jungle, but is protected by the natives, who regard it as sacred. The money of these people consists of large worked pieces (in the shape of a mill-stone) of a semi-transparent spar, which is procured from the Pellew Islands and esteemed very highly; its principal uses are to pay war indemnities and the funeral expenses of the chiefs. Pearl shell of large size is greatly valued and much sought after, and vessels trading in this group can supply themselves with a considerable quantity of provisions for a few pieces of pearl shell.—*Hongkong Telegraph*.

SEYCHELLES.—We hear that the Acting Chief Civil Commissioner has dismissed all the men formerly employed in the Forestry Department, and that many valuable economic plants and seeds that had been forwarded from the Botanical Gardens of Mauritius have been in consequence abandoned. This is much to be regretted, for every encouragement should be given to the inhabitants to turn their attention to other cultures than the fast decaying cocoanut, and "example is better than precept."—*Mercantile Record and Commercial Gazette*.

THE NORTHERN TERRITORY OF AUSTRALIA.

HOWLEY, June 3rd.—A subject introduced at the meeting held here recently was that of restricting Chinese immigration for the future. The past cannot now be remedied, as the Chinese are here and we cannot well get rid of them; but we can and ought to prevent more of them from coming by passing a similar restrictive Chinese Immigration Act to the one in force in South Australia proper. The Chinese now have everything in their own hands here, and if their coming is not prevented in the future it will be impossible for a European population to live here at all. The country has never been in a worse state than at present, the primary cause of which is the stagnation in the mining districts. This is caused by the goldfields, and even the reefs (which Chinese are not allowed to work in other countries) being overrun by them, so that the white miners, who could have developed the reefs, have for the most part left the country. Those who are here will not work amongst a lot of Chinamen, so that every known gold-field and line of reef being occupied by them, there are actually no places left for a white miner to try his luck in; and as the Chinese who hold the ground have already worked out all the surface that is easily got (all the mining they ever will do), and the whites are prevented by their presence not only from testing the deep ground but from remaining in the Territory at all, a state of stagnation is the result, which can only be cured by taking prompt measures to prevent their coming here any more, except in such limited numbers and under such a heavy poll tax as it was found necessary to impose in the neighbouring colony of Queensland.

The pearling boat "Lammeroo" arrived in Port Darwin from Western Australia last week, and two others from the same place will probably be in port by this time. They have done pretty well, and would have done much better had not the weather been so persistently bad as to prevent regular work, besides which measles and fever broke out amongst the crews.

Messrs. Erickson and J. Wood, of Port Darwin, are still on the pearling ground at or near Cambridge Gulf, and have got a good quantity of shell. Two pearling boats arrived in Port Darwin last week from Thursday Island, and reported that between 200 and 300 boats would probably arrive shortly from Torres Straits, en route for the western pearl fisheries, as the accounts from there have been good, and the late pearling season in Torres Straits has been rather a poor one.

It would appear that the Western Australian jarrah is just as susceptible to the attacks of cobra (*teredos navalis*) in water as it is to those of white ants on shore. The "Whampoa" on her southern trip took down a piece cut from one of the trial piles of the jetty, planted some months ago, which was thoroughly perforated by the sea worm. As the jetty piles are to be sheathed with copper, and the wood has otherwise proved to be very serviceable for piles, we do not suppose any alteration of timber will be ordered, as, as yet, the cobra has found it just as difficult to eat its way through metal in the water as the omnivorous white ants have on shore. True, it may be only a question of time and education, but until it is proved that iron and copper are no protection against the insects' encroachments it may be as well to chance it.

The total imports into Port Darwin for the quarter ending March 31 amounted to £24,203, of which £5,053 were from South Australia, £7,460 from New South Wales, £2,550 from Queensland, and £5,563 from Hongkong. The exports during the same period amounted to £22,021, of which £2,612 went to Victoria, £14,205 to New South Wales, £4,445 to Hongkong, and £51 to South Australia. The immigration numbered 174 souls and the emigration 11 souls. Sixteen vessels representing a tonnage of 18,829 tons arrived at Port Darwin in the quarter.—*Australian Register*.

PLANTING IN CEYLON.

Ceylon sets to work with a more purely business air, and boldly advertises herself as a "field for the investment of British capital and energy" in the way of growing tea, cacao, cinchona and other produce. Not coffee, mind! Ceylon has bought her experience dearly, and no more thinks of putting all her eggs into the coffee basket than Jamaica does of putting all hers into the sugar basket. A few hints, therefore, as to what Ceylon planters are thinking of, may not come amiss to our readers in Jamaica and the West Indies generally. There is, perhaps, a special fitness in asking Jamaica to take a hint from Ceylon, seeing that the able Director of Public Gardens and Plantations in the former island, held only a few years ago the same post in the "Isle of Spices." If he only succeeds as well in Jamaica as he did in Ceylon in making the planters turn their practical attention to new products, he will have doubly deserved the thanks of the public at large. After tea, cinchona and cacao, the latest "new loves" of the Ceylon planters are cardamoms and areca palms. The last named is the most recently introduced to the notice of the planters, one of whom, after making practical experiments with about 40 acres of land under this crop, estimates the net profit at about 60r. (say 95s.) per acre. On good soils an even better return may be expected, and further profits are looked for in the utilization of the fibre. As to the market, another planter states that "with practically an unlimited demand, hundreds of millions of people in China, India, &c., using areca nuts, it ranks second to few other enterprizes, and offers at the same time a safe investment for limited capital." Much information on these familiar "new products" will be found in a handbook on "Tea and other Planting Industries in Ceylon," and in the periodical publication the *Tropical Agriculturist*, both issued by Messrs. A. M. & J. Ferguson, of Colombo, to whom the Colony of Ceylon is most indebted for their persistent efforts to foster Cinghalese interests. Mr. John Ferguson, on a recent visit to England, was "interviewed" by the irrepressible, but indispensable, newspaper reporter, and in the little pamphlet above-mentioned he has issued the following revised version of what he said on the all-important question of the class of young men for whom Ceylon has an opening—information which will equally apply to Jamaica and the other West India islands.—*Colonies and India*.

SPIDER SILK.

We recollect once reading a statement to the effect that spiders' webs were equal and even superior to ordinary silk. But an experiment tried by shutting up about sixty spiders together ended disastrously. In the morning only a few bloated spiders were found, which had eaten up the others. There may exist spiders, however, devoid of this cannibal propensity, and further experiments with the right sort of spiders might be more successful. Meantime the enormous quantities of strong and dense spiders' webs in our jungles, which sometimes impede the progress of travellers, might be utilized. A Madras Government paper which has reached us embodies correspondence on the subject initiated by Mr. J. F. Duthie, Superintendent of the Sharunpore Botanic Gardens. He wrote thus to Sir Joseph Hooker:—

By today's mail I am sending you some queer-looking stuff—spiders' silk. It was extremely lovely as I saw it when coming down from Almera the other day. Enormous webs of it stretched between the trees and shrubs overhanging the lake at Bhim Tal in Kumaon. I saw a notice a short time ago in some paper regarding the use which might be made of these strong webs; a particular kind of a golden yellow color, occurring in New Zealand, was specially recommended, and in fact it had been mani-

pulated with success as a substitute for silk. What I saw at Bhim Tal answers very much to the description of the New Zealand kind; and if a supply is wanted for an experiment on a large scale, it could easily be obtained from this locality after the rainy season is over. In a small tin-box enclosed in the packet I am now sending are a few of the spiders, not in very good order, but I had to send for them.

Mr. Thomas Wardle of Leek, England, reported thus on the silk and the spiders:—

The fibre is evidently of a silken nature, and, like silk, it is loaded with a gummy substance. In a boiling soap solution this gum or varnish dissolves, leaving the fibre apparently pure and of the nature of fibroin if not identical with it. Eight micrometric measurements of the diameter of the fibre in different parts of the mass showed great irregularity in thickness

(2300' 2600' 3500' 2800' 3500' 3500' 3500' 3500')

giving an average of $\frac{1}{300}$ inch. It has therefore a considerably finer thread or fibre than silk, Italian silk averaging in thickness $\frac{1}{2100}$ inch. The average strength

of the spider silk is proportionately greater than that of silk, a single fibre of the spider silk breaking with an average weight of $2\frac{1}{2}$ drams (Av.), whilst that of China silk breaks at $2\frac{3}{4}$ drams. The most curious property of this fibre is its elasticity, which is considerably greater than that of silk. Thirty centimetres of it will stretch to an average length of 36.6 centimetres before breaking, while China silk will only stretch to 34 centimetres. Like silk this spider's web silk is lustrous and has a round fibre. Its coating of gum or varnish is disproportionate to the weight of the silk. On boiling with soap it lost $7\frac{1}{2}$ oz. per lb., that is, 1 lb. of the spider silk discharges $7\frac{1}{2}$ oz. of gum. With silk the proportion is much less, seldom being over 25 to 30 per cent. Before boiling in soap the spider silk was well combed to remove all the dirt possible, but a little remained. The fibre appears to dye readily. I enclose a small pattern of it dyed, and also one as I received it and one after boiling in soap. I believe it can be obtained in quantity it might be packed in bales and sent to England where it would readily find a market for being carded and spun into spun silk-thread for sewing or weaving purposes. It is difficult to estimate its marketable value. I dare say it would at any rate realize 2s per lb. It is rather dirty, and this would to some extent detract from its value as compared with silk waste. I have tried to discover how many seripositors this spider has, but beyond noticing under the microscope that the fibres often run in pairs but not regularly, I am unable to trace whether there are two, as in the ordinary silk-worm, or more. Probably an examination of the spider would show this or an undisturbed portion of its secreted silk.

Here is an opening for a new industry. Our only fear is that the scouring of the jungles for spiders' webs, might end in the destruction of so many spiders as prejudicially to destroy the balance of insect life, common flies, mosquitoes and other creatures of the kind becoming inconveniently abundant. But some of our readers might like to try the experiment of breeding silk-weaving spiders in perforated boxes, where each insect, if necessary, could have its own compartment for weaving in.

POSITION AND PROSPECTS OF FIJI.

DEPRESSION IN FIJI—CEYLON MEN LEAVING—THE CAUSE OF FAILURE, DEAR LABOUR—THE NATIVE TAXATION SCHEME—100,000 FIJIANS—AS LABOURERS AND AS PRISONERS—POLYNESIANS AND WAGES—PRODUCE:—COFFEE, LIBERIAN; TEA; CARDAMOMS; SUGAR; COCONUTS.

Fiji, 20th May 1885.

Formerly I used to see a good many letters from different correspondents out here in the *Observer*, but latterly, none; so I conclude those who used to address you, have either left the group for pastures new or have given up writing. The former

is most likely to be the case, as most of the Ceylon planters who were in Fiji have left disgusted at not having been able to make money or at the poor salaries they were receiving. Amongst the Ceylon men who have left I know of Christian, Hedges, Akers, Thompson, and Whitton, and many more, I feel convinced, would leave if they were certain of getting in Ceylon or elsewhere, even the low salaries they are in receipt of now. Fiji has not turned out the "Eldorado" we all expected; it has in fact just turned out the opposite. Instead of making, one loses money in most of the industries embarked in, and, unless things take a radical change for the better, most planters will simply become bankrupt—many of them, I should say, are verging on it or in this state already. It's sad to have to write in this strain of a new colony, but it's the truth and it's no good disguising the fact.

Opinions differ, of course, to a great extent as to the causes which have led to this state of affairs. Some affirm the land is not suitable for some of the products planted; others that the labour, owing to Governmental action, is now so scarce and expensive, that it would not pay to grow anything in any country at the rates ruling; others that the markets are so bad and the prices realized for products so low, that it does not pay to cultivate; and others again, who form the majority, say it's all owing to the native taxation scheme, which greatly interferes with the free working of the native and compels planters to get men from other countries at a far higher rate of wages than the Fijian could be engaged for, besides having to pay a very heavy sum for introduction expenses. The latter subject has been written about over and over again until it is threadbare, without as yet doing any good. Whether the freeing of the Fijians and allowing them to work when and where they liked in the group would be a panacea for all our evils, I am not prepared to say. If they were allowed to do so and pay a capitation tax of £1 each, instead of the same amount in produce as they have to do now, I fancy a good number of them would, at first, be willing to go out and work, but whether they would keep it up is doubtful. Every Fijian has land on which he can plant the little he requires during the year, and, when the novelty of being free had passed over, I think he would prefer staying at home and certainly not go in for regular work. In disposition he resembles, in my opinion, the Sinhalese: likes grog (yagons) drinking, smoking vulkas, and eating and sleeping, with a minimum amount of work. If you add to these qualities that they don't care about hoarding up money, or for so-called luxuries, one would naturally ask why does the Government then not do away with the native taxation scheme? I think the great object is, the preservation of the race by keeping the people in their towns as much as possible together. The year before last, if I remember right, the statistics showed a slight increase in the population; as yet I have not seen those for last year, but should say, owing to hooping-cough among the children, there must be a large decrease. Whether the race can be preserved, only time can show. History points to the fact that where the whites settle, as a rule, the blacks die out. Look at Tasmania, for instance, and see how rapidly the natives are dying in Australia, New Zealand, Hawaii, &c. Should cholera, smallpox or some other epidemic be introduced, it will be a poor look-out for the race, if we judge by what measles did some time ago. The present native population is about 100,000, and it certainly appears an anomaly that we should have to introduce labourers from India, Hebrides, Solomons and other far off islands, when the present planters in the group only require a few thousands, I should say 10,000 at the outside, amongst them altogether. The Fijian will never work so cheaply as he did before, and it can be expected

as owing to the competition the last three or four years his wages have been greatly increased, and he certainly would expect to get as much as the cooly receives. This, planters would not object to pay, if they could get the men and have an ordinance enabling them to get a fair day's work for a fair day's pay, or to be able to get the men duly punished in default. The present ordinance is no good. If the man likes to work, he does so; if not, he can pretty well do what he likes, and it is so difficult to get him punished under the present law, and even when he is punished, the punishment is of such a slight nature, that planters won't go to the trouble of taking them to court. In the country jails the hard labour is a *perfect farce*: the prisoners have no task to do every day that I am aware of, and I have often seen them idling away their time, smoking and talking and, an outsider would certainly not look upon them as prisoners. It is now no punishment to any man being in the country prisons, and it won't be until strict discipline is enforced and he has to do a hard day's work. I have actually known cooly prisoners receive food and tobacco from their wives and leave the jail to come up 4 miles distance, to sleep with their wives and leave early so as to get back to their quarters, without being found out. This state of things is wretched. Coolies have often told me they would rather be in jail even without pay, than work on the plantation. This would not be, if the jail discipline was as it should be. Malingering amongst coolies is a serious evil and will continue to be so as long as they can pay a paltry fine of 1s to 3s without being imprisoned. It is not worth a planter's while to be constantly taking malingers to court, especially should it be, as is usually the case, a long way off. He may make a determined stand at first and take some of the men down and get them fined most probably 1s each for the first complaint. Shortly afterwards he takes the same people down again and get them fined, say 2s. If the new men are a lazy lot, this will only have a slight effect; in a few days' time they will commence shamming again, you don't like to be done, so take the men down a third time and say they get the maximum fine inflicted if convicted, viz. 3s. After this, your patience gets worn out, the game is not worth the candle, if you have to travel far. In my opinion the cooly ought not to have the option of paying a fine after the second conviction. If he knew he would suffer imprisonment for third and subsequent offences of a similar nature and if he really found prison life irksome and the work as it should be hard, it would act as a deterrent. Enough about labour. I am sick of the subject as it's such an unsatisfactory one. I may as well mention, though, before concluding that the wages of Polynesians have been raised. Instead of receiving £3 a year as before, the men now have to get £3 for 1st year, £4 2od, and £5 for 3rd year. Youths and boys in proportion. Men who have worked in Queensland or Fiji previously get £6 per year. Of course all clothing, food, tobacco, &c., are given to the men in addition to wages. Return passage money has also been raised.

Coffee I look upon as a failure. I do not know of any estate, except one, which is giving enough crop this year to pay working expenses—this, too, in spite of a favourable blossoming season last year. The price is now so low that you require a large crop to make the estate pay when your labour is dear. I know of six estates that have been abandoned since I last wrote to you. The owners of the others would, I am sure, be only too glad to sell even at a heavy sacrifice. Leaf-disease visits us annually in a pretty severe form, and traces can be seen all the year round. The export of Arabian coffee from Fiji has never been much and for some years to come won't be

worth calculating. It is not at all likely that new comers will embark in the enterprise, at any rate for some time to come. The few patches of Liberian coffee I have seen, look healthy and are bearing well, but it is too soon to judge whether the speculation will prove a remunerative one. The fine curing establishment which Mr. A. R. Wilson erected in Tavuni has very little work to do,—it's a great pity, as Mr. Wilson went to great expense and trouble and has completed the work in a most substantial and workmanlike manner. I doubt if he will have any coffee to cure this year except his own. This, of course, will never pay. His estate is the exception as regards bearing which I have already referred to. The coffee has a decent, but not by any means what I should call a heavy crop.

Tea.—As I told you in my last we have embarked in this product and I have now about 200 acres planted up and wish to get in 100 more before the end of the year. The ages of the different fields vary from 4 year old plants to some just planted out. The major portion of the 200 acres has only lately been planted, and we have only about 30 to 40 acres off which we pluck. Owing to want of seed and plants we have not been able to plant up our land so rapidly as we wished to. The growth of the plants is rapid, and the oldest tea seems to flush well. I am a tyro in tea planting, and so am unable to tell you myself whether the trees are doing so well as they should do, but two Indian planters who have been here, thoroughly looking over the place, were so satisfied with the appearance and growth of the trees, that they have bought land and are planting it up. This looks well, and I sincerely trust that tea will yet do something for us. It is much appreciated by the local public, and as yet we have not been obliged to export any. I have a No. 1 Davidson's Sirocco at work which does well, and a Thompson's Challenge Roller for hand or other power—I am not satisfied with its work: it does not twist the leaf to my satisfaction and takes too long over its work. The maker, strange to say, never forwarded any instructions either how to erect or work the machine, and, although he was written to months ago for the requisite particulars, none have as yet reached us. In the meantime I have tried the machine with different charges, leaf withered in several ways &c., but without the return in work I calculated on. This may all be remedied on receipt of the instructions. Strange to say, Davidson also never sent instructions till a long time after we had received and erected the Sirocco. Surely makers of tea machinery would find it to their interest to forward pamphlets full of instructions by post either before, or at the same time as, they dispatch the machines ordered!* I will write further about tea when I have gained more experience: at present I cannot do so with confidence.

Cardamoms.—At the end of February 1884 I planted up a patch under partial shade of original jungle. The bulbs were grown from seed procured from Ceylon, and when planted out were nearly or quite a year old. The plants were so tall that I had to top them all. They were planted out 9 x 9 ft. The growth since then has been most satisfactory. The stools, if I may so term them, are in some cases over 2½ ft. in diameter, and on the 13th February this year I noticed for the first time some were flowering—a few days ago I picked some fruit, only a small quantity. If the plants go on as they have done, I shall certainly expect a decent crop next year. They cover all the ground already. The cultivation promises so well that I have been induced to

* So one would think; but our correspondent is by no means singular in his experience.—Ed.

plant up a further acreage, which I still wish to increase, by cutting off two or three bulbs from the original stools and planting them out. This, I suppose, is the best way to extend as I have no plants, although some slight injury may be done to the plants from which the bulbs are cut, and it must to a certain extent impede their growth. At the same time as I planted the clearing under shade, I put out about 40 to 50 bulbs entirely in the open so as to be able to compare the difference in the growth of the two. The latter have formed bigger stools, are not so tall as those under shade; some of the leaves, the oldest, have a yellowish tinge and none have flowered. They look robust and are better than I expected.

Weather.—The enclosed table will give you all information regarding temperature and rainfall here for last and previous years:—

TAKEN AT ALPHA ESTATE, TAVIUNI.

Month.	Rainfall. inches.	Hygrometer.			
		6 a.m.		Noon.	
		D.B.	W.B.	D.B.	W.B.
January ...	22.14	73	71	84	78
February ...	16.97	75	72	85	79
March ...	13.54	74	72	86	81
April ...	7.99	72	69	86	80
May ...	8.65	70	68	83	76
June ...	4.56	68	65½	79	73
July ...	2.60	69	63	78½	73
Aug. ...	2.99	66	63	78	73
Sept. ...	12.97	68	65	80	76
October ...	4.11	66	63	82	73
November ...	7.30	70	68	81	74
December ...	3.59	71	69	86	79
Total ...	107.31	70	67½	82	76
Year 1883 ...	183.11	71	65½	81	76
1882 ...	110.55				

Elevation 1,000 feet above sea-level. June, July and August were very dry months for this elevation. Last year the rainfall for these months was 13.66, 12.86 and 9.50 respectively. There has been a longer drought this year than has been known for many years past in Taviuni.

A. J. STEPHENS,
Observer.

Sugar.—The sugar planters have been despondent lately owing to the fall in the price. Since I last wrote to you I have not been to the Rewa and Navua, the principal sugar-growing rivers, so am unable to give you all the information I should wish to do. Planters still say they cannot make the cultivation pay with present rates ruling. The largest mill on the Navua and the plantations connected with it have lately come to grief and were sold the other day. The labourers, over 500, have all been removed. This is bad for the Navua in particular and sugar planting in general, as such a collapse will frighten other capitalists. On the other hand, two or three new mills have been erected: one on Mango, an island to windward, owned by a Melbourne Co. and managed by a brother of Mr. Borron in Ceylon; another on an island to the north of Viti Levu; and one on the Pa coast in Viti Levu, owned by the new New Zealand Sugar Refining Co., I believe. The sugar made is of first-rate quality, and it is to be hoped all these mills have a prosperous future before them. If sugar cultivation turns out unprofitable, it will almost be a death-blow to Fiji. I have often wondered since my residence here how it is sugar has never done well in Ceylon. You have just as good a climate and as varied and many advantages in the way of cheap and plentiful labour, cheap transport, &c., and I feel convinced if you could only hit upon the proper kind of cane, sugar planting would prove a grand thing in Ceylon. Every effort ought to be made to introduce all kinds of cane and try them in different parts of your island. I know the experiment has been tried; that mills have been erected; that

experienced men have looked after the cultivation, and that large sums of money have been lost; but still, different kinds of cane have since been discovered and some of these might prove a thorough success where the others were total failures. Whether it is worth while to go in for cane culture in face of the enormous beet-sugar manufacture, which I conclude keeps, and is likely to keep, prices down, is a question for those most interested to decide; but that cane could be grown and made to yield a good percentage of sugar if a suitable variety were introduced, I feel certain after what I have seen here.

Coconut Cultivation.—This combined with cattle is, at the present time, the most satisfactory here. Those who possess large properties can make a fair profit after paying expenses, and I don't know of another cultivation which is doing the same. The owners of smaller properties can jog along comfortably without getting into debt. If one can combine cattle with the coconuts all the better. There's a market for fat stock and the beasts thrive and fatten well. The stock originally came from New Zealand and Australia. There's no disease as yet and no leeches, ticks, &c., to bother them whilst grazing. Fat beasts will run from 600 to 800 lb., and the butchers will give from £3 to £12 for them on the place. The coconuts are much smaller than years and take as a rule 5,000 to 5,500 to make a ton of copra. You hear sometimes of 4,500 producing a ton, and sometimes it takes as many 6,000 and over. The price of copra at present is from £9 10s to £10 10s per ton in Levuka. There is always a demand and any quantity can be sold. The major portion goes to Germany. No coconut oil is made for export. Fibre and bristles are occasionally sent in small quantities by one or two planters to the Australian market, but the demand seems to be a poor one. Larger quantities would doubtless be sent if freights were lower. Ceylon, I fancy, can undersell Fiji in these commodities. No coir matting is made out here which is a pity, as there ought to be a ready sale for it. Some of the coconut planters have enquired about a work on coconuts. I see you are publishing one. Please forward me copies.

I will now bring this lengthy epistle to a close. A lot of public meetings have lately been held all over the group for the purpose of trying to get Fiji annexed to New Zealand. The large majority seem to fancy that if it is done our condition would be greatly benefited. You will see full reports in the *Fiji Times* which I conclude you get.—Yours truly, A. J. S.

[A good, sensible letter. We never believed in coffee in Fiji; sugar ought to be its staple, and tea is likely to be a success. The soil and climate are better for sugar and cattle than ours in Ceylon but labor is the difficulty, especially for tea.—Ed.]

PLANTING IN CEYLON AND MYSORE.

(Notes by "Aberdonensis.")

"ECONOMY" AS A FINE ART—THE AGENT-V.-A.-ESTIMATE SYSTEM vs. THE HAPPY-GO-LUCKY-NO-CHECK-ROLL-ACCOUNT SYSTEM—WEEDING UNTIL THERE-ARE-NO-WEEDS vs. THE DIRTY-AND-DIGGING PRACTICE—A PROTEST AND SOMETHING LIKE TEACHING ONE'S GRAND-MATERNAL-RELATIVE-TO-SUCK-EGGS—FROM A MY-SORIAN VISITOR.

Facts are stubborn things and force their way. I do not know whether personal contact with men here, or actual observation of methods, or the convincing power of facts and figures combined, have most to do with this pressure on my mind; but, the more I see and hear, the more I am convinced. Men

are apt to ask how in the world does Ceylon get all the money to carry on. But when you see how the spending of money is carefully guarded, how economy is made a delicate science, how home proprietors, money-lenders, Colombo agents, V. A.'s, superintendents, are all closely studying how to work the thing down to the lowest possible degree,—then, I say, this vigilance makes up for expensive labour as compared with Mysore, this vigilance atones for a shattered credit and weakened powers by directing the precious rupees in the exact direction and at the lowest possible rate. What is the use of arguing as to the beauty of digging a Dumbara soil, and letting the weeds up to sweeten the soil and save wash, when by the process of fortnightly weeding, weeds disappear in accordance with the arrangements of expenditure, leaving the superintendent free to arrange other works on the same precise and delicate balance? The man would like to dig just as he would like more pay, but it is a matter of ways and means. The "way" must be adapted to the "means"; so contract weeding is beautifully adjusted to the "Agent-V.-A.-Estimate system" on account of straightened purses. Thus it will be apparent that the managers of estates are more financiers than agriculturists. I might suggest that your valuable paper be styled "Finance and Agriculture in the Tropics." It's all a case of finance: that is the power that permeates your land.

Then another thing has struck me. Say, in Dumbara or anywhere else, a man says he would like to dig, and would like to do lots of things but is not allowed the cost. Why? Because the estate can't afford it. Yet the estate can afford large extensions of area which means weakened power (as military men or financial men will admit), it can afford to proceed on the most highly coloured castles in the air grabbing at the shadow and losing the substance, and with what result? I see by your contemporary that someone has been in Dumbara and he has been fresh with details furnished. I don't like close details. I prefer generalities. All I can say is that in most cultivations tried in Ceylon greed and conceit get very swagger scientific names. If a man is unclean in his habits, parasites, each with its scientific name, make their appearance. If a plant is in an unnatural state, parasites and strange growths and disease all appear. The Bajawella "pandal" speaks a humbling lesson more to Ceylon than to the honest man who was pushed by financial considerations. The flushing leaves in that darkened acre call out to all Ceylon that Finance is the wrong whip for an agricultural team. You ask "What is to be done?" Hold in your horses and don't burst them because the man inside is in a hurry. Tell the man inside that the more haste the worst speed. The man inside is the controlling financier that uses a red and blue pencil in estimates of expenditure, cutting them down, and a hardhearted V. A. and cruel pressure in estimates of crop putting it on. The man inside, the V. A. driver, the superintendent, horses and the coolie wheels—they are off on a new track. The best man at figures will get the cream, and the agriculturist will be driven out of the country.

I am not going to deal with tea yet. Softly just a bit. Should I be inclined to disagree with the views of those in power I would like to be on board ship on my way back before the howl started. But I do not anticipate this. Only I dread seeing Maria-watte store which I am told is the same as figures in the *Observer* advertisement column.

If Captain Webb had succeeded in swimming down that fearful channel many similar fools would have tried it in vain, but his fate put an end to the folly. Perhaps the too great success of one or two pioneers will be your worst danger in

elevating your standard (in two senses). My idea is: "Pick your men and trust them better, keep down your acreages and do not extend operations until actual result has been reached, and do not have one brain carried by various methods of locomotion from Badulla to Matale, from the confines of Bintenna to far Rakwana applying one hard rule to all and various: 'The greatest result at the cheapest cost with the greatest obedience.'" The rein of economy, the whip of greed, the voice of the man inside, all combined! Oh for my quiet corner in Mysore. When I go back next month I will appreciate it more. ABERDONENSIS.

"WHITE-ANTS" AS ENEMIES TO TEA.

We are sorry to receive the following from a correspondent:—

"If you have not already heard, you will learn with regret that a very serious enemy to tea-planting has appeared. On an estate in Lower Dikoya, whole fields of fine tea have been attacked with *white ants*, killing the trees right out, in some places from 50 to 60 per cent. The ants seem to have eaten up, beginning at the root and stopping a few inches above the ground after ringing the tree of all bark. Curiously enough, the indigenous has escaped, but the other bushes of every age suffer alike. I never heard of white-ants eating growing trees before, and this was a sad sight to see: I put it down to the severe drought. The superintendent did not know the cause of the yellow appearance of his bushes for a long time, but the ram soon cleared the stems, and the reason was apparent."

The virulence and destructiveness of the attack make this case remarkable, for that the *termites*, popularly known as "white-ants," eat living and healthy tissues in the case of tea-plants, is a proposition which the experience of Indian planters, extending over more than a generation, has, unhappily, placed as much beyond doubt as that the "white grub" of a species of cockchafer eats the living and healthy feeding rootlets of the coffee tree. After all that has appeared in the *Observer* on the subject, we are only surprised that our correspondent, who has been long in the island, should be ignorant of the formidable enemy which tea at low elevations, where alone the white-ant can exist, has in that insect. Like our correspondent, we long cherished the conviction that only dead or dying vegetable tissues were liable to the attacks of white-ants, and we were naturally confirmed in this belief by what is so familiar to visitors to the Colombo Cinnamon Gardens, bushes of the spice flourishing while surrounded and the lower portions of their stems closed in by white-ants' nests, consisting of pyramidal mounds of earth. It is probable that the essential oils, hot and pungent, in the bark and leaves of the cinnamon shrub render it distasteful to the insects, and this may afford a hint as to remedies. The cumulative, we may say the unanimous, evidence of Indian planters long ago compelled us to recognize the fact that white-ants *did* attack and destroy living tea bushes, and also the wisdom which we previously doubted of the expensive Indian process of clearing away all timber from tea gardens instead of leaving it to decay and yield fertilizing matter as our coffee estates in Ceylon. And local experiences of the destructive powers of white-ants have not been wanting. About a year-and-a-half ago, we mentioned in the *Observer* what a planter had told us about tea bushes in the neighbourhood of Awissawella being infested with white ants to such an extent that children were employed to go round and scrape away the insects and their earthy coverings from the stems of the trees. In the case mentioned by our present correspondent, the insects seem to have commenced eating the tea bushes

from the root upwards, without showing any sign above ground, which is contrary to the usual habits of the termites. It seems quite probable that the protracted drought at the commencement of the year may have operated so as to have induced the white-ants to move from the dead wood lying on the estate to the living bushes. The great question now will be the best means of eradicating the evil. In our *T. A.* back issues will be found notices of scores of remedies for white-ants, of which probably arsenic is one of the most useful. But the most effectual measure to adopt, and it will be a measure of cultivation, is to attack all the nests on the estate, hoeing down and spreading over the surface the built up soil and digging out and destroying in every case the nest and its occupants, taking care never to miss the queen, a huge grub-like creature. Fowls would be useful in the work of destruction, and we believe many of the coolies would cook and use the white-ants for food. If all the white-ant nests existing were destroyed and no new ones allowed to be formed, while unsparring war was waged against every insect which showed itself, we cannot doubt that the destructive creatures could be exterminated. Timber could be gathered and stacked in convenient places. There is comfort in what seems to be the fact, that only in their earlier stages have white-ants been destructive on Indian estates. Then, again, we suppose that all estates at altitudes of over 3,000 feet (?) or certainly 3,500 are exempt from attacks by white-ants. What their exact limit is we are not prepared to say, but we certainly never saw or heard of any at or beyond 3,500 feet.

A tea planter who has had experience of white-ants on patches suggests that probably in the above case, grub had done the mischief before the white-ants commenced operations. His experience is that white ants attack tea trees which have suffered from grub. But the great point is that in such cases supplies of tea come on so much more quickly and certainly than was the case with coffee. Tea has, no doubt, a variety of enemies in Ceylon as elsewhere; but they can all be fought and conquered; and grubbed fields, when the attack has passed, may become the most prosperous on the plantation.

BRAZIL COFFEE.—A New York correspondent assures the *Batavia Dogblad* of the 23rd June that in Brazil the Rio coffee crop this year reaches four millions of bales. The Santos crop is estimated at two and a half millions of bales, it amounting ten years ago to hardly six hundred thousand bales. Advices from Brazil agree in anticipating heavier yields in years to come with every prospect of still lower prices ruling.—*Straits Times*.

COTTON TREE SEED AS A FOOD.—A French savant claims to have discovered in cotton-tree seed a nutritious matter, presenting some most remarkable features in its compositions. An analysis of the seed of cotton-trees, of which several varieties are cultivated in Bolivia, shows that this is the richest of all known grains in nitrogenous substances. He is convinced that cotton-tree seed will make a flour destined to take an important place as a food for man.—*American Grocer*.

A SPIDER'S CAPACITY.—A gentleman scientifically inclined captured a spider, and, by a careful estimate, made by means of actually weighing it and then confining it in a cage, he found that it ate four times its weight for breakfast, nearly nine times its weight for dinner, thirteen times its weight for supper, finishing up with an ounce, and at 8 p.m., when he was released, ran off in search of food.—*American Grocer*. [Unless the spiders spun web in proportion, it would not pay to keep them for silk production.—Ed.]

TAPROOT OF TEA.—Herewith (says a merchant) a specimen of a tea plant 12 months old from Ythanside, showing the taproot. This may interest you. [We should think so: to see a tea plant 9½ inches above the surface of the soil, at a year old, having a taproot straight away down measuring 52 inches into the earth, is rather unusual! It is worth sending round the *Fort*.—Ed.]

PLANTING IN SEYCHELLES.—In a letter that we have received from Mr. E. H. Edwards, of Mahé [an old Ceylon planter] he says: "You will be glad to hear that I have at last been successful with my tea seed. I find nurseries at a low elevation are not a success, but some plants that I have put out at an altitude of about 1,400 feet are thriving well. Cinchona also will not do at or near sea level; I am going to give it a trial at the same elevation as that where the tea flourishes. My rappers are coming on capitally: nutmeg seeds from Mauritius, I am sorry to say, are a failure: the time in transit is too long. A friend of mine has raised some cardamoms, from seed; I am promised a few plants. Mr. Scott, of your *Gardeas*, is rendering me great assistance; scarcely a mail arrives but I receive seeds of some kind or other from him. I wish I could say I had a helping hand here: the present Head of the Government appears to be dead against any agricultural innovation and I have to contend against no little injustice." We hear that Mr. J. H. Hope was a passenger on board the 'Salazie' on her homeward voyage. This gentleman arrived in Mahé a short time ago on a tour of inspection, and he is so pleased with the climate and general prospects of an agricultural life there, that he has purchased an estate, and now returns to England to bring out his family. We wish him every success. We also hear that Messrs. Galbraith and Maclean have purchased the well known 'Cascade' estate.—*Merchandise Record and Commercial Gazette*.

MR. PRESTOE, the Government Botanist of Trinidad, at the request of the Tobago Agricultural Society, has just paid a visit of inspection to Tobago, where several estates have lately gone into liquidation, with a view to suggesting some form of cultivation which shall replace sugar. He has expressed himself as greatly surprised at finding the island so different from what casual reports had led him to expect, and he declares that it is superior in natural advantages to either Grenada or St. Lucia. Be that as it may, he saw on his tour round the island tracts of land which, as he expressed it, "seemed to have been formed especially to grow cocoa," alongside of other tracts, abundantly watered, which he described as "magnificent cane-growing land, on which central factories ought to be established. His formal report will shortly be issued, which we expect will help to dispel the unaccountably bad impression which prevails about the Colony; but in the meantime an effort is being made to form a company to take up one of the recently sequestered estates for the purpose of adopting Mr. Prestoe's recommendations. An estate of about 3,900 acres, together with all the machinery, building, and live stock thereon, is to be purchased for £4,000, or little more than £1 an acre—one-half to be paid at once, and rest in two years. How many men are there in this country who would be glad to purchase such an estate at such a price for mere purposes of recreation! Properly handled, such a property ought to yield an enormous profit, for even under sugar cultivation the land is really worth ten times the amount proposed to be paid for it. The venture will be brought before the notice of investors simultaneously in the West Indies and in London, and there ought to be no difficulty whatever in raising the money. If one such venture succeeds, the chance of buying up another such an estate on such terms is hardly likely to occur.—*Colonies and India*.

CURRANT GRAPE VINEYARDS IN GREECE.

Few who habitually consume large quantities of the Corinth, or currant grape in the form in which it is imported, and especially at this time of year, are aware of the place at, and the conditions under which the cultivation is carried on. The currant grape is almost exclusively grown in Greece, and the adjoining islands of Zante, Cephalonia, Ithaca and Santa Maura. The mainland of Morea is cultivated along its northern and western shores—the quality of the produce deteriorating as you proceed southward away from the Gulf of Corinth. At Lepanto and Messolonghi in Livadia, the industry is pursued with marked success. Greece is so largely dependent on the currant grape vineyards that any temporary failure of the crop is attended with serious loss as great and as widespread as that attending the failure of the potato in Ireland. The olive, which is another staple product of that part of the world, is being rooted up to give place to currant vineyards. The neighbourhood of the sea is preferred, although the plantations are not as a rule permitted to approach nearer than 500 yards to the shore. The finest sites are at the foot of wooded hills, with a sunny aspect, open to the free circulation of air. Sea fogs and briny mists are beneficial. The currant grape affects a rich light soil with an admixture of sand—the characteristic of most of the arable lands of the ancient Peloponnesus—and a climate with alternations of intense heat and cold, the latter being of short duration. However closely the sites selected may approximate to these requirements, it is a noticeable feature in the cultivation that a uniform quality in the crop cannot be ensured. The soil, exposure and treatment may be identical, and the properties may adjoin, but there will yet be a marked difference in the fruit. The size or the colour of the berry is sure to differ, or the saccharine matter or aroma will abound in the produce of one, and be absent, or deficient, in that of the other. The Zante currant though smaller is preferred for its sweetness and favour to that grown in any other part of Greece. The vineyards are kept free of all other cultivation as the currant is impatient of shade. Sometimes, however, during the earlier years tomatoes and melons are cropped on the same soil, but all good cultivators deprecate anything else being grown between the sets as tending to impoverish the soil, and withdraw from it the elements of plant nutrition which do not naturally abound. In the month of January cuttings are taken off the old plants, and buried until the following March, when they are permanently put out at a distance of four feet from each other. In four years the vine will fruit, but seven or eight years must elapse before it comes into full bearing, and it will continue, under favourable conditions, and good cultivation to yield for upwards of fifty years. The average age of a flourishing plantation is forty years, after which it needs renewing, but trees are met with fully a hundred years old. The produce, however, of these veterans is very small. With the object of securing "bold fruit" the growers "ring out" the stems and branches, an operation performed when the fruit has set, and intended to prevent the descent of the sap. This treatment is prejudicial to the vigor and health of the vines, and also to the keeping qualities of the crop, but it is almost universally practised. It costs £100 to open an acre of currant grape vineyard, and the upkeep averages £10 per annum. This sum makes provision for liberal sulphuring at the rate of 80 pounds per acre. The sulphur being procured from Sicily in fine powder, and sprinkled over the vines as an efficacious remedy against mildew to which they are very subject. The yield averages 2,000 pounds per acre. The best sorts, namely those growing about the Gulf of Corinth, along the northern and western shores of the Morea and in the island of Zante fetch as much as 25 shillings per cwt. The inferior sorts do not realize over 15 shillings per cwt. The average selling price may be put down at £20 per ton, which gives the grower 10 per cent on his capital outlay. Labor is expensive, and higher on the mainland than in the islands, varying from 2 shillings per diem in the latter to 4 shillings in the former. In the island of Zante 10,000 acres are under currant cultivation,

and this acreage is gradually increasing as olives are being rooted out to find room for it, yielding annually 7,000 tons of currants. The entire exports do not exceed 120,000 tons, and at the present time this appears to meet the requirements of the world, but the use of the fruit is extending. It is no longer confined to confectionery, the ravages of the phylloxera having directed the attention of French growers to its utility for wine-making. In recent years over 30,000 tons have been imported into that country for this purpose, and the demand is not likely to decrease. More than a half of the total exports goes to England, but finds its way out again to other parts of the world. 12,000 tons go to the United States directly, and a great deal more indirectly.—*Malras Mail.*

EVILS ATTENDING PLANT CULTURE
IN POTS.

This is a good time to give advice on this subject. It is not a good plan to grow any plant in a pot; but pot culture is a necessity of horticulture, and as all gardeners, great or small, grow an immense proportion of their stock in pots for a shorter or longer season every year, it follows that they should know all they can about pot culture and its evils. Gardeners, and especially amateurs, are so much accustomed to growing plants in pots, that we daresay the idea is a common one, that that is the best way to grow them. It is not the best way, however; on the contrary, except under a few exceptional circumstances, it is the worst way. Very many of the ills which afflict plants are directly or indirectly traceable to their culture in pots. It is an acknowledged fact that green fly, thrips, red spider, mildew, and not a few other pests and diseases which attack plants are encouraged and aggravated by culture in pots. How is this?—some one will ask. And in answer, it may be said that the idea is not a new one, or broached for the first time. Lindley gave the subject his attention, and so did Knight; and inventors have devised pots that were said to overcome or mitigate the evils complained of, but owing either to the price, or inconvenience of using such articles, they have never become popular, and for mostly all purposes the common flower-pot is still in general use.

One of the greatest disadvantages connected with the use of pots is the necessity of standing them in places exposed to the air and sun, and the great fluctuations of temperature and moisture to which the roots of the plants growing in them are thereby exposed. It is very bad for any plant to have its roots in a medium that is liable to be alternately wet and dry, or cold and warm, and these are just the conditions to which pots expose them; hence experienced gardeners are always casting about for some means of protecting the pots, and resort to plunging, shading, sprinkling paths, and devising shelves and ventilating processes, so as to prevent these agencies from working mischief as much as possible. When a plant is newly potted in abundance of soil, and freely watered, the roots are not so much affected; but when they reach the sides of the pot, which they soon do, and there is nothing between them and the sun and air but about an eighth of an inch of porous earthenware, they are liable to serious injury if not watched attentively. When the soil becomes parched in the pots, it shrinks away from the sides, leaving a space between the two; active evaporation begins from the tender roots, which, instead of absorbing moisture, as is their function, part with it, and the consequence is that they are either killed or injured, and the branches suffer in proportion. Where large collections of plants exist, or where those in charge have not time to attend to the wants of the plants, this is quite a common occurrence at this season, and many a plant is irretrievably ruined thereby. Regular attention to watering and shading can only prevent such things happening, and in the case of pot-bound plants a good deal of attention is required, because the soil in the pots soon dries up. To fully understand the condition of a plant situated in a pot as described, it must be remembered that in the natural state, when a plant grows in the ground, the roots have unlimited scope,

and do not experience such conditions at all, whereas in a pot exposed on all sides, evaporation is constantly going on from the roots, the porous earthenware pot acting like a wet cloth put round a bottle of water to keep it cool. As regards temperature, the roots of all plants are naturally subjected to far more uniform conditions than the tops, that is to say, the temperature of the ground does not vary nearly so much as that of the air, and it is found that the nearer these conditions are imitated in artificial culture, the better do plants thrive. This is why pine-apple plants in pots are invariably plunged in a bed up to the rims of the pots, and they cannot be grown and fruited successfully in any other way. Orchard house trees are also always plunged when practicable for the same reason, and so are many kinds of select plants that are found difficult to grow in the usual way.

The remedies for the drawbacks of pot culture are various. Many kinds of plants have of necessity to be grown on stages and shelves in glass houses, where they cannot be plunged, and the cultivator must then do the best he can under the circumstances. The main points to attend to in such cases is not to water the plants during the driest and warmest time of the day, when evaporation is most active, but say in the morning or in the evening. Next, ventilation or air should be given gradually, so as to dry up the moisture slowly, and the pots should be so placed as to shade each other as much as possible. Plants standing with their pots touching each other thrive much better than when the pots are placed widely asunder, and hence close ranking should be the rule, provided the tops have room at the same time. Under other circumstances, the best plan is to plunge the pots up to the rim whenever possible or convenient. Plunging obviates many evils, and it is often a good practice to plunge the pots of favourite subjects in another and larger pot, filling up the space between the sides with ashes or soil. Double-sided pots have been made to meet this end, but they are too cumbersome for general use. A dry cloth, a piece of "frigi domo," for example, or a piece of stout brown paper tied round a pot, answers almost as well. The object in any case is to prevent radiation and evaporation, or the escape of heat and moisture from the soil in the pot, and so preserve the roots in an agreeable medium.—*Field.*

QUEENSLAND SUGAR PROSPECTS 1885-86.

In accordance with our usual custom we lay before our readers, as soon as possible after the close of the sugar season, which is here considered to end on March 31st, a resume of the operations for the past year and a forecast of the probabilities of the coming season, based upon the area of land under cane and governed by the general appearance of the area cultivated. It is needless to remark that the returns for the past year are of the most unsatisfactory nature, generally speaking, and a careful study of the figures we now submit to our readers, will show that while the return per acre has been abnormally low all round, it is evident that in a large number of cases the yield per acre must have been so small as to make it questionable whether it would not have been more advantageous to have left the crop ungarnered, for since in many instances by means of improved processes and superior machinery the quantity of sugar produced per ton of cane has been very large, it follows that in many cases also the return must have been proportionately small. The average production per acre for last crushing is below 17 cwt. per acre, a figure which has not in this district been reached since 1875, and when it is remembered that the prices ruling have been extremely low it will be seen that very severe losses must necessarily have accrued on a large number of plantations. The area of cane crushed during the past season was 13,499 acres out of an area of 15,638, which was twelvemonth ago expected to be fit for milling, thus showing that over 2000 acres of cane which was expected to be fit for manufacture did not actually reach the mills. How it comes that 14 per cent. of the cane returned at this time last year as likely to be fit for crushing remained uncut, can only be accounted for

by the presumption that the inferior condition of the crop and the low prices ruling caused this large percentage to be left on the field. From the area already stated as having been operated on, the output of sugar was 11,350 tons, which amount is upwards of 4000 tons short of the estimated output, a falling-off so serious as to be a matter of grave importance to the growers, millers, and, in fact, all residents in the district. The average production per acre for the season shows a decrease of 8 cwt. per acre over that of the previous crushing. The return of the molasses made during the season is naturally higher than the usual figure, as experience shows that the proportion of molasses to sugar is always greater in a bad sugar year than in a good one, the quantity this year being within a small fraction of 34 gallons to the ton of sugar made. The difference between this and the usual 30 gallons would not appear large, were we not to take into account the superior systems adopted in our mills by reason of which the production of molasses should be reduced. Turning from last season's figures we come to those of the current sugar year, and these certainly give reason for more hopeful results when placed side by side with the splendid appearance which the cane generally presents. We find that the area under cane at present is 17,770 acres, a slight increase over that of last year, though by no means so great an increase as was anticipated, and as would undoubtedly have taken place but for the various adverse circumstances with which the industry has been surrounded during the past twelve months. Of this at present it is estimated that 16,241 acres will be brought to the rollers, but we must be guided by the experience of the past and therefore allow that about 2,300 acres, from one cause and another, will not be cut, and this will leave us, in round numbers, 14,000 acres of cane for this season's milling. We have made a very careful survey of the cane throughout the district, and have consulted a large number of the out most competent growers and manufacturers, and though we have observed a tendency with most people to depreciate the probabilities of the season's output, we come to the conclusion that in placing the estimate at 23 cwt. per acre we have struck a somewhat low average. It is probable that many of our readers will be disappointed, and some surprised to find so low an estimate put forward after hearing the splendid appearance of the crop so frequently commented on of late, but while the general appearance of the fields is undoubtedly fine, we are conscious of the fact that the ratoons will give a comparatively low return, and that many of the plant cane patches, now presenting a splendid appearance on close examination evidence a larger preponderance of "misses" than is usual. Our estimate for the coming crop will therefore be a return of 16,000 tons of sugar. With regard to the financial result of the manipulation of this amount of sugar we will not pretend to make any prediction, the conditions under which the work will be conducted and the state of the markets being of so uncertain a nature; but we are sanguine enough to think that owing to the intervention of Providence in regard to a favorable season that the prospects of the planters are not so dark as they appeared a few months since. Before concluding we would allude to the subject of rum-making, and the figures before us show that some alteration in the excise duties are desirable. The quantity of molasses in 83-84 was 456,252 gallons; the figures for 84-85 were 384,640 gallons; and a glance at the operations of the three local stills discovers the fact that a comparatively small proportion only of the raw material has been manipulated; a proportion so small indeed as to raise a very notable question for enquiry. During 84-85, 187,225 gallons only of molasses were operated on at the stills, producing with the addition of 8,250 gallons of skimmings a total of 82,469 proof gallons of spirit, while the molasses remaining from the previous year's crushing was as above shown 456,252 gallons. This would have produced, had the whole of it been distilled, upwards of 190,000 gallons of spirits. During the year the export of molasses has been almost nothing, and thus we find an enormous amount of raw material unaccounted for, and, as a matter of fact, gone to waste. The loss to the country upon this may be better estimated when we point out that the

excise duty alone at 6s. 8d. per gallon would have, on the waste product, exceeded £20,000, a sum of money which, in view of the present depletion of the Treasury, would have helped materially to swell the receipts of the colony.—*Hackay Standard.*

ENGLISH FARMING IN INDIA.

Talking with an Indian zemindar (landed proprietor) the other day, this man, a Hindu, remarked:—"I wonder English capitalists do not buy up land in Southern India and farm it on their own account. They will put their money into Indian gold mines that won't return them one per cent, when the land would give them twenty." And when I inquired why native capitalists did not enter on such a profitable pursuit, he answered curtly, "They can get 60 per cent on usury," which is very true. The great wants of the land in Southern India are water and manure. The ryots, or peasant farmers, are too poor, and generally too much involved in debt, to dig wells, or to do anything that costs money in the way of irrigation, and they burn their cowdung for fuel, consequently the land gets no fair play. Moreover, they never infuse fresh seed into their crops; indeed, they are only too thankful to get any seed at all, and, of course, buy the cheapest and the worst that is to be had in the market. As for ploughing, they simply scratch the surface of the soil with an implement that looks like a wooden anchor; but then their half-starved draught bullocks can do no more—so much is all that can be expected of them. Despite bad years, debts, difficulties, and taxation, an Indian zemindar on a large scale is usually worth money; some of them are enormously rich, so that, however they do it, they make farming pay.

I believe with my friend the zemindar that a large property in Southern India in such districts as Coimbatore, or Godavery, or indeed anywhere that water was easily obtainable would pay a Syndicate or Company able to expend a considerable capital upon it, and this, too, though I know of sugar estates taken up by Europeans that have failed miserably. The fact is, that these failures were left to native management, and nothing in India left to native management will pay, whether it be a State, a regiment, a property, a business, or what not. Supervision by Europeans is absolutely essential to the success of anything in India; because speculation is rife and no native seems to see the fun of working for another person so long as he is paid for doing so. Active European supervision will, however, produce wonderful results if combined with capital, and I confess I am curious to see what would be the result of good farming by experienced men in the South of India. We all know that large fortunes have been made by indigo planters in Bengal; but the South of India will also grow indigo, and sugar, tobacco, grain, oil-seeds, and other produce of great value. Englishmen, nevertheless, have never, to any extent, gone in for farming on the plains; they have limited their enterprise to coffee, tea, and chinchona planting on the mountains. Not that the climate need deter them. It is the same climate in which Government civilians and military men have to work, and no hotter than many parts of Australia in the summer.

There is a Government model farm at Sydapett, near Madras, where fancy crops are grown; but a Government model farm will hardly serve as a criterion of what a syndicate might do with fifty or sixty thousand acres of zemindaree land. But it is first necessary to describe what that land is. It is, generally speaking, quite unlike an estate at home—unless, perhaps, in the wilds of Ireland. There are no hedges or fences to speak of unless round a standing crop, and not always then, and the estate may be a vast plain, more or less sandy, dotted with patches of grain, such as cholium and raggy, for dry land, and with bright green paddy for wet. The trees will be chiefly palmyras, cocoanuts, according to the distance from the sea, and there will be a prodigious acreage of scrub jungle, otherwise waste land. It is not because the land is worthless, but because the native farmer has not the money to cultivate it. He is over head and ears in debt to the village Shylock, and why should he cultivate more land when all the profits must go into the pockets of Old Sixty per Cent? Why, indeed,

should he do more than just get the handful of grain that keeps him alive, because anything more than this would go to the local money-lender and the landlord together. But it does not follow from this that the land is not good land, and capable of producing large crops. Most likely, if it was properly cultivated, and got some of that manure it now never sees from one generation of agriculturists to another, it would give as good a return as those prairies in the West of America we hear so much of, and it has this advantage over American land, that labour is abundant, and ridiculously cheap. Even the great and rich zemindars, like my friend, do not do justice to their land. Not one of them would ever think of spending a rupee on its improvement if the expenditure could be avoided, and a zemindar who drew, say, ten thousand rupees annually from his estate, would think himself a fool to try and make it, putting money in the land, twenty thousand. It is here that Europeans would have the pull over natives. They would improve, and their profits would increase, whereas the natives stand still, spend their returns in foolish domestic ceremonies, costing all they have, run into debt, and are ruined whenever a bad year overtakes them.

I don't think there would be any great hardship for Europeans in supervising an Indian estate. They would have servants and luxuries of all kinds that the Colorado or New Zealand colonist knows nothing of. And they would have plenty of sport and regular employment; what more need they wish? The indigo planter's life used to be considered the pleasantest in India, and equally profitable crops ought to give as much happiness as the blue dye of commerce. But, of course, experience of natives, and native ways, would be essential; at last to ensure the profits of the estate. As for the estate itself, I fancy, that a good large zemindaree could be purchased in one of the districts I have mentioned on very favourable terms, owing to the ineptness of the zemindars as a class, and to the famines in past times, which have plunged many of them into debt. I don't mean Government waste lands, of which plenty could be had for a trifle; because to clear land would never pay; but to land now under crops (?) save the mark! with a view only to improvement. My idea is that the English capitalist would make two blades of grass grow where the native grows one; and it is not to be forgotten that there is a ready market on the spot for whatever is grown, be it grain or grass. There is not the disadvantage of having to export one's grain. India is so densely populated that the food is insufficient as it is.

I hardly know what the difficulty might be with the Brahmins, the ryots, and native neighbours at first, but probably not much, because capital smooths everything in India. The syndicate of 50,000 acres would be respected, and if not, why the law is at hand, unlike the prairies of America, where there is sometimes no redress. And natives, generally, are beginning to see their profit in the investment of British capital in such enterprises as manufactories, and would no doubt, be equally glad to see English money invested in agriculture. There are some crops, indeed, which it is almost impossible to bring to perfection without a greater outlay than the half-starved Indian cultivator can afford. Tobacco indigo, sugar, all require capital, and the ryot lives from hand to mouth. But wherever money is expended on the land, and manure and water applied to it, the crops will be found magnificent: the pity is that it is only in the neighbourhood of large towns and irrigating channels that one commonly sees anything of the sort. A syndicate would, of course, take up land along the bank of some large river, and would dig wells if necessary. In this way there would be a good command of water, and all the manure of the stock, as well as perhaps the sewage of adjacent towns or villages would be applied to the land. The stock alone should prove a source of profit to an English farmer in India, because the natives are singularly apathetic about breeding cattle, and their acquaintance with the veterinary art is so poor that they are always losing their stock by preventable or curable disease. The improvement of Indian cattle and sheep by judicious crossing with the South American and Australian breeds is a legitimate speculation, and one that would prove highly profitable to an Anglo-Indian farmer who under-

stood his business. Profitable, too, would be the breeding of horses and ponies on a well-watered estate with plenty of fodder. It is for want of fodder, which is want of irrigation, which is want of capital, that horse-breeding speculations in India generally fail.

It would be utterly absurd and useless for any syndicate or individual to undertake the adventure I advocate upon a small scale or with a small capital. The ryots are all poor, but the zemindars are all rich. *Verb. sup.* The bigger the estate, and the greater the capital to expend upon it, the better the chances of making a Maharajah's income from it. And such is India and its inhabitants, that if an estate of 10,000 acres was to return 20 per cent, I should expect one of 20,000 acres to return 40 per cent, always supposing that the capital expended was in proportion with the increase of the acreage. In short, I believe that there are greater gains to be made out of Indian land than out of American, Australian or other cultivated lands; but that to make any gain at all the land must be cultivated on a large scale, and a considerable capital put into it. It may be urged, "Why don't the natives form syndicates themselves if the scheme is so profitable?" but a sufficient reason is that they distrust one another. They would certainly try to rob one another all round, and a syndicate of that kind would not hold together. One word more. I believe that the Government would encourage enterprise of this description for its own advantage, for great undertakings would benefit Government, whereas small ones would only trouble them. And with Government, capital, and knowledge on its side, an English Farming Syndicate for India ought to succeed.—F. E. W.—*Graphic.*

PLANTING IN JOHORE.

There are now fully 2,000 acres under Liberian coffee, I am told, and I am certain this quantity will be greatly increased during the next season. A small shipment of the best Liberian coffee has been sent home from the Batu Pahat district, and we are anxiously waiting to learn the result of the sale in London. The coffee was cured under many disadvantages, but was, on the whole, a very good sample of this product.

Tea.—As yet there are only two gardens in Johore; one belonging to H. H. the Maharajah, about 2 miles from the town, has been handed over to a gentleman who has a coffee estate near by for 3 years, so that he may carry out experiments as to cost of cultivation and manufacture of tea with the labor at present available, I am told he has got down Chinese tea-makers from Amoy, and he is now making tea in the same fashion as that in use in Formosa. He expects to find a good market for it in America and Russia, I believe. The other garden belongs to the Johore Tea Company, and is situated at Taubah Merah, 8 miles from Johore Bahru, on the bank of the Scudai river. There are about 70 acres planted, from 3 years to a few months old, and about 30 acres cleared and ready for planting. About 30 acres at 3 years old is very good indeed, and would compare favorably with great deal of Ceylon tea I have seen of the same age. The balance, although not had, is not so good, having been planted in poor soil. This garden has had many disadvantages to labor under from the first, through frequent changes of superintendents through ill-health; but great difficulty has been labor. I understand that only Chinese and Javanese coolies have been available, and such labor is costly indeed compared with Indian labor, such as you have in Ceylon. That the tea will flush well here, and give tea of excellent quality, has been already demonstrated, so all that is wanted to make tea a success in Johore is cheap labor, and while on this subject, I may mention that we are now almost certain to get it from India, as His Highness has just gone home, and we expect to hear very shortly that the negotiations which have been going on for some time have been completed.

Cocoa.—Of this product I am sorry to say I cannot give a satisfactory account, as from all I have seen and heard it seems to have proved anything but a success. At first, I was inclined to think the dying-

out of the cacao I saw, was caused by neglect, but I am now convinced such was not the case, as I hear that fields of cacao which have had from the first all attention possible in the way of cultivation have begun to go out just the same. For the first year or two it looks flourishing, but after that the branches begin to get black at the tips, and this soon extends all over the tree, which dies down to near the ground. A sucker may then grow up which survives, for, say, another year, and then dies off in the same way. I hear of one or two fields of cacao which are still looking flourishing, but as a whole, I think there can be no doubt that cacao has not proved a success over here.

Cinchona.—The first thing which struck me here on visiting some of the coffee estates was the absence of cinchonas—all the more so as there were many parts of the said estates admirably adapted for the growth of this product, which could have been grown without detriment to the coffee already planted. I only know of one estate in Johore where cinchona is being tried, and I am told it is growing splendidly. One or two nurseries of good seed are being put in this year, and I yet hope to a good acreage under this cultivation, as I am convinced both the climate and soil are well-suited for it. Writing of cinchona reminds me that I heard from a gentleman planting in Sarawak, the other day, and he mentions that his *Ledgeriana* and *Succirubra* of 2 years old have given most satisfactory analysis, viz, 6 per cent. quinine from the former and 3 per cent. for the latter. Liberian coffee of which he has a few acres is doing very well, but cacao is very unsatisfactory, ceara rubber is growing luxuriantly and he has also a field of carlamons, which promises to give a good crop this year. Tea is to be tried this year.

Araca-nuts.—I see this cultivation is beginning to attract attention in Ceylon, and it may interest you to know that a large tract of land is planted with this product in conjunction with cocoanut and other fruit trees in Johore. About 110 miles up the west coast of the Peninsula, the Moar river joins the sea, and a few years ago for miles on each side of this river there was nothing so to speak but mangrove swamp. H. H. the Maharajah, who is always doing something to develop his country and improve the condition of his subjects, induced a number of Javanese and others to settle near the mouth of the river, and gave them every help and encouragement in reclaiming the swamp land; and the consequence is that what was once a mangrove swamp is now a splendid plantation or rather plantations, of cocoanut, aracaunt, durian, duker, mangosteen, mango, and other fruit trees too numerous to mention. There are, I am told, about 50 square miles so cultivated along the south of the river Moar. Near the mouth there is a rising little town named in honor of the Maharaja "Bandar Maharane" where there is a Resident, an intelligent Malay gentleman, a relation of H. H., who does everything in his power to encourage and extend cultivation and improve the settlement.

Health of the Country.—A few years ago there can be no doubt that the country was very unhealthy and every planter who came here suffered more or less from malarial fever, but now, and for some time back I am glad to say, there is great change for the better, and you now seldom hear of anyone getting a bad attack. Many get a touch of fever now and again, but nothing more than one gets in Ceylon, and I think the best proof that the country is now much more healthy is that new comers seem to suffer as little as those who have been here some time. Before, it was just the opposite, the newcomer generally suffering most. As far as personal experience is concerned, I can only say that I have never enjoyed such good health anywhere else as I have since I have been in Johore. I dare say you saw a letter which appeared in the *Straits Times* some time ago, giving an account of a visit to the Chasseriau estate in the island of Singapore. The writer (who, as most people over here now think, describes himself very correctly by saying that he is deficient both of practical knowledge and common sense) gives, to say the least of it, a very imperfect description of the system of cultivation carried out by Mr. Chasseriau. To begin with, I need hardly say that the

remark about the lower branches of the Liberian coffee, trees being cut off is all mistake. The fact is, as a rule, the Liberian coffee over here does not throw out branches within one-and-a-half feet or two feet of the ground, and often does not branch till five or six feet high, in which case it is best to pull such plants out and plant others in their place, as they will never make good trees. I have had the pleasure of going all over the Chasseriau estate with the courteous manager, Mr. Chasseriau, and I will now try and give you an idea of the system which I saw being carried out. The land now being opened up is old tapioca land overgrown withalang and other grass. It is more or less undulating, and there are good, wide roads, on which you can drive, at convenient distances all over the estate. The first thing done is to put on a gang of Javanese or Chinese coolies to hoe all thealang and other grass up and this is then heaped up, mixed with earth in mounds about four feet high and eight feet wide every 40 feet. These mounds are allowed to remain till the whole is thoroughly decomposed, and then, as by that time grass has grown up all over land again, coolies are put on to give it another hoeing. When this is finished, the grass dug up the second time is allowed to dry on the ground for a day or so according to the weather, and is then heaped up in small mounds mixed with earth and burned. The large heaps are then broken up and the burnt earth from the small heaps thoroughly mixed up with them. Holes are then cut 9 feet apart 3 ft. deep, 3 ft. wide at the top and 1½ ft. wide at the bottom. These are filled with the above compost, and, after being allowed to settle down for a week or so, are ready for the plants. The planting is carried out in a most elaborate manner, as follows:—Every plant is brought from the nursery to the field in a transplanter and before planting a hole is made in the compost-filled holes, and on this being filled with a mixture of good, bulky manure, the plant is carefully put in. After this, coolies shade each plant with ferns, and should there be no rain at time of planting, as was the case at the time of my visit, every plant is watered with a watering-can. All I have here described I saw being carried out, and at the time of my visit from four to five acres were being planted daily. The field of Liberian coffee, now about two years old, and which was planted same as above, was covered with blossom and crop when I saw it, and is really a fine field of coffee. In fact, all the coffee I saw on the place is very good indeed. Mr. Chasseriau has every facility for manuring, and says he has no fear of the trees suffering when older, as he can give them periodical applications of burnt earth and other manures, which of course he can easily do, being only about four miles from the town of Singapore, and he can cart manure all over the estate.

I also saw some fine fields of tapioca, from which Mr. Chasseriau hopes to get a good profit, in spite of the present low prices for this product. After this crop he does not intend to plant any more tapioca, but only coffee, and probably tea, of which there is a small field which promises well. There are large, commodious buildings on the estate which can be made suitable for coffee curing at very little expense. Ceylon planters, I daresay, may jump to the conclusion that the cost of work such as I have described is very high, and I confess I thought the same at first, but I am now assured the cost is very little, if any more than the system carried out in Ceylon. Of course, the estate in question is exceptionally favoured in many ways, not the least of which is having a scientific agriculturist like Mr. Chasseriau to carry out the work. It is indeed a great pleasure to go over the estates with him, as he is always ready to give you information about the plantation, and shows in everything how thoroughly his heart is in the work.

To revert to the subject of arcanut cultivation: I may mention that I have been making enquiries amongst the natives here, and I find that, as a rule, arcanuts are planted about 500 to the acre in good soil, and in the fourth year from planting you will get upwards of 500 nuts per tree. If I am not mistaken, arcanuts don't bear in Ceylon before the 6th year from planting, and then I notice a correspondent of yours gives the average yield as 200 nuts per tree; but he also advocates

planting 1,500 trees to the acre. No one here would attempt such a thing, and all the natives I have mentioned this to, expressed their wonder that the trees bear at all, and say such a plantation can never last.—Local "Times."

RHEA FIBRE.

The Manchester manufacturers are now giving increased attention to the use of this fibre, and as it is our province to give all the reliable information obtainable upon every subject likely to benefit tropical planters, we place below some extracts from a paper recently published by Sir Joseph C. Lee, the well-known Manchester millowner. Speaking of the difficulty of cheaply extracting Rhea fibre, he says:—

The problem that many inventors have tried to solve is to make a machine or discover a process by which the work can be done effectually and cheaply, so that the fibre can be sold in London at £40 to £50 per ton in the unrummed state. Various mechanical appliances and methods have been invented, but only two of them seem to fulfil the conditions necessary for successfully treating the fibres. The first of these is a machine invented by Mr. H. Smith and improved by Messrs. Death and Ellwood, of Leicester. It is claimed by the inventor that this machine will clean any vegetable fibre, and particularly Rhea or China grass. To this machine was awarded the prize of 2,000 rupees in accordance with the recommendation of the "Committee appointed by the Government of Bengal to conduct a trial of machines and processes for the extraction of Indian fibres" on the 24th November last year. The report states that the cost of a single machine is £55, that of a double one, complete, £100. A semi-portable engine to work two machines will cost £82 10s. The quantity of water required appears to be about 400 gallons per hour for one machine, but the water can be used twice over. The work turned out in ten hours by one machine is 2,200 lb. of green stalks. This quantity might be expected to give 3 per cent, an out-turn of 66 lb. of good clean fibre. The value of this out-turn at £50 per ton would be about 30s.

The machine is the property of the General Fibre Company, Fenchurch-street, London, and is doubtless a valuable patent, and will be useful in cleaning some kinds of fibrous plants. No Rhea fibre has yet been imported that has been treated by this machine; we can only judge of the practical value from the evidence contained in the official report. In this it is stated that 3 per cent of fibre can be obtained under favourable circumstances from every 100 lb. of green stems. This percentage will contain at least 15 per cent. of resinous matter, which must be discharged before the fibre is ready for the spinner. This will give 2.55 per cent of pure flasse—a small percentage, which cannot be profitable if the fibre is to be sold at £50 per ton. Another drawback to the value of the machine is the quantity of water required to clean the fibre. In a climate like India it is not always possible to obtain water in sufficient quantity. Therefore, if only 30s. worth of fibre can be obtained per day from one of these machines (as stated in the report) it can hardly be said to be a commercial success so far as the treatment of Rhea is concerned. The second plan of treating the Ramia or Rhea is one patented by M. A. Favier, and is a simple method of de-orientating the stems of the plant on fields where they are grown. It is as follows:—

I visited the works at Louviers belonging to the Société de Crédit, accompanied by a director of the Company, Mr. Vian, Professor Urbain, Mr. Paterson, and Mr. Casper, of the firm of Messrs. G. W. H. Brogden & Co., the English owners of the patent, and by Mr. P. Nursey, the editor of the *Iron*, and others. We were shown samples of Ramia grown in France, Algiers, Egypt, India; all de-orientated, some of them by the Favier process, others by methods unknown. Seven different growths of Ramia were selected and placed in a large boiler or high pressure Kier. Probably half a ton of ribbons were thus under treatment, and when they had been thoroughly saturated by a solution of which one of the

component parts, if not the whole, was apparently caustic soda, the top of the kier was fastened down, and steam at a high pressure (30 pounds) was turned in from the bottom of the kier. The boiling extended over a period of five hours. On the kier being re-opened the whole mass of fibre was seen in a black condition. Mr. Urbain took about a pound weight of ribbons and treated them as follows:—He washed them in cold water, then in a solution of hydrochloric acid, again in water, then in chloride of lime, and lastly thoroughly in cold water. The ribbons then appeared in the form of whitish grey flasse, ungunmed and free from the brown pellicle; the fibres could then be easily separated from each other, and were apparently in the condition for treatment by machinery. The operation lasted ten minutes. The inventors claim that by their process 5 per cent of pure ungunmed fibre is obtainable from the green stems.

I see little difference betwixt the process I have described and the one used by bleachers of cotton cloth for dyeing or printing which is necessary to make the cloth chemically pure, and similar drugs are used to kill the husk and brown bark often left in the yarn; this is done without the least injury to the fibre. I am of opinion that the merit of the invention consists in the knowledge, obtained by experiments of the strength of the caustic soda required for destroying the pellicle and reducing it to a state of pulp without injury to the fibre. The after process is a clearing one; it removes the gum and pulp, and the chloride takes away any coloring matter that may remain. This invention may be considered a satisfactory and inexpensive method of ungunming the Ramai fibre, and if the patent rights be obtained by the producer of the yarns it will add to its popularity.

I shall now deal with the cost and production of the plants and the probable future of the industry. Of late years the French have given a great deal of attention to the cultivation and utilization of the Ramia plant. It has been grown in the basins of the Gironde and Rhone, in Algeria, and in Egypt. M. Norbert de Landtsheer, who has written much on the subject, gives the following table, showing the latitude in which the plant can be grown:—

Latitude of country.	No. of crops.	Names of countries corresponding to latitudes.
36° to 46°	2	Bordeaux, Grenoble, Avignon, Turin.
35° to 42°	3	Corsica, Sardinia, Madrid, Naples.
35° to 37°	4	Algeria, Tunis, Northern China, New Zealand.
25° to 32°	4 to 5	Egypt, Delta, Lahore, China, Florida, Mexico, Chili, Ens. Ayres, Australia.
15° to 20°	5	Madras, Bombay, Cochín China, Brazil, Jamaica, Cuba, Hayti.
0° to 10°	5 to 6	Sonatra, Johore, Ceylon, Jayana, Venezuela.

He states also that an acre of cultivated Ramai can give 200,000 stems at a cutting, each stem averaging $1\frac{1}{2}$ oz. In Algeria, where four crops a year can be grown, a profit of £19 12s 6d per acre has been obtained. If we take these figures as being correct—and I have not heard of them being disputed—we have 20,000 stems per acre or 18,750 lb. weight, which will produce about 1,875 lb. of ribbons, and by the Frémy-Urbain ungunming process 937½ lb. of flasse, which at £50 per ton gives 53d. per lb. I was told by the director of the Société de Crédit, &c. that they had signed contracts for 10,000 tons of ribbons at £10 per ton, to be delivered in two years, and that they were prepared to take 100,000 tons at that price. Therefore, if we take two tons of ribbons as costing £20 which will produce one ton of flasse; ungunming, two tons, at £8 per ton, £16; charges, shipping expenses, £4, or 4½d per lb.—£40 per ton. A ton of cotton cloth can be bleached for £6 per ton; the ungunming process being a quicker one should not cost over £5 per ton.

Several companies in India are now growing Rhea, notably the Glenrock Company, and a company has been formed to plant 20,000 acres in Johore where it is expected that five or six crops can be obtained yearly. It will be seen that before many years have passed an enormous quantity of this fibre will be shipped to Europe, and as the plant is perennial, and once planted will last

a hundred years, some idea may be conceived of the yield in prospect. A manufacturing community like Lancashire cannot afford to ignore the new industry which will undoubtedly spring up within a few years. I readily admit that a vast sum of money has been lost by manufacturers in their attempts to develop this new fibre, but, as I have shown, the conditions are now somewhat changed. Formerly, the quantity of fibre imported did not exceed a yearly average of 100 tons, consequently the value has been much affected by the demand, the price at some periods rising to £120 per ton, and at others falling below £50 per ton. We have now the prospect of large supplies of the fibre at a reasonable rate and under more favourable conditions. Makers of Spinning machinery will do well to give their special attention to the preparation of machines capable of treating the long silky fibres of the Ramia. The French are already at work. During my visit to Louviers the gentlemen who accompanied me were granted the privilege of an inspection of the preparing, carding and spinning machinery, but this courtesy was denied to myself on the plea that secrets might be revealed before they were secured by patent right. I was, however, shown the fibre in the silver and also in yarn equal to 10's, 16's, 24's, 30's cotton, all of which seemed satisfactory, and I have since received samples of the fibre I saw treated at Louviers, which are excellent. It will be asked, in what is Ramia better than cotton or hemp? I reply that it is better in many respects. It is nearer in appearance to silk than any other fibre, and, like silk, it is a non-conductor, or nearly so. It can be mixed with silk or wool, and it will give strength to both. It can be produced more cheaply than flax or hemp, and is three times as strong. It is stronger than cotton, and takes better colours—faster and more lustrous. It is invaluable for heads, ropes, hose, sailcloth, cloth for waterproofing clothing for men, Indian army clothing, furniture covering and hangings, cambrics, and summer dresses; and, in the words of a well-known chemist, "It is difficult to say what it is not good for. It is the strongest fibre in nature."

Mr. P. Nursey, O.E., Vice-President of the Society of Engineers, who accompanied Sir J. C. Lee in his visit of the works at Louviers, reports as follows:—

I may premise that the successful utilization of the rhea fibre necessitates that decortication, or the stripping off the skin of the stems of the plant shall be performed by a method which shall ensure that no fragments of the woody stem shall be left adhering to the skin in which the fibre is contained. Moreover, the stems must be decorticated as soon as cut, as the resinous matter in which the fibres are embedded rapidly hardens, a fermentation is set up which injuriously affects the fibre, and it is extremely difficult to deal with the ribbons afterwards; besides which, when decorticated in this condition, some of the fibre is left adhering to the wood, and great waste results. The process of decortication invented by M. A. Favier having been proved to be thoroughly successful in dealing with rhea, and having inspected its working on two occasions, I think it as well first to briefly refer to it, especially as it appears to me to be the most perfect, as well as the most natural, method of producing the ribbons containing fibre for further treatment by the Frémy-Urbain process.

M. Favier's process consists in submitting the stems of the rhea or other fibrous plants to the action of steam at a low pressure for a period of about twenty minutes. The apparatus required is of the most simple and inexpensive character, consisting only of wooden trough-shaped boxes and a low-pressure steam boiler, whilst the operation of stripping the stems after they have been steamed can be performed by unskilled labour, or even by children. This process insures the obtaining of the whole yield of fibre from the plant, without deterioration or waste, and at a small cost.

The Frémy-Urbain process is the joint invention of the distinguished French chemist, Professor Frémy, member of the Institute of France (who is well known for his researches into the nature of fibrous plants and the question of their preparation for the market), and M. Urbain, who is Professor Frémy's principal assistant

in the Government Laboratory, Paris, of which the Professor is chief. The process consist mainly in an alkaline treatment under conditions which vary with the character of the rhea fibre to be treated. A most important factor in the success of Frémy-Urbain process, and that which I regard as the crowning feature of the whole, is the special treatment of the fibre. Throughout the whole process there is not one stage to which exception can be taken on the score of danger to the ultimate fibre, whilst there is on the other hand, a perfect harmony of arrangement and sequence of development.

It is unnecessary for me here to enter into all details of the operations as witnessed by me, and as fully and unreservedly explained to me by Professor Frémy. Suffice it to say that upon one occasion I saw about 800 lb. of ribbons treated at Louviers, and upon a second occasion about half a hundredweight.

With regard to the question of dyed yarns, I may point out that it is essential, in order to take dyes, that the article to be dyed shall be chemically pure. I received Professor Frémy's emphatic assurance that there is nothing whatever in either the Fravier or Frémy-Urbain processes which militates against this purity. The Professor, moreover, has a formula by which the purity or otherwise of the material to be dyed can be readily ascertained.

Taking into consideration the successful results I have seen produced, and the perfect condition in which the fibre can be turned out, I am of opinion that the Frémy-Urbain process is an invention of the highest importance, and, considering the value of rhea fibre as regards its strength and beautifully lustrous appearance when worked up, I am further of opinion that this material, properly prepared, would command a most extensive market. That this would be the case may be inferred from the fact that there is at present a great demand for rhea fibre, notwithstanding that it is more or less imperfectly produced.

From careful observation of the working of the Favier and Frémy-Urbain processes in conjunction, I am satisfied that, as far as the production of pure undamaged fibre of long staple goes, the two processes are in accord, and are thoroughly adapted for each other. Properly conducted, I feel convinced that their results must lead to an important expansion in the textile industry of the country.—*Planter's Gazette.*

THE LIFE OF A PLANT.

BY THOMAS STEPHENSON.

Although the study of vegetable physiology is not directly connected with pharmacy, it is, nevertheless, of considerable interest to all who care to pursue the study of botany a little farther than it is absolutely necessary to do in order to pass their examinations.

It is not my intention, gentlemen, to describe the elementary principles of botany, which I presume you are already well acquainted with. And I wish tonight to enter into the processes of plant life in greater detail, and also to view them in the light of the most recent researches.

The simplest form of growth is that which is seen in the formation of crystals. In this case the growth consists simply in the apposition of fresh particles in a definite direction. Plant growth, however, is very much more complicated, though the apparent causes are very simple. When a seed is put into the ground, we expect that from nothing but air, earth, and water, it will grow up and form a perfect plant. If we examine any ordinary seed, such as a bean, we find that it consists of an embryo plant and two fleshy lobes. These latter are called the cotyledons, and contain enough of nourishment stored up to give the young plant a start in life. If the seed be planted, the young plant begins to grow, sending a root downwards, and a stem and leaves upwards, while the cotyledons gradually die away. Its patrimony being exhausted, the plant must now live on its own account, and manufacture its own tissues from all the nourishment accessible to it, viz., air, water, and any soluble matter which the water may dissolve out of the earth. It is this process of nutrition which we have to consider tonight;

and as the nutrition of the lower plants forms a special study in itself, I shall confine myself to the higher dicotyledonous and monocotyledonous plants. In a typical plant, the root absorbs water containing mineral matter in solution from the soil. This nutriment is conveyed to the leaves and other green parts of the plant, where it meets with carbon dioxide from the atmosphere; the CO₂ and H₂O react, forming starch and giving oxygen back to the air, while the assimilated substances are conveyed to all parts of the plant for nutrition.

In considering the subject in detail, it will be necessary to consider; first the food required; second, the means of obtaining this food; third, the processes of assimilation and respiration, and lastly, the influence of external conditions on the vital processes.

1. *The Food.*—The food required by a plant can best be ascertained by an analysis of the plant itself. If a plant be dried at a gentle heat so as to expel all the water it contains, we find that it loses from $\frac{2}{3}$ to $\frac{1}{2}$ of its entire weight, so that water must be the most predominant constituent of plants. If we take the dried plant and burn it, we find that it disappears entirely, with the exception of a very small and varying percentage of ash. Tobacco smoking forms a practical illustration of this.

Chemical analysis shows that the combustible portion of all plants consists of carbon, hydrogen, oxygen, nitrogen, and sulphur, this last remaining in the ash in the form of sulphates. The ash consists of salts of potassium, calcium, magnesium, iron and phosphorus, generally also sodium, silicon and chlorine, and in marine plants, iodine and bromine. Leaving the water therefore, for the present, out of the question we may conveniently class the chemical constituents of plants under two heads, viz., the organic or essential elements, C, H, O, N, and S, and inorganic or accidental elements, represented by the ash. Cellulose, of which all plants tissue is composed, is made up of carbon hydrogen and oxygen, being in fact identical in composition with starch, into which it can be converted by treatment with sulphuric acid, so as to give the characteristic blue reaction with iodine. This cellulose forms as it were the skeleton of the plant. The living part of the plant consists protoplasm, which is an albuminous body consisting of carbon, hydrogen, oxygen and nitrogen with sulphur. Carbon is the most abundant element in plants, constituting about one-half the entire weight of the dried substance. It is obtained almost exclusively by the decomposition of the CO₂ of the atmosphere in the cells which contain chlorophyll, a process to be explained later on.

Hydrogen enters into the plant in combination with oxygen, as water, and possibly also with nitrogen as ammonia.

Oxygen is taken into plants both in combination with carbon as CO₂, and hydrogen as water.

Nitrogen is not obtained from the air, but must enter the plant in the form of nitrates, or an ammoniacal salt. (The manner in which nitrogenous compounds are obtained by carnivorous plants has already been treated in an able paper on that subject by Mr. Ducean.)

Sulphur is probably taken up as calcic sulphate, which is decomposed by the oxalic acid always present in the plant (caused by the oxidation of the woody tissue) forming the crystals of oxalate of lime, so commonly seen in plants, the sulphuric acid thus liberated giving up its sulphur in the production of albuminoids. The inorganic constituents of plants must now be considered. These are more numerous than the organic, and, though they do not enter into the composition of the vital parts of the plant, are, nevertheless, absolutely essential for the carrying out of their various functions, it having been found by actual experiments that growth is imperfect, and sometimes impossible, without the presence of a certain proportion of inorganic salts. The most important inorganic elements which enter into the composition of plants are potassium, iron, magnesium, calcium, phosphorus and chlorine, and sometimes sodium and silicon. The part which potassium plays in the vegetable economy is as yet but little understood, but it is considered to be essential in the formation of starch by the chlorophyll. Deliquescent salts of potassium are also often present in the cell sap to prevent evaporation. A certain quantity of mineral ash, consisting largely of potassium salts, has been found to be absolutely necessary in green parts of the plant, for the proper carrying out

of the functions of the chlorophyll, but like many other known facts in science, the reason of this has not yet been satisfactorily explained.

Iron has been found to be necessary for the proper formation of chlorophyll, it having been observed that plants which have become pale, may, like human beings under similar circumstances, have their colour restored by the administration of some preparation of iron, and that no green colour can be produced without the presence of iron in the soil. The cause of this is, however, unknown.

Magnesium and *Sodium* also appear to be essential elements, although no special function has as yet been assigned to them.

Silicon is to be found in the stems of such plants as grasses, and in the cell wall of diatoms, in which the function appears to be the stiffening and strengthening of the parts. It is doubtful, however, whether or not silicon is really essential to the plant, as plants are known to be perfect without the presence of silicon, and the prevailing opinion appears to be that its presence in plants is, to a great extent, at least, accidental.

Chlorine has been found to be present, but as plants can grow equally well without it, it is probably accidental also.

Iodine is also found in sea plants, which form one of the chief sources of that substance.

Fluorine is also supposed to be present, as it is found in herbivorous animals.

Phosphoric Acid appears to stand in a certain relation to the production of albuminoids.

Calcium seems to act as a vehicle for sulphuric acid, and also for precipitating the oxalic acid continuously being formed, and which is injurious to the plant. It is thus that crystals of oxalate of lime are so abundant in certain parts of the plant. When plants are grown in fluids which contain all the substances essential for their life, it is found that the substances in solution are not taken up indiscriminately, but that different species of plants supply their wants in different ways. Plants, therefore, appear to have the power of selecting for themselves the substances necessary for their growth. Leguminosae are specially dependent on lime, potatoes and turnips on potash, and cereals and grasses on silica.

It is on this fact that the principal of rotation of crops is founded. During one year, a certain kind of grain exhausts the soil of its own inorganic materials, requiring next year a crop which feeds on different salts, and so on until the soil has again been replenished from other causes.

The system of manuring also depends on the principle that plants require different inorganic salts to feed upon.

2. *The Manner in which this Food is obtained.*—The organ which is chiefly concerned in the nutrition of the plant is the root. This organ may be defined as that part of the plant which fixes it in the substratum from which it derives nourishment. This definition does not apply in both particulars to all plants, some roots, as those of seaweeds, being solely for fixation, and some, as in the duckweed, simply for nutrition. We have, however, at present to deal with only the nutritive functions of the root.

In most text-books it is stated that absorption takes place only at the tip of the root, which has, on that account received the name of "spongolee." It has since been observed that this spongolee now called the "rootcap," acts simply as a sheath to protect the growing point which lies immediately behind it. It is the hairs on the epidermis of the root, and these only, which take in nourishment. These hairs are outgrowths of the epidermal cells, and, like all other cells, are filled with protoplasm and cell-sap. Being very delicate, these hairs are easily affected by gravitation, so as to lie alongside all the particles of soil in their vicinity. The moisture adhering to these particles of soil is absorbed into the hair through the thin cellulose wall, by a process known as endosmose. This process is based on the fact that when two liquids of different densities are separated by any thin organic membrane they tend to change places, the less dense liquid passing through the membrane proportionately faster than the denser one. In the case before us we have the water in the soil separated from the more dense cell-

sap by the thin membrane of the root-hair, and thus by the law of endosmose the water enters the root-hair more quickly than the cell-sap comes out. The water thus absorbed contains, in solution, the various inorganic salts necessary for the life of the plant. Carbonate and sulphate of lime and other salts, insoluble in water, are dissolved by the oxalic acid which is always present in the cell sap, from causes already mentioned, and are thus absorbed. In aquatic plants, as the greater part of the plant is entirely surrounded by water, it requires few, if any, special organs for the absorption of fluid. The roots are therefore either rudimentary or entirely absent. In the duck-weed, for example, the root consists of single long thread, furnished with a root-cap at the end. Absorption takes place from the whole surface of this root, there being no root-hairs. The roots of some orchids which grow on the branches of trees never touch the ground, but derive all their nourishment from the air. Such plants are called "epiphytes." The outer cells of the root are called "velamen," and have the property of absorbing watery vapour from the air. That class of plants called "parasites" also deserves passing notice. These do not derive nourishment from the ground, but get it from a "host." Take, for example, a plant which will acquire great importance in society during the next few weeks—the mistletoe. This, however, is only a partial parasite, because, having green leaves of its own, it requires to take in from its "host" only water containing mineral matter in solution, this sap being elaborated in the leaves. The root is of peculiar construction, one tap-root descending directly into the wood, while two lateral adventitious roots lie along between the wood and the bark.

The dodder is, perhaps, the best example of a parasitic plant. Unlike the mistletoe, it spends part of its life growing in the ground in a normal fashion. In this state it consists of a root and a long slender stem, the end of which gropes about till it finds a plant (preferably clover) to which it fastens itself, and at the expense of which it lives all the rest of its life, the other part of the stem, together with the root, dying away. When the stem finds a host, it coils round it and sends out brnsh-like roots to the base of its host, whence it derives nourishment; in this case, however, fully elaborated and ready for use. When its host dies, the dodder finds its way to another, and often spreads so rapidly as to ruin a whole clover field in a short time.

Having considered the manner in which the fluid is absorbed by the root, we must now consider how it is to be conveyed to the various parts of the plant. We have already seen, that about 75, per cent by weight of the plant consists of water, and that, without that element, life is impossible. In many plants there is also a continual loss of water from the leaves by evaporation. To meet these requirements it is therefore necessary that currents of water should continually pass through the plant in all directions. The old theory of "ascending and descending sap" is therefore untenable, as the sap has to go wherever it is required, which is sometimes up, sometimes down, and sometimes in a lateral direction, finally passing out of the plant in the form of vapour by "transpiration." The causes of these movements are chiefly capillarity and endosmose, but there is also a process of suction caused by the evaporation of water from the leaves, and also another force called "root-pressure." When the roots absorb more water than plant requires, this exercises a pressure which drives the water further up the stem. This water exudes on the margins of the leaves, and as it often gathers on the leaves during night, it is frequently mistaken for dew in the morning. The phenomenon of bleeding, which is seen in trees which have had their branches cut off in spring, is owing either to root-pressure, or to the expansio of air in the plant, caused by variations in temperature, thus driving out the water wherever there is an outlet.

We have now arrived at the most important part of our subject, viz., the processes of assimilation and metastasis. Assimilation is the conversion of the crude materials into substances, such as starch, which may either be used at once for the nutrition of the plant, or stored away for future use. Metastasis is the conversion of these "reserve materials" into new cells, and also into what

are called secondary products, and are of no further use to the plant, such as alkaloids, resins, volatile oils, tannin, gums, etc. While the process of metastasis can take place under any circumstances, that of assimilation requires special conditions for its proper fulfilment. These conditions are—(1) the presence of the green-colouring matter called chlorophyll; (2) sunlight. Any green part of the plant, therefore, which is exposed to light is capable of assimilating, or, in other words, of manufacturing starch from the crude materials. The leaves, however, are the organs chiefly devoted to this purpose, their various parts being specially adapted for this.

The outside of a leaf is covered by a thin layer of cells called the epidermis. This layer contains no chlorophyll, and, therefore, does not manufacture; it simply acts as a protective, and prevents undue evaporation. The epidermis is provided with openings called "stomata," for the entrance of the carbon dioxide in the air, the carbon of which the plant assimilates, giving back oxygen—a process to be detailed later on. Each stoma consists of two crescent-shaped cells called "guard cells." By a peculiar arrangement, which I have no time to detail, these cells separate from one another during sunlight, and come together again in the dark, and thus the stoma opens and closes. These stomata are usually situated on the under side of the leaf. The middle portion of the leaf consists of cells containing chlorophyll. The cells near the upper surface of the leaf, and consequently nearer the light, have more chlorophyll, are long in shape, and are arranged side by side in rows very suggestive of the title given to them of "palisade cells." The cells below these are arranged more loosely, so as to allow free passage of air, and also the evaporation of water, in order that the inorganic salts necessary for assimilation may be more abundantly deposited. These cells are called "spongy parenchyma."

A closer look will show that the chlorophyll is not diffused throughout the cells, but is arranged in round granules. Each granule consists of a network of protoplasm, in which the green chlorophyll is embedded. It is the protoplasm which does the work, the green chlorophyll acting only as a shade to protect it from too intense light.

It remains for us now to consider briefly the influence of external conditions on plant life. It is well known that plant growth can take place only within certain temperatures. The lowest of these is 0° C. (32° F.) at which the water freezes, and the highest is from 40° to 50° C. (about 120° F.) at which temperature the albumen coagulates. Some plants, however, in which the water is protected, can live while the temperature is below the freezing point; and some bacteria have been seen to live in boiling water, having apparently incoagulable albumen.

From 20° to 30° C. (75° F.) is the best temperature for plants to live in. The annual rings in wood are a good example of the effect of external conditions. Owing to variations of heat, food, etc., the cambium works at greater pressure towards the end of the year, thus producing denser wood. Any number of rings can be artificially produced in one year by simply tying a ligature round the stem, and alternately tightening and loosening this ligature. The action of light on vegetation has already been considered. The effect of gravitation on a plant is a tendency to grow downwards. To counteract this influence, many contrivances are present in the stem, such as the firmness of the wood, the uniform distribution of foliage and branches, climbing appliances such as tendrils, and, in many water plants, air-bladders. Owing to the great variety of conditions to which they are exposed, all plants possess a certain power of adaptation to their external conditions.

There are two forces which I have time to allude to only very briefly. These are heliotropism and geotropism. Heliotropism is the force which makes the stem grow upwards; geotropism that which makes the root grow downwards. Light and gravitation combined seem to be the chief causes of these phenomena. But I must refer you for further information to Darwin's exhaustive work on the subject.

After this short sketch of what is already known on the subject, you will see that a vast deal remains yet to be discovered, much of which is of great interest to

pharmacists, and the discovery of which might with advantage be undertaken by pharmacists themselves.

Almost nothing, for example, is as yet known about the formation of alkaloids; whether they are really useful to the plant or merely accidental, can only be conjectured.

It is known from experience that plants possess more therapeutic activity at certain periods of their growth, but the discovery of a scientific law, which would enable the cultivators of medicinal plants to bring these plants to the greatest perfection remains yet to be made.

This is only one of the many as yet unsolved problems, the working out of which would form an interesting and profitable study, and would prove that botany, however much it has been condemned for its predominance of hard names, is one of the most interesting departments of natural science.—*Pharmaceutical Journal.*

A MOTH INJURING DRIED COCOA BEANS.

In the month of October last I received from the proprietors of a warehouse at the East-end of London a box containing a quantity of Cocoa beans, which had been found to have been extensively gnawed all over the outer surface by the larvæ of a small moth, together with some of the grubs, some cocoons all matted together, and some of the moths produced from them; and again, at the beginning of December last, Miss E. Ormerod sent me a quantity of these Cocoa beans similarly infested, which she had received from Guyaquil.

The appearance of the sound Cocoa bean is shown in the upper right-hand figure in the accompanying engraving,* whilst one much gnawed by the larvæ is represented in the left-hand upper figure, which shows a quantity of the pellets of the excrement of the larvæ partially detached from the bean.

The caterpillar, of the natural size and magnified, is represented in the middle of the woodcut; it is long, slender, and very active, wriggling about and running quickly either forwards or backwards; it has six anterior, eight ventral, and two anal claspers; it is of a dirty flesh-coloured grey, with the head darker and fibrous brown, with a patch of the same colour on the first segment behind the head, in which patch the hind portion forms two darker spots; all down the back are two rows of minute black dots, each segment bearing two on each side of the middle dorsal line, and a third more lateral dot forming a triangle with the two dorsal ones. These dots are setigerous; the penultimate segment of the body has one large central and two smaller lateral black spots, and the terminal segment has a transverse black spot (the antennæ in front of the head of the larvæ are represented too long and prominent in the accompanying engraving, and the caterpillar itself is too robust). The chrysalis is of a chestnut shining colour, and is enclosed in a loose silken web, forming with the other cocoons attached to the Cocoa beans a matted mass.

The moth measures about two-thirds of an inch in the expanse of the fore-wings, which are of a pale grey colour, with a faint ochreous tinge, especially towards the inner margin, and with very indistinct but darker greyish markings, forming irregular bars across the fore-wings. The first towards the base of the wings is preceded by a pale band, and the second beyond the middle is grey, followed by a pale band; between these bars are two small ones in the middle towards the costa. On submitting the moths to Mr. H. T. Stainton, our great authority on the tiny or Tinea moths, he informs me that they belong to the family of the Knot-horns (Phycitæ), and are the *Ephestia elutella* (*Phycita elutella*, Curtis and Stephens), or the cinereous Knot-horn of Haworth. He believes that the whole of the species of the genus *Ephestia* have similar habits, and devour all sorts of dried fruits, the larvæ being often found in Raisins and Figs, and they are extremely partial to all preparations of chocolate, flying by scores in warehouses where such things are stored. Mr. Stainton, moreover, believes that in a wild state they feed upon Ivy berries and nuts. In an economical point of view they are noxious insects, and they cannot certainly be called beautiful. One of

* Sorry we cannot reproduce.—Ed.

our correspondents suggests that the eggs are laid in the Cocoa in the West Indies or South America, and that they hatch out and damage the Cocoa here in hot dry weather like last summer. He also asks whether the moths lay their eggs and the young ones are hatched in this country, or whether the eggs are only laid in the green Cocoa bean? He further notices that as soon as cold weather commences the moths and larvae seem to be killed, doubting, however, whether the eggs and chrysalids are also killed. In answer to these inquiries, we believe that in warehouses where the Cocoa beans are stored, and which are infested by these moths, the propagation of the insects is continuous—very similar, in fact, to that of some of our small domestic moths, such as *Tinea sarcitella*, and the little corn moth, *Tinea granella*. It may be questioned whether repeated fumigations with sulphur would not be injurious to the Cocoa beans; it would certainly, however, kill the insects. Benzine, or, better still, naphthaline, would also be equally efficacious in destroying the insects. The subject of these Cocoa de-destroying moths was brought under the notice of the Entomological Society by Mr. W. F. Kirby, on November 5 last, when Mr. McLachlan suggested heat as the only remedy for getting rid of these pests, but Messrs. Weir and Fitch pointed out the impracticability of its application in large bonded and other warehouses. In the case before the Society the stock affected exceeded 20,000 bags. A case was also reported in which a stock of ship's biscuits was attacked, and when the biscuits were removed the moths came out in thousands.

A memoir on another injurious species of this genus, *Ephesia Kuhnella*, Zeller, from North America, which has become naturalized in the Rhine district (where it is known as the meal-moth), forms the subject of several communications in the *Entomologische Nachrichten* of 1884 and the present year.—I. O. W.—*Gardener's Chronicle*.

MESSRS. T. CHRISTY & Co. have recently forwarded a specimen of the flower of the "alvelos," the plant which has lately been introduced as a remedy for cancer and allied diseases. The plant was cultivated in a greenhouse at Sydenham, and produced only a few flowers, most of which, however, dropped off before arriving at maturity. The stem of the plant is fleshy, smooth, and cylindrical, about one-third of an inch in diameter; the leaves are smooth, pale green, lanceolate oblong with a cordate base, sessile and alternate. The flowers are small and green, and the involucre has four wedge-shaped lobes. The flowers have been submitted to Boissier, one of the best European authorities on the genus *Euphorbia*, and so far as can be gathered from the imperfect state of the flowers, he has decided that it belongs to the genus *Euphorbia*, and to a species not described in Martius's 'Flora Brasiliensis,' but almost certainly belonging to the section *Dichilium* and nearly allied to *E. anomala*, Salzm. (*E. insulana*, Velloso).—*Pharmaceutical Journal*.

THE EMIGRATION FROM MADRAS.—The number of emigrants registered in 1883-4 was the smallest recorded during the past 10 years. More than the whole of the decrease is accounted for by the fall in the number of emigrants to Ceylon and British Burma. The decrease in emigration to Ceylon was due to the lessened demand for labour in that island owing to the precarious condition of the coffee-planting industry. The fall in the number of emigrants to British Burma is perhaps explainable by the fact that emigration to that province has been made free, and it is possible that not all the emigrants are registered. Other causes of decrease are the favourable character of the season and the great demand for labor in several districts of the Presidency. About six-sevenths of the total number of emigrants annually go to Ceylon and British Burma, which emigration is now practically unrestricted. Regulated emigration to the Mauritius, Straits, Natal, Martinique and Guadaloupe showed only 6,659 emigrants. There were no great variations in the figures. There were 57,547 emigrants, showing a decrease of 5,229 or 8.3 per cent. The number of emigrants who returned slightly exceeded the number who left India; 79.4 per cent of emigrants returned to Madras and Tinnevely, and most of the remainder to Ganjam and Vizagapatam.—*Planters' Gazette*.

POTATO FUNGUS.—In the *Gardener's Chronicle* (Dec. 4, p. 757), Mr. A. Stephen Wilson figures the sclerotia of the potato fungus, *Phytophthora infestans*, which are encrusted with a coating of oxalate of lime. Some doubt had previously been thrown on the character of these bodies by other observers, owing apparently to their not having been carefully separated from the tissue in which they were embedded previous to examination, and to the fact that they were found in living tissue, in which alone, however, according to Mr. Wilson, they are capable of germinating. Mr. Wilson's observations have been confirmed by Mr. Worthington Smith, who had previously observed a myxocytic fungus coated in the same way with oxalate of lime. These observations suggest the necessity in microscopic investigations of using solvents to remove mineral matter when examining vegetable structures.—*Pharmaceutical Journal*.

LEMON MONSTROSITY.—A correspondent has forwarded a singular monstrosity of the lemon fruit in which a small lemon is formed inside a large one, and just below the stigmatic end, nothing in the external appearance of the lemon indicating the presence of a smaller one inside. The smaller one has also a perfect rind. Dr. M. T. Masters, to whom the specimen has been submitted, states that although this mode of growth is of frequent occurrence in oranges, he has not before seen it in a lemon. In his opinion it is formed by the thalamus, having produced one whorl of carpels, again starting into growth and producing a second whorl. In his 'Teratology,' p. 131, is a description of a similar growth arising from the multiplication of carpillary whorls which subsequently become separated by the growth of the axis. In this case, however, the inner lemon has a rind, which is regarded by Dr. Masters as a development from the axis independent of the carpel, and ultimately covering them over.—*Pharmaceutical Journal*.

THE CULTIVATION OF TEA IN ITALY.—The French Consul at Naples gives an interesting account, in his last report, of the attempts which have been made to acclimatize the tea plant in Italy. The first is said to have been made by the English during their occupation of Sicily at the beginning of the century, when the plant reached a height of 6 ft. in the open air. There is no proof, however, that any crop was obtained, and further attempt seems to have been made until 1871, when some seeds were sown at Caltanissetta, which is in much the same latitude as Jamsacio (in Japan), from which place they were brought. The seeds never sprouted, and a fresh trial made in 1875 with another variety, the *thea sinensis*, also proved a failure. The Government, however, which had taken up the question, was not discouraged, and, after weighing the various opinions which it had elicited, made several fresh plantations of *thea sinensis* in the zone comprised between Florence, Naples, and Sicily. These plantations also came to nothing, but Signor d' Amico, a landed proprietor in the province of Messina, was able to exhibit, at the Agricultural Show held at Messina in 1882, more than a hundred plants of the *thea sinensis*, three years old, which had been grown in the open. Professor Becari, too, who has been to India for the purpose of investigating the growth of tea, is of opinion that there is no reason why it should not succeed in Italy if the plants and the seed are brought from a climate similar to that of the Peninsula, for the fact of its growing in the open air along the Riviera, upon the shores of Lago Maggiore, and at Florence proves that it is to a certain extent a hardy plant. If it has not been more generally grown in Italy hitherto, this, Professor Becari thinks, because the mode of cultivation has been all wrong. The Italians have thought that the plant wanted shade, whereas in India and China it is grown in very open ground and upon a soil which contains a large proportion of sand and oxide of iron. He recommends, therefore, that it should be planted in land not too dry, and in a soil preserving enough moisture to alimnt the plants, such as the oiv-growing fields of the Riviera, the Marcma, and Southern Italy, and that the plants should be brought from the coldest provinces of Japan. The Italian Minister of Agriculture has determined to act upon Professor Becari's report, and has already sent a large order to Japan, besides buying a number of plants from a landed proprietor at Palianza in the province of Novara, who has met with a fair amount of success in his experiments.—*Overland Mail*.

CHAPTER ON CHICKENS.

There are (writes "Silver Pen" in the *S. F. Chronicle*) two distinct manias at present taking full possession of the dwellers in San Francisco, male and female: Art—and—Chickens.

There is a wide difference between the two—one lives after us; the other enables us to live. So I will attack the latter today because the editor of this paper (the one with the magnificent teeth) is always drumming it into my ears to "write something useful."

Now "What does this woman, who writes fashion and hard articles about the human family, know about chickens?" And I might answer you, as I do: I know a good deal more about them than you think far. In point of fact, I am a very respectable old henwife, and have been fooling with chickens for the last 20 years. I have three distinct manias, which are always kept by me at boiling point. First, a flower-garden, in which I can grub and watch the heaven-sent things grow. Next, art. And last, but not least, chickens; chickens, which never lay except when eggs are 20 cents a dozen; chickens, which grow up to be magnificent creatures, then drop down dead at a moment's notice; chickens, which cost you double what you pay in the market for them; chickens, which are never truly a success, but still continue my pet mania.

People fondly think they have only to get a few setting hens, buy some high-priced eggs, set the same, leave them to fate, and then reap the benefit. Alas! *mes amis*, if your experience is mine, you will agree with me that twain babies are infinitely less troublesome, and, in the end, far more remunerative and recompensing, than a whole yard full of the choicest chicks; yet, still, we all persevere in our ideas, and go fruitlessly looking forward to that bright chicken future which never comes—at least, not in this city. There is no use in talking, but this "glorious climate," which rips the voice out of the singer's throat, also closes the eyes and kills with asthma the dainty chick. Nevertheless, I will give my experience in all humility, which may help other neophytes on their onward chicken course. If you have room in your back yards to enter upon the industry, remember it entails endless trouble. You must rise early and feed your pets regularly, in this first place, otherwise, if breakfast is not on time, the erratic things will fly over your neighbour's fence, and it is then always a question whether you find that chicken, until he has come out of the pot, or not, for chicken fricassee is a cheap dinner when the next door's fowls come over uninvited.

This is the very season for a lecture, for now the hens are all on the sit. What a pity women don't take to sitting still every now and then for three weeks, stopping their cackling and being at rest for that definite period. But to resume. If you are wise you will eschew boxes for your sitting hens. Make a hole on the ground, and lay some straw therein, round which you can improvise a little fence of laths, while a good sized box may be used for a cover over the nest. Put within your fence food and water, and let your hen refresh herself when she chooses, for I find that for the first week hens only come off the nest every second day. I have had them sit for four days without stirring. That is their own affair, and the plan of hauling a hen off her nest to make her eat is absurd, but often done. To save your hens, you should sit four together and in this case make the nests close together and enlarge your fence. When the chicks appear you will probably only get 7 out of each nest. Then you can give the entire flock to two of the hens, and let the others go in order that they may commence to lay as soon as they feel like it.

Lately I have had a novel experience. Out of three sittings of choice eggs laid by a friend—O, pardon me—I mean by a friend's hens—that's better—I have got 6 chicks, and those I hatched partly myself. In fact, I appear to myself this week as a living incubator. I had a sitting of 13 eggs, 11 of which were duly chipped, but after wriggling about until the shells had all peeled, leaving the chicks in the skin of the eggs, 2 died in that state of semi-birth, and I determined to hatch the rest myself. I therefore took the eggs and put them in a ba ketful of wool, placing the same in the oven; I then got a good novel and a stool and sat by that oven all day, peeling off, by degrees, the skin. I did this at the end of every three chapters. I never had a finer day's loaf for many a month. In 10 hours the chicks struggled into existence, weak and apparently at the point of death; but I persevered, and taking my basket, well wrapped up in a soft shawl, carried them to bed (*vide* the advantage of being a widow). In this way I kept a spark of life in the chicks, and no more. For three days they would not eat neither could they stand; but virtue has its own reward, and the chicks now eat and are well, thank you. I put my head on the table, with a mess of chopped eggs adjacent, then I mimed the hen; the chicks eat, and run under my chin, which for the time answers for mother; and it is funny to see these small things following me about the kitchen. Ethel declines admitting them to the parlour, therefore I am a banished creature.

I have thus proved that, by taking weak eggs from the hen, they may be brought out, and by keeping them warm for a few days they become strong, for every one is not aware of the fact that a chick rarely eats anything for two or three days. Now what is the reason of the weak eggs? I mean eggs the shells of which peel away. I fancy that there must be a want in the food of the hen, and also confinement goes far to reduce the fertility of the egg. I have my own hens in a limited space, but I often let them out for a run, and the eggs rarely fail. Last year I had an expensive trio of Langshans, and out of three sittings raised two hens. They were too closely confined, in my opinion. The common fowl is the best for the city. They are hardier, and the eggs always turn out well—and an egg is an egg, common or uncommon. To raise fine fowls it is necessary to feed the chicks abundantly. I keep a long run for my chicks, and never let them out for two months feeding them with chopped meat, chopped egg, boiled rice, corned meal, &c., always varying their food from day to day. The result is splendid chickens in three months time. This method lays a foundation of strength which hereafter will not be broken.

People weary me who let their chicks run about from the first, throwing them a little food twice a day. Why should a chicken thrive any more than a baby, if you only half feed it? Hens in confinement should not be too highly fed. I know this to my cost. I reared 40 of the finest buff Cochins-China hens I ever saw last year. They were enormous in size, but the ungrateful creatures took it into their heads to die all of a hop. Think of it! In two weeks they were all lying at the roots of the rose bushes; but I wish you could see the roses this year in consequence—roses à la chicken, I call them—fine and flourishing, still, at a cost I hardly liked to pay; but this proves that there is good in everything. The demise of the fowls saved the expense of manure, and I wish you had seen me picking up five or six dead hens every morning and mournfully, with spade and rake, burying my dead.

Chickens of a much inferior mould now fill my yard, and when I get 24 eggs a day, I say, What does breed, signify?—*i.e.*, in a town chicken yard. Believe me if

you want to succeed in this city with fowls, for eggs only, take the common breeds. They lay their eggs, and when the reaper gathers them in (the chicken reaper) you don't care. The houses should be cleaned out twice a week (I clean mine three times), and well sprinkled with disinfecting power, the perches washed with kerosene; and that reminds me that if you are compelled to set your hens in boxes, always have new ones, filled with clean straw and well-sprinkled with coal-oil to prevent insects. Your hens will then set in peace. Last year I raised some chicks in a large box with a wire front; in the centre I put a coal-oil lamp made firm, with a "mother" in one corner made of strips of old blanket, and those chickens were the finest I had. It is a great mistake to let a hen run at large with young chicks, with cats, &c., in perspective; also some hens are odious mothers, scratching like fiends and flinging the chicks right and left, or trampling them to death. Always choose old, quiet hens as setters, and by confining them as I say you will lose none of your chicks unless very weak. Dirty food, as some people feed to hens, is as poison. Let all they eat be fresh and sweet. It is not necessary to order from the Maison Dorée, but filthy swill is an abominable thing to give to hens. Lots of green stuff in summer time is necessary. I am writing for the benefit of amateurs only. I assure you, to be a good henwife is like learning a trade, in the country chickens take care of themselves.—*Sydney Mail*.

THE TEA ENTERPRISE IN INDIA.

The publication of the reports of the numerous Indian Tea Companies, from year to year, affords us, in Ceylon much valuable information from which we may derive warning as well as encouragement. The fall in the prices of tea has rendered many of the Indian "concerns" unprofitable, but the main cause of want of success seems to have been extravagant outlay in bringing estates into cultivation. Even in cases where every effort was made to "open" at a moderate expenditure, we can well imagine how, in the earlier years of the enterprise, the best intentions were baffled by such circumstances as distance from sources of supply and shipping ports, defective means of communication and costly and precarious labour, with peculiar liability to epidemic and exceedingly fatal sickness. In regard to facile and cheap means of communication the Indian planters of today are far more favourably situated than were the pioneers of the industry, or even the immediate predecessors of those who are now growing tea in Assam and Darjiling. But neither as regards means of communication, climate and salubrity, or labour supply, does it seem to us that the Indian planters, except in rare cases, are equally favored with their Ceylon brethren. In any case, we cannot possibly conceive of such a tale being ever told of a Ceylon estate as is related in the report for 1884 of the Land Mortgage Bank of India in regard to one of the properties of which they are the not very happy possessors. The season's results, the report states, in Sylhet (where some of the finest teas in India have been produced) have been most unsatisfactory, and no wonder, for damaging hailstorms (such as have occurred in Ceylon only rarely in a few districts and in destructiveness not for a moment to be compared to the fearful effects of such phenomena in India) were followed by severe blight, long-continued cold weather, which affected leaf both in quantity and quality, while to crown the list of adverse and disastrous circumstances,

cholera and smallpox broke out and disorganized the labour force. No wonder if there was a loss on the season's working under such adverse circumstances. The very title of Land Mortgage Bank of India shows that it was formed to take up the species of business, "block loans," which are generally considered to be opposed to true banking principles and indulgence in which has brought other financial institutions besides the late Oriental Bank to the ground. The measure of success achieved by the Land Mortgage Bank is shown by its avowed anxiety to get rid of the properties which in the course of its operations it has been compelled to take over and work. From the very full, clear and candid statement of affairs which the Bank has published and which we take over from the *Home and Colonial Mail*, it appears that it owns six properties in Darjiling, four in Cachar and Sylhet, two in Assam and one in the Western Doora, the latter district coming up generally to Col. Mone's ideal of a district good for tea but bad for human health. But without sufficiency of labour even the rich soil and forcing climate of the Doora are of no avail. Our great advantage in Ceylon is that a very large proportion of our tea-growing region is equally salubrious and fertile. The total acreage of the Land Mortgage Bank's estates is 7,136, of which 6,458 in bearing yielded 1,651,712 lb. This is at the rate of about 255 lb. per acre for the whole bearing area, some estates of course yielding much more and some considerably less. We should think that in but rare cases can less than 500 lb. per acre pay, or say 4 maunds, which would be 320 lb. The total expenditure, taking the rupee at 1s 8d, was £78,524 and the gross proceeds of crop £94,403. The profit, from which must be deducted an absolute loss of £3,418 on the working of four out of the thirteen estates, was £19,297. The cost of production per lb. was 11'603d and the average selling price 13'916d, so that the average profit per lb. was 2'313d. We notice that the cost of machinery and, it would appear of 491 acres' extension, were charged against the cost of the year's production, which is certainly not in accordance with the true principles of accounts. The report states that the reduced cost of production and the considerable area of new tea coming into bearing are favourable circumstances. Indeed, the reduction of cost in the growth and manufacture of the tea, ranging up to a saving of 3'69d per lb. in one case, leads to the supposition either that there was laxity in the past or that reductions were made in the expenditure of 1884 which may adversely affect cultivation in the future. The utmost economy consistent with efficient cultivation and careful manufacture is certainly a necessity, in view of the extent to which prices of tea have fallen in the past few years. The expenditure per acre on the whole acreage seems to have been about £11, or somewhat over £12 10s for the area in bearing. The best result is in the case of a Darjiling estate, Moondakootce, and it is so wonderful that we feel surprize that attention was not more specially attracted to it. On this estate of 700 acres in bearing, the output was 210,430 lb. (300 per acre) at a cost of little over £10 per acre, or 8'936d per lb. of tea, the tea realizing 16'814d, or more than twice the cost of production, the profit on this estate being £7,206 or a little over £10 an acre. Against this we have the Western Doora estate that produced tea at a cost of 18'113d per lb., which sold for only 12'251 per lb., the loss on the year's working being £1,693. The manager's judgment seems to have been at fault in controlling his labour force and he was dismissed. It was not in Sylhet alone that circumstances were adverse. There was deficient rainfall in Assam, while severe storms occurred in Cachar. Darjiling experienced a severe drough and unfavourable weather, which makes the

case of the exceptional estate the more remarkable and causes us to wish that fuller details regarding it had been given. What we are told is that the tea on this estate was produced at a saving of 2½d per lb. on 1883. If the circumstances are not altogether exceptional, the case of this estate would seem to prove that with cheap working and careful manufacture 300 lb. of tea per acre will pay very well. The main thing wanting in the table we quote is the absence of the figures for capital expenditure per acre, but these are supplied in the case of other Companies, and, while we know that the original Assam Company was ruined, we also are aware that those who purchased their properties "for a song" have shared dividends of over 30 per cent. The fair way to look at tea planted on coffee land in Ceylon will certainly not be to rate proceeds on the whole original expenditure for opening, or even the half of it. In most cases, we suppose, the accounts will commence *de novo*. The accounts of the Land Mortgage Bank do not afford any information regarding labour force and its cost, but from the Report of the Scottish Assam Company, which appears in the same paper, we gather that the average number of men, women and children on 683 acres in 1884 was 736, or only 53 in excess of one cooly per acre. We should think that the manager's necessity, but not his will, consented to so limited a force. The proper cultivation and harvesting of coffee, when that enterprise was in its prime, required three coolies for every two acres, and with all possible adoption of machinery (unless the recently patented tea-plucking machine is really as great a success as that for picking cotton in America is said to be) we cannot suppose that a smaller proportion will suffice for tea?

Just as we had got "proof" of the above article from the printer, we received the following elaborate analysis by an able correspondent of the accounts of a number of Indian Tea Companies, which most usefully supplements the information derived from the Report of the Mortgage Bank. We therefore append our contributor's article:—

"Most of the Indian Tea Companies made up their balance in June, and this therefore is an opportune season for comparing a few of the results shown; and, seeing that the industry according to a writer in the *Statist* represents a capitalized value of some 10 millions sterling and a cultivated area of from 200,000 to 250,000 acres, producing roughly nearly 70 million pounds tea, a comparison of the results shown by the published reports of the more prominent Indian Companies cannot but be instructive to the planter in Ceylon.

"The same writer above alluded to says, that the great defect which at present characterizes tea accounts is the want of uniformity, which renders it difficult even for an expert intelligently to compare the working of different gardens, or to draw any rational conclusions as to their relative economic merits. The following table exhibits some interesting statistics in connection with the accounts for 1884 of 15 more or less well-known concerns. We may give "Spectator's" letter to the *Statist* in full by and bye. Meanwhile, his statement, that, 'owing to the large increase in production, and the tendency to a progressive shrinkage in prices, it becomes a matter of increasing importance for owners of estates to secure (1) the highest efficiency in management; and (2) the utmost economy in expenditure,' is one which in the present condition of our Ceylon planting enterprise must strike every planter as a truism which cannot be gainsaid. We trust however, that there are to be found not a few practical men capable of demonstrating, that not only in the large manufacturing industries of England is it possible, but that here also it is an accomplished fact, that where the two factors of 'highest efficiency

and 'utmost economy' go hand in hand, there the greatest vitality exists. The table is as follows:—

Tea Companies.	District.	Capital.	Shares.	Average.	Tea made & Tea sold.	Yield per acre.	Cost per lb.	Gross Proceeds.	At per lb.	Profit.	Loss.	Dividend.
£	Assam	£	£10	£	tons	lb.	£	£	£	£	£	%
Lackramjee	Assam	42,240	10	1,435	557,700	263	1 1/4	31,456	1 1/4	2,603	89 1/4	3 1/2

Jhauzie Tea Association	do	36,000	5	1,471	3,725,682	204	1 1/4	...	1 1/4	...	535	5
Mouabund	do	100,000	1	528	309,455	241	1 1/4	8,907	1 1/4	2,389	4 50	9
Lebung	Darjeeling	35,000	10	988	129,800	249	0 11/4	29,174	1 1/4	7,417	...	6
Chaitola	?	82,070	10	686	296,000	446	0 9/4	18,548	1 1/4	2,233	...	10
Jeebait	Assam	25,600	100	553	1,206,677	301	1 1/4	89,125	1 1/4	2,483	...	15
Mookhamcherra	Assam	65,300	20	4,000	1,206,677	301	1 1/4	89,125	1 1/4	21,182	...	9

"The Jorehant Tea Company tops the list with a dividend of 15 per cent, closely followed by the Assam Company with 14 per cent. Two Companies pay 10 per cent viz., Tokai and Pantola, the Lebung and Mookhamcherra each 9 per cent, Chargola 7½, per cent,

* Draft and Tea. † These figures do not agree, but are taken from the Assam Company's report. N.B.—Average price per lb. realized by tea from 3 Companies representing 9,935 acres yielding over 400 lb. per acre was 10 3/4d; average cost of production being 8 1/2d. ‡ Profit at 60d per lb. Average yield per acre of Companies representing 9,439 acres, and yielding over 400 lb. per lb., was 27 1/2d; average cost of production being 14 3/4d per lb., profit 3 7/8d per lb. Revenue.—(a) Excess out of Revenue. (b) Excess to Capital.

Darjeeling Company 7 per cent, Moabund 5 per cent, Luckimpore and Deoje 3½ per cent and 2 per cent, respectively.

"The average cost per lb. of the produce of 11 gardens for which our table furnishes the requisite data was 11'50d and the average price realized was 1'33d, showing an average profit per lb. of 1'83d. Of these 11 gardens 7 paid dividends and 4 show a loss: the average dividend for the 7 was 9'29 per cent, the average cost per lb. 10'30d, the average price realised 1s 2'16d, average profit per lb. 3'86d. Turning to the yield per acre we find the average of 11 gardens in the table was 313 lb. The Assam Company tops the list with 491 lb. per acre off 7,609 acres, made its tea for 7½d per lb. and sold it for 11¾d, and paid the best dividend but one, viz., 14 per cent, the Jorehaut Company paying 15 per cent. The highest price 1s 4½d was realized by the Jorehaut and Moabund Company's teas, the latter being made for 11¼d per lb. from an average yield of 246 lb. per acre off 528 acres. Here the profit per lb. was the highest but one, the acreage under cultivation the smallest of any, but the dividend paid was only 5 per cent. It is to be noted, however, that the report under review was presented at the Company's first ordinary meeting; and it is stated that the profit is taken after paying off all preliminary expenses and that the directors propose to divide only about 75 per cent of the total available, the balance being carried forward to form the nucleus of a working fund. Your London Correspondent alludes to the regret expressed by the Directors of the Assam Company at the inferiority of the tea made by this Company in 1884. The cause is not mentioned, but we have heard a rumour to the effect that it was considered to be due to inexperience in working a new description of drying apparatus. Both the Jorehaut Company's and Assam Company's estates are on the same district, and there is, we suppose, no reason why under ordinary circumstances the teas of the one should not have been as good as those of the other and have fetched as high a price. Had this been the case in 1884, and the Assam Company's teas sold at 1s 4½d without thereby increasing the cost above 7½d, the profit per lb. would have been equal to 8¾d, or very nearly double what it actually was; and possibly this Company might then have paid 25 per cent instead of only 14 per cent dividend for the year—enough even as it was, as your correspondent truly says, to make the mouths of investors water.

"The terms on which the new Ceylon loan has been issued shows that Ceylon investments are coming into favour again, and; when it is known that we can beat India in yield per acre, cheapness of production, and quality of tea, there can be no doubt of the effect on the instincts of capitalists. The danger is, that with the inflow of new capital there, will be another mad rush and its concomitant evils. Meanwhile, there is something selfishly consoling in the thought, that we can place our teas, if need be in London from about 5½ per lb.

"In India the lowest cost of production is associated as might be expected with the highest yield per acre; but it is to be remarked from the prices realized in the cases referred to in our table, that quantity was only obtained apparently at the expense of quality. The highest recorded yield is 491 lb. per acre; but this has been in more than one instance considerably more than doubled in Ceylon, whilst we hear of crops placed f. o. b. at 25 cents per lb., the general average sale price according to Messrs. Geo. White & Co.'s last list being 1s 3¾d per lb. as against 1s 1½d per lb., the average sale price for Indian teas in 1884 as stated by Messrs. W. J. & H. Thompson."

On pages 175-76 will be found the Report and tabular statement of the Land Mortgage Bank of India which we have reviewed above; also the Report of the Darjiling Company, from which it will be seen that a dividend of 7 per cent has been declared, the average for three years being about the same. The average yield per acre is 323 lb., steadily decreasing, however, from 369 lb. in 1882 to 293 lb. per acre in 1884. The average cost per lb. and price realized were both highest in 1883, namely 1s 1'17d and 1s 6'59d, respectively.

THE FRUIT TRADE OF BADULLA, CEYLON.

In June last year Mr. Jas. Irvine addressed a letter to the Assistant Government Agent at Badulla on the subject of a light railway. Towards the end of his letter Mr. Irvine remarked:—

"Give us a cheap railway to Badulla town: the traffic of the town will pay; the villagers will find a market for their produce, even fresh eggs and poultry will find a market. Badulla is noted for fruit, and in this I speak advisedly: 10 acres of an orange grove supplied to the shipping in Colombo will pay as well as 50 acres of coffee in its best days. Badulla could easily supply two car-loads of fruit daily, which at R100 would give R200 daily."

A correspondent having recently referred to this letter, Mr. Irvine writes to us on the subject, and from his letter we quote as follows:—

"So far as fruit cultivation is concerned, I would only ask my doubting friends to look at the enormous fruit trade of the West Indies. Some of the smaller islands are devoted entirely to the cultivation of the pineapple, and others, high and hilly, are devoted almost exclusively to the cultivation of the lime. Those who have read Mr. Cottam's letters will note the enormous extent of plantain or banana cultivation: the fruit trade of the West Indies employs almost exclusively a large fleet of small but fast steamers; in the United States and Canada every train has one or more fruit-cars attached to it during the season; and on Lake Michigan, steamers specially fitted for carrying peaches run from Benton Harbour and St. Joseph to Chicago, a distance of over eighty miles. In Singapore the road from the town across the island to the Old or Johore Straits, a distance of some 14 miles, is lined on each side with regularly-planted orchards the whole way, and every morning hundreds of Chinese swarm into the town with baskets of fruit. Already the Australian colonies are endeavouring to send grapes and pears and other fruit to the English market, and I should think Calcutta, Madras and other large towns in India would prove a good market, especially for plantains. It is the working classes in the Straits in America, and even in England, who purchase most of the imported and other fruit. The villagers in Uva have the ready answer: What is the use of growing anything? there is no market for it. At present with the failure of the native coffee they are so poor they cannot pay their road-tax, and I have been told that Sinhalese from Wilson's Bungalow and thereabout have actually been working on the tea estates on this side, partly to escape being put in gaol for their road-tax, and partly to escape starvation. Be that as it may, I myself have seen large gangs of villagers run into gaol in Badulla and sent to work out their 'statute labor' by weeding the Government compounds, some 20 of these starved wretches doing about as much work as two ordinary coolies. They were well fed in gaol, however, and I have no doubt these unfortunate look back with unalloyed pleasure to the days of their short incarceration. Open up the country, railroad it, and give the people a chance of finding a market: a basket of eggs, fruit and vegetables, or fowls, sold would often enable a villager to pay his tax and keep him out of gaol, and Government would be the gainer in every way. A friend told me recently that he had seen a light railway made into a wretchedly poor and neglected district in Southern Spain by an English Fruit Preserving Company simply to get the peaches and apricots which before were valueless, and the people have benefited largely."

THE CULTIVATION IN INDIA: RESULTS:
THE LAND MORTGAGE BANK OF INDIA
(CRÉDIT FONCIER INDIEN), LIMITED.

Capital £1,697,326, in 95,624 shares of £17 15s. each. Paid up £262,966. Directors: Messrs. J. R. Boyson, chairman, K. P. Harrison, L. Fitzwygram, W. R. Bingley, and H. G. Bainbridge.

The directors' report, presented to the twenty-second ordinary general meeting of Shareholders held at the Cannon Street Hotel, on Monday last, contains the following remarks on tea:—

We subjoin the usual statement showing the results of the working of the several estates during 1884, and with a view to affording you full information relative to the tea expenditure we circulate herewith a separate statement marked B showing the details of such expenditure under specific heads: (we hope to publish statement B in a subsequent issue.)

Darjeeling.—The general result from our estates in this district was fairly satisfactory, and would have been much more so but for the severe drought and unfavourable weather for growth and manufacture which prevailed, more or less, at most of these estates during a considerable portion of the season, and the low prices for tea ruling in this market. The estimated crop was 7,400 maunds or 592,000 lb. and the out-turn was 8,362 maunds or 668,988 lb. The average sale price of the teas from the Upper Division was 1s 1½d. per pound, whilst the teas from the Lower Division realized an average price of 1s 4-13d. per lb. The cost per lb. of the Upper Division's teas laid down in London, (taking Rupee expenditure at 1s 8d.) was 10,044. per lb., and the cost of the Lower Division's teas 9,66d. per lb., the season's profit from the Upper Division being £4,403 18s 5d. and the like profit from the Lower Division £3,475 8s 11d. making an aggregate of £1,3879 7s 4d. The average cost of production of our Darjeeling teas in 1884 was less by 1½d. per lb. than in 1883, the decreased cost in the case of Moondakotee being as much as 2½d. per lb. and we have fair reason to hope that under ordinary circumstances, these economies will be maintained, if not improved. The first moiety of our produce from this district, owing to the causes before mentioned, and coming as it did to a depressed market, failed to realize satisfactory prices; but the latter portion of the crop proved of superior quality, and finding a somewhat improved market materially enhanced the average price of the entire crop; the latter portion of the Meendakotee teas realized an average price of 1s 7½d. per lb., whilst the earlier consignment realized only an average of 1s 1½d. The prospects of the present season are undoubtedly encouraging, the gardens being in good condition, and promising with a continuance of favourable weather, to give us their full estimated crops and of better quality than those of 1884.

Assam.—There was good promise of the estimated crop from our estates in this district being substantially exceeded, but deficient rainfall at a critical period towards the latter part of the season operated as a check and a small shortfall in yield was the necessary result. The estimated crop was 5,893 maunds, or 471,440 lb. and the out-turn was 5,762 maunds or 469,900 lb. being 131 maunds or 10,480 lb. short of the estimated yield. The average sale price of the teas from the Lattakoojan division was 1s 1½d. per lb. or 1-43d. per lb. less than in 1883, but the cost of production having been 10-06d. per lb. in 1884, as against 1s 1½d. in 1883, showing a reduction of 8-69d. per lb. the result has been a profit from the division of £4,208 7s 6d. or £2,067 5s 11d. in excess of the profit in 1883. The average sale price from the Diphoo division was 1s 0-4d. per lb. or ½d. per lb. less than in 1883, but the cost of production having been 11-27d. per lb. in 1884, as against 1s 5-7d. in 1883, showing a reduction of 2-2d. per lb. the result from this division has been a profit of £765 18s 3d. in 1884, against a loss in 1883. The quality of the produce from this district was well up to the general average of Assam teas, and did not fall much below the average of similar produce in 1883. The reduced cost in production, aided by a considerable area of new tea coming into bearing, are favourable features, and afford good grounds for expecting still more satisfactory results from the further development of these properties.

Cachar.—In spite of the severe storms from which our estates in this district so materially suffered, and the subsequent unfavourable conditions of weather and markets in 1884, the teas realized about the same aggregate average as in season 1883, but the serious shortfall in the estimated yield necessarily increased the average cost of production, although every judicious effort was made by the managers to economise expenditure as soon as a shortfall in the crop was seen to be imminent. Several months elapsed before Jalingah recovered from the effects of the hail storms in April and blight did not leave the gardens until September too late to expect a full or even a fair crop. Very creditable and occasionally high class teas came to us from this district especially from Jalingah, and we see fair reason to hope that the present season will show greatly improved results. The estimated crop was 4,900 maunds or 392,000 lb., and the out-turn was 3,667 maunds or 293,360 lb., being 1,233 maunds or 98,640 lb. short of the estimated yield. The average sale price of the teas from this district was 1s 17s. 1d. against 1s 17-4d. in 1883, but the cost of production, owing to the short yield, having been 1s 1-90d. per lb. entailed a loss on the season's working of £136 18s 1d. against a profit in 1883 of £792 9s 4d.

Sylhet.—The season's results from our estates in this district have been most unsatisfactory; the plants were much injured by hailstorms, which were followed by severe blight and a long continuance of cold and most unfavourable weather, which necessarily affected leaf both in quantity and quality, whilst the prevalence of cholera and smallpox at Shabazpore curtailed and disorganized the labour staff to an extent that was most prejudicial (for the time being), to the efficient working of the garden. On the subject of the weather, the manager wrote:—"Throughout the season we experienced a succession of the most unfavourable weather I could imagine it possible to have, and the consequence have been disastrous." Unfortunate as the results from our estates in this district have undoubtedly been, we are unable to attach blame to the management, considering as we do, that the very exceptional circumstances that prevailed sufficiently account for the heavy average cost of production. The estimated crop was 2,575 maunds, or 206,000 lb. and the out-turn was only 1,895 maunds or 151,000 lb. The average sale price of the teas was 1s 1-10d. per lb. against 1s 1-26d. per lb. in 1883, showing a loss on the season's working of £1,044 7s 11d.

Kolabarree laboured under exceptional drawbacks during season 1884 in consequence of difficulties having arisen in connection with the labour force at an important period of the season, which very seriously affected the strength of labour and prejudiced the season's results. Considering that this state of circumstances was principally due to want of judgment on the part of the local manager, who had been in the bank's service for upwards of seven years, we deemed it our duty to put an end to his engagement and to appoint another of the bank's employes to this charge. We trust that under the new management the garden will ere long recover from the effects of the disturbances of the past year and show steady progress towards profitable results. The estimated crop was 1,200 maunds or 96,000 lb. and the out-turn was only 959 maunds, or 76,720 lb. being 241 maunds or 19,280 lb. less than the estimated yield. The average sale price of the teas was only 1s 0-73d. per lb. against 1s 2-38d. per lb. in 1883, whilst owing to the shortfall in yield, to the garden being a comparatively new one, requiring to be supplied with machinery and buildings, and to the other exceptional circumstances to which we have referred, the average cost of production was 1s 6-113d. per lb. showing a loss on the season's working of £1,693.

Crop.—The total out-turn for 1884 was estimated at 21,970 maunds or 1,757,600 lb. and the actual yield in-manufactured tea was 20,616 maunds or 1,651,680 lb. showing a shortfall (arising from the causes before mentioned) of 1,354 maunds or 105,920 lb. The crop was laid down in London (with rupee expenditure taken at 1s 8d.) at 11-00d. being ½d. per lb. less than the cost of our 1883 crop, and realized an average sale price of 1s 2d. per lb. We made no shipments to Australia or America during last season, either directly or through the Calcutta Syndicate. The estimated crop for 1885 is 23,125 maunds 1,850,000 lb. being 2,479 maunds or 198,320 lb. in excess of 1884 crop, and we believe that this estimate will be fully realized

if not exceeded. A small consignment of the new seasons teas from Moudakotee (208 chests) has been sold in this market at an average price of 3s 3d per lb. Up to our latest advices the quantity of tea made was 2,955 maunds, against 3,805 maunds in 1884. The rainfall at the beginning of the season was short but recent advices now point to a fair average season.

Extensions.—During the past year 491 acres have been added to our planted area.

General.—Owing to the contingencies already adverted to, the gross amount of profit from the season's working was considerably less than we anticipated, attributable mainly to shortfall in crop at some of our gardens and the low prices for tea which ruled in this market throughout the season. But for these drawbacks, which were obviously beyond our control, the aggregate of tea profit at credit of the profit and loss account, would not only have covered the current year's expenditure on the bank's general account, but would have reduced to some extent the debit balance brought forward from 1883.

11.—Our expenditure on all accounts (other than tea) during the current year may be estimated at £21,700, whilst our receipts from all sources (other than tea), will not probably exceed £5,000. The estimated cost of our 1885 tea crop is below 11d per lb laid down in London, but taking it at 11d per lb and estimating the average price at last season's low average of 1s 2d per lb, the resulting surplus would be sufficient not only to cover the current year's expenditure debited to profit and loss, but would leave a margin of several thousand pounds to reduce the debit balance from 1884. In moving the adoption of the report, the Chairman said that the loan business of the bank had almost ceased to exist, the amount of the current loans having been brought down to about £35,000. The only unsatisfactory feature was the fact that they had not sold more of their properties in India. That, however, he thought was accounted for by the condition of the money market, and a feeling that the property belonging to the bank, and being locked up, was likely eventually to go for nothing if would-be investors would hold out long enough. On Saturday they had received a telegram from Calcutta stating that a small property had been sold for 20,800 rupees, and the last letters from Calcutta had given them details of various negotiations which, if carried through would eventuate in the sale of a very substantial amount of property—several lakhs of rupees. Their debenture liability had been very materially decreased since December, 1883, and looking at the present amount and the original figures, he could not but consider that the progress made in this direction had been very satisfactory. Since the bank had been in existence they had paid off debentures amounting to £580,920, and this liability had been reduced from close upon £1,000,000 to £320,800. During the same period they had had to meet debenture interest to the amount of £525,000, and the two sums aggregating substantially over £1,000,000. He regarded this fact as very satisfactory, when they remembered the state of things which existed on the present board taking office, when the shareholders, thought that a call was not merely probable, but that it would be impossible for the bank to carry on its operations and meet its liabilities, which at that time amounted to £50,000 a year for drawn bonds and debenture interests without making a call. They had not, however, made any call on the shareholders. He concluded by referring to the growth of their tea estates. The motion was seconded, after which Mr. Bainbridge stated that if the present prospects of the working of the tea estates continued for the rest of the year they would be able to present a better profit and loss account next time than they had done for some two or three years. The report was adopted after considerable discussion. Mr. Buchanan afterwards proposed the following resolution:—"That, in view of the continued unsatisfactory nature of the accounts, the steady fall in the average prices of tea, and the probability of a still further reduction in value, a committee of shareholders, to be nominated by the meeting, be appointed to enquire into the present position and future prospects of the bank, and submit a report thereon." The resolution was seconded, but, after a full reply from the chairman, only five hands were held up in its favour, and the meeting closed with the usual vote of thanks to the chairman and directors.—*Home and Colonial Mail.*

DEPRECIATION IN THE VALUE OF LAND IN ENGLAND.—The value of land in England still continues to fall. "A few days ago," says the *Land Agents' Record*, "an estate of some 500 acres in Cambridgeshire was exposed for sale, but only £22,500 was offered. A few years ago the same property changed hands for £70,000. Much of the land on another Cambridgeshire estate is said to be let at 3s an acre to prevent it from going out of cultivation."—*Sugarcane.*

DARJEELING TEA COMPANY, LIMITED.

At the twentieth ordinary general meeting of this Company the following report was adopted.—The directors beg leave to submit their Twentieth Annual Report on the operations of the Company during the past year. The weather during the manufacturing season of 1884 was most variable and unfavourable for the production of large quantities of fine leaf, and consequently the tea made was far below the amount expected by the manager, at Darjeeling when he prepared his estimate of the crop. For the same reason the quality of the tea at times was rather disappointing; some invoices were, however, received possessing fine flavour, and realized excellent prices. The average rainfall on the plantation during the past three seasons, up to the 9th November in each year, was 118 inches in 1882, 91 inches in 1883, and only 73 inches in 1884.

The great depression in the value of all Colonial produce that has existed so long, has also been keenly felt in the tea market, and, under such adverse circumstances, the results that have been realized, as indicated below, must be considered to be of a satisfactory character to all parties interested in the company's affairs. The directors would desire especially to draw attention to the large savings effected in the expenditure in 1884, as compared with that in 1883, and this was accomplished without in any way diminishing the efficiency of the labour staff, or curtailing the necessary operations on the plantations; on the contrary, the plantations and everything connected with them have been maintained in the highest state of efficiency, and many important improvements of a permanent character have been carried out. The cash receipts in 1884 have fallen short of those in 1883 by about £2,734, but on the other hand, the general expenditure in 1884, as mentioned above, was less than that in 1883 by £2,259, so that the gross profits realized in 1884 have been only £475 less than in 1883.

The following comparative statements show at a glance the operations of the Company during the past three years:—

Total Outturn of Tea, and Cost at Plantations.

	Acres.	lb.	lb. per Acre.	R.
In 1882 ...	1,534	566,102	at 369	195,336
" 1883 ...	1,562	473,810	at 303	182,965
" 1884 ...	1,686	473,206	at 298	174,932

Gross Expenditure and Cost per lb. of Tea after deducting the Difference in the Rates of Exchange.

In 1882, £27,256 ...	cost per lb.	0s 11 8/2d
" 1883, £25,461 ...	"	1s 1/17d
" 1884, £23,767 ...	"	1s 0/18d

Account Sales, Weight of Tea, Average Prices, and Proceeds.

In 1882, 553,027 lb. at ...	1s 3/32d	£35,336
" 1883, 463,681 " at ...	1s 6/59.1	£35,927
" 1884, 468,239 " at ...	1s 5/41d	£33,975

The directors beg leave to recommend to the members the declaration of a dividend at the rate of 7 per cent, free of Income Tax, payable on and after the 11th May, 1885. After providing for this dividend a balance will remain on the profit and loss statement for 1884 of £782 16s 3d, which will be carried to the credit of the reserve fund.

Dividends Declared.

On 1882 Crop of Tea 6 per cent.
" 1883 " 7 " "
" 1884 " 7 " "

The total sums set aside from the profits as a reserve fund, amount to £4,057 17s 2d. The manager at Darjeeling has prepared estimates for 1885, on the basis that in a average weather will prevail throughout the season; a diminished rainfall, similar to that experienced during the past season, must necessarily upset an estimate prepared in this way, but under favourable conditions the estimated quantity of tea ought to be produced. The estimated crop of tea and expenditure in 1885 shows the total crop at 520,000 lb., and the total cost £79,694 rupees. Mr. John Farley L-4th and Mr. Henry Smith retire from the direction by rotation on this occasion, and being eligible, they beg to offer themselves for re-election as directors of the Company. Mr. John W. Roberts, the auditor of the Company, begs to offer himself for re-election for the ensuing year.—*Indian Tea Gazette.*

ASSAM AND JOREHOUT TEA COMPANIES.

The Annual General Meeting of the above company was held a few days ago, at 5, Lawrence-lane, Pountney-hill, Cannon-street, Mr. W. Prideaux presiding. The Report presented by the directors set forth that the profit amounted to £27,526, out of which they proposed a dividend of fourteen per cent. for the year, and to carry forward £1,376 19s. 6d. In moving the adoption of the Report, the Chairman referred to the low price of tea which had prevailed during the year, observing that it was attributable, he thought, to the inferiority of the quality of the growth. The cause of this had been inquired into, and he felt confident that the cause was not likely to be one of a permanent character. In fact, on June 14th, he received an encouraging telegram from the acting superintendent stating that he had obtained 4,000 lb. of tea more than in the corresponding period of last year and there was reason to believe that a much larger crop would be gathered in the year than in 1884, at a lower rate of expenditure. After a short discussion the report was adopted.

The Annual Report of the directors of the Jorehaut Tea Company (Limited) states that the quantity of tea manufactured in 1884 was 1,206,677 lb., being 106,462 lb. in excess of the quantity made in 1883, and only 9,231 lb. below the estimate prepared by their superintendent at the commencement of the year. The quality of the teas was of good average standard, but the great depression in the value of tea and colonial products generally operated against the realization of higher prices. In consideration of the valuable services rendered by Mr. James Huttman, as an assistant for nine years and as superintendent for a further period of twelve years, the directors have had the pleasure of presenting him on the present occasion as a special gift with the sum of £500, chargeable against the profit and loss account for 1884. The receipts amounted to £82,125 and the expenditure to £61,943, leaving gross profits £21,182, which have been appropriated as follows:—Commissions on profits, £3,071; directors' extra fees, £250; present to J. Huttman, £500; income-tax, £421; dividend at 15 per cent. £15,000; and reserve fund, £1,940.—*Home News*

POWDERED RICE AS A STYPTIC REMEDY has a great effect on fresh wounds, much superior to oxide of zinc. By mixing from 4 to 11 per cent. of it with lint, and using the lint thus treated as a compress, it is very effectual and more valuable than subnitrate of bismuth, salicylic acid, or carbolic acid.—*Med. Press.*

DIKOTA, 27th July.—After a long spell of fine planting weather we had a few rather bright days about a week ago followed by some more rainy days, and today it is again fine and looks as if it would continue so. A large acreage of tea has been planted this season as you will see by the returns for your Directory, and, notwithstanding the extensive nurseries put in by almost everyone last year, plants are very scarce and selling at from Rs 5 to Rs 6 per 1,000 according to quality. It is now just two years since the rush into tea began in this district, and a considerable acreage will be giving regular pluckings from about November next. Several new factories are being started and more being talked of. One hears very little about coffee, and decent crops are few and far between: some have simply none at all. The ground has been cleared of the trees in many places, so as to give the tea a fair chance; in others the lower primaries have been lopped up, and the coffee that has in no way been interfered with is getting smaller by degrees and beautifully less every day. Cinchona is lasting out wonderfully and has doubtless been the one thing that has enabled many of us to turn the corner. In another two years or so most estates will be able to get along comfortably without it.

PHORMIUM TENAX, OR BOWSTRING HEMP.—The great strength of this valuable fibre has long been known and appreciated, but comparatively few are aware of the therapeutic qualities of the plant. Somewhere about the year 1869 or 1870, a letter appeared in the *Melbourne Argus*, signed by Mr. Francis A. Monckton, bearing witness to the extraordinary healing-properties of the *Phormium tenax*, commonly known as New Zealand Flax, from that time until the present he has used it in hundreds of cases, including lacerations and amputations of every description, and he has no hesitation in saying that there is nothing known in the old world that can equal it in producing healthy granulations. Mr. Monckton uses a strong decoction—the stronger the better—made from the roots and butts of the leaves, boiled for twelve hours. At one time he had to make it fresh every second day, as it readily ferments and deteriorates; but since carbolic acid came into vogue, he keeps it for any length of time by adding about an ounce of equal parts of carbolic acid and glycerine to every quart. Mr. Monckton says he requires no other antiseptic precautions, but simply syringes the lesions occasionally with it, and maintains cotton wool or lint soaked in it, constantly to the parts affected. If there are no foreign matters to be discharged there will be no discharge, in support of which he instances the case of a man whose forearm he lately amputated after it had been shattered through dynamite. The ligatures were thirty-two days in coming away, and the amount of pus from the operation up to that time would not amount to a tablespoonful. The same patient had the soft parts of the other arm torn and blown into such a mass of shreds that the members of the staff thought it was hopelessly lost beyond repair. Mr. Monckton asserts that with the same treatment it became as sound and as useful as before, and exhibits only scars, showing where new skin had been formed.—*Planters' Gazette*.

CONSUMPTION OF COMMODITIES IN BRITAIN.—Mr. Goschen in speaking at Manchester on depression in great branches of trade, such as the iron and mining industries, thus depicted the bright side:—“I have spoken of the profits, but profits and savings are not the same things, and though there have been comparatively, I believe, fewer profits among merchants and manufacturers, the savings of the country seem still to be accumulating. Lord Derby has pointed to the increase in the savings banks. That is, doubtless, a most satisfactory point. There is an increase both in the amount deposited by the working classes in their savings banks and their friendly societies. Well, then, what other tests are there of the prosperity of the country? There is one which it is impossible to pass by—and that is the question of the consuming powers of the country. Now, with regard to the consuming powers of the country, the statistics are decidedly satisfactory. We have drunk more tea than in any year before; we have consumed more sugar, we have consumed more wool in our manufactories, we have consumed more cotton in our manufactories, we have employed more servants, we have taken out as many licences to shoot, we have had as many carriages—in none of the great departments of expenditure, whether touching these working classes or the well-to-do classes, was there any sign of falling-off in consumption, except in one, or let me say, in two. In the consumption of spirits a decline is noticeable. (Cheers) We drink now only ten glasses of spirits for every 13 that we drank in the greatest drinking year, which was the year 1875 (cheers), and we have cut off one glass out of ten during the last four or five years. In tobacco, also, there is a very slight decrease; we have cut off one pipe or one cigar out of every 35, and that is supposed to be due partly to the higher duty.—*London Times*, June 26th.

CROU-CHOU PICKLE.—The recipe which I have proved to be most trustworthy, is as follows:—“Take 2 lb. of green tomatoes, brinise them, then add two or three medium sized onions, sliced according to size, and six chillies; scatter salt over it, letting it stand fifteen hours, then strain away the moisture, and cover the remainder with good vinegar. Bake this in an oven for one hour, and then press the pulp into jars. Now take a dessert spoon each of mustard, pepper, mixed spice, half teaspoon each of sugar and cloves, a little cinnamon, and four chillies, adding sufficient vinegar to make this quite thin. Boil it and pour over contents of jars while boiling hot.” Another good recipe under the heading “Tomatoes for pies” may also be acceptable to some of my readers who may have a quantity of green fruit too backward to ripen. Pick the tomatoes green; scald them and take off the skins. Put them into a preserving pan, and let them boil for half-an-hour. Cut them up, and put in 1 lb. of sugar to 3 lb. of tomatoes, and let them cook for half-an-hour longer. Season them with the juice and peel of lemon, and put them away in jars. These make very good pies in the winter, and resemble gooseberries.—*Planter and Farmer*.

FIJI.—An old Ceylon planter writes:—“I have often regretted having come out here. Planting prospects are poor in the extreme and have been steadily getting worse ever since I arrived. One just exists, and as for making money, it's simply at present out of the question. Those who possess coconut plantations can, by the greatest economy and hard work, supplementing by food growing, &c., manage to keep their heads above water. All the others, I may say almost without exception, are in debt and likely to remain so unless things take a great change. Labour is the great bugbear. It is getting scarcer and dearer every year. Polynesians will soon be a thing of the past unless their immigration is facilitated and their cost of introduction greatly reduced. By the paper I see all Mr. W. Fillingham Parr's land is to be sold on account of the mortgage. I am sorry, as he has been some years out here and has had a hard fight for it all along. This season has passed over without a blow. After the lengthy drought everyone predicted a hurricane, but fortunately the prophecy turned out wrong.”

COCOA IN DUMBARA.—One who has recently been through the district of Dumbara writes to us as follows:—“I was very agreeably surprised to see how well all the Dumbara estates were looking when I visited the district the other day. All the effects of *helopeltis* and drought have almost disappeared. I am positive that, had the shade and shelter trees not been ruthlessly cut down, the damage done would have almost been imperceptible. The only places where it can at present be seen are on the ridges on which at one time many shade trees were planted. I have been told that the late Robt. Tytler would not allow his son to plant up Palakelly with cocoa until the shade trees were well above the ground and would afford shelter to the young plants; and how wise this was recent events have proved. Rajahwella has, I suppose, suffered the most, because its shade trees were cut down at one fell swoop, whereas those on Palakelly were mostly “ringed” by the superintendent and remained standing for a much longer time. But planting shade is again being rapidly proceeded with, though it will be years before all traces of the damage done can be repaired. The blossoms now set all over the valley are most abundant, and the crop to be picked towards the end of the year will be heavy. Trees are in splendid condition, this south-west monsoon having suited Dumbara better than any other district. If one could always rely upon such seasons, cocoa planting there would pay twice as well as tea any where. Koudasala was looking well as I passed through and Ambecotta is much better than I expected. The hardworking manager is doing his utmost to replace the shade and shelter he removed some time ago under the impression that it was the best thing for the estates. Experience has proved the contrary in a most unmistakable manner and all that can now be done is to wait till the time has replaced what was removed in grievous error.—*Local Times*.”

Correspondence.

To the Editor of the "Ceylon Observer."

CACAO IN THE LONDON MARKET; AND HOW TO CATCH HELOPELTIS.

11th July, 1885.

DEAR SIR,—Has your London Commercial Correspondent a 'down' on cacao? or perhaps, may be, he is of a bilious nature and cannot drink it; but is that a reason why it should be left out in the cold? Just look, and see what he says: "Coffee fairly good," "Tea A 1"—all the other products are gone to the dogs (at least he says so in so many words): forgetting perhaps that he is putting cacao with the rest of them. Then someone else always says: "Coffee up 1s, good news for coffee planters!" but nothing is said when cacao goes up 5s or so! Oh no, Mr. Editor, this is rather one-sided. We cacao planters toil on quietly in spite of all, and, thank goodness, the rains we have had pretty nearly washed all the fly away, and I think therein every chance of our being able to keep the small pest down, and rather more than simply "keep the pot boiling."

I have thought of a plan which may be of use in exterminating the helopeltis, viz.: Get the chatty-man to make a false pot,—that is a clay one,—as near the shape of the real thing as possible; have it burnt as red as he can get it, and then fill it with some sweet syrup (jaggery treacle) and poison (arsenic is the best for flies) and seal up the end, or cork it; hang it in the tree and the mixture will soak through the clay and keep it continually moist, giving the insects plenty of juice with little or no waste of the liquid: it may act, and I should say it would be inexpensive after the first outlay. Strong tea and sugar would probably do. I have made a mould and intend letting you have a pot in the course of a short time, when you will see exactly what I mean.

By-the-bye the next tour you take in the planting districts, look at cacao and glance at tea by way of a change!—Yours faithfully,
BUSY B.

HARVESTING OF CINCHONA BARK.

Deltota, 16th July 1885.

SIR,—I am sorry I am unable to give my experience about what "B." asks, as I never shaved a portion of the tree leaving two strips. I cannot understand why this is done at all, as "B." himself says less work is done per cooly, and when the trees are shaved a second time the bark will not be as valuable as when the whole stem is shaved at once. I have shaved trees ranging from two to six years, and I have found the younger trees renew bark much faster and better than older trees, and I would recommend "B." to take a very thin slice of shavings from the whole stem instead of leaving strips. Including lopping I got an average of 53 lb. twig and branch per cooly. I cannot say the exact amount my trees cost for hatching; the amount of nett bark I harvested was 28,631 lb. The outturn of dry at 33 per cent 9,448 lb. which cost me Rs 25-09: i. e. for harvesting, cutting mana, hatching, drying, packing and cost of watchman, or at the rate of 6 6 cents per lb; cost of cart hire, train fare &c., at 3 cents more will make 9 6 cents, or a little less than 10 cents delivered at the Colombo store.

Can you or any of your correspondents let me know why on some estates trees are coppiced about 2 feet from the ground? One superintendent told me this stem was left for staking the resulting snicker after coppicing. This to my mind is as sensible as amputating a man's leg and leaving a piece of bone to stick out. I have seen coppiced shoots from stems of this kind about 2½ to 3 feet high a year or more after coppicing, while where the stem has been sawn ½ ft. from the ground the shoots are betw een 4 and 7 feet high at the same age. B. E.

MR. A. WHYTE ON HOW TO GROW "ROSES" IN COLOMBO, WITH HINTS APPLICABLE TO

ALL ELEVATIONS: No. I.

DEAR SIR,—In one of your late issues, I observed a correspondent asked for information on the best method of growing roses in Colombo, a question which has frequently been put to me. I have not had any experience in the cultivation of the rose at so low an elevation, but have been successful with the introduction and raising of many new and choice varieties in Kandy. As much of the treatment required here will apply to Colombo and Galle and other elevations, I give, with pleasure, my experiences, in the hope they may be of some little service to your correspondent, and others interested in and devoted to the culture of the *Queen of Flowers*. As with most other pursuits we engage in, unremitting care and attention is necessary, if we wish to attain success in rose growing; and the other principal secrets of that success, will generally be found under the following heads, viz., *situation, soil, manure, drainage, selection, and arrangement.*

I.—SITUATION is all-important. In gardens, how often do we find a large mango tree flourishing in the centre of the principal flower plot, surrounded with crotons, hibiscus and rose bushes &c. all drawn, weak and spindly, struggling for an existence, among the gormandizing roots of the mango; such a situation might form a charming spot for a fernery, or a bit of rock work, where Begonias, Caladiums, Dracenas, Alocasias &c., would thrive, provided sustenance was given them; for the rose it is a cemetery. As has been remarked, "it takes umbrage in a two-fold sense; robbed above and robbed below, robbed by branches of sunshine and by roots of soil, it sickens, droops and dies." Of this we may rest well assured, that no rose tree worth growing, will flourish or "blossom as the rose," under the drip, or the shade, or even in the proximity of a mango, coconut or other fruit or forest trees. Queen Rosa will brook no rivals, and will sternly resent their intrusion; the plot of ground selected for the rosarium, must be solely devoted to roses, and, if possible, be so situated as to catch the first rays of the sun, and be exposed to them till about noon, when for the remainder of the day, the roses should have shade from the burning sun in the lowcountry. A good plan to get rid of the roots of trees from the adjoining compounds, is to have trenches dug along two sides of the garden. These will not only prevent the roots from trespassing, but will act as drains in carrying off the surplus moisture.

The next object we ought to have in view, is shelter for our roses; shelter to shield them from cutting and parching winds, and from the salt-laden sea-breeze, so fatal to almost all vegetation. In Colombo, this is already generally provided by the compound walls, which form excellent shelter in the absence of walls, double hedges of Madras Thorn, or Hibiscus (shoe-flower) or belts of tall Crotons and Lettuce trees, will answer well, and for a temporary protection, until these get up, a fence of cadjacs will suit admirably. The best shelter belt plants we know of for upcountry are the acacias (wattles) with good deep trenches along the boundary, to keep the roots from trespassing and to act as drains. On the other hand, the rosarium must not be boxed up too closely, as a free circulation of air is as essential to the health of the rose, as is a moderate exposure to the rays of the sun. Pot roses in verandahs ought to have the morning or afternoon sun and be turned out as often as possible in dull and rainy weather.

II.—SOIL—The principal varieties of soil to be dealt with at Colombo and along the sea-coast, consist either of more or less decomposed laterite (cabbok) or a

deposit of sea-sand, or a mixture of the two. We believe that the average cabook soil, when deeply trenched, drained and liberally enriched with farmyard manure, is by no means a bad one for roses. When the soil is of a strong, stiff and adhesive nature, we would strongly recommend that portions of it be charred or burned and that it be rendered lighter by an admixture of strong sand, ashes and charcoal broken up into small nodules. Another most valuable soil, or we might call it soil and manure combined, is calcined ant-hills which can be procured at no great outlay. These conical mounds form natural kilns, and when a flue is opened at their base and a strong heat established inside the cones, they can be broken down and charred by degrees. These ant-hills will each yield on an average, a cart-load of most valuable rich soil, admirably suited for roses and pot plants. The sea-sand deposit, the principal soil of the Cinnamon Gardens, is by no means infertile, and it is astonishing what it will produce when manure is freely added to it. To see what can be done by an earnest and skilful horticulturist, with this apparently worthless barren stuff, one has only to visit Mr. Wright's delightful gardens at Turret Road. There will be found flourishing in great variety, choice plants and shrubs of the tropics, as also flowers and vegetables of more temperate climes, and on one occasion, we recollect seeing beds of melons producing delicious fruit in abundance. We need scarcely say, however, that this light sand, which sometimes extends to a considerable depth, is not suitable for roses. It ought to be largely replaced or mixed with strong, red, rich and, if possible, virgin soil. A mixture of the sand deposits, cabook, liberally enriched with farmyard manure, ought to grow roses fairly well; but the soil in which the rose delights is deep, rich, comparatively strong land, in which to throw down and fix firmly its long wire-like roots. In preparing the soil for the reception of the rose plants, we would recommend that it be deeply and uniformly trenched and liberally mixed and enriched with farmyard manure during the operation. A very common system of planting the rose, but, in our opinion, a very objectionable one, is to dig a huge hole and discard the soil thus excavated, no matter whether it be poor gravelly inert stuff, or fine strong red soil, just the kind most suitable. This rose grave is then filled in with manure, leaf-mould, coir refuse and any other rich materials at hand, without a single basketful of good honest soil. The drainage from the usually baked soil all round, naturally finds its way into this reservoir, the contents of which soon get saturated, and in wet weather the whole mass becomes a sour sodden spongy dung pit on which gigantic stocks of *clery* might be grown, but which is certainly no congenial home for the rose. Treated in this way, it seldom does so well as it would have done on the original soil, well trenched, forked and enriched with, say one-twentieth part of the manure thus wasted. When planting out the rose trees, it is well to mix with the soil all round the roots, a basketful of old decayed manure mould, which will encourage and hasten the growth of new rootlets.

III.—MANURE, judiciously selected and applied, is most essential to success in rose growing. The handiest and one of the very best manures, is ordinary farmyard compost. By this we mean, the dung and refuse from the stable and cow-house, pig and poultry manure and the ashes and refuse from the kitchen, all well mixed and fermented. The stage of decay, at which the manure ought to be applied, will depend greatly on the nature of the operation and the consistency of the soil. If for newly trenched land of a stiff clayey nature, it need not be over well decomposed, as the half-decayed litter, when well amalgamated with the soil acts admirably in render-

ing it more friable and porous. In the case of lighter and more porous soils, the compost ought to be thoroughly fermented and well decayed, but in no case would we recommend the dung heap to be left till it becomes little more than rich black mould. It has then lost to a great extent, its principal fertilizing and stimulating property—its ammonia. We can also recommend bones as an excellent and lasting manure for roses, and we would advise its being applied in combination with peonac, and wood ashes, in the proportions of 1, 2 and 3 respectively—the principal use of the ashes being, to ward off the attacks of white-ants, beetles and other injurious insects attracted by the peonac.

Night Soil is a very powerful and suitable manure, for roses, but in connection with it we have the usual prejudices to contend with, and the difficulty in its application.

Of fish manure we have had no experience, but should imagine it would be suitable, strong and stimulating.

As regards *artificial manures*—they are dangerous, and require to be used with the greatest caution. Many years ago in the West Indies we had painful experience of the mischief caused by some of these manures and to this day we have a wholesome dread of them. Guano and sulphate of ammonia if used at all, ought to be given only in a highly-diluted form, and applied as a very weak solution, of, say, 1 oz. 1 drachm respectively to the gallon of water.

We will now give as briefly as possible, a list of manures suitable for roses, and available here, in the order of merit generally assigned to them, by our great English rosarians, Turner of Slough, Paul of Cheshunt, &c., &c.

- 1.—FIG MANURE, very powerful and efficacious.
- 2.—NIGHT SOIL, highly recommended.
- 3.—FARMYARD MANURE, one of the best, and least offensive to our noses.
- 4.—BONES, an admirable and lasting manure, would recommend it in combination with peonac and ashes.
- 5.—BURNED EARTH AND ANT HILLS, most useful manure, especially in the case of wet and adhesive soils.
- 6.—SOOT, very beneficial, especially for tea roses.
- 7.—GUANO, too stimulating, throws up luxuriant wood and foliage, but comparatively few blossoms. Never use a stronger solution than one ounce to the gallon of water.
- 8.—SULPHATE OF AMMONIA, still more stimulating, and dangerous, and to be used with great caution say, 1 drachm to gallon of water.
- 9.—BLOOD of animals, very suitable for roses, producing fine blossoms.

Finally, on the demise of any of our domestic animals or pets, by all means let us honor them with a tomb among the roses. Decaying animal tissue is most beneficial, but should not be placed in too close proximity to the roots, until well decomposed.

IV.—DRAINAGE.—A free exit for all superfluous moisture, both above and below, is of the greatest importance, and in the case of stiff retentive soils is absolutely necessary. In the latter case let parallel drains be cut, at intervals of 12 or 15 ft. and 34 to 4 ft. in depth. The draining is of course the best, and perhaps the cheapest in the long run as space is saved, and no periodical weedings and cleaning out are required. As to the form of tile to be used, we should recommend simple tapering tubes of say 13 inches in length, and so made, that the tapering end of one fits loosely the thick end of the other, for say about an inch. The advantages this form of tile has over the ordinary sole tile, is, that they are less apt to get displaced and choked, are easier laid down and cheaper. They cost little more than ordinary roofing tiles or say R15 per 1,000 feet. The diameter of the tube ma-

of course be regulated according to the amount of water to be carried off, or say from 2½ to 4 inches, and to guide the potter, a plug of wood ought be given him, exactly the size of the inside of the tile, and which he would use as a mould A. WHYTE.

LOCAL QUININE MANUFACTURE.

16th July 1885.

DEAR SIR,—Have you not drawn a wrong inference from the report made by Dr. Cleaver on this experiments in India, and the reply of the Madras Government? You say it is a "warning of difficulties to be overcome," whereas I read it quite differently. Dr. Cleaver himself reports that "there are no insuperable difficulties," and complained only of want of chemicals and apparatus. On the strength of this his friends tried to bespeak Government support for operations on a large scale.

But the Madras Government proved that Dr. Cleaver's estimate of cost of manufacture was excessive, and that his estimate of returns was too low, both of which exaggerations on his part (very natural under the circumstances and the necessity for caution) show rather the remunerative nature of the business, while I search in vain for the "difficulties."—Yours truly, R. W. J.

P. S.—I had not been able to read the paper in your issue of the 9th until today.

[Mr. Böhringer of the Milan Factory when in Ceylon dwelt on the high temperature even at Nuwara Eliya as a difficulty in working the chemicals so as to manufacture sulphate of quinine, and he said the argument as to freight of bark told pretty well against the freight of sulphuric acid, soda, &c., from Europe.—Ed.]

TEA AT A LOW ELEVATION.

SIR,—I shall be glad if some of your correspondents will kindly give me the benefit of their experiences on the cultivation of tea at a low elevation of 300 to 500 ft.

Which is the better variety to cultivate, indigenous Assam or a good hybrid?

Would you plant 5x5 for the former and 4x4 for the latter? or at what distances?

What should be the respective outturn of made tea from the two varieties planted in good jungle soil as above mentioned in 2ed, 3rd, 4th and 5th years?

Is the flavour of indigenous tea more delicate than hybrid, and how do the prices compare one with another?

Which variety is considered the most profitable to cultivate?—I am, sir, yours faithfully, S.

[In reply to "S." 's enquiries a "Tea Planter" gives the following reliable information; but we would encourage further discussion if need be:—

"(1) For very fine soil, in a wet district, elevation 300 to 500 ft., indigenous tea would be best; but for inferior soil, a good hybrid. (2) I would plant the former, under such conditions, 5x4, and the latter 4x3½ or 4x3. (3) I am not prepared to say exactly what the difference in yield would be, but believe it would be in favor of the indigenous: in rather poor soil, or a dry district, the hybrid would answer best. (4) The flavor of indigenous tea is believed to be more delicate than hybrid, but I have been unable to confirm this. (5) Under suitable conditions the indigenous would be the most profitable to cultivate."—Ed.]

HARVESTING CINCHONA BARK AND THE PROPER MODE OF SHAVING.

Agrapatana, 20th July 1885.

DEAR SIR,—My attention has been drawn to a letter in the *Observer* signed "B. E.," who seems at a loss to understand why cinchona trees should be shaved in alternate "strips" in preference to "all round" the tree. I would refer him to the reasons given by David Howard who introduced this system of shaving and, I think, explained it in a letter to the *Observer* in August or September 1853. His theory is that shaving thinly all round the tree does not make renewed cellular tissue, which contains the alkaloids, but only the outer skin is renewed. Another advantage is that the bark renews from the edges of strips left on the tree, as well as from the cambium outwards. I have tried this system of shaving for some time past, and it has been most successful. The bark renews much better than it did when I shaved all round the tree, and the tree suffers much less from being shaved in this way. The trees are shaved five and six times before they are coppiced, and then the result of coppicing has been as satisfactory as the shaving.

As regards coppicing 2 feet or so from the ground, my reasons for doing this are, 1st, to prevent the harm done from excessive bleeding which often takes place and frequently causes death. By leaving the stump the bleeding is more gradual, &c., and the shock is felt less than when sawn close off; 2ndly, the stump affords a good general protection for the young suckers, especially in coffee where constant works are going on; 3rdly, where there is wind, it makes a capital stake for the growing sucker, and indeed can be used for this purpose to advantage anywhere. After it has served these purposes, and when the suckers are large enough to be independent of it, it can of course, if preferred, be removed; but this is by no means a necessity. The general tendency of the growing sucker is to get a firm hold on to the root of the old tree and to strike into the earth. There are some however which start higher up on the stump, and for the benefit of these the stump might be sawn down to make more room for suckers, but there is certainly no necessity whatever to do this in any other case, as the lower suckers, which are generally the strongest and most healthy, are not affected in any way by the stump, at that stage. I fail altogether to see what analogy there is between an amputated leg, with a piece of bone sticking to it, and a cinchona tree coppiced for the express purpose of forcing out suckers to take its place. The surgical operation may be something similar, but the reasons for this operation and the results required are as opposite as opposite can be.

My experience of the growth of resulting suckers from coppiced trees is quite the reverse of "B. E.'s" and it extends over many years and a large acreage, and this is not my experience only.

I see no reason whatever why the bark harvested from fairly representative trees, from 3 to 6 years old, with mana grass available for covering, should not be delivered at the Colombo store for 10 cents a lb. Of course a good deal depends on the proportion of "branch bark," or on the other hand "coppings." This might make the cost either more or less.

CINCHONA.

LIME JUICE: VARIOUS METHODS OF PRESERVING—WHICH IS BEST?

22nd July 1885.

SIR,—In your *Tropical Agriculturist* Vol. IV., page 951, I notice Mr. John Shortt gives a simple method of preserving lime juice, by allowing it to stand in a cool place for 2 days, and then bottling and sealing;

but in Vol. III., page 887. an extract from the *Pharmaceutical Journal* by Michael Conroy, F. C. S., says that immediately on the juice being extracted it is run into puncheons and sealed up; again another quotation from the same journal, page 748 of Vol. III., says by heating the juice to 150 Fahr. and bottling at that heat, immediately sealing the bottles, preserves the juice.

Can anyone tell me, which of the above methods is the best, or what the proper way is for preserving lime juice for the London market? and, after collecting and bottling it, can the bottle be reopened and the juice put into casks, and shipped to England for sale? or, if it is exported in bottles, what would be the cost, and what would it realize in the London market.—Yours faithfully? S. B.

CACAO AND *HELOPELTIS ANTONII*.

July 24th, 1885.

DEAR SIR,—I should be glad to know if any of your readers who are engaged in the cultivation of cacao have observed any diminution in the ravages of the *H. Antonii* lately.

I have remarked a great change in the last three weeks. Trees, which were till now infested with these insects, appear to be entirely free, both old and young sending out fine healthy roots and suckers, without a sign of the fatal black spots, suckers having been hitherto especially subject to their attacks. Many old trees, which appeared to be dead, are showing signs of vitality once more, and, most noticeable of all, I have failed to come across a single specimen either of the young or perfect insect during a careful search. It would be interesting to know whether this has been remarked elsewhere, and whether it is only attributable to the season, or that better times are in store for this "distressful" industry.—Yours faithfully,
ROBIN HOOD.

LOCAL QUININE MANUFACTURE.

DEAR SIR,—Will you excuse me for again referring to this subject, it being one in which a good many people are interested?

There is nothing said in the Madras Report, either by Dr. Cleaver or the Government, about "not getting the chemicals to work properly," even in India; and it would be interesting to know by whom this objection was first started, or, say, experienced. Did Mr. Bohringer speak from his own knowledge and experience in Italy and America, or did he but repeat the assertion of some other competent, or incompetent, experimenter in India? It is well known that during the summer-months, both in Italy and in America, the heat is, both night and day, much greater than the mean at Nuwara Eliya. Do the factories there stop work, or feel inconvenienced at such times?

As regards the other objection, "freight of chemicals to Ceylon," that resolves itself into a mere question of figures, which, when proper comparison is made, I think would vanish as a serious obstacle. Let us take a lesson from the said Madras Report. Dr. Cleaver offered to contract with the Madras Government to manufacture for them at the rate of R18 per lb. of febrifuge produced. It could probably be done cheaper here, say for R15 per lb. Take local values at 25 cents a lb. for bark, and the febrifuges at R2 per oz. and suppose a planter has 2,000 lb. of bark for disposal. Of this he sells 1,000 lb. at 25 cents and realizes R250. But the other 1,000 lb. he sends to a local factory, as he did his coffee, to be cured—or, in other words, to be converted into alkaloids. On an analysis of about 4 per cent he would receive 40 lb., or say 500 oz. of quinine &c., which at the value, already fixed, viz. R2 per oz., he would sell for R1,000, or R750 more than for the bark,

Of this he would have to pay the factory for 40 lb. of febrifuge at R15 or R600, leaving him a nett sum of R400 as against R250 for that which he sold.

Now it is evident that only a slight alteration of any of these figures would bring out vastly different results. But I have no doubt that, in practice, it would be found that these figures very much understate the advantages that would accrue to the planters from a local factory—for both *branch* and *twig* would often give 4 per cent for alkaloids, and good barks often double, so that I believe the planter would more often double his income from his bark than make only the above small profit by means of a local factory.—R. W. J.

[We are very pleased to find our correspondent so sanguine even in the face of the present low price of quinine. Mr. Bohringer's opinion was expressed in answer to our urging him to establish a local Factory as a branch of the Great Milan concern; but of course there was too much at stake in the latter and therefore his opinion may have been that of one predisposed to run down local manufacture. We have had a letter today from the man, of all others, best able from experience to give an opinion on the questions raised, Mr. Gammie of Sikhim. He reads the *Tropical Agriculturist* regularly and as all this correspondence will be reproduced there, we have no doubt he will favour us with his views in answer to our present appeal.—Ed.]

COFFEE-LEAF-DISEASE: No. I.

DEAR SIR,—Your correspondent who writes: "Writers on this subject should always remember that all scientific authorities" (as a rule one leads and others follow) "agree that hemileia on coffee is as independent of insect cause as rust on wheat," is a little disappointing. Surely he does not expect the public to surrender commonsense for what after all are but theories of scientists.* I am quite open to conviction, and will be satisfied if any scientist will explain how a fungus acknowledged to be without power of locomotion, can find its way from the upper to the lower surface of the leaf, then travel to the stomata and burrow through the tissues? It is but begging the question to say it does this without demonstrating the "how." Is it not more probable that the disease has its origin where it develops, in the tissues of the leaf? PUCK.

No. II.

DEAR SIR,—Will you kindly grant me the privilege of contradicting a remark appearing in a letter of a correspondent signed "Puck" in your Supplement of the 15th instant, as it tends to convey a very erroneous impression? He states that I am "bold enough to come forward in support of a theory propounded by General Braybrooke, that the origin of leaf-disease was in the sap of the tree." Now, if my gentle "Puck" had read my letter upon the subject a little more carefully, he would have found that I said no such thing. I neither support this theory nor any theory whatever for which I have not got ocular demonstration. What I did say was, that, after careful and patient investigation of the life-history of the insect described by me. I have been led to the conclusion that the evil effects of leaf-disease were due to it more than to the so-called fungus, and I am now more than ever confirmed in my opinion from the fact that I have since been able to detect the insects running through the internal tissues of the leaf, and my own conviction is, whatever may be the cause and effect of the yellow *fungoid* mould which accumulates on the under surface of coffee leaves, that the primary cause of the epidemic is due in the first

* Not theories, but conclusions from careful observation and experiment. The spores float on the atmosphere, and as soon as one reaches a stomate, it enters.—Ed.

instance to the mature *aphide* and the work of the speedy decay of the leaf is accomplished by the *larva*. Briefly I mean to assert, that, supposing no physical or chemical connection can be traced between the fungoid deposit and the insect, and although the former were altogether removed, a still more formidable enemy would exist in the shape of its unfortunate host and its *larva*.

You said, sir, in your footnote to my letter, that I ought to have read Marshall Ward's reports before discussing such a question, and doubtless I would have done so had they been within my reach; but probably had I seen those reports before I was induced to study this insect's life, I should not have devoted any attention to the subject at all, and what you simply mean, I take it to be, is that we should

"Rather bear the ills we have

Than fly to others which we know not of."

I did not, by any means, intend my letter to have the effects of a hand-grenade thrown among my fellow planters but as a harbinger of hope, for the tail of a snake is more dreaded than its head when the latter is hidden from us. So it is with leaf-disease. If however we should happen to stumble upon the root of the evil, surely we can look at it straight in the face with cheerful fortitude knowing that we have some hope of applying an effectual remedy. But if I have done wrong in unreservedly offering to the public the results of my researches, I shall say no more about it.

I am not aware what insect Marshall Ward may have referred to. There are no less than six different kinds of insects which I have found existing on coffee leaves alone, but the one which I have particularly alluded to is the transparent aphide which is the only one that penetrates beneath the *epidermis*.

I ask no one to accept of my convictions before testing the accuracy of my assertions. Agricultural instinct, in spite of systems, classifications and scientific frowns, has, before now, fathomed facts, while scientists were hopelessly adrift on the undulating waves of theory. If my intuition is found to be correct, it must be admitted that there is little hope of the disease dying out so long as a single aphide remains alive. It may be less virulent after a previous attack, as it often is, or it may apparently disappear for a season until a fresh brood of insects spring up. On the other hand, if my theory be altogether groundless,

"Behold! the jaws of darkness to devour it up."

But the remedy I have suggested, so far as I am able to judge from the trees on which I have tried it, is, I think, the most effectual whether the effects are due to a fungus or to the insect.

OBERON.

P.S.—On second thoughts I consider it is my duty, Mr. Editor, to send you the enclosed sample leaf taken from 18 months old cinchona (*officialis*) planted amongst the coffee to enable you to judge of facts for yourself and give publicity to them or not as you may think best. This is the effect of the same identical insect. You will be able to perceive the enormous holes punctured by these minute creatures at the base of the veins just as they do with coffee leaves, and you may possibly be able to find some of the transparent aphids still remaining in the holes. These were full of them before I pressed the leaf last night. The fungus however does not appear to be yet ripe or it may, in this case, assume a different nature.

It was only quite recently that I noticed the insect attacks cinchona as well as coffee, and I myself started appalled to contemplate what it may next do to tea planted among coffee or on land where coffee had previously been.

Whatever you may think, sir, it is full time that this insect was being looked after.

I am not inclined to enter into any such nonsense as a discussion about the creature's bodily members and what not. I have pointed out your enemy and shown its powers of destruction. Go and attack it at once or you will only be able to withstand it ultimately with rich soil and abundant manure of the very best quality. O.

[The leaf sent by "Oberon" has got mislaid: if he sends another, or better, a few leaves in a match-box with the insects, we shall have them examined; but "O." is conjuring up a big spectre on a very slender foundation.—Ed.]

HELOPELTIS AND ARSENIC: A WARNING.

DEAR SIR,—Seeing no one else has done so, allow me to sound a note of warning, so that your correspondent may hear it, who is going to exterminate (?) *helopeltis* with arsenic. This poison is not to be trifled with: it is more than probable that the insect he hopes to destroy, having abundance of natural food, will take no notice of the trap; but it is quite likely that many other insects, even birds, rats and squirrels, may, and no one can tell where the mischief will end. I have known birds to die from eating poisoned insects, and cats to die from eating the poisoned birds. I have known many cases of domestic fowls dying from the same cause, dogs and cats lost from eating poisoned mice and rats. I once lost a much valued terrier from eating a poisoned rat. It must be remembered that arsenic never loses its destructive power over life: much suffering and loss amongst our pets and poultry could, I expect, be traced to poison carelessly used, particularly to that pernicious stuff, phosphorus, so generally used to destroy mice &c. and which is supposed to be harmless to most other creatures. ZOOZOO.

COFFEE-LEAF DISEASE.

DEAR SIR,—If I have trodden on our good friend "Oberon"'s toes in any manner I apologize by assurance that it was quite unintentional on my part.

I take it "Oberon" and "Puck" are one in doubting whether coffee leaf-disease is propagated by the orange-colored fungus dubbed "spores." "Oberon"'s discovery of an almost transparent aphide (should it not be aphid?) will be an important factor in future investigations: so, like a good man, Mr. Editor, do not choke us off by saying, the spores do, as a matter of fact, enter the leaf, but admit the possibility of the spores being the effect and not the cause. I, at least, must hold this view until it is explained how a thing said to be without the power of locomotion can yet travel at its will. PUCK.

That the spores enter the stomata and that subsequently the mycelium spreads through the cells and feeds on the life-blood of the leaves, are facts as certain as that the atmosphere consists of hydrogen, oxygen and nitrogen in certain proportions. To trace the fungus to insect origin would be as scientific as the idea, attributed to Thwaites, but which he indignantly repudiated, that the disease was in the juices of the plant, or the outrageous rubbish of that emptiest of collapsed windbags, Montclar, that the fungi developed from ulcers in the substance of the stem! A gentleman to whom true science and careful observation are dear is so troubled about "Oberon"'s aberrations, that he sends us a copy of Marshall Ward's latest report to be forwarded to that writer. The scientist states:—

"Such ignorance I could scarcely have supposed possible after all that has been done in the matter. I was glad to see your decided editorial comments; but in my opinion you should not give such misleading nonsense a place in your columns. It is everybody's interest—even the writer's—to sink such rubbish in oblivion. As I have before said to you, I think, when a writer professes to have

valuable and novel information to give to the public, the result of *personal observation*, he ought to be refused publication unless he is prepared to put his name to his statements. This would not stop any *real* contributions to knowledge, but would induce a good many hasty individuals to pause before committing themselves. "It is a fact that few men can observe accurately and report truthfully: it requires training and self-discipline and much patience. How strange a characteristic, too, in the inaccurate (so-called "practical") man, is that instinctive dislike to the strict methods and well-grounded results of true observation. Such people are very numerous; like heretics they cannot be argued with, but only prayed for!" And so our correspondent will pray for "the five wits" of "Oberon," that they may be enlightened so that he may cease to confound animal organisms with vegetable. But as regards ourselves: ours is not a purely scientific organ, but a popular journal, in which even non-scientific and anti-scientific correspondents must be allowed to have their fling. "Oberon"'s writings and others like them may perchance afford men like our scientific correspondent a hint which, followed up, might lead to valuable scientific discovery. "Puck" is a person of considerable intelligence, but he and others like him distrust the scientific conclusions because unfortunately they leave so little hope of a remedy. They, therefore, catch at every straw and swallow such chaff as "Oberon"'s. —ED.]

ROSE CULTIVATION IN COLOMBO.—Cultivators of roses, and especially, those who would fain follow in their footsteps, will read with pleasure and profit, the letter in which Mr. A. Whyte of Kandy gives so much practical information on pages 179-180.

BUGS.—I notice in the June number of the *Tropical Agriculturist* at pages 908 and 909 an article on "Green Bugs and Coffee" and learn that an old acquaintance of mine, a little speckled bug, has been paying Mr. Downall's estate, Monerakanda, one of its periodical visits. I first came across this bug on Kahagalla estate during the crop season of 1860 to 1861 in very large numbers, the coolies bringing them in with the "palam" or cherry in thousands. Seeing several cherries perforated with a little round hole near the stalk part, and hearing from the coolies of the depredations of this bug to their paddy crops on the Coast of India, where it was well-known as the "velamapochhie" or harvest bug (as I interpret it), I collected a number of the bugs and perforated cherries and sent them to the late Mr. Alex. Brown, who again sent them to Mr. Nietner, whose report I got, and, as far as I can recollect, Mr. Nietner said the insect belonged to the same family as the green fetid bug, and that its procreative powers were not very great and that we need not be alarmed at the harm it would do, or to the same extent as we used to be at the ravages of the "black bug" in the days of old. I think you will find a brief notice of the speckled bug above alluded to in "Nietner's Enemies of the Coffee Tree." The coolies said, at some seasons on the Coast of India, this bug covered their paddy fields and destroyed their crops by sucking the juices from the young paddy before the grain began to harden, and that they were obliged to abandon their fields in consequence. I watched this "droughty" bug at work on the young coffee berries: he first cut a little round hole through the skin and tender parchment and then with a proboscis-like sucker abstracted the juicy delicate matter which forms the bean and thus satisfying both hunger and thirst at the same time, much as the Sinhalese do with a "kurumba" or drinking coconut. The strangest part of it was that he operated on tender coffee berry did not lose its vitality, but continued to form skin and parchment and ripen as if nothing had occurred in its internal arrangement; the operated on side was always empty and I had to put down 2 or 3 per cent of the crop to *extra* light coffee from this cause. The following season this bug was nowhere, and although I have come across the little wretch in after years I never heard of its depredations to any great extent: its visits must be like those of angels "few and far between." Mr. Downall will perhaps be glad to know this. J. A.

ABYSSINIAN COFFEE, we see it stated in an article on the trade of the Red Sea ports, is principally sent to Djeddah and Upper Egypt, it is not, however of first-rate quality, but, at the same time, it has a special aroma; it is sold at 16 dollars per canatro of 113 rottoli.

THE RED "SHOEFLOWER," so common in Colombo, is greatly admired by all visitors from Britain or Australia. In India, the natives call this scarlet hibiscus *Suryamani*, the jewel of the sun. The tree so common in the streets of Colombo, and everywhere around, *Thespesia populnea*, popularly called "the tulip tree" from its beautiful blossoms, is known to the Sinhalese as *Surya*, the tree of the sun. *Michelia Champaca*, on the other hand, is *Sapu*, the flower of light. The Hindus call the blue "morning glory" *Suryakanti*, sunshine. Those who originally gave such names were possessed of the poetical instinct.

ENEMIES OF TEA CULTIVATION IN INDIA.—In going over the reports of various Indian Companies, we find that in two cases serious loss is attributed to mosquito blight (*helopeltis*) and green fly, pests from which we cannot hope to be always exempt. But certainly estates in Ceylon are not likely to suffer as one of the properties belonging to the Eastern Assam Company suffered in 1884. Owing to a terrible outbreak of cholera, which is indigenous in Assam, but only rarely visits Ceylon, the costly labour force had been so reduced that only a small quantity of tea was made, costing 13½d per lb. and selling at only 8½d.

GOLD IN BORNEO.—The Segama Gold field is thus referred to in the *North Borneo Herald* received today.—The result to date of the Gold Working on the Segama River may be considered as fully establishing the fact that it will yield a profit to those who may desire to follow the search. When Mr. Walker the Commissioner of Lands returned he left behind him a party consisting of two boats and six men who had co-operated with him in his investigations. These men worked in the bed of the river until the rains caused such a rise that they were forced to give up. The last day the water was breast high and each time the men dipped to fill their little scoop (a coconut shell) they disappeared bodily in the water! The total gold for six days working was say 3 oz. 0 dwt; 4 grs. The best day's work was 80 grs: to the one pan. The highest return to one pan in one day previously recorded had been 45 grs: and this had been taken from near the same place, viz: below Pulo Kawak, but Mr. Walker is of opinion that a greater weight was probably got when river working for two days above the Sungei Bilang. Mr. Walker's investigations were necessarily of a tentative nature. The attempt to find workable beds of gold in the Sungei Bilang, the tributary of the Segama River where gold was first announced proved a failure. The gold in that stream is less worn than any gold since obtained, and the party found it in the top of conglomerate, but on blasting the rock failed to find it inside. The existence of quartz in the bed of the stream and the fact that some of the gold is attached to minute pieces of quartz, points to that rock as the possible matrix both for the gold in the tributary and the main river. The production of gold in appreciable quantity has caused much interest. The natives on the river say that they will search for gold which previously they have not done, with the exception of the one mao Pangeran Kahar, who with the Hadji Daud and Sulaman announced its existence. The Chinese and Malays of Sandakan are both arranging parties to go up the river when the fine weather sets in; and we trust they will be formed of experienced men so as to contain the first element of success. The next important point is proper working machines and tools. One Australian Chinaman has brought a plan of a cradle which the Commissioner of Lands is having made, but it would be well to get the latest information on these points from the best sources. Of the existence of other metals Mr. Walker is of opinion he found no trace, unless the chemical examination of the specimens brought down should prove the contrary. Specimens of so-called Cinnabar and Tin were daily found when washing, but on examination were rejected as worthless.

TEA-PREPARING MACHINERY.

Mr. Frater, of Messrs. Walker & Greig, Badulla, has very nearly perfected and patented two tea-rolling machines which, if all accounts that reach us be correct, are likely to attract a good deal of attention from Ceylon planters in the future. Mr. Frater's first patent—the Colonial Tea Roller—has already been the subject of some comment in the press. Since then, he has been hard at work on a smaller machine which he calls the "Eureka." It will be adapted for hand-power and will not occupy more space than $3\frac{1}{2}$ by $2\frac{1}{2}$ feet. It can be made of different sizes, however, the smaller being estimated to roll 50 or 60 lb. of withered leaf approximately per hour: the larger, which can have gear to connect with a steam or water motor, to roll 80 lb. per hour. In this machine there is, we understand, a principle introduced with reference to the charging of the leaf, quite novel and which is expected to prove a great success from its convenience. Mr. Frater is confident this machine will be very suitable for young gardens just commencing to make tea, and he hopes to price the "Eurekas" at from R300 to R500 each, the machines being found very compact, easy to drive, accessible in every way, durable (the framework being all cast-iron). These qualities are true, also, of the large "Colonial" roller, which is to be made in six sizes, capable of rolling from 50 to 200 lb. of withered leaf—the latter involving two rolls per hour. The middle No. 3 size of the "Colonial" is 3 by 4 feet: several samples of the tea rolled by it have been approvingly reported on by experts, and a Madulima plantation will be the first on which a "Colonial" roller will be erected. We shall look with much interest for the results of the working of this purely local invention, and we wish Mr. Frater all success in his inventions. Mr. MacInnes of the same firm (Messrs. Walker & Greig) is, as we mentioned the other day, engaged in perfecting a tea-drier, from which a good deal is expected by those who have learned something of the design. The sample of Haputale tea we reported on the other day was treated in Mr. MacInnes's drier. The use of these new machines is not likely to be confined to the Uva district, although the want of railway communication and the heavy cost of transport are drawbacks to their convenient introduction into our older tea districts.

A NEW GUTTA-PERCHA TREE.—Instigated by the threatened dearth of the gutta-percha tree (*Isopandra gutta*), M. Heckel has sought a substitute and claims to have found it in the *Birtyspermum Parkii* (Kotschy) of Equatorial Africa, and abundant in latitudes between Upper Senegal and the Nile; especially in the forest of the Niger and Nile regions. It affects the argillaceous and ferruginous soils of Bantarras Bouré and Fonoa-Djalou, where the Africans gather its fruit which yields a gresca called *karite*. The juice or milk is obtained by incision from the bark, and on evaporation resembles gutta-percha. M. Heckel states that he has sent seeds to various French colonies, and also to England, in the hope that the latter country will try the experiment of introducing the tree into her vast tropical possessions. M. Heckel also calls the attention of English botanists and chemists to the divers India *Bassias*, as he is led by analogy to infer that they might furnish milky products similar to the *Bassia Parkii*.—*South of India Observer*.

LETTERS FROM JAMAICA.—No. 7.

RAIN AT LAST—EFFECT OF THE DROUGHT—A VISIT TO "BELLEVUE"—TROPICAL PRODUCTS—FRUIT GROWING AND CACAO CULTIVATION PROFITABLE INVESTMENTS—A RECIPROCTY TREATY WITH CANADA—LAW IN JAMAICA—A CSEOLE "BELL."

BLUE MOUNTAIN DISTRICT, 3rd June 1885.

DEAR SIR,—The much-prayed-for "seasons" of May rains have come; they were much needed especially in the centre of the island. I have heard of "pens" where a large number of cattle were dying daily from want of water, and of the owner of the estate having to send ten miles for water for household purposes. Even close here in the valley of the "Yallabs" the drought has been very severe, and I fear the settlers will have very short and light crops, as was the case last year. This dry weather is good for the Blue Mountain, as it causes the trees to throw out a good blossom. In wet years crops are very uncertain, as the tops of the hills seem to be in continual showers and mist.

On my return from Kingston last week, whither I had been to be present at the Queen's Birthday Ball—a good old custom kept up here as well as in other colonies, but, strange to say, there is no levée—I took the opportunity of accepting Mr. John Davidson's kind invitation to pay his property a visit. "Bellevue" is situated a few miles out of Kingston on the first rise of what are termed the "Red Hills." The soil I fancy to be similar to what is met in certain parts of Devonshire. The house is some 1,500 feet above the sea-level, so it is a sharp pull as soon as one leaves the "Ligunesa" plain, and the road is not well kept, and does not reflect creditably upon the Commissioners of St. Andrew's Parish. The "great house" is built on an eminence overlooking the plain, and commanding a grand sea-view in front, and at the left of the Port Royal and Blue Mountain ranges; it is a very large mansion built in the old slave days when money was plentiful and labour cheap; it is quite fit for a viceregal residence, and might easily be the Governor's country-house, for there is always a breeze, and it is never very hot there; fancy walls 18 feet high to the ceiling, and a noble, enclosed verandah or "piazza," 60 to 80 feet long and 20 feet wide. The property was originally planted with pimento trees, some of which are now old and of a large size; there are also other fine park-like trees round the residence, which made Sir Anthony Musgrave observe, when he visited Mr. Davidson, that for the first time since he had left England, he felt once more as if in England. Besides pimento and some anatto trees, there is coffee on "Bellevue," but the products to which the proprietor has of late years directed his attention are bananas, oranges and cacao, these are all thriving very promisingly, the cacao (the dwarf species evidently) already yielding returns which, of course, will increase yearly as the trees grow older and the cultivation is extended, the bananas also bearing largely, and the orange trees commencing to give fruit; consequently this fine property must year by year increase in value. Mr. Davidson deserves very great credit for the enterprise that made him try the growth of cacao so near to Kingston, and at such an elevation. I noticed also some cardamoms doing very well along a little swampy ravine; such places suit them best. I believe Mr. Sant of "Langley" has been most successful in the cultivation of cardamoms on the north side at an elevation of about 2,000 feet above the sea. The more I see and hear of Jamaica the more I am convinced, that, for a young man who has sufficient capital and who has first acquired the necessary experience, fruit growing and cacao culti-

ation are about as good and promising investment^s as can be obtained in the tropics: there is abundance of suitable land on the north side within reasonable distance of the shipping ports, and now that the quarantine is removed, the trade of New Orleans, the Mississippi valley, as well as that of Baltimore, Philadelphia, New York and Canada, is open to our Jamaica banana and orange growers: there is indeed a very good prospect and opening for those who have the capital and need employment for their sons. As to Jamaica "cacao" there is no reason why in time it should not be as much a favorite in the market as that of Caracas, Trinidad, or Ceylon.

A Commission appointed by the Legislative Council has lately proceeded to Canada with the object of bringing about a reciprocity treaty with the Dominion; if successful, it should be a good thing for our sugar planters to have that market more fully opened to them, and the poor people will get their salt-fish, flour, etc., at even a more reasonable rate than they do at present. If a treaty of the same nature could be obtained with the United States, the prospects of our sugar industry would much improve.

As to "law" affairs in Jamaica, there is a Chief Justice and two Puisne Justices; the Supreme Court is held at Kingston; the Judges sit also occasionally at Circuit Courts: in the country parishes. There are also District Courts, these seem to have become very unpopular, and the general idea seem to be that they should be discontinued; but it strikes one that an intermediate tribunal should exist between the Supreme Court and the petty sessions or Police Courts for the trial of important land cases and cases involving a large amount of money. The existing system of allowing a defendant to elect whether he will be tried by the petty sessions or the District Court, even though it be a most trivial case, should be discontinued, and the powers of the petty sessions and Police Courts be enlarged and defined, so that even trials for trespass, and non-payment of rent, small debts and such like causes might be tried by the stipendiary magistrate or local Justices of the Peace, who are usually planters or business men, all well versed in the laws and customs of Jamaica; if it were so, people would be saved the expense and trouble of travelling long distances to obtain legal redress, sometimes having to attend two or threetimes before their cases can be finally settled. At present if I find a man for bad work, misconduct, or impertinence, and he takes me to court, he may, to spite me and cause me annoyance and expense, elect to have his case tried by the District Court Judges at Eslington, many miles off, where there is no resthouse or convenience of any sort for travellers; and in other parishes the distances poor suitors have to travel to the District Court are even much greater. I hope therefore that the law will be revised. A Commission has been sitting to collect evidence and sent out a printed list of questions for answers, to all from whom an opinion would be of service.

I heard a very good story the other day which will amuse your readers: it is real Jamaica. A creole labourer came to town on Saturday with his earnings, and amongst other purchases bought a pair of boots: after long parleying with himself whether he should put them on there and then or keep them for church next morning, he determined to adopt the latter plan, so slung them over his shoulder and merrily went on his way, till coming to a bad gully he knocked his big toe against a stone, nearly tearing off the nail; after wincing and making wry faces and getting over the pain as best he could, he exclaimed: "My king, werry good ting I no put on dem new boots."
—Yours faithfully,
W. S.

COFFEE IN UVA CEYLON: THE SPRING VALLEY AND UVA COMPANIES' REPORTS.

Enclosed with this letter you will receive the reports of the Spring Valley and Uva Companies. We have not been led to anticipate that those reports will be particularly satisfactory; but they will at all events, we are informed, set forth certain facts which justify a confident hope that the long lane is being turned, and that those reports which may follow will be able to announce a very improved state of affairs. In this connection it occurs to me to mention that very curious intelligence has been received from the Companies' local management which seem to afford ground for hope that the leaf-disease which has so long distressed your planters is, if not positively leaving you, at all events showing a diminished virulence of effect which may herald the entire loss of power by it to produce ill-effect upon the coffee crop. On the Uva estates during last autumn they had a most splendid blossom. The hope to which such an appearance would naturally give rise had, however, too often been disappointed in the past to warrant the directors building much upon it, or their agents in estimating for a good yield of coffee thereupon. Year after year had seen the spring accompanied by a virulent attack of leaf-disease and the trees lose both leaf and berry. In accordance with this precedent, the early months of the current year witnessed as strong an outbreak of the disease as ever; but when the superintendents naturally expected to see it followed by the usual evidence of weakness in the trees they were as surprised as gratified to find the latter resisting it and the berries holding on and filling out almost as well as in the old days before the pest had made its appearance. So, just when the directors were writing out urging the greatest economy in expenditure in view of the anticipated shortness of crop, they receive from their local managers the most satisfactory statement of the prospects for the coming crop, and they now feel justified in counting on a full 5 cwt. to the acre. Now all this may be stale news to you; but certainly no allusion to it has been remarked by us in your overland issue. What does the fact bode? It seems unreasonable not to conclude that the disease, as regards its power for ill-effect on the coffee trees, has worn or is wearing itself out. Certainly, it is a new phase, so far as we at home are aware, in the history of the coffee-leaf-disease, and it seems justifiable to hope that the worst results to be dreaded from the visitation are passing away and that our old friend coffee may again resume its place as a highly profitable investment in Ceylon. Whether with your local knowledge you can endorse this hope we at home do not know; but we confidently expect to hear that you feel able to do so. Everything that tends to show that the long-expected "rift in the cloud" is within sight naturally gives confidence here, and, should the anticipation of the directors of the two Companies under reference be fulfilled, it will be a matter for extreme congratulation to all those interested in Ceylon planting enterprises.

Report of Spring Valley Coffee Company.

The accounts now presented to shareholders comprise a balance sheet, showing the Company's financial position on 31st May, 1885, and the profit and loss account for season 1885-84. Spring Valley crop amounted to the estimate given in last year's report, viz., 3,584 cwt 0 qrs 10 lb of coffee, the proceeds of which were £10,464 6s 9d, or a net average of 59s 6d per cwt. Cinchona bark was sold to the value of £724 19s 7d, and sales of refuse coffee in Colombo realized £258 8s 6d, making a total of £11,747 9s 10d received from sales of produce. The Ceylon expenditure includes £598 8s 8d spent on tea, making the result of the season's working a loss of £222 17s 7d, which, deducted from the balance of £1,673 7s 6d, brought forward from last year, leaves a

sum of £1,450 9s 11d, to the credit of profit and loss account. It will be seen that the average price obtained for the coffee was 9s 8d *per* cwt below that of last year, and with such a small crop it is satisfactory to note that expenditure was so nearly met by produce. For crop 1884-85 now being gathered, the period of blossoming was altogether favourable and a fairly good crop set on the trees. At the beginning of the present year, however, an unusually severe attack of leaf disease passed over the estate, and it was at one time thought that its ravages would prove as fatal as on previous occasions. Contrary to expectations this attack however proved far less injurious than could have been hoped for from past experience, and the latest reports from the property point to a crop in Spring Valley of not less than 5,400 cwt. Timely precautions had been taken to guard against a loss in the event of a repetition of the small crops of the past two years, and expenditure on coffee was reduced to a minimum, so that even with the present low prices, the crop now to come forward will show a fair profit.

The change which has taken place as regards coffee is very marked, and whether the present vigorous appearance of the estate is due to a season favourable both for the blossoming and the maturing of the fruit or to a mitigation of the destructive nature of leaf-disease it is impossible to say. Coffee has been replaced by tea on the portion of Spring Valley referred to in last report, and which, under the most favourable circumstances could only have been made to yield fair crops by incurring heavy expenditure on manuring. The area at present under tea on the estate comprises 289 acres, and all the plants are thriving well. The growth of the experimental patches of tea planted in the autumn 1883 has been so highly satisfactory that, notwithstanding the present favourable appearance of the coffee on the property, your directors fully believe they are warranted in taking the precaution of further extending tea over such area as will prove more profitable under this product than if left in coffee. The area in tea will thus be made up to about 400 acres, leaving a fine sheet, over 1,000 acres in extent, of coffee in capital heart and growing in a soil highly adapted to its requirements. In addition to the above area about 130 acres of tea have been planted on Oolanakande. With the above areas of tea and coffee, commanded as they are by the appliances lately erected for the distribution of manure, favourable influences alone are needed to ensure paying results. It will be seen by the profit and loss account that £724 19s 7d was realized from the sale of cinchona, a little under 9 tons being brought to market. About 2½ tons of good bark will be harvested this year. In future this product will only be planted in separate patches, as it is found to be injurious to tea and coffee when planted amongst them. Mr. Edward Conder, a member of the Board, retires on this occasion, and, being eligible, offers himself for re-election. Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.

REPORT OF UVA COFFEE COMPANY.

A Balance Sheet, showing the financial position of the Company on 31st May, 1885, and Profit and Loss Account for Season 1883-84, are now presented to shareholders. Crop 1883-84, estimated at 5,000 cwts., resulted in a total of 4,908 cwt. 1 qr. 10 lb. The value of this coffee was £13,794 8s 10d, or equal to a net average of 59s 3d per cwt. Refuse coffee sold in Ceylon and proceeds of cinchona bark brought the total receipts from sales of produce up to £15,215 8s 7d. The Ceylon expenditure includes £769 7s 2d spent on tea, making the result of the year's working a loss of £1,390 10s 10d. After writing off this sum from the balance of £2,408 8s 4d brought forward from last year, there remains to the credit of Profit and Loss Account the sum of £1,100 6s 6d. The report issued last year held out hopes that a small profit would have resulted from the working of the year now under review, but the prices obtained for the latter parcels of crop fell off so greatly that, as will be seen by the accounts, the average price is 13s 5d per cwt. below that of the previous year, which fully accounts for the loss sustained. Owing to the appliances for the distribution of bulky manure being in full working order very extensive manuring operations were carried out during season 1883-84, at a small increase of expenditure, on all the Company's estates, especially on such areas as are intended to be permanently retained in coffee. From information just received, the Directors are glad to be able to report that the effect of these operations, coupled with favourable weather, has enabled the trees to mature their fruit in a most unexpected manner, and the coming crop which was at one time estimated at 4,400 cwt. is now expected to yield at least 5,600 cwt.

In view of the low prices ruling last year, and with the prospect that only a small crop might be secured for season 1881-85, the Board took the precaution of reducing expenditure on coffee to a minimum, so as to ensure no loss resulting from that year. With the unexpected increase in the out-turn of the crop a very fair margin of profit may now be looked for. In January last a severe attack of leaf disease swept over the estates, causing much anxiety as to the effect it might have on the crop on the trees. It however, rapidly passed away and the trees have steadily continued to recover, and by last reports the properties were stated to be in vigorous condition. All those portions of the Company's estates where leaf disease had weakened the coffee trees beyond hope of recovery have been planted with tea, and up to the end of last year 362 acres were under this cultivation, and, as far as can be judged at the present time, the growth of the tea plants is perfectly satisfactory. There are, however, further areas of the properties which it is thought would be more profitable under tea than coffee, the Board have, therefore, given instructions to plant up these areas, so that by the end of the year there will be a total of about 650 acres under tea. With the above acreage of tea and the area retained in coffee being in first-rate condition and capable of being readily and cheaply manured, the directors have every reason to look for good paying returns from the properties at no distant date. Cinchona bark to the extent of 6½ tons was harvested during season 1883-84, and the value, as shown by the profit and loss account, was £818 2s 4d. It is expected that about 10 tons of bark will be harvested this season, the amount to be realized by the sale will not, however, be proportionately increased, the bark market being somewhat lower than last year. The further planting of Cinchona is being confined to patches especially devoted to its growth, as Cinchona is found to be hurtful to both tea and coffee bushes when grown among them.

Mr. Henry Hart Potts, a member of the Board, retires on this occasion, and being eligible, offers himself for re-election. Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.

TEA AND MACHINERY.

Further, with regard to these and associated undertakings, we understand that it is Mr. Brown's, their Managing Director's intention to go out to Ceylon about November next, when he proposes to stay for several months. We hear that the expenses attendant upon the planting out of tea have been heavy, as are also those necessary for the provision of the machinery required for tea curing, and Mr. Brown, like a careful conservator of the interests entrusted to him as he is, feels it desirable to personally supervise those expenses. But, independently of that wise intent, there is another and rather singular question demanding his oversight, and that is one which, owing to his engineering knowledge, he is personally highly fitted to conduct. The power available on the estates for driving coffee pulpers and other machinery required for treatment of that product is quite inadequate to the higher demand imposed by the necessities of tea-drying, and it is found that the waterwheels at present erected and their sources of supply cannot cope with the demand that will be made for power directly the tea trees planted begin to flush in any quantity. At present the field has barely furnished samples for testing by experts at home. The report upon these by those gentlemen has been most satisfactory as evidencing the quality of the leaf that can be grown on the Uva estates, and the trees flush at so early a stage of their growth that it is evident that, unless provision for extra power is made at once, the directors will find themselves in a difficulty. It is mainly towards avoiding this last that Mr. Brown's proposed visit is contemplated. With that gentleman I had a long conversation respecting the relative merits of turbines and waterwheels for the provision of the increased power desired. My own view was expressed, that unless a very considerable head of water is available the wheels are preferable to the turbines, both as regards efficiency and economy. With the former you can utilize and multiply mere bulk of supply from a very low head. With the latter a low head is almost valueless and always wasteful, while even when

great head is available the friction arising from the high speed of a turbine so rapidly wears bearings &c., that constant interruption to work is caused by the necessity of frequent renewal. As the water supply on the estates under Mr. Brown's direction is somewhat sparse and affords little pressure, it seems to be most likely that he will resolve when visiting the estates to adopt waterwheels of increased diameter rather than turbines. But no one can be better equipped to determine skillfully in such a matter than Mr. Brown himself, whose name will ever be associated with some of the finest hydraulic machinery ever erected in Ceylon.

THE COLOUR OF COFFEE IN THE LONDON MARKET: THE WYNAAD PLANTERS.

Planters' Association of Ceylon, Kandy, 30th July 1885. The Editor of the *Tropical Agriculturist*, Colombo.

SIR,—I beg to enclose copy of a letter received from the Honorary Secretary of the Wynaad Planters' Association on the subject of the colour of coffee and its effect in the London Market on coffee from Wynaad as compared with former times and submitting questions with a view to ascertaining the cause and in the hope of finding a remedy.—I am, sir, your obedient servant, A. PHILIP, Secretary.

Wynaad Planters' Association, South Wynaad, Vythery, July 8th, 1885.

The Honorary Secretary, Ceylon Planters' Association.

DEAR SIR,—Our Association is endeavouring to find some reason for Wynaad coffee in the last three or four years being so much out of favour in the London Market as compared with former times, and being very generally stigmatized there as bad in color, no matter how good the sample has been pronounced in India. We are anxious to find the cause, with a view to the remedy, and we trust you will be kind enough to give us any information in your power. We are asking the following questions of our friends in India:—

I. How does the bean of coffee grown under shade compare in colour with that grown in the open?

II. Is there any proved system of estate-curing that will affect the colour of the bean?

III. Is there any marked difference in the colour of the bean cured at the West Coast, East Coast or Inland Coffee Works?

IV. How do manures affect the colour?

V. Have the different modes of packing any influence on the colour?

"Colour" in every question of course means the colour in the London Market: reports on the subject in this country are not found at all trustworthy.

We shall feel greatly obliged to you if you can give us any information in answer to these questions, or on any other phase of the matter that we may have omitted to notice.—I am, dear sir, yours faithfully,

(Signed) PERCY BATTY, Hon. Secy.

[See extracts and correspondence further on.—Ed.]

SERICULTURE.—The author of a recent article on the Tassar Silk-worm is Captain Catania, Deputy Conservator of Forests. This gentleman is a keen arboriculturist and has devoted much time and attention to this study, and also to sericulture. He hopes to propagate 60,000 young trees for the Nizam's Palace grounds at Secorouggur.—Madras Mail.

HOME CHARGES ON TEA.—We call attention to the letter on page 189, in which Mr. John Hamilton fears us and his brethren of the planting community in Ceylon with an accurate and useful statement of the effect of the recent changes in the home charges on tea. Although Mr. Hamilton still owns estate property in Ceylon, he has, we believe, fairly settled to mercantile business in London, so that his information on the present and cognate subjects may be taken as reliable. We commend his letter to the special attention of our several Planters' Associations.

Correspondence.

To the Editors of the "Ceylon Observer."

CEYLON SINGING-BIRDS: A WORD IN VINDICATION OF THEIR VOCAL POWERS.

Kandy, 25th June 1885.

DEAR SIR,—We have often heard it remarked, but first generally by those possessed of very limited powers of observation, that in Ceylon, and other tropical countries, where brilliant and varied colors have been granted to birds and flowers, song has been denied to the one and fragrance to the other.

The late Dr. Kelaart has already pointed out, that this is one of those "flippant generalizations, which people are fond of repeating, originally made without investigation, and perpetuated without enquiry."

It is in fact inapplicable to the avifauna and flora of Ceylon, except perhaps as regards our higher mountains, and the barren sandy wastes of some parts of the lowcountry, as also in several of our coffee districts, which have been entirely denuded of forest. In these regions, however, there is a great paucity, an almost entire absence, of bird life, and few of our songsters dwell or even sojourn there.

The observation may apply to the avifauna of a few tropical countries, and to my own personal knowledge it does so, more or less, to the islands of the West Indies and the Spanish Main of South America, where the "Mocking Bird," (a) is almost the only one with any pretensions to musical talent. There, however, the birds far excel those of Ceylon, in the brilliancy of their plumage. While contrasting our song-birds with those so familiar to our school-boy days, and whose nests we were wont to ruthlessly plunder, we are apt to forget, that our feathered friends of the old country, are mute for half the year, or nearly so, and that sweet and powerful as are the songs of the "Mavis" (b) and the "Nightingale," (c) the "Lintie" (d) and the "Laverock," (e) their concerts last but for a season. Here, on the other hand, our birds may be said to breed all the year round, and to sing all the year round. Surely then we cannot expect our songsters, to pour forth their melody, with the same vigor as their congeners of more temperate climes, who give, as it were, but a limited number of performances.

In favourable situations, the wealth of bird-life in Ceylon is simply marvellous, including many more or less gifted songsters: and here, though

We lang to see the broom
Wi' tassels on the lea,
And hear the lintie's sang
O' our ain countrie."

we are nevertheless cheered in the grey dawn of early morning by the rich and long-continued joyous notes of the "Mavis Robin," (f) and, if we saunter out for a morning stroll, in a wooded neighbourhood, or the charming sylvan retreats of "Lady Horton Woods," our hearts are still more gladdened by the mellow flute-like notes of the "Long-tailed Thrush" (g) and the "Oriole." (h) As the morning advances, a host of musical voices greet us on all sides, the bell-like notes of "Babblers" (i) mingling with the sweet love-song of the "Bulbul," (j) and the merry metallic twitterings of "Bush-creepers" (k)

(a) *Turdus polyglottis* (b) *Turdus musicus*. (c) *Luscinia philomela*. (d) *Fringilla*. (e) *Alauda arvensis*. (f) *Copsychus saularis*. (g) *Kittacina macrurus*. (h) *Oriolus Ceylonensis*. (i) *Megalaimidae*, (j) *Pycnonotinae*, (k) *Mutitinae*.

and "Honey Birds." (l) And here too, while pausing to admire the romantic scenery, by the banks of the Mahaweliganga, as it winds its tortuous course to the Park Country, we listen to the exquisitely soothing and plaintive strains of the "Ground Dove," (m) the "Nda Kobeyya" of the Sinhalese.

Even on the plains of Nuwara Eliya we meet with some sweet songsters, peculiar to the highlands: there on a bright sunny morning, by the snug little church, nestling among its stately *casuarinas* and *acacias*, can be heard the rich and mellow notes of whole family of "Kelaart's Yellow-eared Bulbul" (n) and hopping among the tombstones, and flitting his restless tail, the little black "Nuwara Eliya Robin" (o) sings his sweet "love-song to the morn," over the graves of the departed, while, from the jungle hard by, the pleasing and plaintive ditties of the "Black-bird" (p) reach our ear and gladden us.

In truth, Nature, lavish of her tropical gifts, has richly endowed our sylvan warblers with endlessly varied powers of melody, and to the flowers of the forest and the meadow sweet fragrance has been liberally imparted.

A. W.

THE NEW SYSTEM OF CHARGES ON TEA.

12, Great Tower St., E. C., July 10th, 1885.

DEAR SIR,—As you are doubtless aware, the dock companies and Wharfingers have agreed to adopt a new scale of charges upon tea, commencing from 1st July: the Wharfingers, I am told, have bound themselves under a heavy penalty not to allow more than 10 per cent discount on the dock charges. The first question we naturally ask ourselves is, how the new rates compare with the old, and to what extent will shippers of tea gain or lose by the new arrangement? Without entering into particulars it is sufficient to say that the increase in the expense of selling tea amounts to some 40 per cent. Although the new scale of charges is lower, no discount is in future to be allowed by the dock companies (formerly the allowance was 35 per cent), and only 10 per cent by the wharfingers instead of 50 per cent to 60 per cent—the result being an extra charge to shippers of 40 per cent. Before raising a cry against the extra charges it would be as well to look more thoroughly into the existing working of the tea trade and see how far obsolete and unnecessary customs could be dispensed with. It appears the great competition between the docks and wharves resulting in enormous discounts, had reached such a pitch no benefit resulted to either, which necessitated some joint action being taken, the present cause of the above loss to shippers. It is quite possible that large importers of tea will agitate against these new rates, and it seems to me a favourable opportunity for all those interested in the tea trade, and particularly in the interests of a young tea colony like Ceylon that the whole question of the tea trade should be considered from every point of view with the object of finally sweeping away old useless forms and customs, expensive in operation and cumbersome in detail, and of dealing with tea in the simple, easy way that is done with sugar, coffee, and opium, thereby saving these undue charges on the manipulation of tea which dock companies and Wharfingers in self-defence are at present compelled to make.

I am not here alluding to the bulking of tea, which is really a local matter, and, if properly carried out in India and Ceylon at the factory itself, would not have to be done in this country. Indeed where invoices are large and the quality equal, no bulking is now required but a shipment of small, over-assorted parcels would

(l) *Nectarininae*. (m) *Chalcophaps Indicus*. (n) *Kela-artia penicillata*. (o) *Pratincola atrata*. (p) *Merula Kinisii*,

probably be totally neglected unless bulked. In cases where it is printed on the catalogue 'factory bulked,' the merchant takes the risk of after disputes. In China bulking seems to be thoroughly understood, and with a little more experience, and with a larger quantity available for shipment, I am convinced the Ceylon planter with his readiness at acquiring information and unmindful of trouble will soon overcome all difficulties in the matter. A sufficiently large shipment, evenness of character, and not more than three assortments, seem to be the essential points to note.

It is in many respects an advantage to have a fixed scale of charges, and should lead to a more healthy tone throughout, but it behoves us especially to look at the matter from a Ceylon point of view. The charges on tea already are more than treble those on coffee and cocoa, dealers as well as shippers being affected alike. There must be a reason for this being so, and a remedy will have to be found. It is more than likely that in these days of rapid progress with an extending trade like tea, and one occupying a more important position owing to the vast cultivation being carried on in India and Ceylon, that every facility for simplifying tea sales will be adopted when sufficient pressure has been brought to bear on the subject. One or two clever articles in the *Produce Markets' Review* at different times have gone very fully into the matter, thoroughly exposing the absurdity of the present system of weight notes, deposits (a precaution not enforced with any other article of produce), and the necessity insisted on by the Inland Revenue of affixing a penny-stamp to every separate sub-delivery order used for tea, although this is not deemed essential on deliveries made from the weight note, the 3d. warrant stamp being considered a composition for them. But what is this 'weight note' that appears to cause so much complication? The weight note is the key of the whole system. It contains full particulars of the goods, forms a contract, an invoice, and a delivery order. The broker having sold the tea makes up the weight note, and gives it to the buyer who deposits £1 per chest on the value on the Saturday following delivery. To take the calculations in the above mentioned *Review* as an illustration, 600 chests of tea require 100 warrants and 100 weight notes with 15 separate identification marks and particulars on each, and 100 invoices, 1,200 weights have to be copied on the dock documents, and 400 additions of weight, and deductions of tare have to be made, net weights are turned into pounds involving 100 more calculations. Sold price has to be copied 100 times, and 300 calculations, subtractions and additions made before the invoice is completed, warrants and weight notes require 600 signings and stampings. Before 600 chests of tea are ready for delivery to the buyer, 5,000 clerical operations have to be performed, or say 800 operations to every chest of tea in addition to full descriptions on the landing account. I have quoted sufficient to show how cumbersome and unnecessary all this detail is, and how expensive it is, in addition to the risk of the delivery of the tea being stopped owing to a single error in these ceaseless operations. In the case of sugar or coffee the importing merchant gives the buyer an order for so many bags or hog-heads as he may want them, for which he pays so much on account, the balance being settled at the prompt, after deducting interest. Tea gives thirty times the amount of work that sugar does, and why?—in order to continue a system that modern requirements are burdened and hampered by. Whether it is the weight note or the stamp on the separate sub-delivery order that causes the chief obstacle to a reform is not of the smallest consequence, for both of these forms must be swept away, and tea must be worked at the same rates and on the same

system as coffee, sugar and other agricultural articles. But how is this to be accomplished? Simply by combination, and bit by bit the wall of prejudice, by combination, away; but who is to bring it about? Ever will crumble vested in tea plantations both in India and Ceylon backed by the local Press as a commenced Ceylon has been done in cinchona where the interestment. It nominal compared to tea, and it has to be done if a were tea trade where the interests are widespread than the stupendous. To those interested in tea plantations and when the move is once made, the sense of the trade as itself will be added.

I hope you will pardon me the space this letter occupies in your paper, but the object of it is an important one, and one which cannot be taken in hand a day too soon. Five years hence certainly the voice of Ceylon will be weightier in the tea trade than now, but the present is the time to take up the matter, and help to smooth the way for the great future that is before us.—I am, yours faithfully,
JOHN HAMILTON.

PLANTAINS OR BANANAS IN CEYLON.

Nawalapitiya, 17th July 1885.

DEAR SIR,—I beg to submit the following regarding fruit. Your Directory for 1884 says there are only 10 varieties of plantain or banana in Ceylon. If you can insert in this year's book, please note there are 21 varieties of best bananas in Ceylon; all of these 21 varieties I have cultivated in my garden, and they are quite different from each other in appearance and in taste.—Yours obediently,

J. P. ABRAHAM.

A RARE BIRD, THE "INDIAN HOBBY"

(*FALCO SEVERUS*): A FALCON SEEN

IN UVA IN JULY.

DEAR SIR,—The following occurrence of a very rare bird may be of interest to some of your readers. On 7th inst. (July 1885) I was standing behind my store when the alarm notes of various small birds far and near attracted my attention; a robin with a nest brimful of young under the eaves of my store gave utterance to notes indicating intense alarm, which told me the enemy was near, yet I could see nothing. Suddenly, like a rocket, a dark object topped my pulping-house a few yards in front of me. No mistaking the dashing little rauderer: it was a male Hobby, *Falco severus*, in beautiful adult plumage. The pace that little fellow was going at would enable it to catch with ease any bird in the air that I am acquainted with, not excepting the spine-tailed swift, which can do something in the way of clearing space! It fell to my luck to obtain the first recorded specimen of Hobby captured in Ceylon (in 1867), since which till now I have seen no other, unless a small falcon I saw a few years since dash across a paddy-field near Wellaways, was of this species; it was too far off to identify properly, but in my own mind I felt fairly sure that was a young bird of this species and I asked some friends to look out for it when snipe-shooting in that direction. In the present instance there is no room for doubt, and its occurrence early in July adds additional interest to its appearance here. Though a species of fairly wide distribution in the East, it seems to be nowhere numerous and not much is known of its habits. Legge says: "Without doubt the species is migratory here in the cool season," which means the N.-E. monsoon. Now there is a great difference between the 7th of July and the N.-E. monsoon; so I am strongly inclined to doubt very much the above assertion, and to believe it more likely to be a resident probably to the extent of a few

pairs only; though a few may arrive as migrants as well in the cold season, certain it is that all our well-known migrants of the diurnal birds of prey (I allude in particular to the harriers) come over in that season, and their coming and going is as well defined as that of the swallow (*H. rusticus*) or the grey wag-tail (*M. meanepe*), the latter being the very earliest to arrive in this district of all our cold season visitors, and the earliest date I have noticed it at, was the first week in September, but as a rule it arrives a week or two later. I am quite sure the Hobby in question was an adult bird, and therefore almost certainly to have nested at the usual time, which is early spring with all birds of prey, and probably a second batch later on. One can hardly suppose that this bird was a forlorn bachelor rushing through the world in search of a mate! So I commend your readers who take an interest in Ornithology, to try and clear up the mystery as to whether Ceylon may claim as a resident the Indian Hobby. ZOOZOO.

PRACTICAL HINTS ON TEA CULTIVATION.

SIR,—With books now available on every detail connected with the culture of tea, from the seed to the cup, and the *Tropical Agriculturist* monthly, teeming with information, it may be supposed that further hints as regards the elementary stages are quite unnecessary. Having recently come across more than one nursery however, that, through want of attention to simple details, are partial failures, and having in view the many failures of coffee nurseries down—shall I say to the end of the coffee era?—and as the *Observer* penetrates nooks and corners where books have not yet found their way, I am induced to offer you some hints which I trust may be useful to someone;—beginning with

Nurseries.—The soil for nurseries should be free, open, loamy, and rich, for the following reasons:—It is hardly practicable to put in the seed with the eye placed in such a way as the germ of the root would be downward and that of the stem upward; but, if planted in free light soil, it matters little how the seed is placed. Nature has endowed it with sufficient adaptive power to rectify itself. As it grows it will turn itself right and form a straight plant. If on the other hand you put seed in a close, stiff soil some of those that happen to have their eyes down will not be able to come up at all: this accounts for more of the vicinities that occur when seed is planted at stake than is generally thought of. Others will grow up round the seed, not being able to turn it and will form a knotted or club-rooted plant which every experienced planter throws away. There are men whose opinion deserve respect, who tell that nurseries should be made in poor soil, giving as a reason that plants removed from a poor soil to a richer turn out the most successful. I believe that is more of an accepted theory than a sound one or one founded on experience or experiment. Next to good seed, good soil is necessary to get good sturdy well-developed plants. No one ever hears of a planter preferring to buy the thinned starved wires of a poor nursery if he could procure the vigorous plants of a richer soil. In preparing a tea-nursery seven or eight inches depth is enough to dig the soil, and if there is a hard subsoil so much the better to discourage the growth of a taproot. Four feet is a convenient breadth to dig off the beds, with eighteen inch alleys between. I mention these small matters because I saw a nursery the other day, the formation of which had been left purely to coolies. The beds were more like potato drills or ridges than nursery beds, the alleys taking up more of the space than the beds. The beds should be raked to an even surface slightly raised in the middle. Cross lines are the most convenient and the plants easily counted in them. They may be

made by using a kind of heavy rake with five or six wooden angular teeth $\frac{1}{2}$ or 5 inches apart drawn across the bed. The seed may then be planted three inches or thereby apart in the lines and at such depth as to be $\frac{1}{2}$ inch when the surface is levelled.

Planting.—Now as to planting, whether it is the better system to plant seed at stake or to plant stumps or plants from the nursery? Both systems have their advocates, and circumstances will often influence the decision. In case of the land being already open and having to be kept clean, and no nursery available, there is strong inducement to put in seed: the work is done and the cost of making a nursery saved. It should be kept in mind, however, that planting of all kinds should be firmly done: a loosely-filled hole keeps too much water, and the plants have not the same chance to establish their roots nor resist wind. If to avoid these evils the holes are well filled and firmly trodden after putting in the seed, unless in light, loamy soil, many of them for reasons mentioned will never come up, and lots of others unable to turn their seeds will have twisted roots. I think it is preferable to not treat them very much when planted, but go over the field scraping in earth and treading round the plants when they get to be a few inches above ground. Planting with plants or stumps is, I think, much to be preferred. Then is the opportunity to reject inferior plants and twisted roots. Given a good planting season, little supplying will be required, and your clearing will come into bearing ten or twelve months earlier than if planted with seed. I wished to add something more on plants, but I fear I have trespassed too much on your valuable space already.—Yours &c., ARBORICULTURIST.

CARDAMOMS IN HAPUTALE.

Wiharegalla, Haputale, 27th July 1885.

DEAR SIR,—I am sending by this tappal a small box in which I have enclosed a few seeds picked from a clump of supposed-to-be cardamoms. As this palam is three or four times the size of the ordinary cardamom fruit, I shall feel obliged if you will let me know (1) whether they are cardamoms; (2) if so, whether they are Mysore, Malabar, or indigenous, as we have only a one clump producing fruit of this kind in a clearing of 8 acres.—Yours faithfully, ARTHUR LE FEUVRE.

[They certainly seem to be cardamoms and look like Mysore; but the opinion of an expert is required. We shall try and refer the specimens to Dr. Trimen.—ED.]

HARVESTING CINCHONA.

Deltota, July 29th, 1885.

SIR,—I see that "Cinchona" has answered that part of my letter and gives reasons for shaving in alternate strips. The following are against the practice:—Take, for example, a tree shaved for the first time. If shaved in alternate strips, the 2nd shaving (i.e. the strip left the previous time) would not be renewed bark; while, if a thin slice were taken from the whole stem, the 2nd shaving would all be renewed bark. Again see the excessive cost. If the whole tree were shaved, more bark would naturally be obtained from each tree, and each cooly is likely to bring in more bark than if strips were left. The cost of thatching would be so much greater. The same amount of mana will have to be used, although less bark was taken. Taking all this into consideration, I think shaving the whole tree instead of strips the better, because more economical plan.

Against coppicing 2 feet or so from the ground, my reasons are the following:—I have seen the two different ways done on two adjoining estates, and the resulting shoots from trees coppiced near the root give, for the same age, a better growth. (2) A proprietor tried the plan of leaving the stump (2 feet) and gave it up, and his reason he told me was that it did not throw shoots so freely, and, besides, a lot of them died out. (3) I suppose "Cinchona" will allow that dead wood does harm to trees. The high stump left dies off soon, as all the bark is shaved off; it does some harm to the shoots. The cost (10 cents) of bark delivered at Colombo was for shaving alone, no branch bark or coppicings were included.

CROTON OIL TREES: CULTIVATION AND DEMAND FOR SEED.

Polgahawela, 30th July 1885.

SIR,—The following opinion of Messrs. Moore & Co., wholesale druggists, London, as to the demand for croton oil seeds may be of interest to those of your readers who have gone in largely for this product as a separate cultivation. Grown as a shade for cocoa, a small return will satisfy; but as a venture by itself I doubt if it will pay. Provided there is a demand for it, at 20s it would pay, but I fear in a few years there may not be a sale for all that is exported. Evidently the extract in the *T. A.* as to the oil being used for dressing woollens must be a mistake.—Yours,

WILLIAM JARDINE.

Extract.

In reply to yours of the 16th June re croton oil tree, I find the supplies of late have been rather larger than the requirements, and price has fallen from 56s to 40s per cwt. I should not recommend extensive planting, but 50 to 100 bags at a time would sell fairly well.

(Signed) FRANCIS MOORE.

COFFEE AND TEA IN COORG.—Mercaara, 14th July.—Towards the latter end of next week planting should be completed, and it should prove most successful. The weather has been unprecedented since the 2nd of June, at which date the monsoon may be said to have burst. There have been showers and continuous rain ever since, until Saturday the 11th, when the clouds lifted and blue sky was seen for a few hours. There are complaints in South Coorg, of great shortness of labor, and consequently those estates are suffering now. There are the heretofore untended no fresh supplies or young plants got in, during the first rains, and weeds grow rampant, which unless quickly got under, and light brought into the lower branches, there will be very little crop to gather later on; for the leaves quickly rot and drop off, and the tips of the branches dying off, speedily kills the branch back. Much of this result from the policy pursued toward the end of last season, when labor was ruthlessly cut down to avoid further outlay of money; successive changes of management, and a general air of insecurity has, no doubt, affected the cooly maistrics, who will not come in with their contracted gangs of labor. Some men have sent as far as Vellore and Bangalore for coolies to work the estates, and from the West Coast, large gangs of men from Tellicherry, principally, are on their way up to seek contracts. I have seen two clearings being planted up with tea plants, 4ft. by 4ft. as none has been grown before, the experiment is looked forward to with interest; as tea is still a little regarding profit, behind coffee, plants have been quincunxed with the tea seedlings, so that at the end of two years, one can be taken out. Tea is evidently indigenous to Coorg, for in the forest, I have seen trees fifteen to twenty feet high, and well-known to the Coorg villagers, who use it in sickness to allay fevers, by pruning the leave, and then brewing them, drinking the tea, when it is as hot as can be swallowed. I have seen a tree of "Magarippa" coffee in bearing, which, for its age, is short of stature, not robust, and is not so good a plant as an average Coorg coffee tree; the fruit will not be ripe until November next.—*Madras Standard*, July 22nd.

VARIEGATED TEA LEAVES.—A correspondent writes:—"I send you by this post a branch with strange-looking leaves on it taken from a bush in the middle of a field of tea raised from Assam seed; it seems to flush as well as the rest of the tea round about it: can you tell me what it is?" It is tea, with variegated leaves: a common occurrence. The gentleman to whom we referred the branch writes:—"The following lines copied from Bal-four's Class Book of Botany will probably afford the information your correspondent asks for:—'Variation in leaves is produced either by an alteration in the green chromule, or chlorophyll, or by the presence of air in certain foliar cells.' * * * The causes of variegation are stated to be disease in the cellular tissue produced by climate and soil, hybridization, fertilization with various coloured pollen, and grafting."

SUNFLOWERS AS FUEL.—A correspondent of the *Dakota Farmer*, after having tried "turf," coal wood and sun-flowers, has settled upon the last named as the cheapest and best for treeless Dakota. He says: "I grow one acre of them every year, and have plenty of fuel for one stove the whole year round, and use some in another stove besides. I plant them in hills the same as corn (only three seeds to the hill), and cultivate same as corn. I cut them when the leader or top flower is ripe, and let them lay on the ground top or three days; in that time I cut off all the seed-heads, which are put into an open shed with a floor in it, the same as a corn-crib; the stalks are then hauled home and packed in a common shed with a good roof on. When cut in the right time the stalks when dry are as hard as oak, and make a good hot fire, while the seed-heads with seeds in, make a better fire than the best hard coal. The seed being very rich in oil it will warm better and burn longer, bushel for bushel, than hard coal. The sunflower is very hard on land. The piece of ground selected to plant on should be highly enriched with manures.* In the great steppes (prairie region in the interior of Russia and in Tartary) where the winters are more severe than here in Dakota, the sunflowers are, and have been for centuries past, the only kind of fuel used."—*Mackay Standard*.

COPRA.—One of the chief exports of Fiji, as most of our readers are aware, is copra; and, although the trade in this article has assumed large dimensions of late years, it is felt that a much larger business might be done if some inventive genius would manufacture a machine which would cut out the kernel of the coconut. At present the cutting is done entirely by hand with a six-inch knife, and this, as may be imagined, is a very slow process. Messrs. F. R. Yarte & Co., of Fiji, have called upon American inventors to aid the owners of coconut plantations in the manufacture of copra, and we desire to bring the subject before British manufacturers. The firm in question, in their letter to the *Scientific American*, state:—"The machine would be required to cut out the kernel of the nut just as it falls from the tree, but with the outer husk on. We could split them open as we do now, with an axe (at present we have no use for either husk or shell, except for fuel). It must be adapted to cut nuts of variable size, as coconuts vary very much in size and shape, some being quite round and others oval shape and all sizes, simple in construction, and strong without being heavy, as it would be worked by black labour. The motive power could be either hand or foot. It would not matter what size or shape it cut the kernel out, as long as it cuts it in solid pieces, the size we cut out by hand is about three quarters of an inch thick by about three inches long. If such a machine could be made, a large number would be ordered, if not too expensive, as our principal product of export is dried coconut (called copra or c-p-a), and every planter would have some."—*European Mail*.

* "That's so," as our American friend says.—Ed.

AGRICULTURAL EDUCATION IN CEYLON.

It is very satisfactory to learn that the system of practical teaching in the principles of agriculture which the Director of Public Instruction (Mr. H. W. Green) set himself so earnestly to develop, is really taking effect throughout the island. We learn that in every Government Vernacular or Anglo-Vernacular school in the higher standards, theoretical agriculture has been taught since last January in the same way as in England, the text-book used being a translation of the Director's "Primer of Agriculture." Then again all teachers are now compelled to pass in theoretical agriculture before they can get a certificate—a very important stimulus. As regards practical lessons, the "Colombo School of Agriculture" has this year commenced actual work. The students have been trained in the school compound in the use of the new ploughs, and they are going to plough five acres of paddy land belonging to a private owner, for which the records of resulting crop are to be carefully kept. The owner of the land will cultivate in the ordinary way *alongside* of this piece of land which the school cultivates. The comparison cannot fail to be instructive, and the crop returns altogether, if carefully entered, should be interesting in connection with the subject of paddy cultivation. Several of the more intelligent Government schoolmasters after, we are glad to learn, also cultivating, after this fashion. So soon as the Director can provide teachers, it is, we understand, his intention to seek leave from Government to start practical agriculture at several country schools, a piece of land being allotted to each school, and the teacher being partly paid in produce, so as to give him a pecuniary interest in the proper working of the land. This ought to prove a most interesting and beneficial experiment; but manifestly Mr. Green will require a little time to make the necessary arrangements.

Altogether, we are agreeably surprised at the progress made by the Director. And it shows that it is not simply through the medium of the Government Department alone, the work is being done, when we learn that several dozen of the ploughs recommended for paddy-fields have been sold privately, apart altogether from the Government and without any inducement from the Director, although the latter has officially and very properly sent some ploughs to each Kachcheri. But, after all, we may expect more to be done through the gradual influence of the schools than in any other way. No doubt the Government Agents, or at least some of them, will help very cordially; but still a Government Agent, even with the best intentions, can only work on adult men with grown-up conservative prejudices against new fangled ideas; while the Director of Public Instruction may well hope to be able to train up a certain percentage at least, of the schoolboys who can eventually put in practice on their own lands what they learn during their agricultural training. For the prize-takers in this Department who may carry out in after life the lessons they have learnt, the Governor of the day will, we have no doubt, be ready to provide encouragement and reward in the shape of the honours so dear to the native mind and heart. By an live we may find a regular system established for drawing the native assistants to the revenue officers in all the grades of headmen, from the passed pupils of our Agricultural Schools.

DON'T DIE IN THE HOUSE.

"Rough on Rats" clears out rats, mice, beetles, roaches, bed-bugs, flies, ants, insects, moles, chipmunks, gophers. W. E. SMITH & Co., Madras, Sole Agents.

CONSUMPTION OF COFFEE AND TEA IN THE UNITED STATES.

10 LB. OF COFFEE PER HEAD TO 1½ LB. OF TEA. A GRAND FIELD FOR PROPAGATING THE TOTALISM UNTIL 550 MILLIONS LB. OF TEA IS CONSUMED!

London, 10th July 1885.

I enclose copy of an extract from the annual review of the Trade of the United States as published by the Corporation of the Chamber of Commerce of the State of New York, in April last. It contains some interesting figures in regard to the increase of consumption of coffee in the United States.

In their annual report, the Committee of the Chamber thus comment on the increase of consumption which is described as very considerable, in view of the depression of trade, together with the enforced economies brought about by a general reduction in wages among the largest consuming classes of the population:—

"It is difficult to determine satisfactorily the causes that may have led to increased consumption of such an article as coffee, for the reason that those who ought to be reliable authorities are by no means agreed as to the influences by which it has been effected. Increase of population no doubt accounts for some portion of the increase, but only for a moderate percentage of so large an increase as shown by our tables.

"For the remainder it is claimed by some that coffee is distinctly a poor man's diet, and that when times are hard, the labouring classes buy more coffee than in flush times when they are able to indulge in more nourishing and expensive food; others advance the theory that low prices invariably increase the consumption of all food staples; and a third explanation is that our population are slowly becoming more habitual coffee-drinkers than they have ever been before, and that this is particularly the case with respect to the large infusion of the foreign element received within late years. Each and all of these theories are doubtless true in fact, to a certain extent, and when taken together perhaps they sufficiently account for the increased consumption shown.

"On the basis of a population of 55,000,000 the *per capita* consumption last year amounted to 9½ lb."

What good news would this have been for Ceylon twenty years back? But now the all-important question is what about tea? And it is sad to find that on this more interesting product the Chamber has literally nothing worthy of record to report. The whole subject is dismissed in the annual review in a few formal lines, and the following figures showing the total imports of tea during the past few years at all ports of the United States explain how small relatively is the importance of the American tea trade:—

Trade.	1860	..	124,131,747	lb.
"	1881	...	55,984,276	"
"	1882	...	67,861,744	"
"	1883	...	70,575,478	"
"	1884	...	78,310,651	"

and it is stated in the report that "for the season 1884-85 the indications are at present that the receipts of all kinds including indirect shipments from Great Britain will be about 75,000,000 pounds against 68,000,000 pounds last season."

The discrepancy between these figures for 1884-85 and those given above for 1884 probably arises from the year in the former case commencing at some date other than 1st January.

It would seem then, that, whereas each of the 55,000,000 of Americans consumes nearly 10 lb. of

coffee, he consumes less than 1½ lb. tea annually, What a strange contrast to the state of things in this, the mother-country! It would have been interesting if the Chamber of Commerce had extended the scope of their speculations and put forth the various possible reasons which acting together have caused Englishmen to drink nothing but tea, and their descendants to drink nothing but coffee.

One thing is clear, that the United States of America open a vast missionary field for the Ceylon tea-planter. Think of a possible consuming power of 550,000,000 lb. of tea annually, even at this present date!

W. M. L.

THE COFFEE TRADE.

In our last report we noticed the year 1883 as the turning point in the coffee trade. In the increased consumption, a result of low prices caused by an artificially forced production, the industry passed into more conservative management, and its results were satisfactory to both importers and jobbers.

Unfortunately this healthy reaction was not maintained, and from causes, perhaps, not entirely inherent to itself, the trade was again, in 1884, depressed and unsatisfactory to all concerned. The liquidation of the Brazil Syndicates, noticed in our last, was a perpetual menace to the stability of prices, and caused a timidity in purchases which destroyed all animation or speculative feeling.

The total receipts of coffee for the United States from all sources was two hundred and thirty thousand tons in 1884, against two hundred and twenty-eight thousand tons in 1883, an increase of two thousand tons. The total deliveries for consumption were two hundred and twenty-four thousand tons in 1883, against two hundred and three thousand tons in 1883, an increase of twenty-one thousand tons—10·15 per cent—an increase which has created some surprise. The per capita consumption of the United States in 1884 was 9½ lb.

Of the importations, New York received in 1884 one hundred and seventy-seven thousand tons, against one hundred and eighty-nine thousand tons in 1883, a decrease of twelve thousand tons, and the total deliveries were one hundred and seventy thousand tons, against one hundred and sixty-three thousand tons in 1883, an increase of seven thousand tons. There has been considerable change in the aggregates of trade at the seacoast ports, Baltimore and New Orleans having notably increased their importations; a result, as is shown, of lower railroad freights from Baltimore to the interior than from New York, and cheap river freights from New Orleans. The receipts at New York still represent nearly seventy-seven per cent of the entire receipts east of the Rocky Mountains—less by six per cent than the representation of 1883, but in excess of that of any year previous.

Prices opened at twelve and one-quarter cents for fair Rio in January 1884, declined to nine and three-quarters in June, July and August, and remained at this point at the close of the year.

Experience has shown that no estimates of unharvested crops, especially of coffee, are reliable. Enough that a full average crop is now anticipated, and that it will prove ample to meet even the large consumption which is now recorded.

CAPE GOOSEBERRY.—A correspondent writes:—"I send by post to you, enclosed in a match-box, a sample of what I think to be rather a freak of gooseberry nature (Cape Gooseberry); two berries in one shell or skin." Not common, but occasionally occurs in most fruits of the kind.

COFFEE REDIVIVUS.—Lindula, 29th July.—Mr. A. H. Thomas has very great faith in the revival of coffee, and does not approve of planting tea in coffee, either one or the other; and from what I've seen all the way up I agree with him. Coffee in large fields here looks well and fit to bear, and, if H. V. has worn itself out and its life history be coming to an end, coffee will flourish green again.—W. F.

CEYLON UPCOUNTRY PLANTING REPORT.

3rd August 1885.

Black bug continues its havoc, and you hear of its advance into "fresh fields and pastures new," appearing in Udappussellawa, Haputale and elsewhere. I have sad experience of what a buggy estate means, and those who are just entering on this hard trial have my deepest sympathy. And yet there is nothing being done for it, no combined effort to check its advance. Is it because we all acknowledge that coffee like a bankrupt estate is being gradually wound up? or that we accept the conclusions of the late Dr. Gardner that nothing can be done—this *ipse dixit* of thirty or more years ago—and fold our hands? I have an enthusiastic friend who spurs such an ignoble course. "Be beaten with that poochie!" he says with fine scorn, and then sits down to his microscope to renew his examination of the pest. What time has he not spent in patient search and ingenious experiment. He can describe its gait, the action of its mandibles, knows the number of its legs, the length of its antennae, and has calculated to a fraction the angle of the cock of its ridiculous tail. He invites verification of his statements, sets you down before the instrument, and awaits your report with an interrogatory "Well?" "Do you mean to tell me," he says, "that all the science of the nineteenth century can't give us a cure for that?" And deprecating discussion you meekly reply: "I should think not." "Then why is the thing allowed to go on unchecked! What has the Government done to fight it? Has the Director of the Royal Botanic Gardens turned his attention towards discovering an antidote? and where, oh! where is the Planters' Association, and its Committee in the matter?" So he goes on—a terrible fellow—and yet, when you think of it, there is—"a method in his madness." He has a last thrust which comes home to all of us: "What if it should spread to tea?" What if it should? you say to yourself, conjuring up its results and then—what a vision! He may be late in preaching his crusade, but not too late; it had been well if something had been done earlier, but there are fine fields of coffee yet to be spared from ravishment, without considering at all the future of tea.

To those who know this insect well, it makes its presence felt in many ways. It checks your energy, baffles your skill, leaves you with a heavy deficit, and sits on you like a nightmare. It has influences even subtler than these and affects really valuable efforts for social amelioration. Fancy its spoiling the good taste of an orator who had introduced the pest "to point a moral and adorn a tale." The audience was a youthful one, and for the sake of the young digestion knowledge had to be crumbled down. After an introduction our enemy was thus described:—"Black-bug is an insect. It is—well—it's not the least like the bug with which you are all so well acquainted"! And to this it has come at last! I shudder when I think where it may next appear. Already on the platform; what if it should find its way into the pulpit?

Ah! my good enthusiastic friend, the days surely are ripe for your sending round the fiery cross. So leave your microscope, and in the columns of the *Observer* preach your crusade.

PEPPER CORN.

NEW WITHERING APPARATUS.—The arrangements of the tats on Sem'awatta estate, the joint invention of Mr. D. Fairweather and his assistant, Mr. Westland, is certainly most ingenious. Instead of the sloping arrangement, which lifts up and is let down, to be met with on most estates, Mr. Fairweather's tats travel between an upright framework, and are prevented from "sagging" by a hook or a guide attached to wires which pass along the framework between each tat. A crank, which works a rope, draws out these tats into position, and discharges them one by one in a most simple and effective manner so that the leaf is subjected to a minimum of handling, whilst great rapidity is obtained in the spreading of the leaf. We believe the Marlawatte tea factory is being fitted with the new withering apparatus and we have no doubt that other factories will adopt this convenient arrangement, which, for its completeness and simplicity, reflects great credit on its ingenious inventors.—Local "Times."

ARECA-PALM CULTIVATION.

(By an Old Palm Planter.)

RESULTS OF EXPERIENCE AND OBSERVATION IN
THE LOWCOUNTRY.

I have not been following the *puwak* discussion very closely, but that makes little difference, as my opinion on that as on most subjects is entirely independent, though that again is no measure of their value. Jack Bunsby's opinions were hard to get at and turned out hardly worth the trouble of reaching them, so it may well be with mine.

My first proposition is, that every plant that needs sunshine requires the space it can cover, at thriving maturity. In the case of all palms, the length of the leaf from the stem to the extremity of a mature and healthy tree is one half the distance that the trees should be planted in a field. This rule however, in the case of the coconut, is modified by the habit of the tree. The coconut leaf is eighteen feet, and by the above rule should be planted thirty-six feet apart, but the leaf only descends to a right-angle with the stem after it has done its duty and been succeeded by others; twenty-five feet is therefore found in that case to be the best practical distance.

The leaf of the arcaut is only from three to four feet in length, at its maturity, and maintains its position at so acute upward angle with the stem; therefore at six feet apart, the leaves of opposite trees will barely touch. I am therefore of opinion that ten feet apart, is more space than is necessary and that 435 trees will not take out of an acre of land all it is capable of yielding. I think seven feet ample space, and at that distance, we get 888 plants into the acre.

My own experience is the utter failure of nursery plants, and tolerable success from placing the seed at stake. Were I now going into this cultivation, I would dig eighteen inch holes, and at the beginning of the S. W. rains place the seed three inches deep in the centre of the holes.

I believe the Ceylon arcauts are the lowest priced in the markets, and anyone going into the cultivation should secure the best varieties from other lands. I have seen a kind that would save the vast labour needed for husking the native varieties, as the nut has a smooth surface and the husk is clean fibre.

THE ACCOUNTS OF INDIAN TEA COMPANIES.

"Spectator" writes to the *Statist* the following letter which was alluded to in our review of Indian Tea Companies the other day:—

"The Indian tea industry represents a capitalized value of some ten millions sterling, and a cultivated area of from 200,000 to 250,000 acres of planting, producing, roughly nearly 70 million pounds of tea. Owing to the large increase in the production, and the tendency to a progressive shrinkage in prices, it becomes a matter of increasing importance for owners of estates to secure—(1), the highest efficiency in management; (2), the utmost economy in expenditure. The attainment of these two requisites concurrently appears at first sight scarcely practicable. Thoroughly efficient management and administration (especially of landed property, where the local executive is so far removed from central control) must, almost of necessity, be pretty costly; and, on the other hand, any approach to pinching economy trenches dangerously upon efficiency. In the large manufacturing industries of this country, however, where competition has rendered existence a simple question of 'survival of the fittest,' it has been found practicable to combine the two apparently opposite conditions, and it is in those industries where the two factors go hand-in-hand that the greatest

vitality is found to exist. One of the causes which has mainly contributed to this result is, that by collating and comparing results of working under different conditions, it has been found practicable to arrive at the highest point of economy in all the processes of manufacture; and to ascertain that what one can do another can achieve has been mainly attained by a careful and intelligent comparison of accounts. In the case of tea-garden companies and partnerships, a more or less systematic method of accounts has long existed, and many of the larger concerns publish very clear and intelligible figures. But the great defect which at present characterises tea accounts is the absence of uniformity, which renders it difficult, even for an expert, intelligently to compare the working of different gardens, or to draw any rational conclusions as to their relative economic merits. As this is the season when most of the companies make up their balances, I think it is an appropriate time to direct attention to the question. If some simple and uniform method can be adopted, I venture to think that a much more intelligent interest in the working of properties will be aroused among shareholders, and much discontent, as well as sharp and unfair criticism of executive agents and managers, might be avoided. I throw out these suggestions in a general way, but should be glad in a subsequent letter to indicate in detail the forms which, so far as my experience goes, would seem most amply and suitably to meet the requirements of the case."

NOTES OF A JOURNEY ACROSS THE MALAY
PENINSULA.

Four days after starting from Kuala Bernam, Mr. Swettenham and his party arrived at the upper reaches of the Bernam river, which are beautiful and picturesque. Mr. Swettenham considers this river could be shortened by 57 miles by the construction of 7 miles of canal, which would require to be both wide and deep, the influence of the tide being felt 80 miles from the mouth of the river. Four days later, the watershed was crossed at an elevation of 3,150 feet above the sea level. This ridge is very sharply defined, for not far from the source of the Bernam, which flows westward, are found the sources of nine streams which converge at no great distance. Their confluence forms the Lipis which, together with the Jelei and Temelin, forms the Pahang river. About a mile before Permatang Linggi is reached, the Lipis flows over a slate bed, and gold is found further down. Toh Bakar, the headman of the district, in a conversation with Mr. Swettenham, complained bitterly of the manner in which taxes were squeezed out of himself and his people. An annual census is made, and a tax called *hasil banchi*, amounting to \$1.33 is levied from each person, while a more extortionate system of obtaining money consists in the Rajah sending worthless articles to his subjects, for which they are obliged to pay a stated price. All gold must be sold to the Rajah, and, when a chief visits him, every man in the district has to pay \$2 towards his representative's travelling expenses. Shortly after leaving Serébu, a rock called Batu Rimau was passed. The natives suppose that this is the petrified body of a tiger, the head being in Jelei. At a spot near Kuala Trusang, 20 Chinese were digging gold. About a quarter of an acre had been worked by former miners, who were said to have obtained 5½ katis from a hole 60 feet in diameter, but were obliged to discontinue their search because a poll tax of \$8 a head had been imposed. At Penjun, the Chinese Farmers hold a complete monopoly, and hence the great cost to consumers of ordinary articles. For instance, a tin of kerosine oil costs \$2; a kati of tobacco, \$1; 10 pieces of gambier, 8 cents; and a ball of opium 22.

Mr. Swettenham says it is a great mistake to suppose that coconut trees will not flourish in any place over 50 miles from the sea, because he has seen them everywhere.

Kuala Temelin is noted in Pahang for its earthenware, which, owing to the remoteness from any market, is not manufactured in any large quantities. The shapes of the jars obtained were considered good, and the decoration even artistic.

Though it would be absurd to say that there are no mosquitoes in Pahang, there are certainly fewer there than in Singapore or Malacca. Agriculture, including the cultivation of rice and fruits, the rearing of cattle (buffaloes are very cheap), sheep and poultry, some gold washing, and the manufacture of mats and silk cloth are the chief industries of Pahang.

This was Mr. Swettenham's fourth visit to Pahang, and he gives a gloomy account of a country which would, if placed under proper administration, not only ameliorate the condition of its people by encouraging them to utilize the valuable commodities that lie within their reach, but also enrich immigrants in various ways. "Without proceeding to details," he says, "those whose experience of the Peninsula has been confined to the Protected Native States would be rather astonished at the manners and customs still prevalent in the governing class in Pahang, and if Europeans will risk their capital in any large undertaking here, and can manage to comply with their obligations, get business transacted, and obtain justice and satisfaction in their dealings with those they are brought in contact with, I think it will be a little surprising."

[It is time surely that Pahang were "protected" into good government. There is the making of a great and valuable Dependency in the Malay Peninsula, when it is ruled as India is now ruled.—Ep.]

NETHERLANDS INDIA NEWS.

(Translated for the "Straits Times.")

Batavia, 7th July.—We have received for notice in our columns, a copy of a work entitled "A Handbook for Cocoa Planters," by E. J. Bartelink, a cocoa planter in Surinam. The firm of J. H. Bussy at Amsterdam has brought the book out. It is handy and handsomely got up with every prospect of becoming an oft consulted authority here. [Of course in Dutch.—Ep.] Cocoa has now come into fashion in many districts in this quarter of the world. When coffee proves disappointing, cocoa is often looked forward to as a substitute in many lands. In Deli, numerous experiments have been made with it on land no longer suitable for tobacco. Less extensively, cocoa is a crop in which many landholders take an interest. The work is written for West India people, and is based on experience gained there. It is none the less of importance here from its showing how growers go to work with cocoa in a country where cultivating it has proved a success. In the preface, the author states, on convincing evidence, that in Surinam, there may be found cocoa estates each yielding high profits which, passing over from generation to generation as abiding heritages, after a long series of years of continual attention and care, prove not only to have lost nothing of their original value, but rather to have risen in value. The difference of soil and climate brings on however questions which often cannot be answered on the strength of experience acquired in another soil and climate. Thus it appears that, in the West Indies, the evil so often besetting cocoa here namely, that of the fruit on reaching a certain stage of growth turning black and rotting away, is not widespread enough to be dealt with in this handbook. Leaving it out is certainly not due to oversight, for the description of all that bears upon cocoa growing is, in his work, set forth apparently very fully, neatly and clearly.—Batavia Dagblad.

BLUE GUM.—It is generally supposed that the blue gum is not a good timber tree. Of course there are no trees over 20 years old on these hills—but one I had cut down about 14 or 15 years old, when the sap was supposed to be in the ground, was cut into scantlings, large and small, and planks 13 ft. long, 1 ft. broad, and 1½ inch thick, and although these were exposed for months from the day they were sawn, they did not perceptibly warp or crack. Blue gum is an exceedingly tough wood, and hardens very rapidly after being cut down, and unless wrought immediately is very hard on carpenter's tools.—Cor., M. Mail.

MAJOR-GENERAL R. MOROAN writes from Ootacamund, under date 17th instant:—"Mr. Redmond, in writing to you about a wire tramway from Coonoor to Mettapolium, observes regarding the *Eucalyptus Globulus* or Blue Gum: 'Of course there are no trees over twenty years old on these Hills.' The Blue Gum was introduced by me to these Hills as far back as 1855, and I planted many thousands of them in that year. These trees may be found at Tudor Hall, and all over the Hills, and are now not 20 but 30 years old. One cut down lately at Tudor Hall, was found to be 200 feet long. Many have 151 cubic feet of timber in them. I fear Mr. Redmond takes too sanguine a view of their value when delivered at the foot of the Hills."—Madras Mail.

SCIENTIFIC ASSISTANCE IN TEA WITHERING.—The *Indian Planters' Gazette* writes:—"What we wish to impress upon tea owners is the necessity of a little practical scientific assistance. At the present moment the chemistry of tea is unknown, beyond a few broad generalisms. At present, for instance, the want of withering machines so as to prepare leaf in wet weather, is one of the great requirements of the industry, and with some knowledge of the different grades of temperature and chemical change at which the different stages of manufacture set in, would probably enable some planter to solve the difficulty and relieve his brother planters of a great deal of anxiety in the height of the manufacturing season. In the meantime it is a much disputed point whether to keep over improperly withered leaf, or to roll it off. By the former process the appearance of the tea is improved at the expense of the liquor, and by the latter process the opposite is achieved. There is one established fact, and that is, that cool withering houses are preferred and no doubt they answer their purpose in fine weather, but in wet weather what is to be done? Some sort of forcing is necessary to make a way for the incoming leaf, and to prevent putrid fermentation setting in the already plucked leaf. In former years the old style of *choolahs* was used and the waste heat from them utilized, but, as a rule, the tea made in leaf so treated was far from good, and invariably in autumn came out a dirty green, no doubt due to some chemical change caused by the heat generated by the *choolahs*. In making *namooona* teas in former years it was customary to put the rolled mass on to the fire before fermentation set in, and perhaps we may not be wrong in believing that leaf withered by hot air gives some hybrid between *namooona* and 'green' teas, as some of the stages of fermentation have been set agoing by the high temperature of the house. We do not say that this is correct; we merely put it forward as some solution of the current; and we think this is one of the most important points on which a chemist could be of great use to the planter. If the 'Fathers of Tea' will give practical men practical hints on tea making they will confer a lasting benefit on the industry." As regards withering we cannot help repeating our impression in favour of the use of Blackman's Air Propeller to send currents through tea-houses.

TEA CULTIVATION.—The tea committee has found a very suitable portion of land for the culture of tea; it is at Quartier Militaire. This gives us hopes that Mauritius will soon be able to say, we produce more than sugar; we shall no longer be accused of monoculture; we export sugar, but we export other produce. We are beginning to produce our own soap, which is sold daily in very large quantities, Mauritian-soap, which we expect to export to other countries next year.

N. LAKHIMPUR.—Been having a turn round the District last week. Gardens I visited all looking healthy except one which has not yet got over the red spider and green fly, the former still very bad. Each manager vying with his neighbour as to who can make the best tea profitably. In the manufacture dark cool rooms with thermometers, &c., all the go and liquoring several times a day to get the proper flavor and color of cutturn. Weather showery, fairly good or tea.—*Home and Colonial Mail.*

ALLEGED FUNGICID ORIGIN OF "BERI-BERI."—The following statement, if Dr. Taylor's discovery can be relied on, seems very important:—We (*Chinese Recorder*) have been favoured by a short visit from the Rev. Wallace Taylor, M.D., of the A. B. C. F. M. Mission, Osaka, Japan. Dr. Taylor's discoveries regarding the origin of the disease *Kaké*, better known as *beriberi*, are of the greatest interest. He traces it to a microscopic spore, which is often found largely developed in rice, and which he has finally detected in the earth of certain alluvial and damp localities*.

CINCHONA BARK IN LONDON.—A mercantile correspondent writes to us from London:—"The sales of bark at auction on Tuesday, 30th June, went off steadily. The reappearance of Mr. C. G. Meier as a buyer (he having obtained an extensive Continental Agency) caused some considerable sensation, and for a short period had a depressing effect on the sales. The future of bark apparently looks more satisfactory, provided the market is not rushed with oversupplies from Ceylon. The unit ranges from 4½d to 5½d. A very large proportion of the Ceylon bark ranges now below 2½ per cent. Bogawantalawa lately has sent in two or three parcels of renewed officinas, analysing over 6 per cent quinine. The Dock Companies and wharfingers have arranged among themselves a new scale of charges on tea from 1st July, the main point of which is the docks will allow no discount on charges, and all the wharfingers agree to allow a uniform discount 10 per cent of the latter's charges; the result will be an increased charge of 40 per cent on present rates."

PRESERVING FISHES.—Success writing about the Madras taxidermist, so famous for preserving fishes in almost their natural states, we have seen the following paragraph in the *Indian Agriculturist*:—"We learn that Dr. Rowell, principal medical officer in the Straits Settlements, has set an example which might well be followed to a greater extent than it has hitherto been in this country, although we are well aware of the good work done in a similar direction by Dr. Day and Dr. Shortt. We refer to the formation of a scientific collection of the fishes and crustacea inhabiting both the seas and the rivers of the Malayan peninsula. Dr. Rowell, we find, obtained the assistance of a taxidermist trained at the Madras Museum under Dr. Bidle, and with his assistance he has got together specimens of something like 100 different species, in which the natural colours of that fish are most wonderfully preserved. It is intended to place the present collection in the Raffles Museum at Singapore, but Dr. Rowell proposes also to send home duplicates of as many his collection as possible to the Indian and Colonial Exhibition next year, where they may be expected to prove objects of attraction.

* Curious that in all the discussions on coffee in Ceylon one has used this expressive word. We have constantly used the periphrasis of "all eggs in one basket."—Ed.]

AGRICULTURE IN MYSORE.—Colonel Hay, in charge of the Amrat Mahal Department, has obtained the sanction of the Dewan to the formation of experimental farms in Mysore, for the cultivation of guinea and other grasses, and the storing of green fodder in silos to provide wholesome forage for cattle during the hot season, the scarcity of fodder during the past season having proved such a great calamity. Rs. 500 has been sanctioned for the purpose. A recent experiment with a silo on the Kungul farm was productive of excellent results.—*Civil and Military Gazette.*

A SECOND VERSION OF "THE RED SHOEFLOWER" &c.—The red shoeflower is called by the Sinhalese 'wada mal,' and by them and the Tamils 'sapattu mal' in imitation of the English from the fact that the flowers are used to blacken shoes with. I never heard it called 'suriya manui.' The Colombo avenue tree, *Thespesia populnea*, called the 'tulip tree' because its flowers are like those of the tulip, is the "suriya-gaha." The sunflower is the 'suriyakanti' of the Sinhalese, and I don't think the morning-glory is ever called by such a name.—Cor. [Our correspondent forgets that the names given were those used in Northern India, not Ceylon.—Ed.]

SOAP AT THE WHARF.—The other day some 500 cwt. of soap manufactured from illupei oil were sold by public auction at the wharf and bought by Moormen at about Rs. 10 per cwt. This is said to have been imported from India by some Chettics and confiscated as undervalued. The Moormen say that for the purposes of duty it was valued at Rs. 75 per cwt., and they laugh at the idea of confiscation for the difference of 25 cents. The importer is said to be fortunate in securing ready cash all in a lump and on so short a notice in lieu of having to wait for years to realize his capital by the sale of the soap in his boutique.—Cor.

COPPER IN ARRACK.—In a very interesting report by the Madras Government Chemical Examiner from which we should like to quote largely if we had room, occurs a paragraph of local interest inasmuch as the spirit in which copper was detected may have been distilled in Ceylon:—

Copper in arrack.—It is noteworthy that a great many specimens of arrack contain copper in appreciable quantity. Mr. Newman made an estimation of it in some cases, but it was never found in such amount as to be injurious to health. It is probably derived from copper condensers used in distillation. The fact is important because copper might possibly be found in dangerous quantities in the arrack first distilled through a corroded copper condenser; also because a medico-legal question might arise as to the presence of copper in spirit used to preserve substances submitted to chemical analysis in cases of suspected poisoning.

COL. MONEY ON CEYLON TEA.—Col Money writes to the *Indian Tea Gazette*:—"Ceylon goes ahead and some wonderful accounts of the yield per acre have come home. But it should be remembered young planters are always sanguine. I believe there have been some large yields, 1,000 pounds and upwards per acre, but there may be exceptional cases. One planter writing lately in a Colombo paper assumes 300 to 400 lb. as the yield in many places. I think the yield will probably exceed Indian, for they pick pretty well all the year round, but it is a question if they are wise to do it." But be the yield more or less the generality of Ceylon teas are very good, and no one can doubt India has a formidable rival in that island. I wish they would calculate their tea in maunds as we do. It is simpler and takes fewer figures.

* I see red-spider is already in Ceylon. How greatly this pest diminishes the yield in India! It will assuredly do the same there.

ESTATES AND CREDIT.—A proprietary Planter, who, while determined to act on St. Paul's principle, "Owe no man anything," is working his properties without agents or cash credits and is therefore dependent for funds on getting his produce away and drawing against shipment, expresses the opinion that "it means ruin to think of borrowing money in these days, and that if an estate cannot be kept going on its own merits it is best to throw it up at once."

EMANCIPATION OR CIVIL WAR IN BRAZIL.—The *Rio News* thus concludes an article on the slavery question in Brazil:—A compromise, therefore, could only produce temporary lull, sufficient perhaps to hide from the country the abyss to which it was softly gliding, but the abyss is none the less there and will be, sooner or later, surely reached. As there are physical diseases only curable by heroic remedies, so are there social cancers only to be extirpated by distress, and perhaps misery for a period, and although this sentiment is somewhat thread-bare, it will serve as preface to our project which is: decree the immediate abolition of slavery throughout the Empire of Brazil.

SOUTH COORG, 7th July.—Our rainfall to date has been very favourable, about thirty inches; the crops are large and vigorous, but the tendency for prices to remain low damp the spirit of enterprising owners of the soil. A good many reductions have been effected, and working expenses cut down to the lowest. The cry of "no money in the country" rings in every person's ears, while one large firm has issued a circular indicating further reductions next year if prices don't rise. This is very hard on Superintendents who work hard to get the crop and who have no control over the coffee-market! Their prospects are gloomy and each fears to send for his daily tappal in case the fatal notice of "your services are no longer required &c." should turn up, but every cloud has a silver lining, so let us hope for better things to come; past experience has taught proprietors to economise now.—*Madras Mail*.

TEA IN SYLHET.—A correspondent of the *Calcutta Englishman* says:—Until a week ago, bright hot days with rain at nights was the weather prevailing in North Sylhet. For tea better weather than this could not be desired; it brings on the flushes in grand style and accelerates the fermentation of leaf. Profiting by seasonable weather and favourable conditions generally, most of the gardens in North Sylhet are getting on with their manufacture gaily; the Lallakhal Garden being, I hear already upwards of two hundred maunds in advance of its out-turn for the corresponding period of last year. Bar accidents, the crop for 1885 should be a bumper one. But what is good weather for tea is not always enjoyable weather for man, and I for one hail the change from hot steamy days to rainy weather once more with satisfaction. Yesterday we had several inches; and as I write, heavy rain is falling with a persistency that bodes evil for the dwellers on low lands.

LEAF-DISEASE IN NETHERLANDS INDIA.—The following paragraph shows that the coffee fungus is pursuing in the Eastern Archipelago the same desolous course as it took in Ceylon:—Batavia, 11th July.—Regarding the coffee leaf-disease in Mid Java, a Samarang newspaper gives some discouraging figures furnished by Mr. Mac-Gillivray, of the Satirong estate, on which, in 1884, the crop was only between one-third and one-fourth of that gathered in 1883. The information bore upon about 30 estates which, during 1884, as compared with 1883, had suffered heavily more or less according to their respective height above sea-level, but whose collective yield in 1884 amounted to only 25 065 piculs against 61 872 in 1883. On some of these estates, the outturn fell from 1,800 to 120 piculs. Taken altogether, it appears that in 1884 compared with the previous year the collective crop on these 30 estates was short to the value of eleven hundred thousand guilders, some of them bearing a disproportionate share of the loss.—*Batavia Dagblad*.

WOOD VALUABLE FOR TEA BOXES is thus noticed in the proceedings of the Madras Agri-Horticultural Society:—A small bag of seed of *Erodia meliifolia* (wood valuable for tea boxes), from J. S. Gamble, Esq., Conservator of Forests, Northern Circle.

INDIARUBBER PLATES FOR ARMOUR.—Under Admiralty directions, an extraordinary experiment is to be made at Portsmouth, and the results are anticipated with remarkable interest. Targets coated with india-rubber sheets are to be fixed on sides of armour-plate resistance, and they will be subjected to progressive gunnery tests, commencing with a six-pounder quick firing gun and increasing, if possible, up to a 6in. nine-ton breech-loader. Should the trials be attended with success, as is expected by some experts, the arming of men-of-war will be almost revolutionised, indiarubber sheets, specially prepared, being largely substituted for armour plates.—*Weekly Echo*.

SNAILS AND ECZEMA OR SKIN IRRUPTIONS.—We recommend the following curious experience, sent by a clergyman to the *Standard*, to residents in the Far East:—"Some year ago, suffering from a severe attack of eczema, for which I could get no relief, while walking one evening in my garden, and in great pain, I happened to cast my eye upon a snail, and as my leg was burning and the snail looked so cool I at once rubbed it over the itching part, and found immediate relief; so much so that I got two or three more, and, breaking off the shell, applied them, letting it dry in. That night I slept in perfect ease, and of course followed up my new found remedy, and in a few days eczema was all gone, and, I am thankful to say, never returned. I have recommended the same to my friends who have suffered from the like complaint, and all have found relief. It is, also an almost infallible cure for skin diseases, and deserves to be better known than it is."—*Strait Times*.

THE QUEEN OF FLOWERS IN CEYLON.—On many upland estates in Ceylon we have seen not only garden plots but hedges brilliant with a wealth of roses. But until the receipt of a basket from Mr. A. Whyte of Kandy, a few days ago, we had but an imperfect idea of the perfection of form, colour and fragrance to which the very finest species of roses can be brought in our island by careful and intelligent cultivation. When the basket was opened, a scene of exquisite beauty was suddenly revealed, the many-petalled, compact and large blossoms displaying every shade of crimson, pink, glorious golden-yellow and white. The basket was more than half filled with damp moss, and in this were placed a number of porous earthen pots which held the bouquets of roses, the stems of the flowers being also in damp moss with which the pots were half filled. So packed, Mr. Whyte told us, he was able to send his roses in good condition to distances so remote from Kandy as Galle. Our readers will now know where to apply for the most exquisite of floral adornments, on occasions of marriages or other festive meetings, or for the brightening of every-day life, especially to the ladies of families. There was a large bunch of vari-coloured and sweetly fragrant roses in each pot, and each of the bunches was made up of a number of smaller bouquets, so that the flowers could be concentrated, or spread over the tables of a drawing-room or boudoir at pleasure. Mr. Whyte, besides being a well-informed naturalist and a competent taxide mist (in which characters we trust he may be employed to add to the interest of the Ceylon Court in the Colonial and Indian Exhibition), has the instincts and feelings of a true artist and deserves encouragement from those who delight in the curiosities and "things of beauty" of the animal and vegetable world of Ceylon. He is the best practical interpreter of our natural history who can be consulted.

AGRICULTURE IN SIAM.

(Translated for the "Straits Times".)

Mr. Hamel, the Netherlands consul general at Bangkok, draws the following dark picture of the state of agriculture in Siam, in his official report for 1884:—

As I have repeatedly set forth in my previous yearly reports, this country from being intersected generally speaking as it is by many large rivers which yearly overflow widespread plains, is extremely fertile and were the Government to give the least help or slightest encouragement, there is no reason why Siam, so far as rice growing is concerned, should not run Burma and Cochim China very close. Nothing is, however, done by the authorities in this respect. Neglect of a matter of such high importance to the people at large is rather to be noted than otherwise. Everything of the kind is left to private enterprize, notwithstanding that a large revenue from rice cultivation flows into the State Treasury both from direct taxation on the standing crops and duties on grain exports. Whenever the particular interests of some head official do not come into play, not the slightest outlay is made for either canalization or irrigation. Even the canals around and near Bangkok are not regularly kept at a proper depth. Hence it is that many a time in the dry season cultivators cannot take their produce to market from insufficient means of communication. It is generally taken for granted among rice dealers here that, of late years, rice, especially the kind styled a field rice, has fallen off in quality and become lighter and more brittle, and after husking, yields a much larger amount of broken grain than formerly. This points to the desirableness of improvement either by importation on a large scale of better seed grain from other districts, or by closer supervision over cultivation. With the exception of small experiments now and then by enterprising private individuals, nothing whatever has been done in this line. In December last year, I had an opportunity of going up the Ban Pa Kong river. Not many years ago, a great number of sugar mills were found there, most of which have, however, disappeared. Care is now grown there for local consumption only. Two rice mills were almost the only signs of industrial activity along this large stream. The fertile fields along both banks lie mostly uncultivated. At distances of more than twenty English miles hardly a dwelling house, much less any cultivation came under notice. In all directions so far as the eyesight reached, there were stretches of lonesome, unfrequented plains overgrown with high grass which only awaited the industrious hands of cultivators to yield abundant fruit. I also noticed the same state of things along other large streams which traverse Siam, such as the Mekong and Tchouin. Even the highly fertile valley of the Menam is no exception thereto. I hence deem there are good grounds for coming to the conclusion that on a twentieth part of fertile fields of Siam has been brought under cultivation. Years ago an enlightened and enterprising Siamese laid before the Government a scheme for setting up a large Cultivation Company, with its support and co-operation, to till this waste land, and, with that object, to further the immigration of Chinese labourers, but it was repeatedly rejected for fear of political complications. Yet it is to the industrial enterprize of the Chinese that Siam mainly owes what few improvements have been carried through. Even without direct interference on the part of the Government, a great deal might be done to make the country more flourishing and productive, were only the Government mindful of gradually introducing much needed reforms in its ruling system, and, by the appointment of salaried officials, and other measures as well, checking the extortion and

arbitrary proceedings of the legion of high and low officials, who, as matters now stand, live exclusively by knavery and extortion which naturally works harmfully in every way, and cannot further by any means the growth of public well being.

Mr. Hamel further takes note of the circumstances that in 1884, 13,000 to 15,000 head of cattle were exported from Bangkok, they being conveyed regularly to Singapore by steamers carrying on the average about 200 head each trip as deck loading. This trade which yields high profits is almost exclusively in the hands of Klings and Malays under British and Netherlands protection.

As to teak wood, the consil-general reports that the Siamese kind as it becomes better known in Europe, comes into greater demand and reaches almost the same value as the Maulmein article. Supplies of it from the interior fell below the average in 1884 from the low stage of water in the rivers preventing cargoes of it coming down on rafts. Should the rivers this year be more navigable, larger supplies than usual may be expected with a prospect of higher prices from greater demand. The trade in the article is said to be best carried on in small vessels, from their light draft enabling them to pass the bar below Bangkok, thereby saving much outlay and trouble. Mr. Hamel concludes the report by noting that direct trade between Siam and Netherlands India was smaller in 1884 than in former years from Java needing less rice from that country, and from fewer of the Siamese fish called Platu being caught owing to its growing scarcity in the Gulf of Siam.

ELEMENTARY TREATISE ON AGRICULTURE

PART I. (IN TAMIL) BY C. BRITO ESQ.

The above is the title of a neatly printed book of 76 pages a copy of which has been sent to us by the author. Its 9 Chapters are thus distributed.

- Chap. I. Arithmetic and Geometry.
- II. Astronomy and Geography.
- III. Geology.
 - Earth Fire Water,*
- IV. Chemistry.
 - Elements and Compound Substances,*
- V. Biology.
- VI. Animal Physiology.
- VII. Botany.
- VIII. Agriculture, Soil, Improvement Vegetable Products, Manure, Water, Ploughing, Sowing, Reaping, Animals, Paddy.
- IX. Meteorology.

Although the concrete sciences are more engaging to young minds than the abstract ones, yet it is a fact, inexplicable as it is, that the former are deferred to a later period in the students' course than the latter. In our schools, science is taught only in the higher classes, in English Schools; and it is not at all taught in the Vernacular, perhaps for the obvious reason that proper text books can be had only in English and to learn from them they must first go through the English Grammar and the English language. Mr. Brito's book professing to be a Tamil text book of science cannot be too highly recommended to the vernacular schools. The curious school boy will find in it many curious things which cannot fail to excite him to more extensive pursuits. To know in a practical way how to measure a piece of land, how to account for day and night, how two bad poisons can join together and produce our curry salt, to know that our earth was formerly a round ball of rock with fire in the middle, that even now there is fire within the Earth enough to melt stones and metals that there is no such thing as fire, but it is only a sign of the separation of two elements, that water is not an element, that the great and mysterious tank at Nilavara can be explained away as an Artesian well, that diamond is a kind of coal, ruby alumina, that even the simple act of a man's walking is equal to carrying a weight 360 cwt., that there are such things as animal trees, that although certain animals are cut and backed to pieces, yet every piece will become a

new animal, that trees breath just as men, that the age of dogs is 20 years, cat 15, hare 8, elephant 100, pig 25, horse 30, ass 30, camel 50, goat 12, cow 15, ewe 100, peacock 20, fowls 10, tortoise 100 all these and the like are both amusing and instructive to learn. The farmer, the grocer, the medical practitioner, the headman, the housewife, the smith and every class of men will find in this book many useful facts and hints. Mr. B. recommends English ploughs for our use saying that it costs only 12 annas to plough an acre with an English plough while with a native plough, it costs 50 annas. He also tells us that the Americans cultivate their paddy in a different way from ours which is so good and suggests that it is the very paddy which should be introduced here as a change for the soil. We also learn that we Tamils are 15 millions strong.

Speaking of the dignity of agriculture his words are so true and impressive that we will quote them in English as nearly as possible. "But in our country the soil is hungry, cattle hungry, tenant hungry, farmer hungry, subject hungry and the King also hungry. If the hunger of the soil be appeased" every other hunger will be appeased. We acknowledge the book with thanks.—"Ceylon Patriot," July 17th.

GOOD COFFEE CROPS.—Not alone in Uva are there good coffee crops this season: Mr. Cantlay can show 200 acres on the Mount Vernon property with 5 cwt. per acre, according to present appearances; Bearwell has 4 cwt. over 200 acres; Belgravia is to do well as usual; while in the Wallaha valley there are several good crops, if only leaf-disease would not disturb calculations at this critical time. North of Kandy, the return of coffee from the older districts is almost, if not quite, *nil*, owing to the ravages of bug.

THE FAME OF THE CEYLON TEA ENTERPRISE has indeed reached a height, when at the meeting of shareholders in the Land Mortgage Bank of India, one gentleman, Mr. Buchanan, announced as a fact—and he was not contradicted—that "80,000 acres of tea in cultivation in Ceylon a year or two ago, had increased to 540,000"!—What next? Strange, however, that a roomful of people, all interested in "tea," did not notice this gross exaggeration on the face of it. When Ceylon gets to half this area, or say 200,000 acres, some years hence, it will be time for India tea planters to put their house in order.

WHITE-ANTS AND ELEVATION IN CEYLON.—A planter writes:—"Re your worthy article on white-ants, what would be the elevation of Fernlands, Pundaluooya? There white-ants attempt to pull down store and hungalaw. I do not think it is so much elevation, as if they have a free passage from low-lying paddy-fields to the estates, but a strip of juggle will stop them." Fernlands store in Pundaluooya must, we suppose, be situated at about an elevation of 3,000 feet above sea-level. There is something in what our correspondent says.—We have just learned, however, that the proprietor of Fernlands never heard of his store being attacked by white-ants!

COFFEE IN COORG, Mercara.—Our supply of Mysore cooly labor is but slowly coming in as yet, there has evidently been considerable delay in the west province from want of rain for planting grain and cereals; men who have now come in, say that only in the end of May, when the weather was so cyclonish in Coorg, did they get sufficient rain to plough; since which time rain has been general, and grain is much cheaper. I do not know of any new estates being opened this year; planters are waiting for the clouds to lift a little more, before utilizing their jungles. We have had some capital planting or supplying weather since the 2nd instant, when the monsoon may be said to have commenced. There has been rain every day since, and persistent high winds, which have done some small damage, but it is wonderful growing weather. There has been some disappointment felt from the effects of Ringer, which in new clearings has largely attacked last year's plants, and killed off about 30 per cent. This insect is never seen at work; it sleeps by

day in holes in the ground under fallen leaves if possible, then when darkness comes it emerges forth, eats the tender bark of the young stem, perhaps half an inch in width, but completely round the stem, and does nothing more: that plant dies, but the grub or Ringer lives on, and attacks more plants. It was in March last I first saw the effects of the pest, and was puzzled to know the evil at first, ascribing it to grasshoppers: it was accident which led to my finding them to be night prowlers, for at first I procured some thin breasted, long legged, hungry country fowls, and turned them at liberty in a new clearing, but they only seemed to get lost, without checking this mysterious ringer, which was now getting a nuisance and a danger: so eventually I had to get lanterns, and with persuasion mustered a few coolies, to search after dark, and pop them into bottles. Filling the bottles with boiling water afterwards was quite a pleasure. I have not noticed any fresh attacks, since the monsoon came on.—*Madrass Standard.*

TEA IN JAPAN.—As the season progresses, says the *Japan Mail*, of July 11th, people begin to discover that happily the gloomy prospects outlined in Notification No. 20, of the Department of Agriculture and Commerce, are not likely to be fully realized. We were told by the compilers of that remarkable document that the climatic irregularities of the spring seemed to portend serious agricultural misfortune, and that the crops of tea and wheat had already showed deficiencies of fifty and forty per cent. respectively, as compared with normal yields. It was certainly true, at the time of the notification's issue, that owing to late frosts and want of manure, tea shrubs had not been productive at the first pulling. But the conditions of tea cultivation render it rash to foretell definite results at an early stage, inasmuch as the second crop of leaves may, and frequently does, prove sufficiently prolific to compensate previous deficiencies. Such, indeed, is said to be the case this year. The market returns show settlements of ninety thousand piculs up to the end of June, against eighty-seven thousand at the same period of 1884.

COCONUTS AND CRABS ON THE KEELING ISLANDS.—Landward the soil is tilled by the great coconut crab (*Birus latro*). It is chiefly nocturnal in its habits, making tunnels in the ground larger than rabbit burrows, lined for warmth (?) with coconut fibre. It feeds almost exclusively on fallen coconuts, using its great claw to denude the fruit of the husk surrounding it, and to get at the eye of the nut, which it has learned is the only easy gateway to the interior. Of the three eye spots seen at the end of a coconut, only one permits an easy entrance. The *Birus* does not waste its energies in denuding the whole nut, and it never denudes the wrong end. Having pierced the proper eye with one of its spindle ambulatory legs, it rotates the nut round till the orifice is large enough to permit the insertion of its great claw to break up the shell, and triturate its contents, whose particles it then carries to its mouth by means of its other and smaller cheliferous foot. From this nutritious diet it accumulates beneath its tail a store of fat, which dissolves by heat into a rich yellow oil, of which a large specimen will often yield as much as two pints. Thickened in the sun, it forms an excellent substitute for butter in all its uses. Mr. Forbes also discovered it to be a valuable preserviug lubricant for guns and steel instruments; and only when a small bottle of it, which he had had for two years, was finished, did he fully realise what a precious anti-corrosive in these humid regions he had lost. The coconut tree as a rule is a branchless palm, but on West Island, one of the Keeling group, Mr. Forbes noted its rare occurrence as a branching tree, which; instead of fruiting spikes, invariably produced persistent branches crowned with a bunch of leaves—adding to the beauty of the already graceful palm. Under favourable circumstances, it appears, the coconut can produce its first fruit within four years from the fall of the seed nut from its parent tree, while it can go on for an unknown period throwing out every month a new fruit spike, bearing from seven to four, to ten nuts, which require from eight to thirteen months to ripen.—*Field*

FIJI SKETCHER.—BY VIII.

OUR COCONUTS.

Our coconuts from Fiji are not unfamiliar objects on the Melbourne wharves, and are even hawked about your streets. Juveniles are also acquainted with them in the shape of white shavings, most fascinatingly crystallized over with tinted sugars, and exposed in that fairyland of delight, a first-class confectioner's window. Coir fibre, coir rope, and coir matting are well known too, I have no doubt; but you cannot realize all about the coconut in Southern Australia; and your scenes and surroundings are quite different from those in which the handsome palm and its useful products flourish. Nay, you cannot know the nut in its proper drinking stage, a smooth green thing which, when the top is struck off, is a fountain of clear, delicious liquid, cool and sweet, and as much as a man can drink. Nor in some merchant's offices is the dried kernel, tons of which they used to regularly sell before the Germans well-nigh monopolized the trade, known very much about—if we are to accept the testimony of Mr. William Seed, once a very popular Inspector-General of Police in Fiji. He asserted that when visiting Sydney, he was informed by a leading merchant that copras formed a large item in the exports of Fiji. "Copperas!" said the astonished Mr. Seed. "Why, I never heard we had any there." "Oh, yes, it is your chief article of export." "Can't be. It is impossible that I should not have known it had such been the case." "Nonsense!" urged the positive and intelligent Sydney merchant. "I ought to know, for I have sold hundreds of tons of it." That beat Mr. Seed into patient resignation to the inevitable, but it came out in time that *copra* was what was meant, and as that commodity appears in market reports and price quotations, as "copras rising" or "copras £9 3s. per ton," the mineral or chemical product, copperas, and the vegetable product, *copra*, were regarded as one and the same by the leading Sydney merchant, according to Mr. Seed. Mr. Seed, who was well known here to be entirely without the bump of veneration, audaciously asserted that the same ignorance existed in Melbourne! If so, there is an opening even for such an article as this, which is not intended for an exhaustive monogram on the coconut.

The first peculiar and distinctive feature of the isles of Fiji to a voyager from Victoria is the surge-rimmed reef; the second is the coconut palm. As it stands upon some breezy cape waving like a bunch of ostrich feathers on a slight cane stem, in the distance it at once catches the eye as something new and quite a thing of beauty. Then, as the island shores are drawn nearer to, the long lines of tall palms fringing the white coral sand of the beach delight the gazer, and he feels that he has got into another world. The South Sea islets have a picturesqueness of their own, derived from high and fantastically broken outlines; from a picturesque, if dangerous setting of coral-edged reef-rings; from outposts of "patches," over which the sea breaks with startling force; and also from the lovely verdure with which the hillsides are clothed, a perfect study of many shades of exquisite green. But a very great deal of their charm is really due to the elegant and ever-pleasing effect of the palms that crown the heights or stand in thick groves on the flats, or border with a tall and stately palisading the gleaming sands. Nature for centuries has thus adorned Fiji, the long, rolling waves of the Pacific washing the plain, brown nuts from some distant strand, and casting them where aught else would perish, but where they take root and thrive. The dark brown, unsightly, unpromising lumps, drifting as mere waifs of the careless sea, possessed within them the potentialities of great beauty, and marvellous usefulness, and future wealth, and as they slowly draw near the coral lands of Fiji they meet glory to the islands, food, drink, timber, and corlage to the people, and prosperity and money to the Messrs. Hennings. But the aborigines have supplemented with their own fitful toil the slow, grand processes of Nature. A large proportion of the palms of Fiji have been planted, and nearly every village meant a grove of coconuts, and almost every grove of nuts indicates the site of a native village,

But in addition to this, to the work of Nature and the work of Fijians, a great deal has been done by foreign settlers, pioneer planters, and enterprising colonists. Large areas of land have been placed under cultivation by these later factors in the development of the country, and nut planting has been carried on scientifically, and with regularity and study—but not in all cases with success. Nature and the Fijians certainly seemed to have known best. Yet, failures apart, there are some noble estates of coconut groves in the group. These are not to be found about Suva, that objectionable place having scarcely a palm to indicate that there are any in the country at all, but on Vanua Levu, and the Windward Islands. And it is a glorious sight to look from a vessel's deck upon a hill-side clothed with hundreds upon hundreds of fine palms, with full, large crowns of sheeny fronds, the trees set out with mathematical regularity; or to stand on a flat, grassy area under a forest of palms, which rear their graceful heads to an equal height above you, their tall stems ranging far away to the left, right, front, and back of you. "Under the palms" browse cattle, who leisurely perform a double duty, fattening themselves for the market and keeping the ground clear. In this way coconut trees and cows do well together, provided that the trees have passed their minority before their bovine friends are introduced. Some fine coconut estates are at Savasavu Bay (notably Mr. Fenton's), and from there comes a supply, too, of beef for Levuka's Smithfield Butchery. Attention is now being paid to the rearing of well-bred stock, as the grazing has proved such a success. Mango Island has a glorious show of nut palms growing on its hill-sides and nestling in thick profusion in its valleys, and there may be seen the plant in every stage of its growth, from the hoary old patriarchs planted by the aboriginal residents on the island to young things that boast more leaves than stem and have been set out in equidistant rows by order of Mr. Borron, the manager. Of these there are over 500 acres, and, from time to time, more will be put in, until the isle shall be one mass of fruitful green. The finest coconut beach in the country is to be seen at Lomaloma, where for miles there is a good wide road, and many handsome avenues of native planted palms. The most restful, delicious, and altogether Edenlike portion of the group is this same Lomaloma. No one arriving in Suva could ever imagine that there was a Lomaloma in Fiji.

I have spoken of the planting of these "royal nuts," as Kingsley called them, by Dame Nature herself, who washed them on coral beaches by her fast-following waves; but it must not be forgotten that the dear old lady's efforts have been largely supplemented by her intelligent children, the anthropoids. The Fijian took up the work, and assisted nature to make the islands beautiful, though the idea of the beautiful must have been a very latent motive with him, for he is the most out-and-out utilitarian that I know. And his mode of operation is this:—He begins with the nut just when the Warranbob planter does with his potato—when it sprouts. That soft, pale, white mucilage which you see in the green drinking nut, surrounding the pint and a half of liquid, becomes the hard, white substance which you know so well in Melbourne, this may be compared with the white of an egg. A yellow substance forms and gradually absorbs the whole cavity occupied by the sweet liquid, and this, known as "vara" (the indigestible delight of all children), is the yolk of the egg, and from it comes the germ of life. Whether this coconut egg, called a "griffin's egg" in an old MS. is holoblast or mesoblast may be left to the keen, dividing mind of him who telegraphed so wisely concerning the ovum of the duck-billed platypus to the British Association at Montreal. But from this vara springs a tiny shoot which finds its way out at an eye in the hard shell, with wonderful foresight hard and temporarily closed for the occasion. The sprout asserts itself, opening the tough husk with a lance-point, and then throwing out leaves in the open air. Now the Fijian eye takes notice of it, and the nut is removed from the ground where it had fallen from the parent palm, undamaged by its great

descent, or by the thud with which it had announced itself as about to begin an independent life: and the owner puts it in a row with several others, all in like interesting condition. I have seen hundreds of these infants lying in a row, and vigorously sprouting all the time. When the plant is very fairly outside what originally contained it, then it is taken to a place where the earth has been loosened, and stuck in there. A few occasional seedlings, and the youthful palm must, like the youthful Arab of Hotham or Collingwood, take care of itself. These nuts are planted by the sea-shore (for they best love the coral strand and the kiss of the sea's salt lip) on the little flat deltas, on promontories, hill-sides—everywhere; even right in the heart of the hill-country, where there is no saltwater (and coconuts were not supposed to grow many miles from the seashore), they are found. But there is perceptible difference between the drinking nuts grown inland and those that flourish on the littoral. One canny practice that the Fijians have may be observed when looking at ridges, especially the crowning ridges of small islands. Here, exactly on the dividing line, palms are put so that as the mature nuts fall some will roll to one side and others in the opposite direction, and in that way many palms will rise up self-worn on both of the slopes. Any plan for the economizing of personal effort meets the approval of these children of the sun, the Fijians. Where an Englishman seeks to save time, they only desire to save work. In these later years the interests of the coconuts have been taken in hand by men of a civilized race, and they have been planted "according to Cocker," and in great numbers with almost mathematical precision. Weeding has been systematically attended to, and no detail neglected which could bear in any way upon the very best prosperity and productiveness of this interesting source of income. Mother Nature did well, the Fijians did better, the white man has done best. But some visitors in Wairarapa last year were slow to distinguish between the irregularity of nature and the regularity of man—the white man. Turning into a coconut estate on Yuna Point, where the palms stood in proper regulation order, like troops upon parade, "Look here!" they cried, "here's a coconut grove; what a lot of them! And how singularly even they grow—all the same distance apart. Wonderful!" And the worthy proprietor, who had spent his hours with tape and line arranging this curious equidistance, listened while Nature herself received the whole of the praise. Perhaps, the same tourists on their way through Kyneton ascribed the long wheat furrows there to the conscientiously regular action of a small earthquake.

And now, as we have seen the nut palms growing as nature, Fijians and settlers have placed them, let us see what use they are put to. The Fijian has the first use, we might say; but in some of the Windward Isles there is a creature lower in the scale of being that first begins to utilize the nuts. It is a crab, a huge landcrab, with most powerful and terrible claws, *Bergus latro*, the Latins call him. Ugavule (Oogahvooleh) he is styled by the soft-eyed bipeds of the place. *Bergus latro* "swarms" up a palm, lays hold upon a promising nut, and husks it; gets at it somehow, and enjoys the succulence within. In a list of items presented to the Sydney Museum a little while back, I saw mentioned the husk of a coconut with the marks upon it of the claws of that thief, *Bergus latro*. The natives are said to have an amusing way of outflanking this big crab, and taking him in the rear as he descends from his airy perch and godlike feast; they tie some grass round the stem of the palm at a good height from the ground. Monster *Bergus* descends backward like the bear, and, in time, comes to the grass, whereupon he straightway imagines himself to have arrived at *terra firma*, lets go all hold, and the demolition can be imagined. After the crab comes the Fijian, as claimant of the seductive nuts. He "goes for them," walking up the tree, not climbing, as I defy the most agile larrikin to do. Squatted in the crown, he has a choice before him, for there blooms the tiny blossom and stands the baby nut and there hang other nuts of all stages right up to the mature thing which is ready to drop upon the bosom of mother earth. Tapping with his finger-nail the smooth green and yellow green globes around him, he can tell by the sound what particular ones are in the proper stage

for drinking purposes, and I much doubt if any Tasmanian piano-tuner could do the same. Detaching a number of the right sort, that come thumping down, he follows after himself not coming headlong indeed, but with a very *facilis descensus* movement by aid of the hands and feet alone. A stake is chosen, sharpened at both ends, stuck into the ground, and on the upward point the green-husked nuts are struck, the stake piercing the tough covering and an adroit movement of the wrists wrenches off great portions of this until the white shell is laid bare. So simple does the operation seem, but it is so difficult. Wairarapa tourists lightly think themselves quite equal to the performance, and they "job" the nut on to the stake, happy if they miss piercing their fingers as a side issue, and try, and wrench, and push till their faces grow alarmingly hot, and the perspiration tide-mark rises on their silky coats between the shoulders. One after another tries and fails, when the brown-skinned lad steps forward again, and with a smiling face easily does the denuding work, and "without turning a hair," as we say at Flemington. Just a knock, but one not to be acquired in haste by a European. A blow or two with a long knife, or a stone, or another nut, and a round piece is knocked from the shell, and the citadel has fallen—the nut and all it has in yours. Contrast this ease and method with the frantic struggles of our boyhood, in endeavoring to get past the tough husk and hard shell and into the treasure-house of an old coconut bought in the Melbourne streets. Of course, the natives have abundant use for the nut, as food, as a scraped concomitant to various made dishes, as a drinking cup, water monkey, material for fibre, and so forth; but the principal commercial use to which they put it is the manufacture of copra. This copra is formed of the hard, kernel-like lining, cut into strips and dried in the sun. Now, it is an easy matter for a native to make this product copra. He simply collects the old nuts as they fall from the tree, and with one blow of an axe cleaves them in half through fibrous husk, hard shell, and white kernel; the hemispheres are then hung upon rude stagings, where the sun hardens, dries, or toughens them. Wet spoils the process, and has to be looked out for. The toughened lining is now cut from the nut by a knife in strips, and these, dried again, are put into coarse bags for shipment. A native who has palm trees can thus easily make copra to pay his taxes with, or to obtain cash from local traders for the purchase of such goods as he requires, and may be considered to be in easy circumstances. Just now the Fijians are not utilizing their nuts as far as they might, and there has been a falli-off in the export for the past year in consequence.

And now comes in the Europeans' share in the business and utilization of the nut. Not only do they husk and bag the coconuts whole and send them to the neighbouring colonies, but they buy of the natives their copra, and they also make it themselves, for there is no surer income in Fiji than that from a coconut estate. The said copra once purchased is collected in small craft, such as decked cutter-boats and small schooners, and brought into Levuka. The U. S. S. Co.'s inter-isular steamer also savours strongly of the stinking stuff, and half-poisons her passengers with the vile reek that proceeds from such a villainous but profitable cargo. At Levuka this cargo is stored, chiefly by German firms, such as Messrs. P. Hoerder & Co. and (*facile princeps*) Mr. W. Hennings, who is agent for the South Sea kings, Godfrey & Co., of Samoa. One English firm, Messrs. H. Cave & Co., is also in the business. Hither come German barques, which bring merchandise from Hamburg, and take back copra, or simply act as collectors, and sail to Samoan ports, to Tonga, and then to Fiji, picking up contributions from each place until they are full. English vessels arrive from London, and go back to Falmouth, with what Cave & Co. have got stored ready for them. But the Germans are, *par excellence*, the copra traders of the South Pacific. Their shipping is ever in these waters, and they work their old ships so economically and pay such low wages that they defy competition. From New Britain to Fiji, including the Friendly, Navigator's, and other groups, the copra trade is almost entirely in the hands of the watchmen of the Rhine. The large amount of Government copra (paid in by the natives as their

taxes) is sold by contract, tenders being made every year, and the successful tenderer takes all that the state has to give him at a certain fixed rate per ton; and in more than one instance the contractor has burned his fingers. No coconut oil is made now in the group, except a small quantity by the natives for their personal adornment, they being worshippers, just as Mr. Matthew Arnold says the Parisians are, of the Goddess of Lubricity. In the former days a great business was done in the oil line between here and Australia, and those were the days of abundant casks and hogheads, oil drums or "coppers," and great square iron tanks, left about in various parts of the island for the oil to be poured into and kept till the ship came round. One skipper, who sailed from Levuka to Sydney with a cargo of casks of oil, told me that when he left these casks were not quite full, that the vessel made a long run out of the tropics in one direction, consequently lying on one side all the time. That the cold weather into which she ran congealed all the oil to a hard mass in the casks, just as you may see is the case with the hair oil in a barber's shop, and that, in consequence, when she had to "go about" the cargo had a decided list to one side, which seriously affected the trim of the ship. A similar process of congealation takes place in a cargo of copra on the voyage to Europe. Looked at in a Levuka store, it seems like a railway cutting composed of brawn. But when this is in the ship's hold it gradually compacts into a solid mass, and then in the cold latitudes it freezes hard until it becomes as rock, and is a difficult subject for treatment by those who wish to get it away into the stores of Hamburg.

The principal copra merchant of Fiji is Mr. William Hennings, whose elder brother, Mr. Fred. Hennings, was the leading coconut-oil trader before copra became the fashion. A good story is told in connexion with this gentleman. Some years ago a Sydney draper, visiting an island in which he had purchased a share, found that a boat-load of visitors had come ashore, and he at once proceeded to do the honours of the island. He had been but a few days in Fiji altogether, but very kindly undertook to explain many things; and selecting a quiet and innocent-looking young man, he said good-naturedly to him, "This is a banana tree." "Ah! indeed!" was the reply gratefully accorded. Presently came another piece of information as the two stood beneath a gracious palm, whose feathery crown was rustling in the trade wind. *This is a coconut tree!* "Oh! ah! yes!" said the other, and shortly after that they parted. At lunch the two men were formally introduced, and the Sydney draper, as soon as he heard his young friend's name, discovered that he had been learnedly discoursing on bananas and coconuts to Mr. Hennings!

In closing this paper I may say that the *Government Gazette* has just been issued, giving certain trade returns for 1884-5. Therein it says that there has been a decrease in the export of copra since 1881 of 1,888½ tons, and £17,406. The amount exported in 1884 was 5,613 tons, valued at £69,612, 665 tons of this being raised outside of the colony and brought into it, as to a copra rendezvous, before the final shipment to Europe. Last year £17,980 worth went to Falmouth, £6,432 to Hamburg, £22,951 to Lisbon, and £17,344 to Liverpool, £338 to Sydney, and £2,029 to Melbourne. Lisbon and Falmouth simply mean that the vessels go there for orders, and then sail to the particular port which is fixed upon as the market. Once I saw a vessel, the "Aurora," last from Siberia clearing out of Levuka port one early morning with a cargo of copra, worth £30,000, which she was to bear to Germany.

It is held by some in Fiji that the copra production would be considerably increased were the present taxation system abolished, and a payment in money made optional. That then the natives would have additional stimulus to make the required article and use up the coconuts which otherwise go to waste; that the amount of competition which exists among the numerous traders would secure good prices to the producers, who are naturally shrewd in little financial transactions; and that the traders themselves could more quickly and economically collect the stuff and bring it to the depots. That, in fact, trade would be stimulated by that which is the soul of business—competition—instead of being deadened by what

largely approaches to a monopoly. And, lastly, that the Fijians themselves would benefit materially by being allowed to freely raise their own produce as best they like, and dispose of it when they please, and to whom they please, and as they please. There are those amongst the well-qualified to form an opinion who hold that the state would, in this way, get all her taxes, and the commerce of the country be quickened and improve. —*Australasian*.

PLANTING IN JOHORE.

Your correspondent "C. R." having asked for further information about arecanut cultivation, I have made further enquiries, and learn that arecanut trees grow best when planted in the open as a separate cultivation. When planted in conjunction with other trees, they are inclined to grow up weak and spindly. Several natives have assured me that to grow arecanuts successfully they should never be planted closer than 9 feet apart, and, if 10 feet, so much the better. They mentioned, as an instance of this, the fact that at a place, up the west coast, arecanuts were planted 5 and 6 feet apart, and a few miles further they were planted 10 feet apart, the soil being the same in both cases. The trees planted 10 feet apart give more than double the crop from the close planted piece, and the nuts are both larger and of fine quality. I fancy the arecanuts over here are the same as your correspondent mentions, viz., two, which bear large, and, comparatively speaking, soft nuts, and one with smaller, but very hard nuts. I am told the latter are generally sent to the Indian market. When I told my native friend what "C. R." says about the saving in gathering the nuts, when the trees are planted close together, he asked me, if there were no bamboos in Ceylon, for he says a long bamboo is all that is wanted. Arecanuts planted 10 feet apart in good soil over here give an average of 750 nuts per tree when six years old, and give a crop every seven to eight months. If there is any further information I can get for your friend on the above subject, I shall be happy to do so. I have seen in a Straits paper an extract from the *Ceylon Observer* giving an account of an interview with Mr. Wm. Hole, Private Secretary, to H. H. the Maharajah, of Johore. Mr. Hole rightly enough gives a very glowing account of the revenue derived from the gambier and pepper industry, but I regret to see that he thinks the European planting enterprise of so little account; in fact, he thinks it has been the cause of great loss to the Maharajah through "the construction of roads and other facilities for them." Now, I have not the slightest intention of denying that the Maharajah has given great encouragement to the European planters, having already borne testimony to that effect, but I certainly think it is very unfair to saddle the European planters with the cost of road construction, whereas, as everyone here knows, the gambier and pepper planters derive more benefit from the roads that have been made than the coffee planters do; and in fact the roads would have been made although there had not been a coffee estate in the country. It is true enough that coffee Arabia, of which Mr. Watson was the pioneer, has proved a failure, but Liberian coffee has taken its place, and will ere long more than recoup all the losses incurred on the other. No one has done more towards bringing this about than Mr. Watson has, and at the present time no one has a larger stake in the planting enterprise in Johore. While the Maharajah has given every encouragement to the European planters, he has given equal, if not greater, facilities to the Chinese gambier and pepper planters; who, while they swell the revenue of the country by the taxes on gambier, pepper, and opium, on the other hand are doing incalculable damage by the indiscriminate manner in which they carry on the cultivation. For miles on every side of Johore Bahru there is little or no forest to be seen now, where some 20 or 30 years ago there was nothing but heavy valuable timber. Now there is nothing but long stretches ofalang grass with patches of scrub and a few strips of jungle near the Jaw gambier and pepper gardens left in this locality. Now all this is caused by the Gambier and Pepper cultivators who made off to fresh land furthe

afield as soon as they found their gardens falling off in yield, instead of applying manure. From the top of any hill you will see innumerable park-like glades which are very pleasing to the eye at a distance, but on closer inspection they turn out to be cultivated and abandoned gambier and pepper gardens, the abandoned ones being overgrown withalang grass, and are in the proportion of at least 2 to 1 of those in cultivation. To enable you to understand how this state of things comes out I will try and explain the system pursued by the Chinese gambier and pepper planters. When a Chinaman wants to open a garden he generally goes off to one of his countrymen in Johore or Singapore, enters into an agreement with him to the effect that the merchant advances money, food, and opium to the planter from time to time, taking good care not to let his advances exceed, say, two-thirds the value of the garden. The planter for his part has to sell all the produce of his garden to the merchant at a fixed rate, which rate is always considerably below the real market value. You can, therefore, understand that the profits of the merchant are enormous, and that the planter is generally in debt. The gardens as a rule are from 8 to 10 acres, which are planted in the following proportions, viz., about 1 or 2 acres of pepper vines and the balance with gambier. The forest is felled and burned off as for coffee, the piece intended for pepper is dug up and prepared most carefully, pepper cuttings planted about 8 feet apart, and a jungle post about 10 feet high sunk in the ground beside each plant, to which it is eventually trained. The balance of the clearing has very small holes cut about 6 feet apart, in which young gambier plants are put and left to fight it out with thealang grass, ferns, and other weeds, which soon spring up. In 18 months from planting, the gambier gives a return which helps the planter to pull along till his 1,000 or 2,000 pepper vines begin to give crop when 3 years old. On each side of a gambier and pepper garden here is a reserve of forest 8 chains wide, in which he has the right of cutting any timber he may want for posts for his vines, firewood for boiling down his gambier or for making burned earth, which with the refuse from the gambier boilers is the only manure applied to the pepper vines when the garden is any distance from a town. If a little more care was given to the gambier, there can be no doubt that, not only would the returns be greater, but the garden would last much longer—the gambier being generally worn out long before the pepper begins to fall. As soon as the planter finds that the pepper is giving out, he looks about him for another piece of forest and starts afresh. If this kind of cultivation is allowed to grow unchecked it is only a question of time, and that of no great length, before the whole of the valuable forest in this country will be destroyed. The rise in the price of pepper some months ago has given a great impetus to the opening up of gardens.

The only remedy I can see to stop the destruction of so much valuable timber would be to try and induce the planters to grow their pepper vines on trees planted for the purpose, such as dadap, cotton tree, &c, and they might also be bound down to cultivate their gambier, at least to the extent of keeping out thealang, and, if the land was to be abandoned, the planter should be bound to plant a certain quantity of forest trees on it. It is a well-known fact that pepper grown on live trees, such as dadap and cotton, is much more lasting, costs less in cultivation, and gives more crop than it does grow on the jungle posts; and that the gambier would be all the better for a little more cultivation is also certain. When land has been "chenaed" in Ceylon it certainly deteriorates, but not to the same extent as the land here after gambier and pepper has been grown on it. In the former case "cheddy" soon grows up and eventually jungle trees, but when thealang grass once gets hold of the land nothing will grow in conjunction with it.

I am glad to see Mr. Hole spoke favorably of tea in Johore. The gentleman who is carrying out the experiment of making Olong tea in the Formosan fashion for the American market has just brought down some more men from Amoy, also boxes, lead, paper, and in fact, everything required to turn out tea similar to the

above. As soon as India labor is available, however, I fancy he will revert to the Indian method, as there is no comparison between the cost of preparation with Tamil and Chinese. Indian labor will be available very soon now, as the labor question is virtually settled and Johore will be able to get Indian labor on the same terms as Singapore and the protected native states. Mr. Hole would have been more correct had he said that the construction of a railway was contemplated. So far only a flying trace has been made for about 10 miles out of Johore Bahru in the direction of Gunung Fullai. If the proposed railway is made, it will open up a most valuable tract of country for planting purposes, and at the same time the splendid timber will be made available. I very much doubt a railway ever being made round the island of Singapore, but, if a tramway was laid down from Singapore to Kramji, on the opposite side of the island, facing Johore Bahru, I believe it would pay handsomely. The distance is about 14 miles, and 3 coaches run both ways twice daily.—G.—Local "Times."

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

PARIS, June 13.

It has now become a maxim that farming profits depend largely on the superiority of the animals maintained. Hence, the judicious breeding and rearing of domestic animals becomes the basis of successful agriculture. Inferior eat as much as well-bred stock, are more difficult to develop and to fatten. In the case of cows, the milk is less abundant, and certainly in point of quality not rich.

These ideas are rapidly sinking into the minds of Continental agriculturists. In France, especially in the breeding of horses, there is progress to note. The Government, as far as it has been able, has discouraged the covering of mares with half-bred stallions. A closer eye is kept on uares, to see they have no transmissible defects. If sire or dam has straight shoulders, or a large head, the effort is made to minimize these points, by selecting a parent which has neither of the faults. Breeding mares ought to have deep and sloping shoulders. There are breeders, who in case of draught animals, prefer the upright shoulder, but this formation is considered to be at the cost of rapidity of motion. Perhaps the truth lies between the extremes. Farmers are giving up the habit of breeding from mares too young. The mother ought to be fully developed, before being put to the stallion, and such can hardly be earlier than five years. Stallions seven years old, are considered the youngest age for breeding; their joints will thus be well-kurtted and the formation of the frame compact. Fat stallions are not in favor; obesity is a sign, not of health, but of disease. It is only when 30 months old, foals are now put to their first farm work, as an amusement rather than a task, and gently treated.

In feeding horses generally, they ought never to have too much or too little food; they must never be stinted when in the growing stage or employed at work. They must never be overfed, because, like cattle, pigs or sheep, they are not destined for the butcher. Encourage the putting on of flesh or muscle, but not of fat. Excessive feeding in animals or man induces lethargy. Now a certain amount of vigour is necessary for healthy life and work. The Percheron horses, drawing the busses and doing vau work in Paris, are now in excellent condition as compared with former years; they receive more maize, and their fodder is said to be chaffed; they get less oats, that which has taken the fire, but not the strength out of them. Experiments are being conducted to test the value of rye-bread in feeding draught horses, which is not an uncommon diet in Belgium and Germany. In Belgium, the farm horses receive white-driuks—of rye or buck—wheat flour, in water, and often a little colza oil-cake is added. The Flemish farmer seeks ever to have his horse in the best working condition.

In Central Asia, the Turcoman covers his horse day and night, to be so warm as to melt its fat, muscle being all that is wanted. Its food and water are reduced to an incredible minimum. Dry lucern is replaced by cut

straw, and oats by barley meal mixed with mutton suet. For maladies, bleedings, change of diet, and felt-applications boiled in salt water, and for cuts, washing the wound, and at night placing a poultice of horse dung, mixed in warm water. In the morning, another careful washing and dusting over with the ashes of burnt felt. In twenty-four hours cicatrization will ensue. Turkoman horses have no manes owing to the covering cloths employed, or they are cut down, so that a top knot only is left on the head. They have no bits, but a thin bridle, neither whip nor spur is employed; the reins are left loose; the horse can do 40 to 100 miles in a day of 20 or 24 hours.

Belgium is generally cited as the headquarters of crop-rotating. Putting aside all theories, no hard and fast rule can be fixed on the subject, as each country is influenced by dissimilar circumstances. The greater the variety of crops, the less the cultivator will be at the mercy of market fluctuations. Till and manure the soil efficiently, which, while ever producing, will at the same time become ameliorated. Asparagus cannot be grown on the same ground after fifteen years, yet the soil is extremely rich for any other plant. The Helianthus will kill every strawberry plant for a large distance within its reach. Why?—we do not know. The advantage of rotating crops is admitted, but local circumstances ought to dictate the details of the rotation. Never allow two crops of the same kind to follow successively, fall back on a cleansing crop that permit the land to be weeded and disperse with following.

The Vigilance Committee of Ganized, at Lyons, to watch the invasion of the phylloxera has centralized the reports of 276 sub-committees, operating over an area of 19,000 acres. The conclusions drawn are as follows:—Sulphuret of carbon gives only good results when the arable soil is less than 12 inches in depth, or when it is so argillaceous, as to become compact, or when the sub-soil is impervious. In the first case, the diffusion of the carburet is too rapid; in the second, too difficult. Further, all the vines should be treated from the first appearance of the disease not separately but collectively; apply doses of $\frac{1}{2}$ to $\frac{3}{4}$ of an ounce per square yard, and never make the injections between the vines, but never touching the latter, and close up well the holes, do not apply it when the sap is in its upward or downward movement. Manure suitably; the holes are not to be more than from 6 to 8 inches deep. The same committee has established schools to teach how to graft vines, and purchases all fertilizers, &c., for vineyards, direct from from the manufacturer.

Near Castres (Tarn), an epidemic has broken out among ducks, caused by their feeding on the leaves of the *Adiantum Glabulosum*, or Japanese lacquer. The juice of this plant is very burning, and produces inflammation of the digestive organs, ending in death.

M. de Vilmorin was in the habit of raising wheat by selecting the best grains, and the latter from the most robust ears. He found this plan defective; better to select from an entire plant, which presents the greatest regularity in point of growth, uniformity in stooling, and equality in height of stems. Thin sowings are essential to obtain these.

Ko-coff, near Morlaix, is a celebrated colony of kitchen gardeners, who send their products not only to Paris, but to England, Denmark and Russia. It may truly be said, that it was man, not nature, made there the soil. Two centuries ago, only onions were cultivated! the rocks or stones were converted into artificial soil, by application of seaweed, sea sand rich in animalcules, and manure. The seaweed proved not only a dissolvent, but a stimulant, and kept the dry and scanty earth humid; the sand prevented the clay from becoming compact and hard. All the gardens, varying in extent from one-half to ten acres, are cultivated with the spade. Two men are considered sufficient to manage an acre. The rotation is onions, carrots, parsnips and broccoli or cauliflower, not only during the same year, but on the same grounds; by means of simultaneous and catch crops, and having recourse to nursery beds, four crops are obtained from the same plot. Leeks, a-paragus, garlic and cabbage, are also extremely raised. The artichokes of Roscoff are celebrated; one

stem contains often 25 to 30 heads. Land has risen in value three-hundred-fold within the last forty years, and the cultivation keeps pace with the times, as the conscripts, after serving their period under the flag, bring back with them new ideas and fresh experience from the countries in which they have been quartered.

It is likely that agriculture will be the earliest in the field to reap the advantages from the new Congo Colonies. The copra cake is becoming a necessity for cattle feeding on the Continent, and two companies are in the course of formation, to make plantations in Belgium and French Congo, for the culture of coconut trees.

Lime is a specially valuable agent in French farming. Inquiries have been instituted, to poll as it were, French agriculturists, as to their views on that substance. The replies have been summarized as bearing on the physical and chemical action of lime on soils. The explanations of science are not quite satisfactory so far. Added to clay lands, lime opens and renders them more friable, permitting in dry seasons the moisture to ascend and bathe the parched soil, while preventing fissures and all caking chemically, lime induces decay in organic matters difficult to be decomposed, transforming them into assimilable food. Perhaps, it facilitates the liberation of potash in clays. In the form of carbonate it favors the process of nitrification, but not so powerfully as in the sulphate state. Quicklime acts contrarily.

A mixture of lime and manure is held by very many to be inimical, as it expels the ammonia. But some, remembering that azote exists in three states in manure, and in that primarily of assimilable nitric acid, whose formation lime promotes such a gain is not to be ignored. Again, lime according to competent authorities, renders also phosphoric acid assimilable. Swiss scientists hold lime is necessary in the soil to induce the action of potash. On peaty land, lime corrects acidity; in this case it should be applied in the quick form. For meadow top-dressing lime must ever be applied in the compost state; if farm yard manure be added, the earth and lime ingredients are mixed apart some time previously. The pasturages of Normandy attest the excellence of this fertilizing agent. In the case of tired land, lime should be applied in small and repeated doses.

M. Pollet prepares an excellent compost, and which doubles the yield of hay on natural meadow by mixing chaff, barn refuse, and cut straw, with phosphates, wetting the mass and so inducing fermentation. Analysis showed it was three times richer than the best farm-yard manure, and costs him about 1½ fr. per cubic yard. In Switzerland, superphosphate and sulphate of ammonia are the chief fertilizers for grass lands, and where the first plays the leading part. Strange, chloride of potassium if mixed with these is injurious but relatively excellent when applied alone.

In Germany, sugar beet after being pulled, is allowed to lie three days on the field. The leaves in fading are said to return their potash to the bulb, and as the potash is popularly held to produce the sugar, hence the explanation, why this practice adds to the saccharine richness.

PARIS, July 11.

Manure is the chief factor in the augmentation of the produce of the soil. Plants, like animals, draw their food exteriorly, and are admirable apparatuses for the transformation of mineral matters into living substances, plants not possessing like animals, the faculty of locomotion, ought, for their development, to find in the medium where they live and die—the soil and atmosphere, the elements indispensable to their existence. On the quantity of assimilable substances placed within the reach of plants during the period of their growth, will depend the intensity of their development, and consequently the richness of the yield.

Of the twelve or thirteen mineral substances, whose assembly under the influence of life make up the tissue of plants, four or at most five; but in the majority of cases, only three are what the farmer will have to take seriously into account, either to maintain or increase the fertility of the soil. These three mineral matters are: Nitrogen, potash and phosphoric acid. Lime and magnesia rarely

make default, so as to call for a direct restitution. With respect to iron, sulphur, chlorine, soda, silica, and carbon, the soil is sufficiently supplied with the first five, and the air abundantly rich with carbonic acid for the second, as never to call for special applications.

Except in the case of soils where lime has to be added for other than plant food ends, the former has only to occupy himself with potash, nitrogen, and phosphoric acid. Now the average yield of an acre of wheat in France is about 16 bushels, that which means, straw included, an annual removal from the soil of 29 lb. of azote, 27 lb. of potash, and 13 lb. of phosphoric acid. Only a part of this quantity or the moiety at most is returned to the soil under the form of manure. If then land be not unexceptionally rich, its fertility must diminish. There are grain regions in America and Italy, where such has occurred to the extent of 50 per cent. To augment the fertility of the soil, more nitrogen, potash, and phosphoric acid must be added, than what the grain, milk, meat, &c., produced, carry away, and that the ordinary supply of farm yard manure at best, only represents a part of what has been so carried off.

It was only in 1840 that Liebig and his disciples explained the true theory of exhaustion of soils. Till then, it was supposed fertility depended on organic matters. By the analysis of soils and the ashes of plants, Liebig showed that nitrogen, potash and phosphoric acid were the essential ingredients of fertility, and that the soil itself and the atmosphere sufficed for the rest. But other equally important discoveries remained to be made to complete Liebig's work: that of the absorbent power of the soil for fertilizing substances, as demonstrated by Huxtable, Thompson, and Way, and what is known as the dialytic phenomena, revealed by Graham. It was presumed that the plant took up by its roots the potash, phosphoric acid and nitrogen, that is to say, ammonia, in a solution of water, and that these matters filtered out of the soil. Now Way has demonstrated, by direct experiment, that such is not the case; they are held prisoners by the absorbent power of the earth. It is not the same with lime, soda and nitric acid which pass through the soil, as if in a filter. This explains, why in water from field drains, springs, and all land waters, these substances are present, while a trace of potash, ammonia, and phosphoric acid can hardly be there detected.

Schloesing has confirmed, that this potash, &c., cannot exist in the soil in a state of solution. On examining the liquid of fertile land, he found these nutritive minerals to be absolutely insufficient to account for the development of the plant. How then does the plant obtain its food?

Graham, Sachs, and Foeller have proved by repeated experiments, that animal or vegetable membrane has the power, when surrounded by a liquid on one side to dissolve, without filtrating a solid substance placed on the other side, but capable of being dissolved in that liquid. Now the liquid in the interior of plants is acid, and by virtue of that acidity capable of dissolving mineral phosphates in contact with the external tissue—the membrane, of the roots, and without the aid of any bathing solution form the soil itself. Hence the practical deduction, the fecundity of a soil depends, first, on the state of dissemination of the fertilizers therein, and next, on their contact with the rootlets; the more numerous this contact the better the plant will be nourished and the more superior the yield.

The farmer cannot count then on the rain to dissolve the potash, phosphoric acid, &c., he must rely on his own skill to distribute such minutely in the soil, to allow it to absorb them, and so reach the roots everywhere. The nitrates, those precious sources of nitrogen, are not absorbed by the soil, as they filter through it. Hence, apply the potash, phosphate and ammonia manures, when tilling, and cover in, as deep as the roots of the crop to be cultivated generally penetrate; but in the case of nitrates, apply them only when covering in sowings. For getting this distinction, may explain the failure of many chemical manures. M. Peterman has experimented with manures, on the same soil, at variable depths, with beet, he obtained returns differing by 33 to 41 per cent in favor of manure ploughed down 6 and 12 inches, as compared with that harrowed in,

INDIA RUBBER IN MOZAMBIQUE.

The collection of Indiarubber in Mozambique is of very recent date; but it has so rapidly extended that it now forms the largest and the most valuable export of the Colony. Not less than £50,000 worth of Indiarubber passed through the Custom-house during 1883; whereas in 1873, the export was only of the value of £443.

The rapid extension of the rubber industry is due entirely to the natives, and in its working they have been left from the very commencement to follow their own devices. An enormous number of valuable trees have been destroyed by them. They also bring into the market an inferior quality of rubber extracted from the roots of the trees. When the natives see that no more juice can be drawn from the stem, and believe the tree to be dead, it is their custom to pull up the roots, and by pounding and boiling to extract the last trace of rubber from them. It appears that the Indiarubber exported from the northern portion of the province, is drawn from only one species of plant of the genus, *Landolphia* whereas there is reason to believe that two, if not three, species exist in the same locality. Two new species of this plant, called by the natives Mbuugu and Mtolia, were sent to the Royal gardens at Kew in 1878. One of these, the Mbuugu, is to be found upon the mainland of Mozambique. Consul O'Neil has met with his species upon several parts of the coast, but now here do the natives appear to be aware of its value. Growing upon more humid soil than the species from which the rubber of Mozambique is extracted, it yields a more watery juice, which the native has not yet discovered a method of coagulating. On being asked if they never attempted to collect it, they have replied: "It is impossible, it is too watery, we can only use it for making bird traps." Smearred over and about the traps, it adheres to the feathers of the birds, and retarding their flight, makes them easy captives. There is also another species upon the coast land of Mozambique, called by the natives "Rava," utilized for the extraction of rubber, and bearing a like watery juice. The milk of both these may be coagulated by the application of the juice of the lime, as is done in the collection of a similar species of rubber in Madagascar. The market value of the rubber drawn from these plants yielding a very watery juice would probably always be less than that which is wound off by hand; for in losing weight for months after collection. "But," says the Consul, "this collection is easier, and in the untouched forests that exist of these distinct species of the rubber plant, I think I may venture to say, there lies an additional source of wealth to the province."—*Indiarubber and Gutta-percha Journal*.

THE AMERICAN RUBBER "CORNER" OF 1882.

The annual product of crude rubber amounts to many millions of dollars, and in its manufacture in America alone from 30,000,000 dols. to 40,000,000 dols. are invested. Yet within three months, by shrewd and audacious and skilful manipulations, a single individual "cornered" this commodity, forced up the price from 95 cents to 1 dol. 20 cents per pound, and kept it at the latter point for several months, notwithstanding that the nominal price of crude rubber is from 60 cents to 65 cents a pound. The man who did all this was one J. C. Gonçalves Vianna, barão de Gondoriz. He had before shown his ability as a remarkably bold and successful speculator. Once a promising clerk in the rubber exporting house of Victor Rodrigues d'Oliveira, of Pará, Brazil, he was in 1877 admitted to partnership, and soon became controlling spirit of the firm. His first great achievement was executed in 1879, when by skilful scheming he forced the price of rubber from 40 cents to 1 dol. per pound, and made for himself a fortune of several hundred thousand dollars. In 1881, he attempted a similar experiment, but this time met with less success. Treacherous contracts made by his junior partner with New York merchants involved him in great difficulties, and long negotiations, after he saw that he must fail, resulted in his paying 52,000 dols. in cash to two of the manufacturers whom he had treated most shabbily. Failing in this attempt, he next,

in July 1882, bent his energies to organize a gigantic syndicate to control the rubber market of the world. At that time the ruling price of Pará rubber was from 90 to 95 cents per pound, to which price it had been elevated by purely natural causes. Backed with heavy capital, he set to work buying the new crop as fast as it arrived at the exporting markets of Brazil. For months he seemed to be completely successful. The price of rubber went up, up, up. Manufacturers were astonished at the audacity of one man attempting to monopolize the market, and at first abstained from purchasing at the extreme price he named. But afterwards, being forced to purchase against contracts that they had already entered into for manufactured goods they excepted his terms, and sparingly, it is true, bought to protect those goods. Fortunately for the manufacturers, the early part of the season of 1882, had produced about 40 per cent. more manufactured goods than usual, and as the end of the season drew near it was seen that the supply of goods was far in excess of the demand. The price of the raw material had been forced by the Baron to a dangerous height, and for manufacturers to continue business meant for them to accumulate goods which had an unprecedented cost, and they could see no market in which to dispose of them. Therefore, they felt obliged to protect themselves, and many of them agreed at meetings held about the middle of October 1882, to close their factories until the trade should warrant their paying the extreme prices which the Baron demanded. Baffled by this unexpected flank movement, the Baron attempted to unload his enormous stock, but without success. Again finding himself blocked, and that the rubber which his friends had on hand was costing him by shrinkage in weight and interest from 60,000 dols. to 70,000 dols. per month to carry the bold speculator submitted to the inevitable, and the manufacturers soon had good reason to congratulate themselves on the success of their combination.—*Indiarubber and Gutta-percha Journal.*

THE INDIARUBBER SUPPLY.

We have referred, in previous numbers of this Journal to the important subject of the Indiarubber supply; both in connection with the wasteful methods of consumption adopted in Brazil and elsewhere, and with reference to the efforts now being made to extend the cultivation of rubber-bearing plants. That our cute American cousins are alive to this question is shown by the following paragraphs extracted from one of their mercantile journals.

The increase in the consumption of Indiarubber in this country (says the *Boston Commercial Bulletin*) has been very large within the past ten years, and more particularly within the latter half of the decade. This is owing both to the great increase in the consumption of rubber boots, shoes, and clothing, consequent upon the increase in population, and to the multitude of new uses to which rubber has been put, to the almost total exclusion of the horn. Our imports of Indiarubber are classed together with gutta-percha, both being on the free list, and being, to some extent, similar articles. They amounted to 21,646,320 lb. in the fiscal year ended June 30, 1883, and valued at 15,511,066 dols. By far the larger portion was Indiarubber. Our imports from Brazil alone footed up 8,600,000 dols. in 1883, while we imported from Central America, United States of Columbia and other South American countries, to the value of about 3,000,000 dols., and African Indiarubber, imported for the most part, viz England, foots up about 2,000,000 dols. The great bulk of our supply, however, and the best rubber also, comes from Brazil, where its collection and preparation in the crude state for shipment forms the principal resource of the two great provinces of the Amazon Valley: Pará and Amazon. Next to coffee and sugar, rubber occupies third place in Brazilian exports. Notwithstanding this, hardly any thought is given to the future of this great industry in Brazil. The same wasteful and exhaustive system of collecting the rubber which has been in vogue for half-a-century is followed today. The industry is chiefly in the hands of an uneducated and half-civilized nomad population of

Indian mixture, and is pursued in a crude way, with no thought beyond immediate profit. In consequence, millions of rubber trees have been destroyed, and many others abandoned from premature and excessive use.

The waste in this way is so great that many well informed Brazilians fear that, unless better methods are employed, this rich resource will, before many years, suffer a serious and perhaps fatal decline. In the few cases where care is exercised in not tapping trees in the months of August and September, when they change their leaves, groves have yielded continuously for thirty years, and are still in good condition. The rubber tree requires a growth of from twenty-five years before it produces the milky sap which forms the rubber. Hence little or nothing has been done to propagate the trees, and everything about the business is carried on as if the supply of trees would never give out. Brazil imposes a very heavy export-tax on rubber, amounting, state and provincial, to 22 per cent from the province of Pará and 21 per cent from the province of Amazon.—*Indiarubber and Gutta-percha Journal.*

A BOTANICAL PROBLEM.

(To the Editor of the *Pharmaceutical Journal.*)

Sir,—Witnessing the felling of some trees the other day I was surprised to find in the centre of the duramen about 3 feet from the ground, of a common elm (*Ulmus campestris*), a cavity containing about 4 ounces of a reddish, coloured substance. Now, as the aperture could not have been formed mechanically, I was curious to learn what the component parts of the peculiar earthy matter were. I found upon analysis that it was composed of about 90 per cent of iron as an oxide, with lime, silica, potash and soda, and some organic matter. As this would appear to me to be an extraordinary amount of iron to have ascended in the sap to the point stated, and by its accumulation filling the niche in the trunk, I shall be glad to hear if any of your readers and brother-chemists have witnessed a similar curious phenomenon.—A. BALL, Walton Place, East Molesey Surrey.

GATHERING CAOUTCHOUC IN EQUATORIAL AMERICA.—The tapping of the trees they had discovered was being actively carried on. The adventurers, clad in ragged pantaloons, the body naked, were behaving like demons, under the supervision of their chief, round the gigantic Figs (*Ficus*), whose bark they were tearing off by slashing it off with their hatchets. The operation reminded me of the process of gathering resin in the Lanes of Gascony. But here, instead of zinc cups to receive the resinous juice, the *caucheros* placed Heliconia leaves, on which the precious latex flowed, white as milk. The liquid was collected and poured into calabashes (*totumas*), where it soon coagulated and formed caoutchouc, ready to be packed and exported.—ED. ANDRE in *Le Tour du Monde*.

BANANA CULTURE IN HONDURAS.—Honduras is rapidly assuming importance among the larger countries in Central America. According to the *Commercial Advertiser*, it has increased 50 per cent in population in the last ten years. The lands outside of the main towns are being bought from the Government by citizens of the United States and by Germans. The object of these new settlers is to establish Banana plantations. The soil of Central America is peculiarly adapted to the growth of this fruit, which can be raised at what would seem to be a ridiculous expense. The market for Bananas in New York is good, and the sale of them pays a profit of about 20 per cent. The purchase of these lands has netted the Government about 1,500,000 dollars during the last year, and as it owns about 1,000,000 acres, there is a fair prospect of its enriching itself within the ensuing five years.—*Gardeners' Chronicle.*

THE FALL IN PRICES.

Mr. Giffen, in the able paper which he has contributed to this month's *Contemporary* on Trade Depression, leaves us in one perplexity. If his theory, which is also Mr. Goschen's, as to the fall in prices is correct—and of its correctness in the main we have no doubt—we do not see why the fall should not go on till a range of prices has been reached unheard of in our time. He maintains, and, as we think, proves, that what is called the "depression" in trade, is in a great degree imaginary. There has been a decline in the amount of business done by the nation, but it is comparatively trifling, a mere fluctuation, such as has repeatedly occurred, and much less severe than that which followed 1866. The foreign trade of the country has declined by six per cent, the goods traffic of the Railways by about one and a half per cent, and the production of pig-iron by ten per cent, but the remaining reductions are nearly imperceptible. There is no reason, as regards the general volume of business done, for the existing outcry, which is due almost exclusively to a different cause. There has been a fall in prices which has astounded, and, in some cases, ruined, the oldest calculators, and which apparently proceeds from some general and far-reaching cause, and which all over the world has brought values down to a figure previously unknown. The following table shows in a way every one can understand the range, the continuousness, and the extent of this fall in the great articles of consumption:—

Prices of Leading Wholesale Commodities in January 1873, 1879, 1883, and 1885, Compared.				
	1873.	1879.	1883.	1885.
Scotts pig-iron, per ton...	127s	48s	47s 8d	41s 9d
Coals, per ton ...	30s	19s	17s 6d	18s
Copper, Chili bars, per ton	£91	£57	£45	£48½
Straits tin, per ton	£142	£61	£93	£77½
Wheat, <i>Gazette</i> average, per qr.	55s 11d	39s 7d	40s 4d	34s 11d
— red spring, at New York, per bushel...	£1.70	£1.10	£1.18	91c.
Flour, town made, per sack 47s 6d	37s	38s	32s	32s
— New York price, per bl...	£7.55	£3.70	£4.30	£3.25
Beef, inferior, per 8 lbs...	3s 10d	2s 10d	4s 4d	4s
— prime, small, per 8 lbs	5s 3d	4s 9d	6s	5s 4d
Cotton, mid. upland, ½ lb. 10d	53d	41d	51-11ths	6d
Wool, per sack ...	£23	£13	£12	£11
Sugar, Manilla musca, per cwt 21s 6d	16s	16s 6d	10s	10s
Coffee, Ceylon, good red ..	80s	65s	78s 6d	71s
Pepper, black Malabar ½ lb. 7d	4½d	5½d	8d	8d
Saltetre, foreign, per cwt. 28s	19s	19s	15s 3d	15s 3d

A fall like this, as Mr. Giffen points out, frightens even experienced dealers, who, though they expect fluctuations, are not prepared for catastrophes; and by raising the impression that calculation is futile, embitters and depresses them even more than their losses do. They feel as if fate were against them, and actually, in some trades—notably copper—refuse to make calculations, declaring publicly that something has happened to copper, and that their experience is of no value. Moreover, though Mr. Giffen does not mention this, the fall dismays the classes most able to proclaim their sufferings aloud. The country suffers nothing from it, for the distributor and consumer reap between them the whole benefit; but the producers feel as if the heavens had suddenly been overcast. Every owner of arable land, every tropical planter, every holder of mining property, and every wool-grower has become poorer, often to a ruinous extent, and sees no prospect except of becoming poorer still. Take, as two well-known illustrations, the position of men who hold shares in Australian sheep-runs, or in the smaller copper-mines. The former have been docked of half their receipts, the latter of all, for the fall in copper has passed the point at which profit is obtainable. Naturally all these classes cry aloud, swell the volume of the dealers' complaints, and declare that the country,

which is quite unhurt, is rapidly progressing towards ruin. There has been in truth a vast transfer of property to the multitude at the expense of proprietors, and they cannot endure the process. Every man who wants copper gets it at half the price he paid in '73 and while he is silent, or perhaps even ignorant—for the coppersmith pockets much of the difference—the seller of copper cries with alarm.

The facts are unmistakable and not denied, but there is argument as to their explanation. One theory is over-production, and no doubt in some trades there has been over-production; but this cause alone could not produce so general a fall. "There is no reason," says Mr. Giffen, "to suppose that the multiplication of commodities relatively to the previous production has proceeded at a greater rate since 1873 than in the twenty years before that. Yet before 1873 prices were rising, notwithstanding the multiplication of commodities; and since that date the tendency has been to decline." There must, therefore, be some other cause; and Mr. Giffen finds it, as Mr. Goschen found it, in the appreciation of gold owing to the diminished production of the metal, and to its nearly universal adoption as the currency of the European peoples. The world has absorbed in thirteen years £200,000,000 of gold, and the annual production now scarcely repairs waste, even if with the increased quantity of coin liable to attrition it does quite repair it. There is, in fact, a "strain" upon the metal, which it can scarcely bear,—a competition for it which steadily raises its price as expressed in commodities, and which, for one curious result, has almost arrested the coinage of gold at the British Mint. For the ten years ending 1870, the Mint coined £5,000,000 a year, in 1871, nearly £10,000,000; and in 1872, £15,000,000; but since that year the average has been £1,500,000 only. There is, in truth, too little gold for the increasing business done; and as it is the universal standard in Europe and North America the "shrinkage of values" in Europe and North America has been universal, and has made all men not living on fixed incomes or on wages, perceptibly less rich.

So far, we understand Mr. Giffen and agree with him, though we might argue that he underrates the effect of quicker communications in reducing price; but we do not understand why he stops here. Why should not the demand for gold go on until it is, say, twice as dear as it is, and all prices fall away when expressed in gold to half their present amount? The demand for currency is over, perhaps, though we are not sure of that, a Russian demand being quite conceivable; but population increases, the production of commodities increases, the business of the world increases, and the new multitude of transactions have all to be paid for in gold. The production of gold, however, not only does not increase but diminishes, till it is doubtful whether, supposing no increase of demand, the regular supply would be sufficient to repair the regular waste. Gold is used-up, like everything else, and the waste in mere attrition has only this year perplexed and annoyed the British Treasury.

Why, then, should not the process go on and the sovereign, which now purchases two-thirds of a quarter of wheat, be able, say in 1900, to purchase a whole quarter, thus fining the producers of wheat by some 30 per cent of their apparent receipts? There is no reason to expect a new supply of gold, and no reason to believe, as Mr. Giffen remarks, that paper will relieve it proportionally more than it has hitherto done. If the use of cheques and bank-notes could stop the demand for gold, it ought to have done it already, and it has not done it! The truth being that such use of paper is not a substitute, but only a relief. The amount of paper employed increases with the volume of business, but it does not assume a new proportion to that business. The strain upon

gold, therefore, ought now to send all prices expressed in gold continuously down, and this is the conclusion to which Mr. Giffen evidently tends; but he abstains from a final opinion. In his last paragraph he talks of signs that the depression is over; but his permanent view is evidently expressed in these words:—"We can hardly be sure yet that the causes of the recent change in the course of prices have fully worked themselves out. For the present, the tide appears to have turned. Prices all round are somewhat higher than they were at the end of last year, and the state of the money-market is such that a further rise may be supported without a stringency supervening. But we should still rather expect from period to period a tendency in prices to fall. The annual production of gold, not having increased for ten or fifteen years, but having, if anything, slightly diminished and tending still to diminish, is now even less in proportion to the whole stock in use than the annual production was to the stock in use ten or fifteen years ago. Population and wealth at the same time are increasing at even a greater rate than they did.

The permanent tendency seems necessarily downwards. The increase of the means of production, in order to keep the supply of gold proportioned to that of commodities, should be at a greater rate and should be proportioned in some way to the mass of gold existing, and not to its annual production. But, in fact, the annual production of gold is maintained with difficulty, while that of all other commodities increases."

The fall, of course, matters nothing in the long-run to any one. The producer can accept one sovereign a quarter for his wheat just as well as two, when he is paying only one sovereign for rent and wages, instead of two, and he shares with everybody else in the general benefit of cheapness. He does not eat gold, and he gets all the things he wants for less gold than before. But men have imaginations as well as pockets; contracts, especially leases, run for years, and a reduction of wages, such as is taking place in America and is possibly coming here, involves a great deal of class fighting. There will be a great deal of misery while the process goes on, especially among producers, and a great readiness to believe in quackeries like protective duties and projects for currency reform. The bi-metallist, who has the advantage of being fanatic, will have the liveliest time of it; and we should not be surprised if the new Parliament heard a great deal about the need for paper currency. Fortunately, the leaders of opinion are tolerably sound economists; for if it were not so, most dangerous experiments might even now be tried. We have not forgotten the way in which the cry for "the dollar of our fathers" swept the United States, and have an incurable suspicion that the weak point in Democracy is its resolute ignorance and incapacity in relation to finance. It will tax itself boldly and successfully, that is certain; but whether it will bear a decline in nominal wages without bursting into fury, we none of us yet know.—Spectator.

WHITE-ANTS.—After the testimony borne by residents in Udussellawa and Madulsima, we certainly must admit the existence of white ants in Ceylon at over 4,000 feet elevation, in the dry favourable climate of Uva. Not only so, but Mr. Egan of Pundaloya shews that in that district the pests are at work up to 4,700 feet! This is quite a revelation to us. There is just one qualification that the bottom of this estate is said to border on lowlying paddy fields. Has any one found white ants in Dimbula, Dikoya, or Makeliya? We certainly thought that on the Western and Kandy side of the mountain ranges, we were correct in giving 3,500 feet as the extreme limit of the abode of these pests.

WHITE-ANTS AND OTHER INSECT PESTS.

(By an Old Planter.)

Till some years ago, when the white-ants destroyed for me thousands of cacao seedlings, I laughed to scorn all who gave them credit for touching any living tissue. I had lived among them for more than twenty years, and thought myself perfectly acquainted with their habits. That they destroy cacao plants I have seen; and am now ready to believe, on good evidence, that they will devour other things, though I have only seen the one thing myself; and even now I would like to be assured that no other enemy had prepared the tea plants for them. I know that they are ready enough to walk into a tea stem or branch that the borer has already prepared for them, but hitherto I have not discovered an attack on a healthy tea plant. Long may it be so.

I have levelled down many scores of ant-hills, but I have not found an ant the less for that; they are everywhere, and the least neglect of the necessary precautions is sure to be punished immediately, outside or in.*

Although the white-ant has spared the tea hitherto, we are not without insect enemies. The borers are not in great numbers, but I am almost daily coming on their work, and they are found alike in small twigs and stout branches.

The flush is regularly ruined on special trees by what very much resembles the work of *helopeltis*; but I have been unable to discover that or any other insect, on or about the bushes so affected.

For the first time, about two years ago, I found an insect located on several cacao plants in great numbers, hanging from the under surface of the leaves which were perforated with many holes. I cleared the plants at first by picking them by hand, but in a few days they were as numerous as ever. The cacao they had fastened on died out, as well as that free from them, and about a year ago I found them on a single tea bush, which I cut down, and it grew up again free from them. Lately the insect has made its appearance again, not on one, but on many bushes. Its presence is proclaimed by a general unhealthy look and many yellow spots on the leaves.

The only remedy I know is to cut down the bush and burn it. This insect begins life as a very minute grub, which, at its first appearance, sticks to the bark of its native leaf under a pyramidal case, which it enlarges as it grows till it assumes the form of an open bag, hung by a thread; out of this bag he comes out to feed at night, and stays inside all day. When he attains to mature grubhood, he seals himself in, and remains suspended till he comes to his perfect state. I have not succeeded in getting the perfect insect, which is probably a small beetle. The substance of the bag is as strong as shoe leather.

LONDON DOCK CHARGES ON TEA.—The comparison should be made thus: a chest of tea weighing 80 lb. to 120 lb. was under the old rates charged 2s 1d, less 50 per cent discount i.e. net 1s 0½d per chest. Under the new rate the charge for a chest of similar weight will be 1s 6d net, a difference of 5½d per chest, i.e. an addition of 44 per cent on the old net rates. As the old rates did not pay, that a change was necessary, most people were prepared to allow, but the addition has certainly been more than most people will approve, and carries the question from one extreme to the other.—Cor., *Indian Tea Gazette*.

* Levelling down the nests is not sufficient. The breeding combs and the queen ought to be scooped out and destroyed.—ED.

INFERIORITY OF THE WYNAAD COFFEE BEAN.

[See letter of Wynaad Planter's Association on page 54.—Ed.]

At the monthly general meeting of the Wynaad Planters' Association, reported in the *Madras Mail* of 20th June, a matter of great interest to those who have sunk money in Coffee estates in Wynaad and the Nilgiris was discussed, namely, the inferiority of the Wynaad coffee bean, and the low price it fetches compared with other districts and with former years, and it seems to have been resolved to address a series of questions to other Planters' Associations asking for their views and experience on the subject. The first of these questions touches on the matter of shade, and its effect on the quality of the coffee bean, and here the Wynaad Planters' Association are very nearly arriving at the conclusion of the whole matter. No one who has travelled in Coorg and Mysore with his eyes open, can but have observed that on estates noted for their fine sample, the open secret of their superior bean in simply dry climate and dense shade Mysore coffee always commands the best price in the London market, and one has only to compare a sample of it with a sample of the finest Wynaad coffee to see at once the immense superiority of the former over the latter, both in size and colour. It was at one time thought that the Mysore tree, or Munzerabad chick, as it is called, produced a finer bean than the Coorg or Wynaad tree, but this has been proved to be a fallacy, and Mysore planters are now uprooting their old Munzerabad chicks, and planting Coorg trees in their place; and to prove that the tree has nothing to do with it, I heard that last year, a well-known Mysore planter sent home the coffee from his Coorg and Munzerabad trees separate, and on reaching the London market the Coorg coffee was sold as Mysore, and the Mysore as Coorg, while I myself know estates in Wynaad and Coorg with a dry climate, where shade is being perseveringly planted, and where the coffee improves in quality and fetches a better price every year. That any proved system of estate-ownership will affect the colour of the bean I do not believe. I have heard that on some estates in Wynaad the coffee is washed, after lying only 12 hours in the vats, the superintendent thinking thereby to improve the quality of his coffee; but the result would only be dirty parchment, and no improvement in the colour of the bean. Neither do I think that it matters where the coffee is cured, although no doubt something depends on careful drying, peeling, and garbling, and I believe that this work would be most efficiently done on the Malabar Coast. The use of manure could not improve the quality of the bean, although theoretically pruning might. The manures used in Mysore are the same as those put out in Wynaad, and all manures, especially artificial and stimulating compounds, have the effect of making the trees give exhausting crops of inferior coffee. In regard to the packing of coffee, I cannot give an opinion, but I should think it would always be best to send one's coffee to the London market by a chartered coffee ship, in preference to shipping it along with a mixed cargo by P. and O. or British India steamers. To have a good sample of coffee, the shade trees must be tall, and I fear that Wynaad planters who only think of beginning to plant shade now, will have to wait some eight or ten years to see any improvement in the size and colour of their bean. Meanwhile their only chance is to try and make up for inferior quality by quantity, and it may be some melancholy satisfaction to them to hear, that the average yield of the Mysore estate is a good deal below that of Wynaad. To counterbalance his small crops, the Mysore planter pays 25 per cent less for his labour than the Wynaad planter, and as a rule it is abundant; his shade being

dense, his expenditure on weeding and pruning is reduced to a minimum, he gets a better price for his coffee, and he has practised from the first the most rigid economy in his estate expenditure. The Wynaad planter, on the other hand, has to pay a long price for labour, when he can get it; his expenditure on weeding, handling, and pruning is very heavy, his coffee fetches a wretched price, and many planters becoming involved are hampered, harassed, and harried in all their operations by their Agents on the Coast. His lot has not fallen in pleasant places, he must patiently wait on if he can, till the clouds roll by. If he has funds he can grow shade and put out manure, and should all his efforts end in failure he can at least say, "Tis not in mortals to command success,

But we'll do more, Sempronius, we'll deserve it."

—*Madras Mail*, July 1st.

[Shade for Arabian coffee may be good in the drier portions of Southern India, but the conclusion almost universally adopted in Ceylon is that where coffee will not succeed without shade it had better not be grown at all.—Ed.]

THE COLOUR OF COFFEE.

In the *Madras Weekly Mail* of 11th July, the following letters appear:—

Sir,—In your issue of the 1st July you have a letter from a correspondent who treats of a subject of immense importance to planters in general, and especially to those of the Wynaad, who have now for two years running lost money owing to the inferior colour of their coffee. Your correspondent thinks that it is an 'open secret' that it arises from want of a dry climate and dense shade, such as you may see in Coorg and Mysore. I was for two years in a broker's office in Mincing Lane, when Mysore coffee of celebrated marks was, as now, at the head of the market. But it was never colory coffee. It was, on the contrary, a thick heavy bean, and very much coated with the silver skin, and of a peculiar character of its own. It was always bought for the home trade, whereas the best colory coffee was bought for export. So that I think that as far as colour goes, your correspondent's open secret may shut up again.

But it is a fact that we in Wynaad cannot produce colory coffee? I think it is rather that we cannot get it landed in London as colory coffee. This year I sent home overland samples which were reported on and valued as colory, but when the bulk from which the samples came arrived in London the colour had gone, and the new values were not within 6/., or £6 a ton, of the former ones, though in the meantime the market quotation had slightly risen. The question is: why? ACHROMAT.

II.

Sir,—What does your correspondent mean by saying, when writing of the "inferiority of the Wynaad coffee bean," "the use of manure could not improve the quality of the bean, although theoretically pruning might." On a heavily-manured estate in Coorg as high as 62 per cent of A. has been obtained. On another estate in the Wynaad, into which manure has been poured with no sparing hand, almost as good an outturn has been reached. This estate has yielded 6½ cwt. per acre, average for eleven seasons, and 7½ for the last three, over nearly 400 acres, and the coffee is bought by grocers chiefly for the purpose of putting in their shop windows. Inasmuch as A. coffee fetches the best price, except sometimes the small percentage of peaberry, it is obvious that herein lies the chief point, and I fail to see what your correspondent means by manure not improving the quality, &c. Later on he says:—"If he (the planter) has lands, and can grow shade, and put out manure," &c. What is the manure for: to grow the shade, weeds, or improve the quality and quantity of the bean? Too much attention has been paid to what may be called extra clean weeding, and far too little to manuring. In some districts clean weeding is a necessity; in others I could name estates that have brought ruin on their owners through persisting in it. In one case the

proprietor got well into a good gravelly sub-soil the first season, and expected coffee to grow, while the real richness of his land was far on its way to the coast. Mysore coffee once held a long lead; I doubt if it does so now,—other districts have caught it up. I do not remember to have seen it noticed, that the decline of the Ceylon estates, and the agricultural depression in England followed almost immediately after the mania for artificial manures. I have seen some that remained under the trees apparently unchanged for two years. I know of another lot that was applied at the rate of 20 tons per acre, merely to report it as 'applied.' It had no visible effect of any kind, and the cost of application was mere waste of money. Artificial manure from England is dangerous stuff to touch, even if bought under a guaranteed analysis. With a freer use of bones, fish, pounce, the dry earth system of bedding cattle, and ensilaging, planters need never go out of the country for manure. Coffee is undoubtedly benefited by partial shade in some districts, but it is a question whether heavy manuring and high farming will not do more to improve Wynaad coffee than heavy shade.

A WYNAAD CHETTY.

III.

Sir,—The Honorary Secretary of the Wynaad Planters' Association having invited all those interested in coffee to give their views with regard to the present inferiority of the coffee bean in the Wynaad, I send you these few lines on that subject. The Association seeks for information on five points, the first of which refers to shade. During my connection with several estates in South and South-East Wynaad, the difference between coffee trees growing under shade, and those grown in the open, I could not help noticing; in Wynaad shade is of all things most necessary for the growth of coffee; trees grown under shade, especially that of the *attley* and *jack*, not only thrive well, but they, as a rule, bear very heavily, and produce a superior quality of bean, whereas those grown in the open, and in the same sort of soil and climate, do not seem to do half as well. I consider shade, on all estates situated under an elevation of 4,000 feet, very necessary for coffee, and, as a rule, as most of the estates in Wynaad only have an elevation of between 3 and 4,000 feet, the cultivation of attley and jack trees on coffee will tend more to the benefit of the coffee trees than patent manures. On the Nilgiris, where many of the estates are at an elevation of over 4,000 feet, shade is not required; in fact coffee trees do better in the open, and they bear heavily and produce a good quality of bean, whereas in the shade at a high elevation, the trees, although they thrive very well and produce a large bean, yet they do not bear heavily, and it takes a long time for the berries to mature and ripen. But on lowlying estates, even on the Nilgiris, shade answers very well. The second point under discussion is the curing of the coffee on the estate. This subject deserves every attention, as the proper curing of coffee on the estate sets the colour of the bean, and if the berries are allowed to ferment, either while in the cherry, or after once taken out of the vats, the colour is sure to be effected. Coffee should be sent through the pulper as soon as possible after it is picked, and on no account should it be kept in the cherry long enough to heat after pulping. No hard and fast rule can laid down as to the number of hours the coffee in the parchment should be allowed to ferment in the vats, as that will greatly depend on the time of the year, and the temperature in the vats. On the high estates of the Nilgiris between 35 to 40 hours are required to allow the coffee to ferment just to the proper degree, but on lower estates and in warmer climates less time is necessary. In Wynaad, probably 20 to 24 hours' fermentation will be found to be sufficient. Either over or under fermentation in the vats affect the colour of the bean. Care, attention and knowledge of the temperature in the vats, will soon enable every planter to come to a right decision, with regard to the number of hours required to allow coffee to ferment (without over-doing it) on his particular estate. Great care should be taken not to allow coffee to heat after it is once taken out of the vats and washed; neither should coffee be stored up thickly; plenty of ventilation

and careful spreading out of the parchment coffee is very desirable. The third question refers to the place where coffee should be cured after it leaves the estate. I do not think it matters much. When the coffee is prepared for shipment, it not the locality of the curing factory on the plains which affects the colour of the bean, but rather the care and attention paid to the coffee, after their arrival at the factory, which ensures good curing. * * *

As to the fourth question, about manure, the great object is to get the tree to thrive; it does not much matter by what manures this object is gained, provided forcing manures are not used. Cattle manure is of all manures, patent or otherwise, the best and safest, but when this cannot be had, bone and potash in small quantities and well mixed with sholah earth is a good substitute. I have often used lime with advantage for coffee on clay soils. Lime judiciously used is a great help, and tends to keep off leaf disease. I now come to the fifth and last question, with regard to the mode of packing for shipment. This subject can have but little to do with colour or whether the coffee is packed in good new double bags, or in boxes thoroughly dried. I prefer packing in double bags myself, as coffee so packed is better stored in the steamers; cases being very apt to get broken. This color of the bean will, however, suffer if packed in steamer containing sugar, &c., and consequently it is preferable to send our coffee home in one of the chartered steamers instead of the B. I. S. N. Company's boats, which carry goods of all sorts.

Coonoor, 3rd July 1885.

O. E. P. V.

In the *Mail* of 17th July the following letters appear:—

Sir,—The alleged deterioration in the color of the Wynaad coffee bean is a very serious matter for planters, and I am sure the planting community will be grateful to you for ventilating the subject in the *Mail*. That careless drying on the estate is the cause I cannot think, as far more care is now taken in this matter than formerly. Ten or fifteen years since very little pains were taken, and coffee was often despatched with the surface water just dried off. Sabonachin [*sic*, for Sabonadière!—Eo.] in his book on coffee, published in 1870, considers that two days' exposure to a hot sun is sufficient for drying coffee before despatching to the coast. Now every planter knows that this would barely bring the coffee down to 40 lb. per bushel. The old generation of planters were much against having the coffee too dry before despatching. Their reason was that coffee dried beyond a certain point would absorb moisture from the atmosphere in transit, and by this second wetting would lose color when subsequently re-dried on the coast. The rule I was taught twenty years ago was, to dry until the silver skin would rub off, and coffee so cured was always of a good color. Of late years the constant cry of the coast curers has been that the coffee has not been properly dried on the estate. I have had coffee at 30 lb. per bushel reported as "quiet wet." The consequence is that planters have dried more and more, until now coffee is generally dried to from 30 lb. to 34 lb. per bushel before despatching. This saves the coast curers trouble, but is, I believe, one reason of the bad color of our coffee. I heard from a manager of curing works last season that coffee which had been despatched at 33 lb. had turned out a better color than that from the same property at 30 lb. I, for my part, intend to go back to the old system of drying the color into the bean, and not out of it again, and let the curers grumble as much as they like. While I think the mode of drying has some effect on the color, I cannot but allow that it is small compared with that of leaf disease. The latter, I hear, is the chief cause of bad colour as well as small bean.

July 12th.

E. N.

II.

Sir,—In submitting answers called for by the Hon. Secretary, Wynaad Planters' Association, in his letter of 1st instant, it must be understood that these are mere opinions based on insufficient and altogether uncertain evidence. Taking the questions seriatim:—

1. That grown under shade is a larger and finer bean. The color too, is, probably better, but that is improved,

Ceylon produces the finest colony coffee in the world, and it is all grown in the open. Mysore coffee commands a high price for other reasons than its color.

2. Pulping green or over-ripe fruit, incipient fermentation in heaped cherry or heaped parchment. Each and all of these will affect the color of the bean injuriously. It is probable that drying in shade has a favourable effect on color.

3. Inland-cured coffee is sometimes equal to, but generally inferior to that cured on the West Coast. I have no experience of East Coast curing.

4. The best soils produce the best colored coffee. Manures enrich the soil. There can be little doubt, then, but that they exert a favorable influence on the color and quality of the bean.

5. I am not aware that different modes of packing have much effect on color, but consider that packing in double bags will best preserve the quality of the coffee. One thing is certain, that coffee grown in rich soil is superior in color to that grown in poor soil. Another thing is certain, that coffee grown a proper distance within the ghats is superior to any grown on the ghat line. This last fact is probably a mere corollary of the first. Ghat land is often very productive for a few years, but the slopes are steep, and this productiveness vanishes with the vanishing soil. So far as our knowledge goes, and this is a very small way, it is the conditions of soil and climate which chiefly influence the color of coffee. It is possible that drying under shade may affect the color of coffee. This remains to be proved. It is probable, too, that coffee grown under shade is better colored than that grown in the open. Whether this has been proved or not is of little consequence, so far as Coorg is concerned, for it is an undisputed fact that coffee will not exist in the open, beyond a very limited time. This last fact, too, may be found to have to do with deterioration of the soil. It is well known that shade preserves soil. It is further known that shade improves soil. The whole matter, then, appears to resolve itself into a question of soil, and Wynaad planters and all planters must exert themselves to keep up and improve the fertility of their estates. There must always be a great diversity of opinion as to the best methods of cultivation to bring about this result. That shade is the most important factor cannot be doubted by anyone who approaches the question with an unprejudiced mind. Manure is good for the soil, clean weeding is good for the soil, turning over is good for the soil. Good soil gives good coffee. Therefore all these methods and others are to be resorted to, if a bean of good quality and color is to be produced.

Though much of the above is mere unmastered opinion, it is all deserving of further observation and experiment. Coorg, 11th July. J. O.

III.

Sir,—I am glad to see that a discussion fraught with so much interest to planters has been started in your journal, and that you have given it your own careful attention. The consensus of opinion as yet published points to shade as absolutely necessary, and in this opinion I decidedly concur. The difference of coffee under shade and in the open is most marked, and teaches its own lesson, especially with regard to the size and appearance of the bean, and it is therefore superfluous to enlarge on the subject. I do not think, however, that what I consider the real cause of the deterioration in color, in the last year or two, has been touched upon yet, planters blaming coast curing, and coast curers giving the reort courteous to planters, but with little or no benefit to the discussion. I hold that the primary cause of the deterioration in color is the abnormally dry and hot seasons that have been experienced during the last two or three years, which prevented any early growth of foliage, and thus partly deprived the bean of its chief means of existence. In fact, I hold that coffee has been suffering from temporary asphyxia which was bound to affect the growth and color of the bean more or less. Both shaded and unshaded coffee appears to have suffered, but of course the latter far more severely; and I think that the fact of Coorg coffee having been better than Wynaad is due to the fact that in Coorg shade was extensively adopted fully five years ago, while the majority of Wynaad estates have not yet, or only recently, gone in for it. The Coorg shade, though, generally speaking, of only comparative recent growth, is

sufficient to partially benefit the coffee, and as it grows larger will do so further, while Wynaad on the contrary is still without this protection. Of course there are exceptions, and it would be interesting to ascertain if well-shaded estates have suffered as well as unshaded estates, and if so, in what proportion. I said that this was the primary cause, but of course in many cases it has been intensified by want of manure, insufficient cultivation or bad curing caused by a number of planters being so hard up. I consider, however, that these causes are secondary, and only apply to individual cases, as it is a fact that in one district in Wynaad the color of, I believe, the whole coffee was reported unfavorably on in spite of manure cultivation and careful curing; and this applied to estates belonging to different proprietors and under different managements, thus clearly indicating some natural cause which should be guarded against if not altogether prevented. Again, no mention is made of the ravages of leaf disease, which, added to by the absence of early leaf-producing rain, is enough to make the stoutest-hearted planter despair. The remedy here again is shade, and how so many years have been allowed to elapse without its adoption is a mystery. Coffee which could fight against disease and drought, is now too old to do so, and is being weakened crop after crop; and now when it requires shelter and help, it finds it not.

I have also a strong objection to the system of planting cinchona thickly amongst coffee, and I should not be at all surprised if this proved an aid in depreciating the value and appearance of coffee. Wherever coffee is seen under large and thickly planted cinchona, it is found to be in a very bad way, and I think that the same deleterious influence is exerted in different degrees, according to circumstances, by cinchona. Taking the above point of view to be correct, it is seen that the great cause of the present deterioration in coffee is produced by natural means, partially beyond the planter's control; but I maintain that, by attention to good shade, efficient cultivation and curing, and also to care in avoiding picking until the berries are fully ripe, the evil effects of unseasonable and protracted drought can be to a great extent avoided, and the general price of crops considerably improved. It does not come within the scope of the present letter to dilate on the subject of proper cultivation, this being a matter that is, or should be, well understood by planters generally; but on one point, i. e., the effects of manure, I am surprised, equally with "A Wynaad Chetty," at the statement of your correspondent in your issue of the 1st instant, that manure "could not improve the quality of the bean," and can only attribute it to an error of expression. Given a field of coffee equal in all respects, manure one-half and leave the other half unmanured, and there can be no doubt as to which half would bear the better sample of coffee. SCOR.

Nilgiris, 13th July.

IV

Sir,—I have perused with interest your leader, and your correspondents' three letters on the above subject in your issue of the 8th instant. You referred to Ceylon in your article. I am an old Ceylon planter, quite as compeited of my planting lore as any member of the brotherhood (self-approbative and severely contumacious, as the Bengalee Babu said of himself), and though a deserter, am still of opinion that the Ceylon planter is the salt of the tropical planting world, for he gives more time and puts more individuality into his work than his Indian confrere is supposed to. The remarkable growth of the tea industry is the proof, if any was required, of his pluck, good sense and ardour; he was wrecked, but for the past two or three years has been building into himself an ark. With this premise for excuse (or added insult), your planting readers will forgive me for divulging that, in Ceylon, the Indian planter is deemed guilty of taking life pretty easy, and arguing theoretically of cause and effect, when he should be learning opinions, and proving them experimentally. If this discussion becomes known to Ceylon planters, the majority will immediately conclude it is akin in nature to the constant controversy in journals devoted to tea as to the one true mode of manufacture. Tea house mysteries were quickly laid bare and called "humbug," and you must put it down to my early training in that

supercilious school that I cannot but think the present discussion smacks of twaddle also. Having told you what a very superior person I should be, now for the information which, you will permit me to add, was acquired on eight estates, all varying somewhat as to climate, soil and rainfall, and confirmed by the opinions of three old planters related to me in different degrees:—(1) "Each district, almost each group of estates, has its own particular color, due to climate and soil." Conditions being favourable, it is certain that an estate in any district in a particular year will have as good a color as is possible in that year, qualified by my remarks given below. If any portion of an estate does happen to give better color than the rest, work for it if the reason can be discovered, not forgetting that no artificial manure, but the phosphates have, so far as my experience goes, any influence on color, and they only in a very small degree.

(2.) 'Color' is reported to be modified in more or less degree by (a) 'Weather'—Deficient rainfall and a big crop. (b) 'Big Crop' invariably gives bad average color, though the first half or three-fourths of a crop may be quite up to the mark; watch the picking carefully, keep the colory separate, advising curing agents of same.

(c) *Cultivation*.—Scientific pruning and rational manuring mollify the effect of dry weather or a big crop, putting heart into the trees, as is well-known; steamed bone meal and freshly burnt coral lime gave me the boldest berry I ever picked. It topped the London market for a month, but the color could not be said to be absolutely better than the rest of the crop. It looked better truly, but the berry was so bold it shewed deep color just as a double thickness of glass is apparently deeper in hue than a single pane. Phosphates of bones and of lime are very useful in stimulating sluggish trees: trees which standing on good soil do not crop; these highly stimulating manures are death to land only too ready to bear. After a heavy crop it is the "happy despatch" I have seen a field simply extinguished.

(d) *Shade*.—If on good soil and at the lower elevations, and then only, gives good color; if the soil is wanting, crop and color are equally poor.

(e) But the greatest factor in determining color, in any particular year.

(f) *Is the stage of ripeness when the berry is picked*. The best color is attained when picking is racing dropping; it is absolutely essential for good color that the berry should be distinctly over-ripe, and with this is linked fermenting, for in that condition it ferments quickly and cleanly. Berries not fully ripe require a longer time on the cisterns, and if I am not mistaken, require to keep this maximum heat also longer to detach the mucilage. In this connection I do not altogether disregard the opinion of those who contend that damage is done to color by overheating, but I limit the possible damage to berries not fully ripe which are more liable to be affected by extraneous influences. Let any one try the experiment of allowing good ripe parchment to stand six or eight hours longer than usual in the fermenting cistern, and declare on his honor that the color was in any way affected; I have often tried and utterly failed to distinguish any harm. It stands to reason that ripeness and good quality (which most certainly is inclusive of color) are synonymous. Why should a coffee fruit be considered in a different light from other fruits? I write clearly on this point, for many young planters are so afraid of crop dropping that they lose for their crop the benefit of a week's sojourn on the trees, and that the last and most important week. Watch the rapid development of the berry in the last month in weight and in color, and then call me foolish when I say that the week lost may be a quality lost.

(g) *Condition when leaving the estate*.—I used to consider three scorching days at low elevations—and from four to seven days on the higher estates—of drying as sufficient; if kept long in store, another half day before despatch to sweeten it. For a ten days' journey coffee should not weigh more than 33 lb. per bushel, and in transit, packing in three-bushel bags is far preferable to heaping a quantity loose in a cart covered by a mat; if the coffee is not well dried, it is offering a premium to rot.

3. Very much depends on the coast curing establishment, and I would advise planters to patronize that store which has the best account sales; part of the higher prices, one may be sure, is attributable to better curing under skilled European management. Distrust all stores where the manager is not really a capable experienced man, for without the knowledge, he must depend on his native subordinates: rotten reeds in such matters at the best of times.

4. "Voyage Home."—Insist on agents choosing a quick ship and a clean cargo; what do they charge commission for?

5 "Rain."—So long as the rainfall is sufficient so much, more or less, makes not an atom of difference. If it rains so continuously that the parchment cannot be dried, keep it in wet cisterns, with water running through, and it will be sweet and colory; why should it lose its color if kept cool? Negligence excuses itself by averaging "heating;" it is an utter mistake to pre-suppose it. I have had parchment twenty-nine successive days in running water, and though it was discolored the berry inside was as well colored as the rest of that crop.

To sum up, dry weather occasionally affects color; cultivation perhaps a little. The best results may not be husbanded owing to ignorance or carelessness, but he who strictly attends to thorough ripeness when picking, and dryness when despatching, has done almost all he can for the color. Careful cultivation especially, pruning with discretion, and manuring with care gives a bold bean, enhancing the color and consequently the price: contra high-priced coffee is customarily called colory by brokers.
M. P.

Then in the *Mail* of 28th July Mr. Quarre writes:—

A. The only difference that is observable in bean matured under shade, and in the open (in the same locality) is, that the bean under shade is more elongated, and has less specific gravity, generally with a marked diminution of peaberry, and from its more moist properties ferments quickly.

B. The only means of producing the colour which influences the London brokers is by fermentation, and that of course can only be effected on the estate by the planter himself. The present failure in colour may be ascribed to the comparative small daily pickings of a few score bushels, instead of as many hundreds being heaped in the cherry loft, and after passing through the pulper being placed in capacious cold, enunam built vats. It will be obvious that fermentation generates quicker in a large mass than in a small one, and that wooden cisterns accelerate fermentation, especially if some of the previous days fermented slimy juice is left in the vats. It must also be borne in mind that longer periods are required to produce fermentation in higher elevations. I remember in the days of "bumper crops" in the bamboo district, a planter got behind with his pulping though working day and night; the cherry was tough with fermentation in the loft; and yet this excessively fermented coffee, though very badly washed for the lack of water, fetched exceptionally high rates. Native cured coffee has often a better colour than plantation. Coffee in high elevations should be fermented at least 36 hours, which fact the late Mr. C. W. Reed successfully proved on the "Gaynd Estate."

C. This would be better put. Is there no difference between coast cured coffee and those cured inland? Coffee is best cured in a dry as well as warm temperature. All things being the same, I decidedly prefer inland curing. I remember an old Civilian who had kept some coffee two years in the plains, and of which a London Broker offered to buy any quantity at any price named. The coffee gets a transparency of colour from the moisture in the bean being absorbed by dry heat, the oily matters remaining, and so influencing the colour.

D. Manure affects the size and weight of the bean; but I fail to see how it would affect the colour.

E. Packing in cases and casks preserves the colour of the coffee better than bags. All coffee pales, and becomes transparent in colour from age, as long as it is not mouldy.

In a later issue of the *Mail* appears the following letter:—

Sir,—I have been much interested in several letters on this most serious question to us Planters, published in your paper. I have perused all most carefully, and there is no doubt a good deal in all the opinions given. Cherry picked at an insufficient stage of ripeness, kept too long and allowed to heat before pulping, and leaving parchment almost dry to get wet again, are, I am almost convinced, the chief causes of bad colour. In some districts it is almost impossible to keep your coffee once nearly dry,—for you cannot store insufficiently dried parchment,—and owing to continued wet weather, however nicely covered with matting on the barbaques, rain will get through. Besides, it is very injurious to cover up half dry stuff like this. This could be remedied by having some barbaques built under rather lofty sheds, open all round, for drying parchment that has had the water fairly dried off in the open. A better plan would be to have “Pucka” tables on rails, that could be run in under the sheds in case of rain; and the extra cost would pay in the better colour of the bean. Now as to picking half ripe cherry. The natives in Wynaad never pick their coffee till it is quite purple, and almost tumbling off; they then “strip” everything at once; they do pick some green berries then, but these are either fully matured, if not, a very small percentage not worth reckoning, and I have invariably noticed that their cherry, when pounded out into clean coffee, seems to have a far superior color to our parchment coffee when pounded out. Every native will tell you their ‘purpu’ (clean) coffee has a better color than ours, for we pick half ripe coffee. Fully ripe cherry pulps easily; a far less percentage ‘cut,’ ferments much quicker for washing, and turns out a fine sample of parchment.

25th July.

COOROOMBER.

In the *Mail* of August 4th a correspondent criticizes Mr. Quarme, and gives his own ideas as follows:—

Sir,—What shall he say who cometh after the irremissible Mr. Quarme! I can only leave him to the tender mercies of my Wynaad brethren, whilst faintly breathing the hope that the latter gentlemen will not ‘fail to “make a note of it,” and henceforth refrain from picking their crops by bushels instead of by tons. It is to be hoped that Mr. Quarme is prepared to shew those reprehensible, supine Wynaad planters where those same tons are going to come from! The question under discussion, I believe, is: “What is the deterioration in quality of Wynaad grown coffee?” I refrain from answering, Sir, because I believe, those most interested are sick of theories, and the most elaborate statement of my position on this point would be met with the impatient reply: “Theory, Sir, mere theory; we have got no money to throw away on expensive theories.” For this reason I beg to be excused from expressing my views, trustworthy and well-grounded though I know them to be. Perhaps, however, I might just venture to hazard the suggestion of an heroic measure that will make my Wynaad brethren’s hair stand on end. Provided A. B. has still a decent soil to work on, but which, alas! can only show coffee bushes unable to mature their crop (or do anything decent for that matter), let him pick out the poorest bushes, carefully train the best sucker that the bush is capable of, from as low down as possible, and then stump the bush. In order to avoid all possibility of being charged with theorizing, let me here fall back upon well-proved facts, which will, however, bear recapitulation. What are some of the chief advantages derived from shade?

Firstly.—The foliage of coffee-bushes under shade is generally of a healthy, dark green colour, and altogether fit to discharge its important function healthily.

Secondly.—The soil under shade does not get caked in the hot season, and hence remains permeable to the fertilizing influence of light and air.

Thirdly.—Under shade the formation of nitrates does not proceed with such wasteful rapidity as in the open, and consequently the fertilizing elements of the soil are better conserved.

Fourthly.—Unless the shade tree be a surface feeder its roots bring up stores of fertilizing matter which the feeding rootlets of the coffee bush cannot reach, and the said coffee bush ultimately benefits on the deposit of fallen leaves.

These are only a few out of the numerous advantages to be derived from shade. In conclusion, I may quote an extract from “Engineering” which looks suspiciously like theory:—

“Recent researches by M. Maumené have shewn that the metal manganese exists in various growths as a salt of an organic acid. The proportion in cacao is very great, as it is in coffee, tobacco, and especially in tea. In the fifty grammes of ashes left by a kilogramme of tea, there were found five grammes of metallic manganese. There are plants, however, in which no manganese is found, such as oranges, lemons, onions, &c. Many medicinal plants contain it, as for example, cinchona, white mustard and the lichen (*Rocella tinctoria*). Tea, coffee and other plants require an abundance of manganese in the soil for their proper cultivation, and the absence of it may account for the failure of many plantations.”

Perhaps Mr. Hughes, of Ceylon fame, will kindly enlighten us further on the point, and Mr. M. A. Lawson will also take up the tale. Leaving these gentlemen to fight it out, I meanwhile subscribe myself.

Neilgherry Hills, 30th July.

ONE OF THEM.

Another correspondent is rather hard on Ceylon planters:—

Sir,—Your correspondent “M. P.,” must pardon me if I fail to see how he in any way explains the deterioration in colour in the last few years. In the first place, Ceylon men are and have been quite sufficiently plentiful in Wynaad to have “proved experimentally” to us how we should improve the colour, by such care as “M. P.” recommends. That their colour is no better than that of other planters is proved by the fact that the coffee from the whole district is much the same, and the leading Ceylon planter in this part is one of the most energetic enquirers at association meetings into the cause of the bad colour of Wynaad coffee. “M. P.” has shown us what the Ceylon planter thinks of himself and others. He must excuse my saying we have generally found Ceylon planters a failure here. They do not seem to be able to work with Wynaad labour, and therefore, perhaps, we rarely see the results we expect after so much lecturing. The crux which “M. P.” fails to explain, is why the same men on the same estates, several of them superior Ceylon men, and working far more carefully than they did six years ago, cannot produce anything like the bean they did then at a far lower cost. And why, may I ask, “M. P.” was Ceylon coffee such a wretchedly poor sample in London during 1884, if curing has anything at all to do with it? There can be no doubt at all of the cause. The one great change in our conditions in the last fifteen years has been the advent of leaf disease. This did not tell much on the sample for six or seven years, but now it has, and more especially on crop taken from trees grown from diseased beans, or say, since 1873, by which time the disease was fairly established and telling on the old trees. Young coffee does not grow and cover the ground as it did fifteen years ago, even though planted on similar soil alongside magnificent old trees. It grows well till the first check from crop or drought, and then loses every leaf with leaf disease. If vigorous coffee on good land, it will look magnificent again in three months, but only these drains on the trees which ruin the sample. Now for a remedy. One has been found in leaving the ghaat, and going inland to bamboo land, where the sample always has been better than on the average ghaat estates, but which formerly was shunned on account of borer, drought killing the trees after a few magnificent crops, and fever killing the planter. Shade now saves the trees, and clearing has checked the fever, but I doubt very much if shade gives the colour. Climate, a dry, not forcing climate, gives the colour and boldness; and shade is necessary for the coffee to last. Mysore and Coorg are both too hot and dry for coffee without shade, but it does not therefore follow that shade and not climate is the cause. A second remedy is a cattle manure with a little bone dust, a sure and certain remedy with or without shade, but as it costs at least

R60 per acre, what planter can afford it now even once in two years? A third remedy may possibly be found in bone dust and potash, with or without peonac applied under shade. This could be applied for half the cost of cattle manure, but is apt, without a shade, to kill the trees with overcropping, putting my experience is a heavy crop 11 cwt. per acre, on the trees of a very inferior sample. Shade I think it very possible may succour the trees by shielding them from the sun, when it is hottest, and when exhausted by a heavy crop they are least able to bear it, and by adding vegetable mould, that is moisture and depth of soil, for the roots to work in. But it remains to be proved if any but bamboo estates will crop under shade, and will not suffer in the rains from leaf rot. In any case, I doubt if shade has any effect on colour, beyond shielding from strain, trees forced either by climate or phosphates into heavy cropping. Of course the less strain on your tree the more vigorous it is, and the more vigorous your tree the better your sample. But shade alone will not do it. The best Coorg estates are all very heavily manured with bones and peonac, and would not crop without it. Your correspondent "Scot" is inclined to attribute the falling-off of the sample to planting cinchona among the coffee, and rightly says coffee under large and thickly-planted cinchonas is found to be in a very bad way. But can he tell me if any trees under which "if large and thickly planted," coffee would not be in a bad way? If he spends as much money lopping his cinchonas as Coorg planters do lopping their shade, he will find he can grow cinchonas ten feet by ten in his coffee, and it will be all the better for them, and certainly none the worse for six or seven years. In time he may have to thin them out, but it is only a question of light, and not of the cinchona eating up the coffee, or poisoning it. At least that is the experience of S. Wynaad, 23rd July. AN INDIAN PLANTER.

A question of great interest to planters has recently arisen as to the causes of the deterioration of the coffee bean from the standard of former years. Complaints on this subject appear to be general both in Coorg and in Wynaad, but it is in the latter district that cultivators have suffered most. The Wynaad Planters' Association has taken the matter up, and has circulated amongst similar bodies in Southern India a number of questions, in the replies to which, it is hoped, some remedy will be suggested. A correspondent who is familiar with the Mysore coffee plantation, and whose letter was published on the 1st instant, attributes the undoubtedly superior colour of the Mysore bean to the dense shade under which it is grown, and to the dryness of the climate; he says that Wynaad planters are only now beginning to grow shade, and that they must wait another ten years until it has sprung up sufficiently for any improvement in prices. Happily for the Wynaad men, few of whom, we imagine, could stand another decade of depression, our correspondent has fallen into the common error of confounding the *post hoc* with the *propter hoc*. He forgets that the Ceylon coffee grown under diametrically opposite conditions to those prevailing in Mysore, without a stick of shade, and in a damper climate than Wynaad, fetches a high price in the London market. Besides this, it was pointed out some months back in the *Madras Mail* that Wynaad planters are not now only beginning to plant shade, they have been doing so extensively for several years, and none of them would now omit to put out shade-trees with their coffee plants. Moreover, the marked badness of colour has only been noticed within the last year or two. The explanation must then be sought elsewhere.

Does the fault lie with the method of cultivation on the estates, or with the treatment the coffee receives in the curing yards on the Coast? The coast firms are naturally anxious to shift the blame on to the planters, and say that the coffee is picked either before it is ripe, or after it is too ripe, that it is sent down too wet, and that sufficient care is not taken of it on the estates. On the other hand, it has been remarked that no difference of treatment on the various plantations appears

to have made any difference in universally bad prices realized. Whether the coffee was grown in the open or under shade, whether it was manured with cattle or artificial manure, or not manured at all, whether weighing 40 lb. or 30 lb. a bushel when despatched to the Coast, the result was equally disheartening. Of course there may be something in a district having got a bad name, in a past season for want of colour, and buyers being thus made distrustful; but the awkward fact remains, that the overland post samples were in many cases valued in London at £10 or £15 a ton more than the bulk—from which these samples were, presumably, taken—realized when it reached home, the market not having fallen in the interval. The samples of Wynaad coffee in particular were pronounced, both in India and in London, to be unusually good, while the bulk was phenomenally bad. This points to some mismanagement in the curing yards in preparing for shipment if the samples were fairly taken. Here we would draw attention to what our correspondents say in their letters which appear in another page. It might be worth considering whether the reduction in the curing charges, which was almost forced upon the coast firms three years ago, has not led to careless working. It is generally supposed that in a good season the average profit on curing a ton of coffee is R17; at present rates, this would seem quite sufficient. If, however, the drying and packing are badly done, it would perhaps pay planters to return to the old tariff. If the plan now usually adopted, of shipping coffee in double sacks, does not ensure its arriving in good condition, the R5 a ton that was taken off would be well expended on barrels or airtight cases. In the matter of shipping, we would again question the accuracy of the correspondent whose letter we have already noticed, and ask why he considers it better to send coffee by chartered steamers than by the British India line. As a matter of policy it may be well to support the former and keep alive a healthy opposition, but it would be difficult to persuade us that coffee arrives in a worse condition after a voyage of five weeks, than after it has been knocking about the coast for a month between Cochin, Calicut and Tellicherry, in one of the chartered steamers, which then takes about eight weeks more on the way home.

So far as we can judge from the evidence already brought forward on the subject, we are inclined to think that, while a certain amount of mismanagement may be charged against the coast firms, planters are also to some extent to blame. It is a bad time to recommend the letter to provide increased store room, and to spend more money on drying the coffee on their estates. But the low prices they have obtained, are to be attributed partly to their want of attention to these two matters, and they should be considered with the first gleam of returning prosperity, which, we hope, will not be so long in coming as our correspondent suggests. In a rainy crop time the parchment is often allowed to get wet after it has been taken out of the vats, and it is even heaped up in an unventilated store before it is properly dried. Should the experimental plantations, suggested by Mr. Clarke, in the essay we recently reviewed, be established, no doubt this deterioration will be one of the first questions investigated. In the meantime it is no good telling planters, as our correspondent does, "to wait till the clouds roll by;" the clouds have been rolling by the planter for the last five years, and the horizon shows little sign of clearing. It was not by howling that hackneyed ditty that the Ceylon planters lifted themselves out of the ruin caused by the failure of their coffee. With all their brag and affected contempt for other districts, there is much in their conduct that Indian planters would do well to imitate. As long as they could get money to work their coffee, they maintained that no one but themselves understood the art; when four-fifths of the coffee acreage in the island was utterly ruined, they boldly went on for cinchona, and announced to the world that Ceylon was the only country where it could be grown to a profit. Finding this disproved by the hard logic of fact, they rooted out their cinchona and replaced it with tea; and now they gaily talk of driving the Indian and Chinese tea out of the market. In a year or two more they may be digging

up their tea bushes and proving in the Colombo papers that, as an orange-growing country they are on the high road to smash Florida. As a matter of fact, the Ceylon planters are having as hard a time as their Indian brothers; but they manage to keep a bold face to the world, and to attract capital to their industries. With the millions of cachaona that are coming forward in Wynaad and elsewhere, and with the possibilities opened out by the introduction of such products as tea, coca, and fibre, our own planters have no reason to be so extremely despondent.—*Madras Mail*.

TEA IN THE LOWCOUNTRY: ITS TENDENCY TO BLOSSOM.—The following extracts from a private report are given as interesting and perhaps likely to be useful to tea planters. The tendency of tea bushes grown in the hot, ferocious climate of the lowcountry to produce blossom in their early stages instead of leaf is general and has been intensified by the peculiar season this year, but the tendency can be counteracted by judicious pruning and other means. We should be glad to hear from planters who have had experience of this tendency of bushes to flower and who have successfully checked it.

3rd August, 1885.

I have been through —'s tea fields. The oldest patch is in its fifth year, and the rest a year younger, and they loosely estimate the crop of the last twelve months at 200 lb. per acre. In the oldest field the bushes are large, many of them four feet in diameter, and the best jats fully as much in height. They have evidently kept it very close plucked, and high and low, wherever young leaf was. It now appears to me that it will flush no more, till it has been severely pruned, as every bush on the place has masses of flower bud, at every remaining leaf; indeed the whole place is as bad as the worst you saw here, and worse, for the bushes are so much larger, and none of it has been pruned hitherto. They have no advantage over us in their soil, and the growth of the plants is not for their age better. The weed of the land is pasture grass, which is manetic weeded, and buried from time to time in deep holes. They are planting up more land, which was originally planted with coconuts, and swallowed up in jungle. On re-clearing they are taking a crop of kurakkan, while the plants are coming forward in the nurseries—an idea somewhat nstive.

I have no doubt, that if the fields are thoroughly pruned, within this and the next month, that the crop of the next twelve months will be very much greater than in the past season, and that, at present prices, it will pay well.

Mr. — holds, that August is the proper pruning month for this district. He may be right, but I am not prepared to give in my adhesion to this view, till I am better informed. If we are to be troubled every year with this terrible rash of flower bud, I am at present inclined to spring, instead of autumn pruning. Every joint of old wood on the bush in May will produce its bunch of flower bud, and not a new flush-yielding branch, while the growth that extends the old wood is followed up by flower bud to the very points; therefore it appears to me, that spring pruning will be better than autumn pruning in forcing the growth into young flush-bearing wood, instead of wasting the strength of the bush in a useless product. It seems reasonable to suppose that a pound of flower bud will take as much out of the plant as a pound of leaf, and be one of the chief points of scientific treatment required, is to repel the one and force on the other. I believe I will be able to keep last year's planting from running to flower, when the season returns, without much trouble, and what has been done, and is doing, for the two-year old plants is telling already, in the promise of a regular succession of flushes, which we have not had hitherto. The great point is to permit no waste growth, by cutting back all the shoots that rush up a foot above everything else in a few days; then suddenly stopping, and growing a cluster of flower buds at every leaf. I believe that it will be well to keep a party always at work, heading back irregular growth, and cutting out hidebound wood.

THE "TROPICAL AGRICULTURIST."—I am very glad to bear testimony to its very great value, not only to people in Ceylon but to anyone interested in agriculture or planting all the world over.—*Cor.*

ACCORDING to Mr. Leeds, a dental surgeon of New York, caffeine has been found of greater use than cocaine in operations upon very sensitive teeth.—*Burgoyne, Burbridge, Cyriax, and Farries' Monthly Export Prices Current*

THE WASTE CUTTINGS OF CORK are now being employed for making bricks, which can be used for walls, impervious alike to heat or damp. The cork cuttings are reduced to powder in a mortar and mixed with lime or clay, and from this composition the bricks are made in the usual way.—*Overland Mail*.

TEA IN WESTERN HAPUTALE.—We are glad to learn of progress in this district with tea. A correspondent writing on Aug. 5th says:—"I have been busy with tea planting here the last two or three years, but only began with a small acreage, about 10—wish it had been more, as the growth and the flushing are very satisfactory. You will be glad to hear tea over this side seems likely to do well, two samples I sent down to Colombo taken from the bulk being valued respectively:—Orange pekoe 2s 4d to 2s 6d (London value); Pekoe and sonchong 1s 8d to 1s 9d (London value). I was under the impression that July and August being such dry months would check the flushes, but so far the trees seem to flush as well, if not better, than during moist weather. We are getting good weather for our coffee, a product in which I still have faith."

CAVE'S MONTHLY REVIEW.—The July-August number has reached us, the contents being as varied as usual. We quote the following letter:—

DEAR SIRS,—IN THE CITY OF SUNSHINE, by Alexander Allardyce, Vol. I. p. 61, I read, "—fresh leaves of the LIM tree were scattered over the bookcase to repel the white ants, the Indian bibliophile's greatest enemies."

Can you or any of your numerous readers, inform me.—

(1.) What is the Botanical name of the LIM TREE?"

(2.) Whether the tree grows in Ceylon, and if so, by what name or names is it commonly known?—I am, dear sirs, yours sincerely,

A CEYLON BIBLIOPHILE.

The *lim* or *nim* tree (*l* and *n* being constantly interchanged in Hindustani) is the *Azadirachta indica*, which, according to Roxburgh, grows throughout Ceylon as well as India and Burma. Every part of the tree is intensely bitter, the oil extracted from its seeds being the well-known *margosa* oil.

WHITE BUG ON TEA.—A planter sends us a tea leaf covered with white scales, and asks:—"Is this another 'enemy'?" Our entomological referee writes:—"Egg-cases and young of a white or mealy bug; probably Nietner's *Pseudococcus odonidum*; see 'Enemies of the Coffee Tree,' page 5." The following is what Nietner says:—

The insects, in all stages of development, are found all the year round, the propagation being continuous. It appears to me, however, that the males are most plentiful about June and January, than at any other season. They affect dry, hot localities, and are found as well on the branches as on the roots of the trees, to about 1 foot under ground. The eggs are actually laid and enveloped in a white cottony substance; they are oval and of yellow colour. I am not sure that there are not two species in the island, as I find some communities rather flatter and more densely covered with mealy. However, these may be local varieties. The white bug of the Ceylon coffee-tree seems to be identical with the species which is naturalized in the conservatories of Europe, and is perhaps a cosmopolitan. It is closely allied to the *Pseudoc. Cacti* of Linnaeus, the Cochinal insect. There are several insects in the island, resembling the white bug, but being of the size of a six-penny, and even shilling-piece, these belong to the *g. Dorthesia*, and I have generally found the up-country species upon the stem of a Laurel—*Tetraneura Gardineri*, *Thw.*

RICE CULTIVATION IN CEYLON.

We can do no more today (12th Aug.) than call attention to Mr. Elliott's paper on this important subject and the discussion which took place thereon last night at the Colombo Museum. The information thus afforded has a very real practical bearing on a good many controversies which have arisen from time to time in the Planters' Association and the press. We think Mr. Elliott makes out a good case for the success of Irrigation works and the satisfactory result of rice cultivation in certain favourite localities in Ceylon—*malgré* the extraordinary Bluebook returns of the grain crops of recent years from the Batticaloa district. But we quite as strongly hold that in respect of the commencement of large, expensive Irrigation works in other directions, a heavy responsibility rests on the Government to make quite sure of their estimates and of their cultivators being really available, before voting further big sums of public money. Mr. Elliott in replying last night alluded to the field presented in the North and East of the island for an extension of Irrigation which would attract the surplus population of the Jaffna peninsula; but surely (although no mention was made of it) the ominous name of "Kantalsy" must have been at once suggested to the memory of many present. To a continuance of good work in restoring tanks and channels and supplying sluices among the settled agricultural population, no objection can of course be taken; but the less said about further large works, surely the better, until, at least, the result of the very extensive and costly operations now going on at Kalawewa can be fairly appreciated.

It is not perhaps of much use referring to Bluebook returns, after what has been said about them; but we have really no other way of showing even approximately the Grain Supply of the country. In the following return, the first column is made up from the Bluebook, the rest from the Customs Accounts:—

YEARLY PRODUCTION OF RICE AND FINE GRAIN.	IMPORTED RICE ENTERED FOR CONSUMPTION.	IMPORTED PADDY IN UNRESERVED TO REPRESENT RICE*	TOTAL CONSUMPTION OF RICE	
Bushels.	Bushels.	Bushels.	Bushels.	
1865	4,693,605	4,694,119	453,376	9,841,300

* Paddy (rice in the husk) imported at Colombo is chiefly used for horse food, but in the Northern Province it is introduced and converted into rice, for human consumption at the rate of 2 bushels of paddy to one of clean rice in bulk, but in weight 1 bushel paddy is equal to two-thirds of a bushel of rice.

† Return of production not published for this year, found to be defective, and so we have taken the same figures as in 1876.

The Bluebook returns of produce are made up for bushels of paddy and these have hitherto almost universally been reckoned in rice in Ceylon by the simple process of dividing by two—2 bushels paddy equal one of rice. This is true as regards bulk. But some years ago very careful experiments made in India proved that, by weight, three bushels of paddy when unhusked equalled two of rice and this is the proper proportion on which our table is now based. As regards the two districts—Matara and Batticaloa, the contrast between careful and progressive and careless or backward returns is so striking that we cannot do better than quote as follows:—

MATARA DISTRICT.

	Area Cultivated.	Crop Paddy.	Bushels Per Acre.
	<i>Acres.</i>	<i>Bushels.</i>	
1870	30,600	500,000	17
1876	5,583	711,610	20
1883	4,000	776,000	17
1884	47,000	768,000	16

BATTICALOA DISTRICT.

1870	58,000	1,412,000	24
1876	59,000	963,000	16
1883	58,000	680,000	11
1884	67,550	418,000	6

As far back as authentic history extends, Ceylon has been dependent on India for a portion of her grain supply, and so long as there is a large immigrant, or even urban population to support, we do not think it is probable we shall ever be independent. Nevertheless the importance of maintaining and extending local rain culture whenever that can be done with profit to both Government and people cannot be denied. That irrigation will work wonders for any branch of agriculture when systematically applied is almost an axiom all the world over. In California and Florida we found farmers and horticulturists ready to affirm that with irrigation they could raise as much on 10 acres as could be got from 100 unirrigated. But the cost was heavy—as high as £7 10s per acre for supplying 12 inches of water over the soil per annum. The point however is whether in Ceylon, the Government should not devote a portion of their annual "irrigation" vote and some share of the energies of their revenue officers in certain localities to the encouragement of other branches of agriculture besides rice. What was mentioned last night about the change which native enterprise and capital, unaided by Government, has wrought in the Mahaaya Valley through coconut cultivation, surely teaches a lesson which ought not to be lost on the authorities. If Agents did more in suitable districts to encourage and induce the people to plant palms and other fruit trees (as lasting a culture as grain), and now within the rainy zone, tea, we feel sure, that local prosperity would be promoted quite as much as by rice culture. It may be of interest, perhaps, at this time to give the detailed figures showing—so far as the external trade can—the change wrought by the native extension of coconut cultivation within the present generation in Ceylon:—

EXPORT TRADE (CUSTOMS RETURNS).

	1855	1885.
	Cwt.	Cwt.
COCONUT OIL...	83,000	384,000
COIR	48,000	113,000
COPRA	52,000	262,000
POONAC	nil	77,000
COONUTS	12 million	23 millions

Total value of Coconut produce exported... about £2,000,000; about £8,000,000 Here there is certainly one branch of agriculture eminently successful among the natives of Ceylon. The strange circumstance is that the same people who

so readily go in for coconuts with their capital do not care to extend paddy cultivation, even when they have found it to be largely profitable. We remember one native gentleman telling us that the sale of the *straw* from his fields near Colombo repaid his expenses, the paddy crop being all profit, and yet he and his neighbours did not seem eager to extend this cultivation in the same way that they looked after more coconut land. In this way, it may be said that Colombo natives with means do not require encouragement to plant palms and fruit trees, but in other localities the Agents might do much to make a beginning and also to introduce new products. We want, in fact, every Revenue District in the island to have its Experimental Farm or Garden and Annual Agri-Horticultural Show.

"RICE CULTIVATION UNDER IRRIGATION IN CEYLON."

At the meeting last evening (August 11th) in the Colombo Museum to hear Mr. Elliott's paper on this subject, there were present Hon. W. H. Ravencroft (in the Chair), Hon. P. Rama Nathan and R. A. Bosaquet, Messrs. A. M. Ferguson, C.M.C., T. Berwick, J. Capper, A. R. Dawson, H. W. Green, J. B. Cull, E. B. Hurley, R. W. Ievers, J. G. Wardrop, A. M. Ferguson, junior, D. W. Ferguson, W. J. Boake, J. Ferguson, J. J. Grinlinton, W. P. Ranasinghe, J. G. Dean, Treasurer, and W. E. Davidson, Secretary, besides several ladies. After reading the minutes of last meeting, the following new members were proposed and accepted—Messrs. J. Alexander, A. W. Cave, P. de Saram and W. Wrightson.

Mr. ELLIOTT then read his Paper, which, from its important bearing on the agricultural interests of the country, and on a subject hotly contested by planting and other critics of Government measures, we reprint in full as follows:—

PAPER READ BEFORE THE ROYAL ASIATIC SOCIETY, CEYLON BRANCH, 11TH AUGUST 1885, BY E. ELLIOTT, C.C.S.

For many years there has been a widely accepted idea that rice cultivation in Ceylon does not pay. A dictum of Sir C. P. Layard has been generally quoted in support of this, and two writers many years ago* published certain statistics which appeared confirmatory of this unfavourable view; and these were, I believe, allowed to pass unchallenged, though they contained errors, which materially affect the result. However, whether erroneous or not, these opinions and figures referred to a time and to districts, where the attempt had not then been made to provide irrigation. This fact has been overlooked in recent discussions; indeed, both writers and speakers have gone further, and have asserted that it would probably pay better to import nearly all the rice required in the Island, as it is doubtful whether Ceylon can economically compete with India in the production of paddy.

For many years past, I have been unable to accept the low estimate made as to the small profit to be derived from paddy cultivation; but whatever doubts I may have had on this point have been entirely removed by my observation of the effects of irrigation, where that has been provided on a satisfactory basis.

Since the question has been so prominently revived, I have taken considerable trouble to further investigate the subject; and I have been able to collect a very large and varied mass of data as to the yield of paddy, as well as to the actual outlay necessary to bring a crop to maturity in the irrigated lands of the Matara and Batticaloa districts.

The results proved so far more favourable to Ceylon than I had ventured to anticipate, that, when invited by

* Mr. Ludovici's "Paddy Cultivation," and "Speculum" Letters. In "Speculum's" estimate, outlay in labor is excessive, especially for watching, reaping, threshing and husking, while Ludovici takes too high a rate of wages, 7d as the value of a day's labor in a district where no agricultural labor was at the time remunerated in money. Other points in his calculation are equally open to question.

the Committee of this Society to contribute a paper, I readily accepted the opportunity for making my researches public, in the hope of being able to remove doubts which might exist as to the possibility of growing paddy in Ceylon at a cheaper rate than it can be imported from India.

In discussing this question, it is convenient first to review shortly the information available, especially as regards the superior fertility of rice land in India. I have been unable to meet with any reliable returns of the yield of grain in North India, but I recently saw it stated in the newspapers that the average crop in Burma was 42 bushels per acre, and that 1,500 lb. weight of paddy had been harvested from an acre of land in Bengal. The latter is equal to 30 English bushels by measurement or a return of 12 fold according to the ordinary Ceylon rate of sowing. Much reliance cannot be placed on such casual notices as indicating the regular returns from an extended area; but fortunately I have had access to the transactions of the revenue settlement of parts of the Madras Presidency, in which very elaborate statistics are given of the yield of various soils in the irrigated and rich districts, served by the works on the Godavery and Cauvery rivers.

In these publications I find it recorded, that in the Godavery delta soil of good quality will produce, under irrigation, about two poories of 800 seers of paddy per acre, and the next sort about one-and-a-half poories. For the inferior soil about one poory per acre may be assumed. As the poory of paddy weighs 1,200 to 1,400 lb this yield is equivalent to 50, 40 and 26 bushels per acre.

In South Arcot, in the doab of the Coleroon and Vellar which is irrigated by the lower Coleroon anicut, it is stated that 300 experiments gave the following results:—

	Per Acre.	Harris Collums.*	English Bushels.
Island and other alluvial deposits ...	45	47½	
Permanently improved lands near village	40	42½	
Best lands with vandel or sandal† ...	35	38	
Ordinary " " " " " " " " " " " "	30	32	
Best ordinary rich in sandal " " " " " " " " " " " "	40	42½	
Good ordinary " " " " " " " " " " " "	35	38	
Ordinary " " " " " " " " " " " "	30	32	
Ordinary red earth " " " " " " " " " " " "	25	26½	

Col. Baird Smith, in writing of the irrigation works on the Cauvery and Coleroon, gives the average yield in the irrigated lands at 40 bushels per acre; and in his work on Italian irrigation expresses no surprise on learning that in the permanent rice lands of Mantua and Verona the average produce per acre was estimated at 30 to 35 bushels of uncleaned grain, while the temporary land in the same and adjoining provinces yield about one-fifth more or 40 bushels an acre. He adds: "The process of cleaning reduces the rice to about one-third its bulk, so that for permanent land the produce would be nearly 13 bushels of rice."

In a recent order of the Madras Government reviewing the working of the Sydapet Farm, it is recorded that in the reply given by the Director of the Revenue Settlement to the Famine Commission, the average yield per acre of rice lands in this Presidency is stated to be 1,684 lb., and in some localities it exceeds 2,600 lb. These figures represent 35 and 50 English bushels of paddy, and would in the agricultural parlance of Ceylon be spoken of as equivalent to a yield of 15- to 20-fold, on a sowing of 2½ bushels per acre.

It must be remembered that these data are drawn from the hurried trial measurements of the settlement officers, and it has been recently urged, that as these results are deduced from experiments on a limited scale, the tendency is to exaggerated results.

Nor must it be overlooked that there is in India a system of cultivation which is decidedly superior in many respects to that followed in this island; and I have been also assured that in the Madras Presidency much more manuring is done than in Ceylon, though there is still room for improvement in this respect.

Turning to Ceylon, the first matter to be dealt with is the cost of cultivation; and on this point I am able to

* Harris Collum=24 Madras Standard seers of 100 cubic inches=1.06 English bushels.

† Fine mud deposited by the floods.

give very full information, the result of personal enquiry in the Matara and Batticaloa districts. As the details of cultivation differ in many respects in these districts, it is necessary to give a short outline of the practice in each.

In Matara, one or more cultivators jointly undertake the tillage of a field. One at least of these men has generally a proprietary interest in the land. There is no hiring of coolies or money payments for any additional requirements. The work is done on the co-operative or Bee system, neighbours mutually assisting each other without any special remuneration, beyond a good meal provided by the individual whose land is being tilled.

The cultivation of paddy has been so extended in the Matara district, and the available land is so incessantly under crop (two harvests being almost invariably taken from the same land in the irrigated villages), that there is little or no grazing ground left for cattle, and the buffaloes especially have to be driven long distances,* some beyond Tangalla, some 15 miles away, for pasturage.

In consequence of this difficulty and the abundant supply of labor, cattle are very little used and the fields are almost entirely tilled with the mamoty. The soil is dug up and turned three times and then sown, and this occupies a man about 40 days for an area of an amunam or 2½ acres.

As the cattle are folded or driven away, there is no fencing to be done, and watching too has been nearly given up, as all the people live in gardens bordering the fields; and there are no wild animals, such as pigs or elephants, to be guarded against.

Reaping an amunam extent occupies a man 16 days, and threshing and winnowing about 30 days for an average good crop. Allowing a margin for contingencies, the cultivation and harvesting of an amunam of land in the irrigated villages of the Matara district require 90 days of a man's labor or 36 days† per acre; besides an outlay of about 4 bushels of paddy for seed and tools.

I may here mention that Mr. Weeracoddy, in the report of his experiment in Kegalla, gives 34 days per acre as his outlay in labor, inclusive of certain permanent improvements he had to undertake.

In Batticaloa the arrangements for cultivation are not so simple, while the lands are more extensive and a smaller portion of proprietors cultivate their own lands. There are two extensive harvests in each year, known as the "Munmari," which may be termed the winter crop, and the "Kalawellamai," or Spring crop.

For the "Munmari" it is usual to engage cultivators, of whom one is termed the head field servant or Mollakkaran, who has certain privileges and supervises the other three field servants, or four in all, required for an extent of ten amunams. As the long drought which prevails during the south-west monsoon hardens the ground, it is usual to wait for the light rains of September to soften the soil before beginning to plough.

The object kept in view in ploughing with the small native implement (which is similar to that used in other parts of the Island) is by frequently going over the land to thoroughly pulverize the soil. The seed is then sown broadcast without being germinated, and left to spring up by itself under the influence of the first rains, ploughing and sowing going on until stopped by the heavy rains of October. A description of paddy which takes six months to mature is sown at first, and latterly one which requires four months. By this means the most is made of the time favourable to sowing, while the rush at harvest is reduced by the crop not all ripening at the same time.

Cattle are hired for ploughing, and payment made in paddy varying (for a ten amunam extent) from six amunams in the Southern district to four amunams in the Northern, where cattle are more plentiful in proportion to the arable area.

* In Matara district, in 1882, the number of buffaloes was only 10,162, and in the chief irrigated patta, the Gangabodde, only 1,800, or one to every 8 acres. In Batticaloa the number was 36,639 in 1882 or about 1 to every 2 acres cultivated with paddy.

† I find Ludovici in his rice cultivation estimates the labor for cultivating an acre at very nearly the same number of days.

In October and November the field servants complete the fences and repair the ridges, &c.; and ordinarily for three months after this they have but little to do, beyond sleeping at night in the watch-buts, though they are supposed at intervals to patrol the fences. Their days are practically free, and they can engage, if so inclined, in other occupations, which will not take them too far away. As a fact, all grow plots of vegetables and tobacco on the higher portions which are to be found in every Munmari land, besides shooting game, fishing and collecting jungle products. In some localities they are able in January to undertake the cultivation of lands for Kalawellamai, especially in the Southern districts. In March the reaping begins and the crop might be all threshed out by the end of April, but in practice it is stacked and threshed out later at leisure, to admit of the field servants taking part in the cultivation for Kalawellamai now going on.

For reaping, extra assistance is taken on, though not invariably, and costs from three to five amunams (for ten amunams extent) according to locality and the demand for labor at the time. Threshing out the crop is done entirely with buffaloes, which have generally to be hired, and this operation costs from 2½ to 4 per cent of the crop in kind.

Other charges, also paid in kind, are—the "Kuruvikkaran" or bird-boy, who is employed to frighten off the birds at the time of sowing and when the crop is in ear; also the cost of ploughs and mamoties, Vattai Vidhan's fee, &c.; these charges may be put down at two amunams for every ten amunams extent.

The cost of cultivation of an extent of ten amunams (or say 25 acres)* with four or six months paddy for the "Munmari" thus amounts to an outlay (including seed paddy) of about 26 amunams in grain, and the services of four men for a period of 8 months or 960 days of a man.

The Kalawellamai is sown between February and May. The paddy generally used is of a kind which ripens in three months and is germinated before sowing. The lands cultivated for this harvest invariably lie low, and have been generally flooded during the rainy weather of the north-east monsoon. They are consequently much softer and more muddy than Munmari lands, and are trampled with buffaloes (costing six amunams) and tilled with the mamoty. The proportion of field servants required is also smaller, and three can undertake an extent of ten amunams; but on the other hand more additional aid is required in sowing and at harvest time; while the extra charge for reaping and threshing comes to nearly 50 per cent more, viz., 11 amunams against 8 for Munmari. Then there are the usual charges for bird-boy, tools, &c., amounting to 2½ amunams more.

The crop is reaped and threshed between June and August. The cost of cultivating ten amunams extent or 25 acres for Kalawellamai amounts to an outlay of 32 amunams in paddy, and requires the labor of three field servants for five months or 450 days of a man.

In this district also no money wages are paid for agricultural operations, the regular cultivators being remunerated by certain shares and perquisites out of the crop. But if additional assistance is required for any purpose, the ruling rate is a "Marakal" (a quarter of a bushel) of paddy a day. At this rate the expenses of cultivation in grain would average 13 bushels per acre.

This result agrees fairly, though worked out independently, with a reply furnished to a Committee of the Legislative Council, by Mr. Crowther, a proctor and land owner at Batticaloa; in which the cost of cultivating 75 bushels extent by hired coolies is given at 350 bushels on grain, or about 13 bushels per acre. In another estimate for cultivating 10 amunams in the customary manner, Mr. Crowther provides for three field servants and an outlay of 2½ amunams of paddy (exclusive of ground share or rent, and consumption paddy which is an advance repaid at harvest time).

* In Batticaloa district it is usual, according to season, situation, &c., to sow from 2 to as much as 3½ bushels of paddy in an area of an English acre. I have accordingly assumed 3 bushels to the acre as a fair average proportion in my calculations. This makes the amunam sowing extent the same as the Sinhalese districts.

From the Indian reports I find that in the Godavery district where agricultural services are remunerated in grain, the expenses of cultivation are very nearly the same, and are given in the Revenue reports as $3\frac{1}{2}$ pooties of grain for 1 pooty extent, equivalent to 100 English bushels for 8 acres or $12\frac{1}{2}$ bushels the acre. In other parts of the Madras Presidency the rate is very much the same.

Perhaps it is as well I should explain that I have through out dealt with the case of a proprietor working his own land with his own capital, hiring at ready money prices any additional aid he requires in men or cattle, so as to avoid liability for the exorbitant rate of interest charged for deferred payment, which, in Batticaloa, is never less than 50 per cent.

All the information which I have collected (though obtained direct from practical working agriculturists) has been afforded under the impression it was sought with a view of increasing their liabilities to Government. We may consequently, I think, safely conclude that the figures given are very outside estimates, rarely worked up to, and include charges not always incurred. For instance, I have made no deduction for the spare time on the cultivator's hands between sowing and reaping, which a European employer of labour would doubtless find some way of turning to account. Indeed many natives do, to my own knowledge, utilize it for other purposes, as already explained, as the only call on them during this interval is that of watching by night, which is done alternately or by arrangement, so as to admit of at least half the men being absent at a time, and frequently by the substitution of mere children.

Again, as regards harvest operations, I found, when going round, that in many instances these are done by the regular field servants, sometimes aided by their female relatives and children (who get no additional remuneration), and no extra aid is called in, unless the crop is really a heavy one and comes in with a rush; but I have allowed the full charge in all cases.

I will now pass on to consider the quantity of paddy that can be grown on an acre of land. But I must first point out that the yield in Ceylon is generally spoken of by "fold," and ordinarily without reference to the amount of seed sown, or the mode of sowing adopted. In India the seed is, I believe, invariably sown in small beds and the plants transferred when about a month old to the prepared land, in which they are to be matured. Under this system 50 to 60 lb. weight of paddy, or about an English bushel by measurement suffices to sow an acre of land.

In Ceylon (except perhaps in Jaffna on a small scale) this system is not followed; the seed is sown broadcast, and in the Batticaloa district for the Mumhari without being previously germinated as usual in the Sinhalese districts. This leads, I believe, to great waste, as much as $3\frac{1}{2}$ bushels to the acre being, it is alleged, sown in some land in Batticaloa and nowhere less than two; while in the Sinhalese districts it takes six bushels to sow an amunam extent, or about $2\frac{1}{2}$ bushels to the acre. A return therefore which might be termed one of 30-fold in India would be equivalent to one of 12 in most parts of Ceylon, and in some parts to only $7\frac{1}{2}$ -fold. In examining the figures for Ceylon, therefore, it will be well for purposes of comparison to reduce the returns secured to the number of bushels of paddy per acre.

In Mannar, Baldeus speaks of a return of a hundred-fold, and Mr. De Hoedt, late Head Clerk of the District Kachcheri, and a land owner and practical cultivator, assures me that in a favorable season (in the absence of proper irrigation) he has ordinarily obtained a return of 30-fold on a sowing of $3\frac{1}{2}$ bushels or over 100 bushels an acre; and that 25 fold or 87 bushels is the usual return, cultivating in the ordinary native way.

In Matara before irrigation was introduced in favourable localities a return of 30-fold, or 75 bushels an acre, was admittedly obtained; and Mr. Dawson in his report as Grain Commissioner speaks of a similar return being secured in two villages near Hikkadwa. These returns are exceptional, it is admitted, under existing circumstances; but they are mentioned to show what can be, and is being, secured in Ceylon without the stimulus of improved cultivation or regular irrigation.

It cannot be too emphatically insisted that the primary consideration in regard to paddy cultivation is a regular water supply. In its absence the best lands give but an indifferent return, and where it is present the poorest lands give, I believe, a remunerative crop. In the irrigated districts of Matara it is now freely admitted a crop of 30 bushels to the acre is regularly secured frequently twice a year, and in Batticaloa there is ample evidence the return varies from 30 to 60 bushels per acre, with a most slovenly and imperfect style of cultivation, in which very little is done by man and a great deal by nature.

I see it stated in the report of the Irrigation Committee of 1867 that the return in Ceylon was at one time $17\frac{1}{2}$ -fold according to an inscription in the Polonnaruwa tablet. This, I presume, refers to lands irrigated by the tanks erected by the Sinhalese Kings, and I have every reason to believe fairly represents the return nowadays in the irrigated districts in the South and East of the Island. I need not here refer to the evidence on which this opinion is based, as I am content to rest my calculations as to rice cultivation on more moderate returns.

We will first take the case of a gross crop of 25 bushels of paddy to the acre, which would be spoken of as a return of ten-fold in the Sinhalese districts and of seven-fold in South Batticaloa, where the acre is considered as equal to $3\frac{1}{2}$ bushels sowing extent.

Dealing first with Batticaloa, we must from the gross return deduct the outlay in grain for seed, ploughing &c., already detailed, and the Government tithe. These first charges amount to 10 bushels per acre for Mumhari, and leave a nett outturn of 15 bushels as the return for the 38 days' labour bestowed by the cultivator in the sowing and gathering of the Mumhari crop, or about $2\frac{1}{2}$ days' labour for the bushel of paddy.

This is an outside estimate of the most expensive cultivation I know of in Ceylon, and one, I believe, never touched. In Kalavelama lands in which a quicker growing paddy is cultivated after the usual deductions, the cost falls to $1\frac{1}{2}$ day's labor to the bushel; and if a return of 30 bushels to the acre is secured, the proportion is still further reduced to 1 day's labor; while a return of 37 bushels would secure a bushel of paddy for $\frac{1}{3}$ of a day's labor.

In Matara the proportion is as follows:—

For a 25-bushen crop	$1\frac{1}{2}$ day per bushel.
30	" $1\frac{1}{2}$ "
37	" $1\frac{1}{2}$ "

As I have already stated, the expenses of cultivation have erred on the side of liberality, while the return has been taken at a moderate rate; I feel consequently, after a very careful consideration of the whole subject, I am by no means overstating the case in venturing to affirm broadly, that in a fair land, properly irrigated, on an average, a day's labour produces a bushel of paddy.

As I have taken a low rate of yield, I have made no special deductions for unfavourable years, attacks of insects, &c. Flood and drought are the two great enemies of paddy cultivation. The former is not hurtful unless the plants are submerged for an excessive period, fluctuating according to age and variety, and can be guarded against by selection of land and timely sowing. On the other hand these floods do good by the fertilizing matter deposited on the lands, and in every district I have found the best lands are those liable to be inundated at frequent intervals. When irrigation is provided, it is possible to choose the proper time to put in the seed; the cultivation is practically independent of the weather to a great extent, and the danger of drought reduced to a minimum. Caterpillars and flies (or more properly speaking a description of bug) are the next most important enemies of the paddy plant. Caterpillars can generally be got rid of with a good supply of water, and the damage by flies is I believe limited in extent. I recently saw some fields, about which there were loud complaints, and which were said to have suffered more than had ever been experienced in that locality. Enquiry showed the yield had been reduced by about two-fold in fields which ordinarily return 7- to 9-fold. In Madras an allowance of 15 per cent on the full crop of a favorable year is considered sufficient to cover all adverse contingencies.

I have purposely worked out my figures, so far, in days' labor and grain, in keeping with native modes of estimating agricultural outlay. In addressing a European audience, it is necessary to attach money equivalents to these results, based on the value of labor in each locality.

In South Batticaloa, the ordinary rate of pay on the coconut estates is 18 cents per diem, and the hire of an agricultural laborer is a marakal of paddy per diem, which generally changes hands at about the same rate. The road commutation tax in both Batticaloa and Matara is $R1\frac{1}{2}$ in lieu of six days' labor. In neither district is there any special demand for labor except for paddy cultivation. Twenty-five cents a day is therefore an exceptional wage, and a very outside value of time in the local labor market of both districts.

In my opinion the most unfavorable view that can be taken of the situation is that paddy can be grown in Ceylon for $3\frac{1}{2}$ cents a bushel, and that it is probable a large proportion is raised at a cost of 25 cents (six-pence) a bushel; while it can be sold nearly everywhere for at least a rupee, leaving a profit of 75 cents per bushel to meet interest on capital invested, &c.

Turning to India again for a moment, I find that the average selling price of paddy in the Madras Presidency has been 94 cents per bushel during 1881 and 1882 against 96 cents for the three years previous to the famine. To this, on grain coming to Ceylon, has to be added Customs duties amounting on both sides to 26 cents per bushel besides freight and other charges. So that it is not surprising the price of paddy is generally $R1\cdot50$ in the Jaffna market, where alone Indian grain comes into competition with the surplus production of the Batticaloa district, and that surplus comes burthened with charges for transport of over 50 per cent on the cost of production. In the Colombo bazaar Indian paddy generally sells at $R1\cdot37\frac{1}{2}$ per bushel, and the Customs valuation for statistical purposes has for some years been $R1\frac{1}{2}$.

This brings me to the consideration of the cost of bringing Ceylon paddy to market. In Matara not nearly enough is yet grown to meet the demand of the resident population, and consequently there is a market on the spot.

In Batticaloa, on the other hand, an excess over local requirements is produced even in unfavorable years, and in 1883 over 350,000 bushels were exported to Jaffna coastwise, besides what was sent inland to Badulla and Bintenna, of which no account can be obtained. As Jaffna ordinarily absorbs an annual import of about 900,000 bushels of paddy, there is still a considerable margin in this market, so long as Batticaloa can undersell Indian paddy, as it does now.

Batticaloa is further favored by possessing cheap transport to this market, owing to the facilities offered by the extensive backwaters, which are such prominent features on this side of the island; and the fortunate circumstance that both harvests fall within the period when communication with Jaffna by sea is easy and rapid. A considerable number of native vessels engage in the trade, especially during the continuance of the south-west monsoon, and paddy can consequently be transported from the threshing-floors in the fields to any sea-port market in the Jaffna peninsula for about 20 cents per bushel.

A grower of paddy in Batticaloa can therefore, in my opinion, put his paddy into the Jaffna market for about 50 cents a bushel, and secure a profit of about 75 cents a bushel, possibly a little more.

In Matara the extent of waste land is now very small, and as there is considerable wealth in the district, fields in favorable localities fetch fancy prices, running to as much as $R200$ to $R250$ per acre.

In Batticaloa the circumstances are very different and the supply of land is still in excess of the demand. For a limited extent situated in a central locality, an alluvial well-watered plain known as the Karewagupalam, the value rivals if it does not exceed that for the best lands in Matara; but the usual price for ordinary paddy land in cultivation is $R30$ to $R50$ per acre, and at this rate a large proportion of the fields could be purchased. Waste land in this district can be procured at $R10$ per acre and survey fees, payable in four monthly instalments. As the Batticaloa lands when sold are covered with jungle, after cutting out any timber available, purchasers hand over the property for a couple of years to persons who undertake

to clear and cultivate it, taking as remuneration the crops grown during the interval; no ground share is claimed, and the owner advances seed and maintenance paddy which are repayable but without interest. An expenditure of about $R10$ in cash is required to put up the dams and ridges, which are frequently of larger dimensions than is usual in the Sinhalese districts. It is difficult to say what the total cost of assweldumizing comes to in money, but, so far as I can judge, it is not more than $R30$ per acre, a portion of which is generally recouped by the timber.

The task I set myself is now finished, and I trust it will be considered that I have shown paddy can be locally grown, with the aid of irrigation, more economically than it can be imported. I have endeavoured to give a truthful fair epitome of the information I have drawn from the lips of all classes, chiefly the practical field-workers with whom I have been brought more directly in contact during the past two years, especially in the Batticaloa district. As regards expenses of cultivation, my enquiries are more than corroborated by the outside and independent testimony of others to which I have already referred.

The only point which is really open to discussion is the rate of yield. This I have purposely kept low, I believe below the truth, and I appeal to the gentlemen who have experience in such matters, if I have not been most moderate in basing my calculations upon a yield in irrigated lands, which would in the Sinhalese districts be spoken of as varying from 10- to 15-fold and of 7- to 10-fold in the localities where $3\frac{1}{2}$ bushels to the acre are sown.

I have selected for the investigation of this question two districts in which the construction of irrigation works has introduced a considerable element of certainty in the cultivation of paddy, and it is practicable to judge results by pecuniary tests in accordance with European ideas. When a reliable water supply is absent, and paddy growing depends on the rainfall, it is probably liable to more vicissitudes than any other branch of agriculture in the island, perhaps in the world. It would be a waste of time to consider its pecuniary capabilities under such conditions. But fortunately the rainfall in some parts of the island, and in the more populous districts, is well distributed, and paddy cultivation is carried on with results only second to those ensured by irrigation. Where such favorable circumstances are wanting, there is really only one remedy, and that may be summed up in the single word "Irrigation." I know no other of equal efficacy. Improved modes of cultivation, new implements, and fresh seed are all of secondary importance. Where necessary make the water supply tolerably secure, and we may and can rival India, if we do not do so already, in the economical production of paddy, though it may be a long day before we can entirely overtake the local demand. Still the fact remains that while paddy cannot apparently be imported into Ceylon for much under $R1\frac{1}{2}$ per bushel, we can produce it in the island for one-third this sum at the very outside.

Hon. P. RAMA NATHAN opened the discussion by stating that the question Mr. Elliott had set himself to solve was whether Ceylon could grow rice so as to undersell the Indian article in the local market, and he had not only answered that question in the affirmative, but had shown a profit of 75 per cent for the cultivation. This was for the Matara and Batticaloa districts, where Mr. Elliott had spoken of crops as high as 35 to 70 bushels per acre. Mr. Elliott had worked out the cost of cultivation and put it at $R13$ per acre. Now there was a very great diversity of opinion on these subjects, more particularly as to the yield of rice in crop, and this was shown by the report of the Irrigation and Paddy Commission of 1867—on which were Sir R. Morgan, Col. Fyera, Messrs. Parsons, Alwis, Wise, &c.—who said, among other things:—

The Committee have had under their consideration the returns of the quantity of paddy produced in the various districts of the island: these data show that the supposed average yield of ten-fold is rarely obtained, the produce usually ranging from three or four-fold to about eight-fold, whilst in other Eastern countries the return ranges between twenty and fifty-fold. The return in Ceylon during

former periods was seventeen-and-a-half-fold, according to the inscription on the Polomaruwa Tablet, quoted in a preceding page, where the tenth is stated to be one amunam and three pelas. According to the information thus collected it would appear that the yield per acre instead of being as usually supposed thirty bushels, is not more than half that quantity.

The evidence on which this report was based was of the most varied and even contradictory character, and here Mr. Rams Nathan read several extracts showing how native cultivators gave such returns as 24, 56 and 9 bushels as the crop of paddy per acre. His own opinion on the subject was that the average yield for the island was between 20 and 25 bushels, and that 2 rather than 2½ bushels per acre was the proper sowing allowance, making the return, in his opinion, one of 10- to 12½-fold. As regards the cost of production, he thought Mr. Elliott had left out certain charges, such as the wear and tear of implements and tools which he would put at R2 an acre, and interest R3, bringing the total up to R18 per acre against a return of 20 to 25 bushels of paddy valued at R1 each, leaving a margin of from R2 to R7 per acre. This he would compare with the return from coconuts which was, at least, R37½ per acre, or from cinnamon even—or, perhaps, tea. (Applause.)

Mr. J. FERGUSON said that all who had studied this question were accustomed to take their start from the Report of Sir Hercules Robinson's Commission already quoted, in which, after making enquiries and receiving evidence from all parts of the island, it was stated that the average yield of paddy in Ceylon was nearer 15 than 20 bushels per acre, the range being 4 to 8 fold against 20- to 50-fold for other favourite Eastern rice-growing regions. Mr. Elliott had undoubtedly brought together much valuable information respecting the yield and cost of rice in India, but he could not help thinking that as regards the rich alluvial lands of the Gangetic valley and of Burma especially, the returns were under-rated. He had seen an official statement that the average for the ricefields of Burma was 40-fold, which would mean 40 bushels per acre according to their way of sowing, and Mr. Hallett, the co-traveller of Mr. Colquhoun, had stated in respect of the Shan country, north-east of Burma, that the people told him in one large district that they got back 250 times what they put in of paddy. The latest Administration Report on British Burma stated that there were 4 million acres under paddy, and that 100,000 acres were added to the cultivation yearly, the annual exports of rice having risen to a value of £6,000,000 sterling. The estimate for all India was 60 million acres under rice. Looking at the matter broadly, therefore, he did not think anyone could say that Ceylon could be put in comparison as a rice-growing country with Burma or Bengal. But Mr. Elliott had confined his paper to certain favoured districts, and he (Mr. F.) did not think anyone had ever disputed the advantage of irrigation works and rice cultivation in Matara and Batticaloa. At the Royal Colonial Institute he had carefully guarded himself by saying that where the land was suitable for rice-growing in Ceylon, and irrigation could be profitably applied for a resident population ready to take advantage of it, the unofficial public had uniformly supported the Government in such expenditure. He had then the Matara and Batticaloa districts specially in view. Further he could add to Mr. Elliott's instances of very heavy crops in exceptional cases in Ceylon, from the authority of the intelligent Kachcheri Mudaliyar of the North-Western Province (Mr. S. Jayatileke), who had told him that on the banks of the Maha and Deduru oyas after floods with favourable weather, there are fields which give a return of 100 bushels per acre, and others 40 and 50 bushels. But such cases were entirely exceptional, and although he

believed Mr. Elliott's paper to be a generally correct and most valuable account of grain cultivation in the Matara and Batticaloa districts, yet it was very difficult to reconcile it in some parts with other official statements. For instance, it was his (the speaker's) duty—a painful one rather—to study very closely year by year the Government Bluebooks and Administration Reports. Now while in the case of Matara the grain statistics showed good progress and the rate of yield was very steady at an average of 16 to 17 bushels per acre; in the favourite Batticaloa district the case was very different. The maximum of over a million bushels of crop was reached in 1870 with an average yield of 24 bushels per acre, that rate had gone down in 1877 to 17 bushels; in 1883 to 12; and last year the Bluebook figures positively only showed a return of 6 bushels per acre. (A laugh.) So again with the total production of the island; our maximum seemed to have been reached in 1880, since then there had been a heavy falling-off in the local crops. Now they all knew the disrepute attaching to Bluebook returns so far as Agriculture was concerned, but if there was one district more than another from which they ought to have correct reports, it was surely Batticaloa with its steady industry and supervised irrigation. However, passing over that and taking Mr. Elliott's own average of a return of 25 bushels per acre, produced at a cost of 37½ cents per bushel, leaving a profit of 75 cents, or (leaving out carriage) let them say 50 cents per bushel, what was the nett result? Only R12.50 per acre; while as Mr. Rams Nathan had mentioned coconut (or he might add areca-palm) cultivation gave the natives a nett return not under R37½ per acre. Again, Mr. Elliott had almost provoked a comparison with tea, which he (the speaker) thought the Government ought to encourage the Sinhalese villagers to cultivate around their huts and in their gardens after the fashion of the Chinese. A bushel of paddy, according to Mr. Elliott, and a lb. of tea could be produced for nearly the same cost in Ceylon—the one being worth 75 to 100 cents, the other say 50 to 60 cents on the spot. But then even with native cultivation and management, the cropping of tea might safely be taken at 300 lb. an acre and with a profit of 20 cents a lb. that would be equal to R60 per acre against the R12.50 for rice, so leaving a wide margin in favour of tea. Confining attention, however, to the old products and looking at the country as a whole, in what direction did the people display most enterprise? In Burma, without, he believed, any special stimulus from Government or irrigation works, there were about 100,000 acres added yearly to the rice-cultivated area. In Ceylon, 20 to 30 years ago, to take one instance, there was probably not a single coconut patch between Negombo along the Mahaoya towards Polgahawela—now it was almost a continuous expanse of that palm and there were unbroken fields of as many as 5,000 acres. He was not aware that the Ceylon Government had done anything to stimulate this industry, by even a single report on the subj. save that the land was surveyed and put up for sale; but look at the result. Our exports now of coconut oil are between 4 and 5 times what they were 30 years ago; of coir stuffs we send 3 times as much away; copperhul 4 times; nuts, peonac, &c., in proportion—and all this from what may be said to be a purely native industry. (Hear, hear.) Here then, at least for the Western and South-western districts, we have the most profitable investment for native enterprise. But he would not for a moment allege that there were not other districts, and notably Matara and Batticaloa, where rice is best fitted for native occupation and where the Government might well do all they can to extend its culture, seeing the margin of profit is wide enough to satisfy the cultivator after paying for his rent and water supply. One thing

Mr. Elliott had made clear, that the so-called water-rate, considering the certainty brought by irrigation, was most moderate and the Government levy in Ceylon was far less than in India where, as Mr. Elphinstone told the speaker only a few days ago, he found the people at Trichnopoly gladly paying at the rate of R9 per acre year by year for water privileges. In conclusion, he would only say that the wants and capabilities of each district, and its people, in the island must be judged by Government on their own merits, and while he cordially agreed with much that Mr. Elliott had said about Matara and Batticaloa, Government ought not, in other districts at least, to forget that there were other industries worthy of direct encouragement besides rice-growing. (Applause.)

Mr. BERWICK thought that the discussion had travelled a good deal beyond the limits observed by the writer of the valuable paper to which they had listened with so much interest. That paper had to do with rice cultivation solely in the Matara and Batticaloa districts, and he had not risen so much to discuss its merits as to gain information on certain points which puzzled him. He wished especially to know whether any account had been taken of the large original outlay of public money on the irrigation works in districts referred to. Had Mr. Elliott taken this heavy item into his reckoning? As regards the gentleman (Mr. Rama Nathan) who apparently would wish to stop the cultivation of paddy (No. no. from Mr. Rama Nathan) he would like to know if he had considered what the effect would be on the cost to us of imported rice if there were not a large local production to act as a check. (Hear, hear.)

MR. A. M. FERGUSON remarked that Mr. Elliott, by his very interesting and useful paper had proved himself doubly qualified, by national origin and acquired experience, to treat of the subject of paddy. (A laugh.) The facts he had stated with reference to the districts of Matara and Batticaloa showed that good results could be obtained from rice culture in Ceylon, where a steady supply of irrigation water had been provided. But still better results could be obtained, if only the natives under good and scientific advice sowed one bushel of seed to an acre instead of two, germinating the seeds in nurseries and putting out the plants in the fields in drills, as was done in India and more especially in Java, where he had been delighted to see the careful and scientific mode of cultivation adopted by the peasantry. Another great improvement in the culture of rice in Ceylon would be the teaching of the natives to be less extravagant in the use of water. They flooded their fields, instead of irrigating them, thus converting what was intended to be a semi-aquatic plant into one wholly aquatic, its produce being less in quantity and deficient in nutritious properties in proportion to the waste of water. We in Ceylon, with our poorer soil, could not compete with fat alluvials of India and Burma, but Mr. Elliott had shown that rice culture in the island was susceptible of great improvement and could be so conducted as to be remunerative to the natives. But Mr. John Ferguson's figures showing apparent decadence instead of progress in production in the specially favoured district of Batticaloa were so bewildering, that, however sorry he might be to say such a thing in the presence of the honourable gentleman who occupied the chair (Mr. Ravenscroft), he was compelled to regard the question as one of utterly unreliable Bluebook statistics. (Laughter.)

Mr. J. CAPPER said it should not be forgotten that nearly all the rice locally produced was required by the cultivators for themselves and their families—very little was thrown into the markets for sale. The Commission of 1867 had to deal with the returns for the island generally in giving their low estimate

of production, but there had never been any doubt that under irrigation, the cultivation of rice would pay and yield handsome returns. As regards the Blue-books, the figures were indeed a mystery, for in addition to what had been said about Batticaloa, he might mention that the Kurunegala district now showed the heaviest yield—some 26 bushels per acre—in the country and Badulla 21 against 6½ bushels for Batticaloa. (A laugh.)

Mr. A. R. DAWSON, C.C.S., could not with so much confidence speak of Batticaloa, but as regards Matara he could with certainty say—nothingwithstanding any contradiction in the Blue-book returns—that the production of rice had been steadily progressive and he would recommend Mr. Ferguson when in doubt as to the crops to turn from the Blue-book agricultural tables to the Revenue returns which were a sure index to the amount and value of the crops. In the case of Matara, the revenue from grain had greatly increased since the irrigation works were completed. As regards Batticaloa, the system which had prevailed there of selling the rents was a very uncertain, unreliable one and could not fail to lead to much uncertainty as regards the produce returns; but this would all be rectified by the work of the Grain Commission. In reply to Mr. Berwick's enquiry he would state that in some cases the expenditure on irrigation works had been rapid by the cultivators benefited, in a certain number of (ten) annual payments; in others by the addition of a rupee per acre to the rent in perpetuity. He hoped that the paper now read would be the precursor of others equally instructive on the Food Supply of the country, and the various topics connected therewith. (Hear, hear.)

Mr. J. FERGUSON explained that he had not criticized the Matara crop returns, but only those of Batticaloa. He thought, that with the Colonial Secretary in the Chair and so many rising Revenue Officers in the room, they ought to urge the necessity for greater attention in sending in Bluebook returns: the Government Agents ought to compare their revenue and crop statements year by year, and afford in notes useful explanations, or their own opinions on the produce figures where large discrepancies occurred. (Hear, hear.)

Mr. R. W. LEVERS, C.C.S., only rose to mention with reference to Mr. Ferguson's statement about Burma that in a book he was reading the other day, written by a traveller in that country, it was distinctly stated that he (the writer) had learned from the people their return of crops was from 10 to 25 fold—[Mr. J. F.—I referred to British, not native, Burma]. He could not see that the country could differ so much as to allow of a return in another direction of 250 fold as had been stated.

Mr. H. W. GREEN (Director of Public Instruction): I worked out the returns from rice cultivation in Burma not long ago in company with a friend, and we found as the result that the crops were equal to 70 and 150 fold (Laughter.)

Mr. ELLIOTT, in reply on the discussion, pointed out that the discussion had gone over wider ground than he had covered in his paper; indeed, had extended to the whole question of paddy-growing throughout the island, whereas he had restricted his paper to rice cultivation under irrigation, and to what was being done without entering on the question of what might be secured by improved cultivation. He had in his time advised a large expenditure in the Matara district on irrigation, and, now that he could adduce actual results, he was naturally anxious to vindicate the correctness of the views he had so long held. In reply to Mr. Rama Nathan's objections, he pointed out he had given the details of cultivation in his statement and had provided for tools allowing in grain 1 annum of paddy or at the rate of 7½ bushels for 25 acres. Mr. Crowther had allowed 50

per cent more, but his total expenses were under Mr. Elliott's. In Matara he had allowed 1 bushel for 2½ acres, which he believed was sufficient. As regards the quantity of paddy sown in an acre of land, 2½ bushels to the acre had been long recognized and acted on as the proper equivalent in the Indian district. Ludovici also speaks of the usual paddy sowing basis as 2½ acres to the amunam of 6 bushels. In the Batticaloa district the figure varied from 2 to 4 bushels, and he had taken 3 as a fair average. However, this difference but little affected the results. Again, as regards interest, it was difficult to know what rate to fix and what value to place on the land. The lowest rate for money loans in Batticaloa was 16½ per cent and on loans of grain 50 per cent in kind. In view of this Mr. Elliott had only gone into the actual expenditure on the land in raising the crop, such as a superintendent would have to disburse, leaving what might be called the "Colombo charges" to be added according to the circumstances of each case. Still accepting Mr. Rama Nathan's figure of 20 bushels produce per acre and an outlay including interest of R16, he pointed out that paddy would only cost 80 cents a bushel, against 96 the Madras value and R150 the usual selling price of Indian paddy in Ceylon. As regards water-rate Mr. Elliott had allowed for this in the case of Matara, where it was a charge (of R1) in perpetuity. In Batticaloa it was all paid off in 10 years and would be properly chargeable to the capital cost of the land. Against the low rates of yield quoted by Mr. Rama Nathan, Mr. Elliott gave some other instances of returns in excess of those on which he depended, which had been committed to him, one of 60-fold at Vavuniyavilankulam. He also quoted one from the same report as Mr. Rama Nathan had of a return of 150 amunams or 1,125 bushels from 40 acres or 28 bushels the acre from aland in Batticaloa. As regards the gentleman who had quoted Bluebook statistics—which were admittedly untrustworthy in spite of spasmodic attempts of individual officers to make them more correct he reminded his hearers, that, out of some 70,000 acres of paddy land in the Batticaloa district, only 36,000 were affected by the expenditure on irrigation and some of this area was still imperfectly irrigated and require further subsidiary works. He (Mr. Elliott) had always advocated irrigation where there was a nucleus of a population. In Batticaloa where irrigation had been begun it was about 70,000 and it was now over 109,000. He believed that there was room to make other Batticaloas and Mataras in the island, especially in that part stretching from the Giant's Tank to Elephant Pass, to which he believed the surplus population of the Jaffna peninsula would flock if the water-supply could be made secure. In reply to Mr. Capper's query as to the development of rice cultivation in Batticaloa, Mr. Elliott gave the following figures:—

	Area Actually Cultivated.	Land Revenue.
	Acre.	R.
1856	22,655	23,906
1866	41,380	37,157
1876	59,730	77,060
1883	58,916	60,757

The general revenue had increased from £6,071 in 1848 to only £7,315 in 1857, about which time irrigation had been commenced in Batticaloa. It then went up to £10,787 in 1858, and £16,855 in 1861 (but this included £6,872 from land sales.) In 1865 it was £14,840, £21,000 in 1867, and £31,000 in 1883 (including only £1,382 from land sales). The revenue from the arack farms had risen from £680 in 1867 to £2,038 in 1867 and £3,402 in 1883. Stamps gave £2,283 in 1883 against £1,020 in 1858.

Before separating, Mr. RAMA NATHAN wished to correct Mr. Berwick in the thought that he was opposed to paddy cultivation or arguing against it—nothing could be further from his thoughts.

Mr. BERWICK moved a vote of thanks to Mr. Elliott for his timely and valuable paper, on one of the most important subjects which could occupy their attention; and this was seconded by the Hon. R. A. BOSANQUET, who said he had regularly attended their meetings in the hope of gaining information, but that this was the first occasion he could remember on which he really felt he had been instructed and was going away wiser than he came. (Laughter.) He hoped similar discussions of practical value would frequently occur. The vote was carried by acclamation.

In replying to the vote of thanks, Mr. ELLIOTT expressed his belief in the permanency of paddy cultivation. Rice had been grown on the same lands for over 100 years and the crops did not seem to be affected by those general adverse influences of nature, which had so severely tried other branches of agriculture in Ceylon.

The meeting separated about 11 p. m.

REVIEW OF THE OUTLAY AND RESULTS OF IRRIGATION IN CEYLON 1868-83.

As with Sir Arthur Gordon's advent we may be said to have made a new departure in regard to irrigation; it is obviously desirable that the public should be in possession of the results so far, of the system inaugurated by Sir Hercules Robinson in 1868, and so energetically pressed forward by Sir William Gregory.

A Sessional Paper X, of 1884, gives a good deal of information on the subject, but as it was wrapped up in some sixteen pages of undigested figures, without a single column totaled, it was but of limited value to any but the initiated. An abstract of this paper in a convenient form, is given at the end of this notice, which renders it possible for the public to judge how far the results tabulated justify the expenditure of the past.

From this abstract, it will be found that the total expenditure on Irrigation Works from 1868 to the end of 1883 was (in round numbers) R2,600,000, or R46 per acre over an irrigated area *actually under cultivation* of 56,000 acres, of which exactly 20,000 acres have been purchased from the Crown since 1868 (besides about 1,000 more not brought into cultivation).

Against this expenditure a sum of R360,000 has been recouped by the sale of Government lands, while on account of water-rate a sum of R232,000 had been actually recovered and R154,000 was outstanding on the 30th June 1883; but of this, R142,000 was due in the Batticaloa district, but outstanding on this account to the end of 1881 have been since got in. Practically therefore we may treat water-rate as having brought in a sum of R366,000. In addition to this there is a further asset to be taken into consideration, viz, an annual contribution of R8,420, being the water-rate at R1 per acre which certain proprietors (chiefly in the Matara district) have elected to pay in perpetuity under the provisions of the Ordinance. This capitalized at 5 per cent represents a further reimbursement of (say) R173,000.

Summarizing these results we arrive at the *net* outlay as follows:—

Total expenditure on irrigation works from 1868 to 1883R2,600,000
Reimbursements:		
By sale of land benefited	R360,000	
" water-rate terminable	396,000	
" " in perpetuity	(R8,420) capitalized at 5	170,000
per cent	...	926,000
Net outlay	...	R1,674,000

Or in other words, Government have been directly repaid over one-third of the expenditure on the works, and must look for any further immediate return to an increase in the revenue from the grain grown on the lands affected by the additional water-supply provided.

It is not stated in the returns before us, what this amounts to, but it is possible to estimate it from other published reports. For instance, Mr. Elliott records that an increase in the area cultivated in the Batticaloa district of 18,000 acres was accompanied by a rise in the grain revenue between 1866 and 1876 of R30,000.

Again of the Matara district Mr. Dawson reports that "the grain revenue of the divisions in which the irrigation works lie has in consequence risen from an annual average of R43,200 between 1869 and 1875 to one of R56,000 between 1876 and 1882," or an increase of R12,800 in a part of the district where only 6,400 acres have been provided with irrigation.

In view of these figures referring to three-fourths of the irrigated area, it is not taking too extravagant a view to estimate at R1 1/2 per acre the additional revenue due to the expenditure on irrigation, or say R84,000 in the aggregate.

Looked at in another way the result is very much the same, thus:—

Ascertained increase in Matara District	
from 6,000 acres R12,000	
Value of title of new land	
at R2 per acre over 20,000 "	40,000
Increased value of title	
at R1 p.a. on old lands 30,000 "	30,000
Total...56,000	R82,000

We may therefore safely take the value of the Government share of the increased crops at R80,000 per annum, which will be equivalent to a return of 1 1/2 per cent on the nett outlay all over the island, including the expenditure on some of the larger works which have not as yet proved reproductive, such as:—

Tissamaharama S. P.	R210,000	irrigating 450 acres.
Kantalay E. P.	72,000	500 "
Nikaweratiya N.-W.P.	40,000	296 "
Uswewa do.	47,000	75 "
Basawakkulam, Tissawewa,		
Yodaola, N.-C.P.	150,000	232 "
Madavaehchi N.-C.P.	26,000	78 "
Total...R505,000	1,631	

Deducting the expenditure on these premature undertakings from the total bill, the additional grain revenue shows a return of 6 1/2 per cent from the remainder of the works.

As the expenditure, R450,000 (nett) on 4,250 acres, in the North-Central Province has been undertaken admittedly for a special purpose and without any expectation of an immediate return, some may desire to know what are the results exclusive of the outlay in this Province. Thus relieved, the same data give a return of R78,000 against a nett outlay of R1,220,000 or over 6 per cent, which rises again to 9 per cent if we deduct the heretofore unproductive outlay on such works as Tissamaharama, Kantalay, Nikaweratiya and Uswewa.

The expenditure given above includes a considerable sum for repairs to irrigation works due to a great extent to the anxiety to do cheap work in the earlier years of the era under consideration. Allowance for this has to be made on the one hand and on the other for upkeep which has risen from R4,000 in 1870 to R29,000 in 1883. As regards the past it may consequently be taken as having averaged one per cent on the expenditure, but this deduction will almost disappear in the future, as repairs were taken in the last sessions of the Legislative Council to provide for this charge by a special assessment.

Considering that we have had to buy our experience, and that in the anxiety to afford relief the test of "will it pay?" has possibly not been as rigidly applied as it would probably have been by an Association looking for a dividend, the result is decidedly encouraging. Nor in dealing with the matter must it be overlooked that what has been contributed to the general revenue by the paddy-grower. It may be useful therefore to remind those who have recently doubted the justice and wisdom of the outlay on irrigation that it was recorded by the Irrigation Com-

mission in 1867 that "during the past thirty years the people have contributed to the local revenue nearly a million-and-a-half sterling in the shape of grain-tax, and that the only (direct) return for that large contribution has been an expenditure of between 30 and £10,000 on Irrigation."

Since 1868 the average contribution has been at the rate of R1,000,000 per annum or a total of 1 1/2 millions of rupees, and the outlay on irrigation under one fifth of this sum.

The abstract referred to in the opening paragraph is as follows:—

Province and District.	Govt. land sold.		Reimbursements.		Water-rate.	
	Extent.	Amount.	Realized.	Outstanding.	R.	R.
Western Province do., Trincomalee District	1,491	39,507	33,924	2,237	63	318
Eastern do., Batticaloa	15,030	207,389	102,989	14,256
North-Central Province	1,976	15,474	694	700

LEMON CULTIVATION IN CEYLON.

We have seen enormous crops of "citrons" grown on upcountry estates, but only a few lemons, and of those few the coolies seemed to take the lion's share, as they often do of peaches, plums, guavas and other fruits, which European planters calculated on for their own table or for presents to friends. The lemons sent to us by Mr. E. Woodhouse seem quite equal to those grown in Europe, are deliciously fragrant and prove that the true lemon can be successfully grown in Ceylon. By a curious coincidence the same post which brought us Mr. Woodhouse's letter and the lemons brought us also from Mr. J. P. Lewis, Assistant Government Agent, Kandy, the letter from Dr. Bonavia of Lucknow, which we readily print as an accompaniment to Mr. Woodhouse's communication. In contemplating extended cultivation of the lemon, the question of a good market would arise, and from what we saw in Australia, we think

the Southern colonies would take a considerable quantity of the fruit. With the fast voyages now made, lemons might even be sent to Europe. Dr. Bonavia's letter, which is worthy of attention, shows how local use for the lemon can be found and how various acceptable and beneficial preparations of the fruit can be obtained. We commend the subject of lemon (and orange) cultivation to planters who feel that they can not only grow but protect such fruits.

LEMONS GROWN IN CEYLON.

Pallerakelle, Pundaluoya, 8th August 1885.

To the Editor, "Ceylon Observer."

DEAR SIR,—Whilst reading your notice of some Indian gentlemen endeavouring to introduce the culture of lemon, it appeared to me that you were possibly unaware that lemons grow very well at an elevation of about 3,000 feet in Ceylon. I have taken the liberty of sending you per tappal two or three grown here.

From the one tree in bearing, we had this season the first sprinkling of ripe crop—about a couple of dozen. Now we have, what in coffee would be called the first round of picking, 72 ripe fruit. I should think there are, at least, a couple of hundred more green on the tree; and flowers for the second crop in the year are beginning to show themselves. How do they compare with European ones?—Yours faithfully,
EDMUND WOODHOUSE.

DR. BONAVIA'S LETTER ON LEMON CULTURE.

North-west Provinces, India, 23rd July 1885.

Dear Sir,—Allow me to bring to your Society's notice the useful "Malta lemon tree." Many years ago I imported it into the Horticultural Garden of Lucknow. It thrived like a weed. I bidden it on the native stock largely, and disseminated it in various parts of India. Its fruit is equal in every way to that of the Mediterranean, and it produces it abundantly. It layers with great ease; can be raised from seed and in your climate probably also from cuttings, the tops of past years' growth. Since I came here I again began to disseminate it. I sent some to Delhi, the Himalayas, Allahabad, Calcutta, Jabalpur, Puchmari, &c., and have had demands from Tinnevely and Travancore. I am certain it will do well in many parts of Ceylon. It affords many commercial products, such as citric acid, and all its combinations, lemon oil from the rind or candied peel, and essential oil of the leaves, but its great future in India and Ceylon is, I think, the manufacture of *Citrate of Iron and Quinine*, the best tonic after fever. If this could be produced cheaply, there would be a great demand for it as a blood tonic. Its ally, the Seville orange, grows very well also and can easily be propagated by bud and seed. From it is made the best marmalade, oil of neroli from the flowers, and "petit grain" oil from the leaves. I would suggest that your Society try these two plants, if they have them not. I feel certain they will do in Ceylon. Limes grow almost wild in Travancore. I think there is money to be made from oranges and lemons. You might obtain plants of the Malta lemon from Calcutta from the Agri-Horticultural Society of India, Metcalfe Hall. I sent them 50 fine plants a few days ago.—Belleve me, &c., (Signed) G. BONAVIA, M. D., Irigade-Surgeon, I. M. Department, Etawah.

P. S.—From the lemon fruit a fine lemon jelly is made; it is a first rate *antiscorbutic*.

THE TEA-ROLLER PATENT CASE.

D. C. COLOMBO 94,191—JACKSON *versus* KERR.

INTERIM INJUNCTION ALLOWED.

The District Judge of Colombo (Mr. Berwick) yesterday gave judgment upon the plaintiff's motion in this case for an interim injunction, the matter having been argued on the 20th of June last.

After remarking that the delivery of judgment had been delayed till Counsel should send in their authorities, the learned Judge proceeded to consider the jurisdiction

exercised in the matter of Patents, by the Common Law and the Equity Courts in England, remarking that in England the fusion of law and equity is not yet so complete as it has always been under the Roman Dutch Law. He would consider two main questions: first, had the plaintiff made out a *prima facie* case for the allowance of an injunction *pendente lite*; second, if so, had the defendant shown any reason for depriving the plaintiff of the temporary protection to which he was otherwise entitled. As regarded the first question, plaintiff would not be entitled upon a mere emphatic assertion of his right; he must shew (A) a *prima facie* chance of success at the trial, and (B) the probability of irreparable damage, if the protection be not afforded. As regarded (A) the learned Judge, having carefully considered the *pros* and *cons*, thought that there was sufficient reason for allowing an interim injunction on the usual condition of plaintiff's giving a bond with sureties to answer for any injury the defendant might sustain by such injunction. The questions at the trial would chiefly be (1) the validity of Jackson's patent, as to novelty; (2) if valid, whether defendant had infringed it; (3) whether or not the Crown had granted patents to two persons for the same invention, which last would require the evidence of experts for its determination. The Court thought without saying that the probability of ultimate success was in favour of either party, or that the probabilities were even, that there was such a sufficient reasonable probability that plaintiff would be successful as to entitle him to temporary protection. As to head (B) the learned Judge cited Maynz, *Cours de Droit Romain*, § 283; Digest 39-1-19 with Voet's commentary thereon §§ 1, 2, and expressed his opinion that rights under a patent fell under the description of *incorporeal* rights. He thought this requirement was satisfied by the inherent difficulty of estimating the damages a person would sustain by the continuance of an infringement (as suggested by defendant) on the condition of defendant's keeping an account, was practically to allow it unless defendant would submit to terms; and besides, quite apart from any question of the character of the defendant in this particular case, the plaintiff would have great difficulty in finding out how much really was *profit* and how much *cost of construction and sale* in the case of each machine. (The defendant had declined, at the argument, to pay in all proceeds sale of his machines into a separate account.)

The Court now proceeded to deal *seriatim* with the matters of defence relied on.

First, as to grant of patent rights to both parties. Though Copeland *vs.* Webb (11 W. R. 134) had been cited for the defendant, the Court was not prepared to hold that an action analogous to the English *scire facias* was the plaintiff's proper course. The same principles applied to grants of patent rights as to grants of land, and yet during 35 years' experience the learned Judge had never heard of a *scire facias* being required to set aside a Crown grant of land. Whether there really were two patents for the same invention, was a question on which the affidavit evidence was conflicting; but taking the statements in the defendant's own affidavits as true, they showed that his was a different invention from the plaintiff's. Secondly, as to *loches*, this defence was not made out, as the plaintiff deposed that he had first heard in 1884 of the defendant's patent, and did not get copies of his specification till the end of that year. Thirdly, as to the *reventures* of the plaintiff's patent: the Court thought this ground only affected the presumption as to the validity of plaintiff's patent, which it had already considered.

An injunction would therefore issue pending the decision of the action, on plaintiff's giving the necessary security. Costs of the motion to be costs in the cause to abide the final result.—"Examiner."

RICE VS. COCONUT AND OTHER CULTIVATION FOR THE CEYLON NATIVES.

Mr. Elliott very fairly strengthens his position as to the profitable nature of paddy cultivation in irrigated fields, in the letter which we publish be-

low. He doubles the estimated net profit per acre from paddy by recalling the fact that there are usually under irrigation two crops a year, and he very properly dwells on the large preliminary outlay and long delay in waiting for returns from palms and other fruit-trees, or even from cinnamon. This argument, however, scarcely applies to the new product, tea, we may say *en passant*; but there is another fact not specially pointed out so far, which tells in favour of encouraging the paddy cultivator, and which we readily bring forward. It is that paddy cultivation even in the richest districts and best, because most favourable, seasons leaves the cultivators plenty of time between sowing and reaping and reaping and ploughing to give their attention, if they choose, to other cultivation. The combination, therefore, of gardens of palms and other fruit-trees with paddy-fields is a very natural one, and equally so of the patch of coffee around the hut and village which may now be replaced by tea. We see a local contemporary would fain try to make capital out of his unfounded and misleading charge that we want the Government to encourage the cultivation of tea among the people to the supersession of paddy, or even in preference to it over the island. Nothing of the kind, as we think a fair perusal of the remarks published yesterday will show. We say that the requirements and capabilities of each district must be judged on its merits, and that the Government ought to give more attention to other products, besides paddy, for which many large districts are eminently adapted. We are aware of the fact, for instance, that an active, intelligent Assistant Agent for a district admirably adapted for tea, not long ago asked permission of the Government to procure some tea-seed for experiment in the Kachcheri garden and for distribution among the headmen and villagers—and yet he only got a refusal and a snubbing for his pains. Of course, we cannot expect the native villagers for many years to become experts in the preparation of tea even after the primitive Chinese fashion; but there are factories springing up in all directions, in the Sabaraganuwa, Kegalla, Kalutara, Galle and other lowcountry divisions where the tea-leaf plucked by the villagers would be readily purchased at a price remunerative to them as growers. We are convinced that tea is destined to become a favourite product for cultivation with the Sinhalese in many districts. The only question is, should the Government help or encourage the people, in this direction, as well as in respect of other new products, or confine their attention, energy and votes, agriculturally, all over the island, to rice alone and to irrigation works solely in the interests of this one staple? With Mr. Rama Nathan we may say that nothing is further from our thoughts than to stop or discourage the cultivation of paddy; our wish is not to see paddy neglected, but other products looked after as well, and so to see the favours of Government and the revenue, a little more generally distributed.

"RICE CULTIVATION UNDER IRRIGATION IN CEYLON."

DEAR SIR,—With reference to Mr. Rama Nathan's criticisms on my paper, please allow me an opportunity of replying to one or two points which escaped me when closing the debate.

First, I would point out that my original calculations were all made in native measurements of sowing extent and days' labor, to avoid the moot points as to the proper rates of conversion, pay, &c. But to suit a European audience not conversant

with the intricacies of amunams, pelas, kurunis and marakals, I added the results per acre at certain approximate equivalents.

It matters not therefore if it takes 2 or 2½ bushels to sow an acre. For instance, in Matara my figures are 90 days for a sowing extent of one amunam or six bushels. If this extent is equal to 3 acres instead of 2½ (as stated by me) the number of days' labor comes to 30 per acre (and not 36 as given by me).

Returning to the native measurement, an amunam sowing extent will at only ten fold give 10 amunams or 60 bushels in Matara. From this we must deduct, for tithe, seed, water-rate &c., 16 bushels, leaving 44 bushels as the reward of 90 days or a bushel for every two days' labour. So at this low rate of yield the outside cost of growth is 50 cents a bushel, and the profit per acre about R7, on one crop. These results are, I stoutly maintain, below the reality in the irrigated districts, and I see no reason to depart from the figures I have advanced.

As regards the question of interest and pecuniary return, Mr. Rama Nathan overlooked the contingency, nay the *certainty*, in the Matara district, of two crops a year, which at once doubles his figures. In his comparison with coconut and cinnamon, Mr. Rama Nathan also overlooked the larger capital locked up in the investment. A return therefore of R30 per acre is not more than 20 per cent on the cost of creation of such property, while a return of R7 per acre on paddy is equivalent to 18 per cent on R40, the corresponding cost of paddy land, and this from one crop alone. Again paddy will give a return in one year at the outside, while coconuts take ten at least.

I need not enlarge on the benefits of quick returns though accompanied by a smaller profit.—Yours truly,
E. ELLIOTT.

RICE CULTIVATION IN CEYLON.

(Local "Times.")

Mr. Elliott wishes us to understand that his calculation as to the cost of production per bushel of paddy included the Government tithe as well as the water rate, and he further points out that at least three districts—the lands under the Giant's and Kanthalay tanks and the Guriva Pattu—are similarly favorably situated as regards proximity to the coast and consequent facility of transport, as are the Batticaloa lands, whilst the Wannu, to which we referred, is not so badly off as we contended. Figures are given by Mr. Elliott showing that, starting from Anuradhapura, to Matale the cost of transport by cart is 30 cents, and to Jafna 40 cents a bushel. This added to the 37½ cents, which Mr. Elliott declares to be the actual cost of production including all taxes and charges, would allow paddy to be laid down in either of the two markets mentioned above at from 67½ to 77½ cents per bushel, and this—as in either of those places the ruling rate for paddy cannot be less than R1.25—leaves a profit of about 50 cents per bushel. This very satisfactory result is, however, more or less mythical, for the simple reason that the paddy on which this handsome return is to be made is not forthcoming. The Anuradhapura district has as much as it can do to grow sufficient grain to maintain its own sparse population, so that except as a literary exercise it is not much use proving how large a profit could be obtained, if it only produced an enormous surplus of paddy.* We are told that the cultivators are made to repay the cost of irrigation works in ten annual instalments or contribute a rate of R1 per acre perpetually. That this is so in theory we do not deny. But where are the millions of rupees expended by the Government on the construction, repair, and maintenance of the irrigation works of the island? Have they ever come back

* To do the Government only bare justice, this surplus which they are aiming at in constructing the Kuluwewa Irrigation Works, and indeed Mr. Fisher declared in an official report that there have been large exports of paddy in some recent years from his province.—Ed.

to the treasury or are they ever likely to? * We do not deny that paddy can be produced as cheaply as Mr. Elliott contends, simply because we have neither the materials before us, nor the experience necessary, to give an opinion of value; but we have certain stubborn facts before us which *cannot* be explained away. The most obstinate of these is that, as a rule, surplus paddy to any extent is *not* produced in any district of the island even where irrigation helps the cultivators and notwithstanding the enormous profit, at which, according to Mr. Elliott, it can be grown even in the Wannī. How is this accounted for? Were paddy-growing the most unprofitable pursuit in the island there could not be less desire than there is on the part of the Sinhalese to attempt its cultivation on a larger scale than their absolute requirements. How then does Mr. Elliott account for this—so profitable a cultivation and so little desire to extend it? † Surely the circumstance must have been noted by him, but we see no reference to it either in his original paper or in the letter addressed to us today, though we especially referred to it in our last article on the subject. To us, we admit, it is incomprehensible unless the cost of production has been very much underestimated. It is obvious that this estimate is purely an approximate one. Fields are not cultivated by day laborers and paid for in coin. By his knowledge of the subject, Mr. Elliott is able to say that on an average $1\frac{1}{2}$ days' labor produces a bushel of paddy and from that circumstance infers that the cost per bushel can be no more than 37½ cents. But after all, this is an intangible sort of calculation, ‡ and cannot be argued from as if the whole thing were a business transaction, such as Mr. Elliott would have us believe. We are asked not to include the water-rate or the amount of the ten annual instalments which the cultivators are supposed to pay back as the cost of the irrigation works above their fields, but why not we should like to know? Whether this expenditure be regarded as capital expenditure or not, anyone entering into the cultivation as a business would certainly expect to derive interest for the amount of his capital invested. Mr. Elliott's letter extremely interesting, but, after all, the contrast between the rosy picture painted by him and the actual facts before us, is most marked.

THE RICE SUPPLY: MR. ELLIOTT IN EXPLANATION.

Sir,—With reference to your article on my paper on rice cultivation, will you allow me a few words in reply and explanation of the errors of omission laid to my charge, as I think I can show, incorrectly?

As regards the cost of production, permit me to point out that I gave ample details for Matara, and not for Batticaloa alone. The results are very much the same, viz., $1\frac{1}{2}$ day's labor for a bushel of paddy where a crop of 30 bushels to the acre is secured. I may add it is two days where only a crop of 20 bushels is the return; but this is an absurdly low rate of yield in irrigated lands. The money equivalents are 37½ cents and 50 cents per bushel respectively.

You further say on these calculations nothing is put down for commutation tax, water-rate or cost of irrigation. I would indeed deserve censure if I had omitted any allowance

* Here we have ignorance of an official paper published last year, showing the actual outlay and return for irrigation works.—Ed.

† This was exactly our argument at the R. A. S. meeting which, however, was ridiculed by our contemporary; only we confined our criticism to the fact that certain districts were more suited to palms and tea than rice growing. Mr. Elliott, of course, says the want of a regular water-supply prevents extension of rice cultivation.—Ed.

‡ This is really too bad; for Mr. Elliott gave the most minute particulars of every item connected with the work of paddy-growing; he gave more details in fact than we have for coffee or tea, and so far as Batticaloa and Matara are concerned it is indisputable that he made out his position. We take up the ground, on the other hand, that the capabilities of each district and its population agriculturally should not be judged by any hard and fast rule, as if irrigation was a universal panacea in Ceylon.—Ed.

for the tax on paddy lands, but reference to my paper will shew I have all through carefully allowed for the Government *tithe*, which is the tax in some districts commuted, though not invariably, and when it is, generally to the advantage of the grower.

Water rate, as fully explained in my reply, has been provided for in the case of Matara, as it is a *perpetual* tax of a rupee per acre. But it was excluded in the Batticaloa calculations, as there the people have elected to repay the cost in ten annual instalments, and the large works have all been paid for as a matter of fact. It has been in all cases under ten rupees per acre, and I consider this charge is a *capital* one, to be added to the cost of the property, and not to be mixed up with the crop expenses. It is, I believe, intended to make a charge for upkeep, but this will, in Batticaloa at all events, be very small (probably 10 cents an acre); but it has not yet been imposed, and may at present be headed as a "negligible item."

You say further I have omitted the cultivator's "proportion of the cost of the irrigation works which supply him with water." As you have already referred to "water rate" (which in Ceylon is the cultivator's contribution on this account) I don't know what further item you can mean. As you are doubtless aware, every land owner in this island, who benefits by an irrigation work, is bound to repay his proportionate share of the cost in ten annual instalments, or to pay R1 per acre in perpetuity, which Government accepts as interest on the outlay invested. Possibly this only covers the amount spent in upkeep, as remarked by Mr. Dawson, but Government also receive a good return (about 5 per cent) on their expenditure by the increase in the value of the *tithe*, whether rented or commuted.

If you refer to the subsidiary distribution of the water, I may add that, in the irrigated districts, as a rule the water is delivered by the works at the head of the tracts. The further distribution consequently entails very little trouble, and is attended to by the field servants within the limits of time I have charged for, as also is the cleaning and repairing of the minor distributing channels, where any exist, and the water is not simply passed on from field to field.

As regards cost of transport generally, I would remind you that in at least three districts which will probably become large surplus rice-producers, (viz., the Giant's Tank and Kandely lands, for the Tanils, and the Giruwa Pattu for the Sinhalese) there is a good deal of similarity to Batticaloa, viz., in that they lie within 10 to 15 miles of the sea coast where not one shipping to favourable markets is available during at least one nonseason.

As regards the island ports of the Wannī, as I am traveling down the central road I am in a position to supply you with the present rates of transport. Taking Anuradhapura as a central position, where considerable quantities of paddy are now being produced with a promise of a good deal more, I find the rate of cart hire to Matala is R12, or 30 cents a bushel for a load of 40 bushels. To Jaffna the hire is R15 for a similar load, or nearly 40 cents a bushel. Paddy is now selling at 62½ cents a bushel at Anuradhapura, I have been assured by some Jaffna cartmen taking tobacco to Matala whom I questioned today. They told me further they intended investing in paddy on their way back, as they could sell it for 22 to 24 fanams (R1-37½ to R1-50) per bushel in their villages on the peninsula. Thus they will secure a paying load (instead of probably returning empty) besides a profit of some 50 per cent on their investment.—Yours faithfully,

E. ELLIOTT.

Dambool, 15th August, 1885. —Local "Times."

"TEA BOX" writes from Assam to a contemporary:—"Why are not tea planters allowed something for their tea chests? My tea boxes cost me, landed up here in Assam, about R1-1 each, and I have to give them away to any one who is kind enough to buy my teas. It is not fair. Tea buyers may say it is the rule of the trade to allow nothing for a tea box. Perhaps it is, but the sooner the rule is altered the better for the planter." The planter has the remedy in his own hands, and usually, we imagine, applies it by practically including the cost of packing in his calculation.—Madras Mail.

Correspondence.

To the Editor of the "Ceylon Observer."

NORTH BORNEO: MR. HENRY WALKER ON
CANKER IN CINCHONA AND ITS CURE;
GOLD AND TIMBER TRADE IN NORTH
BORNEO.

Land and Survey Department, 29th June 1885.

DEAR SIR,—In the April number of the *Tropical Agriculturist*, p. 764, there is a letter from someone in India, asking for a cure against grub in his cinchonas.

I send you the *British North Borneo Herald* for April, where a possible antidote may be found (see p. 2) in a cure for canker accompanied by white grub in cacao as adopted in the Philippines. The ginger is the wild kind found in the Ceylon jungles and has small marble-like roots. [Here follows a sketch, which we regret we cannot reproduce.—Ed.]

A in the sketch represents the ringing of the tree that is gradually taking place, which must be well cleaned out, and probably grub will be found in the hole or in the adjacent soil. A bit of ginger should be squeezed in and left in the hole.

B is the wedge of ginger to fit the cut C.

It is worth trying.—Glad to see you take an interest in our gold. I took another trip up the Segama River in April, and have some 4 cz. of gold to show. In addition I proved that workable gold exists on about 150 miles of the river, either in the river or in beds of alluvial on the sides of the river. Very suitable for Chinese and Malays. Our timber trade is going to be a big thing. No restrictions are placed on cutting from Government land, and the export tax is only one cent a cubic foot. Six ships have sailed with timber to Australia or China, and the profits are now proved to be very considerable.—Yours very sincerely,
HENRY WALKER.

I was particularly interested in an antidote to canker, or grub, or beetle, which he explained to me. It appears that the cocoa in the Philippines has been for some time affected with a disease which kills off the trees at short notice, and from which, Captain Schueke about a year ago found his plantation suffering. He tried several remedies but without avail. One day a convict (the Government are sometimes willing to lend convict labour at \$4 a month) drew his attention to a sickly tree, and digging round the root produced a couple of white grub, and further explained that a beetle laid its eggs in the bark. Their presence in the bark causes it to turn to a reddish brown like the canker in the cinchona in Ceylon. Having cleaned the tree of these parasites and cut away all the infected bark it was necessary to apply the antidote, which consists of ginger root. A bit of the root is squeezed into the cankered places and also into the bark of the tree, as follows.—A small wedge of ginger is cut, and a downward puncture made in the bark of the tree. The knife is held in the wound which is opened by a slight pressure and the wedge of ginger is pushed in tight. This should be done say in three places, and effect on the tree will be seen in a few days.—*British North Borneo Herald*.

[It will be noticed that it is canker arising from the presence of white grub for which ginger is said to be a cure. We can quite understand the hot ginger, when brought in contact with the grub, being inimic to the creature, but the remedy would be very expensive. Canker in cinchona is not due to grub.—Ed.]

FIRING TEAS: WHAT IS THE CAUSE OF
MANY REPORTS OF CEYLON TEA BEING
"BURNT" OF LATE?

29th July 1885.

DEAR SIR,—In almost every list of tea sales which has come to hand lately, the remark *burnt* appears attached one or more marks in the list, and on several occasions has been commented on by the London brokers. So much has this been the case that no surprise need be felt should Ceylon tea ere long become notorious for this defect. In most instances if enquiry is made as to mode of firing, this will be found to have been done by machinery, and those who imagined and worked in the fancied security that tea could not be burned in the old "Sirocco" doubtless attributed the burning to some defect in the machine employed. My experience of drying machinery is limited to the No. 1 "Sirocco," but that this machine with ordinary care will burn tea at a lower temperature than that recommended by the makers, a recent sale affords ample proof. I do not mean burned to such an extent as to show the black or charred leaves noticeable in the outturn from tea burnt in the choolah trays, but sufficiently high-fired to impart a decided burnt flavour to the liquor and entitle the tea to have *very burnt* applied to it in the London market.

Messrs. Davidson & Co, in a circular issued some months ago, pointed to the great advantages tea derived from a final firing in the "Sirocco" and laid considerable stress upon the fact that *tea could not be burnt at a temperature of 300 degrees*. I have not the circular beside me. I, however, took particular note of that remark—it has doubtless influenced others—and decided to work at a temperature under that marked on the thermometer for the first firing and the final firing at 260 to be well on the safe side. All through the season this system was rigidly adhered to; nevertheless the tea is classed as burnt.

I do not write this in disparagement of the "Sirocco"—from what I have seen and heard of other firing machinery, I consider the No. 1 "Sirocco" the best and safest yet tried—but users of these machines should be cautioned against working at a higher temperature than 250 degrees especially in the final firing. I am of opinion that it is during this process that the mischief is done and that the temperature ought to be reduced to about 220 degrees for this operation. The malty flavour so much valued in Mincing Lane can be readily developed at this temperature with little additional expense or loss of time, and what does a trifling increase to the cost signify in comparison with the all-important question of maintaining the reputation already earned for Ceylon teas.
A. F. S.

THE "COLOUR" OF COFFEE OFTEN DEPEND-
ENT ON THE SHADE OF THE MARKET:—HOW
TO SECURE "COLOURY COFFEE" IN
PRACTICE.

DEAR SIR,—Did it ever occur to the Wynaad P. A. that there is a sympathetic relation between the *colour* of coffee and the *tone* of the coffee market? so that, in a buoyant market, buyers, in order to place themselves *en rapport* with sellers in the matter of value, are inclined to stretch the limits within which the classification of coloury shall apply; whereas on a low and depressed market buyers are naturally prone to be more fastidious, and sellers for the time being to acquiesce in a more restricted range? This kind of sympathetic relation is however by no means confined to coffee and the coffee market, but extends to all with which I am acquainted.

The pre-eminence gained by Ceylon plantation for colour in former days was due doubtless to the difference in mode of preparation; but in later times other coffee-producing countries have not been slow to take a leaf out of our book, with the result, that the pre-eminence is less marked than of yore.

That the method of curing coffee has much to do with its colour cannot be doubted; and there can, I think, be equally little doubt that certain conditions of cultivation promote the end in view also. As a rule, the best formed and most fully filled-out bean is susceptible of the best colour; and insofar as leaf-disease, drought, or the opposite extreme, poor soil, wind, neglect, or any other cause, mars the efforts of the trees to produce fine fruit, so will the task of the coffee curer be rendered the more difficult and uncertain.

Given a well-matured crop and the necessary appliances in the way of machinery for curing, and suitable weather for drying the parchment, and, above all, a superintendent who knows what he is about, and the result will be coloury coffee, provided that no undue delay occurs in the transmission of crop to Colombo, and that the curers there understand their business and perform it properly. There is, however, less chance of harm arising to the coffee in Colombo than there is on the estate; for as a rule our operations are not so often liable to be impeded by the weather as they are upcountry.

The colour of coffee depends greatly, although not entirely, on its freedom from silver skin, that filmy integument lying between the parchment and the bean, and if the curing on the estate is such, that this silver skin incorporates itself with the substance of the bean, no known process of subsequent curing in Colombo will wholly remove it; and in proportion as this skin adheres, so does the finished coffee assume a more or less grey appearance prior to packing. The mere adherence of silver skin does not in all probability affect the quality of the coffee, but it is an indication that at some stage in the process of curing, incipient fermentation had occurred; and we know that chemical changes of this nature do affect the flavour as well as the appearance, not only of coffee, but also of cacao, tea and other products, and therefore require to be regulated to a nicety in order to produce the wished-for result.

The question however is, what part, if any, does or ought fermentation to play in the curing of coffee? and the answer probably is, none beyond what is necessary in the washing cisterns to separate the mucilage from the parchment after pulping. Some planters advocate heaping the cherry for 12 to 14 hours prior to pulping; but in certain experiments, which I am informed were made by other planters to test the results from this method, nothing conclusive was obtained to show, that it had any particular advantage in point of colour attained by the bean, the crucial test being the price realized in London. Rapid drying on estate sufficient to prevent heating on the way down, quick transmission to Colombo, and prompt conclusion of operations there, including thorough drying, equal sizing, and efficient packing in casks or double bags, are probably the most favourable conditions for securing the verdict of "good coloury" in a London sales room.—Yours faithfully, C. W. H.

[Another old merchant and estate proprietor sums up his advice to the Wynaad planters in terms almost identical with those used by "C. W. H." so far as the duty of the superintendent is concerned:—not to try to dry his coffee too much on estate, but to get it despatched as soon as possible by the speediest means of transport at his command to the hot dry coast, where it can be carefully attended to in a coffee-curing establishment.—Ed.]

RAINFALL AND TEA IN NORTHERN UVA.

Narangalla, Badulla, 3rd Aug. 1885.

DEAR SIR,—I enclose a return of the rainfall for the past five years. This hill is generally considered an exceptionally dry one, and subject to long droughts; therefore, I shall be glad to learn your opinion on the distribution and the amount annually registered, and whether it is sufficient to encourage the cultivation of tea, as I believe it has been doubted whether tea would do on this side. You will observe that the average for five years equals 104.09 inches, distributed over 142 days of the same period per year:—

Month	Days on which rain fell	No. of days in each year	Total rainfall for year.
August	6	188	96.85
September	6	157	114.00
October	16	137	109.64
November	21	133	88.49
December	22	140	110.91
January	22	138	620.49
February	12	137	1.36
March	6	133	1.30
April	14	133	6.25
May	3	137	1.36
June	5	133	1.30
July	4	138	6.00

Average rainfall for 5 years = inches 104.09.
Average days of rain per year = 142.

I am, dear sir, yours faithfully,
A FORTY-ACRE LOT.

[Certainly the average rainfall and its distribution fully justify tea cultivation.—Ed.]

ENEMIES OF CACAO.

Kandy, 1st August 1885.
DEAR SIR,—I am sending you by this post in a tin box an extraordinary insect, which fell on a cacao tree. Can you or your entomologist tell me what it is? I hope it is not a new plague.—Yours truly,
CACAO.

[Our entomological referee informs us that the insect is of the *Fam. Limacodide, sp. Narosa adala* (Moore) but it feeds on rambutan leaves and will not touch those of cacao, and in any case could do no harm, being a very harmless moth. Our correspondent must be in error about it feeding on cacao leaves? It would be well if some of the food leaves were sent along with any enemies of products, in future forwarded to us for report.—ED.]

WHITE-ANTS AT OVER 4,000 FEET IN UVA.

4th August 1885.

DEAR SIR,—Allow me to inform you that white ants destroy all the timber in buildings in this bungalow and others at a similar elevation, viz., 4,000. In this climate they seem to come any height after their food.

I hope they will leave our tea alone in Uva; for if our coffee be condemned and cut out, cinchona not worth harvesting, cardamoms for the most part stolen, and tea eaten up by white-ants, verily our last state will be the worst.—Yours truly, A. C. I.

P. S.—This is not a Baillie Street scare!

WHITE-ANTS IN PUNDALUOYA AT

4,700 FEET.

Fernlands, 5th August 1885.

DEAR SIR,—With reference to a paragraph in your paper on white-ants on Fernlands and its elevation, I cannot say exactly what the elevation is, but if the top of Kaipogalla estate is 5,000 feet, as it is stated to be, I can show you white-ants at about 4,700 feet in the timbers of a cottaged on Fernlands which is considerably higher than either store or bungalow, in both of which they have been for years.

In your Directory I see Kumbalulu is 4,414 feet elevation, but I don't know what trig. station this is.—Yours faithfully, HENRY L. EGAN.

WHITE-ANTS ATTACKING HEALTHY

TEA PLANTS.

Eton, Pundaluoya, 8th Aug. 1885.

DEAR SIR,—In your issue of the 6th inst., a correspondent mentions that he has never known white-ants to attack a healthy tea plant. On Eton estate I have lost a good many plants from this cause, the stems being completely 'ringed' just below the level of the ground. As the plant takes some time to show the effects of this treatment, the animals have generally cleared off before the damage is discovered. But on one occasion I found the white ants actually at work.

I am inclined to think that the insects are originally attracted by the pegs, which are often eaten clean off below the ground, and that from these they turn their attention to the tea plants close at hand.

A plant that has been ringed will continue to grow for two or three months, the leaves gradually turning yellow and dropping off when the stem dries up; or it may occasionally throw down fresh roots from above the injured part.

Another species of termite—a little yellow insect—is very destructive to garden plants and vegetables at this elevation, and makes the cultivation of potatoes an impossibility.—Yours faithfully,

E. E. GREEN.

WHITE-ANTS IN UVA.

Padulla, 10th August 1885.

DEAR SIR,—With reference to what has lately appeared in your columns respecting white-ants, I find them here at an elevation of from 3,700 to over 4,000 feet, destroying the bark of living and

healthy blue gum, fir, fig and cinchona trees: in the case of the latter, they were attracted by the covering of mana grass put on the trees after a shaving. They also attack coffee in instances where leaf disease has worked its debilitating effect.—Yours faithfully, Q.

WATER-CRESS IN CEYLON.

(Communicated.)

In Moon's time—1824—the common water-cress, (*Nasturtium officinale*, L.) was pretty well naturalized in Ceylon, and since then nearly every stream running through the estates in the Kandyan country has the water-cress growing in it, the plant being known to the Sinhalese as *kakkinu pala*.

In reference to the idea of Natural Selection, we some time ago alluded to the facts recorded by Sir Joseph Hooker, that the water-cress introduced into New Zealand found such a congenial climate there that it grew to a length of 12 feet, and one inch in diameter, and it cost Government £300 per annum to keep the mouth of one of the rivers clear of this introduction to enable the stream to be navigated. A correspondent who took a stroll on the banks of the Dambagastalawaoya from Cymru as far as Elgin, a few days ago, informs us, that, seeing a dense mass of green vegetation on the other side of the river, covering the banks up to the level ground on the top, and not recognizing it, he got a handful of it picked by one of the men in the lines close by, when he found it was a bed of water-cress, one of the top bits of which measured upwards of 3 feet in length and $\frac{3}{4}$ of an inch in diameter, and he believes that entire plants in that bed measure 6 feet and $\frac{1}{2}$ inch, so that we can grow water-cress in Ceylon one-half the size attained in New Zealand!

HEAVY CROPS OF RICE IN CEYLON.—In reference to the large returns of paddy from flooded fields in the North-Western Province, it is worth quoting a letter from Mudaliyar S. Jayatileke of Kurunegala, with fuller information:—"In this district there are a very few first-class fields; on the banks of the Mabaoya and Deduruoya, which are flooded yearly during the heavy rains, there are fields which, with favourable weather if cultivated at the proper season, give forty-fold, that is to say 100 bushels to an acre. Fields of this description may be counted on one's fingers, but with all the advantages you describe, viz.:—a good paddy field, where the water is never wanting and the soil good, and if cultivated during the proper season a return of twenty-fold is sure to be realized. Such fields cannot be cultivated for two harvests in the year, and if cultivated (with plenty of water) &c., the highest crop that could be realized is fifteen-fold. Such fields are few and far between."

PLANTING IN BRAZIL.—The *Gazeta de Noticias* says that a large planter of S. Paulo has notified the *Sociedade Central de Imigração* that he is ready to accommodate, within 24 hours, 300 families of immigrants upon the following conditions: 1st. Cultivation of the coffee trees before bearing, at 50% per annum per 1,000 trees; 2nd. Cultivation of the trees without payment, the immigrant to receive 500 reis per 600 litres of cherries gathered; 3rd. Cultivation of the trees at \$10,000 per *copina* and payment of 240 reis per 500 litres of cherries; 4th. House and free land for planting cereals; 5th. Rations, farm implements and clothing during the first year, to be paid for by deductions from the profits as verified. A very fair advance, and a further proof that S. Paulo continues to lead the rest of the empire in the immigration question.—*Rio News*.

TEA PRODUCTION AND CONSUMPTION
IN CEYLON.

As regards our tea enterprise, we may say that one of the most useful and reliable estimates of our present position and future prospects yet made, is that which we reproduce on page 234 from the pen of Mr. H. K. Rutherford. This gentleman has extensive tea proprietary interests in several districts: and he has evidently studied his subject to some purpose, the result being worked up in the paper contributed to the local monthly trade publication, "The Ceylon Advertiser" (Messrs. W. H. Davies & Co.). It will have been seen that Mr. Rutherford gives the probable export for the current season at 3,880,000 lb. There are, now, only six weeks more available of the present season, but we hope to see 4 million lb. of exports touched if not exceeded. As regards his estimates for three succeeding seasons, we think Mr. Rutherford must be near the mark although we shall be in a better position to judge a little later on when our statistics of acreage are available. The basis on which Mr. Rutherford's calculations are made is, of course, the figures of our planting enterprise, compiled for last "Handbook and Directory"; but a good deal more uncertainty attends the "probable yields" estimated by him as follows:—

1885-86...	Total yield of tea	6,360,000 lb.;
	Local consumption	130,000 lb.; export 6,230,000 lb.
1886-87...	Do.	12,120,000 lb.;
		160,000 lb.; do 11,960,000 lb.
1887-88...	Do.	20,800,000 lb.;
		200,000 lb.; do 20,600,000 lb.

Mr. Rutherford's estimates of yield per acre are very moderate—in the face of the published returns from certain estates—ranging as they do for tea of 4 years old and upwards at from 280 lb. to 330 lb. per acre. There is much however in what is said in criticism of the figures of acreage already recognised as contrasted with the actual export; but when it is remembered how much has been done of late to cultivate and properly work tea which had formerly been comparatively neglected, we cannot help thinking a much better average, 360 lb. all round at least, should be established from next year onwards for all tea over 4 years old. We should be inclined to dispute the acreage return rather than the yield, if the export figures did not bear out this ratio. It is most difficult to estimate a proper acreage for tea planted among coffee or cinchona, and in this way proprietors are apt to exaggerate the actual extent under each product.

Then as regards "local consumption," we think Mr. Rutherford is a good deal below the mark in his figures for the present quantity consumed and especially for the consumption of coming years. He finds that in 1877 the import of China tea was 87,000 lb.; and it so happens that that year saw the maximum consumption of foreign tea in Ceylon. But we submit that if 87,000 lb. of tea selling at from R1 to R1.50 per lb. were taken up by local consumers five years ago, we may very well double that quantity when we consider how large a proportion of the dust and other cheap tea drunk by the natives costs no more than 25 cents, while very fair drinkable tea is obtainable for 50 cents per lb. Another point is the great extent to which the natives along all our main roads and in the villages have substituted tea for coffee as their drink. When the native coffee gardens were flourish-

ing and everything prosperous in Ceylon, we estimated that the local consumption of the berry could not be less than 50,000 cwt.—5½ million lbs. At present, we suppose there is not a fifth of this quantity locally consumed. But tea is everywhere in demand to take the place of coffee, and we should really be inclined, bearing what we do of the way in which tamby pedlars are travelling everywhere selling tea, to double the above figures and say that there must be 400,000 lb. of tea drunk in Ceylon in this year 1885; and three-fourths of this quantity by people who never touched tea so long as coffee was freely available and so long as they could only buy the high-priced foreign tea. And this process of an increasing local demand is to go on and the consumption of tea among the 2½ millions Sinhalese and Tamils must rise rapidly, until by 1887-8, not 200,000 lb. as estimated by Mr. Rutherford, but 800,000 lb. will be required to meet the local consumption in Ceylon, the greater proportion of course being of the very cheapest sorts. This, however, after all, affects the estimates of yield and export only to a slight extent, and in other respects we do not feel called on at present to criticize, but merely to call attention to Mr. Rutherford's carefully worked-out and very useful summary. This much we may say, that we feel sure, if it errs at all, it is on the side of moderation and that a good deal might be said for estimates which would run for the three coming seasons as regards Exports:—7 million, 13 million, and 25 million lb. Probably the actual result will be found between these and Mr. Rutherford's figures as given above.

CEYLON UPCOUNTRY PLANTING REPORT.

A VISIT TO MARIAWATTE TEA FACTORY, NEAR GAMPOLA.

17th August, 1885.

The store is not yet completed, although nearly so. It is built of iron and brick, measures about two hundred and eighty feet in length, and eighty feet wide; has an upper floor boarded with pine, secured to iron beams, and which is to be used as a withering loft; the lower floor is laid with concrete to a depth of about six inches, and will have a covering of pure cement on the top, the withering loft is very well lighted and suited for the purpose for which it was intended, but the lower floor strikes one as being somewhat dark. Why pine-wood should have been selected for the flooring I cannot very well make out, imported too from Scotland, for it is very liable to take fire, and as for white-ants I fancy they would travel miles to get at it, so much is it appreciated by the termites. There is however not much chance of white-ants ever reaching the wood. The ground floor is like a show room of Messrs. Jackson's machinery. There is an engine and boiler, two "Excelsior" rollers, a large sized "Victoria" drier, "Eureka" sorter, and the new "Invincible" tea mill or cutter, all supplied through that eminent firm, and manufactured by Messrs. Marshall, Sons & Co. of Gainsborough. The engine was 12 horse-power, with 14-horse-power boiler, which I was told could easily develop 40 horse-power when required. Although not a professional, I could not but note the ease and sweet working of the engine; and the boiler seemed a fine specimen of English workmanship. I don't know how the makers managed to make the boiler so smooth and round: not a hammer mark to be seen on the flanges or rivets, like a piece of turned ebony in fact. From the engine a belt passes to the long line of shafting through which power is conveyed to the rollers and other machines.

There are two "Excelsior" rollers, and room is provided for an additional two, when required. One of the rollers was fitted with a granite stone rolling cap, which one might fancy heavy enough to crush tea leaf into a pancake; but it seems to do not do so, nor break the leaf in the least. I did not however see the machine at work, as the lower table which had been fitted with a facing of marble slabs had come to grief, the slabs having got cracked through the shutting of the door underneath. Mr. Jackson is going to try a brass-faced table as an experiment, which is thought will do well. The marble one, I was told, gave complete satisfaction, before the shocks of the banging door cracked it. The new brass one is not likely to go in this way. As to the big "Victoria" drier, it's a great machine, does a great deal of work, and costs a great deal of money; on it has been expended a wonderful amount of brain and thought, and it has been brought to such perfection that two coolies can easily manage it and enjoy, at the same time, that much coveted ideal of the Tamil—an easy job. The hum from it is like a spinning mill; it has potentialities which I feel sure were never dreamt of by the inventor, for I fancy it will yet become a favourite deity with Ramasami, and have fowls, arrack and fruit offered to it, so that the teahouse coolies may find grace in the eyes of the roaring Swami within. In the days gone by there was, on most estates, a water-wheel Muniandi, who insisted on his due share of divine honour; but in these late years I have heard very little of him. Unlike our own people, who want hard times to make a saint of a sinner, the genius of the Tamil race runs in an altogether different groove. Big wages with them seems to be an essential to the full development of the religious emotions, and, for the very good reason that an afternoon sacrifice is only another name for an evening revel in the lines. Short work and little pay did more to dethrone "Wheel Muniandi" than—well the labours of the Tamil Cooly Mission, faithful though they be; and although it seems a big thing to create a god, still I fancy that the good wages of the teahouse coolies will be potent enough to accomplish this, and house him in the "Victoria Tea Drier."

The working of the drier is evidently perfection. The leaf is tumbled in at the top, and comes out at the bottom without any handling during the process—the manufactured article. But it has been already explained fully in your pages, when the Carolina drier was described. The Mariawatte one, however, is a very much larger machine, and Mr. Jackson is of opinion that in full work it could deliver considerably over 300 lb. of dry tea an hour. As to the quality of tea, we will soon learn how it pleases in the London market, as a break from the Carolina drier was sent home some time ago, although unluckily detained owing to the late block in the Canal.

The "Eureka" sorter did its work well, and is a complete handy machine. To the end of it was geared the new "Invincible" tea mill or cutter, a toy of a thing in size, into which the large bold leaf was spouted, and reduced into a beautiful regular sample, and this without much dust. The machinery I understand, was erected under the superintendence of Mr. Jackson, and started without a hitch, gratifying alike to that gentleman and the fortunate proprietors of Mariawatte.

But after our eyes had been satisfied, I turn to figures and ask:—"How much does this complete set of tea machinery cost erected in the factory?" and the answer is "Somewhere between R16,000 and R17,000!" It is not everyone who can dance to

that measure. Indeed when the factory is completed it will be a costly building, and R60,000 or R70,000 will be more nearly represent its price than the R40,000 which was the original estimate. There are few proprietors in Ceylon in these days who have such a sum to expend, and fewer still have the courage to spend it. Nevertheless to have such a complete factory in our midst, whose best points we can copy, and whose mistakes we may avoid, is a great boon to Ceylon. Mr. Jackson, whose experience of Indian tea gardens is considerable, does not think there is an equal to it in India. This may be a prejudicial opinion; still for all that, Mariawatte has every reason to be proudly satisfied. Mr. Jackson has "a wrinkle" for extinguishing fires in tea-houses. It is simple enough: buckets all round the building and always full of water. When a fire breaks out at night, the watchman has at hand what in most cases will at once extinguish it, whereas to run for help, gives the flames time to spread, and the help arrives often too late. This seems to me valuable advice.

Mr. Jackson is leaving for home now. Don't you think it well to have him interviewed? I hear he has some ideas on the advantages of turbines over waterwheels for tea work, and has stores of tea lore in general which would prove interesting to the readers of the *Observer* as well as those of the *Tropical Agriculturist*.

I cannot close this long letter, without expressing my thanks to Mr. Jackson and Mr. Orchard, for making a chance outing such a pleasant one, and our party returned from Mariawatte feeling that like the three jovial huntsmen we had

"Powert up an' down a bit, and had a rattlin' day."
PEPPERCORN.

YIELD OF ACREAGE UNDER TEA IN CEYLON.

This subject has not, as far as I am aware, been entered into by others, at least I cannot find any record of it in the Tea literature of Ceylon.

Many individual Estates have been quoted as producing heavy crops, and Proprietors and Superintendents have vouched for the large yields which are being obtained per acre off certain Estates.

When, however, we compare the acreage under Tea in the island with the amount of our exports of the product, it does not, up to date, shew that the average yield of our Estates is likely to exceed that of India, for many years to come.

The last published returns of Indian Tea Companies, representing 42,355 acres, showed a return of 311 lb. per acre, and it will be seen with a reference to the following statement that we have only reached an average of 210 lb. per acre, and will not exceed this before 1888. This, of course, we attribute to our trees not being matured, but look forward to, at any rate, as good a yield per acre as India in the future. In my opinion, it is doubtful if our average yield will exceed that of India to any appreciable extent.

I think, we can, with a fair amount of correctness, foretell what the yield of our acreage will be up to 1888, but any calculations going beyond that date would not come within the pale of accuracy or practical usefulness.

I have for the year 1888 estimated a yield of 20½ million lbs., and I think it is reasonable to suppose that we shall obtain in that year an average of 210 lbs. per acre of 99,000 acres in bearing.

Mr. W. Anderson in March last published a statement showing that there were 85,800 acres under Tea in Ceylon at the end of 1884. I am of opinion this is somewhat in excess of the actual acreage at that date, and I prefer to take 72,000 acres as being nearer the correct amount.

No statistics are yet available for the acreage planted this year, but I think in taking the total at 102,000 acres to the end of 1885, I shall not have exceeded the actual amount planted.

With regard to the local consumption, there is no data available to enable us to say with certainty what quantity is consumed, but I find in 1877 there were 87,000 lb of China Tea imported into the Island, and when it is considered that the Burgher and Native population, who a few years ago drank Coffee, now consume Tea, I think it is reasonable to suppose that the local consumption will rise to 200,000 lb by 1888.

H. K. RUTHERFORD.

17th July, 1885.

PLANTING IN JAVA: TOBACCO.

(Translated for the "Straits Times.")

To show the scant encouragement given to European plantation enterprise in Java, a correspondent draws attention in the *Locomotif* of the 1st July, to the circumstance that, recently, a Chinaman was granted by Government 1,000 bouws of land South of Lumaing for tobacco growing, from its being remarkable that, in such applications for waste land, Chinese meet with scarcely any hindrances in their way, whereas Europeans too often have to wait for months and even years before decision are come to on their applications.

On the 4th July, so says the *Locomotif*, trials were made in experimental gardens at Samarang with a Dutch plough drawn by buffaloes and managed by Javaese under European supervision. The experiments were so far successful as to show that one bouw of land can be ploughed in a single day at a saving of sixty guilders per bouw compared with the customary method—a lessening of outlay by no means to be despised. Next year, ploughs of the same pattern will be set to work on to estates in Java.

ROSES, REAL AND IDEAL.

It was Coleridge, we believe, who remarked how inimitably graceful children are before they learn to dance. Some such sentiment is aroused by the contemplation of what are known as florist's flowers, particularly by certain forms of the modern rose exhibited at the show of the National Rose Society. The poets' flower has suffered strange transmutation by scientific culture. Legitimate progress in its development has long since touched its ultimate point, and in all descriptions save teas the long-suffering rose is being vulgarized. In colour, in form, in odour, the process is well marked. In some mere size is the aim, grossness the result. In others, cold, crude purple tones mingle with dull crimson, with fleshy petals almost scentless. Roses are seldom rosy nowadays, and one goes far to find the "roses blushing as they blow" of the Elizabethan poet. In truth, they blush little and flout much, with a stiff peacock pride from the broomstick heights of standard briars. Not merely in the individual bloom, but in foliage and in habit, have æsthetic principles been violated by florists. Reaction will doubtless come, but protest is delayed by the caprice of fashion, which tends to favour current articles.

In old novels the hero is much given to "pulling" a rose and presenting it courteously to the heroine. With the modern rose he would find it a hard matter unless armed with a knife, while the monstrous growth would embarrass the maiden's bosom. If ever the more beautiful and shapely forms are stamped out by modern improvement, the many allusions to the rose in our poetic literature will need annotation. The roses raved of by Laura Matilda are scarcely known. Cowper's rose that was "washed, just washed by a shower," was probably a cabbage-rose, or some old allied form. The famous bower by Bendemeer's stream was formed of some delicately-petalled variety akin to the China type. These and the "damask roses" of Herrick now linger in quiet old gardens, together with the sweet produce of Provence, the elegant rose of Japan, the Austrian briars, the quaint York and Lancaster—"part rosylike, part candidate"—and many another old-world growth. All these made a shy show at South Kensington, but they were hopelessly routed in the estimate of

the multitude by; the last new thing in circumferences. These charming old flowers live retired, like meek worth "left to herself unheard of and unknown." For such the popular voice is not raised. They bloom only for a little clan of enthusiasts, while the prodigious hybrids of the florist meet with general acclamation.

The National Rose Society might do well to discourage the aims of those florists who denaturalize the rose. No artistic results are produced by forcing the rose to assume the guise of the camellia or peony, or to make it emulative of the exuberant rotundity of a savoy cabbage. To combine the finer forms of the various types is the true ideal development, not to vie with the artificial flower manufacturer, and to follow after ugly eccentricity. It is notable that the old roses more than held their own in the contest though some of the best were ill represented. Among these were "La France" and "Maréchal Niel." Yet, these have never been excelled, nor the attar scent of "Charles Lefebvre," nor the beauty of form and colour of many an old rose now temporarily dethroned. A really good new rose that may compete with old favourites becomes yearly of greater rarity. While it is in the interests of cultivation to recognize new varieties, it is an unsound policy to reward coarse and staring prodigies.—*Saturday Review*.

CEYLON TEA.

Of late years Ceylon tea has attracted so much attention and the competition at the Minging-lane sales for specially favoured brands has been so keen, that the eye of the capitalist, as well as that of the struggling planter, has been directed to Ceylon with a view of obtaining a profitable investment. To all such, as well as to those interested in the production and manufacture of tea, we would recommend the careful perusal of a little pamphlet on Ceylon tea published by A. M. & J. Ferguson, Colombo, and which may be obtained of Messrs. J. Haddon, Bouverie-street, E. O. The book contains valuable information respecting most suitable soil, the selection of seed, the preparation of the land, and the cost of same; also details respecting the enormous yield obtained on certain estates, amounting to as much as 800 lbs. or 1,000 lbs. of made tea per acre. But side by side with this we find words of warning to the young and inexperienced, and a caution to those new to the island, which will be doubtless fully appreciated by all who may be thinking of going to Ceylon with a view of trying their fortunes. The healthiness of the tea gardens on the Ceylon hills at an elevation of 4,000 to 5,000 feet is proverbial, and much in favour of the young planter as opposed to Assam. Special attention appears to be paid to the process of preparing the tea-leaf for market—the fermentation of the leaf, withering, and firing being carried on with every regard to scientific accuracy and with the aid of the most improved machinery. At the present time there is a demand for experienced men who can superintend the manufacture, and take charge of depots on the main roads where the green leaf is purchased from neighbouring planters day by day; for it is an advantage that tea should be made on a large scale—the various qualities being sorted out, as soon as received, for special subsequent treatment.—Time and space prevent us from going more fully into a review of this little pamphlet, but to all those who may think of embarking in the Ceylon tea trade, either as planters or merchants, we would recommend its perusal.—*Crocer*, June 20th.

STRYCHNINE AND HYOSCYAMINE IN SEA-SICKNESS.

In a voyage to Madeira, which he made in the month of January, 1882, Dr. D. Embleton, F. R. C. P., etc., of Newcastle-on-Tyne, had an opportunity of applying Dr. Burggraave's remedy for sea-sickness with

the most satisfactory results. This remedy, as some of our readers may remember, consists in the administration of the Chantcaud granules of *sulphate of strychnine* and *hyoscyamine*, according to the dosimetric method.

The granules contain 1-130th of a grain of active substance in each case. They were given one of each kind, together, every quarter-of-an-hour, up to 8 or 9, when the nausea and sickness usually vanished, and generally gave way to a little refreshing sleep.

Dr. Embleton had supplied himself with the Chantcaud granules simply for his own use, in case he should require them for himself on the voyage. The supply was therefore very limited; but small as it was, it enabled him to treat no less than seven severe cases with the most satisfactory results. The cases were seen by the medical man of the vessel, the "Trojan," and reported by him (Dr. Lory Marsh) in the *Cape Argus* of the 4th of February, and a full account of these interesting observations published in the following July number of the *Journal of Medicine and Dosimetric Therapeutics* of London.

We should add that these same medicaments have been often employed in similar cases by Dr. Gesner, between Dieppe and Newhaven, and several times by Dr. Burggraave himself between Ostend and London, at the time of his discovery.—*Monthly Magazine of Pharmacy*.

INOCULATION IN PLANT LIFE.

The decrease now apparent in the virulence of the coffee leaf-disease, and still more the supposed waning of the effect which its attacks exercise on our coffee trees, have given rise to considerable discussion—as we are informed by a home correspondent—upon the bearing such facts may have upon a theory of inoculation by use among plants. The basis of such discussion appears to rest upon observations of the long continuance of disease among the potato crops of the United Kingdom, and notably among those of Ireland. When that disease was most rife, the generality of scientists pronounced it almost impossible that the plant could survive, and that it was inevitable that for many years at least the cultivation of the favourite tuber would have to be abandoned. Still, the necessity and the force of long-continued custom caused its planting to be persevered with year after year; each successive season, albeit the disease was still present, witnessing a diminution in the force of its attacks and a more than corresponding decrease in the effect of such attacks on the crop.

Now, as with the potato, so, it is argued, it may be with coffee. At no previous period of its history perhaps, since Sir Walter Raleigh brought the precious tuber from America, has the cultivation of the potato throughout the United Kingdom been more extended than at the present time. Although, as we have said, year after year signs of the disease, which was previously so fatal to it, are still to be observed in many widely divergent localities; yet this in no way interferes with the healthy propagation of the root or with the successful cropping results obtained by those who plant it. In Devonshire, as we learn today from a returned Ceylon planter, during the present season, so abundant is the potato crop, that many acres are not being lifted at all: there being no profitable market! What has occurred in respect of the disease in the one case therefore our scientists hold may well be expected to follow in another, and there are a good many interested in Ceylon, we learn, who think there is every reason to expect that coffee may

furnish the illustration in proof of that hypothesis. We are told to look back through history in order to realize how such a hypothesis has been applicable in the case of diseases attacking man and so to furnish ourselves with data for conclusions respecting the somewhat analogous life of plants. The sweating sickness, which, peculiar to England and not spreading to the continent of Europe, broke out as the results of the gathering of camps during the memorable Wars of the Roses, appearing during several successive years in a modified form, soon ceased its visitations altogether, never—so far as can be foreseen—to return. History furnishes many other instances proving that diseases arising from special causes cease to be operative or to possess the power of propagation when those causes are withdrawn. As with human, so with plant life. The planters of Ceylon are now credited with removing the reproach which probably indicated—that we ourselves have always regarded as—the primary cause of the outbreak of coffee leaf-disease, namely, the devotion to a single cultivation of vast areas of disforested country. Our planters are to be comforted by the hope therefore that fresh germs are not likely to be evolved, and that the propagation of the disease will receive no aid by a renewal of first causes.

But, independently of that fact, scientists at home—according to our informant—hold to the opinion that nature at last accommodates herself to the conditions under which she has to work by a process of inoculation, so to speak, which provides in successive generations of plant life its own source of protection against disease. It, in fact, becomes adapted to it, absorbs a certain element of the disease itself, and so becomes fitted by a partial assimilation to resist the overpowering attack which at first destroyed its vitality. The accounts lately received from Uva are regarded as strongly bearing out the view thus adopted by a large number of qualified men in England. The accounts from Balulua estates especially seem to furnish absent proprietors with evidence that in spite of an apparently most violent outbreak of leaf-disease in the early spring, yet the coffee trees subjected to it in that district have parted with neither leaf nor berry, but are rapidly bringing the latter to a maturity, which gratifies the expectations of crops largely reminding them of the days of former prosperity when the *Hemilia vastatrix* was unknown in Ceylon.

If there be anything in this theory of inoculation—and, as we have said, home scientists think they have much evidence in support of it—we might perhaps accept it as affording some ground for hope that the worst days of misfortune for coffee are over, and that the prediction of those who have always held to such a hope are in a fair way for realization. But there will then remain the question as to whether the course of inoculation described may not have so injured the quality of the Ceylon coffee-berry as permanently and seriously to affect the high reputation it has heretofore enjoyed in all the markets of the world. Only time can satisfy critics on this point: but as the quality of the potato growth of England has returned to and even surpassed its earlier normal standard, we are taught to look for a similar rehabilitation in the case of our own once famous product!

Nevertheless, we cannot forget that there must be a wide difference between the favorite tuber with its annual cropping and planting and our perennial coffee tree: the former affords opportunities for varying seed and modes of cultivation which are entirely wanting in the case of the latter. Unfortunately, too, for the theory of home scientists, leaf-disease at this moment is raging in some districts

or, at any rate, on some estates as vigorously as in days gone by; and in other places, a worse enemy in the shape of black bug has appeared, no doubt, on account of the enfeebled condition of trees repeatedly attacked by *Hemilia vastatrix*. On the other hand, it will be interesting to watch whether in Uva, free as it is of bug, a change for the better in coffee generally has been inaugurated with the experience of the present season.

PLANTERS AND MIDDLEMEN.

The *Madras Mail* has the following timely remarks on a subject often discussed in Ceylon. One difficulty in doing away with middlemen is the extent to which they influence the supply of capital to planters. Mr. Goschen in speaking at Manchester described the way in which the cotton trade used to be conducted:—

A New Orleans man consigned his cotton to New York; the New York house consigned it to Liverpool; Liverpool to London, London to Hamburg, and Hamburg sold it to Chemnitz in Saxony or some other spinners. But now the Chemnitz spinner goes direct to New Orleans; the agent visits him there, and a number of intermediate profits and commissions are swept away." Now *mutatis mutandis*, this description of an obsolete way of doing business, which American Saxons have found unworkable in these days of narrow margins, and keen competition, applies very closely to what is still going on in our midst. Indian planters have so long supposed themselves unable to sell their produce without the intervention of middlemen, that it may be difficult to persuade them that they are mistaken; but it is at least possible to show that they ought at least to make an effort to secure better arrangements.

To take an instance with which many of our readers are familiar,—the "account sales" furnished to planters—we find that the London charges amount to rather more than 12 per cent. of the price realised by the coffee when sold. If we omit freight, and marine insurance—at 2½ per cent. by the way—these charges amount to four shillings per hundredweight. It is not necessary for our purpose to criticise these charges in detail, though it might be argued that with English banks discounting at 1½ per cent. 4 per cent is rather a high "interest to buyers," and that with steamers at Bombay competing for freight at sixteen shillings, forty-seven and sixpence per ton is rather an extravagant rate from Malabar. The charges are, however, made by a firm of undoubted respectability, and are, we presume, merely what is customary. A correspondent recently informed us that "colony" coffee is usually bought for export, and as the coffee we are writing about came under this description, we may suppose that after its sale, it was reshipped to some continental port, again incurring all the charges for fire and marine insurance, brokerage, commission, dock dues and freight. As none of these were less than in the former instance, we may at least add another six shillings per hundredweight, or £10 per ton in all, which has, quite unnecessarily to our mind, gone into the pockets of the London brokers and merchants. Why, we may ask, are growers and consumers to be taxed for the support of these gentlemen? Why cannot planters follow the example of the cotton growers referred to above, and deal direct with the continental consumer? Mincing Lane is a great institution, but the planter does not exist solely for its benefit; and Mincing Lane certainly does not exist for his.

The foregoing facts are enough to give our planting readers considerable food for reflection, but they only deal with part of the subject, and we next have to deal with an equally important point, namely, the astounding discrepancy between the wholesale and retail price of tropical produce. The shipment of the coffee with which we are dealing fetched an average price of 56 shillings a hundredweight; an examination of any London co-operative store-list will show that, even where ready money prices are charged, coffee is priced at from one shilling to one shilling and sixpence a pound, nor has the recent fall in prices affected the sum paid by the

small consumer. "The Stores" are supposed to make the smallest profit compatible with covering their working expenses; are we, then, forced to conclude that the buyer at the coffee sales is able to make from one hundred to one hundred and fifty per cent on his bargain, and if he does not, who does? And why, moreover, should not this magnificent difference go to the producer, or at least be divided between him and the consumer? The tea-planters, who are just as badly situated, have made an effort in London to reach the consumer direct. The scheme, although, as far as we can hear, not very heartily supported, has met with some success, and should, we think, be joined in by all classes of Indian planters. Both coast agents and planters would also find it to their advantage to endeavour to lift themselves out of the groove in which they have been running for so long. Produce need not as a matter of course be shipped to London; if a better market offers elsewhere, it should be sent there direct, instead of in the roundabout way it now reaches it. Planters should, above all, try to take a more cheerful view of their position than they usually appear to do judging from the letters that we publish. They should lose no opportunity of pushing their respective districts and products. An opportunity for an advertisement on a very large scale will shortly be given them in the forthcoming Indian and Colonial Exhibition, where we trust that our various planting districts will be found well represented. The time for preparation is none too long, and the Secretaries of Associations ought to bestir themselves. We believe that the Government is willing to give assistance in forwarding exhibits, and in securing space. In spite of Board schools and higher education, our tea and coffee districts are no more than names—if even that—to nine-tenths of the inhabitants of Great Britain, and nothing that may make them better known to the investor should be neglected. There has never been a time when more capital was seeking an outlet. People who are rushing to put large sums into places like Florida and Texas, where they will have to work like slaves for years, should surely have their attention directed to this country, where labour is cheap and abundant, where they would be under British rule, and where they can buy cultivated land for less than they have to pay to "land grabbers" for jungle in Florida.

PLANTING NOTES FROM UVA, CEYLON.

WEATHER AND CROPS—BAD AND GOOD PRUNING—TRANSPORT—HAPUTALE TEA—HIGH PRICED PATANA—ILLEGAL SPORT.

Haputale, 18th Aug. 1885.

The month of July was fine and dry up here, and passed with bright sunshine and very little rain, scarcely an inch of rainfall during the entire month above the Pass, which led us to hope that the maturing of young wood on the coffee bushes would lead to another good crop next year. Unfortunately, however, two or three thunderstorms, accompanied by hail and lightning during the first week of August, and a continuance of wet weather, rather damped our hopes and reduced our expectations. A small blossom has been out during the last few days, but the appearance of spike for the big August and September blossom is very backward, and, unless there is at least another month of very dry weather to ripen up the young wood and cause it to blossom, the prospect for next year is not so very cheering. The coffee bushes are looking in very good trim, and not much punished after the late heavy crop. Unfortunately also for good blossoms, leaf-disease is very bad and pretty prevalent throughout the district at present. Pruning is being proceeded with rapidly, and a better style of pruning and the use of the knife more liberally adopted on many estates than was the fashion of late years; still there are some people who stick to the wretched plan of "docking primaries" and "knife-handling" as it is called, which means picking out the most insignificant quantity of old superfluous wood with the knife, and leaving everything that is likely to bear crop on the trees, which has a very untidy and unsymmetrical look; it is easy to learn a bad system of pruning, and

once taught to S. D.'s and coolies they never unlearn it. Some people, I know, are models of "knife-handlers" and a zigzag fashion of pruning, allowing cross wood in all directions, bending twigs back and planting their trees in a most uncouth manner. It seems to please them to have lots of wood on trees, forgetting that in order to get crop, especially at high elevations, plenty of light and sunshine should penetrate the trees to ripen wood and produce crop. Some dull-heads will never learn a better, once they have been taught a bad style of pruning. Transport of crop to Colombo via Ratnapura has been actively going on, and some estate stores are empty, having finished the dispatch of every particle of crop, including dried cherry and clean coffee. Cattle-disease along the road has been less prevalent and carts have been plentiful, but, owing to the Badulla planters having raised the rate of hire, cartmen and carts have been crowding down to Demodar and Badulla. I hear the rates given at these places are 70 and 75 cents per bushel respectively. The planters down there excuse themselves for raising the rates of hire, in consequence of an incautious statement of a correspondent from Haputale stating that a proprietor up here was offering "one rupee per bushel" to get off all his crop. I cannot find out who this long-pursed gentleman is, and fear the correspondent must have drawn on his imagination. Hapootella and Sherwood estates have completed the dispatch of some 17,000 bushels parchment from the top of the Pass, at the rate of 50 cents per bushel parchment, and in no instance gave a higher rate this season. Carts have been passing down to Badulla by hundreds and loading down there at 70 and 75 cents per bushel, and only a few have missed the opportunity, and now have any bushels in store here. The European firm at Haldummulla who has the greatest share of supplying rice and transporting crop, and who did so well in past seasons, were quite unprepared for this large crop, and the unexpected outbreak of cattle-disease; but I hear they are trying to meet the demand for carts and offering R12-50 additional hire per cart to bring up rice from Colombo—which latter commodity is going up in price, I see. Some people employ chetty contractors to supply their estates with rice and transport crop, but these chetties are failing in their contracts, and not keeping up to engagements. Why people employ these wily fellows I can't see. Generally they are up to some dodges, bribing kanganies to accept inferior rice for their coolies and "not let master know anything about it," and "scrimshanking" with the parchment route, for which they are always buying garden parchment and light coffee, which they resell to the cartmen very cheaply. Those people who have a liking for or "are under obligation" to these wily "cusses" will be sold in the long run.

Since date of my last I have been over at Gonamotava estate seeing the manipulation and manufacture of tea by Mr. T. W. Hills, who has had both Indian and Ceylon experience as a "tea-man." As far as I could judge, and in the opinion of some other gentlemen qualified to express an opinion, the tea manufactured by Mr. Hills was as well-made, fine-flavoured and as good a sample of tea, as any we had seen in the island. So much for Uva tea. Thousands of acres are being planted with this product, and, if the prices at home only keep up, many acres of Uva patanas will be flourishing tea gardens. This reminds me of Mr. Chhallinor's lucky purchase of the excellent piece of patana land between Kahagalla and Rochampton estates, 40 acres, for R2,020, or R50-50 per acre; so you see the bleak and barren patanas on the Haputale Pass are not so worthless after all, and there are hundreds and thousands of acres of such land still to be had for tea cultivation in Uva. The hailstorm about the beginning of the month was chiefly confined to the patanas between this and Bandarawela. The hail stones were about the size of one's thumb nail and oval shaped. During one of the thunderstorms 12 head of cattle were killed on Nahaketta estate, so I heard. Two inquests are reported from near Walawe, one on the body of a Bengali tailor stabbed to death by a woman for his interfering in a quarrel she was having with his wife; the other inquest was on the body of a Tamil man, who blew off his hand and other-

wised injured himself with dynamite, while trying to kill fish in the Walawe river. Large gangs of coolies from the estates, with nets and parish dogs, are in the habit of going about the jungles and patanas battue-hunting indiscriminately, killing all the game they come across in season and out of season, and no notice is taken of this wanton destruction of game and infringement of the game laws by the native headmen, the Police Magistrate, or Assistant Government Agent. Mr. Downall should again bring this matter of battue-hunting before the Legislative Council and stir up these lazy officials; not unfrequently village cattle and buffaloes add to the game-bag of these mighty hunters, for it is unreasonable to expect that one or two hundred coolies would be satisfied with an elk or red deer, a few hares and civet cats; so they make sport of the poor villagers, cattle.

THE CEYLON PLANTING ENTERPRIZE:
IN CACAO AND CARDAMOMS MORE
ESPECIALLY;
"SEEING OURSELVES AS OTHERS SEE US."

(Notes by "Aberdoninsis,"—No. III.)

THOROUGH INSPECTION OF DUMBARA, MATALE AND POLGAHAWELA—CHANGE IN DUMBARA DURING THE LAST THREE YEARS—A SEVERE CRITICISM ON CEYLON PLANTERS—A TRAGIC-SATIRICAL SKETCH OF "HOW THEY DO IT" IN CEYLON—FIRSTLY TO TWELFTHLY WITH THE 'NEW PRODUCT' ADDED—CACAO CULTIVATION—SHADE—BIRDS—RUBBER—WARRIAPOLLA—DRIERS—CLEANERS FOR CACAO AND CARDAMOMS: DIFFERENCES OF WORKING IN CEYLON AND MYSORE—THE RED CACAO—THE PROPER METHOD OF CULTIVATION—HOW 'HELOPELTIS' COMES AND THE REMEDY.

I have had a very favourable opportunity for observing various cultivations, and, though it may appear presumption on my part to "lay down the law," yet I may be pardoned for attempting a review of the effect on my mind of what I have seen. I have been thoroughly over Dumbara and visited Matale and Polgahawela. My visit to Warriapola confirmed and strengthened me in the opinion I formed in noticing the change in Dumbara in three years. Cacao, like most other products, has gone through all the well-known stages seen in coffee. First, there is a great reading-up of books on the subject of a new product. The agricultural literature of the world is ransacked and calculations are carefully made and a liberal allowance is always added on for "the well-known systematic and practical methods and untiring energy of the Ceylon planter." Secondly, friends at home are pressed to come forward and share the spoil of a new Eldorado, and the wherewithal is arranged. Thirdly, large areas are at once planted up according to the diverse interpretations of facts collated from the aforesaid literature. Fourthly, the rumour gets about that Jones has discovered quite a new idea which totally upsets all those idiotical statistics given in the aforesaid literature. Fifthly, someone goes over to the country where men have been carefully studying the requirements of the plant, and, after irritating the residents with snobbish self-assertion and upholding the well-known energy and system aforesaid, and, consequently, losing what he might have gained by courtesy, he brings back a piece of paper full of calculations:—"If men in that country get so much per acre costing so much per acre or per cwt. of produce with their slipshod way, surely in Ceylon with our 'energy' and 'system' we can, at least, double the yield, and then our forcing climate will allow very liberal additions." Now we have arrived at the dilemma. There is a man who has out of his "inner consciousness" discovered an entirely new way, up-

setting calculations derived from "literature," and also a man "who has been" over there "himself." Now we must join these two, and, sixthly, we have the Ceylon style developed. Seventhly, crops and prices are quite startling so as to warrant enormous outlay in stores and machinery, &c., &c. "Why man, you can't get past these figures. We can put so many cwt. at so many rupees in London, and the broker's report speaks for itself." Eighthly, money comes out with a rush and all are hard at work spending it. Gold mining is nothing to it. The thing is as sure as the bank (what bank?) Then, ninthly, some fool who pokes about with a microscope says he has noticed something queer on the plant, a little later on he calls out a note of warning, and the press, the planters, the merchants all hound him into a quiet spot and there is quietness again. Then the crops somehow don't bear out expectations. It requires manure, and, tenthly, we have the analysis of soils gone into by an expert. No, that does not effect what is wanted; and after one idea after another we have, eleventh, an entomologist and a cryptogamist and lots of other "ists" investigating the roots, the stems, the leaves, the fruit, the manure, the earth and the sky. Twelfth, we have "specifics," and all cultivation is stopped in the panic, for behold the calculations are not fulfilled. The specifics do not come off and then the country is in a worse plight owing to stoppage of cultivation. Then, thirteenth and lastly, we have a *New Product*. Oh for the weariness of it! The syren songs of your beautiful island are leading you on, on a veritable will-o'-the-wisp hunt. The forcing nature of your island climate with heat and moisture combined in conjunction with the forcing nature of your British pluck and energy forms a power that will not let you rest and be content, but beckons you on and on with golden dreams and nothing more. The Dead Sea apple is only found out when it is grasped. There is no more mortifying disappointment than that which comes exactly at the moment before actual possession of what is desired. You reproach me for being a croaker and say that is an easy rôle. Well I see your leaders, with hunched heads, greyer beards, and empty pockets, fighting fiercely and stubbornly as only a Britisher can. I see your young men soured and bitter with darkness ahead and a leathing for the country. I have heard of extreme distress. But on the other hand I hear of money beginning to flow in safe quiet channels and not in sudden violent streams. I hear a rattling of dry bones in the valley. The dry bones have begun to assume shape. The hopeful thing is in the *quietness* of many. There are many of the former style, taunting Indian men with their slipshod ways and want of system, boasting that they can beat the world, and forgetting that if they do so they will be "beating" themselves. If Samsen managed to pay off his enemies he hadn't much regard for himself when he loosened the pillars with his biceps. I have heard that 1,600 lb. per acre of tea has been reached—*facilis descensus Averni*.

I. *Cacao*.—"Literature" caused men to believe in shade. The effect of wind and exposure on the cacao near the Mahaweliganga confirmed that idea. A lifetime spent by a patriarch taught him the precept, "Never plant a ridge and never cease from digging." Moreover weeds along with shade did not trouble the planter in deep fine soil as they have in Dumbara, and they were eradicated when they were in the way. Let me describe an old-fashioned Dumbara or Matale estate. The jak-trees with their soft foliage and stems bristling with fruit making work safer for both European

and natives by shading from a fierce sun. The coffee below with its roots kept cool and moist by the shadow and the litter of the leaves. A rich aromatic smell of the pungent fruit pervading the whole atmosphere. Birds lifting their sweet and varied notes as they hunted the insects and obeyed the behests of their Creator. Ah! birds, where are the feathered songsters on the dry blighted ridges where once the jak flourished and Ben-fitted man, bird, beast, and plant? Your sweet notes were wont to waken the planter and fill the glades with rich music as the yellow rays of the sun spread themselves over "the happy valley." Your busy bills and sharp eyes were in full operation and were better pest searchers than little boys with the medicine phials. Little boys know where it is still possible to get a ripe jak fruit, and little boys' bellies get filled by other means than "helopeltis," therefore little birds who depend on insects for their food are the best. Prevention is better than cure. Birds are better than bug-doctors or mould-doctors or any other doctors.

Why say more about Shade? I was glad to see a very nice crop setting beautifully two days ago and the young flushes seem to be growing unblighted. The majority of the men are putting in Rubber because they are thoroughly scared by light, and similarly to the wicked who "love darkness rather than light." Now rubber is a particularly dense cover. It injures plants below it when it begins to fruit. It stands lopping as well as a school-boy enjoys hacking. You can hack it but it fills up the gap—and so you must "keep on doing it" and that costs money. Try rows of it and you find that the gain by lateral shade is equalized or neutralized by the loss by vertical shade; try clumps of it with the same result. Then when you find this out cut it all down and "here ye are again," and not quite in the same place. You remember the parable of the man who had the devil taken out of him and deliberately invited seven other devils, "and the last state of that man was worse than the first." Thus with rubber. You will have lost time, money, opportunity, and now you have your land filled with tuberos roots which are as inimical to good husbandry as the celebrated "cora pilloo" which is sufficiently known in Dumbara.

The "Bois Immortelle" has its indigenous sister in the jungles of Ceylon. The "Inga Saman" and the "luamadilla" are both indigenous as also the sycamore (or true fig) tree. The "charcoal" tree is a light cover and does no harm and is also found in your jungles. I need not enlarge on this, nor need I invite anyone to Mysore. At Warriapella as I accompanied the hospitable, travelled and deep-thinking young owner I could only say: "Surely this is not Ceylon. It is the land of Mysore." He in exact line with R. B. T. is aiming at a "West Indian" property. The Dumbara "lights" aimed at a "Ceylon" property and they have got it with all the concomitants. Kuruwagala and Polgahwala are said "to be good for tea." That has rather a dubious sound, at any rate as regards any other product.

I do not agree with the style of Clerihews. In fact a "Fruit Drier" is more in accordance with my ideas, and these ideas I found to be in perfect consonance with the only man who uses one of those admirable machines. The Sirocco is said to be a "crib" from the American invention. Now in drying material the object is to have moderate heat with the moist draught so as to save fuel and remove steam. Overbalance this and you will find a waste of fuel as compared with the drying power of your heat. Having worked

a Clerihew for three crops in drying cardamom. I am interested to see how they use them in Ceylon. In Mysore a long room twelve feet wide and fifty feet long with a reepled flooring is the style of thing. At one end there is a battery of a few and large pipes with a large furnace (in Ceylon they have many and small pipes, with a small furnace). This leads into the room and pours in a hot blast. Now if you attempted shelves you would end in rather a mess. But in Mysore we can get 160° at the fan end of the room and keep that up. One man said he could get up far above this. "How did the coolies stand it?" I asked. "Oh, I stayed myself two hours." I then asked where the thermometer was, and I saw where he was. But Dumbara men say heat must be very gradual and moderate, as the colour which has been acquired by fermentation, is all driven out of the cacao. At Warriapella I was told the West Indian plan—and quick sudden heat was better advocated. Dumbara men then point triumphantly to the market, and "prod" men are they. The market is really the test. To continue the description of a Clerihew, I must first state that they are used by only one man in India and he it is who maintained the monopoly of the cardamom market in the world for years, Messrs. Walker & Co. of Ceylon (the planters' right hand) sent a man to put up Clerihews on this cardamom place many years ago, and they have been worked there on a very simple plan ever since. I have described the size of room and style of pipes and furnace. The fruit is laid on soft cloth through which the air is easily sucked and care is taken that it be very thinly spread out. The soft cloth is spread on the floor and on one permanent platform and the double fan at the end creates a strong draught. This is the simple "Clerihew." Ceylon men fill up their room with shelves. So that their theory of gradual moderate heat is very difficult to carry out, and is attempted by a crude and clumsy arrangement of moving the trays about. The risk of fire must be very great. Then they have wooden ceilings. I should say that that must be dangerous. We found in India that fireproof ceilings made of lath and plaster were much to be preferred. Before that was adopted serious loss by fire was the result. You can't improve on the sweet simplicity of Clerihew. I saw two Blackman's Air Propellers. It's a fancy article, and, on account of its requiring less power to drive it, is a gain in a district where firewood or water is a difficulty. It cuts the wind out, whereas the fan knocks it out. To use trays properly each layer ought to be in a separate division with communications with the hot flue and the fan. When the air rushes in at the orifice it goes bang into the near and central shelves and dries them, moistening itself and neglecting the side-shelves. To put this right they put coolies on to exchange the hot fruit for the cool fruit and so on, as I said before crudely and clumsily. The weak point lies in the self-satisfiedness in results. There is always room for improvement and this very thing has caused Ceylon as compared to the planting districts of India to be as America is to Great Britain. I know that the cacao which fetched the highest prices was dried in very fierce heat on the floor on the primitive Clerihew system. Increase your air-exhausting power and your furnaces and you will have a drying machine that beats any newfangled notions. If you wish shelves, have them isolated along the whole length so that a current of hot dry air will pass over the surface and remove the moisture in steam. All

have all gone in for stationary heat, and cardamoms and cacao mildew at a very high temperature where there is no draught or *drying current*. They have a room similar to a laundry-maid's drying room with a stove. They only want a chair and a copy of the *Family Herald* and the perspiring, portliness and rounded outlines of a huxom laundrymaid to complete the picture. Instead of linen, there are tiers upon tiers of shelves, and in this stationary heat they complain that their capesles split. But I am off to cardamoms before the time.

The vulgarly known "common red" cacao is by far the finest and most delicate in the world. The new yellow variety is a coarse robust kind and is said to resist disease. That has an ominous yet familiar sound in Ceylon. Something is sorely wanted to resist disease, but it is the conditions rather than the coarseness of texture or quality that should be looked to.

Cacao is eminently a plant that resists artificial pressure. It sulks, it sheds its blossom, it furnishes foliage to make up for undue exposure to the sun. In fact, is not this the case with coffee? Cacao is an elephant not a horse. Force an immature elephant to do a mature horse's work, it will do it but for a time. Men in Ceylon preferred to get experience at their own cost instead of gaining by looking at 200 years' experience in a cacao country. Experience is a lamp that only hangs astern; but often that lamp is ignored and difficulties which have been already safely passed by the beacon-carrying vessel ahead are run against through inattention to the warning light. "Cacao is another myth" was a remark the other day. Aye, only so far that it is not the golden-fruit-bearing tree that was supposed, but not a myth in the sense of a paying industry if carefully studied.

I am thoroughly of opinion that *Helopeltis Antonii* is a plague bred and fostered by the sweetened juices of a weakened tree, and the only remedy is to return to the wise, plain, simple rules that guided your fathers. You know the old story of the sons whose opinion of their father changed as they grew older until they confessed as old men that the old man himself was right after all.

CHINESE SABAH LAND FARMING COMPANY.

[Report of the Directors for the half-year ended 31st December 1884.]

The reports of Mr. Gibson, the Manager of the Suanamber Tobacco Estate, continue satisfactory. His last letter, dated the 21st June, 1885, stated:—

"The tobacco is really growing beautifully just now, and everything at present looks to promise a favourable result. I hope by the end of July to have finished planting with 2,000,000 trees. Immediately this year's tobacco crop comes off the ground I shall hole before undergrowth comes up, and plant out all this clearing with Liberian coffee. We shall then at a very small extra expense have about 300 acres of coffee, which I am certain will be very valuable. I am busy now holing for coffee, and in a few days shall commence planting out the fine nurseries which I am going to bring over from the Siboga."

The Chairman (Mr. F. Major) stated that the first call of Tls. 7 per share, had been paid on 2,052 shares, and the second call, of Tls. 2 50 per share, had been paid on 1,627 shares. In addition to that, there were many foreign shareholders, some of them in England, whom they expected to pay the calls by-and-by. They had made these calls to carry on the tobacco crop of 1885; and he was glad to say that this was going on as successfully as they could wish. They had all read the

report, which contained an extract from a letter of Mr. Gibson's dated the 21st June, and since then they had received another letter from Mr. Gibson, dated the 3rd July in which he said:—
"I am glad to be able to report well of our progress here. The tobacco commences to grow very well, and the weather is all I could desire. We have planted out up to date 959,000, and are still busy planting. It is now July, and in a month more we shall start on jungle-felling for next crop."

Continuing, the Chairman said the prospects of the Company, of course, depended entirely upon the success of the tobacco. They had received altogether about Tls. 87,000, of which they had written off Tls. 34,000. This Tls. 34,000 included all preliminary expenses and everything, so that they started their tobacco estate clear. The balance of about Tls. 54,000, included the value of all the land, and the survey fees expended upon it. Their only difficulty ahead seemed to be about going on next year, and this they would have to discuss later on. Mr. Gibson's letter said that in another month it would be necessary to commence felling for next year's crop, but beyond that he believed the expenses of the 1886 tobacco crop would not commence till about February. Felling would cost \$1,500, so it would be necessary for them to decide whether they would spend this \$1,500 or wait two or three months, and see whether the present crop turned out favourably enough to encourage them to do so.

The Chairman moved:—"That the Directors' report, and accounts for the half-year ending the 31st Dec. 1884, be passed as presented."

Mr. Rivington seconded the motion, and it was carried.

The Chairman remarked that they were doing all they could to make the present tobacco crop a success; and it was generally acknowledged that they had in Mr. Gibson about the best man they could get. If any shareholders had any question to ask he would be happy to answer them.—*Hongkong Daily Press*.

THE MARIWATTE TEA FACTORY is the subject of a graphic description by our correspondent "Peppercorn" on another page (233) to which we attract attention. With reference to Mr. Jackson's movements, we may mention that he is not yet leaving us, but means (now that he has got a good deal of responsibility about machinery off his shoulders) to make a trip round the tea districts, after which our readers will learn some more of the opinions of this practical and experienced visitor in reference to the condition and prospects of tea in Ceylon.—We are glad to see that the Masekeliya Planters' Association have secured the services of Mr. C. S. Armstrong to read a paper on Tea Machinery and Preparation at their next meeting. This is sure to be interesting.

THE LATEST NOVELTY in paper productions is a pianoforte. Wood is discarded in favour of compressed pulp, which takes a high polish and, without staining, shows a cream-white colour. It is said that the "short broken character of the sounds emitted by the ordinary pianofortes" is replaced by "soft, full, quasi-contiguous tone resembling that of the organ." If this be true, another horror has been added to the noisy terrors of life in teeming cities. It is difficult enough now to try and live at peace with one's neighbours with the ordinary pianoforte of commerce tinkling maddeningly and persistently through the life-long day. What existence would be like with the solemn swell of miniature organs booming every hour it is impossible to realize.—*Home News*,

THE MUSICAL INSTRUMENT TRADE IN SAXONY.—This industry, which employs many hundred men in Upper Vogtland, was not very satisfactorily situated during 1884. The imports from Zanzibar have up to the present been very small. Coccoswood was dearer than in the preceding year, and speckled wood rose from 50 to 70 per cent. Brazilwood and horse-flesh mahogany showed no change, and the finer qualities of red ebony brought a little higher prices.—*Kuhlow's German Trade Review.*

TOBACCO.—According to Mr. Crowe, British Consul in Cuba, cigars, suited to the taste of the British smoker, are very difficult to obtain in Havannah. Mr. Crowe allows that there is plenty of "dark, powerful tobacco," of fine quality, at moderate, though by no means low rates. But if a smoker desires a light leaf, with aroma such as the "educated palate of an Englishman" seeks, he must be prepared to pay for it. Only about 10 per cent of the tobacco harvest of Cuba can be classed as of this quality; and apart from the cost of the raw material, the best makers of the best cigars obtain wages which alone would render their handiwork of value. As much as 40 dollars in gold are paid to killed labourers for turning out 1,000 "first-class goods." This means that a cigar of this grade costs two pence for the mere rolling, apart from the boxing, the price of the tobacco, the freight, the Custom-house duty, the interest on the capital expended, or the profits of the two or three middlemen before it gets between the lips of the European consumer.—*H. and C. Mail.*

CINCHONA FEBRIFUGE MANUFACTURE IN INDIA.—Says a Calcutta contemporary:—"The capital outlay by the Bengal Government on the cinchona plantations in Bengal, and the manufacture of febrifuge, since the first commencement of the gardens, has been £10,84,202, which, we are told, has been recouped more than twice over by the saving effected by the substitution of cinchona febrifuge for quinine in the Government medical institutions. Looked at in a more purely commercial light, the operations of last year realized a profit of £37,582, which is equal to a dividend of about 3½ per cent on the capital outlay, exclusive of the saving from the use of the febrifuge. The total revenue for the year was £1,24,225, whilst the expenditure was £81,766. The crop for the year amounted to 339,201 lb. of dry bark, of which 325,125 lb. were red, and 14,076 lb. yellow bark. The whole of this crop, with but a small exception, was made over to the febrifuge factory for disposal. The demand, however, for the febrifuge seems to be decreasing, for the amount issued last year was only 7,152 lb. 4 oz., as against 8,144 lb. 12 oz. in the previous year."

ARROWROOT.—A correspondent, writing from Coomera on 20th July, says:—"The arrowroot-making is uncommonly late this year, only one or two mills having as yet begun the work. Shortness of water is still the cry in some cases, and in others the machinery is not yet ready. There is a good crop of bulbs which the frost will not injure, but delay into the warm and growing weather will lessen the flower of the bulb by the less which shoots will occasion; yet is there no probability of scarcity in the article, or reduction in the quality, there being liberal stocks on hand from last year. The extension, however, in the area under arrowroot appears to have received a check from the reduction in price of the past and present year. Maize is generally a poor crop, and very little, if any, can be spared for town after local wants are supplied. I know of no sales under 4s. From the high hills the severe effects of the frosts of June are visible on all sides in the whiteness of the canefields, and the light-brown of the grains, but the cane on the hills is green, and some of it is even now growing. The mills are crushing their own cane with all speed, and

putting off that of other growers until their own is safe but their will be hardly time to save all before some even of that is unfit for sugar-making; the rest will probably be a loss to the growers.—*Queenslander.*

AGRICULTURE: IN THE CENTRAL AND NORTHERN PROVINCES.—*Quat homines, tot sententiæ:* as many men, so many opinions: as many places, so many methods to suit circumstances. In the Central Province, where the Kandyans, whatever you may say, know not what it is to do without a meal a day, we can understand the necessity of teaching them to take more out of the soil than they usually do, telling them of the necessity of strenuous exertion. The fact is the Kandyans go in only for one tillage during the year, with all their heart, and that is the *naha* harvest. It is only of late, that in the out-skirts of towns a few of them, languidly, grudgingly, because goaded by authority, go in for the *yalla* harvest. The Kandyans altogether live on their native rice. They think it a shame to sell their paddy: and if necessity compels them to do so they do it on the sly. It is a fact that all the beggars in the Central Province are in nationality, either low-country Singhaleses or Portuguese descendants. A Kandyan, a bona fide Kandyan beggar is a "rars bird." The Kandyans rather desire to rot and die than disgrace themselves by begging. They have enough: their soil supplies them the grain for the year: their garden gives them their vegetable store: their jungle gives them their meat: and their garden provides them the few rupees with which they purchase clothes. They do not indulge in luxuries. Their idea of happiness is to lie still. Your glowing eulogy of trade and enterprise, of improving agriculture and getting the best out of the soil are quite wasted; they go home and in dignified sarcasm tell their wives of the fool who wants them to betake themselves to extra labour for no earthly reason at all. Necessity is the mother of invention; and till the Kandyan is driven by necessity, you cannot expect him with all his heart, to espouse the new invention of a plough, or a more educated system of agriculture. In the Northern Province it is otherwise. We live on what the land yields us; and when that fails we starve; or go about pawning our jewels. Agriculture here is our very life and subsistence. It is so with all of us; either in our fields, in our tobacco gardens, in our coconut and palmirah plantations, or in our vegetable gardens. We live by the soil. In no other province do you see gardens so cleanly kept, fenced and enclosed and trees watered by the Egyptian pulley in quite a skilful method of irrigation. Drais or water-courses ramify the garden, conveying the water to a wide basin, dug out round each tree, so that really it is rivers of water that our trees enjoy both morning and evening. Our fields are plentifully manured. We have seen cart-loads of seaweed, which, otherwise waste their "stink" in the sea-shore air, propagating malaria among our fishermen, carried in bullock carts and buried in our fields. We have seen branches of trees and bundles of green leaves from our jungles undergo the same operation. We have seen all dried leaves of Palmirah and cadjans readily asked for to manure our fields. We have seen bones, ashes and cart-loads of other refuse made use of to enrich our soil: which after all is but a surface-mould of manure. The Province seems, originally to have been but a sand-bank, created by the caprice of mother ocean who set her children, wind and wave, to play all sorts of tricks with it. In such a place, and to such hard-working cultivators, your ideas of better ploughs, and a more scientific method of cultivation are all theories which to them seem but the mirage of the desert. We want water. Give us artesian wells. Give us tanks. Let us not depend upon the former and the latter rain, and what we can reserve of rainfalls in our bunds. Let us have a plentiful supply of flowing water: and the Jaffna cultivator will teach you a lesson or two of successful agriculture. Let no Englishman think we do not know to farm, or cultivate grain. When your forefathers went about dycing their skins, and eating only green cheese and curd, we produced the grain that fed us well and our loom produced the cloth which then as now clothe us. Give us water. Give us water; and there shall accrue a revenue from grain produce that will enable you to make a Railway to the, not moon, but the distant sun.—*Ceylon Patriot,* August 14th.

Correspondence.

To the Editor of the "Ceylon Observer."

NOTES ON INSECTS AND OTHER MATTERS.

South of India, 29th July 1885.

The Editor of the "Tropical Agriculturist," Colombo.

Sir,—Will you kindly forward for identification some small flies on the underside of the tea leaves and twig, which I am dispatching by post, and which may or may not reach you, according to the mysterious decrees of the postal authorities whereby a similar parcel dispatched to you last year was returned to me on the score that the parcel was under a certain size? Perhaps this parcel will be returned also as being over a certain size. However you will perceive that the leaves have been sent in a box ten times the size really necessary in order to propitiate the said authorities. In forwarding this box I am called upon to fill up a form in which the said authorities have the exquisite cruelty to require me to put a value upon these pests!

Are Messrs. Armstrong, Hay and Owen yet decided in their opinion as to the reason of Ceylon teas possessing such a superior flavour over Indian teas? It is not becoming in me to have any opinion on such a subject, yet nevertheless I venture to think that I am not a hundred miles off the mark.

Allow me to take this opportunity of tendering you my hearty thanks for the many valuable suggestions given in your excellent periodical, and which suggestions only require consideration and observation in order to turn them into practical use.

To such of your readers as to do not regard their coffee or tea bushes as virtually mere machines which can be made to give crops to order, allow me to recommend most strongly two very valuable books, viz., Johnson's "How Crops Grow" and "How Crops Feed" (American publications; they always will push into the front those Americans).*

On page 126 vol. 4 of the *T. A.* it is stated on the authority of the *Leader* with reference to *var. Eucalyptus salubris*, that its foliage "contains an extraordinary abundance of oil which renders this species significant." Can you, Mr. Editor, verify this statement? Mr. Bosisto gives the following percentages of eucalyptus oil:—

	per cent.	
<i>E. amygdalina</i> ...	3.250	volatile oil.
<i>E. oleosa</i> ...	1.313	do.
<i>E. leucocylon</i> ...	1.060	do.
<i>E. gonocalyx</i> ...	0.914	do.
<i>E. globulus</i> ...	0.719	do.
<i>E. obliqua</i> ...	0.500	do.

So that in his list *E. salubris* is not even mentioned! It is a most important question to decide which of the eucalypti (cultivable in India and Ceylon) supply the largest proportion of oil. Perhaps Dr. Trimen will come to our help?—Yours faithfully,

ONE OF THEM.

[The insects are aphides or plant lice. There are various remedies recommended in "Garden Pests" for getting rid of them in green houses and small gardens, which would be too expensive for application on a large scale. We cannot verify the statement regarding *E. salubris*.—Ed.]

MR. A. WHYTE ON HOW TO GROW "ROSES" IN COLOMBO, WITH HINTS, APPLICABLE TO ALL ELEVATIONS.—No. II.

(Continued from page 181.)

To assist their action, a few small holes may be pierced on the upper side of the tiles, and when laid down they ought to have a covering of brushwood to allow the water to percolate freely and to prevent choking. Another very serviceable and cheap drain may be made from lengths of bamboo, cleared of the inside transverse partitions, perforated on the top and fitting loosely into one

another. When laid down in a green state, these will last for a long time underground. While on the subject of carrying off superfluous moisture, we may touch on the application of moisture or watering. This of course will seldom be required in the rosarium, except in dry weather, when the trees ought to have a good soaking every evening if the ground is porous, and every alternate evening, if the soil is clayey and retentive; frequent and partial watering, which does not reach the roots, often does more harm than good. Syringing after the scorching sun has passed over the rosarium will be of great benefit in reviving the roses. Roses in pots under shelter will of course require water daily, but ought not to be kept constantly wet and sodden. In pot culture perfect drainage is half the battle. As to soil for the pots, let it be the best strong virgin soil procurable, well mixed with, say, one-third of decayed farmyard manure. And now we come to the choosing of suitable varieties or

V.—*Selection*.—Great mistakes are liable to be made in purchasing roses unsuitable for the climate. Many of the grandest show hybrid perpetuals will never bloom in the low country, or in Kandy, and are even very shy in flowering with our most skilled rosariums upcountry. We must therefore confine ourselves to a comparatively small assortment of these splendid roses, a few of the most suitable of which we will name, viz.:—

Baroness Rothschild, a first-rate rose, light rose pink and large.

Captain Christy, a grand rose, light salmon flesh, large and robust, well-built form.

Duke of Connaught, rich, velvety crimson of perfect shape.

Duke of Teck, crimson, large and full.

Eliza Bonlie, white full free flowering and of good form, first-class.

La France, a very grand rose, silvery white, very large, full and fine form, free flowering.

Madame Lacharme, free, white, round form.

Marquise de Castellane, a superb rose, bright, pure rose color, very large.

Nardy Frères, rich violet rose color of perfect form.

Senateur Vaisse, very fine showy red rose of good form.

Coque de des Alpes, charming pure white rose.

Gloire Ducher, superb, very full large deep crimson rose.

Madame Assé, very fine red rose, with shade of purple.

The above varieties of *Hybrid perpetuals* will generally be found to flower freely, and are all superior roses.

The *Tea Roses*, as a class, are very much more to be relied on as free flowerers and most of them are deliciously fragrant. We give a list which we can recommend as suitable for the low country, and which of course will arrive at still greater perfection upcountry, viz.:—

Caroline Kuster, bright lemon yellow, beautiful shape.

Catherine Mermel, a charming light flesh-colored rose.

Devoniensis, the good old sweet-scented tea rose.

Devoniensis climbing, creamy white like old variety.

Etoile de Lyon, sulphur yellow, perfect shape, one of the very best.

Gloire de Dijon, a matchless salmon-colored rose, superb, will do either as a dwarf or creep r.

Homér, rose-colored with salmon centre, large and fine.

Jean Ducher, yellow shaded salmon, large, full and free flowering.

* They are American reprints of English works.—Ed.

Jules Finger, rose with silvery shading, large and fine.

Madam Lambert, bright rose-colored, free and large.

Madame Margottin, citron yellow, large, full and fine form, one of the best.

Madame Willermoz, white, centre salmon, large and full.

Madame Welch, light yellow, large and full, a fine rose.

Niphetos, a lovely waxy white rose, large and full, *Sombrenil*, pure white, in bunches, very fine.

Aldine Sisley, white and rosy peach, good and free.

Comtesse Panisse, copper yellow, tinted violet, large, very full and free flowering.

Madame Joseph Schwartz, white, pretty and very free flowering.

Belle Lyonnaise, deep lemon, large full and fine form.

Madame Berton, straw like *Gloire de Dijon* but quite distinct.

The majority of the above *teas* will be found suitable for pot culture, as well as for the rosarium. Besides these and the *hybrid perpetuals* enumerated, we have among the other classes some choice roses, suitable for all elevations in Ceylon, viz. —

The *Noisette Roses*, in which class we find the matchless

Maréchal Niel, the deep yellow creeping beauty now so well-known.

Lamarque, pure white shaded sulphur, also a magnificent climber.

Céline Forestier, a charming yellow beautifully crimped climber, and *Cloth of Gold*, also a fine yellow fragrant, rambling beauty: and then we may select from among the *Bourbon Roses*.

Madame Isaac Perera, a very large light carmine rose.

Charles Lawson, fine hybrid *Bourbon*, vivid rose colour.

Souvenir de la Malmaison, a grand, large, very full, white rose well-known and introduced here for some time.

If space would permit, we might mention many more suitable varieties from the different classes of roses, but we think it advisable to name only those which we know from personal experience, to be the best and most suitable, especially for low elevations.

Besides the roses enumerated, we have many more common varieties introduced long ago, and these, though wanting in size and symmetry and fullness, ought not to be despised. What they lack in these good qualities, they make up for in profusion of bloom and sweet perfume. They are very old friends with a claim on our affections, and most useful as cut roses in bouquets and for table decoration.

For edging purposes we would recommend the rich crimson *China Cranmoise Supérieure*, and from the *Polyanthas*, the pure white *Ma Parqueritte*, and the rosy pink *Mignonette*.

We will now consider as briefly as possible the *VI.—Arrangement of Our Roses.*—In planting up the rose garden, it will be well to study the nature and habit, as also the colors, of the different varieties. It is quite evident we should spoil the general effect, were we to indiscriminately plant up the space available, with rampant climbing roses, and those of moderate growth and delicate form, all mixed without regard to the habit, height and shades of the different sorts. If the plot be circular, an arbour or summer-house in the centre, formed of climbing roses, is useful and effective in displaying the beauties of, say, *Climbing Devonensis*, *Caroline Kuster*, *Gloire de Dijon*, *Céline Forestier*, and *Maréchal Niel*. The gallant Marshal, like most truly great characters, is modest in his deportment and droops his noble head.

We cannot fully appreciate his matchless face and brilliant uniform, unless we look up to him. The Marshal, when trained as a weeping rose, on an umbrella-shaped frame and in full bloom, is a glorious sight. Around the summer-house let the taller and more vigorous *hybrid perpetuals* and *tea roses* be planted, and gradually as we approach the outer circle, the less vigorous and moderate growing *teas* will display their lovely blooms. The same rule will apply when the borders for the roses are alongside of the garden walls, the latter being covered with the showy creepers, until they become literally walls of roses. A tall archway of roses over the gateway will be in keeping with this arrangement, and will be most effective. Hedges of roses may also be formed by planting stout *tarred* stakes, at intervals of, say, 1 foot with a strong top-rail, or ridge pole. The hardy creeping roses festooned from pole to pole will look very beautiful, and will form a substantial fence and shelter from wind. In all cases, give your roses ample space, so as to derive abundance of nourishment from below, and enjoy a free circulation of air above, — say not less than 3 ft. × 4 ft. for your dwarfs, and at least double that space for your climbing roses. Thin out and prune your roses after a season of rest. Just before the arrival of the little S. W. monsoon, is a good time. Practice will soon indicate to what extent the knife may be used. As a rule, don't spare it.

VII.—Insect Pests.—With reference to *insect* and *other pests*, to the attacks of which the rose is liable such as black and white bug, mildew fungus, beetles, and the larvae of diurnal and nocturnal Lepidoptera, &c., the best, cheapest and most efficacious cure I have yet tried is a mixture of (1) one of lime, (2) two of kitchen wood-ashes, (3) three of sulphur, all finely sifted and dusted on the leaves while covered with dew. A jam-tin with a perforated lid will make a good duster. This mixture will be found to act both as a preventive and a cure, and is most valuable to ward off insects from seed beds. Fumigating with tobacco leaves and syringing with tobacco water are also effective cures, but the best of all antidotes for caterpillars are our insectivorous birds, if they can only be attached to and induced to visit the garden regularly. White-ants are a terrible nuisance in the lowcountry and often ring the rose trees near the surface of the ground in the same way as they injure tea and cacao. The above mixture keeps them off, if applied freely round the stems. Tar everything exposed to them, especially all wooden work, and the bottoms of rose-pots, and raise the pots on tarred bricks. Allow toads and lizards to have the run of the garden, and, if white-ants and caterpillars are making headway, turn a hen with a good brood of chickens into the rosarium every morning: she will soon give a good account of these pests.

It must be kept in mind that we cannot under any circumstances grow roses in Colombo or Galle, or even at the elevation of Kandy, to anything like the same size and perfection, as can be done in the cooler climate of the higher mountain ranges. Still, though we cannot alter our climate, a very great deal can be done, by careful selection and judicious treatment, and there is no reason why we should not have lovely roses, even in our seaside gardens.

But, finally, if we would attain to signal success, we must have *enthusiasm*. If we long to have delightful rosaries—*amena rosaria*—and lovely fragrant show blooms on our tables, we must have roses in our hearts. Worship with faithful devotion at her shrine, if you would court the smiles and favour of the Queen of Flowers. There is no royal road to

rose-growing, and Queen Rosa rewards alike the labours of her ardent lovers and devotees, be they *peers* or *peasants*.

A. WHYTE,

P. S.—As pointed out by one of your correspondents lately, a number of the roses introduced here are known by wrong names, which is apt to create great confusion. I give a few of the misnomers which have come to my notice:—

La France, beautiful large silvery white rose, is often called *Baroness Rothschild*, also a fine large light rose pink flower.

Gloire de Dijon, the splendid salmon-colored rambling rose, is often misnamed *Victor Verdier*, which is of a warm rose color, shaded carmine.

Madame Margottin, fine yellow globular rose, is known as *Gloire de Dijon*.

Souvenir de la Malmaison, a grand large white rose, is erroneously named the *Hundred petal Rose*.

Paul Neron, the enormous rose-colored rose, is misnamed *Mrs. Williams*, and also I think *Mrs. Campbell*, *Deponiensis*, the sweet-scented cream-colored tearose, is known by the general term *Tea Rose*.

Lord Raglan, splendid but sky-dark rose, is misnamed the "*Black Rose*."

Niphetois, beautiful pure white rose, sometimes with tinge of yellow, misnamed the *Wax Rose*.

There are a good many more misnomers, but these are all I can remember at present.

The term *Rosa centifolia* is applied to what includes all the varieties of the *Provenc* or *Old Cabbage* rose to memory so dear!

A. W.

SUCCESSFUL HARVESTING OF CINCHONA BARK.

Agapatana, 11th August 1885.

DEAR SIR,—The latter part of my previous reply to "B. E." was certainly intended to show that shaving in alternate strips was quite as economical as shaving all round the tree, for I saw no difficulty whatever in sending down the bark for 10c. per lb. It is quite evident that "B. E." has never tried this "strip" shaving himself, while I have tried both plans and have no hesitation in saying that after the first or second time I have had no difficulty whatever in getting quite as good, and even better tasks from coolies than I did when I shaved "all round" the tree, and I attribute this to the bark having renewed so much better than it used to do. My missing only costs me about $\frac{1}{2}$ cent per tree. But even supposing that there were a slight excess in cost of harvesting the bark in this way, this would by no means prove it to be a less economical plan than the other; for the extra yield of bark which the tree most decidedly gives and its increased value must of course be taken into consideration, and is of far more importance than a mere difference of a cent or two in the harvesting of it. The analysis of some of the bark which was lately shown me in Colombo, from trees which had been shaved five and six times, completely bears this out. The tree can be shaved the first time all round if required, only leaving one narrow strip, and this can be afterwards followed up by shaving the renewed bark in strips; the principle of which I have already explained. I have just made up the cost of some of the bark sent away from here, and I think even "B. E." will admit that it is not excessive; and that as increased quantity and quality in the bark is secured, he will see that harvesting bark in this way is not such a bad thing after all.

Cost of bark delivered in Colombo including cost of two (2) coverings of all shaved trees and of all transport from store to store, from trees scattered

all about and not from clearings:—

No. 1 lot 43,831 lb. stem including 1 ton of root bark
14,008 „ branch bark

57,839 lb. cost R2,925-41 or say 5½c per lb.

No. 2 38,489 lb. stem (with chips from dying trees).
7,451 „ branch

45,940 lb. cost R3,253-08 or less than 7½c per lb.

No. 3 19,930 lb. as above
2,833 lb. cost R1,349-82 or 6c per lb.

22,813 lb.

Total of these 126,092 lb. cost R7,528-31 or say 6c per lb.

If "B. E." will come up here I will be glad to prove to him the success I have had in leaving the stump on coppiced trees. I gave my reasons for this in my last letter. Different conditions give different results, but I have scarcely such a thing as suckers dying off, and in fact very few failures of any sort which cannot be accounted for on very different grounds.

CINCHONA.

TEA STATISTICS OF COST OF CULTIVATION AND PRICES FOR INDIAN TEA.

DEAR SIR,—Referring to the tabular statements in your issue of 29th ultimo, the first thing that strikes one is that it is not sufficiently comprehensive to be as reliable as might be desired. Take for instance the average gross expenditure, which is stated, as corrected in your *Overland* issue of 1st instant, to be 11-50l per lb., and the average price realized is 1-33d: this shows an average profit on the operations of 11 Companies of 1-53d per lb. Since then, however, we have had the reports of two more Companies viz: the Tiphook and British India showing results which raise the average gross expenditure to 11-64d per lb. and lower the average price realized to 1s 0-40d per lb. and consequently also the average profit to 0-76d per lb. With a still larger number of concerns to deal with, the average might be susceptible of further modification; and it must be borne in mind that the figures in the statement are only representative of about 26,000 acres and 9,000,000 lb. of tea or less than 1th of the total production of the neighbouring continent. Moreover it is evident that all the Tea Companies enumerated do not adopt the same system of accounts, a *sine qua non* in compiling reliable statistics of this nature. In the *Home and Colonial Mail* of 17th July I notice a letter from Messrs. P. R. Buchanan & Co. offering to give the necessary information with respect to the gardens in which they are interested on certain conditions; and it is to be hoped that others similarly situated will follow their example, for the publication of a statistical table of all Tea Companies showing their relative costs of production, bearing areas, costs of extensions, management, agency and dividends earned could not, but be of the greatest value to the tea industry.

Meanwhile, limited as your table is, it seems to bear out some remarks which are to be found in the *Home and Colonial Mail* for 10th July, which are as follows:—

Results of 1884 have been satisfactory to those who made fine tea, and to those whose yield was so large as to bring down cost to a minimum,—but it has not been as profitable to those who realized only a moderate yield and made only medium quality; the reason being, that prices for "medium" have year by year been receding nearer to the range for "common," until the difference has become very slight; while the difference between "medium" and "fine" has become wider. The conclusion is that those who cannot con-

fidently rely upon such a yield as will reduce cost to between 9d and 10d per lb. in London should devote all their energies to improvement of quality.

In the report of the Assam Copman's meeting there are also some remarks to much the same effect. At this meeting Mr. McSwiney said:—

That he must admit that he was to a considerable extent dissatisfied on account of the very low prices obtained for their teas during the past year. He was further disappointed at finding that their chairman had not been able to inform them at present what the mysterious cause was which deteriorated the quality of their tea. The result of that deterioration to the shareholders was very important. He saw by the report that their average price of tea was 11½d. per lb.

The Chairman: It is a little better now. It is 1s.

Mr. McSwiney found that their predecessors in Assam obtained an average of 1s 3d per lb. which was about 4d per lb. more than they did. That was a startling fact, and he very much regretted that there was no explanation of the cause of it. He was the more surprised at that, because he believed that Company in former years was famed for the excellent quality of the tea it produced. Teas of that Company he understood, in past years realized the highest prices in the London market; but now on account of these mysterious causes, their teas appeared to fetch about the lowest price.

The Chairman, in reply, asked the last speaker to do what they had done, and try to ascertain what had been the result in profit (and loss to those Companies which had made those large prices, and he would find that it was anything but encouraging. Their business, and the business of every person engaging in an enterprise of that sort, was to work for a profit; it did not matter how that profit was made. He perfectly agreed with him that it was not satisfactory that the quality of their tea had deteriorated. But to throw out one hint to him: supposing that one cause of the inferiority had been the increase in the quantity and supposing that it was not possible to obtain quantity and quality, it might be a very serious question whether they should sacrifice quantity to obtain quality for their teas. In former years, when they were making small quantities it was easier to make high-class teas; but in making a crop of tea very little short of 3,000,000 lb. a very great deal of low-class tea must be made. If they could make 3,500,000 lb. which they might come to eventually, and they got 2d per lb. profit, making it at 8d and selling it at 10d they would be doing very much better than any Tea Company had ever done. There was but one Company in Assam which had ever worked at anything like the profit they had done. It had worked exceptionally well that year. He was perfectly alive in saying that he believed that there was some inferiority last year; and when he said that they did not come to anything like a definite conclusion as to the cause he said what was true, because they had been gradually introducing machinery, and he thought it quite possible that the inferiority might have arisen owing to some defect in the drying process.

Turning again to your table I find three Companies aggregating 9,638 acres, the yield of whose gardens was an average of 452 lb. per acre, viz.:—

	Acres.	Yield per acre.	Cost per lb.	Price per lb.	Profit per lb.	Divid. end.
Jokai ...	1,433	418	7/45	1/075	5/30	10 %
Assam ...	7,609	491	7/500	1/175	4/25	14 "
Panetola...	596	446	9/87	1/050	2/63	10 "
	9,638	452	8/27	1/033	4/06	11.3

On the other hand, I find three Companies aggregating 5,431 acres, the average selling price of whose teas was 1/4.21 per lb. They are:—

	Acres.	Yield per acre.	Cost per lb.	Price per lb.	Profit per lb.	Divid. end.
Luckimpore...	911	283	1/150	1/412	2/62	3½ %
Mosabund ...	528	246	0/1175	1/425	4/50	5 "
Jorchant ...	4,000	301	1/025	1/425	4/00	15 "
	5,439	277	1/050	1/421	2/371	7.83

Thus the average difference in favour of quantity over quality is 35d per lb. in the case of these Indian Tea Companies, or an extra dividend of 3½ per cent.

In Ceylon quality need not be sacrificed to obtain a yield of 400 lb. per acre; and 1s 2d per lb. in London is a moderate average selling price to reckon on according to the standard thus far arrived at. With a yield of 400 lb. per acre, it should not be difficult for us to lay down our teas in London for 8d per lb.—Yours faithfully, C. W. H.

DOMBA NUTS: THE CULTIVATION AND USES OF "CALOPHYLLUM INOPHYLLUM."

13th Aug. 1885.

DEAR SIR,—In a recent issue under the heading of "Curiosities of the Customs" you mention the export of Domba nuts for their oil. It so happens that last year I was induced to make enquiries on the subject by noticing a number of these nuts shelled and being dried in the sun along the road to Galle, and from all I learned from different sources as to the value of the nuts, yield, &c., for these alone it appeared it might be made a remunerative cultivation. In consequence I was tempted to put in a small nursery, the plants in which have grown freely. But it is not alone for the nuts or oil that the tree is valuable, but it seems that for certain purposes, in the construction of hackeries and riggers and ribs for boats &c., it is the only wood used owing to its toughness and the ease with which it can be bent to shape, and trees of small dimensions are consequently of value. As to the age at which the tree may be expected to come into bearing I have only been able to get very conflicting and I do not think in any case reliable evidence, and this is a point you may perhaps be able to settle. It would also be useful to know the wholesale value of the nuts and oil respectively, at Colombo or Galle, and the extent of the demand. I believe it is largely used as an adulterant for mixing with coconut oil.

R.

[The "Calophyllum Inophyllum" is the *tel domba gaha* of the Sinhalese and the *punga* of the Tamils. Some fine young trees—in fruit and flower a few weeks ago—are to be seen in the General Cemetery, Colombo. All we know of value is that 1,205 bags of punai or domba nuts exported in 1882 were declared at the Customs to be worth R3,000, but the weight or how many nuts in a bag deponent sayeth not.—Ed.]

MINERALS IN CEYLON.

DEAR SIR,—Like the man who felt inclined to kick the postman because the letters he brought were all duns, I suppose I ought to pitch into you for causing my "platinum" to turn out only "iron pyrites." "O what learning is!" as Juliet's nurse exclaimed. Metallurgy and mineralogy are sealed books to me, but I judged it was not silver from its being too hard and not white enough. I therefore oscillated between "tin" and "platinum"; and as, in human nature, "the wish is father to the thought," I chose the latter. Boo, boo! Will you kindly supplement your information with a little further instruction, and inform me briefly how sulphuric acid &c. is made from the pyrites? A course of "Lyell" has since opened my eyes. The metamorphic rock which contains the veins of iron pyrites is the gneiss, soapstone, argillite, schist, or whatever it may be called, and is easily broken up with a jumper. I will send you down some fair office samples for yourself and the Museum, if they have none there.—Yours ungratefully,

PLATINUM.

[A geologist answers the above enquiry as follows:—"Iron pyrites (Fe S₂) is a sulphuret or sulphide of iron, consisting of one equivalent of iron and two of sulphur. The metal is oxidised and dissolved by boiling with concentrated nitric acid, the sulphur separating and rising to the surface of the solution in grey flakes and eventually fusing into yellow globules. A portion of the sulphur thus separated becomes oxidised and forms sulphuric acid. In making the sulphuric acid of commerce, there may be some simpler method of reducing and utilizing the pyrites. Mr. Cochran would no doubt be able to give you reliable information on the subject, being a practical chemist." The position of a country in the ranks of civilization being fixed by its consumption of sulphuric acid, according to a well-known saying, a simple method of manufacturing the article in Ceylon would indeed be advantageous; but we fear this is out of the question and that the process is complicated and expensive.—ED.]

ROSE CULTIVATION IN CEYLON.

Down South, 17th August 1885.

DEAR SIR,—I read with considerable interest Mr. Whyte's letters which appeared in your issues regarding the cultivation and growth of roses in this island, and I am sure that your readers will agree with me, that he deserves our thanks for the valuable information contained in them.

If you will oblige me by referring to your vol. I of the *Tropical Agriculturist* you will find that I started the inquiry on this interesting branch of floral-culture and sought in vain for some time for reliable information. Having been obliged, since then, to work "on my own bottom" so to speak, I have myself acquired experience on the subject and can now with better confidence proceed with the cultivation and growth of roses.

Your readers will observe, that Mr. Whyte's letters are however silent regarding the preliminary steps to be taken in the cultivation of the "Queen of Flowers." In the first place I should like to know, whether it is possible to propagate rose plants from its seed? Secondly in the use of slips (which we have now recourse to) for planting, what is the nature of the slip and the nursery soil required to receive it, to make it grow? I quite agree with Mr. Whyte that cabook soil with an admixture of old farmyard manure is the best suited to make roses grow; but we cannot dispense with the preliminaries if we wish to ensure success. I believe it is well-known that a layer of bits of charcoal spread over the surface soil of the tree, considerably improves the colour and the fragrance of the flower.—Yours faithfully,

TEA-ROSE.

TEA IN MAURITIUS.—The Secretary of the Mauritius Société d'Acclimatation writes to us:—"I am requested to tender to you the best thanks of the Society for your valuable information respecting the different kind of tea-leaves, samples of which were forwarded to you with the request to indicate the species to which they belong."

TEA STATISTICS.—We call attention to the letter of our corres pondent 'C. W. H.' analysing the returns of certain Indian Tea Companies. It is especially instructive to note the comparison between two sets of three representative Companies: in the one case an average yield of 452 lb. per acre is contrasted with an average sale price of 1s 0/33d; in the other the average yield is down to 277 lb. and the sale price up to 1s 4/2d. "C.W.H." like most of us counting on a yield of 400 lb. per acre from average Ceylon tea estates, does not see why our tea should not be laid down in London at 8d per lb. But, how about the low averages worked out by Mr. Rutherford? we are inclined to ask "C. W. H." and others.

ARTESIAN WELLS IN MADRAS.—In December 1884 the Madras Government made an engagement with M. Cornet for the sinking of an artesian well in or near Madras. The depth of this well was estimated at 393 feet, and the cost at Rs15,000. Upon the recommendation of Dr. King, of the Geological Survey, who selected the People's Park, as the best spot for an artesian well, borings were commenced in March last, and after reaching a depth of 58 feet, granit rock was met which was found very hard and difficult to bore through. In order to ascertain whether this granite was merely a detached boulder or part of the strata of the earth in the locality, trial borings within a diameter of 50 feet were made, but they all showed that the same granite was to be met with. The boring operations in the Park were accordingly abandoned, and the result of the search of the country around indicated that a stratum of granite existed for two miles north of the Fort and some miles in land. This being the case, the Government has stepped the operations for the present, pending a selection of some other site by Dr. King.—*Madras Mail*.

SOME CURIOUS FACTS ABOUT RICE are brought to our notice by a Colombo merchant who has, in his day, bought Chittagong rice at Rs1½ per bag (equal to 40 cents per bushel of paddy). He knows of no reason why it should not be sold as cheaply now, from Burma and Bengal, considering the greater facilities for transport to counterbalance the rise in wages. How then has the price so greatly advanced? Simply through the influence of *exchange*. A great part of the Indian and Burma crops is shipped to Europe and the competition for produce is keen. Nevertheless, at this moment rice is rep'rted to be 4s per bushel in England while it is Rs3-50 in Colombo! Ninepence a bushel used to be the price of paddy in Sabaragamuwa and other planting districts at a time when the native crops were far less plentiful than at present and before Sir Wm. Gregory, Sir Hercules Robins n or even Sir Henry Ward had begun to spend large sums on Irrigation Works. How different th' market price now, through the increased demand caused by the planting enterprise and the influence of cheap silver,—and yet, notwithstanding all that has been said, done and spent, how little impression has the local production made on the local market. The reply has often been, that the apathy of the Sinhalese in extending or even keeping up paddy cultivation is owing to the bad-tax or rent on paddy; quite forgetting that the Customs levy on imported grain is even heavier in proportion and is therefore protective of the local rice-growers. Never in fact was an industry so fostered, aided and encouraged by a Government as the Ceylon paddy-growing enterprise and yet somehow it does not result in much progress looked at as a whole.

THE NELLI FRUIT.—A correspondent of the "Jaffna Patriot" writes:—

"NELLIKAY.—This fruit is so delicious when properly preserved in syrup is the largest of the species to be found in Ceylon and also numerous in the Province. A friend has sent me a bottle of these very nicely prepared and candied. Do please ask the Committee to send a few jars of these to the exhibit. And if there be not a large demand for the fruit English taste must be very hard to please." The *nelli* of the Sinhalese (*nellikay* is, of course, Tamil) is one of the two trees most common on our pataanas, the *kahatagaha* being the other. The foliage is somewhat like that of the tamarind. It is *Phyllanthus emblica* of the botanists, and children are very fond of the *nelli-pedi* a fruit like a green plum, sub-acid. Wood durable under water and used for well work; also for agricultural implements, building and furniture. Bark used for tanning and in medicine; chips of wood said to clear muddy water. Fruit is the Emblic Myrobalan and is used as medicine and for dyeing, tanning and food and preserves. The Nelli is often cultivated for its fruit.

MINERALS IN CEYLON.—A Dolosbage resident recently sent us two pieces of stone which resembled jade in their green colouring and general appearance; but an expert pronounces on them as follows:—"The green sample is very like nephrite or jade, but is in my opinion one of the softer forms of quartzite tinged green with an infusion of copper: there is no trace of lime." Another sanguine planter sends us two specimens, one of which he was inclined to think "silver" or "platinum"; but he was not here during the gold fever two or three years ago, when we had samples of similar "silver" from all parts of the country, only unfortunately they were no more than "iron-pyr-itea"—sulphuret of iron, as our referee reminds us, utilized for the manufacture of sulphur and sulphuric acid:—"Iron pyrites.—A very common mineral in metamorphic rocks, such as gneiss, &c. Color, pale bronze, graduating to silvery white and distinguished from copper pyrites by being proof against the edge of a knife."—The story is that one planter carefully filled up two of his admirals with the rich silver ore he had carefully picked up on the otherwise barren totem, during the mining fever of 1881-3! Our friend sends us another sample, which is pronounced upon as follows:—"The black sample is a form of talc schist (talc and quartz), a sort of soapstone (soapy feel), a steatite as known to geologists." In answer to an enquiry of ours:—"I believe we have trap rock such as basaltic rock, greenstone, &c. in the island, and there is no doubt of the existence of granite. A fine out-crop of it was found near Balangoda in the form of graphic granite consisting of felspar and quartz."

CIGARS.—Considering the increased demand that takes place every year for Burma cigars, a note by Mr. Cabaniss, Assistant Director of Agriculture of British Burma, on cigar making in that province, will be read with interest. Mr. Cabaniss personally inspected a number of the manufactories of cigars in Burma, and also a large number of cigar makers working at their own houses. What seems to have struck him most was the unnecessary waste of good material and the universal habit of converting good material into bad material. The cigar makers generally purchase tobacco of two qualities: the first quality for the wrapper, which frequently costs £120 per 100 viss, and the second quality for fillers, or the inside of the cigar, at prices varying from £60 per 100 viss. If mixed qualities are purchased at about £90 per 100 viss, the sorting of leaves has to be done by the makers themselves. It seems somewhat strange that, as Mr. Cabaniss tells us, the smoking quality, or the second quality, is quite as good as that of the first quality, the large difference in price being entirely due to the leaf of the latter being larger and more suitable for making wrappers. Mr. Cabaniss, however, does not tell us whether the tobacco he alludes to is that grown in British Burma, or that imported from Bengal and Madras. A great deal of waste is occasioned in cutting the wrappers, though the trimmings from these are often worked in as filling. A larger quantity of the leaf is more or less damaged when made into cigars by the use of an impure gum or paste for fastening the wrappers. This soon becomes sour, and the cigar becomes mouldy and unsaleable. Notwithstanding all this waste, the prices charged for the cigars, which are at present £1 to one rupee per 100, leave a large profit but Mr. Cabaniss thinks that, by the introduction of a more careful system of working as recommended by him, the price could be reduced to eight annas a hundred.—*Calcutta Englishman.*

MR. D. MORRIS ON THE JAMAICA MUSEUM AND LIBRARY.—The Jamaica Colonial Standard thus summarizes a comprehensive and able address by Mr. D. Morris:—"We published in our issue of the 18th inst. a full report of the address delivered by Mr. D. Morris at the Caverzatione given under the auspices of the Governor of the Jamaica Institute during the six years of its existence. He refers to

the enlargement and improvement that have taken place in the Library and the Museum, and quotes, with high appreciation, the eloquent remarks of the late Richard Hill—one of the most gifted sons of Jamaica—on the usefulness and advantage of a local Museum. In connection with this part of the subject, he mentions the great progress that has been made during the past four years in bringing together collections of the fish, the birds, the insects, the shells, as well as an illustrative collection of island productions such as coffee, cacao, pimento, annatto, fancy and furniture woods, spices and condiments, meal and starches, dye-woods, essential and fixed oils, medicinal substances, honey wax, and other objects pertaining to minor industries. Mr. Morris also takes personal notice of the collection of the land and fresh water shells of Jamaica, and states that the task of classification and re-arrangement has been undertaken by Mr. Henry Vendryes, "whose reputation and standing in this particular branch of science are a sufficient guarantee that the collection will ultimately be brought to the highest condition of efficiency." After mentioning the fact that the grand and noble collections in the British Museum had their beginning in the materials brought together in this island more than two hundred years ago by Sir Hans Sloane, Mr. Morris maintains that in a purely agricultural colony like Jamaica a Museum should possess a series of all that relate to local industries and to a careful and economical utilization of time and money and proceeds to say:—"The importance of such a collection as we trust ultimately to bring together within these walls in aiding the development of local industries cannot be over-rated. To our planters of all classes such a collection will be of incalculable advantage, as it will place before them the nature and character of raw materials and manufactured products and lead them to acquaint themselves with the best methods for extracting dyes, fibres, perfumes, drugs and food products from native plants; while at the same time, they will have before them the raw and manufactured state of foreign products for which both the climate and soil are well adapted, tending to lay the foundation of new industries. The great drawback in the way of prosecuting new agricultural industries is not so much the growth of the plants themselves, but in finding out how to prepare the produce for market in an economical and suitable form and without wasting time and money "in blundering through a host of trials" to the desired ends. Mr. Morris makes due reference to the valuable operations of the Library of the Institute which under the able direction of the energetic Librarian, Mr. Priest, "contributes in no small degree, to the diffusion of the best class of current literature, not only amongst the people of Kingston and the neighbourhood, but by means of its branches through many other portions of the island." Mention is also made of what the Institute has done in establishing a series of public lectures obtaining the extension to Jamaica of the Cambridge Local Examination, and arranging on behalf of the Government and the community at large, for the proper representation of Jamaica at the several industrial exhibition which have taken place during the past few years. In connection with this matter, we deem it right to record the high appreciation which the people of Jamaica entertain of the service Mr. Morris has done, not only in making Jamaica take such a prominent place at the New Orleans Exposition, but in using his endeavour and influence to bring about a removal of the quarantine restrictions which prevented anything like regular, satisfactory, communication with New Orleans.

BRAZIL AND JAVA :
REPORT ON THE COFFEE CULTURE IN
AMERICA, ASIA AND AFRICA.

BY K. F. VAN DELDEN LÆRNE.

In our February Number we gave a short notice of this important work. Since that appeared, the English version, then mentioned as in the press, has been published,* and the handsome volume lies now before us. Printed in Royal Octavo, it occupies 637 pages, besides plates, maps and diagrams.

As we said before, the writer treats the subject of coffee-culture well nigh exhaustively. To the extract we gave in our former number we now wish to add a passage taken from Chapter X., on the Coffee-culture in Brazil, to show our readers how thoroughly the writer enters into the merits of his subject.

After treating in a previous chapter the state of Brazil as to her Revenues, Exports and Imports, means of conveyance (roads, shipping, etc.), Weights, Measures, Coins, etc., Coffee-Trade in its special aspects, the author treats in Chapter X. Coffee Planting. In a general view he discusses the different soils, which in so extensive an area are of course very various, their capabilities for coffee and other cultures, the management and arrangement of the estates, and the different sorts of coffee produced. Moreover Lands, Fazendas: Clearing, Division into gardens, Garden paths, Terraces. He then proceeds to

Planting, Nursery-Beds, Space between Plants, Trees yielding shade, Dressing, Manure Diseases and

Enemies of the Coffee-shrub.

"As a rule the planters, of the Rio and Santos, both follow the old ancestral custom of transplanting three or four-year-old mudas or seedlings out of the gardens.

The mudas are pulled by hand out of the ground, which has previously been slightly loosened. If the tap-root does not break at once, then part of it is cut off, care being taken, however, not to injure the fibrous roots more than can be avoided.

The plant itself is also lopped to a height of 1 or 1½ palms (22 to 23 centimeters). The stumps, about as thick as a man's finger, are conveyed to the gardens in baskets covered with leaves, by the slaves charged with the planting of them. On the broken ground of the Rio zone this is performed in the following way:—On the piece of ground to be planted, a quantity of earth is scooped out on the face of the incline. This is done with the enxada, an instrument resembling the Javanese *patjo*, but almost twice the size and furnished with a handle six feet long. By this means a small spot of level ground is obtained, a kind of tiny terrace, or as it is called in Java, a little *petak*. On this are planted two or three muda stumps side by side or in a triangle. The earth that has been scooped out is now heaped above the level spot, and pressed down a little; it is meant for a temporary dyke to shelter the mudas from the streaming rain-water. Gradually, however, these grooves are filled up again by the earth of the dyke.

In order to protect the young plants, as far as is practicable, from the heat of the sun, some dried or charred boughs and chips of wood, or leafy twigs, are piled up about them.

For the last three or four years pépinières have been making for the new plantations; or, to speak more correctly, for the necessary substitutes. The use of pépinières, however, is not so general as Dr. Couty seems to believe.

The reason why planters have pépinières made now is simply this: that in former days there was no time for it; now there is. Four or five years ago, even the plantations were constantly being extended, so that there were no hands to spare; now there is very little more planting done than is necessary to keep up the existing cafesas.

People shrink from the thought of laying out new gardens now, not only because of the low price obtained for coffee, which of itself paralyses the industry,

* W. H. Allen & Co., 13, Waterloo Place, Pall Mall, London.

but because they are no longer certain of being able to gather the fruit of their labours. The scarcity of labourers is making itself felt more and more, especially now that the traffic in slaves between the northern and southern provinces is rendered practically impossible by the levying of provincial export-duties amounting to from p. st. 150 to p. st. 200 per slave.

There is thus more leisure, more opportunity for careful planting.

But the reader will make a great mistake if he fancies that the Brazilian Pépinières resemble the carefully-constructed, solicitously-tended, nursery-beds of Java.

I have seen three sorts of nursery-beds. The first consists of a less or more open spot on the skirts of the capoeira or not very dense wood, where all the young mudas from 10 to 20 months old, that can be got hold of in the gardens, are stuck into the ground. A collection of those plants of unequal age is called a nursery bed or viveiro. The more advanced coffee-planters, those that pass for specialists, obtain their viveiros by direct sowing. In the middle of the capoeira, for the *matta virgem* or virgin forest is too shady for the purpose, they have the ground dug, and plant the coffee-beans in rows or strips of from 1 to 1½ palms broad. If all the trees come up, the rows are a little thinned out, but even after this process, these crowds of little plants jostling each other present a very strange appearance. In viveiros of this stamp, clods containing from 10 to 20 plants are dug up. These clods are placed in square wooden boxes, and conveyed to the plantation in heavy carts. There the seedlings are removed from the clod one by one, or torn out of it, and planted in the way described above. I must, however, note in passing, that I saw this comparatively careful method of planting on only a very few fazendas, such as S. Clement, *Matta Porcos*, *Bella Vista* (Cantagallo). A third sort of viveiros are those that are made in the gardens themselves between the coffee-shrubs. Such viveiros, however, do not contain more than 25 to 50,000 plants. On the fazenda *Sete Quedas* in the Santos zone I saw viveiros of this last mentioned kind, which were laid out after a new method. The scattered seedlings were brought from the gardens into the viveiro, but in such a way that every group of 5 or 6 mudas made as it were a whole, and were from 1½ to 2 palms distant from the next group. When transplanted into the new garden, or taken to fill gaps in a old cafesal, those mudas, now two or three years old, are not taken from the ground one by one, but form by their groups of five or six a clump of earth, which is transferred to a pit three palms deep by three palms in diameter. This pit has been prepared by slaves six or eight months previously.

When the plants are placed in it, it is not quite closed. People only fill up the crevices between the clump of earth and the pit. In this way, I am assured, the fruit-bearing is expedited by the timely arresting of the growth of the plant. But this advantage is counterbalanced by the great disadvantage, that this way of planting takes a great deal of time, and is consequently very costly. For, while one slave can in one day plant from 400 to 450 of these pulled and lopped mudas, he cannot possibly transport more than 70 or 80 clumps. In the Santos Zone, on the fazenda *Hicaba*, I saw coffee-shrubs planted in yet another manner. The first step there is to dig a pit from 2 to 2½ palms square, and of equal depth. It is immediately filled up half a palm with the earth that has been thrown out, which the slave presses down a little. Then a muda stump is taken and placed at one of the corners of the pit, in such a way as to allow the fibres to spread out. After these have been covered with a little earth, a second muda is planted, and so on till there is one at each of the four corners.

The earth, which is now shovelled in, is stamped down by the slave with both his feet. In this way the pit is half filled up again. The planted hollow is still from half a palm to a palm deep, and remained unlevelled. At the same time some dry grass or leaves are heaped in and around the pit, to prevent

the scorching effects of the sun. Rain gives the planter no concern; for the terra roxa and the terra areia, where this method of planting is usually practised, is so porous that the water cannot remain long enough in the pits to cause the roots to rot. In this way no more than 100 or 120 pits can be made and filled on a day. When no mudas are to be had, the plants have to be reared direct from seed sown. But then from 5 to 8 beans are planted close to each other in a shallow pit made by hand or with the enxada, consequently the direct opposite of the method employed on some fazendas in the Cantagallo (for instance, those of the Viscondes de S. Clement and Nova Friburgo); which is to plant the beans round a little mound which is afterwards levelled down less or more by the rains.

If the beans on one spot all grow, at the end of from 7 to 10 months so many are pulled up, that only three or four of the most vigorous plants remain standing. The seedlings weeded out are then used as mudas to fill up the vacant spots or falhas. The usual planting is September, October and November, although gardens may be planted on through January and February. Several fazendeiros, however, assured me that transplanting may be done at any season of the year, provided it is made a rule to remove unjured, that is to say, unlopped seedlings in the rainy season only, and not against the winter or dry season. The mudas stumps can stand the drought better, and recover their vigour after a few days' rain. It is needless to observe that this method of planting does not produce Brazil single-trunked coffeetrees, such as are almost universal in Java, but very wide-spreading coffee shrubs, that is to say, a brood of 8, 10, or 12 slender stems branching out from the mudas stump. Old cafesacs seen from a distance, struck me as presenting a strong resemblance to plantations of huge inverted besoms, all the more because the protracted drought of 1883 (from April to September) had exerted its parching influence everywhere, but especially on the soalheiro plantations. I have seen gardens almost quite denuded of foliage, the blossoms being dried on the twigs. The thicker and fuller the coffee-shrub grows, the better. In the more fertile lands of the Santos zone, therefore, four mudas are generally planted instead of two or three, as is customary in the Rio zone. I retain a lively recollection of a Paulist fazendeiro, who, attempting in my presence to overgrow a Rio coffee-planter, told him, that one coffee-shrub in the Santos zone is fully equal to a bouquet of three coffee-shrubs from the Rio zone. Although the Rio gentleman held his peace and yet tacitly owned himself defeated in some degree, yet the simile was a trifle too... Paulistic. Without fear of exaggerating, however, we may say that the coffee-shrub in the Santos zone is much larger than the coffee-shrub in the Rio zone, besides being almost as productive.*

The spaces left between the plants are not uniform everywhere. According to differences of soil, to the physical aspect of the estate and its height above the sea, planters in the Rio zone generally leave spaces of 12 by 12, 12 by 14, 14 by 14, and here and there even 15 by 15 palmos; while in the Santos zone the spaces are 14 by 14, 15 by 15, and by way of experiment during the last 3 or 4 years, some lines 16 by 16, 18 by 18, and even 20 by 20 palmos. One cannot, however, without fear of contradiction, venture the general statement that as to the former zone the average space between the plants is 12 by 14 palmos; that is to say, 2.64 by 3.08 meters, while in the latter it does not exceed 15 by 15; that is to say, 3.30 by 3.30 meters.†

* According to the Statistics of coffee-planting, the result is even more favourable to the Santos zone; but we must not forget in comparing them, that coffee-growing in the Rio zone has been carried on for a long time, while in the Santos zone it commenced quite recently.

† 1 Rhineland foot = 0.3139165 meters.
1 " foot = 12 Rh. feet = 3.767358 meters.
1 English foot = 0.2047978 meters.

But the coffee-shrub attains such an immense size by the time it reaches its 10th or 12th year, that it must be admitted that those spaces are by no means too large. Trees yielding shade are unknown in Brazil. It is true that at one time an experiment was made in the Serra Abaixo to protect the cafesacs situated less than 100 meters above the level from the scorching heat of the sun, by planting the Angico.* But it never went further than an experiment. Considering the climate, I think the planters have done right in banishing shady trees from their cafesacs. For the coffee-bean ripens during the winter or dry season, at which time the temperature is so low that the slaves that work in the gardens are dressed in baize. No groves are planted anywhere to break the force of the wind, although many places in both zones suffer from tufaves or violent gusts. The digging of the gardens is considered, even in Brazil, the principal part of the tillage: Yet it is very much neglected in the Rio zone, a fact which is easily explained.

Firstly, there is the dread of landslips, the natural consequence of a too deep or frequent loosening of the soil on those steep, terraced slopes.

But the real cause of the neglect lies in the want of labourers. During the period when prices were high, the new plantations formed were in excess of available hands to work them; and this could no longer be redressed by the purchase of slaves, on account of the high import duties.

A slave of the roça, that is to say, a slave employed in fieldwork, ought only to keep and dress (in the Rio zone) a maximum number of 4,500, or at the utmost, 5,000 trees; seeing that, besides maintaining the roads and bridges, he has to attend to the planting of maize, beans (fílaes), mandioc, batatas, in short, all that is needed on a fazenda for the consumption of the work-people. Well, the passion for planting has been so violent, that in most districts of the Rio zone, a slave has now to attend to more than 7,000 trees. To keep those overgrown plantations in anything like proper order, the owner is now obliged to grow less rice, beans, and sugarcane, and to buy those commodities dearer than he, could rear them himself. The sítantes and small fazendeiros have availed themselves of this circumstance to make their coffee-planting a secondary consideration, and devote themselves more especially to the cultivation of the abovementioned articles of food, which may be disposed of to the large fazendeiros in the neighbourhood, or even in the Rio market.

Such planters, because they have stooped to the pequena lavoura, or small farming, are often nicknamed quitandeiros.† It certainly does seem very strange that the cultivation of the first necessities of life is so much looked down upon in the coffee and sugar-producing provinces of Brazil, that even maize and beans have to be imported from the Southern parts of the Empire and the United States of America. Hence it comes that the so-called quitandeiros drive such a lucrative trade, that the profits of their small farming clear the expenses of their plantations. The same nickname is applied to such fazendeiros as sell eggs, butter, cheese, and pigs, and I have known the coffee-planter, who, constrained by hard times, do this—or rather have it done for their benefit—by the wives of their feltors or over-seers. To return to the dressing of their gardens. In former times the cafesacs were weeded three or four times a year. Now the dressing has to be confined to capinar or cutting down the weeds once or twice, and the capina or thorough dressing of the gardens before the beginning of harvest, generally in the month of May.

The capinar is performed with a chopping knife or force fastened to a handle five feet long; or with

* *Piptadenia colubrina*, Bth. *Acacia virginalis*, Pohl *Acacia angico*, Murt.

† Derived from quitanda, a basket of edibles, fruits and dainties, which the negresses in Rio offer for sale. Those fruit or cake-vendors, who, according to custom, carry their wares about on their shade, called quitandeiras.

a sickle, which, known as *ceifador*, *segador* or *segadeira* dynamic, is to be had for three or four milreis. The ground is loosened merely on the surface—or deeper where the ground is less steep—with the *exxada* or *patjol*. In order to arrest the slow but constant washing down of the alluvial soil, or rather to make up for it in some degree, the loose earth and weeds are heaped up round the rows of shrubs. But even this work is for the most part done injudiciously.

Instead of heaping the loosened earth and weeds horizontally against the slope, and thus forming by degrees a sort of terrace, people leap them in transverse lines, consequently along the slope of the mountain. They acknowledge the inefficiency of the method, which is finding more favour of late years in the district of Cantagallo, and that it is too hard work to be demanded of the already over-worked slaves. In the Santos Zone, where the coffee-shrub yield almost double the average produce of the plant in the Rio zone, plantations are attended to with greater care. As a rule the *cafesases* there are dressed with the *exxada* (*carpa*) five times a year. In the drawing up of agreements, at least, this is one of the first conditions laid upon the colonist. On plantations, however, worked by slave-labour alone, where the same error had been committed as in the Rio zone, the soil cannot be turned over more than twice or thrice a year. The *capinar* is also resorted to in S. Paulo, but only by way of preparation for the *carpa*, or digging of the soil, and not as in the Rio zone instead of that process.

The laying out of new gardens can here and there be agreed for by the job with *mineiros* or natives of Minas Geraes, who now and then establish themselves in a place. The owner hands over to those people a *cafesal* planted by slaves, on condition that they keep and dress the young trees carefully during four successive years, receiving in payment a lump sum of from 300 to 400 reis, that is to say, from 7½ to 9½ per shrub.

These people are bound to fill up *falhas* or gaps, caused by the death of young trees, with new *mudas*. In return, they are entitled, during the four years they have charge of the garden, to plant between the coffee-shrubs everything they require for their own consumption.

The following crops are usually planted between the coffee-trees in both zones:—

a. Turkish wheat or milho, against the mouths of September, October and November.

b. Beans or feyaoes (black in the Rio and red in the Santos zone) against February and March.

c. Cassava or mandioca, against the same time.*

Although in several districts the sugar-cane is also planted between the coffee-shrubs, this is not so general as the cultivation of the three articles of food mentioned above. The sugar-cane, rice (that is the Javanese *padi gogo* or mountain rice), the various sorts of *batatas* and other tubers for feeding pigs, are in the Rio zone grown in the valleys between the morros; in the Santos zone, near the *cafesases*. Plantains are never grown in the gardens, but, like the orange-trees (*laranjeiras*) and *cajueiros* (*Anacardium occidentale*, Linn.), along the garden paths. The dressing of the above-mentioned plants is of course beneficial to the coffee-gardens. It is a curious sight to see these *turnas* or gangs of slaves working in the fields. A *turna* consists usually of from 20 to 25 slaves, male and female, under charge of a *feitor*

* When the price of coffee is high and the harvest large, sugar is bought ready for use, and not manufactured from the sugar cane. On the fazendas the cut canes are left lying, and prepared as they are wanted during four or five years. If it is not planted in the *cafesases*, the cane may be left from 16 to 20 years! The mandioc, the Indian *obi dander* or *sinkong*, may be left three or four years in the field; it is harvested as it is wanted, so that this crop, which, like maize and beans, is easy to harvest, is regularly cultivated by the slaves. On moist lands the mandioc cannot be left so long, at the utmost two years.

or overseer, who is generally himself a slave. Every *turna* has a male or female cook, who prepares their food on the spot. If several *turnas* have to work together (I have seen gangs of from 100 to 125 souls), there is a Portuguese overseer, often termed *administrador*, to superintend the work. As the *exxadas* are provided with very long handles, with which moreover they do not make such a sharp angle as the Javanese *patjol*, the slaves work almost standing, and mostly in a row. The work is constantly accompanied with a soft monotonous chant or quaver; only during the *rogar* in the forest, I have often heard them singing and shouting. If anybody comes to see the work, or passes the field, they always greet him in chorus, with the words, "Louvado seja Nosso Senhor Jesu Christo!" (Blessed be our Lord Jesus Christ!) on which the other answer: "Para sempre!" (for ever!). If one meets a slave alone on the road or in the field, he or she will stretch out the open palm, saying "Abencoe me!" (abense, they pronounce it)—that is "Bless me" and stand still till the answer, "Dios vos abencoe-the (God bless you!) gives permission to pass on. To return from coffee-planting to the cultivation of provisions, it may be accepted as a rule that, as long as space permits, provisions will be planted between the coffee-shrubs, and that the whole year through. On this account new gardens must occasionally be laid out. As I have already said, plantations in the Rio zone suffer greatly from the morros being denuded of their alluvial crust. This incessant waste causes the trees to undergo a perceptible change at the end of 12 or 15 years. The washing away of the soil bares the foot of the trunk to such a degree that one can distinctly see that the shrub is not formed of from 10 to 15 coffee-plants, as I thought at first, but of one compound trunk, that is of from 2 to 4 *mudas* grown together. The part bared often stands from 10 to 20 centimeters above the ground. Now, when we reflect that the *mudas* were originally planted in hollows or scooped pits from 10 to 15 centimeters deep, we must be convinced that in the course of 12 or 15 years the alluvial crust has become shallower by from 20 to 35 centimeters; that is to say from 1 to 1½ palms. Another reason has been pointed out to me why the foot of the coffee-shrub is bared so much. As the *Brazilias* have not the custom to pull the roots as much as possible out of the ground, they gradually rot, and make the soil looser and more porous. The rains press down the soil, so that it sinks on the whole; so that the baring of the foot of the tree must not be attributed altogether to the washing away of the soil.

However this may be, it is a fact that the older the gardens are, the more the roots of the coffee-shrubs stand out above the soil.

Owing to this gradual exposure of the topmost fibres, the plantations begin to suffer greatly after they have reached the age of 15 or 18 years. The shrubs assume all manner of forms. They no longer wax so full and luxuriant, no longer preserve an equal proportion of breadth to length, but begin to change into *saias* and *pernudos*.

By *saias* are meant the coffee-trees that at a height of 3 or 4 palms produce a large number of secondary branches, which gradually get entangled with each other and form a sort of petticoat or crinoline about the trunk. This petticoat or *saia* is the more conspicuous, because the upper part of the shrub is quite naked, or bears at the very top a green plume, which, as a rule, is heavier or lighter according as the plantations happen to be *no negras* or *sauheiras*. The *pernudos* are those coffee-shrubs that have few or no branches close to the ground, but branch out largely farther up.

The leafless *pernudos* present the exact appearance of gigantic inverted *hemus* or *vasouras*.

By far the greater number of *saias* are found on *sauheiro* lands.

I could obtain no satisfactory explanation of this phenomenon, universal as it is throughout the Rio zone.

On my travels through the Parahyba Valley, however, as I steamed past the almost endless succession of coffee-clad morros, I was struck by a fact I had noticed but little on the spot itself. It was just the greater distance that enabled me to perceive what had escaped me when quite near. I saw distinctly that the shadows of the rows of coffee-trees projected into each other; that, so to say, the one row shaded the foot of the other, and sheltered it from the heat of the sun. Would it be too rash to draw the conclusion that the lower part of the already half-exhausted shrub, being thus protected from the greatest heat of the day, obtains up to that height a new life, but at the expense of the upper part?

The pernudos are mostly found on the oldest plantations, and consist for the most part of old saias stripped of their petticoat. At the age of 25 or 30 years they are generally exhausted, and, after being pollarded, may perhaps yield a few average crops at intervals of 2 or 3 years.

This cutting, or rather sawing, the plant down to a stump, is done as a general rule when it is from 20 to 22 years old. It is seldom that the whole shrub is cut down to a height from 2 to 4 palms above the ground. For the most part the oldest and largest lateral branches are first removed, thus reducing the size of the shrub by a half. This must be done as soon as practicable, after the fruit is gathered, if possible in the beginning of September and October.
