henrickson@mail.utexas.edu

ABSTRACT

Leucophyllum coahuilensis is described from a gypsum area in central Coahuila, Mexico. It is characterized by small, sessile leaves, a vestiture of dendritic hairs with long, slender radii, and blue to violet corollas with white on the throat floor with orange maculations. It is unique within the genus in having only 2 ovules per ovary. Recent cytological and molecular data regarding relationships between the Scrophulariaceae and Myoporaceae are discussed.

RESUMEN

Se describe a ***Leucophyllum coahuilensis*** como una especie nueva de suelos yesosos del centro de Coahuila. Se caracteriza por presentar las hojas pequeñas y sésiles, un indumento de pelos dendríticos con radios largos y tenues, y las corolas de color violeta con la superficie interna abaxial de la garganta blancuzca o amarillenta con máculas anaranjadas. La nueva especie es la única del género que tiene dos óvulos por ovario. Se discuten datos citológicos recientes, y las relaciones del género con las familias Scrophulariaceae y Myoporaceae.

INTRODUCTION

Since the publication of the taxonomic monograph of *Leucophyllum* (Henrickson & Flyr 1985) two new taxa have been described (Nesom 1991, 1993) and a third new species is described herein. Additional information on chromosome numbers, anatomical features, and phylogenetic relationships have also been published and are summarized herein.

TAXONOMY

While traveling in central Coahuila on a recently paved highway from San Pedro de las Colonias to Laguna del Rey, I saw extensive, previously unexplored, outcroppings of gypsum. I drove to the slopes, parked my vehicle and within 50 feet found this distinctive new species of *Leucophyllum*.

Leucophyllum coahuilensis Henrickson, sp. nov. (**Figs 1, 2**). TYPE: MEXICO. COAHUILA: N end of Valley of Acatita, 15.1 road mi N of Rancho Acatita where NE-SW running spur (Sierra del Cuchilla) extends to highway, the ridge containing extensive areas of gypsum; collections from the N side of this ridge; 26° 39'N, 103°

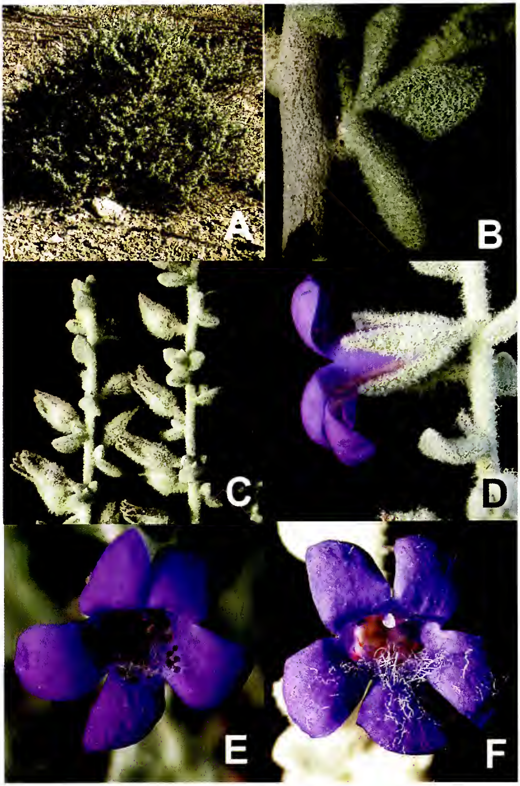

Fig. 1. *Leucophyllum coahuilensis*. **A.** Growth habit, the plant about 5 dm tall. **B.** Short shoot on young stem showing loose vestiture of dendritic hairs. **C.** Inflorescence showing post-flower calyces subtended by leaf-like bracts. **D.** Flower, lateral view, showing strongly vestitured calyx and spreading corolla lobes. **E.** Corolla, face view, showing posterior anthers and orange spots on the lower tube. Note hairs in lower throat and lower lobes. **F.** Corolla, face view, showing posterior stigma, internal spots and hairs on lobes and distal throat. B × 6; C × 1.3; D. × 3; E × 4; F × 4.

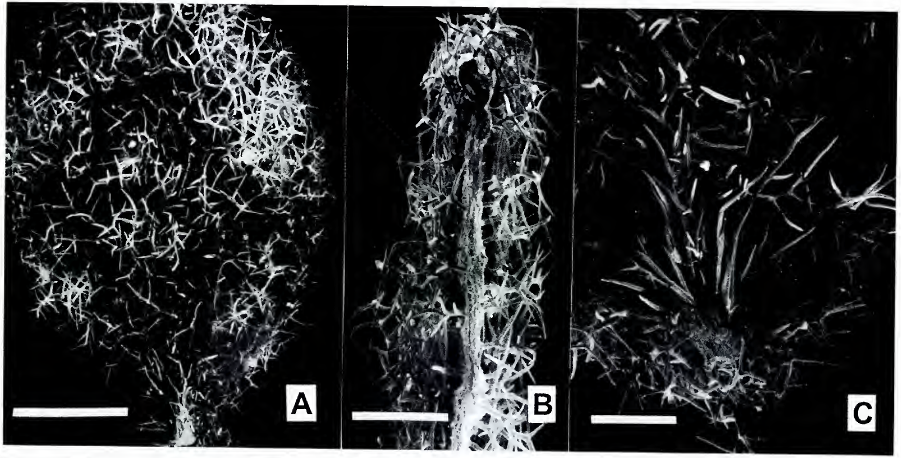

Fig. 2. Leaf vestiture of *Leucophyllum coahuilensis*. **A.** Small leaf 3 mm wide, adaxial surface, showing loose vestiture of moderately branched hairs. **B.** Transverse section of leaf showing thickness of the vestiture in relation to the leaf thickness. **C.** Larger leaf showing tuft of straight hairs in abaxial base. Magnifications: bars = 1.0 mm.

10'W, 1070–1200 m, 20 Sep 1999, *Henrickson 22601 with D. Riskind* (HOLOTYPE: TEX; ISOTYPES: MEXU, NY, GH, US).

Frutices globosi, rami divergentibus, solum profundum gypseum incoli. Folia ovata ad elliptica, parva, sessilis, vestimento dendritico (cum radiis longis gracilibusque), sub pilis dendritici stipitato-glandulosa; axillae foliorum cum caespitibus trichomatum indutae; corollae profunde caeruleo-purpureae coloratae, cum coloribus luteis basi faucum, cum maculae aurantiaceae ad medium faucum, 10–13 mm longae. Fructus cum solis duobus seminibus instructus (non cum seminibus numerosae in fructo quoque, ut in caeteris speciebus generis).

Divaricately branched, broadly globose, densely vestitured, whitish shrubs 3–6 dm tall, 4–8 dm wide, becoming rather thorny due to retention of old divergent stems; young stems with long-shoot internodes 3–13 mm long, the internodes densely white pannose with short dendritic hairs and an overstory of scattered, slender, longer dendritic hairs, with a shorter series of nearly sessile stipitate glands; understory dendritic hairs with 3–5 short nodes, each with 1–4 radii, 0.2–0.35 mm long, the longer scattered emergent hairs somewhat cylindrical with the central axis somewhat zig-zagged, 0.8–1.2 mm long, with 6–10 nodes, the internodes 0.1–0.15 mm long, the radii 1–2 per node, 0.2–0.3 mm long; with age the longer vestiture weathering away to form a closer pannose vestiture that eventually is replaced as older stems develop a light grayish, weathered bark. Leaves alternate on long shoots, and crowded on axillary fascicles; leaf blades ovate, ovate-elliptical, elliptical to obovate, (3.5–)5–9(–12) mm long, (2.2–)3–5 (–7.6) mm wide, obtuse to rounded, sometimes acute at the tip, broadly cuneate to rounded at sessile bases, entire, flat or somewhat saddle shaped, with a white, loose, uniformly dense vestiture on both surfaces, the hairs dendritic, 0.7–1.3 mm long, with zig-zagged rachies with 3–7 nodes, with internodes 0.1–0.16 mm long, the radii 1–2 per node, 0.15–0.4 mm long, ± 0.03 mm thick, the terminal arm often longest, the dendritic vestiture rather open, with the green leaf surface visible through the vestiture, with a close understory of stipitate glands 0.05–0.2 mm long, the basal adaxial surface leaves with a tuft of non-branched, white hairs 0.8–1.7 mm long. Flowers solitary in axils of the long-shoot leaves, on pedicels 1–4.7 mm long, ± 0.25 mm thick, with a dense dendritic vestiture as on the stems; calyces 6–9.5 mm long, the 5 sepals separate to within 0.5 mm of the base, the sepals lanceolate to linear-lanceolate, attenuate, 6–8.5 mm long, to 0.8–1 mm wide, broadest in the middle and narrowing below, strongly dendritically vestitured outside with hairs to 1.5 mm long and with an understory of stipitate glands 0.05–0.2 mm long, the vestiture longer and more dense at the sepal base, the inner sepal surfaces green, with only scattered stipitate glands 0.1–0.3 mm long or also with scattered unbranched hairs; corollas strong blue to violet, with white-yellow at the tube base, and white with scattered orange-brown dots on the throat floor, the orange spots ± 0.5 mm in diameter in several irregular series, the corollas 10–13 mm in total length (with lobes extended), the tube 7–8 mm long, to 4–4.5 mm wide at the distal throat, the 5 corolla lobes ± equal in size and shape and spread, ± oblong, broadly based, rounded at the tips, the upper 2 lobes (3.7–)4–5.5 mm long, 3.2–4.5 mm wide, the lower 3 lobes 4.2–6 mm long, 3–5.5 mm wide, the lobes spreading, often concavo-convex, the corollas moderately stipitate glandular outside with erect hairs to 0.1–0.3 mm long, the lower throat villous within with loosely arranged unbranched, wavy, white hairs 1-1.5 mm long that somewhat block the orifice to the throat; stamens 4, included, epipetalous; anthers white, each 2 lobed, the lower (anterior) 2 anthers 1.2–1.5 mm long (after anthesis), borne on free filaments 1–2 mm long, the adnate filament bases 3–5 mm long, the upper (posterior) anthers 1.7–1.8 mm long, borne on free filaments to 2–3 mm long, the adnate filament bases 3.2–6 mm long; ovary densely vestitured at the tip with erect, weakly branched hairs to ± 1 mm long, with the radii also erect; carpels and locules 2, ovules 1 per carpel produced in the distal fourth of the septa; styles 4.5–7.8 mm long, the stigmatic tip borne ± at the distal corolla tube throat, beyond the anthers, sparsely pubescent throughout with scattered non-branched hairs 0.2–0.3 mm long. Mature fruit and seeds unknown but ovoid immature seeds seen to 2 mm long, 1 mm wide.

Additional collections: **MEXICO. Coahuila:** ca. 31.5 rd mi S of Químicas del Rey on paved road south to San Pedro de las Colonias, area of steep gypsum on E side of rd near 26° 42'N, 103° 10'W, *Henrickson 20526* (TEX); N end of Valley of Acatita, 15.1 rd mi N of Rancho Acatita where NE-SW running spur (Sierra del Cuchilla) extends to highway, the ridge with extensive areas of gypsum, on solid gypsum interbedded with limestone, ± 26° 39'N, 103° 10'W, 20 Sep 1999, *Henrickson 22604 with D. Riskind* (TEX); W end of the Sierra de los Organos, 16 mi N of San Pedro (= Rancho Acatita) on Finisterre-Químicas del Rey highway, in gypsum-limestone area, near 26° 39N, 103° 09'W, ±1150 m, 24 Sep 2002, *Henrickson 23016* (TEX); same location, date, *Henrickson 23025*(TEX). All with duplicates to be distributed.

Leucophyllum coahuilensis is characterized by its small, sessile, ovate leaves, its dense, loose vestiture of dendritic hairs with moderately long rachis internodes (mostly 0.1–0.15 mm long) and few (1–2 per rachis node) thick radii mostly 0.2–0.3 mm long, 0.02–0.03 mm thick (Fig. 2). The sessile leaves also have a distinctive tuft of straight, unbranched hairs at the axil with the stem (Fig. 2C)–a feature not found elsewhere in the genus. All vestitured portions also have an understory of sessile or short-stipitate glands. This same vestiture also occurs on the pedicel and outer sepal surface. While the stems have a dense low understory vestiture that completely obscures the stem epidermis, the vestiture of the leaves is more open, with the green leaf surface clearly visible through the leaf vestiture, unlike some taxa, where the vestiture completely covers the leaf surface. The corollas are dark blue-violet with white marked with orange maculations in the lower throat; they are moderately short (10–13 mm in total length) and are stipitate glandular outside with a dense beard of wavy hairs on the basal throat within. The tip of the ovary has a dense beard of elongate branched hairs. Unlike all other species of *Leucophyllum*, ovules are only 2, one per carpel.

Within the genus *L. coahuilensis* is easily set apart by its two ovules per ovary, its distinctive vestiture, flower color, and sessile, ovate leaves with a basal tuft of unbranched hairs on the leaf axil. It appears most similar to *L. candidum* I.M.Johnston and *L. pruinosum* I.M.Johnston, both of which also have alternate leaves, orange maculations in the lower corolla throat, and vestitured ovary tips. The dendritic vestiture of *L. candidum*, however, has very short rachis internodes, with moderately long lower radii, and highly reduced upper radii, often not much longer than the width of the rachis internodes. As the terminal portions of the hairs fall away, the vestiture becomes very close and uniform (pannose), completely covering the leaf surface. *Leucophyllum candidum* also has petiolate, more broadly ovate, sometimes opposite leaves, and often larger flowers. It occurs from southern Big Bend Texas, eastern Chihuahua, through west-central Coahuila to northern Zacatecas and northeast Durango; its distribution surrounds that of *L. coahuilensis*, but *L. candidum* is not known from gypseous soils.

The new species is also somewhat similar to *L. pruinosum*, but the latter is distinguished by its vestiture that has longer, more slender radii (0.4–0.5 mm long, 0.01–0.015 mm in diameter); by petiolate, thinner, more orbicular leaves often with crisped margins; by more open, abruptly ampliate corolla throats; a preference for non-gypseous substrates; and a distribution around the confluence of the states of Tamaulipas, Nuevo León and San Luis Potosí (Henrickson & Flyr 1985).

The type locality of *L. coahuilensis* lies about one half kilometer east of the paved highway between Química del Rey and the loop highway northwest of San Pedro de la Colonias, about 30.5 miles (51 km) south of Química del Rey and 52 miles (84 km) north of the turnoff from the loop road east of Finisterre. It is part of Ejido Río Aguanaval. The type locality lies on the northern slopes of a northeast-southwest running spur from the range (locally called the Sierra de Cuchilla) that extends from the main range towards the highway. The area contains areas of mixed gypsum and clay, and other areas of nearly pure gypsum where the new species is common. Associates in the area include both obligate gypsophiles: *Fouquieria shrevei, Dyssodia gypsophila, Tiquilia gypsophila, Petalonyx crenulata, Dicranocarpus parviflorus, Nerisyrenia* sp., *Nama constancia, Haploesthes greggii, Euphorbia crepitata* var. *crepitata, Tiquilia gossipina, Selinocarpus purpusianus, Mentzelia mexicana, Drymaria elata*, etc. and non-gypsophils: *Grusonia braditiana, Jatropha dioica, Euphorbia antisiphilitica, Cordia parviflora, Castilleja lanata, Agave lecheguilla, Acacia neovernicosa, Allionia incarnata, Tiquilia greggii, Machaeranthera pinnatifida, Viguiera dentata, Tidestromia gemmata, Anulocaulis eriosolenus, Kallstromia grandiflora*, and *Larrea tridentata*.

On all trips to the site, the plants always produced a few flowers but no mature fruit. I have concluded that the plants were idling, i.e., just producing a few flowers at a time, but not maturing seeds. Perhaps after periods of strong rainfall, the plants will flower more strongly and have the resources to set seed.

RELATIONSHIPS AND MORPHOLOGY OF THE GENUS

Evidence of a close phylogenetic relationship between *Leucophyllum* and the Myoporaceae has been presented from a cpDNA-based molecular phylogenetic study by Olmstead et al. (2001). In this study the Scrophulariaceae is separated into three distinct clades. *Leucophyllum* remained in their Scroph I, or Scrophulariaceae *senso stricto* clade, showing a strongly supported relationship with Myoporaceae, with 100 percent bootstrap values and a high (44) decay value. Olmstead et al. (2001) suggested submersion of Myoporaceae into Scrophulariaceae s.s. along with the Loganiaceae. Robert Chinnock (pers. comm.), who has monographed *Eremophila* of the Myoporaceae, concurred and considered that Myoporaceae should be recognized as a subfamily of the Scrophulariaceae s.s.

In the monograph by Henrickson and Flyr (1985) the single chromosome count for *Leucophyllum* listed in Flyr's (1970) dissertation, obtained from pollen mother cells, was reported as both $n = 15$ and $n = 16$. The former number was a typographic error and the latter number may have been erroneous as well as Flyr (1970) indicated that he had difficulty in obtaining a clear chromosome spread. Read and Simpson (1989) reported $x = 17$ for *Leucophyllum* based on multiple root-tip counts from three species: *L. frutescens*, $2n = 34$; *L. minus*, $2n = 34$; and *L. candidum*, $2n = 68$, the first two diploid; the latter a tetraploid. Thus the base number for the genus appears to be $x = 17$.

Within the Scrophulariaceae, $x = 17$ has been reported from some members of the Tribe Gratioleae, namely *Bacopa* Aubl. ($2n = 68$; Chandron & Bhavanandan 1981), *Limnophila* R. Br. ($n = 17, 34$; Chandrum & Bhavanandran 1986; Subramanian & Pondmudan 1987) and *Picrorhiza* Royle in Benth. ($n = 17$; Jee et al. 1987). A base number of $x = 17$ also has been reported for *Veronica* L. (tribe Digitaleae) along with $x = 7, 8, 21, 32$. Within the Scrophulariaceae base numbers range from $x = 6$–20 and some genera, as *Veronica*, show wide variation in base numbers.

Within the Myoporaceae, Barlow (1971) provided chromosome counts for 58 of the 214 species of the large genus *Eremophila* (Chinnock pers. comm.). All species were $x = 18$, with diploids, tetraploids, and hexaploids occurring. Only two other counts have been published for *Myoporum* are $n = 54$, presumably triploid numbers for *M. laetum* and for *M. laetum* var. *decumbens* (Hair & Beuzenberg 1959), and $2n = 68$, a tetraploid based on $x = 17$, for *M. boninense* subsp. *boninense* by Ono and Masuda (1981). These are the only $x = 17$ counts recorded for the Myoporaceae thus far. Chinnock (pers. Comm..) considers the

Ono and Masuda (1981) count to be in error. A single count for *Bontia daphnoides* (Chinnock, pers. comm.) was *n* = 18. No counts are known for other genera of the family. The cytological data give little information of position of the genus.

Niezgoda and Tomb (1977) found that the Leucophylleae and Myoporaceae have tricolpate, diorate pollen grains of a distinct type not found elsewhere in the Sympetaleae. Karrfalt and Tomb (1983) further noted that the Myoporaceae are distinctive in having epithelium-lined secretory cavities in young stems and leaves. Their study showed that *Leucophyllum* has air cavities in the leaves that expand in a similar manner, although these lack epithelial linings and contents. They considered that the unlined air cavities of *Leucophyllum* may be homologous with the epithelial-lined secretory cavities in *Bontia* of the Myoporaceae. Lersten and Beaman (1998) found no support for the contention that air spaces in *Leucophyllum* were modified secretory cavities of the type found in Myoporaceae, however, they did find a single pair of epithelial-lined secretory cavities at the very leaf tips in three species of *Leucophyllum*. These did show a morphological similarity between *Leucophyllum* and Myoporaceae. Similar cavities are known from the genus *Capraria*, but its familial relationships are also under investigation (Lerston & Curtis 2001).

Carlquist and Hoekman (1986) studied wood anatomy of Myoporaceae and noted that certain xylem differences of *Leucophyllum* would exclude the genus from the Myoporaceae, but that there was a overall similarity of the woods of Myoporaceae and Scrophulariaceae as well as Gesneriaceae.

Comments on other species: Since publication of Henrickson and Flyr (1985) Guy Nesom has published two additional species of *Leucophyllum*. His *L. hintoniorum* Nesom from gypsum in the southeastern corner of Nuevo León, southeast of Aramberri (Nesom 1991) is distinctive in having a vestiture of three types of hairs: a very short understory of stellate-dendritic hairs that form a dense felty base layer; a larger series of stellate-dendritic hairs; and slender uniseriate gland-tipped hairs. With age the larger hairs fall alway leaving a closely pannose vestiture on both leaves and stems. The latter published *L. alejandrae* Nesom from a more arid gypsum area SW of Galeana, Nuevo León, about 68 km away, (Nesom 1993), has a similar vestiture, but narrower, more crowded leaves and smaller flowers. Subsequent collections of *L. hintoniorum* include specimens with much narrower, more crowded leaves, reducing the differences between the taxa. Unfortunately, *L. alejandrae* is known from only two collections, only one with flowers. More collections are needed of *L. alejandrae* in order to evaluate whether it should be considered separate from *L. hintoniorum*.

BOOK REVIEW

GARY PAUL NABHAN and ANA GUADALUPE VALENZUELA-ZAPATA. 2004. **Tequila! A Natural and Cultural History.** (ISBN 0-8165-1937-4, pbk.). The University of Arizona Press, 355 S. Euclid, Ste. 103, Tucson, AZ 85719, U.S.A. (Orders: 520-621-1441, fax 520-621-8899, www.uapress.arizona.edu). $14.95 pbk., $29.95 hbk., 160 pp., 20 b/w, 5 1/2" × 9 1/4".

It is always a pleasure to share in someone else's passion. From the very beginning of this book, it is obvious that Ms. Valenzuela-Zapata and Mr. Nabham enjoy a passion for the agave plant. They bring us along when they gaze over vast hillsides of blue agave and when they compare varieties from all areas of Mexico. They require us to mourn with them how the over planting of one species has led to serious disease and infestation of the agave fields. They take us into the fields as the well trained agave harvesters, or jimadores, chop leaves off the agave to make the pineapple shaped cores that will be roasted and distilled into tequila.

Where the authors do not take us is out onto the patio to sip the finished product with them so we can learn about the different varieties and how to choose a good tequila. The Mexican government's descriptions of the four kinds of tequila are on page 52-3 and then a series of pictures shows the reader every stage of tequila production from planting propagules to the aging process of the finished liquor. Otherwise there is no tasting guide, as one might expect from a book called "Wine!" or "Vodka!"

Good information can be found throughout on cultivation, and there are four appendices ranging from a glossary of terms to species descriptions of agaves used in the tequila industry. There is also material on the cultural history of pulque, mescal and tequila. The main focus of the book to this reader remains the devastating effects of relying on one species of agave. Whether or not it was the authors' intention, the next time I take a sip of tequila I will be reminded of the "gangrene" epidemic in the fields, which is a bitter aftertaste to a favorite drink.—*Karen Hall, Library Volunteer, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

AMARANTHUS ACANTHOBRACTEATUS (AMARANTHACEAE)

James Henrickson

Department of Biology
California State University
Los Angeles, California 90032, U.S.A.
henrickson@mail.utexas.edu

ABSTRACT

Amaranthus acanthobracteatus is described as a new species from the sand dunes at Bilbao near Viesca in southern Coahuila, Mexico. It is a sister species to the dioecious *A. acanthochiton*, that has been recognized as a distinct genus *Acanthochiton*. Both species are psammophytic, dioecious annuals with large chartaceous, sharp-pointed pistillate bracts. The new taxon differs from *A. acanthochiton* in its longer, less cordate, distally recurved pistillate bracts, its larger seeds, larger pistillate inflorescences, and in many minor characteristics. The new species also is larger, with pistillate plants maturing as tumbleweeds.

RESUMEN

Se describe ***Amaranthus acanthobracteatus*** como especie nueva para la ciencia, de las dunas de arena de Bilbao, cerca de Viesca, en el sur de Coahuila, México. Representa una especie hermana de *A. acanthochiton*, especie dioica que ha sido segregada en un género distinto, *Acanthochiton*. Ambas especies son anuales, dioicas y psamófilas, y ambas presentan las brácteas pistiladas grandes, cartáceas y puntiagudas. El taxon nuevo se distingue de *A. acanthochiton* por las brácteas pistiladas más largas, menos cordadas, y recurvadas distalmente, por las semillas más grandes, por las inflorescencias pistiladas más grandes y por muchas características de índole menor. Además, las plantas de la especie nueva son más grandes y, al madurar y secarse, las plantas pistiladas son dispersadas por el viento.

INTRODUCTION

Dioecious *Amaranthus* species are native to North America. They initially were treated in the genera *Acnida* L. (with narrow pistillate bracts and 0–5 pistillate sepals) and *Acanthochiton* Torr. (with very large, conduplicate, chartaceous pistillate bracts) (Bentham & Hooker 1880; Standley 1917; Schinz 1934) until Sauer (1955) combined both genera with the monoecious *Amaranthus* species. Sauer (1957) noted that hybrids between the taxa previously in *Acnida* resulted in fertile offspring (Murray 1940), while hybrids between the *Acnida* group and monoecious *Amaranthus* species formed sterile hybrids, this implying that the *Acnida* taxa may represent a distinct phylad. However, Murray (1940) found that hybrids between species of monoecious *Amaranthus* often produced sterile hybrids as well. The relationship of *Acanthochiton* to the other dioecious taxa has not been specifically addressed. While some regional floras have continued to recognize *Acnida* and *Acanthochiton* as a distinct genera (Correll & Johnston 1970; Martin & Hutchins 1980) their combination with *Amaranthus* has been recognized in the Flora North America series (Mosyakin & Robinson 2003). While *Acanthochiton*, initially appears distinct from *Amaranthus*, Sauer (1955) points out that the differences are only quantitative and that the staminate plants of the taxon are very similar to those of *Acnida* species. Thus Sauer (1955) placed *Acanthochiton wrightii* Torr. into *Amaranthus*. Due to the existence of a previously published *Amaranthus wrightii* S. Wats., he made the combination *Amaranthus acanthochiton* (Torr.) Sauer.

In this paper, I present a second species related to *Amaranthus acanthochiton* from the Bilbao Dunes near the town of Viesca in southern Coahuila.

TAXONOMY AND DISCUSSION

Amaranthus acanthobracteatus Henrickson, sp. nov. (**Figs. 1, 2**). TYPE: MEXICO. COAHUILA: ca. 37 air mi ESE of Torreon on sand dunes at Bilbao, (8 mi NW of Viesca); dioecious; female plant 8 × 18 dm tall-wide with the stems dense, male plant 7 × 10 dm, with stems more erect and open; 25° 25'33.6'N, 102° 53'33.3'W, 3650 ft. elev., 13 Nov 2002, *Henrickson 23209* (HOLOTYPE: TEX; ISOTYPES: MEXU and to be distributed).

Amaranthus acanthochiton (Torr.) Sauer primo adspectu maxime simile, sed bracteis feminis ad maturitatem angustatis basin versus (non cordatis basi), spinis ad apicem bracteae recurvatis, non rectispinis, bracteis tenuibus, non incrassatis, sine reticulis lateribus, seminibus grandioribus 1.7–2.2 (versus 1.2–1.4) mm longis, et dichasiis magnioribus, et amplioribus magnitudinibus plantis differt.

Dioecious, depressed-globose, coarse annuals of sand-dune habitats. Pistillate plants densely branched, to 4–9 dm tall, 9–18 dm wide; central stems erect, to 20 mm in diameter at the base; internodes 3–13 cm long, branching alternately throughout; young stems 1–1.5 mm in diameter, striate, mottled green between the ± 10 yellowish ribs. Staminate plants 3.5–9 dm tall, 4–15 dm wide, with more vertical stems to 8 mm in diameter developed from basal decumbent stems. Leaves of pistillate and staminate plants similar; basal leaves linear-lanceolate, 5–8(–10) cm long, 5–8(–10) mm wide, ascending, obtuse to acute, apiculate at the tip, cuneate at the base; petioles 10–20(–30) mm long; upper-inflorescence leaves more linear, 1–5 cm long, 1–5 mm wide, the margins of all leaves strongly crisped, whitish, the primary-secondary veins whitish beneath. Pistillate plants with flowers axillary to the linear mid- upper-stem leaves, in irregular, dichasial inflorescences that eventually develop into an elongated cluster of ± overlapping bracts to 25 mm long, the inflorescences dichasial at the base, with the two axies usually not branching above, the large, ovate, strongly folded bracts obscuring the upper inflorescence arrangement, the lowest bracts smallest, to 5 mm long, 3 mm wide, the mid bracts largest, 10–16.5 mm long, to 10 mm wide, the distal, youngest bracts ± reduced, 8–12 mm long, the bracts thickened, V-shaped in transverse section, with the midvein straight or outwardly curved, with the sharp tips reflexed, the bracts rounded, cordate only with age at the base, broadest in the lower half, and tapering to the tip, the adaxial bract surface white throughout, the abaxial (outer) bract surface white along the base, the mid and distal portions green, not conspicuously veined,

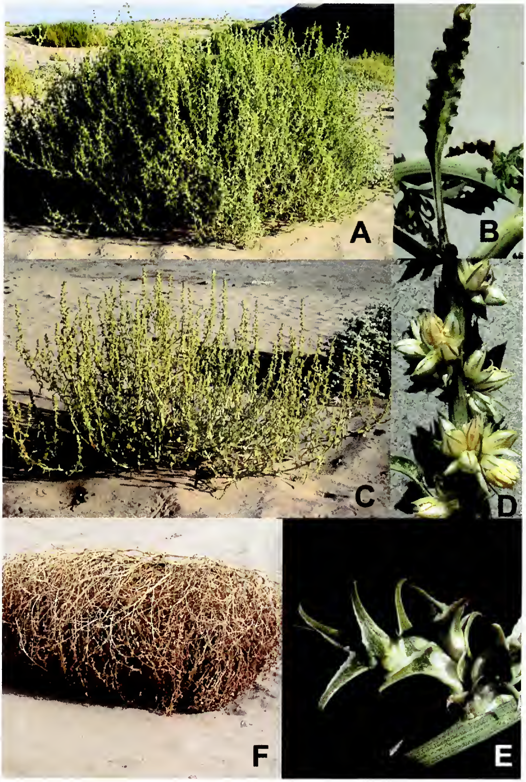

Fig. 1. *Amaranthus acanthobracteatus*. **A.** Pistillate plant, ca. 9 dm tall, 14 dm wide; note density of branching. **B.** Lower stem leaf, showing characteristic shape, long petiole, and strongly crisped blade margins. **C.** Staminate plant, ca. 8 dm tall, 1.2 dm wide; note open aspect of branching. **D.** Staminate globose dichasia with anthers. **E.** Pistillate inflorescence showing characteristic coloration and distal hook at the long bract tip. **F.** Post-mature pistillate plant, upside down—a tumbleweed.

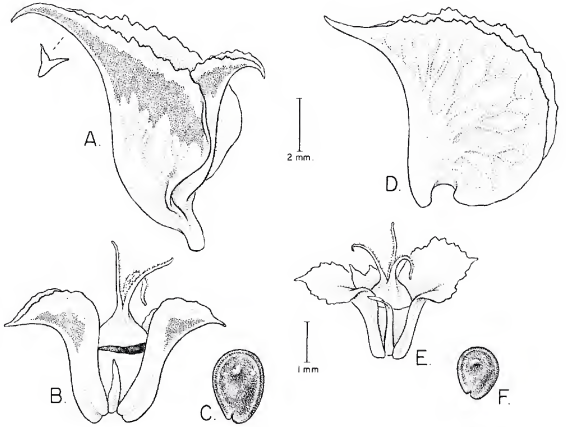

Fig. 2. Comparison of pistillate bracts, flowers, seeds of *Amaranthus acanthobracteatus* and *A. acanthochiton*. **A–C:** *A. acanthobracteatus*. Mature pistillate bracts, note narrow base, bract shape, and decurved tip. **B.** Mature fruit with associated perianth. **C.** Mature seed (all from *Henrickson 23209*). **D–F:** *A. acanthochiton*. **D.** Mature pistillate bract, note cordate base, folded reniform shape, and 6 straight terminal spine. Also note reticulate venation pattern on the bract side. **E.** Mature fruit with associated perianth. **F.** Mature seed (all from *Correll 26563*). The 2 mm scale is for mature pistillate bracts (A, D); the 1 mm scale is for B–C and E–F.

the outer margins thick membranous, white, entire or variously undulate to coarsely toothed, (0.3–)0.5–1.0 mm thick, the midvein white, with age the lower portion of the bracts becoming ± spongy and sometimes the mid portions and margins also becoming spongy at maturity. Pistillate flowers with 2–3 sepals, the two marginal sepals largest, 3–4.5 mm long, with one larger than the other, both swollen-spongy and truncate at the base, the midribs green, excurrent, the whitish margins broad along the claw, and much expanded in the ovate blade below the acute-obtuse tip, the third sepal (when present) oblong, 0.8–2.7 mm long, abaxial. Ovary compressed; styles 2–3, 1.5–2.2 mm long, stigmatic and pilose along their inner surfaces. Staminate plants producing dichasial glomerules of 7–20+ staminate flowers at 2–15(–30) mm intervals along the upper stems, the glomerules subtended by narrow, crisped-margined leaves; bracts 1.2–2(–3.8) mm long, sepal like in structure, white scarious except along the green, excurrent midvein; sepals 5, oblong-elliptical, concavo-convex, 3.3–4.3

mm long, 1.2–1.4 mm wide, scarious except along the slender green midveins, rounded to 2-toothed at the tips, the midveins excurrent for 0.4–0.9 mm, the sepals strongly spreading at anthesis exposing the anthers; anthers 5, oblong, 2–2.2 mm long, ± 0.7 mm wide (before anthesis), apiculate at the tip, yellow, post-anthesis anthers 1.5–1.7 mm long, the filaments initially 0.9 mm long, elongating to 2.0 mm at anthesis. Mature utricles compressed obovate, membranous, the body to 2.3 mm long, to 1.5 mm wide, with a visible circumscissile line of dehiscence in the distal third, the bottom portion smooth or rugose, the cap rugose or not, ± beaked below the filiform styles. Seeds compressed obovoid, smooth, shiny, reddish-brown to reddish-black, 1.7–2.2 mm long, 1.3–1.6 mm wide and 0.8–1.05 mm thick, the embryo radicle pointing downward. Figs. 1, 2.

Additional collections: **Mexico. Chihuahua:** 36 air mi ENE of Escalon along trail to Esmaralda in Bolsón de Mapimí region of CDR scrub; dioecious annual on sandy knoll, near 26° 57'N, 103° 52'W, 3500 ft, 19 Sep 1972, *Henrickson 7755* (RSA); Coahuila. Sand dunes near Bilbao, 6 mi via Hwy 91, S of Mex Hwy 40, robust annual to 5 dm tall, in active dunes, 25° 25'N, 102° 55'W, 12 Sep 1984, *J.E. Bowers 2930, with T.L Burgess, R.M. Turner* (ARIZ); ± 37 air mi ESE of Torreon, on the sand dunes at Bilbao, on Hwy 68, about 10 mi NW of Viesca, near 25° 25'N, 102° 53'W, ± 1000 m, 17 Oct 2002, *Henrickson 23171*, with *D. Riskind*; same locality, 13 Nov 2002; *Henrickson 23202; 23203, 23204, 23205, 23208; 23206, 23207*; all TEX and to be distributed

There is no question that the new taxon is related to *Amaranthus acanthochiton*. Both are branched dioecious annuals of dune systems or sandy soils. In both the leaf blades are crispate; both have broadened and thickened pistillate bracts that fold over flowers and fruit. Both have two large pistillate sepals and 1–3 smaller ones.

But *Amaranthus acanthochiton* differs from the new taxon in several features (Fig. 2). The bracts of *A. acanthochiton* are more reniform in two-dimensional outline, typically cordate at the base, the sharp tip is straight or only slightly curved (but not distinctly deflexed at the tip), the green, mid-bract becomes thickened, spongy and develops a conspicuous raised-reticulate venation pattern on the outer base surface at maurity, the outer membranous margins are more strongly erose-crenate, typically much narrower, (0.4–0.6 mm wide), and the mature pistillate inflorescences are smaller, with fewer flowers. Also, in *Amaranthus acanthochiton*, the pistillate flowers have two larger marginal, clawed sepals, and may have 1–3 smaller, oblong, membranous sepals, 1 on one side, and 0–2 on the other face, however, in the smallest bracts, the pistillate flowers may just have 5 small, oblong sepals. Overall the sepals in *A. acanthochiton* are similar to those of the new species. But in some collections the blades of the larger sepals can become strongly expanded and develop a branching network of veins and have denticulate margins (Fig. 2 E). The larger sepals may also develop thickened, spongy bases at maturity as in the new taxon. Seeds in both are similar in orientation, color and shape, but are smaller (1.2–1.4 mm long, 0.95–1.05 mm wide) in *A. acanthochiton*.

Amaranthus acanthochiton is known from sandy flats and dunes from eastern Arizona (Navajo, Greenlee cos.); western New Mexico (San Juan, Rio Arriba, McKinley, Valencia, Catron, Socorro, Otero, Doña Ana, Luna, and Hidalgo cos.); Texas (El Paso, Hudspeth and Jeff Davis cos.) and northern Mexico, Chihuahua (Samalayuca Dunes south of Cd. Juarez) (Sauer 1955). Reports by Turner et al. (2003) of the species in Brewster, Presidio and Webb cos. have not been substantiated.

In *Amaranthus acanthobracteatus*, staminate plants have a much more open habit than the pistillate plants as can be seen in Fig. 1 A–B. Staminate plants branch at the base and the vertical lateral stems have fewer lateral branches creating an open growth form that would appear to allow for air flow between the stems and outward dispersal of pollen from the plants (Fig. 1C). The pistillate plants, in contrast, are more densely branched at the base and above; the plants forming a dense broadly globose growth form with the main lateral branches curving upward. That would presumably cause entering pollen to slow down, perhaps increasing the possibility of finding a suitable stigmatic surface.

The plants are well known to the local public and in wet years are very common on the dunes where they occur nearly exclusively with *Tidestromea lanuginosa* (Nutt.) Standl. The plants, along with those of *Tidestromia lanuginosa*, are gathered for animal feed by local townfolk. The local name for the plant is "Torillo" or "Herba Voladora," the latter (flying herb) implying that the plants become tumbleweeds at maturity. The overall architecture of the pistillate plants is very similar to that of *Salsola*, (Chenopodiaceae) the Russian thistle, and a later trip to the type locality showed that mature plants indeed become tumbleweeds (Fig. 1F). However, unlike *Salsola*, where a distinct abscission layer forms at the stem-root junction, no distinct abscission layer forms between roots and stem. Rather, as the plants mature, their fleshy roots die, dry out, and eventually break away, leaving the broadly globose plants to tumble across the dunes dispersing the pistillate infructescences and seeds.

ACKNOWLEDGMENTS

I thank Neil Harriman for the Latin translation, Thomas Wendt and Fernando Chiang for the Spanish translation of the abstract, Bobbi Angell for Figure 2, ARIZ, and SRSC for loan of specimens, David Riskind for causing the initial visit the dunes at Bilbao, which I later hit at the peak of flower, and the Plant Resources Center of the University of Texas, Austin for use of facilities.

BOOK REVIEW

Benoît Dayrat. 2003. **Les botanistes et la flore de France: trois siècles de découvertes.** (ISBN 2-85653-548-8). Publications Scientifiques du Muséum national d'Histoire Naturelle, 57, rue Cuvier, 1-75005 Paris, FRANCE. (Orders: Tel. [33] (0) 1-40 79 3700; Fax [33] (0)1-40 79 3858; e-mail: diff.pub@mnhn.fr). Price not given, 690 pp., Illus., color plates, portraits, 6 1/2" × 9 1/2".

This massive work of scholarship is not, Dayrat declares, a history of botany in France but rather the history of the discovery of plants in France from 1753 to the early twentieth century. He details the lives of those authors of at least one species considered valid in current flora. The lives of the early doctors, pharmacists, members of the military and of the clergy, essentially amateurs, their explorations through the various regions of France, their personal triumphs and tragedies, the political and intellectual intrigues make fascinating reading. By their associations many additional botanists are cameoed in extensive footnotes, which also include bibliographical details of published works as well as references from many, often obscure resources, such as regional botanical journals. Each biography concludes with the valid species the author described; these species are again listed under the author's name in a separate section. Every person cited is indexed in one of two indices, the other being comprehensive.

Much botanical history is necessarily included in these biographies: the history of botanical investigations of such influential persons as Lamarck and Jussieu, of Candolle, of the eccentric Alexis Jordan; the first microphotography by Brébisson, and the development of the academic discipline of botany. There is also considerable history of the many botanical and Linnaean societies throughout France and the establishment of her numerous botanical gardens.

As a final word Dayrat, a post-doctoral student at the California Academy of sciences, reflecting on California plants,urges the documentation of the history of discoveries of fauna and flora throughout the world.

This is an important work and should be made accessible to all botanists and those in related sciences.—*Joann Karges, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

TAXONOMIC REEVALUATIONS IN NORTH AMERICAN *ERIGERON* (ASTERACEAE: ASTEREAE)

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

ABSTRACT

Four taxa of *Erigeron* are raised from varietal to specific rank: *E. breweri* var. *klamathensis* to **E. klamathensis** (Nesom) Nesom, comb. et stat. nov., *E. decumbens* var. *robustior* to **E. robustior** (Cronq.) Nesom, comb. et stat. nov., *E. engelmannii* var. *davisii* to **E. davisii** (Cronq.) Nesom, comb. et stat. nov., and *E. utahensis* var. *sparsifolius* is treated as *E. sparsifolius* Eastw. The morphological distinctions of these taxa are equivalent to those of other accepted species of *Erigeron*. **Erigeron poliospermus** var. **disciformis** (Cronq.) Nesom, comb. et stat. nov., is raised in rank from *E. poliospermus* forma *disciformis*. **Erigeron clokeyi** var. **pinzliae** Nesom, var. nov., occupies the major portion of the range of the species; the typical variety is restricted to Clark Co., Nevada. **Erigeron greenei** Nesom, nom. nov., representing a species endemic to California, replaces the later homonym *Erigeron angustatus* Greene. *Erigeron tracyi* Greene is an earlier name for *E. colomexicanus* A. Nels. Taxonomic clarifications are provided for *E. acris*, *E. uncialis* and *E. cavernensis*, and for the interrelated species *E. radicatus*, *E. ochroleucus*, *E. lackschewitzii*, and *E. parryi*. A lectotype is designated for *E. stenophyllus* var. *tetrapleurus*.

RESUMEN

Cuatro taxa de *Erigeron* se elevan del rango varietal al específico: *E. breweri* var. *klamathensis* a ***E. klamathensis*** (Nesom) Nesom, comb. et stat. nov., *E. decumbens* var. *robustior* a ***E. robustior*** (Cronq.) Nesom, comb. et stat. nov., *E. engelmannii* var. *davisii* a ***E. davisii*** (Cronq.) Nesom, comb. et stat. nov., y *E. utahensis* var. *sparsifolius* es tratado como *E. sparsifolius* Eastw. Las diferencias morfológicas de estos taxa son equivalentes a las de otras especies aceptadas de *Erigeron*. ***Erigeron poliospermus*** var. ***disciformis*** (Cronq.) Nesom, comb. et stat. nov., se eleva de rango desde *E. poliospermus* forma *disciformis*. ***Erigeron clokeyi*** var. ***pinzliae*** Nesom, var. nov., ocupa la mayor parte del área de la especie; la variedad típica está restringida a Clark Co., Nevada. ***Erigeron greenei*** Nesom, nom. nov., que representa una especie endémica de California, reemplaza al homónimo posterior *Erigeron angustatus* Greene. *Erigeron tracyi* Greene es un nombre más antiguo para *E. colomexicanus* A. Nels. Se ofrecen clarificaciones taxonómicas para *E. acris*, *E. uncialis* y *E. cavernensis*, y para las especies interrelacionadas *E. radicatus*, *E. ochroleucus*, *E. lackschewitzii*, y *E. parryi*. Se designa un lectotipo para *E. stenophyllus* var. *tetrapleurus*.

Taxonomic modifications are required for North American *Erigeron* L., preceding a treatment of the genus for the Flora of North America project. A new variety is described, a replacement name is provided for a species currently recognized by a later homonym, one taxon is raised from the rank of forma to variety, and four taxa previously recognized as varieties are treated at specific rank. Morphological distinctions of these former varieties are as significant as those separating many other species of *Erigeron*, and species rank is consistent

SIDA 21(1): 19–39. 2004

with current taxonomy within the genus. Clarifications of the taxonomic status of other taxa also are provided. Fuller morphological descriptions will be provided in the FNA treatment.

Erigeron breweri var. *klamathensis* at specific rank

Erigeron klamathensis (Nesom) Nesom, comb. et stat. nov. BASIONYM: *Erigeron breweri* A. Gray var. *klamathensis* Nesom, Phytologia 72:175. 1992. TYPE: U.S.A. CALIFORNIA. HUMBOLDT CO.: Trinity Summit, 2 mi SE of Devil's Hole, exposed rocky points in woods, westerly exposure, 26 Jul 1935, *J.P. Tracy 15515* (HOLOTYPE: UC!; ISOTYPES: JEPS!, MO!, TEX!).

Flowering Jun–Sep. Outcrops, ridges, crevices, rocky slopes, over shale, granite, serpentine, peridotite, chaparral, oak-pine, fir-oak, mixed evergreen woodlands; (450–)700–2150 m; California, Oregon.

Prior to the recognition of var. *klamathensis*, most previous identifications had referred these plants to the sympatric *Erigeron foliosus* Nutt. var. *confinis* (T.J. Howell) Jeps. I originally treated var. *klamathensis* within *E. breweri* A. Gray (Nesom 1992a) primarily because of similarities in vestiture and habit but here hypothesize that a closer relationship of var. *klamathensis* is more likely with *E. foliosus*. Recognition of *E. klamathensis* at specific rank emphasizes its geographic and morphological distinctions and its ambiguous evolutionary affinity.

Erigeron klamathensis occurs in the Klamath Ranges of Siskyou, Trinity, and Shasta counties, California, and adjacent Oregon (Nesom 1992a, Map 5). It is disjunct from *E. breweri*, which is distributed in the Sierra Nevada, southwestern California, and parts of the Great Basin province (Nesom 1992a, Maps 3 and 4) and is more similar in range and ecology to *E. foliosus*, which is primarily a species of coastal ranges (Nesom 1992a, Maps 6 and 7).

Erigeron klamathensis produces glandular phyllaries similar to those of *E. breweri* var. *breweri* and strongly lignescent bases like *E. breweri* var. *porphyreticus* (as well as *E. foliosus* var. *confinis*). The spreading-deflexed orientation of the stem vestiture in *E. klamathensis* is similar to that commonly found in *E. breweri*, but the sparsely pilose-hirsute vestiture of long, stiff hairs differs from the hirsutulous vestiture of *E. breweri*.

Cauline vestiture in *Erigeron foliosus* is consistently antrorsely strigose to nearly or completely absent, but the habit of *E. foliosus* Nutt. var. *confinis* is nearly identical to that of *E. klamathensis* and the phyllaries are similarly glandular. Their similarity in overall appearance, geography, and ecology has led to mixed collections: e.g., a collection from Josephine Co., Oregon (*Denton 2409*, HSC) has one plant of *E. klamathensis* and several stems of *E. foliosus* var. *confinis*, showing no intermediacy. Intermediates between the two are encountered but they are not common.

The rayless *Erigeron petrophilus* var. *viscidulus* (A. Gray) Nesom also is similar in habit to *E. klamathensis*, has similar involucral vestiture, and is partially sympatric with it (Nesom 1992a, Map 8). Var. *viscidulus* should considered among possible close relatives of *E. klamathensis.*

The radiate taxa under consideration can be identified by the following contrasts. *Erigeron breweri* is represented in the key by var. *breweri* because it is the only variety of *E. breweri* similar to *E. klamathensis* in its densely glandular phyllaries lacking non-glandular hairs.

1. Stems strigose to glabrate _____ **Erigeron foliosus**
1. Stems hirsute to hispid-hirsute or pilose-hirsute.
   2. Stems arising from slender, woody basal offsets, these from a strongly developed, woody root; hairs of stems 0.5–1 mm long; inner phyllaries with broad, white, thickened margins, lacking distinctly demarcated green apical areas _____ **Erigeron klamathensis**
   2. Stems arising from slender fibrous-rooted rhizome-like bases, without a strongly developed woody root; hairs of stems 0.1–0.4 mm long; inner phyllaries with green apical areas _____ **Erigeron breweri** var. **breweri**

In addition to the difference in vestiture, stems of *E. klamathensis* average considerably shorter than *E. foliosus* var. *confinis* [6–15(–20) cm tall vs. (10–)15–35 (–50) cm] and the root system usually is distinctly thicker and woodier than in var. *confinis.*

Erigeron decumbens var. *robustior* at specific rank

Erigeron robustior (Cronq.) Nesom, comb. et stat. nov. BASIONYM: *Erigeron decumbens* Nutt. subsp. *robustior* Cronq., Brittonia 6:174. 1947. *Erigeron decumbens* Nutt. var. *robustior* (Cronq.) Cronq., Vasc. Pl. Pacific Northwest 5:175. 1955. TYPE: U.S.A. CALIFORNIA. HUMBOLDT CO.: valley of South Yager Creek, 26 Jun 1932, *J.P. Tracy 10252* (HOLOTYPE: UC).

Erigeron robustior is known from Humboldt, Trinity, and Mendocino counties in northwestern California and is disjunct from *E. decumbens*, which is known from six counties of northwestern Oregon. The two taxa also are separated by consistent morphological differences (key below). It is possible that *E. decumbens* and *E. robustior* have an evolutionary sister relationship, but the magnitude of difference between them is consistent with other accepted species of *Erigeron*, particularly within the "*Erigeron eatonii* A. Gray group," of which they are a part.

1. Involucres (4.5–)5–6 mm high, 9–12 mm wide, phyllaries linear-lanceolate, apically linear-acuminate; disc corollas 3–3.5 mm long; cypselae 1.2–1.6 mm long; heavy soils in seasonally wet or dry upland prairie grasslands; 100–300 m elev. _____ **Erigeron decumbens**
1. Involucres 6–8.5 mm high, 12–18 mm wide, phyllaries narrowly oblanceolate to lanceolate, apically acute to acuminate; disc corollas 3.5–4.5 mm long; cypselae (1.8–)2–3.2 mm long; rocky or gravelly slopes, sometimes over serpentine, glades and meadows, sagebrush; 700–1500 m elev. _____ **Erigeron robustior**

Comments regarding the biology of *Erigeron decumbens* sensu stricto on the Center For Plant Conservation website (CPC 2003) note the following: "This rare species spreads vegetatively via rhizomes over very short distances [of] about 4 inches (<10 cm). Since plants often grow in clumps, it is often difficult to distinguish individuals." In the FNA treatment, these 'rhizomes' are described as 'rhizomiform caudex branches;' plants of *E. robustior* mostly grow singly, without similar vegetative reproduction, but the distinction is not absolute, because *E. robustior* also occasionally produces rhizomiform branches.

Three collections of plants of the *Erigeron eatonii* group from within the geographic range of *E. robustior* are smaller in stature and have smaller heads with elliptic-oblanceolate phyllaries, compared to *E. robustior*. They may represent an undescribed entity. Strother (1987) annotated these collections as "*E. decumbens* var. *robustior* vel aff.," indicating that their identity was uncertain.

Specimens examined: **CALIFORNIA. Humboldt Co.:** near Mad River Buttes, 4739 ft, meadow, 28 Jun 1980, *Baker 2479* (HSC), *Baker 2499* (HSC); Jack Rabbit Valley, along Swayback Ridge 4-wheel drive road 1 mi S of jct with Forest Service road, meadow, 4900 ft, 10 Jun 1980, *Nelson and Nelson 5395* (HSC). *Blankinship s.n.* (UC 87680, fide Strother), 1 Jul 1893, from "Mad River," may be the same entity.

Erigeron engelmannii var. *davisii* at specific rank

Erigeron davisii (Cronq.) Nesom, comb. et stat. nov. BASIONYM: *Erigeron engelmannii* A. Nels. subsp. *davisii* Cronq., Leafl. W. Bot. 3:167. 1942. *Erigeron engelmannii* A. Nels. var. *davisii* (Cronq.) Cronq., Vasc. Pl. Pacific Northwest 5:177. 1955. LECTOTYPE, selected here: U.S.A. IDAHO. IDAHO CO.: Whitebird summit, moist woods, range 2 east, township 29 north, 14 Jun 1941, *R.J. Davis 3254* (MIN; ISOLECTOTYPE: UC). Cronquist (1947) cited the two collections as type material, but he did not specify a holotype. The MIN sheet is annotated by Cronquist as 'type sheet' (fide A.C. Cholewa).

Flowering (Apr–)May–Jul. Bare, rocky ridges and slopes, basalt outcrops, sparsely vegetated woodland openings or edges, commonly with grasses; 1200–1800 m; Idaho, Oregon.

Erigeron davisii occurs in Idaho and eastern Oregon and is geographically disjunct from the range of *E. engelmannii*, which occurs over a wider area to the south and east (Fig. 1). The two are morphologically distinct (key below), and features of *E. davisii* indicate that it probably is equally or more closely related to *E. poliospermus* A. Gray, *E. disparipilus* Cronq., *E. nanus* Nutt., and others. These species are characterized by non-glandular stem hairs of markedly unequal lengths, petiole margins coarsely spreading-ciliate with thick-based hairs, coiling ray corollas, and a tendency for strigose-sericeous achenes. *Erigeron davisii* is distinct among these species primarily in its antrorsely appressed stem hairs; the orientation of the stem vestiture also probably is the reason that it has been hypothesized to be closely related to *E. engelmannii*.

Erigeron engelmannii is similar to *E. davisii* in habit, leaf morphology, coarsely ciliate petiole margins, and has cauline vestiture of nonglandular hairs of disparate length, but it is hypothesized here to be most closely related to *E. pumilus* Nutt. and *E. concinnus* (Hook. & Arn.) Torr. & A. Gray, in agreement

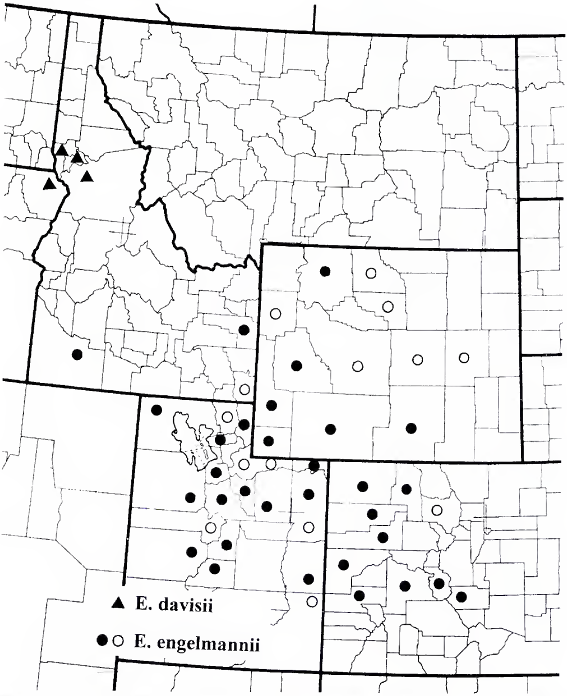

Fig. 1. Distribution of *Erigeron davisii* and *E. engelmannii*. Solid symbols are from collections at NY and BRIT. Open circles are from internet-posted maps (Rocky Mountain Herbarium 1998; Albee et al. 1988) and from Cronquist (1947).

with observations of Cronquist (1947), who noted close similarities among these taxa. All three have ray corollas very narrow (0.8–1.1 mm wide vs. 1.2–1.8 mm wide) and reflexing at the tube-lamina junction (vs. broader and coiling at the tips), disc corollas distinctly inflated and indurate above the tube (vs. not inflated or indurate), and achenes oblong (vs. narrowly obovate). *Erigeron* *engelmannii* shares with *E. concinnus* the unusual combination of densely short-hairy disc corollas and an outer pappus of narrow to broad scales.

In contrast to *E. pumilus* and *E. concinnus* and their other close relatives, the stems and leaves of *E. engelmannii* do not have dense, minute glandularity and ray corollas appear not only to reflex (as in the *E. pumilus* group) but also to coil at the tips (as in the *E. poliospermus* group). This apparent combination of ray behaviors in a single species is rare in *Erigeron*. In sum, *E. engelmannii* has features of both the *E. pumilus* group and the *E. poliospermus* group.

1. Involucres 3.5–5(–6) mm high; ray corollas 5–10 mm long, laminae 0.8–1.1 mm wide, apparently both coiling at the tips and reflexing at the tube-lamina junction; disc corollas inflated and indurate above the tube, puberulent; cypselae 1.4–1.8 mm long, oblong; outer pappus of narrow scales or setae _______ **Erigeron engelmannii**
1. Involucres 5–8 mm high; ray corollas 8–14 mm long, laminae 1.2–1.8 mm wide, coiling at the tips, not reflexing; disc corollas not inflated or indurate, glabrate; cypselae 2.1–2.5 mm long, obovate; outer pappus of setae _______ **Erigeron davisii**

Stems and involucres of *E. davisii* are more densely hairy than in *E. engelmannii*, easily seen with a collection of specimens of both; the difference is difficult to characterize in a key.

Erigeron poliospermus forma *disciformis* at varietal rank

Populations of discoid plants of *Erigeron poliospermus* from localities in central Oregon were originally treated by Cronquist at rank of forma. Geographically discrete discoid population systems, without other morphological differentiation, are generally recognized at varietal rank in other species of *Erigeron*.

Erigeron poliospermus A. Gray var. **disciformis** (Cronq.) Nesom, comb. et stat. nov. *Erigeron poliospermus* A. Gray forma *disciformis* Cronq., Brittonia 6:194. 1947. TYPE: U.S.A. OREGON. CROOK CO.: near camp on Hay Creek, rocky hillsides, 840 m, 12 Jun 1894, *J.B. Leiberg 212* (HOLOTYPE: NY; ISOTYPE: GH).

1. Stems branched at or below midstem, basal leaves and branches originating on elongate internodes from proximal 1–6 cm of primary stem; stems and involucres densely minutely glandular, without non-glandular hairs or sparsely hirsute _______ **Erigeron poliospermus** var. **cereus**
1. Stems unbranched, basal leaves and stems originating from compressed nodes at the caudex apex; stems and involucres sparsely minutely glandular and densely hirsute.
    2. Heads discoid, ray florets absent _______ **Erigeron poliospermus** var. **disciformis**
    2. Heads radiate, ray florets present and conspicuous _______ **Erigeron poliospermus** var. **poliospermus**

Erigeron utahensis var. *sparsifolius* at specific rank

Cronquist (1947, p. 273) observed that *Erigeron utahensis* A. Gray and *E. sparsifolius* Eastw. "intergrade so completely that specific recognition is scarcely possible" and treated them within a single species. He later noted (Cronquist 1994, p. 342) that "the species consists of two wholly intergradient varieties of

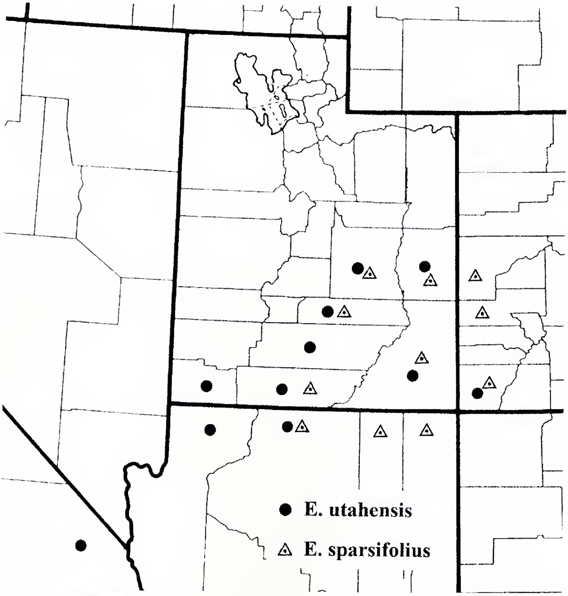

Fig. 2. Distribution of *Erigeron utahensis* and *E. sparsifolius*. Records are from collections at NY and BRIT, as well as several citations from Cronquist (1947).

strikingly different aspect." A large set of collections (NY) confirms the "strikingly different aspect" of these taxa and, in contrast to Cronquist's view, indicates that they are distinct in morphology as well as phenology. The two are sympatric over a significant area (Fig. 2) and are ecologically similar, but in Washington, Garfield, and western Kane counties, Utah, where *E. utahensis* is abundant, *E. sparsifolius* apparently does not occur. In San Juan Co., Utah, where both are common, apparent intermediacy in some collections may be evidence of hybridization, but more generally, *E. sparsifolius* has been identified consistently and it appears to be reproductively isolated from *E. utahensis*. The view that they are "wholly intergradient" is not corroborated by herbarium material. And apparently from field observations, A.H. Holmgren noted (label of *Holmgren 16229*, NY, San Juan Co.) that *E. sparsifolius* is "specifically distinct from *E. utahensis*." The two species can be identified by the following contrasts.

1. Cauline leaves linear, bracteate, relatively even-sized above midstem and continuing to immediately proximal to heads; heads (1–)3–10 from branches well above midstem; involucres 3–5 mm high, 5–8 mm wide; ray florets 10–14(–20), corollas 4–8 mm long; disc corollas viscid-puberulent with blunt-tipped hairs; flowering Jun–Sep ____ **Erigeron sparsifolius**
1. Cauline leaves gradually smaller distally, absent proximal to heads; heads 1–3(–5) from branches from midstem or above; involucres 5–7 mm high, (7–)12–15 mm wide; ray florets 28–40, corollas 10–18(–20) mm long; disc corollas sparsely strigose-villous with needle-like hairs; flowering mid Apr–Jun(–Jul) ____ **Erigeron utahensis**

Erigeron sparsifolius Eastw., Proc. Calif. Acad. Sci. 2, 6:297. 1896. *Erigeron utahensis* A. Gray var. *sparsifolius* (Eastw.) Cronq., Brittonia 6:273. 1947. TYPE: U.S.A. UTAH. SAN JUAN CO.: Willow Creek, 14 Jul 1895, *A. Eastwood 48* (HOLOTYPE: CAS; ISOTYPES: GH!, US!).

Wyomingia vivax A. Nels., Bot. Gaz. 56:70. 1913. TYPE: U.S.A. San Juan Co.: Geyser Canyon, [east slope of La Sal Mountains,] dry rocky hills, 9000 ft, 30 Jul 1912, *E.P. Walker 355* (HOLOTYPE: RM; ISOTYPE: GH!, US!).

Flowering Jun–Sep. Rocky or sandy soil, soil pockets and crevices in sandstone, canyon bottoms, stream terraces; 1100–1700 m; Arizona, Colorado, Utah.

Erigeron utahensis A. Gray, Proc. Amer. Acad. Arts 16:89. 1881. TYPE: U.S.A. UTAH. [KANE CO.:] Kanab, *Mrs. A.P. Thompson s.n.* (HOLOTYPE: GH!; internet image!).

Erigeron stenophyllus var. *tetrapleurus* A. Gray, Proc. Amer. Acad. Arts 8:650. 1873. *Erigeron tetrapleurus* (A. Gray) Heller, Bull. Torrey Bot. Club 25:628. 1898. *Erigeron utahensis* A. Gray var. *tetrapleurus* (A. Gray) Cronq., Brittonia 6:272. 1947. LECTOTYPE, designated here: U.S.A. Kane Co.: Kanab, *Mrs. A.P. Thompson s.n.* (GH!, internet image!). Gray also cited another Utah collection (*F.M. Bishop s.n.*, 1873)—this is mounted on the same sheet as the lectotype.

Flowering mid Apr–Jun(–Jul). Rocky slopes, cliff bases, ledges, and crevices, sandstone outcrops and terraces, sandy soil, gravelly limestone, shale, cottonwood floodplains, creosote bush, blackbrush, blackbrush-Joshua tree, warm desert shrub, salt desert shrub, mountain brush, pinyon-juniper, oak-maple-aspen; 800–2100(–2450) m; Arizona, California, Colorado, New Mexico, Utah. It seems likely that *E. utahensis* eventually will be discovered in southern Nevada.

A new variety within *Erigeron clokeyi*

Erigeron clokeyi is distinct in a number of features: a low, relatively caespitose habit; stems erect to basally decumbent-ascending and mostly monocephalous; minutely glandular stems, leaves, and phyllaries; nonglandular cauline hairs spreading-deflexed; leaves narrowly oblanceolate; and ray corollas reflexing at the tube/lamina junction. The species has been treated as a single unit (Cronquist 1947, 1994; Nesom 1992b), but two expressions of leaf vestiture exist within the species. Plants from the Charleston Mountains in Clark Co., Ne-

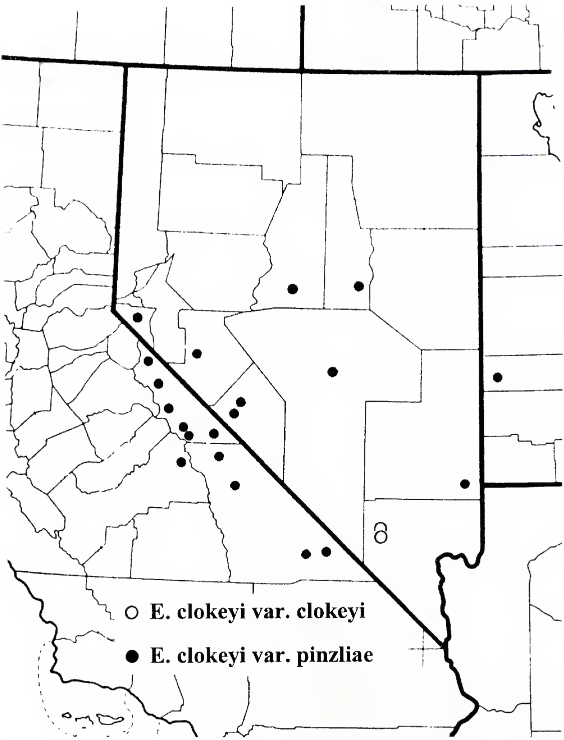

Fig. 3. Distribution of *Erigeron clokeyi*. Records are from collections at NY and BRIT, with additions from CalFlora (2004).

vada (the type locality), have hirsute-strigose leaves; those from other areas of the range (California, Nevada, west-central Utah), including most of the closest populations in southeastern Inyo Co., California, have hispidulous to hirsutulous leaves (Fig. 3). Some plants from Inyo Co. show a tendency toward strigose foliar vestiture. Cypsela size is slightly but consistently different, and the Clark Co. plants appear to have narrower leaves and a greater tendency for the stems to be decumbent-ascending. The two varieties are ecologically similar.

Erigeron clokeyi Cronq., Brittonia 6:214. 1947. TYPE: U.S.A. NEVADA. CLARK CO.: Charleston Mountains, Lee Canyon, brushy meadow, yellow pine belt, 2700 m, 12 Jul 1937, *I.W. Clokey 7742* (HOLOTYPE: NY!; ISOTYPES: LL!, MINN, MO!, NY!, PH, POM, RY, SMU! TEX!, UC, US!, VDB!, WS, WTU).

Erigeron clokeyi Cronq. var. **pinzliae** Nesom, var. nov. TYPE: U.S.A. NEVADA. MINERAL CO: Wassuk Range, road to Mt. Grant summit, 0.7 road mi below spring, T8N, R28E, NE 1/4 sect. 13, ca. 10,000 ft, 7 Sep 1995, *A. Pinzl 11733* (HOLOTYPE: BRIT; ISOTYPE: NSMC).

Differt a *E. clokeyi* sensu stricto vestimento foliorum hispidulo vel hirsutulo et cypselis minoribus.

Flowering Jun–Sep. Dry, rocky habitats, dry meadows, sometimes with sagebrush or mountain mahogany, treeless areas and often with yellow, bristlecone, or limber pines; 2200–3450 m; California, Nevada, Utah.

Differences between the two varieties are summarized here.

1. Leaves hirsute-strigose, hairs basally ascending, otherwise straight and distinctly antrorsely appressed; cypselae 2.2–2.5 mm; Charleston Mountains, Clark Co., Nevada __________ **Erigeron clokeyi** var. **clokeyi**
1. Leaves uniformly hispidulous to hirsutulous, hairs stiffly spreading to spreading-arching; cypselae 1.8–2 mm; east-central California, southern Nevada, west-central Utah __________ **Erigeron clokeyi** var. **pinzliae**

New name for a California species

Erigeron greenei Nesom, nom. nov. REPLACED SYNONYM: *Erigeron angustatus* Greene, Bull. Calif. Acad. Sci. 1(3):88. 1885 (non *Erigeron angustatus* Fries ex Nym., Consp. Fl. Europ. 2:389. 1879). TYPE: U.S.A. CALIFORNIA. NAPA CO.: dry hills on either side of Napa Valley, Jun-Oct, [Napa, 13 Aug 1874], *E.L. Greene 339* (not located with certainty, see comments in Nesom 1992; probable type material GH!).

The name *Erigeron angustatus* Greene has been used (Nesom 1992) for a discoid species now known to occur in Lake, Napa, Sonoma, Tehama, Trinity, Shasta, and Siskyou counties, California. Because *E. angustatus* Greene is a later homonym, it is replaced here. The new epithet commemorates Edward Lee Greene (1843–1915), whose perception of supraspecific natural groups and generic boundaries, in many instances, has proved to be remarkably close to modern concepts.

Status of *Erigeron cavernensis*

Erigeron cavernensis has been treated as a synonym of *E. uncialis* (Cronquist 1994, Nesom 1992b) but *E. uncialis* var. *conjugans*, which closely approaches *E. cavernensis* in its geographical range (Fig. 4), is markedly different from the latter and perhaps more similar to *E. cronquistii*. *Erigeron uncialis* var. *uncialis* and *E. uncialis* var. *conjugans* have features in common between themselves and contrast as a unit with *E. cavernensis*.

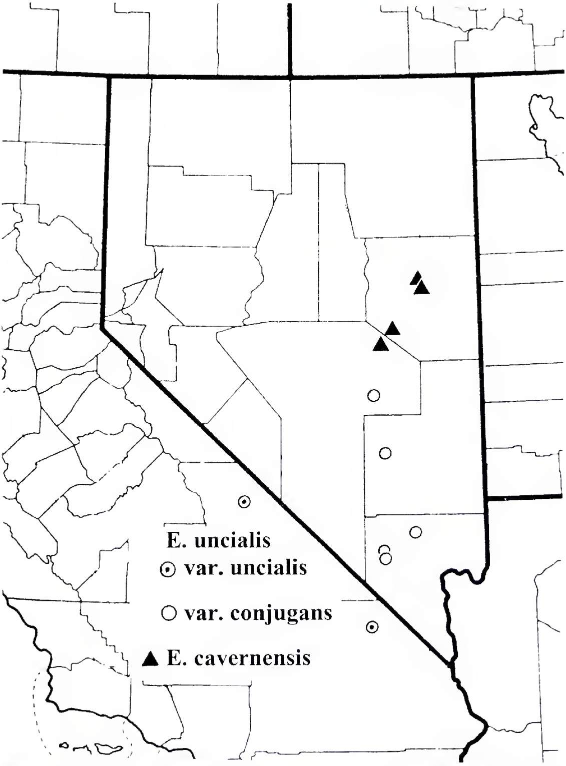

FIG. 4. Distribution of *Erigeron uncialis* and *E. cavernensis*. Records are from collections at NY, NSMC, and BRIT.

1. Phyllaries eglandular or sparsely glandular near the apices and along midregion; stems and leaves eglandular; leaves strigose to hirsute-villous, vestiture less dense on abaxial surfaces; cypselae 1.3–1.8 mm long ________________________ **Erigeron uncialis**

1. Phyllaries evenly densely glandular; stems and leaves glandular; leaves hirsute-canescent, equally hairy on both surfaces; cypselae 1–1.2 mm long _____ **Erigeron cavernensis**

Erigeron uncialis S.F. Blake, Proc. Biol. Soc. Wash. 47:173. 1934. TYPE: U.S.A. CALIFORNIA. SAN BERNADINO CO.: Clark Mountain, 7000 ft, Jun 1933, *E.C. Jaeger s.n.* (HOLOTYPE: POM; ISOTYPE: US!).

1. Stems 0.8–2.5 cm high, hirsute-villous; leaves 1–2 cm long, hirsute-villous to loosely strigose _____ **Erigeron uncialis** var. **uncialis**
1. Stems 3–7 cm high, loosely villous-strigose; leaves 2–4 cm long, sparsely and closely strigose _____ **Erigeron uncialis** var. **conjugans**

a. Erigeron uncialis S.F. Blake var. **uncialis.** Flowering May–Jul. Crevices, cliff bases, usually in limestone, pinyon-juniper, pine-fir; 1900–2600 m; California.

b. Erigeron uncialis S.F. Blake var. **conjugans** S.F. Blake, Proc. Biol. Soc. Wash. 47:174. 1934. *Erigeron uncialis* S.F. Blake subsp. *conjugans* (S.F. Blake) Cronq., Brittonia 6:211. 1947. TYPE: U.S.A. NEVADA. CLARK CO.: Charleston Mts., Kyle Canyon, Big Falls, crevices of vertical rock faces, 9000 ft, 3 Sep 1927, *C.L. Hitchcock s.n.* (HOLOTYPE: POM; ISOTYPE: US!).

Flowering May–Aug. Crevices in limestone cliffs and boulders, yellow pine or limber pine; 2200–2800 m; Nevada.

Erigeron cavernensis Welsh & Atwood, Great Basin Naturalist 48:495. 1988. TYPE: U.S.A. NEVADA. WHITE PINE CO.: Schell Creek Range, 25 air mi SE of Ely, ca. 2 km NE of summit of Cave Mountain, 3172–3233 m, limestone cliffs and rubble, *Pinus flexilis-P. longaeva* community, 18 Jul 1981, *B. Welsh, S. Goodrich, and E. Neese 910* (HOLOTYPE: BRY; ISOTYPES: NY!, POM, RM, UNLV, US!, UT).

Flowering Jun–Jul. Limestone ridges, outcrops, and cliffs, often with bristlecone pine, limber pine, spruce; 2100–3400 m; Nevada, known only from the White Pine Range of White Pine County and adjacent Nye County.

Status of *Erigeron radicatus* and *E. ochroleucus* var. *scribneri*

Confusion has existed in the distinction between *Erigeron radicatus* and *E. ochroleucus*, but the hypothesis is advanced here that they are distinct species sympatric over a significant area. In this view, *E. radicatus* has a wider geographic distribution (Fig. 5) than previously recognized and *E. ochroleucus* is more restricted in range (Fig. 6).

Small plants of *Erigeron ochroleucus*, often identified as *E. ochroleucus* var. *scribneri*, approach *E. radicatus* in aspect and many plants of *E. radicatus* have been identified as *E. ochroleucus* var. *scribneri*. *Erigeron radicatus* is distinctive in its branched caudex, short-villous cauline vestiture, smaller leaves with more reduced vestiture, smaller heads, involucral hairs usually with colored crosswalls, and fewer pappus bristles (see key couplet below). A thick taproot and unbranched caudex usually are contrasting features of *E. ochroleucus* and the phyllaries of *E. ochroleucus* often are apically linear-acuminate and loose, a feature not found in *E. radicatus*.

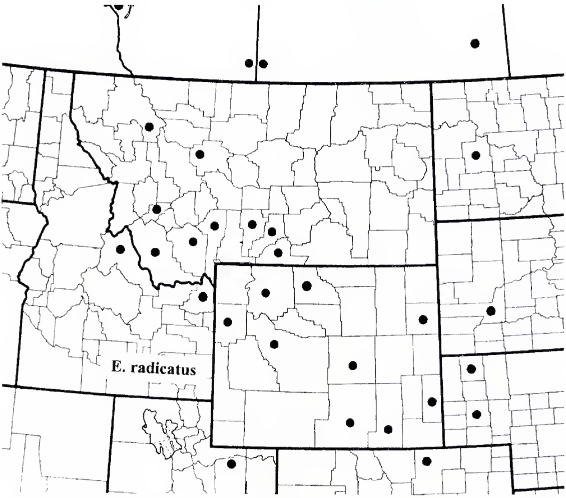

Fig. 5. Distribution of *Erigeron radicatus*. Records are from collections at NY and RM; Nebraska and South Dakota records are from KANU collections, fide Caleb Morse, using the present manuscript as basis for identification.

For the most part, *Erigeron radicatus* seems consistently distinct from *E. ochroleucus*, but I have identified as *E. radicatus* a few plants with involucral vestiture lacking colored crosswalls (eg., Carbon Co., Wyo.: *Dorn 3687*, RM; Fremont Co., Id.: *Moseley 835*, RM) and some plants as *E. ochroleucus* with involucral vestiture with colored crosswalls (e.g., Big Horn Co., Wyo.: *Hurd 208*, RM; Sheridan Co., Wyo.: *Nelson 6149*, RM; Johnson Co., Wyo.: *Nelson 5984*, RM). A few plants with an unbranched caudex are identified here as *E. radicatus* (e.g., Big Horn Co., Wyo.: *Williams 3221*, RM; Gallatin Co., Mont.: *Dorn 914*, RM). Some of these plants of apparently intermediate morphology may represent hybrids or introgressants. The chromosome number is reported as $2n = 36$ from Cheviot Mt., Alberta (Packer & Witkus 1982). A count of $2n = 18$ from Albany Co., Wyoming (Semple & Chmielewski 1987) was from *Erigeron simplex* Greene, the voucher misidentified by Nesom as *E. radicatus*.

Erigeron radicatus often is scapiform at relatively high elevations (2750–3350 m); more eastern populations in the Great Plains at lower elevations (1450–

2550 m) tend to have leafier stems. Plants of the collection from Weld Co. Colorado (rocky ridge ca. 3.4 mi N of Rockport, 6000 ft, *Dorn 8222*, RM), have slightly narrower phyllaries and involucral trichomes essentially without colored crosswalls, but in other respects they are similar to typical (but smallest) *E. radicatus*. Some of the low-elevation populations in Albany and Carbon cos., Wyoming, produce atypically short rays, and I initially regarded the eastern, low-elevation plants as taxonomically distinct. Finally, however, I was unable to find significant difference in other features. Even so, a species over such a wide range of elevation is unusual, both in the U.S.A. and in Canada, where *E. radicatus* occurs from montane sites in Alberta to localities at lower elevation in Saskatchewan. On the other hand, *E. ochroleucus*, one of its closest relatives, occurs over an equally wide elevational range.

Erigeron radicatus Hook., Fl. Bor.-Amer. 2:17, t. 123. 1834. Type: CANADA. Alberta. Mountains near Jasper's Lake, Rocky Mountains, *Drummond s.n.* (isotype, fide annotation in 1945 by Cronquist: NY!). The NY sheet does not have collection information other than a label noting "Erigeron divaricatum Hook., very rare, Hook., Am."

Erigeron macounii Greene, Pittonia 3:162. 1897. Type: CANADA. Alberta: Sheep Mountain, Waterton Lake, 28–31 Jul 1895, *J. Macoun 10858* (type material: NY!). Cited by Cronquist (1947) as a synonym of *Erigeron ochroleucus* var. *scribneri*; placed here as a synonym of *E. radicatus* because of its small (1.5–3 cm long) leaves and few (8) pappus bristles. The leaves, however, are linear-lanceolate and densely strigose and rays are bluish – features more consistently characteristic of *E. ochroleucus*.

Erigeron huberi Welsh & Atwood, Rhodora 103:71. 2001. Type: U.S.A. UTAH. Duchesne Co.: Uinta Mountains, Lake Fork Mtn., T2N R5W S16, NW1/4 of NE1/4, Uinta Base Meridian, plants growing along windswept ridge crest above limestone talus slopes, rocky soils, 10,900 ft, 21 Jul 1998, *A. Huber and C. Wedig 3825* (holotype: BRY; isotypes: MO!, NY!, US internet image!).

Flowering May–Aug. Rocky slopes, ridges, and summits, ledges and crevices, outcrops and talus, usually limestone, alpine tundra; (1450–)1600–2750(–3350)m; British Columbia, Alberta; Saskatchewan; Colorado, Idaho, Montana, Nebraska, North Dakota, South Dakota, Utah, Wyoming.

1. Stems (1–)2–6(–12) cm high, usually arising from tips of short, thickened caudex branches; stems short-villous; leaves (0.5–)1–5(–8) cm long, sparsely loosely strigose adaxially, glabrous and shiny abaxially; involucres (3–)4–6(–8) mm high, hairs of involucre usually with colored crosswalls; pappus bristles (6–)7–11 _____ **Erigeron radicatus**
1. Stems (2–)8–18(–30) cm high, arising from a nearly common point near apex of thick taproot, caudex usually unbranched; stems loosely strigose; leaves (2–)4–9(–12) cm long, usually strigose on both surfaces at least on proximal 1/3–3/4 of blade, glabrous distally; involucres 5.5–7 mm high, hairs of involucre usually without colored crosswalls; pappus bristles 11–15 _____ **Erigeron ochroleucus**

Erigeron ochroleucus Nutt., Trans. Amer. Philos. Soc., 2, 7:309. 1840. Type: U.S.A. [probably central Wyoming, perhaps Natrona Co.]. "Plains of the Oregon" [Trail], [ca. Jun, 1834], *T. Nuttall s.n.* (GH!, PH, UC-photo and fragment).

Erigeron ochroleucus Nutt. var. *scribneri* (Canby ex Rydb.) Cronq., Brittonia 6:189. 1947. *Erigeron scribneri* Canby ex Rydb., Mem. New York Bot. Gard. 1:405. 1900. TYPE: U.S.A. MONTANA. [MEAGHER CO.:] Little Belt Mountains, 12 Aug 1883, *F.L. Scribner 77* (NY!). *Erigeron scribneri* Canby (Bot. Gaz. 15:150. 1890) was published as a "nomen provisorum."

Erigeron tweedyanus Canby & Rose, Bot. Gaz. 15:65. 1890. *Erigeron montanus* Rydb. [nom. nov.], Bull. Torrey Bot. Club 24:296. 1897. *Wyomingia tweedyana* (Canby & Rose) A. Nels., Man. Rocky Mt. Bot. 531. 1909. TYPE: U.S.A. MONTANA. PARK CO.: Jun 1889, *F. Tweedy s.n.* (NY- 2 sheets!).

Erigeron laetevirens Rydb., Bull. Torrey Bot. Club 28:506. 1901. TYPE: U.S.A. MONTANA. SHERIDAN CO.: Big Horn Mountains: Little Goose Creek, 8700 ft., Jul 1899, *F. Tweedy 2005* (NY!).

Flowering Jun–Aug. Rocky or sandy slopes, limestone outcrops and ridges, talus, sagebrush-grassland, juniper-mountain mahogany, ponderosa pine, limber pine, limber pine-Douglas fir, alpine tundra; 1100–3000(–3300) m. Alberta, British Columbia; Montana, Nebraska, South Dakota, Wyoming. The record for British Columbia is added from a report by Roemer (1996, as *E. ochroleucus* var. *scribneri*). Nesom and Murray (2004) report *E. ochroleucus* in arctic and boreal Alaska and immediately adjacent Yukon, long disjunct from the primary range in the western U.S.A. and adjacent Canada.

Plants of *Erigeron ochroleucus* are consistently relatively large in stature and white-rayed in northeastern and central Wyoming (Campbell, Converse, Crook, Fremont, Hot Springs, Natrona, Niobrara, and Weston cos.), where they occur at elevations of 1100–1900(–2400) and at similar elevations in the more montane areas of north-central Wyoming and adjacent Montana (Fig. 6). These plants match the type of the species. In the latter areas, however, at elevations characteristically about 2150–2750 m and ranging up to 3350 m, the plants are smaller and commonly blue-rayed, matching the type of *E. ochroleucus* var. *scribneri*, but such plants also commonly extend downward to 1600 m in these montane areas, and in the area of elevational overlap so much morphological variability exists that it seems impossible to distinguish var. *scribneri*. Smaller, blue-rayed plants also are occasionally encountered even in areas of predominantly larger, white-rayed ones. Reported chromosome numbers are $2n = 18$ from southern Alberta (Chinnappa & Chmielewski 1987) and Sheridan Co., Wyoming (Jones & Smogor 1984). A count of $2n = 54$ from Niobrara Co., Wyoming (Semple 1985) was from *Erigeron caespitosus* Nutt., the voucher misidentified by Nesom as *E. ochroleucus*.

Status of *Erigeron lackschewitzii*

Erigeron lackschewitzii was compared in its original description with *E. grandiflorus* Hook., but it instead is very similar and closely related to *E. ochroleucus*. Nesom (1989) treated it as a synonym of *E. ochroleucus*, but examination of additional collections confirms it as a distinct species. The distribution record for Glacier Co. (Fig. 6) is based on the citation in Lesica (2002). The record for Alberta (Waterton Lakes National Park) is added fide Joyce Gould (Alberta Natural Heritage Information Centre).

1. Involucres 5.5–7 mm high; phyllaries inconspicuously glandular, hairs of villous vestiture without colored crosswalls; ray corollas white or blue; disc corollas 2.8–3.6 mm; pappus bristles 12–15 ____ **Erigeron ochroleucus**
1. Involucres 6–8 mm high; phyllaries densely and conspicuously glandular, hairs of villous vestiture with dark purple crosswalls; ray corollas purple to lavender; disc corollas 3.5–4.3 mm; pappus bristles 15–24 ____ **Erigeron lackschewitzii**

Erigeron lackschewitzii Nesom & W.A. Weber, Madroño 30:245. 1983. TYPE: U.S.A. MONTANA. TETON CO.: Bob Marshall Wilderness Area, Flathead Range, summit of Headquarters Pass, 2365 m, large colony in small, dry meadow on the narrow saddle, 29 Jul 1978, *K. Lackschewitz 8487* (HOLOTYPE: MONTU!; ISOTYPES: COLO!, NY!).

Flowering Jul–Aug. Rocky slopes and ridges, terraces, talus, meadows, usually calcareous; 2250–2500 m; Alberta; Montana.

Status of *Erigeron parryi*

Cronquist (1947) maintained *Erigeron parryi*, noting (p. 190) that it probably is "merely an unusual form" of *E. ochroleucus*, but he later (1955) treated it (at least by implication) as a synonym of *E. ochroleucus*. Collections similar to the type, however, from the region of the type locality in southwestern Montana and adjacent Wyoming (Fig. 6) suggest that *E. parryi* is distinct. Leaves of *E. parryi* are equally hairy (hirsute to strigose-hirsute) on both surfaces, contrasted with the reduced vestiture (loosely strigose) on adaxial surfaces of *E. ochroleucus* leaves. Also, *E. parryi* tends to have smaller heads with fewer rays and the caudices sometimes are branched. The variation in orientation of vestiture is unusual, and as between *E. ochroleucus* and *E. radicatus*, the nature of the differentiation (or lack of differentiation) between *E. ochroleucus* and *E. parryi* is not clear.

1. Leaves 1–2.5 cm long, narrowly oblanceolate, equally hairy on both surfaces; caudices branched or not; involucres 4–6 mm high, 7–10 mm wide; ray florets 22–30 ____ **Erigeron parryi**
1. Leaves 2–6 cm long, linear to narrowly oblanceolate, strigose adaxially, less hairy to glabrous abaxially; caudices usually not branched; involucres 5.5–7 mm high, 10–15(–18) mm wide; ray florets 30–62 ____ **Erigeron ochroleucus**

Erigeron parryi Canby & Rose, Bot. Gaz. 15:65. 1890. TYPE: U.S.A. MONTANA. BEAVERHEAD CO.: Grasshopper Creek, dry hills, 7000 ft, Jul 1888, *F. Tweedy 15* (GH internet image!, NY!, US?). Canby and Rose cited only "*Frank Tweedy 15*" as the type.

Plants perennial, taprooted, caudices with or without short, thickened branches. **Stems** 1.5–5 cm, erect, short-hirsute to loosely strigose-villous, eglandular. **Leaves** basal and cauline, basal narrowly oblanceolate, 1–2.5 cm long, 0.8–2.5 mm wide, entire, cauline on proximal 1/2–2/3 of stem, gradually reduced distally, densely strigose to strigose-hirsute on both surfaces, eglandular, eciliate. **Heads** 1; involucres 4–6 mm high, 7–10 mm wide; phyllaries in (2–)3 equal to subequal series, filiform-attenuate and purplish at apex, sparsely to densely villous-strigose, basal cross-walls sometimes purple, sparsely minutely glandular. **Ray florets** 22–30, corollas 6–8 mm, laminae white to pink or bluish, not coiling or reflexing. **Disc florets:** corollas 2.4–3 mm, throat not indurate or inflated.

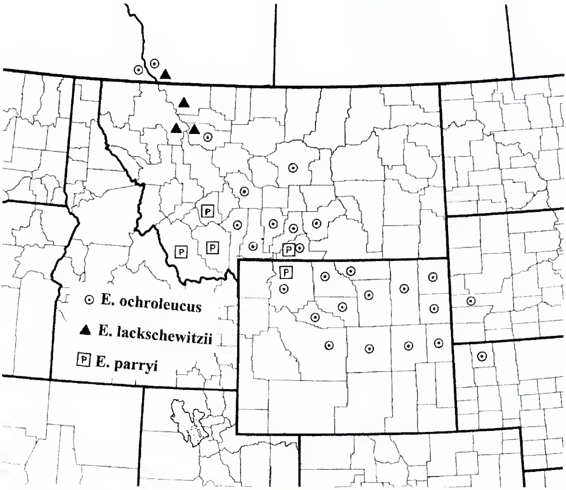

Fig. 6. Distribution of *Erigeron ochroleucus*, *E. lackschewitzii*, and *E. parryi*. Records are primarily from collections at NY and RM (see comments in text).

Cypselae 2–2.3 mm, 2-nerved, densely strigose; pappus bristles 12–15, readily deciduous, outer setae or scales prominent.

Flowering Jun–Aug. Open, rocky sites, limestone and quartzite; 1600–2250(–2600) m; endemic to southwestern Montana and adjacent Wyoming.

Additional collections examined: **U.S.A. MONTANA. Beaverhead Co.:** crest of Red Butte, ca. 8 mi NW of Lima, common, calcareous soil, with *Eriogonum mancum* and *Oxytropis besseyi*, T13S, R9W, Sec 10, 6200 ft, 6 Jul 1986, *Lesica 3928* (NY); exposed ridge crest 2 mi S of Grasshopper Creek, common in gravelly limestone and quartzite-derived soil, 6200 ft, with *Sphaeromeria capitata* and *Eriogonum mancum*, 22 Jun 2003, *Lesica 8657* (RM); Tendoy Mts., above Muddy Creek Rd, abundant on crest of ridge with *Lesquerella alpina*, *Penstemon aridus*, *Hymenopappus* sp., T13S, R10W, Sec 34, 7000 ft, 27 Jun 1987, *Lackschewitz 11307* (NY). **Carbon Co.:** N slopes above Lockheart Ranch, T8S, R28E, S13, *Poa* cover, 4400 ft, 9 Jun 1983, *Lichvar 5913* (RM); Big Pryor Mountain, gravelly soil, S slope, grassland, 8500 ft, 12 Jul 1926, *Williamson 28* (RM). **Jefferson Co.:** slopes of small hill at the head of Negro Hollow 6 mi NE of Caldwell, common in shallow limestone-derived soil, 5200 ft, with *Hymenoxys acaulis* and *Eritrichium howardii*, 17 Jun 2003, *Lesica 8630* (RM). Madison Co.: S end of Ruby Mts., 3 mi S and 3 mi W from Ruby Reservoir Dam, and SW of Mud Springs, common on small silty clay outcrop and occasional in immediately surrounding dry, rolling grassland, 5790 ft, with *Oryzopsis contracta*, *As-*

tragalus vexilliflexus, *Chrysothamnus nauseosus*, *Stipa comata*, *Aster scopulorum*, 4 Jul 1996, *Heidel and Cooper 1488* (RM); Highland Mountains, low ridge ca. 1 mi S of Victoria Mine W of Silver Star, locally common in shallow limestone-derived soil, 5250 ft, with *Cercocarpus ledifolius* and *Eriogonum mancum*, 18 Jun 2003, *Lesica 8640* (RM). WYOMING. Park Co.: Absaroka Mountains, North Fork Shoshone River drainage, ridge E of Pagoda Creek, ca. 1.5–2.5 mi S of US Hwy 14-16 & 20, open rocky areas with scattered Douglas fir and limber pine, 7200–8000 ft, 11 Jun 1986, *Evert 9860* (RM).

Leaves and stems of *Lesica 3928*, *8640*, and *8657* and *Williamson 28* are hirsute with stiffly spreading hairs, similar to those of the type collection; leaves of *Lackschewitz 11307*, *Lesica 8630*, *Lichvar 5913*, *Heidel and Cooper 1488*, and *Evert 9860* are hirsute-strigose with loosely appressed hairs. Although the vestiture of the latter six collections approaches the orientation of that of *E. ochroleucus*, the hairs are stiffer and slightly shorter than characteristic of *E. ochroleucus*.

Peter Lesica (submitted) has reached a similar conclusion regarding the distinction of *Erigeron parryi*, based on field experience, more numerous collections than recorded here, and a morphometric study. My conclusions were reached independently of his but were based on his collections, in significant part, at NY and RM. His concepts of *E. ochroleucus* and *E. radicatus* also are similar to those outlined here but not identical.

Erigeron tracyi an earlier name for *Erigeron colomexicanus*

I have been using *Erigeron colomexicanus* as the name for this species, but both *E. tracyi* and *E. commixtus* were published seven years earlier, simultaneously (immediate succession in the same paper: Greene 1902). Plants of the type collection of *E. tracyi*, as well as those of *E. commixtus*, are early season forms (essentially a basal rosette with a single, subscapiform, monocephalous stem) that had not yet produced runners characteristic of the species.

Erigeron tracyi Greene, Pittonia 5:59. 1902. TYPE: U.S.A. TEXAS. [JEFF DAVIS CO.:] Davis Mts., 28 Apr 1902, *S.M. Tracy* and *F.S. Earle 320* (HOLOTYPE: US!; ISOTYPES: GH!, NY!, OS!).

Erigeron commixtus Greene, Pittonia 5:58. 1902. TYPE: U.S.A. TEXAS. [JEFF DAVIS CO.:] Cañon of the Limpia, mountains of west Texas, 26 Apr 1902, *S.M. Tracy* and *F.S. Earle 279* (HOLOTYPE: US!, ISOTYPES: GH!, NY!, TAES!, TEX!).

Erigeron cinereus A. Gray, Mem. Amer. Acad. Arts n.s., 4[Pl. Fendler.]:68. 1849 (not Hook. & Arn. 1836). *Erigeron divergens* Torrey & A. Gray var. *cinereus* (A. Gray) A. Gray, Smithsonian Contr. Knowl. 3, Art. 5 [Pl. Wright.]:91. 1852. *Erigeron colomexicanus* A. Nels. [nom. nov.], Man. Bot. Rocky Mts., 529. 1909. TYPE: U.S.A. NEW MEXICO. [SANTA FE CO.:] near Santa Fe, 1847, *A. Fendler 374* (HOLOTYPE: GH!; ISOTYPES: GH, NY! UC-2 sheets!, US!).

Taxonomic status of *Erigeron acris* in North America

Erigeron acris L. (Sp. Pl. 653. 1753) has long been recognized as a species widespread in North America, but the nomenclature of these plants and an understanding of their relationship to expressions of the species in Europe and Asia still are unsettled. The type of *Erigeron acris* is a European plant. The taxonomic summary presented here is intended only as an overview.

Most names previously used at infraspecific rank for the American plants refer to Eurasian endemics: *Erigeron angulosus*, *E. asteroides*, *E. droebachiensis*, *E. elongatus*, and *E. politus* (Šída 1998; Tzvelev 2002) (see taxonomic summary below). The name *Erigeron acris* var. *kamtschaticus* was reserved by Hultén (1968a, 1968b) for a single North American collection made at "Junction Firth R. and Mancha Creek on the Alaska-Yukon boundary in August 1961;" he treated all others of the species in North America as *E. acris* subsp. *politus*. Entire-leaved plants, however, apparently are the common form of the species even in the Kamchatka area, and Gleason and Cronquist (1991) and Cronquist (1994) are followed here in using *E. acris* var. *kamtschaticus* as the correct name for the North American plants. Hara (1939) also viewed "the common form in Eastern Asia and North America ... [as] identical with *E. kamtschaticus* DC.," but he treated it as a variety of *E. angulosus*. Czerepanov (1995) and Šída (1998) have treated *E. kamtschaticus* and *E. acris* as separate species, as did deCandolle much earlier, in his original description of *E. kamtschaticus*.

Two other North American taxa closely related to *Erigeron acris* are treated at specific rank in the forthcoming Flora of North America (FNA) account of *Erigeron*: *E. nivalis* Nutt. (= *E. jucundus* Greene, *E. debilis* (A. Gray) Rydb.) and *E. elatus* (Hook.) Greene. *Erigeron nivalis* has often been treated at infraspecific rank within *E. acris*, but the two taxa are broadly sympatric without obvious intergrades in the northwestern U.S.A. and Canada. Both occur over a wide range of elevation and in similar habitats.

Erigeron acris L. var. **kamtschaticus** (DC.) Herder, Bull. Soc. Nat. Moscou Sect. Biol., Ser. 2. 38:392. 1865. *Erigeron kamtschaticus* DC., Prodr. 5:290. 1836. TYPE: "in Kamtschatka," (deCandolle noted "v. s. comm. ab ill. Acad. sc. Petrop.;" Cronquist (1994) noted "holotype at G!"). *Erigeron acris* L. subsp. *kamtschaticus* (DC.) H. Hara, J. Jap. Bot. 15:317. 1939. *Erigeron angulosus* Gaudin var. *kamtschaticus* (DC.) H. Hara, Rhodora 41:389. 1939. *Trimorpha acris* (L.) S.F. Gray var. *kamtschatica* (DC.) Nesom, Phytologia 67:64. 1989.

Erigeron yellowstonensis A. Nels., Bot. Gaz. (Coulter) 30:198. 1900. TYPE: U.S.A. WYOMING. Yellowstone National Park, near Yellowstone Lake, in loose sandy soil in the open pine woods, 6 Aug 1899, *A. Nelson 6348 with E. Nelson* (HOLOTYPE: RM; ISOTYPE: NY!). *Erigeron lapiluteus* A. Nels. [nom. illeg.], New Man. Bot. Centr. Rocky Mts. 530. 1909. *Erigeron lapiluteus* is an illegitimate replacement name for *E. yellowstonensis*.

Erigeron elongatus Ledeb. [nom. inval.], Icon. Pl. Fl. Ross. 1:9, tab. 31. 1829 (non *E. elongatus* Moench 1802). *Erigeron acris* var. *elongatus* (Ledeb.) Mela & Cajand., Suom. Kasv. 566. 1906.

Erigeron politus Fries (misapplied), Bot. Not. (Lund.) 1843:120. 1843. *Erigeron acris* L. subsp. *politus* (Fries) H. Lindb. f., Enum. Pl. Fennoscand. Orient. 56. 1901 (non Schinz & R. Keller 1909).

Erigeron asteroides Andrz. ex Besser (misapplied), Enum. Pl. Volhyn. 33. 1822 (non Roxb. 1814). *Erigeron acris* L. var. *asteroides* (Andrz. ex Besser) DC., Prodr. 5:290. 1836. *Trimorpha acris* (L.) S.F. Gray var *asteroides* (Andrz. ex Besser) Nesom, Phytologia 67:64. 1989. Listed by Tzvelev (2002) as a synonym of the Eurasian *E. podolicus* Besser.

Erigeron angulosus Gaudin (misapplied), Fl. Helv. 5:265. 1829. *Erigeron acris* L. var. *angulosus* (Gaudin) Vacc., Cat. Pl. Vall. Aoste 1:350. 1909.

Erigeron droebachiensis O. Mueller (misapplied), Fl. Dan. 5, 15:4, tab. 874. 1782. *Erigeron acris* L.

var. *droebachiensis* (O. Mueller) Blytt, Norges Fl. 1:562. 1861. *Erigeron acris* L. subsp. *droebachiensis* (O. Mueller) Arcang., Comp. Fl. Ital. 340. 1882.

ACKNOWLEDGMENTS

I am grateful to the staffs at GH, MO, and NY for help during visits there, HSC, NSMC, and RM for loans of specimens, Anita Cholewa (MIN) for observations regarding the type of *Erigeron davisii*, John L. Strother for observations on UC collections and editorial comments in review, Caleb Morse for observations on KANU collections, Peter Lesica for comments on *E. parryi* and relatives, Joyce Gould (Alberta Natural Heritage Information Centre) for information on *E. radicatus* and *E. lackschewitzii* in Canada, and John Semple for providing images of vouchers for previously published chromosome counts, and Dave Boufford for advice on lectotype selection for *E. stenophyllus* var. *tetrapleurus*.

BOOK REVIEW

ESMOND HARRIS, JEANETTE HARRIS, and N.D.G. JAMES. 2003. **Oak: a British History.** (ISBN 0-9538630-8-5, pbk.). Windgather Press, Ltd., 29 Bishop Road, Bollington, Macclesfield, Cheshire SK10 5NX, UK. (Orders: Distributed by Central Books, 99 Wallis Road, London E9 5LN, UK). US $30.00, 208 p., 10 col., 49 b/w illus., 7 1/4" × 9 3/4".

This is not a book about the historical significance of oaks in Britain. This is not a study of the many and varied uses that oaks have supplied over the centuries. This is not a guide to the cultivation of oaks and the restoration of aged and historic woodlands. This is not about the myths and symbology that have surrounded the oak since time immortal. *The Oak: A British History* is all of these and more. Written in a easy to read manner which belies the authority behind the text, this will be a classic for years to come.

The oak has always held pride of place amongst trees in Britain. For centuries, its durability, strength and attractiveness have made it the timber of choice. When the British state was forged in the seventeenth and eighteenth centuries, these qualities made it a metaphor for the virtues of the nation. This book tells the story of man's use of this wonderful natural resource and argues that oak still has a rich future, both as material and as a key element in an ecologically rich countryside The authors are concerned with how people have managed and exploited oakwoods over time and with the uses to which oak timber has been put, in ships, furniture and buildings. As practicing foresters, they revisit with an expert's eye the silvicultural techniques of the past—the methods of propagating, raising, managing, coppicing and felling oak through the tree's life, from acorn to standard. They reveal the skills needed to work with oak timber, and tell the story of the great industries of iron-smelting and shipbuilding which relied on the tree. They also explore the myths, symbols and cultural associations that have connected people in Britain with the oak over hundreds of years. An appendix lists over 700 particularly significant oak trees, with notes on their location, present condition and historical connections. This book is a cultural history not only of a tree, but also of a timber. It reclaims the disappearing forestry and carpentry skills of our ancestors and shows how, in an era of climate change, oak can enrich our future as well as our past

Esmond Harris has spent a lifetime working as a forester, and is a Past Director of the Royal Forestry Society He wrote *The Guinness Book of Trees* (1981), *Trees*(1986), and *Arboles* (1998). Jeanette Harris is a farmer and author Together they wrote the best-selling *Reader's Digest Guide to the Trees and Shrubs of Britain* (1981) and *Wildlife Conservation in Managed Woodlands and Forests* (1997) They run a small farm in Cornwall, where their renovation of woodlands won the 2002 Duke of Cornwall's Award for Forestry and Conservation N D G. James, OBE, was President of the Royal Forestry Society and author of several tree books. He died in 1993, having laid the foundations for this book.—*Gary Jennings, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

ABSTRACT

Erigeron grandiflorus is restricted to the western U.S.A. and southwestern Canada and is treated here to include widespread diploid populations (*E. simplex*) as well as triploids (*E. grandiflorus* sensu stricto). The distinction between *E. grandiflorus* and *E. simplex* has been made primarily on the basis of differences in size and ploidal level, but identifications based on morphology often are arbitrary because differences appear to be widely overlapping. Plants previously identified as *E. grandiflorus* var. *arcticus* Porsild are here treated as **Erigeron porsildii** Nesom & Murray, nom. nov. Distinctions are clarified among *E. grandiflorus* sensu stricto, *E. porsildii*, *E. muirii*, *E. yukonensis*, and the Asian *E. koraginensis*. *Erigeron hultenii* has not been relocated beyond the type collection and is tentatively regarded as an anomalous plant whose relationships are unknown. *Erigeron denalii* includes *E. purpuratus* var. *dilatatus* and *E. mexiae* and is contrasted with *E. pallens* (an endemic of southwestern Canada) and *E. purpuratus*. Recent collections document the occurrence of *E. ochroleucus* in arctic and boreal Alaska and immediately adjacent Yukon, disjunct more than 2800 kilometers from the closest localities in its main range to the south.

RESUMEN

Erigeron grandiflorus está restringido al oeste de Estados Unidos y suroeste de Canadá y es tratado aquí para incluir las poblaciones diploides extensas (*E. simplex*) así como a las triploides (*E. grandiflorus* sensu stricto). La distinción entre *E. grandiflorus* y *E. simplex* ha sido hecha en base a las diferencias de tamaño y nivel de ploidía, pero las identificaciones basadas en la morfología son a menudo arbitrarias porque las diferencias parecen estar ampliamente solapadas. Plantas identificadas previamente como *E. grandiflorus* var. *arcticus* Porsild se tratan aquí como ***Erigeron porsildii*** Nesom & Murray, nom. nov. Se clarifican las diferencias entre *E. grandiflorus* sensu stricto, *E. porsildii*, *E. muirii*, *E. yukonensis*, y la asiática *E. koraginensis*. *Erigeron hultenii* no ha sido vuelta a localizar después de la colección tipo y se trata como una planta anómala cuyas relaciones son desconocidas. *Erigeron denalii* incluye *E. purpuratus* var. *dilatatus* y *E. mexiae* y se contrasta con *E. pallens* (un endemismo del suroeste de Canadá) y *E. purpuratus*. Recientes colecciones documentan la existencia de *E. ochroleucus* en Alaska ártica y boreal y en Yukon, con una disyunción de más de 2800 kilómetros desde las localidades más próximas en su área principal en el sur.

Various taxonomic problems regarding alpine, arctic, and boreal *Erigeron* in North America have been brought into focus during preparation of a treatment of the genus for the Flora of North America (FNANM) volumes. Here we examine some of those problems in detail and provide explanation and documentation for new taxonomic interpretations.

Status of *Erigeron grandiflorus*

Erigeron grandiflorus Hook. was described from southern Alberta, Canada (see typification below), and has since been recognized as a species distributed in alpine regions of the western U.S.A. and adjacent Canada and disjunct northward into arctic Canada and Alaska. Specimen citations by Cronquist (1947) for *E. grandiflorus* were mostly from arctic collections and his descriptive measurements reflected this inclusive view. The arctic plants were recently segregated as *E. grandiflorus* subsp. *arcticus* Porsild and are here treated as a separate species (see topic below).

Erigeron simplex Greene, which has been recognized as a widely distributed species of alpine habitats in the western U.S.A., is very similar to *E. grandiflorus*. Cronquist found overlapping differences between these species in leaf shape and vestiture, number of pappus bristles, and outer pappus morphology. After separating the arctic plants from Cronquist's concept of *E. grandiflorus*, we find that features defining *E. grandiflorus* and *E. simplex* are even more strongly overlapping.

Since Cronquist's monograph (1947), and apart from Spongberg's dissertation study of arctic and alpine species (1971), *Erigeron grandiflorus* has been recognized in the conterminus U.S.A. only in Montana (Dorn 1984) and Colorado (Weber 1987, 1990; Weber and Wittman 1992). In these treatments, contrasts of *E. grandiflorus* with *E. simplex* largely repeated measurements from Cronquist's study. Both *E. grandiflorus* and *E. simplex* were included in the Alberta flora by Moss (1959), also using species descriptions essentially taken from Cronquist (1947). Scoggan (1979) included *E. simplex* as a questionable member of the Canadian flora, based on the sole record from Moss, but Packer's revision of the Alberta flora (Moss 1983) treated only *E. grandiflorus*, with no mention of *E. simplex*. *Erigeron grandiflorus* also has been recognized in British Columbia by Douglas et al. (1998), whose descriptive measurements gave broader ranges than Cronquist's.

Spongberg (1971) regarded *Erigeron grandiflorus* strictly as an apomictic triploid (compared with strictly diploid *E. simplex*) and documented its occurrence in Utah, Colorado, and Wyoming. At some localities, he found triploids "growing intermixed with plants of a larger population of *Erigeron simplex*" (e.g., Clear Creek/Grand Co. line, above Berthoud Pass, *Spongberg 67-243*, TEX). He did not provide a key, but from his comments and annotations, *E. grandiflorus* in southern Canada and the western United States differed only quantitatively in his concept from the more widespread *E. simplex*, with involucres and florets at the higher end of the ranges of size measurements. Spongberg (1971, p. 200) also noted that "because of the intergrading of morphological features of plants of *Erigeron grandiflorus* ... the single most important criterion indicative of this taxon is highly irregular [in shape] and greatly abortive pollen." These pollen features result from meiotic anomalies associated with the triploid condition.

We observe that triploids (including the largest-headed plants) appear to be consistently stipitate-glandular over the whole stem with glandular trichomes mostly 0.2–0.3 mm high, while the diploids (smaller-headed plants) commonly are essentially eglandular or stipitate-glandular with shorter trichomes only just beneath the heads. Many smaller-headed plants, however, are variably glandular, trichome sizes vary, and all collections of *Erigeron simplex* from Arizona and Utah appear to be stipitate-glandular. At least one collection of relatively small-headed plants was counted as triploid and identified by Spongberg as *E. grandiflorus* (*Spongberg 69-30*, TEX).

Spongberg hypothesized that the triploid plants (= *Erigeron grandiflorus* sensu stricto in his view) incorporate a genomic element from an ancestor other than *E. simplex*, but we find that morphological distinctions between the ploidal races are too arbitrary to allow consistent identification. Until more convincing evidence is at hand regarding the evolutionary divergence of these taxa, and until some way might be found to distinguish them with more precision, *E. grandiflorus* is treated here as including the plants generally identified as *E. simplex*.

Erigeron grandiflorus Hooker, Fl. Bor.-Amer. 2:18, plate 123. 1834. TYPE: CANADA. [ALBERTA]. "Summits of the Rocky Mountains," *Drummond s.n.* (GH!, KEW?). Non Nuttall 1834; non Hoppe ex DC. 1836; non Sessé & Mociño 1894. Drummond's collection apparently was made in June or July, 1826 (Drummond 1830), in the vicinity of Jasper or between Jasper and "Lac-la-Pierre," which is about 60 miles north of Jasper.

Erigeron simplex Greene, Fl. Francisc. 387. 1897. LECTOTYPE (Cronquist 1947): U.S.A. Colorado: no other data, 1875, *E.L. Greene s.n.* (ND-G).

Erigeron leucotrichus Rydb., Bull. Torrey Bot. Club 28:23. 1901. TYPE: U.S.A. WYOMING. Big Horn Mountains, 8000 ft, Jul 1899, *F. Tweedy 2003* (HOLOTYPE: NY!).

Plants perennial, from short, horizontal or erect, fibrous-rooted rhizomes, caudex essentially unbranched or with short, thick branches. Stems 2–25 cm high, erect to basally decumbent-ascending, sparsely to moderately pilose to villous-hirsute, variably stipitate-glandular over whole or part of stem, sometimes essentially eglandular. Leaves basal and cauline, basal persistent, oblanceolate to obovate or spatulate, apically rounded, 1–6(–9) cm long, 2–6(–14) mm wide, entire, cauline quickly or gradually reduced upward, not subclasping, sparsely hirsutulous or villous to sparsely strigose or glabrate, sometimes sparsely glandular. Heads 1; involucres 5–8(–10) mm high, 8–20 mm wide; phyllaries in 2–3 series, green or purplish, moderately to densely woolly-villous with flattened hairs, sometimes with reddish crosswalls, minutely glandular at least near the tips. Ray florets 50–130, corollas 7–11(–15) mm long, laminae blue to pink or purplish, rarely white, coiling. Disc corollas 2.4–4(–5) mm long, throat not indurate or inflated. Cypselae ca. 1.8–2.4 mm long, 2-nerved, strigose; pappus of (7–)10–18(–22) bristles, with an outer series of narrow scales. $2n$ = 18, 27 (Spongberg 1971; numerous diploid counts in literature as *Erigeron simplex*).

Flowering Jul–Aug (–Sep). Rocky sites, meadows, alpine or near timberline; 2900–4200 m. Canada (Alberta, British Columbia); U.S.A. (Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Wyoming).

Status of *E. grandiflorus* sensu stricto and *E. grandiflorus* subsp. *arcticus*

The type collection of *Erigeron grandiflorus* and later collections from the same region (southwestern Alberta and adjacent British Columbia) are disjunct by more than 1500 kilometers from the more northern range of *E. grandiflorus* subsp. *arcticus* Porsild. The southern populations are located at the northern tip of the range of the species identified here as *E. grandiflorus* sensu stricto, including *E. simplex*. Porsild (1955) observed that *E. grandiflorus* comprised three "races": Rocky Mountain, arctic, and Alaskan. The 'Rocky Mountain' race corresponds to *E. grandiflorus* sensu stricto, while we are unable to separate the "arctic" and "Alaskan" races and regard them both as composing Porsild's subsp. *arcticus*. Our study of these two entities concludes that they are distinct by a number of nonoverlapping features and that both are appropriately treated at specific rank.

1. Basal leaves oblanceolate to obovate or spatulate, 2–6(–14) mm wide, apically rounded, cauline oblanceolate to narrowly lanceolate, never subclasping; villous involucral vestiture of glassy hairs, often with reddish crosswalls; ray corollas 7–11(–15) mm long; $2n = 18, 27$ ______ **Erigeron grandiflorus**
1. Basal leaves oblong-oblanceolate to narrowly obovate, (3–)5–14 mm wide, apically acute, cauline narrowly ovate to ovate-lanceolate or lanceolate, often subclasping; villous involucral vestiture of whitish hairs, without colored crosswalls; ray corollas 13–17 mm long; $2n = 36$ ______ **Erigeron porsildii**

Erigeron porsildii Nesom & Murray, nom. nov. *Erigeron grandiflorus* Hooker subsp. *arcticus* Porsild, Mus. Natl. Canada, Publ. Bot. (Ottawa) 4:67. 1975. TYPE: CANADA. NORTHWEST TERRITORIES: Victoria Island, SW coast, vicinity of Holman Island trading post, dry, gravelly slope, 8 Aug 1949, *A.E. Porsild 17342* (HOLOTYPE: CAN, color image!, photos in Porsild 1955!; ISOTYPE: ALA!). Non *Erigeron articus* Rouy, Fl. France 8:160. 1903. Rouy's epithet was a variant spelling applied to an "arctic" plant and precludes adoption at specific rank of the similar Porsild name, which denotes the same geography (ICBN, Art. 53, Ex. 9). In order to retain the original type designation, we have chosen to rename the taxon at specific rank. The replacement name honors A.E. Porsild (1901–1977), whose studies and publications over a 60 year period greatly advanced knowledge of the flora of arctic and boreal America.

Plants perennial, from a short, horizontal or erect, fibrous-rooted rhizome (sometimes appearing more like a taproot), sometimes with short caudex branches. Stems (2–)10–20(–25) cm high, erect, sparsely to moderately villous with hairs 0.5–1.6 mm long, usually stipitate-glandular over whole stem with hairs 0.05–0.4 mm long. Leaves basal and cauline, basal oblong-oblanceolate to narrowly obovate, 3–12 cm long, (3–)5–14 mm wide, entire, cauline oblong-lanceolate to lanceolate, often subclasping, gradually reduced upward or nearly equal-sized, densely hirsute to coarsely villous, sparsely stipitate-glandular to minutely glandular. Heads 1; involucres 6–10 mm high, 12–20 mm wide; phyllaries in ca. 2 series of equal length, narrowly lanceolate, apically acuminate, purple at least at the tips, densely hirsute, hirsute-villous, or villous with whitish hairs without colored cross-walls, sparsely stipitate-glandular to minutely glandular. Ray florets 65–110, corollas 13–17 mm long, laminae 1.2–1.7 mm wide, blue to purple or lavender, less commonly white, weakly coiling. Disc corollas 3.8–4.5 mm, puberulent with glandular hairs, throat not indurate or inflated. Cypselae 2–2.5 mm, 2-nerved, sparsely strigose; pappus of 14–20(–25) bristles, with a prominent outer series of setae or narrow scales. $2n = 36$ (Dawe & Murray 1981).

Flowering mid Jun–Aug(–Sep). Alpine ridges and slopes, rock outcrops, cliffs and talus (often calcareous) slopes, shaly gravel and scree, bluffs, grassy ravines, tundra, meadows; (150–)600–1600(–2100) m. Canada (N.W.T.: Districts of Franklin, Mackenzie; Yukon); U.S.A. (Alaska).

Additional collections examined. **Alaska**. Wrangell-St. Elias National Park and Preserve, McCarthy Quad, Wrangell Mts., vic. plateau W of Nizina River, above head of Nikolai Creek, SE-facing shaley scree near ridge crest, 1370 m, 24 Jul 1996, *Batten and Barker 96-66* (ALA); Mt. McKinley National Park, Cathedral Mountain, mile 36, 1–10 Jul 1964, *Hultén s.n.* (NY); Demarcation Point Quad, Kongakut river, 30 km S of Beaufort Sea coast, S-facing river bluff, dominant willow, 29 Jun 1984, *McCarthy s.n.* (ALA); Tetlin National Wildlife Refuge, Nabesna Quad, Mentasta Mts., vic. Nabesna River valley, '4940 Hill' site, alpine screes and seeps, 1506–1628 m, 25 Jul 1996, *Moran 45* (ALA); Mt. McKinley Quad, mountain slope along Stony Creek, 26 Jun 1941, *Murie s.n.* (ALA); Philip Smith Mountains Quad, Yukon River-Prudhoe Bay Haul Road, just E of Galbraith L, tundra slopes and conglomerate outcrops, 915–1220 m, 20 Jul 1976, *Murray 6119* and Johnson (ALA); Circle Quad, Yukon–Tanana Uplands, South Fork Birch Creek drainage, alpine ridges and slopes between Puzzle Gulch and Big Windy Creek, marble outcrops in mica-schist bedrock, lush, dry, S-facing herbaceous slope below outcrops, 1100–1220 m, 8 Jul 1996, *Parker et al. 6537* (ALA); Gates of the Arctic National Park and Preserve, Chandler Lake Quad, Arctic Foothills, Castle Mtn., northern ridge of summit area, 700-1070 m, alpine dryas heath, cliffs, scree and meadows along drainages, in lush herbaceous, N-facing meadow, 30 Jul 2002, *Parker et al. 12891* (ALA); Baird Mountains Quad, Noatak National Preserve, Central Noatak River valley, Grand Canyon, vic. of "Wolf control" cabin, ca. 7 km upriver from Mukachiak Cr. mouth, S-facing acidic bedrock bluffs above floodplain, dry mesic shrub and open shrub-herbaceous vegetation, growing in open, grassy slope, 140–200 m, 19 Jul 2003, *Parker et al. 14959* (ALA, BRIT); Baird Mountains Quad, Noatak National Preserve, Central Noatak R. valley, Sekuiak Bluff, vic. of upstream end of bluff and VABM Windy, N bank of river, 100–150 m, S-facing outcrops and scree, limestone-acidic contact zone, 27 Jul 2003, *Parker et al. 15264* (ALA, BRIT); Denali National Park and Preserve, Healy Quad, Alaska Range, S-facing slopes of main ridge NW of Riley Creek, 1 km SSW of VABM Riley, confined to turfy, graminoid-forb meadow-tundra area on steep, S-facing slope, 3700 ft, 18 Jun 1999, *Roland and Batten 3821* (ALA). **Yukon**. Kluane National Park and Preserve, Dezadeash Quad, St. Elias Mts., King's Throne, vic. Kathleen Lake and Haines Road, 24 Jul 2000, *Caswell 359* (ALA); Richardson Mts., fine broken stones and turf in saddle and adjacent slopes, 2000 ft, 13 Jul 1982, *Cody and Ginns 31788* (ALA); E end of Herschel Island, Mackenzie Bay, Beaufort Sea, slope above stream, 20 Jul 1975, *Cooper 75E* (NY), 14 Jul 1978, *Cooper 634D* (NY), 19 Jul 1975 *Cooper 54A* (NY); Herschel Island, 14 Jul 1906, *Lindstrom s.n.* (NY); Kluane Lake Quad, NW of Slims River, 4500–6300 ft, 9 Jul 1967, *Murray 933* (ALA).

Erigeron porsildii contrasted with *E. koraginensis*

A range of opinions regarding the definitions and distinctions (or lack of distinction) among *Erigeron grandiflorus*, *E. porsildii* (= *E. grandiflorus* subsp. *arcticus*), *E. muirii*, and the Asian species *E. koraginensis* is summarized in Elven et al. (2003, as related by Aiken et al. 2003). It has not been clear whether *E. koraginensis* occurs on the North America continent or whether it might be conspecific with an earlier-named American species, particularly *E. grandiflorus/porsildii*. *Erigeron koraginensis* and *E. porsildii* are the most similar among these species, but here, based on material housed at ALA, we conclude that *E. koraginensis* and *E. porsildii* are distinct and note that we have seen no collections of *E. koraginensis* from North America.

1. Leaves sparsely to moderately villous on both surfaces; villous involucral vestiture of whitish hairs, without colored crosswalls; ray florets 65–110, corollas 13–17 mm long; disc corollas 3.8–4.5 mm long; outer pappus a prominent series of long setae or scales __________ **Erigeron porsildii**
1. Leaves glabrous or essentially so on adaxial surfaces, villous abaxially; villous involucral vestiture of hairs with purple crosswalls; ray florets 45–73, corollas 9–13 mm long; disc corollas 3–3.9 mm long, outer pappus of a few minute setae and narrow scales __________ **Erigeron koraginensis**

Erigeron koraginensis (Komarov) Botschantzev, Not. Syst. Herb. Inst. Bot. Acad. Sci. URSS 16:391. 1954. *Aster koraginensis* Komarov, Fl. Penins. Kamtsch. 3:125. 1930. *Erigeron komarovii* Botschantzev var. *koraginensis* (Komarov) Voroshilov, Byull. Glavn. Bot. Sada (Moscow) 84:34. 1972.

Erigeron komarovii Botschantzev, Not. Syst. Herb. Inst. Bot. Acad. Sci. URSS 16:391. 1954. *Aster consanguineus* Ledeb., Fl. Ross. 2, 2:473. 1845. *Erigeron consanguineus* (Ledeb.) Novopokr., Bot. Mat. (Leningrad) 7:137. 1938 (non Cabrera 1937).

Plants perennial from lignescent thickened but elongate rhizomes 1–4 cm long. Stems erect, 4–25 cm high, sparsely to moderately villous, densely villous beneath the heads, hairs 0.5–1.5(–1.8) mm long, often with colored crosswalls, stipitate glands 0.1–0.3 mm high with colored cross walls. Leaves mostly basal or basal and cauline, basal oblanceolate to oblanceolate-spatulate with rounded to acute apices, 2–7 cm long, 2–10 mm wide, cauline oblanceolate to narrowly lanceolate, (if present) quickly or gradually reduced on lower 1/3–2/3 of stem, not clasping, sparsely villous and minutely and short-stipitate glandular abaxially, glabrous adaxially, margins ciliate and stipitate-glandular. Heads 1; involucres 6–9 mm high, 11–18 mm wide; phyllaries linear-lanceolate, usually purple, in 2 series of equal length, moderately to densely villous, hairs usually with purple crosswalls (at least in proximal cells), stipitate glandular. Ray florets 45–73, corollas 9–13 mm long, 1.2–2 mm wide, blue to white, coiling. Disc corollas 3–3.9 mm long, very sparsely villous, lobes narrowly triangular. Cypselae 2.2–2.6 mm long, narrowly oblong in outline, sparsely strigose-villous, 2-nerved; pappus bristles 19–23, of uneven thickness and length, outer series a few minute setae and narrow scales. Description drawn from nine ALA collections from northeastern Russia; it corresponds closely to the description of *E. komarovii* provided by Botschantzev (1959). $2n = 18$ (summary in Aiken et al. 2003).

The names *Erigeron koraginensis* and *E. komarovii* were proposed in 1954 on the same page of publication. *Erigeron komarovii* was a replacement name for the later homonym *E. consanguineus* (1938), which was based on *Aster consanguineus* (1845); *E. koraginensis* was based on *Aster koraginensis* (1930). We follow the observations of Dr. Kanchi Gandhi (pers. comm.) in recognizing the priority of *E. koraginensis* if *E. komarovii* and *E. koraginensis* are combined: "Although the priority of the type of *E. komarovii* starts from 1845, the priority of the epithet itself starts from 1954. In contrast, the priority of the type and of the epithet in *E. koraginensis* start from 1930."

Erigeron koraginensis is distributed in arctic and eastern Siberia, Wrangel Island, and the Kamchatka region (Botschantzev 1959; Tzelev 2002). Yurtsev et al. 1989 said explicitly that *E. komarovii* occurs on Wrangel Is. and replaced the name *E. muirii* erroneously used in prevous accounts. Czerepanov (1995) listed *E. koraginensis* as a synonym of *E. komarovii*; Botschantzev (1959) maintained them as separate species but by widely overlapping differences. The type of *E. koraginensis* was collected in Kamchatka; the type of *E. komarovii* was collected from Karaginskii Island, in the Bering Sea just off the coast of northeast Kamchatka.

Taxonomic status and distribution of *Erigeron muirii*

Hultén (1968) treated *Erigeron muirii* Gray as a subspecies of *E. grandiflorus* (*E. porsildii*, as identified here), noting that its densely lanate leaves and involucres distinguish it from the typical expression of the latter. Elven et al. (2003) also note that "The hairs of *E. muirii* are very thin, curly, and intermingled, and they are totally different from the stiffer and straighter hairs of *E. grandiflorus* and *E. koraginensis*." *Erigeron muirii* and *E. porsildii* occur sympatrically in northeastern Alaska, but *E. muirii* usually grows in exposed, rocky settings, whereas *E. porsildii* tends to favor meadows. Chromosome counts from Alaska show *E. muirii* to be diploid, *E. porsildii* tetraploid (Dawe & Murray 1981). Two unusual plants on a sheet with six others of typical *E. muirii* may be hybrids between *E. muirii* and *E. uniflorus var. eriocephalus* (J. Vahl) Boivin (Alaska: vicinity of Cape Thompson, 26 Jul 1976, *Roseneau s.n.*, ALA), but we have not seen evidence of hybridization or intergradation between *E. muirii* and *E. porsildii* and agree with Cronquist (1947), Porsild and Cody (1980), Cody (2000), and others in observing that *E. muirii* is appropriately treated at specific rank.

Erigeron muirii A. Gray, Proc. Amer. Acad. Arts 17:210. 1881. *Erigeron grandiflorus* Hook. subsp. *muirii* (A. Gray) Hultén, Ark. Bot. 7:132. 1968. TYPE: U.S.A. ALASKA. Cape Thompson, 1881, *J. Muir s.n.* (HOLOTYPE: GH!).

1. Stems and leaves moderately lanate, involucres densely lanate, all eglandular; cauline leaves narrowly elliptic-lanceolate, not subclasping ______ **Erigeron muirii**

1. Stems and leaves sparsely villous, involucres villous, all glandular to stipitate-glandular; cauline leaves narrowly ovate to ovate-lanceolate or lanceolate, often subclasping ________ **Erigeron porsildii**

Erigeron muirii has been regarded as an endemic of northern Alaska (Murray & Lipkin 1987, Lipkin and Murray 1997), but a herbarium sheet of *E. muirii* at US(!) bears the label "Wrangel Is., Dr. Ross, Corwin 1881." Hultén (1950) commented that personal communication from Soviet botanists led him to doubt the occurrence of *E. muirii* on Wrangel Island (in the Arctic Ocean, between the East Siberian Sea and the Chukchi Sea, off northeastern Russia) and to hypothesize that the specimen at US is incorrectly labeled. Nevertheless, he felt that this explanation needed confirmation.

Knowing of the specimen at US and lacking authentic material of *Erigeron muirii* at LE, V.V. Petrovsky compared the written descriptions and the photograph in Hultén (1950) of *E. muirii* with specimens of *E. komarovii* (= *E. koraginensis*, as recognized here, see section above) and concluded they were conspecific. Petrovsky (1987) therefore included *E. muirii* in the Arctic Flora USSR, under which he included *E. komarovii* Botsch. as a synonym (among many synonyms). Following exchanges of specimens between LE and ALA, it was possible for both sides to examine authentic *E. muirii* and *E. komarovii* and to determine that they are not the same. Yurtsev et al. (1989) removed *E. muirii* from their list of Wrangel Island plants.

The voyage in which Muir participated had numerous ports-of-call, including Cape Thompson (the type locality of *Erigeron muirii*, in northwestern Alaska) and Wrangel Island. In accounts of this voyage published by Muir (1883, 1917), plant lists for Wrangel Island do not include any species of *Erigeron*. It is reasonable to presume that a mistake was made during processing of the specimens and that a Wrangel Island label was assigned to an Alaskan collection, just as Hultén had earlier surmised.

Specimens from Herschel Island on the coast of the northwestern extreme of Canada very near the Alaskan border were included by Hultén (1968) in *Erigeron muirii* (as *E. grandiflorus* subsp. *muirii*). We have determined these specimens as *E. porsildii* and note that other collections from Herschel Island are cited above for *E. porsildii*. Collections of *E. muirii* from which our discussion is drawn are mostly at ALA.

The status of *Erigeron hultenii*

Erigeron hultenii was noted by its author to be "closely allied to the polymorphic arctic-alpine species *E. grandiflorus* W.J. Hooker" (Spongberg 1973, p. 116) and to have a "close morphological resemblance to some plants of *E. grandiflorus* from Alaska" [= *E. porsildii* in the present sense] (p. 119). Contrasts with *E. porsildii*, however (as in the couplet below), exclude it from that species. Despite additional exploration at and near the type locality, plants corresponding to *E. hultenii* have not been recollected and we do not find that *E. hultenii* fits with any other known Alaskan species. We continue to regard it as an anomalous plant of unknown relationships.

1. Leaves 1-veined; ray florets 65–110; disc corollas 3.8–4.5 mm long; achenes 2-nerved; outer pappus a prominent series of long setae or scales ______________ **Erigeron porsildii**
1. Leaves 3-veined; ray florets 20–45; disc corollas 2.5–3 mm long; achenes 4-nerved; outer pappus barely if at all evident ____________________________ **Erigeron hultenii**

Erigeron hultenii Spongberg, Rhodora 75:116. 1973. TYPE: U.S.A. ALASKA: Campbell Creek Valley, 11 mi N of Anchorage, 7 Aug 1965, *L. Strutz s.n.* (HOLOTYPE: S).

Taxonomic status of *Erigeron yukonensis*

Erigeron yukonensis was included within the "*E. grandiflorus* agg." by Polunin (1959), but Hultén (1950) hypothesized it to be closely related to *E. glabellus* Nutt. Later, Hultén formalized this (1967) by reducing *E. yukonensis* to varietal rank within *E. glabellus*. We agree with a number of recent botanists who find *E. yukonensis* to be a distinct species, although its evolutionary relationships are not clear—its eglandular vestiture, elongate basal leaves, and 1–4 heads are uncharacteristic of most of the arctic monocephalous *Erigeron* species. Plants of *E. porsildii* with elongate-lanceolate leaves sometimes approach single-headed *E. yukonensis* in aspect, but *E. porsildii* differs especially in its stipitate-glandular stems and its tendency for oblong-lanceolate to lanceolate, often subclasping cauline leaves.

Erigeron yukonensis Rydb., Bull. New York Bot. Gard. 2:185. 1901. TYPE: CANADA. YUKON: Dawson, 23 Jul 1899, *R.S. Williams s.n.* (HOLOTYPE: NY!). *Erigeron glabellus* Nutt. var. *yukonensis* (Rydb.) Hultén, Ark. Bot. 7(1):132. 1967.

Plants perennial, fibrous-rooted rhizome, sometimes appearing like a taproot, multicipital. Stems 10–30(–40) cm high, erect to basally ascending, often purplish at base, sparsely to moderately hirsute to villous-hirsute, eglandular. Leaves basal and cauline, lower narrowly oblanceolate, rarely oblanceolate-obovate, entire, (1–)4–16 cm x 2–8 mm, middle and upper reduced and narrowly lanceolate, not clasping, sparsely hirsute to glabrous, eglandular. Heads 1–2(–4) from branches at midstem; involucres 6–10 mm high, 12–19 mm wide; phyllaries in 2(–3) series, linear-lanceolate with linear-acuminate tips, sparsely to moderately woolly-villous with whitish, flattened hairs without colored cross-walls, eglandular to very sparsely minutely glandular. Ray florets 42–82, corollas 10–15 mm long, laminae white to pink or pink-purple, coiling. Disc corollas 3.8–5.2 mm long, throat not indurate or inflated. Cypselae 1.7–2 mm long, 2-nerved, strigose; pappus of 15–20 bristles, with an evident outer series of short bristles, squamellae, or scales.

Flowering (Jun–)Jul–Aug (–Sep). Rocky sites and meadows, near timberline and above; 2850–3150 m. Canada (N.W.T.: District of Mackenzie; Yukon); U.S.A. (Alaska).

Additional collections examined. Canada. **Yukon** S end of Lake Kluane, alpine, 24 Jul 1944, *Anderson 9472B* (NY); Moosehide Mountain, W-facing slope, open rocky slope, 20 Jun 1949, *Calder 3266* (NY); Lower Klondike, last half of Jun 1919, *Cockfield 64* (CAN-photo ALA!); near Collinson Head, E end of Herschel Island, Mackenzie Bay, Beaufort Sea, 16 Jul 1975, *Cooper 38A* (NY); Dawson, 30 Jun 1914, *Eastwood 454* (CAN-photo ALA!); Red Mountain near Fort Selkirk, shady slopes, 17 Jul 1899, *Gorman 1109* (NY); Ft. Selkirk, 1-9 Jul 1891, *Hayes s.n.* (NY); White Horse, Yukon River, 1 Sep 1902, *Macoun 78996* (NY, CAN-photo ALA!); Fort Selkirk, 18 Jul 1899, *Tarleton 141* (NY). **NWT**: Inuvik, damp rock ledges by Dolomite Lake in open sunlight, just above ledge with *Woodsia glabella* and *Cystopteris fragilis*, 7 Jul 1965, *Swales 522* (CAN-photo ALA!).

Cronquist (1947) cited a collection of *Erigeron yukonensis* from District of Mackenzie (Richards Island, 1896, *Stringer 16*, no herbarium cited). Wiggins and Thomas (1962) cited an Alaskan collection in AMES from north of the Brooks Range (Utukok River, 5 Jun–15 Jul 1947, *Thompson s.n.*), but the identity of this collection needs to be verified. Cody (2000, p. 581) noted that *E. yukonensis* occurs in "the Yukon Territory west of latitude 135 W, in northern District of Mackenzie east to Coronation Gulf and in Nahanni National Park." See also Map 1104 in Porsild and Cody (1980) and a map in McJannet et al. (1993, p. 38).

The *Erigeron purpuratus—E. pallens* group

Treatments of these species have varied considerably, but we recognize *Erigeron purpuratus* Greene, *E. denalii* A. Nels., and *E. pallens* Cronq. as distinct species. *Erigeron pallens* is rare and endemic of the high mountains of southeastern British Columbia and adjacent Alberta, while the other two are more common and occur in Alaska, Yukon, District of Mackenzie, N.W.T., and extreme northwestern British Columbia, long disjunct from the range of *E. pallens*. The erect, inrolled laminae of the ray florets (giving them a "filiform" aspect) of all three species distinguishes them from other species of *Erigeron* sect. *Tridactylia* Nutt., of which they are members. The leaf-lobing of *E. pallens*, however, is more similar to that of *E. vagus* Payson and *E. flabellifolius* Rydb. (also sect. *Tridactylia*) of the northwestern U.S.A., which are geographically closer to *E. pallens* than *E. denalii* and *E. purpuratus*.

Erigeron denalii has been treated as a synonym or a variety of *E. purpuratus* (e.g., Cronquist 1947, Hultén 1968, Boivin 1972). They are similar in many ways, including the characteristic purplish pappus bristles, and perhaps are most closely related to each other, but the two taxa appear to be partially sympatric and differences in vestiture and leaf morphology are constant. The habitat of *E. purpuratus*, sandy or gravelly alluvium, also is remarkably constant and distinct from that of *E. denalii*. Probably correlated with the loose sands and gravels of its habitat, plants of *E. purpuratus* almost always develop a long and relatively slender but woody taproot; taproots of *E. denalii* are less well defined and often do not show on collections, and the plants usually develop slender rhizome-like caudex branches, well adapted to the downslope instability of the screes typically inhabited by the species.

1. Leaves entire or shallowly 3-lobed at the obtuse to nearly flat apex; pappus tawny-white to yellowish ______ **Erigeron pallens**
1. Leaves entire or with 1–2 shallow lobes on the margins; pappus usually purplish.
   2. Stems 1–5 cm tall; leaves spatulate to oblanceolate-spatulate, 2–4(–5) mm wide, minutely glandular and moderately villous; involucres densely pilose ______ **Erigeron denalii**
   2. Stems (2–)3–9(–14) cm tall; leaves linear- to narrowly oblanceolate, 1–2.5(–3) mm wide, merely minutely glandular or also sparsely hirsute-villous; involucres sparsely pilose ______ **Erigeron purpuratus**

Erigeron purpuratus Greene, Pittonia 4:155. 1900. TYPE: CANADA. YUKON: Fort Selkirk, sandy river banks, 28 Jun 1899, *M.W. Gorman 1065* (ND-G!).

Plants perennial, taprooted, from a diffuse caudex divided into system of slender rhizome-like branches. Stems (2–)3–9(–14) cm high, minutely glandular, villous. Leaves mostly basal, linear- to narrowly oblanceolate, 1.5–3(–4.5) cm long, 1–2.5(–3) mm wide, entire or (mostly on early-produced leaves) with 1 or 2 shallow lateral lobes, minutely glandular, sparsely villous or without nonglandular hairs. Heads 1; involucres 6–9(–10) mm high, 9–15 mm wide; phyllaries in 2–3 series, minutely glandular, sparsely villous, hairs with colored crosswalls and up to 3 mm or without nonglandular hairs. Ray florets 40–90, 5–9 mm long, laminae filiform, 0.3–0.8 mm wide, erect, white to pink or purplish, not coiling or reflexing. Disc corollas 4–5 mm long, throat not indurate or inflated. Cypselae 1.8–2.7 mm long, 2-nerved, sparsely strigillose to glabrate; pappus of 28–40 pinkish to purplish bristles, without an evident outer series. 2*n* = 18 (Dawe & Murray 1979).

Flowering Jun–Aug. Sandy and gravelly stream banks, gravel bars, sandy beaches, gravelly slopes, alpine tundra; 150–1350 m; Canada (Yukon); U.S.A. (Alaska).

Erigeron denalii A. Nelson, Amer. J. Bot. 32:289. 1945. TYPE: U.S.A. ALASKA. Mt. McKinley National Park: Sable pass, at highest point of Park road, rocky slopes, ca. 4000 ft, 8 Aug 1939, *A. Nelson and R.A. Nelson 4058* (HOLOTYPE: RM!; ISOTYPE: US!).

Erigeron purpuratus Greene var. *dilatatus* Boivin, Phytologia 23:134. 1972. TYPE: CANADA. DISTRICT OF MACKENZIE: Redstone River Region, 4 July 1963, *Kvale & Haggard 131* (HOLOTYPE: DAO).

Erigeron mexiae K. Becker, Brittonia 28:144. 1976. TYPE: CANADA. YUKON: Dempster Highway, N of Dawson City, E-facing slope just W of Mile 41, in scree, 5000 ft, 8 Jul 1973, *C.W. Greene 481* (HOLOTYPE: NY!; ISOTYPE: UAC).

Plants perennial, taprooted, with a diffuse, slenderly branching caudex. Stems 1–5 cm high, villous, granular-glandular. Leaves basal and cauline, spatulate to oblanceolate, entire or shallowly 3-lobed at the apex, 1–2 cm long, 2–4 mm wide, mid-cauline larger than the basal and lower cauline, villous, granular-glandular. Heads 1; involucres (4–)5–7 mm high, 9–12 mm wide; phyllaries in 2(–3) series, densely lanate-villous, the hairs to 3 mm long, often with dark purple crosswalls, glandular. Ray florets 30–55, 4–8 mm long; laminae erect, rarely spreading, filiform to narrowly straplike, 0.3–1.2(–2) mm wide, white to lavender. Disc corollas 3.8–4.8 mm long, throat not indurate or inflated. Cypselae oblanceolate-oblong, 3–3.8 mm long, 2-nerved, strigillose to strigose-hirsute; pappus of 20–25 bristles, more or less purple-red tinged or sometimes whitish (variable within populations), without an evident outer series.

Flowering Jun–Aug. Open alpine and subalpine habitats, tundra slopes, openings in spruce-fir woods, gravelly and shaley scree, cut banks; 900–2150 m; Canada (N.W.T.: District of Mackenzie; Yukon; extreme northwestern British Columbia); U.S.A. (Alaska).

Plants of the type collection of *Erigeron mexiae* have ray corollas with relatively broad laminae (1.5–2 mm wide), but ray corolla width is variable in *E. denalii* and *E. mexiae* is here regarded as an extreme variant within the species—in other characters there appears to be no difference.

Erigeron pallens Cronquist, Brittonia 6:240. 1947. TYPE: CANADA. BRITISH COLUMBIA: Glacier, Mount McDonald, 7500 ft, 1 Aug 1913, *Butters and Holway 799* (HOLOTYPE: MINN).

Plants perennial, taprooted, caudex divided into system of slender, rhizome-like branches. Stems 2–4 cm high, sparsely hirsute-villous, minutely glandular. Leaves mostly basal, oblanceolate to spatulate, 1–2.5 cm long, 2–4 mm wide, entire or shallowly 3-lobed at the obtuse to nearly flat apex, sparsely villous, minutely glandular. Heads 1; involucres 6–8 mm high, 9–13 mm wide; phyllaries in 2–3 series, commonly purplish or purple at the tips, sparsely villous, the hairs often becoming tawny, without purple cross-walls, minutely glandular. Ray florets 50–65, corollas 4–5(–6) mm long, laminae white to pink or purplish, ca. 0.5–0.8 mm wide, erect. Disc corollas 3.5–4.4 mm long, throat not indurate or inflated. Cypselae length not observed, 2-nerved, sparsely strigose; pappus of 25–30 tawny to purplish bristles, with a few, short, outer setae. $2n = 18$ (Packer & Witkus 1982).

Flowering Jul–Aug. Alpine talus, shale slides, steep and sparsely vegetated slopes; ca. 2100–3200 m; Canada (Alberta, British Columbia).

A nomenclatural combination attributed to G.W. Douglas (*Erigeron purpuratus* Greene subsp. *pallens*, such as by Moss 1983 and Packer & Witkus 1982), apparently was never validated and is a nomen nudum.

Erigeron ochroleucus in Alaska

Previously undetermined collections at ALA document the occurrence of *Erigeron ochroleucus* Nutt. in arctic and boreal Alaska and immediately adjacent Yukon, disjunct more than 2800 kilometers from the closest localities in its main range, which runs from Nebraska and South Dakota through Wyoming and Montana into southern Alberta and British Columbia (see map in Nesom 2004). The arctic and boreal plants are unequivocally identified as *E. ochroleucus*, although they differ in some ways from those of the southern system: stem height ranges shorter (2–15 vs. (6–)8–18(–20, 30) cm), leaf length ranges shorter (2–7 vs. 4–9(–12) mm), leaves are consistently linear to linear-oblanceolate (vs. linear to narrowly oblanceolate, 1–4(–5) mm wide), hairs of the villous involucral vestiture often (vs. uncommonly) have red crosswalls, ray florets range fewer in number ((18–)30–50 vs. 30–62), and the disc florets range greater in length (3.5–4.5 mm vs. 2.8–3.6 mm). The Alaska and Yukon plants plants might be formally treated as a variety, emphasizing their geographic disjunction, but morphological differences are overlapping and plants from the western U.S.A. can be found that closely match the arctic plants. In the interpretation of Nesom (2004), no varieties are recognized in the southern population system of *E. ochroleucus*.

Erigeron ochroleucus, although very restricted in Alaska and Yukon, is nevertheless common along a section of the Porcupine River from Rampart House in Yukon, but near the International Boundary, downstream below the Lower Ramparts, some 80 kilometers total. The climate is hypercontinental and habitat for this species is at the base of arid slopes with an eastern to southern exposure and adjacent terraces. The vegetation is discontinuous and steppic in character: *Artemisia frigida*, *Bupleurum americanum*, *Calamagrostis purpurascens*, *Agropyron spicatum*, *Phlox hoodii*, and *Erigeron caespitosus* are prominent. Several species also restricted in Alaska and Yukon, and some are also disjunct from their main ranges: *Festuca lenensis*, *Carex filifolia*, *Carex duriuscula*, *Eriogonum flavum* var. *aquilinum*, *Alyssum americanum*, and *Townsendia hookeri*. The two arctic localities for *E. ochroleucus* are climatically very different from the Porcupine River, but edaphically similar: dry sands and gravels (Atqasuk) and well-drained soils (Kadleroshilik Pingo).

Collections examined. **U.S.A. Alaska:** Arctic Slope District, 70 air mi S of Point Barrow, near Eskimo village of Atkasook, 2.9 km SE of Meade River Camp, 15 m, 31 Jul 1975, *Komarkova 45* (ALA). Black River Quad: Arctic NWR, steep southeast-facing steppe slope on Porcupine River, 366 msm, 66° 58' 56"N, 142° 49' 46" W, 4 June 1996, *Murray, Emers, and Jorgenson 12,128* (ALA); Yukon Flats NWR, steep southeast-facing steppe slope on Porcupine River, 66° 59' 15" N, 142° 58' 20" W, 6 June 1996, *Murray, Emers, and Jorgenson 12,153* (ALA). Porcupine River, E of old archeology camp, 66° 59'N, 142° 49'W, S facing bluff, 20 m above river shore, 18 Jul 1995, *Reitz s.n.* (ALA and to be distributed). Porcupine River, 67° 20' N, 141° 18' W, 20 Jul 1980, *Thorson 7-20-80-4* (ALA). First bluff inside Alaskan border [with Yukon, Canada], on Porcupine River, 67° 21'N, 141° 17'W, 275 msm, 17 July 1981, *Viereck and Foote 4536* (ALA). Beechey Point Quad, Kadleroshilik Pingo (no. 41), Kadleroshilik study area, 70° 01'N, 147° 41'W, gravelly areas, 26–28 Jul 1986, *Walker 86-31* (ALA). **CANADA. Yukon:** Porcupine River, Rampart House, 11 July 1951, *Loan 568b* (DAO).

Because *Erigeron ochroleucus* has not been included in floristic accounts of arctic areas, a description is provided here, drawn from 25 plants of the collections cited below. A detailed comparison can be made by comparing this description with that for "southern" *E. ochroleucus* in the *Erigeron* treatment for the developing FNANM volumes (Nesom in prep.).

Plants perennial from a thick, woody taproot, caudex multicipital, unbranched or rarely with short branches. Stems basally ascending, 2–15 cm, loosely strigose to villous-strigose, eglandular or sparsely minutely glandular. Leaves mostly basal, linear to linear-oblanceolate, entire, 2–7 cm long, 1–1.8 mm wide, cauline quickly reduced upwards, sparsely and loosely strigose adaxially, abaxially glabrous at least on distal 1/4–1/2 of blade and strigose proximally, eglandular. Heads 1; involucres 6–8 mm high, 12–16 mm wide; phyllaries in 3–4 series, densely hirsute-villous, hairs whitish or with red-purple crosswalls, densely and minutely glandular. Ray florets (18–)30–50, corollas 8–12 mm, laminae mostly white, less commonly bluish, 1–2(–2.5) mm wide, coiling. Disc corollas 3.5–4.5 mm long, not indurate or inflated. Cypselae 2–2.5 mm, 2-nerved, strigose-villosulous; pappus bristles 12–15, with a conspicuous outer series of thick setae, scales, or squamellae.

The status of *Erigeron pumilus* in Yukon

Porsild (1975) noted the occurrence in southwestern Yukon of *Erigeron linearis* (Hook.) Piper, as the single collection, *H.M. and L.G. Raup 12918*, had been identified on the original label. Hultén (1967, 1968) referred to this collection as *E. pumilus* Nutt., as it has continued to be recognized (e.g., Cody 2000). With caveats as below, our identification of the three plants on this sheet is *E. caespitosus* Nutt. In *E. pumilus* (in contrast to *E. caespitosus*), the stems and involucres are hirsute to hispid-hirsute and glandular, the ray corollas are linear and reflexing, and the disc corollas have distinctly indurate and inflated throats.

CANADA. Yukon Territory: Alpine grassy-stony slope, rays lavender, mountain slope on east side of Big Arm, Kluane Lake, app. Lat. 61° 33'N, 138° 40'W, 20 Aug 1944, *H.M. and L.G. Raup 12918* (ALA).

Erigeron caespitosus has an extended geographic distribution, ranging from Arizona and New Mexico northward into Alaska; it is relatively common in southwestern Yukon (see map in Cody 2000). The Yukon plants in question have strigose cauline vestiture, which contrasts with the normally deflexed to spreading vestiture of *E. caespitosus*, but such variation exists sporadically in the species in other parts of its range, including Saskatchewan as well as various places in the western U.S.A, and the vestiture of *Raup 12918* is more characteristic of *E. caespitosus* for 5-10 mm under the heads. The plants of *12918* also have linear to linear-oblanceolate basal leaves, narrower than normal for *E. caespitosus*, but narrow-leaved plants more clearly identified as *E. caespitosus* also occur in the Kluane Lake area (Murray, pers. observ.). The plants of *12918* are atypical, but we conclude that latent populational tendencies are sporadically expressed in this species--at least a hypothesis of recent hybridization or genetic introgression is not supported, because hybridization with any other species in southwestern Yukon probably would have more conspicuously influenced the morphological features of *12918*.

ACKNOWLEDGMENTS

We are grateful to Barney Lipscomb (BRIT) for help with locating bibliographic material, to NY staff for help on a recent visit, to Kanchi Gandhi for observations and advice on nomenclatural problems, to Susan Aiken for her review comments and a color image of the holotype of *Erigeron grandiflorus* subsp. *arcticus*, to Robert Lipkin for review comments, and to ALA for a loan of specimens to Nesom at BRIT. We gratefully acknowledge the confidence gained by learning that Ron Hartman (RM) had earlier reached the same conclusion regarding the identity of the Alaskan-Yukon populations of *Erigeron ochroleucus*.

BOOK NOTICE

Ben-Erik van Wyk and Michael Wink. 2004. **Medicinal Plants of the World.** (ISBN 0-88192-602-7, hbk.) Timber Press Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $39.95, 480 pp., 793 color photos, 3 tables, 137 diagrams, 6 1/2" × 9 1/2".

Medicinal Plants of the World is a comprehensive and scientifically accurate guide to the best known and most important medicinal plants, including those of special commercial or historical interest. This book is a *Photographic* guide including info on their botany, main traditional uses, active ingredients, pharmacological effects and evidence of efficacy (if known) in a compact, colorful, reference text. *Medicinal Plants* does a wonderful job of conceptualizing the more than 320 plants in the book. The regulatory status of each plant is also given—whether it is listed in one or more pharmacopoeias, including the German Commission E monographs, the new ESCOP monographs of the European Community and the World Health Organization's series of monographs (all species treated in the last-mentioned three works will be found in this book). In the back of the book, the authors do well to include "A Quick Guide to Commercialized Medicinal Plants" and a "Glossary of Chemical, Medical and Pharmaceutical Terms." The book seems to be geared toward the specialist and not the "average gardener." The guide is organized alphabetically by genus species, and common names in subtitles. Without some previous knowledge of botanical names, the user will be referencing the index frequently. Nine hundred plants are covered in the book, but 320 have comprehensive detail including: plant description, geographic origin, therapeutic category, historical and modern uses, active ingredients and pharmacological effects.—*Asha McElfish, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

NOTES ON TYPIFICATION IN *PLUCHEA* (ASTERACEAE: PLUCHEAE)

Guy Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

ABSTRACT

Formal nomenclature and typification are detailed for taxa of the *Pluchea odorata*—*Pluchea camphorata* group. Lectotypes are designated for *Pluchea glabrata* DC., *Conyza marilandica* Michx., *Gynema viscida* Raf., *Pluchea petiolata* Cass., and *Conyza camphorata* Pursh. *Pluchea* (*Conyza*) *marilandica* (Michx.) Cass., which is the type of the genus, is based on a Dillenius illustration that shows features anomalous for *Pluchea*. The identity of several other pertinent taxa also remains ambiguous, but none of them appears to have a bearing on currently accepted nomenclature.

RESUMEN

Se detalla la nomenclatura formal y la tipificación de taxa del grupo *Pluchea odorata*—*Pluchea camphorata*. Se designan lectotipos para *Pluchea glabrata* DC., *Conyza marilandica* Michx., *Gynema viscida* Raf., *Pluchea petiolata* Cass., y *Conyza camphorata* Pursh. *Pluchea* (*Conyza*) *marilandica* (Michx.) Cass., que es el tipo del género, está basada en una ilustración de Dillenius que muestra características anómalas para *Pluchea*. La identidad de otros varios taxa también queda ambigua, pero ninguno de ellos parece tener importancia en la nomenclatura normalmente aceptada.

In connection with production of a taxonomic treatment of *Pluchea* for the Flora of North America (FNA) volumes of Asteraceae, an attempt is made here to clarify typifications for various names associated with two, relatively widespread species of *Pluchea* with petiolate, non-clasping leaves.

Pluchea odorata (L.) Cass.

The typical form of *Pluchea odorata* occurs from northern South America through the West Indies (the type is from Jamaica) and Mexico and is widely distributed through the southern United States, from California and Nevada to Texas and Oklahoma and eastward to North Carolina and Virginia. A large-headed variety of this species, primarily occurring in the northeastern United States, is *P. odorata* var. *succulenta* (Fern.) Cronq. (Cronquist 1980; Khan & Jarvis 1989).

Pluchea odorata (L.) Cass. [var. **odorata**]. *Pluchea odorata* (L.) Cass., Dict. Sci. Nat. 42:3. 1826. *Placus odoratus* (L.) M. Gómez , Anales Soc. Esp. Hist. Nat. 19:273. 1890. *Pluchea odorata* (L.) DC. var. *normalis* Kuntze, Revis. Gen. Pl. 1:357. 1891 (nom. invalid; includes the type of the autonym). *Conyza odorata* L., Syst. Nat., ed. 10. 1213. 1759. Linnaeus cited "Sloan. jam. t. 152. f. 1. Plum. ic. 97." LECTOTYPE (Urb. ex R.K. Godfrey 1952:241–242, 245): JAMAICA. Sloane, Voy. Jamaica 1: plate 152(1). 1707.

The plant illustrated is in the Sloane Herbarium—no data regarding collector, locality, or date (BM, photo Gillis (1977)!, internet image <http://internt.nhm.ac.uk/cgi-bin/botany/sloane/detail.dsml?ID=24>!). Although Godfrey's acceptance of an earlier choice of type by Urban formalized the lectotypification of *P. odorata*, Godfrey misinterpreted the Sloane illustration as referring to the woody species now generally identified as *Pluchea carolinensis* (Jacq.) D. Don. Application of this latter name was clarified by Khan and Jarvis (1989). The herbaceous species treated by Godfrey as *P. purpurascens* is correctly identified as *P. odorata* (see Gillis 1977).

Pluchea purpurascens (Sw.) DC., Prodr. 5:452. 1836. *Placus purpurascens* (Sw.) M. Gómez, Anales Soc. Esp. Hist. Nat. 19:273. 1890. *Conyza purpurascens* Sw., Prodr. 112. 1788. TYPE: JAMAICA: Swartz cited "Conyza l. Brown. jam. 318." and "Conyza major odorata—Sloan. h. l. 258. t. 152. f. 1.." Browne's citation (1756) was "Conyza major odorata, &c. Slo. Cat. 124. & H. t. 152. f. 1." in reference to the same Sloane illustration, which is the same as the lectotype of *Conyza odorata* L. (above). LECTOTYPE (Howard 1989:589): JAMAICA. Sloane, Voy. Jamaica 1: plate 152(1). 1707. The plant illustrated is in the Sloane Herbarium, as cited above for *Pluchea odorata*.

Pluchea purpurascens (Sw.) DC. var. *glabrata* (DC.) Griseb., Cat. Pl. Cub. 150. 1866. *Placus purpurascens* (Sw.) M. Gómez var. *glabratus* (DC.) M. Gómez, Anales Soc. Esp. Hist. Nat. 19:273. 1890. *Pluchea glabrata* DC., Prodr. 5:452. 1836. TYPE: GUADELOUPE: de Candolle cited the following: "in Guadalupa legit olim cl. Badier et recentius Perrottet ad Pointe-à-Pitre." Of specimens identified as *Pluchea glabrata* in the de Candolle herbarium, one is labeled simply "Guadeloupe" and may be the Badier collection; another has more specific data—"Pte. à Pitre, 17 Juin 1824, Perrottet 1825." This plant also was collected on Guadaloupe, and (Urban 1902) indicates that Perrottet was there at least for a period during 1824. The Perrottet collection is designated here as the LECTOTYPE (G-DC fiche 905!).

Pluchea petiolata Cass., Dict. Sci. Nat. 42:2. 1826. TYPE: Details of the protologue are too abbreviated to establish the identity: "ses calathides sont petites, subglobuleuses, et disposées en corymbe terminal; ... ses squames sont ovales, aiguës, presque membraneuses, parsemées de glandes ..." The description of small heads with acute, membranous, sparsely glandular phyllaries suggest that it might be *Pluchea camphorata*, but the heads in a terminal corymb and ovate phyllaries are more like *Pluchea odorata*. Cassini noted that "Nous avons observé cette plante dans l'herbier de M. de Jussieu, ou elle étoit innommée," citing no further detail. One of two specimens in the Jussieu herbarium might have been the one observed by Cassini.

(1) **Cat. No. 8646** (P-Jussieu, fiche 634!)—identified as "*Conyza marylandica* Michx.," with no collection information. The plant has short-petiolate leaves and a terminal capitulescence and is *Pluchea odorata*.

(2) **Cat. No. 8662** (P-Jussieu, fiche 635!)—identified only as "Conyza vulgari accedens Fl. purpurasc.," apparently collected on Hispaniola ("St. Domingo"); this plant also has short-petiolate leaves and a terminal capitulescence and is a representative of *Pluchea odorata* var. *odorata*. This specimen is here designated as the LECTOTYPE of *Pluchea petiolata* Cass.

Pluchea camphorata (L.) DC. var. *angustifolia* Torr. & A. Gray, Fl. N. Amer. 2:261. 1842. *Conyza angustifolia* Nutt., J. Acad. Nat. Sci. Philadelphia 7:109. 1834 (non Roxburgh 1832). TYPE: USA. "In South Carolina, from whence it was received by Mr. Durand" (specimen not located). Torrey and Gray cited the Nuttall publication in full and apparently intended to recognize Nuttall's *Conyza angustifolia* at reduced rank, not realizing that the basionym published by Nuttall was a later homonym. Following Article 58 of the ICBN (Saint Louis Code 2000), the name at varietal rank can be attributed to Torrey and Gray as a nomen novum.

Pluchea odorata var. **succulenta** (Fern.) Cronq. *Pluchea purpurascens* (Sw.) DC. var. *succulenta* Fern., Rhodora 44:227. 1942. *Pluchea odorata* var. *succulenta* (Fern.) Cronq., Fl. Southeast. U.S. 1:175. 1980. TYPE: UNITED STATES. MASSACHUSETTS: Back Bay, Boston, ditch in old marsh, 17 Sep 1910, *E.F. Williams s.n.* (HOLOTYPE: GH!).

Pluchea marilandica (Michx.) Cass., Dict. Sci. Nat. 42:2. 1826. *Conyza marilandica* Michx., Fl. Bor. Amer. 2:126. 1803. TYPE: Michaux cited "DILL. Elth. t. 88. f. 104. nondum perfecte florida" and gave as possible synonyms "*Baccharis foetida*? Walt." and *Erigeron camphoratum*? Linn." He noted that the habitat was "a Pensylvania ad Carolinam." The LECTOTYPE, (designated here) must be the Dillenius illustration, the only element cited in the protologue by Michaux: Hortus elthamiensis 1: t. 88. f. 104. 1732. This plant is identified in the Hortus as "Conyza Marilandica, flore purpureo" and is shown with broadly lanceolate, sessile, serrate leaves and minutely pubescent stems (as illustrated), but the capitulescence is relatively elongate, broken into several subclusters borne on leafy branches and illustrated details show the heads as cylindric-campanulate with phyllaries in ca. 4–5 series and the bisexual florets as strongly goblet-shaped, features not characteristic of *Pluchea*. The specimen in the Sherardian Herbarium (OXF) upon which the drawing was based was identified as "Conyza marylandica" by Klinsmann (fide Druce and Vines 1907).

The voucher specimen at OXF, notated ".88 104 105," bears two branches and was annotated by James Reveal in 1982 as *Pluchea purpurascens* (= *P. odorata*). A digital image made available by Stephen Harris, Curator of Oxford University Herbaria, confirms that identity. An early annotation identifies it as "*Pluchea marylandica*." According to Dr. Harris (pers. comm), "This is the specimen that Druce placed into the Hortus sequence when he worked on the material with Vines in the early 1900s. However, the specimen appears to have been incorporated from the Sherardian Herbarium and bears a different polynomial from that given in the Hortus." Clokie (1964, p. 89) observed that "very few of the specimens that [Druce] did take out [of the Sherard Herbarium] can be identified as originals of the plants in the Hortus Elthamiensis" and she noted specifically that the voucher for t. 88, fig. 104 is 'not the original specimen." The original label on the OXF sheet identifies the collection first as "Baccharis mariana flora pulchra rubenta Acta Philos. No. 246. pag. 401. pl. 22 1690" (by Sherard), then as "Conyza mariana flora pulchra rubenta Mem. Ac. R. Sc. 1719. p. 299 n.s." (by Dillenius). Thus, the identity of this specimen is clear, but its status as a voucher for the subject of the Dillenius illustration is not. Because Cassini typified his new genus *Pluchea* by *Pluchea marilandica*, typification of the genus is ambiguous to the same extent.

In Cassini's establishment of the genus and transfer of *Conyza marilandica* to *Pluchea*, he noted "Cette plante habite l'Amerique septentrionale" and described "l'enchantillon que nous avons observé dans l'herbier de Michaux ... ." Two plants in the Michaux herbarium (P!, P-Michaux fiche 100!) are identified as *Conyza* '*marylandica*.' One is labeled simply "Conyza[,] Maryland," while the second plant is labeled "Conyza marylandica[,] Virgin. et Carol."—both specimens are representatives of *Pluchea camphorata*, although the morphological details included by Cassini (Dict. Sci. Nat. 42:2) do not clearly indicate that he was describing *P. camphorata* rather than *P. odorata*.

Pluchea camphorata (L.) DC.

Based on a photograph of the type of *Erigeron camphoratus* L. received at Harvard from the British Museum, Fernald (1939) made this assessment: "That it is a fragment from the summit of a plant of *P. petiolata* Cass. will be evident to those who know that plant" (p. 461, photo published on p. 459). Fernald's judgement has been accepted by those who have dealt with this common species (e.g. Godfrey 1952, Cronquist 1980, Nesom 1989, and various other floristicians) and is confirmed here. A color image of the Clayton specimen is currently internet-posted as part of the John Clayton Herbarium (The Natural History Museum 2000).

Pluchea camphorata (L.) DC., Prodr. 5:451. 1836. *Erigeron camphoratus* L., Sp. Pl. 864. 1753. Linnaeus cited "Hort. ups. 259" and "Gron. virg. 97. Habitat in Virginia." Gronovius (Flora Virginica, ed. 1, 1739, p. 96) provided a description and referred to "Clayt. n. 165." The description in Linnaeus's own Hortus Upsaliensis of 1748 was nearly identical to the later one of 1753 and also referred to "Gron. virg. 96." As observed by Fernald (1939, p. 460), "Linnaeus composed his diagnosis by adding a portion of Clayton's own description [on the specimen itself] of his plant to that of Gronovius." LECTOTYPE (Fernald 1939:459–461): UNITED STATES. VIRGINIA: without other data, *Clayton 165* (BM!, photo-GH!, photo-Fernald (1939)!, internet image <http://internt.nhm.ac.uk/cgi-bin/botany/clayton/ detail.dsml?RowID=234>!). Clayton's collections in Virginia were made mostly within "a modest-sized region south of the Rappahannock and north of the James River and west to the Blue Ridge" (Sterling 1997).

Pluchea viscida (Raf.) House, Amer. Midl. Naturalist 7:129. 1921. *Gynema viscida* Raf., Ann. Nat. 15. 1820. *Gynema dentata* Raf. ex DC. (in syn., sub *Pluchea foetida*), Prodr. 5:452. 1836. Type: Rafinesque noted that this is "A fine species not uncommon in Kentucky in fields and woods" but cited no specific collection. His description of the "flowers corymbose, terminal and axillary" is a good indication of the identity of the species, especially as only a single species of *Pluchea* is known to occur in Kentucky. Rafinesque (Ann. Nat. 1820) noted that he had previously identified it as *Gynema dentata*, apparently a manuscript name picked up and listed in synonymy by de Candolle. A specimen in the deCandolle herbarium from "Kentucky," without other collection data, is identified in the handwriting of Rafinesque as *Gynema viscida*; another annotation label, also in Rafinesque's hand, for the same plant identifies it as "*Gynema dentata* Raf. N. sp. and *Gynema balsamica* fl. ludov." This specimen serves to establish the identity of *Gynema viscida* (LECTOTYPE, designated here: G-DC, fiche 904!).

Pluchea camphorata (L.) DC. var *glabrescens* Kuntze (nom. nud. invalid.), Revis. Gen. Pl. 1.357. 1891. In the same short paragraph as the listing of *Pluchea camphorata* var. *pubescens* (see below), Kuntze noted "Die bis auf Blattnerven fast kahl werdende Form ist b *glabrescens* O. Ktze. = *Baccharis foetida* L. p.p." No pertinent herbarium material located (fide Fernald 1942; none at NY).

Pluchea camphorata (L.) DC. var. *pubescens* Kuntze (nom. nud. invalid.), Revis. Gen. Pl 1:357. 1891. Fernald (1942, p. 228) observed that "since Kuntze gave no word of description, the name cannot be taken up" (see 1998 ICBN Article 32.1). Kuntze cited only "U. St.: Hoboken [New Jersey], Cairo [Illinois], Miss. [Mississippi? or Missouri?]." A Kuntze collection filed with NY types is marked "b *pubescens*": Illinois, Cairo, 9 Aug 1874, *C.E.O. Kuntze 2886* (NY!).

Doubtful identity

Conyza camphorata Pursh, Fl. Amer. Sept. 2:523. 1814 (non *Erigeron camphoratus* L.). TYPE: Pursh cited only "Icon. Dill. elth. t. 89. f. 105," and this illustration pre-

> sumably must be taken as the LECTOTYPE, designated here: Hort. eltham. 1: t. 89. f. 105. 1732. The Dillenius plate is identified as "Conyza American frutescens, foetidissima Vaill." The indication of its 'foetid' nature supports its identification as *Pluchea*, but no details of florets or fruits were illustrated, and the large, sessile, coarsely serrate-dentate leaves, glabrous stems (as illustrated), axillary clusters of heads, and peculiar renditions of the heads (suggesting linear, equal-length phyllaries) do not support a firm identification even at generic rank.

As a synonym of *Conyza camphorata*, Pursh listed *Baccharis foetida* (in the sense of Willdenow and Walter), which is *Pluchea camphorata* in the sense of the present manuscript. Pursh included *Erigeron camphoratus* [L.] (sensu Willdenow) as a synonym in his treatment of *Conyza marylandica* Michx. Tenets of previous nomenclatural confusion between *Pluchea (Baccharis) foetida* (L.) DC. and the North American petiolate-leaved species of *Pluchea* were outlined by Godfrey (1952).

ACKNOWLEDGMENTS

I am grateful to the staffs of GH, BM, and P for help during recent visits there. Prior to my visit, Charlie Jarvis of the British Museum made critical and accurate observations on the type of *Pluchea (Erigeron) camphorata*. The staff of P also provided a digital image of the specimen cited here as lectotype of *Pluchea petiolata* Cass. Stephen Harris (OXF) made available a digital image of the voucher for the Dillenius illustration of *Conyza marilandica* and comments regarding its origin. James Macklin (PH) searched for the type of *Conyza angustifolia* Nutt. I am grateful to an anonymous reviewer and especially to K. Gandhi (GH) for his helpful comments in review.

ABSTRACT

This paper discusses the circumscription of *Crataegus* ser. *Rotundifoliae* and provides identificatory materials (full descriptions, line illustrations and specimen citations where not previously available) for the taxa of the series occurring in western Canada, defined for the purposes of this paper as British Columbia and Alberta. The variable, widespread and common species *C. chrysocarpa* is reviewed for this area and a local, rather distinct new variety, var. *vernonensis*, is recognized. In addition, one species new to science, *C. sheila-phippsiae* is described.

Key Words: *Crataegus*, Rosaceae, ser. *Rotundifoliae*, western Canada, *C. sheila-phippsiae* sp. nov., *C. chrysocarpa* var. *vernonensis* var. nov.

RESUMEN

Se discute la circunscripción de *Crataegus* ser. *Rotundifoliae* y se ofrecen materiales de identificación (descripciones completas, ilustraciones y citas de especímenes que no estaban disponibles previamente) para los taxa de la serie que se encuentran en el oeste de Canadá, definido a los efectos de este artículo como Columbia Británica y Alberta. La especie variable, muy difundida y común *C. chrysocarpa* es revisada para esta área y se reconoce una nueva variedad local bastante diferente, var. *vernonensis*. Además se describe una nueva especie para la ciencia, *C. sheila-phippsiae*.

Since the first author's review (Phipps 1997) of red-fruited *Crataegus* in western North America was prepared, intensive collecting, particularly in the British Columbia Okanagan, has revealed a number of new species, especially in ser. *Purpureofructi* J.B. Phipps & O'Kennon and ser. *Douglasianae* (Rehder ex C.K. Schneider) Rehder. Here, we deal with ser. *Rotundifoliae* (Eggl.) Rehder (1940) in western Canada, a very wide-ranging series of hawthorns. They occur from the Pacific Northwest of the USA and southern British Columbia in a broad band through southern Canada and the northern United States to Newfoundland and southern New England extending locally southward, in the Rocky Mountains to Colorado and in the Appalachians to northern North Carolina.

The series is a re-ranking of Eggleston's section *Rotundifoliae* (1908b) which in turn is a renaming of Sargent's (1905) 'natural group' *Coccineae* which Eggleston (1908b) considered to be improperly typified. If one follows Eggleston (op. cit.) in which *C. rotundifolia* Moench is divided into two varieties, var. *rotundifolia* (now *C. dodgei* Ashe) and var. *chrysocarpa* (Ashe) Eggl. (now *C.*

SIDA 21(1): 65–77. 2004

chrysocarpa Ashe), one might typify series *Rotundifoliae* with *C. dodgei*, which would seem plausible as *C. dodgei* possesses a round to broadly elliptic leaf and *C. chrysocarpa* normally possesses a ± rhombic leaf. Unfortunately, Moench's illustration (1785) shows a hawthorn with an elliptic leaf, pointed at both ends, nothing like the leaf-shape of *C. dodgei* and not much like that of *C. chrysocarpa* and, regrettably, completely at variance with the text of the protologue. The poor quality of Moench's protologue for *C. rotundifolia* was further compounded by the fact that his name was invalid, *C. rotundifolia* Lam. (1783) being an earlier name for a different species.

In this paper, we avoid the problems associated with typifying *C. rotundifolia*, by considering both *C. chrysocarpa* and *C. dodgei* (not in the area of this paper) to be members of series *Rotundifoliae*. Nevertheless, there is a serious argument for separating *C. dodgei* and immediate relatives from *C. chrysocarpa* and immediate relatives to create two series at which point the typification problem would need to be addressed. In western Canada, all members of series *Rotundifoliae* fall into the *C. chrysocarpa* group and there is considerable variation within it, some only recently recognized.

Inasmuch as the *C. dodgei* group does not occur in western Canada and is perhaps best treated as a different series as suggested above, the following characteristics of ser. *Rotundifoliae* may be understood as only applying to the western forms of the series, i.e. the non-*dodgei* group of species. Series *Rotundifoliae* in this restricted sense are among the smaller hawthorns, typically multi-stemmed bushes 2–4 m tall and very thorny. The leaves are ± rhombic to ± ovate in shape, 2–4 lobed per side with LII (leaf incision index; IFI in latin) 5–20 %, rather glandular on the margins and petiole and typically very hairy adaxially. Anthesis is early, inflorescences 5–18 flowered, with usually pubescent branches bearing caducous, linear-oblong, gland-margined bracteoles. Flowers are mid-sized, 13–18 mm diam.; hypanthium usually hairy; calyx-lobes quite strongly glandular but weakly serrate; stamens 10 or rarely 20; anthers ivory to cream or less commonly pink; styles 3–4. Fruit 8–12 mm diam., usually ±orbicular, hairy or not; calyx-lobes spreading else broken off; nutlets 3–4, sides smooth.

At least superficially, the most similar series in western Canada are *Macracanthae* (Loud.) Rehder with eglandular petioles and laterally eroded nutlets and *Purpureofructi*, which are much larger plants, have stout, shorter thorns and plum-red to purple-black ripe fruit with sides of nutlets ± eroded. Eggleston (1909) placed his *C. williamsii* in ser. *Rotundifoliae* but this species has laterally eroded nutlets, generally slightly larger leaves and is now placed in ser. *Purpureofructi*.

The region explicitly covered by this paper is British Columbia and Alberta although the descriptive text should also cover *C. chrysocarpa* in Saskatchewan and Manitoba.

TAXONOMIC TREATMENT

We recognize here two species of ser. *Rotundifoliae*: *C. chrysocarpa* and *C. sheila-phippsiae*, the former with three varieties. The last-named species is new to science and brings to five the number of *Crataegus* species endemic to the remarkable hawthorn-rich region of the northern Okanagan. The detailed locations cited may be found, more or less precisely, by reference to our sketch-map (Fig. 1).

KEY TO SPECIES

1. Stamens 20; inflorescences glabrous **1. C. sheila-phippsiae,** sp. nov.
1. Stamens 10; inflorescences normally ± hairy **2. C. chrysocarpa**

1. Crataegus sheila-phippsiae J.B. Phipps & O'Kennon, sp. nov. (**Fig. 2**) TYPE: CANADA: BRITISH COLUMBIA. Northern Okanagan, Spallumcheen Mun., McLeery Rd, 50° 20' 59" N, 110° 08' 40" W, roadside, edge of thicket, 1314 ft a.s.l., bush 4.5 m tall, 18 pale pink anthers, 16 May 2002, *J.B Phipps 8334* (HOLOTYPE: UWO; ISOTYPES: ALTA, CAN, DAO, TRT, UBC, UVIC, V).

Frutices, usiter arborescentes, 3–5 m alti; spinae 2.5–4 cm longae; ± tenues vel validae, rectae vel leviter recurvatae, annotinae nitenter atrobrunneae, veteriores atrocinereae; ramuli extendentes glabri, virides; annotini valde nitento-brunnei, veteriores atrocinerei. Folia decidua; petioli 10–20 mm longi, graciles, pubescentes, glandulis secundum sulcum paucis vel pluribus; laminae 4–5 cm longae, ± rhombeae in forma generali, apex acuminata, basis cuneata; 3–4 arguti lobi per latus, max. IFI ca. 20%; margines cum parvissimis acutis dentibus; superficies adaxiales scabro-pubescentes, abaxiales pilosae solo in venis principalibus et in axillis; venatio craspedodroma, 4–5 nervatae per latus. Inflorescentiae 8–18-florae; ramuli glabri, bracteolis caducis, linearibus, membranaceis, glandulo-marginatis. Flores 14–19 mm diam.; hypanthium glabrum extrinsecus; lobi calycis triangulares, glandulo-marginati sed vix serrati; petala alba, ± circularia; stamina 18–20, antheris pallide roseis (raro moderate roseis - *Jackson for Phipps 8407*); styli 4–5, exorientes a caespite parvo pilorum. Fructus 10–12 mm diam., subglobosi, clare carmineo-scarlatini in Augusto exeunte, in maturitate fortiter rubro-purparei; lobi calycis patentes; pyrenae 4–5, dorsaliter sulcatae, lateribus planis.

Shrub, usually somewhat tree-like, 3–5 m tall; thorns 2.5–4 cm long, moderately slender to a little stout, straight or slightly recurved, dark shiny blackish brown at 1 yr, older deep gray; extending twigs glabrous, green, at 1 yr rich shiny brown, older gray. Leaves deciduous; petioles 10–20 mm long, slender, with few to several glands along the sulcus, pubescent; blades 4–5 cm long, ± rhombic in general shape, tip acuminate, base cuneate, 3–4 sharp lobes per side; max LII ca. 20%; margins with very small sharp teeth; scabrous-pubescent adaxially, hairy in the axils and parts of the main veins abaxially; venation craspedodromous, ca. 5 veins/side. Inflorescences 8–18 flowered; branches glabrous bearing early caducous, linear, membranous, gland-margined bracteoles. Flowers 14–19 mm diam.; hypanthium externally glabrous; calyx-lobes triangular, gland-margined, barely serrate; petals white, ± circular; stamens 18–20, normally pale pink but occasionally medium-pink (*Jackson for Phipps 8407*) or puce (*Phipps & O'Kennon 6917*); styles 4–5, arising from a small tuft of hairs. Fruit 10–12 mm diam., subglobose, brilliant crimson-scarlet in late August deepening to a dark burgundy at full ripeness, sepals spreading; nutlets 4–5, dorsally grooved, sides plane.

Crataegus sheila-phippsiae is a relatively scarce species restricted to the northern Okanagan of British Columbia but in some localities rather common as, for instance, just north of the Indian Cemetery on hwy 97A about 2 km south of Enderby. It grows in relatively open and apparently rather dry sites and as such appears to be quite xeromorphic like other members of the same series.

Crataegus sheila-phippsiae is a typical rhombic-leaved member of ser. *Rotundifoliae*. It is easily differentiated from *C. chrysocarpa* var. *chrysocarpa*, to which it is most similar, by its ± glabrous nature, 20 stamens, usually pale pink anthers and greater single-trunk dominance. In the past difficulties have arisen differentiating *C. sheila-phippsiae* from *C. shuswapensis* (ser. *Douglasianae*) in flower in those rare cases where *C. shuswapensis* has 15–18 stamens but we believe that they are now most easily resolved at the flowering stage by the better development of abaxial tufts of hair in the vein axils of *C. sheila-phippsiae* whereas *C. shuswapensis* is usually glabrous there. When in fruit, however, *C. shuswapensis* is quite different from *C. sheila-phippsiae*. The authors now suspect that the attribution of 18 stamens to *C. shuswapensis* in Phipps & O'Kennon (2002) may refer to a plant of *C. sheila-phippsiae* with deeply colored anthers. Of course, the critical eye will also notice differences in leaf color and slight differences in shape, together with subtle habit differences, all difficult to put into words. Also anther color in *C. shuswapensis* is much more variable than in *C. sheila-phippsiae*, ranging from pink to puce.

Persons with the resources might investigate the possibility that *C. sheila-phippsiae* may be a diploid, sexual counterpart of *C. chrysocarpa*, like the *C. suksdorfii*/ *douglasii* pair so elegantly demonstrated by Dickinson et al. (1996).

The species epithet recognizes the important contribution to the study of hawthorns by Sheila Phipps, wife of the first author, which include the typing over the years of hundreds of pages of manuscript, help with proofing of printed text, tending to young *Crataegus* seedlings and assisting at the scene the year this species was recognized in the field with certainty for the first time.

Additional specimens examined: **CANADA: British Columbia.** Northern Okanagan. Mabel Lake Rd., 1.0 km E of centre of Shuswap R. bridge at Enderby, bush 3.5 m tall, fruit burgundy, 07 Sep 2001, *J.B. Phipps 8279 & R.J. O'Kennon* (BRIT, UWO); ca 1.2 mi E of Enderby on road to Mabel Lake, bush 3 m tall, fruit burgundy-red, 20 Aug 1994, *J.B. Phipps 7015a & R.J. O'Kennon* (UWO); ca. 1 mi S of Enderby, gravel driveway to NNE off hwy 97A at Indian Cemetery, bush 2.5 m tall, fruit deep blood red, 20 Aug 1994, *J.B. Phipps & R.J. O'Kennon 7003* (BRIT, UWO); same loc., bush 2.5 m tall, pink anthers, 16 May 2002, *J.B. Phipps 8335* (BRIT, UWO); same loc., bush 2.5 m tall, 20 pale pink anthers, 16 May 2002, *J.B. Phipps 8336* (BRIT, UWO). Same loc., bush 4 m tall, 20 pale pink anthers, 16 May 2002, *J.B. Phipps 8338* (BRIT, UWO); same loc., bush 2.5 tall, 20 pale pink anthers, 16 May 2002, *J.B. Phipps 8339* (BRIT, UWO); same loc., bush 3 m tall, 20 pale pink anthers, 16 May 2002, *J.B. Phipps 8340* (BRIT, UWO); same loc., bush 3 m tall, 20 pale pink anthers, 16 May 2002, *J.B. Phipps 8342* (BRIT, UWO). Same loc., bush 3 m tall, anthers 18, light pink, 22 May 2002, *R. Jackson for J.B. Phipps 8380* (BRIT, UWO); same

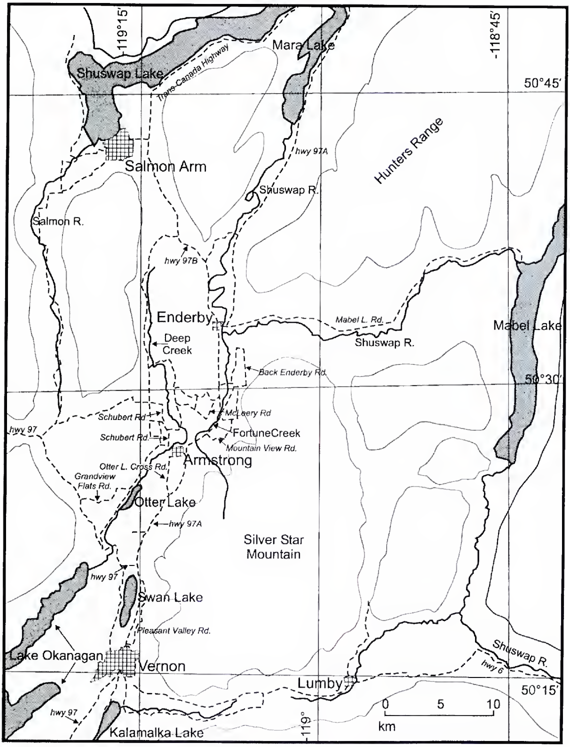

Fig. 1. Sketch-map of the Northern Okanagan-southwestern Shuswap drainage area.

loc., bush 2 m tall, 20 light pink anthers, 22 May 2002, *R. Jackson for J.B. Phipps* 8381 (BRIT, UWO); same loc., bush 3 m tall, 20 light pink anthers, 22 May 2002, *R. Jackson for J.B. Phipps 8462* (BRIT, UWO); some additional duplicates will be distributed later.

2. Crataegus chrysocarpa Ashe, 1900 (FIREBERRY HAWTHORN). *Crataegus rotundifolia* Moench, 1785, sens. auctt., non Lam., 1783. *Crataegus columbiana* Howell, 1898, sens. auctt. Amer. *Crataegus piperi* Britton, 1901. *Crataegus chrysocarpa* var. *piperi* (Britton) Kruschke (1965). *Crataegus columbiana* var. *chrysocarpa* (Ashe) Dorn, 1988. *Crataegus rotundifolia* var. *chrysocarpa* (Ashe) Eggl., 1908a. *Crataegus columbiana* var. *piperi* (Britt.) Eggl.,1908a. TYPE: U.S.A.: COLORADO. LARIMER CO.: foothills of Cache le Poudre Mountains, 6000 ft, 20 Aug 1899, *W.W. Ashe s.n.* (NY!).

Bushes 2–3.5 m tall, sometimes colonial; extending twigs usually appressed-pubescent; 1-year old branches usually dull yellowish-greenish brown or gray-brown to light tan in the east, rich tan but sometimes (as in MN and QU) shiny deep reddish- brown; thorns variable, 3–6 cm long, ± slender to ± stout, straight to slightly recurved, shiny, dark mahogany or blackish at 1 yr. Leaves deciduous; petioles 1–2.5 cm long, ± pubescent, usually narrowly winged distally, ± glandular at least initially; laminas 2–6 cm long, ± rhombic to broad-elliptic, very occasionally broad-ovate in general shape, 2–4 lobed, the lobes sharp to blunt, LII 5–20%; margins with numerous small teeth, these caducous gland-tipped; venation craspedodromous, about 5–6(–7) main lateral veins per side; usually appressed-short pubescent above and pubescent mainly on the veins beneath, variably glabrate later; autumn color yellow, or purplish in very dry spots. Inflorescence 5–10 flowered; branches densely to sparsely villous, bearing caducous, linear, membranous, gland-margined bracteoles; anthesis early. Flowers ca. 15–20 mm diam.; hypanthium villous; calyx-lobes ca. 4 mm long, triangular, margins glandular-serrate, pubescent abaxially; petals ± circular, white; stamens 10(–20), anthers only cream or ivory in the area covered by this paper, styles 3–4(–5). Fruit 8–10 mm diam., usually ± spherical, usually scarlet to deep red or darkened to burgundy if dried and shriveled, ± pubescent, calyx remnants present. Nutlets 3–4(–5), grooved dorsally, their faces plane.

Crataegus chrysocarpa is the second most wide-ranging of North American *Crataegus* species reaching from the landward side of the coastal ranges in

FIG. 2. Line drawing of *C. sheila-phippsiae* from *J.B. Phipps 8332* (UWO) *and J.B. Phipps & R. O'Kennon 6810* (UWO), flowering and flower details; *R. Jacksan for J.B. Phipps 8461* (UWO), fruiting and fruit detail. Scale bars = 1 cm. S. Laurie-Bourque del.

British Columbia, Washington and Oregon to the Atlantic. Its southern limit is Colorado, further north than the New Mexico and Arizona southern limit for *C. macracantha* which otherwise has a broadly similar but rather more southerly range. *Crataegus chrysocarpa* is abundant in the grasslands of the Canadian Prairie Provinces where it nearly always occurs in sunny areas in the bottoms of draws, seepage zone edges on slopes or along shallow ditches. It may also be found occasionally under aspen, generally at the edge of a stand or where the stand is thin and is found in similar habitats in valleys of the inter-mountain areas. *Crataegus chrysocarpa* is the most northerly and cold-adapted species of *Crataegus* in North America nearly reaching Hudson Bay in Ontario.

Crataegus chrysocarpa is a multi-stemmed bush, small for a hawthorn, usually 2–4 m high and, not surprisingly for so abundant a species, somewhat variable, although through most of its western range rather uniform. However a fairly well-marked regional variant, var. *piperi*, which is more thoroughly discussed in Phipps (1997) and which might be worth raising to subspecific rank, occurs west of the Rocky Mountains.

Crataegus piperi has also been synonymized with *C. columbiana* Howell but the first author showed that *C. columbiana* was based on two species and lectotypified it on the *C. douglasii* element (Phipps, 1995). The characteristic ripe fruit color of *Crataegus chrysocarpa* var. *chrysocarpa* in western Canada is bright red, in spite of the species epithet. However, about the third week of August it is a fairly bright orange, which ripens through orange-red to the final color. The fruit of a small percentage of specimens of *C. chrysocarpa* var. *chrysocarpa* observed in the Cypress Hills, Saskatchewan in late August 2001, however, were still golden-orange when most around were bright red. Also, in the same area and time, a lanate form of the type variety was found to have greenish-yellow fruit when congeners were bright red but its fully ripe color seems to occur later and is deep red. A few specimens from Saskatchewan, otherwise indistinguishable from the typical variety, have 20 stamens. See Phipps (1997) for citation of specimens, line illustration and distribution map.

We also take the opportunity here to describe as a variety new variety of *C. chrysocarpa*, the Okanagan endemic taxon, var. *vernonensis*.

The name *Crataegus rotundifolia* Moench has quite frequently been used for *C. chrysocarpa* Ashe, for instance by Packer (1983), though starting with Eggleston (1908a) as noted in the discussion of the series. However, as noted above, Eggleston's sense of *C. rotundifolia* var. *rotundifolia* was obviously *C. dodgei*, a different species.

KEY TO VARIETIES OF *C. CHRYSOCARPA* IN WESTERN CANADA

1. Anthers ivory to cream; ripe fruit usually bright red.
    2. Leaf-blades generally smaller (2–4 cm long) usually sharply but less deeply lobed (LII 5–15%); leaves ± glabrous abaxially ____________________ **2a.** var. **chrysocarpa**

2. Leaf-blades larger (4–6 cm long), sharply and quite deeply lobed (LII ≤ 20%), densely pubescent abaxially ______ **2b.** var. **piperi**

1. Anthers pale pink; ripe fruit usually deep claret-colored ______ **2c.** var. **vernonensis**, var. nov.

2a. Crataegus chrysocarpa var. **chrysocarpa.** TYPE: as species.

Characteristics as key. Variety *chrysocarpa* occurs practically throughout the range of the species and in western Canada in the valleys of southern intermountain British Columbia and the grassland biomes of Alberta, Saskatchewan and Manitoba where it is nearly the only hawthorn. The indumentum of the inflorescence is generally moderately pubescent but rare, densely lanate or ± glabrous forms also occur. A broad-leaved form originally described as *C. sheridana* A. Nels. from Colorado might be varietally distinct and should be looked out for in the area of this paper. Its nearest proven occurrence is in North Dakota. Overall the variation of the typical variety in western Canada is considerable and warrants further study.

2b. Crataegus chrysocarpa var. **piperi** (Britton) Kruschke, 1965. TYPE: U.S.A.: WASHINGTON: Pullman, Sep 1897, *C.V. Piper 1535* (NY!)

Characteristics as key. Widespread in the intermountain zone from Oregon to British Columbia and extending eastwards to Montana, var. *piperi* is the only variety at the western edge of the species' range. In western Montana intermediate forms occur while in the Okanagan when varieties *piperi* and *chrysocarpa* occur together they maintain their distinctness. The indumentum of the inflorescence is ± lanate.

2c. Crataegus chrysocarpa var. **vernonensis** J.B.Phipps & O'Kennon, var. nov. (**Fig. 3**) TYPE: CANADA: BRITISH COLUMBIA: Okanagan Valley, Okanagan I.R. no. 1, Westside Rd., 2 mi SW jct. Hwy 97, natural hedges, bush 3 m tall, habit very erect, fruit plum colored, flesh succulent-mushy, golden, 26 Aug 2000, *J.B. Phipps & S.R. Phipps 8178* (HOLOTYPE: UWO; ISOTYPES: BRIT, CAN, TRT, V).

Frutices, saepe multicaules; ramificatione pauca pro ratione, plerumque 2–3 m altae; spinae 3–4.5 cm longae, nitenter brunnescentes secundo anno exeunte, cinerascentes in maturitate; ramuli extendentes crispo-pilosi et rubi in juventute, glabrescentes; annotini ± nitenter brunnei, veteriores atrocinerei. Folia decidua; petioli 10–20 mm longi, primum ± dense-pubescentes, in maturitate pubescentes, aliquot glandulis secundum sulcum; laminae 3–6 cm longae, ovatae vel ovato-rhombeae in forma generali; apex obtusa vel subacuta; basis cuneata; lobi laterales 3–4/latus, acuti vel ± obtusi apice vix cuspidata, max IFl us. ca. 15%; margines dentibus minutissimis subacutis praeter basales; venatio craspedodroma, 3–4 principalibus nervis lateralibus per latus; superficies adaxiales appresso-scabro-pubescentes, persistentes; superficies abaxiales fere glabrae sed pilosae secundum venas; ± coriaceae in maturitate et saepe leviter convectae, olivaceae; color autumnalis flavus purpura saepe superposita. Inflorescentiae 5–14 -florae; rami lanati, ferentes caducas, anguste-oblongas, membranaceas, glanduli-marginatas, aliquantum brunneo-rubras bracteolas. Flores 18–20 mm diam.; hypanthium extrinsecus lanatum infra, glabrum supra; lobi calycis triangulares, minute glandulo-serrati; stamina 8–10, antheris plerumque pallide roseis; styli 4–5, exorientes a brevissimo caespite pilorum. Fructus 10–12 mm diam., subglobosi, ± pilosi, rubro-purpurei vel fere atri ultra maturitatem; caro aurea; lobi calycis semi-persistentes, erecto-patentes; pyrenae 4–5, sulcatae dorsaliter; lateribus planis.

Shrubs, often multistemmed with relatively little branching, us. 2–3 m tall; thorns 3–4.5 cm long, shiny brownish black at 2 yrs, graying with age, somewhat stout, straight to slightly recurved; extending twigs crisped hairy young, green tinged reddish young, glabrescent; at one year ± shiny brown; older dull gray. Leaves deciduous; petioles 10–20 mm long, ± dense-pubescent at first, largely persisting, with several glands along the margins of the sulcus; blades 3–6 cm long, ovate to ovate-rhombic in general shape, tip obtuse to ± acute, base cuneate; lateral lobes 3–4/side, acute (more likely in smaller or vegetative leaves) to somewhat rounded with a barely cuspidate tip, max. LII us. ca. 15%; margins with very small subacute teeth except near the entire base; venation craspedodromous with 3–4 principal lateral veins/side; adaxially appressed scabrous-pubescent, persisting; abaxially pilose on the veins, surfaces glabrous; rather coriaceous at maturity and often slightly convex, dull olive green; autumnal color yellow often overlayed with dull purple. Inflorescences 5–14-flowered; branches lanate, bearing caducous, narrow-oblong, membranous, somewhat brownish-red, gland-bordered bracteoles. Flowers 18–20 mm diam.; hypanthium externally lanate below, glabrous above; calyx-lobes triangular, minutely glandular-serrate; stamens 8–10, anthers generally pale pink; styles 4–5, arising from a very short tuft of hairs. Fruit 10–12 mm diam.; subglobose, ± hairy, burgundy or lake to nearly black when over-ripe; flesh golden; calyx-lobes semi-persistent, erecto-patent; nutlets 4–5, dorsally grooved, laterally smooth.

Crataegus chrysocarpa var. *vernonensis* is locally common in the northern Okanagan valley between the Vernon area and Salmon Arm. It occurs in the more xeric habitats in which hawthorns of the region are found, for instance, sometimes tolerating sandy soil. For this reason and its early ripening the fruits are apt to shrivel during September when the fruits of other hawthorns in the area are normally still plump. Perhaps for this reason it is under-collected. The particularly xeromorphic nature of var. *vernonensis* is such that it is seldom found growing among the larger, more mesomorphic hawthorns such as members of ser. *Purpureofructi* or *C. okennonii*. It is among the earliest to flower of the hawthorns of the area, typical for all ser. *Rotundifoliae*.

Crataegus chrysocarpa var. *vernonensis* is known from about 17 collection numbers and in diagnostic characteristics it is remarkably uniform. The multistemmed, relatively little-branching, erect habit is conspicuous in well-developed plants, as are the lanate inflorescences, pale pink anthers and fruit already ripe and burgundy-colored in late August. These characters help to distinguish the new species from other members of ser. *Rotundifoliae* while the tendency to blunt lobes in the leaf helps to distinguish it in midsummer from rare lanate forms of sympatric var. *chrysocarpa*.

Additional specimens examined. **CANADA: British Columbia:** Okanagan Valley, Okanagan Indian Reserve no. 1. Hawhola Rd., erect bush, 8 ft. tall, 11 May 2002, *J.B. Phipps & R.J. This is the 7th printing of the second edition; the first printing was in 1991. This new printing comes with corrections (suggested by users) to the good keys and descriptions, new information includes photographs and short biographies of Gleason and Cronquist, author abbreviations standardized, new and much more extensive indexes, and a new looking cover design.

CROTON BIGBENDENSIS (EUPHORBIACEAE), A NEW SPECIES FROM TRANS-PECOS, TEXAS

B.L. Turner

Plant Resources Center
University of Texas
Austin, Texas 78712-0471, U.S.A.

ABSTRACT

Croton bigbendensis B.L. Turner, sp. nov., is described from Trans-Pecos, Texas. It is closely related to *C. dioicus* Cav. and has passed for that species in most treatments of *Croton* for the Southwestern United States and Mexico. *Croton bigbendensis* is largely confined to the lower elevations of the Big Bend Region in Brewster, Presidio, and Hudspeth counties where it dominates sandy flats along the Rio Grande. It is readily distinguished in the field by its bushy habit, and elongate upper internodes, the latter having linear-lanceolate leaves. So far as known, it does not co-occur with *C. dioicus*, nor does it appear to intergrade with the latter in regions of near contact.

Key Words: *Croton*, *C. dioicus*, Euphorbiaceae, Texas

RESUMEN

Se describe ***Croton bigbendensis*** B.L. Turner, sp. nov., de Trans-Pecos, Texas. Está muy emparentada con *C. dioicus* Cav. y ha pasado por tal especie en la mayoría de los tratamientos de *Croton* para el suroeste de los Estados Unidos y México. *Croton bigbendensis* está confinado a las pequeñas elevaciones de la región de Big Bend en los condados de Brewster, Presidio y Hudspeth donde domina a lo largo de las llanuras arenosas del Río Grande. Se distingue fácilmente en el campo por su hábito arbustivo, e internudos superiores elongados, los últimos con hojas linear-lanceoladas. Por lo conocido hasta ahora no convive con *C. dioicus*, ni tampoco parece intergradarse con él en las regiones de contacto cercano.

Field work in the Trans-Pecos region over a several year period has convinced me that there exists an undescribed species of *Croton*, this long hidden within the taxonomic fabric of *C. dioicus*. Its description follows:

Croton bigbendensis B.L. Turner, sp. nov. **(Figs. 1,2,3)**. Type: U.S.A. TEXAS: Presidio Co.: ca. 20 mi W of Hwy. 90 along county road 2017 (dirt road to the Rio Grande), sandy flats along old flood plain of Rio Grande, 22 Aug 2002, *B.L. Turner 22-204A* (pistillate) and *22-204b* (staminate) (holotype: TEX; isotypes: MEXU, SRSC).

Similis *Croton dioico* Cav. sed herba suffruticosa aut suffrutex est ad 0.5 m altus, ramosissimus e basi caulibus super elongatis cum nodis foliis anguste lanceolatis pro parte maxima 1.5–3.0 plo longioribus.

Suffruticose perennial herbs or subshrubs mostly 40–60 cm high, the stems arising from lignescent tap roots. **Stems** densely pubescent with sessile peltate scales, the latter ca. 0.4 mm across. **Lower leaves** lanceolate; uppermost internodes elongate, bearing linear-lanceolate leaves 5–7 times as long as wide, pubescent like the stems. **Staminate flowers** with mostly (8–)9–12(–15) stamens;

SIDA 21(1): 79–85. 2004

filaments pilose, 1.5–2.0 mm long. **Pistillate flowers** with style branches ca. 1 mm long, fruits globose, ca. 5 mm long, 5 mm wide. Chromosome number, 2n = 28.

Representative Specimens: **UNITED STATES. TEXAS: Brewster Co.** Castalon Ranger Station, 17 Aug 1972, *Bacon & Hartman 1438* (LL); Big Bend Natl. Park, Chisos Mts., 26 Jun 1937, *Marsh 41* (TEX); flats N of Chisos Mts., 8 Jul 1932, *Muller s.n.* (TEX); near upper Tornillo Creek Bridge, "subshrub to 0.5 m high," 28 Apr 1984, *Powell & Powell 4329* (TEX); 24.9 mi S of Marathon, 16 Jun 2003, *Turner 23-152* (TEX); 25.7 mi along La Linda highway from highway 385, 16 Jun 2003, *Turner 23-155* (TEX); 4 mi S of highway 2627 along dirt road to Brushy Creek Canyon,17 Jun 2003, *Turner & Dodson 23-163* (TEX); between Todd Hill and Burro Mesa, yellow clay soils, 3200–3500 ft, 1 Aug 1955, *Warnock 12789* (LL, SRSC); Nine Point Mesa Ranch, 22 Apr 1998, *Webster & Westlund 32586* (TEX); near Rio Grande, creek bottoms, Compton Place, 30 Aug 1910, *Young s.n.* (TEX). **Hudspeth Co.:** ca. 5 mi S of Finley RR Station, along dirt road to IH 10, 3 Sep 2002, *Turner 22-226* (SRSC, TEX); 6 mi W of Fort Hancock, 7 Sep 1955, *Warnock 13767* (SRSC). **Presidio Co.:** Big Bend Ranch along Rio Grande, mouth of Canyon Colorado, 5 Oct 1975, *Butterwick & Lamb 1771* (TEX); 4.5 mi N of Ruidosa, 29 May 1941, *Hinckley 1541* (TEX); 3 mi N of Candelaria, 3 Sep 2000, *Billie & Matt Turner 20-508* (MEXU, NY, SRSC, TEX).

MEXICO: CHIHUAHUA. Mpio. Manuel Benavides, ca. 7 mi W of Providencia, silty desert plains, locally abundant, 10 Aug 1940, *I. M. Johnston & Muller 106* (LL).

The species is named for the Big Bend region of Texas and closely adjacent Mexico, to which it is largely restricted.

Altogether, 44 collections of *C. bigbendensis* were examined in this study (LL, SRSC, TEX): 22 from Brewster Co.; 18 from Presidio Co.; and two from Hudspeth Co. Only a single collection was examined from Mexico, this cited in the above.

Johnston (1959) provided a detailed treatment of the Texas species of *Croton*. In this he noted that *C. dioicus* is typified by material collected in the state of Hidalgo, Mexico. He further commented that it is a "widespread" (distributed from Texas to southern Mexico) and "somewhat weedy" taxon, occurring "in disturbed ground along roads and railroads." In spite of the fact that he knew the Trans-Pecos region quite well, he did not discern the species proposed herein.

Finally, it should be emphasized that, to my knowledge, the two species do not occur together, nor do they appear to intergrade in regions of near contact (cf. figs. 4 and 5), hence my recognition of *C. bigbendensis* as a good biological species. Such "cryptic species" are becoming increasingly common in Texas, even in regions that have been well studied: for example, the two new species of *Liatris* created out of the fabric of *Liatris punctata* Hook. (Nesom & O'Kennon 2001), and that of *Nemophila sayersensis* carved out of the previously well-studied *N. phacelioides* Nutt., Simpson et al. 2001).

Lectotypification

Johnston (1959) placed *C. neomexicanus* Muell. Arg. in synonymy with *C. dioicus*, having not seen type material, although he was aware that several early workers had taken up the name *C. neomexicanus* for what should have been called *C. dioicus*. Indeed, early on I thought the former name might apply to what I describe herein as *C. bigbendensis*. To resolve this issue I borrowed type

materials of *C. neomexicanus* from several institutions, the taxon itself typified by diverse collections, some of these said to have been collected by Charles Wright in the Trans-Pecos region of Texas. Clearly the name needed lectotypification, which follows.

In the protologue of *C. neomexicanus*, its author cited three collections: *Charles Wright 1800*, w/o locality, 1851–52; *Charles Wright 642* "Expedition from western Texas to El Paso, New Mexico, May-October, 1849;" and *Berlandier 3211*, Mexico: Nuevo Leon " in campsis," Jun 1844. Specimens of these several collections were borrowed from GH and NY. From among these *Wright 1800* (GH) was selected as a suitable lectotype; isolectotypes were also recorded at GH and NY. The lectotype has both male and female plants mounted on the same sheet, as does the GH isolectotype, the latter mounted on the same sheet with *Wright 642* (a paratype). All of the specimens concerned are quite similar, possessing the habit, upper nodes, and leaf shape of rather typical *C. dioicus*.

Fig. 4. Typical habit of *C. dioicus* (left); habit of living holotype of *Croton bigbendensis* (right).

Fig. 5. Typical aspect of early spring population of *Croton bigbendensis* (ca. 15 mi. NW of Presidio, Texas; note the bushy rounded habit of the plants concerned; individual in foreground is Bill Dodson, father of the sheriff of Brewster Co., Texas).

Chromosome numbers

Urbatsch et al. (1975) reported chromosome counts for 11 collections of *C. dioicus* (nine of these were diploid with 2n = 28, and two tetraploid with 2n = 56 pairs). Examination of the vouchers concerned (LL,TEX) revealed that only one of these (Brewster Co: *Bacon & Hartman 1438*) belonged to what is here described as *C. bigbendensis*. Since chromosome numbers of the *C. dioicus* collections included both diploids and tetraploids, chromosome number alone is not useful in distinguishing between the two taxa.

ACKNOWLEDGMENTS

My wife Gayle provided the Latin diagnosis. Grady Webster and Mike Powell reviewed a preliminary draft of the paper. The following herbaria provided loans of type materials: GH, NY, and US. Thanks to all for the kindness rendered.

The University of Texas
Austin, Texas 78712-0471, U.S.A.

ABSTRACT

Centaurium blumbergianum B.L. Turner, sp. nov., is described from near Ruidosa, Presidio Co., Texas. It is a perennial species with broad open, cymes having no obvious close relatives among the North American taxa described to date. It occurs only along saline streams and in seeps at the base of limestone walls in dead-end canyons where it grows with or near a number of other rare taxa such as the recently described localized endemic, *Arida mattturneri* and the equally rare *A. gypsitherma* (cf. Sida 20 [4]). Photographs of type material are presented, along with an account of its possible relationships to other taxa.

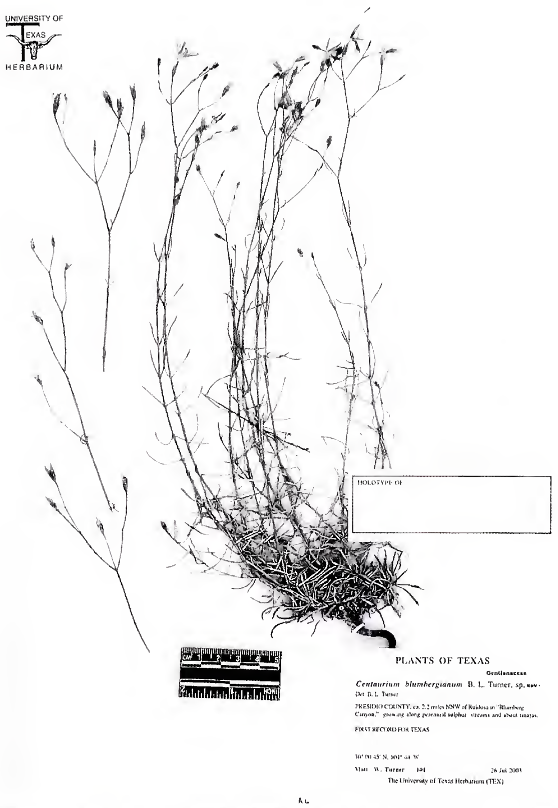
RESUMEN

Se describe ***Centaurium blumbergianum*** B.L. Turner, sp. nov., de cerca de Ruidosa, Presidio Co., Texas. Es una especie perenne con cimas abiertas anchas, que no tiene parientes próximos entre los taxa norteamericanos descritos hasta ahora. Ocurre solamente a lo largo de torrentes salinos y en filtrados de la base de paredones calcáreos de los finales ciegos de cañones donde crece junto o cerca de cierto número de otros taxa raros tales como el endemismo descrito recientemente, *Arida mattturneri* y la igualmente rara *A. gypsitherma* (cf. Sida 20 [4]). Se presentan fotografías del material tipo, junto con una relación de su posible parentesco con otros taxa.

Centaurium blumbergianum B.L. Turner, sp. nov. (**Figs. 1, 2**). TYPE: U.S.A. TEXAS: Presidio Co., ca. 2.2 mi NNW of Ruidosa in "Blumberg Canyon," growing along sulphur streams and about tinajas, 26 Jul 2003, *Matt W. Turner 101* (HOLOTYPE: TEX; ISOTYPES: MO, SRSC).

Simile *Centaurio tenuifolio* (Mart. & Gal.) B.L. Rob. sed habens petala parviora pallidaque et inflorescentiam expansiorum cum flores pauciores.

Perennial tufted herbs to 40 cm high. **Stems** 4-sided, 1–2 mm across, their edges adorned with minute, somewhat scabrous ridges, otherwise glabrous or nearly so. **Leaves** opposite throughout, linear, glabrous, those at mid-stem mostly 15–25 mm long, 0.4–0.6 mm wide. **Flowers** 3–15 per stem, forming an open cyme up to 20 cm across, the pedicels mostly 1.5–3.0 cm long. **Sepals** 5, linear-lanceolate, 7–10 mm long, united at their base for ca. 1 mm; apices slender and narrowly apiculate. **Corollas** pink; tubes 7–9 mm long, becoming transparent at maturity, constricted just below the 5 lobes, the latter 8–9 mm long, 3.5–4.5 mm wide. **Stamens** 5, exserted from tube for 2–3 mm, the anthers ca. 3 mm long at first, but 2–3 mm long and markedly helical at full anthesis. Style exserted from the tube for ca. 4 mm, the stigma somewhat bilobed, ca. 0.5 mm across. **Capsules**



HOLOTYPE OF

PLANTS OF TEXAS

Gentianaceae

Centaurium blumbergianum B. L. Turner, sp. nov.

PRESIDIO COUNTY, ca. 2.2 miles NNW of Ruidosa in "Blumberg Canyon," growing along perennial sulphur streams and about tinajas.

FIRST RECORD FOR TEXAS

30° 00 45' N, 104° 44' W

Matt W. Turner 101 26 Jul 2003

The University of Texas Herbarium (TEX)

Fig. 1. *Centaurium blumbergianum*; holotype (*M.W. Turner 101*, TEX).

FIG. 2. *Centaurium blumbergianum*, type material (upper); close up of corolla (lower).

FIG. 3. James and Olivia Blumberg.

bivalvate, narrowly oval, 8–10 mm long, ca. 3 mm across; ovules numerous to each carpel. **Seeds** ovoid, brown, ca. 0.6 mm long, 0.4 mm wide, at maturity sculpted with a peanut-like raised reticulum.

Among the Texas species, *C. blumbergianum* has no close relatives, although an anonymous reviewer suggests that it might be compared favorably with *C.*

multicaule B.L. Rob., a rather small annual with broadly lanceolate to oblanceolate basal leaves. In contrast, *C. blumbergianum* is a relatively robust perennial with persistent linear basal leaves.

In her treatment of the Mexican and Central American species of *Centaurium* by Broome (1974), *C. blumbergianum* will key to or near *C. brachycalyx* Standl. & L.O. Williams, a species of southern Mexico and Central America. It differs from the latter in numerous characters, including habit, inflorescence, and leaf shape. Except for its small flowers and expanded inflorescence, *C. blumbergianum* would appear to be closest to *C. tenuifolium* (Mart. & Gal.) B.L. Rob., a taxon confined to the mountains of western Mexico (Nayarit to Guerrero).

Among the species of *Centaurium* in the U.S.A. it most closely approaches *Centaurium namophilum* Reveal, Broome & Beatley, a localized species of Nye Co., Nevada and closely adjacent California; *C. blumbergianum* differs in having a more robust perennial habit and much more diffuse inflorescence. *Centaurium namophilum* and the closely related *C. tricanthum* (Greisb.) B.L. Rob. (according to Reveal et al. 1974), are said to "occur near or along stream drainages, marshy places or on alkaline soil." Such habitats also house *C. blumbergianum*.

Etymology.—It is a pleasure to name this remarkable new species for Mr. James Blumberg and his wife Olivia (Fig. 3), residents of Ruidosa, Texas. They own the property concerned and Mr. Blumberg eagerly accompanied Matt Turner and myself in our efforts to collect type material.

ACKNOWLEDGMENTS

I am grateful to James Blumberg for permission to visit the site concerned and to my wife Gayle for the Latin diagnosis. A special thanks to Robert Harms for helping "upgrade" the picture of the Blumbergs. James Reveal and an anonymous reviewer made helpful suggestions.

ABSTRACT

A new combination, *Dendrocalamus stocksii* (Munro) M. Kumar, Remesh & Unnikrishnan, is proposed to accommodate a widely occurring economically important bamboo in South and central India which was formerly described under *Oxytenanthera* Munro and *Pseudoxytenanthera* Soderstr. & R.P. Ellis.

RESUMEN

Se propone una nueva combinación, *Dendrocalamus stocksii* (Munro) M. Kumar, Remesh & Unnikrishnan, para acomodar un bambú de amplia distribución e importante económicamente del sur y centro de la India que fue descrito anteriormente en *Oxytenanthera* Munro y *Pseudoxytenanthera* Soderstr. & R.P. Ellis.

INTRODUCTION

During revisionary studies on some Indian bamboos, the authors undertook a detailed study on the delimitation of *Dendrocalamus* Nees, *Oxytenanthera* Munro, and *Pseudoxytenanthera* Soderstr. & R.P. Ellis. All of the species described in the above genera were critically examined using the specimens deposited in various herbaria including the type specimens. Field examination of the Indian species belonging to these genera was carried out. We found that *O. stocksii* Munro showed more affinity to the Genus *Dendrocalamus* in the vegetative and floral characters.

Oxytenanthera stocksii was first described by Munro (1868) based on the specimen collected by Stocks from the Concan area. This species is distributed in South India, along the Konkan coast up to Karwar. Subsequently, Talbot also collected it from the Coompta River in 1884 and Karwar in 1889. Munro's species was recognized by many later workers, e.g., Beddome (1873), Gamble (1896), Camus (1913), etc. It was, however, Holttum (1956) who asserted that the genus *Oxytenanthera* was truly represented by the African species *O. abyssinica* due to the peculiar nature of its ovary i.e. the ovary attenuate upwards very gradually into a more or less three angled hollow structure which bears the stigmas at its apex and the cavity of the style appears not to be continuous with the cavity which contains the ovule. He concluded that the rest of species described within this genus should be transferred to some other genera. Based on this analysis, Majumdar (1989) transferred this species to a new genus, *Pseudotenanthera* Majumdar. Unfortunately, *Pseudotenanthera* is nom. superfl. and illegitimate for *Pseudoxytenanthera* Soderstr. & Ellis (1988). Nguyen (1990) treated this taxon under the genus *Gigantochloa* but it could not be included under this genus due to the presence of stamens with free filaments. Therefore, Naithani (1991) transferred this species to *Pseudoxytenanthera* as *P. stocksii* (Munro) Naithani. *Pseudoxytenanthera* is characterized by the presence of straggling culms, inflorescence with spikelets of semiverticillate clusters, monadelphous stamens, and three plumose stigmas. *Pseudoxytenanthera stocksii* possesses erect culms, free stamens, and a single plumose style. Although the previous authors described this species with fused filaments, during the present study, it was observed that the anther filaments are short and do not show true monadelphous condition. A close examination from the young stamens to mature stamens revealed that the filaments are totally free. Owing to these characteristic features, it cannot be accommodated within the genus *Oxytenanthera* Munro either. *Oxytenanthera stocksii* differs from *O. abyssinica*, the type species, by having free stamens and monostigmatic ovary. In *O. abyssinica* the stamens are monadelphous and the style is divided into three stigmas.

The culms and branching patterns of *Oxytenanthera stocksii* also resemble those of species of *Dendrocalamus* Nees. As in the case of the type species (i.e., *D. strictus*), *O. stocksii* shows erect culms with short internodes, which have narrow lumen (solid). The inflorescence of *O. stocksii* is a large panicle of spicate heads. Even in *Dendrocalamus*, the inflorescence is composed of round congested globose heads. In both species, the spikelets are few-flowered and there are no lodicules. In *O. stocksii* and in *D. strictus*, the palea is keeled and ciliate on the keels and the paleas of the upper flowers are not keeled. The stamens have short-apiculate anthers and free filaments. Another important character is the vestiture of style and stigma. In both species, the style is sparsely ciliate and ends in a single feathery stigma. In *O. stocksii* and other species of the genus *Dendrocalamus* the basal nodes bear aerial roots.

Oxytenanthera stocksii can be easily separated from *Dendrocalamus strictus* by the distinct auricles and bristles in the culm sheath, comparatively large leaves (15–22 × 1.5–2.5 cm), slender spikelets, slightly apiculate anthers with short filaments, elongated ovary, and oblong caryopsis.

The above observations support the separation of *Oxytenanthera stocksii* from the genera *Oxytenanthera*, *Pseudoxytenanthera* and *Gigantochloa*, which justify its inclusion within the genus *Dendrocalamus*. Morphological characteristics of *D. stocksii* are compared with those of the type species of *Dendrocalamus*, *Oxytenanthera*, *Pseudoxytenanthera*, and *Gigantochloa* in Table 1.

While describing *Oxytenanthera stocksii*, Munro had also noticed its simi-

TABLE 1. Comparison of *Dendrocalamus stocksii* to *Dendrocalamus strictus, Oxytenanthera abyssinica, Pseudoxytenanthera monadelpha* and *Gigantochloa atter* (The type species of genera).

Characters	*D. strictus*	*D. stocksii*	*O. abyssinica*	*P. monadelpha*	*Gigantochoa atter*
Culm surface	matt, wax furry	glossy, wax thin	glossy, wax thin	glossy, wax thin	glossy, wax thin
Culm wall thickness	thick walled	thick walled	thick walled	moderately thick walled	moderately thick walled
Culm sheath auricle	small and rudimentary	well-developed with oral setae	small and rudimentary	well-developed with oral setae	well-developed with oral setae
Spikelets	2-3 flowered	2-3 flowered	1-3 flowered	1-3 flowered	3-4 flowered
Lemma	sparsely hairy	glabrous	sparsely hairy	glabrous	glabrous
Apex of anthers	slightly apiculate	slightly apiculate	perfectly apiculate	perfectly apiculate	perfectly apiculate
Filaments	free	free	United	united	united
Stigma	single	single	Three	three	single

larity to *Dendrocalamus strictus*. The type specimen of *O. stocksii*, housed at Kew (K), is annotated as *D. stocksii* Munro, and therefore it is evident that Munro had previously considered this species within *Dendrocalamus*. However, he treated the species within *Oxytenanthera* due to the presence of slightly apiculate anthers and striated membranous lower palea. The similarities between this species and *Dendrocalamus* were also mentioned by Gamble (1896) who pointed out that the narrow leaves, long petioles and culm sheath were similar to that of *D. strictus*. These similarities also led to the misidentification of this species by subsequent authors. All the previous studies including that of Munro and Gamble were merely based on herbarium specimens, and some of the field characters and floral characters such as the nature of filaments, ovary, palea etc., were omitted. Therefore, they did not observe the correct and distinct characteristics of the species. The field observation on the floral and vegetative characters confirm the present concept of the species and hence a new combination within *Dendrocalamus* is proposed.

This bamboo species, which is economically important, is widely cultivated throughout South India and is utilized for house construction, basket making, ladders, poles, and for several other purposes.

SYSTEMATIC TREATMENT

Dendrocalamus stocksii (Munro) M. Kumar, Remesh & Unnikrishnan, comb. nov. *Oxytenanthera stocksii* Munro, Trans. Linn. Soc. London 26:130. 1868. *Pseudotenanthera stocksii* (Munro) R.B. RESUMEN

Se describe una nueva especie de *Struthanthus* (Loranthaceae) para Costa Rica. Además se adjunta una clave para las especies del genero presentes en el país, incluyendo taxas no reportados aún, pero presentes en zonas cercanas de Nicaragua y Panamá.

ABSTRACT

A new species of *Struthanthus* from Costa Rica is described. A key to the species currently known for the country is given, including two species recorded from Panama and Nicaragua, but not reported from Costa Rica yet.

La familia Loranthaceae está ampliamente representada a lo largo del trópico, conteniendo alrededor de unos 60 géneros y 1000 especies (Kuijt 2001). En Costa Rica se han reportado hasta la fecha 6 géneros y unas 28 especies (Morales, en prep.). Este grupo de plantas está ampliamente distribuido y se encuentra en una amplia gama de habitads y ecosistemas, encontrándose desde el nivel del mar hasta los 3200 metros sobre el nivel del mar, tanto en bosques secos a muy húmedos o áreas semiparamosas o páramos. Su forma de crecimiento les ubica en una posición muy particular desde el punto de vista antrópico, ya que en cultivos frutales representa un problema que se refleja en la disminución de la producción al parasitar dichos cultivos, mientras que en el manejo de los bosques naturales son una fuente de alimento para varias especies silvestres, principalmente aves.

Struthanthus es un género neotropical constituido por unas 70 especies (Kuijt 2001), de las cuales se conocen para Costa Rica 13 especies. Dentro de la familia se puede confundir con *Panamanthus*, pero este último se distingue por tener inflorescencias con las flores solitarias, mientras que en *Struthanthus* las flores están dispuestas en diadas o tríadas. También se puede confundir con *Phthirusa*, cuyo carácter diferenciante radica en la presencia de flores usualmente bisexuales, en contraste con *Struthanthus* que posee flores funcionalmente unisexuales.

En los últimos 15 años, la exploración de regiones montañosas y prácticamente inexploradas del Valle de Candelaria en Acosta, San José y de la Vertiente Atlántica de la Cordillera de Talamanca, Limón, han producido la descripción de varios taxa (Hammel & Zamora 1990, 1993; Morales 1997, 1999), algunos de ellos localmente endémicos y restringidos a estas zonas geográficas. Durante la preparación del tratamiento de Loranthaceae para el Manual de la Flora de Costa Rica, se encontró una nueva especie de *Struthanthus*. Conocida hasta el momento de las áreas geográficas antes expuestas, se describe a continuación.

Struthanthus acostensis L.A. González & J.F. Morales, sp. nov. (**Fig. 1, 2**). TIPO. COSTA RICA. SAN JOSÉ: Acosta, Valle del Candelaria, Fila Zoncuano, 1000–1050 m, 20 Jul 1995 (fl), *Morales 4582* (HOLOTIPO: INB; ISOTIPO: MO).

A *S. burgeri* Kuijt cui affinis, corollae sessilis differt.

Epífita escandente, hemiparásita. Entrenudos de las hojas de 1.5–6.5 × 1.5–4.0 mm. Tallos teretes a subteretes, esparcidamente ferrugineo-lenticelados. Hojas opuestas a subopuestas, pecíolos de 3–8 mm de largo y 1.5–2.0 mm de ancho, con sus bordes continuos a los márgenes de la lamina; lamina de 8.0–12.5 cm de largo y 3.5–8.2 cm de ancho, ovada a elíptica, estrechándose gradualmente hacia el ápice, aguda, atenuada a cuneada basalmente, borde entero y ligeramente revoluto cuando seco, esencialmente glabra, venación pinnada, venas secundarias de 3-9 pares conspicuas, las terciarias conspicuas y a veces formando retículos. Inflorescencias 1 a 6 por axila, 0.7–4 cm, con 2–4 tríadas, subtendidas por bracteas de 0.7–2 mm, una por cada flor; pedúnculo 0.3–2.5 cm de largo, raquis de las tríadas 1.5–7.0 mm de largo; flores amarillentas, sésiles, unisexuales; las masculinas desconocidas, las pistiladas 4–5 mm de diámetro, corola ca. 3 mm, estaminodios fusionados con los pétalos, estilo apical, estigma capitado. Fruto 4.0 × 3.0 mm de diámetro, anaranjado al madurar, subgloboso, obtuso en la base, la superficie cubierta con numerosas y diminutas ranuras o cavidades.

Distribución. —esta especie se encuentra en bosques muy húmedos en la Fila Zoncuaco (Acosta) en el Valle del Candelaria, y en la Cordillera de Talamanca (Alto Urén), a elevaciones entre 700–1100 m. Floración y fructificación entre Julio y Agosto.

Struthanthus acostensis se reconoce con facilidad por sus inflorescencias con 2–4 tríadas pediceladas, flores y frutos sésiles y tallos teretes a subteretes. Anteriormente esta especie fue identificada como *Panamanthus panamensis* (Rizzini) Kuijt, pero este taxa se caracteriza por sus flores solitarias, contrastando con *Struthanthus acostensis* que posee flores en tríadas. También ha sido identificada como *S. burgeri* Kuijt; sin embargo, esta última especie se caracteriza por poseer inflorescencias con más de 4 tríadas y flores pediceladas, mientras que *S. acostensis* tiene flores sésiles dispuestas en inflorescencias de 2 a 4 tríadas. Por otro lado, se puede separar con facilidad de *S. oerstedii* (Oliv.) Standl. por sus hojas muchísimo más grandes, pecíolos más largos y desarrollados, así como por sus flores más grandes y distribución geográfica y preferencias ecológicas distintas.

La etimología de la especie hace referencia a la localidad tipo, zona de cuyas

A continuación se presenta una clave para las especies del género *Struthanthus* conocidas hasta el momento para Costa Rica. Dos especies adicionales, reportadas en zonas limítrofes de Panamá y Nicaragua que podrían encontrarse eventualmente en el país son incluidas.

1. Tríadas sésiles o subsésiles en la antesis, el pedúnculo ausente o inconspicuo, menos de 1.5 mm largo, algunas veces algunos elongados en fructificación (*Struthanthus orbicularis*), pero entonces los frutos más de 9 mm largo al madurar.
    2. Inflorescencias con numerosas brácteas basales papelosas, dispuestas justo en la articulación con las ramitas; tallos viejos (algunas veces los jóvenes y las inflorescencias) conspicuamente lenticelados, las lenticelas 1–2 mm diámetro ____ **S. leptostachyus** (Benth.) G. Don.
    2. Inflorescencias sin brácteas papelosas basalmente o si presentes, entonces inconspicuas o rápidamente deciduas antes de la antesis; tallos viejos sin lenticelas o si presentes, entonces muy pequeñas y menos de 1 mm de diámetro.
        3. Tallos nuevos conspicuamente cuadrangulares o angulados, los más viejos sin lenticelas; hojas nuevas prensiles; frutos 9–13 mm largo, anaranjado púrpura, azul-púrpura, púrpura a negro-púrpura al madurar ____ **S. orbicularis** (Kunth) Blume
        3. Tallos nuevos subteretes a muy obscuramente subangulados, los viejos con lenticelas menos 1 mm de diámetro o sin lenticelas; hojas nuevas no prensiles; frutos 4–5 mm largo, anaranjados a rojizo-anaranjados al madurar.
            4. Láminas anchamente agudas, redondeadas a obtusas apicalmente; tallos diminutamente lenticelados cuando viejos ____ **S. costaricensis** Standl.
            4. Láminas acuminadas a agudas apicalmente; tallos usualmente no lenticelados cuando viejos.
                5. Bosques húmedos de bajura de la Zona Norte & Vertiente Atlántica bajo los 500 m; venación conspicuamente impresa ____ **S. woodsonii** Cufod.
                5. Bosques húmedos de las Cordillera Central & de Talamanca sobre los 1000 m; venación inconspicuamente impresa ____ **S. cansjerifolius** (Oliv.) Eichler
1. Tríadas conspicuamente pedunculadas, algunas veces una pocas espigas subsésiles, pero predominando en el resto un pedúnculo obvio.
    6. Tallos más jóvenes usualmente irregularmente cuadrangulares o angulados.
        7. Láminas muy anchamente obovadas a suborbiculares ____ **S. hartwegii** (Benth.) Standl.
        7. Láminas elípticas, ovado-elípticas a ovadas o lanceoladas.
            8. Inflorescencias con numerosos tríadas, con al menos (5–)7 tríadas; áreas (900–)1500–3000m ____ **S. quercicola** (Schltdl. & Cham.) Blume
            8. Inflorescencias con 3 pares de tríadas; áreas alrededor 600–700 m ____ **S quadrangularis** Kuijt
    6. Tallos usualmente teretes a subteretes, nunca irregularmente cuadrangulares.
        9. Inflorescencias usualmente con 2–3(–4) tríadas.
            10. Láminas acuminadas apicalmente; tallos muy escazamente lenticelados ____ **S. subtilis** Kuijt

Fig. 2. *Struthanthus acostensis* L.A. González & J.F. Morales (*Morales 4582*, INB). **A.** Detalle de las inflorescencias.

10. Láminas agudas a obtusas apicalmente.
    11. Lámina 1.7–6(–8.5) × 0.7–3.3(–4) cm; peciolo 1.5–3 mm largo bosques; secos a bosques húmedos ________ **S. oerstedii** (Oliv.) Standl & Calderón
    11. Lámina 8.0–12.5 × 3.5–8.2 cm; peciolo 3–8 mm largo; bosques muy húmedos ________ **S. acostensis** L.A. González & J. F. Morales
9. Inflorescencias usualmente con más de (4–)5 tríadas; tallos sin lenticelas o esparcidamente lenticelados, las lenticelas no ferrugíneas.
    12. Lámina comúnmente obovada a elíptico-obovada, la venación conspicuamente impresa, los nervios secundarios más basales dando la sensación de una venación palmada; áreas de bosques secos de Guanacaste & Península de Nicoya, 0–600 m ________ **S. cassythoides** Millsp. ex Standl.
    12. Lámina elíptica, ovado-elíptica, anchamente-elíptica o elíptico-lanceolada, la venación inconspicua o levemente impresa, pero los nervios basales no pareciendo palmados, sino típicamente pinnados; áreas de bosques húmedos.
        13. Flores y frutos (todos) conspicuamente pedicelados ________ **S. burgeri** Kuijt
        13. Flores y frutos sésiles, usualmente algunas veces algunos frutos laterales pedicelados, pero siempre el resto sésil.
            14. Venación conspicuamente impresa en ambas caras de la hoja; bosques húmedos de bajura de la Zona Norte & Vertiente Atlántica bajo los 500 m ________ **S. woodsonii** Cufod.
            14. Venación inconspicuamente impresa en ambas caras de la hoja; Bosques húmedos de las Cordillera Central y de Talamanca sobre los 1000 m ________ **S. cansjerifolius** (Oliv.) Eichler

AGRADECIMIENTOS

Esta publicación fue financiada por la Asistencia Holandesa para el Desarrollo (NEDA) a través del proyecto "Desarrollo del Conocimiento de la Biodiversidad y Uso Sostenible en Costa Rica" conducido por el Instituto Nacional de Biodiversidad (INBio). Además, la investigación fue posible además gracias al convenio de cooperación entre el Ministerio de Ambiente y Energía (MINAE) e INBio con el fin de completar en Inventario Nacional de Biodiversidad.

ABSTRACT

Taxonomic limits of *Gonolobus* (Apocynaceae: Asclepiadoideae) in the southeastern United States have been controversial, with some authors recognizing two species and others only one. Over the past 30 years, most authors have tended toward recognition of a single species. However, the morphological variation within the taxon appears complicated and has not been analyzed using a quantitative approach. We analyzed the morphological variation within southeastern *Gonolobus*, based on 143 herbarium specimens from 13 southeastern states, using ANOVA, and mapped taxon distributions. Two distinct *Gonolobus* entities, based on differences in floral character states and geographic tendencies, appear to exist in the southeast, although questions regarding rank recognition remain.

RESUMEN

Los límites taxonómicos de *Gonolobus* (Apocynaceae: Asclepiadoideae) en el sureste de los Estados Unidos han sido controvertidos, con unos autores que reconocen dos especies y otros sólo una. En los últimos 30 años, la mayoría de los autores han tendido al reconocimiento de una sola especie. Sin embargo, la variación morfológica del taxon parece complicada y no ha sido analizada usando métodos cuantitativos. Hemos analizado la variación morfológica en los *Gonolobus* del sureste, en base a 143 especímenes de herbario de 13 estados del sureste, usando ANOVA, y distribuciones cartográficas del taxon. En el sureste parecen existir dos entidades distintas de *Gonolobus*, basadas en diferencias de los estados de carácter florales y las tendencias geográficas, aunque aún quedan cuestiones acerca del rango que merecen.

Climbing milkweeds (Apocynaceae: Asclepiadoideae and Periplocoideae) encompass at least two taxonomically difficult genera in the southeastern United States—*Matelea* and *Gonolobus* (Drapalik 1969; Sundell 1981; Rosatti 1989; Liede 1997). Two closely-related species of *Gonolobus* Michx. have until recently been recognized from the southeastern United States, although opinions over generic placement have differed. Woodson (1941) considered that the genus *Gonolobus* should contain plants characterized by only long, eglandular trichomes, dorsal anther appendages, and smooth, angled or winged follicles, whereas *Matelea* Aubl. should contain plants characterized by glandular and eglandular trichomes, anthers lacking dorsal appendages, and muricate follicles. Unconvinced that dorsal anther appendages should serve as a generic character and citing examples of smooth [but not angled or winged] fruits in *Matelea*, Shinners (1950) argued against Woodson's generic concept and transferred the southeastern

SIDA 21(1): 103 – 116. 2004

Gonolobus taxa to *Matelea*. Later, Shinners (1964) also included twelve of Woodson's (1941) *Gonolobus* combinations in *Matelea*. Drapalik (1969) maintained Shinners' generic view, although admitting to the characteristic differences of southeastern *Gonolobus* from southeastern *Matelea* species in bearing dorsal anther appendages and smooth, winged follicles. Taking a broader geographical perspective of generic morphology and citing the importance and development of anther appendages in the 150 some species of *Gonolobus* outside the southeastern United States, Rosatti (1989) argued for renewed placement of the southeastern taxon in *Gonolobus*. Most recently the concept of *Gonolobus* as characterized by short, capitate-glandular, short acicular, and long acicular trichomes, dorsal anther appendages (typically), and smooth, winged follicles has been used by Stevens (2001). The two *Gonolobus* species historically recognized from the southeastern United States—*Gonolobus suberosus* (L.) R. Br. and *Gonolobus gonocarpos*—have been distinguished primarily by the ratio of corolla lobe length to sepal lobe length and the presence or absence of pubescence on the adaxial corolla surface (Small 1933; Perry 1938; Fernald 1950; Gleason 1952; Radford et al. 1968). Most authors essentially followed Small (1933) in referring the taxon with glabrous corollas and lobes more than twice as long as the sepals to *G. gonocarpos* and the taxon with pubescent corollas and lobes twice as long or less than the sepals to *G. suberosus* (Perry 1938; Fernald 1950; Gleason 1952; Radford et al. 1968). In contrast, Drapalik (1969) considered the two taxa synonymous, having found "plants that would represent both [...] taxa and every conceivable intermediate." However, he stressed that in no manner should his decision be taken to acknowledge that the taxon was uniform throughout its range. Considering that *G. gonocarpos* is state listed as threatened in Florida (Florida Administrative Code Ch. 5B- 40.0055), this study seeks to re-examine the taxonomy of the southeastern *Gonolobus* complex by critically analyzing patterns of morphological variation and their geographical relationships using a quantitative approach.

METHODS

A total of 326 herbarium specimens (from nineteen herbaria) were examined from throughout the range of the southeastern *Gonolobus* complex (i.e., AL, AR, FL, GA, KY, LA, MS, NC, OK, SC, TN, TX, and VA). We selected 143 herbarium specimens (the OTUs in the analysis) for our analyses—the rest were either too poor in condition or lacked some or all organs. Six characters (Table 1), three quantitative and three qualitative, showed variation within the group and were thus chosen for the analysis. Only mature flowers were chosen for scoring of floral characters.

Leaf shape/size and vestiture characters were not chosen for inclusion in the analysis. These characters were not rejected due to high variability, but due to lack of basic understanding regarding intra-individual variation. Leaf size and shape may be influenced by position on the stem (e.g., sun vs. shade leaves) and habitat (e.g., edge vs. forest interior) (Krings, pers. obs.). As collectors rarely indicate the stem position from which samples were taken, parallel comparisons of herbarium specimen leaf material (i.e., comparing sun leaves to sun leaves) is essentially impossible. Leaf pubescence characteristics were also considered uninformative with regard to southeastern *Gonolobus*. Our chi-square tests suggested no correlation between leaf pubescence and either floral character states or the environment (i.e., habitat), as might be expected (unpubl.).

Although inflorescence characters (type and number of flowers borne) have been useful in higher level analyses in the Asclepiadoideae (e.g., Liede 1996, 1997), inflorescence characters were not included in our study based on results of a preliminary analysis of 48 *Gonolobus* specimens chosen primarily from the extremes of the range (i.e., Florida and Texas). ANOVA results showed no significant difference ($F=0.865<F_{Crit}=4.05$) in the mean number of flowers per inflorescence between uniformly-colored and multi-colored specimens (Krings, unpubl.). In the preliminary analysis, flowers were counted for any inflorescence bearing at least one fully opened flower (i.e., corolla lobes completely extended). As flowers are produced sequentially over the life of the inflorescence, visible flower buds were included in the total count of flowers per inflorescence. Specimens chosen for inclusion were those most robust overall—a somewhat arbitrary judgment of the number of inflorescences available and their condition.

Due to the high similarity of fruits of *Gonolobus* in the southeast, collections of the same individuals in flower and fruit would be required to allow correlative evaluation of fruit character utility. Unfortunately, the extremely small number of such collections is inadequate for such an evaluation at this time.

A data matrix was produced by scoring the character states of five characters for all 143 OTUs (see below & Table 1). There were no gaps in the data matrix. A neighbor-joining tree was generated using PAUP 4.0 (Swofford 2002). Frequency distributions were also determined for selected floral character states and tested for significant differences using ANOVA.

Characters

1. *Floral color.*—Individuals of the southeastern *Gonolobus* complex exhibit flowers that are either uniformly green from corolla lobe base to apex or conspicuously dark at the base (variously described as maroon to brown) with lighter tips (typically green). Specimens bearing the former were scored as uniformly green (1) and specimens exhibiting the latter as multi-colored (0) for corolla lobe coloration. On senescing, greenish flowers tend to turn yellowish.

2. *Adaxial corolla vestiture.*—Adaxial corolla vestiture is an important character that has been used to recognize species in the southeastern *Gonolobus* complex (see Small 1933; Gleason 1952; Radford et al. 1968). Adaxial corolla lobe pubescence tends to be laterally distributed. Pubescence is generally concentrated on the right side of corolla lobes (from apex to base) and may extend longitudinally to various degrees across the lobe center to the left. The far left margins (from apex to base) tend to be glabrous in otherwise pubescent flowers. The same asymmetry was also evident in Caribbean species available to us for inspection and may be the case for all pubescent *Gonolobus* species—although such analysis was presently beyond our scope. Specimens were scored as pubescent (0) if pubescence to any degree was observed on the adaxial corolla lobes and glabrous (1) if no pubescence was evident.

3. *Corona.*—Corona characters have in the past been used to distinguish asclepiad genera (see Liede 1996), although caution must be employed if the true homology is not known (see Liede 1996; Liede & Täuber 2002). In our study, we evaluated only the shape of the corona lobes among members of the southeastern *Gonolobus* complex. All coronas in the complex are lobed. However, not all lobes are further lobed (i.e., emarginate at the apex). We scored corona lobes to be either lobed (i.e., emarginate at the apex)(0) or truncate (i.e., squared off at the apex) (1).

4–6. *Quantitative floral characters.*—Measurements of sepal and petal length were taken from between 1 to 5 flowers per specimen, depending on availability and measurability. Flowers with excessive contortion and folding of petals and sepals were avoided. In general, measurements were taken from different flowers, although in a few cases, when availability was poor and lobe length varied infraflorally, multiple corolla lobes were measured from a single flower. For generation of a nearest-neighbor tree, continuous sepal and corolla lobe lengths were coded into one of five range classes and treated as unordered in the analysis (Table 1). The ratio of mean corolla lobe length to mean sepal length was not used in the generation of the nearest-neighbor tree.

RESULTS

It appears that at least two distinct groupings of *Gonolobus* taxa exist in the southeastern United States. The clustering of taxa exhibits strong geographic tendencies (Fig. 1), although petal and sepal length intergrade among OTUs when graphed in a scatterplot (Fig. 2). Based on corolla coloration, taxa can be assigned to one of two groups: (1) a uniformly colored corolla group (UCCG) and a multi-colored corolla group (MCCG). The UCCG is considerably more widespread and exhibits a more western center of gravity relative to the MCCG (Fig. 1). Adaxial corolla pubescence is nearly invariable in the UCCG. Only 3.7% (3 of 81) of the examined individuals exhibit pubescent adaxial corolla surfaces (Fig. 3). Although individuals with uniformly colored petals have been collected in the far eastern states of Georgia, North Carolina, and Virginia, these tend to be rare collections disjunct from the main range of occurrence (Fig. 1).

Table 1. Floral characters and character states. Character 6 used in ANOVA only and not in generation of neighbor-joining tree due to lack of independence vis-á-vis characters 4 and 5.

Character	Character State	
1. Adaxial corolla coloration	Multi-colored (dark center, lighter tips) [0]	Uniformly green [1]
2. Adaxial corolla vestiture	Pubescent [0]	Glabrous [1]
3. Corona	Lobed [0]	Truncate [1]
4. Mean sepal length (mm)	1.5–2.5 [0], 2.51–3.5 [1], 3.51–4.5 [2], 4.51–5.5 [3]	
5. Mean corolla lobe length (mm)	2.01–4 [0], 4.01–6 [1], 6.01–8 [2], 8.01–10 [3], >10.01 [4]	
6. Ratio of Mean corolla lobe length: Mean sepal length	Continuous	

Adaxial corolla pubescence is much more frequent among members of the MCCG (Fig. 3). In fact, two thirds of the examined individuals in this group were pubescent (41 of 62). The MCCG appears to be restricted to a more narrowly defined southeastern range east of the Mississippi (Fig. 1).

Except for a few outliers (e.g., GA2, NC20, VA1, VA23), the geographic clustering is supported by the midpoint-rooted neighbor-joining tree (Fig. 4). Although bootstrapping yielded little support for any one branch of the tree (due to the small number of characters employed), the tree remains informative. Members of the MCCG and UCCG are grouped together—indicating greater within-group similarity across the five morphological characters than between groups.

Individuals of the UCCG exhibit longer mean corolla lobes (mean=7.68) and higher mean corolla lobe length to mean sepal length ratios (mean=2.48) than individuals of the MCCG (Table 2). Results of analyses of variation (ANOVA) indicate the differences in both mean corolla lobe length and corolla:sepal length ratio to be highly statistically significant between the two groups (Table 3).

It is interesting to note that the rare pubescent individuals of the predominantly glabrous UCCG appear to exhibit a similar frequency distribution of corolla lobe lengths and corolla:sepal ratios as pubescent members of the MCCG. ANOVA tests show no significant difference between pubescent UCCG and pubescent MCCG in both mean corolla lobe lengths ($F=0.042 < F_{Crit}=3.99$) and the ratio ($F=0.604 < F_{Crit}=3.99$)—although this may be a factor of the small sampling size of pubescent UCCG members (n=3). Glabrous members of the MCCG appear to exhibit corolla lobe lengths much larger than the more frequent (in terms of specimens examined) pubescent members of the MCCG (Fig. 5B). However, the difference in mean corolla lengths between glabrous and pubescent MCCG is not quite significant ($F=3.559 < F_{Crit}=3.96$). The difference in the

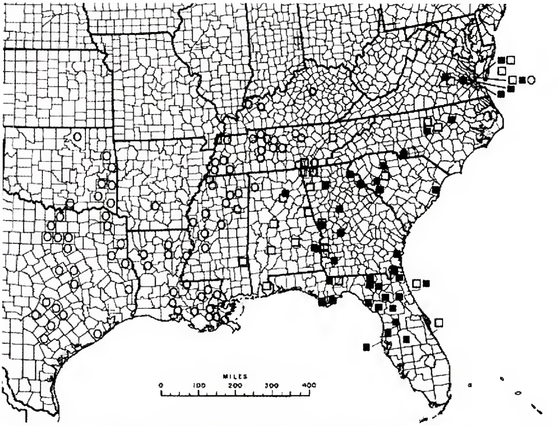

Fig. 1. Distribution map of southeastern United States *Gonolobus* entities. Circles represent individuals with uniformly green corollas—either glabrous adaxially (open circle) or pubescent (closed circle). Squares represent individuals with multi-colored corollas—either glabrous adaxially (open square) or pubescent (closed square).

corolla:sepal ratio between glabrous and pubescent MCCG members is also not quite significant ($F=3.746 < F_{Crit}=3.96$). Although the frequency peak for corolla:sepal ratios of glabrous MCCG members appears to graphically coincide with the peak of glabrous UCCG members (Fig. 5C & D), ANOVA results show a strong statistical difference between the two ($F=9.467 > F_{Crit}=3.93$).

DISCUSSION

The issue of whether more than one *Gonolobus* species should be recognized for the southeastern United States has long confronted taxonomists and has been additionally complicated by the nomenclatural confusion surrounding *Gonolobus suberosus* (L.) R.Br. (see Drapalik 1969; Reveal & Barrie 1992). Small (1933), and later Perry (1938), recognized two species of *Gonolobus* in the Southeast based on corolla pubescence and the ratio of corolla lobe length to sepal length. Small (1933) referred the taxon with glabrous corollas and lobes more than twice as long as the sepals to *G. gonocarpos* (*Vincetoxicum gonocarpos* sensu Small), whereas the taxon with pubescent corollas and lobes twice as long or less than the sepals was referred to *G. suberosus* (*V. suberosum* sensu Small).

Fig. 2. Scatterplot of sepal vs. petal length by flower color and adaxial petal vestiture for *Gonolobus* entities in the southeastern United States.

Fernald (1950) added some less than distinct characters to the mix, including flower bud ("abruptly acuminate" vs. "gradually acute or acuminate"), calyx pubescence ("practically glabrous" vs. "glabrous or ciliolate apically"), and corolla lobe shape ("broadly lanceolate" vs. "linear-lanceolate"), while basically maintaining Small's (1933) pubescence and ratio characters. Gleason (1952) treated only *G. gonocarpos*, stating that *G. suberosus* was "erroneously" accredited to the range of Britton and Brown's flora. However, in a footnote, Gleason (1952) maintained the distinction between the taxa based on adaxial corolla pubescence, forwarded by previous authors (Small 1933; Perry 1938; Fernald 1950). In light of the present analyses, these concepts of specific delimitation are untenable as stated.

Drapalik's (1969) findings of overlapping combinations of character states among *Gonolobus* taxa in the southeast are upheld by our study. However, overlapping character presence/absence combinations are insufficient argument against recognition of multiple taxa. Especially at the infraspecific level and in hybrid zones, some level of character overlap can be expected between individuals sharing some range continuity. Our data support the notion of previous workers (e.g., Small 1933; Perry 1938; Fernald 1950; Gleason 1952), that at least two *Gonolobus* entities occur in the Southeast that could be accorded for-

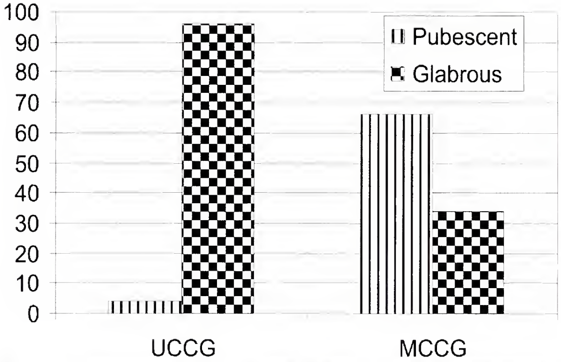

Fig. 3. Percentage of *Gonolobus* specimens exhibiting pubescent or glabrous adaxial corolla lobes in the respective uniformly colored corolla group (UCCG) and the multi-colored corolla group (MCCG).

mal rank. However, contrary to previous workers, we propose that the two groups respectively be defined by uniformly-green versus multi-colored corolla lobes, rather than by corolla/sepal length and adaxial corolla lobe pubescence. Although there are significant differences in mean corolla lobe lengths and the ratio of corolla lobe length to sepal length (Table 3), these character states can overlap at the individual level and cannot consistently separate the taxa. Similarly, adaxial corolla pubescence cannot consistently separate the taxa, being present in both members of the UCCG and the MCCG. However, distinct differences are apparent in the frequencies of the pubescence trait (Figs. 3 & 5). In addition, with respect to their geographic distribution, the frequency of glabrous, multi-colored flower collections increases conspicuously in the zones where the UCCG meets the MCCG (e.g., in Alabama). Similarly, the rare individuals bearing adaxially pubescent, uniformly green corollas occur well within the range of the MCCG. Thus, the respective changes in pubescence frequencies in the MCCG or occurrence of rare character states in the UCCG outside its primary range may be cautiously hypothesized to be an effect of genetic interchange between two taxa intergrading in distribution.

Unfortunately, frequency histograms of corolla lobe length and ratio of corolla lobe length:sepal length size classes within the UCCG and MCCG shed weak light on the matter of intergradation (Fig. 5). Although our analyses support the recognition of two *Gonolobus* entities in the Southeast, the question remains whether these should be recognized at the species level or below. Our

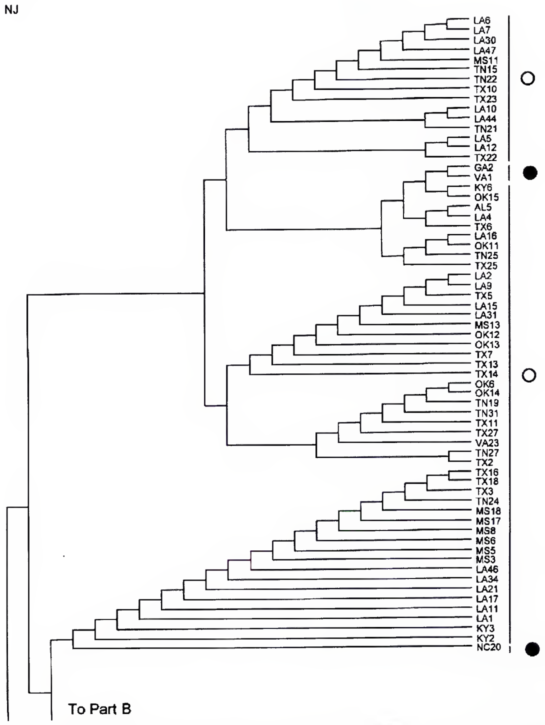

Fig. 4 (Part A). Midpoint-rooted neighbor-joining tree, based on five morphological characters. OTUs are individual specimens of *Gonolobus*. First two characters of alphanumeric code indicate state of origin by standard abbreviation. Second two characters are a unique, sequential number assigned to each specimen studied. Circles represent individuals with uniformly green corollas—either glabrous adaxially (open circle) or pubescent (closed circle). Squares represent individuals with multi-colored corollas—either glabrous adaxially (open square) or pubescent (closed square).

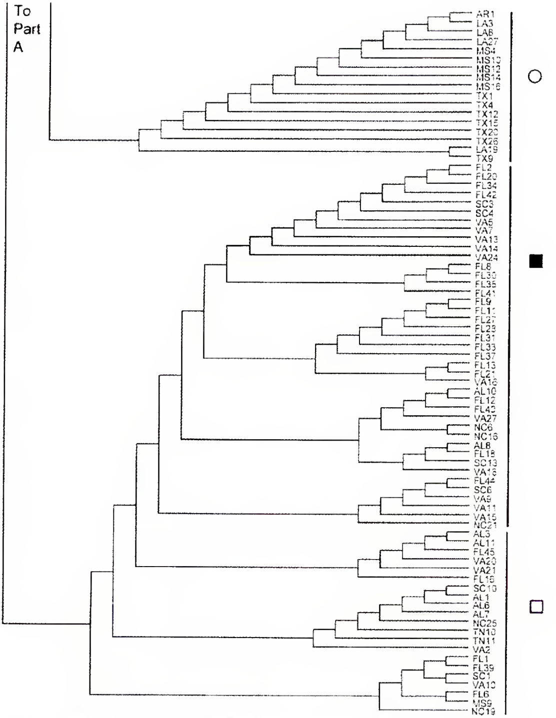

Fig. 4 (Part B).

data can be interpreted either way—two morphologically divergent species potentially hybridizing in overlapping zones, resulting in some morphological intergradation, or two diverging subspecies with morphological intergradation in zones of range overlap. The former interpretation could result from application of a quantitative or phenetic species concept, in which species are distinguished based on differences in means of variables. Although commonly

Table 2. Descriptive summary statistics for continuous floral characters of the uniformly colored corolla group (UCCG) and the multi-colored corolla group (MCCG).

	Mean sepal length	**Mean corolla lobe length**	**Mean ratio (corolla lobe length: sepal length)**
Uniformly colored	3.21 (SD=0.76)	7.68 (SD=1.47)	2.48 (SD=0.61)
Multi-colored	3.08 (SD=0.74)	5.59 (SD=1.73)	1.83 (SD=0.44)

Table 3. ANOVA results for floral character comparisons between the uniformly colored corolla group and the multi-colored corolla group. In both cases, the null hypothesis of no significant difference is rejected.

applied, the underlying theory of this concept remains unclear (see Luckow 1995). In contrast, application of a phylogenetic species concept suggests two infraspecific taxa—populations exhibiting high frequencies of unique traits that may become 'fixed' in the future (Nixon & Wheeler 1990). However, a cladistic analysis that includes other congenerics is necessary to test this hypothesis (Nixon & Wheeler 1990). In the absence of additional data, we cautiously choose to follow (Drapalik 1969) in recognizing a single species until additional evidence is available. Interestingly, the overall biogeographic pattern exhibited by the two *Gonolobus* entities has been observed for other taxa (including fish!) in the Southeast (see Avise 1994) and may be the result of past environmental shifts such as the oceanic incursions and retreats that define today's southeastern Coastal Plain (Sorrie & Weakley 2001). To further elucidate both the question of rank and evolutionary history of the complex, we are conducting genetic analyses of southeastern *Gonolobus* populations using molecular markers and integrating phylogenetic data from Caribbean *Gonolobus* species—some of which have been suggested to be nearest relatives of the southeastern taxa (Scheele 1848).

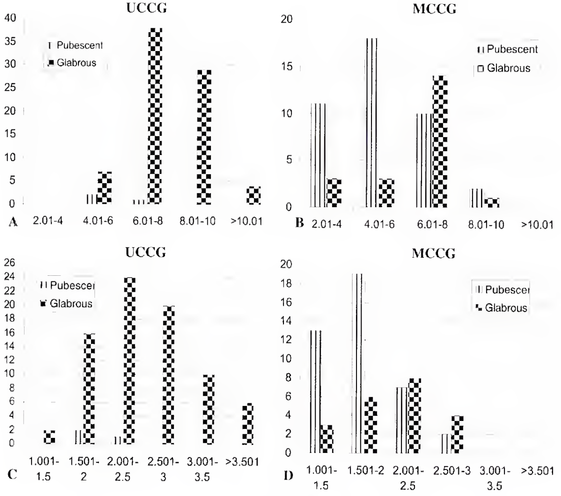

Fig. 5. Frequency histograms for floral characteristics in the uniformly colored corolla group (UCCG) and the multi-colored corolla group (MCCG) of southeastern *Gonolobus*—Corolla lobe length in mm ranges (A: UCCG; B: MCCG) and ratio of corolla lobe length to sepal length (C: UCCG; D: MCCG). Y axes represent number of individuals and X axes respective character state ranges.

Should workers choose to formally recognize the two entities, we provide a brief discussion regarding available names. For more detail regarding the particularly complicated history and nomenclature involved, readers are urged to see Reveal & Barrie (1992) and Krings (2001). In choosing a name for the taxon with uniformly colored petals, past names published for southeastern *Gonolobus* taxa were examined. Walter's type of *Gonolobus gonocarpos* (*Walter 687*, BM!) contains only leaves and roots. In addition, no mention regarding the pubescence of the corolla is made in his protologue (Walter 1788). Thus we cannot be certain to which species the plants that Walter based his description on belong. However, due to the rare occurrence of uniformly colored species in the Carolinas, we propose that his type be considered to belong to the multi-color group. Types for *Gonolobus macrophyllus* Michx. and *Gonolobus laevis* A. Gray, non Michx. are relegated to the multi-color group for the same reason. The protologue of *Gonolobus granulatus* Scheele (1848) is based on the only eligible type specimen collected west of the Mississippi (*Lindheimer s.n.*) and notes glabrous adaxial corolla lobes. Thus, the correct name for the uniformly green-flowered taxon should be based on *Gonolobus granulatus* Scheele and the name for the multi-color flowered taxon should be *Gonolobus suberosus* (L.) R.Br. Alternatively, if the two entities are recognized at the infraspecific level, the correct species name is *Gonolobus suberosus* (L.) R.Br.

ACKNOWLEDGMENTS

We thank the following institutions and their curators for assistance with specimen inquiries, providing photographs of material, and/or providing specimen loans: BM, BRIT, DUKE, FLAS, GA, KY, LL, MISS, MO, NCU, NO, OK, P, TENN, TEX, UNA, USCH, USF, WILLI. Helpful methodological and nomenclatural comments were provided by Tom Wentworth and Paul Fantz, respectively. David Thomas provided PAUP support. Eric Sundell and an anonymous reviewer provided thoughtful comments on a previous version of the manuscript.

POLYPHYLY OF THE GENUS *ECHITES* (APOCYNACEAE: APOCYNOIDEAE: ECHITEAE): EVIDENCE BASED ON A MORPHOLOGICAL CLADISTIC ANALYSIS

Justin K. Williams

Department of Bioloigical Sciences
Sam Houston State University
Huntsville, Texas 77341-2116, U.S.A.

ABSTRACT

A cladistic analysis was performed to test the monophyly of *Echites* (Apocynaceae: Apocynoideae: Echiteae). For the analysis 40 morphological characters were coded for 42 ingroup taxa (22 genera) and three outgroup species (two genera). The results indicate that *Echites* as currently circumscribed is polyphyletic. However, species that fall within the original descriptions of the two subgenera described in *Echites* form monophyletic clades.

Key Words: *Echites*, *Prestonia*, *Thenardia*, and *Thevetia* Apocynaceae, cladistics, morphology, Neo-tropics

RESUMEN

Se realizó un análisis cladístico para comprobar la monofilia de *Echites* (Apocynaceae: Apocynoideae: Echiteae). Para el análisis se codificaron 40 caracteres morfológicos de 42 taxa del grupo (22 géneros) y tres especies como outgroup (dos géneros). Los resultados indican que *Echites* tal como se circunscribe normalmente es polifilético. Sin embargo, las especies que están en las descripciones originales de los dos subgéneros descritos en *Echites* forman clados monofiléticos.

Echites P. Browne was one of the first Neo-tropical Apocynaceae genera established. Consequently, it served as the focal point for the majority of species described in the Neo-tropics. Thus by the mid nineteen-hundreds there were about 375 species of *Echites* described. Woodson (1936) eventually cleared much of the nomenclatural confusion presented by the 300 plus names. In his monumental treatise, Woodson attributed the epithets to an appropriate genus (both newly described and preexisting) and or synonym, recognizing that the species of *Echites* sensu lato represented more than nine different genera. With a foundation established, Woodson (1936, 1938) defined *Echites* sensu Woodson by its twining habit, glabrous salverform corollas without corona, included anthers, and a solitary colleter opposite each of the five sepals. Woodson (ibid) ultimately recognized seven species in the genus that were placed into two subgenera.

Subgenus *Echites* is characterized by having corollas 5–8 cm long, oblique corolla lobes spreading at anthesis, and compact inflorescence with 3–7 flowers (Morales 1997; Williams 2002a). Today four species are recognized in subg.

SIDA 21(1): 117 – 131. 2004

Echites: *E. darienensis* J.F. Morales, *E. turrigera* Woodson, *E. umbellata* Jacq. and *E. yucatanensis* Millsp. (Morales 1997; Williams 2002a).

Subgenus *Psuedechites* Woodson is characterized by having corollas 1.25–2.5 m long, narrowly lanceolate corolla lobes that are reflexed at anthesis and a lax inflorescence with 8–20 flowers (Woodson 1936). Woodson included two species in the subgenus: *E. tuxtlensis* Standl. and *E. turbinata* Woodson. A third species of subg. *Pseudechites* was subsequently described by Monachino (1959): *Echites woodsoniana* Monac. This species would later come to have an intertwining history with *Prestonia* sect *Coalitae* (explained below).

Woodson (1936) divided *Prestonia* into four sections: *Coalitae* and *Acutifoliae*, (both characterized by having small and inconspicuous sepals similar to those of *Echites*); and *Annulares* and *Tomentosae* (both characterized by large foliaceous sepals). Woodson (1931, 1936) included *Prestonia agglutinata* (Jacq.) Woodson (=*Echites agglutinata* Jacq.) in *Prestonia* sect. *Coalitae*. Section *Coalitae* was distinguished from the other three sections of *Prestonia* by its lack of an annular corona at the mouth of the corolla. Woodson (1960) would later describe a second species in sect. *Coalitae* (*P. caudata* Woodson). Later, Gentry (1983) transferred *Echites woodsoniana* Monac. to *Prestonia* (*P. woodsoniana* (Monac.) Gentry) placing it as a member of sect. *Coalitae*. Because of the confusing nature of generic delimitation in the Apocynaceae, and the lack of an annular corona in *E. woodsoniana*, Gentry (ibid) was not confident of his transfer. J.K. Williams (1996) maintained *E. woodsoniana* in *Echites* because it lacked an annular corona at the mouth of the corolla. Morales (1997) would later include all species of *Prestonia* sect. *Coalitae* in *Echites* stating that the "narrowly elliptic to almost filiform corolla lobes [of the three species]... characterize *Echites* subg. *Pseudechites*".

The intermingling history of *Echites* subg. *Pseudechites* and *Prestonia* sect. *Coalitae* indicates the problems taxonomists have had in defining genera in the Apocynaceae. *Echites* subg. *Pseudechites* is a taxon that superficially resembles *Prestonia* section *Coalitae*, which make its placement within the family difficult.

A cladistic analysis using morphological characters was performed with two main objectives: 1) to assess the monophyly of *Echites* sensu Woodson and 2) to identify the placement and sister taxon of subg. *Pseudechites*.

MATERIALS AND METHODS

Taxa analyzed.—Included in this analysis are representative genera of Apocynoideae known from Mexico and Central America. In addition, Old World genera have been included in the study in order to expand the morphological variation and broad geographic range of the Apocynoideae. I did not intend to test the monophyly of the tribes recognized within the Apocynoideae, which is why a larger sampling of genera was not included. However, the genera that were selected represent four (Apocyneae, Echiteae, Mesechiteae, and Wrightieae) of the five tribes in the Apocynoideae recognized by Endress & Bruyns (2000).

Thevetia L. and *Cerbera* L. were selected as outgroups for the analysis. In previous cladistic studies (Endress et al. 1996; Sennblad & Bremer 1996; Sennblad et al. 1998; Potgieter & Albert 2001) *Thevetia* was indicated as one of the closer relatives to the Apocynoideae, and is appropriate for rooting the tree.

Selection of characters.—A total of 45 taxa, representing 25 genera, were included in the present study. Forty characters, representing 105 character states (Table 1), were scored for every taxon presented in this analysis. Character states were selected from those utilized in previous studies (Struwe et al. 1994; Endress et al. 1996; Sennblad et al. 1998; Potgieter & Albert, 2001; Williams 2002b). New characters not included in the above works, but uncovered during the course of this study were also included. Fifteen of the characters were vegetative and the other 25 were floral or reproductive. Analysis indicates that none of the characters are uninformative. The characters and their rationale are discussed in Appendix 1.

Sampling.—Character measurements and states for the data matrix (Table 2) were obtained from herbarium sheets (specimens and label data) and field observations for every representative species included in this study except *Tintinnabularia gratissima* J.F. Morales, and four species of *Parsonsia* R. Br. (*P. heterophylla*; *P. latifolia* (Benth.) S.T. Blake; *P. praeruptis* Heads & de Lange; *P. purpurascens* J.B. Williams). Data for *T. gratissima* was obtained from Morales (1996). The species of *Parsonsia* were included in the study in order to better represent the diversity of *Parsonsia* (a genus with many superficial similarities to *Thenardia* H.B.K.). Morphological data for the four species of *Parsonsia* were obtained from literature descriptions (J.B. Williams 1996; Heads & de Lange 1998).

With the exception of the species of *Parsonsia*, and *Tintinnabularia gratissima*, a representative specimen is deposited at the Plant Resources Center (TEX) for each of the species examined in the morphological cladistic analysis. Further observations and data were collected from material borrowed from or observed at the following herbaria: BM, BRIT, CHAPA, F, FLAS, G, GH, K, MA, METPEC, MEXU, MO, NY, P, SHST, TAMU, TEX, US, WIS.

The pollen of all genera was studied using a light microscope as well as a scanning electron microscope (Philips 515). All genera were examined and measured under the SEM at the Cell Research Center of the University of Texas at Austin.

Cladistic analysis.—The characters and character states (Table 2) used in the analysis were entered into a data matrix using MacClade 3.0 (Maddison & Maddison 1992). A phylogenetic analysis was then performed in PAUP 3.1 (Swofford 1993). A heuristic search by stepwise addition of random trees was performed with 100 replicates and the ACCTRAN, MULPARS and TBR options

in effect. The option for maximum trees stored was set at 10,000. Taxa with multi-state characters were recognized as polymorphic for those characters. Characters were treated as unordered and of equal weight. At the end of the analysis the stored trees were rooted, with both the outgroup and ingroup directed as monophyletic. A strict consensus (Fig. 1) and a majority rule consensus (Fig. 2) tree of the stored trees were produced. Bootstrap values were calculated using 1,000 replicates with the PAUP settings at: full heuristic search, starting trees obtained via stepwise addition, random search set for additional sequences with 10 replicates, branches collapse if maximum branch length is zero, include groups compatible with 50% majority-rule consensus, include only informative characters. The majority rule tree (Fig. 2) is presented along with bootstrap values near or higher than 50%.

TABLE 2. Data matrix of the 40 informative characters used in the phylogenetic analysis[a,b] presented in this study.

a Character numbers and character states correspond to those in Table 1.

b Polymorphic character states are represented by letters as follows: a=0,1; b=0,3; (within the data matrix character states for polymorphic characters were entered as 0/1 etc. Letters are used here for the convenience of aligning the table).

RESULTS

The data matrix (Table 2) of 45 taxa and 40 characters included no characters that were uninformative. Of the 1800 cells in the matrix 14 (.77%) were scored with a question mark for unknown character states. The data matrix included six characters coded as polymorphic constituting .33% of the entries.

The heuristic search yielded a total of 48 equally parsimonious trees of 159 steps and a consistency index (C.I.) of 0.434 and a retention index (R.I.) of .767. The low consistency index reflects the high level of homoplasy (Kitching et al.1998) within the characters selected. The high level of homoplasy probably also accounts for the lower bootstrap values in the basal branches (Fig. 2), thereby reducing stability in the basal clades. Stability is seen in the terminal branches, which is reflected by the higher bootstrap values (Fig. 2). The discrepancy in support for the basal clades versus the terminal clades is acceptable considering that the main focus of this study was to test the monophyly of genera in the Apocynaceae, in particular *Echites*.

The ingroup taxa formed two large clades. The first large clade, Clade I, is comprised of two clades. In the first of these, the Wrightieae clade is sister to two subclades: one is represented solely *Apocynum* (Apocyneae); the other, the *Prestonia* subclade, is comprised of three smaller subclades of genera from Echiteae, in which the genus *Thoreauea* is sister to the other two; one of these is a subclade composed of *Echites* subgen. *Pseudechites* and the two species of *Thenardia*; the other subclade is composed of *Laubertia* and *Prestonia*. The second group of clades in Clade I is comprised of the genus *Trachelospermum*, which is sister to two subclades: the *Forsteronia* subclade, and the *Parsonsia* subclade, which are comprised solely of these two genera, respectively, the first of which is in Apocyneae and the latter in Echiteae.

In Clade II, *Rhabdadenia* is sister to two clades. The first, the *Echites* clade, includes a subclade of *Angadenia* and *Pentalinon* (Echiteae) and *Odontadenia*

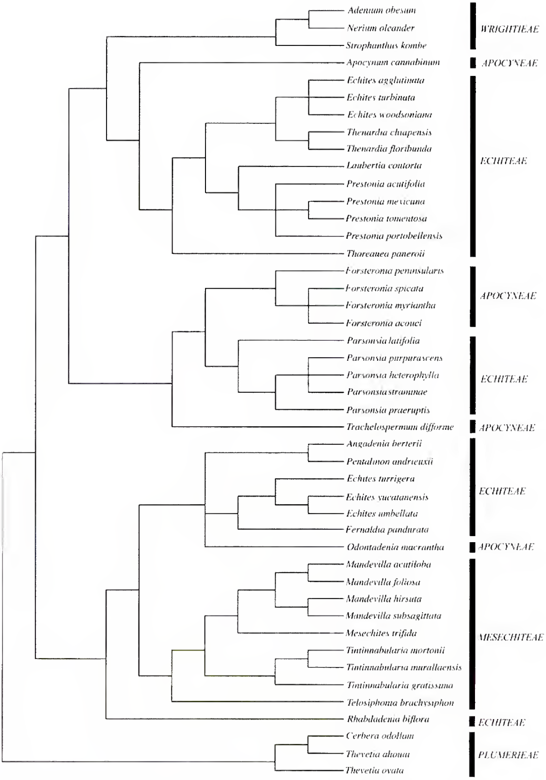

Fig. 1. Strict consensus tree. Taxa in capital letters and to the right of the cladogram indicate Tribes recognized in Endress & Bruyns (2000). Note: *Thoreauea* (Williams, 2002b) was described after Endress & Bruyns (2000) and therefore not included in their treatment. However, *Thoreauea*, as discussed in Williams (2002b), corresponds to the description of the Echiteae and is included in this tribe

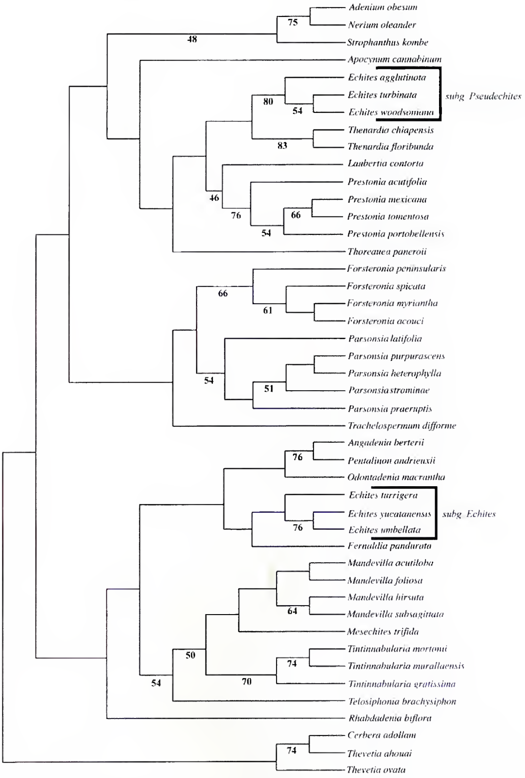

FIG. 2. Majority rule consensus tree calculated from 48 most parsimonious trees (length 165, CI =.434, RI=.767, RC = .333). Numbers below the branches are bootstrap values near or greater than 50%.

(Apocyneae), which is sister to a clade comprised of *Fernaldia* and *Echites* subgen. *Echites* (all Echiteae). The second main clade, the Mesechiteae clade, is composed of representatives of *Mandevilla*, *Mesechites*, *Tintinnabularia* and *Telosiphonia*. Comparing the results obtained here to the latest classification of the family by Endress and Bruyns (2000), the Wrightieae and Mesechiteae are supported as monophyletic, whereas the Apocyneae and Echiteae are polyphyletic.

DISCUSSION

Monophyly of Echites.—The results presented here indicate that *Echites*, as currently circumscribed, is not monophyletic. The placement of subg. *Pseudechites* in a clade both distant and distinct from subg. *Echites* renders *Echites* polyphyletic. This result was not unexpected, since the taxa of subg. *Pseudechites* are morphologically distinct from subg. *Echites* in at least thirteen observable characters (Table 3; three vegetative and 10 floral or reproductive). However, the species that fall within the original description of subg. *Pseudechites* form a well supported (bootstrap 80%) monophyletic clade.

Because of the polyphyletic nature of *Echites* sensu Woodson, based on the number of differences between subg. *Echites* and subg. *Pseudechites*, and the strongly supported monophyletic clade of subg. *Pseudechites*, it is suggested that the species of subg. *Pseudechites* be transferred to a genus separate from *Echites* sensu stricto The new genus and appropriate name combinations are proposed in Morales & Williams (2004).

Phylogeny of subg. Pseudechites.—Both the strict (Fig. 1) and the majority rule (Fig. 2) trees show subg. *Pseudechites* sister to *Thenardia*. A relationship between *Thenardia* and subg. *Pseudechites* was suggested in Williams (1998). The taxa share in common watery sap, leaves with inconspicuous secondary veins, and pollen of similar size. It should be noted however, that despite the similarities in morphology the bootstrap support for the clade comprising *Thenardia* and subg. *Pseudechites* is low (37%). Nevertheless, based on previous observations (Williams 1998) and the data presented here, the hypothesized relationship between *Thenardia* and subg. *Pseudechites* appears relatively sound.

Monophyly and phylogeny of subg. Echites.—Both the strict (Fig. 1) and the majority rule (Fig. 2) trees show subg. *Echites* sister to *Fernaldia* Woodson. There is only one major character difference between subg. *Echites* and *Fernaldia* (salverform vs. infundibuliform corollas; Table 3). It was hypothesized before the analysis that *Fernaldia* might branch with *E. turrigera* Woodson, due to their similar fruit types (follicles fused at the apex; character 32:1) rendering subg. *Echites* paraphyletic. Indeed, bootstrap support (Fig. 2) is 76% for the two subg. *Echites* species with spreading follicles (*E. umbellata* and *E. yucatanensis*) while support for the branch basal to the subg. *Echites* clade is below 50%. Regardless,

TABLE 3. Morphological comparisons of *Echites* subg. *Echites*, subg. *Pseudechites* and *Fernaldia*.

	subg. *Pseudechites*	**subg. *Echites***	***Fernaldia***
Latex	Watery	Milky	Milky
Secondary veins visible	No/yes	Yes	Yes
Tertiary veins visible	No	Yes	Yes
Inflorescence branched	1–3x	0–1x	0x
Corolla	Salverform	Salverform	Infundibuliform
Corolla length	4–9 mm	30–70 mm	35–50 mm
Corolla color	Yellow	White	White
Anther length	3–5 mm	5–9 mm	5–9 mm
Anther bases	Sagittate	Obtuse	Obtuse
Corolline corona behind the anthers	Yes/No	No	No
Follicles fused at apex	Yes	No/Yes	Yes
Pollen diameter	25–30 µm	45–50 µm	45–50 µm
Pollen aperture diameter	3–4.5 µm	5–8 µm	5–8 µm

as presented here both the strict and majority rule indicate subg. *Echites* to be monophyletic.

Tribal and other generic circumscriptions.—As stated in the "taxa analyzed" section it was not the intention of this study to test the monophyly of the tribes recognized by Endress & Bruyns (2000). However, the results presented in the strict consensus trees (Fig. 1) indicate that the tribes Mesechiteae and Wrightieae sensu Endress & Bruyns are monophyletic (each with bootstrap support near or over 50%; Fig. 2) and that the tribes Apocyneae and Echiteae sensu Endress & Bruyns are polyphyletic (Fig. 1). Furthermore the results presented suggest that *Thevetia* is not monophyletic, supporting Potgieter and Albert (2001). However, the results here show *Thevetia* to be paraphyletic, while Potgieter and Albert (ibid) show *Thevetia* to be polyphyletic. The discrepancy in results is due in large part to the much larger sampling of taxa in the Rauvolfiodeae by Potgieter and Albert (2001).

Despite the evidence indicating polyphyly in Apocyneae and Echiteae sensu Endress & Bruyns and paraphyly in *Thevetia*, tribal and generic reconstruction in these taxa is beyond the scope of the present paper and thus the discussion is left to further study and evaluation.

APPENDIX 1

Discussion of the characters utilized in the morphological cladistic analysis of the Apocynaceae. Characters in bold indicate newly uncovered and utilized characters during this study, and have lengthier discussions. The character number is given in parenthesis and corresponds to the character and character states in Table 1.

Latex (1). This character has not been utilized or discussed as a character for cladistic studies in the Apocynaceae. However, field observations of most of the genera ofEchiteae presented in this work indicate that some taxa consistently have watery sap, *Laubertia*, *Echites* subg. *Pseudechites*, and *Thenardia*, versus the typical milky sap typical of most Apocynaceae. *Parsonsia*, which has approximately 40 species, is polymorphic for this character.

Predominate growth habit and leaf arrangement (2–3, respectively). These two characters were utilized in three previous cladistic studies (Struwe et al. 1994; Endress et al. 1996; Potgieter and Albert, 2001). All of the genera of the Apocynoideae included in this study have opposite leaves (whorled in *Nerium*), except *Adenium*.

Colleters (4–6 & 11). Thomas and Dave (1991) provided a discussion of the systematic implications of colleters in the Apocynaceae that will not be repeated here. Endress et al. (1996) and Sennblad et al. (1998) utilized calycine colleters in their studies (character 12 here). I have expanded the use of colleters by including the presence or absence of colleters on other parts of the plant. Character 4, colleters around the stem, Character 5, colleters present on the apex of the leaf petiole of the upper leaf surface, appears to be convergent as it is shared by members of the "*Mandevilla*" clade and the distantly related *Forsteronia*. Character 6, colleters along the upper leaf midrib are only possessed by two species of *Mandevilla* studied here. This character is a synapomorphy which unites *M. subsagittata* and *M. hirsuta*.

Domatia (7). Domatia are only present in two of the genera studied here, *Tintinnabularia* and *Forsteronia*. This character appears convergent, haven arisen in two separate clades.

Venation (8 & 9). Distinctness of the secondary venation of leaves and tertiary venation of leaves has not been utilized in a morphological analysis. Observation in the field coupled with herbarium studies indicates that certain genera have inconspicuous lateral venation. The lack of secondary veins is a character uniting *Thevetia ahouai* with *Cerbera*. The lack of tertiary veins is a character that unites *Thenardia* and *Echites* subg. *Pseudechites*.

Calyx size (10). The majority of taxa in the Apocynoideae have sepals 1–3 mm long, a few have sepals much larger, 5–15 mm. Overall this character is highly variable with large sepals occurring randomly throughout the representative taxa. However, large sepals appear to unify a few of the species of *Prestonia*.

Aestivation (12). With the exception of *Parsonsia* (valvate), dextrorse aestivation is present in all of the taxa in the Apocynoideae included in this study. Aestivation type is one of the few synapomorphies that distinguishes the Apocynoideae from the Rauvolfioideae (sinistrorse aestivation).

Corolla shape ,**color and size**(13, **14**, **18**). Corolla shape was utilized by Endress et al. (1996), color and tube size are new characters. Most of the taxa presented in this work have yellow or white corollas. However, some have maroon corollas. Color was used because *Laubertia* and *Prestonia portobellensis* possess maroon corollas. Consequently the character was utilized to test if the species paired, thereby testing the monophyly of *Prestonia*. In addition, the two subgenera of *Echites* have different corolla colors. In this instance color was utilized to test the monophyly of *Echites*. Corolla tube size is added as an augment to the variability that exists in corolla shape. Utilization of tube size helps to emphasize that although both subg. of *Echites* have salverform corollas, there exists a considerable difference in the lengths of the corollas.

Corolla with epistaminal appendages, corona between petal sinuses, corolla with infrastaminal appendages (15, 16, 17). These three characters were utilized and discussed by Endress et al. (1996).

Filament length (19). An examination of the filaments of the taxa in this analysis indicates that filament length appears to be positively correlated with generic relationships. Short filaments are typical of the taxa in the subg. *Echites* clade (Fig. 1), while medium length filaments are consistent with the "*Prestonia*" clade (Fig. 1). Long filaments are only present in two of the three species of *Tintinnabularia*. In this instance the character was utilized to test the monophyly of *Tintinnabularia*.

Anthers from ribs, stamen exposure, and anther dehiscence (20, 21, 23). Anther ribs are only present in *Thevetia* and *Cerbera* and are used mainly to establish the monophyly of the outgroup. Anther exposure and dehiscence were utilized and discussed in Endress et al. (1996).

Apical appendages on anthers (22). It was presumed before the analysis was conducted that this character was highly convergent. However, it was included as a reference for testing the monophyly of *Tintinnabularia*, which has two species with and one species without elongate apical anther appendages.

Anther morphology, anther-pistil head relationship, pistil head type (24, 25, 26). At least five different types of anthers and pistil heads are exhibited in the Apocynaceae. The different anther and pistil head types have been discussed in Woodson (1930) and Fallen (1986). The important traits that characterize the different anther types are the connective, theca positioning and fertility and the base of the anther body. The union of the anthers and the pistil head is a synapomorphy that unifies the Apocynoideae.

Nectary (27). Several types of nectaries are exhibited by the Apocynaceae. Three different types are here recognized: five free nectaries, nectaries fused into a cup, and nectaries fused into a cup type two. Type two refers to the nectaries of *Thevetia* and *Cerbera*, that are twice as large and twice as wide as those found in the Apocynoideae.

Inflorescence position, inflorescence morphology, inflorescence branching (28, 29, 30). The structure of the inflorescence has not been used in a morphological cladistic analysis of the Apocynaceae. Woodson (1935) has provided a detailed account of the inflorescence types in the Apocynaceae that will not be repeated here. Within the taxa examined only the Wrightieae and Apocyneae (*Apocynum*) have terminal inflorescences, with all of the Echiteae possessing an axillary inflorescence. Inflorescence branching is one of the characters separating subg. *Echites* (not branched) from subg. *Pseudechites* (branched).

Fruit type, follicle orientation, follicles moniliform, follicle color, fruit dehiscence, **fruit texture** (31–36). Of the above characters, only fruit dehiscence has been utilized in a cladistic study (Endress et al. 1996). Fruits have been an underutilized resource in the systematics of the Apocynaceae. This is mainly due to the paucity of fruiting herbarium specimens. Collecting trips were made by the author specifically in the latter part of the flowering season, for the purpose of collecting fruits. From these observations, a pattern emerged. Many of the taxa with presumed relationships had similar fruit types. Characters observed were the union of the follicles, fused at apex, follicles spreading, or fused throughout. The fusion of the follicles, is a useful character in distinguishing species within genera (e.g. *Echites*), but overall the cladistic analysis indicated that follicle union is a convergent character, with spreading and fused follicles occurring throughout the Apocynoideae. In addition, follicle texture was noted. Some follicles were membranous while others were firm and woody. This character was useful in indicating *Echites* as polyphyletic (subg. *Echites* with woody follicles and subg. *Pseudechites* with herbaceous follicles). Lastly, it was noticed that some taxa had straight follicles and others were moniliform. Moniliform follicles occur more frequently in the "*Prestonia*" clade. Fruit color was used to test the monophyly of *Thevetia*. This character is a synapomorphy uniting *T. ahouai* and *Cerbera*, indicating that *Thevetia* as currently circumscribed is paraphyletic.

Seeds with coma (37). This character was utilized by Endress et al. (1996) and by Potgieter and Albert (2001) and subsequently discussed by them.

Pollen apertures, pollen exine pattern, **pollen shape, pollen size** (39–42). Pollen apertures and exine pattern were utilized in Endress et al (1996). The Rauvolfioideae and the Apocynoideae are distinguished by the apertures of the pollen, with tri-porate pollen as a synapomorphy uniting the Apocynoideae. In addition, the pollen of taxa in the Apocynoideae is consistently smooth vs. the Rauvolfioideae which has various exine patterning. Pollen shape, also helps to distinguish the Rauvolfioideae from the Apocynoideae. In general, the Rauvolfioideae have triangular-rounded pollen vs. the Apocynoideae that are consistently spherical. Pollen size was useful for determining intergeneric and intrageneric relationships. For instance, pollen size supports *Echites* as polyphyletic (subg. *Echites*, 45–60 µm vs. subg. *Pseudechites*, 23–35 µm). In addition, within *Mandevilla*, pollen size indicated *M. hirsuta* and *M. subsagittata* to be closely related.

ACKNOWLEDGMENTS

I thank the curators of the following herbaria for allowing me to study and borrow their specimens: BM, BRIT, CHAPA, F, FLAS, G, GH, K, MA, METPEC, MEXU, MO, NY, P, SHST, TAMU, TEX, US, WIS. I also thank B.B. Simpson for providing comments on the running and interpretation of the cladistic analysis, and most especially, I thank Mary Endress for her patience, support and superbly accurate and critical review of the article as well as contribution to the results section.

ABSTRACT

Allotoonia (Apocynaceae) a new neotropical genus segregated from *Echites* is described. In addition, a key to species, descriptions, distribution maps, illustrations and specimens examined are provided for all species.

Key Words. Apocynaceae, Apocynoideae, *Allotoonia*, Echiteae, *Echites*, Neotropics, Mesoamerica, Mexico

RESUMEN

Allotoonia (Apocynaceae), un nuevo género neotropical segregado de *Echites* es descrito. Se brinda una clave para todos los taxa, así como descripciones, mapas de distribución, ilustraciones y especímenes examinados para todas las especies.

In his monumental revision of *Echites* P. Browne, Woodson (1936) established two subgenera: *Echites* (*Euechites*) and subg. *Pseudechites* Woodson. Subgenus *Pseudechites* included the species *E. turbinata* Woodson and *E. tuxtlensis* Standl. and was distinguished from subgenus *Echites* by its smaller corollas (1.25–2.5 cm long vs. 5–8 cm long), lobes narrowly oblong and reflexed (vs. obliquely obovate and spreading), and its many flowered lax inflorescence (vs. compact and few flowered). A third species, *E. parviflora* Sessé & Moç. was subsequently added to subg. *Pseudechites* by Woodson (1938).

Echites went relatively unnoticed for close to 60 years, until Morales (1997) provided a synopsis of the genus. In his work, Morales described an additional species in subg. *Pseudechites* (*E. puntarenensis* J. F. Morales) as well as presented an argument for maintaining *Prestonia agglutinata* (Jacq.) Woodson in *Echites*, resurrecting the older name *Echites agglutinata*.

The morphological cladistic analysis of *Echites* s.l. and other genera of subfamily Apocynoideae presented in Williams (2004) indicates that *Echites* sensu Woodson is polyphyletic. Subgenus *Pseudechites* shows a stronger affinity to other genera of Echiteae sensu Endress and Bruyns (2000) (e.g., *Laubertia*, *Prestonia*, *Thenardia*) than it does to subg. *Echites*. Consequently, the authors have chosen to recognize the species in subg. *Pseudechites* as a distinct genus (*Allotoonia* described below) separate from *Echites* s.s. Table 1 documents the differences between *Allotoonia*, *Echites*, and other selected genera of New World Echiteae.

MORPHOLOGICAL CHARACTERS

Leaves.—The leaves are opposite and entire. Four of the five species have leaves with obscure secondary venation making them readily discernible from *Echites*. One species, however, *A. agglutinata*, has conspicuous secondary veins. *Allotoonia* also shares with others neotropical Apocynoideae, intra-petiolar colleters. All species have glabrous leaves. The leaves of *A. turbinata* are often two to three times longer and broader than those of the other four species. Field studies have shown that these characters are uniform and consistent within a population.

Inflorescence.—*Allotoonia* is readily distinguished from *Echites* by the inflorescence structure. The inflorescence of *Allotoonia* is a helicoid cyme once, twice to occasionally thrice branched, while in *Echites* the inflorescence is a modified dichasium, sometimes appearing racemose, and occasionally reduced to just one flower. The bracts are always inconspicuous and scarious.

Flowers.—The calyx is regular, pentamerous, and with a solitary opposite colleter on the adaxial surface of each sepal, as found in many others members of the Echiteae (e.g., *Prestonia*, *Thenardia*). The sepals are narrowly ovate and 1–3.5 mm long. The shape and dimensions of the sepals for each species corresponds to the shape and dimensions of the bracts subtending the pedicel.

The corolla is salverform, the tube glabrous without. The aestivation is dextrorse as are all other neotropical members of the Apocynoideae. The corolla lobes are very narrowly elliptic to almost filiform, acuminate to long-acuminate at the apex and conspicuously wavy and twisted distally. *Allotoonia* is the only neotropical Apocynaceae genus with wavy and twisted filiform lobes at the anthesis (Figs. 1–2). In *Echites*, the corolla lobes are obovate.

The stamens are included and the anthers are strongly attached at two levels to the spool shaped style head (Fig. 3). The anther shape differs between *Allotoonia* and *Echites* (Fig. 4). In *Allotoonia* an anther is more or less continuous (except for a slight dorsal protuberance), without a marginal rib. In *Echites* the anther has a conspicuous marginal rib that is extended from the basal projections along the entire length up to the apex (Fig. 1 B).

Fruit.—The fruits of *Allotoonia* are composed of two herbaceous, pendulous, follicles (Fig. 5) developing from two carpels postgenitally united at the apex, sometimes free at maturity. The follicles are continuous to obscurely moniliform. The fruits of *Echites* are woody and never moniliform.

Seeds.—The seeds of *Allotoonia* are glabrous, 6–20 per follicle, and rostrate, with the beak slender, narrowly and conspicuously elongate (Fig. 6), while in *Echites* the seeds are inconspicuous to moderately rostrate, with the beak short (sometimes somewhat elongate in *E. yucatanensis*) and gradually acuminate toward the micropylar end (Fig. 7).

Allotoonia J.F. Morales & J.K. Williams, gen. nov. TYPE. *Allotoonia agglutinata* (Jacq.) J.F. Morales & J.K. Williams

Herba volubilis, Forsteronieae, Laubertiae, Parsoniae, Prestonieae, Thenardiae et Thoreauiae affinis; folia opposita petiolata, membranacea, eglandulifera; inflorescentia lateralis pedunculata multiflora; corolla regularis 5-partita, hypocrateriforma, lobis filiformis, revolutis, tubo exappendiculata stamina inserta, glabra; fructus folliculis, seminibus rostrata.

Lactescent lianas, usually herbaceous, more rarely suffruticose, not woody. Stems terete to subterete, somewhat flattened at the nodes, glabrous, not lenticellate, with inconspicuous intrapetiolar colleters, the latex usually watery. Leaves opposite, entire, membranaceous, glabrous or glabrate, the secondary and tertiary veins usually inconspicuous or obscure, petiole with many, minute and filiform colleters in the axils. Inflorescence a helicoid cyme, axillary, glabrous, many-flowered, usually long-pedunculate, bracts scarious, inconspicuous. Flowers pentamerous, the sepals free or very slightly imbricate basally, scarious, bearing a solitary, episepalous entire to variously laciniate colleter within; corolla salverform, glabrous to very minutely and inconspicuously puberulent without, without corona lobes or annular corona, the tube usually longitudinally grooved, with an infrastaminal ribs present below each filament, the limb 5-parted, actinomorphic, dextrorsely convolute, the lobes very narrowly elliptic to almost filiform, acuminate, twisted and wavy distally; stamens 5, included, inserted in the upper part of the corolla tube near the mouth, anthers connivent and agglutinated to the style head, attached in two points to the style head, glabrous to glabrate, thecae with the base sagittate, 2-auriculate, auricles short, but conspicuous, short-acuminate, filaments short, puberulent to pilose, carpels 2, united at the apex by a common stylar shaft surmounted by the fusiform, spool-shaped style head, ovary glabrous, ovules numerous, multi-seriate, nectarines five, separated and distinct, rarely slightly connate basally. Follicles continuous and terete to subterete, or obscurely moniliform, slender and smooth, usually glabrous; seeds comose at the micropilar end, conspicuously rostrate, minutely rugose, numerous.

This genus comprises five species distributed from southern Mexico to northern Panama, and the West Indies. *Allotoonia* is named after Dr. Anthony Leeuwenberg, from the Wageningen University (WAG), The Netherlands, in recognition of his work in the Apocynaceae.

The genus *Allotoonia* is in the subfamily Apocynoideae, tribe *Echiteae* (Endress & Bruyns 2000), as evidenced by the following characters: anthers with the thecae connivent, agglutinated and strongly attached at two levels to the spool shaped style head.

TABLE 1. Morphological characters in *Allotoonia* and selected genera of the *Echiteae*

Genera Morphological Characters	Allotoonia	Echites	Forsteronia	Laubertia	Prestonia	Thenardia	Thoreauea
Latex	Clear	White	White	Clear	White	Clear	White
Secondary veins	Usually inconspicuous	Conspicuous	Conspicuous, rarely inconspicuous	Conspicuous	Conspicuous	Usually inconspicuous	Conspicuous
Inflorescence	Helicoid cyme	Modified dichasium	Thyrsiform	Scorpioid cyme, sometimes reduced and appearing simple or umbelliform subcorymbose	Racemose, subracemose, umbellate, subumbellate, corymbose or	Subumbellate cyme	Trichotomously branched Subumbellate cyme
Bracts	Scarious	Scarious	Scarious	Scarious	Foliaceous to scarious	Scarious	Scarious
Sepals	Scarious	Scarious	Scarious	Scarious	Foliaceous to scarious	Scarious	Scarious
Sepals colleters	Solitary and opposite	Solitary and opposite	Laterally or evenly disposed, rarely lacking	Lacking	Solitary and opposite	Solitary and opposite	Solitary and opposite
Corolla	Salverform	Infundibuliform	Salverform to rotate		Salverform	Salverform to rarely infundibuliform	Rotate Urceolate to campanulate
Corona	Absent	Absent	Absent	Present, continuous around the corolla mouth	Present, continuous around the corolla mouth	Absent	Present, dissected interior to corolla mouth

Genera Morphological Characters	Allotoonia	Echites	Forsteronia	Laubertia	Prestonia	Thenardia	Thoreauea
Lobes	Very narrowly elliptic to almost filiform, acuminate, twisted and wavy distally	Obovate	Oblong to lanceolate	Obovate	Obovate to ovate	Ovate	Ovate
Stamens insertion	included, inserted in the upper part, near the mouth	Included, inserted about midway the corolla tube	Included or variously exserted	Included or variously exserted	Included or apically exserted	Exserted	Apically exserted
Filaments	Free	Free	Free or connate	Free	Free or connate	Partially	Partially connate
Disk or nectaries	5, usually separated, rarely slightly connate basally	5, but usually connate basally	Usually (3–) 5-lobed basally	5, separated to irregularly connate in 5 nectaries	Annular, entire to 5-lobed or divided	5, separated	5, separated
Follicles	Slender, continuous and terete, or obscurely moniliform	Slender, continuous and terete	Slender, divaricate or, parallel, continuous to moniliform	Slender, moniliform, rarely continuous	Divaricate, fusiform, continuous or rarely moniliform	Slender, moniliform	Unknown
Coma seeds	Conspicuously rostrate	Inconspicuously to moderately rostrate	Truncate, sessile	Truncate, sessile	Truncate	Sessile	Unknown

KEY TO THE SPECIES OF *ALLOTOONIA*

1. Corolla lobes (17–)20–27 mm long; corolla tube constricted below the insertion of the stamens; montane rain forest and related disturbed areas between 1500–2350 m ____ **A. turbinata**
1. Corolla lobes 4–14(–16) mm long; corolla tube straight or slightly constricted below the insertion of the stamens; tropical deciduous forest, premontane moist forest, gallery forest, and related disturbed areas, bewteen 0–1200(–1400) m.
  2. Secondary venation of leaves raised and conspicuous, tertiary venation of leaves obscure; corolla lobes glabrous; plants of the West Indies ____ **A. agglutinata**
  2. Secondary venation inconspicuous, not raised, tertiary venation usually inconspicuous; corolla lobes pubescent or glabrous; plants of Mexico and Central America.
    3. Corolla lobes shorter than tube, glabrous; bud pointed; tube 7–9 mm long, ca. 1 mm diam., constricted between middle to base of lobes ____ **A. tuxtlensis**
    3. Corolla lobes longer than tube, hirsute or glabrous; bud round, tube 4–6(–7) mm long, ca. 2 mm diam., straight, not constricted.
      4. Corolla orange to yellow-orange, the lobes hirsute; pedicels 2–9 mm; anthers 3.5–4 mm ____ **A. parviflora**
      4. Corolla white, creamish white to pinkish white, the lobes glabrous to glabrate; pedicels 11–24 mm; anthers (5–)6–8 mm ____ **A. caudata**

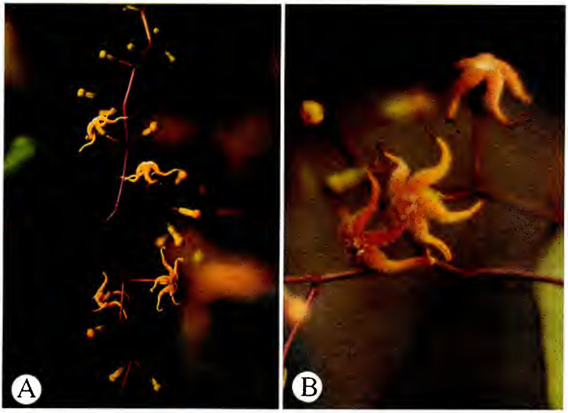

FIG. 2. ***Allotoonia parviflora*. A.** Habit and inflorescences (*Morales & Abarca 8810*, INB). **B.** Close-up of the flowers, showing twisted and elongate corolla lobes (*Morales & Abarca 8810*, INB).

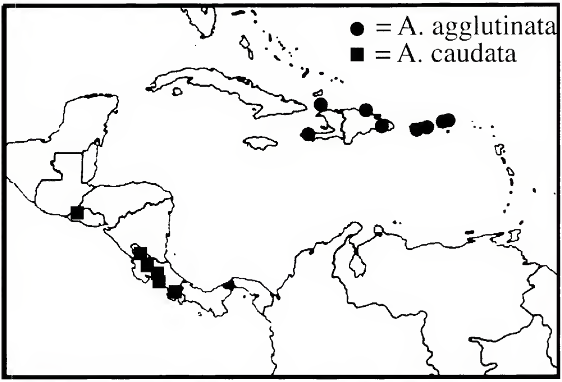

Fig. 9. Distribution of *A. agglutinata* and *A. caudata*.

Habitat and distribution.—Dry forest, gallery forest, shrubby vegetation, thickets, and disturbed areas in the West Indies (Hispaniola, Cuba, Puerto Rico, Jamaica, part of Greater Antilles), at elevations of 0–350 m. (Fig. 9). Associated species include *Abutilon* and *Plumeria*.

Phenology.—Flowering specimens have been collected in January, May–June and September–October. Fruiting collections have been made in January–February and September–October.

Local names.—abrazapalo (Dominican Republic); azufaifo, babeiro (Puerto Rico).

Allotoonia agglutinata is the only species of the genus with conspicuously raised secondary veins. In addition, it has glabrous corolla lobes that are longer than the tube and it is distributed throughout the West Indies. The corolla bud is contorted, similar to the bud of *A. tuxtlensis* (Fig. 10).

A complete list of synonyms for this species as presented by Woodson (1936) is provided here in order to indicate that an earlier generic name does not exist for any of the described species of *Allotoonia*. Although the types collection of *Echites sanguinolenta* Tussac and *E. circinalis* Sw. var. *thomasiana* A. DC. were not located, they are included in the synonymy based on their original descriptions, which matches the *Allotoonia agglutinata* concept used here. Within *Allotoonia*, *A. agglutinata* has the highest number of synonyms, and is the only

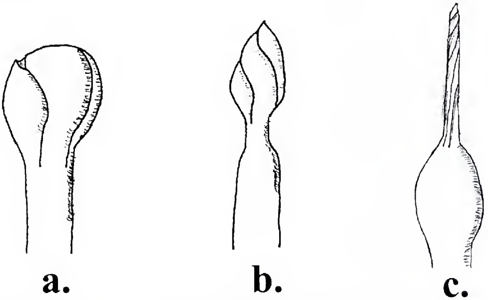

Fig. 10. Flower buds of the species of *Allotoonia*. A. *A. parviflora* (*Williams 96-88*, SHST). B. *A. turbinata* (*Breedlove 25058*, TEX). C. *A. tuxtlensis* (*Hernández 488*, TEX).

species that has been described in multiple genera. None of the genera listed above are legitimate alternatives to *Allotoonia*.

Observations of the Sessé & Mocino collections by the second author indicates that the specimen number *5075* is labeled *Echites obtusifolia*. The species name is written on the back of the herbarium sheet, which perhaps accounts for the specimen being overlooked. Consequently, specimen number *5075* of the Sessé and Mocino herbarium is here designated as the lectotype for *Echites obtusifolia*.

Selected specimens examined. **JAMAICA:** Data lacking: *Swartz 265* (BM). **PUERTO RICO:** Patillas, Guardarraya, Cerro Mala Pascua, 13 Oct 1991, *Axelrod & Axelrod 3091* (INB, UPRRP); Isla de Desecho, W of Puerto de los Botes, *Breckon 4994* (MAPR), *Breckon 5019* (MAPR); Sabana Grande, Susúa forest, 7 Nov 1990, *García & Caminero 3287* (MAPR. NY); Salinas, Camp Santiago, section Lima, date lacking, *Ross & Meletische 253* (MO); near Cayey, Pedro Avila, 22 Sep 1895, *Sintenis 2457* (S); Quebradillas, 24 Jun 1991, *Taylor & Gereau 10493* (MO); Guanica, 25 Jan 1886, *Urban 3565* (BM, P [2 sheets]); Punta Tuna, S of Yabacoa, 11 Oct 1968, *Wagner 1690* (INB). **DOMINICAN REPUBLIC:** Cabo Francés Viejo to Cabrera, 28 Sep 1969, *Liogier 16152* (INB, NY); La Romana: Río Cumayasa, road San Pedro de Macorí-La Romana, 29 Oct 1992, *Zanoni et al. 47051* (INB, JBSD). **HAITI:** La Hotte, Bras Gauche river, 8 Nov 1924, *Ekman 2431* (S); Totue Island, Basse-Terre, 28 Oct 1925, *Ekman 5131* (S, US). **TORTOLA:** Belmont Beach, 30 Oct 1965, *D'Arcy 292*^{d} (MO). **VIRGIN ISLANDS:** Francis Bay area, 6 Jun 1985, *Acevedo* et al. *902* (BM, NY); Coral Bay Quarter, road to Bordeaux, 7 Jan 1991, *Acevedo & Siaca 3819* (INB, US); Reef Bay, Dittlif point, 20 Jan 1991, *Acevedo & Siaca 3974* (MO).

2. Allotoonia caudata (Woodson) J.F. Morales, comb. nov. (**Figs. 1, 11**). BASIONYM: *Echites puntarenensis* J.F. Morales, Brittonia 49:332. 1997. nom. nov. *Prestonia caudata* Woodson, Ann. Missouri Bot. Gard. 47:79. 1960, non Blanco (1837). TYPE:

COSTA RICA: Puntarenas: vicinity of Cascajal, 25 km ESE of Puntarenas, 3 Jul 1949 (fl), *Holm & Iltis 243* (HOLOTYPE: MO; ISOTYPES: A, CR, G, GH, P).

Suffruticose lianas, stem terete to subterete, glabrous. Leaves: petioles 6–19 mm long, with minute pectinate colleters in the axils, glabrous; blade 6–14(–16) × 1.5–5 cm, membranaceous, elliptic to narrowly elliptic, more rarely narrowly obovate-elliptic, apex acuminate, base obtuse to cuneate, glabrous, midvein impressed on both surfaces, the secondary venation scarcely impressed or inconspicuous on both sides, veinlets usually inconspicuous. Inflorescence longer than the subtending leaves, lax, peduncle 4.5–11 cm, pedicels 11–24 mm, bracts ca. 1 mm long, ovate, acuminate, scarious; sepals 1 × 0.5–1 mm, ovate, acute, glabrous, the colleter entire to subentire; corolla salverform, white, creamish white, or pinkish white, glabrous without, tube 6–8 mm long, 2–2.5 mm diam, straight, glabrate around the stamens within, lobes 8–15 × 1.5–2 mm, glabrous to glabrate; stamens: filaments less than 0.5 mm, inconspicuous, anthers (5–)6–8 mm, glabrous, auricles ca. 0.8 mm; ovary 1.5–2 mm, glabrous, style head 1–2.5 mm long; nectaries 0.5–1 mm, entire. Follicles unknown.

Distribution.—Dry forest, savannas, and disturbed areas in northern Costa Rica, southern Nicaragua and El Salvador, 0–600(–1000) m. (Fig. 9). Associated species include *Curatella*, *Lonchocarpus*, *Plumeria*, and *Stemmadenia*.

Phenology.—Flowering specimens have been collected in February, April, June–July, September, and November–December.

Local names.—bejuco de Veneno (Costa Rica, Guanacaste, Nicoya).

Allotoonia caudata is very similar to *A. parviflora* and usually misidentified in herbarium specimens. However, the former taxon is easily distinguished by its white, creamish white, or pinkish white flowers (vs. orange to yellow-orange), with glabrous or glabrate corolla lobes (vs. densely hirsute). Morales (1997) recognized that *Prestonia caudata* Woodson should be treated in *Echites* but a new name was necessary, because the epithet was already occupied by several homonyms (*E. caudata* L., *E. caudata* Burman f., and *E. caudata* Blanco), thus, the name *E. puntarenensis* was proposed. With the transfer of this taxon to the new genus, the original basionym can be used according to article 58.3 of The Code. Therefore, the respective combination is made and *E. puntarenensis* is reduced to synonymy.

Specimens examined. **EL SALVADOR. Santa Ana:** Coatepeque, 3 Sep 1994, *Villacorta & Méndez 2181* (B, LAGU, MO). **NICARAGUA. Chontales:** 3 km N of St. Tomás, 6 Apr 1982, *Moreno 16081* (MO). **Rivas:** Isla Omotepe, Balgue, 28 Nov 1982, *Moreno 18888* (MO); Isla Ometepe, Balgue, 18 Jan 1983, *Moreno 19664* (BM, MO); Isla de Ometepe, 15 Sep 1983, *Moreno 22179* (MO); Isla Omotepe, Mérida, 11 Feb 1984, *Robleto 199* (MO); Isla Omotepe, Volcán Maderas, 18 Jun 1984, *Robleto 912* (MO), 16 Jan 1985, *Robleto 1701* (MO). **COSTA RICA. 3. **Allotoonia parviflora** (Sessé & Moc.) J.F. Morales & J.K. Williams, comb. nov. (**Figs. 2, 12, 13**) BASIONYM: *Echites parviflora* Sessé & Moç., Naturaleza (Mexico City), ser. 2, 1, app. 28. 1888, non Roxb (1832). TYPE: MEXICO. MICHOACÁN: Apatzingan, date lacking (fl), *Sessé & Moçiño 5068* (LECTOTYPE: fide Williams 2002, MA; ISOLECTOTYPE: F; photo F neg. 41238, INB ex MA).

Echites woodsoniana Monac., Bull. Torrey Bot. Club. 86:245–247, f. 1. 1959. *Prestonia woodsoniana* (Monac.) A.H. Gentry, Ann. Missouri Bot. Gard. 70:205. 1983. TYPE: MEXICO. MICHOACÁN: Apatzingan, 13 Oct 1939 (fl), *Hinton 15325* (HOLOTYPE: NY; ISOTYPES: GH, MO, NY, TEX, US [2 sheets]).

Suffruticose liana, stem subterete, glabrous. Leaves: petioles 3–15 mm long, with minute pectinate colleters in the axils, glabrous; blade 3.2–9.2(–11.4) × 0.9–3.6 cm, membranaceous to somewhat subchartaceous, elliptic, narrowly elliptic to narrowly ovate, apex acuminate, acute to acute-mucronate, base obtuse to cuneate, glabrous, midvein impressed on both surfaces, the secondary venation scarcely impressed or inconspicuous. Inflorescence longer than the subtending leaves, lax, peduncle 1.3–7 cm, pedicels 2–9 mm, bracts 1–1.5 mm long, almost linear, acuminate, scarious; sepals 1–1.5 × 0.5–1 mm, ovate to narrowly ovate, acute to acuminate, glabrous to glabrate, more rarely minutely and inconspicuously papillate, the colleter very slightly erose; corolla salverform, orange to yellow-orange, glabrous without, tube 3.5–6 mm long, ca. 1.5 mm diam, straight, puberulent within around the stamens, lobes 8–14(–16) × 1.5–2 mm, densely hirsute adaxially; stamens: filaments less than 0.5 mm, inconspicuous, anthers 3.5–4 mm, glabrous, auricles ca. 0.8 mm, ovary 1.5–2 mm, glabrous, style head 2–3 mm long, nectaries 0.5–1.5 mm, distinct to somewhat connate, entire. Follicles 30–40 × 0.4–0.5 cm, continuous to obscurely moniliform, smooth and glabrous, somewhat twisted distally; seeds 21–27 × 1–1.5 mm, rugose, the creamish coma 3.8–4.2 cm.

Distribution.—Dry forest, premontane moist forest, disturbed areas, savannas, semideciduos forest, rocky forested outcrops, and gallery forest in Mexico, Guatemala, Honduras, Nicaragua, and Costa Rica, at elevations of 0–1100(–1400) m. (Fig. 13). Associated species include *Anacardium*, *Astronium*, *Bursera*, *Enterolobium*, *Lonchocarpus*, *Ficus*, and *Plumeria*.

Phenology.—Flowering January, April–May, and July–December. Fruitng collections have been collected in January-April and November

Local names.—Bejuco de Sapo (Mexico, Guerrero, Zirándaro).

This species has a complicated taxonomic history having been treated repeatedly in *Prestonia*. The history of this species is well documented in Williams (2004).

Allotoonia parviflora is immediately distinguished by its rounded corolla bud (Fig. 10) and pubescent corolla lobes (Fig. 2 B). It is often confused with *A. tuxtlensis*, which has a pointed corolla bud (Fig. 10) and glabrous corolla lobes. Also, *Allotoonia parviflora* consistently has corolla lobes longer than the tube, while the corolla lobes in *A. tuxtlensis* are consistently shorter than the tube.

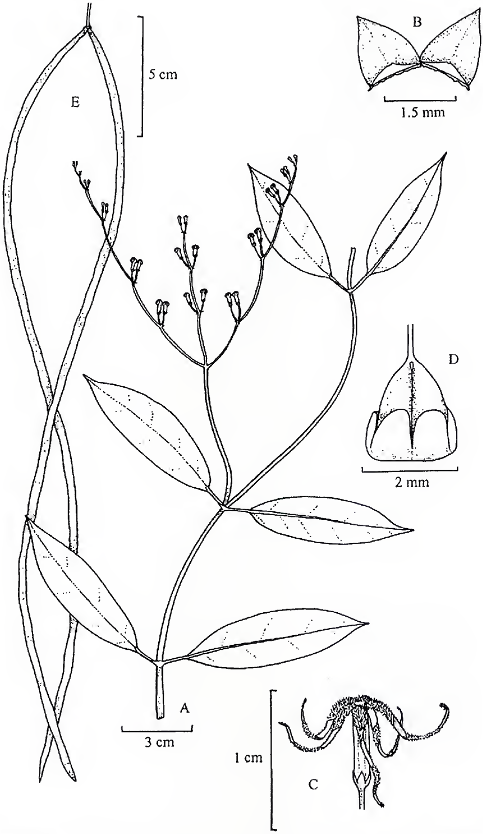

FIG. 12. *Allotoonia parviflora* (A–D from *Morales & Quirós 8241*, INB; E from *Morales 3139*, INB). **A.** Flowering shoot. **B.** Sepals and colleters. **C.** Corolla. **D.** Nectaries and ovary. **E.** Fruits.

The holotype of *E. woodsoniana* (=*Allotoonia parviflora*) at NY has corolla lobes 15–16 mm long, making it appear to be a specimen of *A. turbinata*. *Allotoonia turbinata* differs from *A. parviflora* by its flowering bud, which has the corolla lobes extended upwards rather than folded in (Fig. 10).

Although *Echites parviflora* Sessé & Moç. is a later homonym of *E. parviflora* Roxb., its use in the new combination *Allotoonia parviflora* (Sessé & Moç.) J.F. Morales & J.K. Williams is legitimate according to article 58.3 of The Code.

Monachino (1959) recognized that *Echites parviflora* Sessé & Moç. is a homonym of *E. parviflora* Roxb., and thus regarded its use by Woodson (1936) as illegitimate. Unfortunately, Monachino did not have access to the type of *E. parviflora* Sesse & Moç. and was therefore uncertain as to its true identity. Rather than proposing a new name for the species he decided to re-describe it as a new species, giving it the name *E. woodsoniana* Monach., as was exposed previously by Gentry (1983). Observations of the lectotype of *E. parviflora* at MA by the second author confirm that the specimen is conspecific with *E. woodsoniana*. *Echites woodsoniana* is here treated as a synonym of the new combination *Allotoonia parviflora*.

Specimens examined. **MEXICO. Guerrero:** Tario, Coyuca, 5 Apr 1935, *Hinton et al. 7589* (P, US); Tario, Coyuca, 4 Feb 1934, *Hinton 5863* (US); El Talamo, road Zirándaro-Guayamo, 6 Sep 1982, *Soto & Silva 4355* (INB, MEXU). **Jalisco:** Jilotlán de Los Dolores, Río Tepalcatepec, 21 Sep 1983, *Martínez et al. 4369* (INB, MEXU). **Michoacán:** 4 km e of Apatzingán along river, 3 Jan 1997, *Williams 96-88* (SHST, TEX); Arteaga, road to Playa Azul, 11 Nov 1977, *Koch et al. 77462* (US); Arteaga, road Arteaga to Nueva Italia, 27 Sep 1983, *Martínez & Stevens 4597* (INB, MEXU); along road to Infernillo, 15 Jan 1983, *Miller* et al. 456 (MO [2 sheets]). **Oaxaca:** Mpio. 4. Allotoonia turbinata (Woodson) J.F. Morales & J.K. Williams, comb. nov. (**Figs. 13, 14**). BASIONYM: *Echites turbinata* Woodson, Ann. Missouri Bot. Gard. 21:615.

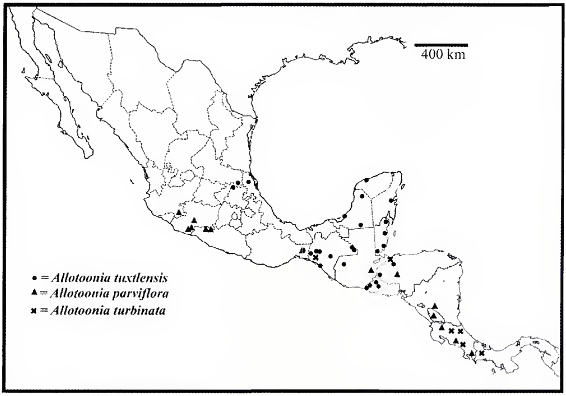

Fig. 13. Distribution of *A. parviflora*, *A. turbinata* and *A. tuxtlensis*.

1934. Type: COSTA RICA: Alajuela: Rancho Flores, 22 Feb 1890 (fl), *Tonduz 2147* (holotype: B [destroyed]; lectotype, here designated: US; isolectotypes: BR [2 sheets]).

Suffruticose liana, stem terete to subterete, glabrous. Leaves: petioles 7–21 mm long, without colleters in the axils, glabrous; blade 4.5–14.5(–17) × 2.1–8.7 cm, membranaceous, rarely subchartaceous, elliptic to narrowly elliptic, apex caudate-acuminate, rarely acuminate, base obtuse to cuneate, sometimes oblique, glabrous, midvein impressed on both surfaces, the secondary venation slightly impressed or inconspicuous. Inflorescence shorter than the subtending leaves, lax to somewhat agglomerate, peduncle 1.5–5.1(–5.4) cm, pedicels 4–15 mm, bracts 1–2.5 mm long, very narrowly elliptic to linear, acuminate, scarious; sepals 2–3.5 × 1–1.5 mm, ovate, long-acuminate, glabrous to glabrate, minutely rugose, the colleter irregularly fimbriate; corolla salverform, greenish yellow, glabrate to inconspicuously and sparsely puberulent without, tube 4–6 mm long, ca. 1.5 mm diam, inflated at the attachment of the stamens, puberulent to glabrate within around the stamens, lobes (17–)20–27 × 1 mm, glabrous to glabrate; stamens: filaments ca. 1 mm, glabrate, anthers 3–3.5 mm, glabrous, auricles 0.5–0.8 mm, ovary 1.5–2 mm, glabrate, style head 1–1.5 mm long, nectaries ca. 1.5 mm, entire. Follicles 20–31 × 0.4–0.6 cm, obscurely moniliform, smooth and glabrous; seeds 27–30 × 2–3 mm, rugose, the tannish coma 3–5.5 cm.

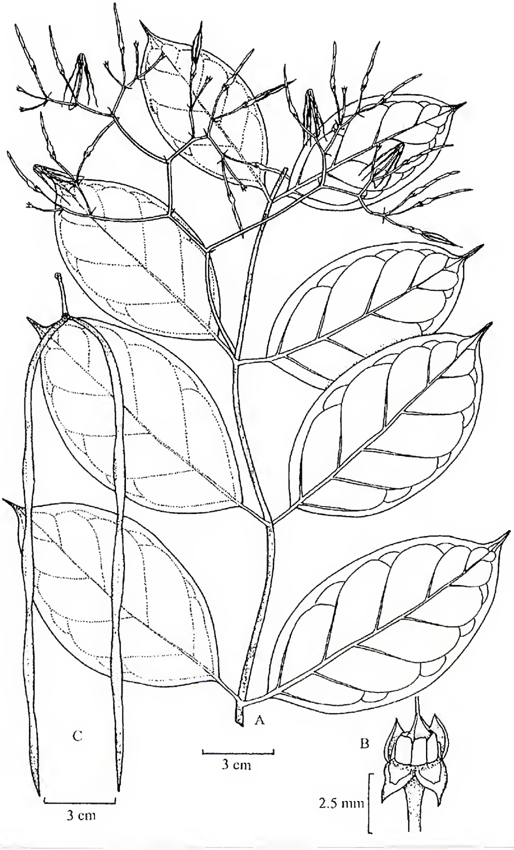

FIG. 14. *Allotoonia turbinata* (A–C from *Kupper 937*, M; D from *Gómez-L. et al., 12142*, INB). **A.** Flowering shoot. **B.** Sepals, colleters, nectaries, and ovary. **C.** Fruits.

Habitat and distribution.—Montane Rain forest and related disturbed areas in Mexico (Chiapas), Honduras, Costa Rica, and Panama, between 1500–2350 m. (Fig. 13). Associated species include *Clethra*, *Eugenia*, *Liquidamber*, *Pinus*, *Quercus*, and *Randia*.

Phenology.—Flowering specimens have been collected in January–May, June, and September. Fruiting collections are reported in January–February, and June.

Allotoonia turbinata is immediately distinguished by its corolla lobes 1.2–2.7 cm long. This species is similar to *A. parviflora* but differs in its corolla lobes which are longer and extended upwards in bud (vs. rounded in bud, Fig. 10).

The elevation range of this species (between 1500 m and 2350 m) is unique, considering that the other species in *Allotoonia* are found mostly at low elevations and the fact that in Mesoamerica very few apocynaceous lianas grow at 1500 m altitude. This species was originally considered endemic to Costa Rica (Rancho Flores, Cordillera Volcánica Central), but further collections have broadened of its known range.

Specimens examined. **MEXICO. Chiapas:** Mpio. Villa Corzo, E base of Cerro Tres Picos near Cerro Bola along a logging road SW of Colonia Agrónomos Mexicanos, 4 May 1972, *Breedlove 25058* (MO [2 sheets], TEX). **HONDURAS. Cortéz:** Montaña Idalfonso, N de Cofradía, 17 Apr 1957, *Molina 6203* (EAP, F). **COSTA RICA. Alajuela:** near Carrizal, 31 Jan 1992, *Gómez-L. et al. 12142* (INB, USJ); Poás, 27 Mar 1932, *Kupper 937* (M [2 sheets]). **Heredia:** Monte Barva, 1845–1848, *Oersted 15544* (C); Las Lajas de San Isidro, Sep 1900, *Pittier 14035* (US). **PANAMA. Chiriquí:** vicinity of Cerro Punta, 21 Jan 1939, *Allen 1524* (MO); Río Chiriquí Viejo Valley, between El Volcán and Cerro Punta, 15 Mar 1938, *White 6* (MO, US); vicinity of Casita Alta, Volcán de Chiriquí, 28 Jun 1938, *Woodson et al. 988* (GH, MO, NY).

5. Allotoonia tuxtlensis (Standl.) J.F. Morales & J.K. Williams, comb. nov. (**Figs. 14, 15**). BASIONYM: *Echites tuxtlensis* Standl., Contr. U.S. Natl. Herb. 23:1164. 1924. TYPE: MEXICO. CHIAPAS: near Tuxtla, 1 Sep 1895 (fl), *Nelson 3080* (HOLOTYPE: US).

Suffruticose liana, stems terete to subterete, glabrous. Leaves: petioles 3–11 mm long, with minute pectinate colleters in the axils, rarely eglandular, glabrous; blade 4.5–11 × 1.4–3.7(–4.8) cm, membranaceous, narrowly elliptic to narrowly ovate, apex acuminate, base obtuse to cuneate, midvein impressed on both surfaces, the secondary venation slightly impressed or inconspicuous. Inflorescence longer than the subtending leaves, lax, peduncle 2.6–8 cm, pedicels 8–19 mm, bracts 0.8–1.5 mm long, ovate, acuminate, scarious; sepals 1.5–1.8 × 1 mm, ovate, acuminate, glabrous, the colleter entire or somewhat laciniate; corolla salverform, yellow to creamish yellow, glabrous without, tube 8–10 mm long, 1.5–2 mm diam, inflated at the attachment of the stamens, puberulent within around the stamens, lobes 6–8 × 1–1.5 mm, glabrous; stamens: filaments inconspicuous, anthers ca. 4 mm, glabrous, auricles ca. 0.5 mm, ovary 1–1.5 mm, glabrous, style head 1.5–2 mm long, nectaries 0.5–1 mm, distinct to somewhat connate, entire. Follicles 13–15 × 0.3 cm, continuous, smooth and glabrous, sometimes somewhat twisted distally; seeds 11–13 × 1.5 mm, minutely and inconspicuously rugose, the creamish coma (2.3–)2.5–3.2 cm.

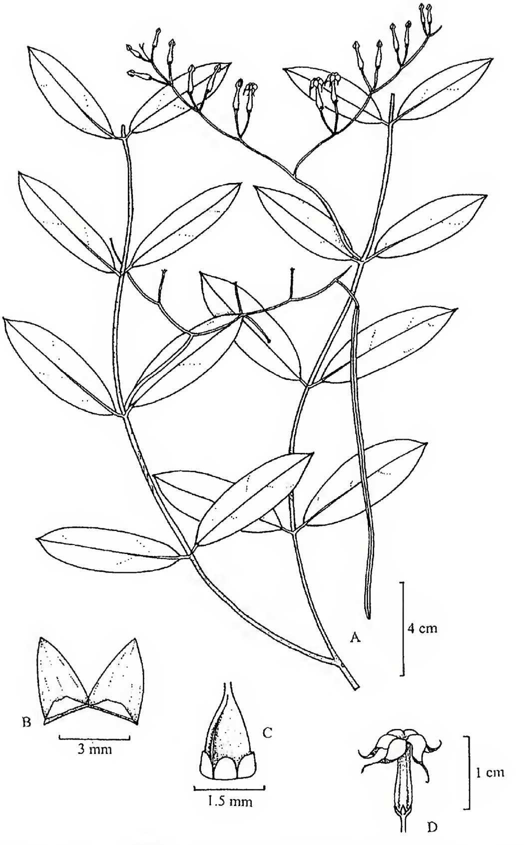

Fig. 15. *Allotoonia tuxtlensis* (A–C from *Arvigo et al. 536*, INB; D from *Renderos 378*, INB) **A.** Fertile shoot, showing the inflorescence and follicles. **B.** Sepals. **C.** Ovary and nectaries. **D.** Corolla.

Habitat and distribution.—Tropical deciduous forest and disturbed areas of Mexico (Chiapas, Campeche, Oaxaca, Quintana Roo, and Yucatán), Belize, Guatemala, Honduras, and disjunct into El Salvador, 100–1200 m. (Fig. 13). Associated species include *Aspidosperma*, *Bursera*, *Ficus*, *Pinus*, *Quercus*, and *Spondias*. This species is occasionally cultivated and it is suspected that the populations in Northern Mexico (San Luis Potosí, Querétaro, and Veracruz) are introduced rather than native.

Phenology.—Flowering all the year. Fruiting collections have been made in January and May.

Local names.—Tasnk'ub ts'aah (México, Huasteca); centipede vine (Mexico); bejuco lengua de culebra (El Salvador, Ahuacapán, San Benito); loroco de Culebra (El Salvador, Cuscatlán). The name Loroco is used for others Apocynaceous lianas in northern Mesoamerica [e.g., *Fernaldia pandurata* (A. DC.) Woodson].

Allotoonia tuxtlensis is readily distinguished from the other species of *Allotoonia* by its contorted and pointed corolla buds (Fig. 10) and its corolla lobes shorter than the tube. In both these respects, *A. tuxtlensis* resembles *A. agglutinata*. The main differences between the two taxa is the conspicuous secondary veins in the leaves of *A. agglutinata* and its restriction to the West Indies. At present no specimens with visible secondary veins in the Mexican and Central American collections of *A. tuxtlensis* have been observed.

This species was considered to be restricted to the Caribbean slopes in northern Mesoamerica (Morales 1997), but it was recently collected in the Cuscatlán Department, El Salvador Alcorn (1984) reported that this species is cultivated and protected in San Luis Potosí, Mexico. She reports that the leaves are used as a medicine in the cure of respiratory problems, including wheezing and difficulty in breathing. The leaves are boiled in a tea and drunk.

Specimens examined. **MEXICO. Campeche:** Calakmul, road to Dos Caminos, 14 Oct 1997, *Alvarez 401* (MEXU, MO); Santa María Xacabacab, 7 Mar 1982, *Cabrera et al. 2062* (INB, MEXU); Champotón, road to Escárcega, 23 Oct 1997, *Carnevali & May 4628* (CICY, MO); Calakmul, road Xpujil-Campeche road, 22 Nov 1997, *Lira et. al. 360*^{a} (MEXU, MO); Calakmul, 24 Nov 1997, *Martínez et. al. 29893* (MEXU, MO); Hopelchén, SE of Xpujil, 23 Jan 1996, *Pascual 150* (MO). **Chiapas:** between Piñola (Las Rosas) and Soyatitán, 27 Aug 1981, *Breedlove 52441* (MO [2 sheets]); Cintalapa, 14 Sep 1981, *Breedlove 52710* (MO); Ococingo, Río Usumacinta, 4 Dec 1984, *Martínez 8987* (INB, MEXU); Cerro Brujo, Ocozocuautla, 25 Oct 1985, *Martínez 14303* (MEXU, MO); NW of Boca Lacantum, 31 Oct 1985, *Martínez 14468* (MEXU, MO); Ococingo, road to Palenque, 4 Nov 1985, *Martínez 14883* (MEXU, MO); Ococingo, 10 Jan 1986, *Martínez 16205* (MEXU, MO); Ocosingo, road to Chapul, S of Boca Lacantum, 18 Apr 1986, *Martínez 18362* (MEXU, MO); Comitán, road to Tzimol, 20 Sep 1988, *Martínez & Stevens 23940* (INB, MEXU, MO); Tonala, Sep 1913, *Purpus 6825* (BM, GH); La Cueva, Tenejapa, 21 Feb 1984, *Shilom 7306* (INB, MEXU); E of Cintalapa, 19 Nov 1984, *Téllez et al. 8126* (INB, MEXU). **Oaxaca:** Santa María Chimalapa, Paso La Cueva, Río Corte, 9 Oct 1984, *Hernández 488* (MEXU, MO, TEX). **Querétaro:** Mpio. RESUMEN

Se discute la utilidad taxonómica de los sépalos para delimitación de secciones dentro del género *Prestonia*. Asimismo, se describe e ilustra una nueva especie de Ecuador, *P. amabilis*, muy inusual por su cáliz campanulado.

ABSTRACT

The taxonomic use of the sepals features for intergeneric delimitation in *Prestonia* is discussed. *Prestonia amabilis* (Apocynaceae, Apocynoideae), a new species from Ecuador, is described and illustrated.

Durante la preparación de una monografía de *Prestonia* (Apocynaceae, Apocynoideae), un total de 55 especies han sido reconocidas, distribuidas desde México al N de Argentina y las Islas del Caribe (Morales, en prep.). Dado el alto número de especies de *Prestonia* originalmente descritas basadas en una sola colección (Woodson 1936), y la alta sinonimia prevaleciente en otros géneros, donde se han presentado situaciones similares (Morales 1999), ha sido necesaria la evaluación de varios caracteres tradicionalmente usados para separar especies (e.g., grado de laceración de los coléteres de los sépalos y de los nectarios o disco nectarífero), lo cual ha comprobado que algunos de ellos son muy inestables y no deben de ser usados como el carácter principal para el reconocimiento a nivel específico, tal y como fue demostrado por Morales (1997 b) para las especies mesoamericanas de la sección Tomentosae. Esto ha conllevado a la sinonimización de varios nombres. Las medidas aquí mencionadas están basadas en los resultados obtenidos durante la preparación de una nueva monografía del género.

La forma y consistencia de los sépalos fue un carácter clave usado por Woodson para separar secciones dentro de *Prestonia*. Sin embargo, dado que la utilidad de estos caracteres es cuestionable (para separar secciones) y junto con el descubrimiento de una nueva especie de Ecuador, con un cáliz bastante inusual, una explicación se brinda a continuación. Los sépalos en *Prestonia* son siempre libres longitudinalmente, estando únicamente ligados en forma basal al hipantio. Los sépalos pueden ser conspicuamente foliáceos o subfoliáceos (e.g., *P. portobellensis* (Beurl.) Woodson) a escariosos (e.g., *P. quinquangularis* (Jacq.) Spreng.). Woodson (1936) distinguió tres secciones basado en la consistencia de los sépalos. De esta manera, él separó la sección *Acutifoliae* de las secciones *Annulares* y *Tomentosae* por sus sépalos pequeños e inconspicuos, escariosos o levemente foliáceos y usualmente reflexos apicalmente (vs. grandes y conspicuos, foliáceos a subfoliáceos y no reflexos apicalmente). Sin embargo, estos caracteres no son totalmente confiables para la separación de estas secciones y la búsqueda de otros más consistentes debe prevalecer, debido a que son subjetivos y están supeditados al criterio de cada taxónomo. Primero, en las especies incluidas en la sección *Acutifoliae*, los sépalos no son consistentemente reflexos en el ápice, pudiéndose encontrar ápices reflexos o no reflexos. Luego, los términos foliáceo, subfoliáceo, o levemente foliáceo son totalmente subjetivos, si no son acompañados de medidas y otros caracteres adicionales, que definan claramente el concepto del monografiador. Por otro lado, algunas especies incluidas en las sección *Annulares* (e.g., *P. longifolia* (Sessé & Moc.) J. F. Morales) tienen sépalos escariosos a muy levemente subfoliáceos, de 3–6(–8) × 2–3 mm, no reflexos apicalmente, los cuales no difieren en gran medida de aquellos de otras especies incluidas en la sección *Acutifoliae* (e.g., *P. lagoensis* (Müll. Arg.) Woodson), con sépalos de 3–6 × 1.5–2 mm, reflexos o no reflexos apicalmente. Por lo tanto, se sugiere utilizar otros caracteres más consistentes, como el tipo y densidad del indumento de flores y frutos, presencia o ausencia de los lóbulos coronales en el interior de la corola, nivel de inserción de los lóbulos coronales (apicalmente exsertos o levemente incluidos, con los ápices casi al mismo nivel de la corona anular vs. profundamente incluidos, con los ápices por debajo de los ápices de las anteras) y textura de sépalos y hojas. Sin embargo, la definición definitiva de las secciones serán comentadas con detalle en la próxima monografía del género.

La última monografía del género *Prestonia* (Apocynaceae, Apocynoideae) fue hecha por Woodson (1936), quien aceptó 61 especies. Cinco especies fueron reportadas en ese entonces para Ecuador, *P. mollis* Kunth, *P. parvifolia* K. Schum. ex Woodson, *P. peregrina* Woodson, *P. rotundifolia* K. Schum. ex Woodson y *P. schumanniana* Woodson, cuatro de ellas endémicas y conocidas por menos de dos colecciones, con solo *P. mollis* reportada también en Perú. Desde 1936, el número de expediciones en Ecuador se han incrementado en forma notable, sobre todo en los últimos 30 años, lo que producido un aumento considerable en el número de colecciones de Apocynaceae disponibles hoy en día. Estos esfuerzos resultaron en la descripción de nuevas especies, algunas de ellas muy raras y endémicas (Morales 1997 a). El proceso de revisión de especímenes para una nueva monografía de *Prestonia* ha llevador a la necesidad de sinonimizar algunos taxa y elevado el número de especies conocidas para Ecuador a 15 (dos de ellas aún sin describir) y llevado a la necesidad de sinonimizar algunos taxa.

Una de estas especies inéditas es muy notable por tener los sépalos connados basalmente, conformando una base campanulada, algo bastante inusual dentro del género y que no fue reportado por Woodson (1936). Especies con sépalos connados a lo largo del tercio o mitad basal son muy raras y solamente otros dos taxas tienen la misma característica, *P. haughtii* Woodson (incluyendo *P. macrophylla* Woodson) y *P. rotundifolia* K. Schum. ex Woodson. Estas tres especies están restringidas a lo largo de los Andes desde la Cordillera Occidental en Colombia, a través de Ecuador hasta el N de Perú y en forma general son conocidas por muy pocas colecciones. Por lo tanto, esta nueva especie es descrita a continuación.

Prestonia amabilis J.F. Morales, sp. nov. (**Fig. 1**). TIPO. ECUADOR. PASTAZA: Hacienda San Antonio de Baron von Humboldt, 2 km NE de Mera, 27 Feb–19 Mar 1985 (fl, fr), *Neill et al.* 5975 (HOLOTIPO: INB; ISOTIPOS: MO, NY, USF, fotocopia en INB).

Suffruticosa volubilis, ramulis minutis puberulis maturitate sparseque puberulis vel glabratis; folia elliptica, 13–23 _ 6.5–13.5 cm, glabra, glabrata vel sparseque puberula, apice breviter acuminata, basi obtusa vel rotundata, petiolus 1–2 cm; inflorescentia corymbosa, lateralibus, bracteis 1–2 mm longis, calycis laciniis ovalis vel ovalis-elliptica, (10–)12–19 mm longis, minute puberulis, corolla salverformis, tubo extus glabro, 14–15 mm, lobis coronae inclusis vel paulo exsertis; folliculis 18–27.5 cm, glabratis.

Liana, ramitas diminutamente ferrugíneo-puberulentas cuando jóvenes, muy esparcidamente puberulentas a glabradas en la madurez, con secreción lechosa, inconspicuamente lenticeladas, coléteres interpeciolares inconspicuos, 0.5–1 mm de largo. Hojas: lámina 13–23 × 6.5–13.5 cm, elíptica, obtusa y abruptamente corta-acuminada o apiculada apicalmente, obtusa a redondeada basalmente, coriácea a subcoriácea, algunas veces algo revoluta marginalmente, glabra y usualmente brillante adaxialmente, inconspicuamente papilada-puberulenta a glabrada abaxialmente, venación secundaria y terciaria conspicuamente impresas, peciolo 1–2 cm. Inflorescencia corimbosa, axilar, usualmente más larga que las hojas adyacentes, con muchas flores, diminutamente y densa a esparcidamente ferrugíneo-puberulenta, pedúnculo 6.5–21 cm, pedicelos (1–) 1.7–2.8 cm, brácteas 1–2 × 0.5–1 mm, escariosas; base del cáliz conspicuamente campanulada, sépalos (10–)12–19 × (3–)4–6 mm, fusionados basalmente a lo largo de 1/3–1/2 de su longitud, coriáceos a subcoriáceos, angostamente ovados a angostamente ovado-elípticos, acuminados a cortamente acuminados, no reflexos apicalmente, diminuta y densamente ferrugíneo-puberulentos, raramente glabrados, foliáceos, coléteres 1–1.5 mm de largo, enteros, subenteros, o diminutamente erosos; corola hipocrateriforme, amarilla y moteada con rojo, glabra exteriormente, tubo 14–15 × 3–4 mm, recto, lóbulos coronales 1.5–2 mm, incluidos o apicalmente exsertos, corona anular entera, conspicua, lóbulos 9–11 × 7–9 mm, obovados; anteras 5 mm, glabras, los ápices conspicuamente exsertos, ovario 1–1.5 mm, glabro, cabeza estigmática ca. 1 mm, disco sobrepasando el ovario, usualmente profundamente y irregularmente pentalobado, eroso a algo lacerado. Folículos 18–27.5 × 0.8–1.2 cm, continuos a levemente moniliformes, esparcidamente lenticelados, glabrados; semillas 16–19 mm, glabras, la coma 3.5–4.8 cm, café oscuro.

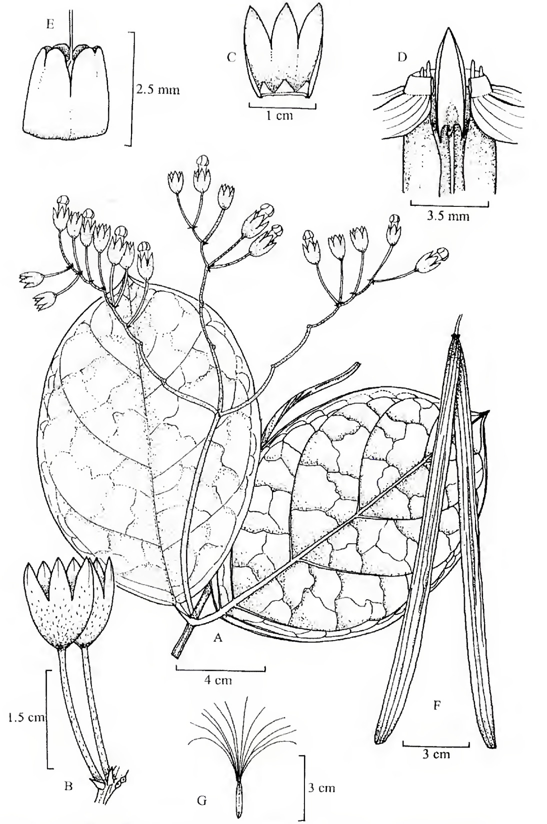

Fig. 1. *Prestania amabilis* (A-E de *Palacios 10102*, USF; F-G de *Brehm s.n.* (INB)). **A.** Ramita florífera. **B.** Cáliz, pedicelos, y brácteas. **C.** Cáliz abierto, mostrando la base cupuliforme y los sépalos fusionados. **D.** Tubo de la corola abierto, mostrando las anteras, corona anular, y lóbulos coronales apicalmente exsertos. **E.** Disco. **F.** Folículos. **G.** Semilla.

Distribución, hábitat, y ecología.—Restringida por el momento a Ecuador, donde crece en bosques muy húmedos y áreas de vegetación perturbada, en elevaciones de 300–1100 m. Especímenes con flores fueron colectados de Febrero hasta Junio, y de Agosto hasta Diciembre. Especímenes con frutos fueron colectados en Febrero, Marzo, y Noviembre.

Paratipos. **ECUADOR. Morona-Santiago:** Limón Indanza, cuenca del río Coangos, río Tsuirin, Oct 1999 (fl), *Ronquillo et al. 1018* (MO). **Napo:** carretera Coca-Loreto, cerca a río Pinguillo, 20 Oct 1988 (fl), *Cerón et al. 5331* (MO, USF); Shinguipino, entre ríos Napo y Tena, 30 Sep 1960 (fl), *Grubb et al. 1688* (K, NY); Tena, carretera Campococha-Chontapunta, 23 Ago 1997 (fl), *Nuñez & Tapuy 616* (MO); NNO de Coca, río Huashito, 27 Oct 1982 (fl), *Pennington 10637* (K, QCA). **Pastaza:** Arajuno, campamentos 11-12, 15-20 Sep 1998 (fl), *Freire et al. 3433* (MO); Puyo, Santa Cecilia, Villano, 1 May 1992 (fl), *Palacios 10102* (MO, QCNE, USF); Puyo, Los Vencedores, carretera Puyo-Macas, 8 Jun 1996 (fl), *Soejarto et al. 9651* (F); Pozo Villano, 3 Dic 1991 (fl), *Tipaz et al. 426* (MO, QCNE). **Zamora-Chinchipe:** Parque Nacional Podocarpus, 4 km al S de Zamora, 30 Nov 2000 (fl, fr), *Brehm s.n.* (INB); Nangaritza, Miazi, río Nangaritza, 28 Jul 1993 (st), *Gentry 80568* (MO).

Prestonia amabilis es similar a *P. haughtii* (incluyendo *P. macrophylla* Woodson) por tener sus sépalos connados basalmente y formando una conspicua base campanulada, pero difiere por su inflorescencia repetidamente ramificada, sépalos diminutamente ferrugíneo-puberulentos (vs. glabros o glabrados), anteras apicalmente exsertas (vs. incluidas) y lóbulos coronales levemente exsertos o al menos al nivel de la corona anular (vs. profundamente incluidos). Esta especie esta además algo relacionada a *P. annularis*, pero difiere por sus inflorescencias más grandes, sépalos ferrugíneo-puberulentos, base del cáliz campanulada, y frutos más gruesos y algo leñosos.

AGRADECIMIENTOS

Quiero agradecer a los herbarios K, MO, NY, QCA, US, USF por el envío de material en préstamo. Asimismo, se agradece al personal del Herbario de la Universidad de Antioquia (HUA), por las facilidades brindadas durante mis visitas a Medellín, Colombia. También deseo agradecer a Gunnar Brehm y Juergen Homeier, quienes suministraron fotografías, material preservado y duplicados de *Prestonia amabilis*.

RESUMEN

Se describe e ilustra una nueva especie del género *Prestonia*, y sus relaciones con taxas relacionados son discutidas. Se brinda un total de 13 nuevas citas de Apocynaceae para Bolivia y se proponen nuevas sinonimias en los géneros *Himatanthus*, *Prestonia*, y *Tabernaemontana*.

ABSTRACT

A new species of *Prestonia* is described and illustrated, and its relationships with related taxa are discussed. In addition, 13 new records of Apocynaceae (subfamily Apocynoideae) are reported for Bolivia and new synonymy on *Himatanthus*, *Prestonia*, and *Tabernaemontana* are proposed

Bolivia es uno de los países menos explorados desde el punto de vista botánico en América del Sur. Hasta la fecha, no se ha realizado ningún tratamiento integral para su flora y prácticamente, la única referencia disponible es el trabajo de Foster (1958), el cual consiste en un catálogo basado en la información de trabajos monográficos previos. Al igual que casi todo el resto de la flora, no existen tratamientos para la familia Apocynaceae (subfamilia Apocynoideae) y las únicas referencias parciales son las monografías de varios géneros (e.g., Monachino 1943, 1945a; Morales 1999, 2002; Woodson 1933, 1936). El incremento de la actividad botánica en los últimos 20 años en el país, han provocado un notable aumento de nuevos reportes y novedades en la flora en general (e.g., Al-Shehbaz 1999; Fuentes 1998; Justiniano y Toledo 2001; Moraes 1996; Navarro 1997; Zuloaga et al. 1993). Como parte del proceso de elaboración de las Apocynaceae para el Catálogo de las Plantas Vasculares de Bolivia, una serie de novedades taxonómicas han sido encontradas. Estas incluyen géneros y especies anteriormente no citados (e.g., *Lacmellea*, *Stipecoma*), nuevas sinonimias (e.g., *Himatanthus*, *Prestonia*) y una nueva especie de *Prestonia*. Para el caso de nuevos reportes, solo se cita un especimen representativo por Departamento, y cuando el caso lo amerita, se brindan comentarios adicionales para cada especie o género. Asimismo, solo se citan géneros o especies que no hayan sido reportados anteriormente en el checklist de Foster (1958) o en los trabajos de Chávez de Michel (1993), Ezcurra (1981, 1984), Fallen (1983), Gensel (1969), Hansen (1985),

SIDA 21(1): 165–174. 2004

Killeen et al. (1998), Leeuwenberg (1994), Marcondes-Ferreira (1988), Meyer (1955), Monachino (1943, 1945a, 1945 b), Morales (1997, 1999, 2002, 2003), Plumel (1991), Rao (1956), Sakane y Sheperd (1987) y Woodson (1933, 1935, 1936, 1951). Para la determinación de la nueva sinonimia en *Prestonia*, todas las colecciones tipo fueron examinadas (a menos que se indique lo contrario) como parte del trabajo monográfico realizado por el primer autor para la serie Flora Neotrópica. Asimismo, las medidas de *P. lagoensis* (Müll. Arg.) Woodson y *Mandevilla scabra* (Hoffmans. ex Roem. & Schult.) K. Schum. utilizadas como referencia de comparación en la descripción de *P. boliviana* y *M. symphitocarpa*, fueron extraídas de las monografías de *Prestonia* y *Mandevilla* (Morales, en prep.), las cuales pueden diferir en alguna forma de los trabajos de Woodson (1933, 1936).

NUEVA ESPECIE

Prestonia boliviana J.F. Morales & A. Fuentes, sp. nov. (**Fig. 1**). TIPO: BOLIVIA. CHUQUISACA: valle del Río Limón, entre Padilla y Monteagudo, 13 Feb 1994 (fl), *Wood 7970* (HOLOTIPO: LPB; ISOTIPOS: INB, K).

Suffruticosa volubilis, ramulis glabris. Folia late ovalia, 8–9 × 4–5 cm, glabra, apice acuminata, basi obtusa vel rotundata, petiolus 1.5–2.5 cm. Inflorescentia racemosa, lateralibus, bracteis 1.5–2 mm longis, scariaceis, calycis laciniis anguste ovatis, 2.5–3 mm longis, glabris, corola salverformis, tubo extus glabro, 8–9 mm, appendicibus lobis coronae paulo exsertis. Folliculis ignotis.

Liana, ramitas glabras, con secreción acuosa, coléteres interpeciolares inconspicuos, menos de 0.5 mm de largo. Hojas: lámina 8–9 × 4–5 cm, anchamente ovada, acuminada apicalmente, obtusa a redondeada o cordada basalmente, delicadamente membranácea, no revoluta marginalmente, glabra, venas secundarias levemente impresas, venación terciaria casi inconspicua o inconspicua, peciolo 1.5–2.5 cm. Inflorescencia racemosa o corimbosa y dicotómicamente ramificada, pero ramificándose solo una vez cerca de la base y pareciendo subracemosa, axilar, usualmente más larga que las hojas adyacentes, laxa, con muchas flores, glabra a glabrada, pedúnculo 5–6.5 cm, pedicelos 2–3 cm, brácteas 1.5–2 × 0.5–1 mm, escariosas; base del cáliz corta e inconspicua, no campanulada, sépalos 2.5–3 × 1 mm, libres a lo largo de su entera longitud, delicadamente membranáceos, muy angostamente ovados, acuminados, los ápices algo reflexos apicalmente, glabros a glabrados, escariosos, coléteres 0.5–1 mm de largo, muy diminuta e inconspicuamente lacerados; corola hipocrateriforme, crema, glabra exteriormente, tubo 8–9 × 2.5 mm, recto, lóbulos coronales 2.5–3 mm, apicalmente exsertos, corona anular entera, conspicua, lóbulos 8–10 × 5 mm, obovados; anteras 4 mm, glabras, los ápices algo exsertos, ovario ca. 1.5 mm, glabro, cabeza estigmática ca. 2 mm, nectarios ca. 1 mm de largo, enteros a subenteros. Folículos desconocidos.

Distribución, hábitat y ecología. Endémica al departamento de Chuquisaca, Bolivia, donde crece en bosques estacionalmente húmedos y áreas de vegetación disturbada asociada de la formación Boliviano-Tucumana, en elevaciones

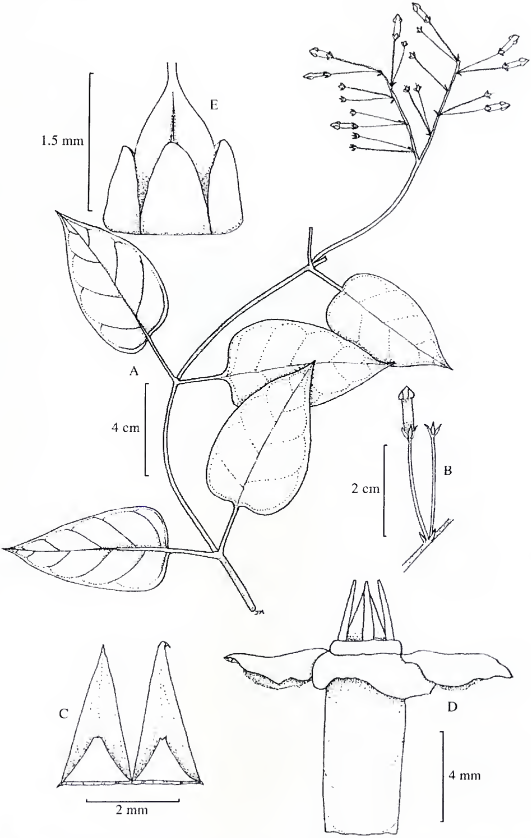

Fig. 1 *Prestonia boliviana* (*Wood 7970*, LPB). **A.** Ramita florífera. **B.** Cáliz, pedicelos, y brácteas. **C.** Sépalos y coléteres, vista adaxial. **D.** Corola, mostrando los lóbulos coronales y anteras apicalmente exsertas. **E.** Nectarios y ovario.

entre 1300–1500 m. Especímenes con flores han sido recolectados en Febrero y Mayo.

Paratipos. BOLIVIA. Chuquisaca: entre Padilla y Monteagudo, río Marcani, 1 Jun 2003 (fl), *Morales 9326* (LPB).

Prestonia boliviana pertenece a la sección *Acutifoliae* por sus flores glabras exteriormente y sépalos pequeños e inconspicuos (Woodson 1936). Esta especie está cercanamente relacionada con *P. lagoensis* (Müll. Arg.) Woodson, ya que vegetativamente son muy similares (e.g., textura y forma de las hojas, estructura de la inflorescencia) y ambas tienen flores con los lóbulos coronales conspicuamente exsertos apicalmente. Sin embargo, *P. boliviana* es fácilmente separada por sus flores con los sépalos 2.5–3 × 1 mm (vs. 3–6 × 1.5–2 mm), tubo de la corola más pequeño, 8–9 mm de largo, (vs. 13–20 mm) y pedicelos más largos, con 20–30 mm de longitud [vs. 8–14(–18) mm].

NUEVOS REPORTES

1. Couma macrocarpa Barb. Rodr., Vellozia (ed. 2) 1:32, pl. 1, f. b. 1891. Solo hemos visto un especimen estéril, pero que sin duda pertenece a esta especie. Debido a la escasez de colecciones suramericanas en la primera mitad del siglo XX, no fue reportada para Bolivia por Monachino (1943). El género *Couma* se reconoce fácilmente por sus hojas verticiladas, pecíolos con coléteres basales y frutos bayas carnosas, usualmente comestibles. El género está ampliamente distribuido en toda la cuenca amazónica, siendo *C. macrocarpa* la especie más común.

Especímenes representativos examinados: **BOLIVIA. Pando:** Federico Román, Río Negro, tributario del Abuná, *Vargas et al. 988* (LPB, USZ).

2. Forsteronia affinis Müll. Arg., Fl. Bras. 6(1):100, pl. 30. 1860. *Fosteronia* es un género mayormente Suramericano, con unas pocas especies presentes en las Islas del Caribe, México y Mesoamérica. Ampliamente distribuida en Colombia, Venezuela, Perú y Brasil, esta especie era desconocida en Bolivia (Hansen 1985), pero recientes colecciones en el Departamento de Santa Cruz, han confirmado su presencia en este país.

Especímenes representativos examinados: **BOLIVIA. Santa Cruz:** Parque Nacional Noel Kempff Mercardo, Campamento Las Gamas, *Foster et al. 476* (MO, USF, USZ).

3. Forsteronia australis Müll. Arg., Fl. Bras. 6(1):103. 1860. Esta especie es bastante rara y anteriormente era conocida solo en Brasil, donde se reportaba de localidades aisladas en los estados de Bahia, Ceará, Goiás, Minas Gerais, Rio de Janeiro y Sao Paulo (Hansen 1985). En Bolivia se conoce solamente en el departamento de Santa Cruz, de los bosques semideciduos chiquitanos.

Especímenes representativos examinados. **BOLIVIA. Santa Cruz:** Florida, Quebrada La Coca, al SO de Bermejo, *Nee 44409* (MO, NY, USF, USZ).

4. Forsteronia graciloides Woodson, Ann. Missouri Bot. Gard. 22:163–165. 1935.

Aunque anteriormente fue conocida solo de Perú y una colección disyunta de Colombia (Hansen 1985), especímenes adicionales han ampliado su rango de extensión a Ecuador y Bolivia, donde es reportada por primera vez. Esta especie se puede reconocer con facilidad por el relativamente pequeño tamaño de sus hojas, con las láminas obovadas y la presencia de domacios pubescentes a lo largo del nervio central abaxialmente.

Especímenes representativos examinados: **BOLIVIA. La Paz:** Abel Iturralde, Parque Nacional Maididi, río Tuichi, arroyo Rudidi, *Paniagua et al. 5099* (LPB, MO).

5. Galactophora calycina (Huber ex Ducke) Woodson, Ann. Missouri Bot. Gard. 19:50. 1932. *Galactophora* es un género de hierbas erectas típico de zonas abiertas y sabanas, restringido a Suramérica, donde ocurre desde la Amazonía colombiana hasta Brasil y Bolivia. Anteriormente era conocida solo en Colombia, Venezuela y Brasil. Aunque históricamente *G. calycina* se ha considerado como una especie distinta de *G. crassifolia* (Müll. Arg.) Woodson (Woodson 1936), es probable que representen una misma entidad, dado que la única diferencia permisible entre ambas es la presencia o ausencia de la pubescencia en hojas e inflorescencias y existen especímenes con un amplio grado de variación en relación a la densidad del indumento, situación que se repite en otros géneros de la tribus *Apocyneae* (e.g., *Odontadenia*) y *Mesechiteae* (e.g., *Mandevilla*). En todo caso, ambas especies son exactamente iguales en el resto de caracteres morfológicos.

Especímenes representativos examinados: **BOLIVIA. La Paz:** Iturralde, Luisita, *Haase 827* (LPB). **Santa Cruz:** Velasco, entre Florida y Bella Vista, *Guillén et al. 2545* (INB, MO, SCZ).

6. Lacmellea aculeata (Ducke) Monachino, Lloydia 7:292. 1944 [1945]. El género *Lacmellea* está confinado mayormente a Sur América, donde la mayor cantidad de especies están restringidas a la cuenca amazónica, aunque si bien, unas pocas especies están presentes en Mesoamérica (Morales 1998). La última monografía fue hecha por Monachino (1944), quién entonces no reportó ninguna especie para Bolivia. *Lacmellea aculeata* está ampliamente distribuida en la cuenca baja amazónica, desde Colombia y las Guyanas hasta Brasil y Bolivia. Una especie adicional, probablemente no descrita y cercanamente relacionada con este taxón, con hojas densamente pubescentes abaxialmente y conocida solo por colecciones con frutos del Departamento de Pando, se encuentra en Bolivia.

Especímenes representativos examinados: **BOLIVIA. Pando:** Rio Madeira, cerca de Abuna, *Prance et al. 8358* (NY, US).

7. Lacmellea arborescens (Müll. Arg.) Markgr. Notizbl. Bot. Gart. Berlin-Dahlem 15:626. 1941. La revisión de *Lacmellea* de Monachino (1944) reportó esta especie como endémica a Brasil, pero el proceso de elaboración de una nueva monografía del género (Morales, en prep.), ha extendido su rango hasta Perú y Bolivia. Esta especie está cercanamente relacionada a *L. ramosissima* (Müll. Arg.) Markgr. pero puede ser separada por sus hojas con nervios secundarios separados mayormente por 2 a 4 mm, lóbulos de la corola de 1–1.5 mm de longitud y frutos globosos a subglobosos, de 9 a 12 mm de diámetro. Otras especies relacionados a estos taxones por Monachino (1944), (e.g., *L. peruviana*) serán sinonimizadas en la próxima revisión del género (Morales, en prep.).

Especímenes representativos examinados: **BOLIVIA. Pando:** Federico Román, Río Abuná, Fortaleza, base naval Abuná, senda hacia la cachuela, *Vargas et al. 1066* (F, LPB, MO, USZ).

8. Mandevilla symphitocarpa (G. Meyer) Woodson, Ann. Missouri Bot. Gard. 19:70. 1932. Aunque originalmente fue conocida como restringida a las Guyanas y Trinidad (Woodson 1933), en el proceso de elaboración de una nueva monografía del género, se ha encontrado que *Mandevilla symphitocarpa* es una rara especie, distribuida ampliamente en toda la cuenca baja amazónica (Morales, en prep.). Este taxa puede ser confundida con la común *M. scabra* (Hoffmansegge ex Roemer & Schultes) K. Schumann, pero *M. symphitocarpa* se puede reconocer fácilmente por sus hojas, con la lámina foliar usualmente glabra (vs. variadamente pubescente a glabrada), flores con la parte inferior del tubo de la corola 4–5 mm de ancho (vs. 2–3 mm), folículos 25–32 cm de largo (vs. 9–23 cm) y semillas 13–16 mm de longitud (vs. 10–12 mm), con la coma 33–37 mm de largo (vs. 14–24 mm).

Especímenes representativos examinados: **BOLIVIA. Santa Cruz:** Serranía de Huanchaca, estación los Fierros, *Foster et al. 13733* (LPB, USZ).

9. Odontadenia anomala (Van Heurck & Müll. Arg.) J.F. Macbr., Field Mus. Nat. Hist., Bot. Ser. 11:35. 1931. Anteriormente reportada como endémica para Perú (Morales 1999), varias colecciones de esta especie fueron localizadas en varios herbarios bolivianos, lo que ahora amplia el rango de distribución hasta Bolivia. Una de las especies más distintivas en el género por sus hojas irregularmente verticiladas.

Especímenes representativos examinados. **BOLIVIA. Beni:** Vaca Diez, Río Beni, puerto de Florida, *Moraes 580* (LPB, USF). **Pando:** Puerto Candelaria, Río Madre de Dios, *Moraes 528* (LPB, MO, P, SI). **Santa Cruz:** Velasco, Campamento La Toledo, camino hacia Florida, *Guillén & Roca 2474* (USZ).

10. Prestonia lagoensis (Müll. Arg.) Woodson, Ann. Missouri Bot. Gard. 23:296. 1936. Esta especie fue conocida por mucho tiempo solo por la colección tipo, hecha por Warming en Lagoa Santa, Minas Gerais, Brasil. Sin embargo, con la futura sinonimización de *P. lindmanii* (Malme) Hoehne (Morales, en prep.), dentro de esta especie, su rango se extenderá notablemente. A pesar de ser relativamente común en Brasil y Paraguay, es conocida en Bolivia por menos de tres colecciones.

Especímenes representativos examinados: **BOLIVIA. Santa Cruz:** Velasco, Cerro Pelao, *Guillén & Surubi 1251* (MO, USZ).

11. Rauvolfia mollis S. Moore, Trans. Linn. Soc. London, Bot. Ser. 2, 4:393. 1895. *Rauvolfia mollis*, no reportada anteriormente para Bolivia (Rao 1956), es una especie cercanamente relacionada con *R. ligustrina* Willd. ex Roem. & Schult. y ambas especies pueden confundirse con facilidad, ya que los caracteres que las separan citados por Rao (1956) algunas veces tienden a traslaparse. En términos generales, *R. mollis* se reconoce de *R. ligustrina* por sus inflorescencias largamente pedunculadas y el indumento usualmente hirsuto de tallos e inflorescencias.

Especímenes representativos examinados: **BOLIVIA. Beni:** Mamoré, 104 km al N de Trinidad, camino a San Joaquín, *Moraes et al. 1521* (LPB). **Santa Cruz:** Velasco, San Juancito, 27 km al N de San Ignacio, *Seidel & Beck 379* (LPB, MO, SI).

12. Stipecoma peltigera (Stadelm.) Müll. Arg., Fl. Bras. 6(1):176. 1860. En la monografía de Woodson (1936), *Stipecoma* era conocido únicamente por menos de seis colecciones, de los estados de Bahia, Goiás, Minas Gerais en Brasil. Sin embargo, el incremento de la actividad botánica en dicho país en el último siglo ha incrementado notablemente el número de especímenes de esta especie. Anteriormente endémico para Brasil, es reportado por primera vez para Bolivia.

Especímenes representativos examinados: **BOLIVIA. Santa Cruz:** Chiquitos, La Mina, Motacuzal, Chochí, *Wood & Landivar 17548* (K, LPB).

13. Vinca major L., Sp. Pl. 1:209. 1753. Esta hierba de origen europeo ha sido introducida ampliamente en los trópicos y se puede encontrar en algunos sitios cercanos a la Paz creciendo escapada de cultivación.

Especímenes representativos examinados: **BOLIVIA. La Paz:** Murillo, Jardíon Botánico Municipal, *Solomon 15602* (LPB, MO).

NUEVA SINONIMIA

1. **Himatanthus sucuuba** (Spruce ex Müll. Arg.) Woodson, Ann. Missouri Bot. Gard. 25:198. 1938 [1937]. *Plumeria succuba* Spruce ex Müll. Arg., Fl. Bras. 6(1):40. 1860. TIPO: BRASIL. AMAZONAS: Manaus, Oct 1851 (fl), *Spruce 1848* (HOLOTIPO: K, ISOTIPOS: F, P).

Himatanthus tarapotensis (K. Schum. ex Markgr.) Plumel, Bradea 5(supl.):50. 1991. *Plumeria tarapotensis* K. Schum. ex Margr., Notizbl. Bot. Gart. Berlin-Dahlem 11: 339. 1932. TIPO: AMAZONAS: Remate dos Males, *Ducke 21607* (HOLOTIPO: RB; ISOTIPO: P).

El basiónimo de *Himatanthus tarapotensis* fue incluido anteriormente en la sinonimia de *H. succuba* por Woodson (1938), pero fue elevado al rango de especie por Plumel (1991). Sin embargo, las diferencias mencionadas por Plumel para distinguir ambas especies (hojas oblongas en *H. succuba* vs. hojas elípticas en *H. tarapotensis*) no son consistentes ni relevantes para mantener ambos taxas como entidades diferentes, pues corresponden a leves variantes morfológicas, sin ninguna discontinuidad evidente o aislada. Además, las colecciones tipo no difieren en el resto de caracteres morfológicos (e.g., inflorescencia, flores).

2. **Prestonia tomentosa** R. Br., Mem. Wern. Nat. Hist. Soc. 1:70. 1811. TIPO: BRASIL. RIO DE JANEIRO: Rio de Janeiro, s.d. (fl), *Banks 684* (HOLOTIPO: BM, foto en BM, INB, NY).

Prestonia cornutisepala Rusby, Mem. New York Bot. Gard. 7:329. 1927, **syn. nov.** *Prestonia cephalantha* Rusby, Mem. New York Bot. Gard. 7:330. 1927, **syn. nov.** Tipo: BOLIVIA. La Paz: Ixiamas, 17 Dic 1921 (fl), *Cardenas 1928* (holotipo: NY; isotipos: K, NY, n.v.).

Prestonia cornutisepala y *P. cephalanta* fueron descritas basadas en la misma colección tipo. *Prestonia cornutisepala*, descrita originalmente para Bolivia, no fue incluida en la monografía de Woodson (1936). La colección tipo no difiere en ninguna forma del tipo de *P. tomentosa*, y por lo tanto debe ser sinonimizada.

3. Tabernaemontana vanheurckii Müll. Arg., Observ. Bot. 168. 1871. Tipo: PERÚ. San Martín: cerca de Tarapoto, 1855–1856 (fl), *Spruce 4209* (holotipo: AWH; isotipos: BM, BP, BR, C, CGE, E, G, GH, GOET, K, L, MO, NY).

Tabernaemontana unguiculata Rusby Mem. New York Bot. Gard. 7:324. 1927, **syn. nov.** Tipo. BOLIVIA. La Paz: Huachi, cabeceras del Río Beni, 21 Ago 1921 (fl), *White 461* (holotipo: NY; isotipos: GH, US).

Tabernaemontana unguiculata fue incluida en la sinonimia de *T. heterophylla* por Leeuwenberg (1994). Sin embargo, despúes del estudio de las colecciones tipos de ambas especies, es claro que *T. unguiculata* es coespecífica con *T. vanheurckii* y por lo tanto, debe ser removida de la sinonimia de *T. heterophylla*, tal y como fue previamente propuesto por Killeen et al. (1993).

AGRADECIMIENTOS

Queremos agradecer a los curadores y directores de los siguientes herbarios B, BM, BOLV, C, CGE, E, F, G, G-DC, GH, K, M, MO, NY, LPB, P, US, USZ por el préstamo y uso de sus colecciones. El primer autor agradece al Missouri Botanical Garden (MO) por el generoso envio de material por regalo de identificación, así como a Stephan Beck (LPB) por la ayuda brindada en su estadía en Bolivia. También queremos agradecer a Mary Endress (Z), por ayudar a clarificar la identificación de las especies de *Malouetia* presentes en Bolivia.

ABSTRACT

Stellaria oxyphylla B.L. Rob. has been rediscovered in northern Idaho; a taxon rarely noted in the literature since its original description in 1898. Our study indicates that *Stellaria oxyphylla* is congeneric with *Pseudostellaria*, thus the new combination is provided. The three western North American members of *Pseudostellaria* have six capsular valves that dehisce by rolling back tightly 2 or 3 revolutions, forming a shallow dish, thus exposing the seeds. *Pseudostellaria oxyphylla* differs from *P. sierrae* Rabeler & R.L. Hartman and *P. jamesiana* (Torr.) W.A. Weber & R.L. Hartman in having internodal lines of hairs (0.5–5 mm wide) on the stems and branches of the inflorescences, but like the last taxon, the stems of *P. oxyphylla* are square in cross section. In general appearance, *P. oxyphylla* is most similar to *P. jamesiana*, the congener widely distributed in the western United States. *Pseudostellaria oxyphylla* and *P. sierrae* share a reduction in stamen number from 10 to 5 and seeds with elongate, rounded tubercles each with 5 to 12 or more minute stipitate glands or conical projections, respectively. *Pseudostellaria oxyphylla* is found along stream banks, often under and near conifers.

RESUMEN

Se ha redescubierto *Stellaria oxyphylla* B.L. Rob. en el norte de Idaho; un taxon raramente presente en la bibliografía desde que se describió en 1898. Nuestro estudio indica que *Stellaria oxyphylla* es congenérica con *Pseudostellaria*, por lo que se hace una nueva combinación. Los tres miembros del oeste de Estados Unidos de *Pseudostellaria* tienen seis valvas en su cápsula, que se abre enrollándose hacia atrás 2 ó 3 vueltas, formando un plato plano, exponiendo de este modo las semillas. *Pseudostellaria oxyphylla* difiere de *P. sierrae* Rabeler & R.L. Hartman y *P. jamesiana* (Torr.) W.A. Weber & R.L. Hartman por tener líneas de pelos internodales (0.5–5 mm de ancho) en los tallos y ramas de las inflorescencias, pero como el último taxon, los tallos de *P. oxyphylla* son cuadrados en sección transversal. En su aspecto general, *P. oxyphylla* es más semejante a *P. jamesiana*, el congénere ampliamente distribuido en el oeste de los Estados Unidos. *Pseudostellaria oxyphylla* y *P. sierrae* comparten una reducción en el número de estambres de 10 a 5, y semillas con tubérculos alargados y redondeados, cada uno con 5 a 12 o más glándulas estipitadas diminutas o proyecciones cónicas, respectivamente. *Pseudostellaria oxyphylla* se encuentra a lo largo de los bancos de torrentes, a menudo debajo y cerca de coníferas.

Stellaria oxyphylla B.L. Rob. has rarely appeared in the literature since it was described in 1898. Most recently, the taxon was relegated to synonymy under *Stellaria calycantha* (Ledeb.) Bong. as C.L. Hitchcock considered it "the robust extreme" of that taxon (Hitchcock et al. 1964). Rabeler (1986) considered *Stellaria oxyphylla* distinct from the *S. calycantha* complex and placed it tentatively under *Pseudostellaria jamesiana* (Torr.) W.A. Weber & R.L. Hartman. Our recent collaboration on the Caryophyllaceae for Flora of North America (Hartman & Rabeler in prep.), necessitates that we resolve the taxonomic status of this plant. Recent field work has provided new material and information on the geographic and ecological distribution of this taxon. Populations of *P. oxyphylla* appear restricted to stream margins in the St. Joe Mountains, Kootenai and Shoshone counties, Idaho, an area where *P. jamesiana* is absent. It likely represents a taxon of conservation concern but intensive field studies are warranted.

After studying the available material of *Stellaria oxyphylla* again, especially in light of our recent description of *Pseudostellaria sierrae* Rabeler & R.L. Hartman and its relationship to *P. jamesiana* (Rabeler & Hartman 2002), we conclude that these species are congeneric. We here make the following new combination, *Pseudostellaria oxyphylla* (B.L. Rob.) R.L. Hartman & Rabeler. The description, illustration (Fig. 1), and geographic and ecological notes supplement the only other published account of the species—the type description.

We investigated the relationship between the North American and Asian species of *Pseudostellaria* when *P. sierrae* was described (Rabeler & Hartman 2002); an overview of the genus can also be found in that article. At least one synapomorphy unites the western United States members of *Pseudostellaria*: six capsular valves that dehisce by rolling back tightly 2 or 3 revolutions, forming a shallow dish exposing the basal placentae with 1 or 2 seeds that may persist, at least briefly, prior to dispersal. In general appearance, *P. oxyphylla* is most similar to *P. jamesiana*. *Pseudostellaria oxyphylla* and *P. sierrae* share a reduction in stamen number from 10 to 5 and have seeds with elongate, rounded tubercles each having 5 to 12 minute stipitate glands or conical projections, respectively. All three taxa have rhizomes with occasional axillary buds, but unlike *P. oxyphylla*, *P. jamesiana* has tuberous thickenings of the rhizomes, while *P. sierrae* has tuberous, cigar-like thickened roots. Considerable excavation of the rhizomes of several plants of *P. oxyphylla* did not reveal additional perennating structures. Unfortunately, very few fully mature seeds are preserved for these taxa on herbarium specimens; this is especially true for *P. jamesiana*. Unlike *P. sierrae* (northern California) and *P. jamesiana* (widespread), with geographical ranges that overlap in part, *P. oxyphylla* appears to be disjunct from the latter taxon.

Pseudostellaria oxyphylla (B.L. Rob.) R.L. Hartman & Rabeler, comb. nov. (**Fig. 1**). BASIONYM: *Stellaria oxyphylla* B.L. Rob., Bot. Gaz. (Crawfordsville) 25:165, pl. 13, fig. 5, 1898. *Alsine oxyphylla* (B.L. Rob.) A. Heller, Cat. N. Amer. pl., ed. 2, p. 4. 1900. TYPE: U.S.A. IDAHO. KOOTENAI CO.: on St. Joseph's River [?], Wies[s]ner's Peak, *Sandberg, MacDougal, and Heller 608*, 8 Jul 1892 (fl), 1,800 m (HOLOTYPE: GH!; ISOTYPES: CAS!, NY!, PH!, POM!, US!).

Perennial, mostly glabrous herb, erect to sprawling, 20–25 cm tall, with stems arising singly, at varying intervals, along rhizomes. Roots vertical to spreading, filiform, 1–8 cm long or more; rhizomes often extensive, branched, whitish to

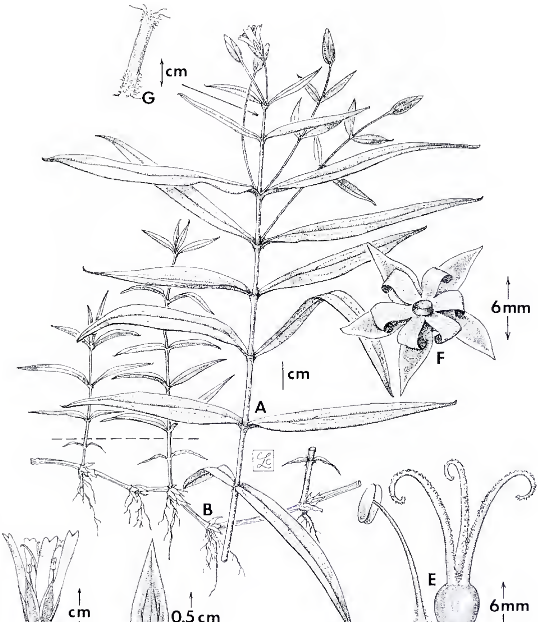

Fig. 1. *Pseudostellaria oxyphylla.* **A.** and **B.**, habit, the stem in A. detached from the base with rhizome, to the right in B. **C.** Flower. **D.** Sepal. **E.** Gynoecium with one stamen attached. **F.** Capsule, dehisced, with subtending calyx. **G.** Upper internode, side opposite the internodal line of pubescence.

tan, square in cross section to rounded with age, 0.5–1 mm in diameter, shiny, internodes 0.1–2 cm long or more, when internodes contracted achlorophyllous bracts often dense, overlapping, axillary buds 2-3 mm long. Stems mostly simple, square in cross section, internodes 1–5 cm long or more below, 1–2.5 cm long in inflorescence, glabrous except for a dense, internodal line of pubescence, 0.5–5 mm wide, trichomes straight to curly, most recurved, uniseriate of 5–9 elongate cells (possibly somewhat glutinous as evidenced by debris adhering to older material). Leaves opposite, sessile, the primary leaves 8–11 pairs on main stem, lanceolate to lance-elliptic, ascending to spreading, 6–12 × 0.7–1.2 cm, little reduced above, exstipulate, bases connate with transverse margin 0.3-0.6 mm wide, leaf surface flat, often pustulate (30×), margins often revolute, smooth to granular or sometimes papillate, sparsely ciliate proximally, midrib often sparsely pubescent adaxially, smooth, shiny, and often prominent abaxially. Inflorescence consisting of paired flowers, or one abortive, on pedicels often terminating secondary branches in the distal 3–7 axils, progressively reduced upward from pairs of normal leaves to scarious bracts, lanceolate to linear-lanceolate, 2–10 mm long; pedicels 1.5–4.5 mm long. Flowers perfect, chasmogamous, regular; sepals, inner lanceolate, outer narrowly ovate, 6.5–7 × 1.5–2.5 mm, glabrous, margins narrowly scarious, ciliolate in proximal half, midrib and lateral pair of nerves obscure, becoming evident in fruit, acute to acuminate, in fruit proximal 1/5 of sepals often with a thickened, elliptical patch; petals 5, white, strap-shaped, expanding to twice the width distally, 8–9 × 1.5–2 mm, broadly notched, notch 0.8–1 mm deep, the lobes rounded; stamens 5, each with a circular, thickened, basal gland 2–2.5 times the filament width, alternating with the petals, filaments 4–4.5 mm long, anthers yellow; ovary 3-carpellate, with 6–12 ovules; styles 3, 3.5–4 mm long, stigma terminal and adaxial, linear, minutely papillate (30×). Capsule ovoid, 4–4.5 mm long; valves 6, dehiscing by rolling back tightly 2–3 revolutions, forming a shallow dish exposing the basal placentae and plump funiculi. Seeds 1–2, reddish-brown, 2.5–2.6 mm long, circular, plump, radicle prominent, mature seeds with most tubercles broadly conical to elongate, rounded, interdigitating, each with 8–12 or more stipitate glands ca. 0.015 mm long or less (50×).

During the August visit to Pine Creek, most of the inflorescences were brown; most of the fruit aborted. This is likely a consequence of the dry summer. Similarly, it is very difficult to find fruiting material and seeds of *Pseudostellaria jamesiana*, in part because the fruits and seeds frequently abort or mature late in the fall and thus are seldom collected.

While this species has been known for over a century, to our knowledge it had been collected only twice, and never in fruit. The only collection subsequent to the type was gathered by J.H. Christ in 1940 (*Christ 10949*, NY). In August of 2000, Hartman relocated it and returned in June of 2001 to obtain additional material. The known geographic range appears restricted to the St. Joe Mountains and vicinity: extreme west-central Shoshone and southeastern Kootenai counties, Idaho.

Specimens examined: U.S.A. **Idaho. Kootenai Co.:** St. Joseph River [?], Wies[s]ner's Peak, 1,800 m., 8 Jul 1892, *Sandberg, MacDougal, & Heller 608* (HOLOTYPE: GH; ISOTYPES: CAS, NY, PH, POM, US); Pine Creek, just before Middle Fork Pine Creek, on jeep trail to Mount Wiessner, T47N R1E S15, 2,800 ft., 25 Aug 2000, *Hartman 70411* (MICH, MONT, RM); Pine Creek, 0.5 air mi NE of Middle Fork Pine Creek, T47N

R1E S12, 2,700 ft., 25 Aug 2000, *Hartman 70410* (MICH, RM), 12 Jun 2001, *Hartman 71073* (ID, MICH, NY, RM, UC, WTU). **Shoshone Co.:** cliffs along St. Joe River, 7 mi N of Calder, 19 May 1940, *Christ 10949* (NY).

The only floristic work that treats *Stellaria oxyphylla* as a recognized taxon is the unpublished "Manual of the Flora of Northern Idaho" by Carl Epling and Joseph Ewan dated 1941 (page 258 of 1121 page manuscript, original at MO; copies at RM, UC, provided by Alan Whittemore).

Several locations were visited along the St. Joseph River, including the segment in the vicinity of Christ's collecting site, but *Pseudostellaria oxyphylla* was not relocated. The habitat is given as "cliffs," perhaps at their bases. According to the late Douglass Henderson, "Christ's labels are to be viewed as "probably inaccurate"" (letter to Rabeler, Sep 1987).

After Hartman discovered populations of the taxon along Pine Creek, south of Pinehurst, he hiked the switchbacks from the southwest to the saddle, ca. 6,000 feet elevation, between Latour Peak (6,408 feet) and Mount Wiessner (6,185 feet). Neither suitable habitat for nor populations of *Pseudostellaria oxyphylla* was encountered on the slopes and drainages.

ECOLOGY

Pseudostellaria oxyphylla appears restricted to banks along perennial streams and rivers and adjacent moist sites; often under conifers or at the edge of coniferous forests. Due in part to an often extensive rhizome system, 20 to 100 or more flowering stems were found scattered in these sites that often dry out over the summer. On Pine Creek, the scattered populations were found over a 2.5 mile stretch of the creek valley.

ACKNOWLEDGMENTS

We wish to thank Carolyn Crawford for the illustration and the curators of CAS, GH, NY, PH, POM, and US for loans to Rabeler, ID, MONT, MONTU, WS for loans to Hartman, and CAS, MO, and UC for visits by Hartman and Rabeler.

ABSTRACT

Three species of *Prenanthes* occur in Texas. *Prenanthes carrii* Singhurst, O'Kennon, & Holmes is described as a new species endemic to the Edwards Plateau vegetational region. *Prenanthes altissima* is known only from Jasper and Newton counties in extreme southeastern Texas. *Prenanthes barbata* is more widespread but rare in rich hardwood and pine-oak forests in the Pineywoods of eastern Texas, with one record in the Post Oak Savannah of Lamar County. A key to species, descriptions, distribution map, and lists of exsiccatae are included.

RESUMEN

En Texas hay tres especies de *Prenanthes*. Se describe *Prenanthes carrii* Singhurst, O'Kennon, & Holmes como especie nueva endémica de la región de vegetación de Edwards Plateau. *Prenanthes altissima* se conoce únicamente de los condados de Jasper y Newton en el extremo sureste de Texas. *Prenanthes barbata* es más frecuente pero raro en los bosques de madera dura y de pino-roble en los pinares del este de Texas, con una cita en la sabana de Post Oak del condado de Lamar. Se incluye una clave de especies, descripciones, mapas de distribución, y listas de exsicatas.

INTRODUCTION

Correll and Johnston (1970) recognized two species of *Prenanthes* L. in Texas. One, *P. altissima* L. was identified from three specimens all collected the same year from the same location in Newton County. *Prenanthes barbata* (T. & G.) Milstead ex Cronquist was identified from two specimens, one each from Jasper and Nacogdoches counties. By 1993 knowledge of the genus in Texas was based upon seven additional collections of *P. barbata* and two additional collections of *P. altissima*. In 1993 and 1994 Singhurst (1996) conducted a status survey of *P. barbata* in Texas that increased the understanding of its distribution and habitat restrictions. That survey prompted the present expanded study.

The purpose of the present paper is to (1) describe a new species of *Prenanthes* from the Edwards Plateau vegetational region of Texas, (2) report the additional information regarding the Texas distribution of *P. altissima* and *P. barbata*, (3) provide a key to distinguish the three species in Texas and (4)

SIDA 21(1): 181 – 191. 2004

remark on the rarity and abundance of all species treated. Field research and collections made between 1993 and 2003 form the primary basis of this study. The majority of specimens collected are deposited in the Baylor University Herbarium (BAYLU). Other specimens from ASTC, BRIT, LAMU, Rice University Herbarium, Houston Texas (hereafter cited as RICE), SBSC, TAES, TAMU, TEX-LL, US, and the personal herbarium of Steve Orzell and Edwin Bridges were examined and annotated.

Cultivation studies of both *P. barbata* (1993–1994) and *P. altissima* (1998) were conducted at the Stephen F. Austin Arboretum and Tucker Estate, Nacogdoches, Texas. The new species was cultivated in 2003 at the residence of O'Kennon in Fort Worth. Though limited, these cultivation studies provided growth form information that was otherwise unavailable.

TAXONOMIC TREATMENT

Prenanthes L., Sp. Pl. 797–798. 1753.

Nabalus Cass., Dict. Sc. Nat. 34:94. 1825.

Perennial herbs with milky juice and tuberous roots. Leaves alternate, simple and entire to toothed to few-lobed or deeply cleft, or lower ones sometimes several-foliate. Capitula mostly numerous in an elongate, erect and often nodding paniculiform capitulescence; flowers ligulate, perfect, 5–15 in number, white, yellow-white, to greenish-white; involucres cylindric, of 4–8 principal phyllaries, the outer phyllaries (bracts) much reduced; receptacles epaleate. Cypselae cylindric or nearly so, glabrous, mostly reddish-brown, multicostate; pappus of numerous deciduous capillary bristles.

Prenanthes is a genus of approximately 40 species (Rao & Datt 1996) with a predominantly north temperate distribution except for one species of south central Africa (Milstead 1964). Two subgenera are recognized. Subgenus *Nabalus* includes all species of North America and northeast Asia, while the European and African species are in subgenus *Prenanthes*. Classification of the genus is complicated by frequent hybridization and by extreme morphological variation (Cronquist 1980).

Plants of the genus are commonly known as rattlesnake root, cankerweed, or gall of the earth. The name *Prenanthes* is from Greek *prenes* (drooping) and *anthe* (flower). This name refers to the nodding habit of the capitula.

KEY TO THE SPECIES OF *PRENANTHES* IN TEXAS

1. Capitula 5–6 flowered; involucres with 5–6 principal phyllaries, glabrous ________ **P. altissima**
1. Capitula 10–15 flowered; involucre with 6–8 principal phyllaries, pubescent with long coarse hairs.
    2. Lower and midstem leaves shallowly or deeply pinnately lobed, the upper lanceolate to oblong; petioles usually shorter than the blades; capitulescence racemose to slightly paniculate ________ **P. barbata**

2. Lower and midstem leaves sagittiform, the upper ovate to triangular-deltate; petioles usually longer than the blades, capitulescense paniculate ______ **P. carrii**

Prenanthes altissima L., Sp. Pl. 797. 1753. *Nabalus altissimus* (L.) Hook., Fl. Bor. Amer. 1:294. 1833. Type: LINN; IDC microfiche 177.536.III.1.

Prenanthes altissima L. var. *cinnamomea* Fern., Rhodora 10:95. 1908. Type: U.S.A. MISSOURI Monteer, 5 Oct 1905, *Bush 3534* (holotype: GH).

Perennial herbs from a thick and knotty corm-like taproot. Stems erect to 200 cm tall, glabrous, striate, the upper portions not branched or rarely so, leafy towards the base and sparse to leafless in the immediate vicinity of the capitulescence. Leaves ovate to triangular, 3–5 lobed, 2–14 × 1.5–12 cm, the lower ones sometimes withered before anthesis but can also be present; venation pinnate, with 4–6 pairs of prominent secondary nerves separating from the midvein at an angle of ca. 45°, the nerves arcuate, tertiary and quartenary nerves reticulate, surfaces glabrous to villous; bases widely cordate to an obtuse insertion at the petioles, margins dentate, the teeth 0.5–1 cm distant, apices acute to acuminate; petioles 0.5–8.5 cm long, wingless throughout its length; upper leaves reduced in size; deltoid to reniform, shortly petiolate, margins slightly dentate. Capitulescene paniculate, heads disposed in loose axillary clusters in upper axils, 20–28 cm tall. Capitula slender, 12–15 mm long; peduncles to 2–3 mm long, puberulent; bracts (outer phyllaries) lanceolate to ovate, 1–2 mm long, apices acuminate, margins puberulent; primary phyllaries 5, 10–12 mm long, lanceolate, green to lilac, apices acuminate, glabrous. Florets white, 5–6 in number, 10–11 mm long, tubes ca. 6 mm long, ligules 5 mm long, 5-nerved, teeth 5, linear, sparingly glandular, surfaces glabrous, anthers 4 mm long; stigmatic surfaces densely hispid to setose. Cypselae obscurely 5-angled, 5 mm long, golden-brown. Pappus bristles ca. 40–50, yellow-brown, ca. 8–9 mm long, margins finely scabrid.

Distribution.—Known only from Jasper and Newton counties in extreme southeast Texas (Fig. 1); also Quebec to Maine, S to Georgia, Tennessee, Kentucky, Arkansas, and Louisiana.

Phenology.—Flowering from late August through October.

Specimens examined. **TEXAS. Jasper Co.:** Sally Withers Lake area, Autumn 1974, *Watson s.n.* (RICE). **Newton Co.:** FR 1414 about 3 mi SE of Burkeville, 23 Mar 1969, *Correll 36864* (TEX-LL); FR 1414 about 3 mi SE of Burkeville, 15 Oct 1969, *Correll 38172* (TEX-LL); FR 1414, about 3 mi SE of Burkeville, 29 Oct 1969, *Correll & Correll 38217* (TEX-LL); Scrappin Valley, 25 Oct 1974, *Watson s.n.*; Scrappin Valley Preserve, Temple Inland Property, 12 mi NNE of Burkeville, 2 Apr 1998, *Singhurst & Watson 6548* (BAYLU); jct. FM 645 and Hickman Creek, W on Hickman Creek 0.4 mi, 3 Apr 1998, *Singhurst & Watson 6559* (BAYLU); Canyon Rim Trail, Tex. Hwy 87, 0.5 mi N of Mayflower Community, 30 Sep 2001, *Holmes 11997 & Singhurst* (BAYLU); Louisiana Pacific Corp. Nature Trail, 4 mi N of jct. of Tex. Hwy 87 and R255 on Hwy 87, 23 Sep 2003, *Singhurst 12494* (BAYLU); Tex. Hwy 87, 2.1 mi S of jct. with Tex. Hwy 63, SE on Co. Rd. 2.7 mi to Simms Cemetery, Yellow Bayou bluffs and banks, 23 Sep 2003, *Singhurst 12494* (BAYLU).

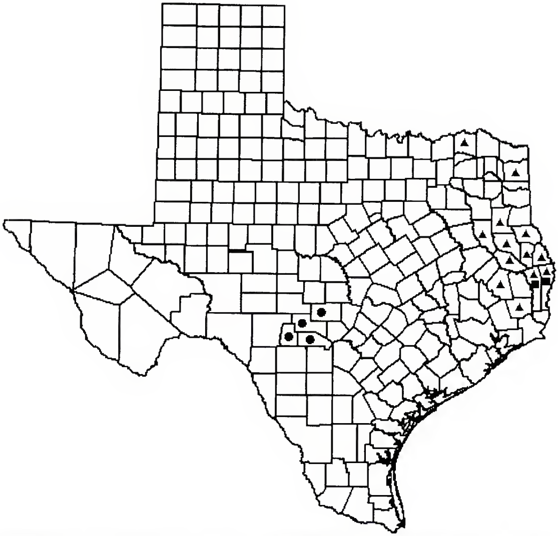

FIG. 1. Distribution map of the genus *Prenanthes* in Texas. *Prenanthes altissima* ■, *P. barbata* ▲, and *P. carrii* ●.

Prenanthes altissima is known from seven locations in the northern portion of Jasper and Newton counties. These locations are the southwestern limit of *P. altissima*'s distribution in Texas. Outside Texas, the nearest documented occurrences are approximately 120 km distant in Evangeline and Rapides parishes, Louisiana (Thomas & Allen 1996). The nearest Arkansas population (Smith 1979) is about 320 km distant. In Texas the species occurs on primary and secondary terraces along stream banks of small perennial spring-fed creeks and banks of larger streams with flood plains that support hardwood forests. *Prenanthes altissima* is associated with *Fagus grandifolia*, *Magnolia grandiflora*, *Acer barbatum*, *Quercus alba*, *Hamamelis virginiana*, *H. vernalis*, *Lindera benzoin*, *Lilium michauxii*, *Tipularia discolor*, *Sanguinaria canadensis*, *Polygonatum biflorum*, *Polystichum acrostichoides*, *Thelypteris hexagonoptera*, *Trillium gracile*, *Spigelia marilandica*, *Solidago auriculata*, and *S. caesia*.

Cronquist (1980) recognized two varieties of *Prenanthes altissima*, var. *altissima* with whitish to pale brown pappus, occupying the greatest part of the distribution of the species, and var. *cinnamomea* of Missouri, Arkansas, Louisiana, and, though not cited by Cronquist, presumably Texas. This variety is characterized by bright yellow-brown or almost orange pappus. Gandhi and Thomas (1989) used this varietal name to refer to the Louisiana forms of this taxon. However, Thomas and Allen (1996) merged var. *cinnamomea* with var. *altissima* in the *Atlas of the Vascular Flora of Louisiana*. Color variation of the pappus does not appear to justify recognition at the varietal level.

Prenanthes barbata (Torr. & A. Gray) W.L. Milstead ex A. Cronquist. Brittonia 29:223. 1977. *Nabalus fraseri* DC. var. *barbatus* Torr. & A. Gray, Fl. N. Amer. 2:481. 1843. *Prenanthes serpentaria* Pursh var. *barbata* (Torr. & A. Gray) A. Gray, Syn. Fl. N. Amer. 1(2): 434. 1886. *Nabalus barbatus* (Torr. & A. Gray) Heller, Muhlenbergia 1:8. 1900. *Nabalus serpentaria* Pursh var. *barbatus* (Torr. & A. Gray) Mohr, Contr. U.S. Natl. Herb. 6:755. 1901. TYPE: U.S.A. ALABAMA: *Buckley s.n.* (SYNTYPE: GH; ISOSYNTYPE: NY). The GH specimen is here designated as lectotype. The other syntype cited, *Macbride s.n.* from the Saluda Mountains of [Polk Co., North Carolina], was not located but from location seems to refer to *P. serpentaria* Pursh.

Perennial herbs from thick corm-like taproots, occasionally connected by slender rhizomes. Stems erect, 50–150 cm tall, simple below, glabrous, the upper portions often branched, glabrate to pilose to hispid to semiarachnose to villous, leafy except in the immediate vicinity of the capitulescence. Leaves oblanceolate to spatulate, 5–20 × 1.5–5 cm, the lower ones usually withered before anthesis, venation pinnate, with 4–6 pairs of prominent secondary nerves separating from the midvein at an angle of ca. 45 degrees, the nerves straight to arcuate, tertiary and quartenary nerves reticulate, surfaces glabrate to sparingly puberulent-pilose; bases attenuate, the lower to long winged petioles, margins entire to denticulate to dentate to lacerate-parted (especially lower leaves), the teeth 1–2 cm distant, apices acute to rounded; petioles 0.5–6.5 cm long, winged for most of its length; upper leaves reduced in size; elliptic to oblanceolate, sessile to shortly petiolate, margins mostly entire to denticulate to less commonly dentate to lacerate-lobed at the bases. Capitulescene racemose to paniculate, 5–36 cm tall. Capitula cylindric to semicampanulate; peduncles to ca. 1 cm long, glabrate to tomentose to villous; bracts (outer phyllaries) lanceolate to narrowly ovate, 2–5 mm long, apices acuminate, margins subentire, midribs with few to numerous coarse bristles; primary phyllaries 6–8, 13–16 mm long, linear-oblong to narrowly lanceolate, green to purplish, apices acute to rounded to an acute point, finely puberulent, occasionally with glandular hairs, margins entire, midribs with few to numerous coarse bristles. Florets white, 10–12 in number, 12–13 mm long, tubes ca. 5–6 mm long, ligules 5–6 mm long, 5-nerved, teeth 5, linear, sparingly glandular, surfaces glabrous, anthers 5–5.5 mm long; stigmatic surfaces setose-hispid. Cypselae obscurely 5-angled, 5–5.5 mm long, golden-brown. Pappus bristles ca. 50, white to yellow-brown, ca. 8 mm long, margins scabrid.

Distribution.—Eastern Texas from Hardin County north to Lamar County (Fig. 1); also Alabama, Arkansas, Georgia, Kentucky, Louisiana, and Tennessee.

Phenology.—Flowering from late August through November.

Specimens examined: **TEXAS. Angelina Co.:** Comp. 94, Angelina National Forest, ca. 0.7 mi S of junction of FS Rd 303 and FS Rd 302 on FS Rd 303, jct. of FS Rd 303 and Big Creek, 11 Nov 1994, *Singhurst 3609* (BAYLU). **Cass Co.:** ca. 0.4 air mi SW of jct. of Tex. The distinctness of *Prenanthes barbata* was first recognized but never formalized by Milstead (1964). The name was subsequently adopted by Correll and Johnston (1970) and gained general acceptance; it was formalized by Cronquist in 1980.

The species was considered rare by Correll and Johnston (1970) because it was known only from Jasper and Nacogdoches counties. Turner et al. (2003) presented an expanded distribution in east central Texas that included six counties. Turner et al. also used the name to refer to plants of the Edwards Plateau which, in this study, are considered a distinct species. *Prenanthes barbata* occurs in mesic ravine slope forests that are dominated by *Fagus grandifolia-Quercus alba* series (Diamond et al. 1987) and on mesic hardwood sites with *Quercus shumardii*, *Q. muhlenbergii*, *Q. alba*, *Q. michauxii*, *Pinus taeda*, *Carya ovata*, and *C. myristicaeformis*.

Prenanthes carrii J.R. Singhurst, R.J. O'Kennon, & W.C. Holmes, sp. nov. (**Fig.2**). TYPE: U.S.A. TEXAS. BANDERA CO.: Lost Maples State Natural Area, above and below Upper Forks of Mystic Canyon Trail, 1 Sep 2003, *Singhurst & Singhurst 12496* (HOLOTYPE: BAYLU).

A *P. barbatae* similis sed foliis sagittiformibus differt.

Perennial herbs from tuberous tap roots with similar side roots. Stems simple, erect, occasionally rather long branched in area of inflorescence, 80–150 cm long, strigose to tomentose in upper half, scattered strigose to glabrous basally. Lower leaves sagittiform (ovate, ovate-deltate to broadly elliptic in general contour), 13–25 × 7–12 cm, light green, chartaceous, venation pinnate, with 3–5 pairs of prominent secondary nerves separating from the midvein at an angle of about 45 degrees, nerves straight to slightly antrorsely curved, tertiary and quartenary veins reticulate; surfaces glabrate to lightly puberulent-setose especially on nerves; bases attenuate, truncate to widely cordate, occasionally deeply pinnately divided at base near petioles, margins coarsely and irregularly dentate, mostly 1–2 cm distant, teeth subspinose-mucronate, apices acute to rounded; petioles 2.2–13 cm long, broadly winged for half or more of its length by the decurrent leaf bases; upper leaves reduced in size, elliptic, occasionally nearly sessile or with winged-decurrent petioles to about 1 cm long, otherwise similar to lower leaves; bracteal leaves reduced in size, less prominently dentate to occasionally subentire. Capitulescence paniculate, 20–50 cm tall; capitula cylindric to semicampanulate; peduncles, 4–9 mm long, tomentulose, with 5–12 or more linear-subulate to narrowly lanceolate hispid bracts (outer phyllaries) 2–4 mm long; primary phyllaries 8, 9–11 mm long, mostly lime green to pinkish-rose to lavender, linear-subulate to lanceolate, apices acuminate, outer surfaces glabrate except for the sparingly hispid midrib, apical margins minutely ciliate. Florets 9–11 per capitulum; 11.5–13.5 mm long, tubes 4–7 mm long, ligules ca. 7 mm long, 5-nerved, teeth 5, linear-oblong, 0.07–0.1 mm long, apical surfaces papillate; anthers ca. 5.5 mm long; stigmatic surfaces densely hispid-setose. Cypselae irregularly angled to more often terete, ca. 6.3 mm long, golden yellow to tan, prominently 12–15 costate. Pappus bristles white to tan to yellow, 7–8 mm long, 30–40, margins scabrid.

Fig. 2. *Prenanthes carrii*: **A.** habit, **B.** upper bracteal leaves, **C.** middle leaf, **D.** basal rosette leaf, **E.** florets, **F.** pappus, **G.** mature achene and **H.** immature achene with ligule/anther detail. Illustration by Linny Heagy 2004. Specimens used in illustration include a combination of *Singhurst & Singhurst 12496* (BAYLU) and *O'Kennon s.n.* (BAYLU).

Distribution.—Southwest Edwards Plateau (Bandera, Gillespie, Kerr, and Real counties) of Texas (Fig. 1.)

Phenology.—Flowering late August to November.

PARATYPES: TEXAS. **Bandera Co.:** Lost Maples State Natural Area, Upper Can Creek, 17 Nov 1999, *Singhurst 8533* (BAYLU); Love Creek Preserve, The Nature Conservancy of Texas, 2 Nov 2002, *Singhurst 11544* (HOLOTYPE: BAYLU). **Gillespie Co.:** 7 mi N of Harper in rich creek canyon off Threadgill Creek, Oct 1993, *O'Kennon 11914* (TEX-LL). **Kerr Co.:** along rocky spring branch, Lacey's Ranch, 3 Oct 1916, *Palmer 10893* (US); without specific location, 13 Oct 1940, *Parks s.n.* (TAES); 12 mi S of Kerrville along Lamb Creek, Oct 1993, *O'Kennon 11898* (TEX-LL); 5.3 mi N of jct. of Kerr/Bandera County line on Tex. Hwy 16, Upper Lamb Creek, 17 Nov 1999, *Singhurst 8534* (BAYLU); cultivated [propagules from Upper Lambs Creek], 18 Oct 2002, *O'Kennon s.n.* (BAYLU). **Real Co.:** Lost Maples State Natural Area, 27 Oct 2001, *Singhurst 11526* (BAYLU); upper reaches of Mill Creek, Grey Wolfe Ranch, 2 Nov 2002, *Singhurst 11554* (BAYLU).

Prenanthes carrii is morphologically similar to *P. crepidinea* Michx., *P. alata* (Hook.) D. Dietr., *P. sagittata*, (A. Gray) A. Nels., *P. bootii* (DC.) D. Dietr, and *P. barbata*. This group was proposed as a new subsection in Milstead's (1964) unpublished (thus never formalized) dissertation. The group is characterized by paniculate to racemose capitulescences, leaves at least short petiolate, flowers white to creamy and usually numbering 7–38 per capitulum, inner phyllaries 6–15, and outer phyllaries (bracts) mostly 7–13 per capitulum. Leaf characteristics of *P. carrii* resemble the sagittiform shaped leaves of *P. alata*, *P. crepidinea*, and *P. sagittata*. The new species appears to be most closely similar to *P. barbata*, particularly in the paniculate nature of the capitulescence. The two species may be distinguished by the characters referenced in the key. Additional traits distinguishing *P. carrii* from *P. barbata* include its taller height of 80–150 cm, strigose to tomentose vestiture, and primary phyllaries 9–11 mm long. *Prenanthes barbata* is usually 55–125 cm tall, has tomentulose to subarachnose vestiture, and has primary phyllaries 11–14 mm long.

Prenanthes carrii occurs primarily in rich soils in woodlands at the upper reaches of canyons where springs flow due to geologic contacts. Where these contacts occur, there is a vegetation transition between the species of *Quercus laceyi*, *Q. muhlenbergii*, *Q. texana*, and *Acer grandidentatum* and the creekside seepage shelves dominated by *Platanus occidentalis*, *Cephalanthus occidentalis*, *Adiantum capillus-veneris*, *Thelypteris kunthii*, and *Cladium mariscoides*. The species is normally associated with *Aristolochia serpentaria*, *Carex edwardsiana*, *C. planostachys*, *Lindera benzoin*, *Senecio obovatus*, and *Verbesina virginica*. Other central Texas endemics occurring with or near *P. carrii* include *Chaetopappa effusa*, *Clematis texensis*, *Matelea edwardsensis*, *Philadelphus texensis*, *Tragia nigricans*, *Tridens buckleyanus*, and *Styrax platanifolius* var. *stellatus*.

Etymology.—The species is named in honor of William F. Carr of The Nature Conservancy of Texas. Bill is deeply committed to preserving the botanical heritage of Texas and is currently one of the most active plant collectors in the state.

ACKNOWLEDGMENTS

We wish to thank the curators of the herbaria cited for access to the specimens used in this study. Special recognition is given to Geraldine Watson who accompanied the senior author to the sites where she had previously collected *Prenanthes*. Amber Swanson, Curatorial Assistant of the Harvard University Herbaria, provided a digital photograph of the designated lectotype of *Prenanthes barbata*. We thank Guy L. Nesom for his Latin translation and for reviewing the manuscript. Appreciation is also expressed to the landowners who graciously permitted access to their properties and to Bill Carr for his field assistance and access to Love Creek Preserve. We also give special thanks to David Riskind at Texas Parks and Wildlife Department who granted us access to Lost Maples State Natural Area and reviewed the preliminary manuscript. We also want to thank Larry Brown of Spring Branch Science Center Herbarium and Sandi Elsik and Warrens Pruess of Rice Herbarium for their assistance with specimen records. We also extend our deepest gratitude to Linny Heagy. Her amazing artistry exemplifies the details of the newly-described *Prenanthes carrii*.

TWO NEW SUBSPECIES OF *MICROSERIS LACINIATA* (ASTERACEAE) FROM THE SISKIYOU MOUNTAINS

Kenton L. Chambers

Dept. of Botany & Plant Pathology
Oregon State University
2082 Cordley Hall
Corvallis, Oregon 97331, U.S.A.
chamberk@science.oregonstate.edu

ABSTRACT

Microseris laciniata subsp. ***siskiyouensis*** and subsp. ***detlingii*** are described as endemics of the floristically "central" region of the Siskiyou Mountains of Oregon and adjacent California. These taxa have novel morphological features differentiating them from the related *Microseris laciniata* subsp. *laciniata* and subsp. *leptosepala* also found in this region. The populations are kept separate by allopatry and by adaptation to different edaphic conditions, and thus have different vegetation associations. Intermediate populations occur where pairs of taxa meet and the ecological differences are modified by habitat disturbance.

RESUMEN

Se describen ***Microseris laciniata*** subsp. ***siskiyouensis*** y subsp. ***detlingii*** como endemismos de la región florística "central" de las Montañas Siskiyou de Oregón y la adyacente California. Estos taxa tienen característica morfológicas que los diferencian de sus parientes *Microseris laciniata* subsp. *laciniata* y subsp. *leptosepala* que también se encuentran en esta región. Las poblaciones se mantienen separadas por alopatria y por adaptación a condiciones edáficas diferentes, y así tienen diferentes asociaciones de vegetación. Aparecen poblaciones intermedias donde contactan pares de taxa y las diferencias ecológicas se modifican por alteraciones del hábitat.

INTRODUCTION

The perennial species of *Microseris* subgen. *Scorzonella* were last reviewed taxonomically by Chambers (1957) in preparation for the generic treatment in Abrams and Ferris' *Illustrated Flora of the Pacific States* (Chambers 1960). An attempt was made to compartmentalize the extensive variation of *M. laciniata* into two subspecies, subsp. *laciniata* and subsp. *leptosepala*, based principally on the shape, width, and pubescence of the involucral phyllaries and on differences in distribution. The species ranges from western Washington south through Oregon to just north of San Francisco in California, principally west of the Cascade Range but extending east to Klamath and Lake Counties, Oregon, and Siskiyou, Lassen, and Modoc Counties, California. The subsp. *leptosepala* occurs in the more coastal parts of the Coast Range, especially in the Klamath Mountains region, but is also in northwestern Oregon including the lower Willamette Valley. The subsp. *laciniata* is more interior, being the common form from Pierce County, Washington south to Douglas County, Oregon and from southern Humboldt County to Sonoma County, California, as well as in the Great Basin part of the range. Intergradent forms are frequent, especially in the Willamette Valley and Curry County, Oregon, the northern California Coast Range, and in populations east of the Cascade Range.

In this earlier study, additional puzzling variation was found in the Siskiyou Mountains of southwestern Oregon and adjacent California, but it could not be resolved using the few available herbarium specimens from this rugged and poorly explored region. This variation was lumped into *Microseris howellii*, which we now know to be a narrowly endemic species which is limited to exposed serpentine sites in the Illinois River Valley of Oregon. Field research by the present author suggested that two additional forms of *M. laciniata* should be recognized taxonomically from the Siskiyou region, and their ranges have recently been mapped through the collecting efforts of a number of interested colleagues (see Acknowledgments section). These entities have been presented informally (Chambers 1993) but have not yet been validly published.

Some diagnostic features of these new entities were presented by Mauthe et al. (1982) and compared with 9 other samples of *Microseris laciniata* representing much of the species' range. Capitulum and fruit morphology was the principal object of this investigation. It was suggested that there was "a rather small number of unlinked genes allowing for a rather free recombination of character states" and that "the characters that distinguish these two groups of populations (subsp. *laciniata* and subsp. *leptosepala*) recombine freely" in some populations. Crossing experiments (Pires 1980) show that hybrids between taxa in the *M. laciniata* complex are no less pollen-fertile than intrataxon crosses. An important result of these and previous studies of *M. laciniata* (Bachmann and Price 1979) was the validation of pappus part number as a highly consistent morphological feature of these two named subspecies. In both, the number varies among cypselae of single heads but is always constrained from 5 to 10. Frequencies of average pappi numbers follow patterns of rather simple Poisson distributions between 5 and 10, as would result from the interaction of a minimum of two pairs of genes (Bachmann & Chambers 1978).

Both of the newly recognized subspecies have average pappi numbers that are above 10–up to 16.6 in subsp. *detlingii* and 20.3 in subsp. *siskiyouensis*. In other respects, these two new subspecies are very different in morphology and in edaphic and vegetation associations. The newly available suite of collections of these taxa shows that each has an area of intergradation with an adjacent subspecies of *M. laciniata*—subsp. *detlingii* with subsp. *laciniata*, and subsp. *siskiyouensis* with subsp. *leptosepala*. Hence they are parts of a single genetic complex and are best placed as subspecies rather than as separate species. Their addition to the flora of the Siskiyou Range means that this region is an unusually rich center of diversity for perennial *Microseris*, containing 5 recognized taxa. These taxa have defined distribution patterns and characteristic habitat preferences, which allow them to persist as separate populations in this limited geographic region.

Microseris laciniata (Hook.) Sch. Bip. subsp. **siskiyouensis** K.L. Chambers, subsp. nov. (**Figs. 1, 2, 3**). TYPE: U.S.A. CALIFORNIA. DEL NORTE CO.: Hwy. 199, 5.0 mi by road up the Smith R. from Patricks Ck. Guard Station, on a rocky diabase knob overlooking the river, in shallow soil covered by mosses, lichens, and *Selaginella* sp., with *Melica harfordii*, *Luina hypoleuca*, *Sedum* sp., 10 Jul 1964, *K.L. Chambers 2242* (HOLOTYPE: OSC; ISOTYPES: MO, NY, UC).

Microseride laciniato subsp. *leptosepalo* (Nutt.) K.L. Chambers similis a qua segmentis pappi numero 10–24 varians setis minute barbellatis differt; chromosomatum numerus $2n = 18$.

Perennial herbs with 1–3 fleshy biennial taproots; *stems* to 65 cm high, well-branched above, except on depauperate plants, leafy, the floral peduncles arising terminally and from leaf axils; *leaves* linear or narrowly lanceolate, attenuate, sometimes sparsely toothed or pinnatifid with narrow lobes; *involucres* 10–17 mm high, with a series of lanceolate inner phyllaries and a variable number of shorter outer ones ranging from linear to lanceolate-attenuate or deltoid-attenuate (Fig. 1B shows the narrowest type of outer phyllaries), both outer and inner series usually densely furfuraceous (that is, covered with the minute scaly trichomes that are a generic feature of *Microseris*), inner phyllaries usually lightly black-villous dorsally and minutely white-strigulose ventrally; *florets* 13–48+ in number, with yellow ligules 15–22 mm long; *cypselae* pale to dark brown, 3.5–5.5 mm long, 10-ribbed, the ribs usually smooth or lightly scabrous, often lightly hispid near the apex on outer fruits; *pappi* scales 10–24, 0.5–2.0 mm long, lanceolate to linear-lanceolate, white or brownish, bristles minutely barbellate, white.

In the region under discussion, subsp. *leptosepala* and subsp. *siskiyouensis* are practically indistinguishable in habit. Therefore, Figure 1 can represent either taxon. Cypsela and pappi are illustrated in Figure 2, with enlargements of the pappi to show the bristle differences from the scabrous-awned subsp. *leptosepala*, left, and the plumose-awned species *Microseris nutans* (Hook.) Sch. Bip. on the right. The bristle difference with subsp. *leptosepala* breaks down where the taxa are sympatric in western Curry Co., Oregon and Del Norte Co., California. Here both subspecies have barbellate bristles, and they are distinguished only by pappi number—5–10 per cypsela in subsp. *leptosepala*, 10–24 per cypsela in subsp. *siskiyouensis*.

Distribution.—*Microseris laciniata* subsp. *siskiyouensis* is limited to the Siskiyou Mountains in Del Norte and Siskiyou counties, California and Josephine and Jackson counties, Oregon. The most common habitat is in grassy openings of second growth woodlands, in non-serpentine soil or well-developed forest soil over serpentine bedrock. It also occurs on non-serpentine rock outcrops, as at the type locality. Frequently associated woodland species are *Pseudotsuga*

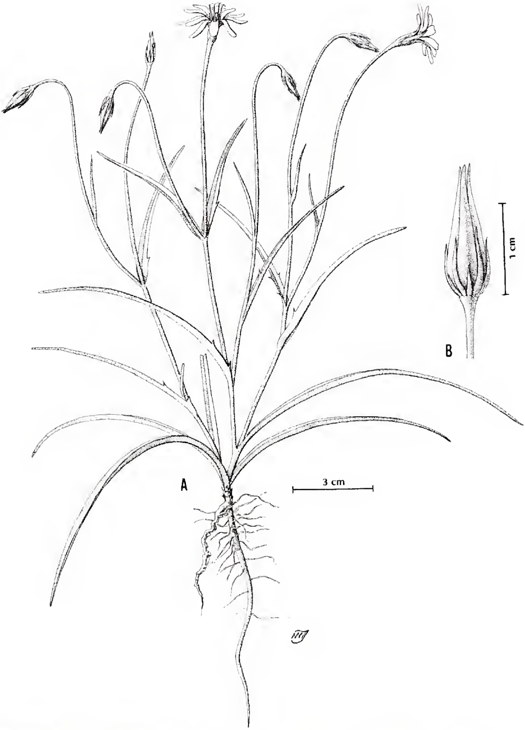

FIG. 1. *Microseris laciniata* subsp. *siskiyouensis*. **A.** Habit of plant at anthesis. **B.** Head with developing fruits.

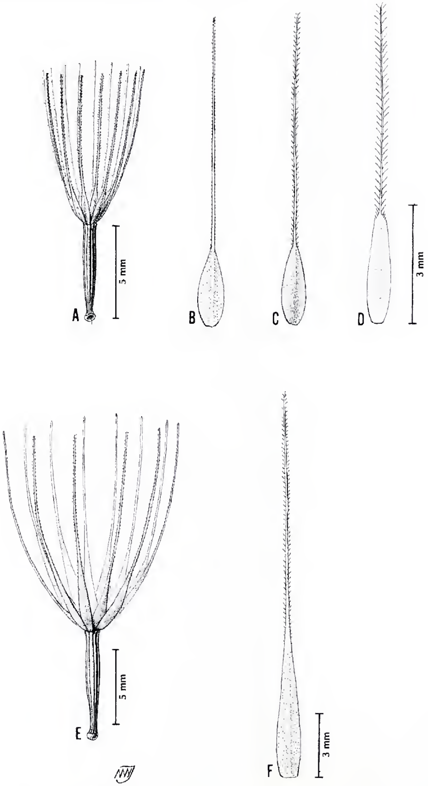

Fig. 2. Cypselae and pappi of various *Microseris* taxa. **A.** Cypsela of *M. laciniata* subsp. *siskiyouensis* bearing 15 pappus parts. **B.** Pappus part of *M. laciniata* subsp. *laciniata* or subsp. *leptosepala*, with scabrous bristle. **C.** Pappus part of *M. laciniata* subsp. *siskiyouensis*, with minutely barbellate bristle. **D.** Pappus part of *M. nutans*, with plumose bristle. **E.** Cypsela of *M. laciniata* subsp. *detlingii* bearing 12 pappus parts. **F.** Pappus part of *M. laciniata* subsp. *detlingii*, with minutely barbellate bristle.

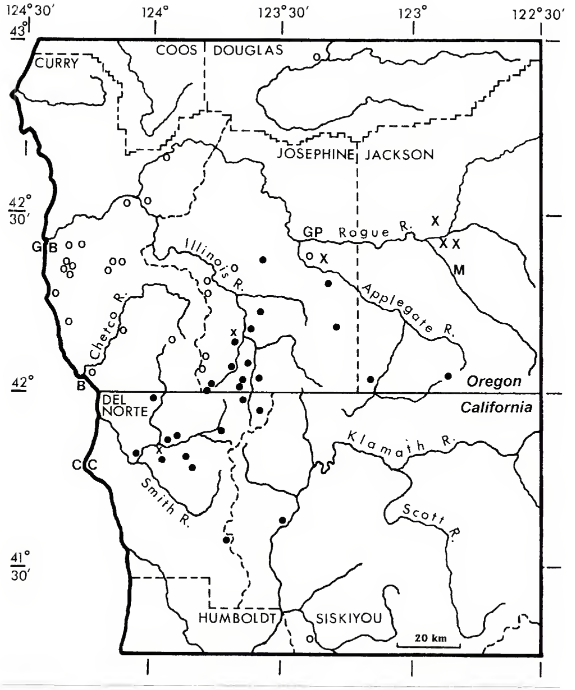

FIG. 3. Distribution of *Micraseris* taxa in the western Siskiyou Mountains. Black circles = *M. laciniata* subsp. *siskiyouensis*; open circles = *M. laciniata* subsp. *leptasepala*; small Xs = intergradent populations between these two taxa; large Xs = *M. laciniata* subsp. *laciniata*. Cities: B = Brookings; CC = Crescent City; GB = Gold Beach; GP = Grants Pass; M = Medford. *Microseris howellii* is omitted.

menziesii, *Pinus lambertiana*, *P. jeffreyi*, *Calocedrus decurrens*, *Quercus garryana*, *Q. kelloggii*, *Arbutus menziesii*, *Arctostaphylos canescens*, *Rhododendron macrophyllum*, and *Ceanothus integerrimus*. Elevations are 30–2100 m.

Flowering.—May–Jul, depending on habitat and elevation.

Figure 3 maps the known populations of subsp. *siskiyouensis*, represented by black circles, while the known localities for subsp. *leptosepala* in the Siskiyous are shown as open circles. The pattern of parapatry and the region of contact in western Josephine County are evident. Two sites have been identified, marked by small Xs, where intermediate populations are known, containing many plants with 10 or fewer pappus parts and others with average pappi numbers in the range of subsp. *siskiyouensis*. One such population, at Gasquet Flat, Del Norte County (see *Chambers 5168*, below) was well sampled by Mauthe et al. (1982), who reported the average numbers of pappi in a sample of 149 plants. The frequencies of plant averages, grouped by whole numbers, are as follows: 9–10: *56*; 10.1–11: *55*; 11.1–12: *15*; 12.1–13: *8*; 13.1–14: *8*; 14.1–15: *6*; 15.1–16: *1*. Although the genetics of pappi numbers are not known, one can speculate that this is a population of subsp. *leptosepala* showing a history of hybridization with subsp. *siskiyouensis*. The second site with an intermediate population, West Side Road in Josephine County (*Chambers 5522*, below), though not as well sampled, shows a similar range of pappi numbers between the two subspecies. For comparison, select plants in 10 populations of subsp. *siskiyouensis* more remote from subsp. *leptosepala* had the following average pappi numbers: 13.2, 15.0, 15.2, 15.5, 15.6, 16.8, 17.0, 17.3, 17.6, and 20.3. The large Xs in Figure 3 mark populations assignable to subsp. *laciniata*; these are discussed below under subsp. *detlingii*.

Collections of *Microseris laciniata* subsp. *siskiyouensis* mapped in Figure 3. **U.S.A. CALIFORNIA. Microseris laciniata (Hook.) Sch. Bip. subsp. **detlingii** K.L. Chambers, subsp. nov. **(Figs. 2, 4, 5).** TYPE: U.S.A. OREGON. JACKSON CO.: Siskiyou Pass, S side on the old highway where it joins Hwy. 5, 2.1 mi N of Hilt exit, grassy openings in *Quercus breweri/Amelanchier pallida* brushland, in heavy clay soil on slope above road, 22 Jun 1967, *K.L. Chambers 2868* (HOLOTYPE: OSC; ISOTYPES: BRIT-SMU, CAS, MO, NY, RSA, UC, US, WS, WTU).

Microseride laciniato subsp. *laciniato* similis a qua marginibus foliorum plerumque integris caule non ramoso radice longissimo segmentis pappi numeris 9–19 varians squamis 4–9 mm setis minute barbellatis differt; chromosomatum numerus $2n = 18$.

Perennial herbs with 1–2 much elongated fleshy biennial taproots; *stem* erect, to 55 cm high, usually simple, leafy near the base; *leaves* lanceolate or oblanceolate, acute to attenuate, tapering below to a clasping, winged petiole, glabrous, entire or rarely sparingly dentate or pinnatifid, margins often undulate; *head* single on a terminal, naked or bracteate peduncle, a second peduncle sometimes arising from the axil of a lower leaf; *involucres* 13–25 mm high, the inner series of phyllaries equal, lanceolate, often black-villous dorsally, the outer phyllaries imbricate in several series, broadly lanceolate to elliptic or round, cuspidate to acuminate, glabrous, sometimes purple-spotted, the outermost 3–7 mm wide; *florets* 18–85+, with yellow ligules 18–22 mm long, often purple-striped dorsally; *cypselae* 5–9 mm long, gray to brown, 10-ribbed, ribs smooth or hispid on outer fruits; *pappi* scales 9–19, 4–9 mm long, lanceolate, silvery (brownish on herbarium specimens), bristles minutely barbellate.

Distribution.—*Microseris laciniata* subsp. *detlingii* is endemic to a limited area east and south of Medford and Ashland, Jackson County, Oregon, extending north to near Butte Falls and south over Siskiyou Pass to the California state

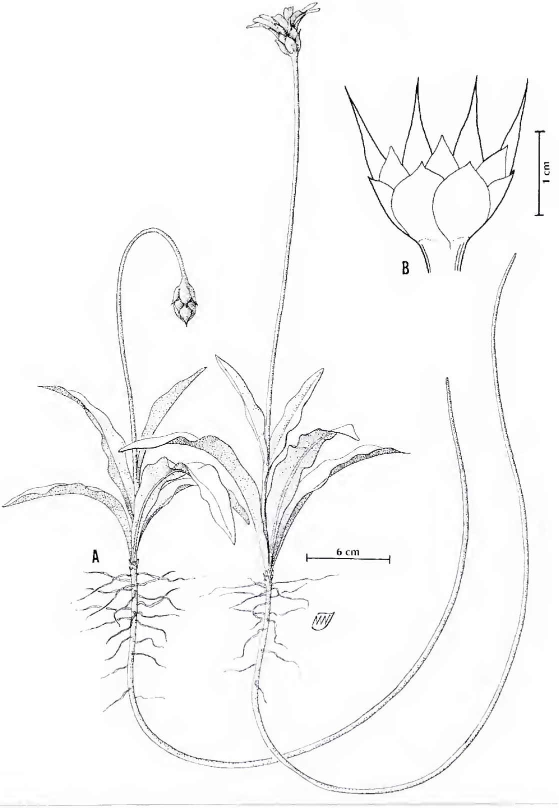

Fig. 4. *Microseris laciniata* subsp. *detlingii*. **A.** Habit of plant at anthesis. **B.** Pressed head showing phyllaries.

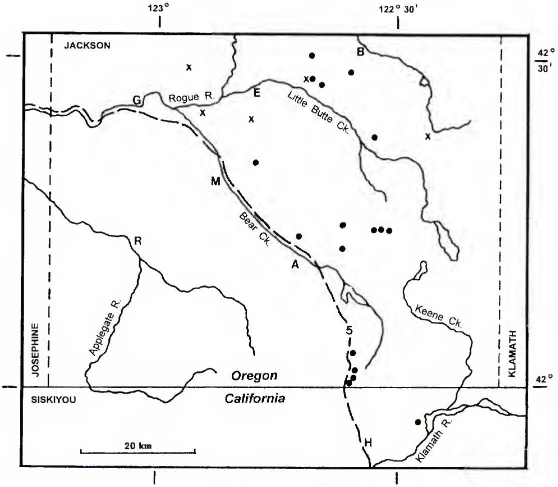

Fig. 5. Distribution of *Microseris* taxa in southern Jackson Co., OR and adjacent Siskiyou Co., CA. Black circles = *M. laciniata* subsp. *detlingii*; Xs = *M. laciniata* subsp. *laciniata*. Cities: A = Ashland; B = Butte Falls; E = Eagle Point; G = Gold Hill; H = Hornbrook; M = Medford; R = Ruch. Dashed line = Interstate Highway 5.

line (Fig. 5). One population has been found in adjacent Siskiyou County, California. The subspecies occurs only in montmorillonite clay soil, sticky when wet and hard and cracked when dry, on grassy slopes and openings in shrublands and forest edges. The geology of the type area, south of the summit of Siskiyou Pass, was included in the thesis of Richard Carlton (1972), who identified the underlying rocks at the type locality as fossil-bearing claystones and siltstones of the early Eocene Colestin Formation, lacustrine in origin and possessing clay minerals of the montmorillonite-mica type. Farther north, near Ashland and Medford, similar clay soil develops in younger Eocene deposits of volcanic-derived sedimentary rocks (McKnight 1971). The complex geology of this region also includes sandstones and volcanic lahar and ash-flow deposits. Adaptations of subsp. *detlingii* to this unusual substrate include an exceptionally deep, slender taproot (Fig. 4) and the ability to reproduce clonally by adventitious buds on the lateral rootlets. Colonies are often limited to patches of loose soil turned up by gophers or squirrels. Associated species are *Pinus jeffreyi*, *Quercus breweri*, *Q. garryana*, *Amelanchier pallida*, *Ceanothus cuneatus*, *Arctostaphylos viscida*, *Toxicodendron diversifolium*, *Festuca idahoensis*, *Achnatherum lemmonii*. Elevations are 600–1450 m. Flowering occurs May–Jun.

Etymology.—The name is in honor of Prof. LeRoy Detling, longtime curator of the University of Oregon herbarium, whose 1950 collection first alerted the author to the peculiar features of this plant.

Figure 5 shows the limited distribution of subsp. *detlingii*, as well as the nearby occurrence of populations, marked by Xs, which the author places in subsp. *laciniata*. The latter specimens, listed below, occur on substrates other than the "heavy clay soil" or "rocky clay soil" consistently mentioned on the labels of subsp. *detlingii* specimens. North of Medford, subsp. *laciniata* is found on rocky alluvium, as at the Agate Desert (*Chambers 3080*), and differs from subsp. *detlingii* in having pinnate leaves, multiple arched-ascending stems from the base, consistently 10 pappi, and lacking an unusually elongate taproot. However, the pappi scales are up to 4 mm long, nearly twice the usual range of subsp. *laciniata*, and are barbellulate. On Kanutchan Creek just north of Little Butte Creek, collections by Greenleaf (*1418, 1435*) contain both subsp. *detlingii* and plants with highly pinnatifid leaves and basal branching like that of subsp. *laciniata* at Agate Desert. The habitat is described as *Quercus garryana/Pinus ponderosa/Arbutus menziesii* woodland. We expect that more intergradation will be found between the two subspecies in this area, depending on soil type and disturbance, for example by erosion and cattle grazing. A pappus member of subsp. *detlingii* is shown in Figure 2B, where it is compared with both subsp. *siskiyouensis* and with the common type in subspp. *leptosepala* and *laciniata*.

DISCUSSION

The Klamath Region, including the Siskiyou Mountains, has long been recognized as an area of high endemism and as a center of floristic diversity (Whittaker 1961). Factors favoring this diversity, mentioned by Whittaker, include a steep climatic gradient from the coast inland, high rainfall and moderate temperatures, much-dissected topography, and diversity of bedrock, and hence of soil types. The complex geological history and origin of the varying substrates are described by Coleman and Kruckeberg (1999). Types of endemism and an analysis of the endemic flora were presented by Smith and Sawyer (1988). These authors list the two taxa newly described here, whose names were available on herbarium annotations, and also *Microseris howellii*, a previously named endemic of serpentine barrens in the Illinois River valley of Josephine County, Oregon. This species, and the other *Microseris* taxa mentioned above, illustrate very well the importance of edaphic and climatic factors in keeping separate the parapatric members of this complex.

Proceeding from west to east, *Microseris laciniata* subsp. *leptosepala* occupies the more coastal region of Curry County and is found on serpentine barrens as well as non-serpentine meadows and forest edges. The peculiar vegetation and characteristic flora on serpentine barrens in the Siskiyous are discussed in Coleman and Kruckeberg (1999). Examples of serpentine sites among the specimens of subsp. *leptosepala* cited above are Pine Point (*Hawk s.n.*), Gold Beach to Agness road (*Chambers 5162, Stansell s.n.*), Signal Buttes (*Stansell s.n.*), S of Gold Beach (*Sundberg 1098*), Buckskin Peak (*Rolle 256*), and 7 miles W of O'Brien (*Kagan s.n.*). Endemic to serpentine barrens farther east in the Illinois River valley is *M. howellii*, a close relative of *M. laciniata*, having 5–10 pappi but differing in its pappi scales 3–5 mm long. Parapatric in Oregon with *M. howellii* is *M. laciniata* subsp. *siskiyouensis*, which avoids open, rocky serpentine barrens but occurs in adjacent forested sites in loam soil. No hybrid populations have been noted between these two taxa. To the east, *M. laciniata* subsp. *laciniata* is on alluvial and deeper loam soils in grasslands and mixed oak woodlands near the Rogue River. Finally, *M. laciniata* subsp. *detlingii* is endemic to montmorillonite clay soils from 600–1450 m elevation in the Medford-Siskiyou Pass area.

The differentiation of *Microseris* taxa in the Siskiyous, and their maintenance as genetically separate populations, has involved both an adaptation to different substrates and a geographical separation into different climatic zones.

This has led to an unusual richness of species and subspecies in this limited region of southwestern Oregon and adjacent California, which is in line with the frequently mentioned floristic diversity of the Klamath-Siskiyou Mountains in general.

NEW TAXA AND NEW COMBINATIONS IN NORTH AMERICAN *CIRSIUM* (ASTERACEAE: CARDUEAE)

David J. Keil

Biological Sciences Department
California Polytechnic State University
San Luis Obispo, California 93407, U.S.A.
dkeil@calpoly.edu

ABSTRACT

Six new varieties are proposed in North American *Cirsium* (Asteraceae: Cardueae): **C. arizonicum** (A. Gray) Petrak var. **tenuisectum** D.J. Keil var. nov., **C. eatonii** (A. Gray) B.L. Rob. var. **viperinum** D.J. Keil, var. nov., **C. edule** Nutt. var. **wenatchense** D.J. Keil, var. nov., **C. occidentale** (Nutt.) Jeps. var. **lucianum** D.J. Keil, var. nov., **C. scariosum** Nutt. var. **robustum** D.J. Keil, var. nov., **C. scariosum** Nutt. var. **toiyabense** D.J. Keil, var. nov. Additionally, twenty new combinations are presented: **C. arizonicum** (A. Gray) Petrak var. **bipinnatum** (Eastw.) D.J. Keil, comb. nov., **C. arizonicum** (A. Gray) Petrak var. **chellyense** (R.J. Moore & Frankton) D.J. Keil, comb. et stat. nov., **C. arizonicum** (A. Gray) Petrak var. **rothrockii** (A. Gray) D.J. Keil, comb. et stat. nov., **C. clavatum** (M.E. Jones) Petrak var. **americanum** (A. Gray) D.J. Keil, comb. nov., **C. clavatum** (M.E. Jones) Petrak var. **osterhoutii** (Rydb.) D.J. Keil, comb. et stat. nov., **C. cymosum** (Greene) J.T. Howell var. **canovirens** (Rydb.) D.J. Keil, comb. et stat. nov., **C. eatonii** (A. Gray) B.L. Rob. var. **eriocephalum** (A. Nelson) D.J. Keil, comb. nov., **C. eatonii** (A. Gray) B.L. Rob. var. **hesperium** (Eastw.) D.J. Keil, comb. et stat. nov., **C. eatonii** (A. Gray) B.L. Rob. var. **peckii** (L.F. Hend.) D.J. Keil, comb. et stat. nov., **C. eatonii** (A. Gray) B.L. Rob. var. var. **clokeyi** (S.F. Blake) D.J. Keil, comb. et stat. nov., **C. edule** Nutt. var. **macounii** (Greene) D.J. Keil, comb. et stat. nov., **C. horridulum** Michx. var. **megacanthum** (Nutt.) D.J. Keil, comb. et stat. nov., **C. inamoenum** (Greene) D.J. Keil, comb. nov., **C. inamoenum** (Greene) D.J. Keil var. **davisii** (Cronquist) D.J. Keil, comb. et stat. nov., **C. ochrocentrum** A. Gray var. **martinii** (P. Barlow-Irick) D.J. Keil, comb. et stat. nov., **C. pulcherrimum** (Rydb.) K. Schum. var. **aridum** (R.D. Dorn) D.J. Keil, comb. et stat. nov. **C. scariosum** Nutt. var. **americanum** (A. Gray) D.J. Keil, comb. nov., **C. scariosum** Nutt. var. **citrinum** (Petrak) D.J. Keil, comb. nov., **C. scariosum** Nutt. var. **coloradense** (Rydb.) D.J. Keil, comb. et stat. nov., **C. scariosum** Nutt. var. **congdonii** (R.J. Moore & Frankton) D.J. Keil, comb. et stat. nov. Lectotypes are designated for several of these taxa.

RESUMEN

Se proponen seis variedades nuevas en *Cirsium* (Asteraceae: Cardueae) de Norteamérica: ***C. arizonicum*** (A. Gray) Petrak var. ***tenuisectum*** D.J. Keil var. nov., ***C. eatonii*** (A. Gray) B.L. Rob. var. ***viperinum*** D.J. Keil, var. nov., ***C. edule*** Nutt. var. ***wenatchense*** D.J. Keil, var. nov., ***C. occidentale*** (Nutt.) Jeps. var. ***lucianum*** D.J. Keil, var. nov., ***C. scariosum*** Nutt. var. ***robustum*** D.J. Keil, var. nov., ***C. scariosum*** Nutt. var. ***toiyabense*** D.J. Keil, var. nov. Se presentan además veinte combinaciones nuevas: ***C. arizonicum*** (A. Gray) Petrak var. ***bipinnatum*** (Eastw.) D.J. Keil, comb. nov., ***C. arizonicum*** (A. Gray) Petrak var. ***chellyense*** (R.J. Moore & Frankton) D.J. Keil, comb. et stat. nov., ***C. arizonicum*** (A. Gray) Petrak var. ***rothrockii*** (A. Gray) D.J. Keil, comb. et stat. nov., ***C. clavatum*** (M.E. Jones) Petrak var. ***americanum*** (A. Gray) D.J. Keil, comb. nov., ***C. clavatum*** (M.E. Jones) Petrak var. ***osterhoutii*** (Rydb.) D.J. Keil, comb. et stat. nov., ***C. cymosum*** (Greene) J.T. Howell var. ***canovirens*** (Rydb.) D.J. Keil, comb. et stat. nov., ***C. eatonii*** (A. Gray) B.L. Rob. var. ***eriocephalum*** (A. Nelson) D.J. Keil, comb. nov., ***C. eatonii*** (A. Gray) B.L. Rob. var. ***hesperium*** (Eastw.) D.J. Keil, comb. et stat. nov., ***C. eatonii*** (A. Gray) B.L. Rob. var. ***peckii*** (L.F. Hend.) D.J. Keil, comb. et stat. nov., ***C. eatonii*** (A. Gray) B.L. Rob. var. var. ***clokeyi*** (S.F. Blake) D.J. Keil, comb. et stat. nov., ***C. edule*** Nutt. var.

SIDA 21(1): 207–219. 2004

macounii (Greene) D.J. Keil, comb. et stat. nov., ***C. horridulum*** Michx. var. ***megacanthum*** (Nutt.) D.J. Keil, comb. et stat. nov., ***C. inamoenum*** (Greene) D.J. Keil, comb. nov., ***C. inamoenum*** (Greene) D.J. Keil var. ***davisii*** (Cronquist) D.J. Keil, comb. et stat. nov., ***C. ochrocentrum*** A. Gray var ***martinii*** (P. Barlow-Irick) D.J. Keil, comb. et stat. nov., ***C. pulcherrimum*** (Rydb.) K. Schum. var ***aridum*** (R.D. Dorn) D.J. Keil, comb. et stat. nov., ***C. scariosum*** Nutt. var ***americanum*** (A. Gray) D.J. Keil, comb. nov., ***C. scariosum*** Nutt. var. ***citrinum*** (Petrak) D.J. Keil, comb. nov., ***C. scariosum*** Nutt. var. ***coloradense*** (Rydb.) D.J. Keil, comb. et stat. nov., ***C. scariosum*** Nutt. var. ***congdonii*** (R.J. Moore & Frankton) D.J. Keil, comb. et stat. nov., También se designan lectótipos de varios de estos taxa.

Preparation of a taxonomic treatment of *Cirsium* Mill. (Asteraceae: Cardueae) for the upcoming Asteraceae volumes of the Flora of North America has entailed a reevaluation of many of the published taxa. The only comprehensive treatment of North American *Cirsium* species (Petrak 1912, 1917) is long out of date. Revisions or cytotaxonomic studies have been published for several species groups (Frankton & Moore 1961, 1963; Moore & Frankton 1962, 1964, 1965, 1966, 1969, 1974; Ownbey 1952; Ownbey & Hsi 1963, 1969; Ownbey & Olson 1969; Ownbey et al. 1975), and many of the species have been included in state or regional floristic treatments (e.g., Cronquist 1955, 1994; Dorn 1992; Gardner 1974; Howell 1960; Keil & Turner 1993; Munz & Keck 1959; Munz 1974; Weber 1996; Weber & Wittmann 1987; Welsh 1983; Welsh et al. 1993), but these treatments have been uneven and limited in scope. Political boundaries often mark the application of differing taxonomic constructs. In my investigations I have examined North American *Cirsium* as a whole and across the breadth of its geographic range.

Cirsium well deserves its reputation as a taxonomically difficult genus. One of the most challenging aspects for a taxonomist studying New World *Cirsium* is the presence of species complexes that are apparently evolutionary works in progress. Some of the thistles, especially in the mountainous western part of North America, are frustratingly polymorphic with mosaic and overlapping patterns of variation and intergradation of characters. Early taxonomists, basing their work on a limited sampling of the morphological diversity, named many of the forms as species, and the literature is robust with species names. The infilling that results from more collectors visiting more localities within the ranges of these complexes has blurred the boundaries between many of the proposed species and often added forms that do not "fit" the characters of named species. As I faced the challenges of preparing the FNA treatment I recognized that maintaining some of the named entities as species would for consistency require a further proliferation of species names.

I have chosen to go the other way. Instead continuing the proliferation of ill-defined microspecies I treat the plants in question as rapidly evolving, only partially differentiated assemblages of races that have not reached the level of stability that is usually associated with the concept of species. In a molecular phylogenetic investigation Kelch and Baldwin (2003) found unusually low rates of molecular divergence relative to the ecological diversity of New World *Cirsium* and suggested that the genus has undergone a rapid ecological diversification on a continental scale. Certainly there is much variation within these groups that deserves a level of taxonomic recognition, or that at least should be mentioned, but I think it much more prudent to recognize these as infraspecific taxa—entities that may be expected to freely intergrade—than species. I view species as entities that should be consistently recognizable. Within a large genus such as *Cirsium* the amount of infraspecific variation and the degree of geographical separation among races varies from species to species and from geographical race to geographical race. Races occupying contiguous habitats often intergrade freely in zones of contact whereas races currently isolated by geographic or habitat barriers often have more discrete variation patterns. Both situations may occur in a single species.

Infraspecific taxa in *Cirsium* have been recognized in various taxa at the rank of form, variety, and subspecies. In the Flora of North America (Flora of North America Editorial Committee 1996) the trivial rank of form, representing sporadic variants without a geographic range, is not used. Some *Cirsium* variants recognized in the past as varieties are the equivalent of forms. In *Cirsium* both variety and subspecies have been used in the context of morphologically distinguishable geographical races. The rank of variety has been used more widely. The Flora of North America Guide for Contributors (Flora of North America Editorial Committee 1996) stipulates that only one infraspecific rank (subspecies or variety) be recognized within a genus. As used by most workers in *Cirsium* taxonomy the choice of rank has been a matter of preference, and I view them as equivalent. I have chosen to use variety rather than subspecies because only one change from subspecies to variety has to be made to follow the Flora of North America Guidelines whereas the use of subspecies as the infraspecific rank for formally recognized geographical races would require many more nomenclatural innovations.

The overall product of my studies will be detailed in the FNA treatment (Keil, in press). Presented below are six newly proposed varieties and validation of twenty new combinations for North American *Cirsium.*

Cirsium arizonicum (A. Gray) Petrak var. **bipinnatum** (Eastw.) D.J. Keil, comb. nov. BASIONYM: *Cnicus drummondii* Torr. & A. Gray var. *bipinnatus* Eastw., Zoe 4:8. 1893. TYPE: COLORADO: Johnston Cañon near where it joins Mancos River, Sep 1892, *Eastwood s.n.* (HOLOTYPE: CAS; ISOTYPE: MIN).

Cirsium arizonicum (A. Gray) Petrak var. **chellyense** (R.J. Moore & Frankton) D.J. Keil, comb. et stat. nov. BASIONYM: *Cirsium chellyense* R.J. Moore & Frankton, Canad. J. Bot. 52:547. 1974. TYPE: ARIZONA. Apache Co.: Canyon de Chelly, 1 Jul 1961, *Norman 680* (HOLOTYPE: DAO).

Cirsium arizonicum (A. Gray) Petrak var. **rothrockii** (A. Gray) D.J. Keil, comb. et stat. nov. Basionym: *Cnicus rothrockii* A. Gray, Proc. Amer. Acad. Arts 17:220. 1882. Type: ARIZONA: Rocky Canyon, 1874, *Rothrock 289* (lectotype, here chosen from syntypes, GH). Gray (1882) described *Cnicus rothrockii* based upon two collections (*Rothrock 289* and *Lemmon 2794*).

Moore and Frankton (1974) selected *Rothrock 289* as the lectotype collection of *Cnicus rothrockii*. However, they cited as lectotype specimens of this gathering from both GH and US. According to Article 9.2 of the International Code of Botanical Nomenclature (Greuter et al. 2000) "a lectotype is a specimen or illustration designated from the original material as the nomenclatural type." Moore and Frankton's designation of two specimens at different institutions as lectotype fails the requirement that a single specimen serve in that role. I agree with their designation of *Rothrock 289* as the lectotype collection and here choose the GH specimen as lectotype for the taxon.

Cirsium arizonicum (A. Gray) Petrak var. **tenuisectum** D.J. Keil, var. nov. Type: CALIFORNIA. San Bernardino Co.: New York Mountains, Keystone Canyon, 2.1 road mi from Ivanpah Road, ca. 1670 m, *Pinus monophylla-Juniperus osteosperma* woodland; scattered in rocky wash channel; associates: *Fallugia paradoxa, Prunus fasciculata, Gutierrezia sarothrae, Atriplex canescens, Eriodictyon angustifolium, Yucca brevifolia, Opuntia echinocarpa, Menodora scabra, Ephedra nevadensis, Penstemon* sp., *Machaeranthera canescens, Purshia mexicana, Muhlenbergia porteri, Ericameria linearifolia, Salvia dorrii, Lycium cooperi, Yucca baccata, Berberis* sp., *Rhus trilobata, Sphaeralcea* sp., *Ipomopsis agregata, Datura wrightii, Artemisia dracunculus*, and *Achnatherum hymenoides*, 5 Nov 1999, *Keil 28401* (holotype—flowering stem of plant D, OBI; isotypes [the letter in parentheses represents the individual], ASU (A), BRY (C), CAS (B), CDA (C), DAO (D), GH (D), MIN (D), MO (C), NY (C), OBI (A, C), RSA (A), TEX (D), UC (B), US (D)).

Caulibus et costis abaxialibus glabris ad tomentosis trichomatibus tenuibus non-septatis, spinis principalibus foliorum 5–30 mm longis, et corollis rubellopurpureis distinguatur.

Stems thinly arachnoid tomentose, ± glabrate, without septate trichomes. Leaves deeply divided, often nearly to the midvein, abaxially arachnoid tomentose or sometimes glabrate, without septate trichomes, adaxially thinly arachnoid or glabrate; principal marginal spines 5–30 mm, often stout; cauline leaves narrowed at base to truncate or ± clasping, but not or only slightly decurrent. Involucres cylindric to campanulate; phyllary spines 5–25 mm, stout. Corollas reddish purple, 25–35 mm, the tube 10–13, throat 5–8 mm, lobes 10–13.5 mm; style tips 1–2 mm.

Paratypes: **CALIFORNIA. San Bernardino Co.:** New York Mountains, Carruthers Canyon, 1615–1645 m, 6 Nov 1999, *Keil 28402* (NMC, OBI, OSC); New York Mountains, Keystone Spring, 1585 m, 13 Oct 1935, *Munz 13862* (UC). Nevada. Clark Co.: SW slope of NW Spring Mts., upper Clark Canyon, yellow pine vegetation, 7000-7600 ft, 9 Jul 1970, *Beatley 11355* (UNLV); Charleston Mts., Charleston Peak, gravelly wash, with *Pinus scopulorum*, 2270 m, 18 Jul 1938, *Clokey 8182* (PH, UC, UTC(2), WTU(2)), Charleston Mts., Kyle Canyon at bridge, wash with aspens, 2300 m, 3 Aug 1935, *Clokey 5609* (UC), Charleston Mts., Charleston Park, gravelly wash, yellow pine belt, 2300 m, 25 Jul 1936, *Clokey 5609*

(UC, UTC, WTU); Charleston Mts., Lee Cañon, in limestone, 8000 ft, 4 Aug 1913, *Heller 11057* (PH, UC); Charleston Mts., Pine Cr., 6700 ft, 4 Sep 1927, *Jaeger 2202* (UC); Charleston Mts., near Charleston park resort, plentiful, 8000 ft, 12 Sep 1925, *Jaeger s.n.* (UC); Spring Range, Toiyabe National Forest, Kyle Canyon Rd. (Nevada Rte. 157) just W of junction with Nevada Rte. 157, Ponderosa pine forest, 6930 ft, 17 Aug 2002, *Keil 29112* (OBI); Spring Mountains, Toiyabe National Forest, Las Vegas Ski and Snowboard area in Upper Lee Canyon, 36.299°N, 115.696°W, subalpine forest with limber pine, bristlecone pine, white fir, quaking aspen, wax currant, and common juniper, 9200 ft, 17 Aug 2002, *Keil 29114* (OBI); Red Rock Canyon Recreation Lands, Mouth of Velvet Canyon, with *Celtis reticulata*, *Quercus turbinella*, and *Chrysothamnus paniculatus*, 4400 ft, 6 Jun 1990, *Leary et al. 4006* (UNLV); Spring Range, NW of Las Vegas, upper Lee Canyon between ski area and saddle at head of Wallace Canyon, conifer forest with *Pinus flexilis*, *P. longaeva*, *Abies concolor*, and *Populus tremuloides* on steep limestone slopes and canyon bottom, 8700–9900 ft, 31 Aug 1986, *Sanders et al. 6881* (OBI).

The *Cirsium arizonicum* complex is a group of closely related taxa of the southwestern United States and northwestern Mexico. This species complex was revised by Moore and Frankton (1974), who recognized eight species, three of them newly described. In Moore and Frankton's key to species of the *C. arizonicum* complex, var. *tenuisectum* keys to *Cirsium nidulum* (M.E. Jones) Petrak, and these authors cited a chromosome count from the Spring Mountains population of var. *tenuisectum* as *C. nidulum*. Moore and Frankton's rather imprecise range map does not include the New York Mountains for *C. nidulum* or any other member of the *C. arizonicum* complex, and there is no indication that Moore and Frankton were aware of the thistles from this mountain range. *Cirsium nidulum* is the name that has been used for the New York Mountains thistle in various floras (Howell 1960; Munz and Keck 1959; Munz 1974; Keil and Turner 1993, 2002). As a part of my research on *Cirsium* for the Flora of North America project, I have examined many specimens, including types, from throughout the range of the various members of the *Cirsium arizonicum* complex, and I have concluded that the *C. arizonicum* complex should be treated as a single polymorphic species. It has become evident that the name *Cirsium nidulum* has been widely misapplied; the type is a very spiny plant of var. *arizonicum*. The plants from the Spring Mountains and New York Mountains represent a previously unnamed variety.

Cirsium clavatum (M.E. Jones) Petrak var. **americanum** (A. Gray) D.J. Keil, comb. nov. BASIONYM: *Cnicus carlinoides* Schrank var. *americanus* A. Gray, Proc. Amer. Acad. Arts 10:48. 1874. TYPE: COLORADO: Rocky Mts., lat. 39–41°, *Hall and Harbour 339* (LECTOTYPE, here chosen from syntypes, GH).

The varietal epithet *americanum* was based upon syntypes from both Colorado and California. The latter are referable to *Cirsium remotifolium* (Hook.) DC. Gray (1874) cited two Colorado collections, *Greene s.n.* and *Hall and Harbour 342*. Cronquist (1994) stated that "*Hall & Harbour 342*, Rocky Mts., Colo., is the first collection cited and has been taken to be the type; original at GH!" I agree with the choice of *Hall and Harbour 342* and am validating its designation as lectotype.

Cirsium clavatum (M.E. Jones) Petrak var. **osterhoutii** (Rydb.) D.J. Keil, comb. et stat. nov. BASIONYM: *Carduus osterhoutii* Rydb., Bull. Torrey Bot. Club 32:131. 1905. TYPE: COLORADO. EAGLE CO.: Red Cliff, 1902, *Osterhout 2706* (HOLOTYPE: NY; ISOTYPE: RM).

Cirsium cymosum (Greene) J.T. Howell var. **canovirens** (Rydb.) D.J. Keil, comb. et stat. nov. BASIONYM: *Carduus canovirens* Rydb., Mem. N.Y. Bot. Gard. 1:450. 1910. TYPE: MONTANA. MADISON CO.: Jack Creek Cañon, 7000 ft, 15 Jul 1897, *Rydberg and Bessey 5213* (HOLOTYPE: NY).

Cirsium eatonii (A. Gray) B.L. Rob. var. **eriocephalum** (A. Nelson) D.J. Keil, comb. nov. BASIONYM: *Cirsium eriocephalum* A. Gray, nom. illeg.; *Carduus hookerianus* Nutt. [var.] *eriocephalus* A. Nelson, in J.M. Coult. & A. Nelson, Man. Bot. Rocky Mts. 585. 1909. TYPE: COLORADO: headwaters of Clear Creek and the alpine ridges lying E of Middle Park, 1861, *Parry s.n.* (LECTOTYPE, here chosen from syntypes, GH).

This taxon was originally named *Cirsium eriocephalum* by Gray (1863), but this name was a later homonym. Because of the illegitimate status of *C. eriocephalum*, a priorable autonym was not created by publication of *Cirsium eriocephalum* A. Gray var. *leiocephalum* D.C. Eaton (1871). However, Nelson's recognition of *Carduus hookerianus* var. *eriocephalus* established this epithet at the varietal level with Nelson as the author of the epithet, not Gray [ICBN Art. 58]. Nelson did not cite rank for infraspecific taxa but his trinomial combinations are to be treated as varieties (ICBN Art. 35.4).

Cirsium eatonii (A. Gray) B.L. Rob. var. **hesperium** (Eastw.) D.J. Keil, comb. et stat. nov. BASIONYM: *Cnicus hesperius* Eastw., Bull. Calif. Acad. Sci. ser. 3, 1:122. 1898. TYPE: COLORADO: La Plata Mts., Mt. Hesperus on Bear Creek Divide, Aug 1892, *Eastwood s.n.* (HOLOTYPE: CAS).

Cirsium eatonii (A. Gray) B.L. Rob. var. **peckii** (L.F. Hend.) D.J. Keil, comb. et stat. nov. BASIONYM: *Cirsium peckii* L.F. Hend., Madroño 5:97. 1939. TYPE: OREGON. HARNEY CO.: Alvord Ranch, E base of Steens Mt., 6 Jun 1927, *Henderson 8521* (HOLOTYPE: ORE).

Cirsium eatonii (A. Gray) B.L. Rob. var. **clokeyi** (S.F. Blake) D.J. Keil, comb. et stat. nov. BASIONYM: *Cirsium clokeyi* S.F. Blake, Proc. Biol. Soc. Washington 51:8. 1938. TYPE: NEVADA. CLARK CO.: Charleston Mts., 6 Aug 1937, *Clokey 7456* (HOLOTYPE: US; ISOTYPES: BRY, DAO, GA, MO, PENN, PH, RM, UC).

Cirsium eatonii (A. Gray) B.L. Rob. var. **viperinum** D.J. Keil, var. nov. TYPE: NEVADA. WHITE PINE CO.: Snake Range, Humboldt National Forest, Snake Creek Canyon, above Johnson Lake, steep rocky slope, granite, common, 11,000 ft [3353 m], 10 Aug 1964, *Holmgren and Reveal 1588* (HOLOTYPE: UTC; ISOTYPES: WTU, MIN).

Capitulis rare arachnoideis trichomatibus non-septatis, corollas lavandulis ad purpureis, 29–35 mm longis, setis longissimis pappi 20–25 mm distinguatur.

Plants erect, 2.5–4 dm. Leaves glabrous or nearly so on both surfaces. Capitula 1–5, subsessile or short-peduncled, in raceme-like or corymbiform capitulescence. Involucres 3–5 cm, thinly arachnoid with non-septate trichomes; outer phyllaries with numerous lateral spines; spine tips of phyllaries stout. Corollas lavender to purple, 29–35 mm, the tube 9–12.5 mm, the throat 9–12 mm, the lobes 9–11 mm. Longest pappus bristles 20–25 mm.

PARATYPES: **NEVADA. White Pine Co.:** Snake Range, Mt. Washington, bristlecone pine forest just S of the peak, T12N, R68E, Sect. 11, plants growing with *Pinus* on limestone gravel slopes, 11,300 ft [3444 m], 9 Aug 1985, *Tiehm 10107* (CAS, COLO, MIN, OSC, UNLV); Mount Moriah, N end of Snake Range, moist limestone derived sandy to rocky soil, on S-facing slope with *Phlox*, *Aquilegia*, *Crepis nana*, *Allium*, and *Erigeron*, T18N, R69E, Sect. 10, 11840 ft (3500 m), 2 Aug 1999, *Niles et al. 5818* (UNLV); 12 mi SW of Baker, Humboldt National Forest, Snake Range, N side of Mt. Washington, T12N, R68E, E 1.2 of Sect. 11, with scattered bristlecone pine, 11,000 ft, 12 Sep 1983, *Goodrich et al. 20063* (BRY); 13 mi SW of Baker, Snake Range, S slopes of Mt. Washington, T12N, R68E, N 1/2 of Sect. 14. upper edge of bristlecone pine-limber pine forest, 11,000 ft, 12 Sep 1983, *S. Goodrich et al. 20063* (BRY).

Cirsium eatonii var. *viperinum* is apparently endemic to upper elevations of the Snake Range of White Pine County, Nevada. Capitula of var. *viperinum* are similar in size to those of var. *clokeyi*. However, var. *viperinum* is a shorter plant (2–4 dm vs. 4–15 dm) with longer corolla tubes (9–12 mm vs. 3.5–7 mm), and longer pappus bristles (longest bristles 20–25 mm vs. 16–18 mm). Ranges of the two varieties are separated by about 340 km. Putative hybrids between *C. inamoenum* and *C. eatonii* var. *viperinum* are known from the Snake Range.

Cirsium edule Nutt. var. **macounii** (Greene) D.J. Keil, comb. et stat. nov. BASIONYM: *Carduus macounii* Greene, Ottawa Naturalist 16:38. 1902. TYPE: BRITISH COLUMBIA: Chilliwack Valley, 13 Jun 1901, *Macoun 26451* (LECTOTYPE, here chosen from syntypes, NDG).

Cirsium edule Nutt. var. **wenatchense** D.J. Keil, var. nov. TYPE: WASHINGTON. CHELAN CO.: Nason Creek, banks of streams, 660 m, 30 Jul 1893, *Sandberg and Leibgerg 626* (HOLOTYPE: ORE; ISOTYPES: CAS, UC).

Capitulis generaliter solitariis, in pedunculis 10–30 cm portatis et involucris 3–4 cm altis et 4–5 cm diametro distinguatur.

Capitula mostly solitary; peduncles 10–30 cm. Involucres 3–4 cm, 4–5 cm diam., moderately arachnoid; phyllary apices long-acicular, widely spreading, spine tips 5–15 mm. Corollas 29–33 mm, the tube 9–11 mm, the throat 8–12 mm, the lobes 9–10 mm. Style tips 3–4 mm. Cypselae 4.5–6 mm, dark brown; longest pappus bristles 20–25 mm.

PARATYPES: **WASHINGTON. Chelan Co.:** Wenatchee Mts., trail to Snow Lakes, rocky granitic alpine slopes, 11 Aug 1952, 4000 ft, *Thompson 17135* (WTU); Yakima Region, 1883, *Brandegee 922* (UC); Nason City, 2000–3000 ft., Jul 1893, *Sandberg and Leiberg s.n.* (MIN); Yakima Region, Wenatchie, Aug 1883, 6500 ft, *Tweedy s.n.* (YU). **Kittitas Co.:** Mt. Stuart, Cascades, Aug 1898, *Elmer 1217* (MIN).

Cirsium edule var. *wenatchense* is apparently endemic to the Wenatchee Mountains, in the eastern Cascade Range of central Washington. Little is known of its variation or habitat. Because none of the specimens are complete individuals, the overall stature of the plant is unknown. I am not aware of any recent collections of this taxon.

Cirsium horridulum Michx. var. **megacanthum** (Nutt.) D.J. Keil, comb. et stat. nov. Basionym: *Cirsium megacanthum* Nutt., Trans. Amer. Phil. Soc. 2nd ser., 7:421. 1841. Type: LOUISIANA: banks of Mississippi near New Orleans, *Little s.n.* (lectotype, here chosen from syntypes, PH).

Cirsium inamoenum (Greene) D.J. Keil, comb. nov. Basionym: *Carduus inamoenus* E.L. Greene Fl. Fran. 479. 1897; *Carduus undulatus* Nutt. var. *nevadensis* Greene, Proc. Acad. Nat. Sci. Philad. 44(1892):361. 1893 (homotypic synonym of *C. inamoenus*). Type: CALIFORNIA: E of Truckee or near that place, Aug 1883, *Greene s.n.* (lectotype, here chosen from syntypes, ND-G).

Cirsium inamoenum (Greene) D.J. Keil var. **davisii** (Cronquist) D.J. Keil, comb. et stat. nov. Basionym: *Cirsium davisii* Cronquist, Leafl. W. Bot. 6:46. 1950. Type: IDAHO. Bannock Co.: University of Idaho farm, Pocatello, 8 Jun 1931, *Davis s.n.* (holotype: WS).

Cirsium occidentale (Nutt.) Jeps. var. **lucianum** D.J. Keil, var. nov. Type: CALIFORNIA. San Luis Obispo Co.: Cuesta Ridge, along main road (USFS Rd. 29S11.3) 1.3 mi W of E boundary sign for Cuesta Ridge Botanical Area, ca. 4.3 mi W of Hwy. 101, scattered along disturbed roadside, serpentine, 2460 ft, 22 Jun 1989, *Junak and Ayers 4073* (holotype: SBBG; isotype: OBI).

Habitu erecto, capitulis conspicue pedunculatis, involucris 2–4 cm diametro, atropurpureis, floccoso-arachnoideis, et corollas purpureo-atrorubens 20–24 mm distinguatur.

Plants erect, 3–20 dm. Capitula long-peduncled, elevated well above lower leaves; involucres 2–4 cm diameter, dark purple, floccose-arachnoid; middle phyllary tips generally 5–8 mm, 1–3 mm wide, straight or upwardly curved, ascending to spreading. Corollas 20–24 mm, dark purplish red.

Paratypes: **CALIFORNIA. San Luis Obispo Co.:** Los Padres National Forest, W-facing cleared slope below TV towers just E of West Cuesta Ridge Rd. at eastern botanical area boundary sign, ca. 3 mi W of Hwy. 101, 22 Jun 1989, *Ayers and Junak 754A* (OBI, SBBG); 0.3 mi from hwy 101 along West Cuesta Ridge Rd., chaparral, S-facing slope, roadside, ca. 1540 ft, 4 Jun 2000, *Bushakra and Bushakra 35* (OBI), *36* (UC), *37* (MIN), *38* (ASU); Cerro Alto, 13 May 1958, *Hardham 3288* (SBBG); near summit of ridge W of upper Lopez Canyon, open W-facing slope, 5 Jun 1964, *Hoover 8932* (OBI); ridge NW of Cuesta Pass, serpentine area, disturbed roadside, 17 Jun 1965, *Hoover 9430* (OBI); Black Butte Research Natural Area, SE base of Peak 3, steep rocky opening at edge of *Quercus agrifolia* woodland at margin of unburned area, 2 May 1995, *Hrusa 12258* (CDA, OBI); Cuesta Ridge Botanical Area, N of main road, just S of KSBY television towers, ca. 2.7 mi W of Hwy. 101, 28 Jun 1989, *Junak and Ayers 4098* (SBBGG); Cuesta East in area burned by Gay Mt. and Las Pilitas fires, fire succession area in chaparral, 17 May 1987, *Keil et al. 20162* (OBI); San Luis Obispo, 187_, *Lemmon 41* (PH); along road to cypress forest below summit of TV peak, W of Cuesta Grade and Hwy. 101, 28 Jun 1968, *Smith 10095* (SBBG); S entrance to Cuesta Botanical Area, serpentine soil, 7 Jun 1971, 2500 ft, *Wiese 97* (OBI).

Cirsium occidentale var. *lucianum* is restricted to San Luis Obispo County, California where it occupies a narrow corridor along and adjacent to the main ridge of the southern Santa Lucia Mountains. In *The Jepson Manual* Keil and Turner (1993) treated these plants as an atypical race of *C. occidentale* var. *californicum*. They resemble small-headed plants of var. *californicum* but differ in their dark, reddish purple corollas and darkly pigmented involucres. They approach the ranges of var. *californicum* and var. *venustum* but are not known to grow with either of these varieties. Wells (1983) and Keil and Turner (1992) reported the occurrence of hybrid swarms between these taxa in which emergent phenotypes differing from either parent have been observed. *Cirsium occidentale* var. *lucianum* may represent a stabilized emergent form derived by prehistoric hybridization between var. *californicum* and var. *venustum*.

Cirsium ochrocentrum A. Gray var. **martinii** (P. Barlow-Irick) D.J. Keil, comb. et stat. nov. BASIONYM: *Cirsium ochrocentrum* A. Gray subsp. *martinii* P. Barlow-Irick, Novon 9:320. 1999. TYPE: NEW MEXICO. CATRON CO.: NM Hwy. 12, 5 mi E of San Francisco River bridge at Reserve, 5800 ft. elev., 28 Jul 1997, *Barlow 97-8* (HOLOTYPE: US; ISOTYPES: ASU, MO, NMC, UNM).

Hsi (1960) in an unpublished dissertation proposed recognition of this taxon as a species, noting its resemblance to *C. ochrocentrum*. Barlow-Irick (1999) formally described it as a subspecies of *C. ochrocentrum*, demonstrating its intergradation with typical *C. ochrocentrum*. As indicated above I have chosen to recognize varieties rather than subspecies in my FNA treatment of *Cirsium*, and I make the change from subspecies to variety in deference to the FNA Guide for Contributors.

Cirsium pulcherrimum (Rydb.) K. Schum. var. **aridum** (R.D. Dorn) D.J. Keil, comb. et stat. nov. BASIONYM: *Cirsium aridum* R.D. Dorn, Vasc. Pl. Wyoming, 2nd ed. 304. 1992. TYPE: WYOMING. FREMONT CO.: ca. 6 mi N of Sweetwater Station, barren chalky hills, 6700 ft, 26 Jul 1990, *Dorn 5105* (HOLOTYPE: RM).

Cirsium scariosum Nutt. var. **americanum** (A. Gray) D.J. Keil, comb. nov. BASIONYM: *Cirsium acaule* Allioni var. *americanum* A. Gray, Proc. Philad. Acad. Nat. Sci. 1863:68. 1863. TYPE: COLORADO: Rocky Mts., lat. 39–41, *Hall and Harbour 339* (HOLOTYPE: GH).

Cirsium scariosum Nutt. var. **citrinum** (Petrak) D.J. Keil, comb. nov. BASIONYM: *Cirsium quercetorum* (A. Gray) Jeps. var. *citrinum* Petrak, Bieh. Bot. Centralbl. 35:363. 1917. TYPE: CALIFORNIA. SAN DIEGO CO.: Warner's Hot Springs, 10 Apr 1913, *Eastwood 2629* (HOLOTYPE: CAS).

Cirsium scariosum Nutt. var. **coloradense** (Rydb.) D.J. Keil, comb. et stat. nov. BASIONYM: *Carduus coloradensis* Rydb., Bull. Torrey Bot. Club 32:132. 1905. TYPE: COLORADO: Pagosa Springs, 28 Jul 1899, *Baker 644* (HOLOTYPE: NY; ISOTYPES: MO, ND-G, POM).

Cirsium scariosum Nutt. var. **congdonii** (R.J. Moore & Frankton) D.J. Keil, comb. et stat. nov. BASIONYM: *Cirsium congdonii* R.J. Moore & Frankton, Canad. J. Bot. 45:1738. 1967. TYPE: CALIFORNIA. MONO CO.: Bridgeport Valley, 3.5 mi NW of Bridgeport along U.S. Hwy. 395, edges of winter overflow of Buckeye Creek, 6505 ft, *Bacigalupi et al. 8015* (HOLOTYPE: DAO).

Cirsium scariosum Nutt. var. **robustum** D.J. Keil, var. nov. TYPE: CALIFORNIA. SISKIYOU CO.: N side of Stateline Rd., Hwy 161 to Tulelake, 5.2 km E of Hwy 97, 10.5

km NE of Dorris, T48N, R1E, sect. 16, 14 Jun 1977, *Fuller 20216* (HOLOTYPE: mounted on 3 sheets, CDA; ISOTYPE: CDA).

Habitu caulescente caulibus proximale ramosis, capitulis evidenter pedunculatis, apicibus phyllariorum interiorum expansis scariosis erosodentatis, et corollas albidis distinguatur.

Plants caulescent, 2.5–7 dm. Stems solitary from base, often very stout, proximally simple and distally branched or branched throughout, leafy, glabrous, villous with septate trichomes, or arachnoid-tomentose. Leaves oblanceolate to elliptic, deeply pinnately lobed, villous with septate trichomes or thinly arachnoid-tomentose, abaxially thinly to densely arachnoid-tomentose, villous with septate trichomes along the midvein. Capitula 3–many, evidently peduncled at stem tips (in age clustered axillary capitula sometimes developing), subtended and ± overtopped by upper leaves or these ± reduced. Involucres 2.5–4 cm; outer and middle phyllaries lanceolate to ovate, the spine tips 1–6 mm, slender to ± broad and flat; tips of inner phyllaries linear-acuminate or more commonly expanded as a scarious, erose-toothed appendage, often contorted. Corollas white, 30–36 mm, the tubes 14–22 mm, the throats 7–12 mm, the lobes 5–10 mm; style tips 6–8 mm. Cypselae 4–6.5 mm; pappi 22–32 mm.

PARATYPES: **CALIFORNIA. Siskiyou Co.:** Gazelle, moist meadows, 20 Jun 1905, *Heller 8077* (PH); Butte Valley W of Dorris, occurring in large patches, 16 Jul 1982, *Shaw s.n* (CDA); E of McCloud along Hwy. 89, 7.7 mi W of Shasta Co. line, roadside drainage in lodgepole pine forest, 24 Jul 1992, *Keil and Keil 23571* (OBI); 5 mi N of Gazelle, 14 Jul 1948, *Pryor 3704* (CDA); 4 mi N of Gazelle, 26 Jul 1950, *Pryor s.n.* (CDA); without locality, 22 Jul 1954, *Huse s.n.* (CDA); Hwy 99, 2 mi S of Gazelle, T42N, R6W, roadside meadow, 9 Jul 1959, *Fuller 2738* (CDA). **OREGON. Klamath Co.:** Keno, bank of Klamath River, 6 Jul 1920, *Peck 9279* (DS); 15 mi S of Diamond Lake, moist ground, 7 Jun 1937, *Peck 19736* (WILLU). **Lake Co.:** 9 mi S of Summer Lake P.O., swampy meadow, 19 Jun 1941, *Peck 20809* (UC, WILLU); along Johnson Creek, Summer Lake, 12 Jul 1928, *Constance 9478* (ORE); 6 mi NE of Lakeview, 29 Jun 1937, *Peck 19624* (WILLU).

Cirsium scariosum var. *robustum* is known only from northern California (Siskiyou County) and south-central Oregon (Klamath and Lake counties).

Cirsium scariosum Nutt. var. **toiyabense** D.J. Keil, var. nov. TYPE: NEVADA. LANDER CO.: N of Toiyabe Range, Silver Creek, 10.5 mi E of Nevada 8A, 12 airline mi N of Austin, T21N, R44E, Sect. 22, edge of wet meadow, 17 Jul 1970, 7000 ft, *Holmgren and Holmgren 4476* (HOLOTYPE: MIN; ISOTYPES: ASU, WTU).

Habitu caulescente corollas purpureis lobis 5.5–8 mm longis distinguatur.

Plants subacaulescent to erect, 0.5–5.5 dm. Stems usually simple, leafy, glabrous to villous or tomentose with septate trichomes, sometimes thinly arachnoid tomentose. Leaves oblong to oblanceolate or elliptic, pinnately lobed or often unlobed, adaxially green, glabrous or villous with septate trichomes, abaxially green and ± glabrous to white-tomentose. Capitula 1–10+, sessile or short-peduncled, crowded at stem tips, usually subtended and ± overtopped by upper leaves. Involucres 2–3 cm; outer and middle phyllaries lanceolate to ovate, the spine tips 2–4 mm, slender; tips of inner phyllaries acuminate and entire or abruptly expanded into a scarious, erose-toothed appendage. Corollas rose-purple, 23–31 mm, the tubes 11–16 mm, the throats 4.5–8.5 mm, the lobes 5.5–8.5 mm; style tips 3.5–4.5 mm. Cypselae 4–6 mm; longest pappus bristles 22–25 mm.

Paratypes: **NEVADA. Humboldt Co.:** Paradise Valley, NE of Winnemucca, T42N, R39E, Sect.14, irrigated meadow, 24 Jun 1967, 4700 ft, *Gentry and Davidse 1627* (ASU, DS, KANU, WTU); Virgin Valley, Virgin Valley campground, banks of pond, 16 Jun 1978, 4820 ft, *Tiehm and Rogers 4457* (CAS); Buckskin Mt.-Hinkey Summit road 2 mi from Buckskin Mt. summit, wet meadow, 1 Jul 1978, *Grimes and Packard 1183* (COLO); Kings River, Disaster Peak Range, 28 Jun 1924, *Archer 123* (ASU). **Lander Co.:** Toiyabe Range, hills around Austin, 22–25 Jul 1913, *Kennedy 4400* (PH, UC); Reese River, ca. 10 mi W of Austin, moist pasture, 31 Jul 1939, 5400 ft, *Hitchcock and Martin 5580* (UC, WTU); Toiyabe Mts., Jul 1868, 6000 ft, *S. Watson 689* (YU). **Nye Co.:** Millett, 4 Jul 1931, 5500 ft, *Linsdale and Linsdale 637* (CAS). **Washoe Co.:** near Glendale, Truckee meadows, 18 Jul 1913, 4500 ft, *Kennedy 3054* (PH, UC); White Pine, Steptoe Valley, Monte Neva Hot Springs, 21 mi N of McGill, white salt-crusted loam around spring, 4 Jul 1966, 6000 ft, *Holmgren and Reveal 2810* (WTU). **OREGON. Harney Co.:** Sod House School S of Malheur Lake, in marsh with *Typha*, 21 Jun 1958, *Raven and Solbrig 13368* (CAS); McDermitt Canyon, wet meadow, 4 Jul 1927, *Henderson 8522* (CAS); vicinity of Malheur Field Station, ca. 1/4 mi E of North Butte, edge of marsh with invading weeds, 11 Aug 2000, 4080 ft, *Keil 29092A, B* (OBI).

Cirsium scariosum var. *toiyabense* occurs from northern Nevada to southeastern Oregon and southern Idaho.

ACKNOWLEDGMENTS

I gratefully thank the curators of the various herbaria who have made specimens available to me for this project and patiently waited for me to return the loans.

DONALD MACE WILLIAMS. 2003. **Timberline U.S.A.: High-Country Encounters from California to Maine.** (ISBN 0-87421-571-4, pbk.). Utah State University Press, 7800 Old Man Hill, 1151 East 700 North, Logan, UT 84322-7800, U.S.A. (Orders: 435-797-1362, 435-797-0313 fax). $17.95, 225 pp., 5 1/2" × 8".

KEY WORDS: Nature, mountains, sports, recreation and hiking. This book is about timberline adventures and the various people who adventure there as well as some scientists who study those areas. According to the author, "My main hope in writing this book, I suppose, was to show what it is about the treeless parts of high mountains that awes, attracts, and frightens me and millions of other hikers. Also, I wanted to see how, in each of the major ranges of the lower forty-eight states that get above timberline—the Rockies **[Part I]**, the Sierra Nevada **[Part II]**, the Cascades **[Part III]**, and the northern Appalachians **[Part IV]**—the high country is different form that of the other three ranges. For both purposes, I hiked."

ANDREW PARKER. 2003. **In the Blink of An Eye: How Vision Sparked the Big Bang of Evolution.** (ISBN 0-465-05438-2, pbk.). Basic Books, A Member of the Perseus Books Group, 387 Park Avenue South, New York, NY 10016, U.S.A. (Orders: 212-340-8100, 212-340-8115 fax, www.basicbooks.com). $15.00, 316 pp., b/w photos, line drawings, 5" × 8".

Author Comments: "The big Bank in animal evolution was perhaps the most dramatic event in the history of life on Earth. During this blink of an eye in such history, all the major animal groups found today evolved hard parts and became distinct shapes, simultaneously and for the first time. This happened precisely 543 million years ago, at the beginning of a period in geological history called the Cambrian, and so has become known as the 'Cambrian explosion'. But what lit the Cambrian fuse? "... In short, we know very well *what* happened during evolution's Big Bang, indeed numerous books have already been written on this question, but we don't know *why* it happened. *Why* it happened is the puzzle this books sets out to solve."

The book attempts to solve the 543 million year old puzzle in 316 pages in ten chapters: **1)** Evolution's Big Bang. **2)** The Virtual Life of Fossils. **3)** The Infusion of Light. **4)** When Darkness Descends. **5)** Light, Time and Evolution. **6)** Colour in the Cambrian? **7)** The Making of a Sense. **8)** The Killer Instinct. **9)** The Solution. **10)** End of Story?

A NEW NAME AND A NEW COMBINATION IN *SOLIDAGO* SUBSECT. *GLOMERULIFLORAE* (ASTERACEAE: ASTEREAE)

Rachel E. Cook[1] and John C. Semple

Department of Biology
University of Waterloo
Waterloo, Ontario, CANADA N2L 3G1
jcsemple@sciborg.uwaterloo.ca

ABSTRACT

The following new name and new combination are proposed: *Solidago caesia* var. *zedia*, *Solidago curtisii* var. *flaccidifolia*.

RESUMEN

Se proponen el siguiente nombre y combinación nueva: *Solidago caesia* var. *zedia*, *Solidago curtisii* var. *flaccidifolia*.

The following new name and new combination are presented in order to have them available for use in our treatment of *Solidago* L. for the Flora North America project (Semple & Cook, submitted). Cook (2002, Ph.D. thesis) revised *Solidago* subsect. *Glomeruliflorae* (Torrey & A. Gray) Nesom, including cytogeography and multivariate morphometric analyses. Detailed papers on the taxonomy and biosystematics of subsect. *Glomeruliflorae* are in preparation.

Solidago caesia L. var. **zedia** R.E. Cook & Semple, var. nov. (**Fig. 1**). TYPE: U.S.A. LOUISIANA. EAST FELICIANA PARISH: LA-67, 2.5 km S of Felps (LA-422), vicinity of small creek, 13 Oct 1991, *J.C. Semple & B.A. Suripto 10108* (HOLOTYPE: WAT; ISOTYPES: BRIT, MO).

Differt a Solidago caesia var. caesia foliis caulinis rhombico-ovatis.

Perennial from woody caudex-like rhizomes. Stems one to many, arching (27.7–)31.6–54.1–76.6(–99.1) cm tall occasionally with one to several elongated lateral branches, glaucous, usually blue to purple anthocyanin colored, glabrous to slightly pubescent in the inflorescence (0.0–)0.6–6.2–11.8(–17.0) hairs/mm^2. Basal leaves absent at flowering time. Lower stem leaves lanceolate to rhombic, sessile, (47.3–)57.0–70.0–83.1(–91.8) mm long, (13.0–)14.4–17.7–21.1(–24.0) mm wide, sparsely pubescent above (0.0–)0.0–1.1–2.2(–3.6) hairs/mm^2, (0.2–)1.6–3.3–5.0(–6.0) hairs/mm along the vein, glabrous to sparsely pubescent below (0.0–)0.0–0.2–0.9(–2.7) hairs/mm^2, (0.0–)0.1–2.5–4.9(–8.0) hairs/mm along the vein, leaf apices acuminate, margins with (4.0–)5.0–6.9–8.7(–9.3) serrations. Upper stem leaves lanceolate to rhombic, sessile, (23.0–)32.4–43.0–53.6(–60.3) mm long,

(5.6–)6.7–9.1–11.6(–13.9) mm wide, glabrous to sparsely pubescent above (0.0–)0.1–1.1–2.2(–3.0) hairs/mm^2, (0.8–)1.6–3.8–5.9(–8.6) hairs/mm along the vein, glabrous to sparsely pubescent below (0.0–)0.0–0.2–0.9(–2.0) hairs/mm^2, (0.0) 0.4–2.6–4.9(–7.5) hairs/mm along the vein, margins entire to slightly serrate with (0.0–)0.0–1.8–3.6(–7.0) serrations. Capitulescence short axillary and terminal racemiform-paniculiform clusters, inflorescence (8.9–)11.4–20.8–30.2(–38.7) cm long with heads secund. Involucres (4.8–)5.4–6.1–6.8(–7.2) mm high, (3.1–)3.1–3.9–4.7(–6.3) mm wide; phyllaries in several unequal series, outermost phyllaries (0.9–)1.0–1.1–1.2(–1.3) mm long, lanceolate, acute; innermost phyllaries (2.5–)2.8–3.3–3.7(–4.1) mm long, linear-oblong, obtuse to acute, single nerved. Ray florets (1.0–)1.9–2.7–3.5(–4.0), strap yellow, (1.5–)1.8–2.3–2.7(–3.4) mm long; corolla (1.3–)1.5–1.7–1.9(–2.0) mm long; achenes (1.1–)1.3–1.7–2.1(–2.6) mm long, sparsely to moderately pubescent; pappus (1.6–)2.2–2.6–3.1(–3.4) mm long. Disc florets (3.0–)3.8–5.2–6.6(–7.0), yellow; corolla (2.0–)2.1–2.5–3.0(–3.7) mm long; corolla lobe (0.9–)1.1–1.3–1.4(–1.6) mm long; achenes (1.2–)1.4–1.7–2.0(–2.2) mm long, moderately to densely pubescent; pappus (2.4–)2.6–3.0–3.4(–3.6) mm long. Chromosome number: $2n=18$.

Solidago caesia var. *zedia* is distinguished by its shorter, broadly lanceolate to rhombic leaves (Fig 1). Variety *zedia* is found in the wet, lowland areas of southern Arkansas, Mississippi, Louisiana, Alabama, Georgia and into northwestern Florida.

Etymology.—The varietal name is an alphabetical reference to it being the last taxon recognized during work by our Canadian laboratory, eh.

KEY TO THE TWO VARIETIES OF *SOLIDAGO CAESIA*

1. Lower midstem leaves long and narrowly lanceolate, 5–15 cm long, 0.8–3 cm wide; stems strongly arching; Nova Scotia to Wisconsin south to Florida and Texas ____ **S. caesia** var. **caesia**
1. Lower midstem leaves shorter and broadly lanceolate, 5–9 cm long, 1.3–2.4 cm wide; stems weakly arching; restricted to the wet, lowlands of Arkansas, Mississippi, Alabama, Georgia, and Florida ____ **S. caesia** var. **zedia**

Solidago curtisii Torrey & A. Gray var. **flaccidifolia** (Small) R.E. Cook & Semple, comb. et stat. nov. BASYONYM: *Solidago flaccidifolia* Small, Bull. Torrey Bot. Club 25:477. 1898. TYPE: U.S.A. GEORGIA: Rome, 1872, *Chapman s.n.* (HOLOTYPE: NY!)

The var. *flaccidifolia* is distinguished by its leaves being more elliptical and more pubescent than those of var. *curtisii*. The range of var. *flaccidifolia* includes the mountains of Tennessee, Kentucky, Virginia, North Carolina, and Georgia, as well as lowland areas in southern Georgia, Alabama and Mississippi. It can be found at low to moderate elevations in shaded woods and thickets. This variety has been found to be tetraploid and hexaploid. A complete discussion of the taxon will be presented in a paper, now in preparation by R.E. Cook.

ABSTRACT

The new combination *Krigia cespitosa* (Raf.) K.L. Chambers var. *gracilis*, based on *Apogon gracilis* DC., is proposed, and a lectotypification of the basionym is given. A neotype is created for *Serinia cespitosa* Raf. The hexaploid hybrid *Krigia* × *shinnersiana* is described from the Blue Ridge Parkway, North Carolina, representing an allopolyploid of the cross *Krigia biflora* (Walter) S.F. Blake × *Krigia montana* (Michx.) Nutt.

RESUMEN

Se propone la nueva combinación *Krigia cespitosa* (Raf.) K.L. Chambers var. *gracilis*, basada en *Apogon gracilis* DC., y se hace una lectotipificación del basiónimo. Se crea un neotipo para *Serinia cespitosa* Raf. El híbrido hexaploide *Krigia* × *shinnersiana* se describe del Blue Ridge Parkway, North Carolina, y representa un alopoliploide del cruce *Krigia biflora* (Walter) S.F. Blake × *Krigia montana* (Michx.) Nutt.

THE VARIETIES OF *KRIGIA CESPITOSA*

Krigia Schreb., *Nomen Conservandum*[1], has a large synonymy, considering its rather modest number of species. Shinners (1947) recognized only seven species but listed eight synonymous generic names. This excess of names may have resulted from the various authors' overemphasis on pappi differences and the contrast between annual and perennial habit within the genus. One species, as recognized here, consistently lacks pappi and, on this basis, was segregated as *Serinia* Raf. (Rafinesque 1817) and *Apogon* Elliott (Elliott 1823). DeCandolle (1838:261) placed *Serinia* in his Compositae Incertae Sedis but recognized *Apogon humilis* Elliott and added a second species, *Apogon gracilis* DC. These two species were again recognized by Gray (1884), and a third species, *A. wrightii* A. Gray, was described, differing from the others by the possession of "an obscure vestige of pappus." The final union of *Apogon* and *Serinia* with *Krigia* was done by Shinners (1947), who included *Krigia gracilis* (DC.) Shinners and *Krigia oppositifolia* Raf. (=*Krigia cespitosa* (Raf.) K.L. Chambers, formerly *Apogon humilis*) but placed *Apogon wrightii* Gray in synonymy under the latter species.

---

[1] As explained by Kim and Turner (1992), the International Code of Botanical Nomenclature (Greuter et al. 1988) erroneous stated that the basionym of the conserved type species, *Krigia virginica* (L.) Willd., is *Tragopogon virginicus* L., whereas it should be *Hyoseris virginica* L. This mistake is perpetuated in the current Saint Louis Code (Greuter et al. 2000). I second the proposal by Kim and Turner that this be corrected in the next edition of the Code.

We now know much more about this cluster of taxa, from chromosome studies and the detailed molecular analyses by Kim and co-workers (Kim & Mabry 1991; Kim et al. 1992; Kim & Jansen 1994). *Krigia gracilis* and *K. cespitosa* both are diploid annuals with $n = 4$ and have similar epappose, fusiform cypselae. They are practically indistinguishable in the chloroplast cDNA and nuclear rDNA traits studied (summarized in Kim & Turner 1992). *Krigia wrightii* (A. Gray) K.L. Chambers ex K.-J. Kim is annual and tetraploid, with $n = 9$, and has more barrel-shaped cypselae often with a pappus of vestigial scales (figured in Kim & Turner 1992:180). In a cladistic analysis of cDNA and rDNA data, a 100% bootstrap value provided by 51 synapomorphies separated it from the cluster that includes *K. cespitosa* and the related *K. occidentalis* Nutt. It is probably an ancient allopolyploid between a *K. cespitosa*-like species and one of the pappus-bearing annual species of the genus (Kim & Turner 1992).

Prior to the work of Kim and Turner, systematists in Texas recognized *Krigia gracilis* and *K. cespitosa* as different species (Shinners 1958; Correll & Johnston 1970). Their emphasis was on morphological traits, especially the difference in size of heads and florets (corollas 5–10 mm long, involucres 5.3–8.5 mm high in flower, 6.2–8.5 mm high in fruit in *K. gracilis*, versus corollas 2–4 mm long, involucres 3–4.3 mm high in flower, 3.3–5.3 mm high in fruit in *K. cespitosa*). To these authors, *K. gracilis* was endemic to central and south-central Texas in the Blackland Prairie, occasionally west to the Llano region, mostly in clay-loam soil but also in adjacent regions of sandy soil, even becoming weedy in fields and disturbed ground (Shinners 1947). *Krigia cespitosa* is much more widespread, extending from central Texas east to Florida, the Carolinas, and Virginia, and north to Kansas, Missouri, and Tennessee. In herbarium studies done much earlier by the present author, the area of overlap between the varieties in Texas formed a north-south band, from Denton and Tarrant Cos. east to Hunt Co. in the north, and from Travis and Hays Cos. east to Harris Co. in the south, with an extension east to Polk and Angelina Cos. Kim and Turner (1992) took a different view of these taxa. Based on their field and herbarium studies, they extended the range of *K. gracilis* from eastern Texas to "adjacent Oklahoma, Arkansas, and Louisiana," and they noted the presence of populations intermediate in head and flower size. Due to this pattern of intergradation and to the high similarity revealed by their DNA analysis, they proposed that the large-flowered types be reduced to the rank of *K. cespitosa* forma *gracilis* (DC.) K.-J. Kim (Kim & Turner 1992:196; Diggs et al. 1999).

My purpose here is to make a different proposal for these taxa, based on several considerations. The first is the geographical pattern, in which a widespread small-flowered type intergrades at the western edge of its range with a morphologically distinctive and geographically limited large-flowered type. Geographical races marked by interbreeding in the area of overlap are more often accorded the rank of variety than of forma. Weight must also be given to the nature of the morphological differences, as they represent a developmentally coordinated syndrome of variation in the reproductive organs. The large-flowered race may differ in breeding system, through pollinator attraction, an increased frequency of outcrossing, and genetic mixing in the otherwise self-pollinating reproductive mode exhibited by the two varieties (Kim & Turner 1992). Intraspecific differences in reproduction associated with conspicuous floral-size differences have been noted in other genera of Cichorieae and have been accorded varietal status. Examples known to the author are *Agoseris heterophylla* (Nutt.) Raf. var. *californica* (Nutt.) Jeps. (Chambers 1963), and *Glyptopleura marginata* D.C. Eaton var. *setulosa* (A. Gray) Jeps. (Jepson 1925), both of which are large-flowered races in typically smaller-flowered species.

To allow the recognition of this morphologically distinctive geographic race at a higher taxonomic level than forma, the following combination is proposed:

Krigia cespitosa (Raf.) K.L. Chambers var. **gracilis** (DC.) K.L. Chambers, stat. nov. (**Fig. 1**). *Apogon gracilis* DC., Prod. 7:79. 1838. *Krigia gracilis* (DC.) Shinners, Wrightia 1:205. 1947. *Krigia cespitosa* (Raf.) K.L. Chambers forma *gracilis* (DC.) K.-J. Kim, Brittonia 44:196. 1992. TYPE: [TEXAS] "de Bejar a Austin, Avril 1828, *Berlandier No. 1637*" (LECTOTYPE: G-DC, the larger left-hand plant of 3 on the sheet; ISOLECTOTYPES: G, GH, US).

The need for lectotypification of the basionym was first suggested by the wording of DeCandolle's description, which includes the phrase "*achaeniis scabris brevissime papposis.*" Since *Krigia gracilis*, as the name has been used by American botanists, totally lacks pappus, I became concerned that DeCandolle was dealing with a mixed collection, perhaps including *K. wrightii* or *K. occidentalis*. With the kind assistance of Dr. F. Jacquemoud and Dr. L. Gautier of the Herbarium, Conservatoire et Jardin botaniques de la Ville de Geneve, it has been determined that the Berlandier type sheet is a mixed collection, the left-hand plant possessing epappose cypselae and the right-hand plant having vestigial pappus resembling the illustration of *K. wrightii* published by Kim and Turner (1992:180). To maintain the present usage of the epithet *gracilis*, I have designated the left-hand plant as the lectotype. The isolectotype at GH studied by Shinners and Kim consists only of *gracilis*-type plants that lack pappi. Another duplicate in the general herbarium at Geneva, ex Herbier Moricand, clearly shows two *gracilis*-type plants and two of the pappus-bearing species. My notes from 1965 on the isolectotype at US, "ex Herb. Musei Britannici," state that it has 2 plants of the *gracilis*-type and 4 plants with muticous pappi. Whether the second species in Berlandier's collection is *K. wrightii* or a muticous form of *K. occidentalis* is not clear, although a photograph of the Herbier Moricand sheet strongly suggests the latter.

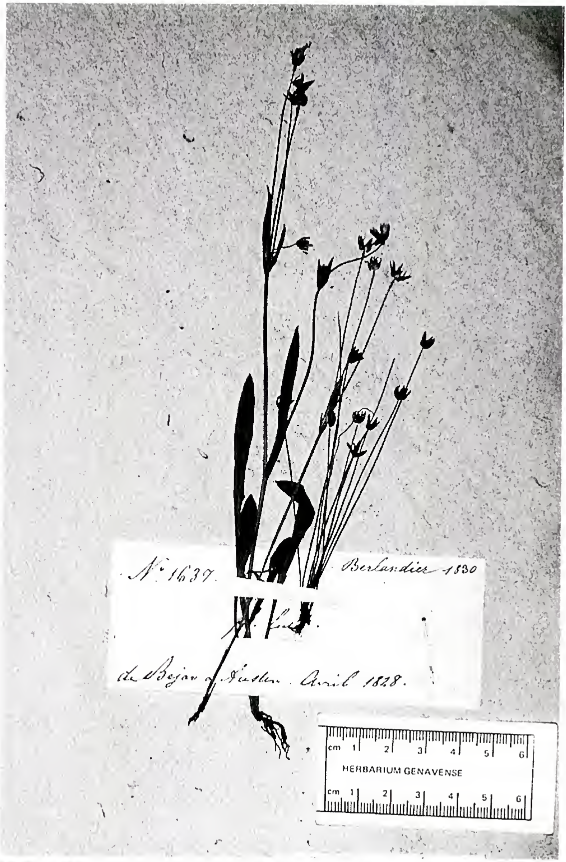

Fig. 1. Type sheet of *Apogon gracilis*, G-DC; lectotype plant is the tall specimen at the left.

Krigia cespitosa (Raf.) K.L. Chambers var. **cespitosa.** *Serinia cespitosa* Raf., Fl. ludov. 149. 1817. *Krigia ? oppositifolia* Raf., op. cit. 57, nom. invalid. *Krigia cespitosa* (Raf.) K.L. Chambers, J. Arnold Arbor. 54:52–53. 1973. *Krigia cespitosa* (Raf.) K.L. Chambers forma *cespitosa* in K.-J. Kim, Brittonia 44:196. 1992. TYPE: LOUISIANA: Natchitoches, open ground, 15 Apr 1915. *E.J. Palmer 7220* (NEOTYPE: MO! ISONETOTYPE: NY!)

As is well known, Rafinesque's *Florula Ludoviciana* (1817) was a translation of part of the French traveler C.C. Robin's publication describing his voyages to Louisiana, Florida, and the West Indies, in which Rafinesque proposed many new species and genera. Collections by Robin have never been located. The above species was described first on page 57 as *Krigia? oppositifolia*, but that name was rejected by the author on page 149 of the "Additions," and *Serinia cespitosa* was substituted (Chambers 1973). American authors have been in agreement as to what species Rafinesque was referring, but its name has not before been typified.

A HYBRID *KRIGIA* FROM THE MOUNTAINS OF NORTH CAROLINA

It was long ago reported that a hexaploid hybrid population of *Krigia* occurs on the Blue Ridge Parkway northeast of Ashville, North Carolina (Chambers 1965; Vuilleumier 1973), but its formal taxonomic recognition has been delayed until the present. The parental taxa are *K. montana* (Michx.) Nutt. ($n = 10$) and *K. biflora* (Walter) S.F. Blake ($n = 5$), whose area of sympatry is limited to the southern Appalachian Mountains. *Krigia montana* is endemic to this region (Shinners 1947; Wiser 1994), occurring mainly on granitic balds, cliffs, talus, and roadbanks, principally in North Carolina but extending into South Carolina, Georgia, and Tennessee in similar habitats. It is consistently tetraploid (Tomb et al. 1978). *Krigia biflora* is much more widespread, occurring in woodlands and low prairies throughout the northeastern United States and parts of southern Canada, ranging south to Georgia, Alabama, and Arkansas, with disjunct populations in Colorado, New Mexico, and Arizona (Kim & Turner 1992). In the Blue Ridge of North Carolina it is found principally in the shrub bald community (Ramseur 1960), and both diploid ($n = 5$) and tetraploid ($n = 10$) populations are known.

At Craggy Gardens on the Blue Ridge Parkway, ca. 12 air line km northeast of Asheville, Buncombe County, hexaploid plants were found that were intermediate in various respects between the two above species. Their population will be described below. Samples from this site, along with samples of *K. montana* and of diploid and tetraploid *K. biflora* were contributed to the research of K.-J. Kim, University of Texas, and are mentioned in his various publications. His biochemical studies involved the whole genus and included both chloroplast DNA, examined through restriction site analysis, and nuclear rDNA, for which restriction sites and ITS sequences were utilized. Because the chloroplast genome is inherited maternally, it was expected that the hybrid's chloroplasts would resemble one parent more than the other. In the cladistic analysis, the maternal parent proved to be diploid *K. biflora* (Kim et al. 1992). In the ITS sequence study, the hybrid did not associate closely with either parent but instead, in the strict consensus tree, formed an unresolved branch at the node basal to the two parents (Kim & Jansen 1994). However, a relationship of the hybrid with *K. montana* was shown in the analysis based on rDNA restriction sites (Kim and Mabry 1991). The hexaploid "exhibited combined length polymorphism patterns of the diploid *K. biflora* and the tetraploid *K. montana*." These studies leave no doubt that the Craggy Gardens plants are indeed the allopolyploid hybrid of *K. biflora* × *K. montana*.

In order to call attention to this hybrid and to provide a name for use by those interested in studying it further, the following taxon is here described:

Krigia × shinnersiana K.L. Chambers, hybrid nov. (**Fig. 2**). TYPE: U.S.A. NORTH CAROLINA. BUNCOMBE CO.: Craggy Gardens, Blue Ridge Parkway 18.6 mi N of junction with Hwy. 70 E of Asheville, at the observation hut on grassy bald above the parking lot, elev. 5340 ft, grassy turf over granite substrate, 21 Jul 1968, *K.L. Chambers 2880* (HOLOTYPE: OSC; ISOTYPES: GH, MO, NY, OSC, US).

Hybrida inter *Krigiam bifloram* et *K. montanam* intermedia caule inferne et superne ramoso foliato ramis superne folia redacta ferens ab capitulis longi-pedunculatis 1–3 simul terminatis, cypselis 3.5 mm longis, floribus aurantiaco-luteis, chromosomatum numerus $2n = 60$.

Perennial herb with short rhizome, propagating by adventitious buds from the rootlets, stems decumbent or erect, to 65 cm tall, leaves of the basal rosette 8–30 cm long, oblanceolate, tapering to a narrowly winged petiole, acute, entire or dentate to pinnatifid with remote, straight or arcuate, acute lobes, lower cauline leaves similar, 14–25 cm long, upper leaves reduced, lanceolate with broad, clasping petiole, peduncles 14–28(–30) cm long, glandular-villous towards apex, involucre 7–10 mm high in flower, 8–13 mm high in fruit, phyllaries 11–13, equal, lanceolate, attenuate, green, glabrous or lightly glandular-villous, florets 20–23 mm long. The name honors Lloyd H. Shinners, whose valuable monograph (1947) forms the basis for studies of the genus.

Additional collections: **U.S.A. NORTH CAROLINA. Buncombe Co.:** Blue Ridge Parkway, mile 364.4 R., Craggy Flats, in bald near trail shelter on Craggy Gardens nature trail, 14 Jul 1977, *T. Govus 231 and Dan Pittillo* (WCUH). **Buncombe Co.:** Scattered in grassy bald, top of Craggie Mt., 15 Jul 1935, *H.J. Oosting 35453* (DUKE).

A comparison of habit and flower color in *Krigia × shinnersiana* and its two parents is given in Table 1. Differences in the cypselae also were noted (Fig. 3). Fruits of the hybrid were consistently longer, at 3.5 mm, than in either *K. biflora* (3.0 mm) or *K. montana* (2.5–3.0 mm). In *K. biflora* the ribs of the cypselae are low and of equal prominence nearly to the base, whereas in *K. montana*, 3 ribs are usually more prominent than the others in adaxial view, some other ribs being suppressed. In *K. × shinnersiana* the ribs in adaxial view arise at the base in groups of 3, with the central rib being more prominent to near the cypsela

apex. The number of bristles per cypsela was compared, using mature heads collected in glass vials to avoid shattering the delicate pappi (Table 2). Bristle numbers in *K. biflora* are distinctly greater than in *K. montana*, while the hybrid numbers vary from those of *K. montana* up to an approximately intermediate number. If bristle number is assumed to have a genetic component, the range of numbers in the hybrid, sampled at different times from the type locality, suggests that two or more different genotypes are present.

The type locality is reached by a trail heading south 0.5 km from the Visitors Center at the Craggy Gardens parking area, to a hikers' shelter constructed of weathered chestnut beams. The grass bald south of the shelter is being invaded by small shrubs of *Rhododendron catawbiense* from the surrounding heath bald community (Ramseur 1960:90). *Krigia montana* is common on Craggy Pinnacle north of the parking area but was not seen in the heath or grass bald communities along the south trail. *Krigia biflora* was never noted in this vicinity during my field studies. Observations made in 1995 found the hybrid to be abundant in two areas of the bald, forming colonies near small shrubs of *Rhododendron* and *Vaccinium*. The absence of variation in transplants from

Table 1. Comparison of habit and flower color of *Krigia biflora, K. montana*, and *K.* × *shinnersiana*. *Measured by means of Nickerson Color Fan (Munsell Color Co., Baltimore, MD). Floral pigments of *Krigia* spp. identified as carotenoids by Harborne (1997).

Krigia biflora	***Krigia* × *shinnersiana***	***Krigia montana***
Stems naked below or with one large leaf low-down; modified clasping leaf higher up.	Same as *K. montana*	Cauline leaves well-developed, with axillary branches above basal leaf rosette.
Main stem ending in umbellate cluster of 2–6 naked floral peduncles.	Main stem ending in cluster of 1–3 naked floral peduncles.	Main stem usually terminated by a single naked floral peduncle.
Terminal cluster of peduncles subtended by 1–3 bracts up to 3(–5) cm long.	Terminal peduncles subtended by 1–3 bract-like leaves up to 9(–11) cm long.	Terminal peduncle subtended by 1–2 leaves up to 18 cm long.
Later inflorescences may arise in axils of clasping upper leaf and lower stem leaf.	Same as *K. montana*	Later inflorescence branches arise in axils of stem leaves and leaves subtending terminal peduncle.
First floral peduncle not arising singly from basal leaf rosette.	Same as *K. biflora*	First floral peduncle may arise singly near basal leaf rosette.
Flower color Munsell Hue 10YR 8/10 moderate orange yellow.*	Flower color Munsell Hue 5Y 8/12, vivid yellow.	Flower color Munsell Hue 7.5Y 8/12, vivid greenish yellow.

Table 2. Mean number of pappi bristles per cypsela in plants of *Krigia biflora, K. montana*, and *K.* × *shinnersiana*. Collections of the latter taxon were made at Craggy Gardens at various times. The standard deviation, range, and number of cypselae sampled are given. See Appendix for other locality information.

Collection	**Mean**	**S.D.**	**Range**	**Number**
1207 biflora 2x	36.86	2.97	30–42	28
1404 biflora 4x	31.88	3.15	26–39	24
2894 montana	15.38	1.36	13–18	16
2881 montana	18.67	1.36	16–22	27
2887 montana	21.13	1.46	20–23	8
2889 montana	21.88	1.45	19–25	16
2888-1 shinnersiana	18.49	1.64	14–22	38
2880 shinnersiana	19.48	1.35	16–22	29
2888-2 shinnersiana	20.74	1.95	18–23	50
2879-2 shinnersiana	21.16	2.41	17–26	76
1362 shinnersiana	24.17	2.17	21–28	12
2879-5 shinnersiana	24.80	2.07	20–28	20
2879-3 shinnersiana	27.70	1.52	25–30	20

each colony suggests that reproduction is largely clonal. One such colony was located 31 m southeast of the shelter, just east of an incised walking trail, while another was found 28 m southwest of the shelter, west of a second trail. The two colonies differ in leaf shape (nearly entire vs. sharply pinnately lobed) and probably represent different genotypes. Fruit-set is high when hybrid plants are cross-pollinated experimentally, but seedling establishment may be infrequent in the dense stand of *Carex* and grasses of the bald.

As discussed by Wiser and White (1999), grass balds of the Southern Appalachians were used as summer grazing pastures until around 1930, but they are not maintained by current natural processes and are subject to woody plant invasion. The bald at the type locality, under the name Craggy Flats, was described by Pittillo and Govus (1978), who included a brief list of the herbaceous flora. *Krigia* × *shinnersiana* was mentioned in this list under the name *K. biflora* (voucher checked by the author). It is tempting to speculate that the hybrid originated over 70 years ago, in the period of cattle grazing, when habitat disturbance was greater than now and open ground was more available for hybrid seedling establishment. The two parental species must have been in genetic contact over a long period of time in this mountainous region, and we can expect to find the products of their hybridization at other sites as well. Evidence of this is the discovery of pentaploid plants referable to *Krigia biflora* at two sites along the trail up Mt. Pisgah from the Blue Ridge Parkway, Haywood County, NC (*Chambers 2891, 2893*). The habitat was trail-side in a shrub bald about 50 m below the summit communications tower, in very different conditions than the grass bald at Craggy Flat. Morphology of the plants suggests a contribution of *K. montana* to their origin. It is hoped that this report will stimulate interest and further study by persons to whom these sites on the Blue Ridge Parkway are readily accessible.

ABSTRACT

The following 18 new combinations in *Eremogone* are proposed: *Eremogone capillaris* var. *americana*, *E. congesta* var. *cephaloidea*, *E. congesta* var. *charlestonensis*, *E. congesta* var. *crassula*, *E. congesta* var. *glandulifera*, *E. congesta* var. *prolifera*, *E. congesta* var. *simulans*, *E. congesta* var. *subcongesta*, *E. congesta* var. *suffrutescens*, *E. congesta* var. *wheelerensis*, *E. eastwoodiae* var. *adenophora*, *E. franklinii*, *E. franklinii* var. *thompsonii*, *E. kingii* var. *plateauensis*, *E. kingii* var. *rosea*, *E. macradenia* var. *arcuifolia*, *E. macradenia* var. *ferrisiae*, and *E. macradenia* var. *kuschei*.

RESUMEN

Se proponen las siguientes dieciocho combinaciones nuevas en *Eremogone*: *Eremogone capillaris* var. *americana*, *E. congesta* var. *cephaloidea*, *E. congesta* var. *charlestonensis*, *E. congesta* var. *crassula*, *E. congesta* var. *glandulifera*, *E. congesta* var. *prolifera*, *E. congesta* var. *simulans*, *E. congesta* var. *subcongesta*, *E. congesta* var. *suffrutescens*, *E. congesta* var *wheelerensis*, *E. eastwoodiae* var. *adenophora*, *E. franklinii*, *E. franklinii* var. *thompsonii*, *E. kingii* var. *plateauensis*, *E. kingii* var. *rosea*, *E. macradenia* var. *arcuifolia*, *E. macradenia* var. *ferrisiae*, y *E. macradenia* var. *kuschei*.

During preparation of the treatment of the Caryophyllaceae for *Flora North America* (Rabeler and Hartman, editors, in prep), the decision was made to recognize the genus *Eremogone* Fenzl (= *Arenaria* subgenera *Eremogone* (Fenzl) Fenzl and *Eremogoneastrum* F. Williams sensu McNeill 1962).

Nepokroeff and Wagner (pers. comm.; see also Nepokroeff et al. 2001) conducted a DNA survey of the Caryophyllaceae, using sequence data from matK and the rps16 intron. Over 79 species constituting 38 genera were included, with emphasis on the subfamily Alsinoideae. The phylogeny illustrated *Arenaria* (*sensu* McNeill (1962), excl. *Minuartia* and *Moehringia*) to be polyphyletic, with two major, distinct clades. While one clade includes members of four of McNeill's subgenera, including *Arenaria serpyllifolia* L., the type of *Arenaria*, and the genus *Moehringia*, the second clade includes seven species (five from subgenus *Eremogone*, three North American and two Asian, and two Asian members of subgenus *Eremogoneastrum*). Within that clade, *Arenaria bryophylla* Fern. (subg. *Eremogoneastrum* from Asia) clusters closely with *A. aculeata* S. Watson and *A. kingii* (S. Watson) M.E. Jones (subg. *Eremogone* from North America), suggesting that the relationships between the subgenera may also need examination. The results indicated that the *Eremogone* group, including both subgenera, is strongly supported as monophyletic.

Eremogone was treated by McNeill (1962) as a subgenus of *Arenaria* containing eight sections (64 species, our compilation; ca. 70 species (Zhengyi et al. 2001)) closely allied with subgenus *Eremogoneastrum* (ca. 22 species). Members of subgenus *Eremogone* are found from western Europe through Asia, east to southern Alaska and northwestern Canada, disjunct to southwestern Canada and the western United States. The composition of *Eremogone* sensu Ikonnikov (1990) excludes McNeill's monotypic section *Monogone* Maxim. (the Tien Shan Mountains and the Altai Region), two of the species from his section *Scariosae* (northern Iran and Turkish Armenia), and his sect. *Pungentes* (two species, Spain and North Africa).

As outlined by McNeill (1962), *Arenaria* subgenus *Eremogoneastrum* is confined to three centers with two species (*Arenaria hookeri* Nutt. and *A. franklinii* Dougl. ex Hook.; a third, *A. pinetorum* A. Nelson is a variety of the former) in western North America, the type, *A. festucoides* Benth., known from India, Pakistan, and China, and the remainder (ca. 6 species) Sino-Himalayan in distribution. Seventeen species are now known from China (Zhengyi et al. 2001); most are Sino-Himalayan, nine were published since 1979. Ikonnikov makes no mention of *Arenaria* subgenus *Eremogoneastrum* in either of his synopses of *Eremogone* (1973, 1990).

In North America, both Maguire (1947, 1951; treated in Maguire (1951) as *Arenaria* sect. *Pentadenaria* Williams) and Hickman (1971) recognized a broader concept of *Arenaria* section *Eremogone*, including the two western American members of subgenus *Eremogoneastrum* (*A. hookeri* and *A. franklinii*). Maguire treated those species as related to but of uncertain placement, while Hickman considered them to be intermediate between sections *Eremogone* and *Alsine* (= *Minuartia*). *Eremogone* as presented here is currently accepted in floras of Colorado (Weber & Wittmann 1992 and subsequent updates at *http://cumuseum.colorado.edu/*) and Wyoming (Dorn 2001).

Morphologically, *Eremogone* consists of woody based perennials with a cespitose or matted habitat, filiform to subulate leaves with scarious bases, stiffly erect or ascending flowering stems, and cymes that are open to congested or umbellate. This is contrasted with the remaining North American (north of Mexico) members of *Arenaria* (ca. 9 species), that are annuals or perennials with either a caespitose habit or ascending to trailing stems, broader (ovate to lanceolate, sometimes narrowly so) leaves, and flowers often solitary or in few-flowered, open cymes.

Ikonnikov (1973) and Holub (1974) both noted that a base chromosome number of $x = 11$ also distinguished *Eremogone* from *Arenaria* ($x = 10$). Of the approximately 30 species of *Eremogone*, as here defined, which have been counted, only three counts (including two for *E. fendleri* that appear not to have been vouchered; that taxon was counted by Hartman (1971) as 2n = 44) are not based on $x = 11$. Contrary to their notion, *Arenaria* s.s. is cytologically more diverse; while many counts are based on $x = 10$, counts based on $x = 11$ are known in two subgenera as well as five sections of subg. *Arenaria* (Rabeler, pers. compilation from standard chromosome atlases).

Most of the nomenclatural combinations for the 13 North American species of *Arenaria* to be included in *Eremogone* are available (Ikonnikov 1973, 1974; Weber et al. 1981); by contrast, only a few of the infraspecific taxa have the appropriate combinations (Weber et al. 1981; Dorn 2001).

The following combinations are needed for the genus *Eremogone* in North America in anticipation of the *Flora North America* treatment (Hartman, Rabeler and Utech, in prep).

Eremogone capillaris (Poir.) Fenzl var. **americana** (Maguire) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria capillaris* Poir. subsp. *americana* Maguire, Bull. Torrey Bot. Club 74:41. 1947. *Arenaria capillaris* var. *americana* (Maguire) R.J. Davis, Madroño 11:144. 1951. *Eremogone americana* (Maguire) Ikonn., Novosti Sist. Vyssh. Rast. 11:174. 1974.

Eremogone congesta (Nutt.) Ikonn. var. **cephaloidea** (Rydb.) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria cephaloidea* Rydb., Bull. Torrey Bot. Club 39:316. 1912. *Arenaria congesta* Nutt. var. *cephaloidea* (Rydb.) Maguire, Bull. Torrey Bot. Club 74:46. 1947.

Eremogone congesta (Nutt.) Ikonn. var. **charlestonensis** (Maguire) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria congesta* Nutt. var. *charlestonensis* Maguire, Bull. Torrey Bot. Club 73:326. 1946.

Eremogone congesta (Nutt.) Ikonn. var. **crassula** (Maguire) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria congesta* Nutt. var. *crassula* Maguire, Bull. Torrey Bot. Club 74:45. 1947.

Eremogone congesta (Nutt.) Ikonn. var. **glandulifera** (Maguire) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria congesta* Nutt. var. *glandulifera* Maguire, Amer. Midl. Naturalist 46:501. 1951.

Eremogone congesta (Nutt.) Ikonn. var. **prolifera** (Maguire) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria congesta* Nutt. var. *prolifera* Maguire, Bull. Torrey Bot. Club 74:47. 1947.

Eremogone congesta (Nutt.) Ikonn. var. **simulans** (Maguire) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria congesta* Nutt. var. *simulans* Maguire, Bull. Torrey Bot. Club 74:48. 1947.

Eremogone congesta (Nutt.) Ikonn. var. **subcongesta** (S. Watson) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria fendleri* A. Gray var. *subcongesta* S. Watson, Botany [Fortieth Parallel]. 5:40. 1871. *Arenaria congesta* Nutt. var. *subcongesta* (S. Watson) S. Watson, Bot. Calif. 1:69. 1885. *Arenaria subcongesta* (S.Watson) Rydb., Bull. Torrey Bot. Club 24:244. 1897. *Arenaria burkei* Howell, Fl. N.W. Amer. 1:85. 1897.

Eremogone congesta (Nutt.) Ikonn. var. **suffrutescens** (A. Gray) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Brewerina suffrutescens* A. Gray, Proc. Amer. Acad.

8:620. 1873. *Arenaria congesta* Nutt. var. *suffrutescens* (A. Gray) B.L. Rob., Proc. Amer. Acad. Arts 29:295. 1894. *Arenaria suffrutescens* (A. Gray) A. Heller, Muhlenbergia 6:96. 1910.

Eremogone congesta (Nutt.) Ikonn. var. **wheelerensis** (Maguire) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria congesta* Nutt. var. *wheelerensis* Maguire, Bull. Torrey Bot. Club 74:48. 1947.

Eremogone eastwoodiae (Rydb.) Ikonn. var. **adenophora** (Kearney & Peebles) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria eastwoodiae* Rydb. var. *adenophora* Kearney & Peebles, J. Wash. Acad. Sci. 29:475. 1939.

Eremogone franklinii (Dougl. ex Hook.) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria franklinii* Dougl. ex Hook., Fl. Bor. Amer. 1:101. 1831.

Eremogone franklinii (Dougl. ex Hook.) R.L. Hartman & Rabeler var. **thompsonii** (M. Peck) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria franklinii* Dougl. ex Hook. var. *thompsonii* M. Peck, Torreya 32:149. 1932 ('*Thompsoni*').

Eremogone kingii (S. Watson) Ikonn. var. **plateauensis** (Maguire) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria kingii* (S. Watson) M.E. Jones subsp. *plateauensis* Maguire, Bull. Torrey Bot. Club 74:54. 1947. *Arenaria kingii* var. *plateauensis* (Maguire) Reveal, Great Basin Naturalist 35:344. 1975.

Eremogone kingii (S. Watson) Ikonn. var. **rosea** (Maguire) R.L. Hartman & Rabeler, comb. et stat. nov. BASIONYM: *Arenaria kingii* (S. Watson) M.E. Jones subsp. *rosea* Maguire, Bull. Torrey Bot. Club 73:326. 1946.

Eremogone macradenia (S. Watson) Ikonn. var. **arcuifolia** (Maguire) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria macradenia* S. Watson var. *arcuifolia* Maguire, Bull. Torrey Bot. Club 74:51. 1947.

Eremogone macradenia (S. Watson) Ikonn. var. **ferrisiae** (Abrams) R.L. Hartman & Rabeler, comb. et stat. nov. BASIONYM: *Arenaria macradenia* S. Watson subsp. *ferrisiae* Abrams, Ill. Fl. Pacif. States 2:151. 1944.

Eremogone macradenia (S. Watson) Ikonn. var. **kuschei** (Eastw.) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria kuschei* Eastw., Proc. Calif. Acad. IV. 20:140. 1931. *Arenaria macradenia* S. Watson var. *kuschei* (Eastw.) Maguire, Bull. Torrey Bot. Club 74:51. 1947.

ACKNOWLEDGMENTS

We wish to thank Kanchi Gandhi (GH) for nomenclatural advice and Molly Nepokroeff (SDU) and Warren L. Wagner (US) for sharing with us results of their molecular work on the Caryophyllaceae.

(Orders: 609-883-1759, 609-883-7413 fax). $29.95, 504 pp., 227 line drawings, 457 color photos, 7" × 10".

This revised edition accounts for more than 2,000 species of wildflowers, trees, shrubs, weeds, and ferns in the San Francisco Bay Region. The introduction includes discussion on scientific names, common names, and geographic ranges of plants, measurements, how to use a key, conservation issues, using native plants, and general references. A full chapter is devoted to San Francisco Bay Region's plant communities and their environments. Keys for identification of the major groups of plants are followed by an alphabetical listing of families for ferns, fern allies, gymnosperms, dicots and monocots. There is a brief description of the family followed by a key to the various taxa in the family with line drawings for selected taxa following the keys. An impressive section of the book is the color plate part in which almost one quarter of the taxa are illustrated with a nice color photograph.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, Texas 761202-4060, U.S.A.*

ABSTRACT

New combinations and new genera for species in *Xylothamia* are provided, reflective of recent phylogenetic data indicating the polyphyletic nature of that genus and the need to revise its taxonomy. Four species of *Xylothamia* are subsumed under the genus *Gundlachia*, necessitating the following new combinations: ***G. diffusa, G. riskindii, G. triantha*** (the type for *Xylothamia*), and ***G. truncata***. Four new genera are recognized for lineages without available generic names. ***Neonesomia*** includes ***N. johnstonii*** and ***N. palmeri***. Each of the other three genera are monotypic, ***Chihuahuana, Medranoa***, and ***Xylovirgata***, and they accommodate ***C. purpusii, M. parrasana***, and ***X. pseudobaccharis***, respectively.

Key Words: Asteraceae, Astereae, *Xylothamia, Chihuahuana, Gundlachia, Medranoa, Neonesomia*, and *Xylovirgata*, Chihuahuan Desert, Sonoran Desert, Caribbean plants

RESUMEN

Las nuevas combinaciones y los nuevos géneros que se ofrecen para las especies en *Xylothamia* son el reflejo de los datos filogenéticos recientes que indican la naturaleza polifilética de ese género y de la necesidad de revisar su taxonomía. Cuatro especies de *Xylothamia* se incluyen en el género *Gundlachia* que hace necesarias las nuevas combinaciones siguientes: ***G. diffusa, G. riskindii, G. triantha***, (la tipo para *Xylothamia*), y ***G. truncata***. Se reconocen cuatro nuevos géneros para los linajes sin nombres genéricos disponibles. ***Neonesomia*** incluye ***N. johnstonii*** y ***N. palmeri***. Cada uno de los otros tres géneros es monotípico, ***Chihuahuana, Medranoa***, y ***Xylovirgata***, e incluyen a ***C. purpusii***, ***M. parrasana***, y ***X. pseudobaccharis***, respectivamente.

INTRODUCTION

Xylothamia, a genus of nine shrubby species from northern Mexico, Baja California, and southern Texas, was proposed by Nesom et al. (1990) to accommodate certain species of *Haplopappus* (sensu Hall 1928) and certain *Ericameria* (sensu Urbatsch 1978), plus similar and more recently described taxa. Studies designed to evaluate relationships among North American Astereae using parsimony analysis of external (ETS) and internal transcribed (ITS) DNA sequence data has shown *Xylothamia* to be polyphyletic (Urbatsch et al. 2003). Four of the nine species in *Xylothamia* and *Gundlachia* formed a robustly supported clade in this sequence-based study. The other five species were, in general, unresolved in a clade that also contained species in the genera *Amphiachyris, Bigelowia, Euthamia, Gutierrezia, Gymnosperma*, and *Thurovia* (Urbatsch et al.

2003). Figure 1 summarizes the phylogenetic relationships among taxa treated in the present study and those related. The tree is derived from figure 4 published in Urbatsch et al. (2003) where additional, explanatory information may be found. The purpose of this paper is to provide names for species of *Xylothamia* reflective of their phylogenetic placement in this sequence based study with consideration for their morphological and cytological variation as well.

Gundlachia, according to Lane (1996), who last considered its taxonomy, is restricted to the Caribbean region and consists of two species, *G. domingensis* and *G. corymbosa*. The former is known from the Bahamas, Cuba, and the Dominican Republic, while the latter consists of six varieties, and ranges from coastal Venezuela northward through the Greater and Lesser Antilles to the Bahamas and Cuba (Lane 1996). Although *Gundlachia* had not been included in their cpDNA-based study, Lane et al. (1996) and Nesom (1991, 1993) were in general agreement on its placement within the *Gutierrezia* lineage sensu Nesom (1993). *Gundlachia* is expanded herein to accommodate *X. diffusa*, *X. riskindii*, *X. triantha*, and *X. truncata*. *Gundlachia* now encompasses six species. Its geographic range is expanded from the Caribbean and nothern South America to include parts of mainland Mexico, the Baja California peninsula, and southwestern Texas. Formal nomenclatural combinations for these *Xylothamia* are made in keeping with the botanical code (Greuter et al. 2000). Generic synonymy for *Gundlachia* as treated herein is also updated because it encompases *X. triantha*, the type for *Xylothamia*.

With regard to the other five species of *Xylothamia*, *X. johnstonii*, and *X. palmeri* constitute a robustly supported clade (Urbatsch et al. 2003) that is herein proposed as the new genus *Neonesomia*. The three remaining species of *Xylothamia* are each treated as monotypic genera because they are not unambiguously supported as monophyletic or placed within existing genera based on DNA sequence data (Urbatsch et al. 2003), and they are each morphologically unique. *Chihuahuana*, *Medranoa*, and *Xylovirgata* are the generic names proposed for each of the three taxa.

Gundlachia as reconstituted in this study and its sister clade containing the five former species of *Xylothamia* plus *Amphiachyris*, *Bigelowia*, *Euthamia*, *Gutierrezia*, *Gymnosperma*, and *Thurovia* are supported as a monophyletic lineage based on ITS/ETS sequences (Urbatsch et al. 2003) and approximates what Nesom (1991) called the *Gutierrezia* group. Nesom (1991) credited the cpDNA enzyme restriction studies of Suh (1989) and Suh and Simpson (1990) for initially helping to define this group as monophyletic. Although *Gundlachia* had not been part of the aforementioned DNA investigations, Nesom (1991) aligned it with this group because of its sharing several anatomical and morphological features discussed in part by Anderson and Creech (1975). *Chrysoma* and *Sericocarpus* were subsequently aligned with the former ten genera of the *Gutierrezia* lineage (Nesom 1993) which Nesom subdivided into two groups. *Amphiachyris*, *Gutierrezia*, *Gymnosperma*, and *Thurovia* were assigned to the redefined *Gutierrezia* group. Features shared by most taxa in this group are reduced pappus, short disc corolla lobes, annual life cycle in certain species, and base chromosome numbers of x = 4, 5 (Nesom 1993). The remaining six genera were designated the *Euthamia* group (Nesom 1993) that are typically perennial herbs or shrubs with pappus of capillary bristles and a base chromosome number of $x = 9$.

Chrysoma and *Sericocarpus* in the ETS + ITS sequence based phylogenies were placed more closely to *Solidago* and allies (Urbatsch et al. 2003) and not part of the *Gutierrezia* lineage sensu Nesom (1993). Results by Noyes and Rieseberg (1999) for *Sericocarpus* were similar while *Chrysoma* was not included in their study. Lane et al. (1996), based on cpDNA restriction site data, provided support for a clade containing six of the ten genera of the *Gutierrezia* lineage. *Chrysoma*, *Gundlachia*, and *Sericocarpus* were not investigated and *Xylothamia* constituted part of their *Ericameria* lineage (Lane et al. 1996). Branch support and decay index scores for *Xylothamia*'s inclusion in the *Ericameria* lineage ranged from one to zero (Lane et al. 1996).

Sequence support for the *Gutierrezia* group within the *Gutierrezia* lineage (sensu Nesom 1993) is equivocal based investigations of Urbatsch et al. (2003), depending on optimality criteria and databases analyzed. *Amphiachyris*, *Gutierrezia*, and *Gymnosperma* constitute a robustly supported lineage in the Bayesian ITS + ETS tree. However, *Thurovia* appears as an unstable member of the *Gutierrezia* group sensu Nesom (1993). Only when this data set is analyzed with PAUP* ratchet are *Thurovia* and *Amphiachyris* sisters (Urbatsch et al. 2003). Otherwise *Thurovia* was not affiliated with the *Gutierrezia* group. It was sister to *Bigelowia* in PAUP* ratchet of the combined ITS + ETS + indels and to *Neonesomia* in the Bayesian tree resulting from the combined ITS + ETS. Sequence data offered no support for the *Euthamia* group of the *Gutierrezia* lineage sensu Nesom (1993).

Characters that support and diagnose the *Gutierrezia* lineage as delineated in Urbatsch et al. (2003) i.e., without *Chrysoma* and *Sericocarpus*, include leaves showing xerophytic adaptations such as often being filiform or otherwise reduced in size, somewhat coriaceous in some taxa, usually punctate and resin coated, and often supporting a variety and abundance of trichomes; capitula generally small, borne in sessile clusters or on short peduncles; phyllaries basally indurate with a thickened apical patch; stamen insertion below the apex of disk corolla tube; cypselae small, cylindrical to turbinate, and often sericeous.

NOMENCLATURAL TREATMENT

1. Chihuahuana Urbatsch & R.P. Roberts, gen. nov. TYPE: *Ericameria purpusii* Brandegee, Univ. Calif. Publ. Bot. 4:191. 1911. = *Chihuahuana purpusii* (Brandegee) Urbatsch & R.P. Roberts, combination made herein].

Fruticulus ramosus, folia lineari-lanceolata ca. 2 mm longa acuminata in axillis filiorum 3–10 mm longorum linearium acuminatorum decurrentium demum cinereorum spinescentium fasciculatis; capitula ramos terminantibus 6–7 mm alta fere sessilia discoidea; corollae 8–10, luteola in lobos ovato-lanceolata inaequaliter sectis.

Densely branching shrubs to 30 cm tall; stems mostly concealed by the persistent closely spaced leaves with small axillary clusters; leaves sessile, acicular, narrowly triangular with a thickened midrib composed mainly of a large bundle of fibers, erect, 3–10 mm long, ca. 1 mm broad at base, hirtellous due to a dense covering of uniseriate conic trichomes, bases somewhat decurrent, apices sharply acute; capitula discoid, solitary, campanulate, 4–5 mm wide; phyllaries graduated, the inner 5–6 mm long; eradiate; disk flowers 8–10, corollas hairy 4.2–5.0 mm long; cypselae densely sericeous; $x = 9$.

Prominent features, distribution, and relationships.—*Chihuahuana*'s needle-like, non-resinous, hirtellous leaves with a large midvein consisting of a bundle of fibers is unique in the *Gutierrezia* clade where its relationships are not fully resolved (Urbatsch 1975; Urbatsch et al. 2003).

Etymology.—The generic name was selected because it is a member of the Chihuahuan Desert flora.

1a. Chihuahuana purpusii (Brandegee) Urbatsch & R.P. Roberts, comb. nov. BASIONYM: *Ericameria purpusii* Brandegee, Univ. Calif. Publ. Bot. 4:191. 1911. *Haplopappus* [*Aplopappus*] *purpusii* (Brandegee) S.F. Blake. Contr. U.S. Natl. Herb. 23:1491. 1926. *Xylothamia purpusii* (Brandegee) G.L. Nesom, Sida 14:112 1990. TYPE: MEXICO. COAHUILA: Cerro de Macho, Jun 1910, *Purpus 4479* (HOLOTYPE: UC!).

Distribution, ecology, and relationship.—Chihuahuan Desert region in southwestern Coahuila and adjacent locales in Chihuahua and Durango, rocky hills in gypseous or limestone soils (Nesom et al. 1990). Detailed descriptive information and distributional data for this species (as *X. purpusii*) are provided in Nesom et al. (1990).

Chihuahuana purpusii was originally described in *Ericameria* then transferred to *Haplopappus* by Blake (1926). Hall (1928) placed the species in *Haplopappus* section *Asiris* with five other species mostly of Great Basin distribution. This species was then reinstated in *Ericameria* (Urbatsch 1978) and subsequently placed in the newly created genus *Xylothamia* (Nesom et al. 1990). Foliar anatomy, morphology, and flavonoid profiles for *C. purpusii* are unique (Urbatsch 1978; Urbatsch et al. 2003). ETS/ITS sequence-based phylogenies indicate the affinities of *C. purpusii* are with the *Gutierrezia* clade rather than with species in section *Asiris* (Urbatsch et al. 2003).

2. Gundlachia A. Gray, Proc. Amer. Acad. Arts 16:100. 1880. TYPE: *Solidago domingensis* Spreng., Syst. Veg. 3:539. 1826].

Xylothamia G.L. Nesom, Y.B. Suh, D.R. Morgan & B.B. Simpson, Sida 14:106. 1990. TYPE: *Aplopappus trianthus* S.F. Blake, J. Wash. Acad. Sci. 28:485. 1938 *Gundlachia triantha* (S.F. Blake) Urbatsch & R.P. Roberts.

Evergreen shrubs to 2.0 m tall, stems unbranched to abundantly branching, angular to minutely ridged; leaves usually evenly spaced along the stems, spreading to occasionally appressed, sessile to short petiolate, narrowly to broadly linear to obovate, flat to involute-terete, punctate, resinous; capitula usually clustered at branch tip, clusters few and sometimes hidden by the subtending leaves or numerous and organized into racemes or paniculate to corymbiform capitulescences; involucres cylindric, turbinate, or narrowly obconic, phyllaries 2–5 seriate, linear-lanceolate to ovate with an apical resin pocket, basally chartaceous, indurate, margins translucent; ray flowers 0–13, corollas 1–6.5 mm long, white to yellow; disk flowers 3–50, corollas 4.0–5.5 mm long, white to yellow, lobes 1.0–2.5 mm long, slightly irregular, usually laxly recurved, style branches 1.0–2.2 mm long, linear lanceolate to ovate, ratio of appendage/stigmatic length variable with different species; cypselae turbinate to cylindrical, 1.0–2.5 mm long sparsely to densely pilose to sericeous; pappus of ca. 40, slender, flattened, barbellate bristles, 3.5–5.0 mm long; $x = 9$

Prominent features, distribution, and relationships.—*Gundlachia* as treated in this study consists of six species known from the Caribbean, northern South America, northern Mexico, Baja California, and southwestern Texas. Its monophyly was robustly supported by DNA sequence data as a lineage sister to one consisting of several other taxa primarily from western North America. All taxa in this genus are shrubs usually with resinous, punctate leaves that are linear lanceolate to spatulate in three species, *G. corymbosa, G. domingensis,* and *G. riskindii* and filiform in the other three. Capitulescences are often large, corymbose to paniculate in *G. corymbosa, G. domingensis,* and *G. diffusa*; they are more reduced and cymose in *X. triantha. Gundlachia riskindii* has solitary capitula whereas *G. truncata* has two or three capitula clustered at their twig apices. Phyllaries in *Gundlachia* are resinous to glutinous and basally indurate.

All species are xeropytes. *Gundlachia corymbosa* and *G. domingensis* inhabit mainly sandy or stony soils in or near coastal habitats of various Caribbean islands, while *G. diffusa* occupies similar habitats of the Gulf of California region of Sonora and Baja California. *Gundlachia riskindii* appears to be restricted to exposed limestone areas in pine-oak woodland at around 2100 m in Coahuila and adjacent Nuevo León, Mexico. The other two species occur in the Chihuahuan Desert region associated with elements more typical of that flora such as *Atriplex, Larrea, Prosopis, Suaeda,* etc. Specific descriptions, distributional data, and supporting documentation for the species of *Xylothamia* here considered as *Gundlachia* are provided in Nesom et al. (1990). Similar data for *Gundlachia truncata* as a species of *Xylothamia* can be found Nesom (1992). Lane (1996) provided detailed species descriptions, distributional data, other pertinent information, and keys to varieties of *G. corymbosa.*

There is no indication whether the *Gundlachia* clade first evolved in the Caribbean, in Mexico, or elsewhere since species relationships within it are not well-resolved (Urbatsch et al. 2003). The clade sister to *Gundlachia* consists of North American taxa. These two clades taken together also appear to be related to North American species, although few Central and South American species have been investigated (Urbatsch et al. 2003). Regardless of where the *Gundlachia* clade first appeared, dispersal rather than plate tectonics must have been a factor in its evolution since the approximate present position of the Caribbean islands relative to North and South America predates the estimated age of the Asteraceae (Graham et al. 2000; Bohm & Stuessy 2001).

KEY TO SPECIES OF *GUNDLACHIA*

1. Leaves linear-lanceolate to spatulate, laminar, more than 2 mm wide.
  2. Capitula typically solitary at branch tips; plants of Coahuila and Nuevo León, Mexico ____ **G. riskindii**
  2. Capitula generally in large, dense, corymbose or paniculate clusters several cm broad; plants of the Caribbean.
    3. Capitula in corymbose clusters; involucres cylindric; ray corollas <4 mm long; Bahamas, Greater and Lesser Antilles ____ **G. corymbosa**
    3. Capitula in paniculate clusters; involucres obconic or turbinate; ray corollas >4 mm long; plants of northern Bahamas, Cuba, and Hispaniola ____ **G. domingensis**
1. Leaves filiform, less than 2 mm wide, nearly as thick as broad
  4. Leaves densely clustered along the terminal 2–3 cm of the branches, surfaces glutinous, not evidently punctate; capitula eradiate, in clusters of 2–3, mostly concealed by foliage; disk flowers 3–5; Coahuila, Mexico, Cuatro Cienegas basin ____ **G. truncata**
  4. Leaves more widely spaced on stems, internodes generally much >2 mm long, surfaces resinous, somewhat punctate; capitula eradiate or rays 1–3, rays mostly concealed by the involucre; disk flowers 3–7.
    5. Stems glabrous; ray flowers 0–3; coastal habitats of the Gulf of California region, Baja California and Sonora, Mexico ____ **G. diffusa**
    5. Stems papillate, scabrous; rays absent; disk flowers 3(–7); widespread in the Chihuahuan Desert of southwestern Texas, Chihuahua, Coahuila, Durango, and Nuevo León, Mexico ____ **G. triantha**

New specific combinations in *Gundlachia*

2a. Gundlachia triantha (S.F. Blake) Urbatsch & R.P. Roberts, comb. nov. BASIONYM: *Aplopappus[Haplopappus] trianthus* S.F. Blake, J. Wash. Acad. Sci. 28:485. 1938. *Ericameria triantha* (S.F. Blake) Shinners, Field & Lab. 19:133. 1951. *Xylothamia triantha* (S.F. Blake) G.L. Nesom, Sida 14:113. 1990. TYPE: UNITED STATES. TEXAS. BREWSTER CO.: Chisos Mountains area, along road from Study Butte to Terlingua, 31 Aug 1937, *B.H. Warnock 1126*, (HOLOTYPE: US!; ISOTYPE: LL!).

Distribution, ecology, and relationships.—This species is widespread in the Chihuahuan Desert region ranging from Brewster County, Texas, to eastern Chihuahua, Coahuila, northeastern Durango, and west central Nuevo León, Mexico. It grows on gyp-seous, calcareous, igneous, or saline soil substrates on slopes or desert flats generally associated with *Atriplex*, *Prosopis*, *Larrea*, *Suaeda*, and various desert species at elevations 700–1500 m. Flowering normally occurs from July to October which undoubtedly depends on the timing and abundance of rainfall. Its resinous, adi-axially caniculate, filiform leaves, and often three-flowered capitula are diagnostic.

Based on sequence data *G. triantha* and *G. truncata* are strongly supported as sisters (Urbatsch et al. 2003) (see Fig. 1). Nesom (1992) indicated that the two are similar in having linear, involute leaves, eradiate, few-flowered capitula, and similar style appendages. *Gundlachia diffusa* receives moderate support as the sister to this clade in most analyses except for parsimony analysis of the ETS + ITS data sets where it is sister to *G. domingensis* (Urbatsch et al. 2003). When describing *G. triantha* Blake, (1938) discussed its morphological similarity to *G. diffusa*. Urbatsch (1978) noted the similarity in flavonoid profiles between these two taxa. At the time these studies were made *G. truncata* was unknown. Nesom et al. (1990) commented on the *Euthamia*-like inflorescences of *G. triantha* and *G. diffusa*. Sequence data show that *Euthamia* is but distantly related to these taxa, indicating possible convergence in this feature (Fig. 1).

2b. Gundlachia diffusa (Benth.) Urbatsch & R.P. Roberts, comb. nov. BASIONYM: *Ericameria diffusa* Benth., Bot. Voyage H.M.S. Sulphur 2:23. 1844. non *Aplopappus diffusus* DC. 1836. *Solidago diffusa* (Benth.) A. Gray, Proc. Amer. Acad. Arts 5:159. 1861. *Bigelovia diffusa* (Benth.) A. Gray, Proc. Amer. Acad. Arts 8:640. 1873. *Chrysoma diffusa* (Benth.) E. Greene, Erythea 3:10. 1895. *Xylothamia diffusa* (Benth.) G.L. Nesom, Sida 14:109. 1990. TYPE: MEXICO. BAJA CALIFORNIA SUR: Magdalena Bay, 1839, *R. Barclay & B. Hinds s.n.* (HOLOTYPE: BM?).

Linosyris sonoriensis A. Gray, Proc. Amer. Acad. Arts 8:291. 1870. Basionym: *Haplopappus* [*Aplopappus*] *sonoriensis* (A. Gray) S.F. Blake, Contr. U.S. Natl. Herb. 23:1490. 1926. *Aster sonoriensis* (A. Gray) Kuntze, Rev. 1:317. 1891. TYPE: MEXICO. SONORA: District of the Yaqui River, 1869, *E. Palmer s.n.* (HOLOTYPE: GH!).

Distribution, ecology, and relationships.—*Gundlachia diffusa* occurs in Baja California Sur and coastal regions of Sonora, Mexico, where it inhabits various soil types including coastal sand dunes, gravel plains, and salt flats from near sea level to around 100 m. Its habitat preferences appear to be similar to the two species of *Gundlachia* from the Caribbean. Based on leaf morphology the species resembles the two Chihuahuan Desert species in this genus. When well-developed, its inflorescences can be large and paniculate and appear similar to those in *G. corymbosa*. Its species relationships are somewhat equivocal but appear to be closest to *G. triantha* and *G. truncata* and are discussed under to the former.

2c. Gundlachia riskindii (B.L. Turner & Langford) Urbatsch & R.P. Roberts, comb. nov. BASIONYM: *Ericameria riskindii* B.L. Turner and Langford, Madroño 29:234. 1982. *Xylothamia riskindii* (B.L. Turner and Langford) G.L. Nesom, Sida 14:113. 1990. TYPE: MEXICO. COAHUILA: ca. 24 km E of Saltillo, S side of Sierra La Viga, ca. 6.5 km E of Jamé along wood cutter's road, 10,00 ft, 15 May 1977, *Henrickson et al 16156b* (HOLOTYPE: TEX!; ISOTYPE: MEXU, RSA).

Distribution, ecology, and relationships.—This apparently rare species is known from southeastern Coahuila and adjacent Nuevo León where it occurs on exposed limestone areas and in gypseous soils in pine-fir-oak woodlands at 2100–3000 m elevation. It is distinctive in having small spatulate leaves and radiate capitula with a large number of disk and ray florets. Originally, *G. riskindii* was described as *Ericameria* but then transferred to *Xylothamia*. Concerning its sister taxon relationships, results differ depending optimality criteria used in DNA sequence analysis. In the PAUP ratchet analysis of the combined ITS/ETS sequences support is provided for its basal position in the *Gundlachia* clade. In the parsimony derived trees that included indels, the Caribbean and Mexican species are resolved as sister lineages, where it is basal to the latter (Urbatsch et al. 2003). When indels were excluded, the species is basal in the *Gundlachia* clade (Fig. 1). Flagelliform trichomes having a subterminal appendage attachment characterize the Caribbean species and similar trichomes are seen in *G. riskindii*. This unusual trichome type, along with spatulate leaves and certain DNA evidence suggest that *G. riskindii* may represent the ancestral state for *Gundlachia* or may be a link connecting the Caribbean and the Mexican species.

2d. Gundlachia truncata (G.L. Nesom) Urbatsch & R.P. Roberts, comb. nov. Basionym: *Xylothamia truncata* G.L. Nesom, Phytologia 73:318. 1992. Type: MEXICO. Coahuila: Mpio. Cuatro Cienegas, ca. 2 km W of town of Cuatro Cienegas, along dirt road paralleling railroad, hard packed gypseous sand, 18 Oct 1985, *Nesom 5254* (holotype: TEX!).

This rare species is know only from the Cuatro Cienegas basin in Coahuila, Mexico, where it was collected on alluvial, gypseous sands. It is readily recognized by its involute linear leaves crowded near the branch apices that largely concealing its flowering capitula (Nesom 1992). The nearly identical ITS/ETS sequences of *G. truncata* and *G. triantha* robustly support their sister relationship despite their distinctive morphologies. Nesom (1992) had suggested the possibility of *G. truncata* being an abnormal growth form of the later, but field observations offered no evidence supporting this hypothesis.

Distribution, ecology, and relationships.—Both *Gundlachia corymbosa* and *G. domingensis* grow in the Caribbean region. The former occurs in eastern Cuba, the Bahamas, the Greater and Lesser Antilles, and northern Venezuela. It is distinguished from its counterpart by its corymbose capitulescences, cylindric involucres, ovate phyllaries, and ray corollas shorter than 4 mm. Six varieties are recognized within the species. Three of these, *G. corymobsa* varieties *apiculata*, *cubana*, and *foliosa*, have corymbs reduced to a few capitula concealed by the leaves, which is a feature seen in two species in Mexico, *G. riskindii* and *G. truncata*. The leaves of *G. corymbosa* var. *apiculata*, a taxon from the mountains of eastern Cuba, are similar in form to those of *G. riskindii* but larger. *Gundlachia domingensis* is known from the northern Bahamas, Cuba, and Hispaniola and is distinguished by its paniculate capitulescences, turbinate involucres, linear-lanceolate phyllaries, and ray corollas about 5.0 mm long. Both species appear to grow on well-drained sandy and stony substrates from near

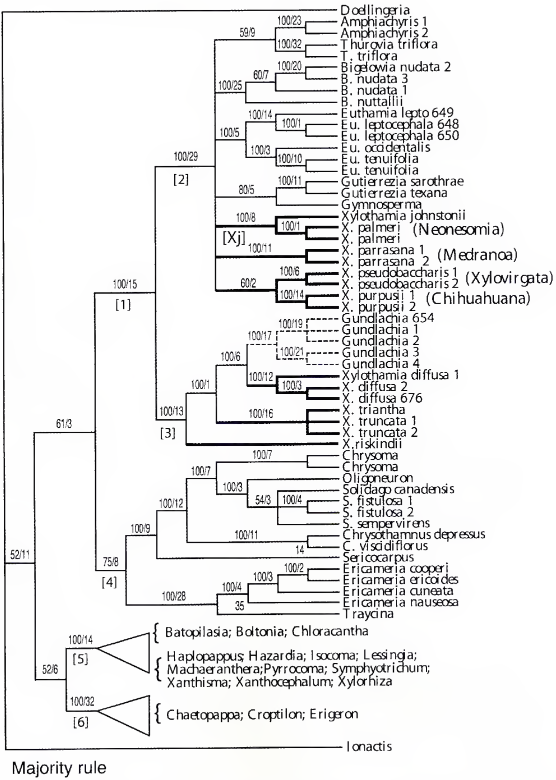

FIG. 1. 50% majority rule consensus tree derived from PAUP* ratchet analysis of the combined ETS + ITS data sets without indels and based on Fig. 4 published in Urbatsch et al. (2003). Fractional numbers designate branch support/branch length. Branches in bold highlight taxa traditionally treated as *Xylothamia*. Dash line branches highlight taxa traditionally treated as *Gundlachia*. Generic names proposed in the present study are indicated parenthetically. Taxa of the lower most clades not immediately relevant to the present study are merely listed for each major lineage.

sea level to 2500 m elevation. Greater details for these two species are provided in Lane (1996).

3. Neonesomia Urbatsch & R.P. Roberts, gen. nov. Type: *Aster palmeri* A. Gray, Proc. Amer. Acad. Arts 17:209. 1882. ≡ *Neonesomia palmeri* (A. Gray) Urbatsch & R.P. Roberts.

Frutices ad 3 m alta; caules ramosissimi aliquantum aromatici, ramunculis foliosis valde porcatis; folia 1–4 cm longa 1–2(–5) mm lata linearia elliptica ad anguste oblanceolata, laminis complanatis cum costis elevatis abaxialibus; capitula radiata solitaria vel in cymis fasciculatis ad apices ramulorum, paniculis laxis; involucra plerumque turbinata 4–6 mm longa; phyllaria valde gradata linaria; flosculi radii 5–15, corollae ca. 2–5 mm longa alba ad flava; flosculi disci 8–20, corollae 3.5–5 mm longa alba ad flava, limba aliquantum asymmetrice 5-lobata; pappi setosi; cypselae ca. 1.5 mm longae dense strigosae ad sericeas.

Shrubs to 3 m tall; much-branched, somewhat aromatic, leafy twigs strongly ridged, internodes 2–10 mm long; leaves 1–4 cm long, 1–2(–5) mm broad, linear, elliptic to narrowly oblanceolate, blades flat with conspicuously raised midvein abaxially, pubescent with flagelliform trichomes, margins entire to minutely ciliate; capitula solitary or in cymose clusters at branch tips these arranged in loose panicles; involucres usually turbinate, 4–6 mm long; phyllaries strongly graduated, linear, blunt to somewhat acute, thick, firm, resinous, mostly stramineous but with an apical glandular patch occupying much of the tip region; rays flowers 5–15 corollas ca. 2–5 mm long, white, pale yellow, or yellow; disk flowers 8–20, corollas 3.5–5 mm long, with a tube 1–1.8 mm long and poorly differentiated from the asymmetrical 5-lobed limb, shorter lobes 0.9–1.5 mm long, longest up to 3.3 mm long; pappus of setose bristles; cypselae ca. 1.5 mm long, densely strigose to sericeous; $x = 9$.

Prominent features, distribution, and relationships.—*Neonesomia* contains two species, *N. palmeri* from Nuevo León, Tamaulipas, and southern Texas and *N. johnstonii* from San Luis Potosí, which grow on rocky hillsides, brushy shrublands, and coastal dunes (Johnston 1970; Nesom et al. 1990). Species in this genus are characterized by their shrubby habit, ridged twigs, flat leaf blades with prominent midveins, small radiate capitula, and white to yellow corollas with somewhat zygomorphic disc corollas. They resemble the herbaceous perennials in *Euthamia* in leaf and growth form, but differ in being non-rhizomatous shrubs with deeply lobed, somewhat zygomorphic disc corollas.

Etymology.—*Neonesomia* commemorates Guy Nesom, Botanical Research Institute of Texas, zealous student of the Astereae and other Asteraceae who has significantly contributed to understanding their systematics. Additional information for these taxa is found in Nesom's treatment of *Xylothamia* (Nesom et al. 1990).

The genus *Neonesomia* is strongly supported as a clade in the gene-based phylogenies of Urbatsch et al. (2003). Based on parsimony analyses of ITS +ETS + INDEL data it is basal to a clade consisting of several xerophytic, mainly western North American taxa, including *Amphiachyris, Bigelowia, Chihuahuana,* *Euthamia, Gutierrezia, Gymnosperma, Medranoa, Thurovia,* and *Xylovirgata* (Urbatsch et al. 2003). Weak support for its sister relationship to *Thurvoia* was seen in the ITS/ETS Bayesian tree derived in that study. Otherwise its sister relationship was unresolved (Fig. 1) and kinship among the above cited genera is uncertain (Urbatsch et al. 2003).

KEY TO SPECIES OF *NEONESOMIA*

1. Ray and disk flowers 12–15 and 15–20, respectively; corollas yellow; flowering May to June; San Luis Potosí, Mexico ______ **N. johnstonii**
1. Ray and disk flowers 5–11 and 9–14, respectively; corollas white to very pale yellow; mainly flowering August to October; southern Texas and Nuevo León and Tamaulipas ______ **N. palmeri**

New combinations in *Neosomia*

3a. Neonesomia palmeri (A. Gray) Urbatsch & R.P. Roberts, comb. nov. BASIONYM: *Aster palmeri* A. Gray, Proc. Amer. Acad. Arts 17:209. 1882. TYPE: UNITED STATES. TEXAS. MAVERICK CO.: Eagle Pass on the Rio Grande, Sep–Oct, 1879. *E. Palmer 516* (LECTOTYPE: GH!; ISOLECTOTYPES: PH, US; Johnston 1967). *Isocoma palmeri* (A. Gray) Shinners, Field & Lab. 18:2. 1950. *Ericameria austrotexana* M.C. Johnston, nom. nov., SouthW. Naturalist 12:106. 1967, non *E. palmeri* (A. Gray) H.M. Hall. *Xylothamia palmeri* (A. Gray) G.L. Nesom, Sida 14:110. 1990, non *X. palmeri* var. *pachylepis* (H.M. Hall) G.L. Nesom ex M.A. Lane & R.L. Hartman, Amer. J. Bot. 83:364. 1996

Distribution, ecology, and relationships.—This species is known from most counties in southern Texas, i.e., Atascosa, LaSalle, and San Patricio cos. southward into the states of Nuevo León and Tamaulipas, Mexico, mostly of open, brushy habitats on or near the Gulf Coast in sandy or saline soils from near sea level to 600 m. *Neonesomia palmeri* is distinguished from its sister species in having fewer flowers per capitula and paler yellow corollas. Its ITS/ETS sequences showed little differentiation from *N. johnstonii* in Urbatsch et al. (2003). *Neonesomia palmeri* was first described as a species of *Aster* and subsequently placed in various other genera including *Isocoma* (Shinners 1950), *Ericameria* (Johnston 1967), and *Xylothamia* (Nesom et al. 1990). Nesom et al. (1990) proposed a close relationship of *N. palmeri* to *Medranoa* (*Xylothamia*) *parrasana* and *Xylovirgata* (*Xylothamia*) *pseudobaccharis,* a hypothesis not robustly supported by analyses of DNA sequences.

3b. Neonesomia johnstonii (G.L. Nesom) Urbatsch & R.P. Roberts, comb. nov. BASIONYM: *Xylothamia johnstonii* G.L. Nesom, Sida 14:110. 1990. TYPE: MEXICO. SAN LUIS POTOSÍ: Bagre, Minas de San Rafael, May 1911, *C.A. Purpus 5021* (HOLOTYPE: GH!; ISOTYPE: US).

Distribution, ecology, and relationships.—This taxon is known from central San Luis Potosí, Mexico where it apparently grows on steep slopes at elevations of 120–1500 m. In addition to the diagnostic features presented under *N. palmeri,* flowering times also differ with *N. johnstonii* blooming in the spring and *N.*

palmeri in the fall. Habitat preferences for the two taxa differ: *N. johnstonii* grows on steep hillsides at higher elevations than *N. palmeri*, which inhabits the Gulf coastal plain often on sand dunes near the water. Based on sequence data *N. johnstonii* and *N. palmeri* form a robustly supported clade, but the two taxa differ little from one another in sequence data indicating their close affinity (Urbatsch et al. 2003).

4. **Medranoa** Urbatsch & Roberts, gen. nov. Type: *Ericameria parrasana* S.F. Blake, Contr. Gray Herb. 52:26. 1917. ≡ *Medranoa parrasana* (S.F. Blake) Urbatsch & R.P. Roberts.

Frutex ramosus caule tenui cortice griseo glabro donato, ramulis uventate viridibus dense papilloso-glandulosis viscosis non puberulis dense foliosis; folia linearia mucronulata ut ramuli punctata et viscose complanata supra suplana vel paullum concave sutus subconvexa; involucri 3-seriati paullulum gradati 3.5–4 mm alti praecipue supra glandulari-viscosa ceterum subglabra infra valde indurate coriacea albida apice appendice appressa subherbacea lanceolata munita.

Shrubs to 2 m tall, much branched; branches ascending, mostly terete or remotely ribbed, bark smooth, becoming slightly fissured, tan becoming dark gray; twigs numerous, to 8 cm long, internodes smooth to obscurely sulcate, 1–4 mm long, green resinous, scabridulous; leaves evergreen, sessile, crowded, 5–12 mm long ≤ 1.5 mm wide, narrowly elliptic-oblanceolate, flat to canaliculate, decurrent on stem, surfaces resinous, punctate; capitulescence somewhat corymbiform, capitula solitary or cymose at branch tips; involucres 2–3 seriate, campanulate, 3–5 mm high, 4–7 mm wide; phyllaries imbricate, moderately graduated, mostly chartaceous, 2.5–4 mm long; capitula radiate, with ca 30 flowers, ray flowers 5–11, pappus bristles ca. 80, setose, subequal, 2.5–4 mm long, silvery tan, corollas 5–8 mm long, ligules elliptic, 3–7 mm long, 1–2 mm wide; disk flowers ca 20, corollas pale yellow, 4–5 mm long, lobes spreading to recurved, unequal in length, shortest 0.8–1.2 mm long, longest 1.5–2.2 mm long, style branches 2–3 mm long, appendages narrowly linear, apices acute, 1.5–1.8 mm long, pappus same as on ray flowers; cypselae turbinate, ca. 2 mm long, pilose; $x = 9$.

Prominent features, distribution, and relationships.—*Medranoa* is unispecific with its only species occurring in the Sierra de Parras region of Coahuila and Zacatecas. Shrubby habit, deeply pitted, resin coated leaves, relatively large capitula, and thickened style branches are features diagnostic for this taxon. Sequence based data robustly support its placement in the *Amphiachyris/Gutierrezia* clade (Urbatsch et al. 2003). Weak support is provided in that study for a sister relationship with *Chihuahuana* (*X. purpusii*) or with a clade composed of *Chihuahuana* plus *Xylovirgata* (*Xylothamia pseudobaccharis*).

Etymology.—The generic name *Medranoa* is in honor of Francisco Gonzlez Medrano, MEXU. He has worked for many years on desert and dryland floras of Mexico—mostly Tamaulipas and Tehuacan, and has trained several young botanists. Additional information about this taxon can be found in the treatment of *Xylothamia* by Nesom et al. (1990).

4a. Medranoa parrasana (S.F. Blake) Urbatsch & R.P. Roberts, comb. nov. [BASIONYM: *Ericameria parrasana* S.F. Blake, Contr. Gray Herb.52:26. 1917]. *Haplopappus parrasanus* (S.F. Blake) S.F. Blake, Contr. U.S. Natl. Herb. 23:1490. 1926. *Xylothamia parrasana* (S.F. Blake) G.L. Nesom, Sida 14:111. 1990. TYPE: MEXICO. COAHUILA: Sierra de Parras, rocky slopes, Mar 1905, *Purpus 1005* (HOLOTYPE: GH!).

Distribution, ecology, and relationships.—The single species in this genus grows on rocky slopes in the Sierra de Parras region of southern Coahuila and northern Zacatecas. Originally it was described in *Ericameria* by Blake (1917) who later transferred it to *Haplopappus* (Blake, 1926). Subsequently, it was placed in *Xylothamia* (Nesom et al. 1990). In the DNA sequence-based trees, it is placed in the clade composed of *Amphiachyris, Bigelowia, Chihuahuana, Euthamia, Gutierrezia, Gymnosperma, Neonesomia,* and *Thurovia* (Urbatsch et al. 2003). *Medranoa* is basal to a clade of *X. pseudobaccharis* and *Chihuahuana purpusii* in parsimony analyses of the ETS/ITS/INDEL data set place. It is a weakly supported sister of *Chihuahua purpusii* in the Bayesian analysis (Urbatsch et al. 2003).

Medranoa parrasana is distinguishable from other taxa in the *Amphiachyris/Gutierrezia* clade by the combination of its shrubby habit, narrowly elliptic-oblanceolate, flat-canaliculate, resin-covered leaves with numerous, well-organized depressions, and its campanulate capitula bearing 5–11 ray and 15–22 disk flowers. The thickened style branches wherein the vascular trace bifurcates or expands in size distally in each branch is unique among taxa in this clade. Additional information about this taxon can be found in the treatment of *Xylothamia* by Nesom et al. (1990).

5. Xylovirgata Urbatsch & R.P. Roberts, gen. nov. TYPE: *Haplopapus pseudobaccharis* S.F. Blake, J. Wash. Acad. Sci. 40:47. 1950. ≡ *Xylovirgata pseudobaccharis* (S.F. Blake) Urbatsch & R.P. Roberts.

Frutex scoparium metralis glaberrimus modice resinosus, ramis et ramulis multis erectis pallide viridibus striato-angulatus; folia anguste linearia integerrima plano paullum incrassata omnino non vel solum supra obscurissime punctata usque ad 1.4 cm longa 1 mm lata.

Intricately branched, broomlike shrubs to 1 m tall; stems slender, bark becoming whitish with age; branches and twigs strongly ridged and angled; leaves present mainly on present years growth, widely spaced, somewhat erect, blades 2–15 mm long, ≤1 mm wide; capitula radiate solitary at branch apices arranged in loose racemes; involucres campanulate to turbinate, 3–4 mm wide, phyllaries graduated, the inner 3–5 mm long, thickened subapical glandular structure present; ray flowers 3–6, ligules apically 2–3 denticulate, 2.3–3.0 mm long, ca. 1 mm wide; disk flowers 7–14, corollas 4.0–4.5 mm long unequally 5 lobed, shorter lobes ca. 1.3 mm long, longer lobes ca. 2.3 mm long; cypselae ca. 1.3 mm long, sericeous; pappus similar on disk and ray cypselae, ca. 30 subequal setose bristles; $x = 9$.

Prominent features, distribution, and relationships.—*Xylovirgata* is unispecific and known only from western Coahuila, Mexico. It is recognized by its broom-like appearance due to its woody, erect, intricately branched habit, as referenced by its generic name, and its conspicuously ridged stems, reduced, widely spaced, inconspicuous leaves. This entity is clearly related to taxa in the *Amphiachyris/Gutierrezia* clade, where there is weak support for its sister relationship to *Chihuahuana* in trees resulting from parsimony analysis of ETS/ ITS sequence data (Urbatsch et al. 2003). When indel data were added to the data set support for this relationship is supported more robustly. Bayesian and bootstrap analyses resulted in its placement as one of several unresolved basal elements in the *Amphiachyris/Gutierrezia* clade (Urbatsch et al. 2003). Additional descriptive data for this taxon can be found in Nesom et al. (1990).

5a. Xylovirgata pseudobaccharis (S.F. Blake) Urbatsch & R.P. Roberts, comb. nov. BASIONYM: *Haplopapus pseudobaccharis* S.F. Blake. J. Wash. Acad. Sci. 40:47. 1950. *Ericameria pseudobaccharis* (S.F. Blake) Urbatsch, Sida 7:299. 1978. *Xylothamia pseudobaccharis* (S.F. Blake) G.L. Nesom, Sida 14:112. 1990. TYPE: MEXICO. COAHUILA: arid limestone hills of Sierra Paila, Valle Seco, General Cepeda, 1700 m, 4 Jul 1944, *J.C. Hinton (G.B. Hinton et al.) 16546* (HOLOTYPE: US!; ISOTYPES: GH!, NY!).

Distribution, ecology, and relationships.—*Xylovirgata pseudobaccharis* is known only from western Coahuila, Mexico, where it grows on limestone or gypsum slopes. Its suggested relationships to *Neonesomia* (*Xylothamia palmeri, X. johnstonii*), *Medranoa* (*X. parrasana*), and *Gundlachia riskindii* (*X. riskindii*) (Nesom et al. 1990) are not supported by sequence-derived phylogenies (Urbatsch et al. 2003). Sequence data provides some support for its sister relationship with *Chihuahuana purpusii*. Additional descriptive and distributional data for this taxon as *Xylothamia pseudobaccharis* are presented in Nesom et al. (1990).

ACKNOWLEDGMENTS

We thank Kurt Neubig for providing the Latin diagnoses, Tom Wendt (LL, TEX) for his assistance in providing materials for DNA extraction and other herbarium matters, and to herbarium curators at BRIT, GH, MICH, MO, NY, UC, and US for their assistance. We appreciate Guy Nesom reviewing the manuscript.

BOOK NOTICES

FLORAS AND CHECKLISTS

NATHAN SMITH, SCOTT A. MORI, ANDREW HENDERSON, DENNIS WM. STEVENSON and SCOTT HEALD (eds.) 2004. **Flowering Plants of the Neotropics.** (ISBN 0-691-11694-6, hbk.). Princeton University Press, 41 William Street, Princeton, NJ 08540, U.S.A. (Orders: 609-258-5714, 609-258-1335 fax). $75.00, 616 pp., 307 color photos, 258 line illus., 6 tables, 8 1/2" × 11".

The American tropics is one of the great hotspots of biological diversity, harboring 35% of the world's flowering plants. This magnificent new book from Princeton University Press provides standard treatments for more than 280 families of flowering plants that occur in this region, and is the culmination of the work of 150 botanists from around the world. The goal of the editors was to provide an authoritative reference to plant families that are known to occur in tropical America. They have accomplished their goal, as this book will be an essential reference guide for anyone interested in learning about the rich diversity of the neotropical flora. The text describes features of each family, the diversity of genera and species, classification, geography, ecology, natural history, and important uses. Students learning tropical flowering plant families and their characteristics will find the family features and descriptions especially useful. The excellent identification key to the families treated in the book and the *Aids to Identification* in Appendix V will be of special interest to anyone who wishes to learn to identify neotropical flowering plant families. The editors also provide other useful reference tools, such as a comprehensive botanical glossary, and comparisons of family concepts across the various classification systems, including Cronquist, Dahlgren, and Judd et al. More than 300 color photographs and 250 botanical line drawings provide expert visual aids for identifying and learning about the families.—*John Janovec, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

R.J. PETHERAM and B. KOK. Photography by E. Bartlett-Torr. 2003. **Plants of the Kimberley Region of Western Australia. Revised Edition.** (ISBN 1-920694-04-8, pbk.) University of Western Australia Press. (Orders: International Specialized Book Services, 920 NE 58th Avenue, Ste. 300, Portland, OR 97213-3786, U.S.A., 503-287-3093, 503-280-8832 fax, www.isbs.com, email: info@isbs.com). $40.50, 553 pp., color photos, 6" × 8 1/2".

Publisher Comments: "For many years *Plants of the Kimberley Region of Western Australia* has been an important resource for pastoral managers and rangeland advisors in managing vegetation and land-use issues. This revised edition includes changes to 50 plant names, and also updates the introductory sections about the Kimberley region and the principles of rangeland management. The 240 species covered in the book are organised in three sections: grasses and herbs (110), shrubs (40) and trees (90), and constitute a unique flora not dealt with in any other single volume."

"With its straightforward text and excellent photographs, this book will also be a valuable reference for students of ecology and range science, as well as appealing to nature-lovers, conservationists and travellers in the Kimberley region."

ABSTRACT

An unusual form of *Calycadenia* from north central California was studied in greenhouse culture and confirmed to be self-compatible, a condition rare in *Calycadenia*. Based on the distinctive morphology and breeding system of this taxon, it is described and illustrated as a new species, *Calycadenia micrantha*. Although clearly related to *C. truncata* and apparently included in *C. truncata* DC. subsp. *microcephala* H.M. Hall ex D.D. Keck, this name was rejected as a basionym for the new species because of ambiguities regarding the type, the original description, and specimens cited and/or annotated by Keck.

RESUMEN

Se estudió una forma inusual de *Calycadenia* del centro-norte de California en cultivo de invernadero y se confirmó que es autocompatible, una característica rara en *Calycadenia*. Se describe e ilustra como una nueva especie basada en la diferente morfología y sistema reproductor de este taxon, *Calycadenia micrantha*. Aunque claramente emparentada con *C. truncata* y aparentemente incluida en *C. truncata* DC. subsp. *microcephala* H.M. Hall ex D.D. Keck, este nombre fue rechazado como basiónimo para la nueva especie por algunas ambigüedades relacionadas con el tipo, la descripción original, y los especímenes citados y/o anotados por Keck.

INTRODUCTION

For some years we have been aware of a unique population of plants related to *Calycadenia truncata* and growing on Elk Mountain in Lake County, California. In 1990 we received a similar specimen from David W. Isle, Forest Botanist for the Mendocino National Forest in California. The plant had been collected near the Wilson Camp area of southern Colusa County. Morphologically, the plant was clearly related to *Calycadenia truncata*. However, like the Elk Mountain specimens, Isle's plant was shorter and more slender than most and had very tiny heads with only 1 or 2 obscure, tiny ray flowers and 1 or 2 disk flowers.

Subsequently, several additional populations of this taxon were located in adjacent Lake County. The heads and rays suggested the possibility of self-compatibility, a condition rare in *Calycadenia*. In conjunction with ongoing biosystematic research on *Calycadenia*, a number of populations of this taxon were studied in greenhouse culture. All individuals were self-compatible, a condition known to exist in only one other species of *Calycadenia*, *C. hooveri* G.D.

SIDA 21(1): 259 – 265. 2004

Carr. In addition, although dozens of reciprocal crosses of these populations with self-incompatible forms of *Calycadenia truncata* have been made, cypselae with embryos were generated only when the self-compatible form served as the female parent. Carr (1975) noted the same phenomenon in *C. hooveri* and suggested that it may be the result of unilateral interspecific incompatibility, as discussed in Lewis and Crowe (1958).

The investigation of these unique plants led to re-evaluation of a previously described taxon, *Calycadenia truncata* DC. subsp. *microcephala* H.M. Hall ex D.D. Keck. According to Keck (1946), "This subspecies is separated from *Calycadenia truncata* subsp. *scabrella* (Drew) Keck, to which it is most nearly related, by the reduced number of disk-florets (3 or 4 instead of the usual 8 to 15) and the smaller heads." Additionally, he recognized the existence of intergradation between these subspecies. It appears from Keck's description and discussion that his small-headed taxon clearly includes the tiny-rayed self-compatible taxon described here but also includes other small-headed *C. truncata* populations.

Keck (1946) listed a number of specimens, and subsequently annotated numerous additional specimens, representing *C. truncata* subsp. *microcephala*, including locations from southern Trinity County to Lake County and in the Santa Lucia mountains of Monterey County. Some of these specimens are representative of a small-headed, self-compatible taxon but others represent populations of self-incompatible *C. truncata* plants with somewhat larger heads and rays. Depauperate individuals are common in populations of annual plants, especially in harsh years. Specimens of *C. truncata* prepared from such depauperate plants, especially those poorly pressed or without flowering heads at anthesis, could easily be confused with the new, small-headed, self-compatible taxon proposed herein.

To better understand his concept of *C. truncata* subsp. *microcephala*, attempts were made to field-verify all collections referred to this taxon by Keck in his original publication (1946) and subsequent specimen annotations. This was difficult as most collections cited, including the type locality, have not been re-located. Additionally, the type locality cited (*H.M. Hall 9602*, Mill Creek Canyon about 8 miles eastward from Ukiah, Mendocino Co., CA.) has no habitat that would support *Calycadenia* within ca. 3–4 miles. Hall may have accidentally written down the wrong mileage or possibly transposed a 3 with an 8. Regardless, there is very little likelihood that the type specimen was collected near the suggested location. There are sites 2–4 miles east of Ukiah with habitat that may have supported *Calycadenia* in the past but these sites are now largely occupied by agriculture. In any case, there appears to be no way to relate the type specimen to an extant population in the field.

After careful consideration, and for a variety of reasons, we believe the circumscription of Keck's *C. truncata* subsp. *microcephala* is not the same as the new species proposed herein. The questionable nature of the type, the ambiguity in the description and cited specimens, and the likelihood that Keck had no knowledge of the derived breeding system of the new taxon described below, lead us to conclude that use of the epithet "*microcephala*" for this new species is untenable.

RESULTS AND DISCUSSION

Calycadenia micrantha R.L. Carr & G.D. Carr, sp. nov. (**Fig. 1**). TYPE: U.S.A. CALIFORNIA. TRINITY CO.: ca. 1 mi N of Mad River Rock on rd. to Mad River Rock from Low Gap, S of the Mad River Ranger Station, 40°23'10"N, 123°29'01"W, 1340 m, 22 Aug 2003, *R.L. Carr 3801* (HOLOTYPE: UC; ISOTYPES: OSC, US).

Herba annua. Caules graciles 1–5 dm ramorum saepe multis glabris curvatis ascendentibusve. Folia basalia 2–5 cm × 2–3 mm proximaliter rosulata distaliter deminuta linearia. Bracteae pedunculares 2–4 mm hispidulae plus minusve pectinato-fimbriatae glande una grandi capitata terminali. Capitula 1(–3) in quoque nodo; phyllariis 1–2, 4–5 mm; paleis 2–3, 5–6 mm hispidulis villosulis ad marginem superum interdum cum glande una parva capitata terminali; flosculis radialibus 1–3 lamina 2–2.5(–3.5) mm sinu 0.5(–1) mm; flosculis disci 1–3; cypselis radialibus aspero-rugosis glabris epapposis; cypselis disci plerumque abortivis glabris epapposis.

Annual herbs. **Stems** 1–5 dm, slender, generally less than 2(–3) mm diameter at the base, branches often many, generally beginning near mid-stem, arcuate to ascending; glabrous, often purplish, especially distally. **Leaves** in basal rosette 2–5 cm long, 2–3 mm wide, sessile by a widened base, becoming more remote and reduced distally, linear, hispidulous adaxially and along the margins, often with longer, hispid hairs adaxially; leaves of the inflorescence 5–20 mm long, linear with a widened base, hispidulous, sometimes with a few awn-like bristles along the margin. **Heads** 1(–3) per node, sessile or nearly so. **Peduncular bracts** 2–4 mm, these and associated reduced leaves terete to strongly flattened, glabrous to hispidulous, commonly also with 1–8 long, pectinate bristles on the margins; apex bearing 1 large tack-shaped gland. **Phyllaries** 1–3(–6); 4–5 mm, each partly enfolding a ray cypsela, the abaxial surface glabrous to more or less hispidulous, especially toward the tip, sometimes bearing a few scattered, stout bristles; distal margins with shaggy hairs; apex occasionally with a single small tack-shaped gland. **Receptacle paleae** 2–3; 4–6 mm, each associated with a disk cypsela, the abaxial surface glabrous to more or less hispidulous, especially toward the tip, sometimes bearing a few scattered, stout bristles, distal margins with shaggy hairs; apex occasionally with a single, small, tack-shaped gland. **Ray florets** 1–3(–6); fertile, corolla bright yellow, laminae 2–2.5(–3.5) mm long by 2–4 mm wide, 3(–4)-lobed, sinuses ca. 0.5 mm, the middle lobe(s) smallest, symmetric, oblong to narrowly triangular, the outer lobes asymmetric, basically oblong to obovate but excursion of outer margin from midline greater than that of the inner margin, the tube 1–1.5 mm. **Disk florets** 1–3, 3–4 mm, yellowish. **Ray cypselae** ca. 3 mm long, ca. 2 mm wide, more or less triangular, rough-wrinkled, glabrous, pappi none. **Disk cypselae** ca. 3 mm long, mostly abortive,

Distribution and ecology.—Dry, open, rocky ridges, hillsides and talus; 500–1,500 m; Colusa, Lake, Trinity and Monterey counties, California. This species grows only in areas of low plant density, in or closely associated with exposed rocky areas or areas of packed mineral materials. For this reason and because survivorship is low, populations are generally small with few individuals. The species is surviving in an extremely limited and very fragile habitat.

Etymology.—Name Gr., *micr*, small; *anth*, a flower. Referring to the reduced ray flowers compared to most other species of *Calycadenia*.

Compared to some other taxa of *Calycadenia*, *C. micrantha* is remarkably uniform morphologically. The variation that is seen between populations is

Table 1. Comparison of selected features of *Calycadenia micrantha* and *C. truncata*.

Character	Calycadenia micrantha	Calycadenia truncata
Stem height	1–5 dm	2–12 dm
Leaf length	2–5 cm	2–10 cm
Peduncular bract length	2–4 mm	1–12 mm
Phyllary length	4–5 mm	5–10 mm
Ray floret number	1–3(–6)	3–6
Ray corolla lamina length	2–2.5(–3.5) mm	(4–)5–12 mm
Disk floret number	1–3	3–25
Disk floret length	3–4 mm	4–6 mm
Breeding system	Self-compatible	Self-incompatible

about that seen within populations. The overall size, branching and coloration of the plants, the overall size and position of the heads, the number, size, and position of the peduncular bracts, involucral bracts, ray ligules, ray achenes, receptacular bracts, disk flowers, and disk cypselae is very constant. The major variation seen is in the vestiture of the basal/proximal cauline leaves and that of the leaves associated with heads and the peduncular, involucral, and receptacular bracts. The basal and proximal cauline leaves are nearly always hispidulous but the presence of longer, stiff, bristly hairs ranges from sparse to rather dense. The leaves and bracts of the inflorescence are nearly always more or less hispidulous but the presence of pectinate hairs and other bristles varies considerably, as does the presence of hairs on or near the tips of the involucral and receptacular bracts. Additionally, the presence of the smaller tack-shaped gland on the tips of the involucral or receptacular bracts is variable, although uncommon overall.

As discussed above, the populations treated here as *Calycadenia micrantha* have previously been considered conspecific with *C. truncata*. Salient features that help distinguish the two species as circumscribed here are presented in Table 1. Some of the most striking differences relate to the reduced capitulum associated with the self-compatible breeding system found in *C. micrantha* (Fig. 2).

In greenhouse cultivation of *C. micrantha*, we have noted that the middle lobe of ray flower laminae is commonly subdivided, yielding a 4-lobed lamina with two small symmetric central lobes and two larger, asymmetric outer lobes. Heads may contain a mixture of ray flowers with 'normal' and 'aberrant' laminae. It is not known to what extent this phenomenon occurs in natural populations. We have noted the same phenomenon at very low frequencies in other species or hybrids of *Calycadenia* in cultivation.

ACKNOWLEDGMENTS

We are grateful to Kenton L. Chambers, emeritus professor of botany, Oregon State University, for preparation of the Latin diagnosis. We also thank the curators at UC and SBBG for making specimens available to the first author. We thank Bruce G. Baldwin (UC) and an anonymous reviewer for reviewing the manuscript.

Ted J. Case, Martin L. Cody and Exequiel Ezcurra. (eds.). 2002. **A New Island Biogeography of the Sea of Cortés.** (ISBN 0-19-513346-3, hbk.). Oxford University Press. (Orders: Oxford University Press, 2001 Evans Road, Cary, NC 27513, U.S.A., 800-451-7556, 919-677-1303 fax, www.oup.com). $95.00, 652 pp., figures, maps, graphs, tables, 6 1/2" × 9 1/2".

Publisher Comments: "This updated and expanded *A New Island Biogeography of the Sea of Cortés*, first published nearly 20 years ago, integrates new and broader studies encompassing more taxa and more complete island coverage. The present synthesis provides a basis for further research and exploration in upcoming years of the biologically fascinating Sea of Cortés region."

"The new *Biogeography* includes a section on the conservation issues in the Sea of Cortés, past accomplishments, and conservation needs as yet outstanding."

Donald G. Crosby. 2004. **The Poisoned Weed, Plants Toxic to Skin** (ISBN 0-19-515548-3, hbk.). Oxford University Press. (Orders: Oxford University Press, 2001 Evans Road, Cary, NC 27513, U.S.A., 800-451-7556, 919-677-1303 fax, www.oup.com). $59.95, 214 pp., figures, graphs, 24 color figures, 6 1/2" × 9 1/2".

Publisher Comments: "Toxic plants affect the skin of almost everyone on earth. Many such "dermatotoxic" species were well known to the Ancients and later generated centuries of medical research, but The Poisoned Weed is the first comprehensive book specifically about this topic. Crosby covers a wide range of these plants."

Poison ivy and relatives (Anacardiaceae) are not the only culprits included in the book.

James F. Hancock. 2004. **Plant Evolution and the Origin of Crop Species. Second Edition.** (ISBN 0-85199-685-X, hbk.) CABI Publishing, Wallingford, Oxon OX10 8DE, UK and 8756 Massachusetts Avenue, 7th Floor, Cambridge, MA 02139, U.S.A. (Orders: www.cabi-publishing.org, Oxford University Press, 2001 Evans Road, Cary, NC 27513, U.S.A., 800-451-7556, 919-677-1303 fax, www.oup.com). $100.00, 313 pp., graphs, b/w photos, line drawings, 6 1/4" × 91/4".

Publisher Comments: "This book is probably the only current volume to combine discussion of plant evolution with that of crop origins. The first edition was published in 1992 by Prentice-Hall, and has now been fully revised to reflect recent advances. The key features include a description of the process of evolution in native and cultivated populations of plants, a review of when and where major crops where domesticated, and a discussion of the subsequent development of crops over time. There is also greater integration of the information on evolution and crop origins compared with the first edition."

TWO NEW VARIETIES OF *AGOSERIS* (ASTERACEAE: LACTUCEAE)

ABSTRACT

Agoseris grandiflora var. *leptophylla* occurs predominately west of the Cascade Mountains from southwestern British Columbia to western Oregon and is morphologically and geographically distinct from *A. grandiflora* var. *grandiflora*. The two varieties are parapatric and intermediate forms are found where they occur together. *Agoseris heterophylla* var. *quentinii* is known from Sonoran Desert regions of Arizona and New Mexico and is geographically isolated and morphologically distinct.

RESUMEN

Agoseris grandiflora var. *leptophylla* está predominantemente al oeste de las Montañas de las Cascadas desde el suroeste de la Columbia Británica hasta el oeste de Oregón y es morfológica y geográficamente distinta de *A. grandiflora* var. *grandiflora*. Las dos variedades son parapátricas y se encuentran formas intermedias allí donde conviven. *Agoseris heterophylla* var. *quentinii* es conocida de las regiones del desierto de Sonora en Arizona y Nuevo México, está aislada geográficamente y es diferente morfológicamente.

INTRODUCTION

Agoseris Raf. is a genus of perennial, lactucoid herbs that are found throughout western North America. One species is known from temperate regions of southern South America. Some *Agoseris* are considered taxonomically challenging. This is due, in part, to similar or overlapping morphologies between certain species and/or the formation of occasional hybrids between sympatric species. In addition, most members of the genus are very widespread and often contain local forms or regional phases that can appear quite distinct. Past attempts to formally recognize these forms or phases have largely failed as they either occur as sporadic populations or they form broad clines, thus their separation becomes arbitrary. Despite these challenges, in a recent review of *Agoseris* (Baird 1996) two variants were discovered that were geographically and morphologically distinct enough to merit nomenclatural recognition.

Agoseris grandiflora (Nutt.) Greene var. **leptophylla** G.I. Baird, var. nov. TYPE: U.S.A. WASHINGTON: PIERCE or LEWIS CO.: "dry open ground, upper valley of the Nisqually River," 19 Jul 1896, *Allen 225* (HOLOTYPE: GH; ISOTYPES: CAS!, DS!, K!, NY! [2 sheets], UC!, WS!).

Varietas haec ab var. grandiflora differt capitulis minoribus et flosculis paucioribus, plerumque 40–60+, phyllariis involucri saepe cum maculis purpureis, foliis et lobis perangustis, plerumque ca. 2–4 mm latis, magis saepe in habitationibus humidis vel sylvaticis vel umbriosis.

Perennial herbs, ± acaulescent; **leaves** linear-filiform to narrowly oblanceolate, 10–25(–36) cm × 1–4(–8) mm (excluding lobes), toothed (rarely) to laciniately lobed or pinnatifid, sub-glabrous to villous; lobes mostly in 3–5 opposite to sub-opposite pairs, linear to filiform, spreading to antrorse, often with a reduced secondary tooth or lobe on distal side of base of each primary lobe; **heads** borne singly, erect, scapiform; peduncles 15–40 cm tall at anthesis, 25–75(–96) cm tall at maturity, mostly 2–4 leaf lengths when mature, 3–4 mm in diameter, proximally glabrate, distally villous to tomentose, non-glandular; **involucres** campanulate, 2–4 cm tall at maturity; phyllaries ± ovate-attenuate, in 4–5 series, subequal at anthesis, unequal at maturity, usually entire, rarely dentate, herbaceous, often purple spotted and/or with a rosy-purple medial stripe, adaxially sub-glabrous to tomentose, abaxially glabrous or villous, margins ± ciliate; hairs whitish-opaque or translucent, non-glandular; outer phyllaries apically spreading to squarrose, not overtopping the inner series at anthesis; inner phyllaries erect, elongating, exceeding the outer at maturity; receptacles naked; **florets** 40–60+; corollas equal to or just exceeding phyllaries at anthesis, yellow, often with an abaxial purplish stripe on the outermost; tubes 4–5 mm; ligules 3–5 × 1 mm; anthers ca. 1 mm; **cypselae** pale brown to whitish, 15–24 mm long, 10-ribbed, beaked, glabrous or slightly scabrous, homogenous or outermost slightly different; bodies fusiform, 3–6 mm, abruptly contracted to their beaks; ribs ridged to sub-alate, straight; beaks 11–18 mm long, filiform, mostly 3–4 lengths of cypsela bodies; **pappi** of capillary bristles in 2–3 series, 7–15 mm long, white; $n = 9$ (Tomb et al. 1978, voucher: *Chambers 2238* (OSC-143201), reported as *Agoseris apargioides* subsp. *maritima*).

Common name.—Puget Sound agoseris.

Agoseris grandiflora var. *leptophylla* occurs primarily west of the Cascade Mountains from Vancouver Island and southwestern British Columbia, south throughout the Puget Sound trough and Willamette Valley to southwestern Oregon and northwestern California (see Fig. 1). It also occurs eastward through the Columbia River gorge and sporadically on the eastern slopes of the Cascade Mountains in Washington and Oregon. Some specimens from the moist, western slopes of the Rocky Mountains of British Columbia and northern Idaho (panhandle region) are assignable to var. *leptophylla*. Ecological notes on specimen labels suggest that var. *leptophylla* occurs most commonly in lowland prairies or open forest habitats within the region outlined.

As a whole, *A. grandiflora* manifests two or three geographic phases that grade together and cannot be satisfactorily or consistently separated. Conversely, var. *leptophylla* represents what is arguably the most distinct phase of the species, with the specimens of var. *leptophylla* from the Puget Sound region

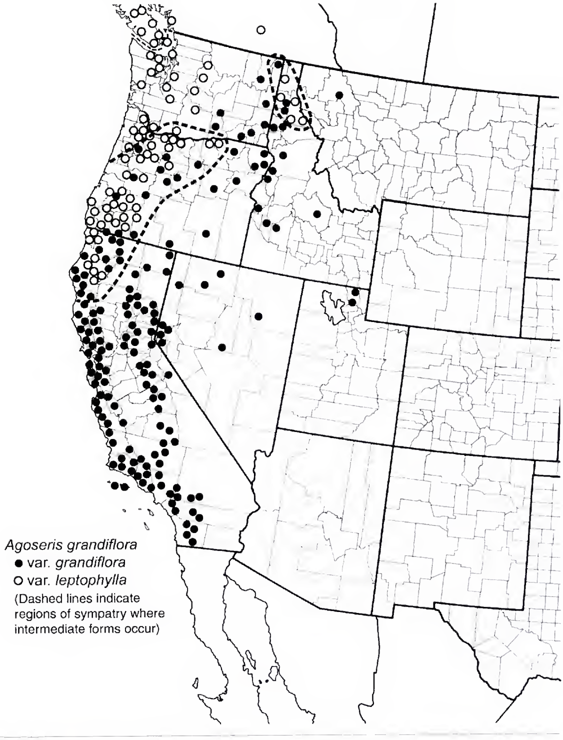

FIG. 1. Approximate distribution of *Agoseris grandiflora* in western North America. The two accepted varieties transition primarily within the regions indicated by the dashed lines (intermediate specimens not mapped).

morphologically the most distinct from var. *grandiflora*. Within this region var. *leptophylla* appears to completely supplant var. *grandiflora*. Jones (1954) felt this was only the "expressions of different environmental regimens" and that the morphological overlap and geographical transition between this variant and the remainder of the species was too great to justify recognition of intraspecific taxa. The separation and transition between the two varieties of *A. grandiflora*, however, are no different than that found between other well-accepted varietal pairs within *Agoseris* (e.g., *A. aurantiaca* var. *aurantiaca* and var. *purpurea*, or *A. glauca* var. *glauca* and var. *dasycephala*). In the Columbia River gorge and southern Willamette Valley, extending into northern California, and in the panhandle region of northern Idaho, the two varieties do intermingle and intergrade such that the distinction between them falters and not all specimens are clearly assignable to one or the other variety. In general, var. *leptophylla* differs from var. *grandiflora* by its more diminutive size, slender, laciniately lobed leaves, slender peduncles, smaller heads with fewer florets, and outer phyllaries subequal to (rather than longer than) inner phyllaries at anthesis. The following couplet will assist in separating the two varieties:

1. Leaves ± entire, toothed, or pinnatifid, mostly 10–35 mm wide (excluding lobes), rarely less, lobes lanceolate to oblanceolate; involucres 3.0–5.5 cm tall at maturity, florets mostly 150–500+, rarely fewer; outer phyllaries often with a purplish medial stripe, usually not spotted ____ var. **grandiflora**
1. Leaves mostly laciniately pinnatifid, mostly 2–4 mm wide (excluding lobes), rarely wider, lobes filiform to narrowly lanceolate; involucres 2.0–4.0 cm tall at maturity, florets mostly 40–60, rarely more; outer phyllaries occasionally with a purplish medial stripe but often purple spotted ____ var. **leptophylla**

Specimens assigned here to var. *leptophylla* have often been identified as *Agoseris laciniata* (Nuttall) Greene or *A. grandiflora* var. *laciniata* (Nuttall) Jepson, names based on *Stylopappus laciniatus* Nuttall. In 1834–1835, Thomas Nuttall collected the types of four *Agoseris* taxa from the Willamette Valley of western Oregon, all of which he placed in *Stylopappus*. Three (*Stylopappus elatus*, *S. laciniatus*, and *S. laciniatus* var. *longifolius*) were collected at the mouth of the Willamette River and belong to the enigmatic *Agoseris* ×*elata* (Nuttall) Greene (Jones 1954; Baird 1996). The fourth (*Stylopappus grandiflorus*) was collected on the "high plains" or "hills" of the Willamette (the exact location is not known but possibly in present-day Marion or Polk Counties; see Ewan, 1971) and is the type of *Agoseris grandiflora*; the specimen is teratological but is clearly assignable to *A. grandiflora*. The type description of *S. laciniatus* seems to describe *A. grandiflora* var. *leptophylla* and applying the name "*laciniatus*" to this variant of *A. grandiflora* seems an appropriate course of action. However, the lectotype (Nuttall's original gathering at BM) of *S. laciniatus* appears to be part of the *A.* ×*elata* hybrid complex and is therefore excluded from *A. grandiflora* (Jones 1954; Baird 1996). The lectotype of *S. laciniatus* var. *longifolius* (also teratological) is more clearly of hybrid origin, with *A. grandiflora* var. *leptophylla* as one of the putative parents.

Agoseris heterophylla (Nutt.) Greene var. **quentinii** G.I. Baird, var. nov. TYPE: U.S.A. ARIZONA: Pima Co.: "On gravelly slopes in scrub oak – mesquite openings; altitude 4000 ft., Sawmill Canyon, near upper well, Santa Rita Mountains," 26 Mar 1945, *Gould and Haskell 3045* (HOLOTYPE: LL; ISOTYPES: ARIZ!, CAS!, DS!, GH!, NY!, UC!).

Varietas haec aliis differt forma valde acauli, foliis saepe decumbentibus lobatis et abaxialiter glabris sed adaxialiter pubescentibus, lobis rotundatis vel obtusatis raro foliis dentatis vel integris, scapis tomentosis prope apicem, involucris floriferis sessilibus vel his aliquanto longioribus sed foliis scapum superantibus, acheniis costatis vel porcatis, sine variatione varietatum ceterarum.

Annual (winter annual?) herbs, acaulescent; **leaves** oblanceolate to spathulate, 2–12 cm × 3–9(–12) mm, spreading to prostrate, adaxially pubescent, abaxially glabrous, mostly lobed, rarely toothed; lobes in 2–3 pairs, rounded to blunt, lacking secondary denticulations; **heads** borne singly, erect, ± sessile to scapiform; peduncles to 26 mm tall at maturity, mostly less than 0.5 leaf lengths at anthesis (rarely longer), 0.5– 3 leaf lengths at maturity, villous to tomentose, proximally ± glabrate, distally tomentose; **involucres** campanulate to hemispheric, 1–2 cm tall at maturity, sometimes proximally pubescent, hairs yellowish-translucent, glandular; phyllaries lanceolate, in 2–3 series, subequal at anthesis, unequal at maturity, entire, herbaceous, often with a purplish medial stripe, adaxially lanate, hairs whitish-opaque, abaxially ± glandular-villous, hairs purple-septate, translucent (intermixed with whitish-opaque hairs), marginally ± ciliate to lanate; outer phyllaries erect to squarrose, not elongating at maturity; inner phyllaries erect, ± elongating at maturity; receptacles naked; **corollas** ± equal to phyllaries at anthesis, yellow, outermost often with an abaxial purplish stripe; tubes 2–3 mm; ligules 2–3 × 0.8–1.5 mm; anthers 1 mm or less; **cypselae** pale brown to whitish, 9–10 mm, ca. 10-ribbed, beaked, ± glabrous, ± homogenous; bodies fusiform, 3–4 mm, gradually tapering to abruptly narrowing to their beaks; ribs ridged, straight, not diminishing proximally; beaks 5.0–6.5 mm long, 1.5–2.5 lengths of cypsela bodies; **pappi** of capillary bristles in 2–3 series, 4–9 mm, whitish.

Common name.—Arizona agoseris.

Agoseris heterophylla var. *quentinii* is known from Arizona and New Mexico (see Fig. 2). It most commonly occurs in desert grasslands, scrublands, and open woodlands between 1200 and 2000 m. It is found on various mountain ranges from the vicinity of the San Francisco Peaks southeastward to southeastern Arizona and southwestern New Mexico. It has not yet been reported from Mexico, although it has been found not far from the border in the Baboquivari and Huachuca mountains of Arizona and the Peloncillo Mountains of New Mexico.

The principle features that distinguish var. *quentinii* from the other two varieties of *A. heterophylla* are its strongly acaulescent form, leaves adaxially pubescent and abaxially glabrous, peduncles apically tomentose and typically much shorter than the leaves at anthesis, and homogenous cypselae that lack the morphological variation and heterogeneity typical of this species. The three varieties of *A. heterophylla* accepted here may be separated using the following key:

1. Corolla ligules 2–4 mm long, ± equaling phyllaries; anthers less than 1.5 mm long; leaves entire, toothed, or lobed, the lobes mostly 2–3 paired; found in California and/or elsewhere.
    2. Peduncles mostly 1.5–4.5 leaf lengths at anthesis, proximally glabrous or glabrate, distally glabrous or ± pubescent; leaves glabrous or uniformly pubescent; wide-

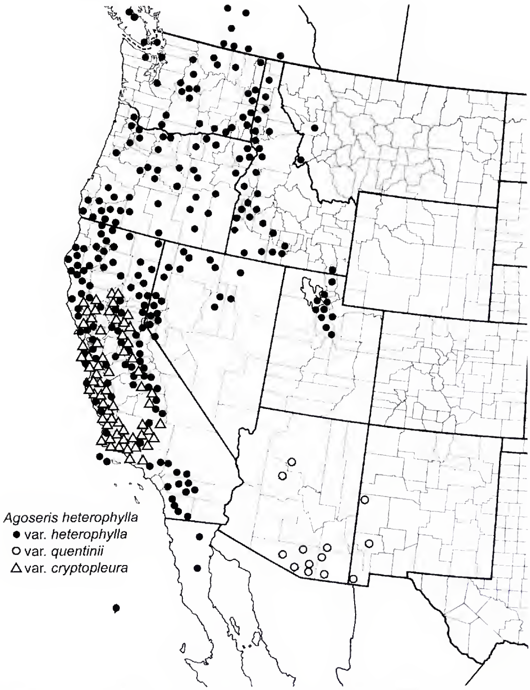

Fig. 2. Approximate distribution of *Agoseris heterophylla* in western North America.

spread in western North America but not known from Arizona or New Mexico ________ var. **heterophylla**

2. Peduncles 0–1 leaf length at anthesis, proximally glabrous or glabrate, distally tomentose; leaves adaxially pubescent, abaxially glabrous; desert regions of southern Arizona and New Mexico ________ var. **quentinii**

1. Corolla ligules 10–15 mm long, much exceeding phyllaries; anthers 2–4 mm long; leaves toothed to lobed, the lobes mostly 3–5 paired; coast ranges and foothills of central California ________ var. **cryptopleura**

Agoseris heterophylla var. *quentinii* is named in honor of Quentin Jones, Ph.D., who monographed *Agoseris* for his doctoral thesis (Jones 1954). His work was instrumental in stabilizing and establishing much of the current nomenclature within the genus. He was the first to recognize that specimens of *A. heterophylla* from Arizona and New Mexico are distinct from the remainder of the species. His manuscript name was never published.

ABSTRACT

George Engelmann, in his description of *Passiflora affinis*, never designated a holotype for the species, nor has a lectotype been designated in subsequent literature addressing Engelmann's work or North American *Passiflora*. A lectoype is designated here and a discussion and clarification of the geographic range of this species in the United States is provided.

Key Words: *Passiflora affinis*, lectotypification, geographic distribution, Ferdinand Lindheimer, George Engelmann, Charles Wright, Charles Parry, Benno Matthes

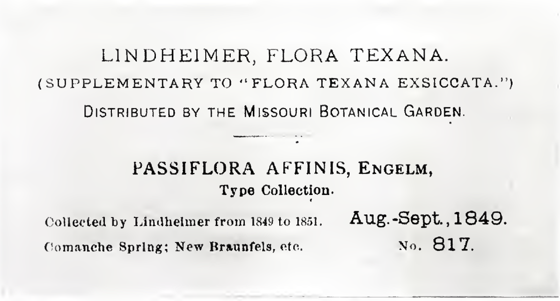
RESUMEN

George Engelmann, en su descripción de *Passiflora affinis*, nunca designó un holotipo para la especie, ni tampoco se ha designado un lectotipo en la literatura subsiguiente que trata el trabajo de Engelmann o las *Passiflora* norteamericanas. En este trabajo se designa un lectotipo, y además se hace una discusión y clarificación de la distribución geográfica de la especie en los Estados Unidos

INTRODUCTION

Passiflora affinis Engelm. is a warm-temperate and subtropical species of oak-juniper savannas and mesic woodlands from central Texas and northeastern Mexico (Schulz 1922; Killip 1938; Correll & Johnston 1970; Diggs et al. 1999). The type collection was made by Ferdinand Lindheimer in August to September 1849 at Comanche Spring, Bexar County, Texas. The type series was distributed in 1907 by the Missouri Botanical Garden as a part of a long-forgotten portion of the Flora Texana Exsiccata (Blankinship 1907), although it was originally described several decades earlier (Engelmann 1850a).

The labels distributed with the type series in 1907 (Fig. 1) are potentially misleading, presenting the type locality as "Comanche Spring; New Braunfels, etc.," Comanche Spring and New Braunfels occurring perhaps 30 miles apart. However, Engelmann (1850b), Blankinship (1907), Killip (1938) and Lindheimer correspondence with George Engelmann, found in the archives of the Missouri Botanical Garden, make clear that it was collected at Comanche Spring alone. Lindheimer spent the majority of the growing season of 1849 at that site, returning to New Braunfels only at the end of that year (Engelmann 1850b;



LINDHEIMER, FLORA TEXANA.
(SUPPLEMENTARY TO "FLORA TEXANA EXSICCATA.")
DISTRIBUTED BY THE MISSOURI BOTANICAL GARDEN.

PASSIFLORA AFFINIS, ENGELM,
Type Collection.

Collected by Lindheimer from 1849 to 1851. Aug.-Sept., 1849.
Comanche Spring; New Braunfels, etc. No. 817.

Fig. 1. The collection label found on specimens of the type series of *Passiflora affinis* distributed in 1907 (see Blankinship 1907), this label from a duplicate at GH.

Blankinship 1907). Comanche Spring was on the property of a friend of Lindheimer's, Baron Ottfried Hans von ("John O.") Meusebach, an early settler and founder of several communities in central Texas (King 1967). The spring was probably very close to Meusebach's house near the headwaters of Salado Creek, in what is now the Camp Bullis Military Reservation (Ivey 1979).

Although Englemann (1850a) did clearly state the type locality in the protologue, he did not designate a holotype, and neither Blankinship (1907) nor Killip (1938) later designated a lectotype from the *P. affinis* type series.

Passiflora affinis Engelm., Bost. J. Nat. Hist. 6:233. 1850. (**Fig. 2**). Type: TEXAS: [Bexar Co.:] Comanche Spring, Aug–Sep 1849, *F. Lindheimer 174* (lectotype, here selected: GH!; isolectotypes: ARIZ!, BM!, BR!, BRIT-SMU!, C!, CAN!, G! (2), GH!, K!, MEXU, MO!, NY!, P!, PH!, TEX!, UC!, US!, W!).

Liana, often suckering from roots, stems terete, glabrous, minutely puberulent to scabrous when young; tendrils glabrous; stipules linear-setaceous, erect, glabrous, 0.1–0.2 cm; petioles glabrous, glandless, 0.4–4.5 cm; leaves glabrous, entire, shallowly to deeply 3(–5)-lobed, broadly ovate in general outline, basally cordate, truncate, to cuneate, 1–8(–10) cm long by 1.5–10(–14) cm wide, lobes ovate to obovate, rounded to truncate, entire to apiculate, often basally narrowed, laminar nectaries round, often in two obscure lines, each running from base of leaf near petiole apex toward the larger sinuses; inflorescence of two or rarely one flower per node, flowers fragrant, erect, stipe + pedicel 1.0–3.5 cm, slightly elongating in fruit; floral bracts glabrous, 3, occasionally deciduous, green to purple, linear-subulate to rarely ovate, 0.1–0.3 cm; flowers 3–5 cm in diameter; sepals moderately reflexed, lanceolate to linear-lanceolate, rounded

Fig. 2. The lectotype of *Passiflora affinis* at GH.

to acute, pale green to white, 1.0–1.6 cm long, 0.2–0.4 cm wide; petals moderately reflexed, linear-lanceolate, subulate, acute, pale green to white, 0.6–1.3 cm long, 0.1–0.2 cm wide; corona of 2 series of filaments, outer series linear-filiform, sinuous, weakly reflexed or not, tapering distally and terminating in a clavate apex, basally purple, apically green, white in between, 0.9–1.8 cm long, inner series filiform, erect, clavate, pale purple with green basally, 0.15–0.3 cm long; floral tube shallowly convex to nearly flat, operculum erect, incurved, plicate, pale purple to white, 0.1–0.2 cm long, nectar ring absent, limen erect, incurved, white, 0.1 cm wide; androgynophore 0.7–1.0 cm long, terete, pale purple; stamen filaments green with purple, 0.4–0.6 cm long; anthers green with purple margins, 0.25–0.4 cm long; ovary globose to subovoid, glabrous, styles purple, filiform, glabrous, 0.5–0.7 cm long, stigmas broadly expanded, round, 0.1–0.2 cm wide; berry, purple-black, ovoid, globose, to dorsiventrally compressed, 1.0–1.5 cm long, 1.0 cm wide; seeds dark brown to black, flattened, obovoid, acute, transversely sulcate, 0.25–0.35 cm long, 0.2–0.3 cm wide, with white arillate swelling to one side; germination epigeal.

It would be anticipated that a specimen chosen as the lectotype of an Engelmann name at the rank of species or below would be at the Missouri Botanical Garden where many of his collections reside, St. Louis, Missouri, being Engelmann's home from the early 1830s until his death in 1884 (White 1896; Yatskievych 1999). However, the protologue describes both flowering and fruiting material and none of the examined duplicates of this collection have flowers and fruit except for the specimen chosen as the lectotype at GH (Fig. 2). Most duplicates seen are sterile or have few fruit, the only other flowering specimen being at BRIT-SMU. All of the duplicates distributed in 1907 have mass-produced labels numbered *817*, whereas one of the two GH specimens, the one with flowers, has a much older, mostly hand-written label, numbered *174*. Lindheimer had his own field numbers, whereas Englemann used separate numbers based on the distribution order of the Flora Texana Exsiccata following the Bentham and Hooker sequence (Blankinship 1907). Blankinship does note (p. 170) that *174* is the Lindheimer number, which corresponds to the Engelmann number *817*, therefore these numbers refer to the same collection. The handwriting on the label of the now-lectotype is almost entirely Engelmann's, identifying the plant as *Passiflora triloba*. Elsewhere on the label and in the lower right-hand corner of the specimen is written "affinis" in what is probably Asa Gray's handwriting. In addition, this is the only specimen of the type series that indicates habitat information as it is cited in the protologue, stating that the plant was growing in "shady places" and "climbing high over trees." None of the series distributed in 1907 gives habitat details. The only detail in the label of the lectotype that differs from the protologue and the 1907 labels is the date, the older label stating "Sept 1849" whereas the protologue and newer labels state "Aug.-Sept. 1849" (Fig. 1). However, this does not make the older label incongruent with the protologue, and because of the other information on it and the presence of flowers on this specimen alone it is the best choice for the lectotype.

GEOGRAPHIC DISTRIBUTION

In Texas *P. affinis* is typicallyfound growing over Cretaceous limestone or much less commonly over Precambrian igneous rock or late Tertiary sandstone and clay (Sellards et al. 1932; Spearing 1991). In northeastern Mexico (see specimens examined) it grows over Cretaceous limestone, shale and sandstone (Dirección General de Geografía del Territorio Nacional 1981a, b; Padilla y Sanchez & Aceves-Quesada 1992). The currently known distribution of *Passiflora affinis* in Texas is shown in Fig. 3, based on herbarium and literature surveys, indicating that it is nearly restricted to the southern Edwards Plateau and Lampasas Cut Plains (Diggs et al. 1999; Turner et al. 2003).

A population was once collected in Fayette County, Texas, by Benno Matthes (see specimens examined), representing the eastern range-limit of the species in the United States and in an area with different geology than where this species occurs elsewhere in Texas. Matthes, a German settler and naturalist in Fayette County, lived for a short period in the town of Round Top, where he collected several plant specimens from late 1853 until mid-1854 (Geiser 1941). In this area he apparently collected *P. affinis* (=*Matthes 274*), with specimens deposited at the Muséum National d'Histoire Naturelle, Paris and the Naturhistorisches Museum, Vienna (Killip 1938). This specimen still exists at P, but it was not found at W in a recent search, although W does have a fragmentary Matthes specimen of *P. lutea* labeled "bei No. 274," suggesting that the two species were probably growing together. Matthes initially outlined his botanical discoveries in this area, although without mentioning *Passiflora* (Matthes 1855a). He later provided a more detailed field account (Matthes 1861) where he mentioned finding at the upper margin of a riparian forest "*Passiflora triloba*" with "*Clematis coccinea*" and *Cornus florida*. This may have been to the southwest of Round Top near Cummins ("Cummings") Creek, along which he had been known to collect (Matthes 1855b, 1861). Although mesic forest edges are appropriate habitat for both *P. affinis* and *P. lutea*, such a habitat at the inner edge of the coastal plain may seem more appropriate for the latter species (e.g. Cooperrider 1995; Alford 2000) versus those of *P. affinis* on the Edwards Plateau and associated uplift. However, much of Fayette County, including the Round Top area, is underlain by sandstone and clay of the Catahoula and Oakville formations, both which can contain calcareous portions, particularly the latter (Sellards et al. 1932; Proctor et al. 1974). Furthermore, the springs in Fayette County are also known to be alkaline (Brune 1981). This suggests that much of Fayette County can provide habitats consistent with the primarily calciphilic preferences of *P. affinis*.

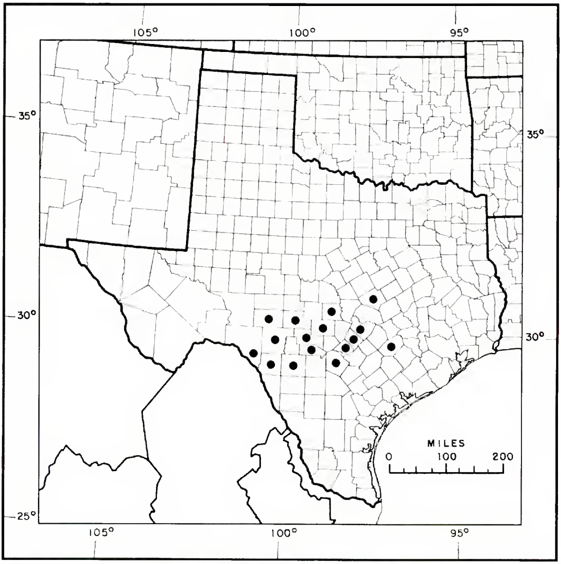


Fig. 3. Geographic distribution of *Passiflora affinis* in the United States based on herbarium surveys and floristic summaries (Diggs et al. 1999; Turner et al. 2003).

Killip (1938) reported the presence of *P. affinis* in New Mexico, citing a Parry specimen at US from Doña Ana county, labeled "chiefly in the valley of the Rio Grande, below Donana." This specimen was collected by the botanical survey party attached to the United States and Mexican Boundary Survey, consisting of John Bigelow, Charles Parry, Arthur Schott and Charles Wright (listed on the collection label as "C.C. Parry, J.M. Bigelow, C. Wright, & A. Schott"; see specimens examined). However, the only *P. affinis* collection cited in the botanical report of the Boundary Survey is by Bigelow in October (but with no year given) along the Devils River (Torrey 1859) in what is now Val Verde County, Texas, perhaps 350 miles from Doña Ana County, New Mexico. The Boundary Survey travelled within close proximity to the Rio Grande for several hundred miles south and west of Doña Ana County after the Treaty of Guadalupe Hidalgo was signed with Mexico in 1848, following the end of the Mexican-American War (Emory 1857). Therefore it should not have been assumed that this specimen was collected within the present boundaries of New Mexico.

In contrast, Killip (1938) did not similarly interpret the vague labels of *P. affinis* specimens collected by Charles Wright to suggest that this species occurred in New Mexico. Three collections could have been interpreted as such, one at GH (*Wright 217*) labeled "from Western Texas to El Paso, New Mexico, May to October 1849," another at GH and US with the same information but numbered *218*, and another with no number at NY and PH labeled "N. Mexico, 1851" (see specimens examined). It is surprising that they were not, with El Paso attributed to New Mexico in two of these three collections and "N. Mexico" also potentially interpreted in the same way, or as "northern Mexico."

Wright's number *217* is actually a distribution number given by Asa Gray for his Plantae Wrightianae part I (1852), whereas Wright's field number corresponding to *217* was *404*, collected on the 9th of June, 1849. His travel route (Geiser 1935) and his field notes, summarized in Shaw (1987) and available in the Gray Herbarium archives at Harvard University, indicate that *217/404* was collected "on the banks of the Leona" close to present-day town of Uvalde, Texas. Wright *218* was the distribution number for Wright's field number *734*, collected on the 25th of July 1849, among the "hills of the Devil's River" in present-day Val Verde County, Texas, although Gray (1852) consistently referred to the Devils River as the "San Pedro River", following the geographic names used by French (1850; Shaw 1987). Wright's "N. Mexico, 1851" may be the same as that referred to by Gray (1853), collected "on the Sabinal, western Texas, July," in what is now Uvalde County. However, Gray (1853) gives no distribution number for this specimen. In Wright's 1851 field notes in the GH archives *Passiflora* is entered only twice, once having been found on Chicon Creek (in modern Zavala County, Texas) in May 1851 and another time found in the "mountains near Santa Cruz, climbing among rocks," in Sonora, Mexico, July 1851, with no mention of the genus in his 1852 notes. The Chicon Creek *Passiflora* matches the entry in Gray (1853) for *P. tenuiloba* and the Santa Cruz specimen matches the entry (and protologue) for *P. inamoena* (=*P. bryonioides* Kunth). In July 1851 Wright was hundreds of miles away from the Sabinal River, in the vicinity of El Paso and southwestern New Mexico (Shaw 1987). It is possible that he collected this *P. affinis* specimen in this area, but without entering it into his field book, although that seems unlikely because he was a fastidious note-taker during his explorations of the border region. The only time he appeared to relax his note-taking was at the end of his travels in 1852, on his return to San Antonio, when on July 2nd he records his final collection in what is now western Crockett County, Texas (Shaw 1987), over 100 miles to the northwest of the Sabinal River in Uvalde County. It seems probable that Wright collected this specimen not in 1851 but in 1852, east of Crockett County on his return to San Antonio, which would have taken him through present-day Uvalde County. Shaw (1987) mentions that these post-July 2, 1852 notes tend to be folded-up in the fragment folders of the specimens themselves. Such notes tend to be only with GH specimens because of Wright's professional association with Gray. No duplicate of this specimen exists at GH so such information is probably lost. Furthermore, Gray often cut up notes and correspondence to make into fragment folders (W. Kittredge, pers. comm.). Thus if these notes still exist at GH they may form a packet on one of the over five million specimens in the herbarium.

These three Wright collections and the single Parry collection were obtained within what is currently west-central Texas, some of this area having been included in a southeastward extension of the Mexican province of New Mexico prior to the signing of the Treaty of Guadalupe Hidalgo (Commons 1990). Thereafter, all that is presently part of modern Texas was considered to be within the United States, Texas having claimed most of what is now modern New Mexico, northward through parts of Colorado and Kansas, into Wyoming, this land later purchased from Texas by the United States in the Compromise of 1850 (Stephens & Holmes 1988; Beck & Haase 1989). With these Parry and Wright collections made after Guadalupe Hidalgo in an area that has subsequently been considered to be part of Texas only, any interpretations in herbarium labels or in the literature of these collections having come from New Mexico or northern Mexico are in error.

Despite the potentially misleading labels on these specimens, *P. affinis* has never been reported from modern New Mexico in any floras of that state, which is fortuitous because a similar situation with vague herbarium labels may have led to the potential misreporting of *P. tenuiloba* for New Mexico (Martin & Hutchins 1981). Therefore, it can be assumed that the geographic range of *P. affinis* is restricted only to central Texas, with scattered populations in northeastern Mexico. The potential confusion created by old, vague labels, can lead to floristic uncertainty and this alone should be an inspiration to all botanists to be extremely thorough in making their collection labels.

Specimens examined: **MEXICO. Nuevo Leon. Mcpo. Lampazas de Naranjo:** Rancho Resendez, Lampazas, 22 Jun 1937, *M.T. Edwards 298* (GH). **Mcpo. Monterrey:** Monterrey, Sierra Madre Oriental, 23 Jul 1933, *C.H. Mueller & M.T. Mueller 100* (GH). **Mcpo. Santiago:** trail between Potrero Redondo & Las Ajuntas, 24 Aug 1939, *C.H. BOOK NOTICES

Timber Press

MARK F. LARGE and JOHN E. BRAGGINS. 2004. **Tree Ferns.** (ISBN 0-88192-630-2, hbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $39.95, 360 pp., 131 color photos, 3 tables, 12 line drawings and 15 maps, 7 3/8" × 10 3/8".

This book is about ferns that look like trees. Tree ferns are true ferns and reproduce as other ferns by production of spores. Some of the species are beautifully displayed in the many color photographs provided in the book. The dust jacket says, "This volume is *the* source of information on the living tree ferns. It surveys all the families, genera, and species, including those that are suitable for the home garden. It offers up-to-date taxonomy and detailed descriptions as well as in-depth coverage of everything from tree fern use to conservation. In recognition of the horticultural importance of tree ferns, the authors provide extensive cultivation information, including propagation and diseases and pests."—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, Texas 761202-4060, U.S.A.*

DAVID E. ALLEN and GABRIELLE HATFIELD. 2004. **Medicinal Plants in Folk Tradition, an Ethnobotany of Britain and Ireland.** (ISBN 0-88192-638-8, hbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $29.95, 432 pp., 31 color photos, 57 b/w illustrations and 1 map, 6" × 9".

Publisher Comments. This book provides the first comprehensive account of medicinal uses of wild plants by the country folk of Britain and Ireland. Two of Britain's foremost ethnobotanical scholars mined nearly 300 published and unpublished sources, including information gathered by the Irish Folklore Commission in more than 1000 manuscript volumes, to chronicle the fascinating uses of more than 400 plant species."

"Among the many kinds of plants recorded here are a seaweed used in Scotland against 'all maladies except the Black Death', a mushroom stewed in milk in Norfolk to soothe cancer of the throat, a fern identified in Ireland as a 'herb of the seven gilts' for its reputed ability to cure diseases, and the remarkable range of benefits attributed to nettles. Such information, in addition to being interesting in and of itself, offers a starting point for phytochemical and pharmacological investigations of plants whose utility may have been overlooked. An appendix of veterinary uses is provided Illustrations include 57 carefully chosen drawings and 31 colour photographs by Deni Bown."

THYMOPHYLLA SETIFOLIA VAR. *GREGGII* (COMPOSITAE)

John L. Strother

University Herbarium
1001 Valley Life Sciences Bldg.
University of California
Berkeley, California 94720-2465, U.S.A.
strother@uclink4.berkeley.edu

The types of the names *Thymophylla greggii* and *T. greggii* var. *radiata* have been treated as convarietal within *Dyssodia setifolia* (Lagasca) Robinson or *Thymophylla setifolia* Lagasca; (e.g., M.C. Johnston, Field & Lab. 24:67. 1956; J.L. Strother, Univ. Calif. Publ. Bot. 48:65–66. 1969; J.L. Strother, Sida 11:378. 1986).

I have used the name *Thymophylla setifolia* Lagasca var. *radiata* (A. Gray) Strother. That name is illegitimate under Article 11.6 of the International Code of Botanical Nomenclature (W. Greuter et al., 2000. Regnum Veg. 138:i–xviii, 1–474). For treatment of the variety in forthcoming *Flora of North America north of Mexico*, a new combination is required:

Thymophylla setifolia Lagasca var. **greggii** (A. Gray) Strother, comb. nov. BASIONYM: *Thymophylla greggii* A. Gray var. *greggii*, established by *Thymophylla greggii* A. Gray var. *radiata* A. Gray, Smithsonian Contr. Knowl. 3(5):119. 1852.

BOOK NOTICES

Timber Press

JENNIFER TREHANE. 2004. **Royal Horticultural Society Plant Collector Guide Blueberries, Cranberries and Other Vacciniums.** (ISBN 0-88192-615-9, hbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $29.95, 272 pp., 66 color photos, 7" × 9".

Publisher Comments: "This book clarifies the *Vaccinium* story for any reader, whether an enthusiastic gardener or someone who is simply curious about blueberries and cranberries and would like to widen the picture and maybe even learn a little about some of the lesser known vacciniums. It will inform and inspire those who have either never grown *Vaccinium* plants before or have put just a tentative toe in the water and would now like to go in a little deeper. The book contains a wealth of information to get a reader started on growing blueberries, cranberries and even lingonberries."

LEE REICH (Illustrations by Vicki Herzfeld Arlein). 2004. **Uncommon Fruits for Every Garden.** (ISBN 0-88192-602-7, hbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $24.95, 308 pp., 51 color photos, 29 line drawings, 1 map, 6" × 9".

Publisher Comments: "Lee Reich provides a valuable guide to fruits and berries that add an adventurous flavor to any garden. Though names like jujube, juneberry, maypop, and shipova may seem exotic at first glance, these fruits offer delectable rewards to the gardener willing to go only slightly off the beaten path at local nurseries. Reliable in the toughest garden situations, cold-hardy and pest-resistant, they are as enticing to the beginning as to the advanced gardener. This expanded sequel to the author's celebrated *Uncommon Fruits Worthy of Attention* offers new fruits, new varieties, and new photos and illustrations to entice the reader into an exciting world of garden pleasure."

TWO NEW COMBINATIONS
IN THE GENUS *PACKERA* (ASTERACEAE)

Debra K. Trock

Herbarium, Department of Plant Biology
Michigan State University
East Lansing, Michigan 48824-1312, U.S.A.

ABSTRACT

Two new varietal combinations in *Packera* (Asteraceae: Senecioneae) are made based on work completed for the *Flora of North America north of Mexico* project.

RESUMEN

Se hacen dos nuevas combinaciones varietales en *Packera* (Asteraceae: Senecioneae) en base al trabajo completado para el proyecto *Flora of North America north of Mexico.*

Packera is a relatively recent North American segregate of the much larger cosmopolitan genus *Senecio.* Áskell and Doris Löve first proposed the recognition of *Packera* as a distinct genus based on chromosome numbers and morphological trends (Löve & Löve 1975). They initially transferred eight species of arctic plants to this genus. Subsequently other authors have transferred most of the remaining taxa (Weber & Löve 1981; Jeffrey 1992; Trock & Barkley 1998; Bain 1999; Kartesz 1999).

Preparation of a treatment of *Packera* for the forthcoming *Flora of North America north of Mexico* has brought to light the need for two additional nomenclatural combinations.

Packera streptanthifolia (Greene) W.A. Weber & A.Löve var. **borealis** (Torr. & A. Gray) D.K. Trock, comb. nov. BASIONYM: *Senecio aureus* L. var. *borealis* Torr. & A. Gray, Fl. N. Amer. 2:442. 1843. *Senecio cymbalarioides* Nutt. var. *borealis* (Torr. & A. Gray) Greenm., Ann. Missouri Bot. Gard. 3:117. 1916. *Senecio streptanthifolius* Greene var. *borealis* (Torr. & A. Gray) J.F. Bain, Rhodora 90:293. 1988.

Packera subnuda (DC.) Trock & T.M. Barkley var. **moresbiensis** (J.A. Calder & R.L. Taylor) D.K. Trock, comb. nov. BASIONYM: *Senecio cymbalarioides* Nutt. subsp. *moresbiensis* J.A. Calder & Taylor, Canad. J. Bot. 43:1399. 1965. *Senecio moresbiensis* (J.A. Calder & R.L. Taylor) G.W. Douglas & G. Ruyle-Douglas, Canad. J. Bot. 56:1710. 1978. *Packera moresbiensis* (J.A. Calder & Taylor) J.F. Bain, Novon 9:457. 1999.

ACKNOWLEDGMENTS

I am grateful to Luc Brouillet and Guy Nesom for reviewing this manuscript, and to Alan Prather and Ted Barkley for providing helpful comments. I would also like to thank the curators of the following herbaria for their loan of specimens: ALA, CAN, COLO, DAO, MICH, MONT, MSC, NY, OSC, V, WTU.

ABSTRACT

The following new combination in *Persicaria* is made: *Persicaria meisneriana* (Cham. & Schltdl.) M. Gómez var. *beyrichiana* (Cham. & Schltdl.) C.C. Freeman.

RESUMEN

Se hace la siguiente combinación nueva en *Persicaria*: *Persicaria meisneriana* (Cham. & Schltdl.) M. Gómez var. *beyrichiana* (Cham. & Schltdl.) C.C. Freeman.

Persicaria Mill. sect. *Echinocaulon* (Meisn.) H. Gross is represented by five species in North America north of Mexico. Park (1988) monographed the section as part of *Polygonum* L. Following evidence from morphological (Haraldson 1978; Ronse Decraene & Akeroyd 1988; Ronse Decraene et al. 2000) and molecular studies (Lamb Frye & Kron 2003), sect. *Echinocaulon* will be included in *Persicaria* Mill. in the forthcoming treatment of Polygonaceae in the Flora of North America. Consequently, the following new combination is required.

Persicaria meisneriana (Cham. & Schltdl.) M. Gómez var. **beyrichiana** (Cham. & Schltdl.) C.C. Freeman, comb. nov. Basionym: *Polygonum beyrichianum* Cham. & Schltdl., Linnaea 3:42. 1828. *Polygonum meisnerianum* Cham. & Schltdl. var. *beyrichianum* (Cham. & Schltdl.) Meisn., Fl. Bras. 5:19. 1855. *Tracaulon beyrichianum* (Cham. & Schltdl.) Small, Fl. S.E. U.S., 380, 1330. 1903. Type: n.v., see Park (1986).

ACKNOWLEDGMENTS

I thank Kanchi Gandhi for his assistance verifying the nomenclature. Jim Zarucchi, Caleb Morse, Guy Nesom, and Mihai Costea provided valuable comments.

AN EVALUATION OF *ANTHENANTIA* (POACEAE)

Robert Kral

Botanical Research Institute of Texas and
Vanderbilt University (VDB)
509 Pecan Street
Fort Worth, Texas, 76102-4060, U.S.A.

ABSTRACT

Anthenantia, a small Panicoid grass genus of the southeastern U.S.A. is evaluated morphologically. The two previously known taxa, *A. rufa* (Elliott) Schultes, and *A. villosa* (Michx.) Beauv., together with a proposed new species, *A. texana*, are described, compared, and illustrated, and their relationships are discussed.

RESUMEN

Se evalúa morfológicamente *Anthenantia*, un pequeño género de gramínea panicoide del sureste de Estados Unidos. Los dos taxa conocidos previamente, *A. rufa* (Elliott) Schultes, y *A. villosa* (Michx.) Beauv., junto con la nueva especie propuesta, *A. texana*, se describen, comparan, e ilustran, y se discuten sus relaciones.

Anthenantia Beauvois is treated in most recent floras (Small 1903 1933; Hitchcock 1951; Radford et al. 1968; Correll & Johnston 1970; Gould 1975; Hatch et al. 2001; Barkworth et al. 2003), as a panicoid grass genus of two species, these confined to the Coastal Plain Physiographic Province and adjacent physiography within the southeastern United States from eastern North Carolina to Florida, westward (exclusive of the Mississippi Embayment) to Arkansas and eastern Texas. The genus was named by Palisot de Beauvois (Ess. Agrost. 48, 151, pl. 10, f.7, 1812) and based upon *Phalaris villosa* Michx. (Fl. Bor. Amer. 1:43. 1803). A second species, *Aulaxanthus rufus* Elliott (Bot. S.C. & Ga. 1:103. 1821), was incorporated by Schultes (Mantiss. 2:258. 1824), thus becoming *A. rufa* (Elliott) Schultes and forming a bitypic genus. So far as southeastern U.S.A. floristics are concerned, the only supplemental descriptive information appears to have come from G.V. Nash, who noted some extra-typical *A. rufa* in populations of that species from South Carolina westward, these mentioned in J.K. Small's Flora (1903, p. 79), as "A form, *A. rufa scabra* Nash."

Lately I have had some questions on the genus, the provocation being first from trying to fit the two previously known species into my "Guide to the Flora of Alabama and Middle Tennessee" (in prep.), second from trying to understand the patterns of morphological variation over the known range of the genus. Trips to and from Fort Worth, Texas across the Gulf South in recent years, together with fieldwork over much of the southeastern U.S.A. over the past four decades and study of collections in the herbaria BRIT/SMU, DUKE, MISSA, NO,

SIDA 21(1): 293 – 310. 2004

TAES, TENN, TEX/LL, and USF have allowed me to form concepts regarding these taxa. As a result, a third taxon has been discovered.

In this study the sequence will be 1) detailed discussion of *Anthenantia* as a genus, presented in standard descriptive sequence; 2) a descriptive key, including the new species; 3) technical descriptions of the three, each followed by some discussion of habitat and distribution; 4) illustrations, the first three being figures of the species, the fourth a plate with additional morphological detail.

Anthenantia Beauv., Ess. Agrost. 48, 151, pl. 10, f. 7. 1812. TYPE SPECIES: *A. villosa* (Michx.) Beauv. [= *Phalaris villosa* Michx.].

Habit loosely caespitose, slender perennials, perennating by shallow, concavely-arching, scaly rhizomes spreading as axillary branches from older shoot bases. **Roots** fibrous, shallow; adventitious roots not observed. **Culms** wandlike, mostly 70–120 cm tall, terete, finely multicostate, smooth, leafiest at and toward base. **Leaves** lowermost transitional to rhizomal scales, almost entirely multicostate, firm, scale, just upculm transitional to short, then longer, bladed members, then to uppermost ones, most distant and with long, tubular-conduplicate sheaths and short, erect blades; lower (basal) sheaths often open, either angled- or rounded-concave; upper sheaths progressively more rounded-conduplicate, tubular: leaf blades linear or lance-linear to linear-spathulate or linear-gladiate, flat to strongly involute or flattened-conduplicate, the margins variously hirsute or pilose-ciliate, scabro-ciliate, scaberulous, or entire, the apices mostly asymmetrically broadly acute, scabro-serrulate, often with midrib exsert as a mucronula; surfaces strongly multicostate, abaxially smooth, adaxially with strongest costae, these and their intervals smooth to variously scaberulous or papillate, sometimes with rounded microhairs, and in one species with erect, pilose intercostal hairs to 2 mm. Ligule present as a narrow, transverse, purplish or brownish, often sinuous zone, this elevated as a low, erect to antrorse ridge or scale crested with minute to elongate papillae, ciliae, tubercles or scales, or erose. Note! Measures and character of ligules are taken from lower culm leaves; ligules of median and upper leaves can sometimes have longer hairs or scales than given here! **Inflorescence** paniculate, the upper scape a slender, naked peduncle above the short, erect blade of the elongate-sheathed upper leaf, mostly narrowly oblong to elliptic, lanceolate or ovate in outline, compact or loose, mostly 10–20 cm, the lowest nodes with primary branches whorled and usually longest, the internodes progressively closer, with progressively shorter primary branches, ultimate branching and rebranching sinuous, bending upward, terminating in cupuliform receptacles. **Spikelets** erect on cuplike receptacle, at maturity broadly obovoid or ellipsoid, slightly compressed dorsiventrally, 3–4 mm long, exposed surfaces greenish and/or reddish, and at maturity densely cloaked with narrow, longitudinal bands of reddish, pinkish or pale, sharp, straight trichomes 1–2 mm long, lending a fuzzy look to the whole inflorescence; first glume lacking; second glume and lower lemma broadly obovate, obovate or elliptic, cupuliform, slightly longer than all other spikelet parts, abruptly acuminate, 5-nerved with broad, hyaline, entire borders, the opposing lemma slightly narrower, less convex, both with strong bands of trichomes alternating with the median nerves, but the outermost (lateral) nerves narrowest, surmounted by waxy-papillose zones with protruding trichomes, the second glume with its thin border lapping over the edges of the opposing lemma. Lower (first) lemma and its palea sterile or male, rarely with a bisexual floret, the palea hyaline, oblong- oblong-ovate or oblong, mostly apically two-toothed, shallowly two-keeled, two-nerved, or nerves lacking, entire 'with broad involute borders. Second lemma and its palea enclosing a perfect flower, cartilaginous, narrowly ovoid or lance-ovoid, plano-convex, at maturity brown to deep red-brown or appearing nearly black, with hyaline borders broadening toward scale apex, those of lemma finely ciliate, both with acuminate, incurved, crisped-bordered tips, at anthesis looking like a slightly opened bird's beak, the lemma back strongly rounded proximally, the palea slightly rounded apically, medially and distally two-nerved, shallowly two-keeled, plane or slightly concave between the nerves. **Florets** those of the lowest (first) lemma either male or sterile; those of the upper (second) lemma bisexual. Perianth of two, asymmetrically flabellate, bilobed lodicules. Stamens 3, anthers oblong-linear to elliptic-linear, extrorse, 1.5–2.5 mm long, the very accrescent filaments attaching to anther adaxially at a very short connective, shoving the anthers out of the floret apex as they reach lengths of 4 mm or more. Ovary at anthesis with uneven dorsiventral symmetry, looking much like an ovoid-bodied, small-headed insect, the arched abaxial and convex side with two short, broad, lateral grooves, the more level, adaxial side with a broad, shallow, concave surface, the small "head" with two lateral, narrowly subulate-terete branches, these bent outward, proximally, then upward, narrowing distally, ca. 2.5 mm long, each abruptly thickening to become the axis of a dark, dense stigmatic "brush" ca. 2.5 mm, these shoved out laterally as the floret opens. **Caryopses** broadly and tumidly obovoid, 1–1.8 mm long, yellow-brown, the bulbous apex apiculate, the oblique base dorsiventrally narrowed and oblique, the hilum an oblong depression on the palea side, the embryo under a large, rimmed disc on the lemma side.

Distribution.—Three species in North America, Atlantic and Gulf Coastal Plain and contiguous physiography exclusive of the Mississippi Embayment, North Carolina south to peninsular Florida, west to southern Arkansas and eastern Texas.

Phenology.—Typically flowering from mid-July through October.

KEY TO THE SPECIES

1. Adaxial surface of leaf blade with erect or variously directed, strumose pilosity, these hairs arising from intercostal sulcae; principal leaves with blades shallowly auricled, slightly bent outward from sheath; longer primary panicle branches 1/3–1/2 as long as whole panicle, these usually naked-based and widely ascending (to 45° or slightly more) giving panicle an ovate or broadly elliptic outline; glume and lower (outer) lemma surfaces often with longitudinal broad, reddish bands; spikelet trichomes commonly reddish, or pale with red or pink tips; ligule base reddish, its edge ascending-ciliate, the pale hairs to 1(–1.5) mm ______ **1. A. texana**
1. Adaxial surface of leaf blade lacking trichomes of any sort (save for occasional papillae or microhairs), sometimes scabrid; principal leaves with blades either strongly auricled and bent outward from their sheathes, or lacking auricles and erect to gradually bowed outward with no geniculation; longer primary branches of panicle either less than 1/3 panicle length or branching near base, seldom (save in a few extremes of no. 3) widely ascending, and generally with a narrower outline and a denser look; glume and lower lemma with or lacking red pigmented longitudinal bands; ligule base with edge ranging from papillate-tuberculate to variously ciliolate or ciliate or with a line of narrowly triangular scales.
   2. Principal (lower) leaves strongly auriculate at junction of blade and sheath, thus blades of lower culm leaves "breaking" away from sheaths at narrow to wide angles, these same ciliate at least proximally, with spreading to ascending strumose-hirsute cilia; pigmentation of leaves, spikelets and their trichomes usually with little or any red; fertile lemma and palea lustrous brown; anthers at anthesis brown; ligule rim of lower principal leaves minutely erose or lacerate-ciliolate or with a line of irregular, flat-based cilia mostly under 1 mm ______ **2. A. villosa**
   2. Principal (lower, bladed) leaves weakly, if at all, auriculate at junction of blade and sheath, thus this zone, if viewed from side, usually showing but a slight projection and a few pilose hairs, sometimes ascending-pilose-ciliate at blade base, or lacking hairs entirely; blades not perceptibly "breaking" away (geniculate) but flowing into their sheaths., suberect or slightly excurved; pigmentation of leaves, spikelets and their trichomes variously reddish or purplish, thus the foliage, scapes and spikelets darker; fertile lemma and palea similarly lustrous but a darker, red-brown to near black; anthers at anthesis dark brown; ligule rim of lower principal leaves nearly perpendicular, its edge commonly papillose- tubercular, minutely ciliolate, finely erose, or with a line of short narrowly-triangular-based pale cilia ______ **3. A. rufa**

1. Anthenantia texana R. Kral, sp. nov. (**Figs. 1, 4**). U.S.A. TEXAS. HOUSTON CO.: 2.5 mi W of Kennard city limit by TX Hwy 7, in Sam Houston National Forest; sandy clay loam of clearings in and edges of pine (*Pinus taeda, P. echinata*) and hardwood flats, 30 Sep 2002, *R. Kral 92270* (HOLOTYPE: VDB; ISOTYPES: AUA, BM, BAYLU, CLEMS, DOV, DUKE, FLAS, FSU, GH, ILLS, JSU, K, KANU, M, MICH, MO, MU, NCSC, NLU, OSC, P, TEX, U, UAM, UNA, USCH, US, VPI, VSC, WILLI).

Planta perennis, gracilis. laxe caespitose, squami-rhizomatosa, (40–)50–100(–120) cm alta. Folia principalia vulgo suberecta vel leviter excurvata, 15–50 cm longa, leviter auriculata, leviter geniculata, ad basim culmorum approximate, sursum remota; ligula albociliata, ciliis (0.5–)1(–1.5) mm longis; laminae foliorm adaxialiter strumoso-pilosae, pilis erectes vel ascendentibus, ad 2 mm longis. Squamae exteriores spicularum alterne longitudine rubrae et virides. Lemma et palea secunda coriacea, atrocastanea. Antherae maturae atroferrugineae, ca. 2 mm longae.

Perennial (45–)60–100(–120 cm high, loosely caespitose, the shoot bases connected by short (–7 cm) concavely arching, shallow scaly rhizomes 2–4 mm thick. Culms slender, wand-like, leafiest at and toward base, the lowermost leaves mere ribbed yellowish scales 5–15 mm, soon grading to bladed members. Principal leaves (15–)20–40(–60) cm, ascending, the longest with blades several times longer than their open but somewhat "V"-shaped or rounded sheaths., grading to the uppermost, this with its erect blade much shorter than its convolute-tubular slender sheath; sheath summit with two low but evident, usually cartilaginous, pilose-edged auricles, the transverse narrow, usually purple, ligular scale projecting forward at an angle, its edge a band of pale ciliae (5–)1(–1.5 mm; blade lance-linear to linear, mostly 4–7(–10) mm wide, base thickened at rounded auricle area, there often ascending-pilose, here breaking from the sheath, distally narrowing, often flattened or "v"-troughed to plane or variably deeply concave or almost conduplicate, abruptly narrowed to a broadly and obliquely angled apiculate tip, abaxial surfaces of sheath pale to green tinged with red, those of blades mostly deep green; adaxial surface of blades pilose with pale, erect or ascending, pustular-based trichomes to 2 mm arising from deep intercostal sulcae. Panicle outline ovate to elliptic or broadly lanceolate, 7–15(–20) cm, the lowest group most distant, the primary branches ascending, sometimes to 45° or slightly more, the longest of a whorl also naked-based and mostly 1/3–1/2 or more the total length of the panicle, the whole with secondary branching progressively more and shorter toward branch ends, giving the wide panicle base a much more open look. Spikelets turgidly obovoid or ellipsoid, 3–4 mm, at flowering time with longitudinal smooth zones of second glume and outer palea reddish alternating with green, the alternating rows of pustular-based trichomes red to pale pink or purple. First palea hyaline, 2-keeled, bifid, hairless, slightly shorter than the opposing lemma, tristaminate or stamens lacking. Second lemma and palea about equaling subtending second glume, a deep, lustrous red-brown or near black, the hyaline margins gradually widening, ciliolate, to a crisped, ciliate apical border; flower usually perfect simply pistillate. Caryopses 1.5–1.8 mm long.

Distribution.—Sands, sandy clay loam, sandy peat or silts of pine flatwoods, pine-oak barrens, bog edges, ditchbanks, clearings, Gulf Coastal Plain and contiguous physiography west of the Mississippi delta, southern Arkansas, Louisiana and eastern Texas.

Phenology.—Flowering mid-July through October.

This species has in the past been identified as *A. villosa*, particularly the broader and more distinctively auriculate-leaved, paler-haired examples (i.e. Texas specimens, Calhoun Co., 1 Dec 1928, B.C. Tharp [TEX]; Nueces Co., 25 Oct 1931, B.C. Tharp [TEX]). Many, because of their darker green or reddish pigmentation of foliage, darker spikelet pubescence, narrow, more erect leaves, have been identified as *A. rufa* (a large majority of east Texas examples, all Arkansas examples, most examples from western Louisiana. The "*villosa*" morphs of the species from southeast Texas may suggest a genetic influence of that species, since *A. villosa* is the only other Texas native, it and *A. texana* often mingling where ecotones are obliterated by disturbance. But, in such instances, the two appear to retain most, if not all, distinguishing features. In Beauregard Parish, western Louisiana, both west and east of DeRidder, I observed many hundreds of the two in recently logged areas of pine savanna. In each site *A. villosa* (*Kral 91997B, 93286*) occupied sandier small rises but often would be within a few feet of clumps of *A. texana Kral 91997A, 93287*), which would be on slightly moister substrate. In those sites I had no trouble distinguishing the two, the former with broader leaf blades distinctly "breaking" away and with paler spikelets in narrower, denser inflorescences, the latter with narrower, geniculate, but less evidently so, and with darker spikelets in broader, more diffuse inflorescences. I plan further fieldwork in western Louisiana so as to see if there are examples there of mixed populations of *A. texana* and *A. rufa* and will prepare a report on that situation. Should there be such mixtures, from what information I have so far, all the *A. rufa* would be predicted to be forma *scabra*, while *A. texana* should show no scabrosity and a consistently geniculate leaf blade, together with a longer ligule. So, while there are distinct overlaps in regard to given characters for the three taxa, the pale, intercostal pilosity of strumose-based hairs is unique to *A. texana*.

2. Anthenantia villosa (Michx.) Beauv., Ess. Agrost. 48, 151, t. 10, f. 7. 1812. (**Figs. 2, 4**). BASIONYM: *Phalaris villosa* Michx., Fl. Bor. Amer. 1:43. 1803. TYPE: U.S.A. "In sabulosis Carolinae," *Michx. s.n.* (HOLOTYPE: P!).

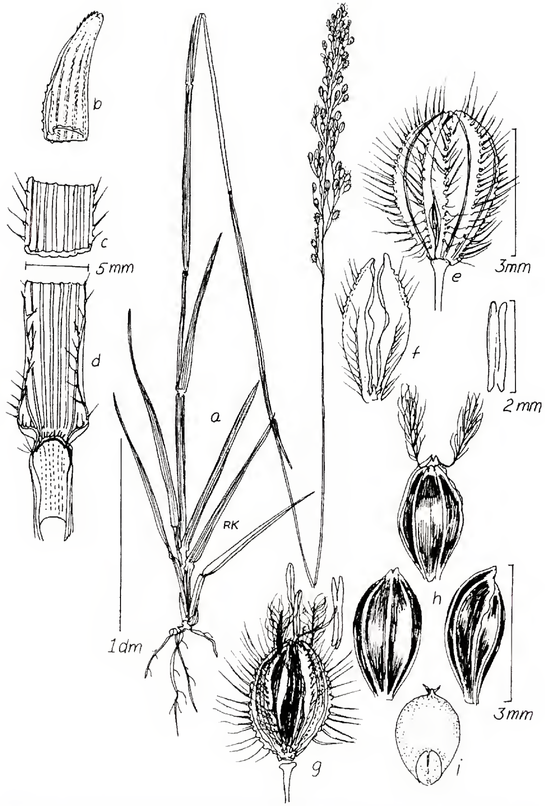

Fig. 2. *Anthenantia villosa* (Michx.) Beauv. (from *Kral 90571*). **A.** Habit sketch. **B.** Leaf apex, side view. **C.** Sector of lower leaf blade, adaxial viewed. Adaxial view of leaf/sheath junction. **E.** Side view of spikelet. **F.** An anomalous "extra" floret (left); anther (right). **G.** Spikelet at anthesis. **H.** Three views of fertile (upper) floret, abaxial (palea side) view, stigma brushes protruding (above), abaxial view (below, left); side view (below, right). **I.** Mature caryopsis (Hilum side).

Aulaxanthus ciliatus Elliott, Sketch Bot. S. Carolina 1:102. 1816. *Aulaxia ciliata* (Elliott) Nutt., Gen. Pl. 1:47. 1818. TYPE: "in dry pine barrens, flowers September – October," (HOLOTYPE: CHARL "BY-3965"!).

Elliott suggested the possibility that his *A. ciliatus* might be the same as *Phalaris villosus* Michx., noting "*Phalaris villosa*? Mich. 1. p. 43." To be sure of Elliott's concepts, I visited the Charleston Museum in December 2003 to examine the type material. Thanks to the consideration of Albert Sanders, curator of the Elliott Herbarium, I was quickly shown the Elliott types of *Aulaxanthus ciliatus* and *Aulaxanthus rufus*, both mounted on a single sheet and in good shape. The right hand specimen is a small but readily identifiable specimen (CHARL "BY-3965") of *Anthenantia villosa*, marked by Weatherby as the type of *Aulaxanthus ciliatus* Elliott by Weatherby in 1941. To be absolutely sure of the identity of Michaux's *Phalaris villosa*, At my request, Barney Lipscomb (BRIT) made photocopies of my plates of *A. villosa* and *A. rufa* and sent them unlabelled to Porter Lowry (P). The Michaux type clearly matched my unlabelled plate of *Anthenantia villosa*.

Panicum erianthum Poir., Encycl. Sup. 4:284. 1816.

Panicum hirticalycinum Bosc. ex Roemer & Schultes, Syst. Veg. 2:468. 1817.

Perennial (50–)60–130 cm high, loosely caespitose, perennating by short, scaly rhizomes from older shoot bases, Culms slender, wand-like, leafiest at or toward base. Lowest leaves imbricate, yellowish, multicostate scales, grading to long-bladed principal leaves 15–40 cm, the sheaths rounded-conduplicate, opening distally, there with a narrow, wavy-transverse ligule, each edge terminating at a prominent thickened auricle., there with a tuft of pilose hairs, the ligule base ascending at a wide angle from the leaf surface, or even an erect, low wall of tissue, its edge variously short-ciliate (mostly not over 0.5 mm), or irregularly papillate-erose or with short, narrowly triangular squamellae; blades mostly lance-linear, lower ones distinctly breaking away from sheaths at various angles sometimes nearly 90°, 4–9(–15) mm wide, plane or inrolled, margins strumose-hirsute-ciliate, often also strongly papillose at least proximally, apex flat, triquetrous to rounded-conduplicate, or compressed-conduplicate, usually obliquely acute, scabro-ciliolate. Upper culm exserted 1–2 dm above the-erect, short-linear upper leaf blade as a slender peduncle terminating at a mostly narrowly elliptic to cylindric or lanceoloid panicle, this (5–)10–20(–25) cm, the whorls of primary branches ascending to erect, mostly closely rebranching to produce a generally dense, rarely interrupted inflorescence of yellowish to silvery-green spikelets. Spikelets obovoid to ellipsoid, 3–4 mm long, the rows of pustular-based trichomes typically silvery or pale, the outer scales with mostly green or pale green surfaces, the hyaline first palea slightly shorter than its lemma, often with a line of ascending clear trichomes lateral to each keel, the floret either sterile or staminate; second lemma and palea coriaceous with distal edges hyaline-ciliate, surface brown to dark brown, this floret typically perfect. Anthers at maturity narrowly oblong-linear, ca. 2.5 mm, yellowish-brown. Fruit ca. 2 mm long, yellow-brown.

Distribution.—Sands, sandy clay, sandy loams, moist to rather dry sites, mainly pinelands, particularly the longleaf pine-turkey oak system, oak-pine barrens and flatwoods, upper edges of bogs, ditchbanks, sandy clearings, Atlantic and Gulf Coastal Plain and contiguous physiography from North Carolina south to South Florida and west, except for the Mississippi Embayment, into eastern Texas.

Phenology.—Flowering mid-July through October (or November in southern range).

I have not yet seen the three *Anthenantia* in one place, although this might be possible in western Louisiana or even eastern Texas. But were such to happen, *A. villosa* would be distinguishable at a glance. It is the most robust of the three, has the least rusty pigmentation in leaf and culm (save sometimes for pinkish internodes and spikelet hairs), has generally paler vesture, the plants therefore giving the overall effect of pale green. The lower culm leaves are more visibly auriculate and tend to spread more, and the blade margins are more coarsely and conspicuously strumose-hirsute-ciliate. Pigmentation of anthers and of the coriaceous lemma and palea is paler. The hyaline palea of the lower (first) floret is unique, since it usually has rows of ascending, long, stiff, pale trichomes parallelling and external to each of the two keels (see fig. 4). On the other hand, in character of culm, in pigmentation, character and orientation of leaves and in character, shape, and indumentum of inflorescence, it is easy to see why the other two have traveled under the same epithet for such a long time. This will be discussed under *A. rufa*.

Anthenantia villosa occupies the driest habitats of the three. It extends further up sides of sandhills, is in higher zones within ecotones between uplands and low, and is in the higher spots in flatwoods and savannas. It is the most frequent associate of *Aristida stricta* in Longleaf pine sandhills. Future studies probably will show that there is genetic exchange between it and *A. rufa* and *A. texana*, particularly where ecotones have been broadened through disturbance.

Leptocoryphium drummondii Müll. Berol., Bot. Zeitung (Berlin) 19:314. 1861. TYPE: U.S.A. LOUISIANA: [1831–1832?] *T. Drummond.*

Perennial (50–)60–125 cm high, loosely caespitose, perennating by short, scaly rhizomes from older shoot bases. Culms slender, wand-like, leafiest at or toward base. Lowest leaves mere scales, transitional to principal leaves 12–60 cm, with blades much longer than sheath; sheaths often red-brown or purple tinged, variously folded conduplicately, narrowing gradually to similarly folded blade, the connecting auricle minute or not evident save as a few pilose spreading hairs at ligule ends or even these lacking; ligule wavy-transverse, usually a narrow, erect ridge 0.2–0.4 mm high, typically purplish, its upper edge papillate, minutely lacerate, rarely ciliolate with cilia at most 0.5 mm (uppermost leaves

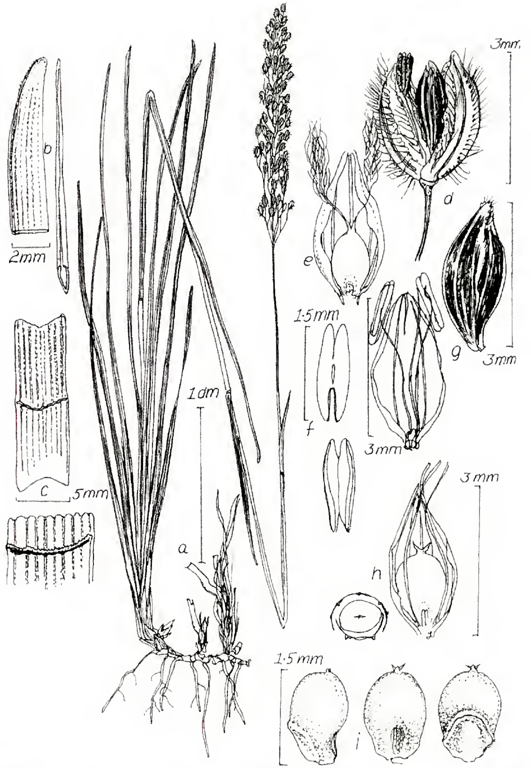

Fig. 3. *Anthenantia rufa* (Ell.) Schult. (from *Kral 90519*). **A.** Habit sketch. **B.** leaf apex, side view (left), adaxial edge (right). **C.** Leaf blade/sheath junction, lower leaf, adaxial view (above); leaf blade/ sheath junction, adaxial view, ligule. **D.** Spikelet at anthesis. **E.** "Cleared" fertile lemma with young developing fruit. **F.** Adaxial view of anther. **G.** Adaxial view of first (lower) palea at anthesis (below left); side view of upper (second) lemma and palea (above right). **H.** Perfect floret, with ripening fruit (right); idealized cross-section of perfect floret, including lemma (left). **I.** Three views of ripe fruit, side view (left), hilum side (middle), embryo side (right).

often with distinctly longer cilia!); blades mostly erect to ascending-excurved, continuous with sheath apex, not at all geniculate, linear to linear-gladiate or linear-spathulate, (3–)4–8(–10) mm wide, flat to rounded-involute or variously folded-conduplicate, margins entire,- or sparsely pilose-ciliate proximally, or scabrid, the surfaces pale to deep green, or purple-tinged, smooth to papillate or scaberulous on the costae, apex mostly conduplicately sharply folded, or open at a wide angle, obliquely broadly acute, apiculate. Panicles ovoid to lanceoloid, ellipsoid, or cylindric, (8–)10–20(–25) cm, branching mostly strongly ascending to nearly erect, the lowest whorl often with some primary branches 1/3 the total panicle length or more, but mostly floriferous to near base, thus the inflorescence mostly dense. Spikelets mostly broadly ellipsoid to obovoid, 3–4 mm, with exposed outer surfaces alternating with longitudinal bands of green and red, the bands of trichomes reddish to deep purple, rarely pinkish, very rarely pale. Lower floret usually staminate, often sterile, sometimes perfect; upper floret with coriaceous lemma and palea deep red-brown or castaneous, appearing nearly black, the hyaline borders broadening distally, there ciliate, often crisped and finely ciliate apically, their flower usually perfect. Anthers at anthesis narrowly oblong, ca. 2–2.5 mm, deep purple-brown, appearing black. Ripe caryopses 1.5–2 mm, yellowish-brown.

Distribution.—Sands, sandy peats, silts and sandy clay of pine flatwoods and bogs, edges of bogs, acidic seeps and seep slopes, and pine savanna, Coastal Plain and contiguous geology, North Carolina south to peninsular Florida, west into Louisiana, possibly eastern Texas.

Specimens examined.—Note! In Small's *Flora of the Southeastern United States* (1903, p. 97) appears the citation., under *Anthenantia rufa* "A form, *A. rufa scabra* Nash, differing from the above in having the sheaths and blades scabrous, occurs in similar situations in South Carolina, but mainly from Alabama to Louisiana. Fall." This information appears in some present-day reference sources, but inconsistently, sometimes the taxon being given as a variety, in other instances as a "form" (as per Small). Since Nash and Small were colleagues at the New York Botanical Garden, and since Small passed along the characteristics in 1903 for what he referred to as a form, it must be assumed that the name received no further published attention. I have been unable to find any actual formal presentation. and Small appears to have let the matter lapse as of 1903; certainly it did not carry forward to his 1933 "Manual." Whatever the case, Nash should be credited for his observations. It is true that there are populations of scabrid *A. rufa* from the Carolinas west to Louisiana, and there are associated characters such as the presence (usually) of a tuft of pilose hairs at a small triangular projection where ligule meets margin, this often accompanied by a short line of slender pilose cilia above and below along contiguous margin. However, these latter characters tend to vary independently, as does the degree of scabrosity of leaf blades and sheaths. My own conclusion is

to leave the situation as Small had it. "*Scabra*" morphs show a gradation westward, particularly in the increase of scabrosity and hairs at and around the ligular edge, mostly from Alabama and panhandle Florida west into 'Louisiana. Regrettably, large loans from DUKE and NCU were annotated *A. rufa* without checking "scabra" characters. They are entered with an asterisk so as to provide an idea of distribution of *A. rufa* in the Carolinas, and a more careful check for the few, if any, "scabra" morphs will be made.

CONCLUSIONS

My study of *Anthenantia* has been based on field observation along with careful artwork and morphologic evaluation. Such foci allow the following:

1. *Anthenantia*, so far as the North American flora is considered, is a distinct genus of panicoid grasses. It is the only genus in our area to combine (1) a scaly-rhizomatous, loosely caespitose habit (2) a paniculate inflorescence, with (3) spikelets similar to those of *Panicum* but lacking a first glume, (4) the second glume and first lemma 5-nerved, with at least the median three flanked by narrow longitudinal rows of elongate, often papillose-base (strumose) trichomes, and (5) two florets, the lower "glumelike" lemma with its hyaline, bicarinate palea enclosing a male floret or sterile, the second (or upper) lemma and palea coriaceous, enclosing a (usually) perfect floret.

2. A third "species-level" taxon, *Anthenantia texana*, exists west of the Mississippi Embayment, where it may share area, if not exact habitat, with *A. villosa* and possibly also *A. rufa* in eastern Texas and western Louisiana. *Anthenantia texana* may actually be the only species to be found in Arkansas.

3. An examination of the synonymy and taxonomic dispositions in *Anthenantia* and morphologically adjacent genera seems (to me) to show a definitely confused set of concepts. Since the whole tribe, for that matter the whole family, is having a vigorous and very controversial "shakedown," it is useful to point out two genera with strong resemblance to *Anthenantia*, namely *Leptocoryphium* Nees and *Melinis* P. Beauv. *Leptocoryphium* has two species: *L. lanatum* (Kunth) Nees ranges from Argentina north into Mexico and the Anti'lles, in the north of its range frequenting pine savanna, oak-pine land, open savanna, and pasturage within these systems. In short, it has an "*Anthenantia*-type" habitat. My first encounter with the species was in Nicaragua ("Zeylaya, burnt savanna by road to Limbaika, ca. 1 km e of jct. rd to Limbaika, 10 July 1982, *R. Kral 64344*"). I did not identify the plant but did note its strong resemblance to *Anthenantia*. From my recent examination of herbarium material and from excellent descriptions by Pohl for Flora Meso-america (1994) and Flora Nicaragua (2001), I am further intrigued. The species is described as having a cormose, fibrillose base but otherwise seems to differ vegetatively from *Anthenantia* in no significant way. The inflorescence is paniculate, sinuously branched, the spikelets are similar in design, the lower glume is lacking, the second glume and lower palea have the same nervation, with trichomes elongate and in longitudinal rows. The only significantly different character state in the spikelet seems to be in the lower floret, which has no palea and which is sterile. The upper floret in character and dimensions of lemma and palea and in perianth, stamens, and gynoecium is very similar. The fruits are similar. I suggest that if a tight description of *Leptocoryphium* were spaced so that a similar one of *Anthenantia* were laid in on alternate lines, there would be a strong agreement. It is significant that one of the most excellent of observers, George Bentham, treated *L. lanatum* as *Anthenantia lanata* (Kunth) Benth.

Melinis P. Beauv., an African genus of 22 species, also is similar to *Anthenantia* but appears to be a more distant relative and is in fact placed in subtribe Melinidinae by current authors, while *Anthenantia* and *Leptocoryphium* are morphologically aligned with subtribe Digitariinae. The two species of *Melinis* in the Americas are the weedy invasives *M. repens* (Willd.) Zizka ssp. *repens* (*Rhyncheletrum repens* [Willd.] C.E. Hubb. = *R. roseum* (Nees) Stapf & C.E. Hubb.) and *M. minutiflora* P. Beauv., which are rapidly occupying disturbed sandy or gravelly areas (overfarmed situations, fields, railroad rights-of-way, etc.). The former has gotten into the range (if not the habitat) of *Anthenantia* in northern Florida, south Georgia, and Texas. The latter is so far confined to Florida. A quick scan of a living *M. repens* makes one note the strong resemblance to *A. villosa*. The general dimensions of culm, leaf (shape, surfaces, ciliate blade margins, the geniculate "bend," the character of ligule and auricle) and the feathery panicle of pinkish to silvery-white hairy spikelets, all are deceptively similar. However, a closer look reveals a different plant base, namely caespitose but not rhizomatous, the culms often short-decumbent, themselves geniculate at base and with adventitious roots. In the panicle the spikelets, at first appressed-silky-pubescent, later "fuzzy" with elongate spreading trichomes, are superficially similar to *Anthenantia*, but a closer inspection reveals (a) lateral compression rather than dorsiventral, (b) two glumes, both keeled apically and aristate, and (c) second glume and lower lemma about equal in length with lower half gibbous, the rounded backs prominently pustular-papillose, the hairs liberally interspersed, not in longitudinal rows, the upper half abruptly narrowed to a strongly-laterally compressed, keeled, aristate (in the glume) beak. Finally, while the two florets are similar in composition to *Anthenantia* (lower floret with a hyaline, 2-keeled palea and tristaminate flower, the upper one typically perfect and navicular) the lemma and palea are chartaceous rather than coriaceous and show a slight lateral compression. The caryopses, while slightly similar, also show bilateral symmetry and an eccentric style base.

Thus, I have the impression that *Leptocoryphium*, having so many characters in common, could indeed be merged with *Anthenantia*, an opinion already given by George Bentham. For *Melinis*, on the other hand, the symmetry of spikelet, the presence of two awned glumes, the disposition of hairs and papillae on the laterally (rather than dorsiventrally) compressed scales or their tips, and the chartaceous, rather than coriaceous, laterally compressed upper floret constitute a significant set of differences and suggest a different evolutionary alliance.

ACKNOWLEDGMENTS

The help of curatorial and management staffs of all is hereby gratefully acknowledged as well as for careful editorial suggestions by agrostologist Victoria Hollowell (MO). The invaluable help of Barney Lipscomb and that of Porter Lowry (P) is greatly appreciated. Barney made digital images of my drawings of *A. rufa* and of *A. villosa* and sent them to Porter, who compared them with Michaux's type collection of *Anthenantia villosa*. The kindness of these two gentlemen is gratefully acknowledged!

ABSTRACT

Calamagrostis coahuilensis P.M. Peterson, Soreng & Valdés-Reyna, sp. nov., and ***Calamagrostis divaricata*** P. M. Peterson & Soreng, sp. nov., from México are described and illustrated. *Calamagrostis coahuilensis* occurs on calcareous slopes in the mountains of southeastern Coahuila and southwestern Nuevo León; and *C. divaricata* occurs on moist slopes and mossy cliffs of southwestern Durango. *Calamagrostis coahuilensis* is morphologically similar to *C. purpurascens* but differs by having shorter anthers (1–1.2 mm long), nearly smooth ligules, scaberulous rachises, glabrous or minutely antrorsely scabrous sheath summits, and somewhat dense but not spikelike, greenish panicles. *Calamagrostis divaricata* seems morphologically allied to *C. pringlei* but differs by having wider panicles (4–10 cm) with branches reflexed spreading and divaricate, shorter spikelets (3.4–4.3 mm long), shorter glumes (3.4–4.3 mm long) that are both 1-veined, and shorter lemmas (3.8–4.3 mm long) with an awn inserted on upper 1/4 to 1/3.

RESUMEN

Se describen y se ilustran para México ***Calamagrostis coahuilensis*** P.M. Peterson, Soreng & Valdés-Reyna, sp. nov., y ***Calamagrostis divaricata*** P.M. Peterson & Soreng, sp. nov. *Calamagrostis coahuilensis* se encuentra en laderas calcáreas en las montañas del sureste del estado de Coahuila y suroeste del estado Nuevo León; y *C. divaricata* se encuentra en laderas húmedas y riscos musgosos del suroeste del estado de Durango. *Calamagrostis coahuilensis* es morfologicamente similar a *C. purpurascens* pero difiere en poseer anteras más cortas (1–1.2 mm largo), lígulas casi lisas, raquis escaberuloso, ápices de las vainas glabros o escasamente con escabrosidad antrosa, y panículas densas pero no espigadas, de color verdusco. *Calamagrostis divaricata* parece morfologicamente relacionado a *C. pringlei* pero difiere en poseer panículas mas amplias (4–10 cm) con ramificaciones reflexas, extendidas y divaricadas, espiguillas mas cortas (3.4–4.3 mm largo), glumas más cortas (3.4–4.3 mm largo) ambas uninervadas, y lemas mas cortas (3.8–4.3 mm largo) con una arista insertada desde 1/4 hasta 1/3 arriba de la mitad.

Calamagrostis is characterized as having single-flowered spikelets, one or three-veined glumes as long or exceeding the floret in length (rarely slightly shorter), non-keeled lemmas that are membranous or cartilaginous (infrequently hyaline), usually with a single dorsally attached awn (rarely awnless), a callus with a crown of hairs, caryopses with short hilums and without apical hairs, and lodicules that are apically membranous (Clayton & Renvoize 1986; Watson &

Dallwitz 1992). Worldwide, *Calamagrostis* includes between 230 (Watson & Dallwitz 1992) and 263 (reported by D. Clayton & B. Simon, pers. comm. 2004) species. In North, Central, and South America 131 species are reported in Soreng et al. (2003). In México the following 11 species of *Calamagrostis* are recognized: *C. erectifolia* Hitchc., *C. eriantha* (Kunth) Steud., *C. guatemalensis* Hitchc., *C. intermedia* (J. Presl) Steud., *C. oridzabae* (Rupr. ex E. Fourn.) Beal, *C. pringlei* Scribn. ex Beal, *C. purpurascens* R. Br., *C. rigescens* (J. Presl) Scribn., *C. tolucensis* (Kunth) Trin. ex Steud., *C. valida* Sohns [syn.=*C. mcvaughei* Sohns; McVaugh (1983) was the first to select this name as a synonym, see Article 11.5 for equally published species in the Code of Botanical Nomenclature (Greuter et al. 2000)], and *C. vulcanica* Swallen (Chimal 1987; Espejo-Serna et al. 2000).

While collecting grasses and specifically searching for unique forms of *Trisetum* in Durango, México (Finot et al. 2004) in the fall of 2003 the first author gathered a specimen that seemed to be an undescribed species. At first glance this specimen appeared to be two or more flowered but upon closer inspection and under magnification all spikelets contained a single floret. After studying morphologically similar material from México collected by the first author, an additional undescribed species was found in Coahuila. The two new species are clearly members of subfamily Pooideae, tribe Poeae, subtribe Agrostidinae (Soreng et al. 2003, 2004). We describe these two specimens as new species of *Calamagrostis*.

Calamagrostis coahuilensis P.M. Peterson, Soreng & Valdés-Reyna, sp. nov. (**Figs. 1, 2**). TYPE: MÉXICO. COAHUILA. Sierra Madre Oriental, 32 mi SE of Saltillo and 8 mi SE of Jame on road to Sierra La Viga, 3240 m, 29 Sep 1990, *P.M. Peterson, C.R. Annable & J. Valdés-Reyna 10051b* (HOLOTYPE: US!).

A *Calamagrosti purpurascenti* R.Br. antheris 1–1.2 mm longis. ligulis fere laevigatis, rhachibus scaberulis, vagina apicali glabra vel scabrella antrorse, paniculis aliquantum densis sed non spicae similibus, viridis, recedit.

Caespitose perennial with intravaginal and extravaginal shoot initiation. Culms (22–)40–100 cm tall, erect, glabrous; internodes glabrous. Sheaths 6–28 cm long, shorter than the internodes, glabrous, often fibrous below with age; margins smooth; cataphylls and lower sheaths glabrous; summit glabrous or minutely antrorsely scabrous. Ligules 5–8 mm long, membranous often lacerate, firmer below, nearly smooth, apex obtuse to acute. Blades 8–20 cm long, 2–4 mm wide, flat, apically acuminate, glabrous, scabrous above. Panicles (7–)9–20 cm long, 0.5–1.2 cm wide, contracted, somewhat dense but not spike-like, greenish; rachis scaberulous; inflorescence branches mostly 2–10 cm long below, the branches, ascending and tightly appressed, mostly floriferous near base, one or two per node. Spikelets 5.8–7.2 mm long, 1-flowered, tightly appressed to the branches, dark greenish; pedicels 0.6–4 mm long, ascending, scaberulous; rachilla 2.4–3 mm long, covered with stiff hairs, the hairs 0.5–1 mm long. Glumes 5.8–7.2 mm long, lanceolate, about equal or subequal in length, longer than the

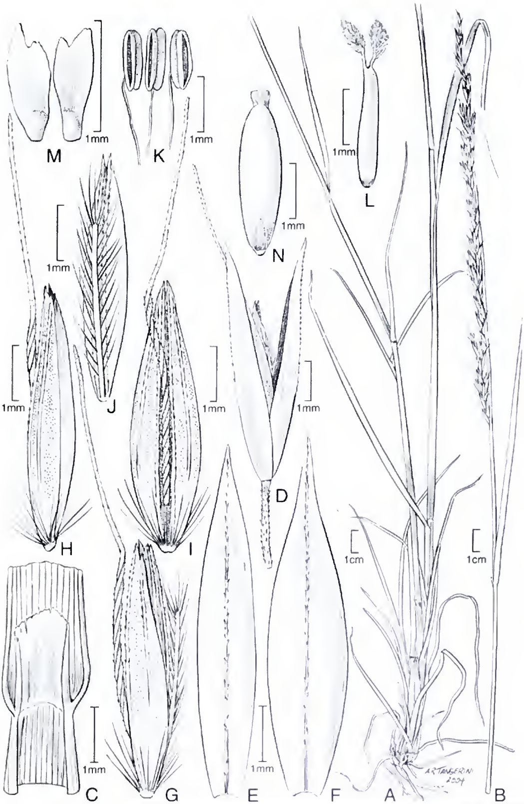

Fig. 1. *Calamagrostis coahuilensis* (*Peterson, Annable & Valdés-Reyna 10051b*). **A.** Habit. **B.** Inflorescence. **C.** Sheath, ligule, and blade. **D.** Spikelet. **E.** Lower glume, dorsal view. **F.** Upper glume, dorsal view. **G.** Floret, lateral view. **H.** Lemma, lateral view. **I.** Lemma, dorsal view. **J.** Palea with rachilla, dorsal view. **K.** Stamens. **L.** Pistil. **M.** Lodicules. **N.** Caryopsis, dorsal view.

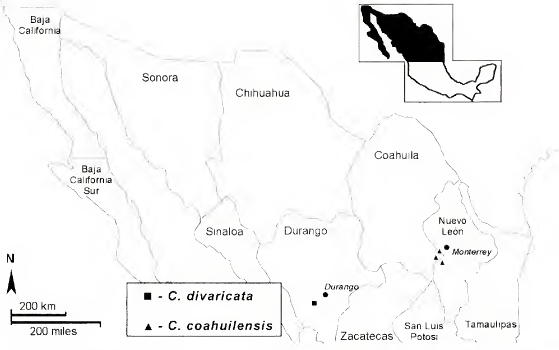

Fig. 2. Distribution of *Calamagrostis coahuilensis* and *C. divaricata* in México.

floret, membranous, 1-veined, scaberulous along vein; margins hyaline; apex acute. Lemmas 5–5.7 mm long, lanceolate, membranous, yellowish-green, conspicuously 5-veined near base, scaberulous, awned; apex acute, entire or bifid; awn 8–10 mm long, golden below and purplish above, borne near the base on the lower 1/6, inserted in a groove below and twisted and once-geniculate above; callus obtuse with white hairs, the hairs 0.8–1.8 mm long. Paleas 5–5.6 mm long, about as long as the lemma, hyaline, 2-veined, the veins scaberulous, green; apex acute, entire. Lodicules ca. 1 mm long, lanceolate, lobed, glabrous. Stamens 3; anthers 1–1.2 mm long, purple. Ovary ca. 0.2 mm long, glabrous; styles 2, separate; stigmas 2, feathery, whitish. Caryopses 2–2.5 mm long, fusiform, light greenish.

Phenology.—Flowering in late August, September, and early October.

Distribution.—*Calamagrostis coahuilensis* is known from the mountains of Coahuila and Nuevo León growing on calcareous slopes with *Abies mexicana* Martínez, *Pinus culminicola* Andresen & Beaman, *P. hartwegii* Lindl., *Hesperostipa spartea* (Trin.) Barkworth, *Poa ruprechtii* Peyr, *Holodiscus discolor* (Pursh) Maxim., *Quercus greggii* (A. DC.) Trel., and scattered *Populus tremuloides* Michx.

Additional specimens examined (PARATYPES): **MEXICO. Coahuila:** municipio de Arteaga, near summit of Coahuilon, SE of San Antonio de Las Alazanas and SE of Saltillo, 3120 m, 17 Oct 1989, *P.M. Peterson, J. Valdés-Reyna & J.A. Villareal* 8399 (ANSM, US); 29 Aug 1986, *J.A. McDonald* (TEX). **Nuevo León:** municipio de Galeana, Cerro el Potosí, 3600 m, 3 Aug 1989, *A. García-Arévalo* 66 (ANSM, CIIDIR); cumbre de Cerro Potosí, ca. Galeana, 29 Aug 1986, *J.A. McDonald* (TEX); Ladera S, 26 Jul 1985, *J.A. McDonald* (TEX); *J. Ochoa-Guillemard* 983 (COCA).

Calamagrostis divaricata P.M. Peterson & Soreng, sp. nov. (**Figs. 2, 3**). TYPE: MÉXICO. DURANGO. Sierra Madre Occidental, ca. 3 mi S of Hwy 40 at Mexiquillo, Arroyo Paso Resbaloso (23°42'46.2"N-105°39'45.1"W), 2520 m, 14 Sep 2003, *P.M. Peterson, M.S. González-Elizondo & G. Teña-González 17774* (HOLOTYPE: US!; ISOTYPES: ANSM!, CIIDIR!, MO!, RSA!, US!).

A *Calamagrosti pringlei* Scribn. ex Beal paniculis 4–10 cm latis, ramis reflexis, effusis et divaricatis, spiculis 3.4–4.3 mm longis, glumis 3.4–4.3 mm longis, univenis, lemmatibus 3.8–4.3 mm longis, arista inserta supera 1/4–1/3, recedit.

Loosely caespitose perennial with short rhizomes and extravaginal shoot initiation. Culms 52–96 cm tall, erect to slightly decumbent near base, glabrous; internodes glabrous. Sheaths 8–20 cm long, shorter or longer than the internodes, glabrous; margins smooth; cataphylls and lower sheaths glabrous; summit glabrous. Ligules 2–3.6 mm long, membranous often lacerate, decurrent below; apex truncate, ciliolate. Blades 15–60 cm long, 1–3 mm wide, flat or involute, apically acuminate, glabrous, scabrous above. Panicles 9–16 cm long, 4–10 cm wide, ovate, open, lax, sparsely flowered, greenish; rachis scaberulous; inflorescence branches mostly 2–8 cm long below, the branches delicate, ascending and spreading, naked near base, whorled; lower inflorescence nodes with 3–6 branches. Spikelets 3.4–4.3 mm long, 1-flowered, spreading from the branches, yellowish-green; pedicels 1–5 mm long, ascending to reflexed and spreading, scaberulous; rachilla 1.6–1.9 mm long, covered with stiff hairs, the hairs up to 1.5 mm long. Glumes 3.4–4.3 mm long, lanceolate, about equal in length, shorter or longer than the floret, membranous, 1-veined, scaberulous along vein; margins hyaline; apex acute to acuminate. Lemmas 3.8–4.3 mm long, lanceolate, membranous, yellowish-green, 5-veined, scaberulous, awned; apex acute, entire; awn 4–6 mm long, yellowish, borne on the upper 1/3 or 1/4, straight or twisted and once-geniculate; callus obtuse with short white hairs, the hairs 0.2–1 mm long. Paleas 3.8–4.4 mm long, as long or slightly longer than the lemma, hyaline, 2-veined, the veins scaberulous, green; apex acute, entire. Lodicules 0.7–0.8 mm long, lanceolate, lobed, glabrous. Stamens 3; anthers 1.8–2.2 mm long, yellow. Ovary 0.2–0.4 mm long, glabrous; styles 2, separate; stigmas 2, feathery, whitish. Caryopses 1.8–2.5 mm long, fusiform, light brownish.

Phenology.—Flowering in September.

Distribution.—*Calamagrostis divaricata* is known only from the type locality growing on moist slopes and mossy cliffs with *Pinus cooperi* C.E. Blanco, *P. durangensis* Martínez, *P. ayacahuite* C. Ehrenb. ex Schltdl., *Quercus sideroxyla* Bonpl., *Arbutus occidentalis* McVaugh & Rosatti, *Cupressus arizonica* Greene, and *Muhlenbergia alamosae* Vasey.

DISCUSSION

Calamagrostis coahuilensis remained undetected by biologists for almost 19 years. The first collections of this species were apparently made by McDonald

Fig. 3. *Calamagrostis divaricata* (*Peterson, González-Elizondo & Teña-González 17774*). **A.** Habit. **B.** Inflorescence. **C.** Sheath, ligule, and blade. **D.** Spikelet. **E.** Lower glume, dorsal view. **F.** Upper Glume, dorsal view. **G.** Lemma, dorsal view. **H.** Lemma, ventral view. **I.** Palea with rachilla, dorsal view. **J.** Palea, dorsal view. **K.** Stamens and pistil. **L.** Gynoecium, mature. **M.** Lodicules.

in 1985 from the Cumbre de Cerro Potosí. All specimens that we have seen from Coahuila and Nuevo León that were previously determined as *C. purpurascens* or *C. pringlei* are *C. coahuilensis*. Therefore, *C. purpurascens* is not found in México. *Calamagrostis coahuilensis* is morphologically similar to *C. purpurascens*, but can be separated from the latter by having anthers that are shorter (1–1.2 mm long), ligules that are nearly smooth, a scaberulous rachis, sheath summits that are glabrous or minutely antrorsely scabrous, and greenish panicles that are somewhat dense but not spikelike (Table 1). Populations of *C. coahuilensis* are separated from the closest known locality of *C. purpurascens* in the Sangre de Cristo Mountains, Taos County, New México (Allred 1993) by over 800 mi. McDonald (1990) and Garcia-Arevalo and González-Elizondo (1991) first reported *C. purpurascens* from Coahuila and Nuevo León, México. Apparently, Manuel González-Ledesma, John Reeder, and Charlotte Reeder identified the grasses for McDonald (1990) since they appear in the acknowledgments for having reviewed that family. This is not surprising since in most characteristics the range of variation in *C. coahuilensis* overlaps that of *C. purpurascens*. An adequate illustration (*Ochoa 983*) of the new species appears in Beetle's (1987) treatment of the grasses of México, although he referred to it as *C. pringlei*.

It is surprising that *C. divaricata* is known only from a single, recent collection since it occurs near a rather heavily used tourist destination. *Calamagrostis divaricata* seems morphologically allied to *C. pringlei* and can be differentiated from the latter by having wider panicles (4–10 cm) with branches reflexed spreading and divaricate, shorter spikelets (3.4–4.3 mm long), shorter glumes (3.4–4.3 mm long) that are both 1-veined, and shorter lemmas (3.8–4.3 mm long) with an awn inserted on upper 1/4 to 1/3 (Table 1.).

The infrageneric classification of *Calamagrostis* has not been critically tested, and it is not usually discussed for the New World, other than the acceptance of the segregate genus *Deyeuxia* by some South American taxonomists (Rúgolo de Agrasar 1978, 1998; Villavicencio 1995). The genus (including *Deyeuxia*) is divided into at least four subgenera with many sections, subsections, and series (Rozhevits & Shishkin 1963; Tzvelev 1976; Wasiljew 1960). All of these Russian agrostologists placed *C. purpurascens* in *Calamagrostis* sect. *Deyeuxia* (Clarion ex P. Beauv) Rchb., and Wasiljew (whose classification was world-wide in scope) placed *C. pringlei* in the same section. Several infrageneric taxa were accepted for the New World (Soreng et al. 2003). Based on callus hair length (1/2 or less the lemma length), lemmas membranous, and presence of a well-developed rachilla extention, both of the new species appear to belong in *Calamagrostis* subgen. *Deyeuxia* sect. *Deyeuxia*. A key for separating the two new species from other species of *Calamagrostis* in northern México (Chihuahua, Coahuila, Durango, Nuevo León, Sinaloa, and Tamaulipas) follows.

Table 1. Salient features comparing *Calamagrostis coahuilensis*, *C. divaricata*, *C. pringlei*, *C. purpurascens*, and *C. valida*.

Characters	***C. coahuilensis***	***C. divaricata***	***C. pringle***	***C. purpurascens***	***C. valida***
Cataphylls & lower leaf sheath abaxial surface	glabrous	glabrous	densely hirtellous	glabrous or scaberulous	glabrous
Leaf sheath summit abaxial surface	glabrous or minutely antrorsely scabrous	glabrous	glabrous	glabrous or minutely retrorse-Strigulose	Densely hirtellous
Leaf blade & ligule adaxial surface	glabrous or nearly smooth	glabrous	glabrous	scabrous	sparsely hirtellous
Inflorescence width	0.5–1.2 cm	4–10 cm	2–4 cm	0.8–1.5 cm	(1.5–)4–10 cm
Inflorescence branches, arrangement & spikelet placement	ascending and closely appressed; ±floriferous to base	ascending, reflexed spreading to divaricate; not floriferous to base	ascending, loosely appressed or spreading; not floriferous to base	ascending and closely appressed, spike-like; +floriferous to base	ascending, appressed to base spreading; ± floriferous to base
Spikelet length	5.8–7.2 mm	3.4–4.3 mm	(4.5–)5–5.8 mm	5–9 mm	4–6.5 mm
Spikelet color	greenish	yellowish-green	pale green to purplish	yellowish-purple	yellowish-purple
rachilla length	2.4–3 mm	1.6–1.9 mm	1.5–2 mm	1.8–3 mm	1.5–2 mm
rachilla hair length	0.5–1 mm	0.8–1.5 mm	1–2 mm	1–2 mm	2–3 mm
Glumes length	5.8–7.2 mm	3.4–4.3 mm	(4.5–)5–5.8 mm	5–9 mm	3.4–6.5 mm
Upper glume, number of veins	one	one	three	one	(one) three
Lemma length	5–5.7 mm	3.8–4.3 mm	4.5–5 mm	4–7 mm	3.4–5 mm
Lemma surface	smooth	scaberulous	scaberulous	scaberulous	smooth
Lemma veins, aspect	conspicuous	inconspicuous	inconspicuous	inconspicuous	inconsp./conspicuous
Lemmatal awn insertion	base, lower 1/6	upper 1/4 to 1/3	lower 1/3 to middle	lower 1/6 to 1/3	near middle
Lemma apex	entire or bifid with age	entire	entire	bifid	two or four setae or teeth (prolongation of veins)
Callus hair length	0.8–1.8 mm	0.2–1 mm	0.2–1 mm	0.7–2 mm, occasionally absent	1.3–2.8(–3.5) mm
Anther length	1–1.2 mm	1.8–2.2 mm	2.2–2.4 mm	1.5–3.5 mm	1.4–2.2 mm
Anther color	purple	yellow	yellowish-purple	purple or yellow	yellow or purple

KEY TO THE SPECIES OF *CALAMAGROSTIS* IN NORTHERN MÉXICO

1. Panicles 0.5–1.5 cm wide, contracted, densely flowered; lemma awn inserted at base or on lower 1/6 to near lower 1/4; anthers 1–1.2 mm long _____ **Calamagrostis coahuilensis**
1. Panicles 1.5–10 cm wide, narrow to open and loosely flowered; lemma awn inserted from lower 1/3, middle, and upper 1/4; anthers 1.4–2.4 mm long.
    2. Lemma apex with two or four setae or teeth (prolongation of veins); callus hairs 1.3–2.8 mm long; rachilla hairs 2–3 mm long; leaf blade, ligule, and summit of sheath sparsely hirtellous _____ **Calamagrostis valida**
    2. Lemma apex entire and without setae or teeth; callus hairs 0.2–1 mm long; rachilla hairs 0.8–2 mm long; leaf blade, ligule, and summit of sheath glabrous.
        3. Upper glume 3-veined; spikelets (4.5) 5–5.8 mm long; lemmas 4.5–5 mm long, awn inserted on lower 1/3 to middle; panicles 2–4 cm wide, the branches loosely appressed or spreading but not divaricate _____ **Calamagrostis pringlei**
        3. Upper glume 1-veined; spikelets 3.4–4.3 mm long; lemmas 3.8–4.3 mm long, awn inserted on upper 1/3 to 1/4; panicles 4–10 cm wide, the branches reflexed spreading, divaricate _____ **Calamagrostis divaricata**

ACKNOWLEDGMENTS

We wish to thank the Smithsonian Institutions, National Museum of Natural History, Biodiversity and Inventory Program, and Research Opportunities Fund for supporting the fieldwork. Appreciation is extended to Alice R. Tangerini for providing the illustrations; Susan J. Pennington for preparing the distribution map; Alain Touwaide and Dan Nicolson for correcting the Latin diagnoses; Kelly Allred and Rich Spellenberg for checking the distribution records in New Mexico; and Teresa Mejia-Saulés for finding inconsistencies in the manuscript.

ETHNOBOTANY OF *RHODIOLA ROSEA* (CRASSULACEAE) IN NORWAY

Torbjørn Alm

Department of Botany
Tromsø Museum
University of Tromsø
N-9037 Tromsø, NORWAY

ABSTRACT

Rhodiola rosea is a widespread species in Norway. It is well known in Norwegian folk tradition, with a variety of vernacular names, of which many reflect its traditional uses. Past use as a cure for scurvy in cattle may explain names with the prefix *kalv-* ("calf"). Its widespread use as a hair wash is also reflected in vernacular names. In the past, *Rhodiola* was planted on turf roofs to protect them from fire, i.e. as an apotropaic (supposedly averting evil forces); this tradition is documented as early as the 13th century.

SAMMENDRAG

Rosenrot *Rhodiola rosea* er en vanlig og vidt utbredt art i Norge. Den er vel kjent i folketradisjonen, med en lang rekke folkelige navn. En god del av disse gjenspeiler artens tradisjonelle bruksområder. Bruk som et botemiddel mot skjørbuk hos kyr kan forklare de mange navnene på *kalv*. Den flittige bruken til hårvask går likeens igjen i mange lokale navn. Tidligere ble rosenrot ofte plantet på tovtak for å beskytte dem mot brann, dvs. som er verneråd; denne tradisjonen er dokumentert allerede på 1200-tallet.

INTRODUCTION

Rhodiola rosea L. (Crassulaceae) (syn. *Sedum rosea* (L.) Scop., *S. rhodiola* DC.) is a common species in the mountains and coastal districts of Norway, occurring abundantly both on coastal cliffs and in alpine habitats, from sea level to 2280 m a.s.l. in the mountains of Central Norway (Elven 1994). The lowland plants belong to subsp. *rosea*, whereas those of high mountain habitats are similar to the arctic subsp. *arctica* (Boriss.) Á. & D. Löve (Elven 1994). The species as such is easily recognizable.

The genus *Rhodiola*, formerly often included in *Sedum*, comprises about 50 species, centered on the mountains of East Asia (Springate 1995). Whereas *Sedum* has hermaphroditic flowers, many *Rhodiola* species, including *R. rosea*, are dioecious (Lippert 1995). *Rhodiola rosea* is a hemicryptophyte with thick rhizomes. The annual shoots are unbranched, and densely clad with flat, fleshy leaves. *Rhodiola rosea* has a circumpolar-montane/alpine distribution (Hultén & Fries 1986; Lippert 1995). Hultén (1958) considered *R. rosea* "A collective species consisting of numerous races differing chiefly in size, form and dentation of the leaves and in the colour of the flowers."

Rhodiola rosea has received increased attention during the last few years, not least due to its alleged medical properties, e.g. as an adaptogen, supposedly enhancing memory, stress mastering, etc.; some of these effects have been confirmed by recent studies (Boon-Niermeijer et al. 2000; Spasov et al. 2000). Germano & Ramazanov (1999) provide extensive references to Russian literature on its medical properties. For a review of current knowledge, see Brown et al. (2002).

Folk tradition claiming positive health effects derives largely from Asia (eastern Russia, Mongolia, China). Norwegian tradition is less inclined to claim "wondrous" properties, but may provide valuable information of potential uses. Both the rhizomes and flowering stems of *R. rosea* have found a number of uses in folk tradition in Norway. The present paper aims at a comprehensive review of the ethnobotany of *R. rosea* in Norway, including vernacular names, medicinal uses and other traditions. Unless otherwise stated, all citations have been translated from Norwegian.

Sources

Høeg (1974) assembled a vast body of information on plant names and uses in Norway, including a three-page chapter on *Rhodiola rosea*. It is largely based on his own data, and fails to incorporate more than a fraction of existing literature, e.g. the interesting note of Søreide (1952). Nordhagen (1934) studied the old tradition of planting *R. rosea* on house roofs in Norway. Alm (1996a) discussed its past use as a cure for scurvy. Recently, Dragland (2001) reviewed data on *R. rosea* as part of a project aimed at commercial cultivation in Norway. His report includes some ethnobotanical data, but these are largely culled from Høeg (1974) and some secondary sources.

Scattered notes on *R. rosea* and its uses in Norway occur in numerous other publications on folk medicine and other traditions. In addition to these, I have incorporated some data from archival sources, mainly NFS (Norsk folkeminnesamling/Norwegian folklore collection) and NOS (Norsk ordbok, seddelarkivet/Norwegian dictionary, card archive). Furthermore, some data have been excerpted from my own ethnobotanical field work in North Norway; these are referred to as "interview + year." Informants are not identified here; transcripts and some recordings of the original interviews are stored at the Department of Botany, Tromsø Museum (TROM).

Vernacular Names

In Norwegian folk tradition, widespread and well-known plants are usually known either under a single, ubiquitous vernacular name (e.g. *blåbær*, "blue berries" for *Vaccinium myrtillus* L.), or display a substantial array of widely different names (e.g. more than 100 names for *Dactylorhiza maculata* (L.) Soó, see Alm 2000). With more than a half-hundred Norwegian vernacular names recorded so far, *Rhodiola rosea* belongs to the latter group. No record of its Norse name (or names) seems to have survived (Heizmann 1993); the oldest names included in the present paper date back to 1599. A compilation of Norwegian and Sámi names is found in Table 1. Some are of local use, and may be confined to a single village; others are widespread. A couple of name-groups (see Fig. 1) are of particular interest:

a) In Western Norway, *R. rosea* has a set of names with the prefix *syste*—or *syster, systre, søster* and similar terms (Høeg 1974; Lagerberg et al. 1955; Lid 1941; Nordhagen 1934; Søreide 1952; Strøm 1762), e.g. *systegras* ("-gras"), *systelykjil* ("-key"), *systerøter* ("-roots"). Nordhagen (1934) noted only a deviant form, *systergras* ("-grass"), and suggested that *syster* (interpreted as meaning "sister") might refer to the occurrence of separate male and female plants—perhaps a rather too botanical explanation, though Høeg (1974) noted that people at least locally had noticed that there were two different kinds of plants. The latter author recorded a number of similar names, partly with *syste-* and partly with *syster-*. He suggested the latter to be correct, perhaps influenced by the linguist Ivar Aasen's record of *søstregras* ("sisters grass") at Sunnmøre in the 1830s (see Lid 1941). Evidently, Høeg was not aware of the discussion in Søreide (1952), who argued convincingly that the prefix was related to the verb *syste* or *syfte*, "clean" or "purify." *Syftesok* is an old calendar term for July 2, at which date apotropaic plants (e.g. twigs of *Alnus* sp. and *Juniperus communis* L.) were placed in the fields to ward off vermin (Bugge 1921; Riste 1916; Søreide 1952; Wille 1786). Thus, *systegras* and similar names may suggest that folk tradition ascribed *Rhodiola rosea* abilities to ward off evil. This is confirmed by the widespread belief in the plant's ability to protect against fire (see below). The prefix *syster-* (and *søster-*), i.e. "sister," is probably a younger re-interpretation of an old name.

b) In most of North Norway, *R. rosea* is known under names with the prefix *kalv-* or *kalve-* ("calf"), e.g. *kalvegress* ("calf grass"), *kalvedans* ("calf dance"), and others (Alm 1996a; Elvebakk 1979; Heltzen 1834; Høeg 1974; Lagerberg et al. 1955; Mørkved 1996; Øksendal 1977; Qvigstad 1901; Strompdal 1929; NOS). *Kalverot* ("calf root") is also mentioned from the Bergen area in 1599 (Bring 1758; Holmboe 1953; Lagerberg et al. 1955; Rørdam 1873). The name may well derive from North Norway, which was the source of most of the fish exported from the major trade port of Bergen. The origin of the prefix *kalv-* is unclear. Alm (1996a) suggested that it might be due to the past use of *R. rosea* as cattle fodder, potentially an important cure for scurvy (see below). An alternative explanation is a relation to the old Norse term for the thick muscle on the hind side of the leg (Lagerberg et al. 1955), still known (by a Norse loan-word) as *calf* in English. If so, *kalv-* might refer to *R. rosea*'s thick leaves. At least some of the associated suffixes support the former interpretation, e.g. *kalvegror* ("calf growth") and perhaps the widespread *kalvedans* ("calf dance"); an unlikely acitivity for starving cattle. Reichborn-Kjennerud (1922) suggested that *kalvedans* could refer to the plant's dancing and nodding behaviour in wind, but this leaves the

Table 1. Norwegian and Sámi vernacular names for *Rhodiola rosea* in Norway. Names are given with modern Norwegian and North Sámi spellings; deviant spellings used in the original sources are indicated. "Interview" refer to ethnobotanical records made by the author. As far as possible, geographic origin is indicated, using present-day administrative units (counties and municipalities). English translations are literal, but note that some may be folk re-interpretations of older names (see text). A few terms cannot be translated, e.g. the suffix *tort*, otherwise a frequent vernacular name for *Cicerbita alpina* (L.) Wallr., and *mo/mosott*, which are widespread Norwegian terms for a somewhat diffuse disease.

Gálbberáhta	Calf sprout	North Norway: Finnmark: Alta (interview 1998)

TABLE 1. continued

Vernacular name	English translation	Area and source
North Sámi		
Gálbberássi	Calf grass	North Norway: Troms: Lavangen (Qvigstad 1901:311, as galbe-rasse); Finnmark: Deatnu/Tana (interview 1996)
Gálbberássit	Calf grasses	North Norway: Troms: Lyngen (Qvigstad 1932:78, as galberaset)

prefix unexplained. The few Sámi names recorded so far, *galbberáhta* ("calf sprout") and *galbberássi* ("calf grass"), belong to the same name complex.

c) Vernacular names with the prefix *hår-* ("hair") occur in parts of southern Norway (Dahl 1898; Donali 1988:587; Høeg 1974; Lagerberg et al. 1955; Nordhagen 1934; Reichborn-Kjennerud 1941; Rise 1947; Schübeler 1888; NOS). They obviously reflect the use of a decoction of *R. rosea* as a hair wash. Vernacular names incorporating the term *kaur* or *kaure*, meaning something curly, may also refer to such use (Nordhagen 1934, 1947).

d) *R. rosea* has sometimes appropriated vernacular names more frequently used for other species, e.g. *smørbukk* ("butter buck"), more frequently a name for *Hylotelephium telephium* (L.) Ohba (syn. *Sedum telephium* L.), e.g. in inland areas adjacent to the latter's mainly coastal distribution (Halvorsen 1988; Kirkevoll 1940), and *taklauk* ("roof onion"), normally *Sempervivum tectorum* L., at a few stations (Vegusdal 1979).

e) A deviant name, *knerke*, was recorded from Hammerfest, Finnmark by Høeg (1974); two informants both explained it as an onematopoeticon: "it squeaks when the flowers are touched"; "if the leaves are touched, one hears a squeaking sound" (translated from Norwegian). This seems to be a well-known tradition in parts of Finnmark; one of my own informants knew the name *kalvedans* from the same area, but suggested *knerke* as an alternative name: "That sound when you touch them, it says [knerke]... I think it was a sound-like name we had." (interviews 1998 & 2002). A few other, sound-based vernacular names are known from North Norway (Table 1).

Rosenrot ("rose root"), the "official" Norwegian name of *R. rosea*, has been introduced through floras. It was first used in the Danish herbal of Paulli (1648), probably based on the German *Rosenwurz*, and has no root in Norwegian folk tradition (Høeg 1974; Nordhagen 1934).

Only two Sámi names for *R. rosea* have been recorded in Norway: *gálbberássi* both in Troms and Finnmark, and *gálbberáhta* in the latter county. *Gálbberássi* is obviously a Norwegian loan-word, identical to "kalvegras." Qvigstad (1901, 1932) noted it from Lavangen and Lyngen, Troms. It is still used, and was re-

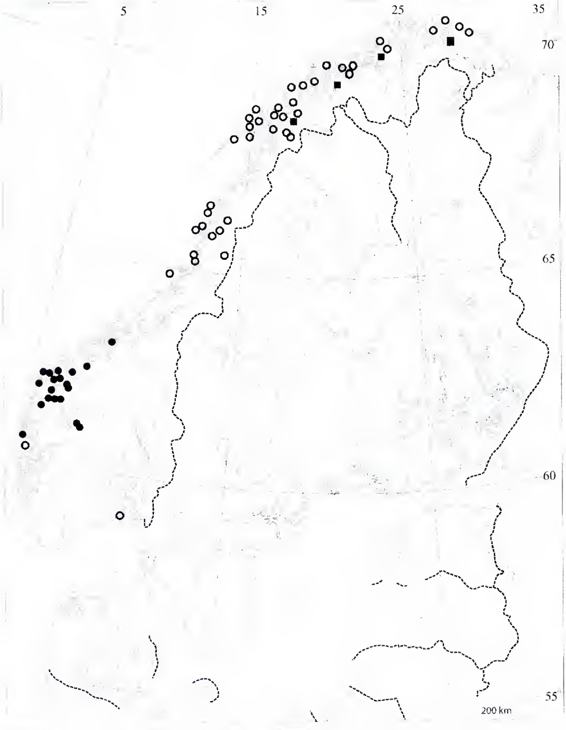

Fig. 1. Geographical distribution of two major groups of vernacular names for *Rhodiola rosea* in Norway. **A.** Norwegian names with prefix of the *syste(r)/søster* type, based on the verb *syfte* or *syste*, "protect" (dots). **B.** Names with a prefix meaning "calf": Norwegian *kalv-/kalve-* (open circles) and North Sámi *gálbbe-* (squares).

corded in the Deatnu/Tana area of Finnmark in the 1990s (Alm & Iversen, unpublished data).

Rhodiola rosea as a Cure for Scurvy

Nordal (1939) studied the contents of vitamine C in various plants species traditionally used to treat scurvy in Norway. Scurvy-grass *Cochlearia officinalis* L. and cloudberries *Rubus chamaemorus* L. may have been the most important of these, at least for human use (Alm 1995, 1996b; Eckblad 1989). *Rhodiola rosea* contains less vitamine C; 12 mg/g (rhizome) and 33 mg/g (fresh leaves) according to Nordal (1939, 1946). Still, it may have been an important source, in particular for livestock (Alm 1996a). Insufficient feeding of cattle during the winter was an established tradition in Norway, and if spring was late, livestock could be heavily affected by scurvy. Cloudberries (and, perhaps less so, scurvy-grass) were reserved for human consumption, but *Rhodiola rosea* was not. Secondly, due to its preference for cliff habitats, the rhizomes could be collected even in late winter. It is also one of the first plants to sprout in spring, and both rhizomes and fresh shoots may thus have served as an important remedy for scurvy in livestock. Records in Elvebakk (1979) and Høeg (1974) confirm that *R. rosea* was usually collected during the period of fodder shortage in late spring. As noted above, such use is a likely explanation for the wide-spread vernacular names with *kalv-* as a prefix, which may thus reflect the species' importance for making cattle (and calves) survive (Alm 1996a; Høeg 1974).

A letter to Olaf I. Rønning, then curator at Tromsø museum, was sent as a response to his popular account (Rønning 1959) of *R. rosea* and its uses. The comment, based on tradition at the west coast of Senja island, Troms county, confirms the use as cattle fodder:

> "In my childhood, about the turn of the century [1900], we [as] children were frequently told to collect *kalvegror*, i.e., *rosenrot* [*Rhodiola rosea*]. It was used as fodder for calves, [which had been] born during the winter, in spring. As it was almost always a shortage of fodder [at this time], the *kalvegror* was a welcome food for the calves (and a vitamine source). The *kalvegror* sprouted earlier than other plants (in our area of southern Berg, and the islets) and was easy to get hold of" (letter from Paul Hay, Gryllefjord, dated January 20, 1960).

Some early data on *R. rosea* ethnobotany, including its use as an antiscorbutic, were recorded during the Danish-Norwegian king Christian IV's naval expedition to the northern outposts of his kingdom in 1599 (Alm 1996a; Nielsen 1873). At least two of the Danes participating (Sivert Grubbe and Jonas Charisius) wrote diaries. A comparison of the two leaves no doubt that Grubbe was the better botanist; his diary (Bring 1758; Rørdam 1873) contains scattered notes on plants seen during the voyage. Despite this, Charisius (1773-76) is more frequently cited, often from an 18th century transcript by Hans Paus (extracts e.g. in Hansen & Schmidt 1985).

Although the most interesting comment on *R. rosea* was made during a visit to the NW Kola peninsula, now on Russian territory (but also claimed as belonging to the king's territory), it is worth recording here: "On this island Kildin there is found a kind of herb at the shore, which the Sámi and Russians call orpin, and [which] is very remarkable to use for scurvy, the root smells of rose, and tastes well in beer" (Charisius 1773-76:74; Hansen & Schmidt 1985:191, translated from Danish).

Qvigstad (1901), in his survey of Sámi plant names, accepted *orpin* as an East Sámi term. It is not, however, included in a dictionary of East Sámi as used in the Kola Peninsula (Genetz 1891). As noted by Alm (1996a), *orpin* is the French name of *R. rosea*, and it is highly unlikely that a similar name should occur in both East Sámi and Russian. The suggestion that it was termed thus by the Sámi is obviously wrong; educated Russians could perhaps have known this name. Qvigstad (1901) couples *orpin* with the Norwegian term *Stubberod*, seemingly as a translation. The latter name is mentioned in Grubbe's Latin diary, in the entry for May 18, 1599:

> "Collegimus in isto monte herbas, quas angli vocant orpin, Norvegi *Stubberod*, præsentissimum remedium contra scorbutum, in illis locis valde familiare. Capitaneus noster usus est illius herbæ foliis loco acetarii." (Bring 1758:40–41)—"In this mountain we collected some herbs, which the English call *orpin*, the Norwegians *stubberod*, an excellent remedy for scurvy, and very frequent in these places. Our captain [king Christian IV] used the leaves of this plant as a salad."

Thus, Grubbe certainly did not record *orpin* as a local name (though it was hardly an English term either, as he believed). *Stubberod* (*stubberot* in present-day Norwegian) is clearly identified as a Norwegian name, otherwise unknown, but easily comprehensible; its meaning ("stump root") is a descriptive term for the rhizomes in their early spring state, i.e., just at the time they were presumably gathered as a cure for scurvy.

Pontoppidan (1752) also noted that *R. rosea* had "en herlig Kraft mod Skiørbug"—"a splendid force against scurvy." Gunnerus (1766) mentioned that "Radix scorbuticis salutaris"—"the root heals scurvy"; this seems to be the last suggestion of human use as an antiscorbutic in Norway.

Rhodiola rosea as Food

Both the rhizomes and green parts of *Rhodiola rosea* are edible. Human consumption is well known from other areas, e.g. Siberia, but seems to have been rare in Norway—at least according to our present knowledge. Ruge (1762), vicar in Valdres, advocated plantations of *R. rosea* as food in times of need, but it is unlikely that this idea was based on local tradition. On the contrary, he referred to Egede (1741), who had noted that the rhizomes were eaten in Greenland. Ruge added that "I have eaten it myself, both fried and roasted as well as cooked, and neither in taste nor effect have I found it unpleasant." (Ruge 1762:286).

Høeg (1974) recorded a single, modern instance of *R. rosea* consumption in western Norway; an informant from Uvdal (Buskerud, SE Norway) claimed that the leaves had been ground and mixed in dough. In addition, children could eat the fresh leaves.

According to Engan (2002), people at Sørfold in North Norway used ground bark of birch (*Betula pubescens* Ehrh.) as a flour substitute during times of need. The resulting flour was coarse and hardly suited for dough. In order to improve it, an unidentified alpine herb called *fjellbu* ("mountain plant") was added. The brief description included fits *Rhodiola rosea*, and hardly anything else, suggesting that it may have had some tradition as an emergency food. No information is given on the plant part used, only that it was boiled before being added to the flour.

Rhodiola rosea as Hair Wash

A decoction of *R. rosea* has been widely used as a hair-wash in Norway, e.g. along the western coast northwards at least to Nordland (Donali 1988:587; Gunnerus 1766; Høeg 1974; Hukkelberg 1952; Lagerberg et al. 1955; Reichborn-Kjennerud 1922, 1941; Rise 1947; Strøm 1762; NOS). This is frequently indicated by its vernacular names (see above), as noted e.g. by the latter author: "In the fjords, it is called Søster-Græs [i.e. sister grass], but otherwise everywhere [at Sunnmøre, western Norway] Haar-Voxter [hair growth], because one boils it in water and washes the hair with it, in the belief, that it will grow well thereafter" (Strøm 1762:119). Two hundred years later, folk tradition in Møre og Romsdal remained unchanged: "*Søstergras* [sister gras] is also called *hårvokster* [hair growth] because if one boiled it in water and washed the hair with it, the hair would grow much better afterwards" (Hukkelberg 1952:37).

The motivation for using *R. rosea* as a hair-wash, according to folk tradition, varies slightly. Some claimed that it prevented hair loss (Donali 1988; Rise 1947), and ensured a long, fine hair, others that it stimulated hair growth or healed various complaints affecting the hair, e.g. dandruff. An undated archival note, again from Møre og Romsdal, adds a piece of folk etymology: "Women who were about to loose their hair made a kind of hair oil from *rosenrot* which made the hair grow well—for this reason [it was] called *søstergras* [sister grass]." (NFS Maurits Fugelsøy III:7).

At Narvik in Nordland, North Norway, folk tradition claimed that plants for use as hair wash should be collected in spring or early summer:

> "If you manage to collect *kalvegrot* before the cuckoo [*Cuculus canorus*] cries, and then boils a decoction from it, it is good for washing the hair." (NOS, unpublished 1940s note by Hallfrid Christiansen).

Other Medical Uses

Apart from its use a an antiscorbutic and as a hair-wash, *Rhodiola rosea* has found little use in Norwegian folk medicine. Høeg (1974) noted that it had been used as a remedy for lung diseases at Volda, W Norway, but also that this might be inspired by its local vernacular name, *lungerot* ("lung root"). From the Nordfjord area of W Norway, Krogh (1813) merely noted that the rhizome was sometimes used as a medicine, and considered an adstringent. According to Kirkevoll (1940), *R. rosea* was "much used as an ointment for wounds" in the

Valdres area of interior SE Norway. In Sunnfjord, W Norway, a poultice of *R. rosea* and ground oats *Avena sativa* L. was used to treat wrenched or swollen limbs (Reichborn-Kjennerud 1922; NFS Gade-Grøn 149). The vernacular name *mosottrot*, used in Snåsa, Nord-Trøndelag (Høeg 1974), also implies a medical use. In folk medicine, *mosott* was a frequently diagnosed, if rather ill-defined disease, usually treated with magical means, in particular "measuring" the patient's body with a woolen tread.

In Lyngen (Troms, North Norway), Sámi folk medicine used a decoction to treat urinary disorder (Qvigstad 1932; Steen 1961): "A decoction of *Rhodiola rosea* (...) is drunk, and the softened roots [rhizomes] are rubbed at both sides of the joint. When the urine starts to drip, another mouthful is consumed." (Qvigstad 1932:78; translated from German).

In his late 17th century topographical description of Finnmark, district govenor Hans H. Lilienskiold mentioned that the Sámi of Finnmark used rose water to treat eye diseases (Qvigstad 1932). No further details are given. *Rosa majalis* J. Herrmann is the only species of the genus occurring in Finnmark, but it is very rare, and it it thus possible that the cure was a decoction of *Rhodiola rosea*, with its characteristic, rose-like odour.

Folk Veterinary Medicine

Apart from its use to heal (or prevent) scurvy, there are few records of *Rhodiola rosea* being used in folk veterinary medicine in Norway. Høeg (1974) noted that people at Hølonda (Sør-Trøndelag, Central Norway) had used it as a "horse medicine, long ago"—which does not exclude the possibility that even this was as a cure for scurvy.

In Hardanger, W Norway, a decoction was given to cattle to treat many kinds of disease, in particular intestinal parasites (Reichborn-Kjennerud 1922). The original record, by Lars T. Steine, dated 1920, is found in the NFS archives:

> "*Hedlekaure* is the name of a plant that grows preferably in the shade (...) It was used for all kinds of animals; it was boiled and given in drink; it was good for many kinds of livestock diseases in particular intestinal parasites" (NFS Gade-Grøn 148).

***Rhodiola* on House Roofs**

Rhodiola rosea was formerly a frequent sight on turf roofs in Norway. According to a widespread tradition, its presence there should protect against fire, e.g. caused by lightning (Fægri 1944; Haukdal 1961; Høeg 1974; Lagerberg et al. 1955; Nordhagen 1934; Vegusdal 1979). A similar tradition related to *Sempervivum tectorum* L. is widespread in Europe. *S. tectorum* is not an indigenous species in Norway, but has a long history of cultivation, and is naturalized at scattered stations in southernmost Norway (Elven 1994; Nordhagen 1941). Both living plants and the associated traditions are likely to have been imported from Central Europe during the middle ages. Further north in Norway, in areas where *S. tectorum* does not thrive, *Rhodiola rosea* has acquired a similar reputation of protecting roofs from fire. According to folk tradition in Gauldal, Central Norway, its purpose was to avert the anger of Tor, the Norse god who controlled thunder and lightning:

> "It was the god Tor who was to be appeased by planting *fjellkransen* on the roof. When he saw the yellow flower on the roof, he passed by without striking it with fire." (Haukdal 1971:141).

The occurrence of an unidentified herb "on everyone"s house roof" in Bergen in the early 13th century is mentioned in the saga of the Norwegian king Håkon Håkonssøn. Nordhagen (1934) argued convincingly that the unnamed plant had to be *R. rosea*. Its use on house roofs is also mentioned in a 16th century description of Bergen (Nordhagen 1934, 1941), and remained well-known as long as turf roofs were common, i.e. well into the early 20th century. This practice is documented from much of southern Norway, especially along the west coast, northwards to the Salten area of Nordland, North Norway (Donali 1988; Grue 1943; Haukdal 1961; Høeg 1974; Kirkevoll 1940; Leirfall 1968; Nordhagen 1934; Søreide 1952; Strompdal 1929; Vegusdal 1979; Vreim 1943). In Beiarn, Nordland, people believed that the custom had been introduced from Bergen (Vegusdal 1979).

Melheim (1953) studied the flora of turf roofs in Hornindal, W Norway in the early 1930s. *Rhodiola rosea* was still frequent, and always planted if found on house roofs, but people could not any longer give any traditional reason for this practice: "Some said it was because the plant was so beautiful, others because great-grandpa had wished it, others because their neighbours had it like that." (Melheim 1953:49).

Norman (1894), in his flora of Norway north of the Polar Circle, recorded numerous stations of *R. rosea* on house roofs, noting for one of these that it was "som sedvanlig plantet"—"as usual planted." Nordhagen (1934) saw several roofs with planted *R. rosea* in Nordland in the 1930s, and recorded vestiges of an oral tradition related to such use. Vreim (1943:50) noted that he had seen "whole roofs of" *R. rosea* in Beiarn, Nordland. Vegusdal (1979:142) recorded a fading tradition in the same area: "Old superstition said that *fjelljkauren* [*R. rosea*] on the roof had power to protect from fire. Lately, some have retained the custom to keep up the old tradition at the farm, or because they found it decorative. In the past, there were few turf roofs, at least at Øynes, on which *fjelljkaur* had not been planted, and they grew well." This tradition may have been known further north as well, as indicated by the following note from Alta, Finnmark: "In Sámi, we call it *gálbberahttá*. And it used to grow on old turf roofs." (interview 1998).

Sempervivum tectorum may form dense mats of leaf rosettes, which may to some extent protect turf and straw roofs from fire (Fægri 1944). *Rhodiola* does not, and there is not much reason to believe that the plants as such had any real protective value. However, the belief may have some ecological justification. In Central Europe, *Sempervivum tectorum* thrives on old turf roofs, since these provide more humid conditions—and would thus less easily burn—than young or new roofs, which are much drier, just as *R. rosea* in Norway is often found on old turf roofs. Still, the Norwegian tradition of planting *Rhodiola* on turf roofs is likely to have been inspired by similar use of *Sempervivum tectorum* in areas further south, with *Rhodiola rosea* serving mostly as an apotropaic. Old photographs (e.g. in Nordhagen 1934 and Fægri 1944) frequently show only a single or a few plants placed along the ridge of the roof. On the other hand, Vreim (1943), in a booklet on timber houses and turf roofs, considered this as a useful practice, offering protection of the weakest part of the turf cover. In some cases, e.g. at Meråker (Nord-Trøndelag, Central Norway), *R. rosea* was placed over the door (Høeg 1974), reflecting a widespread European tradition of plants used as apotropaics to guard the house entrance.

The use of *R. rosea* on house roofs is probably rare by now, although many turf roofs still exist. A late 2002 search of the digital photo database at Tromsø museum yielded 908 photographs of turf roofs all over Norway, but not a single one with visible *R. rosea* stands.

People's belief in *R. rosea* as an apotropaic, protecting houses from fire, may be the reason for its celebrated mention in the saga of king Håkon Håkonssøn. In 1218, his mother, Inga of Varteig, was challenged to prove the royal parentage of her son by an ordeal of carrying hot iron. Prior to the task, Sigarr of Brabant, an employe of Earl Skule, suggested to one of her friends that she could protect herself from burns by salving her hands with the juice of a plant. When questioned where to find this wondrous herb, Sigarr answered "þat vex á þínum húsum ok hver manns hér i Bjorgyn"—"it grows on everyone"s house roof here in Bergen." As noted by Nordhagen (1934), *R. rosea* is the only likely candidate. Nordhagen, however, fails to note that the offer was refused; Earl Skule was one of Inga's enemies, and she may have had reason to consider the suggestion as an attempt at foul play (Hertzberg 1912)—perhaps as a means of persuading her that she had nothing to fear from the ordeal, and thus agree to it. If so, the plan failed. The ordeal was successfully completed, as far as the historical sources can tell without resorting to the protective powers of *R. rosea*, and Inga's son Håkon Håkonssøn went on to become one of the most illustrious Norwegian kings.

DISCUSSION

The uses recorded for *Rhodiola rosea* in Norway are closely reflected in other areas settled by people of Norse origin. Debes (1673) noted that a decoction was used as a kind of "rose water" in the Faroes, presumably as a hair wash; an ointment was used on wounds (Nordhagen 1934). An unpublished Faroese dictionary from about 1670 lists *R. rosea* as *hjalpirót* ("help root"), suggesting some kind of medicinal use, e.g. to improve hair growth (Lange 1960). In Iceland, a decoction of the fresh rhizome was used to wash the head as a cure for headache (Nordhagen 1934); such use was a part of older school medicine. *Rhodiola rosea* was also dried, mixed with butter, and used as an ointment on old wounds (Hallgrímson 1964; Mohr 1786).

In Greenland, the rhizomes of *R. rosea* were eaten by the Eskimos or Inuits (Birket-Smith 1928; Egede 1741; Høygaard 1941; Hughes 1960; Schübeler 1888); leaves and shoots were also consumed. It was also eaten by the Eskimos of North America. In Alaska, both the rhizomes, stems and leaves were eaten, partly fresh (Porsild 1953), fermented or frozen (Moerman 1998). The Eskimos of Nunivak Island, Alaska, prepared a tea from the flowers (Griffin 2001).

The former use of *R. rosea* to treat (or avoid) scurvy is in accordance with its rather high contents of vitamine C. Høygaard (1941, table D) found it to be the richest terrestrial plant source of vitamine C available to the Eskimos in his study area at East Greenland.

Rhodiola rosea is also found in the mountains of Central Europe, and had acquired some reputation as a medicinal plant in this area as well. It is included in several early herbals, e.g. Fuchs (1543) and Bock (1551), and the rhizomes (Radix rosea) were sold in pharmacies. The comments in the major Danish herbal of Paulli (1648) seems to be based mainly on Central European tradition. *Rhodiola rosea* does not occur in Denmark, and its use here was based on cultivated plants—Paulli noted that it was found in some "noble gardens"—possibly supplemented by plant material imported from Norway. Both in Denmark and in Central Europe, *R. rosea* was used to cure head-ache (Paulli 1648, Lippert 1995). The German-speaking farmers of South Tyrol (Italy) believed that a decoction in milk promoted pregnancy (Marzell 1979).

In terms of medical properties, the peoples of eastern Asia have found a much wider use of *Rhodiola* species than that of *R. rosea* in Norway and other parts of Europe. In Russian Siberia, *R. rosea* was considered an aphrodisiac, and supposed to ensure a long life. In Mongolia, it was used to treat cancer and tuberculosis. In China, both *R. rosea* (imported) and other *Rhodiola* species were prized for their medical qualities (Germano & Ramazanov 1999). As a cure for tuberculosis, *R. rosea* was also used by the western Eskimos of North America; the disease was treated with raw flowers (Lantis 1959). The Eskimos of Nelson Island, Alaska, used *R. rosea* to treat sores (Ager & Ager 1980).

Rhodiola species, e.g. *R. quadrifida* (Pall.) Fisch. & Mey., *R. rosea*, and *R. sacra* (Prain ex Hamet) S.H. Fu, are currently the focus of substantial interest in terms of medical and pharmacological properties. Studies of Asiatic species have revealed a vast array of chemical compounds (see Brown et al. 2002, Kurkin & Zapesochnaya 1986, Yoshikawa et al. 1995, 1996, 1997), including some with promising antiallergenic effects. The only biochemical study of Norwegian *R. rosea* so far, by Rohloff (2002), identified various terpenes and volatiles, but failed to identify some constituents (rosiridin, rosiridol) reported from Russian material of *R. rosea* (Kurkin et al. 1995), and found only neglible amounts of octadecadienoic acid, heptanol derivates and hexadecanoic acid, claimed by Belov et al. (1994) to be some of the main constituents. Thus, the biochemical characteristics of *R. rosea* may vary according to geographical origin, and Norwegian plants could differ from those found in Asia in terms of pharmacological properties—which would be in accordance with folk tradition in the two areas. Alternatively, its potential qualities were undetected in Norwegian tradition, or other plants were considered more effective. Norwegian *R. rosea* is rich in the phenylpropanoid rosavin (S. Dragland, pers. comm.), specific to *R. rosea* and now considered to be one the most important constituents in terms of medical activity (Brown et al. 2002), which might support the latter hypothesis. The sparse or absent use of *R. rosea* as food in Norway may also have a biochemical explanation; according to Høygaard (1941), Norwegian *R. rosea* has a much sharper taste than the plants found in Greenland.

At present, the old traditions related to *R. rosea* in Norway are probably fading away, e.g. its former use as an apotropaic on house roofs. The vernacular names are more likely to survive, at least as long as *R. rosea* remains a well known and popular ornamental, especially in rock gardens.

NOTES ON "COFFEE" FROM THE KENTUCKY COFFEETREE (*GYMNOCLADUS DIOICUS*, FABACEAE)

John P. Spaeth and John W. Thieret

Department of Biological Sciences
Northern Kentucky University
Highland Heights, Kentucky 41099, U.S.A.

ABSTRACT

The roasted/ground seeds of the Kentucky coffeetree (*Gymnocladus dioicus*, Fabaceae) were sparingly used in pioneer times as a substitute for arabica coffee. Preparation of the beverage, opinions on its smell and taste, toxicity of the plant, and history and present-day status of this use of the seeds are discussed.

RESUMEN

Las semillas del café de Kentucky (*Gymnocladus dioicus*, Fabaceae) se usaron en los tiempos de los pioneros como un sustituto del café. Se discute la preparación de la bebida, opiniones sobre su olor y sabor, toxicidad de la planta, historia y estatus actual del uso de las semillas.

INTRODUCTION

The assertion that the roasted and ground seeds of the Kentucky coffeetree (*Gymnocladus dioicus* (L.) K. Koch; Fabaceae) (hereafter KCT) can be brewed into a coffee-like beverage and that the Kentucky and Tennessee pioneers made such a beverage from them is repeated frequently in American and even European literature on New World edible wild plants (e.g., Allen & Allen 1981; Bean 1973; Browne 1857; Fernald & Kinsey 1958; Loudon 1838; Loz 1890; Nicholson 1883; Peterson 1978; Rogers 1905; Sargent 1889; Saunders 1920; Vannorsdall 1958; Wampler 2000). Most of the reports are quite definite concerning the pioneers: yes, the seeds were indeed so used by them. Some, though, are a bit uncertain, e.g., "Pioneers may have made a coffee substitute from [the] seeds" (Stacy 1992). Braun (1961) noted that the making of "coffee" from the seeds in Kentucky was in the Bluegrass region, where the tree is as common as or even more common than in most other places.

The Kentucky coffeetree ranges from New York to South Dakota, south to Virginia, and Oklahoma (Little 1977 [range map]; Spaeth n.d.). Its seeds (Fig. 1) are borne in large, woody, brown pods (legumes) (4.3)12–16.5(25?) cm long, 4–5 cm wide, and 1–2 cm thick. The pods remain on the tree throughout much of the winter; at a distance the tree appears to have a flock of birds among its leafless branches. Each pod contains a fleshy pulp in which are embedded 1–9 dark olive brown, hard seeds 1.1–2 cm long and wide and 0.6–1.3 cm thick. The seeds are rock hard—"adamantine," as Rogers (1905), with but slight hyperbole, well

Fig. 1. Kentucky coffeetree (*Gymnocladus dioicus*). Left, pods. Lower right, seeds (a U.S. penny included for size comparison). Upper right, ground seeds, the "coffee."

described them. Later, Rogers (1917) wrote: "How the pioneers ever crushed [the seeds] is a puzzle to all who have tried to break one with a nutcracker."

Living in the Bluegrass region and having access to an ample supply of the seeds, we decided to experiment by preparing a potable drink from them. Next we investigated the matter of toxicity of KCT and the history of beverage use of the seeds. Results of our trials and studies are reported here.

THE "COFFEE"

We found only four recipes for roasting the seeds. One internet site suggested roasting a cup of seeds, one layer thick, in an oven for 30 minutes (Rolen 2001). No temperature was specified, and 30 minutes did not seem to us long enough for any toxins possibly present in the seeds to dissipate (see "Toxicity" below). Another source, which we followed, gave more details: Brill and Dean (1994) suggested a "safe" way to make KCT coffee: bake the seeds in a "covered roasting pan" at 300° F for 3 hours (similar instructions are in Brill [2002] and Phillips [1998], although Phillips suggested 350° F).

On 5 Aug 2003, we put 30 seeds into each of four Pyrex jars labeled 1, 2, 3, and 4, respectively. One layer of seeds covered the bottom of each jar. The jars were roasted at 150° C (≅300° F). During the roasting, the room had at first an aroma of peanut butter. Jar 1 was removed after 2.0 hours, jar 2 after 2.5 hours, and jar 3 after 3.0 hours by which time four of the seeds had burst ("popped"). By the time jar 4 was removed (3.5 hours), the room had an aroma of something burning; 11 seeds had popped.

The next step was to establish a method of breaking the seeds, which were still rock hard. Without a corn grinder available (and fear that if we did have one, the seeds would break the grinder), we used pliers and a mortar and pestle. The seeds were first cracked open one-by-one with the pliers over the mortar. As they were cracked, most shattered or exploded so the cracking was done under a cloth that covered the mortar. They were then coarse-ground with the pestle, pulverized (Fig. 1) in a coffee grinder, and placed back into their respective jars, which were covered in plastic wrap to retain freshness. There appeared to be no relationship between the ease of cracking the seeds and the roasting times.

To make the "coffee," one heaping teaspoonful of ground seeds was placed in $^{3}/_{4}$ of a cup (≅175 ml) of boiling water. (This probably would have been the method used by pioneers.) The grounds were stirred and allowed to settle to the bottom. Twenty people were granted the opportunity to smell and taste this historical drink; their responses are listed in Table 1. No one claimed to enjoy the taste or the experience. All agreed that an overpowering and persistent aftertaste remained.

When the "coffee" was sweetened with sugar, the brew became "more palatable." The four participants who tasted it rated it as "acceptable," "like sweetened tea," "still rather unpleasant," and "could get used to it." The general consensus was that KCT "coffee" is not destined for supermarket shelves. A lot of work, with little pay-off, goes into roasting and grinding the seeds; this may be why some literature rates the brew as a poor substitute for coffee. The second author of the present paper drank about 1/3 cup of sweetened KCT "coffee" every day for 2 weeks, hoping that, with familiarity, the flavor might improve for him; it did not.

Yet, in contrast, some individuals rate the beverage more highly. Brill (2002) called it "the world's best caffeine-free coffee substitute"; his wife, too, likes the drink (Brill, pers. comm., Oct 2003). Phillips (1998) wrote that the beans make "a decent cup of caffeine-free coffee." The brew has been described also as "palatable and wholesome" (Thwaites 1905).

TOXICITY

Anyone wishing to prepare "coffee" from KCT seeds will probably have some interest in reports of the plant's toxicity to various organisms. KCT has long

TABLE 1. Opinions of the taste and smell of "coffee" brewed from ground, roasted seeds of Kentucky coffeetree in a 20-person taste/smell test, October/November 2003, Northern Kentucky University. Identical opinions were expressed by

several participants.

Taste	Smell
Akin to mud	Earthy
Horrible	Chocolaty
Fruity	Stale coffee
A little bit like coffee	Hint of mocha
Why bother?	Chocolate coffee
Like coffee with a touch of chocolate	Low-quality coffee
Like espresso	Like bakers chocolate
Bitter	
Like mocha	
Like bargain coffee	
Three-day-old brewed coffee	
Not worth the effort	
Hint of sour	
Really bad	
Bad after taste	
Pungent	
Not at all like coffee	

been known to possess poisonous properties, both for livestock and humans, though it is by no means a toxic plant of major significance (Kingsbury 1964). The toxin appears to be water soluble; intoxication of livestock has been reported after the animals drank water into which KCT pods had fallen. An extract from the leaves is said to poison flies (Bronaugh 1991; Chesnut 1898; Millspaugh 1887), a report that should be investigated. Toxins are found in all parts of the plant, especially fresh growth, and can cause "stomach and intestinal disorders with diarrhea, vomiting, irregular pulse, and coma" (Hardin & Arena 1974). For over a century, this poisoning has been attributed to the alkaloid cytisine (e.g., Chesnut 1898), but the presence of this compound has never been confirmed in KCT. Unusual amino acids and an alkaloid are reported from the seeds (Southon 1994), but these compounds are not likely to be of toxicologic significance (Burrows & Tyrl 2001).

One's desire to try making "coffee" from the seeds would probably be tempered by statements such as the following: "Only a few cases of human poisoning have been reported from eating the seeds or using them to make a coffee substitute" (Stephens 1980). ". . . chewing one or two [seeds] would not be expected to produce toxic effects" (Lampe & McCann 1985). "Eating the seeds" or "chewing one or two" would, of course, be most unwise because they are so hard; chewing them would be like chewing small rocks.

It appears, though, that there is probably little to worry about with the "coffee." "The toxin is heat labile" and "[the seeds] are not toxic when parched" (Burrows & Tyrl 2001). Nevertheless we do not recommend the "coffee" until more is known about the poisonous compounds in the seeds.

HISTORY

Pioneer times

The earliest appearance of the name *Kentucky* [italics ours] coffeetree—as opposed to simply coffeetree—we have noted is in an April 1785 entry in one of the diaries of George Washington: "Planted ... eight nuts from a tree called the Kentucke [sic] coffee tree . ..." (Jackson & Twohig 1978). According to Hill and Fountain (2003), the Kentucky coffeetree was

> promoted by early land developers who wanted to get settlers out to the "far west" (which included Kentucky at that time). Coffee, a popular beverage, was expensive and hard to find away from coastal ports. Land developers advertised Kentucky as a place where a tree grew with beans that could be roasted and brewed to make a fine coffee substitute. Although drinkable, the beverage was no substitute for coffee, and the early settlers quickly dropped it as soon as the real thing became available.

We were unable to verify this account in spite of extensive searching of literature and internet.

The earliest link we have found between KCT seeds and the "coffee" is in John Filson's *The discovery, settlement and present state of Kentucke* [sic] (Filson 1784): "The coffee-tree greatly resembles the black oak, grows large, and also bears a pod, in which is enclosed good coffee." This statement, however, does not inspire confidence that the author actually partook of the "good coffee" "enclosed" in the pods or that he knew of the *seeds* being the basis for the drink.

In *Pioneer life in Kentucky 1785–1800* (Horine 1948) a letter is quoted from Kentucky pioneer Daniel Drake to his adopted daughter that is definite on the use of the seeds for a beverage: "[We gathered] those wild fruits which were so precious to us in the absence of the cultivated. Some of them were for immediate use, or little thought of except by the children; others had a more permanent value, and were stored for winter . ... Among the latter, grapes, nuts, crab apples, and occasionally the hard seeds of the coffee tree, ... of which, by way of change from Bohea tea [*Camellia sinensis*), we made a substitute for coffee." This report, even in the absence of any other, would seem to verify the pre-1800 use of a beverage made from the seeds of KCT.

Bakeless (1965) wrote about the complaints of a man who, during the 1780's, was a guest at one of the "dreadful" hovels providing food, drink, and bed to Kentucky travellers:

> Nothing to eat but bear meat and 'corn-meal dodgers.' And nothing to drink but whisky ... and coffee 'composed of an article that grew some eight hundred or one thousand miles north of where coffee tree [*Coffea arabica*] ever did grow.' This beverage was brewed from the pod [sic] of the Kentucky 'coffee tree.' The resulting fluid was described by a charitable geographer of the period as 'not unlike coffee.' Another traveler, still more charitable, described it as 'a pod in which is good coffee-seed.'

Michaux (1817; French version 1812) wrote that "the name of coffee tree was given to this vegetable by the early emigrants to Kentucky and Tennessee, who hoped to find in its seeds a substitute for coffee: but the small number of persons who made the experiment abandoned it, as soon as it became easy to obtain from the sea ports the Coffee of the West Indies" (see also Keeler 1900). This, too, has the ring of a reliable report.

The extent of use of the seeds for a beverage recorded by Michaux differs much from that given by others. Saunders (1920) wrote that "a century ago such use of them was quite prevalent in what was then the western wilderness, and travelers' diaries of the time make frequent mention of the practice." Medsger (1972) wrote that "the pioneers apparently made much use of the seeds of this tree, which were roasted and ground, then used as a substitute for coffee." According to Clute (1943), KCT "coffee" was "often" resorted to when the supply of arabica coffee was exhausted. We have made a wide search through the literature—literally many hundreds of sources—and have found nothing that corroborates these statements. Michaux, we believe, was right in his assessment of the frequency of use.

It is perhaps indicative of the *infrequency* of use of KCT "coffee" that Porcher (1863), in his Civil War era *Resources of the southern fields and forests*, did not mention *G. dioicus* even though he listed various coffee substitutes. The tree's range does extend into the far northern part of the area covered in the book (Little 1977; Spaeth n.d.). Perhaps, too, arabica coffee, in spite of war-induced scarcity, was sufficiently available so that substitutes were generally not important; Dick (1974), in his book on the "southern frontier," mentioned that "by 1840 black coffee was coming into use as a beverage." Loudon (1838) noted that the use of KCT seeds for "coffee" had long since been discontinued. Wilson (1905) noted that the "coffee" use had "long since ceased." A 1902 paper on KCT did not mention the "coffee" even though it considered "economic uses" (Anonymous 1902). Gibson (1913), describing the "coffee" as black and bitter and noting that "a little of it would go a long way with a modern coffee drinker," wrote that "when the Kentuckians were able to procure coffee they let the wild substitute alone."

Kentucky and Tennessee were not the only places where this beverage was tried. Thomas Nuttall (1821) apparently had drunk the "coffee": in early 1819 he wrote in the record of his journey into the Arkansas Territory, "Among the trees, we still continue to observe the coffee-bean (*Gymnocladus canadensis*), now loaded with legumes, the seeds of which, when parched . . . produce a substitute for coffee greatly inferior to the *Cichorium* [chicory]." At that writing, he was near the confluence of the Ohio and Mississippi rivers. And in southwestern Iowa during the winter of 1819–1820, KCT "coffee" was drunk by members of S.H. Long's expedition to the Rocky Mountains (Thwaites 1905).

Seeds of KCT were not the only coffee substitute used in early Kentucky.

Another report on the pioneers (Goode 1989), from an area of the state in which KCT is lacking or exceedingly rare (Little 1977), stated that ground parched corn sweetened with honey made a "reasonably tasty substitute for coffee." Other substitutes included parched "tubers," rye, wheat, acorns, beans, chestnuts, chicory, chinquapins, cotton, grapes, peanuts, English peas, persimmons, okra, sorghum, sugar cane, "Irish" and sweet potatoes, and dandelion—and even, in desperation, wood shavings (Anonymous n.d.; Howard 1975; March 2000; Mitchell 1991).

Writing about pioneer Kentucky, Cotterill (1917) mentioned that "Tea and coffee were reserved for the sick and were considered as a mark of effeminacy if taken by people in good health." Was this, in addition to the scarcity of arabica coffee in those early times, maybe one reason to seek a coffee substitute?

One might wonder where the pioneers got the idea of preparing a beverage from these seeds, which seem to us to be a most unlikely source. The seeds certainly do not look like the "beans" of arabica coffee, and the task of preparing them for brewing is daunting. The pioneers might have learned the process from Native Americans; Smith (1928) reported that the Meskwaki Indians cooked the seeds and then ground them and boiled them to make "coffee." These Indians, however, were in Wisconsin, not Kentucky. But perhaps some Kentucky tribes knew of the use and shared the information with the pioneers. Indians of the Missouri River region (Gilmore 1991; Moerman 1998) knew of KCT but apparently did not make a beverage from the seeds although they roasted and ate the seeds and prepared a "food" from the pounded seeds. According to Phillips (1998), "the roasted beans are a reasonably good nut, especially when salted or soaked in salted water and re-baked." We infer that the roasting time, though not stated, is about $^1/2$ to 1 hour.

It is also possible that some pioneers familiar with arabica coffee but suffering coffee deprivation simply tried to make a beverage from KCT seeds, producing a brew that they liked and about which they spread the word.

KCT "coffee" during the Civil War

During the early days of November 2003 we were told by a Civil War history buff (who wishes to remain anonymous) that he had heard from a Civil War re-enactor that, during that war, quite limited use was made of KCT seeds as "coffee." The taste of the "coffee" was reportedly so bad that it made hardtack—those plain flour-and-water biscuits that were often moldy or infested with maggots and weevils (Billings 1887)—seem good by comparison. In her *Civil War plants and herbs*, Mitchell (1996) noted that the seeds are the basis for a "coffee," a report apparently based on Anonymous (1995). But she gave no indication that they were actually *used* for that purpose during the war although, of course, they could well have been. Arabica coffee was apparently a favorite non-alcoholic beverage of soldiers ("how delicious the aroma of it, and how readily each man disposed of a quart" [McCarthy 1882]). Although arabica coffee was available at least some of the time (Locke 1870), its supply in the south was sometimes uncertain because of the vicissitudes of war on land and the Lincoln-ordered blockade of southern ports from Virginia to Texas.

The George Rogers Clark connection

In going through hundreds of KCT websites we came upon one from Storm Lake, Iowa, a city that has a "tree museum" in which various "historic" trees are planted (Anonymous 2003b), among them a "George Rogers Clark Kentucky Coffee tree." The text concerning the tree is as follows: "During the Civil War, George Rogers Clark attempted to develop a coffee bean tree to replace regular coffee which was unavailable during that time. However, since the coffee was not pleasant to the taste, the project failed." Is this statement credible? Certainly not in the timing of Clark's posthumous interest; he died in 1818. One wonders, too, how one could "develop" a tree during the short time span of the Civil War. But we decided to investigate further.

We directed a query to Storm Lake, hoping to learn the source of their KCT. We were given the name of an individual in Louisville; later checking showed that he and another person were involved in a heritage tree program and that one of them is deceased. Two letters to the first man have gone unanswered; we suspect that he, too, has died.

We learned that Clark did send KCT seeds to Thomas Jefferson at Monticello. Indeed, in the Kentucky legislation (Anonymous 2003a) that established *G. dioicus* as the state tree of Kentucky (S.B. 150, approved 8 Mar 1976; later rescinded), one of the "whereas's" is this: "WHEREAS, in 1783 General George Rogers Clark did send seeds of the Kentucky coffeetree to Thomas Jefferson at Monticello and which seeds produces [sic] trees still gracing the grounds of Monticello." In a letter dated 4 Dec 1783 Jefferson wrote to Clark: "We received here about a week ago your obliging letter of Oct. 12. 1783, with the shells and seeds for which we return you many thanks" (Jefferson 2003). One can but assume that among the included seeds were those of KCT. (As an aside, this letter is the one in which Jefferson asked Clark if he would like to lead [an exploration party] into the country from the Mississippi to California.)

We found a brief quote said to be from Clark's October 1783 letter to Jefferson: speaking of KCT, Clark wrote "It makes beautiful shade and we think it will flourish with you" (Anonymous 2003a). Did Clark also mention in the letter the "coffee" use of the seeds of the tree? Inquiries to the Jefferson collection at the Princeton University Library (Linda Monaco, pers. comm., 16 Oct 2003) and to the Monticello Library (Bryan Craig, pers. comm., 16 Oct 2003) elicited the response that the letter is apparently lost.

Finally, we were referred to a person said to be knowledgeable about GRC's correspondence: Julia Parke, former director at Locust Grove, Clark's Louisville home. In an October 2003 telephone conversation with her, the second author was told that she had known of the 12 Oct 1783 letter and that yes, GRC did mention in the letter not only the horticultural possibilities of the tree but also the use of Kentucky coffeetree seeds for "coffee." Thus the Storm Lake report of Clark's interest in KCT had been somewhat exonerated.

CURRENT USE OF KCT "COFFEE"

In an article on various wild-growing substitutes for arabica coffee, Serlin (1977) wrote, "All last winter, along the Ramble in New York City's Central Park, I've seen people pinching coffee costs by scuffing through fallen leaves for precious pods under a stand of Kentucky Coffee Trees." In October 2003, wondering about the frequency of such foraging by New Yorkers, we telephoned Steven Brill, well-known author and educator on the subject of wild edible plants. He told us that, in his years of visiting Central Park, the only foragers he had seen were those accompanying him on his field trips.

According to some of these foragers, the seeds apparently can be used as a chocolaty seasoning in cakes and cookies (Brill & Dean 1994). One seed added to carob-flavored ice cream can make the product "taste more like chocolate than ever" (Brill 2002).

We checked with several more people knowledgeable about the subject of edible wild plants. None knew of anyone who had prepared a drink from KCT seeds.

Other than the reports of Brill (2002), Brill & Dean (1994), Phillips (1998), and Serlin (1977) and the recent brewing of "coffee" from KCT seeds here at Northern Kentucky University, we have located no evidence of significant extant use of the beverage. Even if current edible-plant books mention the use, we suggest that KCT "coffee" is mostly a curiosity from a time now past, being indulged in only by an occasional one of those individuals who eat their way through the landscape (often with tasty rewards). It poses no serious threat to Maxwell House or Starbucks.

CONCLUSION

Limited use of KCT seeds as a coffee substitute was made in pioneer Kentucky and elsewhere. It would appear that the many post-pioneer reports of a KCT-seed-based beverage derive ultimately from a few early accounts; Drake's, Long's, Michaux's, Nuttall's, and possibly Clark's. The Kentucky coffeetree is of essentially no present-day concern as a beverage plant.

ABSTRACT

A literature search was conducted to determine the medicinal flowering plants found in Pakistan and used as remedies for various disorders or diseases. The taxonomic position, distribution and flowering period of these plants are described to facilitate their collection at blooming. There are 95 species belonging to 85 genera and 43 plant families. Most of the species belong to Fabaceae and Asteraceae (17 and 13 species respectively), followed by Malvaceae (7 species), Lamiaceae (6 species) and Boraginaceae (4 species). Apocynaceae and Rosaceae contained 3 species each. It is important for the sustainability of Pakistani medicinal plant industry to consolidate the plant-resource database and explore the national and international markets for its medicinal flora. It is imperative that large scale cultivation projects be implemented and that priority species of the medicinal plants be salvaged. Pakistan also needs expanded research efforts into cultivation, production and conservation of medicinal plants. Institutional linkages are urgently needed between all the Pakistani research and development organizations dealing with medicinal and aromatic plants.

RESUMEN

Se realizó una exhaustiva búsqueda bibliográfica acerca de las angiospermas medicinales de Pakistán utilizadas como remedios contra enfermedades de diversa naturaleza. Se preparó una lista de las especies encontradas con referencia a su posición taxonómica. Se incluye su distribución y período fenológico para facilitar su recolección en el momento óptimo de la floración. El listado comprende un total de 85 géneros y 95 especies pertenecientes a 43 familias. La mayoría de las especies pertenecen a las familias Fabaceae y Asteraceae (17 y 13 especies respectivamente) seguidas de Malvaceae (7 especies), Lamiaceae (5 especies) y Boraginaceae (4 especies); Apocynaceae y Rosaceae presentan 3 especies cada una. Resulta importante para la industria sostenible pakistaní de plantas medicinales consolidar el banco de datos disponibles y explorar los mercados nacionales e internacionales que atañen a su flora medicinal. Es imperativo aumentar los proyectos de cultivos a gran escala y preservar la prioridad de las plantas medicinales. Pakistán necesita también extender los esfuerzos de investigación a los problemas sobre cultivo, producción y conservación de plantas medicinales. Destacamos asimismo la imperiosa necesidad de desarrollar un sistema de transferencia institucional entre la investigación y las organizaciones de desarrollo que intervienen en los procesos industriales de plantas medicinales y aromáticas en Pakistán

SIDA 21(1): 357 – 368. 2004

INTRODUCTION

The flora of Pakistan is very rich due to the diverse climatic and soil conditions in its different ecological regions. The country has around 6000 species of wild plants; about 400–600 are considered to be of medicinal importance. Pakistan has considerable significance from the point of view of medicinal plants (Nasir et al. 1972) and has been correctly called as the floral emporium of medicinal plants (Rizvi 1998). An estimated 80% of the rural population in Pakistan depends on traditional medicines for their primary healthcare needs, the majority of that are plants or their active principles (Shinwari & Khan 1998).

The sustainable harvesting of medicinal plants has great economic potential. Although some medicinal plants, such as *Carthamus tinctorius*, *Crocus sativus* and *Passiflora edulis*, are locally grown but require knowledge about the proper collection and preservation of these important medicinal plants (Rizvi 1998; William & Ahmad 1999). However, medicinal plants are used both in the indigenous medicinal system and by pharmaceutical industries (Shaheen et al. 2003).

Many different flowering species, such as *Artemisia absinthium*, (Gul-e-afsantee), *Matricaria chamomilla* (Gul-e-babuna), *Viola odorata* (Gul-e-banafsha), *Rosa damascena* (Gul-e-surkh), and *Crocus sativus* (Gul-e-zafran), are known as potential sources for curing various liver diseases (Bach 1994; Bisset 1994; Duke 1986; Khan et al. 1996). Safflower (*Carthamus tinctorius*) has been used for centuries in Europe and Asia as a laxative and diuretic (Keville 1995). Passionflower (*Passiflora edulis*) is reputed to have anti-spasmodic and sedative properties and used widely as an ingredient in herbal remedies (Reynold et al. 1994). The aqueous extract prepared from the calyx of *Hibiscus sabdariffa* is reported to possess cathartic activity (Haruna 1997).

Classification of medicinal plants is organized in different ways depending on the criteria used. In general, medicinal plants are arranged according to their active principles in their storage organs of plants, particularly roots, leaves, flowers, seeds and other parts of plant (Shaheen et al. 2003). These principles are valuable to mankind in the treatment of diseases (Shaheen et al. 2003; Shinwari & Khan 1998). According to the literature there are many Pakistani medicinal plants (Bach 1994; Nasir & Ali 1972; Rizvi 1998; Shinwari & Khan 1998) that could be used for remedies, medicinal preparations and future utilization (Bach 1994; Bugti 1998; Mahmood et al. 1996; Nasir & Rafiq 1995; Shinwari & Khan 1998; Zaman & Khan 1970). This paper presents the taxonomy of Pakistani medicinal flowering plants, their regional distribution, and flowering periods.

MATERIALS AND METHODS

A literature search was conducted to find out which Pakistani plants are used as remedies for various disorders or diseases (Bach 1994; Bugti 1998; Duke 1986;

Mahmood et al. 1996; Malik & Farooq 1984; Nasir & Ali 1972; Nasir & Rafiq 1995; Rizvi 1998; Shaheen et al. 2003; Shinwari & Khan 1998; Zaman & Khan 1970). The taxonomic position of species with medicinal properties was determined. Their distribution and flowering period was also noted to facilitate their collection at blooming. The plants included herbs, shrubs, vines and trees. The genera were arranged alphabetically within each family. The nomenclature and classification followed Nasir and Ali (1972), and author citations followed Brummitt and Powell (1992).

RESULTS AND DISCUSSION

Ninety-five Pakistani species distributed among 85 genera and 43 plant families were found to have medicinal properties (Table 1). The largest numbers of species were found in Fabaceae and Asteraceae (17 and 13 species respectively), followed by Malvaceae (7 species), Lamiaceae (5 species) and Boraginaceae (4 species). Apocynaceae and Rosaceae each contained 3 species of medicinal plants. Other families contained only one or two species of medicinal plants (Table 1). Their flowering period and distribution were also worked out and presented in Table 1. The medicinal plants that are commercially exploited in large quantities occur mainly in four ecological regions of Pakistan: alpine and high altitude; temperate mountain forests; sub-tropical foothill forests; and arid and semi-arid scrubs (Ali & Qaiser 1986; Shaheen et al. 2003; William & Ahmad 1999).

A number of medicinally important Pakistani plants are found in the moist alpine and high altitude areas, especially in the northwestern valleys (Nasir & Ali 1972; Shaheen et al. 2003; William & Ahmad 1999). Most plants of these areas are slow growing perennial species, which require several years of vegetative growth before reproduction by seed (Shaheen et al. 2003). Some of the species are classified as threatened or vulnerable if the current rate of collection continues. Endangered plant species of this area includes *Podophyllum hexandrum, Saussaurea costus, Picrorrhiza kurrooa, Aconitum heterphyllum,* and *Corydalis* sp. (Shaheen et al. 2003). Care should be taken in the conservation of plants with medicinal flowers so that their existence is not threatened.

The origin of Unani (Greek) medicines goes back to the material medica of numerous early civilizations. Unani medicine traces its origin to Greek medicine, which was adopted by the Arabs and thereafter spread to both Europe and Indo-Pak subcontinent (William & Ahmad 1999). There are about 27 large, Pakistani herbal-manufacturing companies, which produce Unani medicines on a commercial scale (Shaheen et al. 2003). The number of herbal-medicine manufacturers in the non-organized sector runs into the hundreds. The annual gross income of some large herbal manufacturers is comparable to that of multinational companies in Pakistan. About 50,000 traditional healers, including homeopaths, are serving about 60% of the population, especially those living in rural areas (Shaheen et al. 2003; William & Ahmad 1999).

TABLE 1. The taxonomy, distribution, and flowering period of some of the medicinal flowers of Pakistan.

Species	Flowering period	Distribution	Medicinal Remedies
MONOCOTYLEDONS			
Poaceae			
Cymbopogon jwarancusa (Jones) Schult.	Jul–Oct	Found in Karachi, Multan, Chitral, NWFP, Quetta, Gilgit	Detoxifier, astringent and tonic
Zea mays L.	Feb–May	Cultivated in Sindh, Punjab, NWFP	Astringent, chloretic, diuretic and remedy for urinary infection
DICOTYLEDONS			
Acanthaceae			
Adhatoda vasica Nees = *Justicia adhatoda* L.	Feb–Apr	Planted in Karachi, Sindh	Asthma, bronchitis, gonorrhea, highgrade fever and conjunctivitis
Amaranthaceae			
Achyranthes aspera L.	Sep–Apr	Found in Gilgit, Karachi, Punjab, Baluchistan	Anti-hemorrhoidal
Celosia cristata L. = *Celosia argentea* L. var. *cristata* (L.) Kuntze	Oct–Dec	Grown in gardens	Astringent, anti-diarrheal and for irregularity of menstrual cycle
Anacardiaceae			
Mangifera indica L.	Jan–Mar	Grown in Punjab and Sindh	Astringent, urinary infection, catarrh, anti-diarrheal, anti-dysentery, veneral diseases
Apocynaceae			
Catharanthus roseus (L.) G. Don.	Throughout out the year	Cultivated and naturalized in the tropics	Asthma, anti-leukemia, eyes salve and flatulence
Pergularia extensa Jacq. = *Pergularia daemia* (Forssk.) Chiov. var. *daemia*	Sep–Apr	Found in Karachi, Sindh, Lasbella, Peshawar, Rawalpindi	Anthelmintic, emetic, expectorant
Vinca major L.	Dec–Mar	Found in Parochial, Abbottabad, More hills	Fresh flowers are purgative
Asclepiadaceae			
Calotropis procera (Aiton) W.T. Aiton	Throughout the year	Widely distributed in deserts throughout Pakistan	Asthma, catarrh, cold, cough, cholera, and for dyspepsia
Asteraceae			
Achillea millefolium L.	Aug–Mar	Occurs in Gilgit, Swat, Murree, Poonch, Baluchistan, Chagia	Hypotensive, haemostatic to arrest bleeding
Artemisia absinthium L.	Aug–Sep	Grows in Thandiani	Anthelmintic, anti-scorpion venom and anti-snake venom

TABLE 1. continued

Species	Flowering period	Distribution	Medicinal Remedies
Artemisia maritima L.	Aug–Sep	Found in Astor, Baluchistan, Chitral, Swat	Dyspepsia, tonic and anti-helminthic
Calendula officinalis L.	Dec–Apr	Cultivated in many parks and gardens of Pakistan	Duodenal-gastric ulcers, hypotensive, emmenagogue and cures skin diseases
Carthamus tinctorius L.	Apr–Jul	Distributed NWFP, Baluchistan, (Harnai), Punjab	Emmenagogue, laxative, sedative, stimulant
Chrysanthemum cinerariifolium (Trevir.) Vis.=*Tanacetum cinerariifolium* (Trevir.) Sch. Bip.	Mar–Jul	Cultivated in Peshawar, Abbottabad	Aperient, conjunctivitis and dyspepsia
Helianthus annuus L.	Jul–Sep	Widely cultivated in Pakistan	Anti-diarrheal, anti-inflammatory carminative, diuretic
Matricaria chamomilla L. = *Matricaria recutita* L.	Jul–Jan	Found in plains of Punjab, Pishin	Analgesic, antiseptic, carminative, anti-convulsant, diuretic, liver diseases, dyspepsia
Silybum marianum (L.) Gaertn.	Mar–Apr	Found in Lahore, Peshawar, Saidu Sharif, Abbottabad, Mirpur, Rawalpindi	Flower heads are consumed for diabetes control
Tagetes erecta L.	Jun–Nov	Grown in gardens of Pakistan	Anti-dote against wasp stings, cure for eczema, diuretic
Tanacetum gracile Hook.f. & Thomson	Jun–Aug	Found in Hunza, Baluchistan	Anti-helminthic
Taraxacum officinale F. H. Wigg. Group	Feb–Apr	Widely distributed throughout Baluchistan	Aperient, diuretic, stimulant, stomachic, tonic, detoxicant
Xanthium strumarium L.	Jul–Aug	Found in Karachi, Gilgit, Chitral, Baluchistan, Swat, NWFP, Hazara	Flowers useful for tooth-ache
Balsaminaceae			
Impatiens balsamina L.	Jul–Oct	Cultivated in Karachi, Chitral, Murree	Antibiotic activity, inter-costal neuralgia and useful in lumbago
Bignoniaceae			
Millingtonia hortensis L.f.	Nov–Mar	Cultivated in Sindh, Punjab	Cures asthma
Stereospermum suaveolens DC. = *Stereospermum colais* (Buch.-Ham. ex Dillwyn) Mabb.	May–Jun	Occurs in Rawalpindi District	Aphrodisiac, hiccoughs

TABLE 1. continued

Species	Flowering period	Distribution	Medicinal Remedies
Bombacaceae			
Bombax ceiba L.	Dec–Mar	Cultivated as roadside and garden plant in Pakistan	Diuretic and laxative
Boraginaceae			
Arnebia benthamii (Wall. ex G. Don) I.M. Johnst.	Oct–Nov	Found in Makran, Kaghan, Poonch	Angina, fever, pharyngitis
Borago officinalis L.	Jan–Feb	Reproduced from seeds at Karachi	Anti-cancer agent (breast or face), corns, sclerosis and tumors
Onosma hispidum Wall. & G. Don	Mar–Jul	Found in Pishin, common in Landikotal, Swat, Chitral, Kaghan	Cardiac tonic, stimulant
Trichodesma indicum (L.) Sm.	Aug–Oct	Occurs in Mangopir	Flowers used as emullient and diuretic
Brassicaceae			
Cheiranthus cheiri L. *Erysimum cheiri* (L.) Crantz	Mar–May	Cultivated in gardens	Cardiac disorders, emmenagogue, remedy for impotence and paralysis
Byttneriaceae			
Pterospermum acerifolium (L.) Willd.	Dec–Jul	Cultivated in Islamabad, Peshawar as an introduced tree	Dehydration, otalgia, haematuria, massage
Cannabaceae			
Humulus lupulus L.	Jul–Aug	Found in Pangi on the upper Chenab	Anti-septic, female inflorescence used as diuretic, emmenagogue, dyspepsia
Caprifoliaceae			
Sambucus nigra L.	Mar–Apr	Occurs in Parachinar, Nathiagali, Hazara	Laxative, anti-pruritic and stimulant of blood circulation
Cucurbitaceae			
Trichosanthes dioica Roxb.	Jun–Oct	Found in Punjab, Ravi, Chenab,Doab, Rawalpindi District	Lowers total cholestrol and blood sugar
Fabaceae (***Caesalpinioideae***)			
Bauhinia purpurea L.	Sep–Nov	Cultivated in Punjab, NWFP, Rawalpindi	Flowers are used as purgative
Bauhinia variegata L.	Feb–Apr	Cultivated in Pakistan	Flowers are aperient
Caesalpinia pulcherrima (L.) Sw.	Apr–Sep	Cultivated in gardens of Pakistan	Asthma, bronchitis, anti-pyretic, expectorant, anti-malarial
Cassia alata L. = *Senna alata* (L.) Roxb.	Oct–Dec	Sometimes cultivated in Pakistan	Laxative. Useful in skin texture

TABLE 1. continued

Species	Flowering period	Distribution	Medicinal Remedies
Cassia fistula L.	Apr–May	Naturalized throughout Pakistan. Cultivated in Karachi, Punjab	Cough, diphtheria, laxative, edema
Cassia siamea Lamk. = *Senna siamea* (Lam.) H. S. Irwin & Barneby	Oct–Dec	Cultivated in Karachi, Sindh	Anthelmintic, anti-hypertensive, asthma, dandruff, insomnia, laxative, tranquilizer, sedative
Delonix regia (Bojer ex Hook.) Raf.	May–Jun	Planted in Karachi, Hyderabad, Lahore	Anthelmintic
Tamarindus indica L.	Feb–Apr	Grown in Sindh, Punjab, Jehlum, Karachi	Anti-viral against New Castle disease virus, astringent and sedative
Fabaceae (*Mimosoideae*)			
Acacia nilotica (L.) Delile	May–Jun	Found cultivated or wild in Sindh, Punjab, Baluchistan, NWFP	Useful in jaundice and palpitations
Albizia lebbeck (L.) Benth	Jul–Oct	Grows in Sialkot to Hajara, Bajaur, Malakand	Aperient, boils, carbuncle, antibacterial
Prosopis cineraria (L.) Druce	Apr–Jul	Found in Sindh, Baluchistan, Punjab (in Thal and Cholistan deserts)	Beneficial against miscarriage
Fabaceae (*Papilionoideae*)			
Butea frondosa Roxb. = *Butea monosperma* (Lam.) Taub.	Mar–Apr	Cultivated in Punjab, NWFP	Anti-pyretic, appetizer, aphrodisiac, blood purifier, diuretic, tonic, viral hepatitis
Butea monosperma (Lam.) Taub.	Mar–Apr	Cultivated in Punjab, NWFP	Astringent, aphrodisiac, boil depurative, diuretic, gout, anti-leprosy agent
Pongamia pinnata L. = *Millettia pinnata* (L.) Panigrahi	Apr–May	Cultivated in Sindh, Punjab	Flowers are used in diabetes
Sesbania grandiflora (L.) Pers.	Aug–Mar	Planted in Karachi, Kutch, Sindh, Punjab	Flower juice improves vision (as eye drops)
Sesbania sesban (L.) Merr.	Apr–Nov	Found cultivated and wild in Sindh, Punjab	Anti-fertility activity reported
Trifolium pratense L.	Feb–Apr	Occurs in Chitral, Astor, Swat, Hazara	Anti-asthmatic, anti-spasmodic, bronchitis and expectorant
Iridaceae			
Crocus sativus L.	Oct	Propagated by bulb in Baluchistan	Beneficial for liver, brain, heart, regulates the menstrual function

TABLE 1. continued

Species	Flowering period	Distribution	Medicinal Remedies
Lamiaceae			
Hyssopus officinalis L.	Jun–Sep	Cultivated in Kashmir, Pangi, Upper Chenab	Used for chest congestion, flower tea is expectorant
Leucas aspera (Willd.) Link	Aug–Feb	Found in Jammu, Ghat, Ravi, Chenab, Doab	Anti-tussive, decongestant for children
Mentha longifolia (L.) Huds.	Feb–May	Common in home gardens	Carminative and stimulant
Ocimum basilicum L.	Nov–Apr	Cultivated in Karachi, Baluchistan, Punjab	Decongestant
Pervoskia abrotanoides Kar.	Sep–Oct	Occurs in Baluchistan, Chitral, Gilgit, Hunza, Quetta, Ziarat	Anti-pyretic
Linaceae			
Linum usitatissimum L.	Feb–Apr	Cultivated in Karachi	Cardiac and nerve tonic
Lythraceae			
Lawsonia inermis L.	Jun	Found in Sindh, Baluchistan, Punjab	Anti-pyretic, sedative, soporific
Magnoliaceae			
Michelia champaca L.	Throughout the year	Cultivated in Punjab, NWFP	Used in dyspepsia, anti-pyretic, anti-emetic
Malvaceae			
Abutilon indicum (L.) Sweet	Feb–Mar	Widely distributed in Karachi, Sindh, lower hills of Punjab	Anti-diarrheal, demulcent, anti-hemoptysis, sedative and decongestant
Althaea officinalis L.	Jul–Oct	Grows in Azad Kashmir, Peshawar, Rawalpindi	Emollient, demulcent, diuretic, bronchial catarrh and rheumatism
Gossypium herbaceum L.	May–Jul	Cultivated as a crop in Punjab and Sindh	Extracted flowers used as abortificient and for inducing menstrual flow
Hibiscus cannabinus L.	Autumn–Winter	Cultivated in Sindh, Karachi, Swat, Punjab, Chitral	Gastritis and popular laxative
Hibiscus rosa-sinensis L.	Apr–Sep	Grown as ornamental plant in Punjab, Sindh	Cardiac tonic, expectorant, anti-pyretic, anti-tussive, decongestant
Hibiscus sabdariffa L.	Aug–Sep	Cultivated in Karachi	Cathartic activity
Urena lobata L.	Sep–Dec	Occurs in Lahore, Jehlum, Changa Manga	Aphthosis, expectorant, decongestant
Meliaceae			
Azadirachta indica A. Juss	Mar–Apr	Found in Sindh, southern Punjab, lower Baluchistan	Adrenalgic stimulant, dyspepsia, also used in skin diseases
Melia azedarach L.	Mar–May	Found in Sindh and Punjab	Poultice to relieve headache, nervousness

Table 1. continued

Species	Flowering period	Distribution	Medicinal Remedies
Moringaceae			
Moringa oleifera Lam.	Feb–Apr	Cultivated in Rawalpindi, planted in Sindh	Cholagogue, diuretic tonic
Musaceae			
Musa sapientum L. = *Musa ×paradisiaca* L.	Feb–Sep	Cultivated in Sindh, Punjab, NWFP	Anti-hypoglycemic
Myrtaceae			
Myrtus communis L.	Apr–Jun	Wild in Baluchistan, NWFP	As anti-septic, disinfectant
Nyctaginaceae			
Mirabilis jalapa L.	Nov–Jan	Found in Karachi, NWFP, Hunza, Gilgit	Anti-hemorrhoidal
Nymphaeaceae			
Nelumbo nucifera Gaertn.	May–Jul	Found in Charsada, Multan, Shahdara	Cardiac tonic, diuretic, anti-pyretic
Oleaceae			
Jasminum grandiflorum L.	Warm season	Occurs in Peshawar, Karachi	Aphrodisiac, astringent, carminative, dysentery, hepatitis, suppress excess lactation
Jasminum sambac (L.) Aiton	Jul–Oct	Occurs in Karachi, Lahore, Islamabad	Anti-pyretic, cardiac tonic, lactifuge
Paeoniaceae			
Paeonia emodi Wall. ex Royle	May–Jun	Common in moist ground. Kaghan, Thandiani, Chitral, Bahrin, Poonch	Anti-diarrheal
Papaveraceae			
Papaver rhoeas L.	Jun–Sep	Cultivated in gardens	Bronchitis, hoarseness, sedative, sudorific
Passifloraceae			
Passiflora incarnata L.	Jul–Sep	Cultivated in Karachi	Asthma, dysentery, insomnia, whooping cough
Pontederiaceae			
Eichhorina crassipes (Mart.) Solms	Apr–Jul	Occasionally found filling ponds in plains	Arthritis and gout
Punicaceae			
Punica granatum L.	May–Jun	Commonly grown in Quetta, Sibbi, Karachi, Punjab, NWFP	Anti-diarrheal, dysentery, bronchitis

Table 1. continued

Species	Flowering period	Distribution	Medicinal Remedies
Rosaceae			
Eriobotrya japonica (Thunb.) Lindl.	Jul–Aug	Cultivated in sub-Himalayan zone	Flowers are expectorant
Rosa ×damascena Mill.	Jan–Jul	Cultivated in gardens of Pakistan	Anti-HIV, aperient, cardio-active, liver protector
Rosa foetida Herrm.	Jan–Jul	Found in Baluchistan, Kurrum, Quetta, Ziarat	Anti-diarrheal
Sapotaceae			
Bassia latifolia Roxb. = *Madhuca longifolia* (L.) J.F. Macbr.	Jul–Aug	Cultivated in Sindh, Punjab	Regarded as bronchitis, cooling, cold, anti-tussive, demulcent and tonic
Scruphulariaceae			
Verbascum thapsus L.	Jun–Aug	Common in Chitral, Mansehra	Coughs, diarrhea, febrifuge, stimulant, pharyngitis
Solanaceae			
Datura metel L.	May–Jun	Weedy places, Karachi	Smoke as anti-asthma
Solanum surattense Burm. f. = *Solanum virginianum* L.	Jun–Nov	Throughout Pakistan	Paresthesia, carminative
Rubiaceae			
Ixora coccinea L.	Jul–Jan	Cultivated in Karachi	Cure sores, relieve blood, ulcers
Tropaeolaceae			
Tropaeolum magus L.	Dec–Feb	Cultivated in Karachi	Natural anti-biotic
Verbenaceae			
Nyctanthes arbor-tristis L.	Aug–Oct	Naturalized in Punjab, Rawalpindi, NWFP, Mardan	Anti-pyretic, faintness, anti-vertiginous
Vitex negundo L.	Mar-Jun	Cultivated in Thai, Swat, Mirpur	Cardio tonic, cholera, diarrhea, useful for liver disorders
Violaceae			
Viola odorata L.	Mar–May	Naturalized in Nathia gali, Hazara, Kaghan, Swat, Chital	Liver protector, decongestant

Pakistan has the potential for sustainable utilization of its medicinal flora. Basic infrastructure also exists to carry out research and development activities in this field. However, more attention needs to be paid to the systematic propagation, collection and conservation of medicinal plants. It is important that the country consolidates its plant-resource database, explores the international and national markets for its medicinal flora, and implements large scale cultivation projects and salvage projects for its more important medicinal-plant species. Pakistan needs an expansion of research efforts into cultivation, production and conservation of medicinal plants. There is also a dire need to develop a system of institutional linkages among all the research and development organizations dealing with the Pakistani medicinal and aromatic plant industry.

ACKNOWLEDGMENTS

Special gratitude is expressed to Joseph H. Kirkbride, USDA, Agricultural Research Service, Beltville, MD, for his help in checking the nomenclature and taxonomy of the plants and Mohammad Nawaz, California Department of Health Services, Sacramento, CA, for valuable suggestions and helpful criticism on the manuscript. The authors are also grateful to Zahoor Ahmad, Pakistan Agricultural Research Council, Islamabad, and Prof. M. Iqbal Choudhary, H.E.J. Research Institute of Chemistry, University of Karachi, Karachi, Pakistan for providing many original reprints used in the preparation of this paper.

ABSTRACT

We examine the etymology and the first names of *Cuscuta*, as well as some unexplored aspects in the early history of parasitism concept. The name "Orobanche" was used for the first time by Theophrastus possibly for *Cuscuta*, however for sure not for the today's broomrapes. The etymology of the generic name is neither Arab nor Greek, as commonly thought, but Aramaic and/or Hebrew. The ideas of parasitism from medieval ages are merely a regression of the Greek ancient concept. Whereas the ancient Greeks view the parasites as originating from their own seeds, during the medieval times and as late as the 17th century, *Cuscuta* plants were literally believed to arise from their hosts. Several lesser known uses of these plants during ancient and medieval times are explored in the Old as well as in the New World.

RESUMEN

Se examinó la etimología de los primeros nombres de *Cuscuta*, así como, aspectos no explorados en la historia del concepto de parasitismo. El nombre "Orobanche," fue utilizado por la primera vez por Teofrasto, posiblemente refiriéndose a *Cuscuta*, sin embargo, seguramente no para los actuales "jopos de lobo." La etimología del nombre genérico no es ni árabe ni griega, como se creía comúnmente, aunque puede ser arameo y/o hebreo. El concepto con respecto a las plantas parásitas desde la edad media es solamente una regresión al antiguo concepto griego. Mientras que, el punto de vista de los antiguos griegos era que las plantas parásitas se originaban de sus propias semillas, en la Edad Media, a finales del siglo XVII, las plantas de *Cuscuta* se consideraron que literalmente surgían de sus hospedadores. Los usos de estas plantas en los tiempos antiguos y en la Edad Media son prácticamente desconocidos, por lo que éstos se están explorando en el Viejo y el Nuevo Mundo.

INTRODUCTION

Cuscuta is a worldwide distributed genus, that comprises about 150 species of parasitic plants (dodders) (Yuncker 1932). The etymology of the generic name is not clear since it has commonly been said to be either Greek (e.g. Dawson et al. 1994) or Arabic (Austin 1980). The history of these intriguing plants, and of parasitic plants in general, has been traced back to antiquity (Mirande 1900; Kuijt 1969). Such plants must have drawn the attention of both early scholars

---

SIDA 21(1): 369 – 378. 2004

and farmers. As Theophrastus wrote: "the oddity is that a plant grows exclusively on another plant, and not on the ground. ..." (De causis plantarum 2:17.5, 1976). Since then, the concept of parasitism has evolved slowly. The early history of parasitism in plants is particularly poorly known. We examine the first names of *Cuscuta*, some unexplored aspects in the history of parasitism concept, and several less known uses of these plants.

Was Orobanche one of the first names of *Cuscuta*?

Theophrastus referred to a plant called "*ὀροβάγχη*" ("vetch strangler" from "orobos" - vetch - *Vicia ervilia* (L.) Willd.?, and "anchone" - to strangle) because "it overspreads the whole plant (of vetch) and holds it fast as if it were in coils, for it is thus that (vetch-strangler) strangles the plant" (Inquiry into plants 8.8.4, 1916). It is certain that, when using this name, Theophrastus did not have in mind the broomrapes (today's *Orobanche*), because he apparently spoke about these in the next paragraph, under a different name. Thus, he mentioned *αἱμόδωρον*, which is said to be like another unnamed plant that "springs straight from the roots of cummin" (*Cuminum cyminum* L.), and both these plants are "somewhat more peculiar in their habits." This *αἱμόδωρον* attaches itself to fenugreek" (*Trigonella foenum-graecum* L.) and its "root is more or less round" (Theophrastus, Inquiry into plants 8.8.5, 1916). Both these latter plants are probably the actual *Orobanche*, which cannot be the *ὀροβάγχη*, the "vetch-strangler." It would be tempting to assume that "*ὀροβάγχη*" (the vetch-strangler) is *Cuscuta*. This would mean that one of the first names of *Cuscuta* was *Orobanche*. In support of this hypothesis are the habit of the plant and the chapter about weeds in which Theophrastus mentioned it (Inquiry into plants 8.8.3–5, 1916). Unfortunately, the "vetch-strangler" was not further described or mentioned elsewhere by Theophrastus, and Pliny the Elder did not carry on this name.

The Labyrinth of names and languages

Theophrastus also spoke about the "small Syrian weed kasytas (*κασύταζ*) that grows on trees, thorn-bushes and certain other plants" (De causis plantarum 2:17.3, 1976). Mirande (1900) argued that "kasytas" is probably not *Cuscuta*. He suggested that since Pliny's subsequent reference to this plant ("cadytas") allegedly alludes to some aromatic properties, this plant may be *Cassytha* spp., a coastal plant from Lauraceae resembling *Cuscuta* in the parasitic habit. It must be noted that Pliny in his description (Natural History 13:129, 1951) amalgamated "kasytas" with other, unnamed plant from the account of Theophrastus. About this unnamed plant, Theophrastus said that is "sown in the dog days on the thorn-bushes in Babylonia that sprouts the same day and then speedily envelopes the bush" (De causis plantarum 2:17.3, 1976). Pliny referred to these two plants as if they were a single one, and added that this plant "is used in making spiced wine and it is cultivated for this purpose" (Natural History 13:129, 1951). An even earlier indication to the preparation of a drink can be found in the

Talmud: "Why are not sufferers from ra'athan in Babylon? Because they ... drink beer containing *Cuscuta* (growing on) the hizme shrub" (Kethuboth 77b; see Epstein 1961). Epstein (1961) indicated that the "hizme shrub" is "Spira (Spina?) Regia." We could not determine what this spiny shrub was: *Tragacantha* (*Astragalus tragacantha* L.), *Rhamnus* spp., *Paliurus* spp., *Berberis* spp., *Zizyphus*? Therefore, Theophrastus' "kasytas" may be either *Cuscuta* or *Cassytha*, and the etymology of the two names is probably the same. Even in the 16th century, Fuchs (1542) used the name "*Cassutha*" for a dodder (Fig. 1) that, judging by its mentioned host, was apparently *Cuscuta epilinum* Weihe.

Several authors mentioned that the name has Greek origin (e.g. Dawson et al. 1994). But "kasytas" does not have any meaning in Greek and it would be more logical to assume that the name was introduced. Although Austin (1979) initially suggested that that the name comes from Aramaic, he mentioned later that the name has an Arabic origin (Austin 1980). However, apparently "kushkuut," "kashuut" or "koshoût" as Arabic names of *Cuscuta* are early Aramaic neologisms (Fraenkel 1886; Nakhle Al-Yassu'i 1986). Many ancient Arabic words, especially related to agriculture were introduced from Aramaic (Nakhle Al-Yassu'i 1986). Based on the new root "k-sh-w-th," the word "kushsha" meaning in Arabic "a lock of hair" was probably derived (David Mehall, pers. comm). Since Theophrastus mentioned Babylonia (Assyria) as a place of origin for "kasytas," this was probably from the geographical source of the name as well. Indeed, the etymology can be retraced in Syriac Aramaic and Hebrew (ksutha and ksuth, respectively), two closely related Semitic languages. The triradical root of the verb K-S-Y (Kaph, Shin, Yodh) means "to cover." Based on this root, a verbal noun that signifies "cover," "clothing" or "garment" is constructed in both languages: K-S-W-T (in Hebrew) and K-S-W-T-A (Kaph, Shin, Waw, Tav, Aleph) in Aramaic (Yona Sabar, pers. comm.; Paul Flesher, pers. comm; Sokoloff 1990). "Ksutha" is often mentioned in the Talmud (see Epstein 1961) and other Jewish-Aramaic texts such as the Targums (Jastrow 1950; Bowker 1969; Sokoloff 1990). The word was introduced into Arabic, Persian and Greek, creating a bridge between these fundamentally different languages and cultures.

Before Pliny, Dioscorides said that "Epithumon ... is ye flower of ye harder Thyme, & like to Satureja" (4:179, see Gunther 1959). Pliny mentioned two types of Epithymum: "one which is like the flowers of the thyme and satureia" ("*qui est flos e thymo satureiae simili*") and another one "that grows without a root, has slender a head like a long mantle, is red in color and is dried in the shade" ("*sine radice nasci, capite tenui similitudine pallioli, ruben, siccari in umbra*") (26:55–56). The recognition of these two "types" persisted until medieval age, when Tragus (1552) and Parkinson (1640) considered that they belong to "one kind growing on different herbs." Between the 16th and 17th centuries, dodders were called differently depending on the author. For example, Casper Bauhin (1623) used both "Epithymum" and *Cuscuta*. A common practice during that

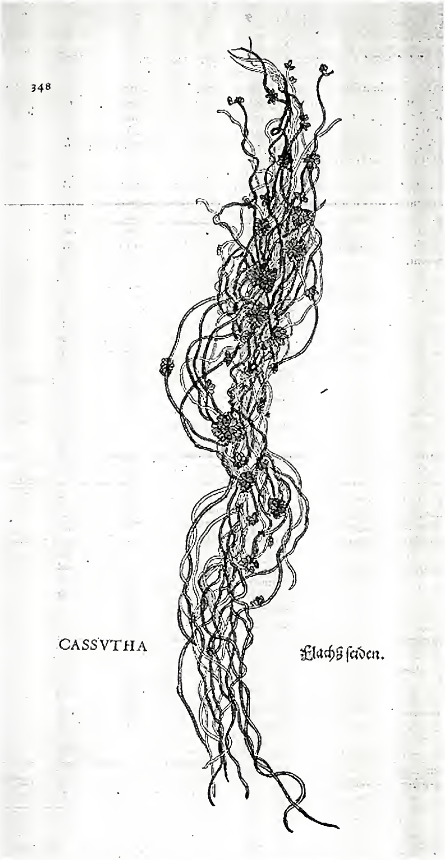

Fig. 1. *Cuscuta* spp. (probably *C. epilinum*). Fuchs, 1542.

time was to create a Latin name based on the hosts the dodders are growing upon, e.g. "Epithymum" (on *Thymus* spp.), "Epilinum" (on *Linum* spp.), "Epimajorana" (on Majoran), "Epistoebe" (on Stoebe - *Vicia* spp.), "Epiurtica" (on *Urtica* spp.) (e.g. Gerard 1633; Parkinson 1640). Apparently, Ray (1682) and Tournefort (1694–1695) were the first to retain only *Cuscuta*, which was later officially endorsed by Linnaeus (Sp. Pl. 124. 1753).

The parasite, "a spontaneous act of nature"

Kuijit (1969) suggested that the earliest reference to parasitic plants belongs to Theophrastus. However, an even earlier record can be found in Aristotle: "for even among land-plants there are some that are independent of the soil, and that spring up and grow, either parasitically upon other plants, or even entirely free (De partibus animalium 4:681b, 2001). Ancient Greeks were well-aware of the parasitic phenomenon. Even rooted, green lianas, like the ivy (*Hedera helix* L.) were regarded as "taking the food that belongs to the tree" (Theophrastus, De causis plantarum 2:17.4, 1976). And approximately three centuries latter, Pliny wrote: "it is a well-known fact that trees are killed by ivy" ("*hedera necari arbores certum est*") (Natural History 16:243, 1951).

The animal-oriented biological treaties of Aristotle have influenced our understanding of plant parasitism for almost 2000 years. Theophrastus was Aristotle's student and he developed many of the ideas of his teacher. "It may perhaps be that like animals, plants are fond of one another and live together" (Theophrastus, De causis plantarum 2:17.5, 1976). Or, that "some (plants) come from seed as through by a spontaneous act of nature. The latter come from rotting earth or from rotting parts of plants: for some are not constituted separately by themselves but are produced on trees, for example the mistletoe" (Aristotle, De generatione animalium 1:715b. 25–30, 1965). Following this idea, Theophrastus observed that maybe some plants "came from a corruption of something in the host" similarly to "some animals that can arise from other animals" (De causis plantarum 2:17.5, 1976). For example, like "those insects (such as lice and bed bugs) that ... live on the flavors of living flesh ... (and are produced) from the moisture from animals" (Aristotle, De partibus animalium 31:556b. 21–28, 2001; also De generatione animalium 1:715b. 5, 1965). But it must be emphasized that the Greek spontaneous concept does not preclude the origin of the parasite from seeds: "birds eat its fruit and let their droppings fall on the host tree." (Theophrastus, De causis plantarum 2:17.6, 1976). The wonder of ancient Greeks came from their belief that since plants "absorb the food already prepared from earth with their roots" they don't need a stomach, and they don't produce excrement (Aristotle, De partibus animalium 2.10, 2001). This is why plants "not growing on the ground at all is astonishing" (Theophrastus, De causis plantarum 2:17.5, 1976). In the Babylonian Talmud, the parasite was explicitly depicted as an integral part of its host: "if one plucks *Cuscuta* from shrubs and thorns ... one is culpable as if it inserts his hand in an animal's bowels and detaches an embryo" (Shabbath 107b; see Epstein 1961).

Later, Arabians were inspired by Greek science and introduced it into Europe. The ancient meaning of the "spontaneous act" degraded and the parasite was literally viewed as arising from its host. For instance, Francis Bacon, in the England of the early 17th century, believed that mistletoes were an exudation (sap) "that the tree doth excern and cannot assimilate," and that the idea of birds spreading its seeds is merely a "fable" or a "tale" (Sylua Syluarum 556–557, 1626). This misconception was reflected in the "Uva Barbata" or "Le Raisin Barbu," a *Cuscuta* spp. parasitizing *Vitis vinifera* L., and considered together with its host either as an entirely different species of grape wine (Tabernaemontanus 1588–1591), or a "monstrosity," a metamorphosis of the normal species (Jean Bauhin 1591). As late as 1831 such a blemish was connected to the appearance of the comet in the previous year (Kuijt 1969). In conclusion, the "spontaneous" concept regarding the origin of parasitic plants from medieval ages was merely a regression of the ancient Greek concept.

Rufinus, a forgotten botanist of the 13th century, was probably the first to observe that "*Cuscuta* ... is born in meadows and it ties to other plants, which it kills" ("*Cuscute ... nascitur in pratis et ligat alis herbas et necat eas*") (Rufinus approx. 1300 A.D.; see Thorndike 1946). His short note passed unobserved by all botanists and herbalists, and about three centuries later, Parkinson (1640) rediscovered that dodders "spring from their owne seede." He emphasized the discovery several times to "let all others understand": ... it may appeare plainely to any that neither Tyme, Savory, or any other herbe, doe naturally of their owne seede bring these strings or laeces but that they spring from their owne seede, either shed or scattered of themselves upon ground, or coming among the seedes of other hearbs that are sowne" (Parkinson 1640).

Cuscuta, the strength of weakness

Theophrastus compared parasitic plants with grafted shoots and buds that "get food that is more readily available and that has been prepared and practically concocted" (De causis plantarum 2:17.6, 1976). A good understanding of the parasitic phenomenon can be also encountered in the Babylonian Talmud, at approximately 100 BC. Although apparently it takes its food "from air ... *Cuscuta* derives its nourishment from soil (through its host); for we may observe that when the shrub (on which *Cuscuta* grows as a parasite) is cut off, *Cuscuta* dies" (Erubin 28b; see Epstein 1961). But "a plant seeking such food would be weak in its nature" (Theophrastus, De causis plantarum 2:17.6, 1976). Furthermore, such plants must be weaklings since they don't sprout and grow by themselves (Theophrastus, De causis plantarum 2:17.6, 1976). The same idea of helplessness, exemplified with "cadytas" and "viscum," can be found at Pliny: "because they have no abode of their own and consequently live in that of others" (“*namque cum suam sedem habeant, in aliena vivunt*,” Natural History 16:39. 243–244, 1951). In a sense this is true; today we know that during the parasitizing stage, *Cuscuta* depends entirely on the nutrients provided by its host (Dawson et al. 1994). Nonetheless, gradually the harmful effect of dodders on their hosts outweighed other considerations. Fuchs (1542) noted that *Cuscuta epilinum* “grows ... over plants, quite often entangling them so thickly with its web that shuts off the sun like a tent. ... It forces out growth from the host plant, and strangles it with its filamentous stems, or, by continuous sucking of the mother’s (host’s) sap, reduces it to exhaustion” (Historia Stirpium:347). Even today, it is intuitively seductive and deeply rooted in our unconscious fears to imagine plant parasitism in terms of animal parasitology.

The hot or cold character of dodders and several old uses

Quoting Phoenicians and Arabs, Fuchs and other medieval herbalists (Ruellius 1529; Gerald 1633; Parkinson 1640; Culpeper 1652) believed that the curative powers of dodders depend on the “character of the parent (host): if it invades a warm plant, it strengthens its heating nature, and if it clings to a cold one, it will acquire the cold strength” (Fuchs, Historia Stirpium:349, 1542). This is why during medieval times, dodders were named according to the host they are growing upon (see above) (e.g. Gerard 1633; Parkinson 1640). Among these, “Epithymum” was said to have the best therapeutic properties because *Thymus*, its host, is dry and hot in the third degree, as indicated by Galen (Tragus 1552; Gerard 1633; Parkinson 1640; Culpeper 1652). “Physitians crying up Epithymum, (most of which comes from Hymettus in Greece, or Hybla in Sicilia, becaus those Mountains abound with Time) he is a Physitian indeed that hath wit enough to chuse his Dodder according to Nature of the Diseas and Humor peccant” (Culpeper 1652).

“That dodder growing upon Tares (*Vicia* spp.), being the most frequent in London, and wherewith our markets are onely in a manner furnished and Apothaecaries shoppes stored from thence ... can have no effectual quality comparable to Epithymum for ... Tares are hard of digestion and binde the bellye and the nourishement of them engendereth thicke blood apt to turn into melancholie” (Parkinson 1640). Today we know that, indeed, the parasite forms a biochemical continuum with its host, and that its chemical makeup may depend on the latter. Primary metabolic compounds, minerals, xenobiotics, secondary products (e.g. alkaloids and cardenolides), herbicides, viruses, and mycoplasmas are translocated from the phloem of the host via the haustoria to the parasite (Dawson et al. 1994). “You are what you eat” couldn’t be more true for these plants.

Dioscorides, and later Pliny, recommended “Epythimum” as a purgative, as well as “for melancholicall, & ye puffed up with wind, ye quantity of an acetabulum to ye quantity of 4 dragms with honey & salt, and a little Acetum

(4:179, see Gunther 1959; also Pliny the Elder, Natural History 26:55). In an Arabic text dated before 1000 AD it is written: "If you put an euquia of blood (of the black dog) with a mithqal[2] of grounded *Cuscuta*; who will take this will never be reached by the spirits which causes enchantment. The meat (of black dog) in food with salt, is good a antidote against infantile epilepsy" (Alfonso-Goldfarb 1999). Other Arabic uses of *Cuscuta* have been reviewed by Guigues (1909), Hamarneh (1973) and Levey (1966). These were the main uses of dodders, which were later retained by all medieval herbalists. For example, Gilbertus Anglicus, around 1250 endorsed "Epithymum" as a remedy in a mixture of plants that "purge the head of evil humors" (Getz 1991). Culpeper (1652) noted that it is also good "to purge black or burnt Choller, which is the cause of many Diseases of the Head and Brains, as also for the trembling of the Heart, faintings, and swounings." Since dodders are under the sign of Saturn, "this helps by Sympathy, & strengthens al the parts of the Body he rules: Melancholy, Addust Choller, Trembling, fainting, swooning, Spleen, Hypochondria, Obstructions, Gall, Jaundice, Liver, Disury" (Culpeper 1652).

ACKNOWLEDGMENTS

Many thanks are due to Guy Nesom, Ovidiu Constantinescu and Daniel Austin who reviewed the manuscript and made interesting observations. Numerous linguists kindly helped in our search for meanings and possible etymologies of *Cuscuta*: Paul Flesher, Yona Sabar, and Michal Sokoloff with the Hebrew and/or Aramaic, and Safa Jubran, David Mehall, Hanita Brand, Irfan Shadid and Binyamin Abrahamov with the Arabic. Safa Jubran sent us the book she translated with Ana Maria Alfonso-Goldfarb. Sawsan Oran and Mohammed Sawaie gave us names of *Cuscuta* from Northern Africa. Rabbi Nissan oriented our search toward the Talmud. Yolanda Camacho translated the Spanish abstract.

ABSTRACT

The genus *Amsonia* was named for Dr John Amson, a physician in Williamsburg, Virginia, in the mid-nineteenth century.

RESUMEN

El genero *Amsonia* fue nombrado por Dr. John Amson, un médico de Williamsburg, Virginia, en la mitad del siglo diez y nueve.

Amsonia Walter is a genus of about twenty species native to North America and eastern Asia, of which the best known is *A. tabernaemontana* Walter, the eastern bluestar. The name *Amsonia* was first applied to that species by John Clayton of Gloucester, in colonial Virginia, in the 1750s, and ever since that time uncertainty has persisted and statements have differed as to its derivation or eponymy.

Clayton did not include the name *Amsonia* in the manuscript that he sent to the Dutch botanist Johan Frederik Gronovius, much of which Gronovius (1739) incorporated into his *Flora Virginica*. At that time Clayton thought that the bluestar might be considered a species of *Nerium* (oleander), and designated it "*Anonymus Suffrutex foliis Salicis alternis...Nerii species.*" He gave it the name *Amsonia* in the later manuscript (not extant) on the plants of Virginia that he sent to Peter Collinson in England in 1757, but that work was never published. He also included the name *Amsonia* with specimens and seeds that he sent to British and European botanists. Still later Clayton proposed a different name for the eastern bluestar, based on the form of the seeds, but that name likewise remained unpublished. By then, the name *Amsonia* had become inseparably associated with this species, which had quickly become popular in British horticulture following its introduction as *Amsonia* by Philip Miller in 1759 (Smith 1819; Berkeley & Berkeley 1963, 1982).

Linnaeus received a description of the eastern bluestar from his former student Daniel C. Solander in 1761. Solander, who was living in London at the time, had based this description on plants he had seen in the gardens of Peter

[1]Contribution No. 112 from the Royal Botanical Gardens, Hamilton, Ontario, Canada.

Collinson and James Gordon, supplemented with information from Clayton's manuscript. He informed Linnaeus that Clayton had called the species *Amsonia*, but added that "whence the name was taken I know not," nor did any of the botanists in London and vicinity of whom he had inquired; they believed "that Clayton named it for someone in North America" (letter from Solander to Linnaeus 16 November 1761, excerpted by Berkeley & Berkeley 1963). In 1762 Linnaeus received a sketch and information on the eastern bluestar from the botanical artist Georg Dionysius Ehret, with a promise of specimens to be sent via Solander (Calmann 1977). Ehret had been approached with regard to illustrating the work that Clayton had sent to Collinson, and had studied specimens collected by Clayton. Later that year Linnaeus (1762) named the species *Tabernaemontana Amsonia*.

The "*Anonymus Suffrutex*" was designated *Clayton 306* by Gronovius, but no such specimen is in the Clayton herbarium now at BM. The Linnaean herbarium at the Natural History Museum in Stockholm (S-LINN) contains a specimen of the eastern bluestar from the herbarium of Clas Alströmer, who had acquired it from Andreas Dahl. It is labeled "Tabernaemontana Amsonia" and "Dahl a Linné P" in Dahl's handwriting, indicating that Dahl had received it from Linnaeus himself (Lindman 1908). It was perhaps part of a collection made by Clayton and given to Linnaeus by Ehret or Gronovius, or it may have been obtained by Solander from a cultivated plant.

Amsonia was published as a genus name by Thomas Walter in 1788. The name of the type species, *Amsonia Tabernaemontana* Walter, was based on *Tabernaemontana Amsonia* L. Walter gave no derivation or eponymy for the name.

Many recent references state that *Amsonia* was named for "Charles Amson." The earliest association of the forename Charles with *Amsonia* that I have found was by Loudon (1830), according to whom the genus was named for "Charles Amason [sic], an American traveller." This eponymy for *Amsonia* was soon adopted in other British and Continental European references. The surname was altered to "Amson" by Paxton (1840), who identified Charles Amson as "a traveller in America." Nicholson (1884), whose wording has been retained in the successive editions of the *Royal Horticultural Society Dictionary of Gardening*, identified Charles Amson as a "scientific traveller in America."

It may be pertinent to the credibility of this eponymy that Loudon almost certainly would have seen Smith's (1819) account of the Neotropical genus *Amasonia* L.f. (Verbenaceae). As noted by Smith, Linnaeus filius had stated that *Amasonia* was named "in memory of Amason, a traveller in America" (translation), whom, according to Smith, "M. [Alexandre] De Thies [had] baptized Thomas." Smith was skeptical, because he had "never been able to learn any tidings of such a person." Linnaeus filius provided no forename or further information, and may merely have assumed that South America's largest river, the name of which is spelled "Amason" in Swedish and some other European languages, was named for an explorer. Loudon, however, having seen statements that *Amasonia* was named for Thomas Amason, may have followed De Thies's alleged precedent a step further and arbitrarily coined the name Charles Amason, and designated that imaginary person, like Thomas Amason, "an American traveller."

Of *Amsonia*, Smith (1819) said that "no positive account of the meaning or origin" of the name could be given, noting only that it had originally been bestowed by Clayton. He speculated that the spelling of the names *Amasonia* and *Amsonia* might represent an error, and that both genera might have been named for the British Admiral George Anson, Baron Anson of Soberton. Rafinesque (1838, 1840) accepted this eponymy with none of Smith's uncertainty and "corrected" the spelling to "*Ansonia*," but no others have done so.

The eponymy given by Loudon and Paxton was probably the basis for Gray's (1856) statement, in the second edition of his *Manual*, that *Amsonia* was "said to be named for a Mr. Charles Amson." That uncertain wording was retained through the sixth edition of *Gray's Manual*. Wood (1861) expanded it to "Dedicated to Charles Amson, of S. Carolina?" The speculative addition was not explained, but may have been made because the genus name was published by Walter, whose botanical activity had been confined to South Carolina. Britton and Brown (1896) stated with no such reservation that the genus was named "for Charles Amson of South Carolina." That wording was soon adopted in other American publications.

Woodson (1928) was skeptical about references to "Charles Amson." He consulted encyclopedic and historical references and made inquiries of historical societies in Virginia and the Carolinas, and found no evidence that any Charles Amson had lived or traveled in Virginia or the Carolinas during the colonial period or contributed to the knowledge of their natural history. Likewise, using more recent biographical references and publications from that history-conscious region, as well as Internet search engines, I found no record of any Charles Amson in those colonies during the 18th century (except as the supposed eponym of *Amsonia*). Nor have I found any mention of either of Loudon's "travellers" in any other context. Consequently, I share Smith's, Gray's, and Woodson's skepticism about their having existed. Had they lived and explored the wilds of the Americas, it seems unlikely that they could so greatly have impressed Clayton and Linnaeus filius, and at least have been known to Loudon, yet so completely have escaped the attention of historians and biographers. A thorough search would be complicated by the apparently independent origins of the surname Amason in England and Scandinavia. Even if these Amasons existed, however, there is ample evidence, presented below, that the apocynaceous genus *Amsonia* was not named for either of them.

The earliest extant indication that *Amsonia* was named for a physician is in a letter written 30 December 1759 by Ehret (Berkeley & Berkeley 1963), who had probably seen words to that effect in Clayton's manuscript or correspondence. Apparently not distinguishing between Carolina and Virginia as Clayton's place of residence, he wrote that *Amsonia* had been named "perhaps for a doctor in Carolina."

An indication of the eponymy of *Amsonia* by Clayton himself appears in a letter from him to the Philadelphia botanist John Bartram dated 1 September 1760, in which he said that he had previously proposed that the plant be named *Amsonia* "for a doctor, here" (William and Mary College Quart. Hist. Mag., ser. 3, 6: 319. 1926; Woodson 1928). Woodson inferred from Clayton's use of "here" that *Amsonia* had been named for "a physician of Gloucester County, Virginia." He added that "regarding his complete name, or the positive spelling of his family name, doubt still remains." The same letter was probably the basis for the statements by Robinson and Fernald (1908) and Fernald (1950), in the seventh and eighth editions of *Gray's Manual*, that *Amsonia* was "Named for Dr. Amson, physician of Gloucester, Virginia, in 1760, and friend of John Clayton." Combinations of "Charles Amson," from Loudon, Paxton, Gray, and Britton and Brown, and "physician" and "Virginia," from Robinson, Fernald, and Woodson, have come to prevail in recent publications.

Berkeley and Berkeley (1963, 1982) found from a source on Virginia medical history (Blanton 1931) that Dr. John Amson had been practicing in Williamsburg, Virginia, in 1751. They (1982) concluded that "Clayton had named the new genus *Amsonia* in honor of his friend Dr. John Amson of Williamsburg." I have not found this information repeated by any more recent botanical authors.

The Berkeleys found one other published reference to this Dr. Amson, which noted only that he frequently used the expression "neither here nor there." Present-day search engines, although not providing all standard biographical data, do lead to further information about the Dr. Amson who was Clayton's contemporary in colonial Virginia.

Records in the Archives of Colonial Williamsburg, compiled and annotated by Mary A. Stephenson (1961), confirm the Berkeleys' finding that John Amson, a "Doctor of Physic," lived and practiced in Williamsburg in the mid-18th century. Clayton would have considered Williamsburg, ca. 22 km away across the York River in James City and York counties, near enough to Gloucester to justify the use of "here" in writing to Bartram in Philadelphia, especially since he had spent part of his youth in Williamsburg and members of his family lived there.

I have found no definite information on this Dr. Amson's genealogy or his life prior to his practicing medicine in Williamsburg. Records compiled by the Church of Jesus Christ of Latter-Day Saints provide limited data on a few individuals named John Amson who lived in England and Scotland during the first 40 years of the 18th century, but no data on anyone by that name in colonial Virginia. The record perhaps most likely to be relevant is that of John Amson, son of James and Margaret Amson, who was baptized 24 July 1699, at the age of one year, in St. Sepulchre Church, London (where Captain John Smith of early

Virginia history had been interred). The time and (in view of data presented below) the country fit, but nevertheless it is by no means certain that this was the same John Amson.

Although an English origin is not unlikely, the name Amson does not appear in Munk's Roll of the members of the Royal College of Physicians. However, since the surname is not common, it does seem probable that Dr. John Amson of colonial Virginia was the John Amson, M.D., who received that degree from the university at Rheims (now Reims), France, 2 September 1722. Such credentials would have been impressive in colonial America, consistent with the apparent reputation (below) of Dr. Amson of Williamsburg as one of the "best Physicians" in Virginia. This record is from a list of early students from the British Isles at medical schools in continental Europe, compiled by Dr. Harold T. Swan (1996). This compilation was based on manuscript notes that had been in the possession of the medical historian Dr. Robert W. Innes Smith at the time of his death in 1933 (originals at the University of Sheffield). Aside from the data noted above, it states only that this John Amson was English, as distinguished from Scottish or Irish. According to Dr. Swan (pers. comm. 11 April 2003), Innes Smith's notes contain nothing further on Amson. He considers it unlikely that Innes Smith found additional information at Reims, because many of the university's records from the relevant time had been destroyed, presumably during the French Revolution.

I have not found when Amson arrived in America, if in fact he was of English birth. The earliest record of his presence in Virginia that I have encountered is from 1738, when the estate of the late Dr. Charles Brown of Williamsburg retrieved a book that Amson had borrowed from Brown's library (James 1895).

A physician in Williamsburg in 1738 could hardly have avoided the controversy associated with John Tennent, a "practitioner of medicine" in that city (Blanton 1931; Jellison 1963). Tennent's domestic medical manual, *Every Man His Own Doctor*, was highly popular, but some physicians questioned his competence and objected to his pursuit of financial recognition from public funds. In particular, his advocacy of the use of *Polygala senega* L. became obsessive, and his reactions toward those who took issue with him became intemperate. He felt that physicians who held medical degrees from European universities were unjustifiably disdainful of those who had obtained their qualifications through apprenticeship and independent study. I have found no record of Amson's involvement in this controversy. In one of his statements in his own defense, however, Tennent (1738) implied that medical degrees were awarded too freely at Rheims, alleging that one had inadvertently been bestowed upon a horse. Rheims may by chance have provided an anecdote that Tennent considered suitable for his purposes, but one wonders if someone with a degree from Rheims was among those whom Tennent perceived as a hostile medical establishment.

In 1746, Amson bought the property identified as Lots 212–217, Block 36, City of Willamsburg, County of York, from Thomas Jones, nephew-in-law of the naturalist Mark Catesby. These lots at the intersection of Boundary and Scotland streets had been so numbered by the Trustees for the Land when the city was laid out. Much later they included the site of "Wheatlands," the home of the artist Georgia O'Keefe during her late teens. The property included at least one house plus outbuildings when it was acquired by Amson. He owned and resided on this property until his death. About 1751 he purchased from Henry Tyler 180 acres of land just outside the Williamsburg city limits (Stephenson 1961). As well as being a physician Amson appears to have been a planter, or gentleman farmer, as men primarily associated with other enterprises or professions often were in colonial times. At least as early as 1746 he was an alderman (Stephenson 1954), and in 1750–1751 he was mayor of Williamsburg (Bodie et al. ca. 1999).

In 1758 then-Colonel George Washington had been ill for some time, probably with dysentery, although he was concerned that he might have consumption. He traveled from Mount Vernon to Williamsburg "to receive the Advice of the best Physicians," and there consulted Dr. Amson on 15 March (Fitzpatrick 1931–1944, including a letter from Washington to Colonel John Stanwyx, 5 March 1758). Fitzpatrick, in editing Washington's papers, commented that Washington "seems to have received the proper treatment, for he was able to be back to his command at Fort Loudon April 5." Amson may also have treated Daniel Parke Custis, whose widow Washington subsequently married; he was listed among the creditors of Custis's estate, although Dr. James Carter was recorded as having been the attending physician during Custis's last illness (Stephenson 1959; Abbot 1988).

A few other references to Dr. John Amson of Williamsburg appear in historical sources. He was among the "officials of the government of Virginia" who signed an oath of allegiance to King George II (Virginia...1738–1752), probably having done so upon becoming alderman or mayor. York County records indicate that as of 21 September 1747 he was paying taxes on five "tithables," i.e., indentured slaves (Stephenson 1961). His name appears in the account book of the Yorktown merchant William Lightfoot (Lightfoot 1740–1764), and he was one of those who proved the will of Philip Lightfoot in 1748 (Tyler 1894). The jurist John Blair recorded having visited Amson's gardens 24 March 1751 (Tyler 1899), but wrote nothing about the gardens.

Neither Ms. Stephenson nor I have been able to determine the date of Amson's death, although the well-indexed *Virginia Gazette* usually published obituaries of prominent Williamsburg residents. His will was proved in the General Court of Virginia, of which the records from the relevant period are not extant (Stephenson 1961). His death evidently occurred after November 1761, when he was listed as a creditor of the estate of John Parke Custis, son of Daniel (Stephenson 1959; Abbot 1988), and before July 1765. Records of land ownership include that of a transaction in July 1765 in which Anne Anderson is said to have inherited the six lots and the buildings thereon in Williamsburg plus the 180 acres outside the city from "the late Dr. Amson." Mrs. Anderson, who was at that time the wife of Robert Anderson of Williamsburg, is thought likely to have been Amson's daughter, or possibly his widow if she had soon remarried, but the relationship has not been determined (Stephenson 1961). I have found no mention of any other individuals with the surname Amson in eighteenth-century Williamsburg and vicinity.

What may be Amson's only extant writing therefore appears to have been published posthumously, either from a handwritten heirloom or as a reprint from an earlier publication. This (Amson 1776) is a prescription for the treatment of whooping cough, which included several botanical ingredients, in quantities deemed appropriate for a boy of ten. The treatment began with an emetic containing ipecachuana and oxymel of squills (*Urginea maritima* (L.) Baker, a mild source of cardiac glycosides). This was followed first by chamomile tea, then by elixir paregoricum (an opiate) in pennyroyal tea and mint water. The next day the treatment called for gum ammoniac (resin from *Dorema ammoniacum* D. Don) in pennyroyal tea, mixed with the juice pressed from two hundred woodlice in white wine, with saffron and honey.

GUY STERNBERG and JIM WILSON. 2004. **Native Trees for North American Landscapes**. (ISBN 0-88192-607-8, hbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $59.95, 552 pp., 513 color photos, 96 line drawings and 1 map, 8 1/2" × 11".

This is a book of detailed information on North American native trees for landscapes and gardens. The authors say they exclusively focus upon the cultivation and preservation of native trees. Most of the book is devoted to what the authors call the "Menu of Native Trees." Basically that is the ninety-six trees which are the feathered species. Each species begins with a silhouette of the tree and a leaf, description, leaves, flowers and fruit, best seasons, native and adaptive range, culture, problems, similar and related species, and comments. Oh, let's not forget the very nice color photographs that compliment each featured species.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, Texas 761202-4060, U.S.A.*

ABSTRACT

A pH drift experiment was conducted to determine the HCO_3^- uptake potential of Texas wild rice (*Zizania texana* Hitchc.). In 15 separate experimental runs, total inorganic carbon to alkalinity ratio varied between 0.93–0.99 and final pH varied between 8.54–9.21, strongly suggesting Texas wild rice is an obligate CO_2 plant unable to utilize HCO_3. The estimated CO_2 compensation point for Texas wild rice is 2 µmol l^{-1}.

Data from this study provide physiological evidence for the positive relationship between current velocity and biomass productivity observed in Texas wild rice (Power 1996a, 1996b, 2000; Poole & Bowles 1999; Saunders et al. 2001) and provides water resource managers with information they need to manage and protect the San Marcos River ecosystem.

RESUMEN

Un experimento de la variación del pH fue utilizado para determinar el potencial de absorción de HCO_3 del arroz salvaje de Tejas (*Zizania texana* Hitchc.). En 15 experimentos separados, la relación entre el carbono inorgánico y la alcalinidad varió entre 0,93–0,99 y el pH final varió entre 8,54–9,21, sugiriendo que el arroz salvaje de Tejas es una planta CO_2 obligatoria incapaz de utilizar el HCO_3. El punto estimado de compensación del CO_2 en el arroz salvaje de Tejas es 2 µmol l^{-1}.

Los datos de este estudio proporcionan la evidencia fisiológica para la relación positiva entre la velocidad actual y la producción de la biomasa observadas en el arroz salvaje de Tejas (Power 1996a, 1996b, 2002; Poole y Bowles 1999; Saunders et al. 2001) y ofrecen a los encargados de los recursos hídricos la información que necesitan manejar y proteger el ecosistema del río San Marcos.

INTRODUCTION

The San Marcos River arises from springs within the City of San Marcos, Hays County, Texas and flows 8.1 river km in a southeasterly direction before it joins the Blanco River. The source aquifer for the San Marcos River is the Edwards Aquifer, the sole source of municipal, agricultural, and industrial water for 1.5 million people in central Texas. Water is pumped continuously from the Edwards Aquifer for human use, but is recharged only during rain events. As water is pumped during drought periods when recharge is minimal, the level of the aquifer drops, threatening spring flow to the San Marcos River and other local spring systems. The spring-fed San Marcos River provides habitat for five federally listed species: fountain darter (*Etheostoma fonticola*), San Marcos gambusia (*Gambusia georgei*), San Marcos salamander (*Eurycea nana*), Texas

SIDA 21(1): 389 – 398. 2004

blind salamander (*Typhlomolge rathbuni*), and Texas wild rice (*Zizania texana*). The primary threat to each species is reduced spring flow from the source aquifer (U.S. Fish and Wildlife Service 1996). The threat became critical during a drought event in 1990 and all five species were the focus of an endangered species lawsuit initiated in 1991 (Sierra Club v Lujan, No. MO-91-CA-69). One outcome of the lawsuit was creation of a water authority to manage the aquifer for human use and to protect the San Marcos River ecosystem for endangered species by maintaining adequate spring flow. Defining "adequate" spring flow for a species is a monumental challenge met by research systematically addressing ecological and physiological aspects of the species.

The target species for this study was Texas wild rice. This species is endemic to the San Marcos River, TX and was listed as endangered in 1978 (U.S. Fish and Wildlife Service 1985). Texas wild rice is a perennial, submersed macrophyte now commonly found in swiftly flowing water. Under these conditions, it produces long, ribbon-like, submersed leaves and reproductive culms. Culms can become emergent and produce wind pollinated, terminal inflorescences. Nodes along each culm give rise to roots and asexual clones, called tillers. A thorough description of the species and its habitat is provided by Terrell et al. (1978), U.S. Fish and Wildlife Service (1995), Poole and Bowles (1999), and Saunders et al. (2001).

Texas wild rice has two distinct phenotypes under wild and cultured conditions. Wild plants found in flowing water (>0.46 m s^{-1}) in the San Marcos River are perennial and primarily submersed, although reproductive culms are present. Under cultivated conditions in slow moving water (<0.05 m s^{-1}), Texas wild rice has low vegetative productivity compared with study plants grown in faster flowing water ranging from 0.29–0.49 m s^{-1} (Power 1996a, 2002). Texas wild rice in slow moving water ranging from 0.001–0.12 m s^{-1} is primarily emergent, sexually reproductive, and annual to short-lived as is common for other North American *Zizania* species (Terrell et al. 1978; Power 1996a, 2002). Primarily emergent plants with low biomass productivity are especially vulnerable to herbivory because of the potential for loss of reproductive culms prior to seed set and the ultimate loss of the plant because of a shortened life span.

Carbon utilization by macrophytes has been shown to influence photosynthesis in experimental studies (Smith & Walker 1980) and may be an important factor influencing phenotypic variation in Texas wild rice. The relative concentrations of carbon species dissolved in water are influenced by pH. At lower pH proportionally more CO_2 is available; as pH rises, equilibrium shifts to HCO_3^-, then $CO_3^=$. Macrophytes utilize inorganic carbon in the form of CO_2 for photosynthesis and all submersed species are able to extract this form of dissolved inorganic carbon from the water when it is available. In addition, some submersed species show the ability to extract efficiently HCO_3^- from the water while others exhibit little or no ability to do so (Allen & Spence 1981; Maberly

& Spence 1983; Sand-Jensen 1983; Spence & Maberly 1985). In addition to the absolute concentration of dissolved inorganic carbon, the flow environment of the submersed leaves also influences their ability to extract carbon from the water. Flowing water reduces the thickness of the boundary layer surrounding leaves through which gases move predominantly by diffusion. Slower diffusion of CO_2 across the boundary layer can limit photosynthesis in still or very slow moving water (Smith & Walker 1980).

Differential carbon availability combined with carbon uptake potential may contribute to phenotypic variation in Texas wild rice and provide a physiological explanation for its preference for a flowing water habitat. The purpose of this study was to determine the bicarbonate uptake potential of Texas wild rice.

METHODS AND MATERIALS

Carbon use by Texas wild rice was examined using plants taken from culture after seedlings had been growing about three months in an outdoor cement raceway. The raceway was supplied with water pumped from the Edwards Aquifer and with chemistry similar to that of the San Marcos River. The plants had 4–6 leaves, each of which was 20–30 cm in length. The plants were maintained in aerated river water (4.5 meq l^{-1} alkalinity) under artificial illumination (250 μmol $m^{-2} s^{-1}$ PAR; 14:10 light/dark photoperiod) at laboratory temperature (22° C) until utilized. All experiments were conducted within four days of arrival of plant material at the lab.

For comparison data are also presented for *Hydrilla verticillata*, a submersed aquatic species known to be well adapted for extracting bicarbonate from water due to its unique, C-4 like photosynthetic pathway (Holaday & Bowes 1980). *Hydrilla verticillata* apical stem fragments were collected from culture ponds at the Lewisville Aquatic Ecosystem Research Facility, Lewisville, TX.

The pH drift technique described by Allen and Spence (1981) was used to determine the HCO_3^- uptake potential of Texas wild rice. This method involves continuous measurement of pH in a solution bathing actively photosynthesizing plants in a closed system at constant alkalinity (ALK). The method relies on shifts in abundance of the three species of dissolved inorganic carbon (CO_2, HCO_3^-, $CO_3^=$) with pH. In a closed system, plants will continue to photosynthesize until inorganic carbon can no longer be extracted from the bathing solution. When photosynthesis ceases, the final pH of the solution is dependent on the concentration of total dissolved inorganic carbon (C_T) in solution which depends upon the carbon-extracting potential of the plant.

The pH endpoint of these experiments varies with a plant's ability to utilize HCO_3^- and on the alkalinity of the solution. Carbon dioxide obligate plants (those which cannot utilize HCO_3^-) cannot shift the pH of the bathing solution past the point where free CO_2 disappears from solution (pH ca. 9.2 depending on alkalinity). The CO_2 content of the solution at the pH where photosynthesis ceases is considered the CO_2 compensation point for that species. Removal of CO_2 from the water results in increased pH, but has little impact on C_T, and does not impact ALK.

Other aquatic plants are also able to utilize HCO_3^- as a source of inorganic carbon. In a closed system, these plants will shift the pH well above the threshold where CO_2 disappears. In this case, the final pH of the solution depends on the total C_T pool available as well as the affinity of the plant for HCO_3^-. The HCO_3^- content of the solution at the pH where photosynthesis ceases is considered the HCO_3^- compensation point for that species. The removal of HCO_3^- from solution has a stronger impact on C_T but still does not impact ALK, since the buffering capacity lost by the consumed HCO_3^- is balanced by the production of OH^-. The C_T:ALK ratio at the end of a pH drift experiment is considered a relative measure of a plant's ability to utilize HCO_3^- (Maberly and Spence 1983). The C_T:ALK ratio of CO_2-obligate plants is very close to 1.0, while the ratio of HCO_3^- users is well below 1.0.

Oxygen and pH were continuously measured in a re-circulating closed system. The experimental apparatus consisted of a glass incubation chamber, an acrylic probe block, and a submersible centrifugal pump, all connected by gas tight tubes of butyl rubber (total volume 400 ml) and submerged in a temperature-controlled water bath (20° C). The incubation chamber was a glass cylinder 5 cm in diameter × 30 cm long. A glass tube connector was fused to one end, while a ground-glass fitting with another glass tube connector was fused to the opposite end to allow access to the cylinder for plant tissue insertion and removal. Water was re-circulated at an approximate velocity of 2 cm s^{-1} through the incubation chamber and was sufficient to remove diffusive limitations of photosynthesis. The acrylic sensor mounting block allowed both pH and O_2 sensors to be screwed in so that the electrode tips were continually bathed by the re-circulating solution. The pH electrode (Ross combination electrode) had a sensitivity of 0.01 pH units and was connected to a pH transmitter (Jenco 629). The fast-response, low-consumption Clark-type polarographic oxygen sensor (YSI 5331) was connected to an oxygen meter (Cameron Instrument Corp). The oxygen electrodes were calibrated by submersing the probe in N_2-sparged water and fully aerated water at incubation temperature. pH sensors were calibrated prior to use utilizing pH 7.0 and 10.0 buffers. Outputs from the pH transmitter and the oxygen meter were continuously monitored by a computer equipped with data acquisition software (Strawberry Tree Workbench PC). The sensors were monitored continuously and data recorded every 3 minutes. Calibrations did not drift over the time-scale of the experiments. Alkalinity of the bathing solutions were determined by titration with dilute hydrochloric acid (APHA 1992).

Entire Texas wild rice rosettes consisting of 3–6 leaves (0.2–0.3 gdw) were used in the experiments. Light was provided by specialized fluorescent aquaria lights (6700 K) providing saturating light intensities (500 μmol m^{-2} s^{-1} PAR). The bathing solutions used for the experiments were either San Marcos River water (Alk = 4.5-5.0 meq l^{-1}), a general purpose culture solution (Alk = 0.82 meq l^{-1}; Smart and Barko 1985), or intermediate mixtures of the two. Prior to the start of the experiment, the incubation chambers were flushed with a bathing solution which had been bubbled with a gas mixture composed of 350 ppm CO_2 (atmospheric concentration) and 6% O_2 (approximately 30% atmospheric concentration) in nitrogen. This reduced the O_2 concentration to about 75 μmol l^{-1} while maintaining normal dissolved inorganic carbon and pH levels of the bathing solutions. Lowering the initial O_2 concentration allows photosynthesis to proceed for extended periods within the closed system without potential complications due to O_2 supersaturation which increases photorespiration.

Photosynthesis was measured as the rate of O_2 evolution in the closed system through time. Corrections were made for total volume of the incubation apparatus, and the results normalized to plant dry weight. Experiments were allowed to proceed until photosynthesis stopped and the pH stabilized. This usually consisted of 2 to 3 hour runs, although longer runs up to 12 hours were made to verify that steady state conditions were achieved in the shorter runs.

Concentrations of different carbon species as a function of pH and temperature were estimated from equilibrium constants and formulae in Stumm and Morgan (1981).

RESULTS

Table 1 shows the results of 15 independent pH drift experiments conducted on Texas wild rice and three experiments conducted on *H. verticellata*. Alkalinity was measured prior to the experiment for each bathing solution as was the final pH at the apparent photosynthetic compensation point. Total carbon and CO_2 were estimated based on these data. The C_T:ALK ratio for all experiments was very close to 1.0 and varied between 0.93–0.99, strongly suggesting that this species is a CO_2 obligate plant which is unable to utilize HCO_3^- at a rate sufficient to keep up with photosynthetic needs (see Maberly and Spence 1983). For CO_2-obligates, the CO_2 concentration at the end of the pH drift experiment represents a conservative estimate of the CO_2 compensation point for the species. In this series of experiments, the values varied from 1–13 μmol l^{-1}.

Rates of photosynthesis as a function of pH for two C_T concentrations are shown in Figure 1A. As expected, the rates of photosynthesis at a given pH are higher for the higher C_T solution. Since pH controls the proportion of C_T present as CO_2, the level of CO_2 present in the two solutions was actually very different. However, both data sets show a linear and strong reduction in photosynthesis as the pH of the solution approaches 9.0. In Fig. 1B these data are re-plotted to

TABLE 1. Summary of pH drift experiments for Texas wild rice and *Hydrilla verticillata* conducted in closed systems including alkalinity (Alk) of bathing solution, final pH, final concentration of total inorganic carbon (C_T), CO_2 remaining at the end of the experiment and the ratio of C_T/Alk.

show the relationship of photosynthesis to actual CO_2 levels. The linear nature of this curve at low CO_2 is characteristic of CO_2-obligate plants and the extrapolated X-axis intercept of 2 µmol l^{-1} provides a reliable estimate of the CO_2-compensation point of photosynthesis for this species (Sand-Jensen 1983).

DISCUSSION

The experimental method used in this study identifies the upper pH limit for positive net photosynthesis. Net photosynthesis by Texas wild rice approached zero as pH approached 8.7 when CO_2 was 0.5% of total dissolved inorganic carbon. Bicarbonate in the bathing solution at pH 8.7 was 97.5% of total dissolved inorganic carbon. At this pH there was abundant HCO_3^- available for plant uptake. If Texas wild rice had the ability to remove HCO_3^- rapidly, positive net photosynthesis would continue after CO_2 was exhausted, driving pH above 9.2. During this study, no photosynthesis occurred above 8.7 suggesting submersed leaves of Texas wild rice are unable to take up HCO_3^-.

Carbon dioxide availability to submersed aquatic plants is a function of the interplay between water current velocity, leaf boundary layer thickness and

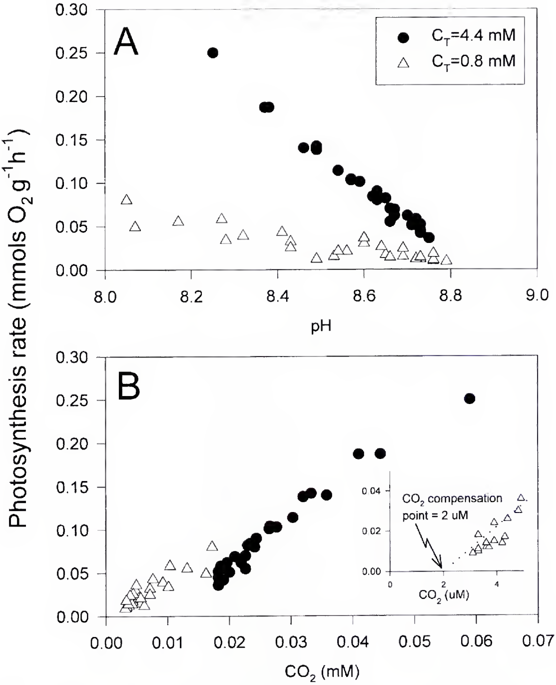

Fig. 1. Apparent net photosynthetic rate by Texas wild rice in a closed water-flow system. A) Plants take up CO_2 for photosynthesis, driving up pH. Photosynthesis ceases when pH reaches approximately 8.7. B) Estimated CO_2 compensation point for Texas wild rice is 2 μmol l^{-1}.

concentration gradient between surrounding water and leaf surface; as flow increases, boundary layer thickness decreases and CO_2 availability increases. Using a closed water-flow system Madsen and Søndergaard (1983) found apparent photosynthesis was stimulated by increasing velocities and a maximum rate was reached at 0.008–0.0012 m s^{-1}. In contrast, Madsen et al. (1993) found photosynthetic rates decreased with increasing current velocity and suggested that physical stress imposed on plants by agitation or stretching in flowing water was a key factor in the observed response. Ribbon-like submersed leaves of Texas wild rice are adapted for flowing water and can reduce carbon limitation by exploiting the flowing water habitat where boundary layer surrounding leaves and diffusion distances for CO_2 are reduced and leaves are continually bathed with carbon-rich water. In contrast, in slower moving water, photosynthesis by submersed leaves of Texas wild rice are probably carbon limited and few submersed leaves are produced, a greater proportion of biomass is allocated to reproductive parts, and plants are less productive overall (Power 2002). Emergent reproductive culms most likely are not carbon limited because culms obtain CO_2 from the atmosphere where CO_2 is more readily available owing to the higher diffusion rate and current velocity in air relative to water (Madsen & Sand-Jensen 1991; Denny 1993).

Texas wild rice is one of five endangered or threatened species which occur in the San Marcos River. As the result of a lawsuit involving the listed species, a water authority was created by the Texas Legislature to manage the source aquifer for the San Marcos River (Texas Legislature 1993). Flow requirements for Texas wild rice are important because of the legal requirement to manage the source aquifer for human needs while simultaneously protecting aquatic and wildlife habitat and protecting listed species. The potentially conflicting management goals of providing aquifer water for human use while maintaining adequate spring flow for endangered species cannot be attained without information concerning the habitat requirements for the listed species. Numerous surveys have identified flowing water habitat as a requirement for Texas wild rice and experimental studies have consistently shown a positive relationship between current velocity and productivity as well as biomass allocation to submersed plant parts (Power 1996a, 1996b, 2002; Poole & Bowles 1999; Saunders et al 2001). Data from this study provide a physiological explanation for these observations and furthers our understanding of habitat requirements for Texas wild rice.

ABSTRACT

Quantitative methods were used to compare the flora of the Post Oak Savanna and Oak-Pine-Hickory ecoregions of the West Gulf Coastal Plain. The analyses show that the two areas are nearly identical floristically.

Key Words: Post Oak Savanna ecoregion, Oak-Pine-Hickory ecoregion, biogeography. West Gulf Coastal Plain

RESUMEN

Se usaron métodos cuantitativos para comparar la flora de las ecoregiones Post Oak Savanna y Oak-Pine-Hickory de la llanura costera del West Gulf. Los análisis muestran que las dos áreas son casi idénticas florísticamente.

INTRODUCTION

A half century ago, Webb (1950) examined the methodology of biogeographers who worked in Oklahoma and Texas and found that not only they did not agree among themselves on the location and description of biogeographic regions, but that regional delineation was subjective. He suggested a remedy: "Quantitative methods must be developed before general agreement on the extent of the major [ecoregions] can be reached. As long as personal opinion and individual judgment are the only bases for judging the extent of the [ecoregions], fundamental and insoluble differences of opinion will continue" (Webb 1950:246). This situation remains essentially unchanged today (MacRoberts & MacRoberts 2003a). The purpose of this paper is to describe the botanical similarities and differences between the Post Oak Savanna (POS) region or ecoregion and the adjacent Oak-Pine-Hickory (OPH) region or ecoregion (herein region, ecoregion, and vegetation area are used interchangeably).

STUDY AREAS

The Post Oak Savanna region (POS) of Texas has been considered a distinct vegetation area (ecoregion) since Harshberger (1911) mapped it, but it was Shantz and Zon (1924) and later Gould (1962) who gave it its modern shape (MacRoberts & MacRoberts 2003a) (Fig. 1).

The POS region has been described repeatedly. It is a gently rolling or hilly region comprising 30,000 to 40,000 sq. km with elevations from 90 to 250 m above sea level. Annual rainfall is 75 to 115 cm with highest rainfall in May and June. The Carrizo Sands extend along the length of the region. Soils on the uplands are acid sandy loams or sands. Bottomland soils are generally acid sandy loams and clays. Prairies are scattered throughout, notably in the south. The area contains a diversity of plant communities, from hillside pitcher plant bogs, peat bogs, and upland marshes to open xeric sandylands, oak-hickory forests/woodlands, prairies, and bottomland floodplains. Overstory trees in the uplands are primarily *Quercus stellata* Wang., *Q. margaretta* (Ashe) Ashe ex Small, *Q. marilandica* Muenchh., and *Carya* spp. The virtual absence of pine is emphasized. Understory vegetation includes common grasses *Schizachyrium scoparium* (Michx.) Nash , *Sorgastrum nutans* (L.) Nash, *Panicum virgatum* L., *Tridens flavus* (L.) Hitchc., *Bothriochloa saccharoides* (Sw.) Rydb., *Nassella leucotricha* (Trin.& Rupr.) Pohl, *Chasmanthium sessilifolium* (Poir.) Yates. Further description of the POS region can be found in many sources (e.g., Correll & Johnston 1970; LBJ School of Public Affairs1978; Hatch et al. 1990; Telfair 1999).

McBryde (1933) conducted the first major floristic study of the POS region, emphasizing the Carrizo Sands. Recent studies have been on grasslands (Smeins & Diamond 1983), bogs and marshes (MacRoberts & MacRoberts 1998, 2001), creek systems (Telfair 1988), and xeric sandylands (MacRoberts et al. 2002a). What has not been studied is the floristic similarities and differences between the POS region and its adjacent "ecoregions" or "vegetation areas" (MacRoberts & MacRoberts 2003a).

The OPH region, to which we mainly compare the POS region, consists of about 175,000 sq. km in east Texas, west Louisiana, south Arkansas, and southeast Oklahoma. It is characterized by the presence of pine and by the frequent co-dominance of pine, oak, and hickory in the forest or woodland canopy. Precipitation is about 100 cm per year. The terrain varies from nearly level to gently undulating. Upland soils are generally acidic sandy loams and sands over sandy loam and clay. Bottomlands are acidic sands and clays and loams. The dominant vegetation is a mixed pine-hardwood forest on the uplands and a mixed hardwood forest on the bottomlands. *Pinus taeda* L. and *P. echinata* Mill. occur throughout. *Pinus palustris* Mill. is confined to the southern part of the OPH region. Principle hardwoods are those that occur over most of the southeast coastal plain: *Liquidambar styraciflua* L., *Quercus* spp., *Nyssa sylvatica* Marsh., *Magnolia* spp., *Ulmus* spp., *Populus deltoides* Bart. ex Marsh., *Carya* spp., *Acer* spp., *Fagus grandifolia* Ehrh., *Fraxinus* spp., *Taxodium distichum* (L.) L. Rich. Further description of the OPH region can be found in many sources (e.g.,

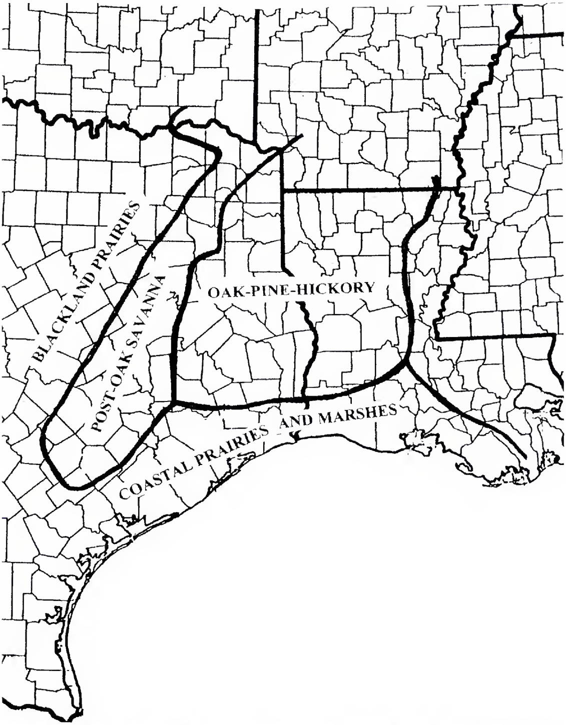

Fig. 1. Traditionally recognized ecoregions of the West Gulf Coastal Plain.

see Correll & Johnston 1970; Hatch et al. 1990; Telfair 1999 and references contained therein). The longleaf pine portion of the OPH region (often considered to be a separate ecoregion itself, is not so considered here) in southeast Texas and south-central Louisiana has been by far the best studied portion of the OPH region (see Harcombe et al. 1993; MacRoberts & MacRoberts 2003a for literature).

METHODS

1. In order to determine the uniqueness of the POS region, we examined the distribution of the taxa on the Singhurst et al. (2003) list of the flora of the 4,466 ha Gus Engeling Wildlife Management Area (GEWMA) in Anderson County, in the middle of the POS region. This sample contains 830 native taxa from a wide variety of communities and habitats including bogs, marshes, xeric sandylands, stream bottoms, and oak-hickory woodlands. Using all available sources (e.g., Hatch et al. 1990; Thomas & Allen 1993-1998; Turner et al. 2003; *Flora of North America*; Evans n.d.), we determined how many of the taxa on the Singhurst et al (2003) list occur in the OPH region and/or in the coastal region of southeast Texas and Louisiana and how many of them are either confined to the POS region or to that region and areas westward.

2. Since high endemism is often considered a key indicator of ecoregional uniqueness (Tahktajan 1986), we studied the distribution of endemic West Gulf Coastal Plain taxa to see how many are unique to the POS region (see MacRoberts et al. 2002b for West Gulf Coastal Plain endemics and their community affiliations).

3. In order to discover the North American affinities of the POS region, using Kartesz and Meacham (1999) we plotted the North American distribution by state or regional area of the 830 native taxa on the Singhurst et al. (2003) GEWMA list. We converted the results into percentage of taxa that occur in each state or regional area (see MacRoberts & MacRoberts 2003b for details of this method).

RESULTS

1. Ninety-eight percent of the native taxa found at GEWMA also occur in the OPH and/or coastal plain regions of Texas and Louisiana. Only two percent are either endemic to the POS region or reach their eastern limit in the POS region.

2. Of the approximately 100 endemic taxa of the West Gulf Coastal Plain, only nine are endemic or near endemic to the POS region. These are *Abronia macrocarpa* L. Galloway, *Brazoria truncata* (Benth.) Engelm. & Gray, *Hymenopappus carrizoanus* B.L. Turner, *Lactuca hirsuta* Muhl. ex Nutt. var. *albiflora* (Torr. & Gray) Shinners, *Monarda viridissima* Correll, *Paronychia setacea* Torr. & Gray, *Polygonella parksii* Cory, *Rhododon ciliatus* (Benth.) Eping, and *Valerianella florifera* Shinners. All of these taxa are associated with a single plant community: xeric sandylands (MacRoberts et al. 2002b). This community accounts for fifty percent of the endemics in the West Gulf Coastal Plain and is associated with the Carrizo Sands and other upland sandy areas and terraces that run the length of the POS region and spread out across the OPH region (McBryde 1933; MacRoberts & MacRoberts 1994, 1995, 1996; MacRoberts et al. 2002a). The remaining West Gulf Coastal Plain endemics occur in either both the POS region and the OPH region or in the OPH region alone.

3. The GEWMA flora is overwhelmingly eastern and notably southeastern (Fig. 2). Ninety-five percent of the taxa occurring at GEWMA occur in Louisiana, 92 percent in Arkansas, 89 percent in Oklahoma, 85 percent in Mississippi, 81 percent in the Carolinas, and 53 percent in New York and the New England states, but only 28 percent in New Mexico. This is consistent with our previous finding that eastern flora characterizes east Texas to about 95 degrees W. longitude, at which point east begins to give way to west over the next 300 km (MacRoberts & MacRoberts 2003b). GEWMA is located at about 96 degrees W. longitude on the eastern edge of this broad transition zone, and is thus essentially eastern, as the above figures indicate.

DISCUSSION

Unfortunately, for our floristic analysis there is no operational definition of ecoregion or any of the other "chorionomic" categories (e.g., region, province, district, subdistrict) that biogeographers use (Takhtajan 1986). The best definition we have found for ecoregion is that it is a distinct assemblage of natural communities and species involving a fairly large geographical region (Ricketts & Dinerstein 1999; The Nature Conservancy 2003). Takhtajan (1986) also states that endemism is fairly high, notably at the species and subspecies level. But these statements are of little help since they do not designate whether 25% or 50% difference in species composition constitutes a distinct assemblage or just what percent of the total should be endemic.

Nonetheless, our main finding is that the POS region differs only insignificantly from the OPH region. Far fewer than one percent of its taxa are endemic to it and only about two percent of its taxa do not also occur in the adjacent region to its east.

As part of our floristic study of the POS region, we examined and compared all community classifications for the POS and OPH region to see how many communities described for the POS region were unique to it (Marks & Harcombe 1981; Diamond et al. 1987; Harcombe et al. 1993; Texas Natural Heritage Program 1995; Nesom et al. 1997; Turner et al. 1999; Van Kley 1999a, 1999b; Bezanson 2000; Fleming et al. 2002; Louisiana Natural Heritage 2003; Singhurst et al. 2003). While this was not a quantitative analysis, we found the community structure of the POS region to be virtually identical with the OPH region. No community appeared to be unique to it. Those communities that typify it: upland post oak hickory forest/woodland, xeric sandylands, prairies, glades, baygalls, and so forth also occur in the OPH region (e.g., Marietta & Nixon 1983, 1984; Ward & Nixon 1993; Nesom et al. 1997; MacRoberts et al. 2002a). If there is anything distinctive about the POS region, it is that some of these communities (e.g., xeric sandylands, prairies) are more common in that region than they are farther east. Ironically, while the absence of pine is the feature most often noted for the POS region, pine does occur in the POS region, most dramatically

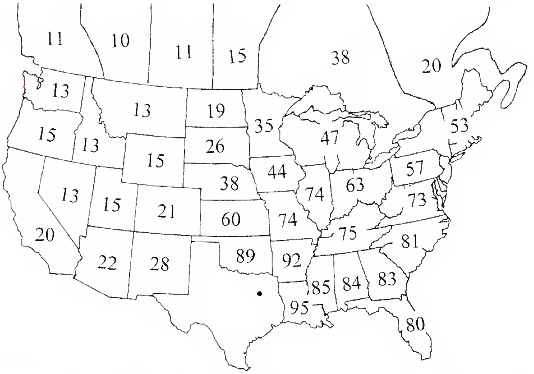

Fig. 2. Association of Post Oak Savanna flora expressed as percentages of flora at Gus Engeling Wildlife Management Area occurring in each state, province, or region. Dot in Texas is the location of Gus Engeling Wildlife Management Area (see text for further explanation).

at its western edge in Bastrop County, where *Pinus taeda* is often a dominant or co-dominant canopy species (Wilson 1990).

Neither a botanist nor a plant ecologist familiar with the southeastern flora would find much new in the POS. The main difference would be the absence of pines in some areas and the different frequency of communities and thus taxa in others. Even the few endemics to the region are tied to one community type—xeric sandylands—which occurs as far east as southwest Arkansas, central Louisiana, and southeast Texas (MacRoberts & MacRoberts 1994, 1995, 1996; MacRoberts et al. 2002a). The difference between the POS and the OPH regions is one of degree, not of kind. This finding agrees with a number of previous workers who have indicated the lack of a sharp boundary between the OPH and POS and who have questioned the floral uniqueness of the POS altogether (e.g., Tharp 1926; McCarley 1959; Diggs et al. 1999; MacRoberts & MacRoberts 2003a). Basically, the POS region is part of the 300 km ecotone between east and west, just as is the north central Texas prairie and cross timbers region (Diggs et al. 1999; MacRoberts & MacRoberts 2003b).

BOOK NOTICE

Timber Press

Denise Wiles Adams. 2004. **Restoring American Gardens: An Encyclopedia of Heirloom Ornamental Plants, 1640-1940**. (ISBN 0-88192-619-1, hbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $39.95, 420 pp., 155 color photos, 37 b/w photos, 154 line drawings, 1 table, 8 1/2" × 11".

The meat of this great book is the "Encyclopedia of Heirloom Ornamental Plants." The heirlooms are alphabetical under broad categories like Heirloom Trees, Heirloom Ornamental Shrubs, Heirloom Bulbs and Tuberous Plants, Heirloom Roses, etc. Each heirloom plant is listed with most of the following descriptive information: **1)** Scientific name, **2)** Common names, **3)** Synonym, **4)** Family, **5)** Nativity [native or exotic], **6)** Date of introduction into North America, **7)** Earliest American citation, **8)** Hardiness zone, **9)** Description, **10)** Design notes, **11)** Remarks, **12)** Heirloom varieties, **13)** Related species, and **14)** Historical commercial sources

I really like this book a lot! It is filled with hard to find information, great images of plants from old catalogs, as well as beautiful colored plates of the past three centuries, and modern color photographs.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, Texas 761202-4060, U.S.A.*

A QUANTITATIVE STUDY OF THE VEGETATION SURROUNDING YELLOW LADY-SLIPPER ORCHID (*CYPRIPEDIUM KENTUCKIENSE*, ORCHIDACEAE) POPULATIONS AT FORT POLK IN WEST CENTRAL LOUISIANA

ABSTRACT

The vegetation around five populations of yellow lady-slipper orchid (*Cypripedium kentuckiense* Reed) at Fort Polk, Louisiana were sampled using circular nested plots. Measurements included frequency, mean density, mean cover percent, mean dbh, importance value, and diversity (richness). The yellow lady-slippers at Fort Polk were associated with forests composed mainly of American beech (*Fagus grandifolia*), eastern hophornbeam (*Ostrya virginiana*), white oak (*Quercus alba*), horsesugar (*Symplocos tinctoria*), and witch hazel (*Hamamelis virginiana*) in the overstory and an abundance of poison ivy (*Rhus radicans*) and broad beechfern (*Thelypteris hexagonoptera*) in the understory.

RESUMEN

Se muestreó la vegetación alrededor de cinco poblaciones de *Cypripedium kentuckiense* Reed en Fort Polk, Louisiana mediante parcelas anidadas circulares. Las medidas incluyen frecuencia, densidad media, recubrimiento medio, diámetro medio a la altura del pecho, valor de importancia, y diversidad (riqueza). *Cypripedium kentuckiense* en Fort Polk está asociado a bosques compuestos principalmente por haya americana (*Fagus grandifolia*), *Ostrya virginiana*, roble blanco (*Quercus alba*), *Symplocos tinctoria*, y *Hamamelis virginiana* en el dosel arbóreo y abundante zumaque (*Rhus radicans*) y *Thelypteris hexagonoptera* en el sotobosque

INTRODUCTION

Yellow lady-slipper (*Cypripedium kentuckiense* Reed) is an herbaceous perennial in the Orchidaceae family. This species is reported from the southeastern U.S. in AL; AR; KY; LA; MS; OK; TN; TX; and VA (USDA, NRCS 2002). Globally this species is ranked G3 which is defined as either rare and local throughout its range or found locally (even abundantly at some of its locations) in a restricted range (e.g., a single physiographic region) or because of other factors making it vulnerable to extinction throughout its range, or with 21-100 known extant populations or 3,000 to 10,000 individuals (NatureServe 2003). It is ranked S1 in AL, GA, LA, OK, TX, and VA. An S1 species is defined as being critically imperiled in a state because of its extreme rarity (5 or fewer known extant populations) or because of some factor(s) making it especially vulnerable to extirpation. It is listed as S1/S2 in TN, S2/S3 in KY, S3 in AR, and SU in MS. The S2 ranking is defined as imperiled in the state because of rarity (6 to 20 known extant populations) or because of some factor(s) making it very vulnerable to extirpation while the S3 ranking is defined as rare and local throughout the state or found locally (even abundant at some of its locations) in a restricted region of the state, or because of other factors making it vulnerable to extirpation (21 to 100 known extant populations). The SU ranking is for those species that are possibly in peril in the state but with an uncertain status and more information is needed. Thirteen populations of this orchid are known from east Texas (Liggio & Liggio 1999). In Louisiana, it is reported from 11 parishes with four from unverified reports (Louisiana Department of Wildlife and Fisheries; Natural Heritage Program 2003).

The habitat for this species is described as mature floodplain forests and the slopes of mesic (relatively dry) ravines (Oklahoma Natural Heritage Inventory 2001) and rich, mesic to dry, deciduous forests on well-drained alluvium and bases of slopes, or mucky seeps; mostly 0–400m (Flora of North America Editorial Committee 2002). Orzell (1990) describes the habitat for this species as terraces and lower moist slopes in small stream valleys of pine-hardwood forests. This author lists the common trees of the canopy as American beech (*Fagus grandifolia*), white ash (*Fraxinus americana*), black gum (*Nyssa sylvatica*), and southern magnolia (*Magnolia grandiflora*). The understory species reported by Orzell (1990) include flowering dogwood (*Cornus florida*), red maple (*Acer rubrum*), chalk maple (*Acer lecoderme*), bigleaf snowbell (*Styrax grandifolia*), and American hornbeam (*Carpinus caroliniana*). Orzell (1990) also reports that two shrubs species, maple-leaf viburnum (*Viburnum acerifolium*) and arrow wood (*Viburnum dentatum*) are frequently associated with this orchid. Herbaceous plants often found associated with yellow lady-slippers include cranefly orchid (*Tipularia discolor*), slender wood sedge (*Carex digitalis*), partridge berry (*Mitchella repens*), Christmas fern (*Polystichum acrostichoides*), Walter's violet (*Viola walteri*), eared goldenrod (*Solidago articulata*), broad beech fern (*Thelypteris hexagonoptera*), and slender wake robin (*Trillium gracile*) (Orzell 1990). The habitat in Louisiana is reported to be mesophytic woods, calcareous forests, and hardwood slope forests (Louisiana Department of Wildlife and Fisheries; Natural Heritage Program, 2003). A search of the literature yielded no quantitative data on the habitat for yellow lady-slipper throughout its range. The objective of this study was to quantitatively describe the habitat for yellow lady-slipper in west central Louisiana.

Five distinct groups of yellow lady-slipper are known from the Fort Polk Military Installation in Vernon Parish, Louisiana. Three of the five groups are located at one site while two are located at a different site. The two sites are located about six kilometers apart and each is a well drained ravine in a mesic hardwood forest. Each ravine has a small, intermittent stream at the bottom. The soils at both sites are Eastwood silt loam (Soil Survey Division, Natural Resources Conservation Service, United States Department of Agriculture 2003). These five groups have been observed for the past ten years with four clumps having flowered and one clump not flowering during this period.

METHODS

Three nested circular plots were sampled with the center of each of the five yellow lady- slipper groups serving as the center point of the plot. All trees and shrubs (woody non-vine species taller than 6 ft = 1.83m) were sampled within a 15m radius circle; shrubs and saplings (woody non-vine species shorter than 1.83m = 6 ft) and woody vines were sampled within a 5m radius circle; and all herbaceous species were sampled within a 1m radius circle. During the sampling period, the number of stems was counted and recorded for all species in the samples. For the trees and shrubs within the 15m radius samples, the dbh was measured at the standard 1.37m (4.5 ft) height using a diameter tape and recorded to the nearest 0.1 cm. For herbaceous plants, woody vines, and shrubs and saplings, cover was determined by measuring the area occupied by the individuals of the species in the sample. For the few species with only one or two individuals per sample, the actual area was used. For those species with more than two individuals per sample, the mean area was calculated by summing the area occupied by three or more randomly selected individuals of the species and dividing by the number of individuals selected. The cover was then calculated by multiplying the actual area or mean area times the number of individuals and then dividing by the area of the plot, 78.035m^2 for the 5m radius plots and 3.14m^2 for the 1m radius plots. The cover was converted to a percent by multiplying by 100.

All data were entered into a Microsoft Excel spread sheet for storage and calculation of variables. The mean diversity (richness) and mean density were calculated for each of the five plots for all plant groups while the mean dbh was calculated for trees and shrubs and mean cover percent was calculated for herbaceous plants, woody vines, and shrubs and saplings. The frequency and mean density were calculated for each species. The mean dbh was calculated for tree and shrub species and the mean cover percent for all other species. The relative values for each of these variables (frequency, mean density, mean dbh, and mean cover percent) were calculated by dividing the value for a species by the total for all species. Each value was converted to a percent by multiplying by 100 and the sum of these relative values was used to calculate the importance value.

RESULTS

The number of species totaled seventy-eight (78) with nine (9) woody vines, twenty-one (21) herbaceous plants, and forty-five (45) tree, shrub or saplings (Table 1). The mean number of species per sample ranged from 9.00 for woody vines to 23.80 for shrubs and saplings. The mean number of stems per sample (density) averaged 651.40 per sample for all plants and ranged from 77.00 for trees and shrubs to 216.80 for shrubs and saplings. The mean cover percent for all plants was 240.74 percent and ranged from 8.68 percent for woody vines to 159.86 percent for herbaceous plants. The mean dbh per sample was 877.98 cm.

The frequency, mean density, mean dbh, and importance value for the tree and shrub species are in Table 2, while the frequency, mean density, mean cover percent, and importance value for the appropriate plant group are in Tables 3, 4, or 5. The species are arranged in descending importance value in all four tables. The three most important tree and shrub species are American beech (28.12), white oak (*Quercus alba*) (27.73), and horsesugar (*Symplocos tinctoria*) (25.94) (Table 2). Eastern hophornbeam (*Ostrya virginiana*) was the dominant shrub and sapling species with an importance value of 55.01 followed by witch hazel (*Hamamelis virginiana*) (31.63) and horsesugar (23.64) (Table 3). The most important woody vine species was poison ivy (*Rhus radicans*) (128.28) and accounted for almost one-half of the total importance value of 300 while crossvine (*Bignonia capreolata*) (33.42) and common greenbrier (*Smilax rotundifolia*) (33.34) ranked second and third respectively (Table 4). The dominant herbaceous species was broad beechfern (*Thelypteris hexagonoptera*) with an importance value of 125.18 followed distantly by partridge berry (37.19) and longleaf woodoats (*Chasmanthium sessiliflorum* (20.51) (Table 5).

DISCUSSION

Allen et al (1994) reports physiognomy data for 4m radius samples in a beech forest area in the Louisiana Arboretum in Evangeline Parish near a yellow lady-slipper population. The diversity (richness) for this beech forest includes a mean of 8.20 species for the shrubs and saplings and 5.10 species of trees and shrubs compared to 23.80 species for shrubs and saplings and 19.00 for trees and shrubs in this study. The density and cover percent in the beech forest for the shrubs and saplings were 76.10 stems and 42.88 percent, respectively, which compared to 216.80 stems and 72.20 percent in this study. The mean trees and shrub density in this study was 77.00 compared to 10.30 in the Arboretum beech forest. The mean dbh in this study was 877.98 cm compared to 50.68 cm at the Arboretum. Newman (1995) reports physiognomy data from 4m radius samples in a hardwood slope forest in Caldwell Parish, Louisiana. This site is a short distance south of a yellow lady-slipper population in extreme southern Ouachita Parish. The shrub and sapling data from the Caldwell site included a mean diversity of 15.82 species compared to 23.80 species in this study; mean density of 67.65 stems compared to 216.80 stems; and mean cover percent of 39.56 percent compared to 72.20 percent. The trees and shrubs from the Caldwell Parish study

Table 1. Community physiognomy variables (diversity, density, cover percent, and dbh) in samples around yellow lady-slipper populations at Fort Polk, La.

	Diversity (Richness)				
	All Plants	**Trees & Shrubs**	**Shrubs & Saplings**	**Woody Vines**	**Herbaceous Plants**
Mean	48.00	19.00	23.80	9.00	10.20

Range	45–51	16–22	18–27-	8–10	8–14
Total Number	78	33	41	12	21

	Density				
	All Plants	**Trees & Shrubs**	**Shrubs & Saplings**	**Woody Vines**	**Herbaceous Plants**
Mean	651.40	77.00	216.80	205.20	152.40
Std Dev.	83.46	20.41	55.95	77.86	88.49
Range	644–706	55–108	175–310	106–317	71–286

	Cover Percent				DBH (cm)
	All Plants	**Shrubs & Saplings**	**Woody Vines**	**Herbaceous Plants**	**Trees & Shrubs**
Mean	240.74	72.20	8.68	159.86	877.98
Std Dev.	141.53	25.44	2.81	136.79	124.00
Range	113.63-449.00	39.67-109.82	4.65-11.80	34.55-365.49	741.10-1011.20

had a mean diversity of 4.20 species compared to 19.00 in the present study; mean density of 8.28 stems compared to 77.00; and mean dbh of 68.03 cm compared to 877.98 cm. Some of the larger numbers in this study in comparison to both of these reports can be attributed to the difference in sample size, but the Fort Polk yellow lady-slipper area seems to be more diverse, with a higher vegetation density, and a higher basal area.

The five yellow lady-slipper populations at Fort Polk were associated with a forest composed of American beech, eastern hophornbeam, horsesugar, white oak, and witch hazel in the overstory and an abundance of poison ivy and broad beechfern in the understory. This description is very similar to the qualitative report of associated species by Orzell (1990) except that American hornbeam (*Carpinus caroliniana*) was not found in the sampled area at Fort Polk. The three most important shrubs and saplings reported from Caldwell Parish by Newman (1995) include American beech, red maple (*Acer rubrum*), and eastern hophornbeam and the top three reported from the Louisiana Arboretum by Allen et al (1994) include native bamboo (*Arundinaria gigantea*), pawpaw (*Asimina triloba*), and pignut hickory (*Carya glabra*). All of these species were found in the Fort Polk study except for pawpaw and pignut hickory. The three most important species of trees and shrubs in Caldwell Parish included flowering dogwood (*Cornus florida*), sweet gum (*Liquidambar styraciflua*), and east-

ern hophornbeam, and in the Louisiana Arboretum the three most important species were American hornbeam, flowering dogwood, and American beech. All of these species were in the Fort Polk site except for the notable absence of American hornbeam. The absence of American hornbeam could be explained by the Fort Polk site being slightly drier than the other sites as American hornbeam's wetland ranking is FAC and eastern hophornbeam's ranking is FACU- (USDA-NRCS 2002).

This study is apparently the first report of quantitative data on the vegetation associated with yellow lady-slippers. The vegetation around other yellow lady-slipper populations throughout its range should be sampled and compared and contrasted to our results to provide data for ecologically sound management decisions to preserve and expand the populations of this threatened species.

ABSTRACT

Baygalls are a plant community associated with small streams in west central Louisiana. Plots from a 1986 study on the effects of sedimentation on baygall vegetation were resampled in 2001. Nested subsamples were used and the same areas were sampled during each time period. Importance values were calculated using frequency, individual density, stem density, and dbh. In 1986, the sedimented and control baygalls were significantly different in all variables except for woody individual density and woody stem density. In 2001, dbh was the only variable not significantly different between the control and sedimented baygalls. In the sedimented area between 1986 and 2001, the woody plant variables increased while herbaceous plant variables decreased. Woody species, *Liquidambar styraciflua* and *Alnus serrulata* showed a large decrease, however, *Toxicodendron radicans*, *Smilax rotundifolia*, and *Ligustrum sinense* increased. In the control baygalls, four fern species increased in importance value.

RESUMEN

Los "Baygalls" son una comunidad vegetal asociada a pequeños torrentes en el centro-oeste de Luisiana. Las parcelas de un estudio en 1986 sobre los efectos de la sedimentación en la vegetación baygall se volvieron a muestrear en 2001. Se usaron submuestras anidadas y se muestrearon en cada periodo las mismas áreas. Los valores de importancia se calcularon usando frecuencia, densidad individual, densidad de tallos, y diámetro a la altura del pecho. En 1986, los baygalls sedimentados y de control fueron significativamente diferentes en todas las variables excepto para la densidad individual de leñosas y densidad de tallos leñosos. En 2001, el diámetro a la altura del pecho fue la única variable no significativamente diferente entre el control y los baygalls sedimentados. En el área sedimentada entre 1986 y 2001, las variables de plantas leñosas aumentaron mientras que las variables de plantas herbáceas disminuyeron. Las especies leñosas *Liquidambar styraciflua* y *Alnus serrulata* mostraron una gran disminución, sin embargo, *Toxicodendron radicans*, *Smilax rotundifolia*, y *Ligustrum sinense* aumentaron. En los baygalls de control, cuatro especies de helechos incrementaron su valor de importancia.

INTRODUCTION

Baygall is a colloquial term that refers to the small drainage systems and to the vegetation developed along the streams (Allen et al. 1990). In the center of most baygalls is a small sandy or gravelly-bottomed stream that is intermittent in the upper drainage and usually continuous in the lower portions of the drainage. The smaller streams drain into slightly larger streams and ultimately into a larger watercourse. Baygalls are surrounded by pine forests and are narrow in the upper portion gradually widening downstream to a maximum width of 20–50 meters. Drainage from the surrounding upland pine forest percolates downward until it reaches an impervious layer of clay or rock typically forming seepage areas throughout the baygall. Pitcher plant bogs are found in open areas in and along the edge of many baygalls (Allen et al. 1987). The woody vegetation in the baygalls is predominately broad-leaved (dicotyledonous) deciduous or evergreen trees or shrubs contrasting with the very common evergreen (gymnospermous) needle-leaved trees of the upland pine forests. The vegetation developed along the floor of the baygall is sparse and contains a number of ferns, bryophytes, especially peat moss (*Sphagnum* spp.), and a few shade-tolerant flowering plants.

METHODS

In the summer of 2001, six baygalls used in a 1986 study (Allen et al. 1990) were examined for resampling. The study area in one of the sedimented baygalls was completely destroyed and thus was excluded from resampling. One of the two transects in two different control baygalls could not be relocated. Two transects were resampled in the one sedimented baygall with a total of 37 subsamples. Four transects in four different control baygalls were resampled with 94 subsamples. The 1986 data from these 37 and 94 relocated samples only were used for comparisons with the 2001 data.

In 1986, the starting point for each transect was randomly located in the center of a baygall using random numbers and pacing. The transect extended perpendicular from the baygall stream upslope to the end of the baygall vegetation or sedimented area. Subsamples were established using metal poles at one meter intervals along the transect. Most of the original metal poles were still in place along the transects. In both sampling periods, nested subsamples were taken along the transects at each of the one meter markers. A 0.09 meter (0.3 meter × 0.3 meter) quadrat was used to sample the herbaceous plants. The sample was taken on the upstream side of each point. The shrubs (woody plants with a dbh (diameter at breast high at approximately 4.5 feet) of less than 4 inches and/or shorter than 25 feet) were sampled using a 1 meter square quadrat with 1/2 meter on each side of the transect center line. The trees (woody plants 4 inches dbh or larger and/or 25 feet or taller) were sampled using 10 meter × 1 meter quadrat with 5 meters on each side of the transect center line. All species and total number of stems were recorded in each quadrat at each subsample. The dbh was recorded to the nearest 0.1 cm for woody taxa of sufficient height

Some of the herbaceous taxa could only be identified to genus, family

(Poaceae or Cyperaceae), or class. Data were entered and analyzed using Microsoft Excel software. The community physiognomy variables were calculated by summing the value for each subsample and dividing by the number of subsamples, 37 for sedimented baygalls and 94 for control baygalls. Species richness was calculated using all plant taxa. Individual density (number of individuals per subsample) and stem density (number of stems per subsample) were calculated for herbaceous taxa and also for woody taxa. The dbh was also calculated for woody taxa.

The population variables were calculated for all taxa by summing the value for each subsample and dividing by the number of subsamples, 37 for sedimented baygalls and 94 for control baygalls. The frequency (percentage of subsamples of occurrence) and mean value for individual density and stem density was calculated for all taxa. The mean value for dbh was calculated for the woody taxa of sufficient size. Relative frequency, relative individual density, and relative stem density were calculated for all herbaceous taxa from the sedimented baygalls by summing the values for all herbaceous taxa in the sedimented area and dividing the value for each taxon by the total. The relative values for frequency, individual density, and stem density were calculated identically for the herbaceous taxa from the control baygalls and for woody taxa from both control baygalls and sedimented baygalls. All relative values were then converted to a percentage. The importance value for each herbaceous taxon was calculated by summing the values for relative frequency, relative individual density, and relative stem density. The importance value for each woody taxon was calculated by summing the values for relative frequency, relative dbh, relative individual density, and relative stem density. The total importance value for all herbaceous taxa is 300 and for the woody taxa is 400.

Most plants were identified in the field by the senior author, and voucher herbarium specimens for most taxa were collected, mounted, and filed at Ft. Polk. Duplicates of many of the taxa were deposited in the Herbarium of the University of Louisiana at Monroe (NLU). Some taxa were identified in the laboratory using Allen, (1980 or 1992); Correll and Correll (1972); Correll and Johnston (1970); Diggs et al. (1999); Godfrey and Wooten (1979, 1981); or Radford et al. (1968). The scientific names are from USDA, NRCS (2002).

RESULTS

The mean physiognomy community variables (species richness, dbh, woody individuals, woody stems, herbaceous individuals, and herbaceous stems) per subsample for the sedimented and control baygalls for 1986 plus 2001 are presented in Table 1. The standard deviation is also given. The student's t-test was used to compare variables between control 1986 and control 2001, sedimented 1986 and sedimented 2001, control 1986 and sedimented 1986, and control 2001 and sedimented 2001. Allen et al. (1990) reported that t-test comparisons showed

TABLE 1. Community Physiognomy data (Species Richness, DBH, and Density) in control (94 subsamples) and sedimented baygalls (37 subsamples) for 1986 and 2001 at Fort Polk, La. All variables are significantly different at the 0.05 level between: control 1986 and control 2001; sedimented 1986 and sedimented 2001; control 1986 and sedimented 1986; and control 2001 and sedimented 2001, except where noted. Standard deviation is included in parentheses.

	Control Baygalls		**Sedimented Baygalls**	
	1986	**2001**	**1986**	**2001**
Species Richness	4.79 (2.36)	6.28(2.41)	7.32(2.67)	5.00(2.12)
No. Woody species	34	42	25	27
No. Herbaceous Species	24	23	34	3
DBH (cm)	17.16[a] (23.54)	17.71[a,b] (21.94)	6.19(21.64)	14.19[b] (15.30)
Woody Individual Density	7.13[c](4.40)	12.80(5.94)	6.73[c] (4.34)	10.41(5.59)
Woody Stem Density	8.10 (5.05)	15.87(7.42)	7.35[c](5.22)	11.32(6.14)
Herbaceous Individual Density	1.94[a](3.05)	1.38[a](1.64)	15.05(8.35)	0.16(0.55)
Herbaceous Stem Density	4.21[a] (7.82)	4.24[a] (6.10)	22.30(19.41)	0.19(0.62)

[a] Not significantly different between 1986 and 2001 control baygalls

[b] Not significantly different between 2001 control and 2001 sedimented baygalls

[c] Not significantly different between 1986 and 2001 sedimented baygalls

all variables between the control 1986 and sedimented 1986 data to be significantly different. However, when the data for the relocated samples only are used, the woody individual density and woody stem density were not significantly different between the control and sedimented baygalls in 1986. When the control 1986 data are compared to the control 2001 data, the species richness, woody individual density, and woody stem density were the variables that were significantly different. A comparison of the 1986 sedimented data to the 2001 sedimented data reveals that all six variables are significantly different. In the 2001 control and sedimented data, dbh was not significantly different while the other five variables were all significantly different. In Table 1, the variables that are not significantly different are indicated by: [a] if between 1986 and 2001 control baygalls; [b] if between 2001 control baygalls and 2001 sedimented baygalls; and [c] if between 1986 control baygalls and 1986 sedimented baygalls. The most dramatic changes from 1986 to 2001 occurred in the sedimented baygalls with great increases in dbh (6.19 cm to 14.19 cm), woody plant individuals (6.73 to 10.41), and woody plant stems (7.35 to 11.32). Large decreases occurred in herbaceous individuals (15.05 to 0.16) and herbaceous stems (22.30 to 0.19).

The importance values for each woody taxon in the control and sedimented baygalls for 1986 and 2001 are in Table 2. In 1986, the woody taxa with the highest

importance value (>20.00%) in the control baygalls were *Nyssa sylvatica, Magnolia virginiana, Smilax rotundifolia, Persea palustris, Lyonia lucida, Ilex coriacea,* and *Pinus taeda* and in 2001, the top taxa were *Nyssa sylvatica, Magnolia virginiana, Ilex coriacea, Lyonia lucida, Persea palustris, Pinus taeda, Toxicodendron radicans,* and *Viburnum nudum.* In the sedimented baygalls in 1986, the most important taxon was *Nyssa sylvatica* with an importance value of 148.97%, which was almost five times as much as the second most important taxon. In 2001, *Nyssa sylvatica* was still the most important taxon, but its importance value was only 69.28%. In the sedimented baygalls in 1986, other taxa with importance value greater than 20.00% were *Liquidambar styraciflua, Itea virginica, Cephalanthus occidentalis, Quercus nigra/laurifolia,* and *Acer rubrum.* In the same sedimented baygalls in 2001, the taxa with more than 20.00% importance value were *Toxicodendron radicans, Pinus taeda, Ligustrum sinense, Smilax rotundifolia, Morella cerifera,* and *Magnolia virginiana.*

The importance value for each herbaceous taxon in the control baygalls for 1986 and 2001 are in Table 3. In 1986, the taxon with the highest importance value was Poaceae followed by *Rudbeckia scabrifolia, Dichanthelium tenue, Viola primulifolia,* and herbaceous dicotyledons. In 2001, the five taxa with the highest importance value (in decreasing order) were *Dichanthelium tenue, Woodwardia aerolata, Rudbeckia scabrifolia, Carex leptalea,* and *Chasmanthium laxum.* In 2001, there were only three herbaceous taxa observed in the sedimented baygalls (Poaceae 137.91%, *Chasmanthium laxum* 108.06%, and *Mitchella repens* 54.03%); this contrasted tremendously with the 43 taxa recorded in 1986 in all subsamples (Allen et al. 1990) and the 34 taxa in the relocated subsamples. The taxa with the highest importance value in 1986 were Poaceae, *Lycopus* spp., Herbaceous dicotyledons, *Juncus diffusissimus,* and *Juncus coriaceus.*

CONCLUSIONS

In 1986, the data indicated that sedimentation had a significant effect on the baygall vegetation community. The student's t test showed four variables to be

highly significantly different between the sedimented and control or non-sedimented baygalls. Species richness and herbaceous individuals and stems had increased in the sedimented baygalls while the dbh had decreased. Sedimentation had killed many of the larger woody plants which explained the decrease in the dbh. The increase in species richness and herbaceous individuals and stems probably occurred because the addition of sedimentation created a more mesic habitat.

When the two areas (control and sedimented) were compared again in 2001, the dbh had increased in the sedimented baygalls and was no longer different

(Table 1). A comparison of the sedimented area 1986 data to the 2001 data revealed that the species richness had decreased from 7.32 to 5.00 species per sample. The number of woody individuals and stems had almost doubled and the dbh had more than doubled in the sedimented baygalls. The biggest changes in the sedimented baygalls occurred with the herbaceous plants where the mean number of individuals decreased from 15.05 to 0.16 and the mean number of stems decreased from 22.30 to 0.19 stems. These changes in the sedimented baygall indicate that this area is changing from an open area to a forested area. The increase in trees and shrubs has created more shade and caused a large decrease in the number of herbaceous plants. The number of herbaceous species decreased from 34 to 3.

In the control baygalls between 1986 and 2001, species richness, woody individuals, and woody stems had all increased significantly and the dbh, herbaceous individuals, and herbaceous stems had remained fairly constant. These changes and lack of change could be attributed to normal succession in the baygalls.

Nyssa sylvatica is a tree that seems to be little affected by sedimentation, as its importance value is very high in the sedimented baygalls in 1986 (Table 2). The tree (*Liquidambar styraciflua*), shrubs (*Alnus serrulata* and *Cephalanthus occidentalis*), and vine (*Toxicodendron radicans*) seem to grow better in the sedimented areas as indicated by the increase in their values. Tree species (*Magnolia virginiana* and *Pinus taeda*), shrub species (*Persea palustris* and *Ilex coriacea*), and the vine (*Smilax rotundifolia*) seem to have been affected by sedimentation as their values decreased in the sedimented baygall. In 2001 in the control baygalls, the shrubs (*Ilex coriacea* and *Lyonia lucida*) had increased in importance value and is probably linked to natural succession in the baygalls. The sedimented baygalls had undergone more dramatic changes between 1986 and 2001 where early successional species (*Liquidambar styraciflua* and *Alnus serrulata*) showed a tremendous decrease in importance value; *Alnus serrulata* was completely absent in 2001 and *Liquidambar styraciflua* decreased from an importance value of 35.10% to 7.58%. The shade tolerant vines (*Toxicodendron radicans* and *Smilax rotundifolia*) increased greatly in importance values. The introduced species (*Ligustrum sinense*) had a large increase in importance value from 7.74% in 1986 to 47.47% in 2001. Most of these changes seemed to be linked to succession in a sedimented area except for the introduced species filling in the niches normally occupied by native shrubs.

The notable change in the herbaceous taxa in 1986 was the increase in the number of weedy taxa in the sedimented baygalls that were not present in the control areas or were present in small numbers (Allen et al. 1990). Some of the weedy taxa include several species of *Juncus* and *Solidago*, *Diodia teres*, *Ambrosia artemisiifolia*, and *Bidens aristosa*. The creation of a new habitat in the sedimented baygalls is the reason for the invasion by the weedy taxa. All of the ferns (*Athyrium felix-femina*, *Osmunda cinnamomea*, *Woodwardia aerolata*, and *Woodwardia virginica*) were not found in any of the sedimented samples but were present in the control samples. All four showed an increase in importance value between 1986 and 2001 in the control baygalls. The fern taxa in the sedimented baygalls in 1986 apparently decreased because of increased sun exposure caused by the death of trees in the baygall. These fern species probably increased in value in the control baygalls in between 1986 and 2001 as a result of increased shade. In 2001, the sedimented baygalls changed dramatically with virtually no herbaceous plants persisting. The dense shade produced by the trees and shrubs greatly decreased the number of herbaceous plants, especially weedy species.

BOOK NOTICES

Blackwell Publishing

ROBERT L. ZIMDAHL. 2004. **Weed-Crop Competition, A Review. Second Edition.** (ISBN 0-8138-0279-2, hbk.). Blackwell Publishing Professional, 2121 State Avenue, Ames, IA 50014, U.S.A. (Orders: 1-800-862-6657, 1-515-292-3348 fax, www.blackwellprofessional.com). $54.99, 224 pp., graphs, 7" × 10".

Publisher Comments: "For the past 20 years, the first edition of this text has been widely cited as an authoritative academic reference. The latest edition continues the tradition set by the original book and covers weed science research that has been published since 1980. This book aims to reduce the instance of research duplication—saving scientists and supporting institutions time and money."

"Not only does the second edition of Weed-Crop Competition review, summarize, and combine current research, it critiques the research as well. This text has the potential to accelerate advancements in weed-crop competition, which remains an important factor affecting crop yields. Weed scientists, crop scientists, plant ecologists, sustainable agriculturists, and organic agriculturists will be well-pleased with this long overdue and much needed new edition."

Contents: **1)** Introduction: An historical Perspective. **2)** Definition of Plant Competition. **3)** Competition in the Community. **4)** Influence of Competition on the Plant. **5)** The Effect of Weed Density. **6)** The Effect of Competition Duration. **7)** The Elements of Competition. **8)** Weed Management Using the Principles of Competition. **9)** Methods Used to Study Weed-Crop Competition. **10)** Models and Modeling. **11)** Conclusion: The Complexity of Competition

NELS R. LERSTEN. 2004. **Flowering plant Embryology.** (ISBN 0-8138-2747-7, hbk.). Blackwell Publishing Professional, 2121 State Avenue, Ames, IA 50014, U.S.A. (Orders: 1-800-862-6657, 1-515-292-3348 fax, www.blackwellprofessional.com). $79.99, 224 pp., b/w photos, line drawings, 7" × 10".

Publisher Comments: "This richly illustrated reference text, with more than 350 figures, presents general angiosperm embryology using examples from economically important plants. The unique focus of this book on economically significant plants makes *Flowering Plant Embryology* a "must-have" for all plant science researchers and students."

"Drawing from his career of teaching botany, and his original embryological research, Lersten emphasizes the plant species that affect human livelihood, including weeds, ornamentals, and other cultivated plants that are used for commercial products. Topics are treated with a uniformity of style that boosts comprehension, and technical terms are well-defined. The book presents research results, hypotheses, and speculations about why things are as they are, and also offers supporting facts and specific examples. This book provides a firm foundation for thorough understanding of embryological diversity among economic plants and belongs in the library of every plant scientist."

ABSTRACT

The objective of this study is to fill a floristic data gap for southwest Oklahoma. Based upon a review of the Atlas of the Flora of Oklahoma database, it was noted that Tillman County was floristically under-documented. This paper reports the results of an inventory of the vascular plants in Tillman County. A total of 371 taxa of vascular plants in 253 genera and 74 families were collected. The most species were collected from the families Asteraceae (65), Poaceae (67), and Fabaceae (25). There were 123 annual and 248 perennial species. Forty-one species of woody plants were present. Forty-two exotic species were collected representing 11% of the flora. A total of 266 previously unreported species were documented. Five species tracked by the Oklahoma Natural Heritage Inventory were located, none of which were Federally listed as threatened or endangered.

RESUMEN

El objetivo de este estudio es completar los datos floristicos del suroeste de Oklahoma. Basados en una revisión de la base de datos del Atlas of the Flora of Oklahoma, se percibió que el Tillman County estaba subdocumentado florísticamente. En este artículo se publican los resultados de un inventario de las plantas vasculares en Tillman County. Se colectaron un total 371 taxa de plantas vasculares de 253 géneros y 74 familias. La mayoría de las especies se colectaron de las familias Asteraceae (65), Poaceae (67), y Fabaceae (25). Había 123 especies anuales y 248 perennes. Estaban presentes cuarenta y una especies de plantas leñosas. Se colectaron cuarenta y dos especies exóticas que representan el 11% de la flora. Se documentan un total de 266 especies no citadas previamente. Se localizaron cinco especies con seguimiento por el Oklahoma Natural Heritage Inventory, ninguna de las cuales estaba listada federalmente como amenazada o en peligro.

INTRODUCTION

North American botany has had a long tradition of floristic exploration and inventory (Ertter 2000a). Nevertheless, floristic inventories are of continued

---

[1] corresponding author: (405)325-1985, e-mail: *bhoagland@ou.edu*

SIDA 21(1): 429 – 445. 2004

value for research, conservation, and management purposes (Palmer et al. 1995). For example, it has been recently documented that new taxa are discovered and described at a rate of 60 per year (Ertter 2000a). Inventories are also crucial to biogeographic research by filling gaps in the geographic distribution of taxa at all levels. Floristic inventories play a role in plant species conservation, both in locating populations of rare and/or undescribed species and bringing their presence to the attention of conservation organizations (Radford et al. 1980; Stuessy & Sohmer 1996). The lack of accurate florisitc data can jeopardize the long term persistence of sensitive species (Ertter 2000a). Finally, floristic inventories aid resource managers in locating populations of sensitive species and documenting the arrival of exotic and nuisance species (Barkley 2000). Ignorance of the presence of exotic species can be detrimental to sensitive species and/or exert adverse economic impacts (Ertter 2000b).

The objective of this study was to fill a gap in floristic data for southwest Oklahoma. Based on the Atlas of the Flora of Oklahoma database (AFO; Hoagland 2003), Tillman County is a floristically under-documented county. Prior to 1996, the year collecting began for this study, only 175 species were reported from Tillman County (Hoagland 2003). The first collection gathered in Tillman County was a specimen of *Eryngium diffusum* by G.W. Stevens on 17 October 1924. Peak years for plant collecting in Tillman County prior to this study were 1936 (30 specimens) and 1940 (45 specimens).

Study Area

Tillman County (Fig. 1) occupies 237,503 hectares and is located within the Subtropical Humid (Cf) climate zone (Trewartha 1968). Summers are warm (mean July temperature = 28.9° C) and humid, and winters are relatively short and mild (mean January temperature = 3.5° C). Mean annual precipitation is 78.7 cm., with periodic severe droughts (Oklahoma Climatological Survey 2003). Physiographically, the study area is located in the Osage Plains section of the Central Lowlands province (Hunt 1974) and within the Central Redbed Plains province of Oklahoma (Curtis & Ham 1979). The surface geology of Tillman County is predominately red sandstone and shale formed from shallow-marine and alluvial deposits of Permian age (Branson & Johnson 1979).

There are eight soil associations in Tillman County (Lamar & Rhodes 1974). The two predominant soil associations are the Tipton-Hardeman-Grandfield, which occurs on the floodplains of the Red and North Fork of the Red River and is nearly level, loamy, sandy soil with loamy subsoil, and the Ford-Tillman, which is a nearly level to gently sloping upland, loamy soil with loamy and clay subsoils. The Clairemont-Asa-Miller Association occupies bottomlands and is deep, nearly level soil which is loamy, clayey throughout (Lamar & Rhodes 1974).

The predominant potential natural vegetation in Tillman County (Duck & Fletcher 1943) includes the Mixedgrass Eroded Plains, which would occupy

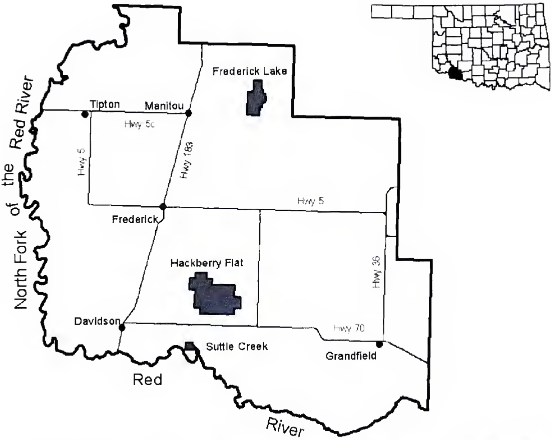

FIG. 1. Location of the three sites selected for florisitic sampling in Tillman County, Oklahoma.

138,565 hectares (58%) on loamy soil and shallow rocky soil, and 68,635 hectares (29%) of tallgrass prairie (Duck & Fletcher 1943). Sandsage grassland occupies 10,360 hectares (4%) and occurs on deep sand deposits along the North Fork of the Red River, Red River, and Otter Creek. Mesquite grassland occupies 4,403 hectares (2%). Bottomland forest occupies 15,540 hectares (6%).

METHODS

Collections were made at three locations: Hackberry Flat Wildlife Management Area (HF), and Lake Frederick (LF), a municipal reservoir, and Suttle Creek (SC) a Bureau of Land Management (BLM) holding along the Red River (Table 1). At each of these locations, collection sites were established for intensive floristic sampling. Sites were selected following a review of U.S. Geological Survey 1:24,000 topographic maps and field reconnaissance. The predominant vegetation association at these sites was classified according to Hoagland (2000). Collections were also made randomly throughout each location and the county. Collections at HF were made from April to October, 1996, and at LF and SC from April through October 2000, from March through October 2001. Vouchers for exotic species (defined as those species not native to North America) were made

TABLE 1: Location and elevation data for sample sites. Coordinates represent the north and southern most latitude and the east and west most longitude of each study site. Coordinates are presented in decimal degrees.

Site	North	South	East	West	Max. Elev.	Min. Elev.
Frederick Lake	34.54°N	34.51°N	98.87°W	98.90°W	381m	360m
Hackberry Flat	34.30°N	34.25°N	98.89°W	98.98°W	366m	349m
Suttle Creek	34.23°N	34.22°N	98.96°W	98.97°W	358m	332m

from naturalized populations only, thus excluding cultivated and ornamental plants. Specimens were processed at the Robert Bebb Herbarium of the University of Oklahoma (OKL) following standard procedures. Manuals used for specimen identification included Waterfall (1973), Great Plains Flora Association (1986), and Diggs et al (1999). Origin, either native or introduced, was determined using Taylor & Taylor (1991) and USDA-NRCS (2003). Nomenclature follows the United States Department of Agriculture-Natural Resources Conservation Service (USDA-NRCS 2003). A voucher set was deposited at OKL. Sorensens' Index of Similarity (Pielou 1984) was calculated for pairs of sites in order to determine similarity of floras.

RESULTS AND DISCUSSION

A total of 371 taxa of vascular plants in 74 families and 253 genera were collected in Tillman County. Among the angiosperms, 97 were monocots and 270 were dicots. In addition, one fern ally and one gymnosperm was recorded. The Asteraceae (65), Poaceae (67), and Fabaceae (25) had the greatest number of species. Genera with the greatest number of species were *Dalea* (6), *Cyperus* (5), *Panicum* (5) and *Bromus* (4). One hundred and twenty-three species were annuals and 248 were perennials. Forty-one species of woody plants were collected: 20 trees, 13 shrubs, and 8 woody vines.

Forty-two introduced species (11% of the flora) were collected in Tillman County. This is comparable to the number of exotics collected at the Chickasaw National Recreation, located in south-central Oklahoma, where 12% of the flora was composed of exotic species (Hoagland & Johnson 2001). The families with the greatest number of introduced species were Poaceae (17), Brassicaceae (5), and Asteraceae (4). Genera with the most exotic species were *Bromus* (4) and *Echinochloa* (3). Species tracked by the Oklahoma Natural Heritage Inventory (ONHI) were *Abronia fragrans* (G5, S2S3), *Argythamnia humilis* (G5,S2S3), *Cenchrus echinatus* (G5, S1), *Escobaria vivipara* (G5, S2S3), and *Malvella leprosa* (G5, S1S2). Species are ranked according to level of imperilment at the state (S) and global (G) levels on a scale of 1–5; 1 representing a species that is imperiled and 5 one that it is secure (Groves et al. 1995). No Federally listed threatened or endangered species were encountered.

Species richness was highest at LF (Table 2) and lowest at HF, which was by far the largest site (Table 3). The low species richness may be due to the fact that 97% of the land cover was classified as disturbed. Although LF was smaller in area than HF, which had the lowest species richness, there were more habitat types present. SC, which had the second lowest species richness, was 65% disturbed (Table 3). LF was only 10% disturbed. However, the number of annual species, which often indicates the degree of disturbance, was highest at LF, not HF.

Although all three sites were in close geographic proximity, Sorensen Indices were below 0.5 (Table 4). The highest similarity was scored for the comparison of HF and LF, which shared 53 species (Table 5). The high number of arenaceous species at SC may account for the low similarity index values between that site and the other two. Interestingly, the highest similarity was between the largest sites.

The AFO database (Hoagland 2003) lists 175 species for Tillman County that were collected prior to 1996. Seventy species in the Atlas database were not collected in this study. There were eight families in the AFO database that were not collected in this study; Acanthaceae (*Dyschoriste linearis* and *Justicia americana*), Apocynaceae (*Apocynum cannabinum*), Cuscutaceae (*Cuscuta cuspidata*), Dryopteridaceae (*Woodsia obtusa*), Fumariaceae (*Corydalis aurea*), Polemoniaceae (*Ipomopsis longiflora*), and Pteridaceae (*Pellaea atropurpurea*). Of the remaining species, 107 were reported both in AFO database and in this study. When that number is subtracted from the total of species in the checklist, this study contributed 266 species previously unreported from Tillman County. When the species unique to the AFO and this study are summed, along with the number of shared species, this gives a total of 441 species in Tillman County, a 40% increase in our previous knowledge.

Seven habitat types were found at the three primary collecting sites (Table 2). The actual number of habitat types at each site ranged from 3 to 6. A brief description of each habitat type follows.

Sandbars and dunes (SB)

Sandbars and dunes occurred only at the SC site. Vegetation on sandbars, which were in the Red River channel, was sparse, however *Cyperus esculentus*, *Heliotropium curassavicum*, and *Tamarix chinensis* were present. Sandunes, which occurred along the floodplain and terraces of the Red River, were vegetated by the *Artemisia filifolia/Sporobolus cryptandrus-Schizachyrium scoparium* shrubland association (Hoagland 2000). Associated species included *Dalea villosa*, *Prunus angustifolia*, *Calylophus serrulatus*, *Eriogonum anuum*, *Sideroxylon lanuginosa*, *Rhus aromatica*, *Vitis acerifolia*, and *Zanthoxylum hirsutum*. Tracked species found in this habitat type were *Abronia fragrans* and *Cenchrus echinatus*.

Site	Total	Unique	w/LF	w/HF
Hackberry Flat	121	45		
Lake Frederick	185	87		53
Suttle Creek	182	88	63	41

Aquatic and wetland habitats (AQ)

Aquatic habitats were found at LF and SC. Aquatic environments at LF were composed of the 341 hectare Lake Frederick and its shoreline. Vegetated areas were on the upper reaches of the lake, where the *Polygonum pensylvanicum–P. lapathifolium* herbaceous association (Hoagland 2000) was common. Associated species included *Eleocharis palustris, Juncus torreyi, Potamogeton pectinatus, Schoenoplectus pungens,* and *Xanthium strumarium.*

Wetlands at SC were formed by seeps and springs that emerged at the base of sand dunes and flowed into Suttle Creek. The vegetation in the seeps and springs was best characterized as the *Rorippa nasturtium-aquaticum* herbaceous association (Hoagland 2000). Associated species included *Eclipta prostrata, Hydrocotyle verticillata, Lobelia cardinalis, Ludwigia palustris, Myosurus minimus,* and *Ranunculus scleratus.*

Along broader stretches of Suttle Creek, the *Schoenoplectus americanus - Eleocharis* spp. herbaceous association (Hoagland 2000) was predominant. Associated species included *Amorpha fruticosa, Cephalanthus occidentalis, Distichlis spicata, E. palustris J. torreyi, Polypogon monspeliensis, Symphyotrichum subulatum* and *Typha domingensis.*

Disturbed areas and old fields (DA)

Disturbed areas occurred at all three sites and was the predominant cover type at HF and SC. Disturbed area designations included mowed lawns, roadsides, and other sites exhibiting signs of physical disruption. Common plants in disturbed areas included *Bothriochloa ischaemum, Cynodon dactylon, Daucus pusillus, Melilotus officinalis,* and *Mollugo verticillata.* Old-fields were characterized by *Ambrosia trifida, Amaranthus rudis, Cnidoscolus texanus, Conyza canadensis,* and *Sorghum halepense. Malvella leprosa* was the only species tracked by ONHI found in this habitat type.

Pasture (PS)

This habitat type occurred only at HF, where *B. ischaemum* had been planted on 67 ha in the northwest corner of the site. The pasture was essentially a monoculture of *B. ischaemum* with a few widely scattered individuals of *Prosopis glandulosa.*

Mixedgrass prairie (MG)

Mixedgrass prairie occurred at all three sample sites, but was most extensive at LF. *Bouteloua hirsuta - Bouteloua curtipendula* herbaceous association was common on coarse, shallow soils. Associated species included *Aristida purpurascens, Bouteloua rigidiseta, Crotonopsis elliptica, Leucelene asteroides, Lithospermum tenellum, Opuntia phaeacantha, Schizachyrium scoparium*, and *Thelesperma filifolia* (Hoagland 2000, Crawford 2002). On loamy soils, the *Schizachyrium scoparium - Sorghastrum nutans* herbaceous association predominates. Common associates include *Andropogon gerardii, A. purpurascens, Bouteloua curtipendula, Panicum virgatum, Sporobolus cryptandrus*, and *Symphyotrichum ericoides. Argythamnia humilis* and *Escobaria vivipara* were found in this habitat type and also in mesquite shrubland.

Mesquite shrubland (MQ)

This habitat type, representing the *Prosopis glandulosa/Bouteloua* sp. shrubland association (Hoagland 2000), was found only at LF. Unlike *P. glandulosa* shrublands throughout Tillman County, the herbaceous vegetation at LF was predominantly native species (Crawford 2002). Dominant grasses included *Bouteloua curtipendula* and *Schizachyrium scoparium*. Associated species included *Aristida purpurascens, Bouteloua rigidiseta, Echinacea angustifolia, Erioneuron pilosum, Eryngium leavenworthii, Opuntia phaeacantha, Sorghastrum nutans, Sporobolus cryptandrus, Symphyotrichum ericoides*, and *Thelesperma filifolia*.

Bottomland forest (BLF)

Bottomland forest occurred at LF and SC. Two vegetation types occurred in this category: *Fraxinus pennsylvanica - Ulmus americana* forest association and the *Populus deltoides/Salix (exigua, nigra)* forest association (Hoagland 2000). Associated species included *Ampelopsis cordata, Celtis laevigata, Teucrium canadense*, and *Toxicodendron radicans*.

ANNOTATED CHECKLIST

Annotated species list for Tillman County, Oklahoma. The first entry is the collection number (the prefix **BLM** = Suttle Creek, a Bureau of Land Management holding on the Red River, **HF** = Hackberry Flat Wildlife Management Area, and **PC** = Lake Frederick). Specimens with the prefix **M9** or the suffixes **BWH** or **98** represent specimens collected outside the three areas inventoried), followed by origin (**N** = native, **I** = introduced), life history (**A** = annual, **Bi** = biennial, **P** = perennial), and habitat (**SB** = sandbars and dunes, **AQ** = aquatic, **DA** = Old fields and disturbed areas, **PS** = pasture, **MG** = mixedgrass prairie, **MQ** = mesquite shrubland, and **BLF** = bottomland forest). Voucher specimens were deposited at the Robert Bebb Herbarium at the University of Oklahoma (OKL).

Cyperus acuminatus Torr. & Hook. ex. Torr.; HF0158; N; P; DA

Cyperus squarrosus L.; 0119-90; N; A; AQ

Cyperus croceus Vahl; PC-168; N; A; DA

Cyperus esculentus L.; HF0151; I; P; DA

Cyperus odoratus L.; BLM0427; N; P; DA

Eleocharis montevidensis Kunth.; BLM031, N; P; AQ

Eleocharis palustris (L.) Roem. & Schult.; HF0019, PC-135; N; P; AQ

Fuirena simplex Vahl; BLM0357; N; P; AQ

Schoenoplectus americanus (Pers.) Volk ex Schinz & R. Keller; BLM067; N; P; AQ

Schoenoplectus pungens (Vahl) Palla. var. *longispicatus* (Britton) S.G. Sm.; PC-133; N; P; AQ

Schoenoplectus maritimus (L.) Lye; BLM0451; N; P; AQ

IRIDACEAE

Nemastylis geminiflora Nutt.; PC-2; N; P; DA, MG

Sisyrinchium angustifolium P. Mill.; HF065; N; P; DA, MG

Sisyrinchium chilense Hook.; PC-16; N; P; DA

JUNCACEAE

Juncus marginatus Rostk.; M9.132; N; P; AQ

Juncus torreyi Cov.; BLM0355, PC-132; N; P; AQ

LILIACEAE

Allium canadense L.; BLM0076; N; P; DA, MG

Cooperia drummondii Herbert; HF0141; N; P; MG

Erythronium albidum Nutt.; PC-232; N; P; BLF

Nothoscordum bivalve (L.) Britton; HF0166, PC-68; N; P; DA, MG, MQ

NAJADACEAE

Najas guadalupensis (Spreng.) Magnus; 2085-BWH; N; A; AQ

POACEAE

Aegilops cylindrica Host; HF051; I; A; AQ

Andropogon gerardii Vitman; BLM0435, PC-200; N; P; MG, MQ

Andropogon glomeratus (Walt.) B.S.P.; BLM0424; N; P; AQ, BLF

Aristida purpurascens Poir.; BLM0369; N; P; DA, MG

Aristida purpurea Nutt.; BLM0161, HF0104, PC-27; N; P; DA, MG

Bothriochloa ischaemum (L.) Keng var. *songarica* (Rupr. ex Fisch. & C.A. Mey.) Celarier & Harlan; HF0139, PC-22; I; P; DA, PS

Bothriochloa saccharoides (Sw.) Rydb.; HF047, PC-60; N; P; DA, MG, MQ

Bouteloua curtipendula (Michx.) Torr., BLM0363, HF0105, PC-172; N; P; MG, MQ

Bouteloua hirsuta Lag.; PC-173; N; P; MG, MQ

Bouteloua rigidiseta (Steud.) A. S. Hitchc.; BLM0180, HF060, PC-21; N; P; MG, MQ

Bromus catharticus Vahl; BLM046, HF036, PC-63; I; P; BLF, DA, MQ

Bromus commutatus Schrad.; PC-46; I; A; DA

Bromus japonicus Thunb. Ex Murr.; BLM0509, HF01; I; A; DA, MQ

Bromus secalinus L.; HF09; I; A; DA

Buchloë dactyloides (Nutt.) Engelm.; BLM051, HF02, PC-61; N; P; DA. MG. MQ

Cenchrus echinatus L.; BLM0322; N; A; SB

Chloris cucullata Bisch.; BLM0183; N; P; SB

Chloris verticillata Nutt.; HF0103; N; P; DA, MG, MQ

Cynodon dactylon (L.) Pers.; BLM0432, HF0100, PC-128; I; P; DA, PS

Digitaria sanguinalis (L.) Scop.; BLM0450; N; A; DA

Distichlis spicata (L.) Greene; BLM0312; N; P; AQ, SB

Echinochloa colona (L.) Link; BLM0434; I; A; AQ

Echinochloa crus-galli (L.) Beauv.; BLM0431; I; A; AQ

Echinochloa crus-pavonis (H.B.K.) Schult. var. *macera* (Wieg.) Gould; PC-194; I; A; AQ

Echinochloa muricata (Beauv.) Fern.; HF0101; N; A; AQ

Elymus canadensis L.; PC-114; N; P; BLF, MG, MQ

Elymus virginicus L.; BLM0147, HF0110; N; P; MG, MQ

Eragrostis cilianensis (All.) Vign. ex Janchen; BLM0328, HF0168; I; A; DA

Eragrostis hirsuta (Michx.) Nees; BLM0449; N; P; DA, MG, SB

Eragrostis hypnoides (Lam.) B.S.P.; HF078; N; A; AQ

Eragrostis sessilispica Buckl.; PC-76; N; P; DA

Eriochloa contracta Hitchc.; HF0126; N; A; DA, MG

Eriochloa sericea (Scheele) Munro ex. Vasey; PC-71; N; P; DA, MG

Erioneuron pilosum (Buckley) Nash; BLM028, PC-59; N; P; MG

Hordeum pusillum Nutt.; BLM044, HF042, PC-29; N; A; DA

Leersia oryzoides (L.) Sw.; BLM0430; N; P; AQ

Leptochloa fusca (L.) Kunth.; BLM0511, HF0135; N; A; DA

Leptochloa panicea (Retz.) Ohwi ssp. *brachiata* (Steudl.) N. Snow; HF0152, PC-192; N; P; DA

Muhlenbergia asperifolia (Nees & Meyen ex Trin.) Parodi; BLM0437; N; P; AQ

Nassella leucotricha (Trin. & Rupr.) Pohl; BLM0195, PC-4; N; P; MG

Neeragrostis reptans (Michx.); PC-193; N; A; AQ

Panicum capillare L.; HF0124, PC-160; N; A; DA

Panicum halli Vasey var. *filipes* (Scribn.) F.R. Waller; PC-169; N; P; MG

Panicum obtusum H.B.K.; HF077, PC-156; N; P; BLF, DA, MG

Panicum rigidulum Bosc ex Nees; HF0122; N; P; MG

Panicum virgatum L.; BLM0488, PC-199; N; P; BLF, MG, MQ

Pascopyrum smithii (Rydb.) A. Löve; BLM0486, PC-62; N; P; AQ, BLF

Paspalum distichum L.; HF0150; N; P; DA

Paspalum setaceum Michx.; BLM0487; N; P; AQ

Pennisetum glaucum (L.) R. Br.; BLM0429, HF0130; I; A; DA, PS

Phalaris canariensis L.; BLM0161; I; A; AQ

Phalaris caroliniana Walt., HF033; N; A; AQ, MG

Poa annua L.; BLM047; I; A; DA

Poa arachnifera Torr.; BLM041; N; P; BLF

Polypogon monspeliensis (L.) Desf.; BLM0168; I; A; AQ, SB

Schedonnardus paniculatus (Nutt.) Trel.; HF050; N; P; DA, MG

Setaria parviflora (Poir.) Kerguelén; BLM0359; N; P; DA

Setaria viridis (L.) Beauv., BLM0500; I; A; DA

Sorghastrum nutans (L.) Nash; BLM0433; N; P; MG

Sorghum halepense (L.) Pers.; BLM0484, HF041, PC-124; I; P; DA

Sporobolus airoides (Torr.) Torr.; HF079, PC-182; N; P; DA, SB

Sporobolus cryptandrus (Torr.) A. Gray; BLM0326; N; P; MG, SB

Sporobolus coromandelianus (Retz.) Kunth; PC-183; N; P; DA

Tridens albescens (Vasey) Woot. & Standl.; BLM049, HF063, PC-3; N; P, MG

Triplasis purpurea (walt.) Chapman; BLM0436; N; A; SB

Vulpia octoflora (Walt.) Rydb.; BLM059; N; A; MG

POTAMOGETONACEAE

Potamogeton nodosus Poir.; 2084-BWH; N; P; AQ

SMILACACEAE

Smilax bona-nox L.; BLM0446, PC-203; N; P; BLF

Smilax rotundifolia L., 071-98; N; P; BLF

TYPHACEAE

Typha domingensis Pers.; BLM0375, PC-134; N; P; AQ

ZANNICHELLIACEAE

Zannichellia palustris L.; BLM030; N; P; AQ

MAGNOLIOPSIDA

AMARANTHACEAE

Amaranthus palmeri S. Wats.; HF091; N; A; DA

Amaranthus rudis Sauer; BLM0438, HF115; N; A; DA

ANACARDIACEAE

Rhus trilobata Nutt.; BLM0204; N; P; MG, MQ

APIACEAE

Ammoselinum popei Torr. & A. Gray; HF067; N; A; DA

Chaerophyllum tainturieri Hook.; BLM048; N; A; DA, MG

Cymopterus macrorhizus Buckl.; PC-221; N; P; MG

Daucus pusillus Michx.; BLM0154, HF053, PC-85; N; A; DA

Eryngium leavenworthii Torr. & A. Gray; PC-216; N; A; MG

Hydrocotyle verticillata Thunb.; BLM0502; N; P; AQ

Lomatium foeniculaceum (Nutt.) Coult. & Rose; PC-220; N; P; MG

Sanicula canadensis L.; BLM0499; N; Bi; BLF

ASCELPIADACEAE

Asclepias arenaria Torr.; BLM0492; N; P; MG

Asclepias asperula (Dcne.) Woods; HF054, PC-143; N; P; DA, MG

Asclepias viridiflora Raf.; PC-187; N; P; DA, MG, MQ

Asclepias viridis Walter; PC-53; N; P; MG

Funastrum cynanchoides (Decne.) Schltr.; BLM0345, PC-186; N; P; DA

Matelea biflora (Raf.) Woods; HF054; N; P; DA, MG

ASTERACEAE

Achillea millefolium L.; BLM042, HF022, PC-57; N; P; DA, MG, MQ

Ambrosia psilostachya DC; BLM0352, HF0155, PC-176; N; P; DA, MG, MQ, SB

Ambrosia trifida L.; HF0149; N; A; DA

Amphiachyris dracunculoides (DC.) Nutt.; BLM0439; N; A; DA

Aphanostephus ramosissimus DC.; BLM0201; N; A; SB

Artemisia filifolia Torr.; BLM0425; N; P; SB

Baccharis salicina Torr. & A.Gray; HF0107; N; P; BLF, DA, SB

Berlandiera texana DC.; M9.148; N; P; MG

Bidens frondosa L.; BLM0440; N; A; AQ

Centaurea americana Nutt.; 2126-BWH, PC-70; N; A; DA, MG

Chloracantha spinosa (Benth.) Nesom; BLM0370; N; P; BLF

Chaetopappa ericoides (Torr.) Nesom; BLM0157, PC-10; N; P; MG

Cirsium ochrocentrum A. Gray; HF0108; N; P; DA, MG

Cirsium texanum Buckley; HF094, PC-54; N; P; MG

Cirsium undulatum (Nutt.) Spreng.; BLM0177, HF030; N; P; DA, MG

Conyza canadensis (L.) Cronq.; HF014; N; A; DA

Coreopsis tinctoria Nutt.; HF040, PC-96; N; A; AQ, MG

Dracopis amplexicaulis (Vahl) Cass.; HF031, PC-84; N; A; AQ

Dysodiopsis tagetoides (Torr. & A.Gray) Rydb.; PC-80; N; P; DA, MG

Echinacea angustifolia DC.; PC-93; N; P; MG, MQ

Eclipta prostrata (L.) L.; HF164, BLM0453; N; A; AQ

Engelmannia peristenia (Raf.) Goodman & Lawson; BLM0152, HF059, PC-171; N; P; MG, MQ

Erigeron strigosus Muhl. ex Willd, HF018, PC-6; N, A; DA

Eupatorium serotinum Michx.; BLM0445; N; P; BLF, MG

Evax prolifera Nutt. ex DC; PC-37; N; A; DA

Gaillardia pulchella Foug.; BLM0186; N; A; DA, MG, MQ

Gaillardia sauvis (A. Gray & Engelm.) Britton & Rusby; BLM075, HF028, PC-17; N; P; DA, MG, MQ

Grindelia nuda A.W. Wood; PC-178; N; P; DA, MG, MQ

Grindelia papposa Neson & Suh; BLM00490; N; Bi; DA, MG, MQ

Grindelia squarrosa (Pursh) Dunal; HF0145; N; P; DA, MG, MQ

Grindelia lanceolata Nutt. var. *texana* (Scheele) Shinners; PC-215; N; P; DA, MG

Helenium microcephalum DC; HF081, PC-164; N; A; AQ, BLF

Helianthus annuus L.; HF087, PC-101; N; A; DA

Helianthus petiolaris Nutt.; BLM0329; N; A; DA, SB

Heterotheca subaxillaris (Lam.) Britton & Rusby; HF0109; N; A; DA, MG

Heterotheca villosa (Pursh) Shinners; PC-142; N; P; MG, SB

Hymenopappus flavescens Gray; BLM0188; N; Bi; MG

Hymenopappus scabieosus L'Hér.; M9.147; N; Bi; MG, MQ

Hymenopappus tenuifolius Pursh.; BLM0324, PC-14; N; Bi; MG

Hymenoxys odorata DC.; HF061; N; A; DA, MG

Iva annua L.; BLM0442, HF0146, PC-213; N; A; AQ

Lactuca ludoviciana (Nutt.) Riddell; HF095; N; Bi; DA

Liatris mucronata DC.; BLM0342; N; P; MG

Liatris punctata Hook.; HF0162, PC-212; N; P; MG

Lindheimera texana Gray & Engelm.; PC-15; N; A; MG, MQ

Machaeranthera pinnatifida (Hook.) Shinners; PC-179; N; P; MG

Machaeranthera pinnatifida (Hook.) Shinners ssp. *pinnatifida* var. *pinnatifida*; BLM0187, HF074; N; P; MG, MQ

Packera plattensis (Nutt.) W.A. Weber & A. Löve; PC-13; N; P; BLF

Pluchea odorata (L.) Cass.; BLM0495; N; A; AQ, BLF

Pyrrhopappus grandiflorus (Nutt.) Nutt.; BLM043; N; P; DA

Ratibida columnifera (Nutt.) Wooton & Standl.; HF056, PC-88; N; P; DA, MG, MQ

Senecio vulgaris L.; PC-243; I; Bi; BLF

Solidago missouriensis Nutt.; BLM0353, PC-185; N; P; DA, MG, MQ

Sonchus asper (L.) Hill; BLM036, HF07; I; A; DA
Sonchus oleracea L.; 2088-BWH; I; A; DA
Symphyotrichum ericoides (L.) Nesom; HF0156, PC-181; N; P; MG, MQ
Symphyotrichum subulatum (Michx.) Nesom; BLM0454, HF023; N; A; AQ
Taraxacum officinale G.H.Weber ex Wiggers; PC-244; I; P; DA
Tetraneuris linearifolia (Hook.) Greene; BLM058, PC-11; N; A; MG
Tetraneuris scaposa (DC.) Greene; BLM0174, PC-9; N; P; MG
Thelasperma filifolium (Hook.) A. Gray; BLM0483, PC-47; N; P; MG, MQ
Thelasperma megapotamcium (Spreng.) Kuntze; BLM0181; N; P; MG, MQ
Tragopogon dubius Scop.; BLM0498, HF043, I; A; DA
Vernonia marginata (Torr.) Raf.; PC-166; N; P; MG
Xanthisma texanum DC.; BLM9482; N; A; MG, SB
Xanthium strumarium L.; BLM0349, HF0163, PC 214; N; A; AQ

BORAGINACEAE

Buglossoides arvensis (L.) I.M. Johnston; BLM0156; I; A; DA
Heliotropium curassavicum L.; BLM0343, HF099, N; A; AQ, SB
Heliotropium tenellum (Nutt.) Torr.; PC-106; N; A; MG
Lithospermum incisum Lehm.; PC 236; N; P; MG

BRASSICACEAE

Capsella bursa-pastoris (L.) Medik; PC-249; I; A; DA
Descurainia pinnata (Walt.) Britton; BLM038; N; A; DA
Descurainia sophia (L.) Webb ex Prantl; PC-237; I; A; DA
Draba cuneifolia Nutt. ex Torr. & A. Gray; PC 223; N; A; DA, MG
Erysimum repandum L.; PC-230; I; A; DA
Lepidium austrinum Small; PC 24; N; A; DA
Lepidium densiflorum Schrad.; HF034; N; A; DA
Lesquerella gordonii (A. Gray) Wats.; BLM065; N; A; MG
Lesquerella gracilis (Hook.) S. Wats subsp. *Nuttallii* (T. & G.) Rollins & Shaw; PC-8; N; A, MG
Lesquerella gracilis (Hook.) S. Wats.; PC-223; N; A; MG
Lesquerella ovalifolia Rydb.; PC-44; N; P; MG
Rorippa nasturtium_aquaticum (L.) Hayek, BLM035; I; P; AQ
Sibara virginica (L.) Rollins; PC 229; N; A; DA, MG
Sinapis arvensis L.; HF016; I; A; DA

CACTACEAE

Escobaria vivipara (Nutt.) Buxbaum; 1542-BWH; N; P; MG
Opuntia leptocaulis DC.; BLM027; N; P; MG
Opuntia macrohiza Engelm.; BLM511, HF076; N; P; DA, MG, MQ
Opuntia phaeacantha Engelm. var. *major* Engelm.; PC-49; N; P; DA, MG, MQ

CAMPANULACEAE

Lobelia cardinalis L.; BLM0444; N; P; AQ
Triodanis perfoliata (L.) Nieuwl.; BLM0155; N; A; DA

CAPPARACEAE

Cleomella angustifolia Torr.; 040-98; N; A; DA

CARYOPHYLLACEAE

Arenaria serpyllifolia L.; PC-247; I; A; DA
Cerastium brachypodum (Engelm. ex Gray) B.L. Robins.; PC-224; N; P; DA
Paronychia jamesii Torr. & A. Gray; BLM0494, PC-205; N; P; MG
Stellaria media (L.) Vill.; BLM056; I; A; DA

CHENOPODIACEAE

Chenopodium album L.; HF090; I; A; DA
Chenopodium berlandieri Moq.; HF0157, PC 189; N; A; DA
Chenopodium pratericola Rydb.; HF012; N; A; DA
Cycloloma atriplicifolium (Spreng.) Coult.; BLM0489; N; A; DA
Monolepis nuttalliana (Schultes) Greene; HF017, PC-238; N; A; DA
Salsola tragus L.; PC-180; I; A; DA

CONVOLVULACEAE

Convolvulus arvensis L.; HF086, PC-18; I; P; DA

CORNACEAE

Cornus drummondii Mey.; 0132-98; N; P; DA, MG

CUCURBITACEAE

Cucurbita foetidissima Kunth.; HF070, PC-131; N; P; DA, MG, MQ

ELATINACEAE

Bergia texana (Hook.) Walp.; PC 137; N; P; MG

EUPHORBIACEAE

Acalypha ostryifolia Riddell; PC-188; N; A; DA
Argythamnia humilis (Engelm & A. Gray) Muell., Arg var. *leiosperma* Waterfall; PC-78; N; P; MG

Chamaesyce albomarginata (Torr. & A. Gray) Small; HF096; N; P; DA

Chamaesyce serpens (Kunth) Small; HF089; N; A; DA

Chamaesyce missurica (Raf.) Shinners; BLM0377, PC-125; N; A; DA

Chamaesyce nutans (Lag.) Small; PC-174; N; A; DA

Chamaesyce prostrata (Aiton) Small; PC-108; N; A; DA

Cnidoscolus texanus (Muell.-Arg.) Small; BLM0166; N; P; DA, SB

Croton capitatus Michx.; PC-152; N; A; DA, MG

Croton monanthogynus Michx.; PC-74, N; A; DA

Croton texensis (Klotzsch) Muell.-Arg.; BLM0428; N; A; DA, MG

Euphorbia dentata Michx.; PC-73; N; A; DA

Euphorbia marginata Pursh; BLM0347, HF0143, PC-35; N; A; DA, SB

Euphorbia spathulata Lam.; BLM050, PC-26; N; A; DA

Phyllanthus polygonoides Nutt. ex Spreng; PC-98; N; P; MG

Stillingia sylvatica Garden ex. L.; BLM0203; N; P; MG

FABACEAE

Acacia angustissima (Mill.) Kuntze. var. *hirta* (Nutt.) B.L. Rob.; HF093, PC-141; N; P; MG, MQ

Amorpha fruticosa L.; BLM0151; N; P; AQ

Astragalus lindheimeri Engel. ex A. Gray; PC-32; N; A; MG, MQ

Astragalus plattensis Nutt.; PC-28; N; P; MG, MQ

Chamaecrista fasciculata (Michx.) Greene; PC 204; N; A; MG, MQ

Dalea aurea Nutt. ex Pursh; PC-116; N; P; MG

Dalea candida Willd.; BLM0323, PC-122; N; P; MG, MQ

Dalea enneandra Nutt.; BLM0321, PC 115; N; P; MG

Dalea lanata Spreng.; BLM0306; N; P; SB

Dalea purpurea Vent.; PC-91; N; P; MG, MQ

Dalea villosa (Nutt.) Spreng.; BLM0305; N; P; SB

Desmanthus illinoensis (Michx.) MacM.; BLM0344, HF0111; N; P; DA

Gleditsia triacanthos L.; BLM073; N, P; BLF

Glycyrrhiza lepidota Pursh; BLM0310; N; P; SB

Hoffmannseggia glauca (Ort.) Eifert; HF039, PC-147; N; P; DA

Indigofera miniata Ort. var. *leptosepala;* BLM0159, PC-206; N; P; SB

Medicago minima (L.) L.; PC-31; I; A; DA

Medicago orbicularis (L.) Bartal.; HF045; I; A; DA

Melilotus officinalis (L.) Lam.; BLM0485, HF027, PC-195; I; A; DA

Mimosa nuttallii (DC.) B.L. Turner; BLM0189, HF066, PC-90; N; P; MG, MQ

Neptunia lutea Benth.; PC-100; N; P; MG, MQ

Pediomelum cuspidatum (Pursh) Rydb.; PC-83; N; P; MG, MQ

Pediomelum linearifolium (Torr. & A. Gray) J. Grimes ; PC-95; N; P; MG, MQ

Prosopis glandulosa Torr.; BLM0176, HF068, PC-64; N; P; DA, MG, MQ

Vicia sativa L.; BLM053; I; A; DA

GENTIANACEAE

Eustoma exaltatum (L.) Salisb. ex G. Don; BLM0341, PC-202; N; A; AQ

GERANIACEAE

Erodium cicutarium (L.) L'Hér. ex Aiton; BLM063, PC-240; I; A; DA

Geranium carolinianum L.; 2087-BWH, HF049; N; A; DA

HYDROPHYLLACEAE

Nama hispidum Gray; BLM0153; N; A; MG

KRAMERIACEAE

Krameria lanceolata Torr.; BLM0167, HF057, PC-81; N; P; MG, MQ

LAMIACEAE

Hedeoma reverchonii A. Gray; PC-126; N; P; MG, MQ

Lamium amplexicaule L.; BLM074, PC-239; I; A; BLF, DA

Monarda clinopodioides A. Gray; BLM0197, PC-69; N, A; DA, MG

Scutellaria drummondii Benth; PC-105; N; A; MG

Scutellaria resinosa Torr.; PC-5; N; P; MG

Teucrium canadense L.; BLM0331, PC-129; N; P; BLF

Teucrium laciniatum Torr.; BLM0149, HF055, PC-30; N, P; MG, MQ

LINACEAE

Linum perenne L.; BLM069; I; P; MG, MQ

Linum pratense (J.B.S Norton) Small; PC-103, N; A; MG, MQ

LOASACEAE

Mentzelia nuda (Pursh) Torr. & A. Gray var. *stricta* (Osterhout) Harrington ; BLM0325; N; P; SB

Mentzelia oligosperma Nutt. ex Sims.; PC-121; N; P; MG

LYTHRACEAE

Lythrum alatum Pursh; HF04; N; P; AQ

Lythrum californicum Torr. & A. Gray; PC-130; N; P; AQ

MALVACEAE

Malvella leprosa (Ortega) Krapov.- HF03; N; P; DA

Sphaeralcea coccinea (Nutt.) Rydb.; PC-7; N; P; MG, MQ

MENISPERMACEAE

Cocculus carolinus (L.) DC.; BLM0309; N; P; DA

MOLLUGINACEAE

Mollugo verticillata L.; HF075; N; A; DA

MORACEAE

Maclura pomifera (Raf.) Schneid.; BLM0318, HF069; N; P; BLF, DA

Morus alba L.; BLM0507, HF0117; I; P; DA

NYCTAGINACEAE

Abronia fragrans Nutt. ex Hook.; BLM057; N; P; SB

Mirabilis albida (Walt.) Heimerl; BLM0172, PC-162; N; P; SB

Mirabilis jalapa L.; HF0153; I; P; DA

Mirabilis linearis (Pursh) Heimerl; HF072; N; P; MG, MQ

OLEACEAE

Fraxinus pennsylvanica Marsh; PC-150; N; P; BLF

ONAGRACEAE

Calylophus hartwegii (Benth.) Raven subsp. *pubescens* (A. Gray) Towner & Raven; PC-33; N; P; MG

Calylophus serrulatus (Nutt.) Raven; BLM0202; N; P; MG, SB

Gaura coccinea Nutt. ex Pursh; BLM066, HF044; N; P; MG, SB

Gaura parviflora Dougl. ex Lehm.; PC-191, HF025; N; A; DA

Gaura sinuata Nutt. ex. Ser., PC-158; N; P; MG, MQ

Ludwigia peploides (Kunth) Raven; 2089-BWH; N; P; AQ

Ludwigia repens J.R. Forst.; BLM0198; N; P; AQ

Oenothera grandis Britton; BLM080, 062-97, PC-1; N; A; MG, SB

Oenothera rhombipetala Nutt. ex Torr. & A. Gray; BLM0378; N; Bi; DA, SB

Oenothera speciosa Nutt.; HF037, PC-34; N; P; DA, MG

Oenothera triloba Nutt.; M9.026; N; Bi; MG, MQ

Stenosiphon linifolius (Nutt. ex James) Heynh.; BLM0361, PC-89; N; P; DA, MG, MQ

OXALIDACEAE

Oxalis corniculata L.; PC-246; N; P; DA

PAPAVERACEAE

SAWTOOTH OAK (*QUERCUS ACUTISSIMA*, FAGACEAE) IN NORTH AMERICA

Alan T. Whittemore

US National Arboretum
3501 New York Ave NE
Washington, DC (District of Columbia) 20002-1958, U.S.A.

ABSTRACT

Sawtooth oak (*Quercus acutissima* Carruth.), native to eastern Asia, is widely planted in the eastern United States as a source of food for wildlife (especially turkeys) and as a landscape tree in developed areas. Spontaneous reproduction of sawtooth oak outside of cultivation has now been confirmed for Alabama, Louisiana, Maryland, Missouri, Mississippi, North Carolina, Pennsylvania, and the District of Columbia A complete description and an illustration are provided. Feral populations of sawtooth oak are mostly confined to open, often disturbed areas, and it spreads very slowly, apparently due to limited dispersal of the acorns. Planting of large stands of *Quercus acutissima* in natural areas or revegetating areas for wildlife food is likely to result in the establishment of this exotic species and its spread into adjacent habitats, but the use of sawtooth oak as a landscape tree in developed areas usually poses much less danger of escape.

RESUMEN

Quercus acutissima Carruth., nativo del este de Asia, está ampliamente cultivado en el este de los Estados Unidos como fuente de alimento para la fauna salvaje (especialmente pavos) y como árbol de paisaje en áreas desarrolladas Su reproducción espontánea fuera de cultivo se ha confirmado ahora en Alabama, Louisiana, Maryland, Missouri, Mississippi, North Carolina, Pennsylvania, y el Distrito de Columbia. Se aporta una descripción completa y una ilustración. Las poblaciones silvestres de *Quercus acutissima* están mayormente confinadas a áreas abiertas alteradas, y se expande muy lentamente, debido aparentemente a la dispersión limitada de sus bellotas. El establecimiento de grandes plantaciones de *Quercus acutissima* en áreas naturales o áreas de revegetación para alimento de la fauna salvaje es probablemente la causa del establecimiento de esta especie exótica y su expansión en los hábitats adyacentes, pero el uso de *Quercus acutissima* como árbol de paisaje en áreas desarrolladas tiene mucho menos peligro de escape

Sawtooth oak, *Quercus acutissima* Carruth., is a deciduous tree, native to open woodlands in eastern Asia, from northeastern India east to northern Vietnam and north to Japan and Korea (Huang et al. 1999). It was first introduced to the United States in 1862 (Rehder 1940), but it has only become common in cultivation in the past 50 years. Sawtooth oak has been widely planted as a source of food for wildlife (especially turkeys), because of its fast growth and early, heavy fruiting (Sullivan & Young 1961; Mercer 1969; Hopkins & Huntley 1979; Goelz & Carlson 1997; Stribling 1994). It has also has gained favor in recent years as a landscape tree because of its attractive form, rapid growth, and tolerance of difficult conditions (Spicer 1971; Francis & Johnson 1985; Gilbert & Henry 1988; Hensley et al. 1991; Tuttle 1995; Dirr 1998).

Some concern has been expressed about the use of *Q. acutissima* as wildlife food in the United States. Mercer (1969) said, "The sawtooth oak has aroused some apprehension.... Foresters wonder if it might become a "weed" tree. So far none of the plantings studied has increased in number of trees." Coblentz (1981) suggested that its high germination rate and high resistance to insect damage might indicate that *Q. acutissima* has the potential to spread widely in the southern United States. He noted that the potential for hybridization between sawtooth oak and native North American oaks had not been investigated. He also cited papers indicating that the acorns of sawtooth oak are less nutritious than acorns of native species, and less utilized by North American wildlife, and concluded that long-term management goals will be best met by improved management of diverse native hardwood communities rather than by planting sawtooth oak. Perhaps because of these concerns, many wildlife programs have returned to planting native oaks.

In recent years, *Quercus acutissima* has been reported to reproduce outside of cultivation in six states: Alabama (Younghance and Freeman 1996), Louisiana (Thomas and Allen 1998), Maryland (Terrell et al. 2000), Missouri (Yatskievych and Summers 1993), Mississippi (Kartesz 1999), and Pennsylvania (Rhoads and Klein 1993). The species is not mentioned in the treatment of *Quercus* L. for Flora of North America (Nixon et al. 1997). There are almost no published data on the ecology of sawtooth oak in North America, and the very brief description in Rhoads and Klein (1993) is the only description of the species in a North American identification manual.

Field and herbarium work in the eastern United States, and inquiry among active fieldworkers in the area, indicates that *Quercus acutissima* is escaping at sites across the eastern United States. Spontaneous reproduction of sawtooth oak outside of cultivation has now been confirmed for seven states and the District of Columbia. Since the species is becoming widespread and is being collected more frequently, it seems desirable to supply a full description of *Q. acutissima*, and a summary of its current range and habitat preferences in North America.

KEY TO SEPARATE *QUERCUS ACUTISSIMA* FROM NATIVE OAK GROUPS OF THE EASTERN UNITED STATES

1. Acorns maturing in the first fall after flowering (so all acorns in summer are ± the same size, and immature acorns are not present on the tree in winter). Tips of veins at leaf margin never projecting as bristles. Axils of major veins on leaf underside without conspicuous tufts of hairs. Bark light to medium gray, splitting into loose or more or less persistent ridges, plates, blocks or strips ____________________ White oaks (**Quercus** section **Quercus**)

1. Acorns maturing in the second fall after flowering (thus with large and small acorns on single twigs in summer, and immature acorns present in winter). Tips of veins at leaf margin almost always projecting as bristles 0.5–7 mm long. Axils of major veins on leaf underside usually with tufts of stalked 4–15-rayed hairs 0.3–0.5 mm high. Bark medium to dark gray, splitting into persistent ridges or blocks.

2. Scales of acorn cup lanceolate or strap-shaped, strongly recurved, 8–10 mm long. Leaf unlobed, its margin with 10–23 bristles on each side __________ **Quercus acutissima** (**Quercus** section **Cerris** Loudon)
2. Scales of acorn cup triangular, appressed, 1.5–5 mm long. Leaf not as above: either deeply lobed or with 0–3 bristles on each side __________ Black oaks (**Quercus** sect. **Lobatae** Loudon, sometimes called **Quercus** subgenus **Erythrobalanus** (Spach) Oerst.)

Quercus acutissima Carruth., J. Linn. Soc., Bot. 6:33. 1862. (**Fig. 1**). SAWTOOTH OAK. Trees to 30 m tall. Bark medium to dark gray, divided into narrow persistent ridges. Twigs dark brown, puberulent with 1-5-rayed appressed (occasionally spreading) hairs, or glabrescent, 2–3 mm thick. Buds brown, 5–8 mm long, pubescent (at least the upper half), scales long-ciliate. Petioles 10–39 mm long. Leaf blade lance-oblong to lanceolate or oblanceolate, 11–21 cm long, 3–6 cm wide, base rounded or truncate; secondary veins each (except the basalmost) reaching the margin at the tip of a tooth and ending in a bristle, teeth 10–23 on each side of the blade, well-developed teeth obtuse to acuminate, each tooth ending in a single bristle 2–5 mm long. Upper surface of blade shiny, with scattered inconspicuous simple (rarely 2–4-rayed) hairs; lower surface green, the blade with inconspicuous unbranched appressed hairs, the veins with spreading simple hairs, vein axils with small tufts of ca 4-rayed stalked fasciculate hairs. Calyx of female flower fused to the ovary. Anthers retuse. Styles linear, their tips not broadened. Nuts ripe the second autumn after flowering. Peduncle 0–2 mm long. Acorn cup hemispherical, 14–15 mm long, 18–25 mm wide, covering 0.3–0.5 of the nut, its inner surface smooth, hairy. Cup scales narrowly lanceolate or strap-shaped from a short triangular base, 8–10 mm long, weakly costate, free from cup for their whole length and strongly recurved, the scales at the margin of the cup longer but otherwise not differentiated. Nut ovoid to ovoid-cylindrical, 15–20 mm long, 13–17 mm wide. Inner surface of the shell densely pubescent, abortive ovules near the base, seed coat adhering to the fruit wall.

Flowering in April. Native to Asia, from Korea and Japan south to Vietnam and west to northeastern India.

Representative specimens examined: **ALABAMA. Bibb Co.:** 8 mi S of Centerville along levee dirt road, off of county road 219, 32° 52' 30" N, 87° 00' 00" W, elev. 465 ft, *S.T. Smith s.n.*, 10 Jul 1999 (AUA). **DISTRICT OF COLUMBIA:** Spontaneous small tree 5 m tall, trunk 6.5 cm thick, open grassy (partly cleared) margin of *Quercus* spp. woodland, north side of Beechwood Road near its intersection with Ellipse Road, U.S. National Arboretum, *A.T. Whittemore 00-014*, 29 Aug 2000 (CAS, NA, MOR, MU, UNC, US). **LOUISIANA. Winn Parish:** along paved road leading to Blewer's Pond at Bienville Parish Line, north of LA 126 and NE of Roadheimer, sect. 6, T13N R5W, *K.H. Kessler 1864*, 20 Sep 1981 (AUA). **MARYLAND. Prince George's Co.:** scattered adult trees with frequent saplings, open second-growth *Quercus* woodland, edge of Beltsville Agricultural Research Center along I-495 near the Cherry Hill Rd. overpass, north side of College Park, *A.T. These specimens represent areas where the species is definitely reproducing outside of cultivation. Specimens of planted trees have been seen from most parts of the eastern United States.

Quercus acutissima is easily distinguished from all native North American oaks. No native North American oak has unlobed leaves with numerous marginal bristles, and no native North American oak has the scales of the acorn cup long and reflexed. Sterile specimens of *Castanea* spp. are sometimes confused with *Q. acutissima*. Species of *Castanea* almost always have the leaves and buds in two regular ranks and not crowded at the stem apex. The sole exception to this is *Castanea dentata* (Marshall) Borkhausen, in which the leaves and buds of lateral stems are two-ranked and not crowded apically, as in other *Castanea* spp., while those of the leading stems are arranged in several irregular ranks and ± crowded at the stem apex, similar to stems of *Quercus*. Fertile material of *Castanea* is easily distinguished by characters of the inflorescence (erect and rigid in *Castanea*, pendent and lax in *Quercus*) and fruit (the nut in *Castanea* is completely enclosed in a valvate husk that is covered with long spines, while in *Quercus* the nut is in an unlobed scaly cup). The only exotic oak that resembles *Q. acutissima* is *Q. variabilis* Blume, another Asian species that is rarely cultivated in North America. *Quercus variabilis* is very similar to *Q. acutissima*, differing only in having glabrous twigs, dense stellate pubescence on the underside of the leaf blade, and bark that is usually somewhat corky. A third species sometimes recognized from Asia, *Q. chenii* Nakai, is probably a synonym of *Q. acutissima*.

Quercus acutissima reproduces spontaneously in grassland, open margins of deciduous woodlands, and other open disturbed areas. Sawtooth oak is especially prolific in mowed meadows. Mowing keeps the seedlings small, but does not seem to harm them otherwise. Seedlings are found only in close proximity to adult trees. Careful searches at several sites in Missouri, Maryland and the District of Columbia showed that almost all seedlings and saplings grow within 20 m of an adult tree, and none was found more than 100 m from an adult, suggesting that spread of the tree is severely limited by short seed dispersal.

As with other introduced species (i.e. *Lonicera maackii* (Rupr.) Maxim., Luken & Thieret 1995), sawtooth oak was slow to appear in the North American floristic literature. The first literature report of sawtooth oak as an escape in North America (Rhoads & Klein 1993) came 38 years after the first herbarium collection documenting it (*Schaeffer 49540*, 26 Jul 1955; see specimens examined above), and it is still not treated in many recent floras. This may have delayed recognition of the plant in some areas, since collectors who encounter it may not be able to key it out or find descriptions of it.

Quercus acutissima is a member of *Quercus* sect. *Cerris* Loudon, a group of about forty species native to Eurasia and North Africa. In the past, this group has sometimes been included in sect. *Quercus* (the white oaks; Nixon 1993), but it is now clear that the white oaks and section *Cerris* are not closely related (Manos et al. 1999, 2001). Hybridization between *Q. acutissima* and native oaks, cited as a potential area of concern by Coblentz (1981), is not likely to be a problem. Cottam et al. (1982) attempted numerous crosses between species of sect. *Cerris* and various native North American oak species, with little success. They found that it is very difficult to obtain hybrids between species from different sections of the genus, even when all competing pollen is strictly excluded by bagging and emasculation of the bagged branches. *Quercus acutissima* was not one of the species they used, but they made extensive use of *Q. variabilis*, which is a very close relative based on numerous morphological (Huang et al. 1999) and molecular (Manos et al. 2001) characters. Cottam et al. (1982) attempted pollinations between *Q. variabilis* and sixteen species of white and black oaks, and they were unable to obtain a single hybrid from any of these pollinations.

It is difficult to predict the long-term performance of sawtooth oak in the vegetation of eastern North America, since the decades that have passed since large-scale planting of the species in North America began are less than a full generation for the species. Even so, because sawtooth oak seedlings are able to establish themselves, mature, and set seed in reasonably natural habitats, *Quercus acutissima* should be considered naturalized, in the sense of Nesom (2000). Concerns about planting large stands of *Quercus acutissima* in natural areas seem to be well founded. In such sites, sawtooth oak can be expected to reproduce and spread slowly into adjacent open fields and woodland margins. The use of sawtooth oak as a landscape tree in developed areas usually poses much less danger of escape, primarily because of the short seed dispersal distances of the species. However, trees planted close to disturbed grassland and open woodland may be expected to invade these sites. Furthermore, the heavy acorn drop in autumn and the frequent seedlings in garden beds are undesirable characteristics in a landscape tree and cultivars with lower seed set would certainly be desirable.

SPOROBOLUS COAHUILENSIS (POACEAE): A NEW RECORD FOR THE U.S.A FROM TRANS-PECOS, TEXAS

B.L. Turner

Plant Resources Center
University of Texas
Austin, Texas 78713, U.S.A.

Recent collections by the present author in southern Brewster County has revealed the presence of at least two new, presumably natural, populations of the poorly known *S. coahuilensis* Valdes, heretofore known only by a few collections from gypseous soils of south-central Coahuila, Mexico (Fig. 1). Study of the grass collection at SRSC revealed three additional collections of the taxon from Brewster County made by yet others, these all identified as *S. pulvinatus* Swallen, and mapped as such by Turner et al. (2003). The Reeders of ARIZ suggested that an additional collection from along the Rio Grande in Hudspeth County might also belong to the taxon, which proved to be so. All of these collections follow:

TEXAS: Brewster Co.: West end of Maverick Mt., near Study Butte, 8 Nov 1991, *Powell 5805* (collected by Michael Clark); ca. 3 mi SW of Hen Egg Mt., 2.8 mi W of Hwy. 118 along unpaved South County Road, clayey soils immediately along roadside (ca 29° 27, 103° 33), 31 Oct 2003, *B.L. Turner 23-325* (SRSC, TEX) ; 3.4 mi W of Hwy 118 along South County Road, gypseous silty clays, 26 Dec 2003, *Turner 23-335* (SRSC, TEX); Study Butte, 30 Oct 1966, *Warnock 23434* (SRSC); N of Study Butte, 25 Oct 1968, *Warnock 23395* ? (SRSC). **Hudspeth Co.:** Quitman Mts., S tip of mountains at Indian Hot Springs Resort, "seep area along road at base of hill near Rio Grande," 3400 ft, 12 Oct 1980, *Worthington 6804* (UTEP).

In the treatment of the *Grasses of the Southwestern United States* by Gould (1988), the above collections will key to *Sporobolus patens* Swallen. Gould noted that the latter is "known only from the type collection made at Wilcox, Cochise County, Arizona (*Silveus 3504*, September 26, 1938)." He also noted that *S. patens* might prove to be but a variant of *S. pulvinatus*. *Sporobolus coahuilensis* differs from both in having more numerous smaller florets on longer, more divaricate, pedicels, as nicely illustrated by Valdes (1978) in his original description of the taxon.

In the treatment of the grasses of the Trans-Pecos and adjacent areas by Powell (1994), *S. coahuilensis* will key to *S. pulvinatus*, the only annual species said to occur in the area concerned. Indeed, as already noted, Powell referred several of the above cited specimens to *S. pulvinatus*, the latter readily distinguished from *S. coahuilensis* by its less open inflorescence and appressed florets on shorter pedicels. In the Trans-Pecos, typical elements of *S. pulvinatus*

SIDA 21(1): 455 – 457. 2004

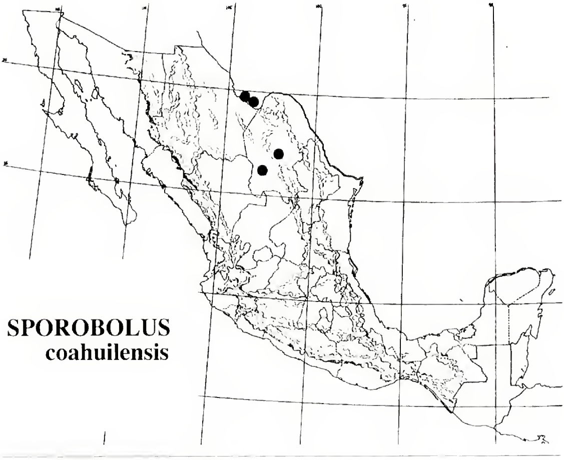

Fig. 1. Distribution of *Sporobolus coahuilensis*.

are known only from El Paso County, these having been reported by Correll and Johnston (1970) as *S. patens*, but subsequently referred to *S. pulvinatus* by Johnston (1990). Turner et al. (2003) mapped the latter as also occurring in southern Brewster County; such plants are accepted herein as *S. coahuilensis*.

In the account of *Sporobolus* for the *Flora of North America* (Peterson et al. 2003), *S. coahuilensis* will key to *S. pyramidatus* (Lam.) Hitchc. Unfortunately, the names *S. patens* and *S. pulvinatus* are not accounted for in their treatment; presumably, they regard the two names as synonymous with their concept of *S. pyramidatus*. Regardless, Peterson (pers. comm..) recognizes *S. coahuilensis* as distinct, as do most recent workers interested in Mexican grasses (e.g., Ortiz, by annotation, TEX).

In the area of Hen Egg Mt. where I first collected *S. coahuilensis* the population concerned was composed of 40 or more very uniform, late-flowering individuals growing with or near the much more abundant earlier flowering *S. pyramidatus*. By no stretch of my imagination might I have included these under the fabric of *S. pyramidatus*. Subsequent collections of *S. coahuilensis* from this same area (on 26 Dec 2003) showed that the latter occurred among or with numerous specimens of *S. pyramidatus*, there being no discernable intermediates between the taxa. During this second visit, approximately nine specimens of *S. coahuilensis* were detected growing with *S. pyramidatus* along a transect of some 40 yards along the edge of a recently plowed roadside.

ACKNOWLEDGMENTS

I am grateful to Charlotte Reeder for calling to my attention that the taxon concerned might be *S. coahuilensis*, and to her husband John, for yet other helpful comments. Thanks also to Richard Worthington at UTEP for the loan of *S. coahuilensis* from Hudspeth Co., the specimen itself composed of ca. five very uniform individuals mounted upon a single sheet.

DALE LINDGREN and ELLEN WILDE. 2003. **Growing Penstemons: Species, Cultivars and Hybrids.** (ISBN 0-7414-1529-1, pbk.). Infinity Publishing.com, 519 West Lancaster Avenue, Haverford, PA 19041-1413, U.S.A. (Orders: 877-BUY-BOOK, 1-610-520-2500, 1-610-519-0261 fax, www.buybookssontheweb.com, Info@buybooksontheweb.com). $17.95, 149 pp., illustrated, 8 1/4" × 10 3/4".

Growing Penstemons begins with a history of Penstemons and the American Penstemon Society. The book is more than an alphabetical listing of species and cultivars with descriptions. Also included are chapters on *Penstemon* hybrids, selecting, growing and caring for Penstemons, methods of propagation, and creating your own hybrids. Eight appendices provide information from Penstemons for beginners to hunting for Penstemons in the wild.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, Texas 761202-4060, U.S.A.*

DOUGLAS CRASE. 2004. **Both: A Portrait in Two Parts.** (ISBN 0-375-42266-8, pbk.). Pantheon Books, 1745 Broadway, New York, NY 10019, U.S.A. (Orders: www.pantheonbooks.com, www.randomhouse.com). $24.00, 320 pp., illustrated, 5 3/4" × 7 1/2".

Publisher Comments: "*Both* is the enchanting account of a remarkable fifty-year relationship: Dwight Ripley, the child heir to an American railroad fortune, and Rupert Barneby, the product of a wealthy, baronial English upbringing, shared an obsession with botany from the moment they met at an exclusive boys' boarding school in England. Together they embarked on a lifelong pursuit of rare plants, first in Europe and then in the United States, where they migrated in the late 1930s. Every spring they explored the American Southwest in a sputtering Dodge, discovering new species and cultivating the spoils at their renowned home gardens. Barneby published so many taxonomic findings that he became a world authority on legumes. But the two men had other interests as well: they were intimates in the expatriate circles that included W. H. Auden and Peggy Guggenheim, and early collectors of painters such as Jackson Pollock and Joan Miró. Ripley, a prescient artist himself, whose startling work in colored pencil was lost in a trunk for several decades before being rediscovered, used his fortune to bankroll much of the avant-garde art scene of the early 1950s."

ABSTRACT

I am reporting two new records of *Eurybia merita* (A. Nelson) G.L .Nesom for California (Siskyou County), and new records of *Aster alpinus* L. subsp. *vierhapperi* Onno for Idaho (Lost River Range) and Wyoming (Beartooth Pass).

RESUMEN

Se hacen dos nuevas citas de *Eurybia merita* (A. Nelson) G.L .Nesom de California (Siskyou County), y dos nuevas citas de *Aster alpinus* L. subsp. *vierhapperi* Onno de Idaho (Lost River Range) y Wyoming (Beartooth Pass).

INTRODUCTION

While reviewing herbarium material in preparation of the treatments of *Aster* L. s. str. and *Eurybia* (Cassini) S.F. Gray for the Flora of North America project, I came across specimens that represent new records for California, Idaho, and Wyoming.

Eurybia merita (A. Nelson) G.L. Nesom

CALIFORNIA. Siskyou Co.: Metcalf's ranch, northeast base of Mt. Eddy, in moist soil in the forest, 3900 ft, 30 Jul 1936, *Heller 12206* (MO); Mountains, 6000 ft, 5 Aug 5 1882, *Pringle 14590* (MO).

The two specimens I was able to examine are both typical *E. merita*, with purple-margined phyllaries and subserrate leaves, among other features. The Heller specimen was originally determined as *Aster* sp. and later annotated to *Aster radulinus* A. Gray by A.G. Jones. The Pringle specimen was identified as *Aster sibiricus* L. var. (=*A. montanus* Rich.; a form approaching *A. radulinus* A. Gray). Identification of both specimens as *E. radulina* (A. Gray) G.L. Nesom is not unexpected given that *E. merita* had not been reported for California (e.g., Allen 1993) and that taxonomic confusion exists between the two species. Yet, examination of a wide range of specimens in the course of preparation of the *Eurybia* treatment for FNA reveals that the two taxa are distinct (I have yet to find hybrid or intermediate material) and clearly identifiable using the following combination of features:

Stems ascending to erect, ± densely villous distally, leaf margins coarsely serrate (teeth mucronate), cauline often clasping; phyllaries without purple margins; rays white (sometimes purplish) __________ **Eurybia radulina**

Stems decumbent to ascending, villosulous distally; leaf margins entire to subserrate or ± serrate, cauline subauriculate or slightly clasping; phyllaries graduated, purple on margins; rays purple (sometimes pale) __________ **Eurybia merita**

In the flora of the Pacific Northwest, Cronquist (1955) stated that smaller forms of *E. radulina* (as *Aster*) with purple rays and anthocyanic involucres were difficult to distinguish from *E. merita* (as *A. sibiricus* var. *meritus*). He then mentioned ecological and geographical separation to advocate segregation of the two taxa and also observed that larger forms of the latter are very distinct from *E. radulina*. Part of the problem may lie (I have been unable to verify this) with the fact that some small individuals of *E. merita* may have been misidentified as *E. radulina*, causing confusion, and from the fact that the ranges of the two species (as exemplified by the records cited above) may not be as disjunct as initially envisioned by Cronquist and others. Though I did not find anthocyanic specimens of *E. radulina* during my study (admittedly a small sample of all material potentially available), the distribution of purplish coloration on the phyllaries of this species (if they ever are purplish) may differ from the typically purplish phyllary margins of *E. merita*. Cronquist (loc. cit.) did not address this issue. Further complicating the problem is the confusion between *E. merita* and *E. sibirica*, a species that barely reaches the conterminous United States. The definition of the range of characters of *E. merita* due to its inclusion within *E. sibirica* may have rendered its delimitation more difficult and thus less efficient. The recognition that *E. merita* is a species distinct from *E. sibirica* is crucial to our understanding of the former.

Given our current knowledge of the distribution of *Eurybia merita* in California, it appears to be of conservation concern in the state. Further study of *E. radulina* specimens in California herbaria may yield further localities for *E. merita* and provide more precise data as to its habitat and distribution there.

Aster alpinus L. subsp. **vierhapperi** Onno

IDAHO. Custer Co.: Lost River Range, Challis National Forest, ridge between two forks of upper Grouse Creek, ca. 1.5 mi W of Grouse Creek Mt., ca 19 mi N of Dickey; T12N R21E S23 NE1/4, 9900 ft, 14 Aug 1984, *Moseley 533* (RM). **WYOMING. Park Co.:** Beartooth Pass, US-212, 10940 ft, 5 Sep 1979, *Semple & Brouillet 4432* (MT, WAT).

Aster alpinus subsp. *vierhapperi* has not been reported from the floras of Idaho (Davis 1952) and Wyoming (Dorn 1977; Nelson & Hartman 1994; R.L. Hartman, pers. comm. 2003) (see also, e.g.,USDA-NRCS 2002, NatureServe 2003). The Moseley specimen was identified as *Aster sibiricus* var. *meritus*, while the Semple and Brouillet specimen was correctly identified but went unreported.

The species is easily recognized by its rosette leaves, single heads with subequal, foliaceous phyllaries, and obconic, flattened, 2-nerved, puberulent, apically glandular cypselae. Yet misidentifications abound with other species of asters, as well as, mostly, with species of *Erigeron*. The Idaho and Wyoming populations fill the gap between the southern Canadian populations of this species in Alberta and the Colorado locations (e.g., Hartman & Nelson 2001). All southern populations are at high elevations in the mountains, which may explain the rarity of records. Given that the Wyoming population is near the border with Montana and given the elevation of mountain ranges there, it is expected that collections of this taxon have been or will be made in this state; it should actively be sought there. Examination of *Erigeron* and other "aster" material from Idaho, Wyoming, Montana, and Colorado may yield further locations. Given the current state of our knowledge, *Aster alpinus* should be considered of conservation concern in Idaho and Wyoming.

CONCLUSION

The discovery of these new state records in well known states such as California, Idaho, and Wyoming from examination of herbarium specimens underscores the importance of herbaria and the value of revisionary and floristic work such as the Flora of North America project to our understanding of the continent's biodiversity.

THE NEW YORK BOTANICAL GARDEN
Institute of Systematic Botany
200th Street and Southern Blvd.
Bronx, New York 10458-5126

THE RUPERT BARNEBY AWARD

The New York Botanical Garden is pleased to announce that Karen Redden, currently a graduate student in the Department of Biological Sciences, George Washington University, Washington, D.C., is the recipients of the Rupert Barneby Award for the year 2004. Ms. Redden will be studying the systematics of a diverse group of legumes centered around *Dicymbe, paloue, paloveopsis, Heterostemon*, and *Elizabetha* that are concentrated in the Guiana Shield area.

The New York Botanical Garden now invites applications for the Rupert Barneby Award for the year 2005. The award of US $1,000 is to assist researchers to visit The New York Botanical Garden to study the rich collection of Leguminosae. Anyone interested in applying for the award should submit their curriculum vitae, a detailed letter describing the project for which the award is sought, and the names of 2–3 referees. Travel to the NYBG should be planned for sometime in the year 2005. The application should be addressed to Dr. James L. Luteyn, Institute of Systematic Botany, The New York Botanical Garden, 200th Street and Kazimiroff Blvd., Bronx, NY 10458-5126, U.S.A. and received no later than December 1, 2004. Announcement of the recipient will be made by December 15.

Anyone interested in making a contribution to THE RUPERT BARNEBY FUND IN LEGUME SYSTEMATICS, which supports this award, may send their check, payable to The New York Botanical Garden, to Dr. Luteyn.

NOTES ON THE DISTRIBUTION OF *PSEUDOGNAPHALIUM LUTEOALBUM* (ASTERACEAE: GNAPHALIEAE)

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

ABSTRACT

The historical presence of *Pseudognaphalium luteoalbum* in Colorado and Pennsylvania is documented by collections from the 19th century, and it is first reported from Louisiana by a recent collection. The species is common in the southern half of California and locally common in southern Florida but uncommon or rare in other states. Historical collections from ballast also record its presence in New York, Oregon, and Washington, but it has not persisted in any of those states.

RESUMEN

La presencia histórica de *Pseudognaphalium luteoalbum* en Colorado y Pennsylvania está documentada mediante colecciones desde el siglo XIX, y esta es la primera cita de Luisiana mediante una colección reciente. La especie es frecuente en la mitad sur de California y localmente en el sur de Florida pero poco frecuente o rara en otros estados. Las colecciones históricas procedentes de lastre también señalan su presencia en New York, Oregón, y Washington, pero no ha persistido en ninguno de estos estados.

Pseudognaphalium luteoalbum (L.) Hilliard & Burtt has been known in the United States from California, Oregon, Washington, Nevada, Arizona, Utah, Florida, and New York (as summarized by Kartesz 1999), and recent reports have expanded the range to include New Mexico, Texas, and Arkansas (Nesom 2001, 2002). A recent collection from Louisiana, as well as historical collections from Colorado and Pennsylvania, are reported here.

LOUISIANA. Winn Parish: roadside along Hwy 84, 0.3 mi W of Cooley Methodist Church, ca. 13.5 mi WSW of Winnfield, area of Kisatchie National Forest, sandy soil in area of pine woods, ca. 100 plants scattered along 50 feet of roadside, 10 Apr 2004, *Nesom G2004-8* (BRIT, LSU, LSUS, MO, NY, NCU, UC, US). **COLORADO.** [Fremont Co.]: Cañon City, along ditches, 22 Jul 1872, *Redfield 188.5* (NY). **PENNSYLVANIA.** [Philadelphia Co.]: Philadelphia, Girard Point, in ballast, Aug 1877, *Parker s.n.* (NY). **NEW YORK.** N.Y., ballast filling, at northern terminus of 8th Ave., Jul 1879, *Brown s.n.* (NY).

Mitchell and Tucker (1997) listed *Pseudognaphalium luteoalbum* for New York as a non-native, non-persistent species; the 1879 collection from an early ballast site cited above perhaps is the basis for that citation. An early record of a ballast waif in Philadelphia, Pennsylvania, is added here. Historical collections from Oregon (Portland in 1902) and Washington (Bingen) also record introductions through ballast, and the species apparently has not persisted in those places (Cronquist 1955; Chambers & Sundberg 1998).

The cited collection from Colorado indicates that the species was present in that state more than a hundred years ago; it seems remarkable that it has not been documented there since then (e.g., Weber & Wittman 1994) but it perhaps is an indication, as probably true also for Oregon, Washington, New York, and Pennsylvania, that winter cold limits the distribution.

Pseudognaphalium luteoalbum is common in the southern half of California and locally common in southern Florida but uncommon or rare in other states. Relatively scattered and recent collections, however, indicate that it is naturalized and actively expanding its range into inland regions, and it probably should be expected to occur abundantly across the Gulf Coast region, once established. In the U.S.A., plants flower April through October and have been collected from roadsides, fields, gardens, ditches, riparian areas, and other disturbed sites. The species apparently is native to Eurasia and has been reported to occur in Africa, Australia, and New Zealand. It has been collected from scattered localities in Mexico.

ACKNOWLEDGMENTS

I am grateful to the staff at NY for their help during a recent visit, and I enjoyed the company of my mother on the April 10th afternoon of cudweed observations in Louisiana.

ABSTRACT

Two native grasses are reported new to Ohio's flora, *Dichanthelium scoparium* (Lam.) Gould and *Muhlenbergia glabrifloris* Scribn. Both species share a similar coastal plain and Mississippi embayment distribution pattern. They were found at localities less than 4.5 km apart and in an area known for southern species reaching their northern limit

RESUMEN

Dos gramíneas nativas se citan como nuevas para la flora de Ohio. *Dichanthelium scoparium* (Lam.) Gould and *Muhlenbergia glabrifloris* Scribn. Ambas especies comparten un patrón de distribución en una llanura costera y desembocadura del Mississippi. Se encontraron en localidades a menos de 4.5 km y en un área conocida de especies meridionales que alcanzan allí su límite norte.

In 2001, Minney collected ***Dichanthelium scoparium***, velvet panic grass (Syn. *Panicum scoparium* Lam.) in Jackson County, Ohio, a species previously not reported for Ohio (Cooperrider et al. 2001; Flora of North America Committee (FNA) 1993). The authors revisited the site in 2002 to collect ecological data and additional voucher specimens. *Dichanthelium scoparium* is a distinctive, large, and easily identified species in a genus notorious for confounding botanists. Flowering culms can be up to 1.3 m in height (Fernald 1950), and are covered with soft, long-spreading hairs with the exception of a glabrous, viscid band below each node.

Distribution of this grass follows a coastal plain and Mississippi embayment pattern (Fig. 1). It ranges from Massachusetts south primarily along the coastal plain to Florida, west along the Gulf Coast to Texas, and north in the interior, primarily in the Mississippi River Valley and its tributaries to southeastern Kansas, southern Illinois, and Kentucky. Habitats for this species are variously reported as "wet soil" (Gleason & Cronquist 1991), "ditches and low woods" (Radford et. al 1968), "damp thickets, swales and shores" (Fernald 1950), "seepage bogs associated with the longleaf pine system" ([Alabama] Al Schotz, pers.

Fig. 1. Map showing the North American distribution of *Dichanthelium scoparium* adapted from Flora of North America Committee (1993).

comm. 2003), and "bottomland and upland prairies, sand prairies, ledges of bluffs, glades, margins of sinkhole ponds, fens, and openings of mesic upland forests, usually on acidic and especially sandy substrates; also roadsides, railroads, and fallow fields (Yatskievych 1999)." The wetland indicator status, as assigned by the U.S. Fish & Wildlife Service (Reed 1988) for the eastern U.S. is FACW (Facultative Wet), meaning that the plant usually occurs in wetlands (estimated probability 67%-99%), but is occasionally found in non-wetlands.

The Ohio population occurs on permanently saturated soil associated with a seepage outflow, and *Dichanthelium scoparium* largely defines the limits of the moist soils. It has formed a dense colony, nearly excluding other plants in some areas of the seepage meadow. While this site is in the right-of-way for a highway, we don't consider it introduced to this site, either intentionally as part of roadside plantings, or unintentionally by passing traffic or some other factor associated with the roadway. Of course, the spread of plants into new regions via roadways is a well-documented phenomenon (Reznicek & Catling 1987). The genera *Dichanthelium* and *Panicum* in Ohio are not known for non-natives, though. In the most recent listing of Ohio flora (Cooperrider et. al 2001), there are 36 species listed for these genera, and only one is not indigenous, *Panicum miliaceum* L. However, *P. miliaceum*, or millet, does not persist in the wild in Ohio, and is most often seen coming up around bird feeders where the seed has fallen to the ground. It should be noted that *Dichanthelium scoparium* is reported in Michigan by the USDA PLANTS Database, but there is no known specimen from Michigan and the report may be based on a synonymy error ([Michigan] Reznicek, pers. comm. 2003). And it was not discovered at another northernmost point in its range—southern Illinois—until 1967 (Mohlenbrock 1973), although it is considered native there. The species was discovered in southwestern Indiana in 1982 ([Indiana] Homoya, pers. comm. 2003) and again in 1998 in southeastern Indiana (Hedge et al. 1999). Another panic grass, *Panicum verrucosum* Muhl., which has a similar coastal plain distribution, is found in southern Ohio in Adams, Athens and Pike counties. It grows in adjacent Pike County on roadside banks along the Appalachian Highway. This species is currently listed as threatened in Ohio (Ohio Division of Natural Areas & Preserves 2002).

Although the *Dichanthelium scoparium* site is along a highway, the floristic composition is similar to parts of The Nature Conservancy's (TNC) Glade Wetland Preserve, which is a mosaic of low, poorly drained wetlands interspersed with higher knolls that support upland species. The preserve is about 4 km east of the *D. scoparium* site (Fig. 2). Plant taxa occurring at both sites include *Agalinis purpurea* (L.) Pennell, *Asclepias hirtella* (Pennell) Woodson, *Asclepias incarnata* L., *Carex annectens* Bickn. var. *xanthocarpa* (Bickn.) Wieg., *Carex complanata* Torr. & Hook., *Carex scoparia* Schk., *Eleocharis tenuis* (Willd.) Schultes var. *verrucosa* (Svenson) Svenson, *Juncus anthelatus* (Wiegand) R.E. Brooks, *Juncus biflorus* Elliott, *Juncus brachycarpus* Engelm., *Lysimachia quadriflora* Sims, *Panicum anceps* Michx., *Panicum microcarpon* Muhl., *Pycnanthemum tenuifolium* Schrader, *Rhynchospora capitellata* (Michx.) Vahl, *Sabatia angularis* (L.) Pursh, *Scutellaria integrifolia* L., and *Sorghastrum nutans* (L.) Nash. Another significant species at the *D. scoparium* site that is not at Glade Wetland Preserve is the state endangered *Scleria pauciflora* Muhl. ex Willd.

Voucher specimens: **OHIO. Jackson Co.:** dominant in 15 m × 10 m patch; scattered mostly in ditch for about 150 m along highway; seepage zone, open grassland, N and adjacent to Appalachian Highway (St. Rt. 32); 2.5 mi E of the Pike/Jackson County line, 5 Jul 2001, *Minney s.n.* (MICH); one large colony, covering several dozen square feet, in prairie-like opening on road bank, along seepage outflow, N side of OH Rt. 32, just E of jct. with C-23, sect. 8; Beaver Quad; Scioto Twp., 16 Jul 2002, *McCormac 7,296, Minney & Gardner* (CLM, KE, MICH, MU, OS).

In 2002, Minney collected ***Muhlenbergia glabrifloris*** Scribn. (clay-pan muhly), another species not reported for Ohio (Cooperrider et al. 2001; FNA 1993). In Gleason and Cronquist (1991) and Fernald (1950) the specific epithet is spelled *M. glabriflora* but we follow Scribner's original spelling, *M. glabrifloris* (FNA 2003). This species has a similar distribution as *D. scoparium*, however, it is un-

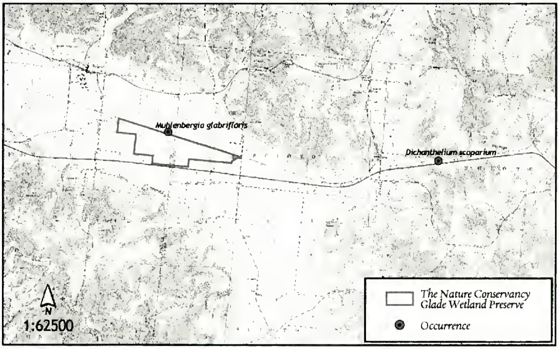

Fig. 2. Map showing the locations of *Dichanthelium scoparium* and *Muhlenbergia glabrifloris* in proximity to each other and The Nature Conservancy's Glade Wetland Preserve, Pike County, Ohio.

common throughout most of its range and is listed as rare in 7 states (NatureServe 2003). It ranges from the coastal plain of Virginia and North Carolina, and from Alabama to eastern Texas north to Missouri, southern Illinois, southwestern Indiana and western Kentucky (Fig. 3). The Ohio site is disjunct, as the closest locales are in Indiana and Kentucky, about 500 km away.

Muhlenbergia glabrifloris has well-developed rhizomes and flowering culms up to 1 m long with multiple lateral panicles. It strongly resembles a common muhly in Ohio's flora, *Muhlenbergia frondosa* (Poir.) Fern., however, the lemma is completely glabrous compared to the bearded lemma of *M. frondosa*. Habitats range from "bottomland forests, mesic upland forests, bottomland and upland prairies, and margins of glades; also railroads" in Missouri (Yatskievitch 1999) and "moist woodlands" in Illinois (Mohlenbrock 1973). Gleason and Cronquist (1991) list its habitat as "mostly in shade on low ground in heavy clay." The Ohio population is located just north of TNC's Glade Wetland Preserve (Fig. 2). The population is located on clay soils in a pin oak flatwoods (Fig. 4), a habitat similar to sites reported from other parts of its range.

Voucher specimen. **OHIO. Pike Co.:** pin oak–swamp white oak forest in clay soils of the pre-glacial Teays River Valley, woodlot about 5 acres in size; 0.5 mi N of the intersection of the Appalachian Highway (Rt. 32) and the Pike-Jackson County Line, 1 Oct 2002, *Minney s.n.* (OS).

The region where these two species were discovered is noted for unusual plant communities that support many rare species, including southern flora at the northern limits of their ranges (Beatley 1959; Spooner 1982). Some examples of

Fig. 3. Map showing the North American distribution of *Muhlenbergia glabrifloris* adapted from Flora of North America Committee (1993).

southern plants that are within 5 km of the Glade Wetland Preserve are *Gratiola viscidula* Pennell, *Magnolia macrophylla* Michx., *Panicum laxiflorum* Lam., *Polygala curtissii* A. Gray, and *Triadenum walteri* (S.G. Gmelin) Gleason. As the Ohio populations of *Dichanthelium scoparium* and *Muhlenbergia glabrifloris* occur in appropriate habitat in native plant communities, and their distribution mirrors that of other similarly distributed southern species, we consider both as native to Ohio. These species likely migrated into southern Ohio via the same route from the Mississippi River Valley into the Ohio River Valley. Similar habitats will be explored in the region for additional localities of these two species.

ACKNOWLEDGMENTS

We thank Al Schotz, Deborah White, Mike Homoya, John Pearson, Chris Frye, David Snyder and Bill Carr of Alabama, Kentucky, Indiana, Iowa, Maryland, New Jersey, and Texas Heritage Programs, respectively, for distribution and habitat information. We also thank Allison Cusick and Marleen Kromer for reviewing early drafts of this paper, and Daniel Boone for bringing to our attention the Indiana populations of *Dichanthelium scoparium*. THE DELZIE DEMAREE TRAVEL AWARD

For assistance to attend the Missouri Botanical Garden
51st Annual Systematics Symposium (8–10 Oct 2004)

Graduate students in plant systematics are eligible to apply for the Delzie Demaree Travel Award, a $250 stipend to help defray expenses related to attendance at the Missouri Botanical Garden 51st Annual Systematics Symposium (8–10 Oct 2004). The 2004 symposium: *Latin American Biogeography—Causes and Effects.* http://www.mobot.org/MOBOT/research/symposium/welcome.shtml

The application should include a letter from the applicant telling how symposium attendance will benefit his/her graduate work and letter of recommendation sent by the major professor. Please send letters of application to: Dr. Donna M.E. Ware, P.O. Box 8795, Herbarium, Biology Department, The College of William and Mary, Williamsburg, VA 23185-8795, U.S.A. 1-757-221-2799; Email: ddmware@wm.edu

Anyone interested in making a contribution to Delzie Demaree Endowment Fund, which supports the travel award, may make contributions by VISA or MasterCard or by a check, payable to Botanical Research Institute of Texas, to Barney Lipscomb, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A. 1-817-332-7432; Email: barney@brit.org. Thank you.

NEW RECORDS OF *ERIGERON* (ASTERACEAE: ASTEREAE) FOR NEVADA

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

Study of specimens from NSMC reveals the presence in Nevada of *Erigeron nanus* Nutt., previously unknown in the state (Nesom 1992).

NEVADA. Elko Co.: Middle Stack Mountain, N end of the Granite Range, 6 airline mi NE of Contact, T45N, R65E, with *Artemisia* on steep gravel slopes of quartzite rock, 7900 ft, 10 Jun 1987, *Tiehm 11224* (NSMC). Originally identified as *Erigeron pumilus*

This is the westernmost locality for *E. nanus*, which previously has been known from the southwestern corner of Wyoming, northern Utah (Daggett and Box Elder cos.), and southeastern Idaho.

The typical variety of *Erigeron eatonii* A. Gray was previously recorded from Nevada by a single collection (**Clark Co.:** Virgin Mts., near the Utah border, *Tiehm 11256*, NSMC) (Nesom 1992). Additional collections verify its existence in the state and broaden the range.

NEVADA. Clark Co.: Virgin Mountains, VABM Virgin, Z11 E761100 N4056310, common throughout the peak area, with *Quercus gambelii*, *Cercocarpus ledifolius*, *Artemisia tridentata*, *Amelanchier utahensis*, *Arctostaphylos pungens*, 7380 ft, *Holland and Leary 4733* (NSMC). **Lincoln Co.:** Wilson Creek Range, Mount Wilson summit area, Douglas fir and aspen, 9250 ft, 17 Jul 1995, *Pinzl 11632* (BRIT, NSMC).

Nevada localities are at the southwestern extremity of the distribution of var. *eatonii* (see map, Fig. 2, Strother and Ferlatte 1988), which ranges to Colorado, Wyoming, southeastern Montana, and southeastern Idaho. *Erigeron eatonii* var. *sonnei* (Greene) Nesom occurs in the western part of Nevada and var. *nevadincola* (Blake) Nesom occurs in the northern half of the state.

ACKNOWLEDGMENTS

Thanks to Ann Pinzl at NSMC for arranging the loan of specimens.

ABSTRACT

Schoenoplectus saximontanus and *S. hallii* (Cyperaceae) are rare in North America and of conservation concern in every state in which they occur. Although the distribution of *S. saximontanus* extends farther west than that of *S. hallii* they are thought to be sympatric in five states in the central portion of their range in the U.S. The two species are indistinguishable vegetatively, but style morphology and achene characteristics are distinctive. In this paper, we report the collection of a putative hybrid from a mixed population of the two species in the Wichita Mountains Wildlife Refuge in OK, describe achenes of *S. saximontanus*, *S. hallii* and *Ss* × *Sh* that were collected from the site in 2002, and discuss the potential effects of hybridization on the two species.

RESUMEN

Schoenoplectus saximontanus y *S. hallii* (Cyperaceae) son raros en Norte América y con preocupaciones por su conservación en los estados en que aparecen of. Aunque la distribucion de *S. saximontanus* se extiende más al oeste que la de *S. hallii*, son simpátricos en cinco estados en la parte central de su rango en los Estados Unidos. Las dos especies son indiferenciables vegetativamente, pero la morfología del estilo y las características del aquenio son diferenciables. En este artículo, se cita la colección de un híbrido putativo en una población mixta de las dos especies en la Wichita Mountain Wildlife Refuge de Oklahoma, se describen los aquenios de *S. saximontanus*, *S. hallii* y *Ss* × *Sh* que fueron colectados en dicho lugar en 2002, y se discuten los efectos potenciales de la hibridación de las dos especies.

Schoenoplectus saximontanus (Fernald) J. Raynal and *S. hallii* (A. Gray) S.G. Smith, two small- to medium-sized members of *Schoenoplectus* section *Supini*, are vegetatively indistinguishable in the field, and are most often separated by achene cross-sectional shape and style morphology (Smith 2002). Both are found in damp sandy soil in ditches or depressions in cultivated fields or pastures and around the edges of temporary ponds. *Schoenoplectus saximontanus* and *S. hallii* are uncommon in North America (Schuyler 1969; Smith 2002) and are listed as species of conservation concern in every state in which they occur.

SIDA 21(1): 475 – 479. 2004

Although populations have been reported from 13 states for *S. saximontanus* and 13 states for *S. hallii* (Smith 2002; O'Kennon & McLemore 2004), populations of both species are transitory in nature and may disappear from an area for 20 or more years before re-emerging (McKenzie 1998), possibly from a long-lived soilbank. Although the distribution of *S. saximontanus* extends farther W than that of *S. hallii*, their ranges have been reported to overlap in six states (IL, KS, MO, NE, OK and TX) (Smith 2002; R. O'Kennon & C. McLemore 2004).

In 1999, *S. saximontanus* and *S. hallii* were found in close proximity at a single location in KS (H. Loring & C. Freeman, pers. comm.). In 2000, a survey of 134 potential population sites on the Wichita Mountain Wildlife Refuge, Indiahoma, OK revealed that individuals of the two species were located at 11 and 14 sites, respectively, with the species growing in mixed populations at five of the locations (Magrath 2002). No evidence of hybridization, however, was reported from either state.

PROCEDURES

In Aug 2001, the sites reported by Magrath (2002) were revisited by Marian Smith, Sam Waldstein (the Refuge Manager) and Paige Mettler, and the possibility of the presence of hybrids was noted. On 28 Jul 2002, Smith, Mettler, and Paul McKenzie collected specimens from several sites where both species were present. Voucher specimens were sent to Galen Smith and Alfred E. Schuyler who independently determined that P. McKenzie collection #2028 (specimens are deposited at PH, OKLA, WIS) appeared to be a hybrid. In the laboratory at Southern Illinois University, Edwardsville, two inflorescences each from individuals tentatively identified during collection of 8 August 2002 as being *S. hallii* or *S. saximontanus* and nine inflorescences from the putative *Ss* × *Sh* hybrid were examined under a dissecting microscope (Nikon Model SMZ800). Style morphology was noted, and achenes were counted and classified as either "normal" or "aborted."

RESULTS

All flowers in the two inflorescences collected from *S. saximontanus* and the nine inflorescences from the *Ss* × *Sh* hybrid had the 3-lobed styles and sharply trigonous achenes that are typical of *S. saximontanus*. All flowers and achenes of the *S. hallii* individuals were typical for that species (2-lobed styles and ovoid, plano-convex achenes). In *S. saximontanus*, *S. hallii* and the putative hybrid, 0%, 4% and 96%, respectively, of the achenes were aborted (Table 1). The five hybrid achenes that appeared to be normal (Table 1) were very similar in size, shape and surface contouring from those produced by *S. saximontanus*.

DISCUSSION

The only previously suspected case of interspecific hybridization of *S. hallii*

TABLE 1. Style morphology and number of normal and aborted achenes from individuals of *Schoenoplectus hallii*, *S. saximontanus* and *Ss* × *Sh* collected from Medicine Tank, Wichita Mountain Wildlife Refuge, Indiahoma, OK

occurred in GA where Smith (2002) reported a specimen that was intermediate between *S. hallii* and *S. erectus*, the third member of *Schoenoplectus* section *Supini* to occur in North America. Until the recent discoveries of mixed populations of *S. hallii* and *S. saximontanus*, there was little reason to expect the existence of hybridization between these two species. In addition to an assumed geographic isolation, the disparate diploid chromosome complements of the two species (*Sh*, 2n = 22; *Ss*, 2n = 50; Smith 2002) render hybridization an unlikely event. However, the collections recently taken in OK suggest that hybrids occur and produce achenes that have the appearance of normality.

Hybridization between *S. hallii* and *S. saximontanus* could be an important consideration in management and conservation concerns for both species. They are rare and occur in transient wetland habitats that may be declining in quality and availability. Because both often inhabit sandy soils along the margins of temporary ponds in agricultural areas, irrigation that lowers groundwater is potentially threatening, as is chemical runoff from fields. In KY (C. Baskin pers. comm.), the only known population of *S. hallii* is threatened by commercial development.

Hybridization may reduce a population by affecting its reproductive effectiveness (Fowler & Levin 1984), its competitive status (Norrington-Davies 1972) and by increasing potential interactions with herbivores (Fritz et al. 1994). The growth rate of a population may be retarded by the production of hybrid seed, which is produced in place of the rare species, i.e., resources are limited and an investment in hybrid seed reduces the amount of energy that can be allocated to conspecific seed. The outcome is the same whether the hybrid seeds abort or are viable. When species cross with equal facility in both directions, a numerically small population will produce a higher percentage of hybrid seed than a locally abundant species when the two are intermixed (Felber 1991; Levin et al. 1996). The numerical disadvantage of a rare species is compounded by the proliferation of fertile hybrids. The addition of these plants to a population containing two related species decreases the proportional representation of the rare species. In time, this backcrossing can result in the assimilation of the rare species, whose genetic identity will become extinct (Rhymer & Symberloff 1996). In the case of *S. saximontanus* and *S. hallii*, both species are rare, but the proportion varies among sites; therefore, it is impossible to predict which species will be most profoundly affected by hybridization. In collection #2028, the putative hybrids lacked any visible characteristics of *S. hallii*. Whether or not this varies, according to the identity of the maternal parent, is as yet unknown. In any case, site managers should be aware of the potential for hybridization, and any census of the species conducted to assess population number and risk of extinction should reflect the questionable status of the mixed populations.

Further work is needed to determine if achenes from the putative hybrid are viable, if they can produce plants, and whether or not these plants are fertile. We have initiated a mating study to answer some questions and plan to examine the achenes collected in the field for viability. Chromosomal studies on meiotic cells of field-collected and lab-grown individuals would be helpful in determining the mechanism of pairing during cell division, and sequencing work on parental and offspring arrays will be necessary to determine if alleles from the putative hybrid population are a combination of both parents. Chloroplast markers would allow one to infer which parent served as the maternal lineage. All of this depends upon further success in field collections and laboratory propagation.

ACKNOWLEDGMENTS

We thank Sam Waldstein and his Refuge staff for their hospitality and invaluable help in locating the study sites. We are grateful to Alfred E. Schuyler, Academy of Natural Sciences of Philadelphia, for his assistance with this project and we greatly appreciate his commitment and dedication in studying *Schoenoplectus* for many years. We thank Larry Magrath and an anonymous reviewer for their comments on the manuscript.

ABSTRACT

Sixteen vascular plant taxa not previously documented for West Virginia are reported with vouchers for each county of occurrence. These comprise of 2 lycophytes, 1 gymnosperm, 6 monocots and 7 dicots. Eleven species are native to the United States while 5 species have been introduced to the United States.

Key Words: vascular plants, West Virginia

RESUMEN

Dieciséis plantas vasculares que no habían sido previamente documentadas para West Virginia son reportadas con testigos para cada condado en donde están presentes. Estas incluyen 2 licopodios, una gimnosperma, 6 monocotiledóneas y 7 dicotiledóneas.

This study presents new information for the flora of West Virginia resulting from reexaminations of existing specimens and additional recent collections at Carnegie Museum of Natural History (CM). The following sixteen taxa are documented for their presence in West Virginia: *Brassica oleracea, Castanea mollissima, Chloris verticillata, Corallorhiza maculata* var. *occidentalis, Hordeum vulgare, Lycopodiella alopecuroides, Lycopodiella ×copelandii, Moehringia lateriflora, Pinus sylvestris, Platanthera ×andrewsii, Rubus elegantulus, Rubus immanis, Rubus meracus, Rubus porteri, Secale cereale,* and *Viola ×malteana.*

METHODS

Since the publications of the Flora of West Virginia (Strausbaugh and Core, 1970) additional plant collections from the state have been made along with reexaminations of existing specimens by specialists. Voucher specimens were prepared using the standard herbarium practices and are deposited at the Carnegie Museum of Natural History Herbarium (CM). Nomenclature follows

Kartesz (1999). Authorities are abbreviated according to Brummitt and Powell (1992). Every county for which there is a voucher specimen at CM is included.

RESULTS

The following entries are additions to the vascular flora of West Virginia. These taxa have not been reported previously as occurring in West Virginia. Taxa are listed alphabetically by family, genus and species with comments and citation of voucher specimens.

BRASSICACEAE

Brassica oleracea L.—Monongalia Co.: Morgantown, 20 May 1910, *K.S. Lashley s.n.*

Significance.—Determined by S.I. Warwick in 1995 for Flora of North America. First report for the state. This introduced species is also present in Pennsylvania, Maryland, Virginia, Ohio and Kentucky (USDA Plants Database).

CARYOPHYLLACEAE

Moehringia lateriflora (L.) Fenzl—Tucker Co.: Monongahela National Forest, ca. 4 mi SE of St. George on county 7 near junction of Horseshoe Run & Cheat River, sandy soil; dry slope along woodlot edge, 15 Jun 1984, *F.H. Utech 84-331.*

Significance.—This is the first report of this species from West Virginia. This native species occurs along the east coast from Maine to Pennsylvania and is rare in Maryland and Virginia.

FAGACEAE

Castanea mollissima Blume—Pendleton Co.: 4 km N of Franklin on US 220, roadside, 21 Aug 1994, *S.A. Thompson & J.E. Rawlins 11904.*

Significance.—This is the first report of this Asian species from West Virginia however it is present in Kentucky (USDA Plants Database).

LYCOPODIACEAE

Lycopodiella alopecuroides (L.) Cranfill—Tucker Co.: W of Thomas, bog, 12 Jul 1947, *H.A. Davis, T. Davis & H.P. Sturm 8310*; 1.5 mi E of junction with SR32 along SR93, turn onto dirt road on right, in old strip mine area 100 yards down dirt road, 30 Jul 1974, *J.G. Bruce, J. Reese & R. Fortney 74054.*

Significance.—Determined by R.E. Preston 2000. First report for the state. This native species also occurs in Pennsylvania, Maryland and Virginia (USDA Plants Database).

Lycopodiella ×copelandii (Eig.) Cranfill [*L. alopecuroides × appressa*]—Tucker Co.: 6 mi S of Thomas, bog, 5 Sep 1976, *D. Jolley s.n.*

Significance.—Determined by R.E. Preston 2000. First report of this hybrid for the state. This native hybrid also occurs in Pennsylvania, Maryland, Virginia and Kentucky (USDA Plants Database).

ORCHIDACEAE

Corallorhiza maculata (Raf.) Raf. var. **occidentalis** (Lindl.) Ames—Pocahontas Co.: Monongahela National Forest, Cranberry Glades Botanical Area at base of Kennison Mountain, bog forest, 17 Jul 1993, *J.S. Shriver, A. Shriver & C. Smith 94*; ca. 20 mi E of Richwood, Monongahela National Forest, bog forest, 11 Jun 1994, *J.S. Shriver, A. Shriver & C. Smith 213.*

Significance.—This species has been listed by the West Virginia Natural Heritage Program as critically imperiled. This native species also occurs in Pennsylvania and Virginia.

Platanthera ×andrewsii (M. White) Luer [P. *lacera ×psycodes*]—Pocahontas Co.: ca. 7 mi ENE of Marlinton, open exposure in marsh, 30 Jul 1994, *J.S. Shriver, A. Shriver & C. Smith 262.*

Significance.—Determined by J.S. Shriver in 1995. First report for the state. This native hybrid also occurs in Pennsylvania and Ohio (USDA Plants Database).

PINACEAE

Pinus sylvestris L.—Pendleton Co.: Mouth of Seneca, pasture border, 29 Sep 1973, *D.E. Boufford 12132.*

Significance.—This is the first report of this species from West Virginia. This European species has been reported to occur from Maine to Maryland along the east coast and from New Jersey through Illinois as far west as Minnesota. This introduced species occurs in the following surrounding states: Ohio, Pennsylvania and Maryland (USDA Plants Database).

POACEAE

Chloris verticillata Nutt.—Marshall Co.: 2.4 mi N along St. Rt. 2 from the Wetzel-Marshall Co. line, dry gravel soil in open riverbottom field, 18 Sep 1980, *E.E. Estep 1367.*

Significance.—"Report as new record for WV in 1981" on annotation, however apparently never published. This native species occurs in Pennsylvania, Ohio, Maryland, Kentucky and Virginia (USDA Plants Database).

Hordeum vulgare L.—Pendleton Co.: along North Fork River, field, 1 Jun 1940, *H.A. Davis & T. Davis 3633.* Randolph Co.: Huttonsville, along roadside, 6 Jun 1945, *H.A. Davis & T. Davis 6678.*

Significance.—West Virginia was one of only two states in the US not having reported this exotic species (the other state is Georgia) (USDA Plants Database).

Secale cereale L.—**Ohio Co.:** Wheeling, Thomson's Hill, 23 Jun 1877, *G. Guttenberg s.n.*

Significance.—West Virginia is one of only two states in the US not having reported this exotic species (other is Oklahoma) (USDA Plants Database).

ROSACEAE

Rubus elegantulus Blanch.—Randolph Co.: W side of river at Old Cheat Bridge, 9 Jul 1972, *E.E. Hutton D-16157.*

Significance.—This is the first report of this species from West Virginia. This record is the southern limit for this native species, which ranges from Maine to Pennsylvania and is disjunct in Wisconsin.

Rubus immanis Ashe—Hampshire Co.: in Gunbarrel Hollow near Capon Bridge, 1 Jul 1948, *H.A. Davis & T. Davis 8575.* Nicholas Co.: Mt. Nebo, on bank between road and run, 26 Aug 1947, *H.A. Davis & T. Davis 8279.*

Significance.—Sheets have *Rubus jugosus* written in H.A. Davis' handwriting. Davis (1990), synonymizes *R. jugosus* with *R. immanis.* This native species also occurs in Pennsylvania, Kentucky, and Virginia (USDA Plants Database).

Rubus meracus Bailey—Nicholas Co.: Strouds Creek, sandy ballast along railroad, 4 Jul 1946, *H.A. Davis & T. Davis 7409.* Webster Co.: near Nicholas Co. line, along road from Camden-on-Gauley, 1 Jun 1949, *H.A. Davis & T. Davis 8765*; Stroud's Creek, near Stemple's garden, across railroad, 2 Jun 1949, *H.A. Davis & T. Davis 8763*; Stroud's Creek at Grassy Run, 25 Jun 1953, *H.A. Davis & T. Davis 10376.*

Significance.—Determined by M.P. Widrlechner 2001. First report for the state. This native species also occurs in Pennsylvania and Kentucky (USDA Plants Database).

Rubus porteri Bailey—Tucker Co.: Roaring Plains, N of Dolly Sods, at picnic grounds, 3 Sep 1960, *W.H. Davis & Mrs. W.H. Davis 12985.*

Significance.—Sheets have written in H.A. Davis handwriting, *R. porteri.* A.M. Fuller in 1970 added "has all the earmarks for *R. porteri.*" Although considered as a synonym of *R. hispidus* by some, we are following the most current classification of Davis et al. (1967). Previously thought to be endemic to Pennsylvania.

VIOLACEAE

Viola _malteana House [V. *conspersa _rostrata*]—Monongalia Co.: White Day Creek, rocky woods, 26 Apr 1942, *H.A. Davis & T. Davis 5308.*

Significance.—Determined by H.A. Ballard, Jr. in 1991. First report for West Virginia. This native hybrid also occurs in Ohio and Pennsylvania (USDA Plants Database).

DISCUSSION

As a result of this study the number of species known from West Virginia has increased. The most notable discovery is a new population of *Corallorhiza maculata.* Specimens were collected by J.S. Shriver, A. Shriver and C. Smith in July 1993 and June 1994 in Pocahontas County. *Corallorhiza maculata* var.

occidentalis was recently rated by West Virginia Natural Heritage Program at a S1 ranking. The state ranking of S1 indicates that the taxon is considered critically imperiled.

ACKNOWLEDGMENTS

We thank the staff of the Western Pennsylvania Conservancy for their assistance. In addition, we would like to acknowledge the many private collectors that have contributed to the CM collections.

ABSTRACT

The occurrence of *Phalaris arundinacea* L., Reed canarygrass, in Texas is reported and a key to the genus *Phalaris* in Texas is provided.

RESUMEN

Se reporta la presencia de *Phalaris arundinacea* L., en Texas y se provee una clave para el genero *Phalaris* en Texas.

During the week of May 20–23, 2002, while compiling data from specimens at the herbarium of West Texas A & M University (WTS), a misidentified specimen of *Phalaris arundinacea* L. was found in the WTS collection. The sheet, originally identified as *Phalaris caroliniana* Walt., was collected by Larry C. Higgins in Hemphill County, Texas on June 29, 1978. Visits were made by the authors to the original collection site to determine whether the species still occurred in the state. In July 2002, the species could not be found, however on July 23, 2003, the species was located and persisting in the vicinity of Lake Kiowa on the Shannon Ranch in Hemphill County, Texas. At that time collections were made, and later accessioned at the S. M. Tracy Herbarium (TAES) of Texas A & M University in College Station, Texas. All specimens were identified using Chase (1951) and McGregor et al. (1986), and subsequently verified using TAES specimens.

The North American distribution of *P. arundinacea* is documented in numerous sources. Chase (1951) indicated a range from Canada extending south to New Mexico, Oklahoma, Missouri, Kentucky, and North Carolina. Allred (1993) cited occurrences in San Juan, Rio Arriba, Mora and Lincoln counties, New Mexico. McGregor et al. (1986), reported the species as common in the northern Great Plains but rare in Oklahoma. *Phalaris arundinacea, was not* listed in Louisiana by Allen (1992) nor in Texas by Correll and Johnston (1979), Gould (1975) and Hatch et al. (1990). Jones et al. (1997) listed *P. arundinacea* L. var. *picta* L. as being in the state, however this is a cultivated variety. No records for the species, in Texas, were found in collections at the University of Texas (TEX/LL) or at The Botanical Research Institute of Texas (BRIT). Inquiries were sent to curators of herbaria in Oklahoma (OKL, OKLA, WOH) and New Mexico (NMCR, SNM, UNM). None reported having collections of *P. arundinacea* from Texas.

Phalaris arundinacea was collected from the SE end of Lake Kiowa, NE of Lake Marvin in east-central Hemphill County, Texas. Lake Kiowa is a small to moderate size lake, ca. 7 hectares, which is fed by Boggy Creek and the Dry Fork of Boggy Creek, just N of the Canadian River. At the site, *P. arundinacea* is locally abundant as an understory species along the SE margin of the lake in association with *Spartina pectinata* Link, *Juncus*, *Carex*, *Salix*, *Baccharis*, *Cephalanthus occidentalis* L., *Scirpus pallida* (Britt.) Fern., *Typha*, and other vegetation associated with mesic to wetland habitats. Although the water level had dropped by the time of collection, there was evidence to indicate the site was inundated earlier in the season. The typical habitat for this species is meadows, stream banks, ditch banks, lake margins, or floating in water, Correll and Correll (1972), Arnow (1987) and Yatskievych (1999). The Hemphill County material appears to be at the southern limits of its distribution where it grows under the canopy of shrubs and trees. This makes finding the species more difficult compared to the populations in its northern distributions. This species may have been introduced to Hemphill County when the lakes, where it is found, were created. This species is distinguished from the other *Phalaris* species in Texas, by the presence of an obvious rhizome, being perennial, and having two reduced florets that are equal in length. *Phalaris* species in Texas are described in Gould (1975), with the exception of *P. arundinacea.*

Phalaris arundinacea L., Sp. Pl. 55. 1753. (**Fig. 1**).
Strongly rhizomatous perennials. ***Culms*** 50–160 cm tall, erect. ***Leaves*** basal and cauline. ***Sheath margins*** open. ***Ligules*** 5–9 mm long, membranous, obtuse (sometimes lacerate), decurrent. ***Blades*** to 35 cm long, to 16 mm wide, flat. ***Panicles*** 6–16 cm long, contracted, cylindrical (compact and sometimes lobed basally). ***Spikelets*** 4–6.5 mm long. ***Glumes*** 4–6.5 mm long, subequal, laterally compressed (keeled), mid-vein wingless, 3-veined, apiculate. ***Sterile floret lemmas*** 1–2.5 mm long, subulate, appressed pubescence, brownish. ***Fertile floret lemmas*** 3–4 mm long, ovate, glabrous to pubescent. ***Fertile floret paleas*** 2.7–3.6 mm long, appressed pubescence. ***Chromosome numbers*** $2n = 14, 28, 42, 56$, and aneuploid counts. ***Flowering period*** May–June.

Fig. 1. *Phalaris arundinacea*: *a*. floret, showing fertile and sterile lemmas; *b*, spikelet showing the strongly keeled glumes, fertile lemma, palea, and anthers; *c*, panicle, interrupted below; *d*, leaf sheath, ligule, blade, and node; *e*, habit, showing creeping rhizome; *f*, upper part of culm, showing panicle. (Used with permission: *A Flora of the Marshes of California*. Herbert L. Mason. University of California Press. 1957)

Specimens examined. **TEXAS**. Hemphill Co.: the old Boy Scout Camp 12 mi E of Canadian, 29 Jun 1978, *Higgins 12099* (WTU); Lake Kiowa, 12 mi E of Canadian, 23 Jul 2003, *Hatch* and *Hatch 8390* (TAES).

A KEY TO THE SPECIES OF *PHALARIS* IN TEXAS

1. Plants perennial; rhizomes present.
    2. Lower florets 2, about equal in length, 1–2.5 mm long ______ **P. arundinacea**
    2. Lower florets 1 or 2, unequal in length, one 0.5 mm long, longer one 1–2 mm long ______ **P. aquatica**
1. Plants annual; rhizomes absent.
    3. Reduced florets 1, scale-like ______ **P. minor**
    3. Reduced florets 2, scale-like.
        4. Reduced florets broad, more than one-half the length of the perfect floret ______ **P. canariensis**
        4. Reduced florets subulate, less than one-half the length of the perfect floret.
            5. Reduced florets 0.4–0.8 mm long ______ **P. brachystachya**
            5. Reduced florets 1–5 mm long.
                6. Panicles 2–7 cm long; culms to 70 cm tall ______ **P. caroliniana**
                6. Panicles 6–15 cm long; culms 60–150 cm tall ______ **P angusta**

ACKNOWLEDGMENTS

The authors thank the following: Angela Huff, Texas Agricultural Extension Service, Hemphill County, for establishing contact with the owner of the Shannon Ranch. Lonnie and Sue Cox, managers of the Shannon Ranch, for providing access to the property and transportation while on-site. David Sissom and Richard Kazmaier, the former and current curators of WTS for providing access to the collection, and the loan of specimens to TAES. The curators of BRIT and TEX/LL for access to their collections. Curators of the following herbaria for their assistance in searching their collections for species records in the region; NMCR, OKL, OKLA, SNM, UNM, and WOH.

SILENE CONOIDEA (CARYOPHYLLACEAE) NEW TO TEXAS

Monique Dubrule Reed

Biology Department Herbarium
TAMU 3258
Texas A&M University
College Station, Texas 77845-3258, U.S.A.

Silene conoidea L., Conoid Catchfly or Cone Catchfly, is an annual or biennial native to Europe. It can be weedy in temperate regions and has been recorded in the U.S. from California, Colorado, Delaware, Idaho, Maryland, Missouri, Montana, Nevada, Oregon, and Washington (USDA, NRCS 2004). The species was not listed for Texas by Correll and Johnston (1970) or by Jones et al. (1997).This is the first report of its occurrence in the state.

In March of 2003, two plants were found growing in a vegetable garden at Peaceable Kingdom Farm near Washington, in Washington County. *Vaccaria hispanica* (P. Mill.) Rauschert, uncommon in the area, was collected nearby. The garden owners suspect the seeds of both may have been introduced in a load of turkey manure.

Voucher specimen: U.S.A. **TEXAS. Washington Co.:** Peaceable Kingdom Farm, Washington, Mt. Falls School Road, vegetable garden, 27 Mar 2003, *Loring, Winston-Mize, and Mize 03-62* (TAMU). Images of the Washington County plants may be seen at http://www.csdl.tamu.edu/FLORA/cgi/gallery_query?q=silene+conoidea.

Silene conoidea somewhat resembles *S. antirrhina* L. (native to North America) and *S. gallica* L. (introduced), but it is larger in all respects. The leaves are lanceolate to oblanceolate, to 1 cm or more wide. The flowers are pink to purplish or white, with the petal blades 8–12 mm long and entire to toothed or notched. The most distinctive feature is the synsepalous calyx, which is 18–30 mm long and strongly inflated-conic at maturity, with about 20—30 strong ribs (Gleason & Cronquist 1991; Hickman 1993).

Silene conica L., another European species, is very similar but has petal blades only 3–6 mm long and a mature calyx only 12–17 mm long (Gleason & Cronquist 1991). It has been collected in the U.S. from Delaware, Maryland, Massachusetts, Michigan, New Jersey, New York, Ohio, Oregon, and Washington (USDA, NRCS 2004). It may eventually be found in Texas.

Though the owners of Peaceable Kingdom do not plan to let *S. conoidea* recur on their property, this is a species known to be weedy and it should be watched for.

SIDA 21(1): 493 – 494. 2004

NOTEWORTHY COLLECTIONS OF *CYPERUS DRUMMONDII* (CYPERACEAE) FROM TEXAS

David J. Rosen

S.M. Tracy Herbarium
Department of Rangeland Ecology and Management
Texas A&M University
College Station, Texas 77843-2126, U.S.A.

ABSTRACT

Recent collections of *Cyperus drummondii* Torr. & Hook. from Texas coastal prairies known as "Nash Prairie" and "Bailey's Prairie" are reported along with ecological notes and a synopsis of its Texas distribution.

RESUMEN

Se citan colectas recientes de *Cyperus drummondii* Torr. & Hook. de las praderas costeras de Texas conocidas como "Nash Prairie" y "Bailey's Prairie". Se añaden notas ecológicas notes y una sinopsis de su distribución en Texas.

Carter et al. (1999) recognized *Cyperus drummondii* Torr. & Hook. as distinct from *C. virens* Michx. and provided maps of the distribution of both taxa in the southeastern United States. *Cyperus drummondii* has been scarcely collected in Texas. Beside the type collection by Thomas Drummond, Denton (1978) reported only two other collections from Texas, *Cory 50890* (US) and *Hall s.n.* (F). In addition to these, Carter et al. (1999) reported *Jones 719* (US). In Texas, this taxon appears to be rare and restricted to the upper portion of the Gulf Prairies and Marshes as defined by Gould (1975). Recently, while conducting surveys of botanical resources on private property in Brazoria County, collections of *Cyperus drummondii* were made from populations encountered on large tracts of moderately disturbed to relatively undisturbed coastal prairie. These collections fill gaps in the distribution of this poorly understood taxon. Since pertinent works (Torrey 1836; Kükenthal 1935–1936; Denton 1978; Carter et al. 1999; Tucker et al. 2003) include scant information on the distribution and ecology of *C. drummondii* in Texas, the following notes and synopsis of its distribution are provided.

Distinguishing Characteristics

Specimens were easily distinguished from *C. virens* by key characters and diagrams provided by Carter et al. (1999). Upon critical examination, the ratio of achene length to scale length is sufficient to separate the taxa. *Cyperus drummondii* is also taller, has fewer and shorter primary inflorescence bracts, and

SIDA 21(1): 495 – 497. 2004

fewer sessile to sub-sessile primary peduncles. As Carter et al. (1999) suggested these characters are best observed in the field.

Habitat

Cyperus drummondii was rare to locally common in poorly drained, fine sandy loam and clayey soils of prairie depressions mapped as Edna fine sandy loam (Crenwelge et al. 1981). These large tracts were topographically intact as was evident by numerous pimple mounds. A composite list of closely associated species for all sites includes: *Axonopus fissifolius* (Raddi) Kuhlmann, *Boltonia diffusa* Ell., *Croton capitatus* Michx. var. *lindheimeri* (Engelm. & Gray) Müll., *Cyperus entrerianus* Boeck., *C. haspan* L., *Diodia virginiana* L., *Eryngium yuccifolium* Michx., *Helianthus angustifolius* L., *Hydrolea ovata* Nutt. ex Choisy, *Juncus brachycarpus* Engelm., *Leersia hexandra* Sw., *Ludwigia linearis* Walt., *Panicum hemitomon* Schult., *P. hians* Ell., *P. virgatum* L., *Paspalum floridanum* Michx. var. *floridanum*, *P. plicatulum* Michx., *Polygonum hydropiperoides* Michx., *Rhynchospora caduca* Ell., *R. corniculata* (Lam.) Gray, *R. indianolensis* Small, *Rudbeckia nitida* Nutt. var. *texana* Perdue, *Sesbania drummondii* (Rydb.) Cory, *Solidago tortifolia* Ell., *Tridens strictus* (Nutt.) Nash, *Tripsacum dactyloides* (L.) L., and *Vernonia missurica* Raf.

Specimens examined. **TEXAS. Brazoria Co.:** Nash Ranch; hay meadow W of CR 25, about 8.7 mi N of its intersection with Hwy. 35 in West Columbia, 25 Aug 2003, *Rosen & Carr 2590* (SBSC, TAES), and 19 Sep 2003, *Rosen 2631* (TEX, VSC); Nash Ranch, Head of the Creek Pasture W of Hwy. 35, about 2.7 mi S of its intersection with FM 1462 in Damon, 25 Aug 2003, *Rosen & Carr 2605*, (BRIT, VSC); Bailey's Prairie; W of FM 521, approximately .4 mi SW of its intersection with Hwy. 35, W of Angleton, 17 Dec 2003, *Rosen & Lange 2684* (MICH, VSC). **Goliad Co.:** 8 mi S of Coleto Creek, S of Victoria on Hwy. 77, hydric roadside ditch, frequent, 06 Jan 1988 *Jones 719* (TAES). **Harris Co.:** Houston, 1872, *Hall s.n.* (F, mixed with *Cyperus virens*). **Orange Co.:** Growing in shallow water, 6.5 mi W of Orange, 16 Nov 1945 *Cory 50890* (LL).

ACKNOWLEDGMENTS

Fieldwork was facilitated by the Nature Conservancy of Texas. Thanks to Diane Schenke and Bill Carr for offering the opportunity for access to the Nash Ranch, and to the curatorial staff at BRIT, F, TAES, and TEX/LL for their assistance. Thanks to Richard Carter, Steve Hatch and an anonymous reviewer for their helpful comments.

walter_holmes@baylor.edu

Ruppia cirrhosa (Pentagna) Grande has been recently collected from Lake Granbury in Hood County and Possum Kingdom Lake in Palo Pinto County, both in North Central Texas. The species was found at multiple locations in Lake Granbury in association with *Stuckenia pectinata* (L.) Boerner. In Possum Kingdom Lake the plant was collected in only one location, a shallow area called the Peanut Patch. In both reservoirs, the species was submersed, had long stems rooted in the sediment in water less than two meters deep, and was abundant in the locations where it was found.

Voucher specimens: TEXAS. **Hood Co.:** Lake Granbury, approximately 0.3 mi ENE of Mallard Pointe, 6 Aug 2003, *Morgan 599* (BAYLU); Lake Granbury, approximately 0.05 mi SW of intersection of Port Ridglea Drive and East Port Ridglea Court, 6 Aug 2003, *Morgan 562* (BAYLU); Lake Granbury, approximately 0.09 mi SW of terminus of East Port Ridglea Court, *Morgan 564* (BAYLU); **Palo Pinto Co.:** Possum Kingdom Lake at the Peanut Patch S of Caudill Mountain, N 32.89253, W 98.50671, 27 Aug 2003, *Morgan 601* (BAYLU).

Lake Granbury has a normal water surface elevation of 693 feet above mean sea level. At normal water surface elevation, Possum Kingdom Lake is 1,000 feet above mean sea level. Lake Granbury lies on the dividing line of the Blackland Prairie Ecoregion and the Oak Woods and Prairie Ecoregion, while Possum Kingdom Lake lies in the Rolling Plains Ecoregion. The terrain around both reservoirs is varied, with rolling topography near the headwaters, and becomes increasingly rugged towards the dam. Lake Granbury is slightly saline with an annual average chloride concentration of 642 mg/L, an annual average sulfate concentration of 228 mg/L, and an annual average total dissolved solids concentration of 1269 mg/L. Possum Kingdom Lake is also saline with an annual average chloride concentration of 995 mg/L, an annual average sulfate concentration of 364 mg/L, and an annual average total dissolved solids concentration of 1,801 mg/L. *Ruppia* is known to frequent water with high calcium and sulfur concentrations (Haynes 2000).

In North America, *Ruppia* has been treated as part of the Najadaceae (Steyermark 1963), the Potamogetonaceae (Thorne 1992), the Ruppiaceae (Correll and Johnston 1970, Haynes 2000), the Zannichelliaceae (Small 1933), and the Zosteraceae (Fernald 1950). We are following Haynes (2000), the most recent account of the North American species available.

SIDA 21(1): 499 – 500. 2004

The genus consists of about ten species of nearly worldwide distribution, with two species, *Ruppia cirrhosa* and *R. maritima* L., recognized in North America (Haynes 2000). Both are known to occur in Texas (Turner et al. 2003). *Ruppia maritima* is limited to the Gulf Coast region of the state with almost all records being from coastal counties, while *R. cirrhosa* is known from nine counties that are widely scattered in the Panhandle, South Texas Plains, along the Pecos River, and the northeast (Van Zandt Co.). The two species may be distinguished by peduncle characteristics (Haynes 2000). The peduncle length in *R. cirrhosa* is greater than 30 mm and the peduncle has five or more coils, while in *R. maritima* the peduncle is 2–25 mm long and has less than five coils. Haynes (2000) also mentions that *R. maritima* is primarily of coastal occurrence and *R. cirrhosa* is mostly of inland occurrence. This is the first report of the genus and species for the area treated in Diggs et al. (1999).

ACKNOWLEDGMENTS

We thank Doug Amburn, Randy Johnston, Kyle Lewis, Craig Goen, and Mike Cox for their assistance in searching for the specimens on Lake Granbury and Kay Barnes for her helpful reviews.

ABSTRACT

The paper evaluates the taxonomic and conservation status of *Osmorhiza bipatriata* Constance & R.H. Shan. The available phylogenetic data support its recognition as a distinct species. It has a highly restricted distribution on Mt. Livermore of the Trans-Pecos region in Texas, as well as in Coahuila and Nuevo León, Mexico. Its habitat on Mt. Livermore is highly restricted within the mesic *Pinus strobiformis* community, where it is associated with several other taxa that are also rare in Texas, such as *Polemonium pauciflorum* S. Watson subsp. *hinckleyi* (Standl.) Wherry and *Aquilegia longissima* A. Gray. The population of *O. bipatriata* on Mt. Livermore is small (< 20 individuals), although apparently healthy, with a full range of age structure. Application of the IUCN Red List criteria shows that *O. bipatriata* is an endangered species [B2ab(iv)]. We recommend careful monitoring of *O. bipatriata* and its associated habitat, and restricted access to its only known locality within the United States.

RESUMEN

En este artículo se evalúa el estatus taxonómico y de conservación de *Osmorhiza bipatriata* Constance & R.H. Shan. Los datos filogenéticos disponibles apoyan su reconocimiento como una especie independiente. Tiene una distribución muy restringida en el Mt. Livermore de la región Trans-Pecos en Texas, así como en Coahuila y Nuevo León, México. Su hábitat en el Mt. Livermore está muy restringido dentro de la comunidad mésica de *Pinus strobiformis*, donde está asociado con otros varios taxa que también son raros en Texas, tales como *Polemonium pauciflorum* S. Watson subsp. *hinckleyi* (Standl.) Wherry y *Aquilegia longissima* A. Gray. La población de *O. bipatriata* en el Mt. Livermore es pequeña (< 20 individuos), aunque aparentemente saludable, con una estructura de edad con el rango completo. La aplicación de los criterios IUCN para la Lista Roja muestran que *O. bipatriata* es una especie amenazada [B2ab(iv)]. Recomendamos un control cuidadoso de *O. bipatriata* y su hábitat asociado, y acceso restringido a su única localidad conocida en los Estados Unidos.

SIDA 21(1): 501 – 506. 2004

INTRODUCTION

Osmorhiza Raf. (Apiaceae subfam. Apioideae) is a small genus of approximately 11 species, including nine that occur in North America (two of which are also disjunct in South America) and one each in Asia and the central Andes. Members of the genus are characterized by their deep brown to black, linear to oblong, fusiform to clavate fruits that are slightly compressed laterally and have a caudate basal appendage and filiform ribs, which in most species bear numerous retrorse bristles (Lowry & Jones 1984). Several recent molecular phylogenetic analyses have shown that *Osmorhiza* is monophyletic and that it is most closely related to the Old World genera *Myrrhis* Mill. and *Geocaryum* Coss. (Downie et al. 2000; Wen et al. 2002; Yoo et al. 2002). These studies have also indicated that all the New World members of *Osmorhiza* evolved from a common ancestor that arrived from Asia, where the genus appears to have originated (Wen et al. 2002). Within the New World clade, a group of largely western North American species forms a well supported subclade that probably diversified relatively rapidly. Two of these species, *O. berteroi* DC. and *O. depauperata* Phil., have subsequently dispersed into the Great Lakes area, eastern North America, and southern South America, and another, *O. mexicana* Griseb., has an interrupted range from northern Mexico to northern Argentina, while the remaining species occupy relatively narrow geographic ranges in the western United States (Lowry & Jones 1984; Wen et al. 2002).

Specimens attributed to one of these species, *Osmorhiza bipatriata* Constance & R.H. Shan, were first collected on September 28, 1935, by L.C. Hinckley on Mt. Livermore in the Davis Mountains of the Trans-Pecos region in Texas (*Hinckley 408*, SRSC). Constance & Shan (1948) described this sweet cicely (herein referred to as the bipatriate sweet cicely) from the Davis Mountains and northern Mexico as a species new to science based on a later collection by Hinckley (26 Jul 1937, *L.C. Hinckley s.n.*; holotype at NY and isotypes at ARIZ and GH). Constance & Shan chose the epithet to reflect the presence of *O. bipatriata* in two countries as well as the two nationalities of its authors. Lowry & Jones (1984) reported several morphological intermediates between *O. bipatriata* and *O. mexicana* collected from sites in northern Mexico, including on Cerro Potosí in Nuevo León, where the two taxa occur sympatrically. These intermediates prompted them to reduce *O. bipatriata* to a subspecies of *O. mexicana*. Recently, Turner et al. (2003) recognized the taxon as a variety of *O. mexicana* because he chose, somewhat arbitrarily, not to use the rank of subspecies in his work (B.L. Turner, pers. comm.).

TAXONOMIC STATUS

Phylogenetic analyses conducted in the last several years using sequence data from the nuclear ribosomal ITS regions and the chloroplast *ndh*F gene and *trn*L-

F regions (Downie et al. 2000; Wen et al. 2002; Yoo et al. 2002) suggest that *Osmorhiza mexicana* and *O. bipatriata* do not form a monophyletic group and indicate that they show considerable divergence in their sequence profiles of these markers (e.g., 1.415% divergence between the ITS sequences). In the ITS phylogeny, the positions of the two taxa are unresolved, although both are closely related to other western North American members of *Osmorhiza* (Downie et al. 2000; Wen et al. 2002). The chloroplast data set suggests that *O. bipatriata* is most closely allied to *O. depauperata* (Yoo et al. 2002). The available data thus do not support the inclusion of *O. bipatriata* within *O. mexicana* at an infraspecific level. The phylogenetic data suggest instead that it should be treated as a distinct species, as initially proposed by Constance & Shan (1948), using either the phylogenetic (Nixon & Wheeler 1990) or the lineage (de Queiroz 2000) species concept. While the presence of morphological intermediates in northern Mexico would appear to be incompatible with the recognition of *O. bipatriata* using the classical morphological species concept, as supported by Cronquist (1978), the phylogenetic data suggest that these intermediates may represent interspecific hybrids or perhaps may have resulted form introgression between *O. bipatriata* and *O. mexicana*. Detailed analyses, however, will be required to assess the origin of these intermediates.

Osmorhiza bipatriata differs from its congeners by its small (9–11 mm long) and glabrous fruits, which are linear-fusiform and taper into a short beak at the apex, and by its very short styles [0.5–0.75 mm long (Lowry & Jones 1984)]. Based primarily on fruit morphology, Constance & Shan (1948) placed *O. bipatriata* in subgen. *Glycosma*, but commented that it possessed characters intermediate with members of the typical subgenus, in particular with regard to its involucel, styles and stylopodium, which are similar to those of *O. mexicana*, which belongs to sect. *Mexicanae* of subgen. *Osmorhiza* (see Constance & Shan 1948; Lowry & Jones 1984). Our molecular phylogenetic studies (Wen et al. 2002; Yoo et al. 2002) show that *O. bipatriata* possesses a large number of unique molecular nucleotide substitutions, suggesting its antiquity. *Osmorhiza bipatriata* is thus perhaps best described as a relict species, which has survived in mesic habitats in the northeastern Chihuahuan Desert, which have undergone a gradual drying since the late Tertiary (Graham 1993).

An illustration of *Osmorhiza bipatriata* is found in Lundell & collaborators (1961: plate 42). Lowry & Jones (1984) provided comprehensive information on its morphology and distribution and cited specimens from both Texas and Mexico deposited in various herbaria. Below are some additional specimens from Texas that we have examined, but which were not seen by Lowry & Jones (1984).

U.S.A. Texas. Jeff Davis Co.: Madera Canyon, Mt. Livermore, 28 Sep 1935, in fr., *Hinckley 408* (SRSC); in wet soil of spring in Madera Canyon, Mt. Livermore, 23 Jul 1945, in young fr., *Hinckley 3489* (SRSC); at the upper spring of Madera Canyon, NW slope of Mt. Livermore, 7300 ft, 12 Sep 1947, in fr., *Warnock & Hinckley 4147* (SRSC); rare at upper spring in Madera Canyon on Mt. Livermore, Davis Mountains, igneous soil, 7500 ft, 11 Sep 1947, in fr., *Warnock & Hinckley 7479* (SRSC); infrequent in igneous soil on upper Madera Canyon of Mt. Livermore, 7500 ft, 23 Aug 1968, *Warnock 23015* (SRSC); upper Madera Canyon, Tobe Spring, NW of Mt. Livermore, just above a large horseshoe wall, in deep mesic canyon under *Pinus strobiformis – Quercus gambelii – Juniperus deppeana* forest, associated with *Rhamnus betulifolia, Symphoricarpos oreophilus, Aquilegia longissima, Polemonium pauciflorum* subsp. *hinckleyi, Salvia arizonica, Geranium caespitosa, Vitis arizonica, Ptelea trifoliata, Galium* sp., and *Thalictrum* sp., N30°38.364', W104°10.746', 7242 ft., 23 Aug 2003, in fl & fr, *Wen et al. 7265* (F).

CONSERVATION CONSIDERATIONS

Osmorhiza bipatriata has a highly restricted distribution, with only a few localities recorded on Mt. Livermore, Texas, and in Coahuila and Nuevo León, Mexico. Until recently, all of the collections from Texas were made by L.C. Hinckley and Barton Warnock (perhaps from the same locality), the most recent of which dates from 1968 (*Warnock 23015*, SRSC). During a recent study trip, we were able to relocate *O. bipatriata* on the northwestern slope of Mt. Livermore. A single, small population was found on 23 August 2003, comprising about 15 individuals, including 5–6 young seedlings. It occupied a small microhabitat with moist, rich soil in a deep mesic canyon under *Pinus strobiformis–Quercus gambelii–Juniperus deppeana* forest that differs considerably from most of the surrounding vegetation, which is primarily dominated by ponderosa pines and various oak species. The plants of *O. bipatriata* on Mt. Livermore were highly heterogeneous phenologically, with some individuals observed in flower, some in young fruit, and others in mature fruit, in addition to a few that were just emerging from the ground after a recent rain shower, which suggests that *O. bipatriata* is particularly sensitive to water availability.

Suitable habitat for *Osmorhiza bipatriata* is apparently rare in the Davis Mountains. Although the population we studied appears to be healthy, as indicated by the presence of a full age structure, from young seedlings to mature adult plants, it is small (less than 20 individuals) and only persists in a restricted microhabitat. Despite three days searching the mountain for comparable habitat, we were unable to locate any other populations. We thus recommend careful monitoring of the only known population in the United States, which may require controlled access to ensure its continued survival. *Osmorhiza bipatriata* also occurs sympatrically with two other rare taxa in the Davis Mountains: *Polemonium pauciflorum* S. Watson subsp. *hinckleyi* (Standl.) Wherry; and *Aquilegia longissima* A. Gray. We also observed two additional rare species (*Quercus depressipes* Trel. and *Aralia bicrenata* Wooton & Standl.) at a higher elevation on the same slope of Mt. Livermore, the summit of the Davis Mountains.

Osmorhiza bipatriata is not currently listed in the Texas Threatened and Endangered Species list (Texas Parks & Wildlife Department 2003) nor in the Threatened and Endangered Species System [TESS (U.S. Fish and Wildlife Service, 2003, *http://endangered.fws.gov*)]. Application of the IUCN Red List criteria (IUCN, 2001; see also *http://www.iucn.org/themes/ssc/redlists/*

RLcats 2001booklet.html) shows, however, that *O. bipatriata* is an endangered species [B2ab(iv)] because it has an area of occupancy estimated to be less than 500 km^2 and because it is both known from fewer than five localities (cf. Lowry & Jones 1984: fig. 17) and appears to have a declining number of subpopulations, as indicated by our observations on Mt. Livermore.

Most species of *Osmorhiza* have a relatively wide distribution (cf. Lowry & Jones 1984). Along with *O. glabrata* Phil., a central Andean endemic, and *O. brachypoda* Torr., found only in California and Arizona, *O. bipatriata* has one of the most restricted ranges in the genus. In the case of *O. bipatriata*, this may at least in part reflect the fact that its fruits lack the caudate appendages and retrorse bristles characteristic of most members of the genus, which are presumed to play a role in dispersal (Constance & Shan 1948; Lowry & Jones 1984), as suggested for the widespread *O. berteroi*, which Cruden (1966) concluded was bird dispersed.

In conclusion, *Osmorhiza bipatriata* is a distinct species with a long evolutionary history. It appears to be among the rarest plant species in the United States, with a single known population of less than 20 individuals occurring in a rare habitat in the Davis Mountains of west Texas. Careful studies need to be conducted to investigate its reproductive biology, seed germination and dispersal biology, ecological preferences, and conservation genetics to develop a suitable management plan for this relict species. Comparative analyses of its congeners with both widespread and restricted distributions should also provide insights into the biology of *O. bipatriata* that may be useful for its conservation. Furthermore, it is necessary to compare the Texas population with those in Coahuila and Nuevo León, Mexico in order to verify that they are indeed conspecific, as suggested by their morphology. The evolutionary consequence or impact of the possible hybridization and introgression between *Osmorhiza bipatriata* and *O. mexicana* also needs to be assessed.

ACKNOWLEDGMENTS

We thank the Nature Conservancy of West Texas for granting access to the Davis Mountains Preserve, authorizing our field study on Mt. Livermore in August, 2003, and providing lodging during the field work; we are grateful to John Karges for helpful advice, Patricia Manning for field assistance, Mike Powell for herbarium assistance, permission to examine the specimens at SRSC, and valuable comments on the manuscript, B.L. Turner for discussion and his open-mindedness of accepting the species status of *Osmorhiza bipatriata*, and George Schatz for assistance with the IUCN Red List analysis. Support for the study was provided by the Field Museum of Natural History, the Chinese Academy of Science (a grant of Excellent Overseas Chinese), and the National Science Foundation (DEB 0108536 to JW).

The genus *Clitoria* includes 35 species that are mostly common in warmer parts of the world. Common names of pigeon-wings or butterfly pea are used for the entire genus (Correll & Johnston 1996). *Clitoria mariana* L. is a perennial herb found throughout the United States, including eastern Texas. This specific species is reported as frequent in eastern and central Texas and infrequent in southern Arizona from the Chiricahua to the Baboquivari Mountains, thus creating a wide gap in the distributional range of the species (Correll & Johnston 1996; Turner et al. 2003). In Arizona it is found under junipers and live-oaks in rich soils (Kearney & Peebles 1964). Confirmed identification of this species was made during a recent study of *Pinus ponderosa* L. and adjacent communities within the Davis Mountains of west Texas. The species was found at the bottom of a slope at approximately 1900 m elevation where the soils were the richest in the general area under ponderosa pine, with associated species including Mexican Pinyon (*P. cembroides* Zucc.), Alligator juniper (*Juniperus deppeana* Steud.), and Texas Madrone (*Arbutus xalapensis* Buckl.). This is the westernmost finding of *Clitoria mariana* in Texas. The isolated finding reported here supports similar conditions described for southern Arizona. *Clitoria mariana* may be found in other scattered locations across the Madrean Province.

Voucher Specimen: **U.S.A. TEXAS. Jeff Davis Co.:** TNC Davis Mountains Preserve, Madera Canyon, W 104° 7' 30" N 30° 39' 30", elevation 1900 m, ponderosa pine community, growing in sandy loam soil, 14 Aug 2003, *Mohammad Bataineh and Amanda Rountree 1* (SRSC).

BOOK REVIEW

JOHN BOIK. 2001. **Natural compounds in cancer therapy: promising natural & antitumor agents from plants & other natural sources.** (0-9648280-1-4, pbk.) Oregon Medical Press, LLC. 325 10th Avenue North, Princeton, Minnesota 55371, U.S.A. (Orders: 800-610-0768; www.ompress.can). $32.00, 521 pp., b/w charts, figures, graphs, and tables, 13 appendices, 8 1/2" × 11".

Seldom does one encounter a seminal work wherein the author tackles the enormously complex immune system, the intricacies of the pathophysiological process involved in malignancies, combined with a most articulate description of botanical and other sources, the constituents of which possess potent anti-neoplastic properties.

The book is divided into three parts: *Part I: Cancer at the Cellular Level*, is comprised of Chapters 2 through 6, and is preceded in Chapter I which presents background information related to Parts I and II, notably, the seven strategies for cancer inhibition; *Part II: Cancer at the Level of the Organism*, and *Part III: Clinical Considerations*.

The topics included in Part I consist of the following: Mutations, Gene Expression, and Proliferation (Chp. 2); Results of Therapy at the Cellular Level (Chp. 3); Growth Factors and Signal Transduction (Chp. 4); Transcription Factors and Redox Signaling (Chp. 5); and Cell-to-Cell Communication (Chp. 6).

Several interesting and salient points are stressed. The central driving force behind the transformation of a normal cell into a cancer cell is mutation; especially through the expression of oncogenes and decreased expression of tumor suppressor genes. Both normal and cancer cells proliferate in response to the same signals, but in cancer the proliferative signals exceed apoptotic signals. At the cellular level, successful cancer therapies (1) can cause cancer cells to assume more normal morphology and function, (2) prevention of cancer cells to enter the cell cycle, (3) induction of cell death through apoptosis, and (4) induction of cell death through necrosis. The first three of these can be accomplished by a variety of natural compounds. To avoid apoptosis and promote proliferation, cancer cells override the control mechanisms that normally regulate these processes in healthy cells. Often cancer cells produce their own growth factors, signal transduction enzymes, and protein moieties. Of the three major transcription factors, cancer cells rely on abnormally low P53 protein activity and abnormally high NF-Kappa B and AP-1 activity. Intercellular communication and cell-matrix interaction are vital processes linking a cell to its environment. Cancer cells frequently exhibit aberrant forms of communication. Increasing E-cadherin expression and increasing gap junction communication can provide useful strategies in cancer treatment.

Part II consists of Chapters 7 through 12. Topics covered include: overview of Angiogenesis (Chp. 7), Natural Inhibitors of Angiogenesis (Chp. 8), Invasion (Chp. 9, Metastasis (Chp. 10), The Immune System (Chp. 11), and Natural Compounds that Affect the Immune System (Chp. 12). A number of valuable observations were noted. While angiogenesis is a normal part of wound healing, it is the major mainstay supporting tumor growth. The difference between wound healing and tumor growth is th4a fact that angiogenesis in wound healing is finite and self-limiting but completely unchecked in tumors. A large number of compounds are capable of inhibiting angiogenesis, especially antioxidants, anticopper complexes, and vitamins A and D_3. Combinations including genistein have shown real promise. Cancer cells produce three compounds that facilitate invasion: abnormal matrix components, enzymes (collagenase and hyaluronidase) that digest matrix Components, and variant CD44 surface proteins that aid cell migration. Metastasis is a five-step process, namely, (1) cell detachment and intravasation, (2) migration through circulatory channels, (3) arrest at a new location, (4) extravasation, and (5) cell proliferation and angiogenesis. it is highly likely that natural compounds could play a significant role in slowing down or abrogating metastasis. The response of the immune system to cancer involves two major processes: (1) innate immune response independent of the tumor antigens, and (2) adaptive immune responses. Ideal results have been achieved when an immunostimulant in combination with materials that prevent immune system evasion. Release of cytokines (IL-2 and the interferons) plus the addition of immune stimulants appear to have the greatest potential for therapy together with inhibitors of PGE 2 or other specific immunosuppressive compounds.

Part III consists of Chapters 13, through 23. Topics covered include. Back- ground for Part III (Chp. 13), Trace Metals (Chp. 14), Vitamin C and Antioxidants (Chp. 15), Polysaccharides (Chp. 16), Lipids (Chp. 17), Amino Acids and Related Compounds (Chp. 18), Flavonoids (Chp 19), Non-flavonoid Phenolic compounds (Chp. 20), Terpenes (Chp. 21), Lipid-soluble Vitamins (Chp. 22), Natural Compounds, Chemotherapy, and Radiotherapy (Chp. 23). Cogent observations include the following. An approach which uses several compounds in combination may be associated with fewer side-effects and possibly superior beneficial actions. Selenium compounds tend to decrease cancer risk while copper and iron appear to increase cancer risk. Depending upon the oxidative stress at the cancer site, antioxidants may either increase or decrease cancer cell proliferation. Polysaccharides have been shown to increase immunostimulation through release of cytokines and to decrease immunosuppressive moieties. They very possibly have other mechanisms which result in tumor inhibition, but many of these mechanisms remain to be calrified. N-6 lipids tend to promote tumor progression, an action probably shared with saturated fats in general. Fish oil, however, especially EPA, has been shown to inhibit cancer progression, decrease angiogenesis, lessen evasion, tendency to metastasize, and inhibit cachexia by reducing TNF-alpha levels. Both glutamine and bromelain appear to have immunostimulant properties. Phenolic compounds, although chemically diverse, seem to be able to inhibit cancer progression through cytotoxic mechanisms. Curcumin, lignans, and quinones may have possible roles in cancer therapy, but they require further study to ascertain their activities. Terpenes probably serve as anticancer agents through potent anti-inflammatory actions. Vitamins A and D., and their metabolites, have the ability to enter the nucleus and directly affect gene transcription. Vitamin E, located on cell membranes, may play a major role in regulating antigen presentation. Combining natural product administration along with either chemotherapy and/or radiotherapy may enhance the efficacy of both modalities of treatment.

With such a wealth of information regarding the favorable effects of natural products in various processes cancer cells depict, it behooves all physicians, especially oncologists, other medical personnel, nutritionists and dietitians, and all persons who interact with cancer patients to peruse, assess, and incorporate those natural factors which they deem best aligned with their philosophical approaches to improve the statistics for cancer survival. But of even more import is for the information contained in this book to be available and utilized by cancer patients, themselves.

This book represents a truly remarkable compilation and assessment of natural products and their potential to significantly influence for good cancer therapies with increased survival of the disease's victims.—*Ivan E. Danhof, Ph.D., M.D., 222 S.W. 2nd Street, Suite 201, Grand Prairie, Texas 75051, U.S.A.*

This illustrated monograph is the most comprehensive generic treatment of legumes for any geographical area of Mexico. The book covers the genera of legumes known to be present in northern Mexico from Tamaulipas to Baja California Sur. The introductory material covers topography, climate, and vegetation types of northern Mexico. Included are 121 genera treated in three families: Fabaceae, Mimosaceae, and Caesalpiniaceae. The Fabaceae is the most abundant family with 87 genera followed by Mimosaceae (19) and Caesalpiniaceae (15). Keys to the families, tribes (only in Fabaceae), genera, and detailed line drawings of distinguishing characteristics are included for most of the genera to facilitate identification. Each genus is provided with a description, followed by distributional information, species number, chromosome number, and economic, ecological, and potential food importance.

The Atlas of Texas covers about 6000 taxa. This is the result of 54 years of herbarium and fieldwork by B.L. Turner, beginning in 1948 at Sul Ross State University, Alpine, Texas. In short, the senior author has examined personally, touched, or "pored over" an estimated several hundred thousand sheets in the preparation of the forthcoming Atlas volumes. Contents include an introduction, atlas of Texas plants arranged alphabetically by family, by genus, by species, and an index.

ABSTRACT

The genus *Dirca* consists of three disjunct species of shrubs. *Dirca palustris* is found in the eastern United States and adjacent Canada; *D. occidentalis* is limited to six counties near the San Francisco Bay in California; and the recently discovered *D. mexicana* is known from one isolated population in northeastern Mexico. The three species have been described and classified according to morphological characters, but the morphological evidence does not provide a clear assessment of the relationships among the species. Morphologically, *D. mexicana* most closely resembles *D. occidentalis*, but known biogeographical trends raise doubt regarding how the three species are interrelated. We used molecular techniques to examine and clarify phylogenetic relationships among the three species of *Dirca*. Evidence from Internal Transcribed Spacer (ITS) sequences and Inter-Simple Sequence Repeats (ISSR) polymorphisms confirms the species-level divergence of *Dirca mexicana* and reveals that, despite their morphological similarity, *D. mexicana* and *D. occidentalis* are the most divergent of the three species genetically, while *D. mexicana* and *D. palustris* are the most closely related. The molecular evidence also demonstrates that *Dirca occidentalis* was the first of the three species to diverge and has undergone the greatest degree of differentiation since divergence.

RESUMEN

El género *Dirca* consta de tres especies de arbustos separadas geográficamente. *Dirca palustris* se encuentra en la parte Este de los Estados Unidos y la parte contigua de Canadá; *D. occidentalis* se limita a seis condados alrededor de la bahía de San Francisco en California, EE.UU.; y la recién descubierta *D. mexicana* se conoce solamente de una población aislada en la parte noreste de México. Las tres especies han sido descritas y clasificadas según sus características morfológicas, pero las pruebas morfológicas han sido consideradas como no concluyentes para hacer una evaluación clara de las relaciones entre las especies. Morfológicamente, *D. mexicana* se parece más a *D. occidentalis*, pero las tendencias biogeográficas establecidas crean dudas sobre el grado de parentesco entre las dos especies. Hemos usado técnicas moleculares para examinar y clarificar las relaciones filogenéticas entre las tres especies de *Dirca*. Por las pruebas que encontramos en las secuencias del Espaciador Transcrito Interno (ETI) [Internal Transcribed Spacer (ITS)] y polimorfismos de Repeticiones de Secuencias Intra-Simple (RSIS) [Inter-Simple Sequence Repeats (ISSR)], llegamos a las siguientes conclusiones: 1. *Dirca mexicana* merece ser catalogada como especie; 2. *Dirca occidentalis* fue la primera de las especies en evolucionar, y ha experimentado el mayor grado de diferenciación desde su divergencia; y 3. Contrario a sus morfologías, *D. mexicana* tiene un grado de parentesco más alto, en términos genéticos, con *D. palustris* que con *D. occidentalis*.

INTRODUCTION

The genus *Dirca* L. is comprised of three species of slow-growing, understory shrubs found almost exclusively in nature on steep, west- or north-facing slopes

SIDA 21(2): 511–524. 2004

above a waterway (Johnson 1994; Nesom & Mayfield 1995; Graves 2004). While *D. palustris* L. is the most common of the species and is found in sparsely distributed colonies over most of eastern North America, the other two species, *D. occidentalis* Gray and *D. mexicana* Nesom & Mayfield, are rare and endemic. *Dirca occidentalis* is isolated to a six-county region surrounding the San Francisco Bay in California, and *D. mexicana* is endemic to only one valley in the Sierra Madre Oriental Mountains of Tamaulipas, Mexico (Nesom & Mayfield 1995; Graves 2004). Although there is interest in the genus due to the obscurity of plants in the wild, the vulnerability of plants in California (Johnson 1994), the discovery of the new species in Mexico (Nesom & Mayfield 1995), and the potential to utilize plants of this genus as shade-tolerant shrubs for managed landscapes (Dirr 1998), no research has been done to determine the phylogenetic relationships among the three species of *Dirca*.

In the most recent treatment of the genus *Dirca*, Nesom and Mayfield (1995) showed the three disjuncts to be morphologically distinct and found that *D. mexicana* more closely resembled *D. occidentalis* than it did *D. palustris*. But, they also questioned the relative similarity of *D. mexicana* and *D. occidentalis* "in view of the well-known pattern of close relationship and disjunction between species of the eastern and southeastern United States and the sierra of northeastern Mexico" (Nesom & Mayfield 1995). Considering biogeographical trends, Nesom and Mayfield (1995) believed the best explanation for the origin of three disjunct species was, first, the isolation of the ancestors of *D. occidentalis* from those of *D. palustris*, and, more recently, the isolation of the ancestors of *D. mexicana* from those of *D. palustris*. Our goals were to resolve the apparent inconsistency between morphological and biogeographical evidence by examining the genotypic relationships among the three species of *Dirca*, to reconstruct the phylogeny of *Dirca* spp. by utilizing methods of molecular systematics, and to determine if molecular evidence supports the classification of *D. mexicana* as a distinct species.

We used two classes of molecular markers, Internal Transcribed Spacer (ITS) sequences and Inter-Simple Sequence Repeats (ISSR), to quantify the genotypic variability of *Dirca*. ITS techniques compare the internal transcribed spacer sequences of the 18S-5.8S-26S nuclear ribosomal DNA. They hold many advantages over other methods, including biparental inheritance, intergenomic variability suitable for phylogenetic inference at the specific, generic, and family levels (Baldwin 1992; Baldwin et al. 1995), and easy amplification with universal primers (White et al. 1990). ITS sequence data are abundant and easily accessible in public databases, enabling direct comparisons among taxa and thus are used extensively for botanical phylogenetics at generic and infrageneric levels (Álvarez & Wendel 2003).

ISSR techniques (Zietkiewicz et al. 1994) are chosen most often for their capacity to resolve molecular differences below the specific level, but ISSRs are also valued because they sample a large portion of the genome and therefore avoid the bias accompanying phylogenies based on the sequence of only one or a few genes (Schrader & Graves 2004). Used together, these two methods can provide excellent resolution of genetic variability at and below the family level and proved effective for assessing infrageneric differences within the genus *Dirca*.

MATERIALS AND METHODS

Samples of genomic DNA were extracted from leaf tissue of 24 seedlings by utilizing the template preparation service of the DNA Sequencing and Synthesis Facility at Iowa State University. The seeds had been collected from plants of all *Dirca* spp. in their native habitats (Table 1). Eight samples of *D. palustris* and seven samples each of *D. mexicana* and *D. occidentalis* were used to compare genetic variation in *Dirca*. In addition, two samples of *Daphne mezereum* L. (Thymelaeaceae) and one sequence from *Hibiscus rosa-sinensis* L., also from within the Order Malvales, were used as outgroup representatives for phylogenetic analyses (Table 1). *Daphne mezereum* and *H. rosa-sinensis* (GenBank sample, Shi & Yuan 2001) were chosen to establish ancestral-character polarity at the generic and family levels, respectively.

ITS methods.—We amplified the entire ITS region (ITS 1 + 5.8S + ITS 2) of each sample by using the universal primers ITS4 and ITS5 (White et al. 1990), separated the ITS bands by use of agarose-gel electrophoresis, cut out bands, and eluted the purified samples from the agarose with the GenElute™ Gel Extraction Kit (SIGMA, St. Louis, Mo.). For ITS amplification, we used 25-µL reaction mixes that contained 50 ng of template DNA, 0.8 µM of each primer, 600 µM dNTP mix (SIGMA), 1× reaction buffer that contained $Mg(OAc)_2$, and 1.5 units of KlenTaq LA DNA polymerase (SIGMA). Thermocycler conditions were 94° C for 5 min (initial denaturing), 94° C for 1 min (denaturing), 45° C for 1 min (annealing), and 72° C for 2 min (extension), for 35 cycles with the final extension at 72° C for 5 min. The purified samples were sequenced on an Applied Biosystems (ABI) 3100 Genetic Analyzer by using the forward primer (ITS5) and the long-read service of the DNA Sequencing and Synthesis Facility at Iowa State University. We used CLUSTAL X Multiple Sequence Alignment Program (version 1.8) to align sequences for phylogenetic analyses and to confirm the presence of the plant-conserved, 5.8S rDNA motif (Jobes & Thien 1997) in all sample sequences.

ISSR methods.—ISSR fragments for each of the 24 DNA samples were amplified for three replications with each of eight fluorescent 3'-anchored ISSR primers [$(CA)_6RG$, $(AC)_8G$, $(AG)_8YT$, $(CT)_8TG$, $(GTG)_3GC$, $(CA)_6RT$, $(CAC)_3RC$, and $(CTC)_3SG$], which were synthesized at the DNA Sequencing and Synthesis

TABLE 1. Origins of the 25 individuals sampled for ITS and ISSR analysis. All plants sampled are from the Schrader and Graves *Dirca* collection at Iowa State University except *Hibiscus rosa-sinensis*, which was obtained through a BLAST search (Shi & Yuan 2001). Latitude and longitude are according to Global Positioning System (GPS) and are included when known.

Facility at Iowa State University. Optimization reactions were run to determine proper reaction conditions and reagent concentrations for consistent PCR amplification. Thermocycler conditions for ISSR-PCR were 94° C for 5 min (initial denaturing), 94° C for 30 s (denaturing), primer-specific temperatures (see below) for 45 s (annealing), and 72° C for 2 min (extension), for 30–33 cycles with the final extension at 72° C for 5 min. Annealing temperatures for the eight primers were 47° C for $(CA)_6RG$, 52° C for $(AC)_8G$, 56° C for $(AG)_8YT$, 52° C for $(CT)_8TG$, 56° C for $(GTG)_3GC$, 48° C for $(CA)_6RT$, 52° C for $(CAC)_3RC$, and 52° C for $(CTC)_3SG$. In our 25-μL reaction mixes, we used 50 ng of template DNA, 1.2 μM of primer, 300 μM dNTP mix (SIGMA), 1× reaction buffer that contained $Mg(OAc)_2$, and 1 unit of KlenTaq LA DNA polymerase (SIGMA).

Amplification products were processed at the DNA Sequencing and Synthesis Facility at Iowa State University. Applied Biosystems (ABI) 377 automated DNA sequencing systems separated the DNA by electrophoresis and collected the gel image. Image data were analyzed by using ABI PRISM™ GeneScan® software that resolves DNA fragment length differences as small as one base pair. ISSR bands (loci) were scored as "1" for band presence and "0" for band absence. Only bands that appeared in at least two of the three replications were considered present. A locus was any fragment length that was present in at least one sample. The resulting two-state (1 · 0) data matrices for the eight primers were combined to form a cumulative data set for assessing molecular relationships among the three species of *Dirca*. Data from three of the primers, $(CA)_6RG$, $(AC)_8G$, and $(AG)_8YT$, were compared with the results of Schrader and Graves (2004) to help assess the relative taxonomic distances expected for specific and subspecific hierarchical levels according to ISSR methods (Tables 2 and 3).

Data analysis.—Cladistic analyses were performed by using PHYLIP (Phylogeny Inference Package; Felsenstein 1995). We used the Dnapars program for Wagner parsimony (Kluge & Farris 1969) analysis of ITS data and the Mix program for Wagner parsimony analysis of ISSR data. The Seqboot program was used for bootstrap (Felsenstein 1985) and jacknife (Farris et al. 1996) analyses (1000 resamplings each), and the Neighbor program for neighbor-joining analyses (Felsenstein 1995). Genetic distances for ITS analyses were generated under the Kimura 2-parameter model (Kimura 1980) by using the Dnadist program of PHYLIP, and genetic distances for ISSR analyses were Euclidean distances (Sneath & Sokal 1973). We compared and contrasted our ITS and ISSR phylogenies, a procedure termed "cross matrix disparity" by Bateman (1999), then merged the two data sets for a "simultaneous analysis" (Nixon & Carpenter 1996) using unweighted distances (Sneath & Sokal 1973) from the two data sets.

RESULTS

ITS.—Sequencing of the ITS region provided complete sequences for ITS 1, the 5.8S rRNA gene, and ITS 2 and provided partial sequences for the 18S (32 nucleotides) and 26S (22 nucleotides) rRNA genes. The ITS region varied in length among the four species we evaluated (630 bp for *D. mexicana*, 617 bp for *D. occidentalis*, 625 bp for *D. palustris*, and 596 bp for *D. mezereum*) and contained ample sequence variation for species-level phylogenetic analysis. The 5.8S rRNA gene was 165 base pairs long in all samples and the sequence was identical in *D. mexicana* and *D. palustris*, with only one site difference for *D. occidentalis* and four site differences for *D. mezereum*, one of which was common to *D. occidentalis*. There was no intraspecific sequence variation among ITS samples from *D. occidentalis*, *D. palustris*, nor *D. mezereum*. There was variation at six sites among the six ITS samples of *D. mexicana* (five insertion/deletions and one transversion, all in ITS 1), but the consensus sequence was identical to the sequence of one of those samples (D.mex 2).

In our phylogenetic analysis, exhaustive searches produced single most-parsimonious trees with each of the two chosen outgroups, *D. mezereum* and *H. rosa-sinensis*, showing 196 and 496 evolutionary steps, respectively. The trees agreed in topology and revealed that, within the genus *Dirca*, the ancestral line of *D. occidentalis* was the first to diverge (Fig. 1 and 2). Bootstrap and jacknife percentages (100% for all clades) showed very strong support for this topology, and our results using the family-level root (outgroup *H. rosa-sinensis*) support the choice of *D. mezereum* as a suitable outgroup for phylogenetic reconstruction of *Dirca*.

Sequence divergence (Kimura 2-parameter distance) between *D. occidentalis* and the other two *Dirca* species (*occidentalis* to *mexicana* = 0.0592, *occidentalis* to *palustris* = 0.0560) was much greater than the divergence between *D. mexicana* and *D. palustris* (0.0074). Results of the neighbor-joining analyses reveal both a much earlier divergence of *D. occidentalis* than the divergence of the other two species and greater differentiation than the other two species since their times of divergence (Figs. 1 and 2). This feature is particularly apparent when the phylogeny is constructed by using a generic-level root (Fig. 1), but is still evident when using a family-level outgroup (Fig. 2).

ISSR.—Amplification with the eight fluorescent 3'-anchored primers yielded 709 ISSR loci (fragment lengths) across the four species. The fine resolution of ISSR techniques is illustrated by the high degree of polymorphisms found among the three species of *Dirca* and the high number of species-specific loci (Table 2). Comparing these results with the results of an earlier, subspecific study that involved the same methods and three of the same ISSR primers (Schrader and Graves 2004), confirmed species-level divergence among the three taxa of *Dirca*. For the three primers used in both studies, the three species of *Dirca* had nearly double the percentage of polymorphic loci and taxon-specific loci of those seen among the three subspecies of *Alnus maritima* (Marsh.) Muhl. ex Nutt. (Table 2). The differentiation revealed in the number of taxon-specific loci found among the three species of *Dirca* was consistent with the

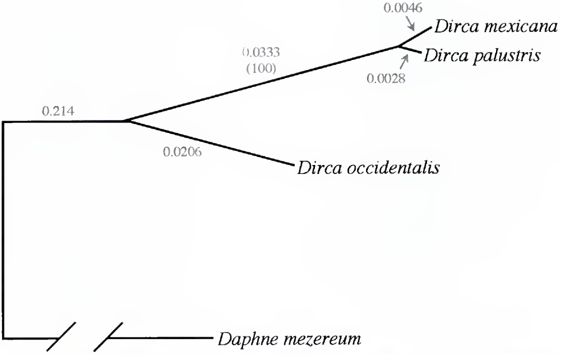

Fig. 1. ITS neighbor-joining dendrogram showing the inferred phylogenetic relationship among the three species of *Dirca*. Topology indicates that of the single most-parsimonious tree. Numbers indicate relative branch lengths; numbers in parentheses are both the bootstrap and jacknife percentages, which were identical. *Dahne mezereum*, another member of Thymelaeaceae, was used as the outgroup in order to establish ancestral-character polarity of the ITS sequence.

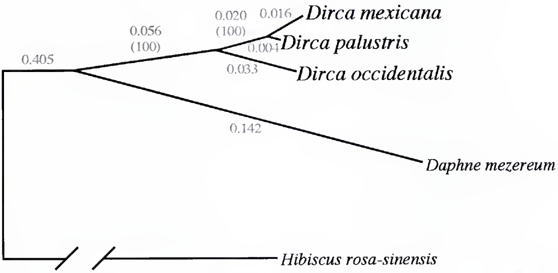

Fig. 2. ITS neighbor-joining dendrogram showing the inferred phylogenetic relationship among the three species of *Dirca* and another member of Thymelaeaceae, *Dahne mezereum*. Topology indicates that of the single most-parsimonious tree. Numbers indicate relative branch lengths; numbers in parentheses are both the bootstrap and jacknife percentages, which were identical. *Hibiscus rosa-sinensis*, another member of Order Malvales, was used as the outgroup to establish ancestral-character polarity of the ITS sequence.

Table 2. Percentage of polymorphic loci and percentage and number of taxon-specific bands resolved by using three (*Dirca* and *Alnus*) and eight (*Dirca*), 3'-anchored ISSR primers. Results for *Dirca* are from the present study; results for *Alnus* were obtained by Schrader and Graves (2004) by using the same methods and three of the same primers as the present study.

	Primers				
	$(CA)_6RG$	$(AG)_8YT$	$(AC)_8G$	Three primers	All eight primers
% of polymorphic loci					
Dirca species	87	95	88	90	83
Alnus maritima subspecies	41	55	46	48	
% Taxon-specific loci					
Dirca species	52	73	47	57	55
Alnus maritima subspecies	15	31	14	22	
# Taxon-specific loci					
Dirca mexicana	7	17	13	37	112
Dirca palustris	9	10	6	25	67
Dirca occidentalis	16	16	11	43	164
Alnus maritima					
subsp. *oklahomensis*	1	3	0	4	
subsp. *georgiensis*	0	1	2	3	
subsp. *maritima*	2	4	0	6	
Alnus japonica	9	16	12	37	

species-level differentiation in taxon-specific loci of the outgroup *Alnus japonica* (Thunb.) Steud. for each and all primers and was over four times that shown among the subspecies of *A. maritima*. Further evidence of species-level divergence was revealed by analysis of the genetic distances between the taxa (Table 3). The distance between the least divergent pair, *D. mexicana* and *D. palustris*, (103) is over five times greater than that of the most divergent subspecies of *A. maritima* (19).

After an exhaustive search, phylogenetic analysis of ISSR data produced a single most-parsimonious tree of 813 evolutionary steps (Fig. 3), and bootstrap and jacknife percentages (100% for both) showed very strong support for this topology. Consistent with the ITS results, ISSR data verified that *D. occidentalis* was the first of the three *Dirca* species to diverge (Fig. 3). Euclidean distances between species based on data from all eight primers were 410 for *D. occidentalis* and *D. palustris*, 392 for *D. occidentalis* and *D. mexicana*, and 302 for *D. palustris* and *D. mexicana*. These genetic distances and branch lengths derived from ISSR markers showed greater relative distance between *D. mexicana* and *D. palustris* than obtained from ITS, indicating a more uniform level of divergence among the three species (Fig. 3). Although divergence was shown to be more uniform,

Table 3. Comparative Euclidean distances for species (*Dirca*) and subspecies (*Alnus maritima*) obtained by the same methods and same three ISSR primers. Results for *Alnus maritima* were derived from Schrader and Graves (2004).

	Euclidean distances
Species level (*Dirca*)	
Dirca mexicana – Dirca occidentalis	110
Dirca mexicana – Dirca palustris	103
Dirca occidentalis – Dirca palustris	119
Subspecies level (*Alnus maritima*)	
oklahomensis – georgiensis	15
oklahomensis – maritima	19
georgiensis – maritima	12

ISSR results confirmed that *D. mexicana* and *D. palustris* are the most closely related of the three species. Our unweighted, simultaneous analysis of ITS and ISSR data (Fig. 4) shows the best synthesis for the phylogeny of *Dirca* based on all available molecular evidence.

DISCUSSION

Based on the results of ITS alone, we might conclude that *Dirca mexicana* and *D. palustris* could best be considered as the same species, a conclusion that would contradict the morphological evidence of Nesom and Mayfield (1995). With ITS, the mean genetic distance from *D. occidentalis* to these two species is nearly eight times greater than the distance between *D. mexicana* and *D. palustris*, and the neighbor-joining phylogeny, produced when using generic-level ancestral character as the root, illustrates how closely related the ITS regions of *D. mexicana* and *D. palustris* are to each other (Fig. 1). Results of ISSR analysis, however, provide conclusive evidence that *D. mexicana* and *D. palustris* have diverged sufficiently to be considered separate species, and they indicate that divergence of the three species is more uniform than indicated by ITS analysis (Table 2 and 3, Fig. 3). Although a suitable explanation for the seemingly contradictory levels of divergence indicated by ITS and ISSRs could be that different genetic markers may be differentially affected by occurrences such as interspecific gene flow or reticulate evolution (Comes & Abbott 1999), a more obvious explanation can be found in a closer examination of the two ITS phylogenies. Including family-level ancestral character (outgroup *H. rosa-sinensis*) in the analysis led to two important insights. First, there is a high degree of differentiation (long branch length) of *D. occidentalis* and *D. mezereum* that is evident after their divergence (Fig. 2), and this differentiation skews the tree produced by using *D. mezereum* as the outgroup (Fig. 1) causing *D. mexicana*

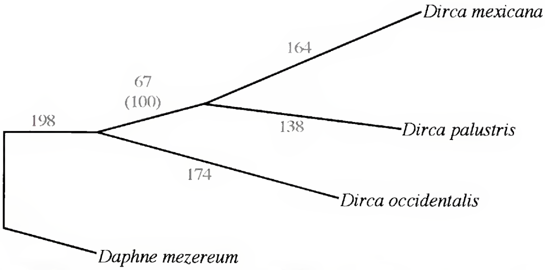

Fig 3. ISSR neighbor-joining dendrogram showing the inferred phylogenetic relationship among the three species of *Dirca*. Topology indicates that of the single most-parsimonious tree. Numbers indicate relative branch lengths; numbers in parentheses are both the bootstrap and jacknife percentages, which were identical. *Dahne mezereum*, another member of Thymelaeaceae, was used as the outgroup to establish ancestral-character polarity of ISSR banding patterns.

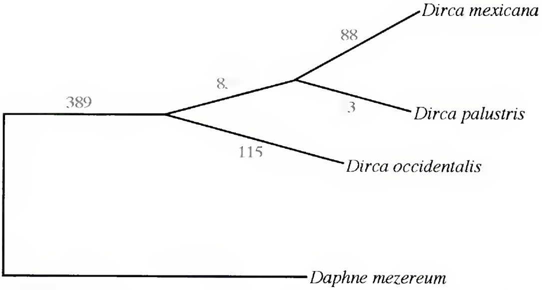

Fig. 4. Simultaneous ITS and ISSR neighbor-joining dendrogram using unweighted Kimura and Euclidean distances, respectively. *Dahne mezereum*, another member of Thymelaeaceae, was used as the outgroup to establish ancestral-character polarity.

and *D. palustris* to be placed further from *D. occidentalis* than they would be otherwise. Secondly, the phylogeny produced with family-level ancestral character in the root corrects for this disproportional differentiation and shows a more uniform species-level divergence between the three *Dirca* species, making the phylogeny more consistent with the results of the ISSRs. Together, the ISSR and ITS analyses support the species designation for *D. mexicana* established by Nesom and Mayfield (1995). These results also reinforce the principle that more than one genetic marker should be used in molecular systematics investigations (Hollingsworth et al. 1999) and that analysis of cross-matrix disparity can be a valuable method of clarifying phylogenetic features (Bateman 1999).

Contrary to the morphological evidence, both ITS and ISSR analyses indicate that *Dirca mexicana* is more closely related, genetically, to *D. palustris* than it is to *D. occidentalis*. This finding, and the findings that *D. occidentalis* was both the first of its genus to diverge and the most differentiated of the three species (Figs. 1–4), help to explain the apparent inconsistency between the morphological and biogeographical evidence noted by Nesom and Mayfield (1995). Although there is a greater morphological similarity between *D. mexicana* and *D. occidentalis*, they are the most divergent of the three species genetically (Figs. 1–4). These findings are consistent with the hypothesis of Nesom and Mayfield (1995) based on biogeography, that *Dirca* was probably continuous across North America as early as the Eocene, and disjunction between *D. occidentalis* and *D. palustris* may have taken place before or around the same time as the movement of *Dirca* into Mexico. This hypothesis seems especially well supported by our ITS and simultaneous phylogenies (Figs. 1, 2, and 4).

The typical ecological niche for the genus *Dirca* is considered to be the cool moist slopes of mature temperate deciduous forests. Both *D. palustris* and *D. mexicana* are found almost exclusively in such settings, and even though it has adapted to a different environment, *D. occidentalis* is struggling to survive amidst a drying climate, removal of overstory trees, and competition from evergreen trees and shrubs (Johnson 1994; Graves 2004). As mentioned by Nesom and Mayfield (1995), paleobotanical evidence suggests that *Dirca* was continuous across the midlatitudes of North America as part of the Eocene/Oligocene expansion of temperate deciduous vegetation that took place after the partial regression of the Cretaceous epeiric sea (Graham 1993). In fact, members of Thymelaeaceae are documented in the late Eocene flora of central Colorado (MacGinitie 1953; Graham 1993). In geologic time, this extensive range was probably short lived. Cooling during the middle Miocene brought the encroachment of coniferous forests from the north (Leopold & Denton 1987), and by the middle to late Miocene, colder winter temperatures and reduced summer rainfall in the area of the Great Plains had initiated the development of prairie grasslands (Graham 1993). While climatic cooling brought the isolation of eastern and western deciduous forests and, most likely, the eastern and western representatives of *Dirca*, it also enabled the movement of eastern deciduous forest element into eastern Mexico following rapid southward retreat of the lingering Mississippi Embayment by the middle to late Miocene (Graham 1973, 1993). Finally, the precursors to modern *D. palustris* and *D. mexicana* probably became disjunct as prairie and coniferous communities in western and southwestern North America spread during the Pliocene and elements of the broad-leaved deciduous forest that had extended into eastern Mexico became isolated (Graham 1973, 1993).

One phenotypic manifestation of the high level of differentiation seen in *D. occidentalis* is its obligate summer dormancy. Only *D. occidentalis* undergoes this drought-deciduous summer dormancy, which coincides with the dry season in the San Francisco Bay area. Trials we have conducted in a greenhouse indicate that this annual phenological event cannot be overcome by manipulation of the environment. The absence of this drought-deciduous trait in the other two species of *Dirca*, and, to the best of our knowledge, the rest of Thymelaeaceae, suggests that considerable change has taken place in *D. occidentalis* since its divergence to ensure survival in its Mediterranean climate (Freitas 1997). Such adaptation is the most plausible explanation for the continued existence of this disjunct species of *Dirca*. Without a means of drought avoidance, it is likely that the precursors of *D. occidentalis* would have expired along with the rest of the western *Dirca* element as western climates became increasingly dry. It is believed that during the Pliocene, the Cascade-Sierra Nevada and the Coast Ranges reached sufficient heights to create an effective rain shadow over the Basin and Range Province, resulting in a change from mesic and summer-wet to the xeric and summer-dry conditions that exist today (Axelrod 1986; Graham 1993). This trend most likely forced *D. occidentalis* into its meager coastal distribution, while promoting selection of the summer-deciduous habit.

The lower level of differentiation in *Dirca palustris* revealed by all four phylogenetic dendrograms should be considered consistent with its much larger potential gene pool and, until recently, its fairly uniform habitat. Because the fundamental niche of *D. palustris* is mature-forest understory, it is likely that, except for the temporary intrusion of glaciers and their adjacent boreal forest biome (Delcourt & Delcourt 1993), the genetic aggregate of *D. palustris* was continuous across eastern North America until the harvest of old-growth forests within the last 300 to 400 years. Future examination of the genetic variation within *D. palustris* should be performed to test this hypothesis and to provide an even clearer picture of the systematics of genus *Dirca*.

ACKNOWLEDGMENTS

We thank Gary Polking and the staff of the DNA Sequencing and Synthesis Facility at Iowa State University for their assistance with ITS and ISSR processing. We are grateful to Dr. Mark Widrlechner for his helpful critique of the manuscript and to Susan Benner and Fredy Romero for assistance with translation of the abstract to Spanish.

ABSTRACT

The new combinations *Gentianopsis detonsa* subsp. *nesophila* and *G. virgata* subsp. *macounii* are published, bringing infraspecific classification into accord with the currently accepted names for the respective species.

RESUMEN

Las nuevas combinaciones *Gentianopsis detonsa* subsp. *nesophila* y *G. virgata subsp. macounii*, son publicadas trayendo la clasificación infraspecific de acuerdo con los nombres actualmente aceptados para las respectivas especies.

The fringed-gentian genus *Gentianopsis* Y.C. Ma is represented in North America north of Mexico by *G. barbellata* (Engelm.) H.H. Iltis and *G. simplex* (A. Gray) H.H. Iltis, which are believed to be relatively distantly related to the other North American species, and by two complexes (sensu Bouillé and Bousquet 1999) for which classifications have varied. These complexes correspond, respectively, to the taxa designated *Gentianella detonsa* (Rottb.) G. Don and *G. crinita* (Froel.) G. Don by Gillett (1957). Recent authors on *Gentianopsis* have generally adopted less inclusive species concepts.

In the *Gentianopsis detonsa* complex in North America the calyx keels are smooth and are suffused with purple. Branches often arise at or near the base of the main stem, except in *G. macrantha* (D. Don ex G. Don) H.H. Iltis. The basal rosettes of leaves are usually persistent at flowering time, and the cauline as well as the basal leaves are obtuse except in *G. detonsa* (Rottb.) Y.C. Ma subsp. *detonsa*. The peduncles are relatively long, those terminating the primary stems often being longer than the stems. Three western taxa in this complex are separated from each other geographically, viz. *G. macrantha*, *G. holopetala* (A. Gray) H.H. Iltis, and *G. thermalis* (Kuntze) H.H. Iltis. They have usually been treated as species in recent literature, although *G. thermalis* is sometimes included in *G. detonsa* as var. *elegans* (A. Nels.) N.H. Holmgren. Some recent as well as earlier authors have treated the remaining North American taxa in this complex as two or three species; others have included all of them in *G. detonsa*.

---

[1] Contribution No. 125 from the Royal Botanical Gardens, Hamilton, Ontario, Canada.

Within *G. detonsa*, three geographic races in North America north of Mexico have usually been accepted as subspecies since they were first so treated by Gillett (1957), viz. subsp. *detonsa*, subsp. *raupii* (A.E. Porsild) Á. Löve & D. Löve, and subsp. *yukonensis* (J.M. Gillett) J.M. Gillett. A fourth taxon, subsp. *nesophila*, is the only representative of this complex in eastern North America. It has more often been treated as a separate species, but neither in the transfer of the epithet to *Gentianopsis* (Iltis 1965) nor in any of the works in which the name *Gentianopsis nesophila* (Holm) H.H. Iltis has been employed has the rank appropriate for this taxon been discussed. Some recent authors, e.g. Blaney and Kotanen (2001), have simply included the taxon *nesophila* in *Gentianopsis detonsa* s. lat., there being no nomenclatural combination under *G. detonsa* by which it could be distinguished.

Subspecies *raupii* is notably variable in vegetative morphology. Plants in some populations approach subsp. *nesophila* in leaf shape and width, as noted by Gillett (1957) and in my studies, whereas other plants are more similar to subspp. *detonsa* and *yukonensis*. Conversely, plants of subsp. *nesophila* from the shores of James Bay sometimes approach subsp. *raupii*. Reports of subsp. *raupii* as a taxon rare in or perhaps extirpated from Ontario (Gillett & Keddy 1983) are based on three specimens from the shores of Hudson and James bays so identified by Gillett in 1957. All of these specimens have also, at times, been identified as *nesophila*. Boivin (1972) commented that they "have the shorter flowers and broader leaves" of *nesophila* and reidentified them accordingly. In my examination of these specimens I found that all three conform to the morphology of subsp. *nesophila*, and differ from that of subsp. *raupii*, in having corolla lobes distinctly less than half as long as the tube, with the margins subentire or merely toothed rather than fringed proximally. Two of these collections, *Dutilly & Lepage 16925* and *Lepage 31666* (both DAO), resemble subsp. *raupii* vegetatively in having fewer leaves than is usual in subsp. *nesophila*, but the third, *Spreadborough 9 Aug 1904* (CAN), fits well within the range of variation of subsp. *nesophila* in all respects. It was reidentified as *nesophila* by Gillett in 1979 (annotation). Cody (1971) and Porsild and Cody (1980) considered subsp. *raupii* to be endemic to the watershed of the Mackenzie and Slave rivers in the Northwest Territories and northern Alberta. In accord with their interpretation, I include all plants of *G. detonsa* s. lat. in the saline coastal meadows on the James and southern Hudson Bay shores in subsp. *nesophila*, rather than treating occasional plants as subsp. *raupii*, i.e., as geographically remote and ecologically anomalous occurrences of a different taxon, within the range and habitat of subsp. *nesophila*.

Subspecies *nesophila* is usually less similar in aspect to subspp. *detonsa* and *yukonensis* than to subsp. *raupii*. Among plants of comparable stature, those of subsp. *nesophila* are more often branched from the base, and the basal and proximal cauline leaves are generally wider, more numerous, and more closely spaced than those of subspp. *detonsa* and *yukonensis*. Also, as noted above, the corolla lobes of subsp. *nesophila* are less than half as long as the tube, whereas in the other subspecies they are more than half as long. Gillett (1957) observed, however, that occasional plants of subsp. *nesophila* from Newfoundland "resemble the typical subspecies [*detonsa*] rather closely." Conversely, some specimens of subsp. *detonsa*, e.g. *Ull 30 August 1987* (CAN) from the shore of Kotzebue Sound, Alaska, and some from Iceland (seen at GH), have a leafy aspect approaching that of subsp. *nesophila*.

Subspecies *nesophila* shares with subsp. *raupii* (while thus differing from subspp. *detonsa* and *yukonensis*) the combination of the calyx abruptly constricted at the base, all four calyx lobes nearly equal in length, a distinctly obconic rather than nearly cylindric corolla tube, proportionately wide corolla lobes with rounded rather than subacute apices, and seed coats with the papillae relatively large and distributed over the whole surface rather than being restricted to the ends (Gillett 1957, 1963). In these respects subsp. *raupii* is more similar to subsp. *nesophila*, from which it is relatively often separated at species rank, than to subsp. *detonsa* or subsp. *yukonensis*, with which it is usually treated as conspecific. The similarities between the taxa *nesophila* and *raupii* were recognized by Toyokuni (1967–1968), who treated them as one species, *G. nesophila*, comprising subsp. *nesophila* and subsp. *raupii* (A.E. Porsild) Toyok., and treated residual *G. detonsa* as another species. Nevertheless, despite the differences in morphology between most plants of *G. detonsa* subspp. *detonsa* and *yukonensis* and those of the *nesophila/raupii* group, the separation of the latter group at species rank does not seem appropriate when *G. detonsa* s. lat. is considered more thoroughly. As noted above, some plants of both subsp. *nesophila* and subsp. *raupii* approach subsp. *detonsa* in vegetative morphology. Subsp. *yukonensis* appears intermediate between subsp. *raupii* and subsp. *detonsa*, with some plants of subsp. *yukonensis* approaching each of those subspecies in morphology. I am, therefore, following Gillett (1957, 1963), Scoggan (1979), and Riley and McKay (1980) in including the taxon *nesophila* among the subspecies of *G. detonsa*, retaining the rank of subspecies that currently prevails in treatments of North American *Gentianopsis*. This requires the following transfer to *Gentianopsis*:

Gentianopsis detonsa subsp. **nesophila** (Holm) J.S. Pringle, comb. nov. BASIONYM: *Gentiana nesophila* Holm, Ottawa Nat. 15:111. 1901. *Gentianella detonsa* subsp. *nesophila* (Holm) J.M. Gillett, Ann. Missouri Bot. Gard. 44:216. 1957; *Gentianopsis nesophila* (Holm) H.H. Iltis, Sida 2:134. 1965; *Gentiana detonsa* var. *nesophila* (Holm) B.Boivin, Nat. Canad. 93:1060. 1966. TYPE: CANADA: QUÉBEC: Anticosti Island, near Salt Lake, *Macoun s.n.*, 9 Aug 1883 (HOLOTYPE: CAN!; photo DAO!).

In the *G. crinita* complex the calyx keels are generally minutely granular- or papillate-scabridulous proximally as seen at 50×, and may or may not be suffused with purple. Branching from the base of the main stem occurs occasionally in *G. virgata* subsp. *macounii* but is otherwise rare. The basal rosettes are often withered by flowering time, and the apices of the cauline leaves are acute to acuminate. Peduncle length varies, often being relatively long in *G. virgata* subsp. *macounii* but otherwise generally being proportionately shorter than in the *G. detonsa* complex. The *G. crinita* complex is predominantly eastern, although the range of *G. virgata* subsp. *macounii* extends west to the Northern Rocky Mountains. Chromosome counts for North American *Gentianopsis* remain few, but a difference in base number formerly thought to exist between the *G. crinita* and *G. detonsa* complexes now seems unlikely.

Gentianopsis crinita (Froel.) Y.C. Ma s. str. is distinguished by its combination of ovate to lanceolate leaves and corolla lobes that are fringed around the apex as well as laterally. In recent literature it has usually been treated as a species separate from the other components of the complex. The remaining taxa in this complex have narrowly lanceolate to linear leaves and corolla-lobe margins that are erose to dentate distally and fringed only laterally if at all. As with *G. detonsa* s. lat., some recent authors have recognized more than one species within this group, whereas others have treated these plants as a single species.

Bouillé and Bousquet (1999) found little divergence in nuclear ribosomal DNA internal transcribed spacers between *G. crinita* s. str. and the rest of this complex, in contrast to the greater divergence between taxa in the *G. crinita* complex and *G. detonsa* subsp. *nesophila*. They found no divergence at all among the other taxa in the *G. crinita* complex. They treated the *G. crinita* complex as a single species, *G. crinita*, consisting of subsp. *crinita* and subsp. *procera* (Holm) Á. Löve & D. Löve. Taxonomic recognition of the other entities was rejected. In more recent years, however, the appropriateness of nrDNA ITS as a genetic marker in the context of the circumscription of species and subspecies has increasingly been questioned. The taxa *virgata* s. str. (*procera* s. str.), *macounii*, and *victorinii* have diverged morphologically to the extent that they have consistently been recognized taxonomically for over 80 years, and they have become subjects of conservation concern. Presumably they have diverged in their DNA as well, even if not specifically in the nr ITS. I consider it appropriate, therefore, to maintain their taxonomic recognition.

Although *G. crinita* s. str. is less strongly divergent from the rest of the *G. crinita* complex than from the *G. detonsa* complex, I am treating *G. crinita* s. str. and *G. virgata* s. lat. as two species, in accord with most of the recent floras in which these species are included (e.g. Gleason & Cronquist 1991; Cooperrider 1995; Voss 1996; Wetter et al. 2001). This permits the continued recognition of the taxa *macounii* and *victorinii* as subordinate taxa within *G. virgata*, as was done by Iltis (in Mason & Iltis 1966) and Cronquist (in Gleason and Cronquist 1991, in both cases under *G. procera*), and by Lammers (2004) in the case of *G. virgata* subsp. *victorinii* (Fernald) Lammers. Morphological considerations do not support the recognition of *macounii* and *victorinii* as species. Both are similar to *G. virgata* subsp. *virgata* in morphology as well as in nrDNA ITS. Intergradation between the two wide-ranging subspecies, *virgata* (*procera*) and *macounii*, was noted by Gillett (1957) and Iltis (1965) and in my own studies.

Gentianopsis virgata has often been called *G. procera* (Holm) Y.C. Ma; on its nomenclature see Pringle (2003). When *G. virgata* is circumscribed as recommended above, one new combination under that specific epithet is required:

Gentianopsis virgata subsp. **macounii** (Holm) J.S. Pringle, comb. nov. BASIONYM: *Gentiana macounii* Holm, Ottawa Nat. 15:110. 1901. *Gentianella crinita* subsp. *macounii* (Holm) J.M. Gillett, Ann. Missouri Bot. Gard. 44:228. 1957; *Gentianopsis macounii* (Holm) H.H. Iltis, Sida 2:136. 1965; *Gentianopsis procera* subsp. *macounii* (Holm) H.H. Iltis, Trans. Wisconsin Acad. Sci. 54:315. 1966; *Gentianopsis crinita* subsp. *macounii* (Holm) Á. Löve & D. Löve, Taxon 31:352. 1982. LECTOTYPE (Gillett 1957): CANADA: ALBERTA: Lees Creek, Cardston, *Macoun s.n.*, 25 Jul 1895 (HOLOTYPE: CAN!; photo DAO!).

TAXONOMY OF THE POLEMONIACEAE: *GILIA* AND *LATHROCASIS*

Verne Grant

Section of Integrative Biology and Plant Resources Center
University of Texas at Austin
Austin, Texas 78712, U.S.A.

ABSTRACT

The infrageneric classification of *Gilia* is reviewed and revised on the basis of numerous phenetic and some molecular characters and by using a taxonomic approach. The result is a broadly defined multisection genus *Gilia* composed of two subgenera and seven sections (sects. *Gilia, Arachnion, Saltugilia, Giliastrum, Giliandra, Gilmania, Campanulastrum*), and a monotypic segregate genus (*Lathrocasis*). This system is compared with that of Porter and Johnson (2000) based primarily on molecular evidence and a cladistic approach. The two systems agree in some dispositions; in fact, the present system follows Porter and Johnson in recognizing *Lathrocasis*; but in other respects the two systems differ greatly. For example, the core genus *Gilia* is divided into six smaller genera in addition to *Lathrocasis* by Porter and Johnson. Basic differences between taxonomic and molecular cladistic approaches lead to the incongruences between alternative systems found here and elsewhere in the Polemoniaceae and in other plant families. These differences are discussed. A weakness of molecular cladistics is the attempt to classify groups by using DNA evidence primarily or exclusively. Better results can be obtained by combining the molecular characters with phenetic characters. There is a continuing need for new taxonomic revisions in the Polemoniaceae and other families that do this.

Key Words: Cladistics, *Gilia*, *Lathrocasis*, molecular systematics, Polemoniaceae, taxonomy

RESUMEN

Se revisa la clasificación infragenérica de *Gilia* en base a numerosos caracteres fenéticos y algunos moleculares, usando una aproximación taxonómica. El resultado es el género multisección ampliamente definido *Gilia* compuesto de dos subgéneros y siete secciones (sects. *Gilia, Arachnion, Saltugilia, Giliastrum, Giliandra, Gilmania, Campanulastrum*), y un género monotípico segregado (*Lathrocasis*). Este sistema se compara con el de Porter y Johnson (2000) basado primariamente en pruebas moleculares y una aproximación cladística. Los dos sistemas concuerdan en algunas disposiciones; de hecho, el presente sistema sigue a Porter y Johnson en el reconocimiento de *Lathrocasis*, pero en otros aspectos los dos sistemas difieren enormemente. Por ejemplo, el núcleo del género *Gilia* se divide en seis géneros más pequeños en adición a *Lathrocasis* según Porter y Johnson. Las diferencias básicas entre la aproximación taxonómica y la cladística molecular dan lugar a incongruencias entre sistemas alternativos como se encuentra aquí y en otros estudios sobre Polemoniaceae así como en otras familias. Se discuten estas diferencias. Un punto débil de la cladística molecular es el intento de clasificar grupos usando primaria o exclusivamente DNA. Se pueden obtener mejores resultados combinando caracteres moleculares con caracteres fenéticos. Hay una necesidad creciente de nuevas revisiones taxonómicas en las Polemoniaceae y otras familias de igual comportamiento.

INTRODUCTION

In the nineteenth century, *Gilia* was treated as a catchall genus for the temperate herbaceous Polemoniaceae that did not fit into the well-defined genera *Polem-*

SIDA 21(2): 531–546. 2004

onium, *Phlox*, and *Collomia*. *Gilia* in that era was consequently very heterogeneous and was subdivided into numerous sections (Bentham & Hooker 1873–1876; Gray 1886; Peter 1897).

In the early twentieth century as the plants became better known morphologically and in the field, it became apparent that many of these sections were only remotely related to one another. Milliken (1904) started the process of reclassification by segregating *Navarretia* and *Linanthus* from *Gilia*. Her *Gilia* remained heterogeneous with six subgenera. Subsequent authors continued the process of pruning by spinning off *Eriastrum*, *Leptodactylon*, *Allophyllum*, *Ipomopsis*, etc. as separate genera, while retaining a polymorphous core genus *Gilia*.

Grant's (1959) treatment recognized a core genus *Gilia* composed of five interrelated sections (sects. *Giliastrum*, *Giliandra*, *Gilia*, *Arachnion*, *Saltugilia*). Section *Giliastrum* has been subdivided subsequently into two or three smaller sections (Grant 1999) (Table 1).

In 1959 I thought that the disparate elements had all been removed from *Gilia*, and Alva Day thought so too, but this was not the case. In later studies using pollen-morphological characters, Day (1993a, b) found a small group of species in *Gilia* sect. *Saltugilia* (the *G. leptalea* group) that did not belong in *Gilia*. It was not clear in 1993 where these species did belong. Day placed them in a section *Kelloggia* of *Gilia* for holding purposes, and later she and I transferred them to *Allophyllum* (Grant & Day 1999).

All these groupings and regroupings were made by taxonomists working within the conceptual framework of traditional or evolutionary taxonomy, using numerous phenetic characters, and changing the system gradually and progressively. In the year 2000, Porter and Johnson published a radically different classification of the *Gilia* complex and of the family as a whole. Their system was arrived at by the approach of molecular cladistics; they used DNA sequence variation in selected organellar genes as evidence, and interpreted this evidence according to cladistic concepts.

In the Porter and Johnson (2000) system, the genus *Gilia* of Grant (1959, 1999) is broken up into seven genera, as shown in Table 1. With regard to one species group, the former *Gilia leptalea* group, both parties agree that it should come out of *Gilia*, but do not agree on where to put it (Table 1). The new monotypic genus *Lathrocasis* was set up for *Gilia tenerrima* (Porter & Johnson 2000); I did not at first accept *Lathrocasis* but do so now in this paper (Table 1). The genus *Gilia* of Porter and Johnson (2000) consists of *Gilia* sects. *Gilia* and *Arachnion* plus part of *Gilia* sect. *Saltugilia*. And their genus *Gilia* is separated at the tribal level from the other sections of *Gilia* (from *Gilia* subg. *Greeneophila*).

How do we explain the large differences between the two contemporaneous and up-to-date classifications of *Gilia* s. l.? Porter and Johnson (Johnson et al. 1996; Porter 1998; Porter & Johnson 2000) claim that *Gilia* s. l. is polyphyletic; their subdivided system is intended to correct the situation. I have argued

TABLE 1. Comparison of two current classifications of *Gilia* and certain gilioid taxa.

Grant system (1999, 2001, this paper)	Porter and Johnson system (2000)	Tribe in PJ system
Gilia* subgen. *Gilia

elsewhere (Grant 2001, 2003a, b) that the claim of polyphyly is not supported by the evidence, except in the *Gilia leptalea* group. The polyphyly issue will be discussed again later in this paper.

The difference between the alternative treatments of the *Gilia* complex can be adequately explained as a result of using the very different approaches of taxonomy and cladistics. The differences in working concepts and methods can be summarized briefly here (see Grant 2003a for review). First, the systematic units of taxonomy are similarity groups or taxa, those of cladistics are inferred phyletic lineages or clades. Second, taxonomy uses a traditional definition of monophyly: any group descended from a close common ancestor; whereas cladistics defines monophyly as a group consisting of **all** the descendants of the common ancestor. A given group can be monophyletic by the taxonomic definition but non-monophyletic by the cladistic definition.

Third, taxonomy employs any and all characters that are useful in distinguishing taxa. Phenetic cladistics sets some restrictions on the characters used. Molecular cladistics uses one or a few preselected DNA segments; the data are valuable but the database is very narrow. Fourth, taxonomy and molecular cladistics sample different parts of the overall genomes. The phenetic characters used in taxonomy are expressions of the chromosomal genome. The organellar DNA used in molecular cladistics is cytoplasmic in origin in the case of chloroplast and mitochondrial genes and is encoded in a special kind of chromosome site in the case or ribosomes.

Finally, there is always a subjective element when a cladogram is transformed into a system of taxa. Is a given clade going to be treated as a genus or a section?

These factors inevitably bring about some differences between taxonomic and molecular cladistic systems of the same plant group. They account for the differences in the tribal classification of the Polemoniaceae of Porter and

Johnson (2000) and Grant (2003b). And they will explain most of the differences in the treatment of the *Gilia* complex.

This brings us to the next question. In cases of incongruence between taxonomic and molecular cladistic systems of classification, which system comes closest to the goal of expressing natural or phylogenetic relationships? The short answer is: sometimes one system or approach, sometimes the other.

I have found the following modes in comparisons of taxonomic with molecular cladistic systems in the Polemoniaceae and other plant groups. (1) Each system is acceptable by its own standards. (2) A cladistic author applies the cladistic definition of monophyly to a taxonomic system which is natural by the taxonomic definition of monophyly, and the cladistic author then falsely accuses the taxonomic treatment of being non-monophyletic. (3) The molecular cladograms reveal a relationship which taxonomists had not noticed and which leads to a desirable revision in the taxonomy. (4) The DNA evidence is in conflict with a pattern of variation in reliable phenetic characters. This is likely to occur when the DNA evidence is derived from cytoplasmic organelles, especially chloroplasts, which are semi-independent of the chromosomal genome which determines most taxonomic characters. A chloroplast DNA cladogram may give a very distorted picture of the organismic relationships in a plant group.

Many plant groups have been studied with respect to both DNA markers and morphological or other phenetic characters. Sometimes the two kinds of characters are in agreement, sometimes they are not, and the latter situation is common. Rieseberg et al. (1996) list 34 seed plant genera in which discordance is found between DNA markers and phenetic characters. The type of DNA that is most common in the list of unreliable markers is chloroplast DNA. Unreliable chloroplast markers are found for example in: *Helianthus* (Rieseberg 1991; Rieseberg et al. 1991), *Quercus* (Whittemore & Schaal 1991), *Eucalyptus* (McKinnon et al. 1999), and *Gossypium* (Cronn et al. 2002).

In *Helianthus* (Rieseberg 1991; Rieseberg et al. 1991), *Quercus* (Whittemore & Schaal 1991), *Gossypium* (Cronn et al. 2002), and *Phlox* (Ferguson & Jansen 2002) it is possible to compare the reliability of chloroplast DNA with that of ribosomal DNA. In each case ribosomal DNA is more concordant with phenetic character variation than chloroplast DNA is.

The various sources of incongruence between taxonomic and molecular cladistic systems, listed above, all occur in the *Gilia* complex and other Polemoniaceae. Examples will be given in this paper.

Old taxonomic treatments are currently being revised by cladistic, mainly molecular cladistic, methods, but cladistic systems are not always right. There is a continuing need for up-to-date taxonomic treatments. Such treatments provide a choice for those who use classifications. With this goal in mind, I have recently revised and updated the tribal classification of the Polemoniaceae (Grant 2003b), and am doing the same here for the genus *Gilia*.

MATERIALS AND METHODS

I assembled as many characters as I could that distinguish major subgroups in *Gilia* s. l. These are mostly gross morphological features but also micromorphological or biochemical.

Among the microscopic characters that are useful in *Gilia* is corolla venation. The lower part of the corolla in *Gilia* has five sets of veins, one set for each corolla lobe, and each set has three parallel veins. The veins of a set branch above or distally. In some sections of the genus, the veins remain separate distally, while in other sections they anastomose distally (Day & Moran 1986; Day, pers. comm.).

The flavonoids in the genus fall into three groups, designated as types A, B, and C, and these types vary among the sections (Smith et al. 1977). Type A flavonoids are kaempferal, quercitin, and myricetin; type B is 6-methoxyflavonal; and type C is C-glycosylflavone (Smith et al. 1977).

A number of studies of DNA sequence variation have been made in the Polemoniaceae (listed in Porter & Johnson 2000; and Grant 2003b. For the purpose of this study I used mainly the papers of Johnson et al. (1996), Porter (1997, 1998), and Johnson and Weese (2000) which have the best coverage of the *Gilia* complex. Johnson et al. present cladograms of cpDNA *matK*, Porter of rDNA ITS, and Johnson and Weese of rDNA ITS, *cpDNA trnL*, and *matK*.

Recently Johnson et al. (2004) have published a survey of the fine structure of the seed coat in *Gilia* and related genera (see their SEM photographs).

The descriptions in the formal classification consist mainly of diagnostic characters. These serve to show the evidence supporting the classification. Good complete descriptions are given by Porter and Johnson (2000).

ANALYTICAL KEY TO THE MAIN GROUPS OF *GILIA* AND *LATHROCASIS*

1. Glandular hairs with tiny black tips; pollen white; seeds one per locule in capsule ________ Genus **Lathrocasis**
1. Glandular hairs where present with amber or colorless terminal glands; pollen blue, yellow or cream; seeds generally several or many per locule in capsule ________ Genus **Gilia**
  2. Pollen blue; stamens inserted in sinuses of corolla lobes; annuals ________ **Gilia** subgen. **Gilia**
    3. Pubescence of long fine intertwined white cobwebby hairs; stipitate glandular hairs often present also ________ **Gilia** sect. **Arachnion**
    3. Cobwebby pubescence not present, pubescence consisting of multicellular trichomes and stipitate glandular hairs.
      4. Plants scapose ________ **Gilia** sect. **Saltugilia**
      4. Plants not scapose, cauline leaves ranging from large on lower stems to small on upper stems ________ **Gilia** sect. **Gilia**
  2. Pollen generally yellow or cream, but blue in one species; stamens inserted in corolla tube, throat, or sinuses; perennials and annuals ________ **Gilia** subgen. **Greeneophila**
    5. Plants usually branching from base with stems spreading, but sometimes single-stemmed; corolla generally campanulate or rotate; seeds mucilaginous when wet.
      6. Small annuals with wiry stems and small flowers ________ **Gilia** sect. **Campanulastrum**
      6. Perennials and some annuals; flowers showy or small ________ **Gilia** sect. **Giliastrum**

5. Plants scapose with a basal rosette and a central leader stem, corolla funnelform or sometimes trumpet-shaped; seeds not mucilaginous when wet or only slightly so.
    7. Lower leaves pinnate with a broad strap-shaped rachis and short lobes ____ **Gilia** sect. **Giliandra**
    7. Lower leaves with a broad blade and lobed margin, the lobes sharp-tipped ____ **Gilia** sect. **Gilmania**

CLASSIFICATION

Genus 1. Gilia Ruiz & Pavon, Prod. Fl. Peruv. 25, t. 4. 1794. Type: *Gilia laciniata* Ruiz & Pavon

Herbaceous perennials, biennials, or annuals, sometimes with a woody or soft woody base. Basal leaves well developed and upper cauline leaves much reduced in size, or moderately reduced in sect. *Gilia*. Generally spring blooming. Flowers usually in loose or glomerate cymes, or sometimes solitary or in capitate heads. Calyx lobes equal in length. Corolla frequently moderate-sized and showy, or small in many species. Pollen pores zonocolporate. Seeds small, angular, and sandy-colored, usually numerous in the capsule. Ancestral basic chromosome number $x = 9$ present in all sections; polyploidy common. Other characters vary between the subgenera and sections.

Distribution and taxa.—Widespread in western United States and Canada and northern Mexico; also in temperate South America. In arid or semiarid habitats, frequent in deserts. About 78 species.

Subgenus 1. Gilia

Leaves pinnately dissected, often bipinnate or tripinnate, but once pinnate or linear in reduced forms. Pubescence varies among the sections. Stipitate glandular hairs often present; they are medium-sized with a large terminal gland that is yellow or amber. Corolla usually funnelform, sometimes long-tubed and subsalverform. Corolla veins anastomosing in distal part of corolla (see Materials and Methods for explanation of this character.) Stamens inserted in corolla lobe sinuses. Pollen blue. Seeds generally numerous in capsules, mucilaginous when wet. Flavonoids of type A and/or C present, but not type B. (See Materials and Methods for explanation of these types.) Basic chromosome number $x = 9$ throughout.

Section 1. Gilia

Plants with leafy stems, the leaves being the largest on lower stems and smaller but well developed on upper stems. Pubescence of multicellular trichomes and medium-sized stipitate glandular hairs. Inflorescence an open cyme, or a capitate head in some species. Corolla concolored or bi- or tricolored with purple spots on the throat and yellow tube. Corolla veins anastomosing. Flavonoids of type A found (see Materials and Methods for explanation).

Distribution and taxa.—Cismontane California to British Columbia and Baja California, and in Peru and Chile. Ten species: *G. achilleaefolia*, *G. angelensis*, *G. capitata*, *G. clivorum*, *G. laciniata* (S. Amer.), *G. lomensis* (S. Amer.), *G. millefoliata*, *G. nevinii*, *G. tricolor*, *G. valdiviensis* (S. Amer.).

Section 2. Arachnion A.D. & V.E. Grant, Aliso 3:214, 1956. TYPE: *Gilia latiflora* A. Gray.

Plants scapose with a basal leaf rosette and central leader stem. Pubescence of long fine intertwined white cobwebby hairs; medium-sized stipitate glandular hairs often present also. Inflorescence an open cyme. Corolla often bi- or tricolored with contrastingly colored lobes, throat, and tube. Corolla veins anastomosing. Flavonoids of type C present.

Distribution and taxa.—Mountains and deserts of western North America, especially numerous in the Mojave desert; also in temperate South America. Twenty-five species: *G. aliquanta*, *G. austrooccidentalis*, *G. brecciarum*, *G. cana*, *G. clokeyi*, *G. crassifolia* (S. Amer.), *G. diegensis*, *G. flavocincta*, *G. inconspicua*, *G. interior*, *G. jacens*, *G. latiflora*, *G. leptantha*, *G. malior*, *G. mexicana*, *G. minor*, *G. modocensis*, *G. ochroleuca*, *G. ophthalmoides*, *G. salticola*, *G. sinuata*, *G. tenuiflora*, *G. tetrabreccia*, *G. transmontana*, *G. tweedyi*. The basic taxonomic treatment is that of Grant and Grant (1956).

Section 3. Saltugilia V.E. & A.D. Grant, Aliso 3:84, 1954. TYPE: *Gilia splendens* Douglas ex H.L. Mason & A.D. Grant, Madroño 9:212. 1948. Genus *Saltugilia* L.A. Johnson in Porter & Johnson, Aliso 19:69. 2000. Type designated by Johnson: *Saltugilia grinnellii* (Brand) L.A. Johnson. See Grant & Wendt (2003) for discussion of type.

Plants scapose with a basal leaf rosette and central leader stem. Pubescence of straight multicellular trichomes and stipitate glandular hairs, or with geniculate multicellular trichomes in *G. stellata*. Inflorescence an open cyme. Corolla usually concolored. Corolla veins anastomosing. Flavonoids of types A and C.

Distribution and taxa.—Central cismontane California to northern Baja California, and to western parts of desert. Woodland and desert habitats. Seven species: *G. australis*, *G. caruifolia*, *G. latimerii*, *G. scopulorum*, *G. splendens*, *G. stellata*, *G. yorkii*.

Gilia latimerii (T.L. Weese & L.A. Johnson) V.E. Grant, comb. nov. *Saltugilia latimeri* T.L. Weese & L.A. Johnson, Madroño 48:198. 2001. Related to *G. australis*.

Comment.—The species in sect. *Saltugilia* fall into two groups. The *G. splendens* group (*G.* splendens, *G. caruifolia*, *G. australis*, *G. latimerii*) is a natural interrelated group of woodland and desert species with mostly large flowers. The second group (*G. scopulorum*, *G. stellata*, *G. yorkii*) consists of small-flowered, mostly desert species which are similar to the G. splendens group in gross morphological characters. This was the basis for grouping them together in the same section in earlier studies (Grant & Grant 1954; Grant 1999).

However, the molecular evidence throws some doubt on this assumption. The *G. splendens* group and the second group form separate clades in the cladograms for chloroplast genes *matK* and *trnL* and ribosomal ITS (Johnson et al. 1996; Johnson & Weese 2000). A new character, sculpturing of the seed coat, also differs between the two groups (Johnson et al. 2004).

Porter and Johnson (2000) treat the *G. splendens* group as a segregate genus, *Saltugilia*, and leave the second group (*G. scopulorum* etc.) in their genus

Gilia. I of course believe that these groups should be treated at the rank of section rather than genus. Otherwise I agree that there is a problem concerning the closeness of the relationships between the two groups and within the second group itself. More morphological, breeding, and molecular studies are desirable to clarify the relationships. In the meantime we have the practical problem of making a place for the second group in the classification system. In the present system, the species of the second group are retained in the sect. *Saltugilia* until we know better what to do with them.

Subgenus 2. Greeneophila Brand, Pflanzenreich 4(250):144. 1907. TYPE: *Gilia rigidula* Benth.

Leaves with broad blades, or pinnately divided, or linear in reduced forms. Small or tiny glandular hairs, short-stalked, the glands translucent and colorless, or herbage sometimes glaucous in sect. *Campanulastrum*. Corolla varying in form: campanulate, rotate, funnelform, or trumpet-shaped. Corolla veins anastomosing or non-anastomosing (see section descriptions). Stamens often inserted in corolla tube or throat, but sometimes in sinuses (see section descriptions). Pollen yellow or cream, but blue in one species (in sect. *Giliastrum*). Seeds generally numerous in capsules; mucilaginous or non-mucilaginous (see section descriptions). Flavonoids of type B (6-methoxyflavonols) present in sects. *Giliastrum* and *Gilmania*; no data for the other sections. Basic number $x = 9$ present in all sections; $x = 9$ and 8 in sect. *Giliandra*.

Section 4. Giliastrum Brand, Pflanzenreich 4(250):147. 1907. TYPE: *Gilia rigidula* Benth. *Giliastrum* Rydb., Fl. Rocky Mts., ed. 2, 699, 1066. 1922. *Bryantiella* J.M. Porter, Aliso 19:70. 2000. TYPE: *Gilia palmeri* S. Wats., Proc. Amer. Acad. Arts 24:61. 1889. *Dayia* J.M. Porter, Aliso 19:71. 2000. TYPE: *Gilia scabra* T.S. Brandegee, Zoe 5:166, 1903.

Perennial herbs with a soft woody base and some annuals, stems branching from base. Leaf consisting of a broad blade with serrate margin, or blade cleft and with lobes, or reduced to a narrow linear rachis with narrow lobes. Corolla generally campanulate or rotate, rarely funnelform (in *G. scabra*); large or small. Corolla violet, blue, pink, or white, sometimes with a yellow tube. Corolla veins separate and non-anastomosing, except in *G. rigidula* where they do anastomose (see Materials and Methods). Stamens inserted in corolla base or throat. Pollen usually yellow, sometimes white, blue in one species (*G. scabra*). Seed coat mucilaginous when wet. Basic number $x = 9$; $n = 6$ and 12 occur in *G. insigne*.

Distribution and taxa.—Colorado and Kansas to Texas and northern Mexico and Baja California, also in temperate South America. Often in semiarid or arid plains and deserts. Twelve species: *G. castellanosii* (S. Amer.), *G. foetida* (S. Amer.), *G. glutinosa* (S. Amer.), *G. incisa*, *G. insigne*, *G. gypsophylla*, *G. ludens*, *G. palmeri*, *G. purpusii*, *G. rigidula*, *G. scabra* (includes *Dayia grantii* J.M. Porter pending further study), *G. stewartii*. See Turner (1994) for a treatment of the Texas and Mexican species. Porter and Johnson (2000) treat *Giliastrum* as a genus.

Gilia castellanosii (J.M. Porter) V.E. Grant, comb. nov. *Giliastrum castellanosii* J.M. Porter, Aliso 19:75. 2000.

Comment.—Gilia scabra of Baja California was poorly understood for many years. Brandegee (1903), who described it, stated that it was related to *Gilia floribunda* in section *Siphonella*. These are old names for *Linanthus nuttallii*. When compiling a list of species names in the 1950s, I followed Brandegee and listed *Gilia scabra* as a synonym of *Linanthus nuttallii* (Grant 1959, p. 140). I did not see herbarium material until much later. Recently Porter has studied this species in the field and laboratory, and gives a full description of its morphology (Porter and Johnson 2000). He also presents molecular evidence as noted below. Porter proposes a new genus, *Dayia*, for *D. scabra* and the closely related *D. grantii*. *G.* (or *D.*) *scabra* seems to fit into sect. *Giliastrum*, though it does differ from other species of *Giliastrum* in having funnelform corollas and blue pollen. Alva Day also views *G. scabra* as a member of sect. *Giliastrum* (pers. comm.).

The molecular evidence consists of sequence variation for the chloroplast gene *matK* and ribosomal ITS (Johnson et al. 1996; Porter 1997; Prather et al. 2000). Molecular evidence could help greatly to clarify the relationships of *Gilia scabra*, but in fact only raises more questions. In the DNA cladograms, *Gilia scabra* forms a clade consisting of itself and *Loeselia glandulosa*. This result is puzzling. *Gilia* sect. *Giliastrum* is only distantly related to *Loeselia* (Grant 2003b). *Gilia scabra* does not have the phenetic characters of *Loeselia*. In the cladograms *Gilia scabra* is adjacent to a *Giliastrum* clade, but *Loeselia glandulosa* seems very much out of place. The possibility of mislabelling plant material suggests itself. The assays of *Gilia scabra* and *Loeselia glandulosa* should be repeated. For the present it seems best to treat *G. scabra* as a member of sect. *Giliastrum*. In the future, with more study, it might be assigned to a new section, *Dayia*, related to sect. *Giliastrum*.

Gilia palmeri of Baja California and *G. glutinosa* of Peru and Chile have been treated as a related amphitropical species pair in sect. *Giliastrum* (Grant 1959). Porter proposes to treat them as a new bitypic genus, *Bryantiella* (Porter & Johnson (2000). The phenetic characters to support this change are not impressive. Porter has some molecular evidence from cpDNA and rDNA to support this proposal but this is unpublished (Porter & Johnson 2000, p. 71). I think these two species belong in sect. *Giliastrum*, and Alva Day (pers. comm.) is of the same opinion.

Section 5. Giliandra A. Gray, Proc. Amer. Acad. 8:276. 1870. Type: *Gilia stenothyrsa* A. Gray. *Aliciella* sect. *Giliandra* J.M. Porter, Aliso 17:27. 1998. *Aliciella* Brand, Pflanzenreich 4(250):150. 1907. Type: *Gilia triodon* A. Eastwood.

Woody-based perennials, short-lived perennials, biennials, and annuals. Plants scapose with a basal leaf rosette, central leader stem, and cymose inflorescence. Lower leaves leathery, pinnate, with a strap-shaped rachis and short lobes. Flowers showy in the perennial and biennial species, mostly small and inconspicuous in the annual species. Corolla in the large-flowered species funnelform or sometimes trumpet-shaped; blue, red, or pink. Corolla veins anastomosing (see Materials and Methods). Stamens inserted in corolla tube or sinuses. Pollen mostly yellow or cream-colored, rarely blue. Seeds not mucilaginous or only slightly so when wet. Two basic numbers, $x = 9$ and 8; $n = 8$ is common in the perennial and biennial species; polyploids are common in the annual species.

Distribution and taxa.—Colorado Plateau, Rocky Mountains, and adjacent plains for the perennial and biennial species; Mojave desert and neighboring deserts for the annual species. Nineteen species. *G. caespitosa, G. formosa, G. haydenii, G. heterostyla, G. humillima, G. hutchinsifolia, G. leptomeria, G. lottiae, G. mcvickerae, G. micromeria, G. nyensis, G. pentstemonoides, G. pinnatifida, G. sedifolia, G. stenothyrsa, G. subacaulis, G. subnuda, G. tenuis, G. triodon.*

Gilia humillima (Brand) A.G. Day ex V.E. Grant, comb. nov. Aliciella *triodon* var. *humillima* Brand, Pflanzenreich 4(250):150. 1907. *Aliciella humillima* J.M. Porter, Aliso 17:41.1998.

Comment.—Porter (1998) has recently revised sect. *Giliandra*, and treats it as a genus, *Aliciella*. He includes the *Gilia latifolia* group in *Aliciella*, whereas I assign it to a neighboring section, *Gilmania*. Porter's (1998) treatment contains much information about the geographical distribution, habitats, chromosome numbers, and other features of the species.

Section 6. Gilmania (H.L. Mason & A.D. Grant) V.E. Grant & A.D. Grant, Aliso 3:299. 1956. Type: *Gilia latifolia* S. Wats. *Gilia* subgen. *Gilmania* H.L. Mason & A.D. Grant, Madroño 9:205. 1948. *Aliciella* subgen. *Gilmania* J.M. Porter, Aliso 17:43. 1998.

Woody-based perennials and annual herbs. Plants scapose with a basal rosette, central leader, and cymose inflorescence. Lower leaves with a broad blade, lobed margin, and sharp-tipped lobes. Corolla funnelform, pink. Corolla venation not recorded. Stamens inserted in corolla tube. Pollen yellow. Seeds not mucilaginous or only slightly so when wet. Basic number $x = 9$.

Distribution and taxa.—Deserts from southeastern California to Utah. Two species: *G. latifolia* (annual) and *G. ripleyi* (perennial).

Section 7. Campanulastrum Brand, Pflanzenreich 4(250):144. 1907. Type: *Gilia campanulata* A. Gray. *Gilia* subgen. *Campanulastrum* H.L. Mason & A.D. Grant, Madroño 9:219. 1948. *Tintinabulum* Rydb., Fl. Rocky Mts., ed. 2, 698, 1065. 1922. Type: *Gilia filiformis* Parry ex A. Gray. *Gilia* subgen. *Tintinabulum* H.L. Mason & A.D. Grant, Madroño 9:220. 1948.

Small annuals. Stems very slender and wiry, branching from base and spreading. Pubescence glandular-puberulent, or commonly glabrous in *G. filiformis*. Leaves small and linear. Flowers solitary. Corolla campanulate, small, yellow or cream. Veins non-anastomosing (A. Day, pers. comm.). Stamens inserted in corolla throat or tube. Pollen yellow. Seeds mucilaginous when wet. Basic number $x = 9$, diploids.

Distribution and taxa.—Desert mountains, California to Utah and Arizona. Three species: *G. campanulata*, *G. filiformis*, *G. inyoensis*.

Comment.—Some phenetic characters of sect. *Campanulastrum* relate it to sect. *Giliastrum*, other characters relate it to sects. *Giliandra* or *Gilmania*. The molecular cladograms for ribosomal ITS and chloroplast genes *trnL* and *matK* show a *Campanulastrum* clade adjacent to a *Giliandra* clade (Johnson and Weese 2000). These authors list the species under generic names, *Linanthus* and *Aliciella*.

The question is how to express the relationships in the taxonomic system. Sect. *Campanulastrum* does not fit neatly into any one of the other sections in subgen. *Gilia*. Including the *Gilia campanulata* group in sect. *Giliastrum* as in Grant (1959) is not the answer. Segregating it as a genus *Tintinabulum* (Rydberg 1922; Grant 1999) obscures the relationship. Treating this group as a section in subgen. *Greeneophilia* seems to be the best solution.

Genus 2. Lathrocasis L.A. Johnson, Aliso 19:67. 2000. TYPE: *Gilia tenerrima* A. Gray.

Small annuals with small flowers. Stems branching from base and ascending. Leaves linear, with one or two lateral lobes, or simple. Pubescence of tiny stipitate glandular hairs with a black dot-like head. Corolla broad-throated funnelform, white or bluish with yellow spots in throat. Corolla veins branching but not anastomosing (Johnson & Weese 2000; Day, unpubl.). Stamens inserted in corolla throat. Pollen white. Pollen exhibiting an unusual zonocolporate condition with the pores in a broad equatorial band (Grant & Day 1999). Seeds rounded, 1 per locule, mucilaginous when wet. Flavonoids not reported. $2n = 36$, $x = 9$. See Johnson and Weese (2000) for a more detailed morphological description.

Distribution and taxa.—One species, *L. tenerrima*. Western mountains from Sierra Nevada, California, to Montana, Wyoming, and Utah.

Comment.—*Gilia tenerrima* possesses a unique combination of characters making it difficult to place in the system. On the basis of some characters, Day and I formerly placed this species in or near the *Gilia campanulata* group (Day 1993a; Grant & Day 1999). However, the more recent molecular evidence does not support this assignment (Johnson & Weese 2000).

A cladogram for rDNA ITS shows *G. tenerrima* as a clade adjacent to the sections *Saltugilia*, *Arachnion*, and *Gilia*. Cladograms for chloroplast genes *trnL* and *matK* agree with the ribosome cladogram (Johnson and Weese 2000). *Gilia tenerrima* is widely separated from *G. campanulata* in all three cladograms. It also differs from the *G. campanulata* group in seed coat sculpturing (Johnson et al. 2004).

In fact, *G. tenerrima* falls outside the range of variation of the genus *Gilia* as described in this paper. It differs from *Gilia* as described here in the type of glandular pubescence, seed shape and number, pollen color, and distribution of pores on the pollen grains.

Gilia tenerrima resembles *Allophyllum* in a number of phenetic characters (Grant 1999; Grant & Day 1999). However, this indication of relationships is not supported by the molecular evidence. *Gilia tenerrima* and *Allophyllum* fall in separate major clades in the molecular cladograms of Johnson and Weese (2000).

Johnson and coworkers set up a new monotypic genus, *Lathrocasis*, for *G. tenerrima* (Porter & Johnson 2000; Johnson & Weese 2000). This is a good solution for the taxonomic problem and is followed here.

Future study of *L. tenerrima* should include cytotaxonomic work. The few populations that have been chromosome-counted are tetraploid. Diploids could well turn up with further exploration and they might shed some light on the ancestry of the known tetraploid form.

DISCUSSION

Phylogenetic Relationships in the *Gilia* Tribe

The tribe Gilieae as defined by Grant (2001, 2003b, this paper) contains the temperate herbaceous members of the family with zonocolporate pollen, as contrasted with other temperate herbaceous groups which have pantoporate pollen. The tribe consisted of the genera *Gilia*, *Ipomopsis*, *Eriastrum*, *Langloisia*, and *Tintinabulum* in the recent treatments (Grant 2001, 2003b). In the present treatment, *Tintinabulum* is reduced to a section of *Gilia* (sect. *Campanulastrum*), and *Lathrocasis* is taken up, resulting in a tribe composed of *Gilia*, *Lathrocasis*, *Ipomopsis*, *Eriastrum*, and *Langloisia*.

The genera fall into two grades with respect to the basic chromosome number, which is $x = 9$ in *Gilia* and *Lathrocasis*, and $x = 7$ in *Ipomopsis*, *Eriastrum*, and *Langloisia*. $X = 9$ is the ancestral condition in the Polemoniaceae and $x = 7$ is derived (Grant 1959).

Gilia is regarded as basal in the tribe and the seven-paired genera as advanced. The latter do exhibit some advanced phenetic characters, such as bracteate flowering heads in *Eriastrum*, bilateral corollas in *Langloisia*, and hummingbird and hawkmoth flowers in *Ipomopsis*. The summer-blooming habit of *Eriastrum* and lowland species of *Ipomopsis* may be an advanced trait.

The woody-based perennials in *Gilia* sect. *Giliastrum* appear to be basal within *Gilia*. The other sections represent branches in a series of radiations. The California-centered annual gilias (sects. *Gilia*, *Arachnion*, *Saltugilia*) are one such major branch. Section *Giliandra* with $x = 9$ and also the reduced number $x = 8$ is another.

The seven-paired genera *Eriastrum* and *Ipomopsis* can be viewed as offshoots of one or two sections of perennial gilias in subgen. *Greeneophila*. The small desert genus *Langloisia* seems to be an offshoot of *Eriastrum*. *Lathrocasis* ($x = 9$) appears to be related to the California-centered annual gilias.

The molecular cladistic approach of Porter and Johnson (2000) and Johnson et al. (2004) leads to a very different classification, as mentioned in the introduction (see also Grant 2001). First, Gilia s. l. is broken up into numerous smaller genera (Table 1). Second, the segregate genera are assigned to three different tribes (Table 1).

Third, these tribes contain mixtures of genera with different ancestral roots as indicated by phenetic characters. For example, Porter and Johnson (2000) group the equivalent of Grant's *Gilia* subgen. *Gilia* together with *Allophyllum* and *Collomia* in their tribe *Gilieae* (Table 1). This is a non-monophyletic grouping according to strong phenetic evidence (Grant 1998, 2001, 2003b). The tribe *Loeselieae* of Porter and Johnson (2000) is also non-monophyletic, containing a mixture of *Loeselia* and most of *Gilia* subgen. *Greeneophila* (Table 1). *Loeselia* and *Gilia* have different roots and are assigned to different subfamilies in the taxonomic system (Grant 2003b).

Gilia Is Not Polyphyletic

Johnson et al (1996) state that *Gilia* s. l. is polyphyletic, repeating the statement several times for emphasis. The same conclusion is stated in other molecular systematic papers (Porter 1998; Porter & Johnson 2000; Weese & Johnson 2001). The authors do not present an explicit verbal justification for their claim. However, it is clear from the context that the basis for their conclusion is a broad incongruence between the existing taxonomic classification of *Gilia* s. l. and their molecular cladograms.

The comprehensive family-wide cladograms of Johnson et al. (1996) were the forerunner of a reclassification of the family as a whole including the *Gilia* complex. The molecular evidence consisted of the sequence variation in the chloroplast gene *matK*. Johnson et al. (1996) made the assumption that the cladograms for *matK* provide a reliable guide for the phylogeny of the species in the family. The clades were assigned informal taxonomic names.

Porter and Johnson (2000) set out to construct a phylogenetic classification system based on molecular evidence; and in practice they took up the cpDNA *matK* clades of Johnson et al. (1996) and transformed these into formal taxonomic groups with taxonomic names. The primary and secondary molecular clades became subfamilies and tribes respectively. Third-order clades became genera or small sets of genera. Evidence from studies of other DNA regions played a supporting role: rDNA ITS (Porter 1997, 1998) and rDNA ITS and cpDNA *trnL* (Johnson & Weese 2000).

Full descriptions of phenetic characters were attached to the taxonomic groups of Porter and Johnson (2000), but it is difficult to see what effect, if any, the phenetic characters had on the circumscription of the groups. In cases of conflict between molecular and phenetic evidence, the molecular evidence routinely prevails.

A comparison of the Porter and Johnson (2000) system with other systems before 2000 is thus a comparison of a cladistic system based primarily on DNA data with a taxonomic classification based primarily on phenetic characters.

In the molecular cladograms of Johnson et al. (1996), clades containing the subgroups of *Gilia* s. l. are scattered in different positions on the graph, and other genera such as *Eriastrum* and *Ipomopsis* lie between them. This topology indicates non-monophyly in cladistics, which uses the cladistic definition of monophyly; and it is probably the basis for Johnson et al.'s (1996) conclusion that *Gilia* is "extremely" polyphyletic. However, the topology is quite consistent with the concept of monophyly used by taxonomic students of *Gilia*. This is an example of a "false accusation" of polyphyly, as mentioned in the introduction.

The pattern of the molecular cladograms is consistent with the phylogenetic hypothesis that *Gilia* s. l. is a basal multisection genus in the tribe *Gilieae*. The sections differ in molecular as well as phenetic characters. Some sections of *Gilia* have given rise to derived genera such as *Eriastrum* and *Ipomopsis*, and these lie between sections of *Gilia* in the cladograms. The same pattern is seen in molecular cladograms of other plant groups and is often misinterpreted as evidence for polyphyly (see Grant 2003a).

Actually, the molecular evidence is in reasonably good agreement with the taxonomic classifications of *Gilia* s. l. The big incongruence is between the taxonomic classification and the molecular-based system. This suggests that the incongruence, or much of it, has developed in the process of converting molecular clades into taxa.

The Genus Concept in *Gilia*

The goal in both evolutionary taxonomy and molecular cladistics is to circumscribe genera so that they are natural or monophyletic. Beyond this basic goal, it is possible, in either school, to adjust the boundaries in various ways ranging from lumping to splitting. The two schools also apply different criteria for circumscription: significant phenetic differences between genera in evolutionary taxonomy, distinctive molecular clades in molecular cladistics. The results are seen in current treatments of *Gilia* where one school's sections are another school's genera.

Alva Day and I and other earlier evolutionary taxonomists such as Herbert Mason (Mason & Grant 1948) have favored a broad multisection genus *Gilia* because the broad circumscription expresses the interrelationships of the sub-branches. Splitting the sections off as a series of segregate genera (*Aliciella*, *Giliastrum*, etc.) obscures their interrelationships. Having one generic name (*Gilia*) for a related set of sections, rather than a different generic name for each subdivision, reinforces the sense of interrelationship, and in addition reduces the memory burden, and facilitates preliminary identification in the field or herbarium.

Gilia s. l. is more difficult to define diagnostically than its constituent sections, but it can be defined. Gilia as treated here is a genus of temperate herbaceous Polemoniaceae that has zonocolporate pollen, a basic chromosome number of $x = 9$, a spring-blooming habit, and generally angular seeds.

ACKNOWLEDGMENTS

Alva G. Day furnished valuable information and opinions. Tom Wendt was helpful in the U.T. Herbarium. Rancho Santa Ana Botanic Garden and Field Museum made loans of herbarium specimens and J.M. Porter donated some specimens. Karen A. Grant read the manuscript. Their help is gratefully acknowledged.

ABSTRACT

A new species of Verbenaceae, *Citharexylum danirae* León de la Luz et Chiang, is described and illustrated. It is known only from the type collection at the north face of Evermann volcano in the remote Socorro Island, the largest of the Revillagigedo Archipelago, in the tropical Mexican Pacific Ocean. Its relationship to *C. caudatum* L. and *C. affine* D. Don is discussed.

RESUMEN

Se describe e ilustra una nueva especie de la familia de las Verbenáceas, *Citharexylum danirae* León de la Luz et Chiang. Hasta hoy es sólo conocida del ejemplar tipo, procedente de la vertiente norte del volcán Evermann, en la remota Isla Socorro, en el archipiélago de las Islas Revillagigedo, ubicada en el Pacífico tropical de México. Se discute su relación con *C. caudatum* L. y con *C. affine* D. Don.

Socorro Island is part of the Revillagigedo Archipelago, a group of three islands scattered off the tropical west coast of Mexico (18°45'N, 111°00'W). Socorro is located 400 km south of the southern tip of the Baja California peninsula, and about 580 km west-southwest of Cabo Corrientes, Jalisco, on the nearest west central Mexican mainland coast.

The floristic knowledge of the island and the archipelago has grown continuously since the late 19th century as result from sporadic botanical explorations, mainly describing new taxa and distributional records. Several floristic checklists also have been published (Johnston 1931; Miranda 1960; Levin & Moran 1989). The latter is the most complete, cataloguing the flora of the islands, particularly that of Socorro, which is the largest and more diverse in species (160 taxa of vascular plants), plant communities, and the richest in plant endemism (27 percent).

From three botanical explorations to Socorro Island by the first author (from 1988–1990), almost 180 duplicates were sent to Dr. Geoffrey Levin, then botanist at the San Diego Museum of Natural History (SD) and head of the Vascular Flora of Socorro Island Project, to contribute to the floristic compilation then in preparation. Of these collections, twelve taxa represent new distributional records (Levin & Moran 1989). The expeditions provided a total of 25

SIDA 21(2): 547–551. 2004

collecting days on Socorro Island that included the first-ever collections on the north side of Evermann Volcano (1150 m).

The collections made on February 25th 1990 on the north face of Evermann Volcano revealed several shrubby species, such as *Spermacoce nesiotica* (B.L. Rob.) G. A. Levin, *Chiococca alba* (L.) Hitchc., *Dodonaea viscosa* Jacq., *Zanthoxylum insulare* Rose, *Lepechinia hastata* (A. Gray) Epling subsp. *socorrensis* Moran, and *Rhamnus sharpii* M. & L.A. Johnston. These species occur in the scrubland that covers the middle elevations of the island. A terrestrial orchid (cf. *Habenaria*), collected in its vegetative stage, was never identified and represented the only member of this family with this habit on the island. Another collection (*León de la Luz 4518*) had remained undetermined in the HCIB herbarium until recently. As it is known only from one specimen it is presumed to be rare on the island. It was collected at 805 m, the highest part of the Mixed or Tropical Scrubland plant community, according to Miranda (1960) and León de la Luz et al. (1996).

The specimen was initially thought to have only inmature flowers, but a recent thorough examination revealed a couple of mature flowers, whose dissection enabled its placement as *Citharexylum*. This is only the third genus thus recorded for Verbenaceae on Socorro Island; the other being *Verbena* and *Lantana* (Levin & Moran 1989). The specimen was compared with descriptions of *Citharexylum* species in floras and monographs available for Mexico: Veracruz (Nash & Nee 1984), the west-central sector (Rzedowski & Rzedowski 2002), the Sonoran Desert (Shreve & Wiggins 1964) the Baja California Peninsula (Wiggins 1980), and the material examined by Moldenke (1958). Although seed and fruiting material was unavailable, it was determined that the specimen represent a new species differing from other taxa in both leaf and flower structure. The new species is herein described.

Citharexylum danirae León de la Luz & Chiang, sp. nov. (**Fig. 1**). TYPE: MEXICO. ISLA SOCORRO: Revillagigedo Archipelago: N side slopes of Evermann Volcano, mixed or tropical scrubland, 805 m elevation, 25 Feb 1990, *José Luis León de la Luz 4518* (HOLOTYPE: HCIB!).

Frutex ad 3 m altus; folia opposita 7–10 cm longa, 4–6 cm lata, ovata, apice acuta, glabrata; inflorescentiae racemosae 12–18 cm longae, pedicellis 1–2 mm longis, bracteatis, bracteis 2 mm longis, foliaceis, oblongo-lanceolatis; corolla albidi, 5 mm longa; calycis tubo ca. 4 mm sepalis parvis, petalis parvis; stamina robusta ca. 1.5 mm longa, filamenta parva, robusta; ovarium pyriforme, robustum, stylo parvo, ad apicem furcato, lobis 2, stigmatosis, parvis; fructus et semina ignota.

Shrub to 3 m high, stems tetragonal, nodes with prominent leaf and bundle scars; **leaves** opposite, ovate, 4–6 cm wide, acute acuminate at the apex, rounded at the base, the margins entire, the leaf blades subglabrous with sparse simple trichomes (less than 0.5 mm), the upper surface lustrous when young, less so with age, with 3-4(-5) parallel veins per side; petioles 15–25 mm long, canaliculate; **racemes terminal,** few branched, 12–18 cm in length, 20–35

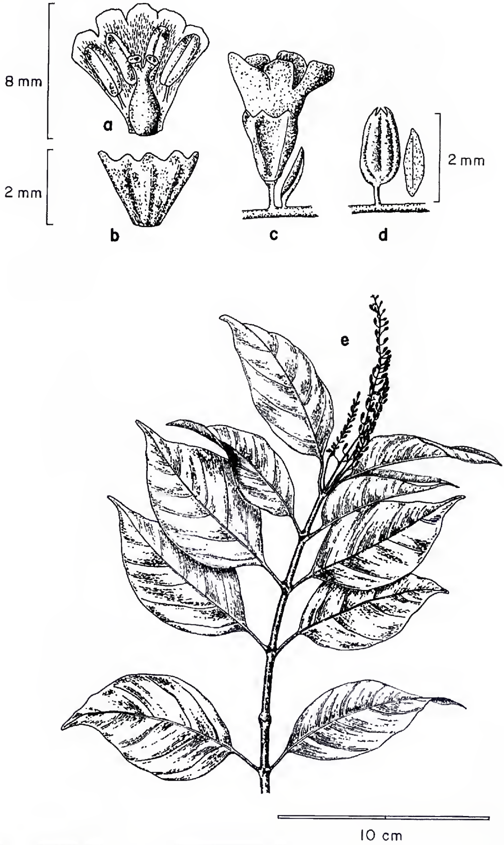

Fig. 1. *Citharexylum danirae* León de la Luz & Chiang. **a)** Dissection of calyx and corolla, note robust pistil and stamens. **b)** Flower. **c)** Flower bud and bract. **d)** Flowering branch.

TABLE 1. Morphological comparison between *Citharexylum danirae, C. caudatum,* and *C. affine.*

Characters	***Citharexylum caudatum***	***C. affine***	***C. danirae***
Habit	shrubby to arborescent	shrubby to arborescent	shrubby
Leaf size	8–17 cm × 2–6 cm	6–30 cm × 3–14 cm	7–10 cm × 4–6 cm
Leaf shape	oblong-elliptic	ovate, lanceolate-oblong	ovate
Leaf apex	short acuminate to acute	acuminate	abruptly acuminate
Leaf base	cuneate	rounded	rounded
Petioles length	0.5–2 cm	1–8 cm	1.5–2.5 cm
Inflorescences	racemes axillary and terminal	racemes terminal	racemes terminal
Pedicels	1–3 mm	1 mm	1–2 mm
Bracts length	up to 1 mm	up to 1 mm	2–2.5 mm
Corolla	white, 3–4 mm	pale blue, 4–6 mm	white-greenish, 5 mm
Corolla lobes	1–2 mm, glabrous	2–4 mm, glabrescent	1 mm, glabrous
Pistil	slender	slender	stout
Anthers	slender	slender	stout (± 1.5 mm)
Calyx at anthesis	tubular-campanulate, 2–3.5 mm	cyathiform, 3 mm	tubular, 4 mm

flowered; pedicels usually alternate along the axis, 1–2 mm; bracts oblong-lanceolate, up to 2 mm, longer than the pedicels; **calyces** to 4 mm in length at anthesis, shallowly 5 toothed, 5 nerved; **corollas** white greenish, twice as long as the calyx tubes, ± 5 mm in length, the short lobes 5, entire, not ciliate; stamens 4, anthers stout, 1.5 mm; staminode 1; ovary stout, ovoid, stout, styles 2, short; stigmas discoid-capitate; mature fruit and seeds unknown.

Etymology.—The new species is named in honor of Miss Danira León, the first author's much-loved daughter.

This new species is close to *C. caudatum* L., a widespread species in tropical Mesoamerica and northern South America, whose main resemblance is the shiny character of the upper leaf surface due to small shiny scales, although such scales seem to be only present in this new taxon at low density on young leaves. Superficially, the shape of the leaves resembles those of *C. affine* D. Don, but the flowers differ significantly. A comparison of the new species with the two species mentioned above is presented in Table 1.

The type locality has been explored botanically only once. This island sector probably harbors more interesting plants.

ACKNOWLEDGMENTS

We thank all the CIBNOR colleagues for those memorable expeditions to Socorro Island from 1988 to 1990. Thanks also to Ira Fogel for proofing the text and Oscar Armendáriz for the beautiful drawings. Critical revision by *Sida, Contributions to Botany* editorial staff, particularly Jim Henrickson, enhanced the quality of the manuscript.

BOOK REVIEW

DOUGLAS CRASE. 2004. **Both: A Portrait in Two Parts.** (ISBN 0-375-42266-8, hbk.) Pantheon Books, New York. (Orders: http://www.randomhouse.com/pantheon/catalog/). $25.00, 303 pp., 6 drawings, 34 photographs, 6" × 8".

Imagine two urbane, erudite, amusing (in several languages) characters. Make one an English aristocrat and the other heir to an American railroad fortune. Give them a group of friends who are the brightest members of the avant-garde on both side of the Atlantic Ocean. Add cameo parts for such luminaries as Juan Miro and Cary Grant. It sounds like the makings of a piece by Noel Coward or Evelyn Waugh.

What we have is a charming biography, *Both: A Portrait in Two Parts* by Douglas Crase. It is the story of the intertwined lives of the eminent botanist, Rupert Charles Barneby, and the horticulturalist-artist, Harry Dwight Dillon Ripley. They met as students at Harrow, drawn together by a mutual love of Latin and a mania for collecting plants. The relationship persisted through University and beyond, resulting in the disinheritance of Barneby by his father. Ripley was an orphan. The two men remained together for 48 years.

The author says that Ripley "was the enabling influence of Barneby's early direction as a botanist through his money, his affection, and the magnificent garden at his estate in Sussex." This place contained three greenhouses, every kind of special habitat, a herbaceous border, and a private herbarium. On the other side, Barneby with his inbred noblesse, was a buffer for the shy Ripley, who suffered from uncontrolled blushing, leading from embarrassment to panic.

After several visits to the United States, the couple moved to New York in 1939. Botany and horticulture continued to be at the center of their lives, but Ripley, the artist, also financed the Tibor de Nagy Gallery, a non-commercial enterprise, which became one of the most influential galleries in New York, when after the Second World War New York was the acknowledged leader in the arts. Ripley and Barneby were patrons and full participants in this exciting world of literature, music, and painting.

All of this is affectionately and gracefully recounted by Mr. Crase, a former MacArthur Fellow. He is not a botanist, but he was a friend of Barneby's and writes knowingly of his hard work and persistence. Although Ripley was regarded as something of a dilettante, he too left an impressive legacy. However, it is the relationship which is subject of this delightful book.—*Ruth Ginsburg, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

ABSTRACT

A taxonomic treatment of *Sporobolus* R. Br. for northeastern México (Coahuila, Nuevo León, and Tamaulipas), is given. Seventeen species and one subspecies of *Sporobolus* are recognized in the study area. *Sporobolus airoides* subsp. *regis* is endemic to Coahuila, and *S. atrovirens* and *S. spiciformis* are endemic to México. Keys for determining the species, descriptions, distributions, specimens examined, illustrations, synonymies, and a brief discussion indicating relationships among all native and adventive species of *Sporobolus* in northeastern México are provided.

RESUMEN

Se presenta un estudio taxonómico de *Sporobolus* R. Br. para el noreste de México (Coahuila, Nuevo León y Tamaulipas). Se reconocen diecisiete especies y una subespecie de *Sporobolus* para el área de estudio. *Sporobolus airoides* subsp. *regis* es endémica para Coahuila, y *S. atrovirens* y *S. spiciformis* son endémicas para México. Se incluyen claves para determinar las especies, descripciones, distribuciones, especimenes examinados, ilustraciones, sinonimias, y una discusión breve indicando las relaciones entre todas las especies nativas y adventicias de *Sporobolus* para el noreste de México.

Northeastern México (Coahuila, Nuevo León, and Tamaulipas), covers an area of 291,955 km^2 or 15 % of the total land of the country. This area includes portions of two natural regions known as the Chihuahuan and Tamaulipan Deserts. These regions are considered a center of origin and diversification of arid and semi-arid plant species. As part of the current revision of the grass flora of northeastern México, an examination of the taxonomy and distribution of the species of *Sporobolus*, was begun to aid the agriculture and livestock industries. This study treats 17 species and one variety, for a total of 18 taxa.

Sporobolus R. Br. is a worldwide genus of more than 160 species occurring in the tropics, subtropics, and warm temperate regions (Clayton & Renvoize

SIDA 21(2): 553–589. 2004

1986; Peterson et al. 1997; Watson & Dallwitz 1992). There are 72 native species of *Sporobolus* in North, Central, and South America; 27 native in the United States and Canada; and 26 native in México (Espejo-Serna et al. 2000; Peterson et al. 2001, 2003, 2005). The genus is characterized by having single-flowered spikelets, 1-nerved lemmas, fruits with free pericarps or "modified caryopses" as proposed by Brandenburg (2003), and ligules with a line of hairs (Peterson et al. 1995, 1997). Species of *Sporobolus* generally inhabit dry, saline or alkaline sandy to clay loam soils in prairies, savannahs, and along disturbed roadsides (Peterson et al. 1997).

The subtribe Sporobolinae, as currently circumscribed, consists of three New World genera: *Calamovilfa* (A. Gray) Hack., *Spartina* Schreb., and *Sporobolus* (Peterson et al. 2005). In the New World the Sporobolinae share most of the same character trends as for the tribe Zoysieae, i.e., spikelets with a single floret, spiciform inflorescences of numerous deciduous racemelets disposed along a central axis, lemmas usually rounded and rarely with apical awns, and glumes often modified and oddly shaped, but differ by having modified caryposes (pericarps reluctantly free in *Spartina*), spikelets oriented abaxially along the aixis (lemma is facing the rachis), lemmas that are similar in texture to the glumes, and paleas that are relatively long and about the same length as the lemma (Peterson et al. 2005).

Within *Sporobolus*, Stapf (1898) first divided the genus into two sections: *Chaetorhacia* Stapf and *Eusporobolus* Stapf. Pilger (1956) then divided the latter section, which he elevated to *Sporobolus* subg. *Sporobolus* (Stapf) Pilg., into six groups based on life form and characteristics of the glumes and panicles. Based on caryopsis morphology, Bor (1960) divided *Sporobolus* into five rather unnatural groups (Baaijens & Veldkamp 1991). Working on the Malesian species, Baaijens & Veldkamp (1991) divided *Sporobolus* subg. *Sporobolus* into five sections based on overall morphology with special attention given to inflorescence branching. More recently, Weakley & Peterson (1998) recognized the *Sporobolus floridanus* complex to include five species in the southeastern United States and based on nuclear ribosomal DNA ITS sequences, Ortíz-Díaz & Culham (2000) presented evidence to support the recognition of at least 10 clades within *Sporobolus*. Recent major revisions of *Sporobolus* include Boechat & Wagner (1995) for Brazil, Simon & Jacobs (1999) for Australia, and Peterson et al. (2003) for the United States and Canada.

The following taxonomic treatment contains a key for determining the species, descriptions, distribution, specimens examined, illustrations, and synonymies for all native and adventive species of *Sporobolus* in northeastern México. This study is based on the examination of herbarium specimens from ANSM, COCA, MEXU, MO, NMSU, TEX, UAT, and US, including the type specimens of most of the species studied.

TAXONOMIC TREATMENT

Sporobolus R. Br., Prodr. 169. 1810. TYPE: *Sporobolus indicus* (L.) R. Br. [lectotype designated by L.K.G. Pfeiffer, Nom. Bot. 2:1274. 1874, also by Nash, Ill. Fl. N. US. (ed 2), 1:194. 1913].

Plants annual or perennial; sometimes rhizomatous, rarely stoloniferous. Flowering culms 10–250 cm tall, erect rarely mat-forming, caespitose (often forming large clumps), glabrous; leaf sheaths longer or shorter than the internodes usually with smooth margins, occasionally ciliate; ligule ciliate, a line of hairs; blades 3–70 cm long, 1–15 mm wide at base, filiform or linear, flat, involute, or terete, not pungent, cauline without auricles. Inflorescence a panicle 0.5–80 cm long, 0.3–30 cm wide, exserted or partially included in upper sheath; rachis smooth; primary branches appressed, spreading, divaricate, or reflexed from the main axis, solitary or loosely whorled, sometimes with capillary branches terminating in a spikelet; secondary branches appressed or spreading; pedicels erect, rarely secund, glabrous, scaberulous or scabrous; cleistogamous spikelets occassionally present, in axillary inflorescences. Spikelets 1–4(–7) mm long, solitary, laterally or dorsally compressed, sometimes terete; disarticulation usually above the glumes, commonly above the upper glume, occasionally below with the lemma and palea falling as a unit; glumes shorter or longer than the florets, very unequal, smooth, glabrous; lower glume without midvien or 1-veined; upper glume about the same length as the lemma, usually awnless, 1-veined; florets 1 per spikelet; lemma entire, awnless, glabrous or hairy, pubescent to pilose, 1-veined, rarely 3-veined, membranous with glabrous veins; palea glabrous, smooth, membranous, margins not enfolding the fruit, 2-veined, often splitting as grain matures; lodicules 2 or sometimes absent, truncate; stamens 2 or 3; anthers yellow, reddish-purple, or olivaceous-plumbeous; stigmas 2. Modified caryopsis a follicoid fruit with a free pericarp, commonly swelling and mucilaginous when wet; hilum punctiform; embryo with an epiblast, scutellar tail, and elongated mesocotyl internode (formula P+PF), endosperm hard. Base chromosome number, $x = 9$, and 10. Named from Greek *Sporo*, 'seed', and *bolos*, 'a throw', referring to the free seeds.

Comments.—The following five species included in this study have been placed in four different sections of *Sporobolus*: *S. atrovirens*, *S. indicus*, and *S. jacquemontii* (sect. *Sporobolus*), *S. virginicus* (sect. *Virginicae* Veldkamp), and *S. purpurascens* [sect. *Triachyrum* (Hochst. ex A. Braun) Veldkamp]. In addition to this, we recognize three prominent "groups" within the northeastern Mexican species of *Sporobolus*: 1) Airoidae – culms tall and densely caespitose; leaf blades as viewed in cross section (Annable et al. 1992) with bundle sheath extensions, first order vascular bundles with flattened adaxial ribs, second order vascular bundles with triangular ribs, and adaxial furrows above the third order vascular bundles; spiklelets dorsally compressed; modified caryopses plump; includes: *S. airoides*, *S. buckleyi*, and *S. wrightii*; 2) Cryptandrae—Leaf blades as viewed in cross section (Annable et al. 1992) with round adaxial ribs with furrows between each adjacent vascular bundle, distinctive fan-shaped bulliform cells, and lack bundle sheath extensions; spikelets laterally compressed; glumes with scabrous nerves; endosperm translucent yellow or orange; includes *S. contractus*, *S. cryptandrus*, *S. flexuosus*, *S. giganteus*, and *S. nealleyi*; 3) Pyramidatae – Panicle branches whorled or sub-whorled; embryo pandurate with a scutellum edge; includes *S. coahuilensis* and *S. pyramidatus*. These three groups parallel those presented by Ortíz-Díaz & Culham (2000) where their group E corresponds to our Cryptandrae and their group G, in part, corresponds to our Airoidae. Our Cryptandrae group is identical to the *Sporobolus cryptandrus* complex presented by Annable et al. (1992), and their *Sporobolus airoides* group includes *S. palmeri* Scribn. and *S. splendens* Swallen that do not occur in the study area.

Morphologically, *S. compositus* and *S. spiciformis* do not appear to be allied with other northeastern Mexican species of *Sporobolus*. *Sporobolus compositus* appears to be allied with *S. neglectus* Nash and *S. vaginiflorus* (Torr. ex A. Gray) Alph. Wood from the United States and Canada, whereas *S. spiciformis* is perhaps related to *S. phleoides* Hack. from Argentina. *Sporobolus compositus*, *S. neglectus*, and *S. vaginiflorus* all have contracted panicles that are included in the uppermost sheath and an embryo nearly as long as the modified caryopsis. *Sporoblous spiciformis* and *S. phleoides* also have contracted panicles with laterally compressed spikelets and upper glumes 1/4–1/2 as long as the floret.

KEY TO THE SPECIES OF *SPOROBOLUS* IN NORTHEASTERN MÉXICO

1. Plants with rhizomes.
  2. Panicles 3–10 cm long, 0.4–1.6 cm wide, contracted, spikelike, dense; culms 10–65 cm tall ____ **16. S. virginicus**
  2. Panicles 30–40 cm long, 10–15 cm wide, open, diffuse, subpyramidal; culms 80–130 cm tall ____ **1b. S. airoides** subsp. **regis**
1. Plants without rhizomes.
  3. Plants annual.
    4. Lower panicle nodes with 1–2 branches; spikelets 0.7–1.2 mm long; lemmas 0.7–1.2 mm long ____ **2. S. atrovirens**
    4. Lower panicle nodes with 7–20 branches (whorled); spikelets 1–1.8 mm long; lemmas 1.2–1.7 mm long.
      5. Pedicels 0.1–0.5(–1) mm long, appressed ____ **14. S. pyramidatus**
      5. Pedicels (2–)3–6(–8) mm long, widely spreading ____ **4. S. coahuilensis**
  3. Plants perennial.
    6. Spikelets usually more than 2.6 mm long.
      7. Lower panicle nodes with 3–5 branches ____ **13. S. purpurascens**
      7. Lower panicle nodes with 1 or 2 (–3) branches.
        8. Panicles terminal and axillary; sheaths without a conspicuous tuft of hairs at the summit ____ **5. S. compositus**
        8. Panicles all terminal, elongated; sheaths with a conspicuous tuft of hairs at the summit.

9. Culms 35–100(–120) cm tall, 2–4(–5) mm diameter near the base; mature panicles 0.2–0.8(–1) cm wide; anthers 0.3–0.5 mm long __________ **6. S. contractus**

9. Culms 100–200 cm tall, (3–)4–10 mm diameter near base; mature panicles 1–4 cm wide; anthers 0.6–1 mm long ______________ **9. S. giganteus**

6. Spikelets 1–2(–2.9) mm long.
   10. Lower sheaths strongly laterally compressed and keeled __________ **3. S. buckleyi**
   10. Lower sheaths rounded.
      11. Leaf sheaths and collar with a conspicuous tuft of white hairs.
         12. Panicles contracted, spike-like; branches appressed.
            13. Culms 35–100(–120) cm tall, 2–4(–5) mm diameter near the base ______________________________________ **6. S. contractus**
            13. Culms 100–200 cm tall, (3–)4–10 mm diameter near the base ______________________________________ **9. S. giganteus**
         12. Panicles open, branches spreading at least from the middle of the rachis to the apex, the base sometimes included.
            14. Culms 10–40 cm tall, 0.7–1.2 mm diameter near base, the base hard and knotty; blades stiff, spreading at right angles ____ **12. S. nealleyi**
            14. Culms 30–100(–120) cm tall, 1–3 mm diameter near base, the base not hard and knotty; blades erect or ascending, not stiff.
               15. Panicles usually exserted, branches divaricate and flexuous, usually tangled between branches or panicles; lower glumes 0.9–1.5 mm long ______________________ **8. S. flexuosus**
               15. Panicles usually included at the base, branches appressed or ascending, not markedly flexuous, not tangled; lower glumes 0.6–1.1 mm long ____________________ **7. S. cryptandrus**
      11. Leaf sheaths and collar glabrous (sparsely appressed pilose in *S. airoides* subsp. *regis*).
         16. Pancles 0.3–3 cm wide, spikelike, the branches appressed to main axis.
            17. Pancles 9–17 cm long, 3–5(–10) mm wide, whitish; glumes unequal, more than two thirds as long as the floret ___ **15. S. spiciformis**
            17. Panicles 7–60 cm long, 5–12 mm wide, not whitish; glumes about equal, less than two thirds as long as the floret.
               18. Spikelets 2–2.6(–2.7) mm long; upper glumes usually 1/2–2/3 as long as the florets, the apex acute to obtuse, entire ____ **10. S. indicus**
               18. Spikelets 1.4–1.8(–2) mm long; upper glumes usually less than 1/2 as long as the florets, rarely longer, the apex truncate, erose to denticulate _________________ **11. S. jacquemontii**
         16. Panicles 3–25 cm wide (somtimes only 0.3 cm wide in immature *S. pyramidatus*), open, the branches widely spreading at least from the middle of the rachis to the apex.
            19. Panicle branches widely divaricate and flexuous, usually tangled within branches or panicles ________________ **8. S. flexuosus**
            19. Panicle branches widely open or erect, not tangled.
               20. Culms 10–40 cm tall, delicate perennials, plants small; leaf blades borne near base; sheaths glabrous or with few ciliate hairs on the margins and summit.
                  21. Panicle branches arranged in whorls at lower nodes;

mature panicles pyramidal (immature and extreme forms spikelike); upper glumes 1.2–1.8 mm long ________ **14. S. pyramidatus**

21. Panicle branches solitary or paired but not in whorls at the lower nodes; mature panicles oblong to ovoid; upper glumes 0.4–0.7 mm long ____________ **2. S. atrovirens**

20. Culms 30–100(–120) cm tall, robust perennials, often forming large tough leafy tussocks; leaf blades cauline; sheaths usually bearded with long hairs on the margins and summit.

22. Panicles 10–45 cm long, the branches naked near the base; pedicels 0.5–2 mm long, usually erect, spreading ____________________________ **1. S. airoides**

22. Panicles 20–60 cm long, the branches densely flowered near the base; pedicels 0.2–0.5 mm long, appressed ______________________________ **17. S. wrightii**

1a. Sporobolus airoides (Torr.) Torr. subsp. **airoides**, Pacific Railr. Rep. Parke, Bot. 7:21 1856. (**Fig. 1, A & B**). *Agrostis airoides* Torr., Ann. Lyceum Nat. Hist. New York 1:151. 1824, non (Poir.) Raspail. *Vilfa airoides* (Torr.) Trin. ex Steud., Nomencl. Bot. (ed. 2) 2:766 1841. TYPE: U.S.A. COLORADO: on the branches of the Arkansas, near Rocky Mountains, *E James s.n.* (HOLOTYPE: NY-327612!; ISOTYPE: US-76255 fragm. & photostat ex herb. Torrey!).

Sporobolus diffusissimus Buckley, Proc. Acad. Nat. Sci. Philadelphia 14:90. 1862. TYPE: U.S.A. TEXAS: Western Texas, 1849, *C. Wright 726* (ISOTYPE: US-3198038 fragm.!).

Sporobolus schaffneri Mez, Repert. Spec. Nov. Regni Veg. 17(19–30):295. 1921. TYPE: MÉXICO. SAN LUIS POTOSÍ: *W. Schaffner s.n.* (ISOTYPE: US-87214 fragm.!)

Sporobolus tharpii Hitchc., Proc. Biol. Soc. Wash. 41:161. 1928. TYPE: U.S.A. TEXAS: Padre Island, 4 Sep 1927, *B.C. Tharp 4772* (HOLOTYPE: US-1299827!).

Densely caespitose perennials. Culms 35–120(–150) cm tall, erect, stout, glabrous below the nodes; base diameter 1–2(–3.5)mm wide, rounded; internodes glabrous. Leaf sheaths 2/3 to about as long as the internodes above, glabrous, shinny, sometimes with a few long hairs near the summit, these hairs up to 6 mm long; ligules 0.1–0.3 mm long; blades (3–)10–45(–60) cm long, (1–)2–5(–6) mm wide, flat to involute, glabrous below and scaberulous to scabrous above; margins mostly smooth to scaberulous. Panicles (10–)15–45 cm long, 15–25 cm wide, open, diffuse, subpyramidal, often included in the uppermost sheath; branches 1.5–13 cm long, ascending to widely spreading 30–90° from culm axis; secondary branches mostly spreading and not floriferous on lower 1/4 to 1/3; pulvini in axils of primary branches glabrous; pedicels 0.5–2 mm long, spreading, glabrous to scabrous. Spikelets 1.3–2.8 mm long, spreading, purplish or greenish;.glumes 0.5–2.4(–2.8) mm long, lanceolate to ovate, membranous, unequal; lower glume 0.5–1.8 mm long, often appearing without a midvein, the apex acute; upper glume 1.1–2.4(–2.8) mm long, apex acute to obtuse; lemmas 1.2–2.5 mm long, ovate, membranous, glabrous, the apex acute; paleas 1.1–2.4 mm long, ovate, membranous, glabrous, the apex acute to obtuse; stamens 3; anthers 1.1–1.8 mm

Fig. 1. *Sporobolus airoides* ssp. *airoides*. **A.** Habit. **B.** Spikelet. *Sporobolus airoides* subsp. *regis*. **C.** Habit. **D.** Inflorescence, apical portion. **E.** Spikelet with stamens.

long, yellowish to purplish. Modified caryopses 1–1.4 mm long, ellipsoid, reddish-brown, striate. $2n = 80, 90, 108, 126$.

Distribution and habitat.—Sporobolus airoides occurs throughout the arid portions of northwestern North America and in México as far south as Puebla. It is common in dry to sandy gravely flats or slopes usually associated with alkaline soils, occurring with *Atriplex canescens* (Pursh) Nutt., *A. confertifolia* (Torr. & Frém.) S. Watson, *Larrea tridentata* (Sessé & Moc. ex DC.) Coville, *Sarcobatus vermiculatus* (Hook.) Torr., *Distichlis spicata* subsp. *stricta* (Torr.) Thorne, and *Ambrosia dumosa* (A. Gray) W.W. Payne; 50–2400 m. Flowering June through November. In northeastern México, *S. airoides* is a halophytic species forming the alkali zacaton grasslands where the edaphic effects of a diverse combination of chloride carbonates and sulfates accumulates to form very saline conditions.

KEY TO THE SUBSPECIES OF *SPOROBOLUS AIROIDES*

1. Sheaths generally glabrous or minutely scabrous on abaxial surface; primary branches of the panicle glabrous, without tufts of hairs in the axils below ____ **1a. S. airoides** subsp. **airoides**

1. Sheaths pilose on abaxial surface; primary branches of the panicle with a tuft of hairs in the axils below ____ **1b. S. airoides** subsp. **regis**

1b. Sporobolus airoides subsp. **regis** (I.M. Johnst.) Wipff & S.D. Jones, Sida 16:164. 1994. (**Fig. 1, C & D**). *Sporobolus regis* I.M. Johnst., J. Arnold Arbor. 24:393. 1943. TYPE: MÉXICO. COAHUILA: Municipio de Ocampo, salt flat 4 km SE of Laguna del Rey, abundant, 1040 m, 18 Sep 1942, *R. Stewart 2653* (HOLOTYPE: GH; ISOTYPE: US-90729 fragm.!).

Rhizomes elongate, knotty with internodes 10–12 mm long, 3–4 mm in diameter. Culms 80–130 cm tall, erect, densely leafy. Leaf sheaths and collars pilose on abaxial surface with hairs 2–4 mm long, glabrous with age; ligules 0.1–0.3 mm long, fimbriate or densely ciliolate; blades 10–30 cm long, 3–4 mm wide, usually loosely involute. Panicles 30–40 cm long, 10–15 cm wide, open, diffuse, subpyramidal, exserted or partly included below, the branches with a tuft of trichomes in the axils; glumes 1–1.8 mm long; lemmas 1.9–2.5 mm long; paleas as long as the lemma.

Distribution and habitat.—Sporoboluls airoides subsp. *regis* is an endemic species known only from Coahuila, México on saline flats of Laguna del Rey, the type locality, and Salinas del Rey. *Sporobolus airoides* subsp. *regis* is distinguished from *S. airoides* subsp. airoides by its pubescent sheaths and tuft of trichomes in the axils of the panicle branches. Wipff and Jones (1994) considered these characters not significant to warrant specific rank, however, they felt that they are significant to warrant infraspecific recognition.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Ocampo, 12 km S of Salinas del Rey, *Henrickson 14152* (TEX).

2. Sporobolus atrovirens (Kunth) Kunth, Revis. Gramin. 1:68. 1829. (**Fig. 2, A–C**). *Vilfa atrovirens* Kunth, Nov. Gen. Sp. 1:138. 1816. *Agrostis atrovirens* (Kunth) Roem. & Schult., Syst. Veg. 2:361. 1817. TYPE: MÉXICO. DISTRITO FEDERAL: in valle Mexicana prope El Penon del Marques, *Humboldt and Bonpland s.n.* (HOLOTYPE: P-Bonpl!; ISOTYPE: BM!)

Small caespitose perennials, sometimes appearing annual. Culms 7–30 cm tall,

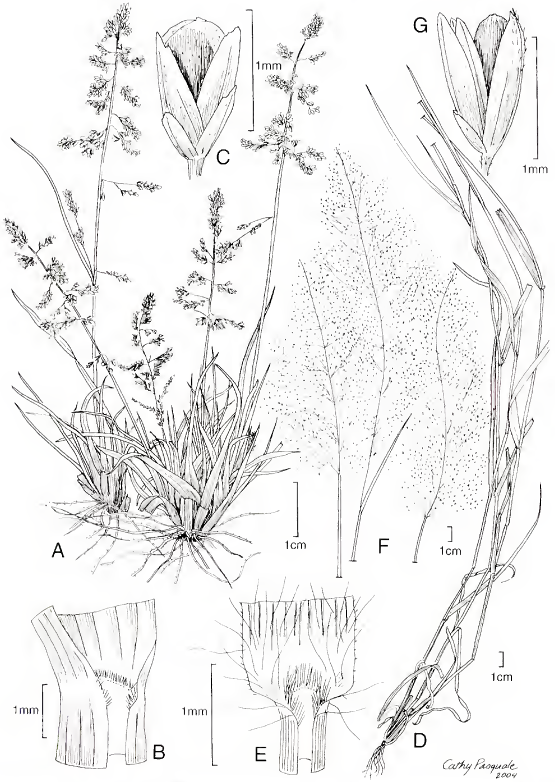

FIG. 2. *Sporobolus atrovirens*. **A.** Habit. **B.** Ligule. **C.** Spikelet with modified caryopsis. *Sporobolus coahuilensis*. **D.** Habit. **E.** Ligule. **F.** Inflorescences. **G.** Spikelet with modified caryopsis.

erect, with 1–2 nodes above the base; base diameter 0.5–0.8 mm. Leaf sheaths short, ciliolate; collar glabrous or with few hairs; ligules 0.1–0.2 mm long; blades 3–15 cm long, 2–4 mm wide, lanceolate, flat, glabrous, borne near base. Panicles 5–20 cm long, 3–10 cm wide, oblong to ovoid, completely exserted; primary branches spreading 70–120° from culm axis, naked below on lower 1/4–1/3, the lowermost solitary or paired at the nodes; pulvini in the axils of the primary branches glabrous, yellowish; pedicels 0.5–1.6 mm long. Spikelets 0.7–1.2 mm long, greenish or purplish to plumbeous; glumes without nerves, apex obtuse; lower glumes 0.3–0.5 mm long, the apex obtuse or erose; upper glumes 0.4–0.7 mm long, the apex obtuse to acute; lemmas 0.7–1.2 mm long, the apex acute to obtuse; paleas 0.9–1.2 mm long, the apex obtuse; stamens 1 or 2; anthers 0.4–0.8 mm long, purplish. Modified caryopses 0.5–0.8 mm long, pyriform or quadroid, somewhat laterally flattened, light brownish.

Distribution and habitat.—*Sporobolus atrovirens* is a rare species for northeastern México usually found occupying xeric habitats in gypsum soils at 10–1500 m. It has been reported in México in Aguascalientes, Baja California, Coahuila, Durango, Hidalgo, Guanajuato, Jalisco, México, Oaxaca, Puebla, San Luis Potosí, Tamaulipas, Tlaxcala, Veracruz, Yucatán, and Zacatecas. In the Sierra La Lagunita at 1450 m, *S. atrovirens* (*Peterson et al. 16690*) was found growing on slopes with a dominant vegetation of *Pinus pseudostrobus* Lindl., *Juniperus flaccida* Schltdl., *Juglans*, *Agave*, and *Muhlenbergia dubia* E. Fourn. Other associated native and adventive species from this site include: *Chloris*, *Tragus berteronianus* Schult., *Urochloa meziana* (Hitchc.) Morrone & Zuloaga, *Paspalum dilatatum* Poir., *Erioneuron avenaceum* (Kunth) Tateoka, *Eragrostis intermedia* Hitchc., *Oplismenus hirtellus* (L.) P. Beauv., *Bromus anomalus* Rupr. ex E. Fourn., *Schizachyrium*, and *Panicum bulbosum* Kunth. This latter site was perhaps unusual for this species since it was in a heavily wooded and shaded environment.

Specimens examined. **MÉXICO. Mora 5358* (UAT); Municipio de Tula, 30 km al SW de Tula, cerca del limite de San Luis Potosí and Tamaulipas, *Gonzalez Medrano F. 4422* (TEX).

3. Sporobolus buckleyi Vasey, Bull. Torrey Bot. Club 10:128. 1883. (**Fig. 3. A & B**).
TYPE: U.S.A. TEXAS: 1883, *S.B. Buckley s.n.* (ISOTYPE: US-556873!).

Caespitose perennials. Culms 40–100 cm tall, erect, glabrous, base flattened, internodes glabrous; base diameter 0.7–3 mm wide. Leaf sheaths 4/5 as long as the internodes to longer than the internodes above, glabrous, margins occasionally hairy near summit, sometimes with a line of hairs from one margin to the next, the hairs up to 1.2 mm long, lower sheaths strongly laterally compressed

Fig. 3. *Sporobolus buckleyi*. **A.** Habit. **B.** Spikelet with modified caryopsis. *Sporobolus spiciformis*. **C.** Habit. **D.** Ligule. **E.** Spikelet with stamens.

and keeled; ligules 0.2–0.4 mm long; blades 12–35 cm long, 4–12 mm wide, flat, glabrous below and scaberulous above; margins smooth to scaberulous. Panicles 15–50 cm long, 7–22(–30) cm wide, open, diffuse, ovate; primary branches ascending to widely spreading mostly 2–17 cm long, not floriferous on lower 1/4 –1/2; secondary branches appressed to loosely spreading; pulvini in axils of primary branches glabrous; pedicels 0.2–1.2 mm long, mostly apressed, scaberulous. Spikelets 1–2 mm long, purplish or brownish; glumes 0.5–1.8 mm long, narrow lanceolate to lanceolate, membranous, unequal, prominently keeled, scaberulous along the distal portion of the keel; lower glumes 0.6–1mm long, the apex acuminate to acute; upper glumes 1.1–1.8 mm long, the apex acute; lemmas 1.2–2 mm long, lanceolate, membranous, glabrous, the apex acute; paleas 1.2–2 mm long, ovate, membranous, often splitting in two between the veins at maturity, glabrous, the apex acute; stamens 3; anthers 0.2–0.4 mm long, purplish. Modified caryopses 0.6–1 mm long, ovoid, slightly flattened, reddish brown. $2n = 40$.

Distribution and habitat.—In northeastern México, *S. buckleyi* is a common species of the Tamaulipan desert scrub on loamy soils near margins of woods sometimes in partial sunlight associated with *Acacia, Quercus*, and *Prosopis* thickets and thorn scrub; 40–700 m. Flowering April to November.

Specimens examined. **MÉXICO. Nuevo León:** Montemorelos, Ojo de Agua. Matorral xerófito. *M. A. Pantí 823* (MEXU), Monterrey. *C. G. 4. Sporobolus coahuilensis Valdés-Reyna, Phytologia 41:81. 1978. (**Fig. 2, D–G**). TYPE: MÉXICO. COAHUILA: 58 air mi SW of Cuatrocienegas, near 26° 17' N, 102° 40' W, 815 m, 15 Aug 1976, *J. Henrickson & B. Prigge 15363* (HOLOTYPE: LL!; ISOTYPES: CSLA, MEXU!).

Annuals. Culms 15–60 cm tall, ascending, glabrous. Leaf sheaths shorter than the internodes, glabrous; ligules 0.5–1 mm long, ciliate, the hairs 0.5–1 mm long; blades 4–12 cm long, 1.5–6 mm wide, flat, spreading, evenly distributed, sparsely ciliate-pustulate above. Panicles 6–22 cm long, (-1)5–13 cm wide, open, sometimes contracted; branches ending in a spikelet, lowest branches whorled, in verticels of 7–20; pedicels (2)3–6(-8) mm long, widely spreading, capillary. Spikelets 1.1–1.5 mm long; glumes thin, the apex acute; lower glumes ca. 0.5 mm long; upper glumes 1.4–1.5 mm long; lemmas 1.3–1.4 mm long, the apex acute; paleas 1–1.3 mm long, hyaline. Modified caryopses 0.6–0.9 mm long, oblong, light brown; embryo 0.2–0.4 mm long.

Distribution and habitat.—In México, *S. coahuilensis* is known only from Central Coahuila, near Las Delicias and Cuatrocienegas. This species has recently been found in Texas (per. comm. B.L. Turner).

Comments.—*Sporobolus coahuilensis* appears closely related to *S. pyramidatus*, a widespread species, and can be separated from the latter species by having long capillary pedicels and wider panicles.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Cuatrociénegas, SE de Cuatrociénegas, *Brigada III 1* (COCA); cerca 45 km SW of Cuatrociénegas, 760 m., *Peterson et al. 10000* (ANSM, US).

Caespitose to solitary-stemmed perennials. Culms (20–)30–130(–150) cm tall, glabrous below the nodes, internodes glabrous; base diameter 0.7–5 mm wide. Leaf sheaths 3/4 to 1 1/2 as long as the internodes above; upper (terminal) sheaths 1–6 mm wide, mostly glabrous, summit with a few hairs up to 3 mm long; ligules 0.1–0.5 mm long; blades 5–70 cm long, 1.5–10 mm wide, flat to folded or involute, glabrous below and glabrous to scaberulous above, sometimes pilose just above the ligule, rarely pilose throughout; margins mostly glabrous. Panicles 5–30 cm long, 0.4–1.6(–3) mm wide, terminal and axillary, narrow, sometimes densely spike-like, the base usually included in the uppermost sheath; primary branches 0.4–6 cm long, appressed, usually floriferous to base; secondary branches appressed; pedicels 0.3–3.5 mm long, appressed, glabrous to scaberulous. Spikelets 4–6 (–10) mm long, stramenious to purplish-tinged; glumes (1.2–)2–5(–6) mm long, lanceolate, membranous to chartaceous, usually with a greenish midvein that is scrabous towards the apex, subequal; lower glumes (1.2–)2–4 mm long, the apex acute; upper glumes (2–)2.5–5(–6) mm long, the apex acute; lemmas (2.2–)3–6(–10) mm long, lanceolate, membranous to chartaceous, rarely 2- or 3-veined, glabrous to minutely pubescent or long, ovate to lanceolate, membranous to chartaceous, the apex acute to obtuse; stamens 3; anthers 0.2–3.2 mm long, yellow to orangish. Modified caryopses 1–3 mm long, ellipsoid and laterally flattened, often striate, reddish brown. 2*n* = 54, 88, 108.

Distribution and habitat.—A rare species in northeastern México, only known from a single collection initially determined by F.W. Gould. Roadsides, railroad right of ways, beaches, cedar glades, pine woods, live oak-pine forests, prairies and many other partially disturbed, semi-open sites; 0–1600 m. Flowering August to November.

Specimen examined. **MÉXICO. COAHUILA.** Municipio de Muzquiz, La Boquilla, Rancho La Encantada, *J. A. Santos s.n.* (ANSM).

6. Sporobolus contractus Hitchc., Amer. J. Bot. 2:303. 1915. (**Fig. 5, A–D**). *Sporobolus cryptandrus* var. *strictus* Scribn., Bull. Torrey Bot. Club 9:103. 1882. *Sporobolus strictus* (Scribn.) Merr., Circ. Div. Agrostol. U.S.D.A. 32:6. 1901, *non* Franchet. Type: U.S.A. Arizona: Banks of Rillita [Rillito] Brook, near Camp Lowell, 15 Jun 1881, *C.G. Pringle s.n.* (isotype: US-825284!).

Fig. 5. *Sporobolus contractus*. **A.** Inflorescence. **B.** Sheath, blade, and portion of culm. **C.** Lower glume. **D.** Spikelet with modified caryopsis. *Sporobolus cryptandrus*. **E.** Habit. **F.** Glumes. **G.** Floret with modified caryopsis.

Caespitose perennials. Culms 35–100(–120) cm tall, erect, glabrous below the nodes, rrounded near base, internodes glabrous; base diameter 2–4(–5) mm long. Leaf sheaths 3/4 to longer than the internodes above, glabrous; margins with ciliate hairs especially on the upper portions, these hairs up to 3 mm long forming a conspiuous tuft near the summit; ligules 0.4–1 mm long; blades (2–)4–35 cm long, 3–8 mm wide, flat to involute, glabrous below and above; margins whitish, somewhat scaberulous. Panicles (10–)15–45(–50) cm long, 0.2–0.8(–1) cm wide, narrow, tightly contracted, dense and spike-like, usually included in the uppermost sheath; primary branches 0.3–1.5 cm long, appressed; secondary branches appressed and floriferous to base; pulvini in axils of primary branches glabrous; pedicels 0.2–2 mm long, appressed, scaberulous. Spikelets 1.7–3.2 mm long, whitish to plumbeous; glumes 0.7–3.2 mm long, narrow lanceolate, membranous, unequal, prominently keeled, scaberulous along the keel; lower glumes 0.7–1.7 mm long, rarely without a midvein, the apex acute to acuminate; upper glumes 2–3.2 mm long, the apex acute; lemmas 2–3.2 mm long, linear membranous, glabrous, the apex acute; paleas 1.8–3 mm long, linear lanceolate, membranous, glabrous, the apex acute; stamens 3; anthers 0.3–0.5 mm long, light yellowish. Modified caryopses 0.8–1.2 mm long, ellipsoid, laterally flattened, light brownish or translucent. $2n = 36$.

Distribution and habitat.—In México, *S. contractus* ranges from Baja California, Chihuahua, and Sonoroa to Coahuila and Nuevo León on dry to moist sandy soils, occasionally in salt-desert scrub associated with *Atriplex confertifolia*, *A. canescens*, *Artemisia tridentata* Nutt., desert grasslands with *Bouteloua* and *Muhlenbergia*, and pinyon-juniper woodlands; 300–2300 m. Flowering July through November.

Specimens examined. **MÉXICO. Sporobolus cryptandrus var. *occidentalis* E.K. Jones & Fassett, Rhodora 52:125. 1950. TYPE: U.S.A. OREGON: Baker County: bars of Snake River, Ballard's Landing, ca. 3 mi NE of Homestead, 8 Jul 1899, *W.C. Cusick 2222* (HOLOTYPE: US-362493!).

Caespitose perennials. Culms 30–100(–120) cm tall, erect to decumbent, base flattened to rounded, glabrous below the nodes, internodes glabrous; base diameter 1–3.5 mm wide. Leaf sheaths 2/3–3/4 as long as the internodes above, glabrous to scaberulous, sometimes ciliate along the upper margins, summit with a conspicuous tuft of white hairs up to 4 mm long; ligules 0.5–1 mm long; blades (2–)5–26 cm long, 2–6 mm wide, flat to involute, erect or ascending, mostly glabrous below and scaberulous above; margins scaberulous. Panicles 15–40 cm long, 2–12(–14) cm wide, narrowly pyramidal, ultimately open, main axis ascending and straight, lower branches longest, usually included in the uppermost sheath; primary branches 0.6–6 cm long, appressed or ascending, spreading 0–130° from the culm axis; secondary branches mostly appressed not floriferous on lower 1/8–1/4; pulvini in axils of primary branches ascending, glabrous; pedicels 0.1–1.3 mm long, appressed, glabrous to scaberulous. Spikelets 1.5–2.5(–2.7) mm long, brownish, plumbeous or purplish-tinged; glumes 0.6–2.5(–2.7) mm long, linear-lanceolate to ovate, membranous, unequal; lower glumes 0.6–1.1 mm long, rarely without a midvein, the apex acute to acuminate; upper glumes 1.5–2.7 mm long, the apex acute; lemmas 1.4–2.5(–2.7) mm long, ovate to lanceolate, membranous, glabrous, the apex acute; paleas 1.2–2.4 mm long, lanceolate, membranous, glabrous, the apex acute; stamens 3; anthers 0.5–1 mm long, yellowish to purplish. Modified caryopses 0.7–1.1 mm long, ellipsoid, light brownish to reddish-orange. $2n = 36, 38, 72$.

Distribution and habitat.—In México, *S. cryptandrus* ranges from Baja California, Chihuahua, and Sonora to Coahuila, Nuevo León and Tamaulipas. This species is found on sandy soils, rocky slopes, washes, calcareous ridges, and roadsides in salt-desert scrub with *Atriplex confertifolia*, *A. canescens*, *Grayia spinosa* (Hook.) Moq., *Ceratoides lanata* (Pursh) J.T. Howell, and *Lycium*; pinyon-juniper woodlands; yellow pine forests; and southwest plains grasslands with *Aristida*, *Bouteloua*, and *Hilaria*; 60–2900 m. Flowering May through November.

8. Sporobolus flexuosus (Thurb. ex Vasey) Rydb., Bull. Torrey Bot. Club 32:601. 1905. **(Fig. 6, A–C)**. *Vilfa cryptandra* var. *flexuosa* Thurb. ex Vasey, Rep. U.S. Geogr. Surv., Wheeler 6:282. 1879 [title page 1878]. *Sporobolus cryptandrus* var. *flexuosus* (Thurb. ex Vasey) Thurb., Bot. California 2:269. 1880. TYPE: U.S.A. NEVADA and ARIZONA: 1871 and 1872, *G.M. Wheeler s.n.* (ISOTYPE: US-556875!).

Caespitose perennials, rarely appearing annual. Culms 30–100(–120) cm tall, erect to decumbent, base flattened to rounded, glabrous below the nodes, and on internodes; base diameter 1–3 mm wide. Leaf sheaths 2/3–3/4 as long as the internodes above, glabrous to scaberulous, sometimes ciliate along the upper margins, summit with a tuft of hairs up to 4 mm long; ligule 0.5–1 mm long; blades (2–)5–24 cm long, 2–4(–6) mm wide, flat to involute, erect or ascending, mostly glabrous below and scaberulous to scabrous above; margins scaberulous. Panicles 10–30 cm long, 4–12 cm wide, open, subovate to oblong, the main axis flexuous and drooping, lower branches no longer than those in the middle, usually with the base included in the uppermost sheath; primary branches 1–8 (–12) cm long, widely spreading to reflexed, flexuous and tangled, mostly spreading 70–130° from the culm axis; secondary branches widely spreading not floriferous on lower 1/8–1/2; pulvini in the axils of primary branches re-

Fig. 6. *Sporobolus flexuosus*. **A.** Inflorescence. **B.** Pulvinus. **C.** Spikelet with caryopsis. *Sporobolus nealleyi*. **D.** Habit. **E.** Spikelet.

curved, pubescent; pedicels 0.3–3 mm long, mostly spreading, scaberulous. Spikelets 1.8–2.5 mm long, plumbeous; glumes 0.9–2.5 mm long, ovate, membranous, unequal; lower glumes 0.9–1.5 mm long, the apex acute; upper glumes 1.4–2.5 mm long, the apex acute; lemmas 1.4–2.5 mm long, lanceolate to ovate, membranous, glabrous, the apex acute; paleas 1.4–2.4 mm long, ovate, membranous, the apex acute; stamens 3; anthers 0.4–0.7 mm long, yellow. Modified caryopses 0.6–1 mm long, ellipsoid, light brownish to reddish-orange. 2*n* = 36, 38.

Distribution and habitat.—In México, *S. flexuosus* occurs in Chihuahua, Sonora, and Coahuila on sandy to gravely slopes, flats, and roadsides in desert scrub with *Atriplex* spp., *Coleogyne*, *Larrea tridentata*, *Grayia spinosa*, *Chrysthamnus*, and *Lycium*; plains grasslands with *Hilaria*, *Buchloe*, *Aristida*, and *Bouteloua*; pinyon-juniper woodlands with *Artemisia tridentata*; and yellow pine forests; 760–2100 m. Flowering May through November.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Cuatrociénegas, Cuatrociénegas, *Brigada III 14* (COCA); Dunas yesosas, cerca de la Poza El Bonito, *J.S. Marroquín s.n.* (ANSM); 45 km SW of Cuatrociénegas, *Peterson et al. 9999* (ANSM, US); Municipio de Ocampo, 4 km S of Laguna El Rey Chemical Plant, *Peterson & Valdés-Reyna 8372* (ANSM, US); 4 km S de Laguna del Rey, de la Planta Quimica, *Valdés-Reyna 2014* (ANSM).

9. Sporobolus giganteus Nash, Bull. Torrey Bot. Club 25:88. 1898. (**Fig. 7, A & B**). *Sporobolus cryptandrus* var. *giganteus* (Nash) E.K. Jones, Contr. W. Bot. 14:11. 1912. TYPE: U.S.A. NEW MEXICO. Doña Ana Co.: White Sands, 4000 ft, 26 Aug 1897, *E.O. Wooton 394* (HOLOTYPE: NY-128297!; ISOTYPE: US-330618!).

Sporobolus cryptandrus var. *robustus* Vasey, Contr. U.S. Natl. Herb. 1(2):56. 1890. TYPE: U.S.A. TEXAS. Presidio Co.: 1887, *G.C. Nealley 746* (ISOTYPE: US-556883!).

Robust perennials. Culms 100–200 cm tall, erect, stout, glabrous below the nodes, base rounded, internodes glabrous; base diameter (3–)4–10 mm wide. Leaf sheaths longer than the internodes above, glabrous, striate, margins with ciliate hairs especially on upper portions, these hairs up to 2 mm long forming a conspicuous tuft near the summit; ligules 0.5–1.5 mm long; blades 10–50 cm long, (3–)4–10(–13) mm wide, flat, glabrous below and above; margins whitish, scaberulous. Panicles 25–75 cm long, 1–4 cm wide, narrow, contracted, dense and spike-like, usually included in the uppermost sheath; primary branches mostly 0.5–6 cm long, appressed to spreading 0–30° from the culm axis; secondary branches appressed and floriferous to base; pulvini in axils of primary branches glabrous; pedicels 0.5–2 mm long, appressed. Spikelets 2.6–3.5(–4) mm long, whitish to plumbeous; glumes 0.6–3.5 mm long, narrow lanceolate, membranous, unequal, prominently keeled, somewhat scaberulous along the keel; lower glumes 0.6–2 mm long, the apex acute to acuminate; upper glumes 2–3.5(–4) mm long, the apex acute; lemmas 2.5–3.5(–4) mm long, linear lanceolate, membranous, glabrous, the apex acute; paleas 2.4–3.4(–3.8) mm long, linear lanceolate, membranous, glabrous, the apex acute; stamens 3; anthers 0.6–1 mm

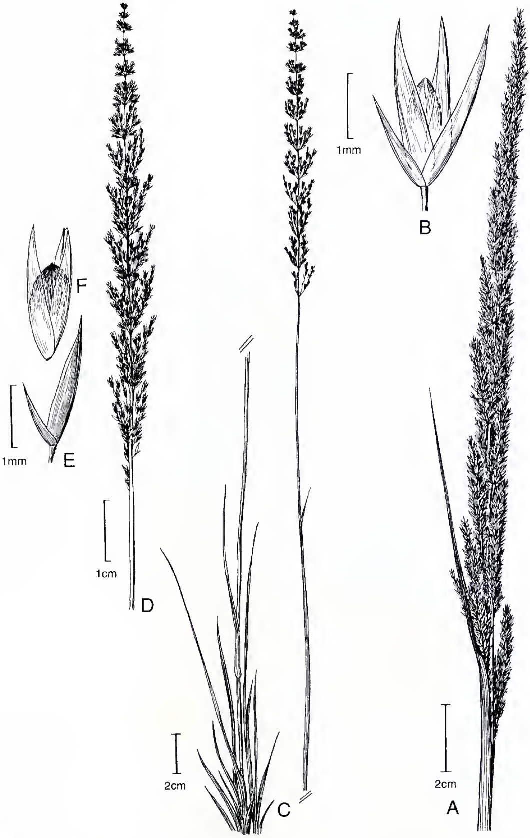

Fig. 7. *Sporobolus giganteus*. **A.** Inflorescence. **B.** Spikelet with modified caryopsis. *Sporobolus purpurascens*. **C.** Habit. **D.** Inflorescence. **E.** Glumes. **F.** Floret with modified caryopsis.

long, yellowish. Modified caryopses 0.8–1.7 mm long, ellipsoid, light yellowish-brown sometimes translucent. $2n = 36$.

Distribution and habitat.—Sand dunes, sandy areas along rivers, calcareous slopes, roadsides, associated *with Acacia constricta* Benth. ex A. Gray, *Larrea tridentata*, *Jatropa dioica* Cerv., *Viguiera stenoloba* Blake, *Juniperus osteosperma* (Torr.) Little, *and Atriplex canescens*; 760–1220 m. Flowering July through October.

Specimens examined. **MEXICO. Coahuila:** Cuatrocienegas, ca 33 (air) mi SSW of Cuatrocienegas, on N slopes of Sierra de Los Alamitos along trail, 6.4 mi S of El Hundido, 28 Sep 1973, near 26°30' N, 102°16' W, *J. Caespitose perennials or at least long-living annuals with tough fibrous roots. Culms 30–100(–120) cm tall, erect, base mostly flattened, glabrous below the nodes, internodes glabrous; base diameter 1–3.5(–5) mm wide. Leaf sheaths 1/2 to about as long as the internodes, glabrous; ligules 0.2–0.5 mm long; blades (6–)10–30(–50) cm long, 1–5 mm wide, flat, glabrous below and above. Panicles 20–35(–50) cm long, 0.3–2.2(–3) cm wide, narrow, contracted, sometimes included in the uppermost sheath; primary branches mostly 0.4–2.5(–5) cm long, appressed sometimes ascending spreading 0–40° from the culm axis; secondary

Fig. 8. *Sporobolus indicus*. **A.** Habit. **B.** Spikelet with modified caryopsis. *Sporobolus jacquemontii*. **C.** Habit. **D.** Primary branch with spikelets. **E.** Spikelet.

branches appressed and floriferous to base; pulvini in axils of primary branches glabrous; pedicels 0.1–1.8 mm long, appressed. Spikelets 2.0–2.6(–2.7) mm long, plumbeous to light brownish; glumes 0.4–1.6 mm long, ovate or obovate, membranous, subequal; lower glumes 0.3–1 mm long, often without a midvein, the apex acute, obtuse to truncate, often erose; upper glumes 0.6–1.6 mm long, the apex acute obtuse to truncate, often erose; lemmas 1.4–2.6(–2.7) mm long, ovate, membranous, glabrous, the apex acute or obtuse; paleas 1.3–2.4 mm long, ovate, membranous, glabrous, the apex acute; stamens 3; anthers 0.5–1.1 mm long, white, sometimes purple-tinged. Modified caryoposes 0.6–1.2 mm long, ellipsoid-quadrate, truncate towards apex, flattened laterally, reddish brown. $2n$ = 18, 24, 36.

Distribtion and habitat.–*Sporobolus indicus* is found throughout the western hemishphere and is common in disturbed places, open areas, roadsides, pastures, along lake shores and beaches in sandy or clay soils associated with many plant communities; 3–2460 m. Flowering throughout the year, more commonly March to December.

11. Sporobolus jacquemontii Kunth, Revis. Gramin. 2:427, t. 127. 1831. (**Fig. 8, C–E**). *Vilfa jacquemontii* (Kunth) Trin., Mem. Acad. Imp. Sci. Saint-Petersbourg, Ser. 6, Sci. Math., Seconde Pt. Sci. Nat. 6, 4:92. 1840. *Sporobolus pyramidalis* var. *jacquemontii* (Kunth) Jovet & Guédès, Taxon 22:163. 1973. TYPE: DOMINICAN REPUBLIC. SANTO DOMINGO: 1827, *V. Jacquemont s.n.* (HOLOTYPE: P; ISOTYPES: L, LE-TRIN-1712.01!).

Plants perennial, densely cespitose, without rhizomes. Culms 40–100 cm tall. Leaf sheaths keeled or rounded, glabrous, ciliate at apex; ligules 0.2–0.4 mm long; blades 10–40 cm long, 2–4 mm wide, flat but soon becoming involute, tapering to a fine point. Panicles 14–35 cm long, 0.4–3 cm wide, contracted, interrupted, and rather lax; primary branches appressed to strongly ascending, spikelet-bearing to the base, the lower branches 1.5–5 cm long, much longer than the adjacent internodes; pedicels 0.1–1.2 (–1.8) mm long. Spikelets 1.4–1.8(–2) mm long, plumbeous to greenish; glumes 0.3–0.7 mm long; lower glumes 0.3–0.5 mm long, obtuse; upper glumes 0.4–0.7 mm long, usually less than 1/2 as long as the florets, faintly 1-veined, truncate, erose to denticulate; lemmas 1.4–2 mm long, elliptic, glabrous, 1-veined, acute; paleas 1.4–2 mm, elliptic; stamens 3(2); anthers 0.9–1.1 mm long. Modified caryopses 0.7–1 mm long, quadrangular, laterally compressed, truncate, reddish brown. $2n = 24$.

Distribution and habitat.—This species is widely distributed and is found in Australia, Africa, and is apparently native to North America, South America, Central America, and the West Indies. In the study area, *S. jacquemontii* is more abundant in the Tamaulipan scrub vegetation at 10–1900 m.

Comments.—Simon and Jacobs (1999) noted that the spikelet morphology is essentially the same as *S. pyramidalis* P. Beavu. However, Simon and Jacobs (1999) observed *S. pyramidalis* and *S. jacquemontii* growing adjacent to each other and noted that individuals thought to be *S. jacquemotii* had shorter culms and lacked pyrimidal shaped panicles. *Sporobolus jacquemontii* has been placed as a synonym of *S. pyramidalis* by Baaijens and Veldkamp (1991) and Laegaard and Peterson (2001). We choose to take the conservative route and retain *S. jacquemontii* at the rank of species until there is more evidence (Peterson et al. 2003).

12. Sporobolus nealleyi Vasey, Contr. U.S. Natl. Herb. 1(2):57. 1890. (**Fig. 6, D & E**). TYPE: U.S.A. TEXAS. Brazos Co.: Brazos Santiago, 1887, *G.C. Neally 752* (HOLOTYPE: US-556888!).

Caespitose perennials from a hard knotty base. Culms 10–40 cm tall, erect, base rounded, glabrous below the nodes and grooved on one side, internodes mostly glabrous; base diameter 0.7–1.2 mm wide. Leaf sheaths 1/2–4/5 as long as the internodes above, villous to tomentose with soft kinky hairs along the margins and back occasionally almost glabrous, the hairs up to 4 mm long; ligules 0.2–0.4 mm long; blades (0.6–)1.5–6(–7) cm long, 1–1.5 mm wide, involute, stiffly divergent from the culms at right angles, glabrous below and scaberulous above; margins smooth. Panicles 3–10 cm long, (0.3)1–5(–6) cm wide, ultimately open, subovate, the lower portion sometimes included in the uppermost sheath; primary branches 0.5–5 cm long, appressed or ascending spreading 0–90° from the culm axis, secondary branches appressed or spreading not floriferous on lower 1/8–1/4; pedicels 0.2–2 mm long. Spikelets 1.4–2.1 mm long, purplish; glumes 0.5–2 mm long, linear-lanceolate to ovate, membranous, unequal; lower glumes 0.5–1.1 mm long, the apex acuminate; upper glumes 1.3–2 mm long, the apex acuminate to acute; lemmas 1.4–2.1 mm long, ovate, membranous, glabrous, the apex acute; paleas 1.4–2.1 mm long, ovate, membranous, the apex acute; stamens 3; anthers 0.7–1 mm long, purplish. Modified caryopses 0.7–1 mm long, orangish to whitish. $2n = 40$.

Distribtion and habitat.—In México, *S. nealeyi* is known only from Coahuila, Nuevo León, and San Luis Potosí on sandy and gravely soils usually derived from gypsum or near alkaline habitats associated with desert grasslands with *Pleuraphis jamesii* Torr., *Muhlenbergia villiflora* Hitchc., *Bouteloua chasei* Swallen, *Dasyochloa pulchella* (Kunth) Willd. ex Rydb., *Ephedra torreyana* S. Watson, *Chrysothamnus nauseousus* (Pall.) Britton, *Atriplex confertifolia*, and *Gutierrezia microcephala* (DC.) A. Gray; 750–2100 m. Flowering June to November.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Saltillo, 53.2 km S of Saltillo on México highway 54 and 28.5 km E on road to La Ventura, *Peterson et al. 10039* (ANSM, US); La Ventura, aproximadamente 80 km S de Saltillo, *Valdés-Reyna 1991, 3503* (ANSM). **Nuevo León:** Municipio de Galeana, Galeana, *J A. Caespitose annuals, larger plants sometimes appearing perennial, with intravaginal branching at base. Culms 7–35(–60) cm tall, erect or decumbent, base rounded, glabrous below the nodes, internodes glabrous; base diameter 1–1.6 mm wide. Leaf sheaths 1/2 to almost as long as the internodes above, glabrous or with ciliate hairs on the margins and summit, the hairs up to 3 mm long; ligules 0.3–1 mm long; blades 2–12(–20) cm long, 2–6 mm wide, flat, glabrous below and scaberulous above, sometimes with a few hispid hairs, mostly borne near base; margins ciliate-pectinate. Panicles 4–15(–18) cm long, 0.3–6 cm wide, open and pyramidal with verticillate branches spreading 30–90°, contracted and narrow when immature; primary branches 0.5–4.5 cm long, not floriferous on the lower 1/3–1/2, lowest branches whorled in verticels of 7–12(–15), lower portions of each branch with elongated glands; secondary branches appressed; pedicels 0.1–0.5 (–1) mm long, appressed. Spikelets 1.2–1.8 mm long, plumbeous or brownish, often secund along the branch; glumes 0.3–1.8 mm long, ovate to obovate, membranous, unequal; lower glumes 0.3–0.7 mm long, without a midvein, the apex acuminate, obtuse or irregularly truncate; upper glumes 1.2–1.8 mm long, the apex acute or acuminate and sometimes scaberulous; paleas 1.1–1.6 mm long, ovate to elliptic, membranous, the apex acute to obtuse; stamens 3; anthers 0.2–0.4 mm long, yellow or purplish. Modified caryopses 0.6–1 mm long, obovoid, faintly striate, light brownish. $2n = 24, 36, 54$.

Distribution and habitat.—*Sporobolus pyramidatus* is common throughout México occurring on disturbed soils, roadsides and railways, coastal sands, and alluvial slopes in many plant communities; 5–1750 m. Flowering March to November.

Comments.—Morphologically, *S. pyramidatus* is very similar to the Eastern Hemisphere *S. coromandelianus* (Retz.) Kunth, suggesting that they are closely related or perhaps represent the same taxon. Further systematic study is necessary to address this question.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Acuña, Rancho Las Norias, *J.A. 15. Sporobolus spiciformis Swallen, Proc. Biol. Soc. Wash. 56:78. 1943. (**Fig. 3, D & F**). TYPE: MÉXICO. COAHUILA: Puerto del norte, Cuatrocienegas, 1460 m, 18 Jul 1939, *L.H. Harvey 1225* (HOLOTYPE: US-176006!).

Caespitose perennials. Culms 30–70 cm tall, erect, mostly glabrous; base diameter 1–1.8 mm wide. Leaf sheaths shorter than the internodes, rounded, striate, scaberulous, glabrous and hairy only at the corners; ligules 0.8–1 mm long, densely ciliate; blades 7–20 cm long, 1.5–2 mm wide at the base, flat or becoming involute or at least boat shaped in section, firm, flexuous, adaxial surface with white ridges. Panicles 9–17 cm long, 3–5(–10) mm wide, spiciform and spikelike, white, often the lower portion included in the sheath; Spikelets 1.6–2.3 mm long; glumes 0.8–1.8 mm long, unequal, hyaline, the apex obtuse to acute, minutely erose; lower glumes 0.8–1.2 mm long; upper glumes 1–1.8 mm long, 1-nerved; lemmas 1.6–2.3 mm long, the apex obtuse to acute, minutely erose; paleas 1.6–2.3 mm long, the apex minutely two-toothed; anthers 1–1.3 mm long, yellow. Modified caryopses 0.8–1 mm long, ellipsoid. $2n = 40$.

Distribution and habitat.—*Sporobolus spiciformis* is endemic to the Chihuahuan Desert Region, reported from Chihuahua, Coahuila, and Nuevo León where it is restricted to saline or gypsum-derived soils associated with *Yucca, Ephedra, Nama, Suaeda, Chilopsis linearis* (Cav.) Sweet, *Prosopis*, and *Petalonyx*; 410–1750 m.

Comments.—*Sporobolus spiciformis* is morphologically similar to *S. phleoides*, an Argentinian desert endemic also commonly found growing on saline soils. *Sporobolus phleoides* can be separted from *S. spiciformis* by having broader leaf blades up to 6.6 mm wide, acuminate lemmas, and shorter anthers only 0.4–0.6 mm long.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Cuatrociénegas, Balneario Los Mezquites, *Brigada III 15* (COCA); Dunas yesosas, cerca de la Poza El Bonito, *J.S. Strongly rhizomatous and stoloniferous perennials. Culms 10–65 cm tall, base flattened or rounded, widely creeping in rows and branching virgately, erect to decumbent, mostly glabrous and smooth and shinny below the nodes, internodes glabrous; base diameter 1–2.2 mm wide. Leaf sheaths 1/2 to almost as long as the internodes above, overlapping, glabrous, ciliate along the margins, summit with a tuft of hairs, the hairs up to 2 mm long; ligules 0.1–0.4 mm long; blades 4–16 cm long, 2–5 mm wide, flat to loosely involute, conspicuously distichous, glabrous below and scaberulous above; margins scaberulous. Panicles 3–10 cm long, 0.4–1.6 cm wide, narrow, contracted, densely flowered and spikelike; primary branches 0.5–2 cm long, ascending and appressed, floriferous to base; pedicels 0.2–1.4 mm long, apressed. Spikelets (1.8–)2–3.2 mm long, ochroleucus to purplish-tinged, sometimes grayish; glumes 1.5–3(–3.2) mm long, ovate-oblong, membranous, subequal, scaberulous along the keel; lower glumes 1.5–2.4 mm long, the apex acute; upper glumes 1.8–3(–3.2) mm long, the apex acute; lemmas 2.1–3 mm long, ovate to lanceolate, membranous, glabrous, the apex acute; paleas 2.1–3 mm long, ovate, membranous, the apex acute to obtuse; stamens 3; anthers 1–1.7 mm long, yellowish. Modified caryopses usually absent. $2n = 20, 30$.

Distribution and habitat.—*Sporobolus virginicus* occurs along sandy beaches, sand dunes, and saline habitats and is particularly common along the immediate coast throughout México associated with *Avicennia*, *Batis*, *Borrichia*, *Distichlis*, *Panicum amarulum* Hitchc. & Chase, *Salicornia*, and *Spartina*; 0–270 m. Flowering May to October.

Densely caespitose perennials. Culms 90–250 cm tall, erect, stout, glabrous below the nodes, base rounded, internodes glabrous; base diameter 2—9 mm wide. Leaf sheaths 2/3 to a little longer than the internodes above, glabrous, shinny, rarely with a few long hairs near the summit, these hairs up to 6 mm long; ligules 1-2 mm long; blades 20–70 cm long, 3–10 mm wide, flat rarely involute, glabrous below and scabrous above; margins scabrous roughened. Panicles 20–60 cm long, 12–26 cm wide, open, broadly lanceolate, exserted; primary branches 1.5–10 cm long, ascending to widely spreading 20–70° from the culm axis; secondary branches appressed and floriferous to base; pulvini in axils of primary branches glabrous; pedicels mostly 0.2–0.5 mm long, appressed. Spikelets 1.5-2.5 mm long, crowded and appressed, purplish or greenish; glumes 0.5–2 mm long, lanceolate to ovate, membranous, unequal; lower glumes 0.5–1 mm long, often appearing without a midvein, the apex acute; upper glumes 0.8–2 mm long, the apex acute to obtuse; lemmas 1.2–2.5 mm long, ovate, membranous, glabrous, the apex acute to obtuse; paleas 1.1–2.5 mm long, ovate, membranous, glabrous, the apex acute to obtuse; stamens 3; anthers 1.1–1.3 mm long, yellowish to purplish. Modified caryopses 1–1.4 mm long, ellipsoid, reddish-brown or blackish, striate. $2n = 36$.

Distribution and habitat.—Moist clay flats and rocky slopes near saline habitats associated with *Atriplex, Acacia, Suaeda, Prosopis,* and *Opuntia*; 5–1800 m. Flowering May to December.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Acuña, 19 km by winding road N of El Jardín, 3 km S of Mina El Popo; E slope of Sierra del Carmen S of Cañón del Diablo, *M.C. ACKNOWLEDGMENTS

We wish to thank the curators at the following herbaria for help locating specimens: COCA, MEXU, MO, NMCR, TEX, UAT; the Smithsonian Institutions, Fellowships and Grants for supporting research visits by JVR and JJOD to the United States National Herbarium; the Scholarly Studies Program, Research Opportunities, Atherton Seidell Foundation, and Biodiveristy Surveys and Inventories Program all at the Smithsonian Institution for financial support; Utah State University for permission to use illustrations that appeared in Flora of North America, Volume 25, prepared by Linda A. Vorobik and Hana Pazdirkova; Cathy Johnson for preparing illustrations; Alice R. Tangerini for preparing the plates; and Kelly W. Allred, Yolanda Herrera Arrieta, and Barney Lipscomb for reviewing the manuscript.

BOOK NOTICES/BOOKS RECEIVED

WILLIAM W. DUNMIRE. 2004. **Gardens of New Spain How Mediterranean Plants and Foods Changed America.** (ISBN 0-292-70564-6, pbk.). The University of Texas Press, P.O. Box 7819, Austin, TX 78713-7819, U.S.A. (Orders: 800-252-3206, fax 800-687-6046, www.utexas.edu/utpress). $24.95, 392 pp., 6" × 9".

Publisher Comments: "*Gardens of New Spain* tells the fascinating story of the diffusion of plants, gardens, agriculture, and cuisine from late medieval Spain to the colonial frontier of Hispanic America. Beginning in the Old World, William Dunmire describes how Spain came to adopt plants and their foods from the Fertile Crescent, Asia, and Africa. Crossing the Atlantic, he first examines the agricultural scene of Pre-Columbian Mexico and the Southwest. Then he traces the spread of plants and foods introduced from the Mediterranean to Spain's settlements in Mexico, New Mexico, Arizona, Texas, and California. In lively prose, Dunmire tells stories of the settlers, missionaries, and natives who blended their growing and eating practices into regional plantways and cuisines that live on today in every corner of America."

Table of Contents: **1)** Pre-Columbian Spain—the Full Hourglass; **2)** Mexico Before Columbus; **3)** Pre-Columbian Agriculture in the American Southwest; **4)** European Plantways to the New World: 1492-1521; **5)** Old World Agriculture Comes to the Mexican Mainland; **6)** Spanish Trade, Technology, and Livestock; **7)** New Mexico's First Mediterranean Gardens; **8)** Into Sonora and Arizona; **9)** The Corridor into Texas; **10)** Hispanic Farmers Return to New Mexico; **11)** Mediterranean Connections to Florida and California; Epilogue; Appendix: Master Plant List; Glossary; Sources; Selected Bibliography; and Index.

BETTY FUSSELL. 1992. **The Story of Corn.** (ISBN 0-8263-3592-6, pbk.)
University of New Mexico Press, MSC01 1200, University of New Mexico, Albuquerque, NM 87131-0001, U.S.A. (Orders: 1-800-249-7737, Fax: 505-277-9270, www.anmpress.com) $24.95, 356 pp., b/w photos, 8" × 9 1/4".

Publisher Comments: "Now in paperback for the first time, *The Story of Corn* is Betty Fussell's mesmerizing account of the extraordinary grain that built the New World. In a form as uniquely hybrid as its subject, it blends history and myth, science and art, anecdote and image, personal narrative and epic to tell the story of this amazing crop and the people who for centuries have planted, eaten, worshipped, processed, and profited from it."

REVISION OF *LOBELIA* SECT. *HOMOCHILUS* (CAMPANULACEAE: LOBELIOIDEAE)

Thomas G. Lammers

Department of Biology and Microbiology
University of Wisconsin Oshkosh
Oshkosh, Wisconsin 54901, U.S.A.

ABSTRACT

Lobelia L. sect. *Homochilus* A. DC. comprises six species, two of which are divided into pairs of geographic subspecies. All are robust polycarpic (iteroparous) perennial herbs or shrubs with relatively large more-or-less racemose flowers on ebracteolate or minutely bibracteolate pedicels; hemispheric or depressed hemispheric hypanthia; bilabiate or subbilabiate (unilabiate in one species) red, orange, yellow, pink, or purple-hued corollas with a straight cylindrical or apically tapering tube equaling or longer than the monomorphic lobes; ventral anthers with tufts of white or yellow trichomes at apex; and oblong or ellipsoid seeds with a faintly striate or minutely reticulate testa (Murata Type D); the three taxa that have been studied cytologically are diploid with $n = 7$. *Lobelia aguana*, *L. ghiesbreghtii*, *L. guererrensis*, and *L. laxiflora* have pedicels longer than the red, orange, or yellow typically bicolored flowers, and are distributed primarily in Mexico and/or Central America; *L. decurrens* and *L. heteroclita*, in contrast, have pedicels shorter than the monochromatic pink or purple-hued flowers, and are confined to the Andes of South America.

RESUMEN

Lobelia L. sect. *Homochilus* A. DC. comprende seis especies, dos de las cuales están divididas en pares de subespecies geográficas. Todas son hierbas perennes robustas policárpicas o arbustos con flores relativamente grandes más o menos racemosas sobre pedicelos ebracteolados o diminutamente bibracteolados; hipantos hemisféricos o hemisférico deprimidos; bilabiados o subbilabiados (unilabiados en una especie) corolas rojas, anaranjadas, amarillas, rosas, o tonos púrpura con un tubo cilíndrico o estrechado apicalmente tan largo o más que los lóbulos monomórficos; anteras ventrales con mechones apicales de tricomas blancos o amarillos; y semillas oblongas o elipsoides con una testa débilmente estriada o diminutamente reticulada (Murata Tipo D); los tres taxa que han sido estudiados citológicamente son diploides con $n = 7$. *Lobelia aguana*, *L. ghiesbreghtii*, *L. guererrensis*, y *L. laxiflora* tienen pedicelos más largos que las flores típicamente bicólores rojas, anaranjadas, o amarillas, y están distribuidas primariamente en México y/o América Central; *L. decurrens* y *L. heteroclita*, por contra, tiene pedicelos más cortos que las flores monocromáticas rosa o tonos púrpura, y están confinadas a los Andes de Sur América.

Lobelia L. is the largest of the 30 genera of Lobelioideae (Campanulaceae), comprising over 400 species of annual and perennial herbs, shrubs, trees, and giant rosette plants, with solitary or racemose (rarely paniculate or corymbose) flowers on bibracteolate pedicels; blue, purple-hued, or white (rarely red, pink, green, or yellow) corollas with the tube dorsally cleft to the base and the lobes monomorphic or dimorphic and the ventral larger; and apically bivalvate capsules or rarely berries (Lammers 1993, 2004; Murata 1995). The genus is virtually cosmopolitan in distribution, with representatives native to the floras of six conti-

SIDA 21(2): 591–623. 2004

nents and several major oceanic archipelagoes. Nearly 38% of the species are indigenous to Africa and another 29% to North America; Asia and Australasia each have about 10% of the species, South America 8%, and Polynesia 3%, while just two species occur in Europe (Lammers, unpublished data).

The last comprehensive monograph of *Lobelia* was that of Wimmer (1953, 1968), who divided its species among three subgenera: subg. *Lobelia* with two sections; subg. *Mezleria* (C. Presl) E. Wimm. (a name unfortunately referable to the genus *Monopsis* Salisb.; cf. Lammers 1999), with two sections; and subg. *Tupa* (G. Don) E. Wimm. with six sections. Further taxonomic structure was indicated by dividing many of the 10 sections into subsections and other subordinate taxa (cf. Lammers 1993). This classification was revised by Murata (1995), who maintained the three subgenera but altered their division into sections, recognizing a total of 14 and abandoning all subordinate taxa.

Among the six sections of subg. *Tupa* recognized by Murata (1995) was sect. *Homochilus* A. DC. Wimmer (1953, 1968) had circumscribed this section to include six species of perennial herbs and shrubs distributed from the southwestern United States to Peru. These species were characterized by their large racemose flowers with a hemispheric hypanthium, bilabiate or subbilabiate red, orange, yellow, or purple corolla with a straight cylindrical tube equaling or longer than the monomorphic lobes; ventral anthers bearded apically with tufts of white trichomes; and faintly striate oblong or ellipsoid seeds (Type D of Murata 1992, 1995).

Although Murata (1995) accepted Wimmer's (1953, 1968) treatment of sect. *Homochilus*, a preliminary study of some of its members (Eakes & Lammers 1996; cf. Hamlin 1995; Lammers 1999) suggested that neither this classification nor that of McVaugh (1943) was optimal, especially at the infraspecific level. Furthermore, since these treatments were published, two additional species thought referable to the section have been described (McVaugh 1965; Lammers 1999). The purpose of the present study, then, was to re-evaluate taxonomic relationships in the section, particularly at the infraspecific level, and to promulgate a formal classification that would satisfactorily reflect these relationships.

TAXONOMIC HISTORY

The genus *Lobelia* was first divided into named subordinate taxa by Candolle (1839), who recognized three sections: unispecific sect. *Trimeris* (C. Presl) A. DC., sect. *Lobelia* [as "sect. Rapuntium," nom. invalid.] with the bulk of the species, and sect. *Homochilus* with six species. This last was characterized by flowers with a hemispheric hypanthium and a red, yellow, or purple bilabiate corolla with an elongate cylindrical tube almost equaling the lobes in length. As originally circumscribed, it was geographically heterogeneous. Its members were *L. decurrens* Cav. of "Chile" (actually Peru; see below), *L. laxiflora* Kunth and *L. rigidula* Kunth of Mexico, *L. kraussii* Graham of Dominica and Martinique in the Lesser Antilles, *L. rotundifolia* Juss. ex A. DC. of Hispaniola and Puerto Rico in the Greater Antilles, and *L. gaudichaudii* A. DC. of O'ahu in the Hawaiian Islands.

Bentham (1876) expanded the circumscription of *Lobelia* by incorporating several genera that Candolle (1839) and others had recognized as distinct. In doing so, he retained Candolle's three sections and added five more: sect. *Tupa* (G. Don) Benth., sect. *Tylomium* (C. Presl) Benth., sect. *Rhynchopetalum* (Fresen.) Benth., sect. *Hemipogon* Benth., and sect. *Holopogon* Benth. As regards sect. *Homochilus*, Hawaiian *L. gaudichaudii* was explicitly removed to sect. *Rhynchopetalum*. Of the two West Indian species in the section, *L. rotundifolia* was removed, presumably to sect. *Tylomium*, but *L. kraussii* was implicitly left in sect. *Homochilus*. Schönland's (1889) classification of the genus was similar and his treatment of sect. *Homochilus* identical. The section was likewise recognized by Uphof (1910) and (under the generic name *Rapuntium* Mill.) by Post and Kuntze (1903).

In treating the North American representatives of sect. *Homochilus*, McVaugh (1943) recognized two additional species as members: *L. aguana* E. Wimm. and *L. ghiesbreghtii* Decne. West Indian *L. kraussii* was removed to sect. *Tylomium*, leaving only plants of the American mainland in sect. *Homochilus*. From his earlier comments (McVaugh 1940), it would appear that *L. decurrens* was also excluded from sect. *Homochilus* (and perhaps even from all of subg. *Tupa*; cf. McVaugh 1965). McVaugh divided *L. laxiflora* into four more-or-less geographic varieties, one of which encompassed *L. rigidula*.

Wimmer's (1953, 1968) treatment of these species was identical, with the following exceptions. *Lobelia decurrens* was definitely included within the section, and divided into two varieties. *Lobelia delessertiana* was segregated from *L. laxiflora* var. *laxiflora*, while *L. laxiflora* var. *nelsonii* was elevated to specific rank as *L. haenkeana* (C. Presl) A. DC. and divided into two varieties. What remained of *L. laxiflora* was then divided into six varieties plus 12 *formae*. This circumscription and classification of sect. *Homochilus* was accepted by Murata (1995).

MATERIALS AND METHODS

Revision of the classification of sect. *Homochilus* was based upon morphological data analyzed via traditional taxonomic methodology (Leenhouts 1968; Qualls 1986; Vogel 1987; Maxted 1992; Watson 1997; Winston 1999). These data were gathered from over 3400 specimens deposited in 38 herbaria (see Acknowledgments for a complete list of institutions); all extant types were seen, either as the original specimen or as a high-resolution image. Definitions of qualitative character states follow Harris and Harris (1994), supplemented by Radford (1986).

The classification promulgated here embodies a morphological species concept (Michener 1970; Cronquist 1978; Stuessy 1990), though it is assumed that the species recognized are more or less equivalent to the biological species (Grant 1981) that would be recognized were data on reproductive behavior available. When it is possible on the basis of morphology to discern clusters of conspecific populations that are geographically coherent, such clusters are recognized as subspecies (cf. Raven et al. 1974; Thorne 1978; Lammers 1988, 1991, 1995, 1999; Thompson & Lammers 1997). It is understood that conspecific subspecies will not be as clearly demarcated as congeneric species, and may show some intergradation in their zone of contact.

Altogether, over the past two centuries, a total of 48 heterotypic names referable to sect. *Homochilus* have been published, together with an additional 45 homotypic synonyms. The protologues for all 93 names were examined. All nomenclature was brought into compliance with current provisions of the *International Code of Botanical Nomenclature* (ICBN; Greuter et al. 2000) and typification was clarified as necessary.

RESULTS AND DISCUSSION

Revising the classification of a genus or infrageneric taxon is essentially a two-stage process (Qualls 1986; Maxted 1992; Watson 1997). First, one must determine the appropriate circumscription of the taxon as a whole, i.e., what individuals and populations to include within it. Second, these constituent units must be divided into a number of subordinate taxa: species and perhaps subspecies.

Circumscription of the section.—A detailed evaluation of the circumscription of sect. *Homochilus* can only be performed in the context of a thorough re-examination of the classification of all 400+ species of *Lobelia*. Murata's (1995) attempts in that direction are probably the best that can be accomplished at the present time without molecular data or phylogenetic analysis. His classification of *Lobelia* is certainly more natural than that of Wimmer (1953, 1968), as it takes into account a larger assemblage of characters. For this reason, Murata's (1995) treatment is accepted here as an overall framework within which to work.

Murata's (1995) studies supported Wimmer's (1953, 1968) circumscription of sect. *Homochilus* and he explicitly accepted it in his revision. However, he did note that additional species might be assigned there. Murata did not study in any detail the Central American and West Indian species treated by Wimmer (1953, 1968) as "species antillanae" within sect. *Tupa* (as sect. *Eutupa* E. Wimm., nom. illeg. sub Art. 52.1) but did comment that they "may be attributable" to sect. *Homochilus* rather than sect. *Tupa*. These species (e.g., *L. assurgens* L., *L. cirsiifolia* Lam., *L. nubicola* McVaugh) do indeed differ from members of sect. *Tupa* as circumscribed by Murata (1995) and Lammers (2000) in their conspicuously bibracteolate (vs. ebracteolate or minutely bibracteolate) pedicels; globose or ovoid seeds with a reticulate testa (Murata Type E) (vs. oblong or ellipsoid with a faintly striate or minutely reticulate testa [Murata Type D]), and diploid (vs. hexaploid) chromosome number. Furthermore, Wimmer's "species antillanae" do indeed resemble sect. *Homochilus* in certain features, including their robust habit; relatively large flowers with red, orange, yellow, pink, or purple-hued corolla; and diploid chromosome number (so far as known; Lammers 1993).

However, these "species antillanae" also differ from sect. *Homochilus* in several important characters. First, their bracteoles are conspicuous and foliaceous (vs. absent or minute in sect. *Homochilus*). Second, the corolla tube is curved or arcuate (vs. straight) with the lobes often unilabiate and deflexed (vs. usually bilabiate or subbilabiate and recurved or straight). Finally and perhaps most significantly, the seeds are ovoid or globose, with a reticulate testa of Murata Type E (vs. oblong or ellipsoid with a faintly striate or minutely reticulate testa of Murata Type D). After weighing all the data, it seems best to exclude Wimmer's "species antillanae" from both sect. *Tupa* and sect. *Homochilus*; they are here recognized as sect. *Tylomium*, following McVaugh (1940, 1943) and other recent authors (e.g., Wilbur 1991; Lammers & Proctor 1994; Buss et al. 2001).

In her detailed account of *Heterotoma* Zucc., Ayers (1986, 1990) mentioned that, on the basis of her very preliminary cladistic analyses, the type of that genus, *H. lobelioides* Zucc., might logically be included within *Lobelia* sect. *Homochilus*. This species does resemble members of sect. *Homochilus* in a number of features, including its robust polycarpic habit; suffruticose stems; racemose inflorescence; ebracteolate pedicels; relatively large flowers with red or orange and yellow bicolored corolla; ventral anthers bearded apically with tufts of white trichomes; faintly striate (Murata Type D) seeds; and diploid chromosome number (Lammers 1993). However, *H. lobelioides* differs conspicuously from any species of *Lobelia* (and is unique among Campanulaceae) in its large arcuate basally inflated nectar spur and in the nearly perpendicular exsertion of the staminal column from the corolla tube during the carpellate phase of the flower (Ayers 1986, 1990). In light of this and the preliminary nature of her cladograms, it is best to follow Ayers' (1986, 1990) recommendation and recognize *H. lobelioides* as the sole species of a distinct genus.

Although *L. decurrens* was included in sect. *Homochilus* from the very beginning, McVaugh (1940) implied that it should be excluded from that section (and perhaps even from the entire subgenus; cf. McVaugh 1965). It does indeed differ from the species included there by McVaugh (1940, 1943) in a number of features, including its rank odor; decurrent leaves; pedicels shorter than (vs. equaling or longer than) the flowers, making the inflorescence appear spikelike (vs. clearly racemose); fimbriate (vs. entire or minutely toothed) calyx lobes; and monochromatic purple-hued (vs. red, orange, or yellow and usually bicolored) corollas. However, *L. decurrens* does resemble the other species of sect. *Homochilus* in its robust polycarpic habit, ebracteolate pedicels, depressed hemispheric hypanthium, straight cylindrical or slightly tapering corolla tube, monomorphic corolla lobes, faintly striate (Murata Type D) seeds, and diploid chromosome number (Lammers 1993). Though it is somewhat discordant in sect. *Homochilus*, it would be even more so in the other sections of subg. *Tupa*, e.g., sect. *Colensoa* (Hook. f.) J. Murata, sect. *Tupa*, or sect. *Tylomium*. For these reasons, *L. decurrens* is assigned to sect. *Homochilus*.

In naming and describing *L. heteroclita*, McVaugh (1965) did not assign his new species to a specific section, merely commenting that it was "apparently referable to the subgenus *Tupa* as delimited by Wimmer." It differs from all other species assigned here to sect. *Homochilus* in its ventrally oblique hypanthium (cf. Ayers 1990) and deep pink unilabiate corolla with a tube that tapers conspicuously towards the mouth. However, it resembles the rest of the section in its robust habit, reduced or absent bracteoles, depressed hemispheric hypanthium, straight corolla tube, and monomorphic corolla lobes. It particularly resembles *L. decurrens*, the only other exclusively South American member of the section, in having pedicels shorter than the flowers, making the inflorescence appear spike-like, and in its monochromatic corollas. As with *L. decurrens*, it is even more discordant in any other section of subg. *Tupa*. It seems best assigned here, and regarded as related most closely to *L. decurrens*.

The newest member of the section, *L. guerrerensis*, was explicitly assigned to sect. *Homochilus* by its authors (Lammers 1999). The degree to which it conforms to that section's characterization is indicated by the fact that all the specimens upon which it was based had previously been identified as *L. laxiflora*, the type of the section.

Species and subspecies.—After a thorough comparative study of all material, it was concluded that just six species could be recognized in sect. *Homochilus*. These are essentially the species assigned to the section by Wimmer (1953, 1968), except that *L. delessertiana* and *L. haenkeana* are subsumed into *L. laxiflora*, and two species described after Wimmer's death are added.

Two of these species exhibit relatively minor variation in morphology that is correlated with geography, making possible the recognition of subspecies. In *L. laxiflora*, the morphometric analysis of Eakes and Lammers (1996) supported the recognition of two subspecies based on leaf dimensions rather than the complex infraspecific classifications of McVaugh (1943) or Wimmer (1953, 1968). Plants of northeastern Mexico and Arizona have very narrow leaves, while those in the rest of the range are wider. This treatment, which is essentially identical to that of Candolle (1839), was implemented by Lammers (1999) and is maintained here. In *L. decurrens*, variation in flower size supports recognition of two subspecies, which differ from the two varieties recognized on the basis of pubescence by Wimmer (1937, 1953). Plants in the northern portion of the range have markedly smaller flowers than those in the south.

Summary.—The circumscription of sect. *Homochilus* adopted here encompasses six species, which fall into two subordinate groups, based on morphology and geography; because of the few species involved, these subgroups are not named formally. The first group (*L. aguana*, *L. ghiesbreghtii*, *L. guerrerensis*, and *L. laxiflora*) comprises species distributed primarily in Mexico and Central America (*L. laxiflora* extends into southern Arizona and southwestern Colombia), with pedicels longer than the typically bicolored red, orange, or yellow flowers. The second group (*L. decurrens* and *L. heteroclita*) encompasses species of the Andes of northern South America with pedicels shorter than the monochromatic pink or purple-hued flowers. One species in each group (*L. decurrens* and *L. laxiflora*) shows geographically correlated variation in morphology and is divided into a pair of subspecies.

TAXONOMIC TREATMENT

Lobelia sect. **Homochilus** A. DC. in DC., Prodr. 7:383. 1839. *Rapuntium* sect. *Homochilus* (A. DC.) Kuntze in T. Post & Kuntze, Lex. Gen. Phan. 479. 1903. TYPE (designated by Murata 1995): *L. laxiflora* Kunth.

Robust polycarpic (iteroparous) perennial herbs and shrubs. Stems 0.2-3 m tall, herbaceous, suffruticose, or woody, single or several from the base, branched or unbranched, erect or ascending, moderately to densely leafy, glabrous or pubescent; latex white or cream-colored, viscous. Leaves alternate, simple, exstipulate, sessile or petiolate, glabrous or pubescent, the lower ones often deciduous; lamina ovate, oblong, narrowly oblong, elliptic, narrowly elliptic, lanceolate, oblanceolate, or linear, chartaceous, flat (cernuous in *L. guerrerensis*); margin entire, denticulate, serrulate, serrate, biserrate, or crenate, plane (minutely revolute in *L. guerrerensis*); apex obtuse, acute, acuminate, or narrowly acuminate; base attenuate, cuneate, obtuse, rounded, or decurrent. Flowers tetracyclic, perfect and proterandrous, zygomorphic, epigynous, pedicellate and resupinate, relatively large and numerous, solitary in the axils of the upper leaves or these reduced gradually to bracts towards the apex and so forming a terminal raceme (the distinction not always clear); pedicels erect, ascending, spreading, or incurved, stiff or flexuous, glabrous or pubescent, ebracteolate or minutely bibracteolate; bracteoles (when present) subulate or linear. Calyx synsepalous; tube adnate to the ovary, forming a hemispheric or depressed hemispheric hypanthium, the base rounded or truncate (ventrally oblique in *L. heteroclita*), glabrous or pubescent; lobes 5, valvate, persistent, subulate, linear triangular, narrowly triangular, or triangular, shorter than the corolla tube, glabrous or pubescent, the margin entire, toothed, or fimbriate, the apex acuminate. Corolla sympetalous, zygomorphic, bilabiate or subbilabiate (unilabiate in *L. heteroclita*), red, orange, or yellow and the lobes often a different color than the tube, or pink or various shades of purple throughout, glabrous or pubescent; tube straight, cylindric or tapering towards the mouth, laterally fenestrate towards base, dorsally cleft nearly to base; lobes 5, valvate, monomorphic; the two dorsal lobes linear or narrowly triangular, recurved or straight (all deflexed in *L. heteroclita*), one-fourth as long to about as long as the tube, acuminate or acute at apex; the three ventral lobes forming a trifid lip, the segments narrowly triangular, slightly shorter than the dorsal, straight or slightly deflexed. Stamens 5, antisepalous, connate for most of their length, exserted, emerging from the corolla above the dorsal lobes, glabrous or pubescent; dorsal anthers longer than the ventral, overhanging the orifice of the tube and partly occluding it; ventral anthers with tufts of white or yellow trichomes at apex; pollen tricolporate, prolate, ellipsoid. Ovary 2-loculed, inferior, adnate to the hypanthium for 1/3-2/3 its length; placentae large, axile; ovules numerous; style 1, slender, terete, with a ring of stiff white hairs near the apex; stigma 2-lobed, the lobes appressed and non-receptive as the style grows through the anther tube, pushing out pollen, after which the stigmas spread and become receptive. Fruit an ovoid or broadly ovoid capsule, 1/3-3/4-inferior, the conical apex dehiscing as two triangular valves; seeds honey-colored, oblong or ellipsoid, compressed, relatively small, the testa faintly striate or minutely reticulate (Type D of Murata 1992). Chromosome number (three taxa known) $n = 7$ (Lammers 1993).

Pollination biology.—Based on floral morphology, it is assumed that the species of sect. *Homochilus* are pollinated by hummingbirds. This assumption of ornithophily is supported for *L. laxiflora* by notes on herbarium labels (e.g., *Bye et al. 9192*, ASU, TEX; *Hurd 6*, MICH; *Marshall 133*, ARIZ, RSA) and by a published photograph (Anonymous 2003). In the bicolorous species, the corolla may change color to varying degrees through the course of anthesis. Typically, the corolla is more uniformly yellowish or orangish in bud or in staminate phase; the red pigments become best developed (and thus contrast reaches its peak) during carpellate phase. This phenomenon has also been observed in *L. excelsa* Bonpl. of sect. *Tupa* (Lammers 2000). The biological significance of such changes has been described by Weiss (1995).

KEY TO THE SPECIES AND SUBSPECIES

1. Pedicels shorter than the flowers, the inflorescence appearing spike-like; corolla monochromatic, various shades of purple (violet, red-purple, magenta, mauve, lavender) or deep pink (South America).
    2. Leaves rounded or cuneate at base; pedicels 15–23 mm long; hypanthium oblique ventrally; calyx lobes entire or with 1–2 minute denticulations per side; corolla tube 29–38 mm long, tapering conspicuously to mouth, corolla lobes 1/4–1/3 as long as tube, all five forming a single ventral lip; filament tube 32–38 mm long; dorsal anthers 4–5 mm long, 1/8–1/7 as long as filament tube (Colombia) ____ **6. L. heteroclita**
    2. Leaves long decurrent at base; pedicels 5–14 mm long; hypanthium symmetrical; calyx lobes fimbriate with 3–9 teeth per side; corolla tube 14–30 mm long, cylindric or tapering slightly towards mouth; corolla lobes 1/3–9/10 as long as tube, two dorsal and three ventral; filament tube 20–33 mm long; dorsal anthers 6–8.5 mm long, 1/4–1/3 as long as filament tube.
        3. Corolla 31–42 mm long, the tube 20–30 mm long, 2.5–3 times longer than the dorsal lobes; filament tube 24–33 mm long, 3.4–4.2 times longer than the dorsal anthers (S Peru) ____ **5a. L. decurrens** subsp. **decurrens**

3. Corolla 22–33 mm long, the tube 14–19 mm long, a little longer than the lobes to 1.8 times longer; filament tube 20–26 mm long, 2.5–3.6 times longer than the dorsal anthers (N Peru) ______ **5b. L. decurrens** subsp. **parviflora**

1. Pedicels equaling or longer than the flowers, the inflorescence clearly racemose; corolla usually bicolored, red, orange, and/or yellow (Mexico and Central America primarily).
   3. Stems, flowers, and ventral surface of lamina white-tomentose; lamina broadest at or near middle, 3.5–8 cm wide, on a petiole 10–30 mm long (Oaxaca) ______ **4. L. ghiesbreghtii**
   3. Stems, flowers, and ventral surface of lamina glabrous or pubescent, but never white-tomentose; lamina usually broadest below middle, 0.2–5 cm wide, sessile or on a petiole up to 7 mm long.
      4. Pedicels 85–210 mm long; calyx lobes 6–18 mm long; dorsal corolla lobes 20–33 mm long, the ventral 18–26 mm long; dorsal anthers 9–12 mm long, the ventral 7.5–9.5 mm long; capsules 10–15 mm long; seeds minutely reticulate (Guerrero to Guatemala) ______ **3. L. aguana**
      4. Pedicels 20–130 mm long; calyx lobes 1–6 mm long; dorsal corolla lobes 10–22 mm long, the ventral 10–21 mm long; dorsal anthers 6–9 mm long, the ventral 4.5–7.6 mm long; capsules 6–12 mm long; seeds faintly striate.
         5. Lamina cernuous, the margin entire or nearly so and minutely revolute; corolla yellow or yellowish orange on tube, red or orange on lobes; anther tube with dense dirty yellow trichomes 2–4 mm long from apex to base; ventral anthers with a tuft of dirty yellow trichomes 1.5–2 mm long at apex; capsules 9–11 mm in diameter; seeds 0.7–0.8 mm long, 0.3–0.4 mm wide (Guerrero) ______ **2. L. guerrerensis**
         5. Lamina flat, the margin denticulate, serrulate, serrate, or doubly serrate and plane; corolla red or orange on tube, orange or yellow on lobes; anther tube with sparse to moderately dense white trichomes 0.5–1 mm long on dorsal surface towards apex; ventral anthers with a tuft of white trichomes 0.7–1.3 mm long at apex; capsules 7–9 mm in diameter; seeds 0.5–0.6 mm long, 0.2–0.3 mm wide.
            6. Lamina 1–5 cm wide, 2–8 times longer than wide, the base rounded, obtuse, or cuneate (Mexico to Colombia) ______ **1a. L. laxiflora** subsp. **laxiflora**
            6. Lamina 0.2–1.4 cm wide, 12–18 times longer than wide, the base attenuate (Arizona & NE Mexico) ______ **1b. L. laxiflora** subsp. **angustifolia**

1. Lobelia laxiflora Kunth in Humb., Bonpl. & Kunth, Nov. Gen. Sp. 3:311 (quarto), 242 (folio). 1819 (Nov). *Rapuntium laxiflorum* (Kunth) C. Presl, Prodr. Monogr. Lobel. 26. 1836. *Tupa laxiflora* (Kunth) Planch. & Oerst., Vidensk. Meddel. Dansk Naturhist. Foren. Kjøbenhavn 1857:154. 1857. *Lobelia persicifolia* var. *laxiflora* (Kunth) Vatke, Linnaea 38:723. 1874. *Dortmanna laxiflora* (Kunth) Kuntze, Revis. Gen. Pl. 972. 1891. TYPE: MEXICO. [GUERRERO:] Acaguisotla, *Humboldt 3918* (HOLOTYPE: P-Bonpl. [IDC-microfiche!; photographs: F! MICH!]; ISOTYPES: B! [photographs: F! MICH!] B-W [IDC-microfiche!]). The isotype at B-W is the holotype of *L. fissa*. Though it seems that the name *L. persicifolia* var. *laxiflora* was used for the nomenclaturally typical "α" variety, neither the type of *L. persicifolia* (see below) nor the name itself was cited; the name thus is validly published under Art. 26.2.

Stems 0.2–3 m tall, herbaceous, suffruticose, or woody, unbranched or sparingly branched, erect or ascending, glabrous or pubescent. Leaves sessile or petiolate; lamina ovate, lanceolate, oblong, elliptic, narrowly elliptic, lanceolate, or linear, 2.5–19 cm long, 0.2–5 cm wide; adaxial surface glabrous or sparsely pubescent; abaxial surface glabrous or pubescent; margin denticulate, serrulate, serrate, or doubly serrate; apex acuminate or acute; base attenuate, cuneate, obtuse, or rounded; petiole (when present) 1–7 mm long, glabrous or pubescent. Flowers solitary in the axils of the upper leaves or forming a terminal raceme; pedicels 20–100 mm long, erect, ascending, spreading, or incurved, stiff or flexuous, glabrous or pubescent, ebracteolate or bibracteolate at or below the middle; bracteoles (when present) linear, 0.5–1.1 mm long. Hypanthium depressed hemispheric, 2–5 mm long, 4–11 mm in diameter, glabrous or pubescent; base rounded or truncate. Calyx lobes subulate, linear triangular, narrowly triangular, or triangular, 1–6 mm long, 0.8–3 mm wide, glabrous or pubescent; margin entire. Corolla bilabiate or subbilabiate, red or orange on tube, grading to orange or yellow on the lobes (rarely all yellow), 24–40 mm long, glabrous or pubescent; tube 14–25 mm long, 4–9.5 mm in diameter at base, 3.5–7 mm in diameter at mouth, cylindric or tapering slightly towards mouth; dorsal lobes linear, 10–22 mm long, 1–2 mm wide, recurved or straight, half as long to about as long as the tube, acuminate or acute at apex; ventral lip 10–20 mm long, the segments triangular or narrowly triangular, 1–10 mm long, 0.5–2 mm wide, acute or acuminate at apex. Filament tube 18–34 mm long, 0.7–2 mm in diameter, reddish or yellowish, glabrous or pubescent; anther tube 1.5–3.9 mm in diameter, the dorsal surface towards the apex moderately to densely pubescent with white trichomes 0.5–1 mm long; dorsal anthers 6–9 mm long; ventral anthers 4.5–7.5 mm long, with tufts of white trichomes 0.7–1.3 mm long at apex. Capsules broadly ovate, 6–12 mm long, 7–9 mm in diameter; seeds oblong or ellipsoid, 0.5–0.6 mm long, 0.2–0.3 mm wide, ca. 0.1 mm thick, the testa faintly striate. Chromosome number $n = 7$ (Ayers 1986).

Distribution.—Found throughout much of Mexico, south through Central America to Panama, and in the Cordillera Occidental of southwestern Colombia, with one population in the southwestern United States, in southern Arizona. The inclusion of the West Indies and Peru within the species' range (Nash 1976; Ayers 2000) was erroneous, as was its attribution to Georgia in the southeastern United States (Don 1838; Knowles & Westcott 1838). Its presence in northern Ecuador, while expected (Jeppesen 1981; Jørgensen 1999), is as yet unsubstantiated.

Cultivation.—The species was introduced to horticulture in 1825 as a half-hardy perennial and is still cultivated today, though not commonly (Hooker 1837; Don 1838; Vatke 1874; Siebert & Voss 1894; Anonymous 1915; Thomas 1990; Lancaster 1991; Huxley 1992; Ayers 2000); it appears that most plants cultivated today represent subsp. *angustifolia* (A. DC.) Eakes & Lammers (see below).

Discussion.—This widespread species shows considerable variation throughout its geographic range in leaf dimensions, pubescence, pedicel posture, and other features. Candolle (1839) was the first to use this variation to divide *L. laxiflora* into infraspecific taxa, recognizing narrow-leaved plants as var. *angustifolia* A. DC. Vatke (1874) expanded on this, dividing the species (under the illegitimate name *L. persicifolia*; see below) into five varieties: var. *laxiflora* (Kunth) Vatke, var. *mollis* Vatke, var. *warscewiczii* (Regel) Vatke, var. *amygdalina* Vatke, and var. *angustifolia* (A. DC.) Vatke. Little or no information on geographic distribution was provided. In support of his classification, Vatke commented that "omnes cultura sibi constant."

McVaugh (1943) divided *L. laxiflora* into four varieties, each of which had a reasonably coherent if overlapping geographic range: var. *angustifolia* (Arizona and Baja California to San Luis Potosi and Oaxaca), var. *laxiflora* (Puebla and Vera Cruz to Guatemala and Honduras), var. *nelsonii* (Fern.) McVaugh (Sonora to Chiapas), and var. *stricta* (Planch. & Oerst.) McVaugh (Michoacan, Jalisco and Nayarit south to Colombia). Wimmer (1953) segregated *L. laxiflora* var. *nelsonii* as a distinct species, *L. haenkeana* (C. Presl) A. DC., and carved three additional varieties out of the remaining three: var. *brevipes* E. Wimm., var. *patula* (Planch. & Oerst.) E. Wimm., and var. *petiolata* E. Wimm. With this classification, the degree of geographic overlap among varieties increased markedly. For example, three of the varieties were ascribed to Colombia, vs. one in McVaugh's scheme, and three to Guatemala, vs. two.

Eakes and Lammers (1996) undertook a detailed multivariate study of morphological variation in *L. laxiflora* and its allies *L. aguana* and *L. ghiesbreghtii*. States of 100 characters in 71 specimens were scored and these data subjected to cluster and principal components analyses. The results of their study failed to support either McVaugh's (1943) or Wimmer's (1953) classification; instead, they supported the original classification of Candolle (1839). Populations of *L. laxiflora* fell into two weakly discriminated clusters: narrow-leaved plants of northeastern Mexico and Arizona, and broad-leaved plants of the rest of the range. For the sake of consistency (cf. Lammers 1988, 1991, 1995), these two taxa were accorded the rank of subspecies by Lammers (1999); that treatment is followed here.

1a. **Lobelia laxiflora** subsp. **laxiflora**

Lobelia persicifolia Cav., Icon. 6:12. 1800, nom. illeg.; non Lam., Encycl. 3:584. 1792. *Lobelia cavanillesiana* Schult. in Roem. & Schult., Syst. Veg. 5:43. 1819 (Dec). *Lobelia cavanillesii* Mart., Ausw. Merkw. Pfl. 12. 1830, nom. superfl. *Rapuntium cavanillesianum* (Schult.) C. Presl, Prodr. Monogr. Lobel. 27. 1836; non *Rapuntium persicifolium* (Lam.) C. Presl, Prodr. Monogr. Lobel. 27. 1836. *Tupa persicifolia* G. Don in Sweet, Hort. Brit. ed. 3:424. 1839 (sero); non (Lam.) A. DC. in DC., Prodr. 7:395. 1839 (Dec). *Siphocampylus cavanillesii* J. W. Loud., Ladies' Fl. Gard. Ornam. Greenh. Pl. 184. 1848; non *Siphocampylus cavanillesianus* G. Don, Gen. Hist. 3:702. 1834, nom. illeg. sub Art. 52.1; nec *Siphocampylus persicifolius* (Lam.) G. Don in Sweet, Hort. Brit. ed. 3:424. 1839. TYPE: MEXICO. Acambaro, *Née s.n.* (HOLOTYPE: MA [photographs: MA! W!]; ISOTYPE: MA!).

Lobelia rigidula Kunth in Humb., Bonpl. & Kunth, Nov. Gen. Sp. 3:311 (quarto), 243 (folio). 1819 (Nov). *Rapuntium rigidulum* (Kunth) C. Presl, Prodr. Monogr. Lobel. 26. 1836. TYPE: "Amérique Équatoriale," *Humboldt s.n.* (HOLOTYPE: P-Bonpl. [IDC-microfiche!; photographs: F! MICH!]).

Lobelia fissa Willd. ex Schult. in Roem. & Schult., Syst. Veg. 5:57. 1819 (Dec). TYPE: "America meridionalis," *Humboldt 3918/Willdenow 3993* (HOLOTYPE: B-W [IDC-microfiche!]; ISOTYPES: B! [photographs: F! MICH!] P-Bonpl. [IDC-microfiche!; photographs: F! MICH!]). The isotype at P-Bonpl. is the holotype of *L. laxiflora*.

Lobelia amygdalina Willd. ex Schult. in Roem. & Schult., Syst. Veg. 5:57. 1819 (Dec). *Rapuntium amygdalinum* (Willd. ex Schult.) C. Presl, Prodr. Monogr. Lobel. 27. 1836. *Dortmanna amygdalina* (Willd. ex Schult.) Kuntze, Revis. Gen. Pl. 972. 1891. TYPE: "America meridionalis," *Humboldt 4425/Willdenow 3992* (HOLOTYPE: B-W [IDC-microfiche!]).

Rapuntium haenkeanum C. Presl, Prodr. Monogr. Lobel. 26. 1836. *Lobelia haenkeana* (C. Presl) A. DC. in DC., Prodr. 7:382. 1839. *Dortmanna haenkeana* (C. Presl) Kuntze, Revis. Gen. Pl. 972. 1891. TYPE: PHILIPPINES. LUZON: *Haenke s.n.* (HOLOTYPE: PR! [photograph: F!]). As with *Rapuntium longifolium* (Thompson and Lammers 1997), the locality was an error and the specimen was actually collected in the New World (Merrill 1923).

Lobelia prunifolia Humb. ex C. Presl, Prodr. Monogr. Lobel. 37. 1836. *Siphocampylus prunifolius* (Humb. ex C. Presl) A. DC. in DC., Prodr. 7:401. 1839. TYPE: Sine loc., *Humboldt 2167* (LECTOTYPE [designated by Wimmer 1953]: B! [photograph: F!]).

Lobelia canescens C. Presl, Prodr. Monogr. Lobel. 38. 1836. *Siphocampylus canescens* (C. Presl) A. DC. in DC., Prodr. 7:402. 1839. TYPE: MEXICO. Pasquaro, *Humboldt s.n.* (HOLOTYPE: PR! [photograph: F!]; ISOTYPES: B! B-W [IDC-microfiche!]).

Siphocampylus bicolor D. Don in Sweet, Brit. Fl. Gard. (ser. 2) 4:pl. 389. 1838. *Lobelia laxiflora* var. *bicolor* (D. Don) Endl., Cat. Hort. Acad. Vindobon. 1:436. 1842. *Tupa bicolor* (D. Don) Planch., Hort. Donat. 78. 1858. TYPE: GREAT BRITAIN. Messrs. Low & Co., raised from seeds collected in Georgia USA by Alexander Gordon (LECTOTYPE, here designated: Don 1838, pl. 389!). Because no specimen that might be considered original material has been found, the plate that accompanied the original description is designated here as the lectotype. The geographic source of the seed is almost certainly an error, unless the plants were cultivated there.

Lobelia ovalifolia Hook. & Arn., Bot. Beechey Voy. 300. 1838. TYPE: MEXICO. [Nayarit: Tepic, 8 Dec 1827 - Feb 1828, *leg.* Lay,] *Beechey s.n.* (HOLOTYPE: K! [photograph: F!]; ISOTYPE: E!). Information in brackets for this and the two following names is taken from the official itinerary (Hooker & Arnott 1830).

Lobelia angulatodentata Hook. & Arn., Bot. Beechey Voy. 301. 1838 (as 'angulato-dentata'). TYPE: MEXICO. [NAYARIT: Tepic, 8 Dec 1827 -Feb 1828, *leg.* Lay,] *Beechey s.n.* (HOLOTYPE: K! [photographs: F! MICH!]; ISOTYPE: E!). The hyphen is deleted from the epithet in accordance with Art. 60.9.

Lobelia lanceolata Hook. & Arn., Bot. Beechey Voy. 301. 1838, nom. illeg.; non (Gaudich.) Hook. & Arn., Bot. Beechey Voy. 88. 1832. *Lobelia laxiflora* f. *lanceolata* E. Wimm., Pflanzenr. IV.276b:683. 1953. TYPE: MEXICO. [NAYARIT: Tepic, 8 Dec 1827 - Feb 1828, *leg.* Lay,] *Beechey s.n.* (HOLOTYPE: K! [photographs: F! MICH!]).

Lobelia concolor M. Martens & Galeotti, Bull. Acad. Roy. Sci. Bruxelles 9(2):46. 1842, nom. illeg.; non R. Br., Prodr. 563. 1810. *Dortmanna concolor* Kuntze, Revis. Gen. Pl. 972. 1891. *Lobelia laxiflora* f. *concolor* (Kuntze) E. Wimm., Pflanzenr. IV.276b:684. 1953. TYPE: MEXICO. VERACRUZ: Xalapa, 4000 ft, Jun-Oct [Nov–Apr on K isotype] 1840, *Galeotti 1972* (HOLOTYPE: BR! [photograph: F!]; ISOTYPES: BR! G! K!).

Lobelia andina Benth., Pl. Hartweg. 213. 1845. TYPE: COLOMBIA. Andes of Popayan, 8000 ft, *Hartweg 1183* (HOLOTYPE: K! [photographs: F! MICH!]; ISOTYPE: K! [photograph: F!]).

Siphocampylus mollis Regel, Flora 33:353. 1850 (21 Jun); non Planch., Fl. Serres Jard. Eur. 6:36. 1850 (incerta). *Siphocampylus warscewiczii* Regel, Schweiz. Z. Gartenbau 1850:131. 1851. *Lobelia persicifolia* var. *warscewiczii* (Regel) Vatke, Linnaea 38:723. 1874. TYPE: GERMANY. Berlin Botanic Garden, grown from seed sent by Warscewicz from Guatemala (neotype here designated: Regel 1851, unnumbered plate!). Because no specimen that might be considered original material has been found, and as no illustration accompanied the original description, a plate published soon after by its author is designated as the neotype.

Tupa costaricana Planch. & Oerst., Vidensk. Meddel. Dansk Naturhist. Foren. Kjøbenhavn 1857:154. 1857. *Tupa costaricana* var. *stricta* Planch. & Oerst., Vidensk. Meddel. Dansk Naturhist. Foren. Kjøbenhavn 1857:155. 1857. *Lobelia costaricana* (Planch. & Oerst.) E. Wimm., Ann. Naturhist. Mus. Wien 46:239. 1933. *Lobelia laxiflora* var. *stricta* (Planch. & Oerst.) McVaugh, N. Amer. Fl. 32A:96. 1943. TYPE: COSTA RICA. Prope Cartago, *Oersted 9245* (LECTOTYPE [designated by McVaugh 1943]: C! [photographs: F! GH! MICH!]; ISOLECTOTYPES: C[4!] [photographs: F!]). Though it seems that the name *T. costaricana* var. *stricta* was used for the nomenclaturally typical ("α") variety, no types were cited and the name thus is validly published under Art. 26.2.

Tupa costaricana var. *patula* Planch. & Oerst., Vidensk. Meddel. Dansk Naturhist. Foren. Kjøbenhavn 1857:155. 1857. *Lobelia laxiflora* var. *patula* (Planch. & Oerst.) E. Wimm., Pflanzenr. IV.276b:683. 1953. TYPE: COSTA RICA. CARTAGO: southern slopes of Volcán Irazú in small patches of woods left in cleared meadows, 2500 m, 27 Mar 1967, *Wilbur & Stone 8747* (neotype here designated: MICH! [photograph: F!]). Because no original material could be located, a specimen from the same general area which conforms to the protologue is here chosen as the neotype.

Lobelia persicifolia var. *mollis* Vatke, Linnaea 38:722. 1874. *Lobelia laxiflora* var. *mollis* (Vatke) Zahlbr., Repert. Spec. Nov. Regni Veg. 14:185. 1916. TYPE: not located. Name based on plants grown in the botanic garden at Berlin in 1854, their origin unknown. McVaugh (1943) reported seeing what he considered the type specimen at B, but did not cite details. It is no longer extant (cf. Lammers 1994), nor does the Field Museum's Type Photograph Collection (cf. Nitecki 1980, Grimé and Plowman 1986) contain a photo of it (C. Niezgoda, pers. comm.).

Lobelia patzquarensis Sessé & Moç., Pl. Nov. Hisp. 152. 1890. TYPE: MEXICO. [MICHOACÁN: Pátzcuaro, in frigidis et saxosis montibus, Sep 1790,] *Sessé and Moçiño Icones Florae Mexicanae 398* (HOLOTYPE: Hunt Institute-6331.119 [color transparency!; photograph: F!]; ISOTYPE: MA [photograph: F!]). The information in brackets is taken from the protologue and McVaugh (1977).

Lobelia nelsonii Fern., Proc. Amer. Acad. Arts 36:503. 1901. *Lobelia laxiflora* var. *nelsonii* (Fern.) McVaugh, Ann. Missouri Bot. Gard. 27:349. 1940. TYPE: MEXICO. JALISCO: along road near Huachinango, oak woods on hills, 4500–5500 ft, 4 Mar 1897, *Nelson 4009* (HOLOTYPE: GH! [photograph: F!]; ISOTYPES: GH! US! [photographs: F! W!]).

Lobelia laxiflora var. *brevifolia* Zahlbr., Repert. Spec. Nov. Regni Veg. 14:185. 1916. *Lobelia laxiflora* f. *brevifolia* (Zahlbr.) E. Wimm., Pflanzenr. IV.276b:684. 1953. TYPE: COLOMBIA. NARIÑO: Pasto, Río Guaitara, 1600–2000 m, *Lehmann 4674* (HOLOTYPE: K! [photograph: F!]).

Lobelia laxiflora var. *foliosa* Zahlbr., Repert. Spec. Nov. Regni Nov. 14:185. 1916. TYPE: COLOMBIA. CAUCA: bei Chapa, 1850 m, über Popayan, 2200m, Mar 1884, *Lehman 3656* (HOLOTYPE: G! [photograph: F!]; ISOTYPES: BM! K! US!).

Lobelia delessertiana E. Wimm., Repert. Spec. Nov. Regni Veg. 19:386. 1924. TYPE: MEXICO. OAXACA: Oct 1842, *Ghiesbreght s.n.* (HOLOTYPE: G! [photograph: F!; fragment: W!]).

Lobelia loretensis M. E. Jones, Contr. W. Bot. 18:68. 1933. TYPE: MEXICO. BAJA CALIFORNIA: Primiera Agua, near Loreto, 19 Oct 1930, *Jones 27279* (HOLOTYPE: POM! [photograph: F!]; ISOTYPE: POM!).

Lobelia costaricana var. *magna* E. Wimm., Repert. Spec. Nov. Regni Veg. 38:85. 1935. *Lobelia laxiflora* f. *magna* (E. Wimm.) E. Wimm., Pflanzenr. IV.276b:684. 1953. TYPE: MEXICO. Sine loc., 1835, *Hegewisch s.n.* (HOLOTYPE: GOET! [photograph: F!]).

Lobelia rensonii E. Wimm., Repert. Spec. Nov. Regni Veg. 38:85. 1935. TYPE: EL SALVADOR. Vicinity of San Salvador, *Renson 54* (HOLOTYPE: NY! [photograph: F!]).

Lobelia haenkeana var. *panamensis* E. Wimm., Ann. Naturhist. Mus. Wien 56:368. 1948. TYPE: PANAMA. CHIRIQUI: forests around El Boquete, banks of rivers, 1000–1300 m, 2 Mar 1911, *Pittier 2869* (HOLOTYPE: US! [photograph: F!]).

Lobelia laxiflora var. *petiolata* E. Wimm., Ann. Naturhist. Mus. Wien 56:369. 1948. TYPE: MEXICO.

OAXACA: Jotao, 4000 ft, *Galeotti 1989B* (LECTOTYPE, here designated: B! [photograph: F!]). Wimmer cited this plus Liebmann material from Chinantla in unspecified herbaria. While I have seen sheets of the latter at BM, MO, and NY, none was annotated by Wimmer, while in 1942 he annotated the Galeotti specimen as "orig!"

Lobelia laxiflora f. *lutea* Standl. & Steyerm., Publ. Field Mus. Nat. Hist., Bot. Ser. 23:98. 1944. TYPE: GUATEMALA. QUETZALTENANGO: above Santa Maria de Jesús, moist thicket, 1650 m, 1 Mar 1939, *Standley 67195* (HOLOTYPE: F!; ISOTYPE: NY!).

Lobelia laxiflora f. *flava* E. Wimm., Pflanzenr. IV.276b:685. 1953. TYPE: EL SALVADOR. Vulcán de San Salvador, brushy slope, 1000–1800 m, 7 Apr 1922, *Standley 22973* (HOLOTYPE: US; ISOTYPE: NY!).

Stems glabrous or pubescent. Lamina ovate, lanceolate, elliptic, narrowly elliptic, or oblong, 2.5–19 cm long, 1–5 cm wide; adaxial surface glabrous or sparsely pubescent; abaxial surface glabrous or pubescent; margin denticulate, serrulate, serrate, or doubly serrate; apex acuminate or acute; base cuneate, obtuse, or rounded; petiole (when present) 1–7 mm long. Pedicels 20–100 mm long, erect, ascending, spreading, or incurved, stiff or flexuous. Hypanthium 2–5 mm long, 4–11 mm in diameter, glabrous or pubescent. Calyx lobes subulate, linear triangular, narrowly triangular, or triangular, 1.5–6 mm long, 0.8–2 mm wide, glabrous or pubescent. Corolla 24–40 mm long; tube 14–25 mm long, 4–9.5 mm in diameter at base, 3.5–7 mm in diameter at mouth; dorsal lobes 10–22 mm long; ventral lip 10–20 mm long, the segments 1–10 mm long, 0.5–2 mm wide. Filament tube 18–34 mm long; anther tube 1.5–3.9 mm in diameter; dorsal anthers 6–8.5 mm long; ventral anthers 4.5–7.5 mm long. Capsules 8–12 mm long, 7–9 mm in diameter. Chromosome number $n = 7$ (Ayers 1986).

Icones.—Cavanilles (1801), pl. 518 [as *L. persicifolia*]; Don (1838), pl. 389 [as *S. bicolor*]; Knowles and Westcott (1838), pl. 69 [as *S. bicolor*]; Loudon (1848), pl. 37 fig. 1 [as *S. cavanillesii*]; Wittmack and Graebener (1889), pl. 1301 and Abbildung 54; Wimmer (1953), figs. 103a1, 103a3 [as *L. laxiflora* var. *petiolata*], 103a4 and 103a5 [as *L. laxiflora* var. *stricta*], 103b [as *L. haenkeana*], 103c [as *L. delessertiana*]; Nash (1976), fig. 54D–I; Wilbur (1977), fig. 6 [as *L. laxiflora* var. *stricta*]; Mason and Mason (1987), p. 228.

Distribution, habitat, and phenology.—Throughout much of Mexico, from Baja California del Sur, southern Sonora, and southern Chihuahua, south throughout Central America to Panama, and in the Cordillera Occidental of southwestern Colombia. Populations occur at elevations of 250–3450 m, in a wide variety of dry to mesic open to shaded habitats, often on slopes, and most commonly associated with various types of coniferous, deciduous, and mixed forests. In the northern portion of its range (Sonora, Chihuahua, Durango), flowering begins in February and continues through June. The flowering season becomes progressively longer to the south: starting in December in Sinaloa and Nayarit, in October from Jalisco and Queretaro south to Oaxaca, and essentially year-round from Veracruz and Chiapas south to Colombia.

Vernacular Names.—Numerous local names have been recorded on herbarium labels and in the literature. In Mexico, these include the Nahuatl names *chipalxochil* and *oxpatzihuatl*; the Tzeltal names *ch'aal wamal*, *pameyat*, *pameyat te'*, *pirima najk*, *tak'inal chikin*, *tujtin pamayat*, *turisna wamal*, and *tzajal nich*; the Tzotzil names *bik'tal ba ikatzil*, *pimil jomol*, *piri nich jomol*, *pojovil jomol*, *poxil yaijel*, *putzil nichim*, *rimon*, *rion vomol*, *sera nich jomol*, and *turisno vet*; and the Spanish names *aretillo* (Vera Cruz), *campanilla* (Puebla), *campanita* (Puebla), *campanole* (Puebla), *chilitos* (Michoacan), *chilillo* (Puebla), *clarincillo* (Jalisco), *cordoncillo* (Puebla), *hierba de burro* (Guerrero), *hierba del manzo* (Nayarit), *huajillo* (Jalisco), *primón* (Chiapas), *yerba del aigre* (Baja California), and *zarcillillo* (Jalisco). In Central America, the plant is known as *caballito* (Honduras), *chilillo* (Guatemala; Nash 1976), *cohetillo* (Guatemala; Nash 1976), *diente de chucho* (El Salvador, Honduras), *diente de perro* (Honduras, Nicaragua), *lengua de chuco* (El Salvador), *pastorcito* (El Salvador), *quiebramachete* (Guatemala; Nash 1976), *srukatzunúm* (Guatemala; Nash 1976), and *yuquilla* (Costa Rica).

Ethnobotany.—Herbarium labels also provide much information on local use of the plant. The Tzeltal use the roots to promote conception, aid menstruation, and relieve flatulence; the leaves and roots to treat stomach pains; the leaves to treat coughs and tuberculosis; and the entire plant to treat heart pains. The Tzotzil use the latex to treat wounds and relieve itching; the roots to relieve colic; and the leaves to relieve diarrhea, fever, and headache. In Puebla, the plant is used in baths to relieve rheumatism; in Veracruz, to treat pimples; in El Salvador, to induce vomiting and treat internal inflammation. According to Weimann and Heinrich (1997), the Nahuatl bathe in an infusion of the aerial parts to treat skin inflammations, local infections, and wounds. Nash (1976) stated that it was sometimes used in Guatemala as a remedy for mange in horses and dogs. Recently, bulk material was collected for pharmacological screening.

Discussion.—As one might suspect from the lengthy synonymy, this subspecies shows considerable morphological variation. Pubescence is especially variable, with plants spanning a continuum from perfectly glabrous to densely canescent. Pedicels vary conspicuously, from stiff erect stalks holding the flowers close to the rachis of the raceme, to lax flexuous stalks that create a very open diffuse inflorescence. However, morphometric analyses by Eakes and Lammers (1996; cf. Hamlin 1995; Lammers 1999) did not reveal any geographically correlated gaps in the pattern of variation, by which additional taxa might be distinguished. The variation is real, but it does not sort itself into a meaningful pattern.

Plants with all-yellow flowers lacking any red or orange pigment have been collected in Jalisco (*Cuevas & Nieves 2210*, WIS; *Iltis et al. 29556*, WIS; *McVaugh 10037*, MICH), Guatemala (*Standley 65175*, F; *Standley 67195*, F, NY), and El Salvador (*Standley 22973*, NY). For those interested in such things, the correct name in this subspecies for plants of this sort is f. *lutea* Standl. & Steyerm.

Representative specimens: **MEXICO. Chiapas:** Pueblo Nuevo Solistahuacán, *Raven & Breedlove 19823* (ARIZ, BM, MICH, TEX). **Chihuahua:** Sierra Charuco, *Gentry 8091* (ARIZ, RSA, US). **Colima:** Colima, *Kerber 117* (B). **Distrito Federal:** Desviación a El Conejo, *Ventura 1234* (CAS). **Durango:** San Ramón, *Palmer 88* (F, GH, MO, NY, US). **Guanajuato:** 7–8 mi above Xichú, *McVaugh 14837* (MICH). **Guerrero:** Petlacala, *Mexia 9034* (ARIZ, F, G, K, MO, NY, W). **Hidalgo:** Hwy 85, *Parfitt & Kaspar 824* (OSH). **Jalisco:** near Guadalajara, *Pringle 3112* (B, BM, BR, E, F, G, GH, GOET, K, MO, MU, NY, PH, RSA, US, W, WIS, WU). **Mexico:** 1 km W of Nanachititla, *Rzedowski 22101* (DS, ENCB, MICH, WIS). **Michoacan:** San Miguel de las Cuevas, *Rzedowski 50603* (F, MA). **Morelos:** 12 mi NE of Cuernavaca, *Ayers & Scott 118* (TEX). **Nayarit:** Tepic, *Lamb 603* (B, DS, E, F, G, GH, MO, NY, US). **Oaxaca:** 5 mi N of Ixtlan de Juarez, *Harriman 14362* (OSH). **Puebla:** 5 km E of Huauchinango, *Fosberg 29389* (MU, OSH). **Queretaro:** 2 km W of Santa Agueda, *Zamudio 6109* (MEXU). **San Luis Potosi:** 10 mi S of Xilitla, *Harriman et al. 10869* (OSH). **Sinaloa:** Canyon de Tarahumare, *Gentry 7168* (ARIZ, GH, MICH, RSA). **Sonora:** Tepopa, *Gentry 1431* (A, ARIZ, F, MO, WIS). **Vera Cruz:** La Monera, *Ventura 317* (ARIZ, DS, ENCB, LL, RSA, WIS).

GUATEMALA. Ahuachapán: 2–3 mi NE of Puente Impossible, *Croat 42156* (MO). **Libertad:** El Boqueron crater, *Davidse & Pohl 2032* (MO). **Morazán:** Montes de Cacaguatique, *Tucker 614* (G, K, MICH, NY, PH). **Sonsonate:** Cerro Verde, *Molina & Montalvo 21727* (NY). **San Salvador:** San Marcos, *Carlson 9* (CAS, MO). **San Vivente:** San Vicente, *Standley 21202* (MO, NY).

NICARAGUA. Chinandega: Volcán San Cristóbal, *Moreno 24998* (NY). **Esteli:** Fila La Estrechura, *Stevens 22794* (MO). **Granada:** Plan de Las Flores, *Moreno 91* (MO). **Jinotega:** 2 mi S of Jinotega, *Wilbur & Almeda 16509* (LL, MICH). **Leon:** San Nicholas, *Moreno 22723* (MO). **Madriz:** Cerro Volcán de Somoto, *Araquistain & Moreno 2116* (ENCB, MO). **Managua:** Sierra de Managua, *Stevens 4749* (ENCB, MO). Matagalpa: Finca Santa Maria de Pstuma, *Williams & Molina 42590* (MICH). **Nueva Segovia:** N of Ocotal, *Atwood & Seymour 5005* (B, BM, MICH, NY, TEX).

COSTA RICA. Alajuela: 6 mi SW of San Ramón, *Wilbur & Stone 9918* (DS, GH, MICH, NY, TEX, US). **Cartago:** Volcán Irazú, *Hill et al. 17809* (F, GH, NY). **Heredia:** Volcán Barba, *Hatheway 1317* (F, GH, US). **Puntarenas:** 10 km W of Monteverde, *Wilbur 14230* (F, MO). **San Jose:** San Ignacio, *Khan et al. 213* (BM, MO).

PANAMA. Chiriquí: Volcán Baru, *Stein 1264* (MO). **Coclé:** 7 km from El Valle de Antón, *Wilbur & Luteyn 11703* (DS, F, GH, LL, MICH, MO, NY, RSA). **Darien:** Cerro Pirre, *Duke & Elias E13716a* (MO). **Panama:** 6 km S of El Valle, *Sytsma & D'Arcy 3562* (CAS).

COLOMBIA. Cauca: Coconuco, *Yepes 337* (COL, F, US). **Nariño:** Yacuanquer, *Uribe 5289* (COL).

CULTIVATION: U.S.A.: Washington, 12 Mar 1870, *Schott s.n.* (F). **Great Britain:** Begonia House, Jan 1892, *anonymous s.n.* (K). **Germany:** Dahlem, 12 Mar 1922, *Schlechter s.n.* (B). **Egypt:** Cairo, 1885, *Schweinfurth s.n.* (B). **Kenya:** Kaporetwa near Kitale, *Verdcourt 2451* (K).

1b. Lobelia laxiflora subsp. **angustifolia** (A. DC) Eakes & Lammers, Novon 9:384. 1999. *Lobelia laxiflora* var. *angustifolia* A. DC. in DC., Prodr. 7:383. 1839. *Lobelia persicifolia* var. *angustifolia* (A. DC.) Vatke, Linnaea 38:723. 1874. *Lobelia laxiflora* f. *angustifolia* (A. DC.) Voss in Siebert & Voss, Vilm. Blumengärtn. ed. 3 1:576. 1894. *Lobelia angustifolia* (A. DC.) Urbina, Cat. Pl. Mexican. 201. 1897, nom. illeg.; non Cham., Linnaea 8:219. 1833; nec Benth. in Endl., Enum. Pl. 74. 1837. TYPE: MEXICO. MEXICO: Toluca, Apr 1834, *Andrieux 267* (LECTOTYPE [designated by Eakes and Lammers in Lammers 1999]: K! [photograph: F!]; ISOLECTOTYPES: K! W!).

Lobelia dracunculoides Willd. ex Schult. in Roem. & Schult., Syst. Veg. 5:56. 1819 (Dec). TYPE: "America meridionalis," *leg.* Humboldt and Bonpland, *Herb. Willdenow* 3989 (HOLOTYPE: B-W [IDC-microfiche!]).

Rapuntium kunthianum C. Presl, Prodr. Monogr. Lobel. 27. 1836. *Lobelia persicifolia* var. *amygdalina* Vatke, Linnaea 38:723. 1874. Both validated by reference to: *Lobelia persicifolia* Cav. sensu Kunth in Humb., Bonpl. & Kunth, Nov. Gen. Sp. 3:310 (quarto), 242 (folio). 1819 (Nov). TYPE: MEXICO. MEXICO: prope Zumpango, *Humboldt & Bonpland s.n.* (LECTOTYPE [designated by Eakes and Lammers in Lammers 1999]: P-Bonpl. [microfiche!]; ISOLECTOTYPES: B, B-W [microfiche!]). Presl's binomial was not an avowed substitute name for *L. persicifolia* Cav., nom. illeg. (see above), as on the same page, he recognized that species under the replacement name *R. cavanillesianum* (Schult.) C. Presl. Similarly, Vatke's trinomial was not a new combination based on *L. amygdalina* Willd. ex Schult., as Vatke explicitly stated that the type specimen of that name pertained to *L. persicifolia* Cav., sens. str.

Lobelia cavanillesii var. *lutea* F. Haage & K. Schmidt, Gartenflora 52:577. 1903. *Lobelia laxiflora* f. *lutea* (F. Haage & K. Schmidt) E. Wimm., Pflanzenr. IV.276b:682. 1953, nom. illeg.; non Standl. & Steyerm., Publ. Field Mus. Nat. Hist., Bot. Ser. 23:98. 1944. TYPE: not located. Name based on yellow-flowered plants raised from seed of normally pigmented progenitors at a commercial nursery in Erfurt, Germany. This spontaneous appearance of yellow-flowered variants from seed has also been observed in *L. excelsa* of sect. *Tupa* (Lammers 2000).

Lobelia nelsonii var. *fragilis* B. L. Rob. & Fern., Proc. Amer. Acad. Arts 43:27. 1907. *Lobelia laxiflora* f. *fragilis* (B. L. Rob. & Fern.) E. Wimm., Pflanzenr. IV.276b:682. 1953. TYPE: MEXICO. MORELOS: Parque Station, rocky hills, 7500 ft, 13 Feb 1907, *Pringle 10360* (HOLOTYPE: GH! [photograph: F!]; ISOTYPES: B! BM! E! F! G[3]! GOET! K! MEXU! MIN! MO! NY! PH! US! W!).

Lobelia laxiflora var. *brevipes* E. Wimm., Pflanzenr. IV.276b:683. 1953. TYPE: MEXICO. BAJA CALIFORNIA: Cape region, Jan–Mar 1901, *Purpus 234* (HOLOTYPE: WU!; ISOTYPES: E! K! MO! US!).

Stems glabrous. Lamina linear, lanceolate, or narrowly elliptic, 5–15 cm long, 0.2–1.4 cm wide, glabrous; margin serrulate or serrate; apex acuminate; base attenuate; petiole (when present) 1–5 mm long. Pedicels 25–85 mm long, erect or ascending, stiff. Hypanthium 3–5 mm long, 6–9 mm in diameter, glabrous. Calyx lobes linear triangular, narrowly triangular, or triangular, 1–6 mm long, 1–3 mm wide, glabrous or pubescent. Corolla 28–38 mm long; tube 14–20 mm long, 5–8 mm in diameter at base, 4.5–6 mm in diameter at mouth; dorsal lobes 11–17 mm long; ventral lip 12–17 mm long, the segments 1–5 mm long, 0.5–1.2 mm wide. Filament tube 21–31 mm long; anther tube 1.7–2.4 mm in diameter; dorsal anthers 7–9 mm long; ventral anthers 5.5–7.5 mm long. Capsules 6–10 mm long, 7–8 mm in diameter. Chromosome number $n = 7$ (Ayers 1986).

Icones.—Martius (1830), pl. 9 [as *L. cavanillesii*]; Hooker (1837), pl. 3600 [as

L. cavanillesii]; Anonymous (1915), fig. 82; McVaugh (1940), figs. 4, 9; Wimmer (1953), fig. 103a2 [as *L. laxiflora* var. *brevipes*]; Thomas (1990), pl. II no. 6; Lancaster (1991), pp. 474–475; Anonymous (2003), pp. 40–41 (unidentified).

Distribution, habitat, and phenology.—Throughout northeastern Mexico, from Sonora and Chihuahua to Puebla, with one population in the United States, in southern Arizona. Populations occur at elevations of 1300–3400 m, in a wide variety of mesic to relatively wet open to shaded habitats, often on stream bottoms and gravel bars, and most commonly associated with various types of coniferous, deciduous, and mixed forests. In the northern part of the range, flowering begins in March, while in the south, it begins as early as October; flowering typically is finished by June or July.

Vernacular Names.—Names recorded on herbarium labels include *aretillo*, *contrahiedra*, and *pericos*.

Ethnobotany.—Labels of several specimens from Puebla mention unspecified medicinal usage of the plant.

Discussion.—Plants from Guerrero, formerly identified as this taxon, differ in a number of morphological traits and have been segregated as *L. guerrerensis* (see below).

Plants with all-yellow flowers totally lacking any red or orange pigment have been collected in Durango (*Breedlove 14314*, CAS, MICH) and Zacatecas (*Jones 397*, POM, US), and have apparently appeared spontaneously in cultivation (Anonymous 1903). There is no legitimate name at the rank of *forma* for plants of this sort in this subspecies.

Representative specimens: **U.S.A. ARIZONA: Santa Cruz Co.:** Sycamore Canyon, *McManus et al. 326* (ARIZ), 1 Jun 1992, *Scott s.n.* (ASU).

MEXICO. Aguascalientes: Sandovales, *Figueroa 24* (RSA). **Baja California:** Arroyo de San Francisquito, *Carter & Ferris 3335* (DS, TEX, US); Sierra Laguna, *Gentry 4431* (ARIZ, DS, GH, K, MO). **Chihuahua:** 1 mi N of Maguarachi, *Ayers & Scott 394* (TEX); Cascada de Basaseachic, *Yen & Estrada 4125* (MU, OSH). **Distrito Federal:** 4 km SW of Santa Lucía, *Rzedowski 27248* (DS, ENCB, MICH); Rancho El Conejo, *Ventura 2610* (ASU, ENCB, MICH). **Durango:** Tobar, *Palmer 255* (C, F, GH, MO, NY, US); 19 mi. SW of Durango, *Ripley & Barneby 13496* (CAS, NY). **Guanajuato:** Guanajuato, *Duges 24* (GH). **Hidalgo:** Tecozautla, *Argüelles 2014* (OSH); Dublan, *Pringle 13095* (B, C, CAS, F, GH, MICH, MO, US). **Jalisco:** 4 km SW of Villa Guerrero, *Flores 2332* (TEX, WIS); 7 mi. Rivera, *Arsène 20600* (MO). **San Luis Potosí:** San Luis Potosí, *Parry & Palmer 560* (B, BM, E, F, G, ISC, K, MO, NY, PH, US); Río Ahogado, *Rzedowski 5459* (ENCB, MICH). **Sonora:** 32 mi. E of Yecora, *McLaughlin 547* (ARIZ); 10 mi. E of Imuris, *Wiggins 11653* (MICH, TEX, US). **Tlaxcala:** Tlaxcala, *Balls & Gourlay B.4831* (B, BM, K, NY, US); Ciénega de San Juan Zacualpan, *Weber 181* (ENCB). **Zacatecas:** 24 mi SW of Jalpa, *Mahler & Thieret 5818* (OSH); San Antonio, *McVaugh 12032* (MICH).

CULTIVATION. U.S.A. Arizona: Tempe, *Keil & Lehto 6197* (ASU). **California:** Berkeley, *Bracelin*

1262 (BR, RSA); San Francisco, *Norris 4343* (OSH). **GERMANY:** Berlin, 1 May 1924, *Schlechter s.n.* (B). **ZIMBABWE:** Salisbury, *Biegel 3977* (K).

2. Lobelia guerrerensis Eakes & Lammers, Novon 9:381. 1999. TYPE: MEXICO. GUERRERO: municipio de Atoyac de Alvarez, a 6 km al SO de Puerto del Gallo, bosque mesófilo de montaña, 2320 m, 29 Mar 1983, *Soto & Martínez 5136* (HOLOTYPE: MEXU!).

Stems 1–2 m tall, woody or suffruticose, branched or unbranched, erect or ascending, glabrous. Leaves sessile; lamina linear or lanceolate, 7–18 cm long, 0.3–1.1 cm wide, cernuous; adaxial surface glabrous; abaxial surface glabrous; margin entire or sometimes with a few distant minute callose teeth, minutely revolute; apex narrowly acuminate; base cuneate or attenuate. Flowers solitary in the axils of the upper leaves; pedicels 60–130 mm long, ascending, spreading, or slightly incurved, stiff, glabrous, bibracteolate below the middle; bracteoles linear, 0.5–3 mm long. Hypanthium depressed hemispheric, 4–5 mm long, 9–11 mm in diameter, glabrous; base rounded or truncate. Calyx lobes narrowly triangular or triangular, 2.5–5 mm long, 1–2 mm wide, glabrous; margin entire. Corolla bilabiate, yellow or yellowish orange on tube, grading to orange or red on the lobes, 35–44 mm long, glabrous; tube 19–25 mm long, 7–10 mm in diameter at base, 6–8 mm at mouth, tapering slightly towards mouth; dorsal lobes linear, 14–22 mm long, 1.5–3 mm wide, recurved, half as long as the tube, acute at apex; ventral lip 12–21 mm long, the segments triangular, 4–8 mm long, 1.5–2.5 mm wide, acute at apex. Filament tube 29–33 mm long, 1.3–1.7 mm in diameter, pale yellow, glabrous; anther tube 2.5–4 mm in diameter, the surface densly covered with dirty yellow trichomes 2–4 mm long; dorsal anthers 8.5–9 mm long; ventral anthers 7–7.6 mm long, with tufts of yellow trichomes 1.5–2 mm long at apex. Capsules broadly ovoid, 8–10 mm long, 9–11 mm in diameter; seeds oblong or ellipsoid, 0.7–0.8 mm long, 0.3–0.4 mm wide, 0.1–0.2 mm thick, the testa faintly striate.

Icon.—Lammers (1999), Fig. 1.

Distribution, habitat, and phenology.—Endemic to Guerrero, Mexico, where it grows on steep wooded slopes and moist banks in pine, pine-oak, and mixed deciduous forests, at elevations of 1890–2750 m in the Sierra Madre del Sur. Flowering begins in early October and continues through February.

Discussion.—This species was first collected by Ynes Mexia in 1937. That initial gathering was identified as *L. laxiflora* var. *angustifolia* by Rogers McVaugh, as were most subsequent collections by their collectors or by specialists. However, multivariate analyses by Eakes and Lammers (1996; cf. Hamlin 1995; Lammers 1999) revealed that these Guerrero plants differed consistently from *L. laxiflora* subsp. *angustifolia* in a number of features, specifically their glabrous herbage, cernuous leaves with minutely revolute and usually entire margin, the reverse pigmenation of the flowers (i.e., tube yellow and lobes red), the longer apical teeth of the ventral corolla lip, the long dense pubescence of the anther tube, and the slightly larger seeds.

Representative specimens. **MEXICO. Guerrero:** Mazatlán, *Berlín 53* (ENCB); 1–3 km NW of Puerto El Gallo, *Breedlove 36058* (CAS, MICH), 37.9 km NE de El Paraíso, *Cowan 4961* (TEX); 6.5 km W de Puerto del Gallo por camino a Paraíso, *Hernández & Tenorio 858* (MICH); second ridge west of Petlacala, *Mexia 9049* (ARIZ, B, CAS, G, K, MO, NY, W); 3 mi SW of Puerto del Gallo, *Reveal et al. 4337* (CAS, GH, K, MICH, MO, NY, TEX); Cerro Alquitrán cerca Tuxpan, 9 Jan 1977, *Schwabe s.n.* (B).

3. Lobelia aguana E. Wimm., Repert. Spec. Nov. Regni Veg. 38:86. 1935. TYPE: GUATEMALA. DEPT. SACATEPÉQUEZ: Volcano Agua, 10500 ft, 4 Feb 1908, *Kellerman 7502* (HOLOTYPE: F!; ISOTYPES: MEXU! NY! US!).

Lobelia laxiflora var. *insignis* Donn. Sm., Bot. Gaz. (Crawfordsville) 16:12. 1891. TYPE: GUATEMALA. DEPT. SACATEPÉQUEZ: Volcan de Agua, 10000 ft, Apr 1890, *Donnell Smith 2173* (HOLOTYPE: US! [photograph: F!]; ISOTYPES: B! K! [photograph: F!]).

Stems 0.5–3 m tall, woody or suffruticose, branched or unbranched, erect or ascending, glabrous or pubescent. Leaves sessile or petiolate; lamina lanceolate or narrowly elliptic, 9–22 cm long, 1.3–4.5 cm wide; adaxial surface glabrous or rarely pubescent; abaxial surface pubescent or rarely glabrous; margin serrulate or serrate; apex narrowly attenuate; base attenuate, cuneate, or rarely rounded; petiole (when present) 1–7 mm long, glabrous or pubescent. Flowers solitary in the axils of the upper leaves; pedicels 85–210 mm long, erect or incurved, flexuous, glabrous or pubescent, ebracteolate or bibracteolate in the lower two-thirds; bracteoles (when present) linear, 1–9 mm long. Hypanthium hemispheric, 4–9 mm long, 8.5–13 mm in diameter, glabrous or pubescent; base rounded or truncate. Calyx lobes subulate, linear triangular, or narrowly triangular, 6–18 mm long, 1.5–3 mm wide, glabrous or pubescent; margin entire. Corolla bilabiate, orange or red on tube, grading to yellow or orange on the lobes, 35–56 mm long, glabrous or sparsely pubescent; tube 18–26 mm long, 8–12 mm in diameter at base, 6–10 mm in diameter at mouth, cylindric or tapering slightly towards mouth; dorsal lobes linear, 20–33 mm long, 2–3 mm wide, recurved, 1/2–3/4 as long as the tube, acute at apex; ventral lip 18–26 mm long, the segments triangular, 1–6 mm long, 0.5–2.5 mm wide, acute at apex. Filament tube 28–40 mm long, 1.2–1.6 mm in diameter, pale yellow or reddish, glabrous; anther tube 3–3.6 mm in diameter, the dorsal surface towards the apex pubescent with white trichomes 0.5–1.5 mm long; dorsal anthers 9–12 mm long; ventral anthers 7.5–9.5 mm long, with tufts of yellowish white trichomes 1.3–2 mm long at apex. Capsules ovoid, 10–15 mm long, 10–12 mm in diameter; seeds oblong or ellipsoid, 0.8–0.9 mm long, 0.3–0.4 mm wide, ca. 0.1 mm thick, the testa minutely reticulate.

Icones.—Wimmer (1953), fig. 103d.

Distribution, habitat, and phenology.—Southwestern Mexico (Guerrero, Oaxaca, and Chiapas) and western Guatemala, on moist slopes and grassy banks in conifer or mixed conifer-deciduous forests at elevations of 1850–3350 m. Flowering from mid-July to late April.

Vernacular Names.—Known as *pitijo* and *coral* in Guatemala (Nash 1976).

Discussion.—This species is very similar to *L. laxiflora* subsp. *laxiflora* but differs in its markedly larger flowers. In Oaxaca, it hybrizes occasionally with *L. ghiesbreghtii* (see below).

Representative specimens. **MEXICO. Guerrero:** 8.5 km NE of Puerto del Gallo, *Barrie & Martínez 696* (NY, TEX); Cerro Teotepec, *Breedlove 36079* (MICH); 7 mi al E del entronque Filo de Caballo/Cerro Toro Muerto, *Cowan 4981* (TEX); 1–2 km E of Cerro Teotepec, *Cruden 1636* (MICH); Asoleadero, *Feddema 2852* (MICH, MO, PH); Pie de la Cuesta Toro Muerto, *Hinton et al. 11081* (K, RSA); Teotepec, *Hinton et al. 11127* (K, NY, RSA, WTU); 22 km al SO de Higueros, *Koch & Fryxell 82120* (MEXU, MICH, NY, OSH, TEX, US); 15 km al NE de Puerto del Gallo, *Martínez & Barrie 5640* (MEXU); 10.8 mi NE of Puerto del Gallo, *Reveal et al. 4316* (MICH, NY, TEX); 9.4 mi NE of Puerto del Gallo, *Reveal et al. 4318* (K, MICH, NY, TEX); Cerro Teotepec, *Rzedowski & McVaugh 227* (ENCB, ISC, MICH), *Rzedowski 16513* (MICH, NY). **Oaxaca:** N of San Jose el Pacifico, *Alexander 700* (MICH). **Chiapas:** Volcan Tacana west, *Matuda 2893* (F, GH, MEXU, MICH, NY, US).

4. Lobelia ghiesbreghtii Decne., Rev. Hort. (sér. 3) 2:341. 1848; non Lem., Ill. Hort. 1:pl. 34. 1854. TYPE: MEXICO. OAXACA: Oct 1842, *Ghiesbreght s.n.* (HOLOTYPE: P [photographs: MICH! WIS!]; ISOTYPES: G[3]! [photographs: F!]).

Tupa crassicaulis Hook., Bot. Mag. 76:pl 4505. 1850. TYPE: GREAT BRITAIN: "Hort. Kew" [received from Mr. Makoy of Liége], *Herb. Hook. s.n.* (HOLOTYPE: K! [photograph: F!]).

Lobelia regalis Fern., Proc. Amer. Acad. Arts. 36:503. 1901. TYPE: MEXICO. OAXACA: Cuicatlán, alt. 550 m, 2 Dec 1895, *leg.* L. C. Smith, *Conzatti 105* (LECTOTYPE [designated by McVaugh 1943]: GH! [photograph: F!]).

Stems 2–3 m tall, woody, commonly branched above, erect or ascending, white-tomentose. Leaves petiolate; lamina elliptic, narrowly elliptic, oblong, or narrowly oblong, 9–20 cm long, 3.5–8 cm wide; adaxial surface glabrous or sparsely pubescent; abaxial surface white-tomentose; margin entire or denticulate; apex acuminate; base cuneate; petiole 10–30 mm long, tomentose. Flowers solitary in the axils of the upper leaves or forming a terminal raceme; pedicels 35–64 mm long, ascending, stiff, ebracteolate or bibracteolate at or above the middle; bracteoles (when present) subulate, 0.5–3 mm long. Hypanthium depressed hemispheric, 4–6.5 mm long, 8.5–10 mm in diameter, tomentose; base rounded or truncate. Calyx lobes triangular or deltate, 3.5–6 mm long, 1–3 mm wide, tomentose; margin entire. Corolla bilabiate, yellow suffused with red or all red, 30–40 mm long, tomentose; tube 17–22 mm long, 7.5–8.5 mm in diameter at base, 6–7.5 mm in diameter at mouth, tapering slightly towards mouth; dorsal lobes linear, 12–20 mm long, 1–2 mm wide, about as long as the tube, acute at apex; ventral lip 10–18 mm long, the segments 1.5–6 mm long, 1–2 mm wide, acute at apex. Filament tube 24–36 mm long, 1.3–1.5 mm in diameter, pale yellow, pubescent; anther tube 2.5–3 mm in diameter, the dorsal surface towards the apex sparsely to moderately pubescent with trichomes ca. 1 mm long; dorsal anthers 7.5–8.5 mm long; ventral anthers 6.5–7 mm long, with tufts of yellow trichomes 1–2 mm long at apex. Capsules broadly ovate, 10–12 mm long, 10–12 mm in diameter; seeds oblong or ellipsoid, 0.5–0.6 mm long, 0.3–0.4 mm wide, ca. 0.1 mm thick, the testa minutely reticulate.

Icones.—Decaisne (1848), fig. 18; Hooker (1850), pl. 4505 [as *Tupa crassicaulis*].

Distribution, habitat, and phenology.—Endemic to Oaxaca, Mexico. Growing on streambanks, in partially shaded loam soil, at 550–2135 m above sea level. Flowering from October to April. Apparently rare, collected but thrice since 1937, in 1960 (*King 2482*), 1966 (*Ernst 2473*), and 1974 (*Walker 72016*).

Cultivation.—This species was introduced to horticulture in the late 1840s (Decaisne 1848, Hooker 1850) but is no longer available.

Discussion.—This species resembles *L. laxiflora* subsp. *laxiflora*, but differs in its dense white tomentum and distinctly petiolate leaves broadest at middle. I have examined a few specimens from Oaxaca that are intermediate in morphology (pubescence, leaf shape and width, petiole length, pedicel length, and flower size) between this species and *L. aguana*, which also occurs in Oaxaca; they are assumed to represent F_1 hybrids. Such specimens have been collected in Juquila (*MacDougall 559.S*, ENCB, NY; *Rzedowski 19533*, MEXU, TEX), Miahuatlán (*Campos & Peterson 3396*, MEXU), and northeast of Sola de Vega (*Villaseñor et al. 1157*, TEX).

Representative specimens. **MEXICO. Oaxaca:** 15 km S of Oaxaca, *Camp & Conzatti 2768* (MICH, NY); Cerro del Tule, *Conzatti 1777* (BM); Montañas de Mitla, *Conzatti & Ostlund 5184* (K); Valle de Tlacolula, *Conzatti & Camp 5236 1/2* (MICH, NY); toward Oaxaca from Mitla, *Ernst 2473* (MEXU); Javejia, *Galeotti 1989* (BR); Oaxaca, *Jurgensen 494* (G); 8–10 miles from Oaxaca, *King 2482* (MICH, TEX); Oaxaca, *Liebmann 7769* (C, W); Río Tehuantepec below Totolapam, *Seler & Seler 1669* (B); between Tlacolula and San Dionisio Chichicapa, *Seler & Seler 1673* (B); Tlalixtac Canyon, *Walker 72016* (NY).

CULTIVATION. Switzerland: Jardin Bot. de Paternie, 14 Mar 1860, *Candolle s.n.* (G).

5. Lobelia decurrens Cav., Icon. 6:13. 1800; non Roth, Nov. Pl. Sp. 145. 1821. *Rapuntium decurrens* (Cav.) C. Presl, Prodr. Monogr. Lobel. 24. 1836. *Tupa decurrens* (Cav.) G. Don in Sweet, Hort. Brit. ed. 3:424. 1839. *Dortmanna decurrens* (Cav.) Kuntze, Rev. Gen. Pl. 2:972. 1891. TYPE: CHILE: In ripis fluminis Claro, *Née s.n.* (LECTOTYPE, here designated: MA!; ISOLECTOTYPES: CONC! F! MA!).

Plants malodorous. Stems 0.8–2 m tall, numerous from the root crown, herbaceous or suffruticose, unbranched, erect or ascending, sparsely pubescent. Leaves sessile; lamina elliptic, narrowly elliptic, narrowly oblong, or oblanceolate, 4–15 cm long, 1.5–2.6 cm wide; adaxial surface glabrous or sparsely pubescent; abaxial surface glabrous or sparsely pubescent; margin biserrate (rarely merely denticulate) with 5–10 falcately triangular acuminate teeth up to 8 mm long per cm; apex acuminate or acute; base long decurrent on stem. Flowers in a terminal raceme; pedicels 7–14 mm long, erect or ascending, stiff, densely pubescent, ebracteolate (but cf. Sweet 1831). Hypanthium depressed hemispheric, 2.5–5 mm long, 5–7 mm in diameter, pubescent; base rounded or truncate. Calyx lobes linear triangular or narrowly triangular, 7–16 mm long, 1.2–4 mm wide, sparsely to moderately pubescent; margin fimbriate with 3–9 thread-like segments up to 4 mm long per side. Corolla bilabiate or subbilabiate, violet, red-purple, magenta, mauve, or lavender, 22–42 mm long, pubescent at least on the lobes; tube 14–30 mm long, 3–6.5 mm in diameter at base, 2.5–5 mm in diameter at mouth, cylindric or tapering slightly towards mouth; dorsal lobes narrowly triangular, 8–16 mm long, 2–4 mm wide, straight or somewhat recurved, 1/4–1/2 as long as the tube, acuminate at apex; ventral lip 8–17 mm long, the segments narrowly triangular, 4–14 mm long, 1.5–3 mm wide, acuminate at apex. Filament tube 20–33 mm long, 0.8–1.4 mm in diameter, reddish or purplish, glabrous; anther tube 1.7–2.8 mm in diameter, the surface glabrous (rarely sparsely pubescent toward apex); dorsal anthers 6–8 mm long; ventral anthers 4.8–6 mm long, with tufts of white trichomes 1–1.5 mm long at apex. Capsules ovoid, 10–15 mm long, 7–9 mm in diameter; seeds ellipsoid, 0.5–0.6 mm long, 0.2–0.3 mm in diameter, ca. 0.1 mm thick, the testa faintly striate. Chromosome number $n = 7$ (Diers 1961).

Distribution.—Endemic to Peru. As with *L. cordigera* Cav. (cf. Thompson and Lammers 1997), the supposedly Chilean type locality of *L. decurrens* appears to be an error (Reiche 1905); this is supported by the labels of some of the syntypes (see below). Reports of the species from Ecuador (Wimmer 1937, 1953) are likewise unsubstantiated (Candolle 1839; Jeppesen 1981; Jørgenson 1999).

Vernacular Names.—According to Wimmer (1929), this species is known in various parts of Peru as *contonya*, *contoya*, *contonsa*, and *contunya*. An isotype of var. *jaensis* E. Wimm. (see below) states "peruvianis vulgo *Concho*."

Ethnobotany.—In Apurimac, this plant is "feared" as a cause of warts (*Stork et al. 10633*). The plant allegedly "exudes a nauseous odor which impedes breathing" (*Eyerdam 10755*), and is regarded as "venenatissi[ma]" and "drastica" (*Pavon s.n.*).

Cultivation.—This species was introduced to horticulture in the 1824 but is no longer available (Sweet 1831; Lindley 1836).

Typification.—In the protologue, *L. decurrens* was said to have been based on plants collected "in regno Chilensi ad ripas fluminis vulgo *Claro* ... Vidi sic. in memorato herbario" [i.e., "*Née herbar.*"]. At MA are four specimens of this species collected by Née. All match the original description, but only two (MA-475909 and MA-475910) bear locality data matching that cited. However, the former is annotated "Nee dedit anno 1804," making it unlikely that Cavanilles saw it prior to publication. For this reason, the latter sheet is here designated as the lectotype, and the former treated as a duplicate. The other two specimens are of interest in regard to the presumably erroneous locality data of the protologue and lectotype. On MA-475908, the locality is given as "Peru Panama y Chile" while on MA-475911, it is "nov. Hispania et Peruvia," suggesting early confusion over the provenance of the specimens. These may well be duplicates of the lectotype with variant label data, but it seems best to treat them as separate gatherings.

Discussion.—Candolle (1839) described an unnamed variety of *L. decurrens*, which he denoted as "β" and equated with *L. foliosa* and with Sweet's (1831) and Lindley's (1836) illustrations of *L. decurrens*; Heynhold (1840) provided the name *L. decurrens* var. *foliosa* for it. Candolle characterized this taxon as having "calyce et corollâ ubiquè hirsutis," but Wimmer (1929) argued that this differed in no way from typical *L. decurrens*.

Subsequently, Wimmer (1937) described var. *jaensis*, distinguishing it from typical *L. decurrens* (including var. *foliosa*) by its long pubescent (vs. glabrous) stem and leaves and corolla 45 mm (vs. 30 mm) long. He equivocated regarding the latter character, however, noting that "longitudo corollae variat inter 26–45 mm."

My own analysis of morphological variation in *L. decurrens* showed that Wimmer (1937, 1953) was on the right track, but erred in emphasizing pubescence over corolla length. In this study, I detected a pronounced north-south increase in flower size in this species. In the northern part of the range, the corolla is as little as 22 mm long, vs. up to 42 mm long in the south. Most of this increase occurs in the tube, which varies from 14 mm long in the north to 30 mm long in the south. This increase in tube length while lobe length stays relatively constant means that the proportionality of the corolla varies. In the north, the tube is often not much longer than the dorsal lobes; in the south, it can be as much as three times as long. Concomitantly, length of the filament tube varies from 20 mm in the north to 33 mm in the south, though the length of the anthers remains relatively constant. As a result, the filament tube is as little as 2.5 times as long as the dorsal anthers in the north, but up to 4.2 times as long in the south.

As noted above, Wimmer utilized variation in vegetative pubescence to distinguish infraspecific taxa in this species. However, my analysis showed that this variation was not as clear cut geographically as flower size variation. Plants in the north tend to be more densely pubescent than those in the south, but there are many exceptions. This explains Wimmer's statement regarding the extreme variation in corolla length within var. *jaensis*. By emphasizing pubescence, his circumscription encompassed both northern and southern plants; pubescent plants occur in both regions. In a similar vein, the leaves of plants in the north generally are less pronouncedly serrate than those in the south, but again with numerous exceptions.

A morphological continuum such as that seen here in flower size can be difficult to divide meaningfully (Stuessy 1990; Winston 1999). However, there seems to be something of a gap in the variation pattern north of Lima; this is best seen in the corolla tube and its proportionality to the lobes. North of that *departamento*, corolla tubes are 20–30 mm long and 2.5–3 times longer than the dorsal lobes; from Lima south, they are 14–19 mm long and only 1–1.8 times longer than the dorsal lobes. This gap makes it possible to recognize two subspecies within *L. decurrens*. Other floral characters (see above) show minor overlap in their ranges, but this is to be expected in a case of parapatric geographic subspecies (Raven et al. 1974; Grant 1981; Stuessy 1990).

As noted above, vegetative pubescence and leaf serration are weakly correlated with geography: the northern subspecies tends to be more densely pubescent and less pronouncedly serrate. Additionally, the northern subspecies tends to occur at lower elevations than the southern: 750–2540 m (with one coastal population at 10 m) vs. 2280–3355 m. The phenology of the northern subspecies lags behind the southern by about a month. The single chromosome count for this species (Diers 1961) was made from plants at Matucana in Dpto. Lima and thus pertains to the southern subspecies. The plants introduced to horticulture in 1824 (Sweet 1831; Lindley 1836) appear to have likewise represented the southern subspecies.

The types of *L. decurrens* and of its var. *foliosa* are referable to the southern subspecies, which thus takes the autonym. I originally assumed that the epithet *jaensis* would be available for the northern subspecies, based on the fact that some of the specimens cited by Wimmer in the protologue (i.e., paratypes) were collected in the north and represented that subspecies. However, careful examination of the holotype showed that it represented the southern race. As a result, the northern race is here described as new and christened with an appropriate if unimaginative epithet.

5a. Lobelia decurrens subsp. decurrens

Lobelia foliosa Kunth in Humb., Bonpl. & Kunth, Nov. Gen. Sp. 3:310 (quarto), 242 (folio). 1819 (Nov). *Rapuntium foliosum* (Kunth) C. Presl, Prodr. Monogr. Lobel. 24. 1836. *Lobelia decurrens* var. *foliosa* (Kunth) Heynh., Nom. Bot. Hort. 1:471. 1840. TYPE: "Amerique Equitoriale," *Humboldt & Bonpland s.n.* (HOLOTYPE: P-Bonpl. [IDC-microfiche!]). The protologue states "Regni Quitensis [i.e., Ecuador], juxta pagum Guancabamba;" this seems erroneous in light of subsequent collections.

Lobelia decurrens var. *jaensis* E. Wimm. in J.F. Macbr., Fl. Peru 6:478. 1937. TYPE: "Perou ou Chile," *Pavón s.n.* (HOLOTYPE: G!; ISOTYPES: CONC! G-BOIS!). The G-BOIS isotype, which was not annotated by Wimmer, carries more specific locality data: Peru, Lurini collibus et Chouchin, Ciuchin in siciis callidis, Apr 1829.

Lamina elliptic, narrowly elliptic, or oblanceolate, 4–10 cm long, 1.6–2.6 cm wide; margin teeth up to 8 mm long. Pedicels 8–14 mm long. Hypanthium 2.5–5 mm long, 5–7 mm in diameter. Calyx lobes linear triangular or narrowly triangular, 9–13 mm long, 1.8–4 mm wide; margin fimbriate with 3–6 segments up to 4 mm long per side. Corolla red-purple, violet, or mauve, 31–42 mm long; tube 20–30 mm long, 4–6.5 mm in diameter; dorsal lobes 9–12 mm long, 2.5–4 mm wide; ventral lip 9–15 mm long, 3–4.5 mm wide, the lobes connate for 1/3–1/2 their length. Filament tube 24–33 mm long, 0.8–1.2 mm in diameter; anther tube 2–2.8 mm in diameter; dorsal anthers 6–8 mm long; ventral anthers 4.8–5.5 mm long, with tufts of white trichomes 1–1.4 mm long at apex. Capsules 2/5–2/3-inferior, 11–15 mm long, 7–8 mm in diameter. Chromosome number $n = 7$ (Diers 1961).

Icones.—Fig. 1A; Cavanilles (1801), pl. 521; Sweet (1831); Lindley (1836).

Distribution, habitat, and phenology.—Endemic to the Andes of southern Peru, from Lima to Arequipa, at elevations of 2280–3355 m, in a wide variety of open to shaded usually mesic environments, including roadsides, fencerows, streamsides, and abandoned fields. Flowering occurs from January to August, and fruiting through October.

Representative specimens. **PERU. Apurimac:** N de Abancay, *Núñez & Vargas 7232* (MO); Abancay, *Soukup 707* (F); Abancay (Río Marino), *Stork, Horton & Vargas 10633* (F, MO); alrededores de Abancay, *Vargas 477* (F). **Arequipa:** 22 km S of Arequipa, *Eyerdam & Beetle 22166* (K, MO); Yura, hills to the east, *Solomon 2817* (F, MO); Yura, *Stafford D.46* (K); Yura, *Williams 2536* (BM, K, NY). **Ayacucho:** Ayacucho to Huancayo, *Balls 6963* (F, K, US); Ayacucho, May 1867, *Pearce s.n.* (BM, K); Ayacucho, *Soukup 4012* (US). **Huancavelica:** just below Huaytará on road Pisco – Ayacucho, *Weigend & Förther 97/625* (F). **Lima:** above Paya, *Asplund 10802* (US); Tambo Viso, Río Rimac, *Eyerdam 10755* (F, NY, US); los baños de Churín, *Ferreyra 3524* (US); entre Chosica y Matucana, *Ferreyra 5325* (US); Ayarpongo, cerca de Churín, *Ferreyra 5358* (US); arriba de Surco, *Ferreyra 6059* (US); Churín, *Ferreyra 6174* (US); Surco, *Ferreyra 7596* (MO, US); Sta. CULTIVATION. Great Britain: "... gathered in Chili or Peru by Mr. Miller and raised in 1824," *anonymous s.n.* (K).

5b. **Lobelia decurrens** subsp. **parviflora** Lammers, subsp. nov. TYPE: PERU. PIURA: Prov. Ayabaca, dry open hillsides, scattered brush, on road to Ayabaca, 18 km above Puente Tandopa (Río Quiroz), 1700m, 24 Sep 1964, *Hutchinson & Wright 6687* (HOLOTYPE: NY!; ISOTYPES: K! MO!).

Plantae ex Peruvia septentrionali, a reliquo speciei floribus parvioribus cum corolla 22–33 mm long (tubo 14–19 mm longo et lobis 1.1–1.8plo longiori) et filamentorum tubo 20–26 mm longo antheris dorsalibus 2.5–3.6plo longiori distinguenda; plantae plerumque plus pubescentes cum foliis minus serratis.

Lamina narrowly oblong or oblanceolate, 6–15 cm long, 1.5–2.4 cm wide; margin teeth up to 5 mm long. Pedicels 7–12 mm long. Hypanthium 3–5 mm long, 6–7 mm in diameter. Calyx lobes linear triangular, 7–16 mm long, 1.3–2.8 mm wide; margin fimbriate with 3–9 segments up to 3 mm long per side. Corolla red-purple, magenta, or lavender, 22–33 mm long; tube 14–19 mm long, 3–6 mm in diameter; dorsal lobes 8–16 mm long, 2–3 mm wide; ventral lip 8–17 mm long, 4–4.5 mm wide, the lobes connate for 1/2–2/3 their length. Filament tube 20–

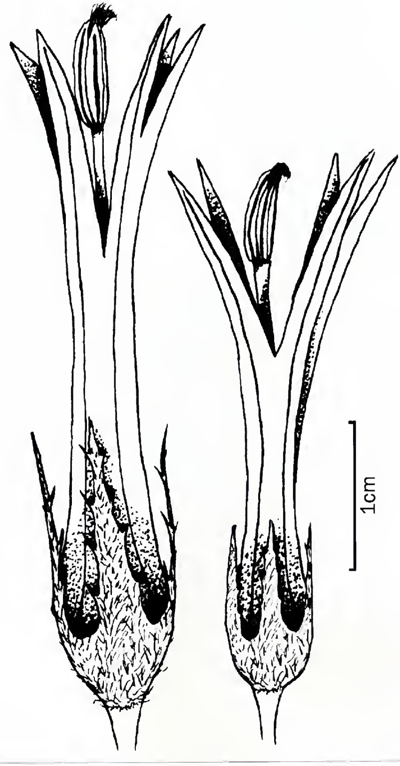

Fig. 1. Flowers of *Lobelia decurrens*. **A.** *L. decurrens* subsp. *decurrens* (based on *Ferreyra 7596*, US). **B.** *L. decurrens* subsp. *parviflora* (based on *Mostacero et al. 1725*, MO).

26 mm long, 0.9–1.4 mm in diameter; anther tube 1.7–2.5 mm in diameter; dorsal anthers 6.5–8 mm long; ventral anthers 5–6 mm long, with tufts of white trichomes 1.2–1.5 mm long at apex. Capsules 1/3–1/2-inferior, 10–14 mm long, 7–9 mm in diameter.

Icon.—Fig. 1B.

Distribution, habitat, and phenology.—Endemic to the Andes of northern Peru, from Piura to Ancash and Huánuco, typically at elevations of 750–2540 m, in a wide variety of open to shaded usually mesic environments, including roadsides, fencerows, streamsides, and abandoned fields; of note is a specimen collected from dunes in coastal desert at an elevation of just 10 m (*Dillon & Whalen 4009*). Flowering occurs from February to October, and fruiting through November.

Representative specimens. **PERU. Ancash:** ca. 48 km N of Pativilca on PanAmerican Hwy., *Dillon & Whalen 4009* (NY). **Cajamarca:** km 156 E of Olmos, *Hutchinson 1417* (MO, NY), *Hutchinson 1418* (F); Llama, *Laudeman 4159* (K); alrededores de Sócota, *Mostacero et al. 1725* (MO, NY); Casa Blanca (Platanar-Lives), *Sagástegui et al. 8774* (NY); E of Quinden, *Sánchez 3407* (F, MO); Balsas-Celendin road, 16–23 km from Balsas, *Smith 6191* (MO, NY). **Huánuco:** Maria del Valle, *Macbride 3567* (F, NY); Huánuco, *Sawada P.58* (F). **La Libertad:** arriba de Plazapampa (Ruta Salpo-Samne), *Leiva & Leiva 552* (F); abajo de Piedra Gorda (Ruta Salpo-Samne), *Leiva, Paredes & Rodríguez 1202* (F, MO). **Piura:** Abra de Porculla, *Sagástegui, Leiva & Lezama 15067* (F, MO).

6. Lobelia heteroclita McVaugh, Ann. Missouri Bot. Gard. 52:404. 1965. TYPE: COLOMBIA. BOYACA: Sierra Nevada de Cocuy, Laguna Seca, in more or less cleared area of cloud forest, ca. 2750 m, 18 Aug 1957, *Grubb, Curry & Fernandez-Perez 599* (HOLOTYPE: US!; ISOTYPE: K!).

Stems 1.5 m tall, herbaceous, apparently unbranched, erect or ascending, pubescent with a mix of short stiff and long lax hairs. Leaves sessile or short-petiolate; lamina broadly elliptic or oblanceolate, 7–10.7 cm long, 2.6–4.5 cm wide; adaxial surface glabrous; abaxial surface with scattered lax hairs 1–1.5 mm long on veins; margin crenate toward apex; apex obtuse or acute; base rounded or cuneate; petiole (when present) up to 0.7 mm long, pubescent. Flowers in a terminal raceme; pedicels 15–23 mm long, ascending, spreading, or slightly incurved, stiff, pubescent with long spreading hairs, ebracteolate or bibracteolate toward base; bracteoles (when present) linear, 1–7 mm long. Hypanthium asymmetrically depressed hemispheric, 2–4 mm long, 6–7 mm in diameter, pubescent; base rounded or truncate, ventrally oblique. Calyx lobes linear triangular, 5–9 mm long, 1.5–2.2 mm wide, sparsely pubescent; margin entire or with 1–2 pairs of minute teeth. Corolla unilabiate, deep pink, 36–47 mm long, glabrous; tube 29–38 mm long, 5–7 mm in diameter at base, 1.5–3 mm at mouth, tapering conspicuously towards mouth, ventrally somewhat gibbous at base; lobes linear, 5–12 mm long, 1.2–1.5 mm wide, deflexed, 1/4–1/3 as long as the tube, acuminate at apex. Filament tube 32–38 mm long, 1–1.4 mm in diameter, pinkish, glabrous; anther tube 2–2.6 mm in diameter, the surface glabrous; dorsal anthers 4–5 mm long; ventral anthers 2.8–3.6 mm long, with tufts of white trichomes 0.7–0.9 mm long at apex. Mature capsules and seeds not seen.

Icon.—McVaugh (1965), Fig. 2A.

Distribution, habitat, and phenology.—Endemic to the Cordillera Oriental of north-central Colombia and known only from the type.

Discussion.—McVaugh (1965) did not specify the affinities of his new species, stating only that it seemed referable to subg. *Tupa*. It is unique within the subgenus by virtue of its ventrally oblique hypanthium (Ayers 1986, 1990). However, on the basis of its habit, pedicels shorter than the flowers (making the inflorescence appear spike-like), reduced or absent bracteoles, depressed hemispheric hypanthium, monochromatic corolla, straight corolla tube, and monomorphic corolla lobes, it is best referred to sect. *Homochilus* and seems most closely related to the other exclusively South American member of the section, *L. decurrens*.

ACKNOWLEDGMENTS

In the preliminary stages of this work, I enjoyed the enthusiastic assistance of Michael James Eakes, an undergraduate intern from the University of Illinois, who was supported by the Office of Academic Affairs of the Field Museum of Natural History. Completion of the research was made possible by Grant #FDR001 from the University of Wisconsin Oshkosh (UWO) Faculty Development Board. Figure 1 was skillfully delineated by UWO graduate student Yvette Evrard, to whom I extend my sincerest appreciation. The curators and staffs of the following institutions are gratefully acknowledged for lending specimens in their care: ARIZ, ASU, B, BM, BR, C, CAS, CONC, DS, E, F, ENCB, G, GH, GOET, ISC, K, LL, MA, MEXU, MICH, MIN, MO, MU, NY, OSH, PH, POM, PR, RSA, TEFH, TEX, UNM, US, W, WIS, WTU, and WU. Special thanks to reviewers Tina Ayers and Tatyana Shulkina for their helpful comments.

BOOK NOTICES/BOOKS RECEIVED

TEXAS GARDENING THE NATURAL WAY

HOWARD GARRETT. 2004. **Texas Gardening the Natural Way: The Complete Handbook.** (ISBN 0-292-70542-5, hbk.). University of Texas Press, P.O. Box 7819, Austin, TX 78713-7819, U.S.A., (Orders: 800-252-3206, 800-687-6046 fax). $34.95, 396 pp., 833 color photos, 13 color illus., 6 maps, 3 line drawings, 8 1/2" × 11".

Howard Garrett's newest book is a masterpiece. He has pulled together all the information contained in his earlier works and has compiled it into one comprehensive and integrated volume. *Texas Gardening the Natural Way* is indeed the complete handbook for Texas organic gardeners.

He has drawn on his previous works for completeness. They include: *Garrett's Plants for Texas* (1996), *Texas Organic Vegetable Gardening* (1999), *Texas Bug Book* (1999), *Herbs for Texas* (2001), *The Organic Manual* (2002), and *Howard Garrett's Texas Trees* (2002).

Consulting the table of contents reveals that there is no topic he has not included in his *Handbook*. He begins with landscape and gardening design, continues with plant selection, maintenance, and nurturing, and concludes with pest control and poisonous plants. Also included are weather data and instructions for building garden structures, including bat houses.

Is your *Plants for Texas* or your *Texas Organic Vegetable Gardening* so thumbed through and so worn that it is in danger of falling apart in your hands? Look no further for a replacement. Every organic gardener, beginning and veteran, should obtain this book. Non-organic gardeners would benefit also from his recommended listings of plants, trees, and herbs, as well as the landscape and garden design instructions. It is recommended for general collections in public libraries, and in arboretum and horticultural libraries.

Howard Garrett is a landscape architect, certified arborist, horticulturist, and organic practitioner in Dallas, Texas.—*Gary L. Jennings, Librarian, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

THREE NEW SPECIES OF *ERIOCAULON* (ERIOCAULACEAE) FROM PENINSULAR INDIA

ABSTRACT

Three new species of the genus *Eriocaulon* L., two species viz., *E. anshiense* & *E. kanarense* from Karnataka and one species *E. konkanense* from Maharashtra are described and illustrated. A distribution map has been provided. A key to distinguish these three species from their allied species is also given.

RESUMEN

Tres especies nuevas del género *Eriocaulon* L. son aquí descritas e ilustradas, dos de ellas., *E. anshiense* y *E. kanarense* encontradas en Karnataka y la tercera *E. kankanense* en Maharashtra. Se proporciona un mapa de distribución de las mismas. Así mismo, se ofrece una clave de identificación para distinguirlas, en la que se incluyen también especies próximas.

INTRODUCTION

The genus *Eriocaulon* L. is distributed throughout the tropical and sub-tropical regions of both hemispheres and is estimated to consist of ca. 400 species (Mabberley 1997). Karthikeyan et al. (1989) enumerated 72 species, 14 varieties and 1 forma from India. Ansari and Balakrishnan (1994) rendered a systematic account of the genus in India, wherein 65 species were treated. Subsequently, various workers (Myrthong et al. 1984; Bole & Almeida 1987; Koshi & Pushpangadan 1993; Yadav et al. 1998; Sreedevi & Binoj Kumar 1999; Khanna et al. 2000; Gaikwad et al. 2002; Gaikwad et al. 2003 (pers. comm.); Punekar et al. 2003; Punekar & Lakshminarasimhan 2002; Punekar et al. 2003; Pradeep & Sunil 2003) have added 16 more species to this genus. Gaikwad and Yadav (2002) reported 40 species from Maharashtra and Das and Singh (2001) reported 35 species from Karnataka. Presently, the genus *Eriocaulon* L. is represented by 84 species in India including the three new species described here.

During the course of botanical exploration in the West Coast and Western Ghats of Indian Peninsula, three interesting specimens of *Eriocaulon* were collected. After a perusal of the literature, comparison with herbarium collections at BSI & K and our own field observations, the specimens were found to be very distinct from other species of *Eriocaulon* and hence have been considered as new species and are described and illustrated here.

1. Eriocaulon anshiense Punekar, Malpure & Lakshmin., sp. nov. **(Fig. 1, 2A).** TYPE: INDIA. KARNATAKA STATE: North Kanara (Uttara Kannada) District, Anshi National Park, waterfall near Mopai Ghat 600 m, 22 Sep 2003, *Punekar 187761* (HOLOTYPE: CAL; ISOTYPES: BSI, MH).

Eriocaulon anshiense E. eurypeplo Körn. similis sed capitulis spinulosis griseis, bracteis involucralibus plerumque acuminatis, bracteis floralibus ad apicem caudatis, sepalis femineis longe acuminatis atque bracteas florales excedentibus, et seminibus plerumque rostratis differt.

Acaulescent rosulate herbs, to 21.5 cm high. Roots fibrous. Leaves linear, oblong or lanceolate, broad at base, apex acute or acuminate, glabrous, almost equal to the sheaths, membranous, 9.5 × 0.7 cm. Peduncles solitary or many, up to 21.5 cm long, 4–5 ribbed, broad at apex, twisted, glabrous. Sheaths up to 11 cm long, glabrous; limb lanceolate, acuminate, entire. Heads hemispherical or depressed globose, sometimes with central depression, 7 × 5 mm, grey, spinulate. Receptacles ovoid, with central depression, pilose. Involucral bracts spreading, hidden inside the head, ovate or obovate, usually acuminate, rarely acute, sparsely hoary dorsally, glabrous inside, straw colored, 1.2–1.6 × 0.8 mm. Floral bracts closely imbricated, broadly cuneate, caudate and dorsally hoary towards apex, ventrally glabrous, black-straw colored, hyaline along margin, 2 × 1.2 mm. **Male flowers:** pedicels minute; sepals 2, free, conduplicate, keeled, obtuse or truncate and hoary at apex, straw colored, chartaceous at margin, 0.9 × 1.1 mm; petals 3, equal, ovate to linear, minute, hairy at apex, gland dotted; stamens 6, anther lobes black. **Female flowers:** pedicels short; sepals 2, free, exceeding the floral bracts, obovate to elliptic, conduplicate, deeply keeled, long acuminate, straw colored with black tinge, dorsally hoary towards apex or in upper half, chartaceous along margins, 2.2 × 0.3 mm; petals 3, free, linear, acute, barbate towards apex, gland dotted, glands elongated, hyaline, 1.2 × 0.2 mm; ovary sessile, ovoid, 0.6 × 0.5 mm; style trifid. Seeds ovoid to ellipsoid, brownish, apiculate or obtuse, 0.8 × 0.5 mm, cells of seed coat transversely elongated, aligned in vertical rows, appendages are of different types in the seeds of same plant, 1 from the middle of the transverse radial wall, so that they appear to be in vertical lines on the surface of seeds, setiform, dilated or hooked at apex.

Eriocaulon anshiense is similar to *Eriocaulon eurypeplon* Körn. (Fig. 2B) but differs from the latter in having spinulate and grey heads, involucral bracts usually acuminate, floral bracts caudate at apex, female sepals long acuminate, exceeding the floral bracts and usually beaked seeds.

Distribution.—The species is so far restricted to few localities of two states viz., water fall near Mopai ghat, Anshi National Park, North Kanara (Uttara Kannada) District, Karnataka State and Usgao, Verlem, Waghai and on the way to Ondoford-Butpal of Goa State (Fig 5).

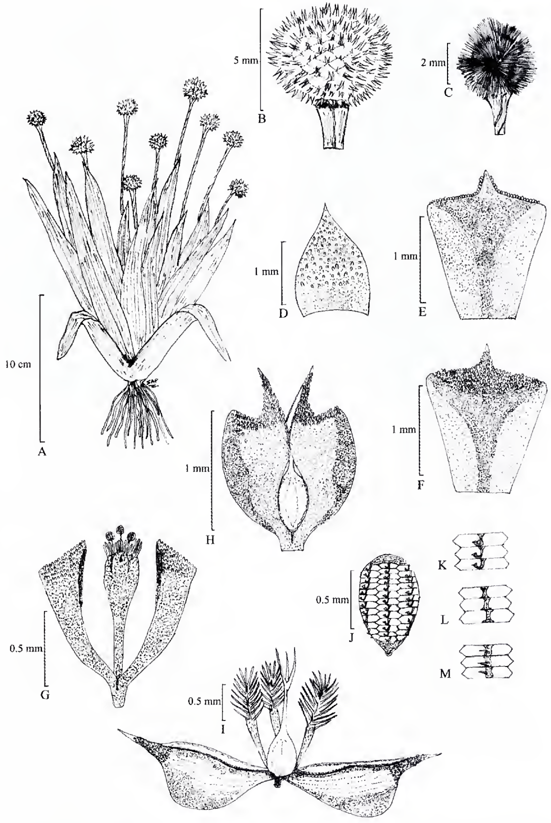

Fig. 1. *Eriocaulon anshiense* Punekar, Malpure & Lakshmin. **A.** Habit; **B.** Head; **C.** Receptacle; **D.** Involucral bract; **E.** Floral bract- ventral view; **F.** Floral bract- dorsal view; **G.** Male flower; **H.** Female flower; **I.** Female flower- sepals spread out to show details; **J.** Seed; **K–M.** Portion of seed showing different types of appendages enlarged.

Fig. 2. A. *Eriocaulon anshiense* Punekar, Malpure & Lakshmin.; **B.** *Eriocaulon eurypeplon* Körn.

Habitat and Ecology.—Grows in dense colonies in the shallow depressions on rocky slopes along the streams surrounded by moist deciduous forests. This species is often found associated with *Coelachne perpusilla, Drosera burmanni, Eriocaulon achiton, E. lanceolatum, Fimbristylis aestivalis, F. dichotoma, Indopoa paupercula, Rotala malampuzhensis, Utricularia reticulata, Xyris indica,* etc.

Flowering and Fruiting.—August–December.

Etymology.—The specific epithet of the new species is based on the type locality viz., Anshi National Park of Karnataka State.

PARATYPES: **INDIA. GOA:** on the way to Ondoford-Burpal, 24 Aug 1963, *Kanodia 89525* (BSI); Usgao, 8 Oct 1964, *Raghavan 103414* (BSI); Verlem, Bhuta Baicha Dongar, 12 Oct 1970, *Singh 125358* (BSI); Waghai, without date, *Singh 124812* (BSI). **KARNATAKA: North Kanara District:** Anshi National Park, Mopai Ghat waterfall 600 m, 7 June 2003, *Punekar & Malpure 187746* (BSI); same locality, 11 Dec 2003, *Punekar 187822* (BSI).

2. Eriocaulon kanarense Punekar, Watve & Lakshmin., sp. nov. **(Fig. 3).** TYPE: INDIA. KARNATAKA: North Kanara District, 15 km S of Ankola on Karwar-Mangalore national highway, 2 Sep 2003, *Watve 187781* (HOLOTYPE: CAL; ISOTYPES: BSI, MH).

Eriocaulon kanarense E. talbotii Ansari & N.P. Balakr. similis sed foliis pedunculisque minoribus, vaginis quam foliis longioribus, capitulis albis, lobis sepalorum masculorum truncatis, antheris nigris, petalis femineis ad apicem eglandulosis et seminibus ellipsoideis rostratis differt.

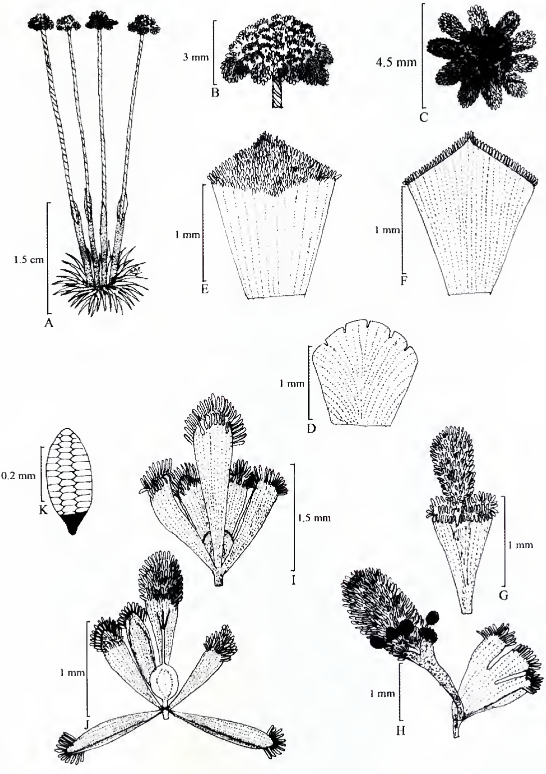

FIG. 3. *Eriocaulon kanarense* Punekar, Watve & Lakshmin. **A.** Habit; **B.** Head- lateral view; **C.** Head- top view; **D.** Involucral bract; **E.** Floral bract- dorsal view; **F.** Floral bract- ventral view; **G.** Male flower; **H.** Male flower- sepal spread out to show details; **I.** Female flower; **J.** Female flower- sepals spread out to show details; **K.** Seed.

Acaulescent rosulate herbs, to 3–5 cm high. Roots fibrous. Leaves linear, broad at base, gradually narrowing towards apex, acuminate, pale green, glabrous, shorter than sheaths, 4 nerved, 8 × 0.6 mm. Peduncles usually 3–4, rarely solitary, up to 4.2 cm long, 5-ribbed, twisted, glabrous. Sheaths up to 1.4 cm long, glabrous; limb lanceolate, acute, entire. Heads hemispherical, 4.5 mm across, white. Receptacles ovoid, glabrous. Involucral bracts spreading, obovate, obtuse and notched at apex, up to 1.5 × 1 mm, straw colored, glabrous. Floral bracts cuneate, usually acute or rarely cuspidate and densely hoary dorsally at apex, blackish, 1.6 × 1 mm. **Male flowers:** pedicels minute; sepals obovate, connate into a spathe of 1 × 0.8 mm, 3- lobed, lobes truncate and densely hairy dorsally at apex, lobes are almost half the length of sepals, black, stipe of corolla 1 mm long; petals 3, unequal, lateral petals minute, hairy at apex, 0.2 mm long, middle odd petal elliptic to oblong, ventrally densely hairy throughout, dorsally glabrous, 1.2 × 0.8 mm, obtuse at apex; anthers 6, black. **Female flowers:** pedicels short; sepals 3, free, subequal, all densely hoary at apex, oblanceolate to oblong, canaliculate, not keeled, obtuse at apex, black, 1 × 0.2–0.3 mm; petals 3, unequal, all obtuse at apex, ventrally densely hairy at apex, dorsally glabrous, eglandular, spathulate, larger petal 1.8 × 0.45 mm, laterals 1 × 0.3 mm; ovary stipitate, globose; style trifid. Seeds ellipsoid, beaked, yellow, dark at one end, 0.4 × 0.2 mm, cells of seed coat transversely elongated, aligned in vertical rows, appendages absent.

Eriocaulon kanarense is similar to *E. talbotii* Ansari & N.P. Balakr., but differs from the latter in having smaller leaves and peduncles, sheaths longer than leaves, heads white, male sepal lobes truncate, anthers black, female petals eglandular at apex and seeds ellipsoid, beaked.

Distribution.—15 km south of Ankola on Karvar-Mangalore national highway, North Kanara (Uttara Kannada) District, Karnataka State (Fig. 5).

Habitat and Ecology.—Common, forming dense cover on lateritic plateau along coast in moist soil in association with *Ammannia* sp., *Drosera indica*, *Fimbristylis* sp., *Trithuria konkanensis*, *Utricularia reticulata*, etc.

Flowering and Fruiting.—August–November.

Etymology.—The specific epithet of the new species is based on the type locality viz., North Kanara District of Karnataka State.

3. Eriocaulon konkanense Punekar, Malpure & Lakshmin., sp. nov. **(Fig. 4).** TYPE: INDIA. MAHARASHTRA: Ratnagiri District, Plateau near MIDC area, Airport road, 7 Sep 2003, *Malpure 187784* (HOLOTYPE: CAL; ISOTYPES: BSI, MH).

Eriocaulon konkanense E. odorato Dalzell similis sed capitulis albis, bracteis involucralibus ad apicem incisis, incisuris 2 vel 3 mumero, sepalis femineis 2 ad apicem obtusis vel rotundatis, seminibus flavis, muris transversalibus seminorum appendiculas 2–4 ferentibus et mures verticalibus seminorum non appendiculatis differt.

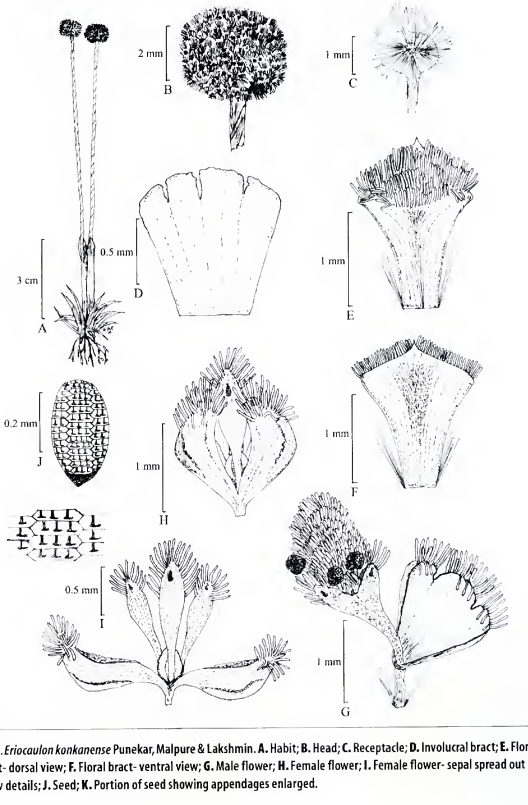

Fig. 4. *Eriocaulon konkanense* Punekar, Malpure & Lakshmin. **A.** Habit; **B.** Head; **C.** Receptacle; **D.** Involucral bract; **E.** Floral bract- dorsal view; **F.** Floral bract- ventral view; **G.** Male flower; **H.** Female flower; **I.** Female flower- sepal spread out to show details; **J.** Seed; **K.** Portion of seed showing appendages enlarged.

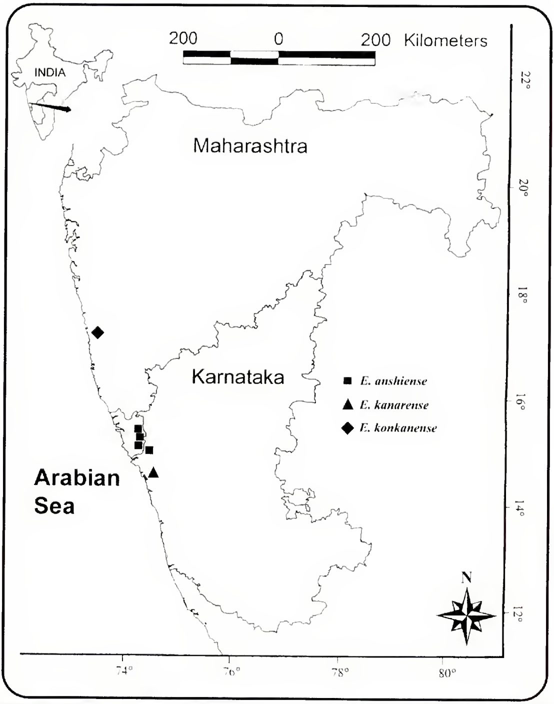

Fig. 5. Distribution map of *Eriocaulon* species.

Acaulescent rosulate herbs, to 16.5 cm high. Roots fibrous. Leaves rosulate, 7–11, linear, broad at the base, tapering towards apex, acuminate, shorter than sheaths, up to 1.7 cm long and 0.25 cm broad, glabrous. Peduncles 1–5, twisted, glabrous, up to 16.5 cm long, 6-ribbed. Sheaths up to 2.7 cm long, glabrous; limb lanceolate, entire, acute. Heads ovoid to quadrangular, 5 mm across, white. Receptacles depressed globose, pilose. Involucral bracts spreading, obovate, rounded and notched at apex, straw colored with blackish tinge, papery, glabrous, 1.2 × 1 mm. Floral bracts oblanceolate, cuneate, acute to acuminate, dorsally hoary and blackish towards apex, hyaline towards base, 1.8 × 1 mm. **Male flowers:** pedicels 0.4 mm long; sepals obovate, connate into a spathe of 1.2 mm long and 0.8 mm across, 3-lobed, lobes truncate to obtuse and dorsally hoary at apex, hyaline with slight blackish tinge; stipe of corolla 0.5–0.7 mm long; petals 3, unequal, laterals linear, minute, middle oblong to narrowly elliptic, obtuse at apex, 1 × 0.3 mm, all densely hoary inside, glabrous outside, gland dotted; stamens 6; anther lobes black. **Female flowers:** pedicels 2–3 mm long; sepals 2, free, oblanceolate, conduplicate, keeled, straw colored with blackish tinge, dorsally hoary and obtuse-rounded at apex, 1.5 mm long; petals 3, free, hyaline, unequal, laterals smaller, 1 × 0.5 mm, hairy at apex, middle larger, 1.5 × 0.2 mm, ventrally hoary in upper half, dorsally sparsely hairy at apex, all oblanceolate, obtuse at apex, gland dotted, stipitate between sepals and petals; ovary stipitate, ovoid, 0.2 × 0.3 mm; style trifid. Seeds ellipsoid, acute, 0.4 × 0.25 mm, yellow; cells of seed coat transversely elongated, aligned in vertical rows, appendages 2–4 from transverse radial walls, setiform, dilated at apex.

Eriocaulon konkanense is similar to *E. odoratum* Dalzell but differs from the latter in having white heads, involucral bracts notched at 2 or 3 places at apex, female sepals 2, obtuse to rounded at apex, seeds yellow, with 2–4 appendages from transverse walls and none from vertical walls.

Distribution.—This species is so far restricted to the coastal lateritic plateau near MIDC area, Airport road, Ratnagiri district, Maharashtra (Fig. 5).

Habitat and Ecology.—Common on coastal lateritic plateau in association with *Eriocaulon parviflorum*, *Eriocaulon richardianum*, *Exacum pumilum*, *Fimbristylis* sp., *Pentanema indicum*, *Rhamphicarpa longiflora*, *Utricularia reticulata*, etc.

Flowering & Fruiting.—August–November.

Etymology.—The specific epithet of the new species is based on the type locality viz., Konkan Coast of Maharashtra State.

KEY TO NEW SPECIES AND ALLIED SPECIES

1. Sepals of male flowers free.
   2. Heads spinulate; involucral bracts usually acuminate; sepals of female flowers longer than floral bracts ______ **E. anshiense**
   2. Heads not spinulate; involucral bracts usually obtuse or subacute; sepals of female flowers as long as floral bracts ______ **E. eurypeplon**

1. Sepals of male flowers connate into a spathe.
   3. Petals of male flowers subequal; anther lobes white ______ **E. talbotii**
   3. Petals of male flowers unequal; anther lobes black.
      4. Sepals of female flowers 2 ______ **E. konkanense**
      4. Sepals of female flowers 3.
         5. Petals of female flowers subequal, glandular; seeds with appendages ____ **E. odoratum**
         5. Petals of female flowers unequal, eglandular; seeds without any appendages ______ **E. kanarense**

ACKNOWLEDGMENTS

The authors are grateful to the Director, Botanical Survey of India, Kolkata for providing facilities and to P.S.N. Rao, Joint Director, Botanical Survey of India, Western Circle, Pune for constant encouragement. One of us (PL) is also thankful to the Keeper, Royal Botanic Gardens, Kew for facilities. Our thanks are also due to N.P. Balakrishnan, Ex-Joint Director, Botanical Survey of India, Coimbatore for his valuable suggestions regarding the species. Help rendered by Melanie Thomas (Wilmot-Dear), Royal Botanic Gardens, Kew for Latin diagnosis and to Lourdes Rico, Royal Botanic Gardens, Kew for the Spanish abstract is gratefully acknowledged. We also wish to thank the Karnataka Forest Department for various help rendered by them and also to Mahesh Shindikar, Ecology Laboratory, Dept. of Botany, University of Pune, who prepared the distribution map.

BOOK NOTICES

ROBERT J. BLACK and EDWARD F. GILMAN. 2004. **Landscape Plants for the Gulf and South Atlantic Coasts.** (ISBN 0-8130-2722-5, pbk.). The University Press of Florida, 15 NW 15th Street, Gainesville, FL 32611-2079, U.S.A. (Orders: 1-800-226-3822, fax: 352-392-7302, www.upf.com). $24.95, 240 pp., 21 b/w drawings, 513 color photos, 11 tables, hardiness zone map, 7" × 10".

Publisher Comments: "Robert J. Black and Edward F. Gilman tell gardeners how to conquer these hurdles and establish aesthetic and functional plants that can adapt to a coastal site. Beginning with basic gardening precepts, they present step-by-step information on specific plants, planting, best landscape uses, cultural needs, and plant maintenance. They address watering, fertilization, pruning, and other care concerns of salt tolerable plants."

"Combined with colorful photographs of more than 400 plants, Black and Gilman's expert advice will be indispensable for all southern coastal homeowners, landscape architects, landscape designers and installers, landscape maintenance personnel, retail nursery personnel, extension agents, and for inland gardeners who face problems that result from salt water intrusion."

Chapter 6 is the Plant Selection Guide listing the plants alphabetical by genus. Plants are listed in four categories: **1)** Salt-tolerant trees, **2)** Salt-tolerant shrubs, **3)** Salt-tolerant vines and ground covers, and **4)** Salt-tolerant palms. Each entry includes a color photograph of the plant.

CHET VAN DUZER. 2004. **Floating Islands A Global Bibliography.** (ISBN 0-9755424-0-0, hbk.) Cantor Press, 12117 Winton Way, Los Altos Hills, CA 94024-6431, U.S.A. (Orders: 1-800-247-6553, www.cantorpress.com). $44.95, 428 pp., 6" × 9".

Publisher Comments: "This book is a unique treasury of information about one of nature's marvels: floating islands. The bibliography contains more than 1800 citations of books and articles in twenty languages on the subject; the entries are annotated and cross-referenced, and there are both thematic and geographic indices. All aspects of floating islands are addressed, including the formation of floating islands, the causes of their buoyancy, their role in the ecology of lakes and wetlands, their flora and fauna, their role in the dispersal of plants and animals, and methods for controlling and managing them. Works are also cited on artificial floating islands used for agriculture, human habitation, wildlife habitat, and improvement of water quality; and floating islands in literature, myth, and legend. The book includes the text and an English translation, with detailed notes, of G.C. Munz's rare 1711 thesis on floating islands, Exercitatio academica de insulis natantibus, as well as photographs of several floating islands."

NOMENCLATURE AND TYPIFICATION IN THE GENUS *USNEA* (LICHENIZED ASCOMYCETES)— IV. *USNEA STUPPEA* & *USNEA SUBSTERILIS*

ABSTRACT

This, the fourth part of our series discussing typification and nomenclature in the lichenized ascomycete genus *Usnea* attempts to clarify the application of the names *Usnea stuppea* (Räsänen) Motyka and *U. substerilis* Motyka. Both names are lectotypified and the differences between the two taxa are discussed.

RESUMEN

Esta, que es la cuarta parte de nuestra serie que discute la tipificación y nomenclatura en el género de ascomycete liquenizado *Usnea* intenta clarificar la aplicación de los nombre *Usnea stuppea* (Räsänen) Motyka y *U. substerilis* Motyka. Ambos nombres son lectotipificados y se discuten las diferencias entre los dos taxa.

INTRODUCTION

Some researchers may consider our approach to the typification of *Usnea* species overly cautious and technical; however, we would like to stress that the taxonomic study of *Usnea* has been (and still is) considered extremely difficult and complicated. Thus it would seem logical that the first step towards a clear and thorough revision of the genus would be a careful, precise review of the application of the published names with regard to their types. Unfortunately, many species of *Usnea* have not been properly typified, and often recent lectotypifications have not taken into account the fact that Motyka's monograph includes the lectotypifications of numerous taxa. It should also be remembered that Motyka's treatment remains the only complete revision of the genus to date.

The two species treated here belong to a series of closely related taxa that remains much confused and poorly understood. The first species, *U. stuppea* (Räsänen) Motyka, has been placed in synonymy with *U. substerilis* Motyka by Halonen et al. (1998). Here, we reject the recent lectotypification of *U. stuppea* by Halonen et al. (1998) because of an earlier typification by Motyka (1936). In order to clarify the typification (and taxonomy) of *U. stuppea* we also examined the type material of *U. substerilis*. As a result we have concluded that the synonymy of *U. stuppea* with *U. substerilis* should be reconsidered. To clarify the application of the name *U. substerilis* we have also chosen a single thallus as the lectotype from among those lectotypified by Clerc (1987).

I. **Usnea stuppea** (Räsänen) Motyka

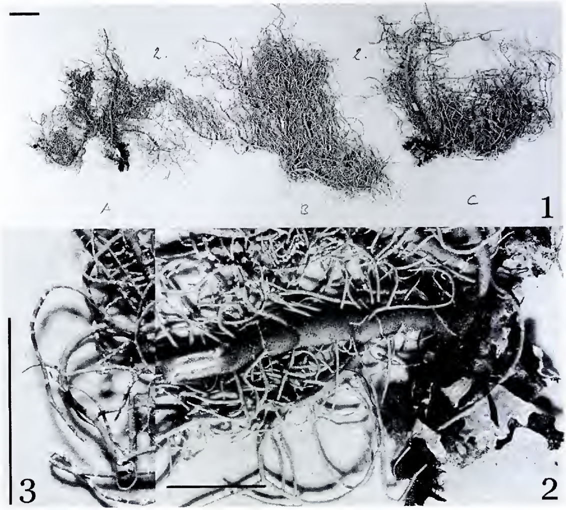
When Räsänen (1933) described *U. comosa* var. *stuppea* he cited only a single locality with a short diagnosis[1]. Later, when Motyka (1936) treated the taxon in his monograph he elevated Räsänen's epithet to the specific rank and lectotypified the name on a specimen in the Räsänen herbarium. Unfortunately, there are three packets in the Räsänen herbarium with the same label data. Two of these were labeled by Räsänen himself (the packet numbered "1" was selected by Halonen et al. (1998) as the lectotype) and one is a specimen of Gyelnik's *Lichenotheca Exsiccati* 17. Only one of these packets retains an annotation by Motyka and thus this is the only packet we can conclusively state was reviewed by him. Because we consider Motyka's (1936) use of the term "type" to be effective lectotypification we consider the packet annotated by Motyka to be the lectotype. Halonen et al. (1998) selected as the lectotype the packet labeled by Räsänen and not annotated by Motyka, apparently because they were not aware of Motyka's previous lectotypification. The lectotypification of Halonen et al. (1998) thus had no standing since it was predated by Motyka's lectotypification. The lectotype selected by Motyka consists of two thalli (marked "A" and "C") mounted on a card with one thallus (marked "B") annotated by Motyka as a different taxon. The thalli marked "A" and "C" agree both with Räsänen's scant original description and Motyka's (1936) later description. The thallus marked "B" contains usnic and norstictic acids (I.M. Brodo, annotation) and was given the manuscript name *Usnea lapponica* var. *americana* by Motyka. Thus, in order to clarify Motyka's lectotypification and the application of this name we select the thallus marked "C" as the "second-step" lectotype (Greuter et al. 2000, Art. 9.14, Ex. 6):

Usnea stuppea (Räsänen) Motyka, Lich. gen. Usnea 1:262. 1936. (**Figs. 1–3**). *Usnea comosa* var. *stuppea* Räsänen, Ann. Missouri Bot. Gard. 20:9. 1933. TYPE: CANADA BRITISH COLUMBIA: Hazelton, on *Picea murrayana*, Sep 1931, *Kujala s.n.* (LECTOTYPE, here designated: H (Räsänen Herbarium; packet marked "2," thallus on right marked "C").

The type collection of *U. stuppea* is a mixture of more than one taxon; we have made an effort to examine some of the duplicates distributed in Gyelnik's *Lichenotheca Exsiccati*. This examination revealed that some duplicates are a mixture of *U. lapponica* and *U. stuppea* while others include other taxa. Likewise the duplicate card in the Räsänen herbarium (packet marked "1") that was cited by Halonen et al. (1998) is also a mixture of *U. lapponica* and *U. stuppea*.

---

[1] Rasanen (1933: 9). "Thallus erectus aut suberectus, brevior fruticulosus, 5–7 cm. longus, laevigatus vel leviter verrucosus, sorediosus, pallido-stramineus, soredia maculiformia, demum parce isidiosa. Medulla laxa, stuppea, K-."



Figs. 1–3. *Usnea stuppea*. **Fig. 1.** Lectotype card, thalli marked A and C = *U. stuppea*, thallus marked B = *U. lapponica*. **Fig. 2.** Detail of lectotype thallus: internal anatomy and basal point of attachment to the substrate. (Note sunken area of cortex on main branch below cut.) **Fig. 3.** Detail of lectotype thallus: small fibrils and secondary branches with soralia lacking isidiomorphs. Scale bar = 1 cm.

The duplicate of *Lichenotheca Exsiccati 17* in Räsänen's herbarium consists of one large thallus of *U. stuppea*.

II. **Usnea substerilis** Motyka

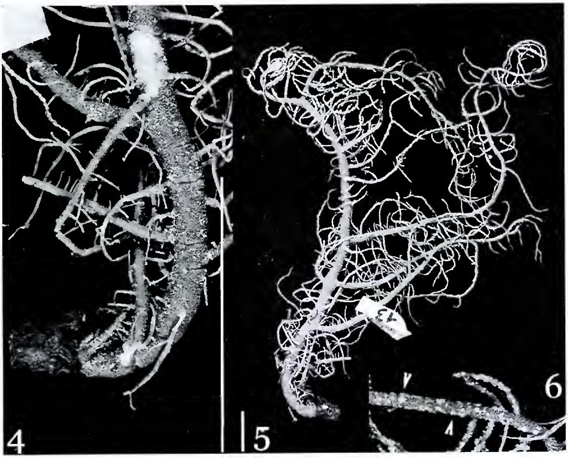
When Motyka (1930) first described *U. substerilis* he did not designate a type specimen. Later, however, he selected an exsiccatum of *Arnold Lichenes Exsiccati 1538b* in W as the lectotype (Motyka, 1936). While treating some of the species of the *U. fragilescens*-group, Clerc (1987) also selected part of an exsiccatum of *Arnold Lichenes Exsiccati 1538b* in W as the lectotype noting that it was a mixture of several taxa. While reviewing the status of *U. stuppea* we also attempted to confirm the typification (and taxonomy) of *U. substerilis*. A loan of the type material from W revealed that the packet selected by Clerc bore no annotation by Motyka, a situation similar to that of *U. stuppea*. This case differs from *U. stuppea*, however, because no specimen matching the data given for the lectotype by Motyka (1936) with Motyka's annotation was located in W. Thus, because no specimen annotated by Motyka could be found his lectotypification must be superseded by that of Clerc (1987). In order to avoid any doubt as to the application of the name *U. substerilis* we have thus chosen to further clarify the lectotypification of Clerc (1987) and select a single thallus from among the thalli selected as the lectotype by Clerc.

Usnea substerilis Motyka, Wyd. Muz. Söask. w Katow. 24. 1930. (**Figs. 4–6**). Type: ITALY. Groeden, ad ramulos emortuos *Laricis* in silva supra Unterkoffel prope St. Ulrich, 1889, *Arnold s.n. – Lichenes Exsiccati 1538b* (Lectotype, here designated: W!(thallus figured herein).

Halonen et al. (1998) placed *U. stuppea* in synonymy with *U. substerilis* Motyka without discussion; however, we prefer to maintain *U. stuppea* as a distinct taxon based on a number of differences in internal and external anatomy. First, in the type of *U. substerilis* the papillae on the primary branches are raised (tall), rounded at the top, and worn off to some degree closer to the base of the thallus. They are also better defined in shape, and gradually sparser, closer to the tips of the main branches. On the secondary branches the papillae also gradually become sparser, larger, and more infrequent towards the tips of the branches. The type of *U. stuppea* however, possesses papillae that are evenly distributed from the base to the tips of the main branches. The papillae themselves are less raised (shorter), and more blunt. On the secondary branches the papillae are nearly absent except close to the point of attachment to the main branch.

The size, shape, and ontogeny of soralia have also been considered valuable characters in distinguishing species (Herrera-Campos et al. 1998; Halonen et al. 1998; Ohmura 2001) and the soralia of *U. stuppea* and *U. substerilis* differ in a number of characters. Those of *U. substerilis* are raised above the cortex (not excavate) and produce few to many small isidiomorphs. As the isidiomorphs are abraded away with age the soralium becomes excavate and larger in size. This is contrasted with the soralia of *U. stuppea* which are not distinctly raised above the cortex and do not produce isidiomorphs. Instead, the soralia produce large coarse soredia, and, with age the soralia become larger in size and considerably deeper (more excavate).

As discussed by Tavares (1987) and Ohmura (2001) cortical anatomy is also a valuable character for distinguishing *Usnea* taxa. The cortex of *U. substerilis* is harder, more rigid, and considerably thicker than that of *U. stuppea* and has a dusty gray-brown (subpruinose) appearance in the herbarium. Likewise, the cortex of *U. stuppea* tends to be softer (occasionally sinking into slight foveae or depressions on the main branches) and lacks the granular appearance of *U. substerilis*. The branches of *U. substerilis* are also distinctly shorter than those of *U. stuppea*. It is important to note that both *U. stuppea* and *U. substerilis* differ from material currently referred to *U. lapponica* Vainio (i.e. thallus "B" on



Figs. 4–6. *Usnea substerilis*. **Fig. 4.** Detail of lectotype thallus: internal anatomy and basal point of attachment to the substrate. (Note rough appearance of cortex and tall raised papillae.) **Fig. 5.** Lectotype thallus, marked No. 13 in packet by P. Clerc. **Fig. 6.** Detail of lectotype thallus: secondary branch and fibrils showing raised soralia with isidiomorphs (indicated by arrows). Scale bar = 1 cm (fig. 4, scale identical for fig. 6), .5 cm (fig. 5).

the lectotype card of *U. stuppea*) by the presence of a subpruinose (*U. substerilis*) or subglabrous (*U. stuppea*) cortex. The cortex of the material here referred to *U. lapponica* is lighter in color (yellower in the herbarium) than those of the other two taxa and glabrous instead of subpruinose or subglabrous.

ACKNOWLEDGMENTS

We wish to thank the curators of the following herbaria for loaning material for this study: BP, FH, H, NY, LBL, S, W. We are grateful for the comments of Gerry Moore and an anonymous reviewer.

ABSTRACT

This paper, the third in a series presenting cases of confusion of nomenclature and typification in the genus *Usnea*, discusses two names of pendent, apotheciate, angulose *Usnea* species from South America. The first, *Usnea alata* Motyka, was not correctly typified by Motyka (1937) at the time of description and is lectotypified here. The second, *Usnea sulcata* Motyka, has been misapplied due to a lectotypification that is in conflict with the protologue; the species is thus re-lectotypified here. A lectotype is also selected for the name *U. angulata* f. *ferruginea* Krempelhuber, which is considered a synonym of *U. sulcata* var. *sulcata*.

RESUMEN

Este artículo, el tercero de una serie que presenta casos de confusión en la nomenclatura y tipificación en el género *Usnea*, discute dos nombres de especies de *Usnea* colgantes, con apotecios, angulosas de Sur América. El primero, *Usnea alata* Motyka, no fue tipificado correctamente por Motyka (1937) en el momento de su descripción y se lectotipifica aquí. El segundo, *Usnea sulcata* Motyka, ha sido mal aplicado debido a una lectotipificación que está en conflicto con el protólogo; La especie es pues re-lectotipificada aquí. También se selecciona un lectotipo para el nombre *U. angulata* f. *ferruginea* Krempelhuber, que es considerado un sinónimo de *U. sulcata* var. *sulcata*.

I. **Usnea alata** Motyka

Usnea alata Motyka is one of the pendent, angulose, apotheciate species of *Usnea* known to occur in South America. Though Motyka (1937) clearly intended a specimen in the Vainio herbarium (TUR) to serve as the type, no specimen annotated as the type by him has been located there. As noted by Alava (1986) there are in fact two specimens matching the collection data given in the protologue. One of these specimens (TUR-VAINIO #000492) represents a collection not distributed in Vainio's *Lichenes Brasiliensis Exsiccati* and the other (TUR-VAINIO #00493) is a duplicate of *Lichenes Brasiliensis Exsiccati* #395. Since Motyka did not indicate if he intended the exsiccati collection to serve as the type there is no way to conclude with certainty which of these two specimens Motyka might have regarded as the type. Thus, we have chosen to lectotypify the species using the specimen distributed in Vainio's exsiccati instead of simply assuming its status as the holotype. It should be noted that Her-

SIDA 21(2): 643–650. 2004

rera-Campos et al. (1998) did not effectively lectotypify *U. alata* when they stated "TYPE: BRAZIL, Minas Geraës, *Chequeira, 1885* (TUR holotype)..." because a single specimen was not cited and two specimens are present in Vainio's herbarium.

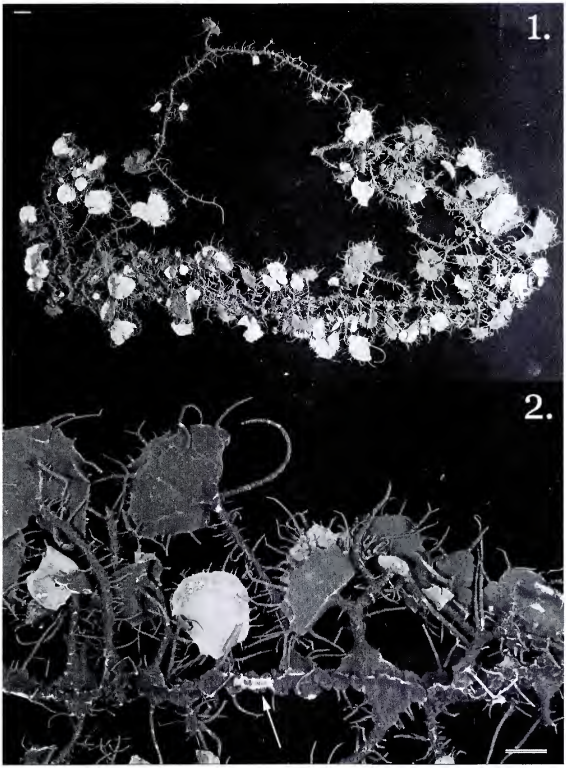
The specimen here selected as the lectotype agrees well with Motyka's protologue and all duplicates of this collection reviewed by the first author are conspecific with the specimen selected as the lectotype.

Usnea alata Motyka, Lich. gen. Usnea 2(1):395–396. 1937. (**Figs. 1–2**). TYPE: BRAZIL. MINAS GERAES: Chequeira, in arbore, 1885, *Vainio s.n. = Lichenes Brasiliensis Exsiccati #395* (LECTOTYPE, here designated: TUR! (Vainio Herbarium #00493); ISOLECTOTYPE: S!

Though *U. alata* was considered a distinct taxon by Herrera-Campos et al. (1998) it seems likely that some authors would consider it conspecific with *U. sulcata* Motyka (as redefined here). These two taxa differ in a number of respects, however, including the type of angulation of the branches, structure and shape of the fibrils, size of the apothecia, and overall appearance. Furthermore, much confusion has apparently resulted from the fact that Motyka changed his interpretation of *U. alata* prior to the publication of the monograph and after he annotated most of the specimens cited therein. That Motyka re-interpreted *U. alata* shortly before its publication is evidenced by the fact that many specimens in S that were annotated by Motyka as *U. alata* or "*U. angulata* var. *alata*" were cited by him as paratypes of *U. sulcata* var. *neutra* Motyka. Indeed, these specimens are not referable to *U. alata* in the sense of the type because they possess apothecia that are generally smaller than those of the type, the branches are angulose (having parallel ridges or sharp foveae) instead of alate, the fibrils are long, slender, regular, and abundant, and the chemistry of the type of *U. alata* apparently differs from that of *U. sulcata* var. *neutra*. (Incidentally, Motyka (1937) reported the type of *U. alata* to have a KOH- medulla; however as reported by Herrera-Campos et al. (1998) the type actually contains norstictic and connorstictic acids.) It is tempting to consider the possibility that *U. alata* represents the non-sorediate, fertile counterpart to *U. paradoxa* Motyka (as defined by Lendemer & Tavares 2003).

II. **Usnea sulcata** Motyka

While the first author was working with *U. angulata* Acharius, a number of problems in typification and taxonomy were encountered involving taxa recently placed in synonymy with *U. angulata* by other authors (Awasthi 1986; Herrera-Campos et al. 1998; Ohmura 2001). One such synonym is *U. sulcata* Motyka. Motyka (1937) described *U. sulcata* without the mention of soralia and with the description of small pruinose apothecia. As Tavares (2002) has noted, this taxon (originally described as apotheciate) was lectotypified with a soraliate specimen that lacked apothecia and the species was then placed in synonymy with *U. angulata* (Awasthi 1986). *Usnea angulata* in our opinion is a



Figs. 1–2. *Usnea alata*. **Fig. 1.** Lectotype thallus. **Fig. 2.** Detail of lectotype: strongly alate branch with "winged" secondary branch attachments; arrow indicates cut through branch showing internal anatomy. Scale bar = 0.5 cm.

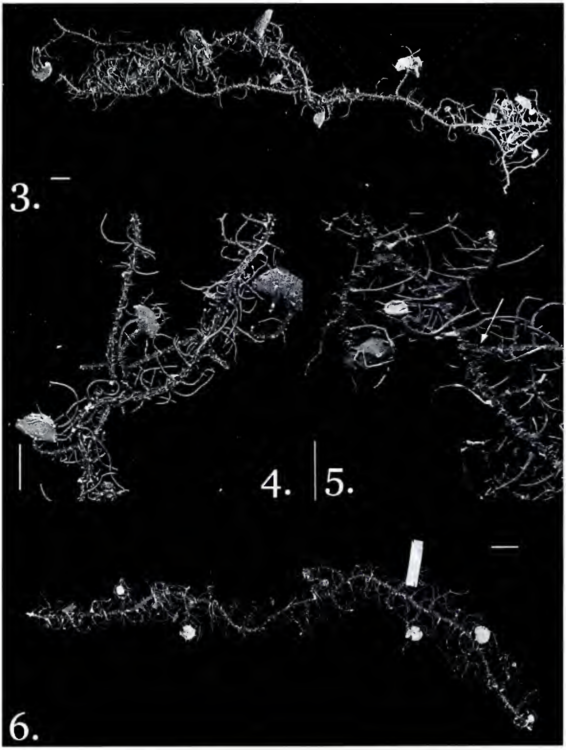
soraliate species from eastern North America and northern Mexico. Apparently these names were placed into synonymy because the lectotype selected by Awasthi (1986) is densely soraliate (not apotheciate) and thus superficially similar to *U. angulata*. All later workers with the exception of Tavares (2002) have continued to include *U. sulcata* as a synonym of *U. angulata*.

Motyka's designation of the type specimen of *U. sulcata* was simply "Typus in Museo Botan. Univ. Fennicae in Turku.—Locus classicus: Brasilia, Minas Geraës, Sitio, 1885 Vainio." As noted by Tavares (2002) there are four specimens in TUR-VAIN matching this description, one of which (TUR-VAIN 00450) was selected by Awasthi as the lectotype. One of us (JCL) has examined all four of these specimens; three of the four thalli are soraliate and thus not suitable candidates for lectotypification. A fourth thallus, though not soraliate, is small, poorly developed, and lacking apothecia. This fourth specimen is a possible candidate for lectotypification (since it does not possess soralia); however, it is too poorly developed to allow positive identification as *U. sulcata* and does not possess apothecia, a feature Motyka described in the protologue. It would seem, therefore, that none of the specimens in TUR-VAIN matching Motyka's published data are ideal for lectotypification. It should be noted that Vainio (1890) stated that all of the specimens of "*U. angulata*" from Sitio were sterile. Interestingly, though the specimens at Turku that were collected at Sitio are not apotheciate, all of the other specimens we have examined that Motyka cited in the protologue are either apotheciate, pycnidial, or lack both apothecia and pycnidia but are not soraliate. Likewise, with the exception of the specimens distributed by Vainio in his *Lichenes Brasilienses Exsiccati*, all of the exsiccati specimens (that we have examined) cited by Motyka in the protologue also are either apotheciate or pycnidial. There is, however, a specimen in Motyka's herbarium (now at LBL) labeled as having come from Sitio that is apotheciate and it is this specimen that we select as the lectotype.

The comparisons Motyka (1937) made between *U. sulcata* and other taxa also serve to confirm that the lectotype selected by Awasthi conflicts with the published diagnosis. Motyka contrasted *U. sulcata* with *U. paradoxa* Motyka, a soraliate taxon (see Lendemer & Tavares 2003) and placed in synonymy with *U. sulcata* a previously described form and a variety of *U. angulata* (*U. angulata* forma *ferruginea* Krphb. and *U. angulata* var. *rubiginosa* Hillmann), both of which are based on apotheciate specimens. Unfortunately, the type material of *U. angulata* var. *rubiginosa* Hillmann was destroyed during World War II and thus is not available for study. It is retained here as a questionable synonym.

Usnea sulcata Motyka var. **sulcata**, Lich. gen. Usnea 2(1):478–480. 1937. (**Figs. 5–6**). TYPE: BRAZIL: MINAS GERAES: Sitio, 1885, *Vainio s.n.* (LECTOTYPE, here designated: LBL! #300.7 (fragment figured here).

= *Usnea angulata* Acharius forma *ferruginea* Krempelhuber, Flora 61(28):437. 1878. TYPE: *Lorentz & Hieronymus s.n.* (LECTOTYPE, here designated: M!; ISOLECTOTYPE: UC!).



Figs. 3–6. *Usnea sulcata* var. *neutra*. **Fig. 3.** Lectotype thallus. **Fig. 4.** Detail of lectotype: angulose branch. *Usnea sulcata* var. *sulcata*. **Fig. 5.** Detail of lectotype: arrow indicates papillate "winged" secondary branch attachment. **Fig. 6.** Lectotype thallus. Scale bar = 0.5 cm.

(?) = *Usnea angulata* Acharius var. *rubiginosa* Hillmann, Repert. Spec. Nov. Regni Veg. 27(16–25):291. 1930. TYPE: BRAZIL. *Sellow* s.n. (HOLOTYPE: B, destroyed).

The lectotype packet (LBL 300.7.) of *U. sulcata* contains fragments of several thalli, four of which possess apothecia. The fragment selected here as the lectotype contains norstictic, caperatic, and connorstictic acids by TLC (R.C. Harris, pers. comm.) and thus is chemically similar to the type of *U. alata* Motyka. It is important to note that the lectotype selected here differs in appearance from the soraliate specimen previously selected as the lectotype (by Awasthi 1986) and possibly does not represent part of the same gathering.

Since we have shown here that *U. sulcata* Motyka is in fact an apotheciate species from South America the previously accepted synonymy with *U. angulata* Acharius should be rejected. *Usnea angulata* f. *ferruginea* Krempelhuber was described without the designation of a type; thus here we have chosen to select the specimen in Krempelhuber's herbarium (M) as the lectotype. It should be noted that the red coloration which Krempelhuber's epithet suggests is not actually a pigmentation of the cortex such as that seen in *U. michauxii* I.I. Tavares or *U. pensylvanica* Motyka but instead is simply a discoloration of the entire collection. No other collection with similar discoloration has been seen by us.

Motyka (1937) also described *U. sulcata* var. *neutra* Motyka on the basis of its medulla having a negative KOH reaction. Later, Rizzini (1952) elevated this taxon to specific rank. Subsequent authors have not discussed this taxon; when re-evaluating the status of the other apotheciate angulose taxa in South America it became clear that *U. sulcata* var. *neutra* was also in need of revision. The type specimen was indicated by Motyka (1937) to be in his personal herbarium (now at LBL); however no such specimen was located in a loan of specimens from LBL of the apotheciate angulose taxa discussed here. Furthermore, it was also clear that there exists much confusion in the use of this name because prior to publishing the name *U. sulcata* var. *neutra* Motyka included specimens later cited as paratypes of *U. sulcata* var. *neutra* in his concept of *U. alata* Motyka. In order to affix the usage of the name *U. sulcata* var. *neutra* to a specimen, we have chosen to lectotypify the name with one of three specimens from S matching the data given in Motyka's protologue. All of these specimens differ chemically from the type *U. sulcata* var. *sulcata* (see below).

Usnea sulcata Motyka var. **neutra** Motyka, Lich. gen. Usnea 2(1):480–481. 1937. (**Figs. 3–4**). *Usnea neutra* (Motyka) Rizzini, Revista Brasil Biol., 12(4):page #. 1952. TYPE: BRAZIL. MINAS GERAES: Ciade de Caldas, 1879. *Regnell s.n.* (LECTOTYPE, designated here: S! #L160 (apotheciate fragment figured here).

Of the specimens lent to the first author from S, three specimens matched the data given in Motyka's protologue for the type of *U. sulcata* var. *neutra* Motyka. Only the specimen selected here as the lectotype was actually identified as *U.*

sulcata var. *neutra* (R. Santesson, undated annotation) and marked "TYPUS" (not in Motyka's hand). It is important to note, however, that at present we do not consider *U. alata* and *U. sulcata* var. *neutra* to be synonyms because they differ both chemically and morphologically. We also prefer to retain *U. sulcata* var. *neutra* as distinct from *U. sulcata* var. *sulcata* because the type specimens of the two taxa also differ on chemical and morphological grounds. (The lectotype of *U. sulcata* var. *neutra* contains the stictic acid complex in addition to usnic and norstictic acids whereas the lectotypes (selected here) of *U. alata* and *U. sulcata* var. *sulcata* lack the stictic acid complex.) As noted above, Rizzini (1952) elevated Motyka's epithet to specific rank; we however choose to follow Motyka's original placement pending further study. It should be noted that *U. sulcata* var. *neutra* Motyka is not synonymous with *U. angulata* var. *neutra* Motyka ex Räsänen, a soraliate taxon. The latter name will be treated in a future publication (Lendemer in prep.).

ACKNOWLEDGMENTS

We wish to thank Orvo Vitikainen (H) for providing data associated with the lectotype of *U. angulata* as well as Paul Silva (UC) for providing nomenclatural advice; also, we thank Soili Stenroos (TUR) for providing access to the Vainio specimens from Sitio, and Jan Bystrek (LBL) for locating the material from Motyka's herbarium. Also, we wish to thank James Macklin (PH) and Richard Moe (UC) for reviewing drafts of the manuscript, the curators of B, LBL, M, and TUR, for loaning material to the first author, and R.C. Harris for performing TLC on several of the specimens cited here.

ABSTRACT

Oenothera pennellii Munz (*Oenothera* sect. *Oenothera* subsect. *Nutantigemma*) was recently placed in synonymy with the widespread and variable *O. pubescens* Willd. ex Spreng. A series of recent collections from Coahuila, Nuevo León, Tamaulipas, and Zacatecas, México, show that *O. pennellii* is a distinctive, subacaulescent, apparently perennial species restricted to northeastern Mexico at relatively high elevations. It is largely allopatric from the widespread, caulescent, annual or biennial *O. pubescens*. Like *O. pubescens*, *O. pennellii* is a permanent translocation heterozygote species

Key Words: *Oenothera* sect. *Oenothera* subsect. *Nutantigemma*, evening-primrose, Mexico, Onagraceae

RESUMEN

Oenothera pennellii Munz (perteneciente a *Oenothera* subsect. *Nutantigemma*) fue colocada recientemente en la sinonimia de *O. pubescens* Willd. ex Spreng., una especie muy variable y de amplia distribución. Las colecciones procedentes de Coahuila, Nuevo León, Tamaulipas, y Zacatecas en México, muestran que *O. pennellii* es una especie distinguible por su hábito sub-acaulescente y que aparentemente está restringida al noreste de México en elevaciones relativamente altas, donde es ampliamente alopátrica con *O. pubescens*, especie caulescente, anual y de amplia distribución.

Oenothera pennellii Munz was described in 1939 and was maintained in Munz's treatment of all North American Onagraceae (1965). Following detailed studies of subsect. *Raimannia*, Dietrich and Wagner (1988) placed *O. pennellii* in synonymy with the widespread and variable *O. pubescens* Willd. ex Spreng. They considered it a rare (five known collections) but noteworthy variant among several in *O. pubescens* (Dietrich & Wagner 1988: 77). Subsequent to that study, many new specimens have been collected in high-elevation areas (2,000–3,600 m) in the northeastern Mexican states of Coahuila, Nuevo León, Tamaulipas, and Zacatecas; most of these collections are deposited at TEX/LL. What previously seemed a sporadic variant now appears to represent a distinguishable species restricted to northeastern Mexico at relatively high elevations, and largely allopatric from *O. pubescens*, which ranges from Arizona and New Mexico to Guatemala, and in South America in the Andes of Colombia, Ecuador, and Peru. The geographical ranges of the two species overlap only in Sierra del Carmen in Coahuila, but the single collection of *O. pubescens* from there was made several hundred meters lower than the lowest known populations of *O. pennellii*.

Oenothera pennellii characteristically has small flowers (petals 6–8 mm long) and is subacaulescent, with stems 0–2(–4) cm long. In contrast, *O. pubescens* usually has petals (6–)15–25(–35) mm long and is always caulescent with conspicuous stems up to 100 cm long, even in adverse moisture regimes. *Oenothera pubescens* never flowers from the basal rosette but has flowers formed in the leaf axils near the tips of the stems, as is typical in the genus. It is also annual or biennial, whereas *O. pennellii* appears to be a short-lived perennial from an enlarged taproot. On this basis I am here resurrecting this regional endemic to species status. Like *O. pubescens*, *O. pennellii* is a permanent translocation heterozygote (PTH) species. Pollen fertility is about 50% judging from several collections (*McDonald 2064*, *Hinton 18858*, *20452*) examined. Permanent translocation heterozygosity has been very important in the evolution of the genus *Oenothera* and several other genera of the Onagraceae. The metacentric chromosomes with pycnotic, condensed proximal regions (Kurabayashi et al. 1962; Cleland 1972; Raven 1979) have been associated with the regular occurrence of rings of chromosomes, resulting from reciprocal translocations. The phenomenon of reciprocal translocations reaches an endpoint of development in the specialized system known as PTH. The best known species possessing this system are the members of *Oenothera* subsect. *Oenothera*, in which the structure and mechanisms were worked out (Cleland 1972; Harte 1994; Deitrich et al. 1997). In addition to the translocations, the system requires balanced lethals, which prevent the formation of the homozygous combinations (most easily observed as ca. 50% infertile pollen), self-pollination, and alternate disjunction of the chromosomes during meiosis.

Oenothera pennellii Munz, Leafl. W. Bot. 2:156, 157. 1939. (**Fig. 1**). TYPE: MEXICO. NUEVO LEON: Sierra Madre Oriental, Mt. "El Infiernillo," Pablillo, SE of Galeana, 2,750–2,900 m, 29 Jun 1934, *F.W. Pennell 17139* (HOLOTYPE: US-01640419, ISOTYPE: PH not seen, POM).

Acaulescent or subacaulescent, short-lived perennial herb from fairly stout taproot; stems occasionally present, 1–4 cm long. Rosette and cauline leaves 2–6(–10) × 0.2–1.5 cm long, oblong-lanceolate, sinuate-pinnatifid to occasionally remotely serrate on smaller leaves, strigillose and hirtellous, especially on the veins. Flowers axillary, arising among the basal leaves or on the short stems. Floral tube 17–30 mm long, nodding prior to anthesis, reddish purple, sparsely hirtellous, the hairs appressed or spreading, and occasionally also strigillose. Sepals reflexed in pairs at anthesis, 5–6 mm long, oblong-lanceolate, pubescent, free tips ca. 0.2 mm long. Petals 6–8 mm long, about as broad, yellow, changing to reddish orange when wilted, slightly notched apically with short tooth in

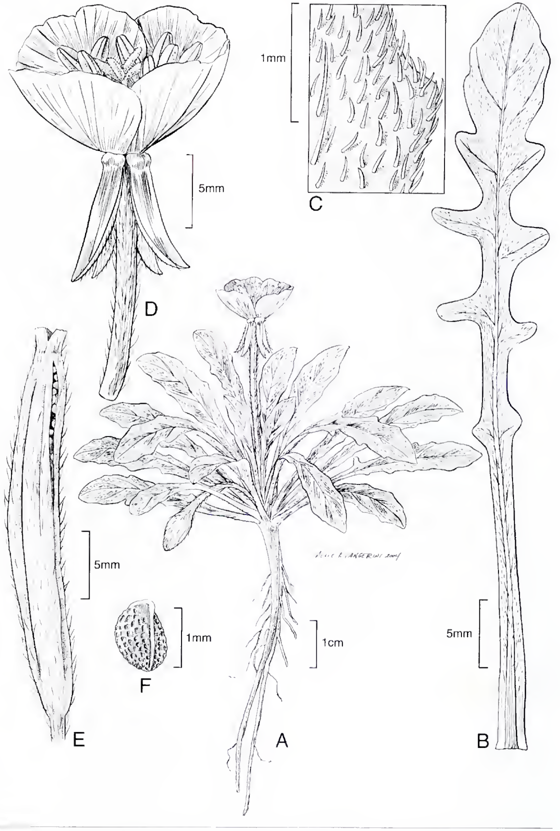

Fig. 1. *Oenothera pennellii.* **A.** Habit (*Hinton et al. 20452* & *Wendt & Adamcewicz 523C*), unopened bud (*Pennell 17139*, holotype). **B.** Leaf (*Pennell 17139*, holotype). **C.** Inset showing pubescence (*Hinton et al. 20452*). **D.** Flower with part of floral tube, but not ovary (*Hinton et al. 18858*). **E.** Capsule (*Pennell 17139*, holotype). **F.** Seed (*Pennell 17139*, holotype).

notch. Staminal filaments 6–7 mm long, subequal; anthers 2–3.2 mm long; pollen ca. 50% fertile. Style 20–35 mm long; stigma surrounded by the shedding anthers at anthesis, the lobes ca. 1.5 mm long. Capsules 16–28 mm long, cylindrical, thin-walled, sessile, hirtellous and strigillose, ca. 3 mm in diameter. Seeds 1–1.2 mm long, light brown, globose-obovoid, with median ridge and shallowly regularly pitted surface.

Distribution.—*Oenothera pennellii* occurs in open areas in mixed conifer (*Pinus, Pseudotsuga, Abies*) and *Quercus* forests and in subalpine *Pinus* forest, Coahuila, Nuevo León, Tamaulipas, and Zacatecas, Mexico, from 2,000 to 3,600 m. Flowering from May through September.

Specimens Examined: **MEXICO. Coahuila:** Madera del Carmen, upper end of Dos Canyon, at road fork to Campo Uno, 23 Jun 1976, *Fryxell 2715* (LL, NY); Sierra Madera del Carmen, at Campo El Tres, an abandoned logging camp in the high country, [29°00' N, 102°36' W], 7 Aug 1974, *Wendt & Adamcewicz 523C* (TEX); Ocampo, along old logging road, of mill at Campo 4 adjacent to sawdust pile, [28°59' N, 102°33' W], 28 May 1975, *Riskind & Patterson 1826* (LL); Sierra de Parras, *Purpus 4624* (UC); Arteaga, Sierra Zapaliname, 27 Jun 1990, *Hinton et al. 20452* (TEX); Sierra del Coahuila, 2 Jun 1985 *Hinton et al. 18858* (TEX); Sierra del Arteaga, Canon de la Carbonera, Las Vigas, [25°20' N, 100°39' W], s.d., *Villarreal & Carranza 3776* (TEX). **Nuevo León:** Picacho de San Onofre, ladera este, 5 Jul 1985, *McDonald 1662* (TEX). **Tamaulipas:** filo y lado este de Peña Nevada, 5 Jul 1985, *McDonald 1630* (TEX); Miquihuana, Sierra de Peña Nevada, ceja y ladera S y SO [23° 35' N, 99° 46' W], 3600 m, 22 Aug 1986, *McDonald 2064* (MO, TEX [2]). **Zacatecas:** Sierra Madre Oriental, Mt. "El Temoroso," N of Aranzazu, 17 Jul 1934, *Pennell 17466* (US).

The five collections cited by Dietrich and Wagner (1988) as the low-growing phenotype are a mix of short-stemmed *Oenothera pubescens* and *O. pennellii*. Three of the collections represent *O. pennellii* and are cited above. The collection from Sierra del Carmen, Coahuila (*Henrickson 11643* [MO]), is *O. pubescens* but was collected in a heavily grazed area and thus had very short stems. Cultivated material of this collection at MO has stems up to 30 cm long and is atypical of *O. pubescens* only in having flowers much smaller than usual (petals ca. 6 mm). Another collection (*Moore 3157* from Hidalgo, MO) also is *O. pubescens* and occurs well outside the range of *O. pennellii*.

The substrate for *Oenothera pennellii* is largely unknown. *Wendt & Adamcewicz 523C* give the substrate as rhyolite, and *Pennell 17466* gives it as gravelly andesite, both volcanics. With the information available it is not possible to ascertain if *O. pennellii* is restricted to volcanic substrates; however, Guy Nesom (pers. comm.) indicates that the type locality is gypseous. Since limestone is very common throughout this region it should be looked for on this substrate as well.

ACKNOWLEDGMENTS

I thank Tom Wendt for calling my attention to the large number of recent collections in TEX of Onagraceae, particularly *Oenothera*, which allowed me to appreciate the distinctions between *O. pubescens* and *O. pennellii*. I thank Alice

Tangerini for her excellent illustration and Denise Mix for assistance with the collections and comments on the draft manuscript. I also appreciate the reviews by Peter Hoch and Guy Nesom, which improved the clarity and information content of the paper.

BOOK NOTICES

Books from the Hunt Institute for Botanical Documentation

Gavin D.R. Bridson, James J. White, and Lugene B. Bruno. 2003. **American Botanical Prints of Two Centuries.** (ISBN 0-913196-75-4, pbk.) Hunt Institute of Botanical Documentation, 5th Floor, Hunt Library, Carnegie Mellon University, Pittsburgh, PA 15213, U.S.A. (Orders: 412-268-2434; 412-268-5677 fax; email: huntinst@andrew.cmu.edu; huntbot.andrew.cmu.edu). $25.00, 239 pp., 114 figs (106 color). Pictorial stiff paper cover, 8" × 10 1/2".

Two centuries of botanical prints is a wide range to cover in so short a book, but this task is managed quite well in *American Botanical Prints of Two Centuries.* Starting with the 19th century, the authors take us through a period of utilitarian prints designed for the sole purpose of botanical research. We see the evolution of the botanical print as one of necessity to one of art.

As technology improved, artists were free to elaborate and put their own personal touch on a piece. Starting with the 20th century, we begin to see the effects of light and color. We see more stylized works, things we would want to hang on the wall.

American Botanical Prints of Two Centuries is laid out very well. There is no table of contents, but there is a very well-organized catalogue of prints including biographical information on the artists on pages 150–195.

It is impossible to merely glance at the prints displayed in this book. Every picture is a work of art, even the utilitarian prints. Who knew a cluster of walnuts could be so enjoyable and beautiful to look at!—*Abra Alexander, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

Gavin D.R. Bridson (Compiler), Scarlett T. Townsend, Elizabeth A. Polen, and Elizabeth R. Smith (eds.). 2004. **BPH-2. Periodicals with Botanical Content: Constituting a Second Edition of Botanico-Periodicum Huntianum (Volume 1 A–M, Volume 2 N–Z).** (ISBN 0-913196-78-9, pbk.) Hunt Institute of Botanical Documentation, 5th Floor, Hunt Library, Carnegie Mellon University, Pittsburgh, PA 15213, U.S.A. (Orders: 412-268-2434; 412-268-5677 fax; email: huntinst@andrew.cmu.edu; huntbot.andrew.cmu.edu). $130.00 (2 vol. set), 1470 pp., 8 1/2" × 11".

Congratulations to the team at the Hunt Institute of Botanical Documentation for a second edition of *Botanico-Periodicum-Huntianum* or *BPH-2*. From an editor who has already used the second edition, here is a big thank you for an incredible job. The first edition of BPH was published in 1968 and recorded periodicals published down to the end of 1967. In 1991, *B-P-H/S* (*Botanico-Periodicum-Huntianum/Supplementum*) was published. With *B-P-H/S*, the number of titles jumped to over 25,000 from the 12,000 recorded in the first edition. Now the new edition adds even more titles bringing the total to over 33,000, about 21,000 additional titles since 1967. "*BPH-2* is a fairly, but not wholly, comprehensive listing by title of periodicals from 1665 to 2000 that regularly contain (or, in some period of their history, included) articles dealing with the plant sciences, their history and bibliography." Good job thou good and faithful servants!—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

TAXONOMY OF *HYMENOXYS* SUBGENUS *MACDOUGALIA* (ASTERACEAE: HELENIEAE: TETRANEURINAE)

Mark W. Bierner

School of Biological Sciences and Plant Resources Center
The University of Texas
1 University Station, C0930
Austin, Texas 78712, U.S.A.
Bierner@mail.utexas.edu

ABSTRACT

A taxonomic treatment is presented for *Hymenoxys* subg. *Macdougalia*, which includes a single species, *Hymenoxys bigelovii*. The treatment includes a discussion of the original circumscription of *Hymenoxys bigelovii* (as *Actinella bigelovii*), the later description of the genus *Macdougalia* to accommodate this taxon, and the eventual placement, based on chemical, cytological, and morphological evidence, of *Macdougalia* within *Hymenoxys* as a monotypic subgenus. The treatment also includes synonymies of *Hymenoxys* subg. *Macdougalia* and *Hymenoxys bigelovii*, lectotypification of *Actinella bigelovii*, and a description and range map for *Hymenoxys bigelovii*.

RESUMEN

Se presenta un tratamiento taxonómico de *Hymenoxys* subg. *Macdougalia*, que incluye una sola especie, *Hymenoxys bigelovii*. El tratamiento incluye una discusión de la circunscripción original de *H. bigelovii* (como *Actinella bigelovii*), la descripción del género *Macdougalia* para acomodar este taxon, y la colocación eventual, basada en pruebas químicas, citológicas, y morfológicas, de *Macdougalia* en *Hymenoxys* como un subgénero monotípico. El tratamiento incluye también sinonimias de *Hymenoxys* subg. *Macdougalia* y *Hymenoxys bigelovii*, lectotipificación de *Actinella bigelovii*, y una descripción y mapa de distribución de *Hymenoxys bigelovii*.

Hymenoxys Cass. subg. *Macdougalia* (A. Heller) Bierner comprises only one species, *Hymenoxys bigelovii* (A. Gray) K.L. Parker. This taxon was originally described as *Actinella bigelovii* A. Gray, *Actinella* Pers. being the generic name commonly used at that time (e.g., Torrey & Gray 1842) for taxa now placed in *Tetraneuris* Greene and *Hymenoxys*. When describing *Actinella bigelovii*, Gray (1853) made no comments that would indicate any hesitation on his part as to its placement in *Actinella*.

Later (1883), when Gray positioned *Actinella bigelovii* in *Actinella* section *Hymenoxys*, he commented, "Connects [section] *Hymenoxys* with [section] *Euactinella*, and with section *Dugaldea* [sic] of *Helenium*." This statement indicates to me that Gray may not have been completely comfortable with his placement of this taxon. His section *Hymenoxys* equates today with *Hymenoxys* subg. *Hymenoxys*, *Hymenoxys* subg. *Phileozera* (Buckley) Cockerell (in part), and *Hymenoxys* subg. *Picradenia* (Hook.) Cockerell (Bierner 2001), his section *Euactinella* equates today with *Tetraneuris*, *Hymenoxys* subg. *Phileozera* (in part), and *Hymenoxys* subg. *Rydbergia* (Greene) Bierner (Bierner 2001; Bierner & Turner 2003), and his section *Dugaldea* [sic] of *Helenium* equates today with *Hymenoxys* subg. *Dugaldia* (Cass.) Bierner (Bierner 2001).

Heller (1898) seems to have been even less sure about its placement, as indicated by his comment, "In habit it is more like the genus *Tetraneuris*, but has a different involucre, and while its involucre is somewhat similar to that of the genus *Picradenia* [= *Hymenoxys* subg. *Picradenia*], there is a wide difference in habit." His solution was to describe the genus *Macdougalia* to accommodate this one taxon, a circumscription followed by Cockerell (1904), Rydberg (1915), and Robinson (1981). Other workers, such as Turner and Powell (1977) and Karis and Ryding (1994), felt there was no clear basis for maintaining *Macdougalia* as a separate genus and submerged it in *Hymenoxys*.

Spring et al. (1994) began their study of chemical components of glandular trichomes in *Hymenoxys* and related genera by recognizing *Macdougalia* as a genus separate from *Hymenoxys*. By the end of the study they were of the opinion, based on sesquiterpene lactone and monoterpene glycoside chemistry, that *Macdougalia* should be incorporated into a broader concept of *Hymenoxys*. Likewise, Bierner and Jansen (1998), who began their study of DNA restriction site variation in *Hymenoxys* and related genera recognizing *Macdougalia* as a distinct genus, concluded that it is in fact congeneric with *Hymenoxys*. The relationship of *Macdougalia* to *Hymenoxys* is further supported by similarities of flavonoid chemistry (e.g., Wagner et al. 1972) and chromosome number, $2n = 30$ being the chromosome number of *H. bigelovii* (Speese & Baldwin 1952; Strother 1966; Bierner unpublished and Parker & McClintock unpublished—see representative specimens) and the predominant number among the diverse taxa of *Hymenoxys* (e.g., Speese & Baldwin 1952; Beaman & Turner 1962; Strother 1966; Sanderson 1973; Turner et al. 1973). In 2001, Bierner formally recognized *Macdougalia* as a subgenus of *Hymenoxys*.

While Spring et al. (1994) were confident about the association of *Macdougalia* with *Hymenoxys*, they were less sure about its relationship to other taxa within *Hymenoxys*. The phenogram prepared from sesquiterpene lactone data placed *H. bigelovii* (as *Macdougalia bigelovii*) closest to *H. hoopesii* of subg. *Dugaldia* and *H. rusbyi* of subg. *Picradenia*. The strict consensus tree prepared by Bierner and Jansen (1998) placed *H. bigelovii* (as *Macdougalia bigelovii*) in the clade containing taxa of *Hymenoxys* subg. *Dugaldia*, *Hymenoxys* subg. *Picradenia*, and *Hymenoxys* subg. *Plummera*, but no clear association with any species in particular was apparent.

Morphology also supports the placement of *Macdougalia* in *Hymenoxys*. The stems, peduncles, receptacles, ray florets, and disc florets of *Hymenoxys bigelovii* are very similar to those of the *Hymenoxys* species in general. Conversely, a substantial number of morphological differences support the recognition of *Macdougalia* as a subgenus.

Hymenoxys bigelovii usually has all simple leaves that are eglandular or sparsely glandular. Among the other taxa of *Hymenoxys*, only *H. hoopesii* has all simple leaves, and only *H. texana* has leaves that are weakly to moderately glandular (all of the other taxa have distinctly glandular leaves).

As in essentially all of the perennial taxa of *Hymenoxys* (and *Tetraneuris* as well), the basal leaf bases of *H. bigelovii* are persistent and tend to thicken the caudices distally as the plants age. The basal leaves of *H. bigelovii*, however, decay down to the veins so that the tops of the caudices usually appear to be encased in a stringy cocoon. I have observed this decay to the veins occasionally in other taxa of *Hymenoxys*, but it is unusual and never creates the appearance of a stringy cocoon.

The phyllaries of *Hymenoxys bigelovii* are in two unequal series, as they are in most of the taxa of *Hymenoxys* (those of subg. *Dugaldia* and subg. *Rydbergia* are in two or three subequal series). The outer phyllaries of *H. bigelovii* are basally connate only slightly to 1/5 their lengths; the outer phyllaries of the other *Hymenoxys* taxa with two unequal series (except for *H. texana*) are basally connate 1/4 to 2/3 their lengths. The inner phyllaries of *H. bigelovii* are narrowly lanceolate to narrowly obovate, have aristate apices, and very distinctly exceed the outer in length; inner phyllaries of the other *Hymenoxys* taxa with two unequal series are usually obovate, have acuminate to usually mucronate apices, and surpass the outer in length only slightly or not at all.

The relationship of *Hymenoxys bigelovii* to other taxa of *Hymenoxys* remains unclear. Its relatively large involucres (13–20 mm high by 23–32 mm wide) might suggest a connection to *H. hoopesii*, *H. brandegeei*, or *H. grandiflora*, but the phyllaries are very different. Perhaps a clue rests with some unusual populations of *H. richardsonii* var. *richardsonii* from Fremont County, Wyoming (e.g., *Fisser 661* and *699* [RM], and *Dorn 3516* [NY, RM]). The phyllaries look so much like those of *H. bigelovii* that I was convinced when I first saw the specimens that these plants represented an undescribed species belonging to subgenus *Macdougalia*, even though the plants had divided leaves (blades are only rarely divided into three segments in *H. bigelovii*) and were well separated geographically from *H. bigelovii*. When I was able to see them in the field, however, it was obvious that they are indeed plants of *H. richardsonii* var. *richardsonii*, but with narrower, longer, aristate inner phyllaries. Yet, this illustrated to me that it is not a long morphologic leap from the involucres of *H. bigelovii* to those of some other *Hymenoxys* species.

TAXONOMY

Hymenoxys subg. **Macdougalia** (A. Heller) Bierner, Lundellia 4:39. 2001. *Macdougalia* A. Heller, Bull. Torrey Bot. Club 25:629. 1898. Type Species: *Actinella bigelovii* A. Gray, Pl. Wright. 2:96. 1853. (= *Hymenoxys bigelovii*)

Hymenoxys bigelovii (A. Gray) K.L. Parker, Madroño 10:159. 1950. Basionym: *Actinella* *bigelovii* A. Gray, Pl. Wright. 2:96. 1853. TYPE: U.S.A. NEW MEXICO. Grant or Sierra Co.: "Copper Mines - on the mountains" (lectotype label), 17 Apr 1852, *Bigelow s.n.* (LECTOTYPE [per previous annotations] here designated: GH!; PROBABLE ISOLECTOTYPES: NY!, US-27506!, US-27507!, US-27508!). The following notation in the protologue, "On mountains near the copper mines, and near the Mimbres, New Mexico; April, June," indicates that Gray was looking at more than one Bigelow collection when he wrote the description. Furthermore, the type sheet at GH contains three Bigelow specimens, one with the notation "Copper Mines" (far right), another with the notation "Near the Mimbres June 1852" (center), and another with the notation "Copper Mines - on the mountains, April 17. 1852." (far left). The specimen to the far left was already annotated as the lectotype when I borrowed it (no name or date on the label), and I likewise annotated it as the lectotype. I did so because there is no doubt at all that Gray was using this specimen; it is the only plant on the sheet that has cauline leaves that are divided into three segments, and the original description includes, "...foliis angustissime linearibus rigidis integerrimis paucisve caulinis trilobis..." In addition, collection information beneath the specimen includes, "*Actinella Bigelovii*, n. sp. (Pl. Wr.)." The lectotype bears no collection number; specimens at NY and US that appear to be part of the type collection bear the number 637. = *Actinea bigelovii* [as *Bigelowii*] (A. Gray) Kuntze, Rev. Gen. Pl. 1:303. 1891. = *Macdougalia bigelovii* (A. Gray) A. Heller, Bull. Torrey Bot. Club 25:629. 1898. = *Actinea bigelovii* (A. Gray) A. Nelson, Univ. Wyoming Publ. Sci., Bot. 1:139. 1926, nom. superflu.

Actinea gaillardia A. Nelson, Univ. Wyoming Publ. Sci., Bot. 1:140. 1926. TYPE: U.S.A. ARIZONA. Coconino Co.: "Rocky hillsides, among Yellow Pine Flagstaff Ariz." (holotype label), 2 Jun 1922, *Hanson 32* (HOLOTYPE: RM-100733!; PROBABLE ISOTYPE: MO-895987!).

Polycarpic perennials. Caudices sparingly branched, thickened distally, usually encased in a stringy cocoon-like covering formed by the veins of the decaying leaf bases. Aerial stems 1–5, erect, usually unbranched distally, green throughout to purple-red-tinted distally to purple-red-tinted throughout, 20–70 cm, sparsely to densely pubescent, often tomentose proximally, eglandular or sparsely dotted with sessile glands. Leaves basal and cauline, alternate, linear to linear-lanceolate to linear-oblanceolate, simple and entire or blades rarely divided into three segments, glabrous or sparsely to densely pubescent, eglandular or sparsely dotted with impressed glands; basal leaf bases expanded, clasping, persistent, sparsely to densely long-villous-woolly. Heads 1–5 per plant, usually borne singly but sometimes in paniculiform arrays. Peduncles (1.5–)6–20(–29) cm, expanded apically, moderately to densely pubescent, densely tomentose distally beneath the involucres, sparsely to moderately dotted with sessile glands. Involucres hemispheric to broadly campanulate, 13–20 × 23–32 mm. Phyllaries in 2 series; outer phyllaries 13–19, basally connate only slightly to 1/5 their lengths, green throughout or yellow to yellow-green proximally and green distally, often purple-red tinted on the margins, lanceolate to narrowly lanceolate or obovate to narrowly obovate, 7–11 × 1.3–2.8 mm, weakly to moderately keeled, apices acute to acuminate, abaxial faces sparsely to densely pubescent, sparsely to moderately dotted with sessile and impressed glands, adaxial faces glabrous or sparsely pubescent, eglandular or sparsely dotted with sessile glands; inner phyllaries 13–18, free, bodies yellow to yellow-green and scale-like, usually green distally, often purple-red tinted at the apices, narrowly

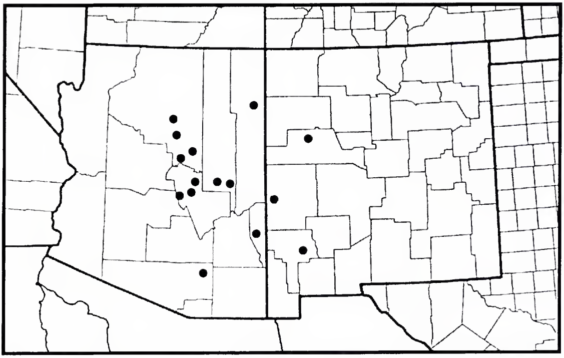

Fig. 1. Known distribution of *Hymenoxys bigelovii*.

lanceolate to narrowly obovate, 8.5–12.6 × (1.1–)1.5–2.2 mm, distinctly surpassing the outer, not keeled or weakly to moderately keeled, apices aristate, abaxial faces glabrous or sparsely pubescent, eglandular, adaxial faces glabrous, eglandular. Ray florets 13–15, pistillate, fertile; corollas yellow, extending well beyond the phyllaries, 13–26 × 5.4–9.5 mm, lobes 3, abaxial faces glabrous or sparsely pubescent, eglandular, adaxial faces glabrous, eglandular. Disc florets 100–250+, bisexual, fertile; corollas yellow, cylindric to cylindric campanulate, 5.7–7.4 × 0.7–0.9 mm, lobes 5, glabrous or sparsely pubescent, eglandular. Receptacles hemispheric to globoid to ovoid, paleae none. Cypselae narrowly obpyramidal, 4.2–4.7 × 0.9–1.2 mm, densely pubescent with straight, forked, antrorse hairs, eglandular; pappi 9–11(–15), obovate- to oblanceolate-aristate, 4.7–7.3 × 0.7–1.3 mm. Chromosome number, $2n = 30$.

Flowering and Distribution.—Flowering May to June. Roadsides, edges of juniper-pine and pine forests, 1375–2470 m. Central to eastern Arizona and western New Mexico (Fig. 1).

Representative specimens examined. **UNITED STATES. ARIZONA. Note.—More than 70 specimens were examined for this treatment. Those listed above were chosen as representative of the geographic distribution and morphologic variation of *Hymenoxys bigelovii*.

ACKNOWLEDGMENTS

I am grateful to the following institutions for loans of specimens: ARIZ, ASU, LL, NY, RM, TEX. I also thank John Strother for his help with the description of *Hymenoxys bigelovii* and José Panero for his help with preparation of the Spanish abstract. Guy L. Nesom and A. Michael Powell provided helpful review comments.

BOOK NOTICE

David J. Wishart. 2004. **Encyclopedia of the Great Plains.** (ISBN 0-8032-4787-7, hbk.). The University of Nebraska Press, P.O. Box 84555, Lincoln, NE 68501-4555, U.S.A. (Orders: 402-472-3584, Fax: 402-472-6214, www.unp.unl.edu) $75.00, 919 pp., b/w photos, 8 1/2" × 11".

Publisher Comments: "The Great Plains is a vast expanse of grasslands stretching from the Rocky Mountains to the Missouri River and from the Rio Grande to the coniferous forests of Canada—an area more than eighteen hundred miles from north to south and more than five hundred miles from east to west. The Great Plains region includes all or parts of Texas, New Mexico, Oklahoma, Kansas, Colorado, Nebraska, Wyoming, South Dakota, North Dakota, Montana, Alberta, Saskatchewan, and Manitoba. The region, once labeled "the Great American Desert," is now more often called the "heartland," or, sometimes, "the breadbasket of the world." Its immense distances, flowing grasslands, sparse population, enveloping horizons, and dominating sky convey a sense of expansiveness, even emptiness or loneliness, a reaction to too much space and one's own meager presence in it."

"With 1,316 entries contributed by more than one thousand scholars, this groundbreaking reference work captures what is vital and interesting about the Great Plains-from its temperamental climate to its images and icons, its historical character, its folklore, and its politics. Thoroughly illustrated, annotated, indexed, this remarkable compendium of information and analysis will prove the definitive and indispensable resource on the Great Plains for many years to come."

What an impressive book this is. The 27 chapters range from African Americans to Water with each chapter being introduced with a major essay or synthesis of the topic. I explored the index to see what was listed under "Cotton." There is a nice summary of Cotton (*Gossypium hirsutum*) and an impressive b/w photo of a Cotton field in West Texas. I looked up to see what information was available on the flora and there is a relatively short entry, yet a nice summary, provided under the Chapter, *Physical Environment*. "More than 2,900 species of vascular plants from some 730 genera in 159 families grow in the Great Plains." The author of this entry cites none other than the *Flora of the Great Plains* (1986).—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

ERIGERON PEREGRINUS AND *ERIGERON GLACIALIS* (ASTERACEAE: ASTEREAE)

ABSTRACT

Erigeron glacialis (Nutt.) A. Nels. (= *E. callianthemus* Greene) is recognized as a species separate from *E. peregrinus* (Banks ex Pursh) Greene. It has most recently been treated as *E. peregrinus* subsp. *callianthemus*. Intermediates between *E. glacialis* and *E. peregrinus* do occur but the two species are mostly distinct even where in close contact in Washington and British Columbia; intermediates are uncommon or absent as *E. glacialis* at the western edge of its range is contiguous or perhaps intermittently sympatric with *E. peregrinus* northward into Alaska. **Erigeron glacialis** var. **hirsutus** (Cronq.) Nesom, comb. nov., is proposed in order to complete the alternate taxonomy. If Cronquist's recognition of two subspecies within *E. peregrinus* is to be followed, the name *E. peregrinus* subsp. *callianthemus* (1943) is incorrect, the precedent for a name at that rank set by *E. salsuginosus* subsp. *angustifolius* (1906).

RESUMEN

Erigeron glacialis (Nutt.) A. Nels. (= *E. callianthemus* Greene) se reconoce como una especie diferente de *E. peregrinus* (Banks ex Pursh) Greene. Ha sido tratada recientemente como *E. peregrinus* subsp *callianthemus*. Se encuentran intermedios entre *E. glacialis* y *E. peregrinus* pero las dos especies son muy distintas incluso cuando están en contacto en Washington y en Columbia Británica; los intermedios son raros o ausentes ya que *E. glacialis* en el límite Oeste de su área vive contiguo o quizás intermitentemente simpátrico con *E. peregrinus* hacia el Norte hasta Alaska. Se propone **Erigeron glacialis** var. **hirsutus** (Cronq.) Nesom, comb. nov., para completar la taxonomía alternativa. Si se sigue el reconocimiento de Cronquist de dos subespecies en *E. peregrinus*, el nombre *E. peregrinus* subsp. *callianthemus* (1943) es incorrecto, el precedente de un nombre en ese rango está establecido por *E. salsuginosus* subsp. *angustifolius* (1906).

A taxon previously known as *Erigeron salsuginosus* (Richards. ex R. Br.) A. Gray was united by Cronquist (1943) at subspecific rank with *E. peregrinus* (Banks ex Pursh) Greene. Cronquist observed that *Erigeron* (*Aster*) *glacialis* (Nutt.) A. Nels. is the oldest name at specific rank to replace the misapplied *E. salsuginosus* but that the type of *E. callianthemus* Greene is more representative of the taxon, thus he used the latter for the name at subspecific rank (see nomenclatural summary below). He later (1947) recognized several varieties within each subspecies.

Erigeron peregrinus subsp. *callianthemus* is widely distributed in the mountains of the western U.S.A. and southwestern Canada, while *E. peregrinus* subsp. *peregrinus* occurs in coastal and near coastal habitats from southern Alaska to the northwestern conterminous U.S.A. Their ranges are largely dis-

SIDA 21(2): 665–672. 2004

tinct (Fig. 1) but the occurrence of intermediates in Washington and British Columbia suggested to Cronquist (1947) that the two taxa were best treated within a single species, a taxonomic arrangement that has since been followed in accounts of North American *Erigeron*. Douglas et al. (1998, p. 252) also noted that the subspecies "intergrade" where ranges overlap. My observation, in contrast, is that intermediates do occur but that even where they overlap or are in close contact in Washington and British Columbia, populations of 'good' subsp. *peregrinus* (without signs of intermediacy) and 'good' subsp. *callianthemus* are more common.

The distribution of subsp. *peregrinus* runs from the Kamchatka area of the Russian Far East (Commander Islands: Botschantzev 1959; Czerepanov 1995) across the Aleutian Islands, southern-central Alaska, southwestern Yukon, and southward along the Alaskan-British Columbian archipelago into western Washington and northwest Oregon (Fig. 1; more detailed maps in Hultén 1950, 1968; Cody 2000). From the Yukon region, it trails southward in a relatively thin line along the Pacific; as noted by Douglas et al. (1998), it is "common in and west of the Coast-Cascade Mountains, rare east of the Coast-Cascade Mountains." Calder and Taylor (1968, p. 533) observed that in the Queen Charlotte Islands "a few collections [of subsp. *peregrinus* sensu stricto] show a tendency towards ssp. *callianthemus* as the involucral bracts are not conspicuously villous and tend to be slightly glandular."

Subspecies *callianthemus* is widely distributed and relatively abundant in montane regions throughout the western U.S.A. as well as in southwestern Alberta and British Columbia. At the western edge of its range from British Columbia northward into Alaska, it is contiguous and perhaps intermittently sympatric with subsp. *peregrinus*. Subsp. *callianthemus* is absent from the Queen Charlotte Islands (Calder & Taylor 1968) and absent or rare in other insular portions of the Alaskan-British Columbian archipelago. It is rare in southwestern Yukon and southeastern Alaska, apparently growing within the range of subsp. *peregrinus*. Scoggan (1979) recorded subsp. *peregrinus* for Alberta, but this probably is based on plants such as *Breitung 16978* (BRIT) from Waterton Lakes National Park, which have phyllaries stipitate-glandular and also sparsely villosulous on the proximal half, "determined by A. Cronquist" as *E. peregrinus* subsp. *callianthemus* var. *scaposus*. Typical subsp. *callianthemus* is the common form in the same region.

In the U.S.A., subsp. *peregrinus* occurs in Whatcom, Skagit, Snohomish, King, and Pacific counties, Washington, and Clatsop Co., Oregon. *Erigeron peregrinus* var. *thompsonii* occurs in Grays Harbor Co., Washington. Typical subsp. *callianthemus* is known from Whatcom, Snohomish, and King counties, and it also occurs in Clallam and Jefferson counties of the Olympic peninsula, Washington, immediately north of Grays Harbor Co. In Oregon, it occurs in Tillamook Co., immediately south of Clatsop Co.

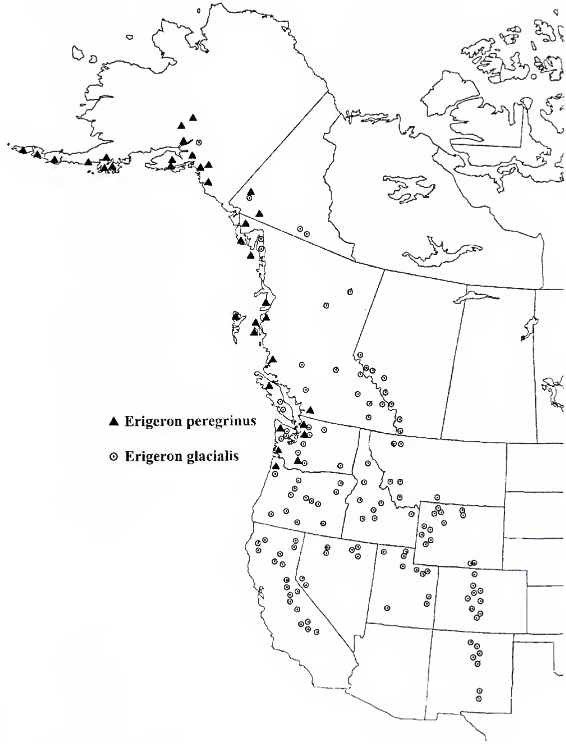

Fig. 1. Summary distribution of *Erigeron peregrinus* and *E. glacialis*. The distribution of *E. peregrinus* continues westward along the Aleutian Islands and into the Kamchatka region.

In the view here, subsp. *peregrinus* and subsp. *callianthemus* are reasonably treated as separate species, *E. peregrinus* and *E. glacialis*, apparently occasionally hybridizing but not intergrading in a sense that would imply the existence of a zone of intermediacy reflecting continuous gene exchange. The two species can be identified by the following morphological contrasts.

Phyllaries eglandular or sparsely sessile-glandular at the apices, rarely sparsely glandular over the surface, sparsely to moderately villous-hirsute on surfaces, margins usually ciliate ______ **Erigeron peregrinus**

Phyllaries densely and evenly stipitate-glandular, without other hairs or rarely sparsely villous on surfaces and margins of outer phyllaries ______ **Erigeron glacialis**

Cronquist (1955) noted other distinctions of *E. peregrinus* (vs. *E. glacialis*): leaves often toothed (vs. usually entire), often soft-pubescent (vs. usually glabrous), peduncular hairs rather loose (vs. close), but these are less diagnostic.

Choice of specific over infraspecific rank in this case emphasizes three factors:

(1) Reproductive isolation, although incomplete, apparently exists between *E. glacialis* and *E. peregrinus*, as noted above.

(2) The distinction between *E. glacialis* and *E. peregrinus* is analogous to that between other closely related species of *Erigeron*, where relatively small but consistent and conspicuous differences in vestiture are significant (e.g., *E. compactus-E. consimilis*; *E. ursinus-E. gracilis*; *E. caespitosus-E. abajoensis*; *E. tracyi* (*E. colomexicanus*)-*E. flagellaris*; *E. engelmannii-E. pumilus*; and *E. flettii-E. algidus-E. simplex/grandiflorus*).

(3) *Erigeron glacialis* may be as closely related to *E. howellii* (A. Gray) A. Gray as to *E. peregrinus*. These three species form a morphological unit and apparently are more closely related among themselves than to any other species. *Erigeron howellii*, which is essentially endemic to an area along the Columbia River in Oregon and Washington, differs from *E. glacialis* in its distally strigillose but otherwise glabrous stems (vs. stems strigillose, more densely so distally), more consistently spatulate basal and lower cauline leaves (vs. leaves linear-oblanceolate to broadly lanceolate or spatulate), consistently white rays (vs. rays blue to rose-purple or pink, less commonly white to pale blue), and habitats mostly at lower elevation. *Erigeron howellii* and *E. glacialis* are nearly identical in involucral vestiture, and a reasonable hypothesis is that the narrow endemic and *E. glacialis* are sister species. This is not intended as a "cladistic argument" for recognition of *E. glacialis* at specific rank, and it is clear that *E. glacialis* is more strongly differerentiated from *E. howellii* than from *E. peregrinus*, but it adds a line of evidence for consideration in this admittedly subjective decision concerning choice of rank.

Erigeron peregrinus (Banks ex Pursh) Greene, Pittonia 3:166. 1897. *Aster peregrinus* Banks ex Pursh, Fl. Amer. Septent. 2:556. 1814. TYPE: U.S.A. ALASKA. Unalaschka, *D. Nelson* s.*n*. (HOLOTYPE: BM).

Phyllaries moderately to densely hirsute to villous-hirsute on the surfaces, margins ciliate; ray corollas purplish to pink or white; upland habitats_________ **Erigeron peregrinus** var. **peregrinus**

Phyllaries very sparsely villous-hirsute to glabrous on the surfaces, margins ciliate; ray corollas white; sphagnum bogs _________________ **Erigeron peregrinus** var. **thompsonii**

Erigeron peregrinus (Banks ex Pursh) Greene var. **peregrinus**

Erigeron unalaschkensis Less., Linnaea 6:122. 1831.
Erigeron peregrinus (Banks ex Pursh) Greene var. *dawsonii* Greene, Pittonia 3:166. 1897.

Erigeron peregrinus var. *dawsonii* was described from the Queen Charlotte Islands, where var. *peregrinus* is abundant. Calder and Taylor (1968) did not recognize var. *dawsonii*, noting that populational variants include plants of both varieties and numerous intermediates.

Cronquist (1955, p. 188) noted that "A phase of ssp. *peregrinus*, resembling var. *peregrinus* but perhaps properly to be segregated, occurs on Saddle Mt. in Clatsop Co., Oreg." Chambers (pers. comm.) observes that these plants "combine the genetic traits of *glacialis* and *peregrinus*," with villous hairs most abundant on the outer phyllaries, dense glandular indument on the inner phyllaries. They are perhaps "best interpreted as derived from a history of gene exchange between *E. peregrinus* and *E. glacialis*, along with segregation and recombination of the genes affecting the principal morphological differences in pubescence. 'Good' *peregrinus* has not yet been found in this part of the state, but 'good' *glacialis* is present nearby."

Erigeron peregrinus (Banks ex Pursh) Greene var. **thompsonii** (Blake ex J.W. Thompson) Cronquist, Brittonia 6:144. 1947. *Erigeron thompsonii* Blake ex J.W. Thompson, Rhodora 34:238. 1932. TYPE: U.S.A. WASHINGTON. GRAYS HARBOR CO.: open bog near Lake Quinault, 10 Jul 1931, *J.W. Thompson 7336* (HOLOTYPE: US!; ISOTYPES: GH!, K, MO!, UC). From details and wording of the protologue and description, it seems clear that Blake wrote both; he was not credited by Thompson, however, other than being cited as sole author of the name and the authorhip must be attributed to Thompson as "ex" rather than "in."

Cronquist (1947, p. 148) observed that var. *thompsonii* "is in a sense intermediate between [*E. glacialis* and *E. peregrinus*] and intergrades both ways." The taxonomic status and evolutionary relationships of this taxon, which is endemic to a small area of the Olympic peninsula in western Washington, need to be investigated in more detail.

Erigeron glacialis (Nutt.) A. Nels., Bot. Gaz. 37:270. 1904. *Aster glacialis* Nutt., Trans. Amer. Philos. Soc. n. ser. 7:291. 1840. *Erigeron salsuginosus* (Richards. ex R. Br.) A. Gray var. *glacialis* (Nutt.) A. Gray, Synopt. Fl. N. Amer. 1, pt. 2:209. 1884. TYPE: U.S.A. Nuttall's protologue observed that the habitat of *A. glacialis* was "with the preceding" species, *Aster andinus* Nutt. [=*Symphyotrichum spathulatum* (Lindl.) Nesom], which was noted to have been collected "on the highest summits of the Rocky Mountains, near the line of perpetual snow, in 42°. About ten thousand feet above the level of the sea. Near summit of Thornberg's Ridge, where we made an ineffectual attempt to cross the Northern Andes, in August, still deeply buried in snow." Gray saw the specimen—"Nutt.!" as indicated in Torrey and Gray (1841, p. 155) and later noted (1884, p. 209) "first coll. by Nuttall in Wyoming." According to Graustein (1967), it is likely that Nuttall's group was on or near Hyndman Peak (Blaine Co., Idaho), at the place they called Thornberg's Ridge or Thornberg's Pass on 12–13 Aug 1834, this confirmed by the expedition narrative reproduced in McKelvey (1955). (HOLOTYPE: PH; HOLOTYPE fragment: CAS).

Stems densely strigillose with loosely appressed, slightly crinkled hairs, most densely strigillose close beneath the heads; leaves glabrous to short-villous on both surfaces ____ **Erigeron glacialis** var. **glacialis**

Stems hirsute to hirsute-villous; leaves hirsute to hirsute-villous on both surfaces ____ **Erigeron glacialis** var. **hirsutus**

Erigeron glacialis (Nutt.) A. Nels. var. **glacialis**

Erigeron callianthemus Greene, Leafl. Bot. Observ. Crit. 2:197. 1912. *Erigeron peregrinus* (Banks ex Pursh) Greene subsp. *callianthemus* (Greene) Cronq., Rhodora 45:264. 1943. *Erigeron peregrinus* (Banks ex Pursh) Greene var. *eucallianthemus* Cronq., Brittonia 6:145. 1947. *Erigeron peregrinus* (Banks ex Pursh) Greene var. *callianthemus* (Greene) Cronq., Univ. Wash. Publ. Biol. 17(5):188. 1955 (in clave).

Aster salsuginosus Richards. ex R. Br. var. *angustifolius* A. Gray, Bot. Calif. 1:325. 1876. *Erigeron salsuginosus* (Richards. ex R. Br.) A. Gray var. *angustifolius* (A. Gray) A. Gray, Proc. Amer. Acad. Arts 16:93. 1880. *Erigeron angustifolius* (A. Gray) Rydb., Bull. Torrey Bot. Club 24:295. 1897. *Erigeron salsuginosus* (Richards. ex R. Br.) A. Gray subsp. *angustifolius* (A. Gray) Piper, Contr. U.S. Natl. Herb. 11:565. 1906. *Erigeron peregrinus* (Banks ex Pursh) Greene var. *angustifolius* (A. Gray) Cronq., Brittonia 6:147. 1947.

Aster salsuginosus Richards. ex R. Br. var. *scaposus* Torr. & A. Gray, Fl. N. Amer. 2:503. 1841. *Erigeron peregrinus* (Banks ex Pursh) Greene var. *scaposus* (Torr. & A. Gray) Cronq., Brittonia 6:146. 1947. *Erigeron callianthemus* Greene var. *scaposus* (Torr. & A. Gray) Breitung, Canad. Field-Naturalist 71:69. 1957.

As earlier observed (Nesom 1992, p. 190), within *Erigeron peregrinus* subsp. *callianthemus*, var. *scaposus* and var. *angustifolius* can be recognized apart from var. *callianthemus* "only as arbitrarily distinguished and intergrading populations." Douglas et al. (1998) also noted that the varieties "often grow together and show a continuous variation." Cronquist (1947, p. 148) regarded var. *scaposus* as a "reduced alpine phase" with the dwarfing "probably genetically controlled," but he observed that it "intergrades profusely with var. *eucallianthemus* ... and both are often present in the same collection." Var. *angustifolius*, also, was seen by Cronquist to be strongly intergrading with other expressions of the species.

If *Erigeron glacialis* is maintained at infraspecific rank within *E. peregrinus*, the taxon *E. peregrinus* subsp. *callianthemus* (sensu Cronquist) includes all varietal taxa, but if the widespread entity identified by Cronquist as *E. peregrinus* var. *callianthemus* is interpreted to include either var. *scaposus* or var. *angustifolius* or both, it should be recognized that both latter names at varietal rank have precedence over var. *callianthemus* (var. *scaposus* the oldest). If any of these varieties are to be recognized within *E. glacialis*, the type of *E. glacialis* represents the alpine form treated as var. *scaposus*. In the taxonomic alternative proposed here, all three of these taxa are included within *Erigeron glacialis* var. *glacialis*.

Further complicating the nomenclature is the observation that the earliest name at subspecific rank in this whole complex is *Erigeron salsuginosus* subsp. *angustifolius* (A. Gray) Piper, from 1915, rendering Cronquist's combination in 1943 based on *E. callianthemus* incorrect (superfluous, because it included the type of "subsp. *angustifolius*"). Thus, if one desires to follow Cronquist's concept of recognizing two subspecies within *E. peregrinus*, the one he treated as "subsp. *callianthemus*" requires a new combination, based on Gray's original *Aster salsuginosus* var. *angustifolius*.

Erigeron glacialis (Nutt.) A. Nels. var. **hirsutus** (Cronq.) Nesom, comb. nov. *Erigeron peregrinus* (Banks ex Pursh) Greene var. *hirsutus* Cronq., Brittonia 6:147. 1947. TYPE: U.S.A. CALIFORNIA. [TUOLUMNE CO.]: Yosemite National Park, vicinity of Lake Tenaya, 8300 ft, Jun 1902, *H.M. Hall and E.C. Babcock 3506B* (HOLOTYPE: UC).

Variety *hirsutus* is restricted to the seven southernmost counties in the range of the species in California (Fresno, Inyo, Madera, Mariposa, Mono, Tulare, and Tuolumne cos.) and in Mineral Co., Nevada. I also have seen plants of typical *E. glacialis* and intergrades toward var. *hirsutus* from Mono, Tulare, Fresno, and Inyo cos., but they apparently are less common than those identified as typical var. *hirsutus*.

ACKNOWLEDGMENTS

I thank Bob Kiger for pointing out that *Erigeron peregrinus* var. *callianthus* is not the correct name when it includes var. *scaposus* and var. *angustifolius* (as I have used it in the past). His comments precipitated the presentation of this taxonomic alternative, which I have anticipated for more than a decade. Ken Chambers further pointed out that the name *E. peregrinus* subsp. *callianthemus* is incorrect, as it was preceded at that rank by "subsp. *angustifolius*." Ron Hartman gave advice on geography of the *E. glacialis* type collection, Kanchi Gandhi reviewed aspects of the nomenclature, James Macklin provided information on the type collection at PH, and Ken Chambers reviewed the whole manuscript and arranged a loan of pertinent specimens from OSU. Review comments by David Murray also were very helpful.

ABSTRACT

Erigeron maniopotamicus G.L. Nesom & T.W. Nelson, sp. nov., a member of the *E. eatonii* alliance, apparently is endemic to east-central Humboldt County and immediately adjacent Trinity County, California. It is sympatric with *E. robustior* but it perhaps is more closely related to *E. eatonii* or *E. lassenianus*.

RESUMEN

Erigeron maniopotamicus G.L. Nesom & T.W. Nelson, sp. nov., un miembro del grupo *E. eatonii*, aparentemente es endémico del Este-centro del condado de Humboldt y el inmediatamente adyacente condado de Trinity, California. Es simpátrico con *E. robustior* pero quizás está más cercanamente relacionado con *E. eatonii* o *E. lassenianus*.

In preparation of a taxonomic treatment of *Erigeron* by Nesom for Flora of North America, three collections (HSC) from Humboldt Co., California, appeared divergent from known taxa of the genus. During a study of the *Erigeron eatonii* A. Gray alliance, Strother (1987, by annotation) identified these collections as "*E. decumbens* var. *robustior* vel aff.," but he did not comment on them in a related publication (Strother & Ferlatte 1988). Nesom (2004) noted that they might represent an undescribed entity. One of the three original HSC collections was made by a coauthor of the current report (Nelson), and in order to investigate their identity, he subsequently made two additional collections of the same entity from the same area. These plants occur within the geographic range of *E. robustior* (Cronq.) Nesom but are morphologically distinct. They are out of the known range of any other species of the *E. eatonii* alliance and are here formally described as a distinct species.

Erigeron manipotamicus Nesom & Nelson

Fig. 1. Habit of *Erigeron maniopotamicus* (isotype, BRIT).

phyllariis elliptici-oblanceolatis vel oblongi-oblanceolatis abrupte acuminatis.

Plants perennial, taprooted (roots [3–]5–8 mm thick); caudex usually simple, rarely with branches to 20 cm long. **Stems** (including peduncles) 2–6(–8), 10–22(–27) cm long, basally ascending to decumbent-ascending, sparsely to densely strigose, eglandular, stems and leaves usually basally purplish. **Leaves** basal and cauline, basal persistent into anthesis, oblanceolate to spatulate-oblanceolate, 3–10 cm long, (3–)5–12(–14) mm wide, strongly to weakly 3-nerved, margins entire, cauline gradually reduced distally or not, usually continuing relatively unreduced to near heads, elliptic-oblanceolate to elliptic-lanceolate, sometimes narrowly lanceolate or oblanceolate, hirsute-pilose to weakly pilose on both surfaces, eglandular. **Heads** 1(–4) on peduncles 0.5–1(–5) cm long, held well beyond leaves at peak anthesis, from branches near midstem or slightly more distal; involucres (5–)6–7 mm high, 9–12(–14) mm wide (pressed), phyllaries in 2–3(–4) equal to subequal series, elliptic-oblanceolate to oblong-oblanceolate, abruptly acuminate, usually each with an orange midnerve, with narrow scarious margins, hirsute-strigose to hirsute-pilose, densely villous at base, eglandular to sparsely glandular. **Ray florets** (16–)21–33, corollas 10–12 mm long, 1.5–2.5 mm wide, laminae white to pinkish or purplish, not coiling (or weakly so) or reflexing. **Disc florets**: corollas 3.2–3.8 mm long, throat not indurate or inflated. **Cypselae** 2–2.5 mm long, 2-nerved, sparsely strigose; pappus of 16–20 bristles 2.5–3 mm long, with a few outer setae ca. 0.1 mm long.

Etymology, habitat, and phenology.—Known only from east-central Humboldt Co. and adjacent Trinity Co., California. The Mad River (whence the epithet) more or less dissects the geographic range of the species. Though the river's name may have been meant to convey the madness (as "angriness") of the torrents and rapids, the epithet here implies that the river is deranged (mad as "crazy"). There apparently is no psychological assessment of the subject, but we like the audile flow of the syllables. Populations of *Erigeron maniopotamicus* occur at elevations of 1350–1500 meters on a tan-colored, rocky, non-serpentine soil sharply distinct from typical regional soils surrounding the sites. The sites are relatively dry and might be described as "barrens" because few other plant species occur there, and they often are bordered by somewhat stunted woods of mixed conifer, mostly Douglas fir. Serpentine outcrops are scattered in the area, especially on ridges, but apparently do not influence the 'erigeron barrens.' Flowering June through August.

Conservation significance.—Because of the limited distribution and few known collections of this species, a more detailed assessment of its distribution and biology would be valuable.

Additional collections examined: **CALIFORNIA. Humboldt Co.:** near Mad River Buttes, Pilot Creek Quad, 40° 42' 15", 123° 44' 41", meadow, 4739 ft, 28 Jun 1980, *Baker 2479* (HSC), *Baker 2499* (HSC); Jack Rabbit Valley, along Swayback Ridge 4-wheel drive road 1 mi S of jct with Forest Service road, Blocksburg Quad, T1N, R5E, NE 1/4 of NW 1/4, Sec. 26, meadow on metasediments, 4900 ft, 10 Jun 1980, *Nelson and Nelson 5395* (HSC); along Swayback Ridge Road, which branches off Forest Service Road 1N08 ca. 1/4 mi past gate, T1N, R5E, Sec. 23, dry open hillside, 4450 ft, 18 Jun 2004, *Nelson 9249* and Carothers (BRIT, HSC, NY, OSC, RM, UC, US); Twin Lakes vicinity, Snow Camp and Twin Lakes trip, with Mr. Murphy, frequent locally in gravelly open places, 26 Jun 1951, *Tracy 19581* (UC 223009, photocopy). **Trinity Co.:** Kitten-Pum [Kettenpom] Valley, 26 Jun 1893, *Blankinship s.n.* (UC 87679, photocopy). [Trinity Co. or Humboldt Co.]: Mad River, 1 Jul 1893, *Blankinship s.n.* (UC 87680, photocopy).

Erigeron maniopotamicus occurs within the range of *E. robustior*, which is known from Humboldt, Trinity, and Mendocino cos. and is recorded as growing in sagebrush-scrub, glades and meadows, and lower montane coniferous forest, sometimes in seeps and sometimes over serpentine, at elevations of (200-)700–1500 meters. In the range of *E. maniopotamicus, E. robustior* is not common—it grows in loamy soil in openings and along edges of moist fir-oak woods and has not been observed in close proximity to *E. maniopotamicus*. No intermediates between *E. maniopotamicus* and *E. robustior* or any other species have been encountered in the present study. Populations of the new species are relatively large (over 200 plants) and are relatively uniform in morphology.

The description of *Erigeron decumbens* subsp. *robustior* Cronq. by Cronquist (1947) (see Nesom 2004 for its treatment at specific rank) probably included measurements of *E. maniopotamicus*, judging from the low ranges of involucral size; one of the specimens that he cited as subsp. *robustior*, *Blankinship s.n.*-UC 87679, is identified here as *E. maniopotamicus*. Our comparisons are primarily drawn from study of collections at NY and HSC. In his review of the present manuscript, John Strother also reviewed collections at UC and sent photocopies of two that are referable to the new species. *Erigeron maniopotamicus* and *E. robustior* are contrasted morphologically in the following couplet.

a. Taproots relatively thick, (3–)5–8 mm wide; stems 10–22(–27) cm long; basal leaves oblanceolate to spatulate-oblanceolate; cauline leaves relatively unreduced to near heads; involucres (5–)6–7 mm high, 9–12 mm wide; phyllaries elliptic-oblanceolate to oblong-oblanceolate, abruptly acuminate ____________ **Erigeron maniopotamicus**

a. Taproots relatively thin, 2–3 mm wide; stems (15–)25–55 cm long; basal leaves linear to very narrowly oblanceolate; cauline leaves usually reduced or none near heads; involucres 6–8.5 mm high, (12–)14–20 mm wide; phyllaries narrowly oblanceolate to lanceolate, acute-acuminate ____________________ **Erigeron robustior**

The *Erigeron eatonii* alliance (sensu Strother & Ferlatte 1988) is recognized by the following set of features: taprooted; caudex branches generally slender, plants not caespitose; stems erect or basally ascending to decumbent, sometimes purplish at the base, proximal internodes not elongate; leaves basal and cauline, linear to oblanceolate, (1–)3-nerved; heads commonly more than one. Distinctions among the taxa often are subtle but discretely defined geographic ranges give confidence that the morphological differences reflect evolutionary differentiation.

Erigeron eatonii comprises a group of contiguous varieties sometimes intergrading at points of contact (see Strother and Ferlatte 1988 for maps). *Erigeron eatonii* var. *villosus* (Cronq.) Cronq. and *E. eatonii* var. *lavandulus* Strother & Ferlatte are exceptions: var. *villosus* occurs north of all other varieties except var. *lavandulus*, which is sympatric with var. *villosus*, and one or both of these probably is justifiably treated at specific rank. *Erigeron canaani* Welsh occurs at the southwestern extreme of the range of *E. eatonii* var. *eatonii* and may be better treated at varietal rank within *E. eatonii*. Among other species of the alliance, *E. jonesii* Cronq. and *E. lassenianus* Greene also occupy essentially allopatric ranges; they are discontinous in morphology from contiguous taxa. The ranges of *E. robustior* and *E. decumbens* are relatively isolated on the western margin the alliance.

There are no sympatric taxa of the *Erigeron eatonii* alliance that appear to have a sister relationship, and the sympatry of *E. maniopotamicus* and *E. robustior* suggests that their relationship also is more distant than "sister." The closest relationship of the new species may be closer to *E. eatonii* itself, perhaps with *E. eatonii* var. *plantagineus* (Greene) Cronq., which is the segment of the species geographically closest to *E. maniopotamicus*. The closest approach of var. *plantagineus* to *E. maniopotamicus* is in the northeast corner of Siskyou Co. and Shasta Co. (Strother & Ferlatte 1988). The two taxa are similar in sizes of involucres, florets, and cypselae but differ conspicuously in habit, particularly in features of caudex and size and distribution of cauline leaves. *Erigeron maniopotamicus* might be treated at varietal rank within *E. eatonii*, but the nature of its relationship there would be ambiguous, and it is morphologically and geographically disjunct from var. *plantagineus*. The leafy stems of *E. maniopotamicus* are more like those of *E. lassenianus* (which approaches the range of *E. maniopotamicus* in northeastern Trinity Co. and Tehama Co.), and it is possible that *E. maniopotamicus* has genetic elements from that species and from *E. eatonii*. In any case, the choice here of taxonomic rank for *E. maniopotamicus* is admittedly somewhat arbitrary. Morphological contrasts between *E. maniopotamicus* and *E. eatonii* var. *plantagineus* are provided in the following couplet.

a. Caudex branches commonly present, usually slender; cauline leaves usually strongly reduced in size from the basal, absent or reduced near heads; phyllaries narrowly lanceolate to narrowly oblanceolate, apically acute; pappus bristles 6–12 ____ **Erigeron eatonii** var. **plantagineus**

a. Caudex usually unbranched; cauline leaves usually continuing relatively unreduced to near heads; phyllaries elliptic-oblanceolate to oblong-oblanceolate, apically abruptly acuminate; pappus bristles 16–20 ____ **Erigeron maniopotamicus**

To place *Erigeron maniopotamicus* in a broader perspective, the following key distinguishes all of the California taxa of the *E. eatonii* alliance.

1. Involucres 6–10.5 mm high, (12–)14–23 mm wide; phyllaries eglandular.
    2. Involucres 6–8.5 mm high, (12–)14–20 mm wide; disc corollas 3.5–4.5 mm long; cypselae (1.8–)2–3.2 mm long ____ **Erigeron robustior**
    2. Involucres 7–10.5 mm high, (14–)17–23 mm wide; disc corollas 4.4–6.8 mm long; cypselae 4–4.5 mm long ____ **Erigeron eatonii** var. **nevadincola**
1. Involucres 4.2–5.6(–7) mm high, 6–12(–14) mm wide; phyllaries glandular or eglandular.
    3. Phyllaries densely minutely glandular ____ **Erigeron lassenianus**

3. Phyllaries essentially eglandular.
  4. Cauline leaves continuing relatively unreduced to near heads; phyllaries elliptic-oblanceolate to oblong-oblanceolate, apically abruptly acuminate _______ **Erigeron maniopotamicus**
  4. Cauline leaves absent or bracteate near heads; phyllaries narrowly lanceolate to narrowly oblanceolate, apically acute.
    5. Caudex branches usually absent or relatively short and thickened; involucres 8–12(–16) mm wide; disc corollas 3.5–5 mm; cypselae 2.8–3.5 mm long _______ **Erigeron eatonii** var. **sonnei**
    5. Caudex branches commonly present, usually slender; involucres (9–)11–12(–14) mm wide; disc corollas 3–4 mm long; cypselae 1.8–2.3 mm long _______ **Erigeron eatonii** var. **plantagineus**

ACKNOWLEDGMENTS

This study originated from observations made possible by a loan to Nesom of the *Erigeron* collection at HSC. John Strother and Ken Chambers made constructive comments that much improved the manuscript. Strother also searched UC-JEPS collections for possible additional material of *E. maniopotamicus* and sent photocopies of the Blankinship and Tracy collections cited here. Tiana Franklin and Amanda Neill (BRIT) provided the digital image.

ABSTRACT

A new species, *Scutellaria petersonaie* B.L. Turner & J.L. Reveal is described from the state of Guerrero, Mexico. It is closely related to *S. hintoniana* of the section Crassipedes, but amply distinct.

RESUMEN

Se describe una nueva especie, *Scutellaria petersonaie* B.L. Turner & J.L. Reveal del estado de Guerrero, México. Está muy relacionada con *S. hintoniana* de la sección Crassipedes, pero es muy diferente.

Scutellaria petersoniae B.L. Turner & J.L. Reveal, sp. nov. (**Fig. 1**). TYPE: MEXICO. GUERRERO: Sierra Madre del Sur, along the Milpillas-Atoyac road via Puerto del Gallo, ca. 58 mi SW of Mexico Hwy 95, ca. 20.5 mi SW of Carrazal del Bravo and 1.8 mi NE of Yerba Santa in a mixed deciduous forest, 17 Oct 1975, *J.L. Reveal, K.M. Peterson, R.M. Harley, & C.R. Broome* 4282 (HOLOTYPE: TEX; ISOTYPES: to be distributed).

Similis *Scutellariae hintonianae* Epling sed caulibus pubescentibus habentibus pilos breves et acclives et laminis in petiolum gradatim decrescentibus (vice laminarum abrupte petiolatum).

Perennial herbs to 50 cm high, arising from fusiform tuberous roots. Primary stems much-branched from the base, moderately appressed-pubescent with upswept small hairs. Leaves opposite throughout, gradually reduced upwards, those at mid-stem mostly 3.0–4.5 mm long; petioles 0.5–1.2 cm long; blades ovate, undulate, somewhat dentate to nearly entire, gradually tapering upon the petioles, the upper surfaces moderately short-pubescent to glabrate, the lower surfaces, venose, glandular-punctate, pubescent along the major veins. Flowers 2 at each of the uppermost several nodes. Pedicels 4–5 mm long. Calyx 5–6 mm long, 3–5 mm wide, pubescent like the stems. Corollas red, 3.0–3.5 cm long, glabrous within at the very base for ca. 3 mm, pubescent thereafter with downswept hairs for ca. 6 mm; upper lip 0.8–1.0 cm long; lower lip 0.4–0.8 cm long. Upper stamens exserted from the tube for 8–10 mm; filaments attached ca. 4 mm below the corolla's orifice; anthers pale lavender, ca. 0.8 mm long. Mature nutlets not examined.

Scutellaria petersoniae is obviously very closely related to *S. hintoniana* Epling (not to be confused with *S. hintonianum* Henrickson), differing mainly in vestiture and leaf shape. *Scutellaria hintoniana* is known only from the state

---

GUERRERO: Sierra Madre del Sur, along the Milpillas-Atoyac road via Puerto del Gallo, about 58 miles southwest of Mexico Highway 95, about 20.5 miles southwest of Carrizal del Bravo and 1.8 miles north-east of Yerba Santa, in a mixed deciduous forest.

Tubers fusiform.

Fig. 1. *Scutellaria petersoniae*, holotype.

of Mexico in oak woodlands, while *S. petersoniae* is seemingly confined to eastern Guerrero, an area well known for its amalgamation of unusual species.

Etymology.—Scutellaria petersoniae commemorates Kathleen M. Peterson, gifted teacher and skilled botanist (p. 1239 of the current issue, Reveal 2004).

With the present description, Epling's previously monotypic section Crassipedes now contains two taxa, both confined to the Pacific slopes of western Mexico. These two species are distinguished within the genus by their habits (rhizomatous herbs) and elongate, pubescent, red corollas. The following couplet should help distinguish the two taxa:

Stems moderately to densely pilose with spreading hairs; blades abruptly petiolate ____ **S. hintoniana**

Stems moderately pubescent with short upswept appressed hairs; blades tapering upon the petioles ____ **S. petersoniae**

ACKNOWLEDGMENTS

Thanks to Tom Wendt for scanning the holotype, and to Gayle Turner for the Latin diagnosis. Guy Nesom and Richard Olmstead are thanked for their helpful reviews.

BOOK NOTICE

Lavishly Illustrated Book on Tropical & Subtropical Trees

MARGARET BARWICK. 2004. **Tropical & Subtropical Trees an Encyclopedia.** (0-88192-661-2, hbk.). Timber Press Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $69.95, 484 pp., 2,305 illustrations, 1,981 in color, hardiness zone map, 8 1/4" × 11 5/8".

Publisher Comments: "Margaret Barwick's lovingly researched book represents the first comprehensive compendium of botanical and practical information on this previously undervalued topic. The culmination of more than forty-five years as a hands on gardener and landscape designer, the work reflects her passion for the subject and her appreciation of what fellow gardeners, both lay and professional, need to know about trees selection for tropical and subtropical climates."

"Listed alphabetically, more than 650 species are covered in detail with information on the size, shape of the tree, its cultivation requirements, ornamental value, and rate of growth. The book is supplemented with the finer detail of flower, fruit, foliage, bark, texture, and fragrance."

"With text that is both scientifically accurate and easy-to-read, the book is lavishly illustrated with more than 2500 photographs, many taken in the wild."

Each genus is represented by a type species, usually chosen as the most typical and well known of the genus. The type species is illustrated by photographs of the overall form, the flowers, fruit, bark and, if possible, the natural habitat. An incredible amount of concise information is summarized in sidebars for each type species. Throughout the book one will find fascinating facts about the plants (from trees that can kill to love, sex, and beauty).—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

ABSTRACT

A new native subspecies of ***Phragmites australis*** subsp. ***americanus*** Saltonstall, P.M. Peterson & Soreng is described. The new subspecies can be separated from the introduced and Gulf Coast North American lineages of *P. australis* by having caducous leaf sheaths, ligules 1.0–1.7 mm long, lower glumes 3.0–6.5 mm long, upper glumes 5.5–11.0 mm long, lemmas 8.0–13.5 mm long, and by possessing chloroplast DNA haplotypes of A-H, S, Z, AA. The new subspecies is clearly distinguished in a PCA analysis and when bivariate plots of the morphological features are compared. Additional work is needed to morphologically distinguish the introduced from Gulf Coast lineages. *Phragmites berlandieri* is lectotypified. A key and distribution maps to the three lineages are included.

RESUMEN

Se describe una nueva subespecie nativa **Phragmites australis** subsp. **americanus** Saltonstall, P.M. Peterson & Soreng. La nueva subespecie puede separarse de los linajes introducidos en la Gulf Coast de Norte América de *P. australis* por tener vainas caducas, lígulas de 1.0–1.7 mm, glumas inferiores de 3.0–6.5 mm, glumas superiores de 5.5–11.0 mm long, lemas de 8.0–13.5 mm, y por tener haplotipos del DNA plastidial A-H, S, Z, AA. La nueva subespecie queda claramente diferenciada en un análisis de PCA y cuando se comparan gráficos bivariantes de las características morfológicas. Se necesita trabajo adicional para diferenciar morfológicamente los linajes introducidos de la Gulf Coast. Se lectotipifica *Phragmites berlandieri*. Se incluyen una clave y mapas de distribución de los tres linajes.

Phragmites Adans. is a cosmopolitan genus found throughout the world and is currently placed in the tribe Arundineae with *Arundo* L., *Hakonechloa* Makino ex Honda, and *Molinia* Schrank, the latter three genera all introduced in North America (Soreng et al. 2004; Zuloaga et al. 2003). *Phragmites* is an erect perennial grass, 2–5 m tall, that can form dense stands. A number of species, subspecies, and varieties have historically been described in the genus *Phragmites* and today four species are recognized: *P. australis* (Cav.) Trin. ex Steud., *P. karka* (Retz.) Trin. ex Steud., *P. mauritianus* Kunth, and *P. japonicus* Steud. All temperate subspecies and varieties are now included under the designation *P. australis* (Clayton 1968). Using five specimens collected in Texas and Mexico, Fournier (1877)

SIDA 21(2): 683–692. 2004

distinguished a North American *Phragmites* (*P. berlandieri* E. Fourn.) from that found elsewhere in the world. Based on measurements of glumes from 28 European specimens and many North American specimens, Fernald (1932) supported this distinction of a North American variety, *P. communis var. berlandieri* (E. Fourn.) Fernald.

Recent genetic studies indicate that three genetic lineages of *Phragmites* are found in North America (Saltonstall 2002, 2003a,b). A lineage endemic to North America is found across much of Canada and in the United States, from New England and the Mid-Atlantic states across to the Pacific coast and into the southwest (Fig. 1a). Regional structuring can be found within this native lineage, with east coast, midwestern, and western populations showing different chloroplast DNA haplotypes (A-H, S, Z, AA, Saltonstall 2003a). Another lineage is found in the southern United States from Florida across to the Gulf of California, and this lineage is also found in Central America and in Asia (Fig. 1b). It is characterized by chloroplast haplotype I (hereafter referred to as the Gulf Coast lineage). A third lineage, chloroplast haplotype M, is EurAsian in origin and was likely introduced to North America since European colonization. It is found across the continent, both in areas where *Phragmites* was historically present and also in places (such as the southeastern US) where *Phragmites* is not native to the flora (Fig. 1c; Saltonstall 2002). Today, this introduced lineage is the most common type of *Phragmites* in North America and can be found in a variety of habitats including both brackish and freshwater marshes, inland fens, along the banks of rivers and lakes, and along roadsides.

With the recognition that both native and introduced populations of *Phragmites* may be present, many state and regional management authorities are now revising their *Phragmites* management strategies with a goal of preserving native populations while controlling introduced ones. This has also encouraged Natural Heritage programs to consider listing native *Phragmites* as a rare or threatened plant in a number of states. However, the appropriate level of taxonomic classification of the different lineages has not yet been clarified.

A number of qualitative characters have been suggested for distinguishing the native and introduced lineages including culm color, culm texture, and adherence of leaf sheaths to culms (Blossey 2002). While these characters appear to be correlated with ecological characteristics, they are problematic in that they are subject to observer judgment and may require observation at different times of the year. Although genetic testing can provide definitive information as to the lineage of a population, quantitative measurements of morphological features may provide a means of confirming origin in conjunction with qualitative characteristics. Robichaud and Catling (2003) performed such an analysis using *Phragmites* specimens collected in southern Ontario and found significant differences in the length of the lower glume between the native and

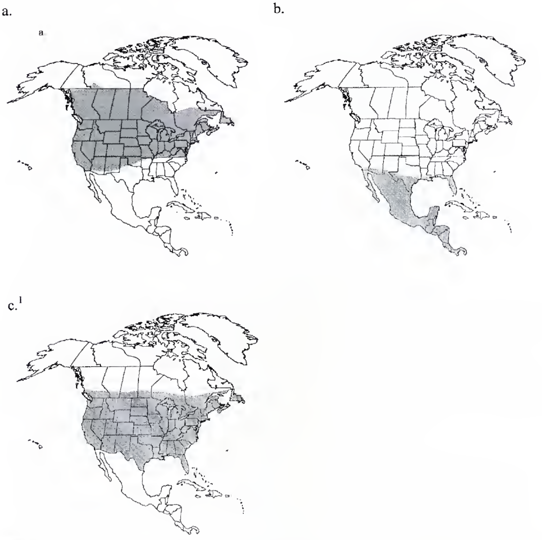

Fig. 1. Distribution of a) Native, b) Gulf Coast, and c) Introduced lineages of *Phragmites australis* in North America. Sources of distribution information include Catling et al. 2004, COMREED 1999, Saltonstall 2002.

introduced population lineages. However, that study was limited by its geographic scope. This study quantifies differences in size seen in the ligules, lower and upper glumes, and lemmas of native, introduced, and Gulf Coast populations of *Phragmites* from North America. We formally recognize the native lineage that occurs in the USA and Canada as *P. australis* subsp. *americanus* Saltonstall, P.M. Peterson & Soreng.

---

[1] Although not documented across the Gulf Coast except for in the Mississippi river delta (Saltonstall 2002), introduced *Phragmites* may already have invaded these regions and certainly has the potential to spread into them. The distribution of introduced *Phragmites* is not known south of the U.S. border and thus is not included in this figure.

METHODS

The genetic lineage of specimens was determined prior to taking morphological measurements. DNA extractions were done using a CTAB extraction protocol (Doyle & Dickson 1987). Lineages were identified either by sequencing two noncoding chloroplast gene regions, *trnT*(UGU)-*trnL*(UAA)5' and *rbcL-psaI*, to determine the chloroplast DNA haplotype (Saltonstall 2002) or using an RFLP diagnostic assay on the abovementioned chloroplast regions that distinguishes the three North American *Phragmites* lineages (Saltonstall 2003c).

Ligules were measured using a Nikon PZ500 dissecting microscope fitted with a 0.1–10 mm micrometer. All samples were obtained from live populations in 1999–2003 throughout the range of *Phragmites* in North America. Several leaf blades per sample were initially observed to see if there was variation in the ligule lengths. Since no within-plant or within-population variation was detected only one leaf blade was examined for the majority of specimens. Ligule length was calculated by measuring the ligule (both the membrane and its hairy margin) at the center of the leaf blade to the nearest 0.05 mm.

Measurements of lower and upper glumes and lemmas were taken from a single inflorescence per clone. Ten glumes and ten lemmas were measured from each specimen. Samples were obtained from live populations during 1999–2003 or from herbarium specimens and cover the geographic range of all *Phragmites* lineages in North America. Measurements were made to the nearest 0.5 mm using a ruler. From each specimen, ten spikelets showing visible rachilla hairs were selected from the middle part of the inflorescence. Upper and lower glume and lemma lengths were measured from the articulated base to the tip. A complete data set of the morphological characters used in this study is available from KS upon request.

Data were analyzed using the PROC MIXED procedure in SAS 8.2. Tukey's comparisons were used to distinguish significant differences between population types. Since the majority of samples measured for ligule length were different from those measured for glume and lemma lengths, the data were randomized and treated as groups representing variation within each of the three genetic lineages. Bivariate comparisons were plotted to illustrate these differences between lineages. A Principal Components Analysis (PCA) was performed using PC-ORD (Version 4, McCune & Mefford 1999) using a correlation matrix of standardized data for the variables.

RESULTS AND DISCUSSION

The morphological characters measured in this study clearly distinguish native from introduced and Gulf Coast *Phragmites* lineages. This mirrors the distinctiveness seen at the genetic level between the lineages, where all native North American haplotypes shared five unique mutations not seen in any other haplotypes (Saltonstall 2002). Native specimens have longer ligules, glumes, and lem-

TABLE 1. Mean values and their significance level for ligule, glume and lemma lengths by *Phragmites* lineages: Native (N), Introduced (I), and Gulf Coast (GC).

Structure	Population Type	Sample size	Mean ± SE (mm)	Significant Difference ($p<0.01$)
Ligule	Native	28	1.26 ± 0.04	I, GC
	Introduced	20	0.69 ± 0.03	N
	Gulf Coast	14	0.57 ± 0.04	N
Lower glume	Native	28	4.6 ± 0.1	I, GC
	Introduced	17	3.4 ± 0.1	N, GC
	Gulf Coast	15	3.9 ± 0.1	N, I
Upper glume	Native	28	7.3 ± 0.2	I, GC
	Introduced	17	5.8 ± 0.2	N
	Gulf Coast	15	6.3 ± 0.1	N
Lemma	Native	28	11.1 ± 0.2	I, GC
	Non-Native	17	9.2 ± 0.2	N
	Gulf Coast	15	10.1 ± 0.2	N

mas than both introduced and Gulf Coast specimens (Table 1; Ligule—$F_{2,59}=120.21$; Lower glume—$F_{2,57}=37.59$; Upper glume—$F_{2,57}=21.01$; Lemma—$F_{2,58}=17.07$; $p<0.0001$ for all comparisons). Of the four characters measured, the ligule is the most definitive in separating the native from the other two lineages (Fig. 2a–c). The length of the lower glume is also a good way of distinguishing native from introduced specimens, although some overlap is seen (Fig. 2d).

The Gulf Coast lineage, although significantly different from others at several measurements, is intermediate between the other two types when comparing these four characters (Table 1, Fig. 2a–d). Thus at this time, it remains difficult to distinguish morphologically and it appears premature to conclude that this lineage is a different species (Jones et al. 1997). It appears more similar to introduced than native *Phragmites* for all morphological measurements, in addition to being genetically more closely related to the introduced haplotype M than the native haplotypes (Saltonstall 2002, 2003a). Additional characters that distinguish this lineage morphologically have yet to be identified. Although not verified quantitatively, the leaf internode distance of the Gulf Coast plants appears to be shorter than both the introduced and native lineages (Saltonstall pers. obs.). The syntype of *P. berlandieri* (*J.L. Berlandier 1446*, US-82049 ex P) was included in our morphological survey and falls within the Gulf Coast lineage. Fernald (1932) did not indicate if he used one of the syntypes designated by Fournier (1877) in his study. Clearly Fernald was referring to the native lineage in his study since the lower glumes range from 4–6 mm long and the upper glumes range from 6–8.5 mm long. To avoid confusion in the future, particularly if one chooses to use the name *P. berlandieri* to include the Gulf Coast lineage, we formally lectotypify *P. berlandieri* E. Fourn., Bull. Soc. Bot. France

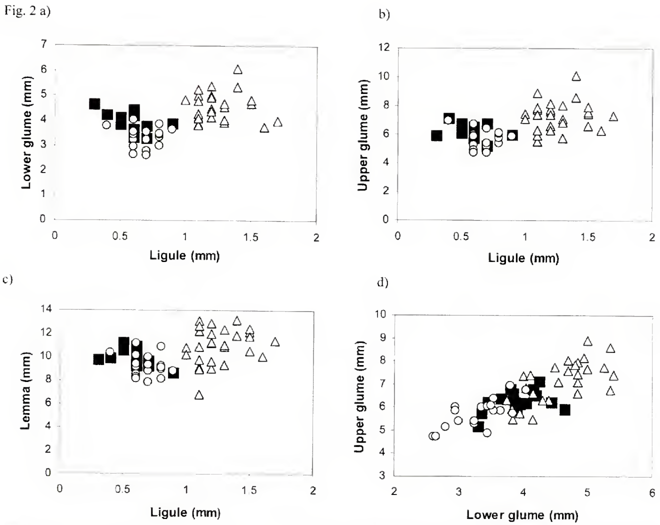

Fig. 2. Bivariate comparisons of morphological data for Native (   ), Introduced (■) and Gulf Coast (○) *Phragmites* individuals.

Table 2. Eigenvector loadings for the principal components (PC). Relative eigenvalues, percent of variance, and cumulative percent of variance are also listed.

	PC 1	PC 2	PC 3	PC4
Ligule	-0.4030	-0.8859	0.2293	-0.0143
Lower glume	-0.5285	0.0584	-0.7301	-0.4292
Upper glume	-0.5489	0.2219	-0.0574	0.8038
Lemma	-0.5069	0.4032	0.6411	-0.4116
Eigenvalue	2.996	0.636	0.267	0.101
% of variance	74.904	15.905	6.676	2.515
Cumulative % of variance	74.904	90.809	97.485	100.000

24:178. 1877. Type: U.S.A. Texas: Laredo, 1828, *J.L. Berlandier 1446* (lectotype: P; isolectotype, the large specimen on the sheet that includes a culm with a complete inflorescence: US-82049 ex W!).

The PCA confirmed and enhanced the above mentioned results further. The first two PC's accounted for 90.8% of the total variation in the data (Table 2, Fig. 3). The first axis alone accounts for 74.9% of the total variance and has negative loadings for the majority of Native specimens and positive ones for introduced and Gulf Coast specimens. Thus more negative values along PCI indicate larger morphological structures (Fig. 2), as seen in the native specimens.

Analysis of nuclear microsatellite DNA indicates that there is little evidence for hybridization between the native and introduced lineages since alleles considered diagnostic for each of the two lineage types were rarely found in the alternative lineage. Further, this nuclear DNA dataset strongly supports the genetic differentiation seen in the chloroplast DNA between the native and introduced lineages (Saltonstall 2003b). Although *Phragmites* has been said to be self-incompatible (Gustaffson & Simak 1963), little is known about the mating system of this genus and it is not known if hybrids between population types can occur. The morphological data clearly support separation of the native lineage from the introduced/Gulf Coast lineages. We have demonstrated that the native lineage has morphological features (longer ligules, glumes, and lemmas) and unique genetic mutations that differentiate it from the introduced/ Gulf Coast lineages. We chose to recognize the native lineage formally as *Pharagmites australis* subsp. *americanus*. The following key using morphological and genotype features is given to separate these three lineages.

KEY TO THE LINEAGES OF *PHRAGMITES AUSTRALIS* IN NORTH AMERICA

1. Ligules 1.0–1.7 mm long; lower glumes 3.0–6.5 mm long; upper glumes 5.5–11.0 mm long; lemmas 8.0–13.5 mm long; leaf sheaths caducous with age; culms exposed in the winter, smooth and shiny; rarely occurs in a monoculture; chloroplast DNA haplotypes A-H, S, Z, AA (see Saltonstall 2002, 2003a) ____ **P. australis** subsp. **americanus** (Native lineage)

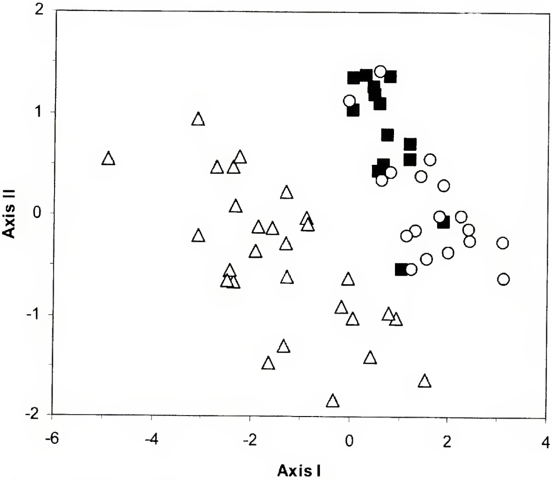

Fig. 3. Principal components analysis of morphological data for *Phragmites australis*: Native ( ), Introduced (■) and Gulf Coast (○) individuals.

1. Ligules 0.4–0.9 mm long; lower glumes 2.5–5.0 mm long; upper glumes 4.5–7.5 mm long; lemmas 7.5–12.0 mm long; leaf sheaths not caducous with age; culms not exposed in the winter, smooth and shiny or ridged and not shiny; often occurs as a monoculture; chloroplast DNA haplotypes I or M.
    2. Culms smooth and shiny; southern California, Arizona, New Mexico, Texas to Florida, throughout Mexico and Central America; chloroplast DNA haplotype I ________ *P. australis* var. berlandieri (E. Fourn.) C.F. Reed (Gulf Coast lineage)
    2. Culms ridged and not shiny; southern Canada from British Columbia to Quebec south throughout the Continental United States; chloroplast DNA haplotype M ________ *P. australis* (Introduced lineage)

Phragmites australis subsp. **americanus** Saltonstall, P.M. Peterson & Soreng, subsp. nov. Type: U.S.A. Montana. Fergus Co.: near the mouth of Dog Creek, 12 Sep 1883, *Frank Lamson Scribner 378* (holotype: US-824621!).

A *Phragmite australi* (Cav.) Trin. ex Steud. vagina caduca cum aetate, ligulis 1.0–1.7 mm longis, glumis inferioribus 3.0–6.5 mm longis, glumis superioribus 5.5–11.0 mm longis, lemmatibus 8.0–13.5 mm longis, recedit.

Plants usually do not occur as a monoculture. Culms exposed in the winter, smooth and shiny, sometimes purplish at the nodes and internodes. Leaf sheaths caducous with age; ligules 1.0–1.7 mm mm long. Spikelet lower glumes 3.0–6.5 mm long, upper glumes 5.5–11.0 mm long; lemmas 8.0–13.5 mm long.

Distribution.—(Fig. 1a). This subspecies is known to occur in southwestern Northwest Territories east and south to California, Arizona, New Mexico, and east to northern Texas, Oklahoma, northern Arkansas, West Virginia and North Carolina, and north to Newfoundland and Quebec.

ABSTRACT

Four species of *Nototriche* are recognized for Ecuador, all are endemic. *N. hartwegii* is re-established. A key, descriptions, and illustrations of the species are provided.

RESUMEN

Se reconocen cuatro especies de *Nototriche* para el Ecuador, todas endémicas. Se restablece *N. hartwegii*. Se presentan clave, descripciones e ilustraciones de las especies.

Nototriche Turcz., es un género netamente andino sudamericano que se distribuye en el páramo de Ecuador y punas de Perú, Chile, Bolivia y norte de Argentina. Comprende alrededor de 130 especies distribuidas entre los 3500 y 5000 metros de elevación. La mayor concentración de especies se encuentra en Perú con aproximadamente 65 especies.

La monografía del género de hace más de un siglo (Hill, 1909) presentó 62 especies. Varios trabajos posteriores de Krapovickas (1950, 1951, 1953, 1957a, 1957b, 1973), Fryxell (1990) y Chanco (1992) han aumentando el número de especies conocidas para el género y una nueva monografía actualizada para la serie *Flora Neotropica* está en camino (Krapovickas y Chanco, en prep.).

En la monografía de la familia para el Ecuador, Fryxell (1992) presentó tres especies: *N. ecuadoriensis* Fryxell, *N. jamesonii* A.W. Hill y *N. phyllanthos* (Cav.) A.W. Hill, las mismas que fueron registradas por Jørgensen y León-Yánez (1999). Recientes colecciones realizadas en el sur del Ecuador indican la presencia de una cuarta especie, *N. hartwegii* A.W. Hill. Ésta fue considerada por Fryxell (1992) como un sinónimo de *N. jamesonii*, pero nuestros estudios del material tipo indican que se trata de una entidad distinta, muy diferente del resto de colecciones de *N. jamesonii*. En este trabajo se restablece la especie *N. hartwegii* A.W. Hill para la flora de Ecuador, que actualmente cuenta con cuatro especies endémicas, duplicando el número de endémicas registrado por Valencia et al. (2000). Además se proporciona su estado de conservación según las categorías de la UICN (2001).

Las especies de *Nototriche* son hierbas de apariencia acaulescente, que forman cojines compactos de hojas densamente arrosetadas en las ramificaciones apicales de los tallos. Los tallos son por lo general subterráneos, profundos, robustos, leñosos y están recubiertos por los restos de las hojas. Las hojas son

SIDA 21(2): 693–703. 2004

flabeladas a ovadas, palmati o pinnatipartidas, glabras a densamente recubiertas de tricomas estrellados; parte de las estípulas y el pecíolo están adheridos y forman una vaina o vagina laminar, membranosa. La porción libre del pecíolo y de las estípulas varía según las especies. Las flores solitarias con pedicelo muy corto se insertan en el punto o debajo donde se separan los ápices libres de las estípulas, carecen de involucelo; el cáliz es gamosépalo, partido en 5 dientes; la corola es vistosa, consiste de 5 pétalos obovados; el androceo es monadelfo con una columna estaminal estrecha, con las numerosas anteras que forman una cabezuela en su ápice; los estilos son hasta 14, más largos que la columna estaminal, los estigmas son clavados. Los frutos son esquizocarpos, variadamente hirsutos, dehiscentes, compuestos de hasta 14 mericarpos, cada uno con arista apical larga o corta.

Todas las especies crecen en las partes más altas de los Andes en hábitats rocosos y arenosos sobre los 3500 m, hasta más de 5000 m de elevación.

Dos especies, *N. pinnata* (Cav.) A.W. Hill y *N. acaulis* (Cav.) Krapov., tipificadas por colecciones realizadas, según las descripciones, por Née en el volcán Chimborazo, provienen probablemente de Perú, ya que de otra manera no se conocen en Ecuador.

CLAVE PARA DETERMINAR LAS ESPECIES

1. Hojas glabras excepto los ápices de los lóbulos con uno o más cilios largos, lámina pinnatipartida con 20 o más lóbulos ligulados; cáliz glabro por fuera, menos los bordes y el nervio medio de los dientes con algunos cilios, viloso en los dientes por dentro ____ **Nototriche ecuadoriensis** Fryxell

1. Hojas pubescentes al menos en la superficie superior, la lámina flabeliforme, lobulada con menos de 20 lóbulos obtusos; cáliz densamente estrellado-tomentoso en ambas superficies.

    2. Superficie inferior de la lámina, estípulas y pecíolo glabra o esparcidamente pubescente, vernicosa; superficie superior densamente tomentosa ____ **Nototriche phyllanthos** (Cav.) A.W. Hill

    2. Superficie superior e inferior de la lámina, estípulas y pecíolo densamente pubescentes.

        3. Lámina estrellado-vilosa con pelos largos y sedosos; parte libre del pecíolo de 2–3 mm de largo; ramas aéreas hojosas formando cilindros de hasta 15 cm de largo × 4–5 cm de diámetro ____ **Nototriche hartwegii** A.W. Hill

        3. Lámina estrellado-velutina con pelos cortos; parte libre del pecíolo de 6–19 mm de largo; ramas aéreas hojosas formando rosetas laxas de hasta 5 cm de largo × 5 cm de ancho ____ **Nototriche jamesonii** A.W. Hill

Nototriche ecuadoriensis Fryxell, Contr. Univ. Michigan Herb. 17:164. 1990. (**Figs. 1A, E**). TIPO: ECUADOR: Cotopaxi/Napo, road San Miguel (Salcedo), Puerto Nuevo (Napo) under construction, 29 km from San Miguel (Cerro Verde Filo), bunch grass páramo and rocky escarpment (78°25'W,0°59'S), 3950–4050 m, 1 Oct 1976, *Øllgaard & Balslev 9929* (HOLOTIPO: AAU!; ISOTIPOS: F!, MO!, NY!).

Hierba perenne, acaulescente, arrosetada o formando cojines compactos; eje subterráneo leñoso, ramificado, en cuyos ápices de las ramas se agrupan las hojas

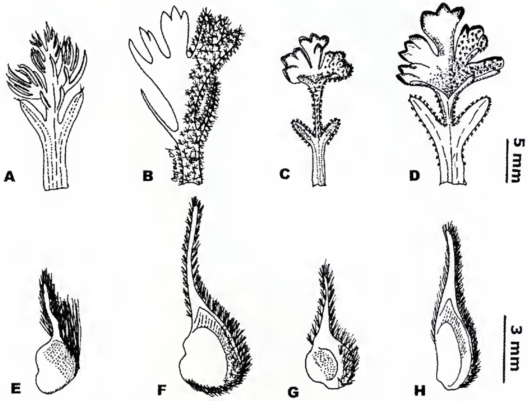

Fig. 1. **Arriba: Hoja con la lámina, la porción libre del pecíolo, la porción libre de las estípulas y la vagina. Abajo: Mericarpos. A y E,** ***N. ecuadoriensis*****. B y F,** ***N. hartwegii*****. C y G,** ***N. jamesonii*****. D y H,** ***N. phyllanthos*****.**

formando rosetas de hasta 4,5 cm de diámetro. Pecíolo y estípulas forman una vagina de 8–11 mm de largo × 3–4 mm de ancho, glabra. Parte libre de las estípulas, ancha, obtusa, de 5 mm de largo × 3 mm de ancho, las superficies glabras, los ápices con algunos cilios. Parte libre del pecíolo glabro, de 1–2 mm de largo. Lámina pinnatipartida, de 8–12 mm de largo × 7–10 mm de ancho, los lóbulos de la lámina con divisiones de segundo orden forman lóbulos ligulados de ápice subagudo, ambas superficies totalmente glabras excepto los ápices de los lóbulos con 1 ó más cilios. Cáliz de 9–12 mm de largo, los dientes triangulares, de 4,5 mm de largo × 3 mm de ancho en la base, el exterior glabro o cercano a ello con algunos pelos largos y suaves en el nervio medio y en los bordes de los dientes, el interior glabro menos los dientes con pelos largos dirigidos hacia el ápice. Nectarios internos basales 5, aislados, más anchos que altos, ca. 1 mm de ancho. Corola glabra, de un violeta pálido (purpúreo en seco); tubo de la corola de 4 mm de largo × 2 mm de ancho. Pétalos de 10–12 mm de largo × 5,5–6 mm de ancho, con una pequeña escotadura apical; cada pétalo se continúa sobre el tubo de la corola formando dos pequeñas "alas" ca. 2,5 mm de largo. Tubo estaminal glabro, más corto que los pétalos, de 4–6 mm de largo, las anteras dispuestas en una cabezuela globosa, subsésiles de color violáceo. Estilos 7 apenas sobresalen de las anteras, los estigmas capitados. Mericarpos de 6 mm de largo (incluidas las aristas de 3 mm) × 3 mm de ancho, con el dorso y el ápice largamente hirsutos.

Material adicional estudiado: **ECUADOR. Pichincha:** Slopes north-west of north peak of Antisana, 4400 m, 00.30S 078.00W, *P.J. Grubb et al. 578* (K, NY). **Napo:** Paramo de Papallacta, sector El Paso, 4060 m, 28 Oct 1984, *Freire 33* (QCA).

Distribución y conservación.—Especie endémica de la Cordillera Oriental, en los páramos del volcán Antisana, Papallacta y Cerro Verde, entre 3950 y 4400 m. Esta especie es conocida sólo de cuatro poblaciones y se la considera como Vulnerable (VU).

Notrotriche ecuadoriensis se distingue del resto de especies ecuatorianas por tener las hojas totalmente glabras excepto algunos cilios en el ápice de los lóbulos y por la lámina pinnatipartida con lóbulos ligulados. Por la presencia de un tubo de la corola es afín a *N. jamesonii*, se diferencia porque esta última tiene la lámina flabeliforme con lóbulos obtusos y por otros caracteres indicados en la clave.

Nototriche hartwegii A.W. Hill, Trans. Linn. Soc. London 7:221–222, pl. 29, fig. 14, 1909. (**Figs. 1B, F y 2**). Tipo: ECUADOR: Cañar: "Monte Assuay ad Las Cruces," 4550 m, *Hartweg 918* (holotipo K!, isotipos: BM (como foto digital), CGE n.v., G como foto digital, NY!, P!).

Hierba perenne, acaulescente, pulviniforme, lanosa; eje subterráneo leñoso, ramificado, en cuyos ápices de las ramas se agrupan numerosas hojas formando masas compactas cilíndricas. Estípulas y pecíolo forman una vagina de 6–7 mm de largo × 3–4 mm de ancho. Parte libre de las estípulas linear, de ápice subagudo, de 5–9 mm de largo × 0,7–1 mm de ancho. Parte libre del pecíolo de 2–3 mm de largo. Pecíolo, estípulas y vagina densamente cubiertos por pelos estrellados largos y suaves en ambas superficies, en los márgenes con pelos estrellados pedicelados más grandes. Lámina flabelada de base cuneiforme, de 10–15 mm de largo × 9–18 mm de ancho en la parte superior, 3-partida, cada segmento se divide en 3 o más lóbulos, el segmento medio entero o poco dividido, los lóbulos oblongos de ápice obtuso, la superficie superior densamente pilosa con pelos estrellados largos y suaves (lanosa), la inferior igualmente pilosa pero en menor proporción. Cáliz de 15–20 mm de largo, los dientes de 11–15 mm de largo × 2,5–5 mm de ancho en la base, el exterior todo piloso con pelos similares a la hoja, el interior glabro menos los ápices de los dientes. Nectarios internos basales 5, aislados, triangulares, de 1,5 mm de alto × 2 mm de ancho. Corola violácea con base blanquecina; tubo de la corola ausente. Pétalos de 20–25 mm de largo × 10–13 mm de ancho, la base con pelos estrellados largos. Tubo estaminal de 12–15 mm de largo, las anteras sésiles reunidas en cabezuela alargada, 2/3 del tubo estaminal, con pelos estrellados largos y caedizos. Estilos y estigmas en número de 12. Mericarpos 12, uniovulados, de 9 mm de largo (incluidas las aristas de 5 mm) × 3 mm de ancho, con pelos estrellados cortos en el dorso y ápices con cilios largos.

Fig. 2. *Nototriche hartwegii* en el Páramo del Cajas, Azuay, Ecuador. Arriba: detalle de las flores. Abajo: hábito mostrando la planta en cojín. Fotografías ©Carmen Ulloa Ulloa.

Material adicional estudiado: **ECUADOR:** "Quito," *Jameson s.n.* (K). Azuay: Parque Nacional Cajas. Road Cuenca-Sayausi-Molleturo, 4110-4350 m, 4 Ene 2000, *Jørgensen et al. 2114* (MO); Parque Nacional Cajas, sendero paragüillas, 21 Nov 2000, 4100-4400 m, *Jørgensen et al. 2422* (MO), 13 Ene 2003, 4100-4180 m, *Ulloa et al. 1184* (MO, USM).

Distribución y conservación.—Endémica de los páramos del sur del país entre 4100 y 4400 m en Cañar y Azuay (la colección de Jameson tiene una localidad como "Quito" que no necesariamente corresponde a la provincia de Pichincha). Esta especie fue recientemente recolectada luego de 150 años. Si bien hoy en día la especie se encuentra protegida dentro del Parque Nacional Cajas, se conoce sólo una población y su área de distribución es muy pequeña por lo que se le considera como En Peligro (EN).

Nototriche hartwegii se distingue por la lámina flabelada con base cuneiforme y poco lobulada; por las numerosas hojas agrupadas en los ápices de las ramas formando cilindros compactos; y por la densidad de pelos largos estrellados (lanosos) que dan a toda la planta una apariencia verde-gris.

Nototriche jamesonii A.W. Hill, Trans. Linn. Soc. London 7:228. 1909. (**Figs. 1C, G**). Tipo: ECUADOR: "Quito," *Jameson 154* (lectotipo: K!; isolectotipos: G n.v. (foto F-neg 23747 en F, MO, NY), GH n.v.).

Nototriche chimborazoensis Hochr., Candollea 16:82. 1957. Tipo: ECUADOR: Chimborazo, 4700-5100 m. *Rauh & Hirsch E-328* (holotipo: G!).

Hierba perenne, acaulescente, eje subterráneo leñoso, ramificado con los extremos apicales cubiertos de hojas dispuestas en rosetas. Pecíolo y estípulas forman una vagina herbácea de 6-7 mm de largo × 2,5 mm de ancho. Parte libre de las estípulas linear-oblonga, de 3-5 mm de largo × 0,8-1,2 mm de ancho. Parte libre del pecíolo de 6-19 mm de largo × 1,2-1,5 mm de ancho. Pecíolo, estípulas y vagina con superficies pilosas (la vagina con la superficie inferior glabra), con pelos estrellados cortos, los márgenes con pelos largos ciliados. Lámina flabeliforme, de 7-9 mm de largo × 9-11 mm de ancho, 3-fida, segmento medio más desarrollado que los laterales, los segmentos divididos en 3 ó más lóbulos oblongo-obtusos; superficie superior de la lámina pilosa velutina, con pelos estrellados cortos, la superficie inferior igualmente pilosa pero menos densa que la superior. Cáliz campanulado, de 8-11 mm de largo, dividido hasta cerca de la mitad en 5 dientes de ápice obtuso, exteriormente todo piloso con pelos estrellados similares a los de la lámina, el interior glabro menos los ápices de los dientes con pelos estrellados más grandes. Nectarios internos basales 5, más anchos que altos, cerca de 1 mm de ancho × 0,8 mm de alto. Corola violácea; tubo de la corola de 2,5-4 mm de largo, piloso. Pétalos de 15-18 mm de largo × 7-9 mm de ancho, la base con pelos estrellados. Tubo estaminal de 8-10 mm de largo, piloso con pelos algo rígidos y esparcidos, las anteras subsésiles dispuestas en una cabezuela oblonga. Estilos y estigmas cerca de 10. Mericarpos 10, de 6 mm de largo (incluidas las aristas de 2 mm de largo) × 2,5 mm de ancho, el dorso con pelos estrellados pequeños, parte superior y aristas con pelos estrellados largos y ciliados.

Material adicional estudiado: **ECUADOR:** Sin localidad, "14.000 ft," *Pearce s.n.* (K). **Bolívar:** Volcán Chimborazo, wind-swept gravel paramo, with open cushion plant association, 4200 m, 01.28S 078.55W, 04 Ago 1979, *Holm-Nielsen 18745* (AAU, F, MO, NY); Superpáramo area W of volcán Chimborazo, ca. 33 km N of Guaranda, 4120 m, 01.30S 078.56W, 29 Nov 1989, *Luteyn 13397* (NY, QCA), 16 Ene 1985, *Luteyn & Cotton 11080* (NY, QCA); Chimborazo, sin col. 4200 m (LIL). **Chimborazo:** "Diversa Chimborazo prope Totorillas ad nives perpect," 4600 m, 7 Jul 1876, *André 3948* (K, NY(2)), 4200 m, *André 3953* (K); Southern slope of Mount Chimborazo, sandy ground, 4600 m, 18 Jul 1939, *Asplund 8379* (F, LIL, NY, P), 4260 m, 23 Jun 1989, *Dorr & Valdespino 6437* (NY, QCA); Arenales del Chimborazo, superpáramo, 4300 m, 19 Oct 2001, *Endara et al. 361* (QCA), 25 Oct 1987, *Ramsay & Merrow-Smith 997* (K, QCA), 10 May 1939, *Penland & Summers 698* (F), 6 May 1927, *Rorud s.n.* (F). **Pichincha:** Cayambe mountain, N side, 4000 m, 24 Oct 1960, *Pennington 22C* (K, NY). **Tungurahua:** El Arenal, On the Via Whymper about 2 km from Cruce Arenal, 4150 m, 17 Abr 1983, *Brandbyge 42143* (AAU), 03 Sep 1983, *Brandbyge 42236* (AAU).

Distribución y conservación.—Especie endémica en los páramos del norte y centro del país entre 4000 y 5100 m. La especie está bien representada en varios páramos por lo que se la considera de Preocupación Menor (LC).

Nototriche jamesonii se distingue por la disposición de las hojas en los extremos de las ramas formando rosetas laxas. La porción libre del pecíolo es bastante larga en relación con las otras especies. La presencia del tubo de la corola es un carácter que comparte con *N. ecuadoriensis* (ver observaciones de dicha especie).

Hill, Bot. Jahrb. Syst. 37:579. 1906; A.W.Hill, Trans. Linn. Soc. London, Bot. 7:231, pl. 29 fig. 12, pl. 30 fig. 9. 1909. TIPO: ECUADOR: Pichincha, in monte Ruccu Pichincha, *Bonpland 3032* (HOLOTIPO: P; ISOTIPO: B-W No. 12731 como microficha).

Hierba perenne, acaulescente, arrosetada o formando densos cojines; eje subterráneo leñoso, ramificado, los ápices cubiertos de numerosas hojas verde-incano. Estípulas y pecíolo forman una vagina membranosa, de 12–15 mm de largo × 3–4 mm de ancho. Parte libre de las estípulas triangular o lineal-subulada de ápice agudo, de 8–10 mm de largo × 2–3 mm de ancho. Parte libre del pecíolo de 4–6 mm de largo × 1,5–2 mm de ancho. Pecíolo, estípulas y vagina con pelos estrellados pequeños en la superficie superior, glabrescente en la inferior, en los márgenes con pelos estrellados más grandes. Lámina flabeliforme, profundamente 3-partida, de 6–12 mm de largo × 10–18 mm de ancho, segmentos

FIG. 3. *Nototriche phyllanthos*, original publicado como *Sida pichinchensis* en Plantas aequinoctiales v. 2 (Humboldt y Bonpland, 1813, pl. 116). Reproducido con permiso de la biblioteca del Missouri Botanical Garden.

3–5-lobulados, los lóbulos ovado-oblongos de ápice obtuso con márgenes frecuentemente enrollados, la superficie superior de la lámina incano-tomentosa, la inferior glabra o subglabra y vernicosa. Cáliz campanulado, de 9–10 mm de largo, los dientes de 5 mm de largo × 3 mm de ancho en la base, el ápice subagudo, el exterior todo piloso con pelos similares a los de la lámina excepto los márgenes con pelos estrellados más grandes, el interior glabro excepto los dientes con pelos estrellados similares a los márgenes. Nectarios internos basales 5, de 1,2 mm de alto × 1,5 mm de ancho. Corola violácea; tubo de la corola ausente. Pétalos de 16–25 mm de largo × 8–10 mm de ancho, la base con abundantes pelos estrellados largos. Tubo estaminal de 9–10 mm de largo, glabro, las anteras dispuestas en una cabezuela oblonga, 4 mm de largo. Estilos y estigmas 7. Mericarpos 7, de 7 mm de largo (incluidas las aristas de 1,5 mm) × 2 mm de ancho, dorso estrellado-ciliado.

Distribución y conservación.—Especie endémica de los páramos del norte y centro del país entre 3500 y 4650 m. Está ampliamente distribuida y por lo tanto se la considera de Preocupación Menor (LC).

Brako y Zarucchi (1993) registraron esta especie para Perú sobre la base del ejemplar tipo y de colecciones del departamento de Huancavelica. Los ejemplares de Rauh P-374(a) y P-450 corresponden a *N. ulophylla* (A. Gray) A.W.Hill, una especie muy distinta de *N. phyllantos*. En cuanto a la colección tipo, apenas tiene la inscripción que dice "Perou," pero bien podría corresponder a alguna localidad ecuatoriana ya que en tiempos de la colonia parte de Ecuador estaba bajo la jurisdicción del Virreinato de Perú. De otra manera no habiendo registros para Perú, pensamos que la especie está restringida a Ecuador.

Fryxell (1992) cita como holotipo de *Sida pichinchensis* una muestra de Humboldt y Bonpland s.n. sobre la base de una microficha del herbario de Willdenow en Berlín. Sin embargo, el Ing. Antonio Krapovikas (com. pers.) nos indica que él considera el holotipo a la colección, por él estudiada, de Bonpland 3032 incorporada en el herbario general de París ya que ese material es el que el autor debe haber usado para describir la planta más no aquel de Berlín.

Nototriche phyllanthos es una especie bastante común, fácil de distinguir por el envés de las hojas glabro y con un brillo singular.

AGRADECIMIENTOS

Agradecemos a los curadores de los herbarios por habernos permitido estudiar o haber enviado en préstamo ejemplares de sus instituciones. C. Aedo (MA), B.Klitgaard (BM), G. Lewis (K), V. Noble (BM), P. Barriga y C. Quintana (QCA), L. Ramella (G), nos ayudaron a obtener fotografías de material depositado en esos herbarios y F. Keusenkothen escaneó la figura 3. A Paul Fryxell y Antonio Krapovickas por la minuciosa revisión del manuscrito. M. Chanco agradece al Ing. Antonio Krapovickas del Instituto de Botánica del Nordeste, Corrientes, Argentina, por las facilidades y el material botánico de estudio brindados durante la estadía en su Institución. El trabajo de campo de C. Ulloa en el sur del Ecuador se llevó a cabo con subsidios de la Nacional Geographic Society (Jørgensen 6327-98 y Ulloa 7744-02).

BOOK NOTICES

Two Books on *Agapanthus* from Timber Press

WIM SNOEIJER. 2004. **Agapanthus: A Revision of the Genus.** (0-88192-631-0, hbk.). Timber Press Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $39.95, 372 pp., 101 color photos, 9 color illus., 7 tables, 6 drawings, 6" 9".

Agapanthus is a genus from southern Africa with about 10 species, but there are hundreds of cultivars. The author has invested eight years of research and scholarship in preparing the "definitive" work on *Agapanthus* in cultivation. The author breaks down his research into six chapters: **1)** Introduction, **2)** Genome Size; **3)** Taxonomy and Nomenclature; **4)** Classification of the Cultivars; **5)** Descriptions of the Genus, Species, and Cultivars; and **6)** Cultivation. An appendix on Breeders/Introducers and Their Cultivars is followed by References and an Index.

HANNEKE VAN DIJK. 2004 **Agapanthus for Gardeners.** (0-88192-656-6, hbk.). Timber Press Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $24.95, 96 pp., 147 color photos, 1 color map, 2 line drawings, 4 color illus., 8 1/2" × 8 1/2".

Publisher Comments: "*Agapanthus for Gardeners* is an informative and practical guide to growing this popular perennial. It includes descriptions of all species and subspecies, along with a selection of 80 cultivars that have proven themselves in the garden and in containers; information on choosing and buying plants, cultivation requirements, propagation, and pests and diseases; and a discussion of *Agapanthus* as a cut flower."

"Illustrated with over 75 photographs, this is a useful companion to Wim Snoeijer's more scholarly and exhaustive *Agapanthus: A Revision of the Genus,* also published by Timber Press."

This small colorful book is truly a little jewel on "The Flower of Love." It covers everything from history to propagating to all the cultivars from A to Z.

ACERCA DE LA IDENTIDAD DE *BACCHARIS SUBSCULPTA* (ASTERACEAE: ASTEREAE)

ABSTRACT

After analyzing protologues and types, *Baccharis subsculpta* Hochr., a supposedly Peruvian endemic, is considered a synonym of the more widespread *B. pulchella* Sch. Bip. ex Griseb. A lectotype is selected for the name of the new synonym.

KEY WORDS: *Baccharis subsculpta*, *B. pulchella*, Asteraceae, Peru

RESUMEN

Después del análisis de los tipos y protólogos, *Baccharis subsculpta* Hochr., una especie peruana supuestamente endémica, es considerada un sinónimo de *B. pulchella* Sch. Bip. ex Griseb. de más amplia distribución. Se selecciona un lectotipo para el nombre del nuevo sinónimo.

PALABRAS CLAVE: *Baccharis subsculpta*, *B. pulchella*, Asteraceae, Perú

El género *Baccharis* L. (Asteraceae) es reconocido, entre las Astereae, por su primacía en cuanto al número de especies que lo integran, todas exclusivamente americanas, como por su complicada taxonomía. Sus aproximadamente 360 especies ocupan un área bastante extensa que abarca toda Sudamérica hasta alcanzar la zona sur de Estados Unidos de América, pero se extiende además por ambas costas norteamericanas más allá del paralelo 40 N. Se desarrollan en condiciones ecológicas muy dispares, habitando desde lugares húmedos hasta sitios muy secos y desde el nivel del mar hasta las mayores alturas andinas (Cuatrecasas 1969); empero, su mayor diversidad se encuentra focalizada básicamente en la región neotropical.

La delimitación de sus especies generalmente se muestra confusa y la interpretación cabal de las mismas ofrece serias dificultades, que radican en el extremo polimorfismo de muchas de ellas (o en una cierta continuidad morfológica en otras que forman complejos o alianzas de especies), así como en la gran cantidad de entidades fundadas, que las más de las veces corre pareja con la superficialidad de las diagnosis e ilustraciones que se han publicado a su respecto. A todo ello se suma su peculiar diecia, que supone una cierta diferencia en la facies de los individuos pistilados y estaminados de una misma especie—que puede inducir a confusión en el observador poco agudo—, y la distribución geográfica, que en algunas de sus especies es muy vasta, poniendo de relieve una gran capacidad adaptativa, mientras que en otras es de extensión muy limitada señalando su condición de endémicas. Por otro lado, sucede también que varias especies son halladas en el campo en poblaciones relativamente grandes, otras en cambio, se manifiestan como individuos escasos; como consecuencia, existen entidades que están bastante bien colectadas y algunas, por contraste, resultan poco representadas en herbario.

Estos factores apenas aludidos han contribuido a que la trayectoria taxonómica experimentada por algunas de las especies de *Baccharis* resultara errática pues, a menudo, una entidad tempranamente descripta, con el transcurso del tiempo, sufrió diversas interpretaciones y determinaciones erróneas; esta situación motivó que los autores posteriores que se ocuparon de alguna manera del género, utilizaran y difundieran otros epítetos para designarla. Lo dicho queda en evidencia al apreciarse la abultada sinonimia que reúnen ciertas especies, v. gr. *Baccharis salicifolia* (Ruiz & Pav.) Pers., *B. rhexioides* Kunth, *B. linearis* (Ruiz & Pav.) Pers., etc.

Baccharis pulchella Sch. Bip. ex Griseb. es un taxón distribuido desde Perú central y meridional hasta el centro de la Argentina. Desde que fuera originalmente descripta por A. Grisebach en 1879—sobre la base de una colección del viajero francés Gilbert Mandon proveniente de Sorata, Bolivia (Fig. 1)—, esta especie ha recibido la atención de otros botánicos en distintas ocasiones, quienes le aplicaron cada cual denominaciones diferentes, no teniendo en cuenta la plasticidad morfológica de la especie; ésta presenta marcado polimorfismo en varios caracteres, a saber: pubescencia (existen desde plantas densamente tomentosas hasta casi glabras), ancho de la hoja (varía desde 0,5 cm hasta 3 cm), disposición de los capítulos (reunidos en cimas corimbiformes difusas—o aun capítulos solitarios—o bien, agrupadas en racimos foliosos bien definidos). En efecto, el estudio de los tipos respectivos no ha dejado duda alguna sobre la identidad de las mismas y, en consecuencia, que se trata de nombres que han originado un listado de sinónimos en décadas recientes (Ariza Espinar 1971, 1973).

Precisamente, el asunto que nos ocupa, y que estimamos conveniente dar a conocer a continuación, ilustra un caso adicional de sinonimia en *Baccharis pulchella* que recientemente hemos advertido. En el intento de determinar ciertos ejemplares peruanos colectados poco tiempo atrás por uno de nosotros (A. G.) en el departamento de Lima, nos encontramos frente a la duda de asignarles este nombre—al que parecían ajustarse bien de acuerdo a literatura moderna (Cabrera 1978; Giuliano 2000) y al estudio de ejemplares de herbario—o, por otro lado, aplicarles el binomio *Baccharis subsculpta* Hochr., correspondiente a una rara planta peruana supuestamente endémica de territorio limeño con la que guardaban indiscutibles semejanzas morfológicas según comprobamos al observar un fototipo de la misma (Fig. 2), y a más del detalle muy sugerente de provenir del *locus typicus* de la especie antedicha, la

Fig. 1. Isotipo de *Baccharis pulchella* Sch. Bip. ex Griseb. (*Mandon 185*, NY [foto LP]).

"cuesta de Puruchuco". Estos antecedentes nos llevaron de inmediato a sospechar de la verdadera identidad de *B. subsculpta*, de modo que intentamos reunir todos los elementos de juicio a nuestro alcance para aclarar nuestra presunción de un posible caso de sinonimia; dispusimos de los protólogos y fototipos de ambas entidades con el fin de estudiarlos y realizar un análisis comparativo. A juzgar

Fig. 2. Lectotipo de *Baccharis subsculpta* Hochr. (*Matthews 758*, K [foto LP]).

por las coincidencias entre ambas diagnosis, como así por la innegable similitud entre los respectivos ejemplares originales—para *B. pulchella* especialmente en el caso del isotipo en NY, ya que los isotipos de K y LP presentan hojas más breves y angostas, demostrando su variabilidad intraespecífica—, resulta indudable que *B. pulchella* es la misma entidad que ulteriormente Hochreutiner volvió a denominar *B. subsculpta*.

Conviene hacer notar que como expresáramos anteriormente, la existencia de la diecia ha motivado, dentro de *Baccharis*, la proposición de nuevas especies basadas justamente en ejemplares funcionalmente estaminados o pistilados. Tal es el caso de *B. subsculpta*, descripta en base a especímenes correspondientes al pie estaminado exclusivamente, mientras que *B. pulchella* lo fuera a partir de ambos tipos de individuos. Sin embargo, como parte de nuestro análisis, examinamos ejemplares de diferentes poblaciones de la especie *B. pulchella*, los cotejamos con el protólogo y con fotos e imágenes del material original peruano de *B. subsculpta* (su presunto sinónimo) y, a nuestro juicio, es imposible hallar la más mínima diferencia de ningún tipo que permita fundamentar separación alguna.

Debe mencionarse que, si bien Hochreutiner incluyó a su *Baccharis subsculpta* en la sección Oblongifoliae DC., este taxón infragenérico era altamente heterogéneo y artificial según su concepción original (cfr. Candolle 1836); luego de la redelimitación que de la misma realizara Cuatrecasas (1967), queda claro que la especie no corresponde en absoluto a dicha sección. Asimismo, en el protólogo de *B. subsculpta* se menciona que la especie es muy cercana a *B. sculpta* Griseb., y que también guarda semejanzas con *B. sphaerocephala* Hook. & Arn. y con *B. grandicapitulata* Hieron.; no obstante, esta aparente similitud es sólo superficial, ya que *B. subsculpta* no presenta afinidades con ninguna de esas especies, pertenecientes a distintas secciones del género.

Por todo lo expuesto, proponemos a *Baccharis subsculpta* Hochr. como un nuevo sinónimo de la muy extendida *B. pulchella* Griseb., lo cual documentamos a continuación:

Baccharis pulchella Sch. Bip. ex Griseb., Symb. Fl. Argent. 181. 1879. TIPO: BOLIVIA. DPTO. LARECAJA: viciniis Sorata, Nov 1858–Mar 1859, *Mandon 185* (HOLOTIPO: GOET; ISOTIPOS: K [foto LP!], LP!, NY [foto LP!]).

= *Baccharis subsculpta* Hochr., Bull. New York Bot. Gard. 6(21):292. 1910. Syn. nov. TIPO: PERÚ. "Cuesta of Perruchuca [Puruchuco]," *Matthews 758* (LECTOTIPO, aquí designado, K, foto LP!); "In Peruvia interiore," *Matthews 564* (sintipo NY, foto LP!). Obs.: La selección del ejemplar *Matthews 758* como lectotipo de la especie se fundamenta principalmente en que dicho espécimen proviene de una localidad explícitamente citada, además del hecho de considerar a éste como mejor representativo de la misma.

AGRADECIMIENTOS

Agradecemos a Charlotte Taylor y a Guy Nesom por las valiosas sugerencias y aportes que condujeron a la versión definitiva del texto. El primer autor desea expresar su reconocimiento a las autoridades y al personal del Herbario del Museo de Historia Natural de la Universidad Nacional Mayor de San Marcos (USM) por las facilidades prestadas; no olvida, por supuesto, al Bach. José Alegría por la lectura diligente del manuscrito.

ABSTRACT

Gamochaeta spicata "(Lam.) Cabr." is based on an illegitimate later homonym (*Gnaphalium spicatum* Lam. 1788, non P. Miller 1768) and is to be attributed as *Gamochaeta spicata* Cabr., nom. nov. Cabrera's "nomen novum," however, also is illegitimate because *Gnaphalium coarctatum* Willd., a replacement name for *Gnaphalium spicatum* Lam., is the first legitimate name for Lamarck's plant. Details in the publication and specimen citations are clarified for the typification of **Gamochaeta coarctata** (Willd.) Kerg., the correct name in *Gamochaeta* for this species. *Gnaphalium spicatum* P. Miller is a synonym of *Pterocaulon virgatum* (L.) DC. *Gnaphalium spicatum* (Forssk.) Vahl is a synonym of *Ifloga spicata* (Forssk.) Sch. Bip.

RESUMEN

Gamochaeta spicata "(Lam.) Cabr." está basado en un homónimo posterior ilegítimo (*Gnaphalium spicatum* Lam. 1788, non P. Miller 1768) y debe consignarse como *Gamochaeta spicata* Cabr., nom. nov. El "nomen novum" de Cabrera, sin embargo, es también ilegítimo ya que *Gnaphalium coarctatum* Willd., un nombre reemplazo de *Gnaphalium spicatum* Lam., es el primer nombre legítimo para la planta de Lamarck. Para la clarificación de la tipificación de **Gamochaeta coarctata** (Willd.) Kerg., el nombre correcto en *Gamochaeta* de esta especie, se brindan detalles acerca de la publicación y citación de los especímenes. *Gnaphalium spicatum* P. Miller es un sinónimo de *Pterocaulon virgatum* (L.) DC. *Gnaphalium spicatum* (Forssk.) Vahl es sinónimo de *Ifloga spicata* (Forssk.) Sch. Bip.

During work preliminary to treatments for *Flora Mesoamericana* and *Flora of North America*, we noted that the species previously identified as *Gamochaeta* (*Gnaphalium*) *spicata* (Lam.) Cabr. (Compositae: Gnaphalieae) should be called *Gamochaeta coarctata* (Willd.) Kerg. Kerguélen's combination (1987) was made preliminary to the Flora of France, after *Flora Europaea* (Holub in Tutin et al. 1976), and it has not been widely used. For example, *Gamochaeta spicata* was used in Freire (1995), but *Gamochaeta coarctata* was correctly used subsequently by Freire & Iharlegui (1997) and Cabrera et al. (2000). Typification of *Gamochaeta coarctata*, however, has been confused, and because the species is a worldwide weed (e.g., Cabrera 1961; Drury 1971; Kerguélen 1987; Nesom 2004a, 2004b), we provide details of typification necessary for convincing use of the name.

In essence, the name *Gnaphalium spicatum* was validly published by three different authors for three different species from three different continents; these species are now referred to three different genera. *Gnaphalium spicatum* Lam. (1788) is the only one of the three that refers to a *Gamochaeta* species. It was used as a legitimate name by Cabrera (1961), but it is an illegitimate later homonym of *Gnaphalium spicatum* P. Mill. (1768). Vahl's combination (1790), based on *Chrysocoma spicata* Forssk., added the third *Gnaphalium spicatum*. Willdenow (1803) provided a replacement name (*Gnaphalium coarctatum*) for Lamarck's (1788) illegitimate *Gnaphalium spicatum*. Cabrera (1961) resurrected *Gamochaeta* from synonymy within *Gnaphalium*, but Kerguélen (1987) was the first to correctly use the first legitimate name for Lamarck's type in *Gamochaeta*.

The nomenclature and taxonomy of the three different names *Gnaphalium spicatum* are as follows:

1. Gnaphalium spicatum P. Miller, Gard. Dict., ed. 8, *Gnaphalium* no. 24. 1768. SYNTYPE: JAMAICA: *Sloane 38 Volume 5:26* (BM, digital image!). It is possible that a Miller collection from the Chelsea Botanic Garden, England is preserved in the Banks herbarium (BM).

Current name.—*Pterocaulon virgatum* (L.) DC.

Distribution.—southern United States to South America (Cabrera & Ragonese 1978).

Miller's protologue reads "24 *Gnaphalium* (*spicatum*) foliis lanceolatis decurrentibus tomentosis, floribus spicatis terminalibus lateralibusque." Additionally, Miller (1768) cited "Elichrysum caule alato, floribus apicatis. Sloan. Cat. Jam. 125," in direct reference to Sloane's polynomial "Helichrysum caule alato, floribus spicatis" (Sloane, 1696:125) as illustrated in Sloane (1707:tab. 152, fig. 5!). Miller stated that the plant "grows naturally in Jamaica, and in other of the hot parts of America" and that it "flowers in July and August, but never perfectly sets seed in England."

Gnaphalium spicatum P. Miller, was not cited in the monograph of *Pterocaulon* (Cabrera & Ragonese 1978) but was listed by Jackson (1893) as a synonym of *Pterocaulon virgatum* (L.) DC. Based on our observation of the Sloane syntype (BM) of *Gnaphalium spicatum* P. Miller, of the cited original illustration (Sloane 1707) of *Gnaphalium spicatum* P. Miller, and of the lectotype of *Gnaphalium virgatum* L. (LINN 993.29, IDC microfiche 177. 578.II.5!), we treat *Gnaphalium spicatum* P. Miller as a synonym of *Pterocaulon virgatum* (L.) DC.

2. Gnaphalium spicatum (Forssk.) Vahl, Symb. Bot. 1:70. 1790, hom. illegit., non P. Miller 1768. *Chrysocoma spicata* Forssk., Fl. Aegypt. 73. 1775. *Ifloga spicata* (Forssk.) Schultz-Bip. in Webb & Berthelot, Hist. Nat. Iles Canaries, vol. 3 (2, sect. 2):310. 1836–1850 [1845]. TYPE: EGYPT: 1761–1763, *Forsskal s.n.* (HOLOTYPE: C, IDC 2200 27.I.1!).

Current name.—*Ifloga spicata* (Forssk.) Schultz-Bip.

Distribution.—Canary Islands, northern Africa east to Pakistan (Davis 1975:100–101).

This widespread herb less than 15 centimeters tall with densely crowded and spiralling filiform leaves and axillary capitula was described from Egyptian material. This species was referred to *Gnaphalium* (Vahl 1790) and in turn to *Ifloga* (Schultz-Bipontinus 1844–1850). Davis (1975) and Anderberg (1991) treated this species as *Ifloga spicata* (Forssk.) Schultz-Bip.

3. Gnaphalium spicatum Lam., Encycl. Méth. Bot. 2:757. 1788, hom. illegit., non P. Miller 1768. *Gnaphalium coarctatum* Willd., Sp. Pl. 3(3):1886. 1803, nom. nov. *Gnaphalium purpureum* L. var. *spicatum* Klatt, Linnaea 42:140. 1878, nom. et stat. nov. *Gamochaeta spicata* Cabr., Bol. Soc. Argent. 9:380. 1961, nom. illegit. *Gamochaeta coarctata* (Willd.) Kerg., Lejeunia 120:104. 1987. TYPE: URUGUAY. Montevideo, *Commerson s.n.* [HOLOTYPE: P-LAM, IDC microfiche 6207.325.I.1!; possible ISOTYPE: P (photographs F!, GH!, TEX!, all photographs from C.B.G.N. negative 37573)].

Cabrera (1961:380–381) cited a sheet ("Des environs de Buenos Ayres... *Commerson*") seen in P as "type" of *Gnaphalium spicatum* Lam. Drury (1971) cited the same sheet as lectotype. The locality on the label of this sheet (Buenos Aires, Argentina) conflicts with that of Lamarck's protologue ("Monte-video"), and the lectotype selection by Drury is rejected here. Although Montevideo, Uruguay, and Buenos Aires, Argentina, are 200 km apart and on different banks of the Río La Plata, these two sheets are, nevertheless, conceivably of the same gathering. The sheet labeled "Buenos Ayres" is listed here as a possible "isotype" not lectotype.

Current name.—*Gamochaeta coarctata* (Willd.) Kerg.

Distribution.—cosmopolitan weed.

The names listed in the above citation of *Gnaphalium spicatum* Lam. are homotypic. *Gnaphalium coarctatum* Willd. (1803) is treated as having been originally a nomem novum for Lamarck's plant, and it dates from 1803. In providing a replacement name for Lamarck's *Gnaphalium spicatum*, Willdenow (1803:1886) cited the locality as "Monte Video" (echoing Lamarck's citation) for the species. On the same page, Willdenow treated the name *Gnaphalium spicatum* (Forssk.) Vahl as referring to an Egyptian species, citing *Chrysocoma spicata* Forssk. as a synonym (see #2, above). In the *Gnaphalium* treatment, Lamarck (1788) did not specifically refer to the earlier *Gnaphalium spicatum* P. Miller.

Cabrera's (1961:380) intended transfer of Lamarck's illegitimate name to *Gamochaeta* (as "*Gamochaeta spicata* (Lam.) comb. nov.") is to be treated as having been originally a nomem novum. *Gamochaeta spicata* Cabr., however, is illegitimate (vidi ICBN Art. 52.1) because the "available" and legitimate *Gnaphalium coarctatum* should have been adopted. Kerguélen (1987) treated *Gnaphalium coarctatum* and *Gnaphalium spicatum* Lam. as homotypic and supplied the correct (in *Gamochaeta*) combination for this plant.

Gamochaeta spicata was treated as a synonym of *Gamochaeta americana* (P. Miller) Wedd. by Nesom (1990), but *G. coarctata* commonly differs from *G. americana* by stems being up to 60 (vs. to 25) cm tall, basal leaves wider (vs. narrower) than 8 mm, involucres 3–4 (vs. 4.5) mm high, and phyllaries blunt and straight (vs. acute, cuspidate, and reflexed), as noted by Drury (1971).

A REVISION OF *AGOSERIS APARGIOIDES* (ASTERACEAE: LACTUCEAE)

Gary I. Baird

Department of Biology, Brigham Young University–Idaho, 525 S. Center St.
Rexburg, Idaho, 83460-1100, U.S.A., bairdg@byui.edu

ABSTRACT

A brief review of *Agoseris apargioides* is presented. The species is redefined to exclude *A. hirsuta*, a grassland species found along the Coast Ranges of California. *Agoseris apargioides* occurs on coastal dunes along the Pacific coast from central California to Washington. Three varieties are recognized: var. *apargioides*, var. *eastwoodiae*, and var. *maritima* (E. Sheld.) G.I. Baird, comb. et stat. nov.

RESUMEN

Se presenta una breve revisión de *Agoseris apargioides*. La especie se redefine para excluir *A. hirsuta*, una especie que se encentra en los pastos a lo largo de las cordilleras costeras de California. *Agoseris apargioides* aparece en las dunas costeras a lo largo de la costa del Pacífico desde el centro de California hasta Washington. Se reconocen tres variedades: var. *apargioides*, var. *eastwoodiae*, y var. *maritima* (E. Sheld.) G.I. Baird, comb. et stat. nov.

In 1816, the Romanzov Expedition (1815–1818) spent the month of October at the Spanish presidio on the north side of what is now San Francisco, California (Chamisso 1836). At this time, L. A. von Chamisso, a member of the expedition, collected the type of *Agoseris apargioides* (Less.) Greene. This species occurs on coastal dunes along the Pacific coast from central California to Washington. In the protologue, Lessing (1831) noted a peculiar feature of this plant: due to its preference for dune habitats, the stems often are buried by drifting sands, leaving a terminal rosette of leaves exposed. These buried stems become pseudorhizomatous, a feature unique within the genus.

In his monograph of *Agoseris*, Jones (1954) mistakenly interpreted the type description of *A. apargioides* as belonging to an allied but separate species, *A. hirsuta* (Hook.) Greene. *Agoseris hirsuta* is a grassland species found along the Coast Ranges of California. It is strictly acaulescent and only rarely occurs adjacent to the Pacific shore (and then not on dunes). Jones (1954) incorrectly treated *A. hirsuta* as "*A. apargioides* ssp. *apargioides*" and *A. apargioides* as "*A. apargioides* ssp. *maritima*." This last subspecies was based on *A. maritima* E. Sheld., the type collected at Coos Bay, Oregon. Within ssp. *maritima*, Jones (1954) recognized two varieties: "var. *maritima*" and "var. *eastwoodiae*," this last variety based on *A. eastwoodiae* Fedde, the type collected at Bodega Bay, California. Jones' (1954) view of *A. apargioides* has been the basis for all recent treatments of this species (e.g., Jones 1960; Chambers 1993).

In my recent monograph of *Agoseris* (Baird 1996), it became apparent that Jones (1954) had misinterpreted *A. apargioides*. The name *A. hirsuta* is here reestablished as the correct name for the inland species. *Agoseris apargioides* is redefined to include just those plants that occur along the Pacific coastal strand. Three variants within *A. apargioides* are morphologically and geographically distinct.

SIDA 21(2): 715–716. 2004

Agoseris apargioides (Less.) Greene, Pittonia 2:177. 1891. *Troximon apargioides* Less., Linnaea 6:501. 1831. TYPE: U.S.A. CALIFORNIA. San Francisco, Oct 1816, *Chamisso s.n.*

Perennials, ± caulescent, buried stems pseudo-rhizomatous. Leaves linear to spathulate, entire to lobate, or filiformly pinnatifid, 3–15 cm × 1–30 mm, glabrous to villous, mostly prostrate to reclining; lobes 3–5(–7) pairs, filiform to spathulate. Scapes 7–45 cm, villous to tomentose, glandular or not. Involucres obconic to hemispheric, 1.5–2.5 cm tall; phyllaries in 2–4 series, glabrous to tomentose and ± glandular; receptacle naked. Florets 25–200; corollas yellow; tubes 2–5.5 mm; ligules 3–16 × 1–3 mm; anthers 1.5–4.5 mm. Achenes 5–12 mm, beaked; body fusiform to obconic, 3–5 mm; beak 3–8 mm. Pappi of bristles, 4–9 mm. $x = 18$.

KEY TO VARIETIES

1. Corolla ligules 3–6 mm long, involucres non-glandular ____ var. **maritima**
1. Corolla ligules 8–16 mm long, involucres ± glandular.
    2. Leaves oblanceolate to spathulate, dentate to lobate; involucres densely villous to tomentose ____ var. **eastwoodiae**
    2. Leaves linear to oblanceolate, entire to dentate or filiformly pinnatifid, involucres glabrous to villous ____ var. **apargioides**

Agoseris apargioides var. **apargioides**. Occurs from San Francisco south to Pt. Sur.

Agoseris apargioides var. **eastwoodiae** (Fedde) Munz, Aliso 4:100. 1958. = *Agoseris eastwoodiae* Fedde, Bot. Jahresb. 31:808. 1904. TYPE: U.S.A. CALIFORNIA. Sonoma Co.: Bodega Point, 4 Jul 1900, *Eastwood s.n.*

Occurs from Pt. Reyes north to about Pt. Arena.

Agoseris apargioides var. **maritima** (E. Sheld.) G.I. Baird, comb. et stat. nov. = *Agoseris maritima* E. Sheld., Bull. Torrey Bot. Club 30:310. 1903. = *Agoseris apargioides* subsp. *maritima* (E. Sheld.) Q. Jones ex Cronq., Vasc. Pls. Pacif. Northw. 5:24. 1955. TYPE: U.S.A. OREGON. Clatsop Co.: Clatsop Beach, 21 Aug 1902, *Sheldon 11250.*

Occurs from Humboldt Bay, California, to Neah Bay, Washington.

NEW SPECIES OF *GAMOCHAETA* (ASTERACEAE: GNAPHALIEAE) FROM THE EASTERN UNITED STATES AND COMMENTS ON SIMILAR SPECIES

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

ABSTRACT

Gamochaeta argyrinea Nesom, sp. nov., is documented from 19 states, primarily in the southeastern U.S.A., and from Puerto Rico. It is a common and abundant species of ruderal habitats and has usually been identified within a broad concept of *Gamochaeta purpurea*, which has a similar but broader geographic range. *Gamochaeta argyrinea* apparently is most closely similar to *G. ustulata*, another species commonly identified as *G. purpurea* but native to the Pacific coast region of the U.S.A. and adjacent Canada. **Gamochaeta chionesthes** Nesom, sp. nov., is described from localities in Arkansas, Louisiana, Mississippi, Alabama, Georgia, Florida, South Carolina, and North Carolina—these plants also have been identified previously primarily as *G. purpurea*. A key and distribution maps are provided for the six species of *Gamochaeta* in the U.S.A. with strongly bicolored leaves: *G. argyrinea*, *G. ustulata*, *G. chionesthes*, *G. purpurea*, *G. simplicicaulis*, and *G. coarctata*. The name *Gamochaeta americana* has been misapplied to *G. coarctata*, but *G. americana* sensu stricto has not been documented for the U.S.A.; it occurs in the Antilles, Central America, Mexico, and South America and is reported to occur elsewhere as an adventive. In order to further clarify its identity, a technical description and commentary are provided for *G. americana*.

RESUMEN

Se documenta **Gamochaeta argyrinea** Nesom, sp. nov., de 19 estados, principalmente del Sureste de U.S.A., y de Puerto Rico. Es una especie común y abundante en hábitats ruderales y ha sido identificada usualmente dentreo del concepto amplio de *Gamochaeta purpurea*, que tiene un rango geográfico similar pero más amplio. *Gamochaeta argyrinea* es aparentemente más parecida a *G. ustulata*, otra especie identificada comúnmente como *G. purpurea* pero nativa de la región costera del Pacifico de U.S.A. y Canadá adyacente. **Gamochaeta chionesthes** Nesom, sp. nov., se describe de localidades de Arkansas, Louisiana, Mississippi, Alabama, Georgia, Florida, Carolina del Sur, y Carolina del Norte—estas plantas también han sido identificadas previamente como *G. purpurea*. Se ofrece una clave y mapas de distribución de las seis especies de *Gamochaeta* de U.S.A. con hojas bicolores: *G. argyrinea*, *G. ustulata*, *G. chionesthes*, *G. purpurea*, *G. simplicicaulis*, y *G. coarctata*. El nombre *Gamochaeta americana* ha sido mal aplicado a *G. coarctata*, pero *G. americana* sensu stricto no se ha documentado para U.S.A.; está en las Antillas, América Central, México, y América del Sur y se cita de otros lugares como adventicia. Se ofrece una descripción técnica y comentarios sobre *G. americana* para clarificar su identidad.

Studies of North American *Gamochaeta* Wedd. (Godfrey 1958; Nesom 1990) have identified plants with leaves strongly bicolored (persistently white-pannose abaxially with a closely matted vestiture completely obscuring the epidermis, evidently green to grayish green adaxially) mostly as *Gamochaeta purpurea*

SIDA 21(2): 717–741. 2004

(L.) Cabr. Review of North American plants shows that more species are present than recognized in these earlier studies and also that some names have been misapplied. Taxonomic studies of *Gamochaeta* in New Zealand (Drury 1971; Webb 1988), where all the species are non-native and include a number of those found in the U.S.A., have been more discerning, at least in some respects, than previous studies of North American species.

In the present study, two species that have been identified mostly as *Gamochaeta purpurea* are described as new to science. One is distributed over a large part of the eastern U.S.A. and also is known from Puerto Rico; the other is known from Gulf Coast states of the U.S.A. Neither of new species keys unambiguously in a recent overview of *Gamochaeta* (Freire & Iharlegui 1997), and a survey of the genus in South America and Central America indicates that neither of these species now recognized in North America has received a name, although it is possible that one or both is native to South America. It also is possible that both are weeds widely distributed on several continents. Hypotheses regarding the nativity of all species of *Gamochaeta* occurring in the U.S.A. are provided in an accompanying discussion (Nesom 2004). All of the species in North America with strongly bicolored leaves are reviewed here.

The distinctiveness of *Gamochaeta* as a genus was emphasized by Cabrera (1961 and later floristic treatments of South American species, e.g., 1963, 1971, 1974, 1978), Dillon and Sagástegui (1991a, 1991b), Cabrera and Freire (1998), and by other botanists who have treated it (e.g., Nesom 1990; Anderberg 1994; Freire & Iharlegui 1997). *Gamochaeta* is distinguished by its combination of small heads in a spiciform capitulescence, concave post-fruiting receptacles, truncate collecting appendages of the disc floret style branches, small achenes with minute, mucilage-producing papilliform trichomes on the surfaces, and pappus bristles basally connate in a smooth ring and released as a single unit.

A widespread new species from eastern U.S.A. related to *Gamochaeta ustulata*

Godfrey (1958) noted variation within what he identified as *Gnaphalium purpureum* and I have observed *Gamochaeta (Gnaphalium) purpurea* sensu stricto growing in close proximity to a "variant" or intermixed with it in many localities in eastern North America. Intergradation apparently occurs rarely if at all and the two entities can be consistently and accurately distinguished, both in the field and herbarium. In fact, the variant is more similar and probably more closely related to *Gamochaeta ustulata* (Nutt.) Holub, a species apparently native to western North America (see comments and description below) than to *G. purpurea*. The plants of eastern North America are recognized here as a previously undescribed species and documented to occur in 19 states.

Gamochaeta argyrinea Nesom, sp. nov. (**Figs. 1, 2, 3, 4, 6**). TYPE: U.S.A. NORTH CAROLINA. Pender Co.: Hwy 421 at junction with Hwy 210, between towns of Currie and Rocky Point, roadsides and grassy median strip, in sandy soil; in close association with *Gamochaeta purpurea* sensu stricto, *Gamochaeta pensylvanica*, *Gamochaeta antillana*, and *Gamochaeta*

PLANTS OF NORTH CAROLINA

Gamochaeta argyrinea Nesom

Pender County. Hwy 421 at junction with Hwy 210, between Currie and Rocky Point. Roadsides and grassy median strip. Sandy soil. Five species of *Gamochaeta*, commonly intermixed along roadside: *G. pensylvanica*, *G. purpurea*, *G. coarctata*, *G. antillana*, and *G. argyrinea*. *Gamochaeta coarctata* and *G. argyrinea* in median strip. Common. **HOLOTYPE.**

28 April 2001
Guy Nesom WMGT 16

Fig. 1. Habit of *Gamachaeta argyrinea*.

PLANTS OF GEORGIA
ASTERACEAE

Gamochaeta chionesthes Nesom, ined.

Meriwether County. Town of Gay, mowed lawn of U.S. Post Office on Hwy 74/85, near jct with Hwy 109. Loamy soil. *Gamochaeta coarctata* and *G. chionesthes* present and abundant at this site; *G. argyrinea* uncommon
Common and abundant. Few plants with involucres lighter colored than normal.
TYPE COLLECTION: HOLOTYPE

14 April 2004
G.L. Nesom GASC04–14

Fig. 2. Habit of *Gamochaeta chionesthes*.

coarctata, all growing along the roadside, 28 Apr 2001, *G. Nesom WMGT-14* (HOLOTYPE: BRIT; ISOTYPES: AKU, BM, BRIT, CANB, CANU, F, GA, GH, K, LP, MEXU, MO, NCU, NSW, NY, P, RB, S, TEX, UC, US, USF).

Differt a *Gamochaeta purpurea* radicibus plerumque fibrosis, foliis caulinis oblanceolatis vel oblanceolati-spathulatis, trichomatis paginarum foliarium adaxialium filiformibus ad basi a apici, capitulis 3–3.5 mm altis, phyllariis intimis laminis oblongis truncato-rotundatis apiculatis ad apices, et flosculis bisexualibus (3–)4–6.

Plants annual to winter annual, densely fibrous-rooted, rarely slender-taprooted. **Stems** decumbent-ascending from the base, 12–40 cm tall, simple or few-branched, closely white-pannose, the vestiture usually of individually evident trichomes, less commonly nearly cloth-like. **Leaves** basal and cauline, basal persisting and green through flowering, basal and lower cauline oblanceolate to oblanceolate-oblong or oblanceolate-obovate, 1.5–5(–8) cm long, 5–12(–18) mm wide, gradually reduced in size upward, not clasping or decurrent, bicolored, closely white-pannose abaxially, persistently very sparsely arachnoid adaxially (sometimes necessary to examine at 10x). **Capitulescence** cylindric in early season, 1.5–5 cm long, 10–12 mm wide (pressed), later producing axillary glomerules from lower nodes and elongating, becoming strongly interrupted and up to 18 cm long (but still narrowly cylindric). **Involucres** campanulate, 3–3.5 mm, imbedded at base in cottony tomentum; phyllaries in 4–6 series, outermost ovate-acute to ovate-lanceolate, tawny-transparent, 1/3–4/5 as long as the inner, inner elliptic-oblong to oblong, stereome ca. 2/3 the length, lamina apically truncate-rounded and apiculate, flexing slightly outward at maturity, hyaline-translucent and slightly brownish-tinged, often purplish tinged around the stereome/lamina junction; receptacles shallowly concave. **Florets**: bisexual 4–5(–6), all corollas purple- to yellow-brown-tipped; pistillate numerous in a broad zone. **Cypselae** oblong, 0.5–0.6 mm long, tan, papillate.

Flowering Mar–Jun(–Jul, –Oct). Roadsides, fields, lawns, open woods, sand to sandy clay, almost always in open, disturbed areas; ca. 0–250 m. USA: Alabama, Arkansas, Delaware, Florida, Georgia, Kansas, Kentucky, Louisiana, Maryland, Mississippi, Missouri, North Carolina, Oklahoma, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, West Virginia; Puerto Rico; Argentina?, New Zealand?, Australia?, Portugal? In the southeastern U.S.A., *Gamochaeta argyrinea* commonly grows with *G. coarctata* and *G. chionesthes*. The epithet (from Gr. *argyreos*, silvery) alludes to the silvery appearance of the plants, especially when growing in colonies.

PUERTO RICO. Barranquitas region, wet place, 700 m, 14 Nov 1979, *Liogier 30027* (NY, UPR); Cuilarte Forest, on slope, 900 m, 16 Jan 1980, *Liogier 30271* (NY, UPR). **Ciales:** Los Tres Picachos, Rt 149, km 35.5, dirt road through old coffee plantation, disturbed wet mountain forest, ca. 600–750 m, 14 Mar 1992, *Axelrod 4213* (NY, UPRRP). **Ponce:** Bo. Anón, Toro Negro Forest Reserve, trail along SE side of Monte Jayuya, wet mountain forest, ca. 1200 m, 24 Apr 2003, *Axelrod 12545* (BRIT); near Cerro de Punta, Jayuya, in thickets, 1200 m, 10 Apr 1982, *Liogier 33089* (NY, UPR); rte 143 at Cerro de la Punta, roadsides and thickets, 1000 m, 29 May 1988, *Taylor 8116* (UPRRP). **Salinas:** Barrio Lapa, Las Tetas de Cayey, summit area of E. peak, 820–830 m, low exposed thicket near brink of cliff, 31 Mar 1988, *Proctor 44634* (SJ).

A population in Davidson Co., N.C. (*Nesom GX1*, as cited above) is a variant—the plants tend to produce small tubers or cormlike swellings. Plants of other populations in the same area often produce offsets that are nearly rhizome-like (e.g., Davie Co., N.C., *Nesom GX2*, BRIT).

Essential differences that distinguish *Gamochaeta argyrinea* from *G. purpurea* are given in the following couplet.

a. Basal leaves persistent and green at flowering; cauline leaves oblanceolate to oblanceolate-oblong or oblanceolate-obovate, trichomes of adaxial leaf surfaces filiform from base to tip; involucres 3–3.5 mm high; inner phyllaries with lamina oblong, apically truncate-rounded and apiculate; bisexual florets 4–5(–6) per head ____ **Gamochaeta argyrinea**

a. Basal leaves usually withered and becoming deciduous at flowering; cauline leaves spatulate, trichomes of adaxial leaf surfaces with basal cells expanded and vitreous; involucres 4–4.5 mm high; inner phyllaries with lamina triangular, apically acute but not apiculate; bisexual florets 3–4 per head ____ **Gamochaeta purpurea**

Plants common in the Pacific coast region have usually been identified as *Gamochaeta purpurea*, but they are more similar to *G. argyrinea* and are identified here as *G. ustulata*. New Zealand plants identified by Drury (1971) and Webb (1988) as *G. purpurea* var. *ustulata* have measurements characteristic of *G. ustulata*, but plants in Portugal identified as *G. ustulata* by Afonso (1984) are more likely *G. argyrinea*. *Gamochaeta ustulata* (Figs. 3, 4, 7) is recognized by its fibrous rooted habit, large, weakly bicolored leaves persistently arachnoid on

Fig. 3. Involucres of *Gamochaeta* species (left to right). (Top) *G. argyrinea*, *G. ustulata*, *G. coarctata*, *G. americana*, (bottom) *G. purpurea*, *G. chionesthes*, and *G. simplicicaulis*.

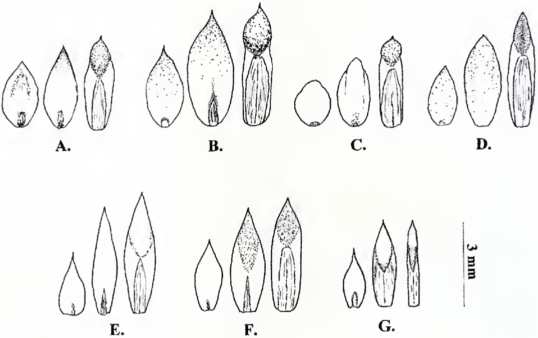

Fig. 4. Phyllary morphology of *Gamochaeta* species: outer, middle, and inner phyllary for each species. **(A)** *G. argyrinea*, **(B)** *G. ustulata*, **(C)** *G. coarctata*, **(D)** *G. americana*, **(E)** *G. purpurea*, **(F)** *G. chionesthes*, and **(G)** *G. simplicicaulis*.

the adaxial surfaces, and large brownish capitula in a thick, usually continuous capitulescence. It differs from *G. purpurea* in its longer duration, thicker and shorter stems, wider and more compact capitulescence, larger capitula, and prominently brown, blunt-apiculate inner phyllaries with a subterminal keel. *Gamochaeta ustulata* and *G. argyrinea* differ primarily by features in the following couplet.

a. Capitulescence 12–18 mm wide (pressed), uninterrrupted or rarely so and only at the base, mostly 1–6(–8) cm long; involucres 4.5–5 mm high; outer phyllaries and often lamina of inner phyllaries dark brown, commonly the whole involucre with a dark brown cast; mid phyllaries with a low, subterminal keel; cypselae 0.7–0.8 mm long ____ **Gamochaeta ustulata**

a. Capitulescence 10–12 mm wide (pressed), early uninterrupted and 1.5–5 cm long, later producing axillary glomerules from lower nodes and elongating, becoming strongly interrupted and up to 18 cm long; involucres 3–3.5 mm high; phyllaries greenish-silvery to stramineous or golden, sometimes light brown but the whole involucre not with a dark brown cast; phyllaries not keeled; cypselae 0.5–0.6 mm long ____ **Gamochaeta argyrinea**

Gamochaeta ustulata (Nutt.) Holub, Folia Geobot. Phytotax. 11:83. 1976 (non Nesom, Phytologia 68:196. 1990). *Gnaphalium purpureum* var. *ustulatum* (Nutt.) Boivin, Naturaliste Canad. 87:34. 1960. *Gnaphalium ustulatum* Nutt., Trans. Amer. Philos. Soc. ser. 2, 7:404. 1841. LECTOTYPE (Nesom 1990): USA. CALIFORNIA: Near St. Barbara in Upper California, [March or April 1836], *T. Nuttall s.n.* (BM, GH-photo!, TEX-photo!).

Gnaphalium pannosum Gandoger, Bull. Soc. Bot. France 65:42. 1918 (non A. Gray 1883; non Schultz-Bip. 1845). SYNTYPES: USA. WASHINGTON. Klickitat Co.: on damp ground, Columbia River, 10 May 1893, *W.N. Suksdorf 1580* (NY-2 sheets, US!); WASHINGTON. Chehalis Co.: near Montesano, 200ft, 8 Jun 1898, *A.A. Heller 3919* (NY-2 sheets!). Images of both the Suksdorf and Heller collections can be seen on NY and US internet sites.

Plants annual to biennial or short-lived perennial, fibrous-rooted. **Stems** erect to ascending, commonly decumbent-ascending and rhizome-like, 10–40 cm tall, densely white-pannose. **Leaves** basal and cauline, basal persistent but often withering by flowering, spatulate to oblanceolate, 2–5 cm long, 6–12(–35) mm wide, apiculate, not clasping or decurrent, continuing upwards little reduced until into the capitulescence, weakly bicolored, adaxial surfaces sparsely to densely arachnoid with persistent trichomes, closely white-pannose abaxially. **Capitulescence** 1–6(–8 or more) cm long, 12–18 mm wide (pressed), uninterrrupted or rarely so and only at the base. **Involucres** campanulate-urceolate, 4.5–5 mm high, base imbedded in cottony tomentum; outer phyllaries broadly triangular-ovate, half as long as the inner, all with a brown or greenish-brown cast, inner with lamina dark brown, apically abruptly obtuse and (on the middle phyllaries) with a low, subterminal keel and apiculum, sometimes purplish at the stereome-lamina junction; receptacles shallowly concave. **Florets:** bisexual (3–)4–6, all corollas yellowish- or sometimes purplish-tipped; pistillate numerous in a broad zone. **Cypselae** oblong, 0.7–0.8 mm long, tan to brownish, papillate.

Flowering Apr–Jul(–Oct). Mostly in coastal and near-coastal localities: dunes and other sandy sites, ocean bluffs, less commonly in clay-loam, fields, roadsides and roadcuts, ditches, cliffs, pine woods, chaparral slopes, tidal marsh edges; 0–650(–1050) m. California, Oregon, and Washington; southwestern British Columbia.

A new species from the Gulf coastal plain

Another species with strongly bicolored leaves, known to me from eight states of the U.S.A. Gulf coastal plain, appears to be undescribed. Among species occurring in North America (including Mexico), it is similar in general aspect to *Gamochaeta argyrinea* because of the basally decumbent-ascending stems, white-pannose vestiture, bicolored leaves (gray-green abaxially), the basal in a persistent rosette, and mostly oblanceolate cauline leaves, but conspicuous details of the vestiture, phyllary morphology, and cypselae are different. It keys to the area of *G. purpurea* and *G. americana* (P. Miller) Wedd. in Freire y Iharlegui (1997), emphazing the bicolored leaves and acute to acuminate inner phyllaries. Concepts of *G. americana* by Cabrera (1963, 1971, 1974), Cabrera and Freire (1998), and others may represent or include this North American species, judging from illustrations of involucral and phyllary morphology, but *G. americana* sensu stricto, as interpreted here (see below), does not occur in the U.S.A. It is possible or even likely that the new species is native to South America, as it is known by relatively few and recent collections in the U.S.A.

Gamochaeta chionesthes Nesom, sp. nov. (**Figs. 2, 3, 4, 8**). TYPE: U.S.A. GEORGIA. Meriwether Co.: town of Gay, mowed lawn of U.S. Post Office on Hwy 74/85, near jct with Hwy 109, loamy soil, *Gamochaeta coarctata* , *G. argyrinea*, and *G. chionesthes* present and abundant at this site, 14 Apr 2004, *G. Nesom GASC04-14* (HOLOTYPE: BRIT; ISOTYPES: CANB, GA, GH, K, LP, LSU, MO, NCU, NY, P, TEX, UNA, US, USF).

Differt a *Gamochaeta purpurea* caulibus ac paginis adaxialibus foliorum with vestimento tenui albido textiloideo, foliis basalibus numerosis persistentibus, foliis caulinis oblanceolatis vel oblanceolati-spathulatis, involucris 3–3.5 mm altis, flosculis plerumque luteis (vs. purpureis) ad apices, phyllariis omnibus apicibus aut laminis brunneis, et cypselis pupureis.

Plants annuals to winter annuals, fibrous-rooted. **Stems** erect to decumbent-ascending from the base, 10–45 cm tall, simple or rarely few-branched, closely white-pannose, the vestiture sheath-like, like a continuous covering by a thin, closely appressed, polished cloth formed of filiform trichomes usually not individually evident. **Leaves** basal and cauline, basal persisting and green through flowering, basal and lower cauline oblanceolate to oblanceolate-spatulate, 2–6(–7) cm long, 5–13 mm wide, gradually reduced upward in size to linear bracts into the lower part of the capitulescence, not clasping, strongly bicolored, light green above but persistently lightly arachnoid with extremely closely appressed, nearly microscopic trichomes, closely white-pannose abaxially. **Capitulescence** cylindric in early season, mostly 3–5(–7) cm long, 10–12 mm wide (pressed), later producing axillary glomerules from lower nodes and elongating, sometimes strongly interrupted and up to 20 cm long. **Involucres** campanulate-cylindric, 3.5–4 mm long, base imbedded in cottony tomentum and lightly arachnoid on the lower 1/4–1/2; phyllaries in 4–5 series, all apically acute to acute-acuminate, outermost ovate, 1/3 as long as the inner, inner oblong-lanceolate, with green stereome ca. 3/5 the length of the phyllary, lamina apically acute, not apiculate, lightly striate, slightly flaring outward at maturity, purplish coloration absent or faint and present only at stereome apex and distal margins; receptacles shallowly concave. **Florets:** bisexual 2–4, all corollas brownish-yellow to purple distally, sometimes purple only on adaxial surface of bisexual corolla lobes; pistillate numerous in a broad zone. **Cypselae** oblong, 0.5–0.6 mm long, purple, papillate.

Flowering (Mar–)Apr–May(–Jun). Disturbed, open sites, especially roadsides, clearings, fields, flood plains, low pastures, lawns and almost any other place that has been mowed, sandy, loamy, and clay soil; 0–200 m; Alabama, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina. *Gamochaeta chionesthes* is abundant and common at least in Georgia and Alabama, where it often grows with *G. coarctata* and *G. argyrinea*. The epithet (Gr. *chioneos*, snowwhite, and *esthes*, clothing) alludes to the bright white, cloth-like covering of the stems and abaxial leaf surfaces.

Collections examined. **U.S.A. ALABAMA. con Co.: along Hwy 32, 4 mi W of jct Hwy 23/4-1 in Alma, mowed roadside and lawn-like area between truck stop store and highway, sandy soil, 15 Apr 2004, *Nesom GASC04—34* (BRIT). **Bulloch Co.:** ca. 15 mi SW of Statesboro along Hwy 321, at jct with Hwy I-16, mowed roadside area, gravelly soil, 15 Apr 2004, *Nesom GASC04—45* (BRIT). **Coffee Co.:** E side of city of Douglas on Hwy 32, near jct Hwy 221/135, lawn area of business, 15 Apr 2004, *Nesom GASC04—32* (BRIT). **Cook Co.:** weedy area between highway and a railroad at Cecil, 30 Apr 1970, *Faircloth 6624* (NCU). **Fayette Co.:** N side of Fayetteville, along Hwy 314, ca. 2 mi N of jct with Hwy 85, roadside, mowed, beside strip of pine woods, 14 Apr 2004, *Nesom GASC04—4* (BRIT, GA). **Fulton Co.:** S side of Atlanta area on Hwy 279 (Old National Highway) 2.5 mi S of I-85/285, at jct with Flat Shoals Road, closely mowed lawn area of quick-stop food store, 14 Apr 2004, *Nesom GASC04—2* (BRIT). **Grady Co.:** upland pine woods alongside a logging trail on Balfour's Nickelville forest, 6.3 mi S of Whigham, 11 Apr 1970, *Faircloth 6541* (MO, NCU). **Greene Co.:** 3 mi SW of Greenboro on Hwy 44, at jct with I-20, lawn area of commercial strip bordering highway, 16 Apr 2004, *Nesom GASC04—57* (BRIT, GA). **Lee Co.:** 7 mi E of Leesburg on Hwy 32 at jct with Hwy 91 to Albany, W side of junction, large mowed field on N side of road, drier than roadsides, compacted sand, 15 Apr 2004, *Nesom GASC04—26* (BRIT, GA, LP, MO). **Montgomery Co.:** 2.4 mi E of Ailey on US 80, 18 May 1976, *Solomon 5562* (MO). **Morgan Co.:** S side of Madison, just off Hwy 129/24 at jct with I-20, lawn area of motel, sloping toward southeast, 16 Apr 2004, *Nesom GASC04—58* (BRIT). **Newton Co.:** S side of Covington, at jct of I-20 and Hwy 142, grassy area beside access road from I-20 to Hwy 142, 16 Apr 2004, *Nesom GASC04—59* (BRIT). **Screven Co.:** Georgia welcome station, N side of Hwy 301 ca. 0.2 mi W of South Carolina state line, mowed lawn area, 16 Apr 2004, *Nesom GASC04—48a* (BRIT). **Sumter Co.:** S side of Americus, at jct Hwy 280/49 and Hwy 19, mowed lot beside pecan orchard, sandy loam, 15 Apr 2004, *Nesom GASC04—22* (BRIT, GA). **Tatnall Co.:** ca. 7 mi SW of Mendes on Hwy 169, at jct Hwy 121, mowed area with lawn grass, beside store, 15 Apr 2004, *Nesom GASC04—41* (BRIT). **Turner Co.:** E side of Ashburn on Hwy 107, mowed, lawn-like area between car wash and store, 15 Apr 2004, *Nesom GASC04—29* (BRIT, NCU). **Warren Co.:** ca. 6 mi NW of Norwood on Hwy 278, at jct of I-20, grassy roadside, 16 Apr 2004, *Nesom GASC04—56* (BRIT). **LOUISIANA. Lincoln Par.:** [Ruston], Illinois Central Railway right of way, clay soil, 3 May 1984, *Wise 39* (DOV). **Natchitoches Par.:** W of Natchitoches near jct of Interstate Hwy 49 and La Hwy 6, hard-packed sandy soil in front of gas station complex, past flower and fruit, 5 Jul 2004, *Nesom GA04—63* (BRIT). **MISSISSIPPI. Covington Co.:** right-of-way, US Hwy 49, 11.8 mi N of Hattiesburg, 8 May 1966, *Temple 2746* (NCU). **Scott Co.:** Raworth Recreation Area, between Forest and Morton, sticky dark clay soil, open areas in loblolly pine forest, 1 May 1970, *Jones 18493* (VDB). **NORTH CAROLINA. Bladen Co.:** 0.2 mi E of Cape Fear River on NC 41, dry roadside [alongside] flood plain forest, 16 May 1976, *Solomon 1895* (MO). **Duplin Co.:** jct of Hwy 40 and Hwy 117, just N of Magnolia, grassy roadsides, edge of ditch, edge of woods, sandy soil, intermixed with *G. purpurea*, *G. coarctata*, and *G. argyrinea*, 28 Apr 2001, *Nesom WMGT 6* (BRIT, MO, NCU, US). **SOUTH CAROLINA. Aiken Co.:** S side of New Ellenton, at jct of Hwy 278 and Hwy 19, roadside area, sandy soil, 16 Apr 2004, *Nesom GASC04—53* (BRIT, LSU, NCU, USCH). **Aiken Co.:** area of Beech Island (SE of Augusta) near jct of Hwy 278 and Hwy 125, at Beech Island Avenue, ca. 7 mi SE of N. Augusta, roadside and ditch edges, sandy soil, 16 Apr 2004, *Nesom GASC04—54* (BRIT, F, MISS, US, USCH). **Allendale Co.:** along Hwy 301, 5.2 mi WSW of jct Hwy 125/278 in Allendale, 8 mi ENE of Savannah River and state line, grassy roadside median of 4-lane highway, sandy soil, 16 Apr 2004, *Nesom GASC04—50* (BRIT, LP, USCH). **Bamberg Co.:** ca. 2 mi NE of Ulmer, at jct of Hwy 301 and Hwy 321, broad lawn area of Connelly Motel, 16 Apr 2004, *Nesom GASC04—51* (BRIT, K, USCH). **Barnwell Co.:** SE side of Barnwell on Hwy 64, 1.8 mi ESE of jct Hwy 3 in Barnwell, mowed, sandy field beside lookout tower, 16 Apr 2004, *Nesom GASC04—52* (BRIT, USCH).

As noted above, *Gamochaeta chionesthes* is similar to *G. argyrinea*, but the former is distinct in significant features, including habit and phenology, vestiture, capitulescence and involucral morphology, and cypselar color. The early-season branches of *G. chionesthes* lie nearly flat, with capitulescences on ascending branch tips. The early branches of *G. argyrinea* are basally decumbent-ascending to ascending, but the capitulescences are more quickly borne on stems completely erect or with erect distal portions. The difference in habit is particularly evident in mid-April, because *G. chionesthes* is several weeks later in phenological development and usually lies nearly flat at the same time that *G. argyrinea* is producing abundant, erect flowering branches. Because of this, it is easy to distinguish the two species when they grow intermixed or in close proximity, as is often the case. Additionally, the stems and leaves of *G. chionesthes* are stiff, almost brittle-feeling, compared to the softer ones of *G. argyrinea*.

The cauline vestiture *Gamochaeta chionesthes* is cloth-like, formed of filiform trichomes usually not individually evident but united in a continuous covering like a thin, closely appressed, polished cloth; the abaxial leaf vestiture sometimes is similar. In the closely pannose cauline vestiture of *G. argyrinea* and *G. purpurea*, the trichomes usually are individually evident in their longitudinal orientation; the cauline vestiture of *G. coarctata* also usually is cloth-like, similar to that of *G. chionesthes*. The "tightening" of the individual trichomes apparently is accentuated during drying, because this feature is more easily observed on herbarium specimens.

The phyllaries of *Gamochaeta chionesthes* are evenly graduate in length, all apically acute and usually the whole lamina or at least the apex of each is brown, usually giving the whole involucre a distinctly brown hue; purplish coloration is absent or faint and present only at stereome apex and distal margins. The brown hue of the involucres is a good "field" character even without a lens; with a field lens, the difference in phyllary shape between *G. chionesthes* and *G. argyrinea* is easily evident. And finally, if mature cypselae are present, the purple ones of *G. chionesthes* are distinct from those of similar U.S.A. species, which are tan.

Gamochaeta chionesthes is contrasted individually with both *G. purpurea* and *G. argyrinea* in the following pair of couplets. In the context of all U.S.A. species with strongly bicolored leaves, *G. chionesthes* also is identified in a key further below.

Gamochaeta chionesthes contrasted with *G. purpurea*:

a. Cauline vestiture a white, closely appressed, cloth-like covering, trichomes usually not individually evident; basal leaves abundant and persistent; cauline leaves oblanceolate to oblanceolate-spatulate; adaxial leaf surfaces appearing not hairy but with a whitish, minutely thin, closely appressed, sheath-like or cloth-like covering (sometimes incomplete) without individually evident trichomes; involucres 3–3.5 mm high; florets mostly yellowish at the apices; inner phyllaries with brown-tinted lamina—purplish coloration, when present on phyllaries, faint and only at the apex and distal margins of the stereome; cypselae purple __________ **Gamochaeta chionesthes**

a. Cauline vestiture densely but loosely pannose or pannose-tomentose; basal leaves often few or not persistent; cauline leaves distinctly spatulate; adaxial leaf surfaces loosely arachnoid, trichomes with basal cells expanded and vitreous; involucres 4–4.5 mm high; florets strongly purplish-tipped; inner phyllaries with whitish or slightly silvery lamina at maturity, often purplish when young; cypselae tan __________ **Gamochaeta purpurea**

Gamochaeta chionesthes contrasted with *G. argyrinea*:

a. Cauline vestiture a white, closely appressed, cloth-like covering, trichomes usually not individually evident; phyllaries evenly graduate in length, all phyllaries apically erect, acute to acute-acuminate, and with brown apex or lamina; bisexual florets 2–4; cypselae purple __________ **Gamochaeta chionesthes**

a. Cauline vestiture closely pannose with trichomes individually evident, minutely filiform and longitudinally oriented, the vestiture uncommonly cloth-like; phyllaries unevenly graduate in length, outer and middle phyllaries ovate to ovate-lanceolate, apically obtuse to broadly acute, inner phyllaries with lamina oblong with apex slightly spreading, truncate-rounded and apiculate, hyaline-translucent and slightly brown; bisexual florets 4–5(–6); cypselae tan __________ **Gamochaeta argyrinea**

Identity of *Gamochaeta purpurea* sensu stricto

Gamochaeta purpurea (Figs. 3, 4, 5) is distributed widely through the world, but the name has been used in various contexts in the U.S.A, often to identify any plant of *Gamochaeta* with bicolored leaves. A narrower, more accurate concept is documented here.

Gamochaeta purpurea (L.) Cabr., Bol. Soc. Argentina Bot. 9:377. 1961. *Gnaphalium purpureum* L., Sp. Pl. 854. 1753. Type: Linnaeus noted "Habitat in Carolina, Virginia, Pensylvania." A Kalm collection (LINN fiche!) may be part of the type material. Two specimens in the Clayton Herbarium (BM) were annotated by James Reveal in 1990 as syntypes: U.S.A. In Virginia, *J. Clayton 385* (GH-photo!, internet images! at <http://internt.nhm.ac.uk/cgi-bin/botany/clayton>). Accessed March 2004.

Gnaphalium rosaceum I.M. Johnston, Contr. Gray Herb. ser. 2, 68:99. 1923. *Gamochaeta rosacea* (I.M. Johnst.) Anderb., Opera Bot. 104:157. 1991. Type: MÉXICO. San Luis Potosí: region of San Luis Potosí, 1878, *C.C. Parry and E. Palmer 426* (holotype: GH!).

Gnaphalium heteroides Klatt, Linnaea 42:137. 1878. Type: MEXICO: locality unspecified, *Ehrenberg 972* (GH fragment and drawings!).

Plants winter annual or annual, fibrous-rooted or slender-taprooted. **Stems** erect to basally ascending-decumbent, 10–40(–50) cm, densely but loosely pannose or pannose-tomentose. **Leaves** basal and cauline, oblanceolate-spatulate to spatulate, basal and lower cauline 1–6 cm long, 5–14 mm wide, persisting or withering at flowering, similarly shaped leaves continuing into at least the lower part of the capitulescence, sometimes closely sinuate on the margins, usually strongly bicolored, closely white-pannose abaxially, adaxial surfaces loosely and sparsely arachnoid, the trichomes with basal cells expanded and vitreous, often glabrescent but at least the basal cells of each trichome persisting. **Capitulescence** initially a continuous cylinder 1–4(–5) cm long, (5–)10–15 mm

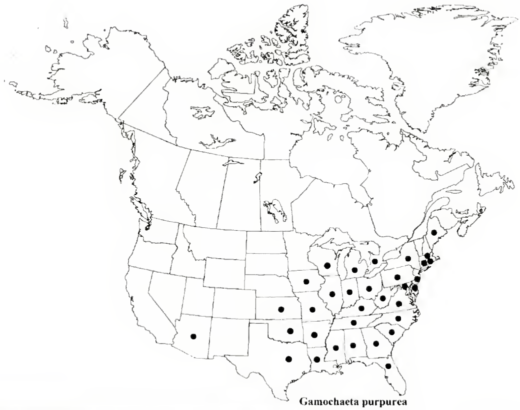

Fig. 5. State-level distribution of *Gamochaeta purpurea*.

wide, the arrangement becoming interrupted and elongate, of widely separated, bracteate glomerules, with lower axillary glomerules often on long peduncles. **Involucres** turbinate-cylindric, 4–4.5 mm long, base imbedded in cottony tomentum and lightly arachnoid on the lower 1/3–1/2; outer phyllaries ovate-triangular, inner triangular-lanceolate, apically acute, usually with a prominently striate texture, lamina purplish when young, becoming whitish or slightly silvery at maturity; receptacles shallowly concave. **Florets:** bisexual florets 3–4, all corollas usually purplish-tipped; pistillate numerous in a broad zone. **Cypselae** oblong, 0.6–0.7 mm long, tan, papillate. $2n = 14, 28$, but identities of vouchers for these chromosome reports need to verified.

Flowering Apr–May(–Jun). Open, usually disturbed habitats, roadsides, fields, woodland clearings and edges, almost always in sand; Canada (Ontario); USA (Arkansas, Arizona, Alabama, Connecticut, Delaware, District of Columbia, Florida, Georgia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maine, Maryland, Massachussetts, Michigan, Mississippi, Missouri, New Jersey, New York, North Carolina, Ohio, Oklahoma, Pennsylvania, Rhode Island, South Carolina, Tennessee, Texas, Virginia, West Virginia); Hawaii; Mexico (Nuevo León, San Luis Potosí, Veracruz, Puebla, Michoacan, Chihuahua, Sonora), Central America (Nicaragua), Antilles (Hispaniola); also reported in South America and as adventive in other parts of the world. In the western U.S.A., *G. purpurea* has

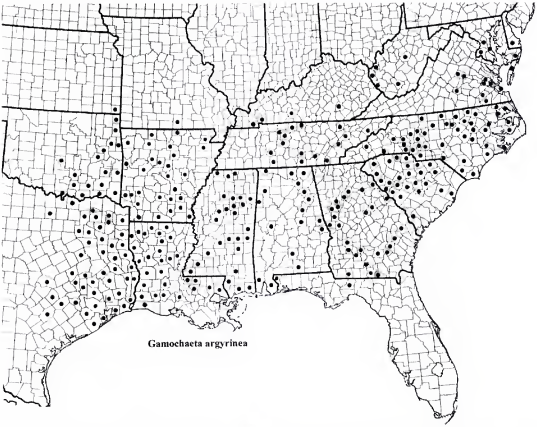

Fig. 6. County-level distribution of *Gamochaeta argyrinea*. With more intensive herbarium surveys and collecting, the distribution probably would be shown as nearly continuous (all counties; personal observation) at least in North Carolina (except perhaps high montane), South Carolina, Georgia, Alabama, Mississippi, and Arkansas. The implied loop in Georgia reflects the route of a collecting trip made in April 2004. The only known record for Pennsylvania (Northumberland Co., as cited in the text) is not shown on the map.

been recorded only from Arizona (see comments and documentation in Nesom 2004). *Gamochaeta purpurea* commonly occurs in disturbed sites, but at least in the eastern and southeastern USA, it seems more often to occur in more nearly natural sites, such as woodland edges and clearings, it is true to sandy soil, and it is my impression that in the last 50 years, *G. purpurea* probably has become much less common. *Gamochaeta purpurea* is uncommon compared to *G. argyrinea*, *G. chionesthes*, and *G. coarctata* (personal observation), in the range of the latter three. The species is rare or extirpated in the northeastern U.S.A. (summary in Kartesz 1999), where the latter three do not occur. *Gamochaeta purpurea* was excluded from Wisconsin's flora by Wetter et al. (2001), but Cochrane (pers. comm. 2004) notes that an undated collection from Sheboygan by Charles Goessl (WIS, photocopy-BRIT!) probably should be accepted as a valid record, although it probably was a garden weed or waif; it remains the only collection for the state. The species is described by Voss (1996) as "doubtless adventive" in the few southern counties of Michigan from which it is known.

Gamochaeta purpurea is recognized by its mostly spatulate cauline leaves,

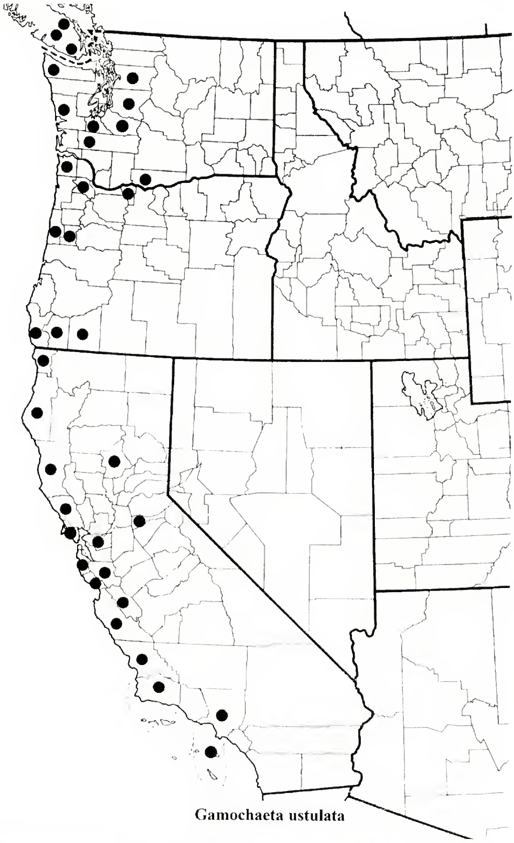

Fig. 7. County-level distribution of *Gamachaeta ustulata*.

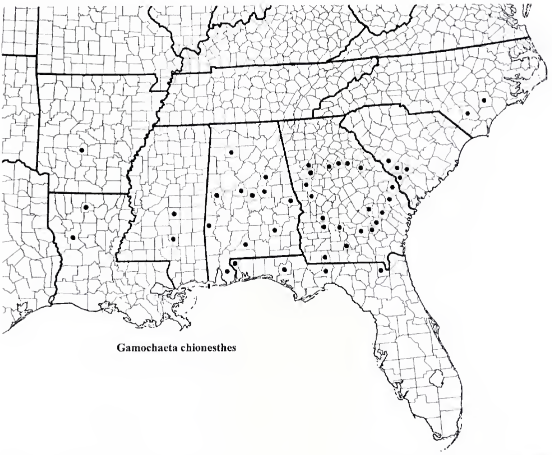

Fig. 8. County-level distribution of *Gamochaeta chionesthes*. At least in Georgia and Alabama, this species is much more common than indicated by the map, and it probably extends across South Carolina. The loop shown in Georgia and South Carolina reflects an April 2004 collecting trip, where the author found it remarkably simple to collect the species in every county sampled.

involucres 4–4.5 mm high, and inner phyllaries with whitish-hyaline, erect, apically acute lamina. The purple-tipped corollas are visible through the translucent lamina. The base of the trichomes on the adaxial leaf surfaces also is a diagnostic character—the basal cells of each trichome are expanded and glassy (use a lens), compared to comparable trichomes of most other species, which are evenly filiform to the very base. The pronouncedly spatulate leaves are distinctive and with experience, one can usually distinguish this species from others by leaf shape, but it is admittedly a subtle difference and the leaf dimensions of *G. purpurea* are similar to those in other species. In localities from Maryland northward, plants of *G. purpurea* are clearly annual, usually producing a small basal rosette and very shallow fibrous roots or a filiform taproot; southward and southwestward from Maryland, the basal rosette tends to be larger and the fibrous roots denser, and plants may be winter annual in this region, or at least the longer growing season is reflected in the plant habit.

I have identified *Gamochaeta purpurea* in various localities in Mexico (state

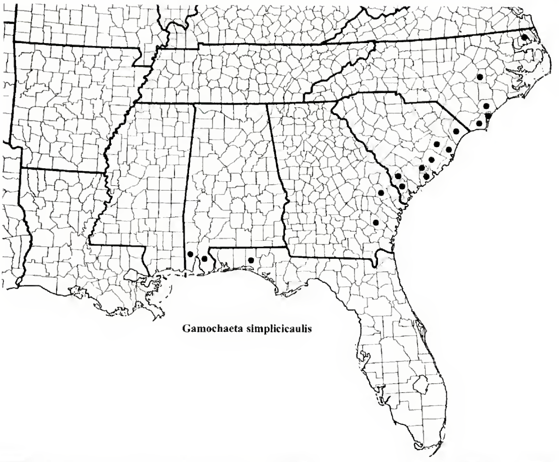

Fig. 9. County-level distribution of *Gamochaeta simplicicaulis*.

citations above) at elevations of 1300–2800 meters. Phyllaries of these plants characteristically are distinctly brownish on the lamina and apices, but the plants otherwise are similar to those of the U.S.A.

Gamochaeta coarctata vs. *Gamochaeta americana* in the USA.

Plants of the U.S.A. previously identified as *Gamochaeta americana* (e.g., Nesom 1990, 1999) are here identified as *Gamochaeta coarctata* (Willd.) Kerg. (Figs. 3, 4, 10). Godfrey (1958) correctly identified these plants as *Gnaphalium spicatum*, although the latter name is now treated as a synonym. *Gamochaeta coarctata* occurs mostly in the southeastern states and also apparently is naturalized in California (see Nesom 2004).

Gamochaeta coarctata (Willd.) Kerg., Lejeunia 120:104. 1987. *Gnaphalium spicatum* Lam., Encycl. Méth. Bot. 2:757. 1788, hom. illegit. (non P. Miller 1768). *Gnaphalium coarctatum* Willd., nom nov., Sp Pl. 3(3):1886. 1803. *Gnaphalium radians* Benth. var. *spicatum* (Lam.) Klatt, nom. illeg., Linnaea 42:140. 1878. *Gnaphalium purpureum* L. var. *spicatum* (Lam.) Baker in Mart., nom. illeg., Fl. Bras. 6(3):125. 1882. *Gamochaeta spicata* Cabr., nom. nov. illeg., Bol. Soc Argent. 9:380. 1961. HOLOTYPE: [URUGUAY]. "In Monte-video," *Commerson s.n.* (P-LAM, IDC microfiche 6207.325.I.1!). Cabrera (1961, p. 380–381) cited as "lectotype" of *Gnaphalium spicatum* Lam. "Des environs de Buenos Ayres," without date, *Commerson s.n.* Lamarck's protologue,

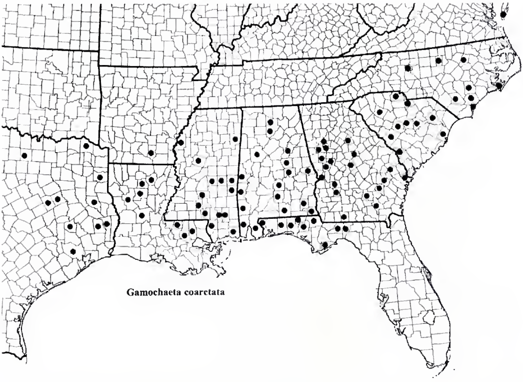

Fig. 10. County-level distribution of *Gamochaeta coarctata*. At least within the outline implied by the records mapped here, the distribution is essentially continuous (all counties; personal observation), probably reflecting a rapid, recent spread. Counties of occurrence in California are cited in Nesom (2004).

however, specified the locality as "Monte-video," as does the P-LAM sheet cited above as holotype. See Pruski and Nesom (2004) for discussion of the typification of this species.

Plants winter annual or biennial(?) herbs, fibrous-rooted. **Stems** basally decumbent-ascending, 15–35(–50) cm tall, usually several from the base, white-pannose, the tomentum usually sheath-like. **Leaves** basal and cauline, basal in a persistent rosette, spatulate to oblanceolate-obovate, (1.5–)3–8(–12) cm long, 6–15(–22) mm wide, cauline gradually or little reduced in size above the basal, not clasping or decurrent, slightly succulent and often becoming crenulate-margined upon drying, strongly bicolored, the adaxial surfaces green and glabrate to completely glabrous, closely white-pannose abaxially. **Capitulescence** usually a dense and continuous cylinder 2–20 cm, becoming branched and highly interrupted in older plants with elongation of branches at lower nodes. **Involucres** cylindric-campanulate, 2.5–3 mm high, shiny and completely glabrous from base to apex; phyllaries: outermost elliptic-obovate to broadly elliptic ovate with rounded to obtuse apices, often slightly but distinctly purplish or rosy, 1/3–1/4 as long as the inner, inner with a distinctly brown-hyaline, apically rounded to blunt, apiculate lamina; receptacles shallowly concave. **Florets:** bisexual 2–3, all corollas usually purplish-tipped; pistillate numerous in a broad zone. **Cypselae** oblong, 0.5–0.6 mm long, tan, papillate. $2n = 28$.

Flowering Apr–Jun. Ditch banks, roadsides, lawns, fields, gardens, sidewalk cracks, shaded spots around buildings; 0–150 m; U.S.A. (Alabama, Arkansas, California, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina, Texas, Virginia); Mexico, Antilles (Jamaica, Puerto Rico), South America, Europe, Japan, Taiwan, Australia, New Zealand. In the southeastern USA, *Gamochaeta coarctata* commonly grows with *G. argyrinea* and *G. chionesthes*. Collections documenting the occurrence of this species in Arkansas, California, and Virginia are cited in Nesom (2004).

Plants of *Gamochaeta coarctata* are recognized by their persistent, slightly succulent, strongly bicolored leaves (green and glabrate or usually completely glabrous on the adaxial surfaces), involucres 2.5–3 mm high, completely glabrous and evidently purplish-tinted, outer phyllaries elliptic-obovate to broadly elliptic ovate with rounded to obtuse apices, and 2–3 bisexual florets per head. It usually can be distinguished at a glance from *G. argyrinea* and *G. chionesthes* because of the distinctive vestiture and involucres.

The status of *Gamochaeta americana*

Gamochaeta americana (Figs. 3, 4) is another species with strongly bicolored leaves. Its occurrence in the U.S.A. has not been documented, which is remarkable in view of its widespread distribution in the Antilles and Mexico. The name has been incorrectly used to identify species of the U.S.A. (Nesom 1990).

The type collection of *Gamochaeta americana* was made from Jamaica (below), and I have studied collections from Jamaica, Puerto Rico, Hispaniola, and Cuba (all at NY) and from South America, Central America, and Mexico (various herbaria). It is reported from New Zealand (Drury 1971; Webb 1988) and Australia (Everett 1990). *Gamochaeta americana* was designated lectotype of the genus by Cabrera (1961, p. 362).

Gamochaeta americana (P. Mill.) Wedd., Chlor. Andina 1:151. 1856. *Gnaphalium americanum* P. Mill., Gard. Dict. ed. 8, no. 17. 1768. *Gnaphalium purpureum* L. var. *americanum* (P. Mill.) Klatt, Linnaea 42:140. 1878. LECTOTYPE (Fawcett & Rendle 1936, p. 206): JAMAICA. 1731, *Houstoun s.n.* (BM, NY-photo!)

Gnaphalium guatemalense Gandoger, Bull. Soc. Bot. France 65:42. 1918. *Gamochaeta guatemalensis* (Gandoger) Cabr., Bol. Soc. Argent. Bot. 9:371. 1961. TYPE: GUATEMALA. Alta Verapaz, *Tuerckheim* (not seen).

Gamochaeta irazuensis Nesom, Phytologia 68:199. 1990. TYPE: COSTA RICA. Volcan Irazú, 10,000–11,330 ft, 1 Dec 1937–1 Jan 1938, *P.H. Allen 702* (HOLOTYPE: F!).

Plants annual to short-lived perennial herbs from a slender, short but lignescent taproot, shallow fibrous roots, or a short, fibrous-rooted rhizome or caudex region. **Stems** usually erect from the base, less commonly decumbent-ascending, 10–40(–65) cm tall, arising singly or less commonly with 2–3 shoots, decumbent stems often developing adventitious roots, loosely lanate-tomentose (not sheath-like). **Leaves** basal and cauline, basal obovate-oblanceolate, 3–7(–10) cm long, 4–12(–16) mm wide, usually withering or withered by flowering and not persisting in a rosette, lower and midcauline often distinctly subclasping (but not auriculate), often slightly decurrent, cauline oblong to oblong-oblanceolate, sometimes narrowly revolute, adaxial surfaces glabrous to glabrate, sometimes more densely and persistently hairy, abaxial surfaces densely white to gray-white pannose. **Capitulescence** a continuous spiciform cluster 1–6 cm long, 8–12(–15) mm wide (pressed), usually becoming much longer and strongly interrupted by development of axillary clusters from lower nodes. **Involucres** campanulate-cylindric, 4–4.5 mm high, shiny and completely glabrous from base to apex; phyllaries in 4–5 series, outermost ovate to lanceolate-ovate with broadly acute to nearly obtuse apices, 1/4–1/2 as long as the inner, inner oblong-lanceolate, with light green stereome 2/3 the length of the phyllary, lamina dark brown-hyaline, apically broadly acute, sometimes nearly rounded, to (less commonly) obtuse apiculate, erect, without purplish coloration or slightly purplish only around the stereome-lamina junction; receptacles shallowly concave. **Florets:** bisexual ca. 3–6, all corollas yellowish distally; pistillate numerous in a broad zone. **Cypselae** oblong, 0.5–0.6(–0.7) mm long, tan, papillate.

Flowering all year, perhaps most abundantly Jun–Sep. Llanos, openings in pine, pine-oak, and deciduous woods, fallow fields, pastures, roadsides and other disturbed sites, commonly in wet or moist soil; 1250–3200 m. Mexico (Chiapas, Chihuahua, Colima, Dist. Federal, Durango, Guerrero, Hidaldo, Jalisco, México (Edo.), Michoacan, Morelos, Nuevo León, Oaxaca, Puebla, San Luis Potosí, Sinaloa, Sonora, Veracruz); Central America (Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, Panama); Antilles (Cuba, Hispaniola, Jamaica, Puerto Rico); South America; Galapagos Islands.

Gamochaeta americana is generally recognized by erect stems, strongly bicolored leaves with glabrate to glabrous adaxial surfaces, the cauline oblong to oblong-oblanceolate and relatively narrow, commonly subclasping and slightly decurrent, heads clustered in an interrupted spike, involucres shiny and completely glabrous, usually with a distinctly brownish cast. The lamina of the inner phyllaries characteristically are dark brown and sharply delimited in color from the proximal portion of the phyllaries; often the whole involucre is infused with brown color.

Considerably more variation is expressed within *Gamochaeta americana*, at least as it is understood here, than in similar species in the U.S.A. In Central America and Mexico, plants of *G. americana* commonly appear to be short-lived perennial, or at least biennial, because of the development of fibrous roots from a short caudex or rhizome or adventitious roots from the lower portion of decumbent stems. In the Antilles (including the type locality, Jamaica), South America, and scattered through the Mexican and Central American range are plants with shallow fibrous roots or a thin taproot—these plants apparently distinctly annual.

Leaves of *Gamochaeta americana* are characteristically strongly bicolored, with adaxial surfaces glabrous to glabrate, but in western Mexico (mostly Durango, Chihuahua, and Sonora), there is a tendency for the adaxial surfaces to be persistently hairy, sometimes resulting in a weakly bicolored appearance. Similar plants also appear sporadically in other parts of Mexico, and Dillon and Sagástegui (1991) noted that similar variation also occurs in South America. In Cordillera de Talamanca region of Costa Rica, a distinctive race with dense, silvery-white vestiture on abaxial leaf surfaces and with sheath-like cauline vestiture is being described as a new species (Nesom & Pruski in prep.).

Identification of *Gamochaeta* species in the U.S.A. with strongly bicolored leaves

The following key distinguishes the six species of *Gamochaeta* with strongly bicolored leaves currently known to occur in the U.S.A. *Gamochaeta americana* is included so that the key might be used in regions outside of the U.S.A., but its position in the first couplet directs the key toward contrasts of species known within the U.S.A. The abaxial leaf surfaces of all of these are white-pannose with a closely matted vestiture completely obscuring the epidermis, while the adaxial surfaces are evidently green to grayish green, glabrous to sparsely arachnoid. Five of these species occur primarily in the eastern and southeastern U.S.A. *Gamochaeta ustulata* occurs mostly in coastal and near-coastal Pacific localities in the western U.S.A. and British Columbia.

From observations in herbarium and field, *Gamochaeta* species in the U.S.A. appear to be remarkably constant in diagnostic morphological features, particularly in the vestiture of stems, leaves, and phyllaries and in the shape, size, and coloration of the phyllaries. The species common grow closely intermixed, but intermediates that might indicate hybridity are not common, or at least they are not often observed. In contrast, the capitulescence may vary in degree of compactness or openness to a greater degree than has been generally recognized. In *G. purpurea*, *G. argyrinea*, and *G. coarctata*, for example, the capitulescence begins as an essentially uninterrupted cylinder but may elongate greatly and become highly interrupted and branched. Keys that utilize a difference of this sort in capitulescence morphology (e.g., Freire & Iharlegui 1997) probably are recognizing artificially separated taxa.

1. Basal leaves usually withering or withered by flowering and not persisting in a rosette, cauline oblong to oblong-oblanceolate, lower and midcauline often distinctly subclasping (but not auriculate), often slightly decurrent ________ **Gamochaeta americana**
1. Basal leaves usually persisting in a rosette at flowering (except in *G. simplicicaulis*), cauline spatulate to oblanceolate, oblanceolate-oblong, or oblanceolate-obovate, none clasping or decurrent.
   2. Basal and lower cauline leaves on elongate internodes, usually withered or absent at flowering, clusters of small leaves usually produced in cauline axils; stems strictly erect, (30–)50–85 cm tall; inner phyllaries apically acute; flowering mostly July–August ________ **Gamochaeta simplicicaulis**
   2. Basal and lower cauline leaves on relatively congested nodes, usually green and persistent at flowering, clusters of small leaves absent in cauline axils; stems erect

to decumbent-ascending, mostly less than 50 cm tall; inner phyllaries apically acute to obtuse or rounded; flowering mostly April–June.

3. Adaxial leaf surfaces usually completely glabrous; involucres 2.5–3 mm high, completely glabrous, with evident purplish coloration; outer phyllaries elliptic-obovate to broadly elliptic-ovate, apically rounded to obtuse; bisexual florets 2–3 per head ____ **Gamochaeta coarctata**
3. Adaxial leaf surfaces with persistent vestiture (sometimes necessary to view at 10x); involucres 3–4.5 mm high, base imbedded in cottony tomentum and often lightly arachnoid on the lower 1/5–1/2, with or without purplish coloration; outer phyllaries ovate, apically acute to acute-acuminate; bisexual florets 2–6 per head.
    4. Stems usually appearing not hairy but with a white, closely appressed, cloth-like covering, trichomes usually not individually evident; involucres 3–3.5 mm high; all phyllaries apically acute to acute-acuminate and brownish; bisexual florets 2–4 per head; cypselae purple ____ **Gamochaeta chionesthes**
    4. Stems usually closely white-pannose with trichomes individually evident, minutely filiform and longitudinally oriented; involucres 3–4.5 mm high; inner phyllaries apically acute or oblong and blunt-apiculate, at least outer and mid phyllaries not apically brownish; bisexual florets 3–6 per head; cypselae tan.
        5. Cauline leaves mostly spatulate, trichomes of adaxial surfaces with basal cells expanded and vitreous; involucres 4–4.5 mm high; inner phyllaries with lamina triangular, apically acute but not apiculate; bisexual florets 3–4 per head; fibrous-rooted or slender-taprooted ____ **Gamochaeta purpurea**
        5. Cauline leaves oblanceolate to oblanceolate-oblong or oblanceolate-obovate, trichomes of adaxial surfaces filiform from base to tip; involucres 4.5–5 or 3–3.5 mm high; inner phyllaries with lamina oblong, apically truncate-rounded and apiculate; bisexual florets (3–)4–6 per head; fibrous-rooted, rarely slender-taprooted.
            6. Capitulescence 12–18 mm wide (pressed), uninterrrupted or rarely so and only at the base, mostly 1–6(–8) cm long; involucres 4.5–5 mm high; outer phyllaries and often lamina of inner phyllaries dark brown, the whole head commonly with a dark brown or greenish brown cast; mid phyllaries with a low subterminal keel; cypselae 0.7–0.8 mm long ____ **Gamochaeta ustulata**
            6. Capitulescence 10–12 mm wide (pressed), early uninterrupted and 1.5–5 cm long, later producing axillary glomerules from lower nodes and elongating, becoming strongly interrupted and up to 18 cm long; involucres 3–3.5 mm high; phyllaries greenish-silvery to stramineous or golden, sometimes light brown but never dark brown, the whole head not with a dark brown cast; phyllaries not keeled; cypselae 0.5–0.6 mm long ____ **Gamochaeta argyrinea**

ACKNOWLEDGMENTS

Staffs of GH, MO, NCU, NY, and US were helpful during recent study at their institutions, ARIZ, ASU, DOV, HSC, LSUS, MO, TEX, UPRRP, USCH, and USF sent loans of specimens, Nancy Elder (University of Texas Life Science Library) helped with literature, and Tom Zanoni (NY), Emily Wood (GH), and Ted Cochrane (WIS) provided specimen data. Review comments by John Pruski and

Susana Freire are appreciated. It also seems appropriate to acknowledge the obsessive compulsion of people and agencies in the southeastern U.S.A. to mow, mow, mow to nearly dirt level, creating a continuous and expansive habitat of fields, lots, lawns, and roadsides that *Gamochaeta coarctata*, *G. argyrinea*, and *G. chionesthes* spread across. These species and other colonizers can only be expected to become more abundant.

BOOK REVIEW

Gardener's Guide for *Hemerocallis*

JOHN P. PEAT and TED L. PETIT. 2004. **The Daylily: A Guide for Gardeners.** (0-88192-666-3, hbk.). Timber Press Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $29.95, 200 pp., 200+ color photographs and illustrations, 7 3/4" × 9 1/4".

Publisher Comments: "Few perennials are as tough and versatile as daylilies (genus *Hemerocallis*), and even fewer offer daylilies' enormous range of color, shape, and growing characteristics. The ease of hybridizing daylilies is a major attraction for the enthusiast. Any backyard gardener can hybridize daylilies, but this blessing of easy breeding can also be something of a curse to the newcomer. Tens of thousands of new daylilies are bred each year. How to choose and grow daylilies amidst this profusion? John Peat and Ted Petit have come to the rescue in this authoritative overview of all aspects of daylily history, cultivation, and breeding. Inspired by R.W. Munson Jr.'s classic treatment, *Hemerocallis*, they fully describe the history of the modern daylily. In the heart of the book, they detail the various types of hybrids and provide indispensable advice for growing all of them well. More than 200 beautiful color photographs and illustrations round out the work."

Hemerocallis is an ornamentally and economically important genus of ca. 15–30 species native to eastern Asia. Growers and hybridizers have developed an amazing number of cultivars over the years. According to the authors there are more than 50,000 registered daylilies and choosing the ones to include in the book was a difficult task. Actually the authors limited their selections to those that were introduced since 1992. So if you're looking for a cultivar older than 1992 you are out of luck. Besides the many colorful pics of the new cultivars, there is practical information on landscaping with daylilies, horticultural requirements, and daylily pests and diseases. IF you love daylilies you will enjoy this book.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

A NEW SPECIES OF *PTILIMNIUM* (APIACEAE) FROM THE ATLANTIC COAST

ABSTRACT

Ptilimnium ahlesii Weakley & Nesom, sp. nov., is described from localities in eight counties of North Carolina, South Carolina, and Georgia in tidal freshwater marshes within 20 miles of the Atlantic coast. The species has been previously identified as *P. capillaceum* but differs from the latter in its conspicuously large ovaries and fruits, which at maturity are 2.7–4.2 mm long and 1.8–2.2 mm wide (vs 1.4–2.5 mm long and 0.8–1.2 mm wide in *P. capillaceum*), in its less-divided leaves, and in its inflorescences with fewer umbellets per umbel and fewer flowers per umbellet. The new species also flowers and fruits earlier than *P. capillaceum* (May–early June, late May–July, vs. mid June–early August, July–September, respectively). *Ptilimnium ahlesii* is rare and restricted to freshwater or slightly brackish marshes, while *P. capillaceum* has a wider geographic range and ecological tolerance, but the two species grow in close proximity in their area of sympatry.

RESUMEN

Se describe **Ptilimnium ahlesii** Weakley & Nesom, sp. nov., de varias localidades en ocho condados de Carolina del norte, Carolina del Sur y Georgia en bordes de charcas de agua dulce en una banda de 20 millas en la costa atlántica. La especie ha sido previamente identificada como *P. capillaceum* pero difiere de ésta por los ovarios y frutos claramente más grandes, que en la madurez tienen 2.7–4.2 mm de longitud y 1.8–2.2 mm de anchura (contra 1.4–2.5 mm de longitud y 0.8–1.2 mm de anchura en *P. capillaceum*), por sus hojas menos divididas, y por sus inflorescencias con menos umbélulas por umbela y menos flores por umbélula. La nueva especie también florece antes que *P. capillaceum* (principios de mayo–junio, finales de mayo–julio, vs. mediados de junio–principios de agosto, julio–septiembre, respectivamente). *Ptilimnium ahlesii* es rara y restringida a charcas de agua dulce o ligeramente salobres, mientras que *P. capillaceum* tiene un rango geográfico y tolerancia ecológica más amplia, pero las dos especies crecen muy próximas en su área de simpatría.

An exceptionally large-fruited form of *Ptilimnium* has been observed and collected in coastal counties of North Carolina, South Carolina, and Georgia (Figs. 1, 2, and 3). This plant apparently drew the attention of the late Harry E. Ahles, then working at the University of North Carolina Herbarium (NCU), and specimens at NCU include annotations in his hand indicating his opinion that they represented an undescribed species to be named "*P. macrospermum*." In the Carolinas "Guide" (Radford et al. 1964), these plants were included in the key and species summaries as "*Ptilimnium macrospermum* Ahles." The following year, it was mapped in the Carolinas "Atlas" in Brunswick, New Hanover, and Pender

SIDA 21(2): 743–752. 2004

counties, North Carolina, and Georgetown and Jasper counties, South Carolina (Radford et al. 1965). Three years later, in the first printing of the Carolinas "Manual," this entity was placed as a synonym of *P. capillaceum* (Michx.) Raf. with the notation that the name was "a nomen nudum" attributed to Ahles, but was confusingly included in the key as "*P. macrospermum*" (Bell 1968, in Radford et al.); in later printings it was also removed from the key, presumably confirming the intent of Bell not to include the taxon. Bell (pers. comm., June 2004) states that he was uncertain of the taxonomic distinctiveness of the taxon, because of the paucity of herbarium material available, and as it had not been validly published he decided not to include it in the "Manual" (see Sorrie 1997 for examples of other unpublished names by Ahles).

The name in similar form has resurfaced in a widely used database (Kartesz 1999), as "*Ptilimnium macrospermum* Kartesz, sp. nov. ined." Additionally, the taxon has been considered to be of conservation concern by the network of Natural Heritage Programs and has been tracked as a rare species under the unofficial name "*Ptilimnium sp. 1*" in North Carolina and Georgia (Franklin 2004, Georgia Natural Heritage Program 2004). The potential conservation importance of the putative taxon demands that this taxonomic and nomenclatural confusion be resolved, and the species has been the subject of field and herbarium study by the authors since 1990. With these additional observations, we conclude that this plant is a distinctive and undescribed species. We are pleased to provide it with a valid name, allowing it to proceed in polite company, rather than under a twice-naked name ("*Ptilimnium macrospermum*"), a non-name ("*Ptilimnium sp. 1*"), or inappropriately ignored under *Ptilimnium capillaceum* (Michx.) Raf. The new epithet validated here honors the original insight of Harry E. Ahles regarding this, as well as his general contributions to the understanding of the flora of the Carolinas through his voracious collecting.

Ptilimnium ahlesii Weakley & Nesom, sp. nov. (**Figs. 1–3**). TYPE: NORTH CAROLINA. Brunswick Co.: tidal freshwater marsh of the Brunswick River, just E of the Brunswick River and just N of the US 74-76 causeway, ca. 2 mi W of Wilmington, growing with *Typha angustifolia*, *Carex hyalinolepis*, *Pontederia cordata*, *Pentandra virginica*, *Sagittaria lancifolia*, *Rumex verticillatus*, and *Taxodium distichum*, 34° 14' 04.7"N, 77° 59'05.7" (NAD 83), *Alan S. Weakley 7317 and Richard J. LeBlond*, 10 Jun 2004 (HOLOTYPE: NCU; ISOTYPES: BRIT, CLEMS, GH, MO, NY, TEX, UGA, US, USCH.

Ptilimnio capillaceo (Michx.) Raf. similis bracteis involucralibus divisis, ramis brevibus styli, et costis lateralibus fructus valde evolutis, sed differt foliis divisionibus 2–3 (versus 3) per nodum, umbellulis 5–8(–13) per umbellam, floribus 5–8 per umbellulam, fructibus majoribus (2.7–4.2 mm longis versus 1.4–2.5 mm), geographica ac habitatione multo magis restrictis, et tempore praecoci florendi ac fructificandi.

Annual, glabrous, caulescent herbs from a short system of fibrous roots, the stems erect, 4–13 dm tall, unbranched or in vigorous individuals branching above mid-stem. Lower stem leaves (often withered by anthesis) phyllodial (re-

Fig. 1. Holotype of *Ptilimnium ahlesii*. Note the nearly phyllodial lower stem leaves, the broadened segments of the mid-cauline leaves, and the large fruits (not fully mature).

Fig. 2. Inflorescence of *Ptilmnium ahlesii* (from an isotype). Note the large fruits, the divided involucral bracts, and the few umbellets/umbel and few flowers/umbellet (as compared to *P. capillaceum*)

duced to the hollow rachis and lacking lateral segments, thus closely resembling the quill-leaves of *P. fluviatile*, *P. nodosum*, and *P. viviparum*) to simply pinnate, the segments (when present) flattened, to 2 mm wide; mid- and upper-stem leaves pinnately decompound, 3–21 cm long, the segments filiform to distinctly flattened, with 2–3 divisions at primary nodes on the rachis; petioles 3–25 mm long, broadly winged, ca 5-ribbed. Inflorescence umbellate, distinctly and irregularly flat-topped (the rays variable in length), once-compound, the umbels terminal and axillary on the upper half of the stem, peduncles 5–14 cm

Fig. 3. Fruits (nearly but not fully mature) of *Ptilimnium ahlesii*, from an isotype.

long; primary rays 5–13, 5–35 mm long, pedicels (2–)4–10, (3–)5–10 mm long; involucre of linear bracts, entire or 3-parted; involucel of linear bracts. Calyx teeth deltoid, acute to subacuminate, persistent; petals white, obovate, 0.6–0.8 mm long; stylopodium conic, the styles mostly slightly shorter than the stylopodium, ascending to erect-ascending or widely spreading; anthers light purplish. Carpophore bifid at the apex. Fruit elliptic-ovoid, slightly compressed laterally, 2.7–3.5 mm long, 1.8–2.2 mm wide, the mericarps loosely connate and usually separated at maturity; dorsal ribs 3, narrow and sharp-edged, the lateral ribs similar but with a broad, rounded, corky-thickened extension, the extensions of the adjacent mericarps connate and forming a broad, conspicuous band around the fruit; oil tubes dark rusty-brown. In tidal freshwater marshes; flowering May to early June, fruiting late May to July.

Collections examined. **UNITED STATES. GEORGIA. Chatham Co.:** Savannah National Wildlife Refuge, along Hwy 17, fresh-water marsh, 14 Jul 1966, *Bozeman 6100* (NCU, distributed as "*Ptilimnium macrospermum* Ahles"). **NORTH CAROLINA. Brunswick Co.:** Wilmington, Jun 1898, *Ashe s.n.* (NCU). **New Hanover Co.:** 1 mi N of US 17 on Wrightsboro Road, marsh, 2 Jun 1949, *Radford 4353* (NCU); brackish marsh on the Cape Fear River on US 17, 29 Jun 1963, *Ahles 58397* (NCU) **Pender Co.:** swamp on Northeast Cape Fear River near Rocky Point—Hampstead Road, 1 Jun 1950, *Radford 5142* (NCU). **SOUTH CAROLINA. Beaufort Co.:** 0.5 mi W of Co. Road 111 on Co. Road 33, cat-tail swamp near Trichinham Plantation, 27 Jun 1956, *Bell 3767* (NCU). **Berkeley Co.:** Cooper River at the mouth of Durham Creek, low salinity, 7 Jun 1990, *McAninch 23* (NCU). **Colleton Co.:** 1.4 mi NE of Ashepoo on US Hwy 17, swamp, 26 Jun 1956, *Bell 3703* (NCU). **Georgetown Co.:** tidal marsh of Baruch Plantation, 20 Jun 1967, *Barry 103* (USCH); Baruch Plantation, fresh-water marsh affected by tidal action, 17 Jun 1969, *Batson s.n.* (USCH); Baruch Plantation, slough in freshwater marsh, 27 Jun 1969, *Batson s.n.* (USCH); occasional in sunny spots in wet swampy woods, W side of South Island Road (S-18) about 4 mi W of Intracoastal Waterway, 16 May 1990, *Nelson 9024* (USCH); Sampit River near US 17A, 9.5 mi W of Georgetown, fresh-water marsh, 13 Jun 1957, *Radford 25139* (NCU).

Relationships within the genus

Ptilimnium is a relatively small genus centered in the southeastern and south-central United States. The five to seven species are separable into subgroups on the basis of differences in morphology and chromosome number, although apparent dysploid differences in chromosome number suggest that the situation may be more complex than the current assessment allows. Plants with leaves reduced to a winged petiole and extended rachis (with lateral segments suppressed, the structures sometimes referred to as "phyllodia") are diploids based on $x = 6$ ($2n = 12$; Easterly 1957; Bell & Constance 1960). These plants have been regarded as comprising from one to three species, *P. nodosum* (Rose) Mathias, *P. viviparum* (Rose) Mathias, and *P. fluviatile* (Rose) Mathias) (Kral 1981; Kress et al. 1994; Bartgis 1997); the appropriate taxonomic disposition remains unclear and is under additional study. *Ptilimnium costatum* (Ell.) Raf. has distinctly petiolate leaves with short, crowded, verticillate segments, long styles, and a tetraploid chromosome complement based on $x = 8$ ($2n = 32$; Easterly 1957). One population of *P. costatum* from Illinois has been counted as $2n = 22$ (Bell & Constance 1960), this perhaps a tetraploid ($x = 6$, $2n = 24$) having lost one pair of chromosomes.

Ptilimnium ahlesii, *P. capillaceum*, and *P. nuttallii* are similar in their relatively short styles (shorter than or equalling the stylopodia) and primarily diploid chromosome number based on $x = 7$ ($2n = 14$; Easterly 1957, Bell and Constance 1960). Tetraploid plants ($2n = 28$) of *P. capillaceum* were reported by Easterly (1957) from central Georgia (Unadilla County). These were found apparently intermixed with diploid plants of the same species and with plants of *P. nodosum* "nearby in the same ditch." Easterly did not comment on any morphological difference between the conspecific diploids and tetraploids. One population of *P. capillaceum* from Florida has been counted as $2n = 16$ (Constance et al. 1976). It is notable that the basal and lower stem leaves of *P. ahlesii*, produced in the spring and typically withering prior to flowering and fruiting, have few to no leaflets, and therefore closely resemble the reduced "quill leaves" of the "Harperella" group of *Ptilimnium* (*P. fluviatile*, *P. nodosum*, and *P. viviparum*). This supports the broader circumscription of *Ptilimnium* as including *Harperella* Rose that has been generally followed in recent decades.

Ptilimnium texense Coulter & Rose was originally described as a species (Coulter & Rose 1909) but later (Mathias & Constance 1944–45; Easterly 1957) interpreted to be of hybrid origin and of intermediate morphology between *P. capillaceum* and *P. nuttallii*. This interpretation has been accepted and repeated by subsequent workers (e.g., Correll & Johnston 1970; Correll & Correll 1972), although Mathias & Constance (1961) placed it in synonymy, without comment, under *P. costatum*. Study of *Ptilimnium* collections at LL,TEX shows only a single entity in Texas (interpreted here as *P. costatum*) other than *P. capillaceum* and *P. nuttallii*.

In the freshwater tidal marshes west of Wilmington, North Carolina, three species of *Ptilimnium* grow in close proximity to one another: *Ptilimnium ahlesii*, *P. capillaceum*, and *P. costatum*. They are morphologically distinctive; no intermediates have been seen. Observations over the past decade further suggest that the flowering times of the three species are largely or completely non-overlapping, with *P. ahlesii* flowering first (May to early June), followed by *P. capillaceum* (mid-June to early August), and then *P. costatum* (late July to August). The phenologic separation provides additional evidence corroborating the status of *P. ahlesii* as a distinct taxon and not merely a large-fruited form of *P. capillaceum*.

Of its closest relatives, *Ptilimnium ahlesii* is most similar to *P. capillaceum*, particularly in its divided involucral bracts, minute calyx teeth, dorsal fruit ribs narrower than the intervals, and lateral ribs with expanded, corky margins encircling the fruit like a band (*P. costatum* also shares the distinctive fruit morphology). The two species are separated by the following contrasts (and see Figs. 1 and 2).

1. Mature fruit elliptic-ovate, 2.7–4.2 mm long, 1.8–2.2 mm wide; umbels flat-topped, irregular, the rays variable in length; umbellets 5–8(–13) per umbel, the rays 5–35

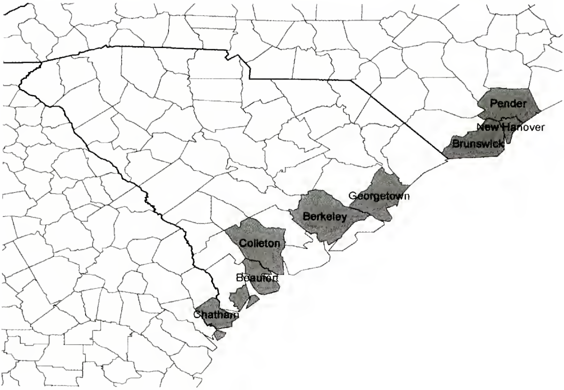

Fig. 4. Map of documented county distribution (in, from north to south, North Carolina, South Carolina, and Georgia) of *Ptilimnium ahlesii*.

mm long; flowers 5–8 per umbellet; petals 0.6–0.8 mm long; leaf segments of mid-stem leaves 15–30(–40), capillary to linear, 0.5–2.0 mm wide; flowering May-early June, fruiting late May-July; tidal freshwater marshes, rare in North Carolina, South Carolina, and Georgia __________ **Ptilimnium ahlesii**

1. Mature fruit ovate to orbicular, 1.4–2.5 mm long, 0.8–1.2 mm wide; umbels generally rounded to hemispheric, the rays generally nearly equal in length; umbellets (5–)9–21 per umbel, the rays 5–21 mm long; flowers usually 10 or more per umbellet; petals 0.3–0.6 mm long; leaf segments of mid-stem leaves 50 or more, capillary, usually less than 0.5 mm wide (except in submersed leaves); flowering June-August, fruiting July-September; ditches, marshes, other wet places; common and widespread in eastern North America, ranging from Massachussetts and New York to Missouri and Kansas, south to Florida and Texas __________ **Ptilimnium capillaceum**

Descriptions by various authors (e.g., Fernald 1950; Mathias and Constance 1944–45; Easterly 1957) of *P. capillaceum* with fruit longer than 3 mm almost certainly included observations of *P. ahlesii*. Annotations by both Constance and Easterly of NCU collections of *P. ahlesii* as *P. capillaceum* appear to confirm this. Associated with the smaller number of umbellets and flowers borne by *P. ahlesii*, as noted in the key, plants produce about 45–70 flowers/fruits per inflorescence, compared to those of *P. capillaceum*, which usually produce over 100. Depauperate plants of *P. capillaceum*, however, can have reduced inflorescences.

It appears that this species is narrowly distributed ecologically and geographically, to tidal marshes associated with the tidal reaches of rivers in southeastern North Carolina, South Carolina, and eastern Georgia (Fig. 4).

ACKNOWLEDGMENTS

We thank the staffs of LL-TEX, NCU, and US for help with herbarium studies at their institutions and staff of USCH for a loan of specimens. Richard LeBlond (North Carolina Natural Heritage Program) assisted with field studies. Ronald L. Hartman and an anonymous reviewer provided helpful suggestions.

ABSTRACT

The following new combinations in the Caryophyllaceae are proposed: *Arenaria lanuginosa* var. *saxosa*, *Eremogone ferrisiae*, *Minuartia nuttallii* vars. *fragilis*, *gracilis*, and *gregaria*, and *Paronychia chartacea* var. *minima*.

Key words: Caryophyllaceae, *Arenaria*, *Minuartia*, *Eremogone*, *Paronychia*.

RESUMEN

Se proponen las siguientes combinaciones nuevas en Caryophyllaceae: *Arenaria lanuginosa* var. *saxosa*, *Eremogone ferrisiae*, *Minuartia nuttallii* vars. *fragilis*, *gracilis*, y *gregaria*, y *Paronychia chartacea* var. *minima*.

During the course of our work on the treatments of *Arenaria*, *Minuartia*, and *Paronychia* for Flora of North America (Hartman, Rabeler, and Utech, in prep.; Rabeler, Hartman, and Utech, in prep.; and Hartman, Thieret, and Rabeler, in prep., respectively), we found the following combinations necessary to consistently treat infraspecific variation.

Arenaria lanuginosa (Michx.) Rohrb. var. **saxosa** (A. Gray) Zarucchi, R.L. Hartman & Rabeler, comb. et stat. nov. Basionym: *Arenaria saxosa* A. Gray, Smithsonian Contr. Knowl. 5 (Art. 6):280 [Plantae Wrightianae, pt. 2:18]. 1853, priority of the autonym established by *A. saxosa* var. *cinerascens* B.L. Rob., Proc. Amer. Acad. Arts 29:293. 1894.

The varietal combination often used for this plant, *Arenaria lanuginosa* var. *cinerascens* (B.L. Rob.) Shinners, is not correct because of Art. 11.6 of the International Code (Greuter et al. 2000) which states that "an autonym is treated as having priority over the name or names of the same date and rank that established it."

Minuartia nuttallii (Pax) Briq. var. **fragilis** (Maguire & A.H. Holmgren) Rabeler & R.L. Hartman, comb. nov. Basionym: *Arenaria nuttallii* Pax subsp. *fragilis* Maguire & A.H. Holmgren, Madroño 8:260. 1946. *Arenara nuttallii* var. *fragilis* (Maguire & A.H. Holmgren) C.L. Hitchc., Vasc. Pl. Pacific North W. 2:258. 1964. *Minuartia nuttallii* subsp. *fragilis* (Maguire & A.H. Holmgren) McNeill, Rhodora 82:499. 1980.

Minuartia nuttallii (Pax) Briquet var. **gracilis** (B.L. Rob.) Rabeler & R.L. Hartman, comb. nov. Basionym: *Arenaria nuttallii* Pax var. *gracilis* B.L. Rob., Proc. Amer. Acad.

Arts 29:304. 1894. *Arenaria nuttallii* subsp. *gracilis* (B.L. Rob.) Maguire, Madrono 8:261. 1946. *Minuartia nuttallii* subsp. *gracilis* (B.L. Rob.) McNeill, Rhodora 82:499. 1980.

Minuartia nuttallii (Pax) Briquet var. **gregaria** (A. Heller) Rabeler & R.L. Hartman, comb. et stat. nov. BASIONYM: *Arenaria gregaria* A. Heller, Bull. S Calif. Acad. Sci. 2:67. 1903. *Alsinopsis gregaria* (A. Heller) A. Heller, Muhlenbergia 8:96. 1912. *Arenaria nuttallii* Pax subsp. *gregaria* (A. Heller) Maguire, Fl. Calif. 1:492. 1914. *Arenaria nuttallii* var. *gregaria* (A. Heller) Jepson, Madrono 8:261. 1946. *Minuartia nuttallii* subsp. *gregaria* (A. Heller) McNeill, Rhodora 82:499. 1980.

While the four infraspecific entities traditionally recognized within *Arenaria* (*Minuartia*) *nuttallii* Pax are often distinct, occasional specimens, especially of varieties *fragilis* and *gracilis*, do intergrade where their ranges overlap, especially in Oregon and Nevada. All have been treated as varieties in at least one earlier treatment of this group and we feel that this is the appropriate rank.

Paronychia chartacea Fernald var. **minima** (L.C. Anderson) R.L. Hartman, comb. et stat. nov. BASIONYM: *Paronychia chartacea* Fernald subsp. *minima* L.C. Anderson, Sida 14:436. 1991.

Postscript.—After additional study of *Eremogone macradenia* (S. Watson) Ikonn., we now believe that *E. macradenia* should be split into two taxa with *E. macradenia* var. *ferrisiae* (Abrams) R.L. Hartman & Rabeler being elevated to species rank (Hartman & Rabeler 2004).

Eremogone ferrisiae (Abrams) R.L. Hartman & Rabeler, comb. nov. BASIONYM: *Arenaria macradenia* S. Watson subsp. *ferrisiae* Abrams, Ill. Fl. Pacif. States 2:151. 1944. *Eremogone macradenia* (S. Watson) Ikonn. var. *ferrisiae* (Abrams) R.L. Hartman & Rabeler, Sida 21:240. 2004.

ACKNOWLEDGMENTS

We wish to acknowledge James Zarucchi (MO) for discovering that the *Arenaria* combination was required and to Kanchi Gandhi (GH) for confirming this fact. Curators of F, MICH, and RM are thanked for providing specimens of the *Minuartia nuttallii* complex.

ABSTRACT

Within the treatment of *Solidago*, Torrey and Gray (1842), there are no textual indicators of the ranks intended for subdivision of the genus, and all of the Torrey and Gray names for subdivisions of *Solidago* are rankless. The new combination **Solidago** sect. **Ptarmicoidei** is made.

RESUMEN

En el tratamiento de *Solidago*, Torrey y Gray (1842), no hay indicadores textuales de los rangos que se hacen para la subdivisión del género, y todos los nombres de Torrey y Gray para las subdivisiones de *Solidago* no tienen rango. Se hace la nueva combinación **Solidago** sect. **Ptarmicoidei**.

Discussions concerned with the ranks of names of subdivisions of genera published by Torrey and Gray (1842) led to the conclusion that by and large such names are rankless unless a rank was explicitly indicated within the text (John Strother, John Pruski, John McNeill, pers. comm. with K.N. Gandhi). Torrey and Gray used the symbol § to represent either a subgenus or section. Unless a rank is explicitly indicated, names marked by the symbol § are rankless as are lower level names marked by indicators such as *, **, *** etc. Within the treatment of *Solidago* (Torrey and Gray 1842, pp. 195-231), there are no textual indicators of the ranks intended, and thus all of the Torrey and Gray infrageneric names in *Solidago* are rankless.

In Gray (1884), sectional and subgeneric ranks are clear. In his preface (vol. 2(1). 1878), Gray used the symbol § and large-type capital letters for names of sections and subgenera. He used nouns for names of subgenera and adjectives for names of sections. Additionally, Gray did mention subsection and further lower divisions (he did not mention series or subseries); he used the symbols *, **, etc. and small-type capital letters for names of subsections. By implication, a *, **, etc. denoted the rank of subsection because those symbols are placed at the beginning of the diagnostic statement and sectional name immediately follows the statement. One may dispute this; we go by implication. For example, *Solidago* [rankless] *Corymbosae* Torr. & A. Gray (in 1842) can be taken as *Sol-*

idago subsect. *Corymbosae* (Torr. & A. Gray) A. Gray (in 1884) because Gray (1884) listed it as "***** ... CORYMBOSAE" [small capitals].

Nesom (1993) summarized the infrageneric taxonomy of *Solidago* and lectotypified some names. He treated the corymbiform, oligoneurate species in a separate genus *Oligoneuron* Small. He accepted Torrey and Gray names with ranks generally accepted at that time by other authors following the rationale for doing so presented by Holmgren (1979) and Jones (1980). Nesom did not validate *Solidago* sect. *Corymbosae* Torr. & A. Gray. One of the criteria for valid publication of a name is that the author (in this case Nesom) must accept and use the name. Nesom cited "Solidago sect. Corymbosae T. & G." as a synonym of *Oligoneuron* sect. *Ptarmicoidei* (House) Nesom; therefore, he did not validate the former name. Semple, Ringius and Zhang (1999) followed Nesom's infrageneric nomenclature, except that they treated *Oligoneuron* as *Solidago* sect. *Corymbosae* Torr. & A. Gray with synonyms but did not list full bibliographic data for each name. Had they done so, they might have inadvertently validated the name at sectional rank.

Solidago L. sect. **Ptarmicoidei** (House) Semple & Gandhi, comb. nov. Based on *Aster* sect. *Ptarmicoidei* House, N.Y. State Mus. Bull. 254. 710. 1924, nom. et stat. nov. based on *Unamia* Greene (1903). *Oligoneuron* sect. *Ptarmicoidei* (House) G.L. Nesom, Phytologia 75:27. 1993. TYPE: *Inula alba* Nutt. = *Aster ptarmicoides* Torr. & A. Gray = *Solidago ptarmicoides* (Torr. & A. Gray) Boivin. [*Solidago asteroides* Semple (in Semple, Ringius and Zhang, U. Waterloo Biol. Ser. 39:72. 1999.) is a superfluous later name for the nomenclatural type because the much older *Aster ptarmicoides* Torr. & A. Gray is accepted as legitimate (see Voss 1996).]

Solidago [rankless] *Corymbosae* Torr. & A. Gray, Fl. N. Amer. 2(2):208. 1842. *Solidago* subsect. *Corymbosae* (Torr. & A. Gray) A. Gray in A. Gray et al., Syn. Fl. N. Amer. 1(2):159. 1884. TYPE: *S. corymbosa* Elliott.

Names of subdivisions of genera are automatically typified by the species name from which the name of the subdivision is derived. For group *Corymbosae*, Torrey and A. Gray included *S. corymbosa*. Nesom (1993:26) erred in designating *Solidago rigida* L. as the lectotype.

Oligoneuron Small, Fl. SE. U.S. 1188. 1903. *Solidago* subg. *Oligoneuron* (Small) House, N.Y. State Mus. Bull. No. 254. 693. 1925. LECTOTYPE [Nesom 1993:26]: *Oligoneuron rigidum* (L.) Small = *Solidago rigida* L.

Unamia Greene, Leafl. Bot. Observ. 1:6. 1903. TYPE: *Inula alba* Nutt. = *Unamia ptarmicoides* (Torr. et A. Gray) Greene, nom. superfl. for *Unamia. alba* (Nutt.) Rydb.

Oligoneuron ser. *Ptarmicoidei* (House) G.L. Nesom, Phytologia 75:28. 1993. *Aster* sect. *Ptarmicoidei* House, N.Y. State Mus. Bull. 254. 710. 1924. TYPE: *Inula alba* Nutt. = *Aster ptarmicoides* Torr. & A. Gray = *Solidago ptarmicoides* (Torr. & A. Gray) Boivin = *Oligoneuron album* (Nutt.) G.L. Nesom.

Oligoneuron ser. *Xanthactis* G.L. Nesom, Phytologia 75:28. 1993. TYPE: *Oligoneuron riddellii* (Frank) Rydb. = *Solidago riddellii* Frank.

Other nomenclatural decisions made by Nesom (1993) related to the rankless Torrey and Gray names include:

Solidago sect. *Solidago*

Solidago subsect. **Maritimae** (Torr. & A. Gray) G.L. Nesom, Phytologia 75:12. 1993.

Based on *Solidago* [rankless] *Maritimae* Torr. & A. Gray, Fl. N. Amer. 2(2):211. 1842. LECTOTYPE [Nesom 1993:12]: *Solidago sempervirens* L. [Nesom made this subsectional name inadvertently.]

Solidago subg. *Stenactila* Raf., Fl. Tellur. 2:42. 1836 [1837]. LECTOTYPE [Nesom 1993:12]: *Solidago sempervirens* L.

Solidago [rankless]] *Uliginosae* Mackenzie in Small, Man. SE. Fl. 1345, 1347. 1933. TYPE: *Solidago uliginosa* Nutt. cited under *Solidago uniligulata* (DC.) Porter.

Solidago subsect. **Triplinerviae** (Torr. & A. Gray) G.L. Nesom, Phytologia 75:8. 1993. *Solidago* [rankless] *Triplinerviae* Torr. & A. Gray, Fl. N. Amer. 2(2):222. 1842; A. Gray, Syn. Fl. N. Amer. 1(2):155. 1884. LECTOTYPE [Nesom 1993:8]: *Solidago canadensis* L. [Nesom made this subsectional name inadvertently.]

Solidago subg. *Brachyactis* Raf., Fl. Tellur. 2:42. 1836. TYPE: *Solidago juncea* Aiton. Nesom (1993:8) erred in designating a LT.; Raf. designated *S. juncea* as the type.

Solidago subg. *Triactis* Raf., Fl. Tellur. 2:42. 1836 [1837]. TYPE: *Solidago retrorsa* Michx. Nesom (1993:11) erred in designating a LT.; Raf. designated *S. retrorsa* as the type.

Solidago [rankless] *Serotinae* Rydb., Fl. Rocky Mts. 868. 1917. TYPE: *Solidago serotina* Aiton (1789), non Retz. (1781) = *Solidago gigantea* Ait.

Solidago [rankless] *Serotinae* Mackenzie in J. K. Small, Man. SE. Fl. 1345, 1350. 1933, non Rydb. (1917). TYPE: *Solidago serotina* Retz. (1781), non Ait. (1789) = ? *S. tortifolia* Ell. (1824).

Legendary Plant Hunter George Forrest

BRENDA MCLEAN. 2004. **George Forrest: Plant Hunter.** (1-85149-461-8, hbk) Antique Collectors' Club Ltd., Eastworks, 116 Pleasant Sreet, Suite 60B, Easthamton, MA 01027, U.S.A. (Orders: 413-529-0861, Fax: 413-529-0862, www.antiquecc.com). $59.50, 250 pp., 80 color and 80 b/w illustrations, 8 1/4" × 11".

Publisher Comments: "George Forrest was a legendary plant collector in the heyday of the British Empire. His career spanned the decades before and after the First World War. Risking his safety and health, he discovered hundreds of new species, introduced many plants to our gardens, and became one of the most outstanding plant collectors in the Sino-Himalaya. As many plants were named after him, he is well known in gardening circles yet this is the first biography of Forrest, and the first book on him for fifty years."

"This book, published to celebrate the centenary of Forrest's first setting out for the mountains of Yunnan, south-west China, brings Forrest to life, drawing on his own letters and those of his contemporaries. It tells of Forrest's adventures and his escape from death at the hands of warring Lamas. It shows the influence of his patrons, describes the excitement of his plant and animal discoveries, and reveals his rivalry with other plant hunters, Reginald Farrer and Frank Kingdon Ward."

I like to read about explorers, adventurers, and discoverers and George Forrest was such a person. He was a naturalist. Appendix 9 in the book lists some 175 genera of plants with a *forrestii* species named after George Forrest. There is a dragonfly (*Temnogomphus forrestii*) named after George Forrest. Then there are birds named after George Forrest. Not just one but six different genera with species named *forresti*. Oh wait, there are some mammals that bear the species name *forresti*, not to mention the 20 or so taxa described as new from Forrest's mammal collection at the Natural History Museum, London (Appendix 10). George Forrest realized he had the support of many people and I'm sure he thanked them in many different ways, but Forrest did the botanist/collector thank you by naming many of his newly discovered plants after them.

If you enjoy the history of exploration then the book—*George Forrest: Plant Hunter*—is for you.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

MISCELLANEOUS NOMENCLATURAL CHANGES IN ASTEREAE (ASTERACEAE)

John C. Semple

Department of Biology
University of Waterloo
Waterloo, Ontario, CANADA N2L 3G1
jcsemple@sciborg.uwaterloo.ca

ABSTRACT

The following new name and combinations are proposed: ***Heterotheca subaxillaris*** subsp. ***latifolia***, ***Solidago*** subsect. ***Multiradiatae***, and ***Symphyotrichum concolor*** var. ***devestitum***.

RESUMEN

Se proponen un nombre nuevo y varias combinaciones: **Heterotheca subaxillaris** subsp. **latifolia**, **Solidago** subsect. **Multiradiatae**, y **Symphyotrichum concolor** var. **devestitum**.

The proposed new name and combinations were determined to be needed during work to prepare the treatments of *Heterotheca* (Semple 2005), *Solidago* (Semple & Cook 2005) and *Symphyotrichum* (Brouillet et al. 2005) for the Flora North America project.

Heterotheca subaxillaris (Lam.) Britt. & Rusby subsp. **latifolia** (Buckley) Semple, comb. et stat. nov. BASIONYM: *Heterotheca latifolia* Buckley, Proc. Acad. Sci. Phila. 13:459. 1862. *Heterotheca subaxillaris* (Lam.) Britt. & Rusby var. *latifolia* (Buckley) Gandhi & Thomas, Sida Bot. Misc. 4:110. 1989. TYPE: TEXAS. Llano Co.: *Buckley s.n.* (HOLOTYPE: PH, not seen).

The weedy *Heterotheca subaxillaris* complex has been treated as a single species without varieties (Nesom 1990) and as four separate species: *H. chrysopsides* DC., *H. latifolia*, *H. psammophila* Wagenknecht, and *H. subaxillaris* (Semple 1996 and earlier authors). Harms (1964) presented data supporting Wagenknecht's (1960) division of the complex into four species and provided a general range map of the four taxa. Nesom (1990) opted to merge all four species into a single undivided species because he did not find taxonomically significant differences between the four putative species. Semple (1996) continued to followed Wagenknecht and Harms. However, after considerable study of members of the complex, I have adopted Nesom's position that only one species should be recognized (Semple 2005). Nonetheless, while much of the supposed differences between regional taxon do not appear to be supported, some phytogeographic patterns in variation occur within the complex and two infraspecific taxa can be recognized based on differences in phyllary traits. Typical *Heterotheca subaxillaris* is for the most part confined to the outer coastal plain from New York to northern Mexico, where they can occur further inland. These plants have a well developed tuft of larger hairs near the phyllary tips (Figs. 1A–H) and are treated here as subsp. *subaxillaris*. This combination of distinctive morphology plus the geographic isolation of much of the range of the morphotype warrant subspecies level recognition following Semple (1974). In contrast, plants of subsp. *latifolia* have phyllaries without such large hairs concentrated near the tip (Figs. 1I–L). Mid series phyllaries of subsp. *subaxillaris* on average are slightly wider (0.62 mm wide) compared to the average width of those of subsp. *latifolia* (0.57 mm wide) with the narrowest occurring in Arizona and New Mexico plants ("psammophila'). However, the ranges in widths overlap so much that the trait cannot be used as a diagnostic difference.

Within each subspecies there appear to be patterns to the phyllary variation but these are not sufficiently strong that additional infraspecific taxa can be justifiably recognized at this time. There is a general geographic trend to the variation in tufted hairs in subsp. *subaxillaris*. Plants with the most hairs in the apical tuft occur from Mexico to Florida (Figs. 1A–D), while the number of hairs generally decreases from Florida to New Jersey and New York (Figs. E–H). Plants with a few hairs near the apex occur scattered across the range of the species and may represent introductions of subsp. *subaxillaris* or the occasional more hairy than normal individual of subsp. *latifolia*. Plants occurring in an arch from Arizona and adjacent New Mexico through Mexico into trans-Pecos Texas tend to be more densely glandular than plants from elsewhere in the range (Fig. 1L) in the United States; these have been treated as *H. psammophila* Wagnknecht. Plants from northeastern Mexico tend to have more glands and more hairs on the mid series phyllaries and are more likely to be weakly perennial; these have been treated as *H. chrysopidis*. Plants treated previously as *H. latifolia* tend to have fewer hairs and fewer glands on the phyllaries than other members of subspecies *latifolia*. These occur across the southern prairies and through the south eastern U.S. on the Piedmont as shown in Harms (1965), although the weedy nature of the species appears to be facilitating dispersal into the range of subsp. *subaxillaris* on occasion. Additional study may find new evidence supporting recognition at varietal or subspecies level for the *psammophila* and *chrysopsides* morphs, but my recent efforts have not discovered such evidence.

Solidago subsect. **Multiradiatae** Semple, subsect. nov. Type: *Solidago multiradiata* L. *Solidago* ser. *Multiradiatae* Juz., Fl. URSS 25:47. 1959. nom. invalid, no Latin diagnosis. *Solidago* subsect. *Multiradiatae* (Juz.) Semple, Sida 20:1605. 2003. non valid name. Type: *Solidago multiradiata* Aiton (**Fig. 2A**).

Solidagini sect. *Solidago* accedens sed capitulescentiis corymbiformis rotundatis differt.

Members of subsect. *Multiradiatae* are distinguished from other species in sect. *Solidago* by having a somewhat rounded-corymbiform capitulescence. Other North America members of the section have variously paniculiform

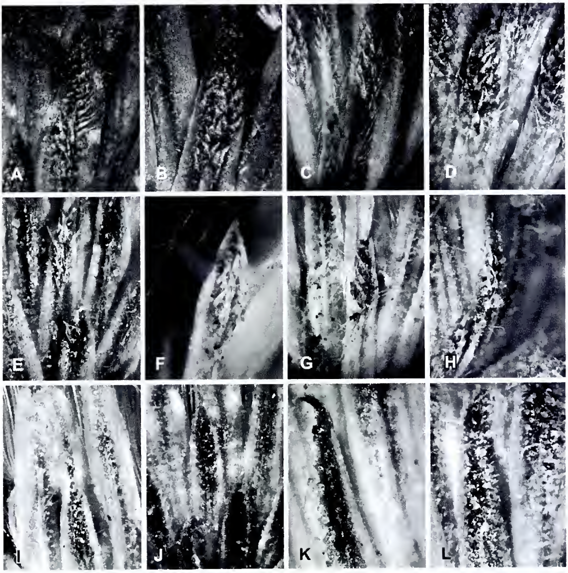

Fig. 1. Phyllary tip variation in *Heterotheca subaxillaris*. **A–H.** Subsp. *subaxillaris*. **A–B.** Mexico. **A.** Veracruz, *Turner 15372* (TEX). **B.** Tamaulipas, *LaSueur 496* (TEX). **C–H.** United States. **C.** Texas, Cameron Co., *King 2* (MINN). **D.** Louisiana, Cameron Par., *Dutton & Pritchett 2549* (WAT). **E.** Florida, Orange Co., *Semple et al. 2557* (WAT). **F.** North Carolina, Brunswick Co., *Bright 6236* (MINN). **G.** New Jersey, Gloucester Co., *Long 60507* (MINN). **H.** New York, Queens Co., *Semple 2031* (WAT). **I–L.** Subsp. *latifolia*. **I.** Mexico, Chihuahua, *Sundberg & Lavin 2811* (TEX; "chrysopsides"). **J–L.** United States. **J.** Georgia, Elbert Co., *Coile 1626* (WAT). **K.** Oklahoma, Caddo Co., *Semple 2735* (WAT). **L.** Arizona, Maricopa Co., *Lehto L19116* (WAT; "psammophila").

capitulescences [*S.* subsect. *Humiles* (Rydberg) Semple]. Like most other taxa in the genus, the phyllaries have a single vein. In robust plants the capitulescence becomes more paniculiform as branches develop from upper stem leaves. Two other species besides the nomenclatural type are included in the subsection: *S. leiocarpa* DC. (Fig. 2B) and *S. spithamaea* M.A. Curtis ex A. Gray (Fig. 2C). These are both narrowly distributed endemics in eastern North America (Semple & Cook 2005). *Solidago leiocarpa* (synonym: *S. cutleri* Fern.) includes tetraploids

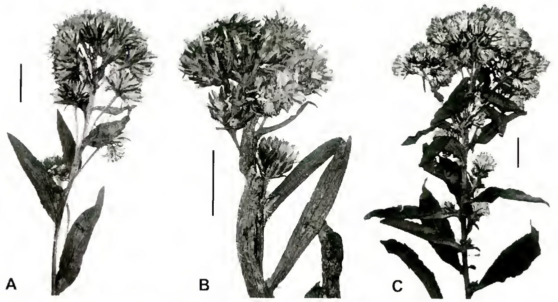

Fig. 2. *Solidago* subsect. *Multiradiatae*, capitulescences. **A.** *Solidago multiradiata*, Yukon, *Chmielewski et al. CC3824* (WAT). **B.** *Solidago leiocarpa*, New Hampshire, *Ringius 1584* (WAT). **C.** *Solidago spithamaea*, North Carolina, *Semple & Suripto 9669* (WAT). Scale bars = 1 cm.

found at disjunct high elevations in eastern New York, the Green Moutains in Vermont, the White Mountains in New Hampshire, and on Mt. Katadhin and a few higher peaks in Maine (Beaudry 1963; Morton 1981; Magee & Ahles 1999). *Solidago spithamaea* includes hexaploids restricted to the highest granitic outcrops in the mountains of western North Carolina (Cronquist 1980; Semple et al. 1984; Semple & Cook 2004). *Solidago multiradiata* includes diploids and tetraploids and is widely distributed across northern North America from the Maritimes to Alaska across Canada and down the cordillera at higher elevations in the western United States to California, Arizona, Nevada, and New Mexico (Semple et al. 1999). Other goldenrods that can have a rounded-corymbiform capitulescence occur in *Solidago* sect. *Ptarmicoidei* Semple & Gandhi, but these have striate phyllaries ((Semple & Gandhi 2004). *Solidago wrightii* A. Gray sometime can also have a rounded somewhat corymbiform capitulesence, but the species has short-petiolate mid stem leaves and often glandular phyllaries (Semple & Cook 2005).

Kanchi H. Gandhi (pers. comm.) noted that my combination proposed last year (Semple 2003) was based on an invalid basionym because the protologue lacked a Latin diagnosis.

Symphyotrichum concolor (L.) Nesom var. **devestitum** (S.F. Blake) Semple, comb. nov. Basionym: *Aster concolor* L. var *devestitus* S.F. Blake, Rhodora 32:145. 1930. Type: U.S.A. Florida. Bay Co.: Lynn Haven, in dry sandy open soil, 13 Oct 1921, *Billington 80* (holotype: US-1116195!).

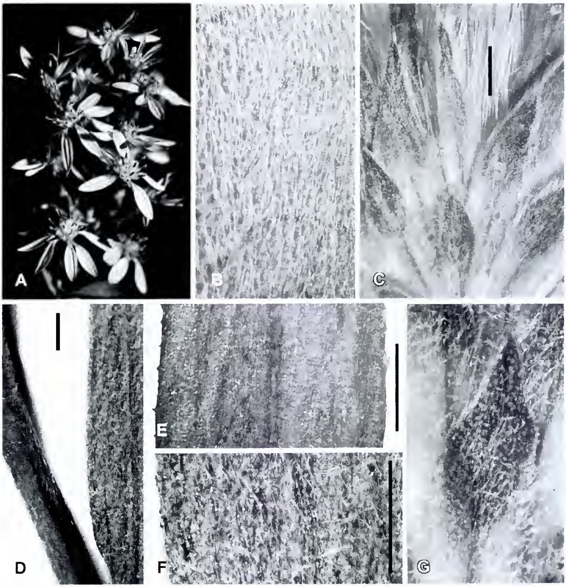

Fig. 3. Morphology of *Symphyotrichum concolor*. **A.** Flowering heads, Florida. **B–C.** Variety *concolor*. **B.** Mid stem leaf surface; Georgia, *Semple & Chmielewski 6213* (WAT). **C.** Phyllaries; Florida, Suwanee Co., *Semple, Brouillet & Canne 3930* (WAT). **D–G.** Variety *divestitum*, Florida; **E,** Bay Co., *Semple & Godfrey 3118*; **D, F–G,** Santa Rosa Co., *Semple, Brouillet & Canne 3880* (WAT). **D.** Mid stem and leaf. **E–F.** Mid stem leaf surfaces. **G.** Phyllary. Scale bar = 1 mm in C, E–F and 1 cm in D.

Symphyotrichum concolor is characterized by its narrow, elongate capitulescence of usually many, violet-rayed heads (Fig. 3A). The var. *concolor* has more moderately to densely silky pubescent leaves and phyllaries (Figs. 3B–C), while var. *devestitum* has glabrous to very sparsely pubescent stems and glabrate to sparsely pubescent leaves and phyllaries (Figs. 3D–G). Plants similar to the type of var. *devestitum* occur in the western Florida Panhandle. The involucres of such Florida plants tend to be larger than those of diploid var. *concolor* (Blake 1930). Very sparsely pubescent-leaved individuals also occur in southern Miss., Ala., Ga., and S.C. These may prove to belong in var. *devestitum* pending more detailed study. Semple (1984) described and illustrated the distribution of diploids (2n = 8) and tetraploids ($2n = 16$) in *S. concolor* under the name *Virgulus concolor*, but did not discuss varieties and noted incorrectly that no obvious differences occurred between diploids and tetraploids. In Florida, the range of tetraploids is contained within the range of var. *devestitum*; tetraploids are currently unknown outside Florida. Cytovouchers of tetraploids in WAT have glabrous to sparsely pubescent leaves and belong in var. *devestitum*. The tetraploid condition may account for the larger involucres.

ACKNOWLEDGMENTS

This research was supported by a Natural Sciences and Engineering Council of Canada Discovery Grant to the author. Joanna Stinson assisted in collecting data on phyllary variation in the *Heterotheca subaxillaris* complex. Guy Nesom is thanked for his helpful review of the manuscript.

BOOK NOTICES/BOOKS RECEIVED

RICARD SOLE and BRIAN GOODWIN. 2000. **Signs of Life: How Complexity Pervades Biology.** (0-465-01928-5, pbk.). Basic Books, 387 Park Avenue South, New York, NY 10016, U.S.A. (Orders: 212-340-8100, Fax: 212-340-8115, www.basicbooks.com) $17.50, 322 pp., b/w photos, drawings, and diagrams, 6" × 9 1/4".

Publisher Comments. "In every major field of biology, from molecular genetics and neurobiology, through animal behavior and ecology, to evolution, extinction, and economics, there are well-known phenomena that today's standard theories are powerless to explain: Why don't cells in identical environments with identical genomes live identical lives? How do such simple creatures as ants and termites manage such complex behavior as building nests? Why did all the animal kingdom's basic body plans appear in a single geological era, and no new ones since? Yet, as Ricard Sole and Brian Goodwin show, various tools of complexity theory can offer us new ways to understand these phenomena. A tour of biology such as you've never seen before, *Signs of Life* is about explaining the unexplainable-by using new ideas to answer questions yesterday's ideas can't help us with."

The authors point out that the real aim of this book is to show how the new ideas are exerting their influence in a variety of biological areas. Signs of Life is divided up into 10 chapters: **1)** nonlinearity, Chaos, and Emergence; **2)** Order, Complexity, Disorder; **3)** Genetic Networks, Cell Differentiation, and Development; **4)** Physiology on the Edge of Chaos; **5)** Brain Dynamics; **6)** Ants, Brains, and Chaos; **7)** The Baroque of Nature; **8)** Life on the Edge of Catastrophe; **9)** Evolution and Extinction; and **10)** Fractal Cities and Market Crashes.

Biodiversity of Deserts

SARA OLDFIELD (Photography by Bruce Coleman Collection). 2005. **Deserts: The Living Drylands.** (ISBN 0-262-15112-X, hbk.). The MIT Press, 5 Cambridge Center, Cambridge, MA 02142-1493, U.S.A. (Orders: 800-405-1619, mitpress-orders@mit.edu, http://mitpress.mit.edu). $29.95, 160 pp., 180 illustrations, color throughout, 12 1/2" × 9 1/2".

Publisher Comments. "Deserts represent the ultimate challenge to life on Earth. Their lack of water and extreme temperatures make survival difficult for both wildlife and people, yet deserts are rich in animal and plant life and culture. Their unique species and ancient civilizations include fragile treasures needing protection in a rapidly changing world. Deserts are among our planet's last great wilderness regions, and they continue to offer scientific puzzles and new discoveries. *Deserts: The Living Drylands* is a celebration of the world's least understood ecosystems. In this richly illustrated book—featuring 180 color photographs—wildlife expert Sara Oldfield leads readers on a journey to some of the most remote places on earth, from the rolling sand dunes of the Arabian Peninsula's Empty Quarter to the ancient rock formations of central Australia. *Deserts* is both a vivid inventory of spectacular images, facts, and stories and an invaluable source of reference. It brings to life our planet's unique arid habitats at a time when they are more in need of protection than ever.

This is a book with incredibly beautiful and often unbelievable photographs. Once you open the book you will not want to close it. If you think you've seen the desert, think again. The seven chapters take you through a survey of deserts of the world: Africa, The Middle East, Asia, Australia, The Americas, and ends with the future of drylands.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

A NEW COMBINATION IN *ANTENNARIA* (ASTERACEAE: GNAPHALIEAE) FROM NORTH AMERICA

ABSTRACT

Antennaria pulcherrima subsp. ***eucosma*** (Fernald & Wiegand) R.J. Bayer, comb. nov., is based on *Antennaria eucosma* (Fernald & Wiegand) from North America. The new combination is essential as a result of the expansion of the circumscription of *A. pulcherrima* to include *A. eucosma.*

RESUMEN

Antennaria pulcherrima subsp. **eucosma** (Fernald & Wiegand) R.J. Bayer, comb. nov., se basa en *Antennaria eucosma* (Fernald & Wiegand) de Norteamérica. La nueva combinación es esencial como resultado de la extensión de la circunscripción de *A. pulcherrima* para incluir *A. eucosma.*

INTRODUCTION

In preparation for publication of my treatment of *Antennaria* Gaertn. for the *Flora of North America North of Mexico*, I came to re-evaluate *Antennaria pulcherrima* (Hook.) Greene, an amphimictic species, occurring as diploid ($2n = 28$) and tetraploid ($2n = 56$) cytotypes from Colorado to Alaska, east to Ontario, and parts of western Quebec. It appears to be uniformly tetraploid throughout its range in Canada and Alaska (Urbanska 1983), but four diploid populations are known from Montana (one population), Wyoming (one population), and Colorado (two populations) (Bayer & Stebbins 1987). Apparently, *A. pulcherrima* arose in the U.S. Rockies as a diploid and presumed derived autotetraploid cytotypes spread north into Canada and Alaska post glaciation. It is generally found in moist willow thickets throughout its range (Urbanska 1983; Bayer & Stebbins 1987). Porsild (1943) suggested that *A. pulcherrima* is restricted to calcareous soils; this has never been empirically demonstrated (Urbanska 1983). *Antennaria eucosma* Fernald & Wiegand is a narrow endemic restricted to limestone and serpentine barrens on the island of Newfoundland and Anticosti Island, Quebec. Like the Canadian populations of *Antennaria pulcherrima, A. eucosma* is amphimictic and tetraploid (Urbanska 1983; Bayer & Stebbins 1987). Its morphological similarity to *A. pulcherrima* is obvious and the two are separated primarily by the presence of prominent flags[1] in *A. pulcherrima* and their usual absence in *A. eucosma*.

Porsild (1943, 1965), who had quite a narrow species concept in *Antennaria*, treated *A. eucosma* as a synonym of *A. pulcherrima*. Urbanska (1983), who studied the ecology, cytology, and distribution of the Pulcherrimae group, while recognizing it as a distinct species, stated that, *A. eucosma* may represent nothing more than a specialized group of populations of *A. pulcherrima* with a distinct ecology. It has the same chromosome number as boreal populations of *A. pulcherrima* and its range is parapatric with that of *A. pulcherrima*. Furthermore, she suggested that *Antennaria eucosma* may have arisen via quantum speciation and genetic drift in geographically marginal populations of *A. pulcherrima* (Urbanska 1983). Ledyard Stebbins and I recognized *A. eucosma* as a distinct species (Bayer & Stebbins 1987, 1993), and we remarked on the problem of its circumscription as a distinct species (Bayer & Stebbins 1993).

Because *Antennaria eucosma* is also morphologically very similar to, and not always consistently distinct from, *A. pulcherrima*, it is best to recognize *A. eucosma* as an infraspecific taxon under *A. pulcherrima*. Stebbins and I applied the same set of taxonomic criteria when evaluating *A. luzuloides* Torr. & A. Gray subsp. *luzuloides* and *A. luzuloides* Torr. & A. Gray subsp. *aberrans* (E.E. Nelson) R.J.Bayer & Stebbins (= *A. microcephala* A. Gray); the two subspecies differ in their ecology, but are not adequately morphologically differentiated to warrant recognizing them as distinct at species rank (Bayer & Stebbins 1993). A scenario whereby marginal populations of tetraploid *A. pulcherrima* in Atlantic Canada, which may already have been adapted to calcareous soils, became genetically isolated and subsequently morphologically and ecologically differentiated from the central populations of *A. pulcherrima*, seems apparent.

TAXONOMY

Antennaria pulcherrima (Hook.) Greene subsp. **eucosma** (Fernald & Wiegand) R.J. Bayer, comb. nov. *Antennaria eucosma* Fernald & Wiegand, Rhodora 13 23. 1911. TYPE: CANADA. NEWFOUNDLAND: Flora of Western Newfoundland, Region of Port au Port Bay, dry limestone barrens, upper slopes and tablelands, altitude 200–300 m, Table Mountain, 16 Aug 1910, *M.L. Fernald & K.M. Wiegand 4144* (HOLOTYPE: GH!; ISOTYPES: CAN!, NY!).

Antennaria carpatica (Wahlenb.) R.Br. var. *humilis* Hook., Fl. Bor. Amer. 1:329. 1834.

KEY TO THE SUBSPECIES OF *ANTENNARIA PULCHERRIMA*

Distal cauline leaves usually flagged; pistillate corollas 4.5–6.5 mm; staminate corollas 4–5 mm; wet habitats in willow thickets at subalpine elevations or subarctic in western North America from Colorado to Alaska, east to Ontario, parts of western Quebec ____________________ subsp. **pulcherrima**

---

[1] Flags are flat, linear, scarious appendages of the leaf tips that are similar to the tips of the phyllaries, not to be confused with ordinary subulate or blunt leaf tips that are essentially green and herbaceous.

Distal cauline leaves mostly not flagged (sometimes flagged just proximal to heads); pistillate corollas 3–4.4 mm; staminate corollas 3–4 mm; limestone substrates in willow thickets of western Newfoundland and Anticosti Island, Quebec _____ subsp. **eucosma**

ACKNOWLEDGMENTS

I thank curators at CAN, GH, and NY for making specimens available for study. Appreciation is extended to Kirsten Cowley, Edward Cross, Guy Nesom, John Strother, and Matthew Unwin for their critique and helpful suggestions concerning the draft manuscript and to J. Tupac Otero for editing the Spanish summary.

NOMENCLATURE OF THE VIRGINIA-BLUEBELL, *MERTENSIA VIRGINICA* (BORAGINACEAE)[1]

James S. Pringle

Royal Botanical Gardens
P.O. Box 399
Hamilton, Ontario, CANADA L8N 3H8
jpringle@rbg.ca

ABSTRACT

Mertensia virginica (L.) Pers. ex Link is the correct name for the Virginia-bluebell. It should not be replaced by *M. pulmonarioides* Roth.

RESUMEN

Mertensia virginica (L.) Pers. ex Link es el nombre correcto para la especie usualmente así conocida. No debe reemplazarse por *M. pulmonarioides* Roth.

Virginia-bluebell or Virginia-cowslip, *Mertensia virginica* (L.) Pers. ex Link, is native to eastern North America and widely cultivated as an ornamental perennial. It has consistently been called *M. virginica* in floras covering its natural range, including all editions of *Gray's Manual of Botany* (Gray 1848, 1856, 1862, 1863, 1867; Gray et al. 1890; Robinson & Fernald 1908; Fernald 1950) and continuing to the most recent state and provincial floras and checklists. That name was accepted in Williams's (1937) monograph on *Mertensia* in North America and in Al-Shehbaz's (1991) monograph on the Boraginaceae of the southeastern United States. It is also the accepted name in horticultural references including *Hortus III* (Staff...1976), the most recent edition of *The Royal Horticultural Society Dictionary of Gardening* (Huxley et al. 1992), *The Plant-Book* (Mabberly 1997), and *The European Garden Flora* (Richardson 2000).

In recent years, nevertheless, this species has with increasing frequency been called *M. pulmonarioides* Roth in horticultural literature and in seed and nursery catalogues. All or most post-1990 use of the name *M. pulmonarioides* is probably derived directly or indirectly from *Index Hortensis* (Trehane 1989), which is an exception among standard references in that the name *M. pulmonarioides* is accepted and *M. virginica* is listed as a synonym. Following the publication of *Index Hortensis*, the name *M. pulmonarioides* was accepted in the 1997 edition of *The American Horticultural Society A-Z Encyclopedia of Garden Plants* (Brickell & Zuk 1997) with *M. virginica* as a synonym. The name *M. pulmonarioides* was also accepted in the 1998/99 edition of the *RHS Plant Finder* (Lord et al. 1998), although in the 2003/04 edition (Lord et al. 2003) *M.*

---

[1] Contribution No. 118 from the Royal Botanical Gardens, Hamilton, Ontario, Canada.

SIDA 21(2): 771–775. 2004

virginica is the accepted name and *M. pulmonarioides* is cross-indexed as a synonym. Schmid (2002), in *An Encyclopedia of Shade Perennials*, commented that with taxonomists having "switched" the long-established name *M. virginica* to *M. pulmonarioides*, the latter name would "show up more and more often."

Nomenclatural matters are not discussed in *Index Hortensis*, and the name *M. virginica* was used in the literature cited for the species. The name *M. pulmonarioides* may have been taken from the original component of *Index Kewensis* (Jackson 1894), in which *M. pulmonarioides* was listed as an accepted name and *M. virginica* as a synonym. No taxonomic publication that specifically discusses the nomenclature of Virginia-bluebell was cited in the extensive bibliography compiled by Al-Shehbaz (1991) or in *The Kew Record of Taxonomic Literature Relating to Vascular Plants* or any of the other bibliographies I consulted. In view of the confusion now associated with the nomenclature of this species, it seems appropriate to present such a study here.

Virginia-bluebell was named and described at the rank of species by Linnaeus (1753) in the first edition of *Species Plantarum*, as *Pulmonaria virginica*. Two specimens are relevant to the typification of this name. One, designated the type by Williams (1937) and accepted as such by Charles E. Jarvis in the Linnaean Plant Names Typification Project (M. Grant, pers. comm.), is from Linnaeus's own herbarium (LINN) and was collected in North America by Pehr Kalm. It bears the Sprague Catalogue number 184.5. From a photograph in the library of the Arnold Arboretum, this specimen is unequivocally identifiable as Virginia-bluebell.

Linnaeus cited an earlier description from Gronovius's (1739) *Flora Virginica*, which had been based on a manuscript by John Clayton. The specimen *Clayton 339*, now in the herbarium of the Natural History Museum (London) (BM), is from Gronovius's herbarium. According to data on the herbarium sheet, it was taken from a plant sent from Virginia to England by Mark Catesby and subsequently cultivated in the garden of Peter Collinson. An image can be seen on the museum's web site, with the designation "Linnaean type status: original element." Its identity as Virginia-bluebell is likewise unmistakable.

The genus *Mertensia* was segregated from *Pulmonaria* in 1797 by A.W. Roth, who gave Virginia-bluebell the new name *M. pulmonarioides*. Roth did not mention the name *P. virginica* L. and may not have been aware that he had described the same species. The name *M. pulmonarioides* should therefore be considered a heterotypic synonym. *Pulmonaria virginica* L., with the species epithet *virginica* retained, was transferred to *Mertensia* in 1829 by J.H.F. Link, who cited *M. pulmonarioides* Roth as a synonym. Link attributed the combination *M. virginica* to Persoon, probably on the basis of herbarium annotations or correspondence, as there is no record of Persoon's actually having published the binomial. The authorship of the binomial may therefore be cited as "(L.) Pers. ex Link" or simply as "(L.) Link." The combination is occasionally attributed to Persoon, following Fernald (1950) or Gleason and Cronquist (1991), who routinely omitted the name of the publishing author in such contexts, but under current rules of nomenclature that is incorrect.

The binomial *M. pulmonarioides* Roth was published before *M. virginica* (L.) Pers. ex Link, but as long as the taxonomic rank is not changed, priority is based on the date of publication of the species epithet rather than on that of the binomial. Adoption of the earliest available species epithet is retroactively required under Articles 11.4 and 52 of the *International Code of Botanical Nomenclature*, 2000 ed. (Greuter et al. 2000). In this case, the earliest available epithet for the species described by Linnaeus is *virginica*, the priority of which dates from 1753, the starting point of botanical nomenclature.

During the interval 1797-1829 three homonyms of the genus name *Mertensia* were published: *Mertensia* Willd. for a genus of ferns; *Mertensia* Thunb. ex Roth for a genus of red algae; and *Mertensia* Kunth for a genus of Ulmaceae. These illegitimate homonyms were used only briefly and by few authors. A search of Broun's (1938) *Index to North American Ferns* and the Internet resources AlgaeBase and The International Plant Names Index (websites) indicated that the species epithet *virginica* was not used under any of those homonymic genus names. Nor did the IPNI or any other index disclose any pre-1829 use of the combination *M. virginica* for any other species in the boraginaceous genus.

In summary.—The traditional use of the name *M. virginica* is compatible with its typification. The epithet *virginica* in this context has priority from the starting point of botanical nomenclature, 1753, whereas that of *pulmonarioides* is from 1797. The binomial *M. virginica* (L.) Pers. ex Link is not a homonym of a name previously used for any other species. The familiar name *Mertensia virginica* (L.) Pers. ex Link is the correct name for the Virginia-bluebell; it should not be replaced by *M. pulmonarioides* Roth.

ACKNOWLEDGMENTS

I am grateful to Mike Grant and W. George Schmid for very helpful correspondence, and to my colleague Dennis Eveleigh for useful information and valued suggestions. I am also grateful to the staff of the Gray Herbarium/Arnold Arboretum Library for access to historic literature and a photograph of the Linnaean herbarium specimen. Crinan Alexander and Guy Nesom are thanked for reviewing the manuscript.

BOOK NOTICES/BOOKS RECEIVED

Wild Orchids of the Southeastern United States

Paul Martin Brown with drawings by Stan Folsm. 2004. **Wild Orchids of the Southeastern United States, North of Peninsular Florida.** (ISBN 0-8130-2749-7, pbk.) University Press of Florida, 15 Northwest 15th St, Gainesville, FL 32611-2079, U.S.A. (Orders: www.upf.com, 800-226-3822). $27.95, 394 pp., color photos, b/w illus., 6" × 9".

Publisher Comments: "In more than 100 years of orchid research in Florida, *Wild Orchids of Florida* is the first field guide to be published for this orchid-rich state. Providing more than 400 color photos as well as line drawings by Stan Folsom, distribution maps, and detailed descriptions of each species, this guide should enable even the novice to easily identify any of the orchids found growing in the wild.

"Illustrated keys are provided to aid in identification. Each of the 117 species and varieties has a full page of text, a line drawing, and distribution map with a facing page of full-color photographs. Species deemed as naturalized, escaped, or waifs are also treated. A final chapter enabling the reader to use this book in the nearby southeastern Coastal Plain states makes it an even more valuable resource."

From the color photos and line drawings to the simple but general range maps, Paul Martin Brown has given us another good Wild Orchids book of the USA, this time from the southeastern United States.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

ABSTRACT

Gnaphalium saxicola is treated at specific rank as **Pseudognaphalium saxicola** (Fassett) H.E.Ballard & Feller, comb. nov. It is likely an evolutionary derivative of *Pseudognaphalium obtusifolium* but is consistently different in a number of mophological characters. No intermediates between *P. saxicola* and any other taxon have been observed.

RESUMEN

Gnaphalium saxicola se trata a nivel específico como **Pseudognaphalium saxicola** (Fassett) H.E.Ballard & Feller, comb. nov. Es aparentemente un derivado evolutivo de *Pseudognaphalium obtusifolium* pero es bastante diferente en un número de caracteres morfológicos. No se han observado intermedios entre *P. saxicola* y cualquier otro taxon.

The "Cliff Cudweed," *Gnaphalium saxicola* Fassett, is endemic to a relatively small area of Wisconsin. It was initially described as a distinct species but subsequently reduced in rank to a variety of *Pseudognaphalium* (*Gnaphalium*) *obtusifolium* (L.) Hilliard & Burtt. Cronquist (1946, p. 121) noted that "At least until a larger series of specimens demonstrates its morphological and genetic discontinuity, it seems better treated as a variety of *G. obtusifolium*." We find that treatment at specific rank most accurately reflects the biological and evolutionary situation and transfer of *G. saxicola* to the genus *Pseudognaphalium* is necessary to reflect newly emerging understanding of natural evolutionary groups in the Gnaphalieae. The new combination will be available for use in the forthcoming "Flora of North America" treatments of Asteraceae.

Pseudognaphalium saxicola (Fassett) H.E.Ballard & Feller, comb. nov. *Gnaphalium saxicola* Fassett, Rhodora 33:75. 1931. *Gnaphalium obtusifolium* var. *saxicola* (Fassett) Cronq., Rhodora 48:121. 1946. *Pseudognaphalium obtusifolium* var. *saxicola* (Fassett) Kartesz, Synthesis N. Amer. Fl., Nomencl. Innov.: no. 32. 1999. TYPE: U.S.A. WISCONSIN. ADAMS CO.: Coldwater

Canyon, Dells of the Wisconsin River, sandstone ledges, 22 Sep 1929, *N.C. Fassett, F.M. Uhler, and W.T. McLaughlin 9590* (HOLOTYPE: WIS!; ISOTYPE: GH!).

Plants annual, filiform-taprooted. Stems erect, 4–15(–30) cm tall, filiform, persistently tomentose with a loose, envelope-like, transparent haze of extremely thin hairs, doubling the stem width, eglandular. Leaves cauline, 4–6, elliptic-oblanceolate to oblanceolate, gradually narrowed to the base, not clasping or decurrent, 5–30 mm, largest at midstem, sessile, green on both surfaces, within veiny reticulum evident, thinly arachnoid-tomentose to glabrate, eglandular. Heads 2–4 in a terminal, capitate cluster, commonly immediately subtended by uppermost cauline leaf, sometimes several clusters in a corymbiform array. Involucres turbinate, 4–5 mm; phyllaries narrowly triangular to narrowly oblong-triangular, acute, in 3(–4) gradate series, whitish to slightly tawny. Pistillate florets 25–28. Bisexual florets 6–7. Cypselae smooth, without raised ridges or papillae.

Flowering (Jul–)Aug–Sep. Mostly bare sandstone cliff faces, ledges, and cracks, S- to E-facing but commonly shaded; 200–300 m; Wisc. (Adams, Columbia, Richland, Sauk, and Vernon cos.).

It seems likely that *Pseudognaphalium saxicola* is an evolutionary derivative of *P. obtusifolium* but it consistently diverges from the latter in many respects. Full details of complementary studies conducted by Ballard and Kowal (1992) and Feller (2000) will be submitted as a combined manuscript for publication but are summarized here in support of the nomenclatural transfer. Phenetic and preliminary greenhouse comparisons of *P. saxicola* with *P. obtusifolium*, *P. helleri* (Britt.) Anderb., and *P. micradenium* (Weatherby) Nesom have distinguished *P. saxicola* by the following: annual duration and absence of a basal rosette; shorter stature (commonly only a few centimeters tall in fruit); loose, partially detaching cobwebby-tomentose pubescence on stems, and complete absence of glands or glandular hairs on stems and leaves; fewer leaf nodes with shorter and broader, thinner and more membranous, essentially glabrous leaves; larger and more open inflorescence; few, small heads with relatively few florets; and more slender, uniformly narrowly acute-tapering, semi-translucent phyllaries. Depauperate individuals of *P. obtusifolium* over its whole geographic range may sometimes be as short as 5–10 cm, approaching the habit of *P. saxicola*; such plants differ from *P. saxicola*, however, in their close and more dense stem vestiture, bicolored and relatively narrow leaves, larger heads with greater number of pistillate florets, and broader phyllaries with rounded apices. No intermediate specimens between *P. saxicola* and any other taxon have been confirmed in hundreds of collections.

Genetic studies of *Pseudognaphalium saxicola* populations using Inter-Simple Sequence Repeats indicate that the taxon is strongly and perhaps obligately apomictic; isolated greenhouse flats set abundant seeds, supporting this hypothesis.

ACKNOWLEDGMENTS

The authors gratefully appreciate the assistance of curators of herbaria at Harvard University (GH), Philadelphia Academy of Sciences (PH), Smithsonian Institution (US), University of Michigan (MICH), University of Wisconsin-Milwaukee (MIL) and University of Wisconsin-Madison (WIS) for facilitating studies of herbarium collections of *Pseudognaphalium*. June Dobberpuhl provided help with development of the project and secured funding from the Wisconsin Bureau of Endangered Resources and the U.S. Fish & Wildlife Service for it. Staff of Wisconsin State Parks were helpful in gaining access to sandstone outcrops for searches.

BOOK NOTICES/BOOKS RECEIVED

Natural Resources Management

P.F. Ffolliott, L.A Bojorquez, and M. Hernandez-Narvaez. 2001. **Natural Resources Management Practices: A. Primer.** (ISBN 0-8138-0913-4, pbk.) Iowa State Press, A Blackwell Publishing Company, PO Box 570, Ames, IA, 50010-0570, U.S.A. (Orders: 800-862-6657; www.iowastatepress.com). $34.99, 256 pp., b/w figures, tables, 5 appendices, 6" × 9".

The topic of natural resources practices are of ever-increasing interest to many. Authors, Ffolliot, Bojorquez and Hernandez-Narvaez, provide a wonderful introduction to the management approaches of many natural resource arenas in their book entitled Natural Resources Management Practices: A Primer. The easy-to-understand text would be appropriate for undergraduate introduction to the topic of natural resources management. In addition, it is well suited for anyone with an interest in the practices that help preserve wildlife, outdoor recreation areas and that help protect soil, water, forests and other natural products and resources.

The text presents management and conservation practices for water, watersheds, rangeland, timber, agroforestry, wildlife, fisheries, outdoor recreation areas, wilderness, fire and pest control, soil conservation, and rehabilitation of disturbed lands. There is also an excellent discussion of the decision-making process when considering various management options in the integrated natural resources management chapter. Each chapter ends with a review of the main features of each management topic.

Throughout the text the reader is encouraged to think of management in a broad ecosystem-based approach and to consider potential impacts from changes in practices regarding one use on other uses or activities in an area. Basic backgrounds for each management topic areas are introduced prior to discussion of management techniques and greatly enhance understanding of the management methodology discussed. The "real world" examples of selected management techniques are incredibly helpful and interesting. Many such real world applications are referenced to journal articles, which allow individual exploration on a technique or topic of interest.

The appendices include various approaches for analyzing and evaluation of management methods. There is a brief introduction to experimental design and statistical analysis of plot studies performed to measure potential impacts of management practices. These plot studies allow researchers to better predict the effectiveness of a management method by testing that method on small-scale areas. Computer simulation modeling, allows researchers or managers to examine impacts and changes that may arise from application of a management technique in a virtual way. Geographic Information Systems (GIS) are discussed as a possible tool in evaluating and guiding management methods.

The authors used English units in a number of examples. English units may increase the understanding of examples for many readers, as they are familiar with feet and inches, but metric units (Systeme Internationale) are considered more appropriate in academia. The authors have provided values in an appendix to allow conversion to metric values if desired.

Natural Resources Management Practices: A. Primer provides a very informative introduction to many facets of natural resources management. The text also provides a well-rounded overview to related topics of data analysis, computer simulation and GIS to evaluate or compare management techniques. The book is recommended not only for science or engineering students, but also for any reader who wishes to gain a better understanding of natural resources management techniques and rationale.—*Lee Luckeydoo, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

PSEUDOGNAPHALIUM CANESCENS (ASTERACEAE: GNAPHALIEAE) AND PUTATIVE RELATIVES IN WESTERN NORTH AMERICA

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

ABSTRACT

Pseudognaphalium canescens, *Pseudognaphalium microcephalum*, *Pseudognaphalium beneolens*, and **Pseudognaphalium thermale** (E.E. Nelson) Nesom, comb. nov., are treated as separate species. A recent treatment of the California flora combined these taxa as subspecies within a single species (*P. canescens*) but earlier floristicians have viewed them as distinct species. The current study also concludes that they are distinct and appropriately treated at specific rank. A nomenclatural and ecological summary and a distribution map are provided for each species and the four are morphologically distinguished in a key. A lectotype is designated for *Gnaphalium wrightii*.

RESUMEN

Pseudognaphalium canescens, *Pseudognaphalium microcephalum*, *Pseudognaphalium beneolens*, y **Pseudognaphalium thermale** (E.E. Nelson) Nesom, comb. nov., se tratan como especies independientes. Un reciente tratamiento de la flora de California combinaba estos taxa como subespecies dentro de una única especie (*P. canescens*) pero los floristas previos las han visto como especies distintas. El presente estudio también concluye que son distintas y que lo apropiado es tratarlas a nivel específico. Se ofrece un resumen nomenclatural y ecológico, así como un mapa de distribución de cada especie, y se distinguen morfológicamente las cuatro en una clave. Se designa un lectotipo para *Gnaphalium wrightii*.

For the forthcoming treatment of *Pseudognaphalium* in the Flora of North America, I will recognize as species four taxa that were recently treated (Stebbins & Keil 1992; Stebbins 1993) as subspecies of a single species: *P. canescens* (DC.) A. Anderb., *P. microcephalum* (Nutt.) A. Anderb., *P. beneolens* (Davidson) A. Anderb., and (as validated below) *P. thermale* (E.E. Nelson) Nesom.

Pseudognaphalium thermale (E.E. Nelson) Nesom, comb. nov. *Gnaphalium thermale* E.E. Nelson, Bot. Gaz. 30:121. 1900. *Gnaphalium microcephalum* var. *thermale* (E.E. Nelson) Cronq., Leafl. West. Bot. 6:47. 1950. *Gnaphalium microcephalum* subsp. *thermale* (E.E. Nelson) G.W. Douglas, Canad. J. Bot. 64:2726. 1986. *Gnaphalium canescens* subsp. *thermale* (E.E. Nelson) Stebbins & Keil, Novon 2:437. 1992. *Pseudognaphalium canescens* subsp. *thermale* (E.E. Nelson) Kartesz, Syn. Checklist & Atlas, Nom. Innov. 1999. *Pseudognaphalium microcephalum* (Nutt.) Anderb. var. *thermale* (E. Nelson) Dorn. Vasc. Pl. Wyoming, ed. 3. 375. 2001. TYPE: U.S.A. WYOMING. [Park Co.]: Yellowstone Park, geyser formations of Norris geyser basin, 25 Jul 1899, *A. Nelson and E. Nelson 6139* (HOLOTYPE: RM; ISOTYPES: GH!, US!).

Gnaphalium williamsii Rydb., Bull. Torrey Bot. Club 37:324. 1910. TYPE: U.S.A. MONTANA. [Flathead Co.]: Columbia Falls, 11 Aug 1894, *R.S. Williams s.n.* (HOLOTYPE: NY!).

Gnaphalium johnstonii G.N. Jones, Univ. Wash. Publ. Bot. 7:159, 176. 1938. Type: U.S.A. Washington. [Thurston Co.]: upper valley of the Nesqually, open, barren ground, 15 Sep 1896, *O.D. Allen 223* (isotype [as so annotated]?: WTU, digital image!).

Flowering Jun–Sep(–Oct). Dry, sandy roadbanks, roadside ditches, river beds and banks, lakeshores, granitic sand, open woods of yellow pine, Jeffrey pine, red fir, Douglas fir, mixed conifer, and mixed evergreen; (50–)300–2300(–2500) m. British Columbia; California, Idaho, Montana, Nevada, Oregon, Utah, Washington, Wyoming.

Pseudognaphalium beneolens (Davidson) A. Anderb., Opera Bot. 104:147. 1991. *Gnaphalium canescens* subsp. *beneolens* (Davidson) Stebbins & Keil, Novon 2:437. 1992. *Pseudognaphalium canescens* subsp. *beneolens* (Davidson) Kartesz, Syn. Checklist & Atlas, Nom. Innov. 1999. *Gnaphalium beneolens* Davidson, Bull. S. Calif. Acad. Sci. 17:17. 1918. Type: U.S.A. California. [Los Angeles Co.]: Crescenta, 1 Sep 1917, *F.E. Burlew 3275* (isotype: GH!).

Flowering (Apr–)Jun–Oct. Dry, open slopes and ridges, river beds, roadbanks and other disturbed sites, sandy flats, dunes, coastal sage scrub, chaparral, yellow pine, foothill pine, blue oak woodland; (1–)50–850(–1950) m. California; Mexico (Baja California).

Pseudognaphalium microcephalum (Nutt.) A. Anderb., Opera Bot. 104:147. 1991. *Gnaphalium microcephalum* Nutt., Trans. Amer. Philos. Soc. ser. 2, 7:404. 1841. *Gnaphalium canescens* subsp. *microcephalum* (Nutt.) Stebbins & Keil, Novon 2:437. 1992. *Pseudognaphalium canescens* subsp. *microcephalum* (Nutt.) Kartesz, Syn. Checklist & Atlas, Nom. Innov. 1999. Type: U.S.A. California. [San Diego Co.]: San Diego, [April or early May], 1836, *T. Nuttall s.n.* (BM, photo-GH!). After examining a photo of the type of *Gnaphalium microcephalum*, Johnston (1924) noted that *G. microcephalum* was correctly applied to the species usually called *Gnaphalium bicolor* Bioletti (= *Pseudognaphalium biolettii* A. Anderb.); he then proposed *Gnaphalium albidum* to account for the species left without a name. The present interpretation, however, of the type and of Nuttall's description is that they refer to *P. microcephalum* in the concept here (see key below). Ferris (1960 , p. 469) examined the photograph of the type and her interpretation of its identity was similar to that here. She commented that "The specimen probably was collected in the spring (see Madrono 2:146–47. 1934) [Jepson 1934]. This would account for the weather-beaten appearance (darkened foliage and rubbed tomentum) of this plant which normally flowers in summer and early fall."

Gnaphalium albidum I.M. Johnston, Contr. Gray Herb. 70:84. 1924. Type: U.S.A. California. San Diego Co.: Granite, in chaparral, 1850 ft, 11 Jul 1916, *M.F. Spencer 69* (holotype: GH!; isotype: US!).

Flowering (Apr–)Jun–Aug(–Nov). Grassy hillsides, gravelly canyon bottoms, coastal sage scrub, chaparral; 50–900(–1800) m. California; Mexico (Baja California).

Pseudognaphalium canescens (DC.) A. Anderb., Opera Bot. 104:147. 1991 (non W.A. Weber 1991). *Gnaphalium canescens* DC., Prodr. 6:228. 1838. Type: MEXICO. Guanajuato: León, *Méndez s.n.* (holotype: G-DC, fiche!, photos F! and TEX!).

Gnaphalium wrightii A. Gray, Proc. Amer. Acad. Arts 17:214. 1882. <b7,10>Type: U.S.A. Texas. [El Paso or Hudspeth Co.]: valley between El Paso and the Guadalupe Mts., Oct [1849], *C. Wright*

394 (LECTOTYPE, designated here: GH!; ISOLECTOTYPES: GH, US!). Gray's protologue referred to three collections: he directly cited (1) *Parry & Palmer 419* (GH) from San Luis Potosi, Mexico, collected in 1878; he cited "*G. microcephalum*, Gray, Pl. Wright, i. & ii., non Nutt." in reference to his earlier identification as *Gnaphalium microcephalum* of (2) a collection by Wright in Texas from the "Valley between El Paso and the Guadalupe Mts.; Oct." (Pl. Wright. [Smithsonian Contr. Knowl. 3(5) 1852] 1:124. 1852) and (3) another collection by Wright in 1851 from New Mexico, "from mountains near the copper mines" (Pl. Wright. [Smithsonian Contr. Knowl. 5(6) 1853] 2:99. 1853).

Gnaphalium albatum Osterh., Muhlenbergia 1:141. 1906. TYPE: U.S.A. COLORADO. Larimer Co.: Canyon of Thompson River, 16 Aug 1905, *G.E. Osterhout 3158* (ISOTYPE [as annotated by C. Anderson, 1972]: NY!).

Gnaphalium sonorae I.M. Johnston, Contr. Gray Herb. 68:99. 1923. TYPE: MEXICO. SONORA: Hermosillo, 1888, *M.A. Crawford s.n.* (HOLOTYPE: GH!; ISOTYPE: US!).

Gnaphalium viridulum I.M. Johnston, Contr. Gray Herb. 70:86. 1924. TYPE: U.S.A. NEW MEXICO. [Grant Co.]: Bear Mts. near Silver City, 2400 m, 19 Sep 1903, *O.B. Metcalfe 742* (HOLOTYPE: GH!; ISOTYPE: US!).

Gnaphalium texanum I.M. Johnston, Contr. Gray Herb. 70:86. 1924. TYPE: U.S.A. TEXAS. [Brewster Co.]: mouth of "Tarlingua" [Terlingua Creek], Sep 1883, *V. Havard 26* (HOLOTYPE: GH!; ISOTYPE: US!).

Flowering Aug–Nov(–Jan). Lava beds, grasslands, oak, pine-oak, and pine woodlands, 1150–2450(–2700) m; Arizona, California, Colorado, New Mexico, Oklahoma, Texas, Utah; Mexico (Baja California, Chihuahua, Coahuila, Durango, Nuevo León, San Luis Potosí, Sinaloa, Sonora, and other states to the south).

KEY TO *PSEUDOGNAPHALIUM CANESCENS* AND PUTATIVE RELATIVES IN CALIFORNIA

1. Basal and lower cauline 1.5–6 mm wide, similarly colored on abaxial and adaxial surfaces, cauline decurrent 5–14 mm, the decurrent portion appearing as a thin line, densely and prominently sessile-glandular beneath the tomentum; plants aromatic.
   2. Stems 20–40 cm tall; basal and lower cauline leaves narrowly oblanceolate, gradually or abruptly reduced in size and becoming linear upwards, not coiling upon wilting; capitulescence corymbiform; involucres 4–5 mm long; phyllaries in 3–4(–5) series, usually slightly hyaline and shiny; bisexual florets (2–)4–7; habitats at (600–)900–2500 m ____ **Pseudognaphalium thermale**
   2. Stems 35–100 cm tall; basal and lower cauline leaves linear to linear-oblanceolate, relatively even in size and shape upwards, usually twisting or broadly coiling upon wilting; capitulescence usually elongate-paniculiform; involucres 5–6 mm long; phyllaries in (4–)5–6(–7) series, usually opaque and dull; bisexual florets (3–)5–10(–13); habitats at 5–800(–1550) m ____ **Pseudognaphalium beneolens**
1. Basal and lower cauline leaves (2–)5–10(–15) mm wide, often weakly bicolored, cauline not decurrent, eglandular (*P. microcephalum*) or eglandular to minutely and inconspicuously sessile-glandular (*P. canescens*); plants not aromatic.
   3. Stems 50–100 cm tall, usually 3–5 mm diameter near the base; leaves eglandular; phyllaries in 4–5 series, outer ovate; bisexual florets 4–9 ____ **Pseudognaphalium microcephalum**
   3. Stems 20–70 cm tall, usually 2–3 mm diameter near the base; leaves eglandular to minutely and inconspicuously sessile-glandular beneath the adaxial tomentum; phyllaries in 3–4 series, outer ovate-lanceolate; bisexual florets (1–)2–5(–6), 4–6 more common in the USA ____ **Pseudognaphalium canescens**

DISCUSSION

All four of the taxa considered here occur in California (Figs. 1–4). *Pseudognaphalium microcephalum* and *P. beneolens* are primarily Californian. *Pseudognaphalium canescens* ranges eastward to Colorado, Oklahoma, and Texas and southward in Mexico as far as Chiapas, although it appears to be rare south of the state of Mexico. *Pseudognaphalium thermale* occurs northward into southern British Columbia, Idaho, and Montana and barely reaches Utah and Wyoming. Stebbins and Keil (1992) observed that in southern California, where all four occur, they "intergrade to such a degree with respect to characters used in current keys (Ferris 1960; Munz 1959, 1968, 1974) to differentiate them — decurrent versus nondecurrent leaf bases, nature of tomentum, character of capitulescence, size and shape of heads, and acute versus obtuse phyllary tips — that they cannot be consistently be separated from each other." Cronquist (1955) earlier treated *Gnaphalium thermale* and *G. microcephalum* at varietal rank within a single species, but his concept of the latter apparently included at least *G. beneolens*. In contrast, other botanists have regarded each of the four as a separate species (i.e., Ferris 1960; Munz 1959, 1968), and I also find that consistent separation is possible.

Local and regional floras in California have treated *Pseudognaphalium microcephalum* and *P. beneolens* as separate species where they occur together: San Luis Obispo Co. (Hoover 1970), "southern California" (Munz 1974), the Santa Monica Mountains of Los Angeles Co. (Raven et al. 1986), and Santa Cruz Island of Santa Barbara Co. (Junak et al. 1995). These two species are sympatric in the southern coastal counties (Figs. 2 and 3) and I have not seen collections that might be indicative of hybridization.

Pseudognaphalium beneolens and *P. thermale* are similar in their aromatic character and their relatively narrow, decurrent, concolored leaves prominently sessile-glandular beneath the other indument. The two are largely allopatric in geographic range (Figs. 3 and 4) and *P. beneolens* generally occurs at lower elevations. Ferris (1960, p. 470) noted that "some plants of the lower western slopes of the Sierra Nevada are intermediate between [*Gnaphalium beneolens*] and *G. thermale*, having the opaque phyllary-tips and larger heads of the former and the growth habit and shorter inflorescence of the latter." My observation is that these plants (e.g., Tuolumne, Mariposa, and Fresno cos.), which I identify as *P. beneolens*, occur at higher elevations than coastal populations and they tend to have slightly wider basal leaves, but otherwise they fit within the species. In any case, even if they are somewhat differentiated from coastal populations, it is not clear that genes from *P. thermale* are the influencing factor. Further, there does not appear to be evidence of intergradation even in Mariposa and Fresno counties, where the two species apparently occur in relatively close proximity.

Pseudognaphalium beneolens was reported for Oregon by Ferris (1960) and

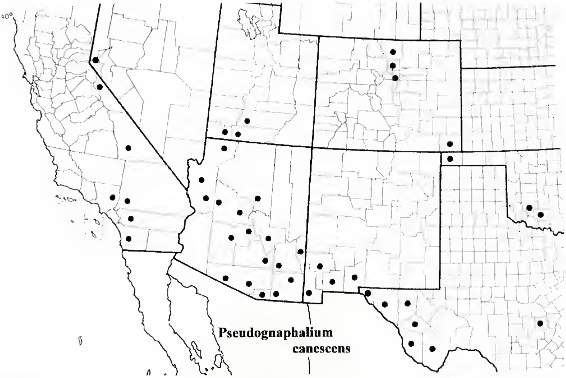

FIG. 1. Distribution of *Pseudognaphalium canescens* in the United States. The distribution continues into south-central Mexico (see text).

Munz (1974) and the current study records its occurrence in immediately adjacent California (Fig. 3), considerably north of the main range of the species. Both records are documented here: CALIFORNIA. Del Norte Co.: Hazelview Summit on Crescent City-Grant's Pass road, 2800 ft, 24 Jul 1928, *Kildale 5813* (LL); OREGON. Josephine Co.: Illinois River between McGuire Gulch and Oak Flat, 1300 ft, 8 Aug 1929, *Kildale 8881* (LL).

Pseudognaphalium canescens and *P. microcephalum* are mostly odorless and have relatively broader, non-decurrent, and weakly bicolored leaves without glands or with minute and weakly developed glands. These two species differ in geography and ecology and it is unlikely that they hybridize.

Variation in *Pseudognaphalium canescens*

Variability in phyllary morphology apparently was the primary basis for I.M. Johnston's descriptions of the several different taxa now treated within *Pseudognaphalium canescens*. Plants of *P. canescens* characteristically produce strongly white-opaque phyllaries with a filiform keel and apiculum, but in the southern portion of its range (Jalisco southeastward) and scattered localities elsewhere, the phyllaries may be more hyaline and lack a pronounced keel and apiculum. Similar plants from New Mexico were the basis for Johnston's recognition of *Gnaphalium viridulum*, but these are not distinct on the basis of other

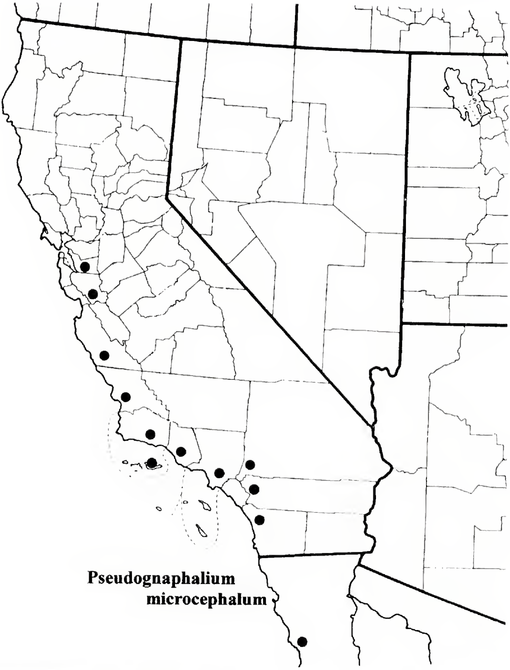

Fig. 2. Distribution of *Pseudognaphalium microcephalum*.

characters. The widely disjunct populations of *P. canescens* in Texas, Oklahoma, and Colorado (Fig. 1) do not appear to be significantly differentiated from those in areas where the species is more continuously distributed.

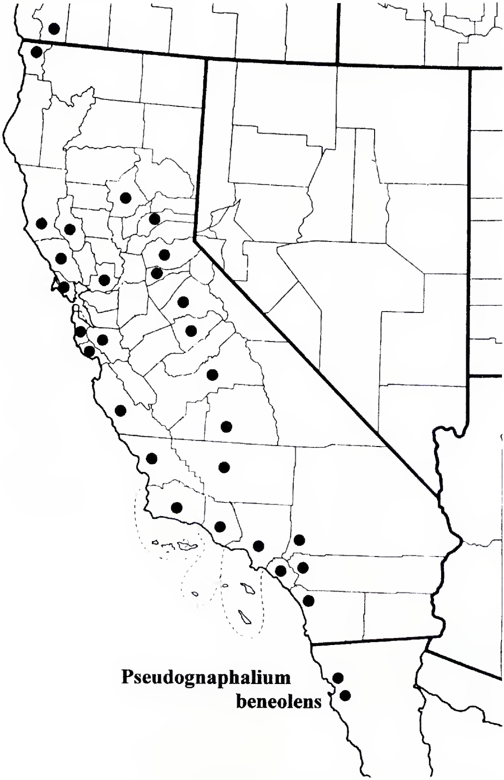

FIG. 3. Distribution of *Pseudognaphalium beneolens*.

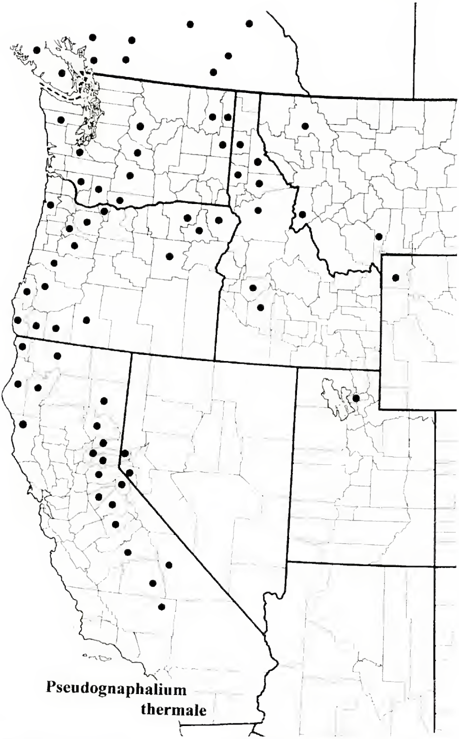

Fig. 4. Distribution of *Pseudognaphalium thermale*. Some records were taken from databases available through herbaria of the University of British Columbia (UBC), Washingon State University (WTU), and Oregon State University (OSU).

ACKNOWLEDGMENTS

David Giblin (WTU) provided data and a digital image of the type of *Gnaphalium johnstonii*, Scott Sundberg (OSU) helped in accessing the Oregon State University database of vascular plants, and Walter Kittredge (GH) provided information on the syntypes and typification of *Gnaphalium wrightii*. Observations and distribution maps are based on specimens from ARIZ, GH, HSC, MO, TEX/LL, and SMU/BRIT, except where noted for Fig. 4. Review comments from David Keil are much appreciated.

BOOK NOTICES/BOOKS RECEIVED

Timber Press book on Lavender

Tim Upson and Susyn Andrews. 2004. **The Genus Lavandula.** (ISBN 0-88192-642-6, hbk.) Timber Press Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $49.95, 442 pp., 30 color plates by Georita Harriott, Christabel King, and Joanna Langhorne), 4 b/w photos, 126 color photos, 28 maps, 41 line drawings, 12 tables, 7 3/8" × 9 5/8".

According to the authors, "***The Genus Lavandula*** is the most comprehensive and authoritative account of lavenders to be published to date." After spending some time thumbing through it, I am inclined to agree. Besides describing some 39 species and their hybrids, it encompasses the taxonomy, distribution, history and cultivation, with additional chapters on propagation, products, chemistry, essential oils, and pests and diseases, in a relatively small book. Besides making a lovely coffee table book, it is incredibly useful when identifying species, with the 31 full page color paintings, 45 line drawings and numerous maps. A part of the book that I found unique was the 50 page chapter on the History of Lavender Cultivation; an A–Z listing of all the people, places and companies involved in the world of Lavender. Among the nine appendices, some that I found to be useful were a highly detailed one on how to photograph lavender, giving advice on lighting, camera, film and backgrounds; Plant Breeders' Rights and Plant Patents; and National Collections and Nurseries, which lists up-to-date information including, telephone and email addresses. With all that's included in this book, I think it is well worth the $49.95 (U.S) it costs.—*Asha McElfish, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

Editor's note.—Appendix 1 list new taxa and combinations of which there are 18 including two new species (*Lavandula samhanensis* and *Lavandula qishnensis*).

A TAXONOMIC REVIEW OF THE *ERIOPHORUM RUSSEOLUM—E. SCHEUCHZERI* COMPLEX (CYPERACEAE) IN NORTH AMERICA

Jacques Cayouette

National Program on Environmental Health–Biodiversity
Agriculture and Agri-Food Canada
Wm. Saunders Building (#49)
Central Experimental Farm
Ottawa, Ontario, CANADA, K1A 0C6
email: cayouettej@agr.gc.ca

ABSTRACT

The taxonomy of *Eriophorum russeolum—E. scheuchzeri* complex in North America is reviewed, including the northwestern North American related species *E. chamissonis*. A key to the taxa including new characters of the medial fertile scales and achenes is presented. The new nothosubspecies ***Eriophorum* ×*medium*** subsp. ***album*** J. Cayouette is described; it represents the hybrid between *E. russeolum* subsp. *leiocarpum* and *E. scheuchzeri* subsp. *scheuchzeri* from northeastern Canada (northern Quebec and Nunavut), based on intermediate characters observed in herbarium specimens. The typical hybrid subspecies, *E.* ×*medium* subsp. *medium* (*E. russeolum* subsp. *russeolum* × *E. scheuchzeri* subsp. *scheuchzeri*) is also characterized and added to the flora of North America (Quebec and Labrador). The two hybrid subspecies are compared to their parental subspecies. Another related taxon, *E. scheuchzeri* subsp. *arcticum*, poorly known in North America, is compared to the typical subspecies and its range is established in northeastern North America. Lectotypes of *E. russeolum* Fries and *E. russeolum* var. *majus* Sommier are here designated.

RÉSUMÉ

Une révision taxonomique du groupe des *Eriophorum russeolum—E. scheuchzeri* en Amérique du Nord est proposée, incluant l'espèce voisine *E. chamissonis* du nord-ouest de l'Amérique. Une clef des taxons basée sur des caractères inédits des écailles fertiles médianes et des akènes est présentée. Une nouvelle notho-sous-espèce, l'***Eriophorum* ×*medium*** subsp. ***album*** J. Cayouette, est décrite, représentant l'hybride entre l'*Eriophorum russeolum* subsp. *leiocarpum* et l'*E. scheuchzeri* subsp. *scheuchzeri*, et localisée dans le nord-est du Canada (nord du Québec et Nunavut), à partir d'observations de caractères intermédiaires sur des spécimens d'herbier. La sous-espèce typique de l'hybride, l'*E.* ×*medium* subsp. *medium* (*E. russeolum* subsp. *russeolum* × *E. scheuchzeri* subsp. *scheuchzeri*), est également caractérisée et rapportée comme nouvelle pour l'Amérique du Nord (Québec et Labrador). Les deux sous-espèces de l'hybride sont comparées à leurs sous-espèces parentales respectives. Un autre taxon voisin, l'*E. scheuchzeri* subsp. *arcticum*, peu connu en Amérique du Nord, est comparé à la sous-espèce typique, et son aire de répartition est précisée dans le nord-est de l'Amérique. Les lectotypes de l'*E. russeolum* Fries et de l'*E. russeolum* var. *majus* Sommier sont désignés.

Key Words: *Eriophorum*, Cyperaceae, hybrid, Canada, Quebec, Labrador, Nunavut, arctic

In the course of the preparation of the collaborative project "la Flore du Québec-Labrador nordique," spearheaded by "le Centre d'Études nordiques" and "l'Herbier Louis-Marie" (QFA), both of Laval University, Quebec City, Canada, the genus *Eriophorum* (Cyperaceae) was found to be very difficult taxonomically, especially within the *E. russeolum* Fries in Hartman and *E. scheuchzeri* Hoppe groups of rhizomatous species with solitary spikelets, in subgenus *Eriophorum*. Approximately 700 specimens from the region of the projected flora were examined, covering the Quebec-Labrador peninsula north of 54° N, including adjacent islands in Hudson Bay and Ungava Bay that belong administratively to Canada's Nunavut Territory. Specimens from outside the region were also studied. Material was examined from the following herbaria: CAN, DAO, FI, GH, MICH, MINN, MT, MTMG, QFA, QFBE, QUE, SFS, TRTE, UPS, and WIS (abbreviations according to Holmgren et al. 1990).

Marcel Raymond (1954) was one of the first to circumscribe the taxa related to *Eriophorum chamissonis* C.A. Meyer and *E. russeolum*. He recognized five different species complexes worldwide based on the color and the shape of the spikelets, the pubescence of the achenes, the color pattern of the medial fertile scales, and in using some distributional characteristics. He also proposed three varieties of *E. russeolum* based on the color of the bristles and the pubescence of the achenes, two colored-bristle forms for *E. chamissonis*, and three colored-bristle forms for *E. ×medium* Andersson which he presumed to represent the hybrid between *E. russeolum* and *E. scheuchzeri*. His key to these taxa was very brief and does not work well. He believed that both *E. chamissonis* and *E. russeolum* occurred in eastern and western North America. In northeastern North America, he separated *E. russeolum* into two varieties based on achene pubescence. Specimens determined by Raymond as *E. chamissonis* in northeastern North America did not match the characters he gave in his publication for that species (first proximal scale length, stem width). It is almost impossible to clearly separate *E. chamissonis* from *E. russeolum* in northeastern North America based on his work.

Later, Novoselova (1993) proposed an alternative circumscription of these taxa, and made other changes in the *E. scheuchzeri* group (Novoselova 1994a, 1994b). She believed that in subgenus *Eriophorum* two rhizomatous species with orange-brown spikelets occur in North America, *E. chamissonis* and *E. russeolum* subsp. *russeolum*. She restricted the range of *E. chamissonis* to North America (both western and eastern North America), considering the Russian material to be referable to other species of the group. She also considered *E. russeolum* subsp. *russeolum* to be an amphi-Atlantic taxon. Ball and Wujek (2002) included *E. russeolum* within *E. chamissonis*, and considered *E. scheuchzeri* to be monotypic.

This investigation supports the circumscriptional concepts of Novoselova (1993, 1994a, 1994b), with the addition of a new taxon to the *E. russeolum*—*E. scheuchzeri* group. Moreover, based on examination of North American rhizomatous taxa of subgenus *Eriophorum* with orange-brown spikelets, it appears that *E. chamissonis* is present only in Alaska and British Columbia, while

Eriophorum russeolum subsp. *russeolum* occurs only in the northeastern North America.

Examination of material from northeastern North America, revealed that rhizomatous specimens with orange-brown spikelets are highly variable. The variation includes typical and atypical *E. russeolum* subsp. *russeolum*, and what is known in western Russia and northwestern Europe as *E.* ×*medium*, the hybrid between *E. russeolum* subsp. *russeolum* and *E. scheuchzeri* subsp. *scheuchzeri* (Novoselova 1993, 1994a), a taxon not previously reported in North America. A few specimens seem to be atypical *E. russeolum* subsp. *russeolum*, or perhaps backcrosses of *E.* ×*medium* with *E. russeolum* subsp. *russeolum*.

Variation is even greater among rhizomatous taxa with white spikelets in the *Eriophorum russeolum* and *E. scheuchzeri* groups. *Eriophorum russeolum* subsp. *leiocarpum* Novoselova can be considered the white phase of *E. russeolum*. Two subspecies can be discerned in the *E. scheuchzeri* group, the common boreal and arctic-alpine subsp. *scheuchzeri*, and the recently recognized high-Arctic subsp. *arcticum* Novoselova. Novoselova (1994b) reported the latter subspecies for Arctic North America, without adequately establishing its distribution in northeastern North America. It should be noted that despite the high variability of *E. russeolum* subsp. *leiocarpum* (Novoselova 1993), some specimens with white spikelets match neither the description of that subspecies nor that of any subspecies in the *E. scheuchzeri* group. Since these specimens have many intermediate characters between *E. russeolum* subsp. *leiocarpum* and *E. scheuchzeri* subsp. *scheuchzeri*, I conclude that they represent a hybrid of these two subspecies. To account for this hybrid, I propose and describe below a new nothosubspecies of *E.* ×*medium*.

With the naming and description of a new taxon, the discovery of a second as new to North America (*E.* ×*medium* subsp. *medium*), and the realization that a third (*E. scheuchzeri* subsp. *arcticum*), while recognized as present, is poorly known on the continent, it has been necessary to identify new characters that help to distinguish these taxa from the commoner *E. russeolum* subsp. *russeolum*, subsp. *leiocarpum* and *E. scheuchzeri* subsp. *scheuchzeri*. The characters are based on various features of the medial fertile scales (size, shape, apex, color pattern), on features of the achenes (size, shape, surface, beak shape and size), and on the lengths of hypogynous perianth bristles and stigmatic branches. Complete descriptions of all six taxa are provided below. The main differences among these taxa are illustrated in Figs. 1–20, summarized in Tables 1 and 2, and employed in the key to the taxa.

As the northwestern North American *E. chamissonis* has been previously reported in northeastern North America, and confused with *E. russeolum*, a complete description is also provided and some of its main differences are included in Table 1 and employed in the key.

General ranges are given for the widespread *E. russeolum* subsp. *russeolum*

and *E. scheuchzeri* subsp. *scheuchzeri*, while selected specimens or paratypes are cited for the other five taxa.

Eriophorum chamissonis

Eriophorum chamissonis C.A. Meyer in Ledeb. Fl. Alt. 1:70. 1829. TYPE: U.S.A. ALASKA: (LECTOTYPE: "Legit Eschsch. in Unalaska," by Novoselova (1993), p. 88).

Herbs perennial with short to elongate rhizomes. Vegetative shoots 1–3, 21–61 cm high, leaf margins glabrous. Stems erect, glabrous, terete in cross section, 27–95 cm high, 1.0–2.2(–2.5) mm in diameter below the inflorescence. Leaves basal and cauline 2–5. Proximal sheaths pale brown, pale reddish-brown to reddish-brown, with orange-brown spots on distal membranous parts, ligules obtuse or truncate. Highest distal sheath situated above or below the medial part of the stem, 2.3–4.2 mm wide, without blades or with reduced blades. Blades of proximal sheaths flat to slightly cymbiform, 25–430 × 1.4–1.5 mm, glabrous in distal parts, the apex rounded. Blades of distal sheaths 0 or 0.9–3.5 × 0.4–1.0 mm. Spikelets solitary, typically spherical at maturity, sometimes widely obovoid, 2–6 × 2–7 cm, with 100–200 florets. Proximal scales 3–7, without florets. First proximal scale olive to pale gray-olive, becoming pale beige with reddish-brown dots in marginal and distal parts, triangular-lanceolate to elliptic, 12–23(–30) × 2.6–6.5 mm, with 4–10 pale orange, pale brown to blackish nerves converging below the apex, acute, acuminate or rarely short-awned. Medial fertile scales with a non demarcated, or demarcated short to slightly extended proximal part, 1.0–2.5 mm long, averaging 19–42% of total scale length, whitish, greenish, pale beige-brown to pale orange-brown, with small reddish-brown longitudinal spots, with medial part frequently grayish or forming a ± extended blackish triangle, with narrow-hyaline or whitish marginal and distal parts, very often covered with small dark reddish longitudinal spots, mostly lanceolate, sometimes elliptic, 4.2–6.3 × 1.2–1.5(–1.8) mm, the widest part near the middle

---

TABLE 2. Selected morphological differences between the two subspecies of *Eriophorum scheuchzeri*.

Characters	*E. scheuchzeri* subsp. *scheuchzeri*	*E. scheuchzeri* subsp. *arcticum*
Spikelet shape	hemispherical	spherical
Proximal fertile scale pattern	missing hyaline margins or reduced margins well-separated from darker body	conspicuous hyaline margins passing to inner various tones of gray, to darker medial and basal parts
Medial fertile scale shape	narrowly lanceolate	lanceolate
Medial fertile scale width at the middle (mm)	0.3–0.7(–0.9)	(0.5–)0.7–1.4(–1.6)
Medial fertile scale apex	narrowly acuminate	acuminate
Medial fertile scale width (mm) at ca. 0.2 mm below the apex	mostly 0.1	mostly 0.2
Anther length (mm)	0.35–0.8	0.6–1.0
Achene color	brown to olive-brown	orange-brown to dark reddish-brown
Achene surface	glossy	dull

or below, with 1–3 incomplete nerves, acute, 0.3–0.5 mm wide at 0.2 mm below the apex. Perianth of 50–80 hypogynous bristles, pale beige-brown (or whitish in f. *turneri* Raymond), 25–40 mm long. Stamens with filaments about as wide as perianth bristles, anthers pale yellow, 0.7–1.6 mm long. Styles with 3(–4) stigmatic branches closed or sometimes spreading at maturity, branches 1.5–2.6 mm long. Achenes orange-brown, ellipsoid or slightly obovoid, trigonous to compressed-trigonous, glabrous or scabrous in the distal part, mostly dull, 1.9–2.6 × 0.8–1.1 mm, base cuneate, apex obtuse, with a straight beak, rarely oblique, slightly conical, 0.2–0.5 mm long, 0.1–0.2 mm wide at base.

Distribution and habitat.—*Eriophorum chamissonis* is restricted to northwestern North America, in Alaska and British Columbia. It is found in various kinds of sphagnum and minerotrophic bogs, marshy and beaver meadows, shallow ponds, muskeg, and heat tundra.

Discussion.—This taxon has a long history of various interpretations, of which the most important are those of Raymond (1954) and Novoselova (1993). As many morphological features of *E. chamissonis* overlap with those of *E. russeolum*, *E. chamissonis* has been frequently mistakenly reported in eastern North America (Raymond 1954; Novoselova 1993) and in eastern Russia. Material from Russia has been reassigned by Novoselova to other taxa such as *E. mandshuricum* Meinsch. subsp. *mandshuricum* or subsp. *sibiricum* Novoselova.

Eriophorum chamissonis is best differentiated from *E. russeolum* subsp. *russeolum* by the following characters (see also Table 1): mostly spherical spikelets with pale beige-brown bristles (typically obovoid spikelets with red-brown to dark orange-brown bristles in *E. russeolum*), anthers 0.7–1.6 mm (1.5–3.1 mm in *E. russeolum*), and various color pattern and shape of medial fertile scales: grayish to blackish middle and distal parts, sometimes with a more defined blackish triangle, with usually narrow-hyaline or whitish marginal and distal parts, very often covered with small dark reddish longitudinal spots (see Novoselova 1993, Fig. 1a), mostly lanceolate, the largest width below or near the middle (usually dark wide medial triangle with wide-hyaline margins, mostly without dark longitudinal spots, typically obovate, sometimes lanceolate or elliptic, the largest width above or near the middle in *E. russeolum*).

There are some individuals in northeastern North America with occasional pale orange-brown spikelets, shorter anthers (0.9–1.9 mm), darker, elliptic or lanceolate medial fertile scales with the largest width sometimes below the middle. At first glance, they could be considered within the variation of *E. chamissonis*, but they differ by two main characters. In *E. chamissonis* the first proximal sterile scale is 12–23(–30) mm long and the stem diameter below the inflorescence is 1.0–2.2 mm, whereas the odd northeastern material has the corresponding measurements of 8–11 mm long and 0.6–1.2 mm in diameter respectively. Those specimens are considered in this paper to be atypical *E. russeolum* subsp. *russeolum* or backcrosses of *E.* ×*medium* subsp. *medium* with *E. russeolum* subsp. *russeolum*. See the discussion below under *E. russeolum* subsp. *russeolum*.

In addition, micromorphological differences in the achene surface of *E. chamissonis* and *E. russeolum* have been pointed out by Tucker and Miller (1990). They also consider *E. chamissonis* to be a western North American species.

Selected specimens: **CANADA. British Columbia:** Hart Highway N of Prince George, 8 mi N of Ft. McLeod, 3 Aug 1954, *J.A. Calder et al. 13949* (DAO); near Hilliers between Parksville and Alberni, 49°16'N–124°46'W, 13 Jun 1961, *J.A. Calder & K.T. MacKay 30390* (DAO); near Kispiox River, about 12 mi NNW of Kispiox, N of Hazelton, 19 Aug 1954, *J.A. Calder et al. 14728* (DAO); along Kitsumkalum Lake road, about 8 mi N of Terrace, 22 Aug 1954, *J.A. Calder et al. 14907* (DAO); Hope Island, off N end of Vancouver Island, between Roller Bay and Mexicana Point, 5 Jul 1961, *J.A. Calder & K. T. MacKay 31290* (DAO); Lake Beautiful, 30 Jul 1935, *P.P. Henson s.n.* (DAO); between Prince Rupert and Galloway rapids, 18 Jul 1954, *J.A. Calder et al. 13216* (DAO); Queen Charlotte Islands (QCI), Graham Island, about 3/4 mi SW of Jalun Lake and 9 mi W of head of Naden Harbour, 1 Jul 1964, *J.A. Calder & R.L. Taylor 35663* (DAO); QCI, Graham Island, Masset Inlet, Mamin River delta at Juskatla, 15 Jun 1957, *R.L. Calder et al. 21358* (DAO); QCI, Graham Island, 4 mi W of Tlell on road to Port Clements, 26 Jun 1964, *J.A. Calder & R.L. Taylor 35457* (DAO); QCI, Graham Island, 2–3 mi E of Tow Hill, 20 Jul 1957, *J.A. Calder et al. 22756* (DAO); QCI, Graham Island, about 1 1/2–2 mi W of Tow Hill and E of Masset, 19 Jul 1957, *J.A. Calder et al. 22726* (DAO); QCI, Moresby Island, Cumshewa Inlet, a few mi N of Moresby Logging Camp, 29 Jun 1957, *J.A. Calder et al. 21938* (DAO); Seeley Lake, S of Hazelton, 24 Jun 1949, *R. Pillsbury 191* (DAO); Sicamous-Revelstoke Highway, E end of Victor Lake, 7 Jun 1953, *J.A. Calder & D.B.O. Savile 8796* (DAO); Southern Cariboo Mountains, Wells Gray Provincial Park, E side of Battle Mt., 1.5 mi NE of Stevens Lake, 25 Jul 1961, *L. & T. Ahti 7092* (DAO); 1 mi NW of Trout Lake on road from Beaton to Kaslo, 10 Jun 1954, *J.A. Calder & D. B. O. Savile 8964* (DAO); about 1 mi N of Trout Lake, 50°39'N–117°34'W, 25 Jun 1962, *J.A. Calder & K.W. Spicer 33647* (DAO). **UNITED STATES. Alaska:** Attu

Island, Peaceful Valley, near Navy Town, 52°50'N-173°11'W, 18 Aug 1983, *B.F. Friedman (83-59) & J.A. Michaelson* (DAO, 2 collections); Eagle River, near Juneau, 28 Jun 1940, *J.P. Anderson 6201* (DAO, 2 collections).

Eriophorum russeolum—Eriophorum scheuchzeri complex

A) Taxa with orange-brown spikelets (**Figs. 1–6**)

1. Eriophorum russeolum Fries in Hartman subsp. **russeolum**, Handb. Scand. Fl. ed. 3:13. 1838. TYPE: SWEDEN. TORNE LAPPMARK, Karesuando, *L.L. Laestadius s.n.* (LECTOTYPE, designated here: "Lappon. Tornens. Karesuando, *L.L. Laestadius s.n.* Herbarium normale Fasc. 3, no 67" UPS V-108936!, DAO (photograph)! The sheet selected bears three specimens, the middle one clearly rhizomatous.

Eriophorum russeolum var. *majus* Sommier, Fl. Ob Infer. 103. 1896. TYPE: RUSSIA. WESTERN SIBERIA: Ob River, *E. Sommier s.n.* (LECTOTYPE, designated here: "Siberia, ad flumen Ob, ripae laevae terra firma Muzhi, solo subpaludoso, sphagnoso, 4-VIII-1880, *E. Sommier s.n.*" FI!, DAO (photograph)! The four specimens on the sheet have scabrous achenes and medial fertile scales with wide-hyaline margins.

Herbs perennial with short to elongate rhizomes. Vegetative shoots 1–3, 19–32 cm high, leaf margins mostly glabrous. Stems erect, glabrous, mostly terete in cross section, 15–55 cm high, 0.7–1.6 mm in diameter below the inflorescence. Leaves basal and cauline 2–6. Proximal sheaths brown, pale brown to gray-brown, with orange-brown spots on distal membranous parts, ligules obtuse. Highest distal sheath situated above, below or near the medial part of the stem, 1.6–3.5 mm wide, with reduced blades. Blades of proximal sheaths flat to slightly cymbiform, 30–240 × 0.9–1.6 mm, glabrous or rarely scabrous in distal parts, the apex obtuse to rounded. Blades of distal sheaths 2–18 × 0.9–1.2 mm. Spikelets solitary, typically obovoid at maturity (Fig. 1), but often ellipsoid, 1.5–4.0 × 1.5–5.0 cm, with 100–150 florets. Proximal scales 3–7, without florets. First proximal scale olive-brown to dark olive-green, becoming pale beige to hyaline in distal parts, triangular-lanceolate, elliptic to ovate, 7–14(–18) × 3.4–4.4 mm, with 3–8 orange-brown nerves converging below the apex, acute, acuminate or rarely short-awned. Medial fertile scales with well demarcated and extended proximal part (Fig. 2), 1.5–3.5 mm long, averaging 30–49% of total scale length, orange-brown to beige-brown, with medial part forming a ± extended dark triangle, with wide-hyaline or whitish marginal and distal parts, typically obovate (Fig. 2a), sometimes lanceolate or elliptic, 4.0–7.5 × 1.3–2.2 mm, the widest part near the middle or above, rarely below, with 1 incomplete nerve, obtuse, acute or acuminate, 0.2–0.5(–0.9) mm wide at 0.2 mm below the apex. Perianth of 50–70 hypogynous bristles, pale to dark orange-brown or red-brown (Fig. 1), 25–32 mm long. Stamens with filaments about as wide as perianth bristles, anthers yellow, 1.5–3.1 mm long. Styles with 3 stigmatic branches open to spreading at maturity, branches 1.2–1.8 mm long. Achenes pale olive-green, gray-olive, dark olive-green or brownish (Fig. 3), obovoid or ellipsoid, trigonous to compressed-trigonous, glabrous (Fig. 3b) or scabrous (Fig. 3a) in the distal part, lustrous or slightly lustrous, 2.05–2.70 × 0.75–1.30 mm, base cuneate, apex obtuse to slightly rounded, with a straight beak (Fig. 3a), rarely oblique (Fig. 3b), conical, 0.2–0.6 mm long, 0.1–0.25 mm wide at base. Figs. 1–3.

Distribution and habitat.—This typical subspecies is amphi-Atlantic, ranging from central Russia westward to Northern Europe and eastern North America, from Newfoundland, Labrador, the Maritime provinces, Quebec, the islands of Nunavut in James Bay to Ontario. Its ecological affinities in North America are boreal and its range does not extend far beyond the treeline. It is found mostly in fens or minerotrophic bogs of various kinds, at the edge of pools, ponds or on lakeshores, the typical habitats for all six taxa in the *E. russeolum* and *E. scheuchzeri* groups.

Discussion.—This is the most common taxon with orange-brown spikelets in northeastern North America. Its distinguishing features are the typically obovoid spikelets and their orange-brown to dark orange-brown color (Fig. 1). The characters of the medial fertile scales are important (Table 1, Fig. 2): a unique color pattern consisting of a long demarcated proximal part, usually orange-brown, that covers up to half the length of the scale (Fig. 2a), a central zone represented by a wide black triangle, and wide marginal and distal whitish or hyaline parts; a wide lanceolate, elliptical or obovate shape, the widest of all the taxa considered here (1.3–2.2 mm), the widest area situated above (Fig. 2a) or near the middle (Fig. 2b) of the scale, with a mostly acute apex (better indicated by measurements taken at 0.2 mm below the apex: 0.2–0.5(–0.9) mm) (Table 1). Anthers and achenes are the longest and largest of all orange-brown taxa. Achenes (Fig. 3) are about equally glabrous or scabrous (Table 1, Fig. 3), which is a bit different from data reported for material from Russia and northwestern Europe (Berggren 1969; Novoselova 1993). Achene beaks are the longest of all the taxa (0.2–0.6 mm) and the widest at the base (0.1–0.25 mm); they are more often straight than oblique. The achene beaks of *E.* ×*medium* subsp. *medium* differ in that they are shorter, narrower and more frequently oblique (Table 1, Fig. 6).

Variation is also encountered in a group of specimens considered atypical because of darker and narrower medial scales, shorter anthers (mostly 1.3–1.9 mm), more frequently glabrous achenes, and achenes with narrower beaks. When these atypical specimens are found outside the range of the hybrid *E.* ×*medium* subsp. *medium*, they could be interpreted as expressions of the variation of *E. russeolum* subsp. *russeolum*. When they occur within the range of that hybrid they could also represent backcrosses of *E.* ×*medium* subsp. *medium* with *E. russeolum* subsp. *russeolum*. Experimental and field studies will be needed to help solve the problem represented by these atypical specimens.

2. Eriophorum ×**medium** Andersson subsp. **medium**, Bot. Not. 1857:62. 1857. (*Eriophorum russeolum* subsp. *russeolum* × *E. scheuchzeri* subsp. *scheuchzeri*) TYPE: SWEDEN. LULE LAPPMARK: prope Quickjock, *N.J. Andersson s.n.* (HOLOTYPE: S, not seen).

Eriophorum ×*gauthieri* Boivin, Provancheria 25:43. 1992. TYPE: CANADA: LABRADOR, Grady and Cross Islands, 26 Jul 1933, *G. Gardner 18* (HOLOTYPE: QFA!; ISOTYPE: QFA!).

Herbs perennial with short to elongate rhizomes. Vegetative shoots 1–3, 8–24 cm high, leaf margins mostly glabrous. Stems erect, glabrous, mostly terete in cross section, 16–42 cm high, 0.7–1.5(–1.7) mm in diameter below the inflorescence. Leaves basal and cauline 3–7. Proximal sheaths green, olive-green, beige-brown, reddish brown to dark brown, with orange-brown spots on distal membranous parts, ligules obtuse. Highest distal sheath situated below the medial part of the stem, 1.8–3.4 mm wide, with reduced blades. Blades of proximal sheaths flat to slightly cymbiform, 50–190 × 0.7–1.6 mm, glabrous or rarely scabrous in distal parts, the apex obtuse to rounded. Blades of distal sheaths 1–13 × 0.4–0.9 mm. Spikelets solitary, hemispherical (Fig. 4), sometimes ovoid or ellipsoid at maturity, 1.4–4.0 × 0.9–6.0 cm, with 100–150 florets. Proximal scales 3–5, without florets. First proximal scale dark olive-brown to blackish, becoming hyaline brown in marginal and distal parts, ovate, 7–11(–17) × 2.2–4.7 mm, with 5–10 orange-brown or pale brown nerves converging below the apex, acuminate. Medial fertile scales with reduced proximal part (Fig. 5), 0.9–1.5 mm long, averaging 17–27(–37) % of total scale length, whitish, pale green or pale beige, with medial and distal parts blackish (Fig. 5a), with marginal and distal parts reduced-hyaline (Figs. 5b–c), lanceolate, 3.6-7.3(–8.0) × 0.7–1.3 mm, the widest part mostly below the middle, with 1 incomplete nerve, acuminate, mostly 0.1–0.3 mm wide at 0.2 mm below the apex. Perianth of 30–50 hypogynous bristles, orange-brown to pale orange-brown (Fig. 4) or red-brown, 15–20 mm long. Stamens with filaments about as wide as perianth bristles, anthers yellow, 0.8–1.5(–1.8) mm long. Styles with 3 stigmatic branches mostly closed at maturity, branches 0.7–2.0 mm long. Achenes chestnut brown (Fig. 6), obovoid, mostly narrowly obovoid, rarely ellipsoid, compressed-trigonous, glabrous, slightly lustrous, 1.6–2.5 × 0.6–0.9(–1.1) mm, base cuneate, apex acute or obtuse, with a straight (Fig. 6b) or oblique beak (Fig. 6a), mostly cylindrical, 0.2–0.3 mm long, 0.1–0.15 mm wide at base. Figs. 4–6.

Distribution.—Described from Scandinavian material, up until now this hybrid had been found only in north central Russia, westward to northern Scandinavia (Novoselova 1993, 1994a). Reports of *E. medium* from an almost continuous range in the Russian Arctic (Tolmachev 1996) do not in every case represent hybrids between *E. russeolum* subsp. *russeolum* and *E. scheuchzeri*, because they refer to a taxon bearing white or orange-brown spikelets. *Eriophorum* ×*medium* subsp. *medium* can now be added to the flora of North America based on collections in Labrador and northern Quebec (Nunavik), ranging from ca 51°N to 59°N. Previous reports of *E.* ×*medium* in North America, mostly from the Northwest, did not represent hybrids between *E. russeolum* subsp. *russeolum* and *E. scheuchzeri* subsp. *scheuchzeri*. *E.* ×*medium* is a boreal amphi-Atlantic taxon like one of its parents, *E. russeolum* subsp. *russeolum*.

Discussion.—This hybrid is occasional in the sympatric range of its two parental species in eastern North America. It had not been previously detected despite the fact that many morphological characters are intermediate between those of the two parents (Table 1). The orange-brown spikelets are more often than not paler and smaller (Fig. 4) than those of *E. russeolum* subsp. *russeolum*, and their shape is highly variable, more often than not hemispherical, like those of *E. scheuchzeri* subsp. *scheuchzeri* (Fig. 7). Anther lengths are intermediate (0.8–1.5 mm) as are the majority of achene characters. The main differences are illustrated by the medial fertile scales which are closer to those of *E. scheuchzeri* subsp. *scheuchzeri* in the preponderance of blackish color, in the frequent reduction of marginal and distal hyaline parts, in the color variation and shortness of proximal parts, in the narrow width (0.7–1.3 mm) and acuminate apex, and in the maximum width mostly being located below the middle (Table 1, Figs. 5, 9). This is in accordance with Novoselova's observations (1993) of *E.* ×*medium* in Russia and northwestern Europe. Some individuals from North America have medial scales with more developed hyaline margins and a narrow central blackish triangle (Fig. 5c), corresponding to material from northern Europe studied by Faegri (1958: Fig. 1D–E) and reported to belong in part to *E.* ×*medium*. I observed the same pattern in some individuals of the hybrid between *E. russeolum* subsp. *leiocarpum* and *E. scheuchzeri* subsp. *scheuchzeri* (Fig. 16c).

The examination of type material of *E.* ×*gauthieri* Boivin (1992), described from Labrador as the hybrid between *E. chamissonis* and *E. scheuchzeri*, shows that it is identical to *E.* ×*medium* subsp. *medium*. Boivin (1992) included both whitish and orange-brown taxa of *E. russeolum* within *E. chamissonis*.

The presence of well-formed achenes in many individuals seems to indicate that some specimens may have become stabilized enough to be considered orthospecies of hybrid origin, as has been hypothesized for plants in northern Europe (R. Elven, pers. comm.). Further studies are needed to confirm this hypothesis.

Specimens examined. **CANADA. Labrador:** Belle Isle, South Point, 51°53'N–55°24'W, 25 Jul 1986, *T.A. Hedderson 4061* (CAN); Black Island, 17–19 Jul 1938, *G. Gardner 38113* (QFA, 2 collections); Grady and Cross Islands, 26 Jul 1933, *G. Gardner 18 [B]* (QFA, 2 collections, holotype & isotype of *Eriophorum* ×*gauthieri* Boivin, mixed with *E. scheuchzeri* subsp. *scheuchzeri*); Indian Harbour & Fox Cove, 16 Jul 1892, *C. B) Taxa with white spikelets (**Figs. 7–20**)

3. Eriophorum russeolum Fries in Hartman subsp. **leiocarpum** Novoselova, Bot. Žurn. (St. Petersburg) 78(8):86. 1993. TYPE: RUSSIA. FAR EAST: E Chukotka, in vicinus pagi Nutepelmen, vallis rivi in sinum Pyngo-pilchin influentes, 16 Aug 1969, *A.A. Neczaeva & T.V. Plieva s.n.* (HOLOTYPE: LE, not seen).

Herbs perennial with short to elongate rhizomes. Vegetative shoots 1–3, 15–21 cm high, leaf margins mostly glabrous. Stems erect, glabrous, mostly terete in cross section, 14–51 cm high, 0.7–1.5 mm in diameter below the inflorescence. Leaves basal and cauline 1–7. Proximal sheaths brown, pale brown, chestnut brown to dark brown, with orange-brown spots on distal membranous parts, ligules acute to obtuse. Highest distal sheath mostly situated below the medial part of the stem, 2.1–3.5 mm wide, with blades reduced or lacking. Blades of proximal sheaths flat to slightly cymbiform, 40–230 × 0.7–2.3 mm, mostly glabrous, the apex obtuse. Blades of distal sheaths 0.2–21 × 0.2–1.1 mm, or lacking. Spikelets solitary, ellipsoid or obovoid at maturity (Fig. 18), 2.0–4.0 × 1.5–3.5 cm, with 150 or more florets. Proximal scales 4–6, without florets. First proximal scale olive-brown, olive-green, dark gray to blackish, becoming pale beige to whitish hyaline in distal parts, lanceolate to ovate-lanceolate, (5.7–)7–16 × 3.0–5.3 mm, with 1–5 orange-brown or blackish nerves converging below the apex, acute or acuminate. Medial fertile scales with moderate to extended proximal part (Fig. 19), 0.8–3.2 mm long, averaging (11–)18–57% of total scale length, orange-brown, pale brown, pale green or whitish, with the medial part forming a ± extended dark triangle, with marginal and distal parts mostly wide-hyaline (Fig. 19a), obovate, lanceolate or elliptic, 3.7–8.4 × (0.8–)1.0–2.4 mm, the widest part near the middle or above, rarely below, with 1 incomplete nerve, acute, 0.25–0.6 mm wide at 0.2 mm below the apex. Perianth of 15–50 hypogynous bristles, white to dull white (Fig. 18), 12–30 mm long. Stamens with filaments about as wide as perianth bristles, anthers yellow or dark yellow, (1.3–)1.5–3.1 mm long. Styles with 3(–4) stigmatic branches barely open at maturity, branches 1.3–3.2 mm long. Achenes pale or dark olive-green, brownish or black-brownish (Fig. 20), obovoid (Fig. 20b) or ellipsoid (Fig. 20a), trigonous to compressed-trigonous, glabrous (Fig. 20b) or scabrous (Fig. 20a) in the distal part, slightly lustrous, 2.0–2.7 × 0.6–1.2 mm, base cuneate, apex obtuse, with a beak more straight than oblique, conical, 0.2–0.5 mm long, 0.1–0.2 mm wide at base. Figs. 18–20.

Distribution.—The group of *E. russeolum* with white spikelets has a very different range from the group with orange-brown spikelets and was found to be distinct enough to be considered a subspecies by Novoselova (1993). Its range is amphi-Beringian, discontinuous in northwestern Russia, continuous from north central Russia eastward to Alaska, the Canadian Yukon and Northwest Territories, the islands and continental portion of Nunavut, the Prairie provinces as far east as Manitoba, with scattered sites in eastern North America: Ontario, Quebec, Labrador, New Brunswick and Nova Scotia, with an extension in Minnesota and Wisconsin. Reports of *E. chamissonis* s.l. from the Rocky Mountains (Ball & Wujek 2002) have not been searched for this study and I dont know if they could refer to *E. russeolum* subsp. *leiocarpum* or not. The present study brought collections from the northern part of Nunavik in Quebec (ca 60°–61°N) to light for the first time.

Discussion.—For a long period in the North American literature, the group of *E. russeolum* with white spikelets was called *E. russeolum* var. *albidum* F. Nylander, and even *E. chamissonis* var. *albidum* (F. Nylander) Fernald or f. *albidum* (F. Nylander) Fernald. In his protologue, Nylander (1846: 10) designated a specimen from Alaska (Kodiak Island) that has not yet been found at LE as the type of his variety. This is not in accordance with Novoselova (1993) who states that Nylander's variety, a taxon she considers a synonym for *E.* ×*medium* [subsp. *medium*], was described from Scandinavian material. Even if one accepts that *E. russeolum* var. *albidum* was described from within the actual range of *E. russeolum* subsp. *leiocarpum*, it is difficult to consider var. *albidum* a synonym for subsp. *leiocarpum* because of a major divergent character of the medial fertile scales in Nylander's protologue. Nylander described var. *albidum*'s fertile scales as being "narrowly-lanceolate" (squamis lineari-lanceolatis), whereas subsp. *leiocarpum*'s are typically obovate, elliptic or lanceolate (Fig. 19). Novoselova's name (subsp. *leiocarpum*) is retained here because the subspecific level is more appropriate for separating the almost non-sympatric *E. russeolum* taxa, and because *leiocarpum* was the first name to be attributed at the subspecific level.

Eriophorum russeolum subsp. *leiocarpum* is quite variable and some specimens can be considered merely as white-colored counterparts to orange-brown *E. russeolum*. Nevertheless, the spikelets of this subspecies tend to be more often ellipsoid than obovoid, the achenes more often obovoid than ellipsoid, and the achene beaks narrower on average than in subsp. *russeolum* (Table 1). This variation is encountered in all parts of subsp. *leiocarpum*'s North American range. Specimens from higher latitudes (e.g. Nunavut) tend to have more blackish medial scales (Fig. 19b), but all other characters are within the variation of the subspecies.

Specimens examined. **CANADA. Yukon:** Kluane National Park, Alder Creek, 60°18'15"N–137°21'45"W, 7 Aug 1974, *R.D. Wickstrom 318.11 K-AC* (DAO); Northern Richardson Mountains, 68°22'53"N–137°07'31"W, 7 Jul 1993, *V. Loewen & J. Staniforth 93-154* (DAO); Idem, 68°11'42"N–137°25'27"W, 17 Jul 1993, *V. Loewen & J. Staniforth 93-252* (DAO); North Yukon National Park, British Mountains, Firth River delta, 69°30'N–139°30'W, 26 Jul 1988, *C. Kennedy 174* (DAO). **Northwest Territories:** The Enterprise-Mackenzie River Highway, mile 50, 16 Jul 1959, *J.W. Thieret & R.J. Reich 5392* (DAO); Porter Lake, 61°44'N, 26 Jul 1970, *W.J. Cody 19107* (DAO), Small Tree Lake, 61°N–105°W, 20 Jul 1961, *J.S. Maini*
