4. Eriophorum ×medium Andersson subsp. **album** J. Cayouette, subsp. nov. (*E. russeolum* subsp. *leiocarpum* × *E. scheuchzeri* subsp. *scheuchzeri*) TYPE: CANADA. NUNAVUT: Baffin Island, Nettiling Lake, 66°40'N–70°W, 28 Jul 1925, *J. Dewey Soper s.n.* (HOLOTYPE: CAN 25686).

A subspeciei typica setis albis vel subcremeis, (10–)22–32 mm longis differt. Verosimiliter hybrida inter *Eriophorum russeolum* subsp. *leiocarpum* et *Eriophorum scheuchzeri* subsp. *scheuchzeri*. Plantae perennes rhizomatibus abbreviatis vel elongatis. Culmi erecti, laeves, teretes, 22–40 cm alti, 0.8–1.1 mm diametro sub spiculis. Vagina superior culmi media parte inferiore inserta, raro ad medium, foliis 0.3–17 mm longis, 0.3–0.8 mm latis, vel nullis. Spiculae unicae, fructificatione hemisphaericae, ovoideae vel obovoideae, 1.6–4 cm altae, setis albis vel subcremeis. Squama sterilis infima 7.1–11.5 mm longa. Squamae fertiles medianae cum proximale parte breviore, 0.5–1.7 mm longa, 9–34% squamae totae longitudinis delemitante, albida, pallide viride vel pallide ferruginea, cum media parte anguste triangulariter atrata, cum marginibus et apice anguste hyalinis, 0.6–1.1 mm latae, squamae media parte inferiore maxima latitudine, apice acuminato, 0.15–0.3(–0.4) mm lato ad 0.2 mm infra apicem. Setae hypogyneae (10–)22–32 mm longae. Antherae 0.9–1.6 mm longae. Stigmatum rami tres vel quatuor, 1.0–2.2 mm longi. Achenia glabra, anguste obovoidea vel ellipsoidea, 0.6–0.9 mm lata, rostro recto vel curvato, praecipue cylindrico, basi 0.1 mm lato. Figs. 15–17.

Herbs perennial with short to elongate rhizomes. Vegetative shoots 1–2, 6–24 cm high, leaf margins mostly glabrous. Stems erect, glabrous, terete in cross section, 22–40 cm high, 0.8–1.1 mm in diameter below the inflorescence. Leaves basal and cauline 2–6. Proximal sheaths beige-brown to reddish brown, with orange-brown spots on distal membranous parts, ligules acute. Highest distal sheath situated below the medial part of the stem, rarely near the middle, 2.2–2.9 mm wide, with blades reduced or lacking. Blades of proximal sheaths flat to slightly cymbiform, 120–150 × 0.8–0.9 mm, glabrous, the apex obtuse. Blades of distal sheaths 0.3–17 × 0.3–0.8 mm, or lacking. Spikelets solitary, hemispherical, ovoid or obovoid at maturity (Fig. 15), 1.6–4.0 × 2.0–4.5 cm, with about 150 florets. Proximal scales 3–5, without florets. First proximal scale dark olive-green or blackish, becoming brown-hyaline or brown-beige in distal and marginal parts, ovate to ovate-lanceolate, 7.1–11.5 × 2.6–3.7 mm, with 3–5 brown to orange-brown nerves converging below the apex, acuminate. Medial fertile scales with a reduced proximal part (Fig. 16), 0.5–1.7 mm long, averaging 9–34% of total scale length, whitish, pale green or pale beige, with the medial part blackish forming a narrow triangle (Fig. 16b), with marginal and distal parts reduced-hyaline (Figs. 16a–b), lanceolate, 3.8–6.7 × 0.6–1.1 mm, the widest part mostly below the middle, with 1 incomplete nerve, acuminate, 0.15–0.3(–0.4) mm wide at 0.2 mm below the apex. Perianth of about 50 hypogynous bristles, white to dull white (Fig. 15), (10–)22–32 mm long. Stamens with filaments about as wide as perianth bristles, anthers yellow-green, 0.9–1.6 mm long. Styles with 3(–4) stigmatic branches mostly closed at maturity, branches 1.0–2.2 mm long. Achenes beige-brown to orange-brown (Fig. 17), narrowly obovoid or narrowly ellipsoid, compressed-trigonous or slightly biconvex, glabrous, slightly lustrous, 1.9–2.5 × 0.6–0.9 mm, base cuneate, apex obtuse, with a straight (Fig. 17b) or oblique (Fig. 17a) beak, mostly cylindrical, 0.2–0.3 mm long, 0.1 mm wide at base. Figs. 15–17.

Distribution.—This nothosubspecies is currently known only in northeastern Canada, from continental Nunavut (Chesterfield Inlet), the Nunavut part of the Arctic Archipelago (Baffin and Southampton Islands, from 63°N to 66°N), south to northern Quebec (Nunavik), in the northernmost part of the peninsula (61°N–62°N) and at treeline near Hudson Bay (57°N–58°N). Since the sympatric range of the two parental taxa covers large parts of the Nunavut and Northwest Territories, the western Canadian provinces, Alaska, and eastern to western parts of Russia, *E.* ×*medium* subsp. *album* is likely to be discovered in some of these major areas. Nevertheless, no specimen from outside of northeastern Canada has yet been identified as this hybrid subspecies (Novoselova pers. comm.). There is a slight possibility that the taxon described from Alaska as *E. russeolum* var. *albidum* by Nylander (1846: 10) and bearing "narrowly lanceolate scales" could refer to that new nothosubspecies, but the type should be searched and examined.

Discussion.—A grouping among specimens that did not fit the normal variation of either *E. russeolum* subsp. *leiocarpum* or *E. scheuchzeri* subsp. *scheuchzeri* was perceived and formally given the taxonomic status of a new nothosubspecies. Although different from these taxa, the specimens shared most of the characteristics of *E.* × *medium* subsp. *medium* except for the color of the spikelets and the length of the stigmatic branches (Table 1). The two subspecies of *E.* ×*medium* share size, shape, apex, color pattern, and maximum width below the middle of the medial fertile scales (Figs. 5, 16); medium-sized anthers (0.9–1.6 mm); and important achene characters (shape, width, beak width and shape) (Table 1, Figs. 6, 17). The shared characters are intermediate between those of *E. russeolum* subsp. *leiocarpum* and *E. scheuchzeri* subsp. *scheuchzeri*. Even if some characters of the hybrid subspecies overlap with extremes of variation of *E. russeolum* subsp. *leiocarpum*, I prefer to consider this taxon as a hybrid because many characters are intermediate between those of the two parental taxa (Table 1). A similar situation has been encountered and studied in a few Arctic *Ranunculus* hybrids (Cayouette et al. 1997).

Some specimens cited as paratypes have been previously considered by other authors as hybrids or potential hybrids involving the whitish *E. russeolum* and *E. scheuchzeri*. Polunin so annotated several specimens from Nunavut (CAN) and later discussed the possibility of *E. russeolum*–*E. scheuchzeri* hybridization (Polunin 1940: 100). Boivin (1992) cited one Polunin collection of the then undescribed *E.* ×*medium* subsp. *album* from Nunavut as a paratype of *E.* ×*gauthieri*, a taxon that Boivin believed to be an *E. chamissonis* × *E. scheuchzeri* combination. All these published remarks match the description of *E.* ×*medium* subsp. *album*.

A form of *E.* ×*medium* subsp. *medium* with white spikelets known as f.

candidum (Norman) Blomgren, has been described from Scandinavia (Hylander 1982). Although not yet known in North America, this form may be expected in the vicinity of the treeline in northern Quebec, where the two subspecies of *E. russeolum* coexist with *E. scheuchzeri*. In the event of its discovery there, *E.* ×*medium* subsp. *medium* f. *candidum* might be mistaken for *E.* ×*medium* subsp. *album*. To avoid any possible confusion, I have selected a type specimen for *E.* ×*medium* subsp. *album* from Nunavut (Baffin Island), where only *E. russeolum* subsp. *leiocarpum* is sympatric with *E. scheuchzeri* subsp. *scheuchzeri*. To date, all specimens of subsp. *album* collected at the treeline in northern Quebec have turned out to be similar to the type specimen selected from Baffin Island (66°N).

As for the typical hybrid subspecies, some paratypes of *E.* ×*medium* subsp. *album* have been seen with good mature achenes, indicating that subsp. *album* has perhaps become a stabilized orthospecies of hybrid origin in some areas. Further investigations are needed to clarify this interpretation.

5. Eriophorum scheuchzeri Hoppe subsp. **scheuchzeri**, Bot. Taschenb. 104, plate 7. 1800. TYPE: AUSTRIA ("... am Tuscher Tauern") (HOLOTYPE: W, monocots destroyed, see Holmgren et al. 1990).

Herbs perennial with short to elongate rhizomes. Vegetative shoots 1–3, 5–30 cm high, leaf margins glabrous. Stems erect, glabrous, terete in cross section, 9–42 cm high, 0.6–1.5(–1.8) mm in diameter below the inflorescence. Leaves basal and cauline 3–5. Proximal sheaths pale green at first, becoming pale or dark orange-brown, with orange-brown spots on distal membranous parts, ligules acute or obtuse. Highest distal sheath very often situated below the medial part of the stem, 2.1–3.6 mm wide, with blades reduced or lacking. Blades of proximal sheaths flat to slightly cymbiform, 25–130 × 0.5–1.4 mm, glabrous or rarely scabrous in distal parts, the apex mostly acute. Blades of distal sheaths shorter, 0.2–55 × 0.2–1.0 mm, or lacking. Spikelets solitary, typically hemispherical at maturity (Fig. 7), 1.0–3.0 × 1.4–4.5 cm, with 150 or more florets. Proximal scales 5–6, without florets. First proximal scale olive-brown or blackish, becoming pale brown, yellowish brown or pale beige in distal parts, and pale beige or hyaline on the margins, widely lanceolate or ovate, 5–12 × 1.6–4.3 mm, with 4–9 beige or olive nerves converging below the apex, acuminate. Medial fertile scales with a short proximal part (Fig. 9), 0.1–0.9 mm long, averaging 2–25% of total scale length, pale green or whitish, with the medial part blackish or dark gray, with marginal parts blackish (Fig. 9a) or narrowly hyaline (Figs. 9b–c), and the distal part dark or hyaline, narrowly lanceolate, 3.2–5.3 × 0.4–1.0 mm, the widest part below the middle or close to the base, with width at the middle 0.3–0.7(–0.9) mm, with 1 incomplete nerve, narrowly acuminate, 0.05–0.1(–0.2) mm wide at 0.2 mm below the apex. Proximal fertile scales very similar (Fig. 8), blackish, with well-delimited narrow hyaline margins (Fig. 8b) or with hyaline margins lacking (Fig. 8a). Perianth of about 30 hypogynous bristles, white or cream white (Fig. 7), 15–25 mm long. Stamens with filaments about as wide as perianth bristles, anthers yellow or pale yellow, 0.35–0.8 mm long. Styles with 3(–4) stigmatic branches barely open at maturity, branches 0.5–1.3 mm long. Achenes beige-brown to olive-brown (Fig. 10), narrowly obovoid, obscurely trigonous, slightly biconvex or plano-convex, glabrous, slightly lustrous, 1.7–2.4 × 0.5–0.85 mm, base cuneate, apex acute, with a beak more often oblique or curved (Fig. 10b) than straight (Fig. 10a), mostly cylindrical, 0.15–0.4 mm long, 0.05–0.1 mm wide at base. Figs. 7–10.

Distribution.—*Eriophorum scheuchzeri* was recently subdivided into two subspecies by Novoselova (1994b), and the typical subspecies is very common and widespread in the southern parts of the Arctic zones. *Eriophorum scheuchzeri* subsp. *scheuchzeri* is an arctic-alpine circumpolar taxon (Novoselova 1994a, 1994b). In North America, it covers both Arctic and Boreal zones (Hultén and Fries 1986). In northeastern North America, it is sympatric with both subspecies of *E. russeolum*, ranging southward to Labrador, Newfoundland, and the southern reaches of James Bay at about 51°N (Scoggan 1978).

Discussion.—The typical subspecies of *E. scheuchzeri* differs from other rhizomatous taxa with solitary whitish spikelets, including their hybrids with the two subspecies of *E. russeolum*, by having the shortest anthers (0.35–0.8 mm) and the narrowest (0.4–1.0 mm) and the most narrowly acuminate medial fertile scales (Table 1, Fig. 9). These scales are dark gray or blackish with narrow hyaline margins or with hyaline margins absent. Achenes are narrowly obovoid, obscurely trigonous, their beaks narrowly cylindrical, and more often oblique than straight (Table 1, Fig. 10). The main differences between subsp. *scheuchzeri* and subsp. *arcticum* are given in Table 2.

6. Eriophorum scheuchzeri Hoppe subsp. **arcticum** Novoselova, Bot. Žurn. (St. Petersburg) 79(4):112. 1994. TYPE: RUSSIA. JENISSEJSK, hibernaculum inter sinus Wildii et Stellingii, 23 Jul 1915, *I. Trzhemesky 35* (HOLOTYPE: LE, not seen).

Herbs perennial with short to elongate rhizomes. Vegetative shoots 1–3, 4–7 cm high, leaf margins glabrous. Stems erect, glabrous, terete in cross section, 11–28 cm high, 0.7–1.6(–1.8) mm in diameter below the inflorescence. Leaves basal and cauline 1–4. Proximal sheaths apple green first, becoming pale orange-brown, with or without orange-brown spots on distal membranous parts, ligules acute or obtuse. Highest distal sheath most often situated below the medial part of the stem or near the base, 2.2–3.4 mm wide, with blades reduced or mostly lacking. Blades of proximal sheaths flat to slightly cymbiform, 15–80 × 0.5–1.1 mm, glabrous, the apex mostly obtuse. Blades of distal sheaths shorter, 2–20 × 0.4–0.8 mm, or mostly lacking. Spikelets solitary, typically spherical (Fig. 11) or slightly flattened at maturity, 1.5–2.5 × 1.5–4.0 cm, with 100 or more florets. Proximal scales 1–4, without florets. First proximal scale blackish, becoming pale brown or pale beige in distal parts, with well developed hyaline margins, ovate-lanceolate, 6–9 × 2.9–4.2 mm, with 3–7 brown or gray nerves converging below the apex, acute. Medial fertile scales with a short proximal part (Fig. 13), 0.5–1.0 mm long, averaging 8–21% of total scale length, pale green, pale brown or blackish, with the medial part grayish or dark gray-brown, with marginal parts dark (Fig. 13b) or narrowly hyaline (Fig. 13a), and the distal part dark or hyaline, lanceolate, 4.0–6.0 × 0.7–1.5(–1.7) mm, the widest part below the middle, with width at the middle (0.5–) 0.7–1.4(–1.6) mm, with 1 incomplete nerve, acuminate, 0.1–0.25(–0.3) mm wide at 0.2 mm below the apex. Proximal fertile scales different (Fig. 12), bicolor, with lower and medial parts dark but gradually passing into various tones of gray and conspicuous marginal and distal hyaline areas. Perianth of 25–40 hypogynous bristles, white (Fig. 11), 16–25 mm long. Stamens with filaments about as wide as perianth bristles, anthers yellow or pale yellow, 0.6–1.0 mm long. Styles with 3 stigmatic branches barely open at maturity, branches 0.7–1.5 mm long. Achenes orange-brown to dark reddish-brown (Fig. 14), narrowly obovoid, mostly biconvex or slightly plano-convex, glabrous, mostly dull, 1.5–2.2 × 0.5–0.7(–0.9) mm, base cuneate, apex acute, with a beak more often oblique or curved (Fig. 14a) than straight (Fig. 14b), mostly cylindrical, 0.15–0.3 mm long, 0.05–0.1 wide at base. Figs. 11–14.

Distribution.—Like *Eriophorum scheuchzeri* subsp. *scheuchzeri*, subsp. *arcticum* is at least partially circumpolar, according to Novoselova (1994a, 1994b), but its range is more High Arctic than the typical subspecies, as is illustrated by its distribution in northern Russia. Novoselova claims that subsp. *arcticum* ranges across Alaska, Arctic North America and Greenland. My results confirm its presence in the Canadian High Arctic Nunavut (from at least 67°N to 81°N) and establish its southern limits on islands in Hudson Bay and in Arctic Quebec at latitude 59°N or 60°N (see specimens examined). Since one cited collection is from Port Burwell, Quebec, its presence in adjacent northern Labrador is expected, but no specimen has yet been positively identified.

Discussion.—Differences between the two subspecies were pointed out by Novoselova (1994b). Since no North American specimens of subsp. *arcticum* were cited in her work, the attempt was made to uncover voucher collections of the subspecies in order to discover the most useful characters to differentiate between the two *E. scheuchzeri* taxa. The results are highlighted in Table 2 and have been confirmed by Novoselova (pers. comm.). The best characteristics were noticed in the color pattern of the proximal fertile scales (Figs. 8, 12), and in the widths of the medial fertile scales if measured near the middle of the scales and at 0.2 mm below the apex (Figs. 9, 13). Scales were wider in subsp. *arcticum* and acuminate (Fig. 13), instead of being narrowly acuminate (Fig. 9) as in the typical subspecies. Mature spikelets tended to be spherical (Fig. 11) in subsp. *arcticum*, rather than hemispherical (Fig. 7) as in subsp. *scheuchzeri*. A color difference was observed in mature achenes (Table 2, Figs. 10, 14). At the southernmost limit of *E. scheuchzeri* subsp. *arcticum* and elsewhere in the sympatric range of the two subspecies, a few specimens tend to be of intermediate nature.

Since only a few voucher specimens of subsp. *arcticum* were collected within the borders of Quebec, I have proposed that it be added to the provincial list of threatened and endangered vascular plant species.

Specimens examined. **CANADA. Nunavut:** Axel Heiberg Island, 79°54' N–87°43' W, 19 Jul 1980, *G.W. Scotter & S. C. Zoltai 45048* (DAO); Baffin Island, head of Clyde Fjord, Jul 1950, *M.E. Hale Jr. 40* (WIS); Devon Island, Truelove Lowland, 75°38' N–84°30' W, 24 Jul 1989, *B.C. Forbes 70* (DAO); Cambridge Bay, 69°03' N–104°50' W, 7 Aug 1950, *E.H.N. Smith & G.K. Sweatman 42* (DAO); Ellesmere Island, east coast, between Baird Inlet and Tanquary Glacier, 78°29' N–76°31' W, 20 Jul 1979, *J. Bridgland 694* (DAO); idem, Eureka, 80°01' N–86°00' W, 19 Aug 1953, *P.F. Bruggeman 697* (DAO); idem, Eureka, 79°59' N–85°50' W, 16–18 Jul 1980, *G.W. Scotter & S.C. KEY TO TAXA (INCLUDING *ERIOPHORUM CHAMISSONIS* AND ATYPICAL *E. RUSSEOLUM* SUBSP. *RUSSEOLUM*)

1. Spikelets with dark to pale orange-brown bristles.
    2. Medial fertile scales 0.7–1.3 mm wide, acuminate, 0.1–0.3 mm wide at 0.2 mm below the apex; achenes narrowly obovoid, glabrous; hypogynous bristles 30–50, 15–20 mm long ____________ **Eriophorum ×medium** subsp. **medium**
    2. Medial fertile scales 1.2–2.2 mm wide, acute, rarely obtuse or acuminate, 0.2–0.5(–0.9) mm wide at 0.2 mm below the apex, achenes obovoid or ellipsoid, glabrous or scabrous; hypogynous bristles 50–80, 25–40 mm long.
        3. Anthers 1.5–3.1 mm long; medial scales with conspicuous hyaline margins and apex, the widest area near the middle or above; spikelets typically obovoid, with dark to pale orange-brown bristles ____________ **Eriophorum russeolum** subsp. **russeolum**

3. Anthers 0.7–1.6(–1.9) mm long, medial scales often with reduced hyaline margins and apex, the widest area not above the middle; spikelets various, spherical, obovoid, or hemispherical, with pale beige-brown to darker bristles.

4. Spikelets spherical, with pale beige-brown bristles; first proximal scale 12–23(–30) mm long; stem below the inflorescence 1.0–2.2 mm wide; medial scales covered with small reddish-brown longitudinal spots in hyaline areas; achene beak rarely curved; western North America _____ **Eriophorum chamissonis**

4. Spikelets obovoid or hemispherical, with pale to dark orange-brown bristles; first proximal scale 8–11 mm long; stem below the inflorescence 0.6–1.2 mm wide; medial scales usually without reddish-brown longitudinal spots; achene beak frequently curved; amphi-Atlantic ____________ atypical **Eriophorum russeolum** and/or intermediates between **E. ×medium** and **E. russeolum**

1. Spikelets with white to whitish bristles.

5. Medial scales (0.8–)1.0–2.4 mm wide, acute, 0.25–0.6 mm wide at 0.2 mm below the apex, widest mostly at the middle or above, with well developed hyaline margins; anthers (1.3–)1.5–3.1 mm long; achenes ellipsoid or obovoid, scabrous or glabrous, beak base 0.1–0.2 mm wide ____ **Eriophorum russeolum** subsp. **leiocarpum**

5. Medial scales 0.3–1.5(–1.7) mm wide, acuminate to narrowly acuminate, 0.05–0.3(–0.4) mm wide at 0.2 mm below the apex, widest below the middle or close to the base, with frequently reduced hyaline margins; anthers 0.35–1.6 mm long; achenes narrowly obovoid, always glabrous, beak base 0.05–0.1 mm wide.

6. Anthers 0.9–1.6 mm long; hypogynous bristles (10–)22–32 mm long; stigmatic branches 1.0–2.2 mm long _________________ **Eriophorum ×medium** subsp. **album**

6. Anthers 0.35–1.0 mm long; hypogynous bristles 10–25 mm long; stigmatic branches 0.5–1.3(–1.5) mm long _________________ **Eriophorum scheuchzeri** s.l.

7. Spikelets hemispherical; proximal fertile scales dark, with dark margins or reduced hyaline margins sharply differentiated from the darker parts; medial scales narrowly acuminate (usually 0.1 mm wide at 0.2 mm below the apex), 0.3–0.7(–0.9) mm wide near the middle; mature achenes beige brown to olive-brown, slightly lustrous _______________ **Eriophorum scheuchzeri** subsp. **scheuchzeri**

7. Spikelets spherical; proximal fertile scales bicolored, with lower and medial parts dark but gradually passing to various tones of gray and conspicuous marginal and apical hyaline areas; medial scales acuminate (usually 0.2 mm wide at 0.2 mm below the apex), (0.5–)0.7–1.4(–1.6) mm wide near the middle; mature achenes orange-brown to dark reddish-brown, mostly dull _______________________ **Eriophorum scheuchzeri** subsp. **arcticum**

ACKNOWLEDGMENTS

The author thanks the curators of the cited herbaria for access to their collections, as well as the following individuals for their help: M. Garneau, R. Néron, and K. Damboise of the Northern Québec-Labrador flora project for the illustrations; my colleagues Y. Dalpé and J. McCarthy for the production of the color plate; M.S. Novoselova for her comments on an earlier version of this paper, her translations from the Russian and for various other bibliographic information; R. Moberg (UPS) for his help in selecting a lectotype of *E. russeolum*; R. Elven, P. Morisset, and M. Dubé for information; P.W. Ball, E. Small, P.M. Catling, and G. Hall for criticism of the manuscript.

ABSTRACT

Liatris graminifolia Willd. is the name generally used for the grass-leaved gayfeather of the southeastern United States. Gray (1884), Gaiser (1946), and Wilbur (1962) observed that the name *Liatris pilosa* (Aiton) Willd. apparently applies to this species and has priority; Fernald and Griscom (1938) dissented, but the present study concurs that *L. pilosa* should replace *L. graminifolia* as the correct name. A lectotype from BM is designated for *Liatris* (*Serratula*) *pilosa*. This specimen probably was collected in New Jersey or Delaware and apparently represents a particularly hairy populational variant of the species that occurs in the area but that intergrades there with plants more characteristic of the species in the broader Atlantic coast region. Two taxa that have been identified as varieties of *L. graminifolia* are here treated at specific rank: *Liatris elegantula* (Greene) K. Schum. occurs on the Gulf coastal plain in Mississippi (rare), Alabama, Florida, and Georgia; *Liatris virgata* Nutt. (= *Liatris regimontis*, *Lacinaria smallii*) occupies an intermediate geographic position, ranging in South Carolina and Georgia northward through western North Carolina into Virginia. These three taxa differ consistently in involucral morphology and the range of *L. virgata* is geographically juxtaposed between *L. pilosa* and *L. elegantula*. Intermediates have not been observed in areas of sympatry at the range margins. *Liatris cokeri* Pyne & Stucky is a fourth member of this group, possibly most closely related to *L. virgata*. A taxonomic summary is provided, including nomenclature, distribution maps, ecological summaries, and a key.

RESUMEN

Liatris graminifolia Willd. es el nombre que se usa generalmente para la planta del Sureste de los Estados Unidos. Gray (1884), Gaiser (1946), y Wilbur (1962) observaron que el nombre *Liatris pilosa* (Aiton) Willd. aparentemente se aplica a esta especie y tiene prioridad; Fernald and Griscom (1938) disintieron, pero en el presente estudio se concluye que *L. pilosa* debe remplazar a *L. graminifolia* como nombre correcto. Se designa un lectotipo de BM para *Liatris* (*Serratula*) *pilosa*. Este espécimen probablemente fue colectado en Nueva Jersey o Delaware y aparentemente representa una variante poblacional particularmente pelosa de la especie que se encuentra en el área pero que se intergrada con plantas más características de la especie en la región Atlántica costera más amplia. Dos taxa que han sido identificados como variedades de *L. graminifolia* se tratan aquí con rango específico: *Liatris elegantula* (Greene) K. Schum. vive en la llanura costera del Golfo en Mississippi (rara), Alabama, Florida, y Georgia; *Liatris virgata* Nutt. (= *Liatris regimontis*, *Lacinaria smallii*) ocupa una posición geográfica intermedia, yendo desde Carolina del Sur y Georgia por el Oeste de Carolina del Norte hasta Virginia. Estos tres taxa difieren consistentemente en la morfología involucral y el rango de *L. virgata* está yuxtapuesto geográficamente entre *L. pilosa* y *L. elegantula*. No se han observado intermedios en áreas de simpatría en los extremos de área. *Liatris cokeri* Pyne & Stucky es un cuarto miembro de este grupo, posiblemente más relacionado con *L. virgata*. Se ofrece un resumen taxonómico que incluye nomenclatura, mapas de distribución, resúmenes ecológicos, y una clave.

SIDA 21(2): 815–826. 2004

Liatris graminifolia Willd. is the name generally applied to the grass-leaved gayfeather, a taxon of the southeastern U.S.A. (e.g., Radford et al. 1968; Cronquist 1980; Figs. 1 and 2). Gaiser (1946) recognized five infraspecific taxa: var. *graminifolia*, var. *elegantula* (Greene) K. Schum., var. *lasia* Fernald & Griscom, var. *dubia* (W.P.C. Barton) A. Gray, and var. *smallii* (Britton) Fernald & Griscom Of these five, var. *dubia* and var. *lasia* both are representative of the Atlantic coast species, as is var. *graminifolia*; var. *elegantula* is treated here at specific rank; and var. *smallii* is treated here as a synonym of another formally recognized species. Fernald (1950) recognized *L. graminifolia* var. *graminifolia*, var. *racemosa* (DC.) Venard (as a replacement name for var. *dubia*), var. *lasia*, var. *smallii*, and var. *virgata* (Nutt.) Fernald. We observe that Fernald's concept of var. *virgata* (1949, 1950) was artificial and that var. *racemosa* represents the same taxon as the type of var. *virgata*. The only recent treatment of the genus in the area that includes all of these variants is Cronquist (1980), who reduced the formally recognized taxa to *L. graminifolia* vars. *graminifolia* and *elegantula*. In our assessment, these two and two more, *L. graminifolia* var. *virgata* sensu stricto and *L. cokeri* Pyne & Stucky, constitute the evolutionary entities of this complex. *Liatris cokeri* is a species of the fall-line sandhills of southern North Carolina and adjacent South Carolina (Stucky & Pyne 1990). Our treatment recognizes four taxa, each at specific rank: **L. pilosa** (Aiton) Willd., **L. elegantula** (Greene) K. Schum., **L. virgata** Nutt., and **L. cokeri**.

Taxonomic rank

It is clear that *Liatris pilosa*, *L. elegantula*, *L. virgata*, and *L. cokeri* are closely related among themselves. Morphological differences among them, mostly in involucral features, are relatively small but they are consistent and a series of principal components analyses (Stucky 1990, 1992) indicates that *L. cokeri*, *L. pilosa*, and *L. virgata* are distinct. *Liatris elegantula* was not included in the analyses by Stucky, and it has consistently been treated as a variety of *L. graminifolia* since Gaiser reduced it in rank. In addition to morphology, the decision regarding the rank of these taxa rests on biology. *Liatris cokeri* is completely sympatric with *L. pilosa* but contiguous or nearly so with *L. virgata* (Figs. 1 and 2). *Liatris virgata* is geographically juxtaposed between *L. pilosa* and *L. elegantula* and probably forms a reproductive barrier between them. From the sample of specimens studied and mapped here, it appears that the degree of sympatry between *L. virgata* and *L. elegantula* may be greater than between *L. virgata* and *L. pilosa*; in neither instance, however, have we seen collections that would clearly indicate that hybridization, intermediacy, or introgression occurs in the areas of sympatry (see comments below). Each of these taxa has been treated at varietal rank, but the nomenclature for treating them as species is already established.

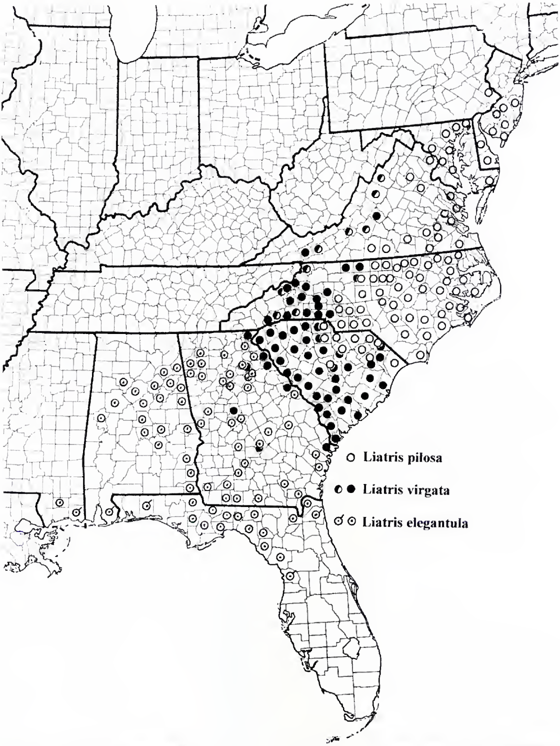

Fig. 1. Geographic distribution of *Liatris pilosa*, *Liatris virgata*, and *Liatris elegantula*. Records are from specimens studied from DOV, NCU, SMU/BRIT, TEX/LL, USCH, and VDB. Tagged symbols for *L. elegantula* in Florida are from Wunderlin and Hansen (2004), in Alabama and Mississippi from Gaiser (1946). Some records for *L. virgata* (half-filled circles) are added from Stucky & Pyne (1990).

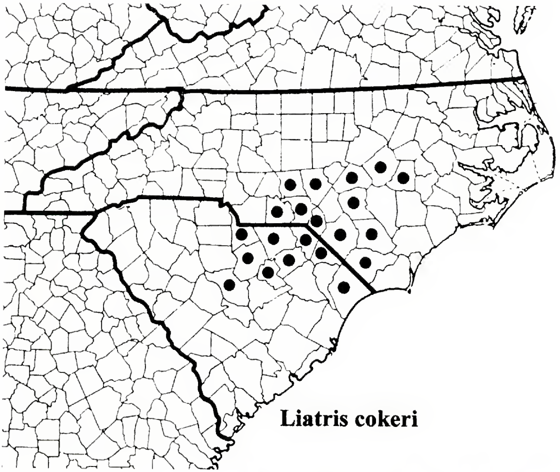

Fig. 2. Geographic distribution of *Liatris cokeri*. Records are from specimens studied from NCU, SMU/BRIT, USCH, and VDB.

Identification of the species

With the maps and following key, we believe that identifications can be made with accuracy and consistency. All key contrasts are not mutually exclusive, but they contribute toward an understanding of distinctions among the taxa. Species descriptions are provided in a treatment of the genus for the forthcoming Flora of North America volumes of Asteraceae (Nesom in prep.).

KEY TO THE SPECIES OF THE *LIATRIS PILOSA* COMPLEX

1. Phyllaries apically rounded, lamina relatively thin, eglandular or with superficial to shallowly inset punctate glands, completely bordered by a narrow, hyaline rim; involucres turbinate (obconic) to turbinate-campanulate.
   2. Stems glabrous to sparsely or moderately pilose distally or over whole stem; leaf laminae glabrous to sparsely pilose on abaxial surface; heads relatively densely arranged, on internodes (1–)2–5(–7) mm long; peduncles 0–10(–17, –80 in proximal region of capitulescence) mm long; involucres (7–)8–10 mm long, phyllaries in (3–)4–5(–6) series; florets (6–)7–12(–13), mostly 9–13 in N.J. and Del. _____ **Liatris pilosa**
   2. Stems glabrous; leaf laminae glabrous; heads relatively loosely arranged, on internodes (2–)5–10(–14) mm long, peduncles 0–2(–7) mm long; involucres 6–8 mm long; phyllaries in 3–4(–5) series; florets (7–)8–11(–13) __________ **Liatris elegantula**

1. Phyllaries apically angular, lamina relative thin or thick, with inset or superficial glands, bordered on the lateral margins but not at the apex by a narrow, hyaline rim; involucres cylindric-campanulate.
   3. Heads densely arranged, on internodes 1–2(–5) mm long, often secund; phyllary apex sharply acuminate-acute, distinctly involute, lamina relatively thin, glands consistently present and superficial at least on proximal portion; florets 4–7(–9) per head; basal and lower cauline leaves 2–5 mm wide, gradually reduced in length distally ____ **Liatris cokeri**
   3. Heads loosely arranged, on internodes 6–15(–20) mm long, not secund; phyllary apex sharply acute to obtuse-angled with a thickened apiculum, not markedly involute, lamina relatively thick, usually with evidently sunken punctate glands, without superficial glands; florets 7–10(–12) per head; basal and lower cauline leaves 4–9(–12) mm wide, quickly reduced in width and length distally ____ **Liatris virgata**

Liatris pilosa: the oldest correct name for *L. graminifolia*

Liatris pilosa (Aiton) Willd. 1803 (based on *Serratula pilosa* Aiton 1789) is the oldest name in the *L. graminifolia* complex but was treated by Gaiser as a synonym of *L. graminifolia* var. *dubia*. Fernald (1950) did not include the name *L. pilosa* in his account of the genus. Gray (1856) had treated *L. pilosa* as a distinct, montane species ("Mountains of Virginia and southward"), but he later (1884) regarded *L. pilosa* as a questionable synonym of *L. graminifolia* var. *dubia*. Fernald and Griscom (1935) examined the "fragments of a head from Aiton's type" of *Serratula pilosa* (from GH, perhaps obtained by Gray from type material at BM), but they concluded that "*Serratula pilosa* has nothing to do with *Liatris graminifolia*" – emphasizing the "long pedunculate" heads (from the type description) and the "linear and acute ... involucral bracts" (from the GH fragments). Gray (1884) had observed these same features and noted that *L. pilosa* represents a 'state' of *L. graminifolia* with "unusually narrow involucral scales." Gaiser's lengthy discussion of the typification of *L. pilosa* (1946, pp. 257–258) indicated that she regarded it as conspecific with *L. graminifolia*, and her placement of it in the synonymy of var. *dubia* seems to have been more of a nomenclatural error than reluctance to use the name because of uncertainty about its identity. Wilbur (1962) accepted *L. pilosa* as the correct name for the species, perhaps based on Gaiser's comments, while acknowledging the different interpretation by Fernald and Griscom; he noted that it seemed undesirable to provide new combinations for infraspecific taxa prior to critical study of infraspecific variation.

After a detailed survey of variation within *Liatris graminifolia* in the context of a study of the whole genus, and with the opportunity to study type material of *Liatris pilosa* from BM, we also conclude that the name *L. pilosa* does indeed apply to the species and must replace *L. graminifolia* as the correct name. Gaiser (1946, pp. 257–258) quoted notes from E.G. Baker of the National Herbarium, who apparently also examined type material of *Serratula pilosa* and whose observations regarding its morphology agree with ours. Some plants from New Jersey and Delaware, at the northern extremity of the range of the species, which have prominently pilose stems and leaf lamina and a tendency to produce long peduncles, are similar to the BM type. We have seen collections of this "morphotype" from Atlantic, Camden, and Cumberland cos., New Jersey, and Sussex and Kent cos., Delaware. The lanceolate, apically acute phyllaries of the *Serratula pilosa* type are unusual for the species over most of its range but this feature appears sporadically in plants of the New Jersey-Delaware region.

Some plants in New Jersey corresponding to *Liatris pilosa* sensu stricto occur in populations of relatively uniform morphology (David Snyder, pers. comm.): these plants have "lower branches up to 11 cm long with up to 5 heads. The branching is most pronounced on the lower half of the stem but the heads of the upper are long peduncled (up to 4 cm long). The branches are strictly ascending. Stems, peduncles, and leaf bases are densely hirsute." On the other hand, plants more similar to those in eastern Virginia and North Carolina apparently are at least as common or more so in New Jersey (Atlantic, Burlington, Cape May, Ocean cos.!) and Delaware (Sussex and Kent cos.!) as the prominently hairy ones. Plants from this region with stems and leaf lamina glabrous or sparsely hairy but with slightly larger heads were identified as *L. graminifolia* var. *dubia* by Gaiser (1946), who cited collections from New Jersey, Delaware, Maryland, District of Columbia, Virginia, and Pennsylvania (Bucks Co.). Our study substantiates the observation that some populations of this region are distinct in their combination of characters, but the tendencies for relatively densely pilose stems and leaves, long-pedunculate heads, more florets per head, and inner phyllaries with subacute apices apparently are only loosely correlated among themselves. We have not been able to meaningfully sort the variation, but this is an area that needs to be investigated more closely.

Liatris elegantula

Plants of *Liatris elegantula* have consistently glabrous stems and leaves, relatively short and distinctly turbinate (obtriangular) involucres with a reduced number of phyllaries (evidenced by fewer series), and the heads tend to be more widely spaced than in *L. pilosa*. Records for this taxon cited by Gaiser (1946) from southwestern Alabama (Baldwin Co.) and adjacent Mississippi (Jackson Co.) have not been examined in this study.

Treatment of *Liatris elegantula* at specific rank is perhaps the most divergent proposal of the current overview. It is most similar to *L. pilosa* in involucral morphology, but small differences between the two are consistent and the geographic hiatus is real. *Liatris elegantula* and *L. pilosa* might be treated as conspecific, as has been generally done, or *L. elegantula*, *L. pilosa* and *L. virgata* might all be considered as a single species, but this would not account for apparent reproductive isolation in areas of sympatry (comments above) or a possible close relationship between *L. virgata* and *L. cokeri*.

Liatris virgata and *L. cokeri*

Liatris virgata has mostly been identified within *Liatris graminifolia* sensu lato, and as observed by Stucky (1992), this name has not been included in most of the pertinent taxonomic literature for the genus, even as a synonym, although one of its synonyms (*L. graminifolia* var. *smallii*) has sometimes been correctly applied. A principal components analysis (Stucky 1992) indicates that *L. virgata* and *L. graminifolia* (*L. pilosa*) are morphologically distinct. The name *L. regimontis* (Small) K. Schum., now understood to be a synonym of *L. virgata*, mostly had been applied to the species segregated by Stucky and Pyne (1990) as *L. cokeri*.

The range of *Liatris virgata* is essentially contiguous with *L. elegantula* on the southwestern margin and with *L. pilosa* on the northeastern margin, but some overlap occurs in both areas (Fig. 1). Although *L. virgata* has been collected in close proximity to both of its closest relatives and all three species flower in generally the same period of time, our observations indicate that the taxa are discrete even in areas of sympatry. For example, from York Co., S.C., we have studied five collections of *L. virgata* (*Nelson 4994*, *Kennemore 917*, *997*, *1046*, *1486*, all USCH) and three of *L. pilosa* (*Nelson 4989*, *4998*, *5024*, all USCH)—all eight of these were collected within Kings Mountain National Military Park. From Richland Co., S.C., we have studied 20 collections of *L. virgata* (USCH, NCU, BRIT) and a single one of *L. pilosa* (*Nelson 11244*, USCH), south of its primary range. Field and herbarium studies are needed to further the understanding of the geographic and evolutionary relationship between *L. virgata* and its close relatives. If hybridization and intergradation prove to be more significant than observed in the current study, treatment of these three taxa as conspecific might be more appropriate.

Spacing of the heads and phyllary morphology are features that provide the most immediate recognition of *Liatris virgata*. Contrasted with *L. pilosa* and *L. elegantula*, the phyllary lamina is thicker and the glands are distinctly sunken into the tissue, and the apex is generally angular (vs. rounded) and lacks the narrow hyaline rim that borders the lateral margins. In Richland Co., S.C., from which numerous collections are available, the apex shape varies from sharply acute to obtuse, but even the obtuse angle is distinct, as the tip characteristically ends in a thickened and slightly raised (keel-like) apiculum or mucro. Similar variation occurs over the range of the species, although a tendency for obtuse apices apparently is more common on the coastal plain.

Variation in *Liatris virgata* also occurs in involucral size and configuration. Larger-headed plants (including the types of *Lacinaria smallii* and *Lacinaria regimontis*) are mostly montane and piedmont. Larger heads are more elongate-cylindric and have phyllaries in 5–6(–7) series with more consistently sharply acute apices, while smaller heads have 3–5(–6) series. Number of florets tends to be slightly higher in larger heads.

Finally, we note that the distribution of *Liatris virgata* from outer coastal plain into montane habitats is unusual, but *L. pilosa* and *L. elegantula* both occur on the piedmont as well as their primary coastal plain range, and other species of *Liatris* range widely across habitats and ecological zones (e.g., *L. squarrulosa* Michx. and *L. aspera* Michx.). Further study of *L. virgata* may demonstrate geographic patterns of differentiation that we have not been able to delimit.

Stucky and Pyne (1990) observed that apparent intermediates between *Liatris virgata* and *L. cokeri* occur on the coastal plain of North Carolina and South Carolina. In the present study, however, we have identified some of those putative intermediates as *L. cokeri*, and we have not confirmed the occurrence of *L. virgata* where the putative intermediates occur in North Carolina (Stucky & Pyne 1990, Fig. 10). *Liatris cokeri* is characterized by phyllaries with acute-angled apices, and this is likely an indication of close relationship to *L. virgata*. Indeed, evolutionary relationships within the *L. pilosa* complex, as outlined here, may be that of two sister pairs—*L. pilosa-elegantula* and *L. virgata-cokeri*.

NOMENCLATURE AND TYPOLOGY

Liatris pilosa (Aiton) Willd., Sp. Pl. 3:1636. 1803. *Serratula pilosa* Aiton, Hort. Kew. 3:138. 1789. *Lacinaria graminifolia* (Willd.) Kuntze var. *pilosa* (Aiton) Britton, Mem. Torrey Bot. Club 5:314. 1894. *Lacinaria pilosa* (Aiton) A. Heller, Muhlenbergia 1:6. 1900. LECTOTYPE, here designated: U.S.A. Cultivated plant, without collection data but the original stock probably from New Jersey or Delaware, probably collected by William Young, Jr. prior to 1783 (BM-Banks Herbarium, photo!, fragment of lectotype GH). A handwritten inscription on the back of the lectotype sheet reads "Hort Kew. 1785" and matches the handwriting of Jonas Dryander (Marshall 1978), who assumed the primary responsibilities of describing and naming plants for the Hortus Kewensis after the death of Daniel Solander in 1782. The publication itself, however, credited authorship solely to William Aiton (see Britten 1912). Photos of the lectotype have been deposited at BRIT, GH, NCSC, NCU, and US.

The protologue of *Serratula pilosa* described the plants as "foliis linearibus pilosis, floribus axillaribus longe pedunculatis" and noted "Nat. of North America. Introd. 1783, by Mr. William Young." William Young, Jr. lived in Philadelphia and made forays into "the Carolinas" as he collected horticultural stock for English gardeners (Harshberger 1917). It seems a reasonable surmise that the material of *L. pilosa* was collected by Young in the region of his home, probably close by in New Jersey or Delaware, where plants of this morphology are known to occur (as also true for the type of *L. dubia*, see below; Keller and Brown [1905] noted records in New Jersey and Delaware for "*Liatris graminifolia pilosa*"). The type specimen presumably was grown in cultivation at Kew Gardens, as Young was supported as "Botanist to their Majestys" in collecting horticultural possibilities. Young informally used the name *Serratula pilosa* for gayfeather material in his plant collection (Young 1985).

Liatris graminifolia Willd., Sp. Pl. 3:1636. 1803. *Lacinaria graminifolia* (Willd.) Kuntze, Revis. Gen. Pl. 1:349. 1891. TYPE: Original not located. U.S.A. NORTH CAROLINA. New Hanover Co. edge of Wilmington, common in the open pine woods skirting the Cypress Tree Park, 24 Oct 1948, *E.O. White s.n.* (NEOTYPE (Gaiser 1950, p. 414): GH, internet image!; ISONEOTYPES: [MO!] noted by Gaiser to have been deposited at NY and US). The collection date apparently was miscited by Gaiser as "25 Oct," because the GH specimen reads "24 Oct" and corresponds in all other details with the citation. Many authors, including Gaiser (1946), have interpreted Willdenow's name as a new combination based on a name of Thomas Walter (*Anonymos graminifolius* Walter, Fl. Carol. 197. 1788), but as noted by Wilbur (1962) and others, Walter's names using "Anonymos" as the genus are interpreted as invalid (ICBN 2000: Arts. 20.4, 43.1). Willdenow's protologue cited "Anonymos (*graminifolius*) ... Walt. carol. 197." and "Habitat in Carolina. 4 (v.s.)" and it fully quoted Walter's description. Despite Willdenow's apparent suggestion that he saw material corresponding to Walter's type, such a specimen apparently has not been relocated. Gaiser (1946, p. 255) noted that observations had been made on a BM specimen labeled "*Chrysosoma affinis* F. 309 (supposedly referring to Fraser) and with Nuttall's annotation *Liatris* in pencil," which she interpreted as authentic type material, but she later rejected this interpretation in favor of a neotype. The only specimen in the Willdenow herbarium identified as *Liatris graminifolia* (B-Willdenow fiche 14838!) is a plant of *Liatris spicata* (L.) Willd. var. *spicata* with a label that notes "Habitat in Pensylvania;" the label also cites "*Anonymos graminifolia* W. carol. 197," but it seems unlikely that Willdenow would have intended this collection as the type for *L. graminifolia*, which he explicitly understood was from "Carolina."

Liatris dubia W.P.C. Barton, Veg. Mater. Med. U.S. 2:223, t. 49. 1819. *Liatris graminifolia* Willd. var. *dubia* (W.P.C. Barton) A. Gray, Manual, ed. 2, 185. 1856. TYPE: U.S.A. [perhaps NEW JERSEY or DELAWARE, in the region where plants of this morphology occur]. This is the only element of potential type material used by the author and presumably stands as the HOLOTYPE (ICBN 2000, Art. 9.1). No collection data were cited, but Barton, a Philadelphia resident, apparently drew the illustration from a live plant, judging from the realistic dimensionality of the drawing, even though the broad leaves and elongate involucres suggest that considerable artistic license was in play. The description and illustration portray a plant with hairy stems and peduncles, linear-lanceolate lower leaves, and loosely arranged, long-pedunculate heads with elongate, "subacute" phyllaries. Gray (1848) mentioned "var. *dubia*" under *L. graminifolia*, but he did not provide a basis of reference to the basionym until the second edition in 1856. Fernald and Griscom (1935) noted that *L. dubia* was "suggestive of Aiton's plant" (i.e., *L. pilosa* s. str.).

Liatris pilosa (Aiton) Willd. var. *laevicaulis* DC., Prodr. 5:131. 1836. TYPE: U.S.A. Nov. Caesar. [Nova Caesarea = NEW JERSEY]. 1835, [no other data,] *Mr. Torrey* (HOLOTYPE: G-DC, fiche!). This plant has long peduncles, apparently glabrous stems, long, narrow phyllaries apparently with subacute apices, and (fide de Candolle) 7–8 florets per head.

Liatris propinqua Hook., Bot. Mag. 67 (n. ser. 14): t. 3829. 1840. TYPE: [U.S.A., cultivated in England]. With regard to its origin, Hooker noted only "Sent from the Horticultural Society's garden of Edinburgh in the autumn of 1839, under the name of *L. paniculata*." The illustration shows a plant with relatively large, turbinate-cylindric, sessile to subsessile heads in a loosely spiciform array, acute phyllaries, and narrowly oblanceolate, punctate leaves prominently ciliate on the proximal margins. The stems and leaf lamina are not described or depicted as being hairy. The common name given by Hooker to this plant, "Sharp-scale spiked *Liatris*," referred to the acute phyllaries. The identification seems reasonable as *L. pilosa*, especially in view of the prominently cilate leaves, but the sparsely pubescent (or glabrous?) stems, acute phyllaries, and relatively few florets ("subdecemfloro," from the description) leave open the possibility that it might be *L. virgata*. The name (*L. propinqua*) is ambiguous in reference until a type specimen is located or designated.

Liatris graminifolia Willd. var. *lasia* Fernald & Griscom, Rhodora 37:183. 1935. TYPE: U.S.A. NEW JERSEY. Camden Co.: Lindenwold, dry sandy soil, 29 Sep 1923, *J.M. Fogg, Jr. 622* (HOLOTYPE: GH).

Flowering (Aug–)Sep–Oct(–Nov). Old fields, pine barrens, scrub oak-pine sandhills, openings in pine, oak, and oak-hickory woods, tidal marsh edges, sandy fields, dune hollows, wet sand near beach, edge of tidal marsh sand to sandy clay-loam; ca. (0–)10–500 m. Delaware, Maryland, New Jersey, North Carolina, Pennsylvania, South Carolina, Virginia.

Liatris elegantula (Greene) K. Schum., Bot. Jahresber. (Just) 29:569. 1903. *Lacinaria elegantula* Greene, Pittonia 4:316. 1901. *Liatris graminifolia* Willd. var. *elegantula* (Greene) Gaiser, Rhodora 48:254. 1946. Type: U.S.A. Alabama. Lee Co.: Auburn, 18 Oct 1896, *F.S. Earle* (Holotype: ND-G).

Flowering Aug–Oct(–Nov). Longleaf pine-scrub oak, pine, live oak-pine, deciduous oak-pine, deciduous flatwoods, sandhills, savanna edges, edge of cypress depressions, depression meadows, live oak-pine-palmetto hammocks, sandy clay or loam, rarely clay; 5–300(–450) m. Alabama, Florida, Georgia, Mississippi.

Liatris virgata Nutt., J. Acad. Nat. Sci. Philadelphia 7:72. 1834. *Liatris graminifolia* Willd. var. *virgata* (Nutt.) Fernald, Rhodora 51:104. 1949. Type: U.S.A. Georgia. [probably Nov 1815], *T. Nuttall s.n.* (Lectotype (Stucky 1992, p. 179): PH!; probable type material, "Hb. Nuttall" s.n., NY! ex BM). Nuttall noted "*Hab.* In Georgia and North Carolina" in the protologue; the PH specimen shows "Geo." as the only collection data. Nuttall later (1841) described the habitat as "In the pine forests of Georgia, and near Newbern, N. Carolina"—the plants from near Newbern are almost certainly *Liatris cokeri* Stucky & Pyne (see Stucky & Pyne 1990). Graustein (1967, pp. 100–101) noted that in mid October, 1815, Nuttall traveled by boat to Savannah, Georgia, and then northward along the Savannah River to Augusta and vicinity, through longleaf pine sandhill vegetation and north at least to "where hills of deciduous trees (oaks, hickories, &) and primitive soil commence." Nuttall's protologue noted that the capitulescence was a subpaniculate and branched raceme and referred to the "long leafy pedicels of the flowers." Gaiser (1946) apparently saw the PH specimen (she referred to it as "isotype") and placed *L. virgata* in synonymy of *L. graminifolia* var. *dubia*, but the latter is here interpreted as a synonym of *Liatris pilosa* sensu stricto. Fernald's concept of *L. graminifolia* var. *virgata* (1949, 1950) was artificial (including many citations from the Atlantic coast region, based on plants with strongly branched capitulescence), though he surely was aware that the type was from Georgia, having indicated that he saw the Nuttall collection or at least a photo of it. Details on morphology of the PH specimen are provided in Stucky (1992).

Liatris spicata L. var. *racemosa* DC., Prodr. 5:130. 1836. *Liatris graminifolia* Willd. var. *racemosa* (DC.) Venard, Rhodora 51:35. 1949. Type: U.S.A. Georgia. Savannah, 1832, no collector indicated (Holotype: G-DC, fiche!). The description by de Candolle noted "capitulis distincte pedicellatis ... caule glabro ... foliis ciliatis ... floribus in invol. 8." The G-DC sheet has 2 branches with heads of nearly identical morphology: one was broken off and the heads are borne on peduncles up to 5 cm long; the other is intact and the distal heads are sessile while the proximal ones are on peduncles ca. 1 cm long. The involucres are campanulate-cylindric, and the phyllaries are apically thickened and subacute, the outer slightly spreading.

Liatris regimontis (Small) K. Schum., Bot. Jahresber. (Just) 26:378. 1900. *Lacinaria regimontis* Small, Bull. Torrey Bot. Club 25:473. 1898. Type: U.S.A. North Carolina. Cleveland Co.: King's Mt., wooded slopes, 27–30 Aug 1894, *J.K. Small s.n.* (Holotype: NY!; isotype: NY!).

Lacinaria smallii Britton, Man. Fl. N. States 927. 1901. *Liatris graminifolia* Willd. var. *smallii* (Britton) Fernald & Griscom, Rhodora 37:182. 1935. Type: U.S.A. Virginia. Smyth Co.: along Dickey Creek on Iron Mtn., 2900 ft, 8 Aug 1892, *J.K. Small s.n.* (Holotype: NY!; isotype: MO!).

Flowering (Jul–)Aug–Oct(–Nov). Edge of swampy woods, creek margins, slopes, clearings, and edges of upland woods, rocky woods, pine-oak woods, mixed deciduous woods, roadsides, Iredell soil, clay; ca. 50–1000 m. Georgia, North Carolina, South Carolina, Virginia.

Liatris cokeri Pyne & Stucky, Sida 14:205. 1990. TYPE: U.S.A. NORTH CAROLINA. Harnett Co.: 0.2 mi E jct NC Rte 27 and Co. Rd. 1243 along NC 27 on S side of road, sandy roadside and margin of longleaf pine/turkey oak/wiregrass association, 23 Sep 1989, *J.M. Stucky 511* (HOLOTYPE: NCU; ISOTYPES: GH, NCSC, NCU, NY, US, USCH).

Flowering (Aug–)Sep–Oct. Sand ridges, sandy fields and roadsides, turkey-oak, longleaf pine-oak; 50–150 m. North Carolina, South Carolina.

ACKNOWLEDGMENTS

The analysis and map for this study were based on specimens were studied from BRIT, NCU, TEX,LL, and VDB (personal visits) and DOV, PH, USCH, and BM (loans). We are grateful to staff at the University of Texas Life Sciences Library for help with access to literature and microfiche, David Snyder, Botanist for the New Jersey Natural Heritage Program, for his insights regarding variation in *Liatris pilosa*, Walter Kittredge and other GH staff for help with data and type images, Milo Pyne for his perspectives on the identity of *Liatris pilosa*, and to Alan Weakley and Bruce Hansen for their review comments.

ABSTRACT

Symphyotrichum rhiannon Weakley & Govus, sp. nov., is described from the Buck Creek ultramafic barren (over serpentinized dunite and olivine) in the Blue Ridge province of southwestern North Carolina. It is similar to *Symphyotrichum puniceum* but different in its smaller stature, thinner rhizomes, subspatulate cauline leaves, narrower and fewer-headed capitulescence, phyllaries with shorter, rhombic-lanceolate apical green zones, and shorter ray corollas. Its geographic range is imbedded within that of typical *S. puniceum* but morphological intergrades have not been observed, despite the co-occurrence of the two taxa within several meters of one another at the type locality. The Buck Creek site is within the Nantahala National Forest; 42 hectares of the site are managed by the United States Forest Service as a Special Interest Area and registered as a heritage area with the North Carolina Natural Heritage Program.

RESUMEN

Symphyotrichum rhiannon Weakley & Govus, sp. nov., se describe del Buck Creek ultrabásico (sobre dunita y olivino serpentinizados) en la provincia Blue Ridge del Suroeste de Carolina del Norte. Es similar a *Symphyotrichum puniceum* pero diferente por su talla más baja, rizomas más finos, hojas caulinares subespatuladas, capitulescencia más estrecha y con menos capítulos, filarias con zonas verdes apicales rómbico-lanceoladas más cortas, y radios de las corolas más cortos. Su rango geográfico está incluido en el de *S. puniceum* típico pero no se ha observado intergradación morfológica, a pesar de la co-ocurrencia de los dos taxa a unos pocos metros en la localidad tipo. El Buck Creek está en el Nantahala National Forest; 42 hectáreas están gestionadas por el Servicio Forestal de los Estados Unidos como un Área de Especial Interés y registrado como un área del Natural Heritage Program de Carolina del Norte.

SIDA 21(2): 827–839. 2004

INTRODUCTION

A new species of *Symphyotrichum* is described from the Buck Creek ultramafic barren in the Blue Ridge province of southwestern North Carolina (Clay County). The naming of this species ends more than twenty years of bewilderment regarding its identity, which has troubled researchers at the site since the late 1970's. Mansberg (1981) was apparently the first botanist to encounter this entity and collect it, a significant component of the ultramafic barren and adjoining woodlands. Despite consulting with experts at the time, she labeled this entity as "unidentifiable aster" and suggested that it might be a hybrid. Collections made during later studies of the vegetation at Buck Creek barren by the North Carolina Vegetation Survey in the 1990s yielded similar confusion, with specimens being identified as "*Aster laevis* var. *concinnus*?," "*Aster surculosus*?," or "*Aster # 1*." Even more recently, U.S. Forest Service botanists involved in the management of Buck Creek barren have been troubled by the identity of this aster and have made additional guesses as to its affinity. Serendipitous circumstances have led to a revisiting of this persistent problem, and following additional study we now decisively describe this species as new.

A comparison of the putative new taxon to all other species of *Symphyotrichum* in eastern and central North America reveals that it has a unique set of characteristics. Furthermore, it does not appear to be a recent or stabilized F1 hybrid, intermediate between any other two species of *Symphyotrichum*, although it is possible (as noted below) that gene flow has been involved in its origin. In our assessment, it is a distinct taxon worthy of specific rank, possibly most closely related to *Symphyotrichum puniceum* (L.) A. & D. Löve.

Symphyotrichum rhiannon Weakley & Govus, sp. nov. (**Fig. 1**). TYPE: U.S.A. NORTH CAROLINA. Clay Co.: Buck Creek Ultramafic Barrens, Nantahala National Forest, 1.3 km N of US 64 on Buck Creek Rd, just NE from Glade Gap, below FS Rd 6269 (above bridge crossing Buck Creek), NW ca. 0.5 km from gate on steep slope above E side of Buck Creek; serpentine barrens, steep W aspect outcrop of dunite and olivine, open woodland dominated by pitch pine and prairie grasses, 3385 ft elev., UTM zone 17S, 261513mE, 3885663mN (WGS-84), 3 Nov 2003, *T.E. Govus and G. Kauffman 1* (HOLOTYPE: NCU; ISOTYPES: BRIT, US, WAT).

Symphyotricho puniceo similis sed differt statura minore, rhizomatibus tenuioribus, foliis caulinis subspatulatis, capitulescentiis angustioribus paucicapitatis, phyllariis zonis apicalibus viridibus rhombi-lanceolatis brevioribus, et corollis radii brevioribus.

Plants perennial herbs, apparently without a distinct caudex, arising from a system of slender, scale-leaved rhizomes 0.5–1 mm wide and up to 10 cm long, older rhizomes woody or lignescent, thickened to 2–4 mm wide. **Stems** 15–40 cm tall, erect from the base, hirsute to hispid-hirsute with spreading to spreading-ascending, uniseriate trichomes 0.2–0.6 mm long (Type A, sensu Nesom 1976), evenly distributed or concentrated in vertical lines, lines especially evident immediately below nodes, hirsutulous below heads, also with closely ap-

pressed, uniseriate trichomes 0.1–0.2 mm long [Type B, sensu Nesom 1976), eglandular. **Leaves**: basal and lower cauline usually not persistent at flowering, subspatulate when present, 3–7 cm long, blades oblanceolate-elliptic, 10–15 mm wide, shallowly crenate to serrate-crenate, prominent midvein and reticulate secondary venation, gradually narrowed to a petiolar region 4–6 mm wide, clasping to subclasping and shallowly auriculate, midcauline usually longer than lower, 5–11 cm long, 8–22 mm wide, with petiolar region remaining evident but becoming shorter and relatively broader or the upper leaves oblong-lanceolate, upper cauline (of capitulescence) 1–3 cm long, 4–6(–8) mm wide, all adaxially scabrous with stiff, thick-based, ascending hairs 0.1–0.2 mm long (foreshortened Type A), abaxially inconspicuously strigose (use lens) with thin, closely appressed trichomes 0.05–0.2 mm long (Type B). **Heads** in a sparsely leafy-bracteate, broadly cylindric-paniculate to subcorymboid arrangement, clustered near branch tips on ultimate peduncles 5–15(–30) mm long; involucres turbinate-campanulate, 6–11 mm wide (pressed); phyllaries in 3–4 weakly graduate series, mostly narrowly oblong-lanceolate, inner 6–7 mm long, outer 1/2–3/4 the length of the inner, outer white-indurate on the basal 1/2–2/3, upper 1/2–1/3 with a rhombic-lanceolate green zone 1.8–2.5(–3.0) mm long from widest point to tip, glabrous or the upper part of the green zone minutely strigose-puberulent, margins usually irregularly ciliolate, eglandular. **Ray florets** 18–32, corollas 6–9 mm long, laminae 0.8–1.4 mm wide, blue to lavender, tightly coiling with wilting or maturity, tube and lower lamina sparsely appressed-puberulent with minute biseriate trichomes (Type C, sensu Nesom 1976). **Disc florets**: corollas (4.0–)4.5–5.5 mm long, yellow but at least the lobes usually turning purple, sparsely appressed-puberulent with biseriate trichomes (Type C), tube 1.5–2.1 mm long, throat and limb cylindric, lobes 0.8–1.0 mm long, erect; style branches with narrowly triangular collecting appendages 0.3–0.5 mm long. **Achenes** oblong to narrowly obovate in outline, slightly compressed, 2.6–3.0 mm long, 0.7–0.9 mm wide, 4–6-nerved (with 1 nerve on each edge and 1–2 on each face), sparsely short-strigose, tan or often purplish at maturity; pappus 1-seriate, of 36–46 barbellate bristles.

Etymology.—*Symphyotrichum rhiannon* is named in honor of Rhiannon Weakley, whose desire to rest during a field excursion led the authors to further investigate and finally resolve this decades-old taxonomic conundrum, and also in honor of the original Rhiannon, a Welsh goddess figure associated with the underworld, and therefore particularly appropriate for a plant endemic to a serpentine substrate.

Additional collections examined. **NORTH CAROLINA. Clay Co.**: Buck Creek Ultramafic Barrens, Nantahala National Forest, 1.6 km N of US 64 on Buck Creek Rd, NE from Glade Gap, 0.5 km below bridge over Buck Creekand W upslope along old road to powerline ROW, E aspect slope of dunite and olivine, pitch pine woodland with abundant prairie grasses, 3280 ft elev., UTM zone 17S, 261347mE, 3885588mN (WGS-84), 3 Nov 2003, *Govus* and *Kauffman* 2 (NCU); Buck Creek Serpentine Pine Barrens; in grassy understory; west-facing slope, midslope; pH 6.5, 20 Sep 1981, *Mansberg* 421 (NCU 575098); Buck Creek Serpentine Pine Barrens; in grassy understory; west-facing slope, lower slope; pH 6.0, 20 Sep 1981, *Mansberg* 422 (NCU 575100); Buck Creek Serpentine Pine Barrens; in grassy understory; west-facing slope, midslope; pH 7.0, 20 Sep 1981, *Mansberg* 423 (NCU 575099).

DISCUSSION

Symphyotrichum rhiannon is closest in morphology to *S. puniceum* and *S. prenanthoides*. These three taxa share a set of features: plants eglandular, stoloniferous; leaves with serrate margins, scabrous upper surfaces, the basal petioled but not cordate, cauline clasping, those of capitulescence reduced in size and relatively few; phyllaries long-acuminate to attenuate, subequal to weakly graduate in length. The leaves of *S. prenanthoides* are distinctly spatulate with dilate-auriculate bases, which contrast with both of the other species, and the new species keys to *S. puniceum* (Radford et al. 1968; Gleason & Cronquist 1991; Cronquist 1980) because of the leaf shape. Of features noted here as characteristic of *S. rhiannon*, only its subspatulate leaf shape apparently is not found in at least a few populations of *S. puniceum*. Thus, *S. rhiannon* might be considered intermediate between *S. puniceum* and *S. prenanthoides*, either from common ancestry or perhaps a result of hybridization. Contrasts between these three taxa are summarized in the following couplet.

1. Basal and cauline leaves distinctly spatulate, abruptly constricted to a petiolar region, auriculate-clasping, the auricles dilated from the petiole base and completely enveloping stem; lower 1/2–1/3 of stem generally glabrous ____________ **Symphyotrichum prenanthoides**
1. Cauline leaves subspatulate or oblong to oblong-oblanceolate or lanceolate, gradually narrowed or not toward the base, base clasping to subclasping but not dilated-auriculate and not completely enveloping the stem; lower 1/2–1/3 of stem generally hairy.
    2. Plants 1.5–4 dm tall; young rhizomes thin, 0.5–1.0 mm wide; midcauline leaves subspatulate, slightly narrowed toward the base to a petiolar region; green area of phyllary apices rhombic-lanceolate, 1.8–2.5(–3.0) mm long from widest point to apex; ray corollas 6–9 mm long ____________ **Symphyotrichum rhiannon**
    2. Plants mostly 4–20 dm tall; young rhizomes thickened, 2–4 mm wide; midcauline leaves mostly oblong to oblong-oblanceolate, not narrowed to a petiolar region; green area of phyllary apices narrowly lanceolate, 2.5–4.0 mm long from widest point to apex; ray corollas 10–15(–20) mm long _____ **Symphyotrichum puniceum**

Apart from the distinction in leaf shape, differences between *Symphyotrichum rhiannon* and *S. puniceum* are largely quantitative and are primarily reductions in size. Stems of the new species are relatively short and the capitulescence tends to be narrower with fewer heads. Phyllaries with short green regions are not generally characteristic of *S. puniceum* but do occasionally occur in the species, but the rhombic-lanceolate green zones and more graduate phyllaries of *S. rhiannon* give the heads a distinctive appearance. The cumulative effect of these and the more quantitative differences, however, coupled with the unique habitat and restricted distribution of *S. rhiannon*, is that the latter can be recognized as sharply distinct. Typical *S. puniceum* occurs in most if not all of the counties in the mountains and piedmont of North Carolina (Radford et al. 1968), where it characteristically grows in wet habitats, especially fens, seepages, swamp forests, wet meadows, and in altered wetlands such as ditches and other drainages.

Fernald (1950) treated *Symphyotrichum puniceum* (as *Aster puniceus* L.) with a number of varietal taxa, but all of these are now recognized as populational variants or intergrading populations except one — Warners and Laughlin (1999) have provided a convincing case for treatment of *S. firmum* (Nees) Nesom as a distinct species, in contrast to many earlier treatments of it as *Aster puniceus* var. *firmus* (Nees) Torr. & Gray or *A. puniceus* var. *lucidulus* Gray. Evidence has been presented for recognition of *S. puniceum* var. *scabricaule* (Shinners) Nesom (Nesom 1997), the only infraspecific taxon currently recognized within the species. It might be argued that *S. rhiannon* would be more appropriately treated at varietal rank, especially in view of its largely quantitative difference, but we infer that the new species is reproductively isolated because its geographic range is imbedded within that of typical *S. puniceum* and morphological intergrades have not been observed, despite the co-occurrence of the two taxa within several meters of one another at the type locality.

It is possible and likely that adaptation to the relatively drier habitat of the serpentine barren play a significant part in the observed size reductions of *Symphyotrichum rhiannon*. Common garden experiments would be of interest to determine what component, if any, of the differences are phenotypic. The differences in leaf shape, however, suggest that other genomes might have been involved in the evolution of *S. rhiannon*. *Symphyotrichum prenanthoides*, which apparently is closely related and which is sympatric with *S. puniceum* over much of its range, has cauline leaf blades distinctly narrowed to a petiolar region and Semple (pers. comm.) hypothesizes that *S. rhiannon* is most closely related to *S. prenanthoides*, apparently weighting the tendency in *S. rhiannon* to produce subspatulate leaves. *Symphyotrichum rhiannon*, *S. prenanthoides*, *S. puniceum*, and *S. firmum* have been treated as members of *Symphyotrichum* sect. *Symphyotrichum* (sensu Nesom 1994), but because hybrids in many parental combinations have been observed in *Symphyotrichum*, hypotheses regarding evolutionary ancestry could justifiably include species of putatively more distant relationship. It is perhaps notable that the stem leaves of *S. rhiannon* are less strongly clasping than those of either *S. puniceum* or *S. prenanthoides*.

Symphyotrichum rhiannon has only been documented within a serpentine plant community endemic to a 120 ha area surrounding Buck Creek in the southern Nantahala Mountains of Clay County, North Carolina (Fig. 2). Serpentine soils in the Southern Appalachian Mountains are very rare, and only a

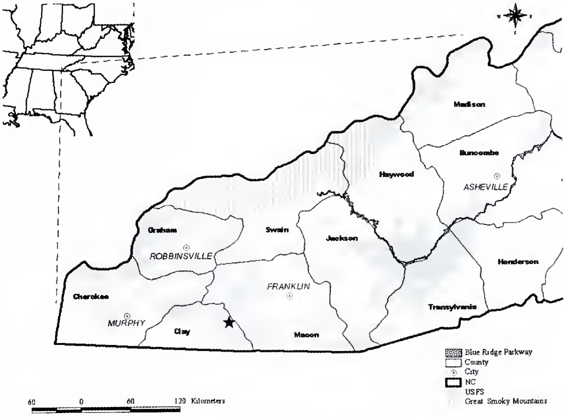

Fig. 2. Location of Buck Creek serpentine site (denoted by star) in Clay County, western North Carolina.

few serpentine barrens have been located and studied, beginning with a pioneering study by Albert E. Radford (1948). The Buck Creek Serpentine Barren was discovered in 1951, following Radford's dissertation, by the late Robert K. Godfrey, then at N.C. State University, and has been periodically studied by botanists and ecologists ever since, as it is the largest and floristically and vegetationally most distinctive of the Southern Appalachian serpentine barrens. In the late 1970s and early 1980s, Laura Mansberg (now Cotterman) conducted the most detailed study of this unique plant community, describing it as a Pine-Savanna (Mansberg 1981; Mansberg & Wentworth 1984). The unusual aster here described as *Symphyotrichum rhiannon* was initially noted during this study by Mansberg, and was referred to in her thesis and subsequent paper as "an undescribed *Aster*." Schafale and Weakley (1990) classified the Buck Creek site as an Ultramafic Outcrop Barren, and considered it to be the best-developed and largest example of this critically imperiled natural community type. The hierarchical United States National Vegetation Classification classifies the community association type as a *Quercus alba–Pinus rigida / Sporobolus heterolepis–Andropogon gerardii* Woodland and assigns it a conservation rank of G1 (Critically Imperiled) (NatureServe 2004).

A physiognomic patchwork of forest, dense grass patches and partially open woodland occurs across the Buck Creek site (Fig. 3). The dominant rock types, serpentinized dunite and olivine, influence the striking vegetation present on this site (Hadley 1949; Pratt & Lewis 1905). Soil depth is variable, ranging from 0 to 60 cm, although rock outcrops represent between 5 and 10% of the local landscape. Soil characteristics reveal higher base saturation, cation exchange capacity, pH, and magnesium relative to surrounding sites in the Nantahala Mountains (Mansberg & Wentworth 1984). The serpentine plant communities occupy both east and west-facing slopes extending from 975 meters elevation along Buck Creek to over 1220 meters elevation atop Corundum Knob. *Symphyotrichum rhiannon* occurs within the woodland and grass-dominated areas.

Within the woodland the forest canopy varies from 20-60% cover depending on the intensity and frequency of recent prescribed burns. The woodland is dominated in the tree canopy by older stunted *Quercus alba* and smaller denser *Pinus rigida* stems. *Tsuga canadensis, Sassafras albidum, Acer rubrum, Oxydendrum arboreum*, and *Amelanchier laevis* also occur within the canopy and subcanopy. Shrub cover is meager, typically occurring in clumps and providing no more than 10% cover. Diagnostic shrub species include *Rhododendron viscosum, Physocarpus opulifolius, Viburnum cassinoides, Kalmia latifolia, Lyonia ligustrina* var. *ligustrina, Vaccinium stamineum*, and *V. corymbosum*.

The grass dominance within the herb stratum is reminiscent of prairie vegetation and presents a striking contrast to the regionally typical herbaceous layer consisting of mesophytic, broad-leaved forbs. *Andropogon gerardii, Schizachyrium scoparium* var. *scoparium*, and *Sporobolus heterolepis* are the most important grasses. Characteristic forb species include *Hexastylis arifolia* var. *ruthii, Thalictrum macrostylum, Packera plattensis, Castilleja coccinea, Phlox ovata, Oxypolis rigidior, Sanguisorba canadensis, Polygala pauciflolia, Asplenium platyneuron, Solidago nemoralis, Symphyotrichum undulatum* and *S. phlogifolium*. A striking contrast within the herb layer is the juxtaposition of both mesophytic and xerophytic species. It is not unusual to observe *Sanguisorba canadensis* and *Oxypolis rigidior* emerging from a grassy thicket of *Sporobolus heterolepis* and *Schizachyrium scoparium*. Mansberg noted a perched water table while surveying the site and suggested that there is a complex soil moisture gradient within the serpentine site (Mansberg & Wentworth 1984). Many of the minerals predominant in mafic and ultramafic rocks chemically weather to clays, and the soils at Buck Creek have a substantial clay component, providing a perched water table and abundant seepage after rains, but drying to highly xeric conditions during droughts.

In response to periodic mining threats, 42 hectares of the serpentine site at Buck Creek are now managed by the USFS as a Special Interest Area and registered as a Natural Heritage Area with the North Carolina Natural Heritage Program. In 1995, the U.S. Forest Service initiated active conservation management

Fig. 3. Buck Creek serpentine woodland in mid August. The dominant grass is *Andropogon gerardii*.

Fig. 4. Emerging grasses at Buck Creek serpentine woodland 3 weeks following a prescribed burn designed to reduce the canopy layer. Prescribed fire was conducted in April of 1995.

Table 1. Status of North Carolina rare plant species documented at Buck Creek serpentine site.

Species	**G-rank**[a]	**S-rank**[b]	**Relative Rarity within North Carolina**
Sporobolus heterolepis	G5	S1	1 of 2 occurrences documented in NC; disjunct eastwards from a primary distribution in the Great Plains
Deschampsia cespitosa ssp. *glauca*	G5	S1	Only known occurrence in NC; disjunct from further west
Elymus trachycaulus ssp. *trachycaulus*	G5T5	S1	Only known occurrence in NC; disjunct from further west
Calamagrostis porteri ssp. *porteri*	G4T4	S1	1 of 8 extant occurrences within NC
Poa saltuensis	G5	S1	1 of 2 occurrences documented in NC; disjunct from further west
Muhlenbergia glomerata	G5	S1	1 of 2 occurrences documented in NC; disjunct from further west
Carex woodii	G4	S2	Dense in forested area within and surrounding serpentine site; northern species near its southern range extent
Calystegia catesbiana var. *sericata*	G3T3	S3	Locally common in Southwestern NC Mts; broad Southern Appalachian endemic
Liparis loeselii	G5	S1	Locally restricted to only a few individuals; circumpolar, near its southern range extent
Gentianopsis crinita	G5	S1	1 of 2 high quality occurrences in NC
Oenothera perennis	G5	S2	1 of 3 high quality occurrences in NC
Ranunculus fascicularis	G5	S1	1 of 2 occurrences documented in NC
Pedicularis lanceolata	G5	S1	1 of 2 drainages with extant populations in NC
Parnassia grandifolia	G3	S2	1 of 3 high quality occurrences in NC
Viola appalachiensis	G3	S2	Largest population documented in NC; Central and Southern Appalachian endemic
Brachyelytrum aristosum (= *B. septentrionale*)	G4G5	S3?	Locally common in higher elevations in the southwestern Mountains of NC; northern species near its southern range extent
Drepanolejuenea appalachiensis	G2?	S2	Remarkable occurrence for tiny liverwort that more typically occurs in mesic hardwood forest; Southern Applachian endemic; with one disjunct occurrence in West Indies

Table 1. continued

Species	G-rank[a]	S-rank[b]	Relative Rarity within North Carolina
Celastrina nigra	G4	S2?	1 or 6 occurrences documented in NC, near eastern range limit
Speyeria aphrodite cullasaja	G5T1	S1?	Only known occurrence in NC; southern Appalachian endemic
Chlosyne gorgone	G5	S1?	Only known occurrence in NC; primarily Midwestern and western species near eastern range limit
Phyciodes batesii maconensis	G5	S2	Largest population documented in NC; southern Appalachian endemic

[a] G-rank indicates global rarity and threat status. See NatureServe (2004) for definitions.
[b] S-rank indicates state rarity and threat status. See NatureServe (2004) for definitions.

of the site, using prescribed fire as the primary tool, resulting in reduction of woody growth encroaching on the site and an increase in herbaceous cover, particularly the grasses once dominant at the site (Fig. 4). Within the last 10 years monitoring plots were established both by both the North Carolina Vegetation Survey and the U.S. Forest Service to document current vegetation and provide a baseline for detecting change. A review of this plot data shows that *S. rhiannon* prefers more open conditions, occurring exclusively within plots (n = 27) with less than 50% tree cover and primarily in plots with less than 33% canopy cover. *S. rhiannon* grows sparsely; cover estimates in plots have not exceeded 2% cover. *S. rhiannon* has either maintained its coverage or slightly increased its density within fire-maintained areas at the Buck Creek Serpentine Barren.

In addition to the presence of the unusual plant community, the presence of rare species adds to the conservation importance of the Buck Creek Serpentine Barren. Seventeen state-listed rare plant species and four state-listed butterfly species occur within the site (Franklin & Finnegan 2004; LeGrand et al. 2004; Gatrelle 1998; Table 1). Most of these species are primarily wide-ranging and globally secure (G4 or G5 rank), yet rare in NC; a few are restricted to only this site within the state. Although serpentine is well known for its tendency to generate locally endemic species (Brooks 1987), relatively few endemics have been described from the serpentine areas in eastern North America. A number of endemics have been described from the well known serpentine barrens of Maryland and Pennsylvania, including *Symphyotrichum depauperatum* (Fernald) Nesom, though the taxonomic distinctiveness of many remains controversial. The less well known serpentine areas in Virginia, North Carolina, and Georgia have not heretofore yielded endemic taxa described. However, a number of odd putative taxa (*Carex, Hexastylis, Rhododendron, Symphyotrichum,* *Thalictrum*) from serpentines in Virginia and North Carolina are currently the subject of taxonomic investigation and may add to a growing list of eastern North American serpentine endemics.

Current information suggests that *S. rhiannon* is a serpentine endemic restricted to the G1-ranked woodland community at the Buck Creek Serpentine Barren. We hope that publication of this species will result in the discovery of other populations, at the few other Southern Appalachian serpentine barrens, though the potential for locating other undocumented occurrences within ultramafic rock influenced woodlands or barrens within the region is probably limited given the overall scarcity of this habitat.

ACKNOWLEDGMENTS

We thank Luc Brouillet (Université de Montréal, MT), co-author of the taxonomic treatment of *Symphyotrichum* for the forthcoming FNA volumes (Flora of North America), for his comments on the distinctiveness of the new species. We thank John Semple (University of Waterloo, WAT) for helpful discussions about the taxon and comments improving the manuscript. We thank the curators of GMU and VPI for the loan of specimens of other *Symphyotrichum* entities found in ultramafic and mafic sites in Virginia.

BOOK REVIEW

Blueberries and Cranberries

Jennifer Trehane. 2004. **Blueberries, Cranberries and Other Vacciniums.** (ISBN 0-88192-615-9, hbk.) Timber Press Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). U.S. $29.95, CAN $39.95, 272 pp., 66 color photos, 7" × 9".

In the new book by Jennifer Trehane, *Blueberries, Cranberries and Other Vacciniums*, she begins by tracing the story of the most widely grown species of *Vacciniums*, blueberries and cranberries. The book deals with their propagation, cultivation, harvest, and uses, including their health benefits; varieties are also fully described. Other relatively unfamiliar, fruiting vacciniums are dealt with in the section on garden cultivation, as are some cold-hardy and neo- or subtopical species and "forms."

The reader should note, the book contains sufficient information on growing blueberries, cranberries, and even lingonberries on a small scale commercial basis, but is not intended as a complete manual for large scale commercial growing.

In part one the author gives a semi-brief overview of the genus, including the history, archaeology, cultivation, pests, diseases, and botany. I found it to be useful in that the information was divided up by the species, common name, and inside that chapter, she covered all the aforementioned topics, specific to that plant.—*Asha McElfish, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

ABSTRACT

The genus *Otostylis* (Orchidaceae) is one of the lesser known genera in the *Zygopetalum* alliance, which has had a problematic taxonomic history. *Otostylis* consists of four species distributed in South America and Trinidad. The purpose of this paper is to provide a synopsis of the genus, with descriptions of the four species and keys for their identification. *Otostylis paludosa* is resurrected from previous synonomy under *O. lepida* and reported as a new record for the genus in Peru, occurring as a dominant herb in bog wetlands of the Department of Madre de Dios.

RESUMEN

El género *Otostylis* (Orchidaceae) es uno de los géneros poco conocidos en la alianza de *Zygopetalum*, que ha tenido una historia taxonómica problemática. *Otostylis* consiste en cuatro especies distribuidas en América del sur y Trinidad. El objetivo este articulo es proveer de una sinopsis del género, con descripciones de las cuatro especies y claves para su identificación. *Otostylis paludosa* dejo de ser sinonimo de *O. lepida* y esta reportado como un record nuevo para el Perú, siendo una hierba dominante en los pantanos del Departamento de Madre de Dios.

INTRODUCTION

The circumscription of orchid genera related to *Zygopetalum* W.J. Hook. has been problematic throughout the history of botany, and periodically all taxa have been united within an impossibly broadly defined *Zygopetalum*. Our modern understanding of generic limits in the group begins with a generally accepted review by Garay (1973). Subsequent authors have dealt with nomenclatural problems (Christenson 1988), generic reviews (Christenson 2002), and the confounding generic issues of taxa lacking pseudobulbs (Dressler 2000).

One of the lesser-known genera in the *Zygopetalum* alliance is *Otostylis*

SIDA 21(2): 841–852. 2004

Schltr. It was described by the German orchidologist Rudolf Schlechter in 1918 in a review of genera previously combined with *Aganisia* Lindl. The name is derived from the Greek *otos*, meaning ear, and *stylis*, meaning column, referring to the conspicuous subapical wings on the column. This character separates it from related genera including *Aganisia*, *Warreella* Schltr., and *Warreopsis* Garay. *Otostylis* has been generally accepted in floristic accounts since its original publication. Rather astonishingly, despite their showy flowers, plants of *Otostylis* have been rarely cultivated in modern times and are only now being reintroduced to horticulture.

The purpose of this note is to provide a synopsis of *Otostylis* and report the discovery of the genus for the first time in southern Peru. Recent collecting of vouchers for botanical and ecological studies in Madre de Dios, Peru, under the auspices of the Botanical Research Institute of Texas (BRIT) and the San Marcos Herbarium (USM) has revealed a substantial population of *O. paludosa* (Cogn.) Schltr., a previously endemic Brazilian taxon incorrectly reduced to synonymy in recent times.

TAXONOMY

Otostylis Schltr., Orchis 12:38. 1918. Type: *Otostylis lepida* (Linden & Rchb.f.) Schltr.

Caespitose terrestrials. Pseudobulbs ovoid, small, typically concealed by bracts and leaf bases. Leaves several, plicate, lanceolate, petiolate, acuminate, sometimes with subsimilar foliaceous bracts subtending the pseudobulbs. Inflorescences axillary erect long-pedunculate racemes, the floral bracts inconspicuous. Flowers numerous, several open at once, showy, long-lasting, predominately white, crystalline in texture. Sepals and petals subsimilar, subequal, free, spreading. Lip unlobed or obscurely three-lobed, subauriculate, with a basal transverse crested callus, sometimes biseriate. Column straight, conspicuously winged, with a short foot; pollinia 4, on a common linear viscidium.

Otostylis comprises four superficially similar species native to South America and Trinidad.

KEY TO THE SPECIES

1. Callus minutely warty, W-shaped with two short continuous arms extending onto the blade of the lip ____ **O. lepida**
1. Callus not warty, entire or biseriate without continuous extensions.
  2. Callus biseriate comprising a transverse ridge with three low parallel keels in front ____ **O. brachystalix**
  2. Callus entire, a high crest.
    3. Callus toothed, inflorescences less than 50 cm tall (northern South America) ____ **O. alba**
    3. Callus ridged but not forming distinct teeth, inflorescences commonly 1 m tall (southern Brazil and Peru) ____ **O. paludosa**

1. Otostylis alba (Ridl.) Summerhayes, Kew Bull. 6:293. 1951. *Aganisia alba* Ridl., Timehri 5:204. 1886; *Zygopetalum venustum* Ridl., Trans. Linn. Soc. Bot., ser. 2, 2:283, t. 47. 1887; *Aganisia venusta* (Ridl.) Rolfe ex J.D. Hooker, Bot. Mag. 118: sub t. 7270. 1892; *Warreella venusta* (Ridl.) Schltr., Die Orchideen, ed. 1:425. 1914; *Koellensteinia alba* (Ridl.) Schltr., Orchis 9:32. 1915; *Otostylis venusta* (Ridl.) Schltr., Orchis 12:41. 1918. TYPE: VENEZUELA: Bolivar, Mt. Roraima district, along the Kookenam River, 1000 m, *E.F. Im Thurn 360* (HOLOTYPE: BM!; ISOTYPE: K!).

Pseudobulbs ovoid, to 1.5 cm long, ca. 1 cm wide and 0.5 cm thick, completely concealed by the leaf bases, apically unifoliate. Leaves 3–4, arching, linear-lanceolate, petiolate, acuminate, to 25 × 2 cm. Inflorescences erect long-pedunculate racemes to 40 cm long, longer than the arching leaves, the floral bracts triangular-ovate, acute, to 0.6 cm long. Flowers 10–12, to 2.5 cm across, white, the callus and surrounding field yellow. Sepals and petals subsimilar, subequal, elliptic, obtuse, the dorsal sepal to 1.3 × 0.8 cm, the lateral sepals to 1.5 × 1 cm, the petals to 1.2 × 0.7 cm. Lip unlobed, elliptic, obtuse, minutely emarginate, to 1.3 × 1.3 cm, the callus a high transverse semicircular crest divided into blunt teeth, ca. 7 mm wide. Column winged, to 1 cm long, width at wings 7 mm wide, width at base 2.5 mm wide, the wings obliquely ovate. Fruits not seen.

Distribution.—Venezuela, the Guianas, and Brazil at elevations around 1000 m (Foldats 1970).

Some authors reduce this species to the synonymy of *O. lepida* (e.g., Dunsterville & Garay 1965; Pabst & Dungs 1977; Senghas & Gerlach 1996; Romero-González 2003) but we are following Foldats (1970) in keeping it separate. *Otostylis lepida* has been recorded from the Brazilian states of Amazonas, Matto Grosso and Para (Pabst & Dungs 1977). The records for Amazonas are likely correct; the records for Matto Grosso are based on the previous inclusion of *O. paludosa* in synonymy; and the records for Para require reexamination of those vouchers, outside the scope of this paper.

2. Otostylis brachystalix (Rchb.f.) Schltr., Orchis 12:39. 1918. (**Figs. 1, 2**). *Zygopetalum brachystalix* Rchb.f., Ann. Bot. Syst. 6:660. 1863; *Aganisia brachystalix* (Rchb.f.) Rolfe, Orchid Rev. 22:200. 1914; *Koellensteinia brachystalix* (Rchb.f.) Schltr., Orchis 9:31. 1915. TYPE: TRINIDAD: *leg. ignot. s.n.* (HOLOTYPE: W, drawing seen).

Pseudobulbs short, ovoid, to 2 cm long, completely concealed by the leaf bases. Leaves 3–4, erect, grass-like, acuminate, to 70 × 2 cm, often half that size. Inflorescences erect long-pedunculate racemes to 70 cm long, longer than the leaves, the floral bracts inconspicuous, ovate, acute, 6 mm long. Flowers 5–30, to 2.5 cm across, sepals and petals white, the lip white with a yellow center. Sepals elliptic, obtuse, to 1.8 × 1.2 cm. Petals obovate, obtuse, to 1.7 × 1 cm. Lip obscurely three-lobed, to 1.2 × 1.2 cm, the lateral lobes small, subauriculate, flanking the callus, the midlobe transversely kidney-shaped, obtuse, the callus a low transverse ridge across the lateral lip lobes in a raised crescent that diminishes to the sides of the lobes. Column stout with conspicuous rhombic subapical wings, to 0.8 cm long, 6 mm wide across the wings, 2.5 mm wide at the base. Fruits capsules, ellipsoid, smooth.

Fig. 1. Habit of *Otostylis brachystalix* from the Aripo Savannah wetland of Trinidad-Tobago. (Photograph by Julian Kenny, Trinidad-Tobago, 2003)

Fig. 2. Inflorescence and flowers of *Otostylis brachystalix* from Trinidad-Tobago. (Photograph by Julian Kenny, Trinidad-Tobago, 2003)

Distribution.—Trinidad, Colombia (Ortiz 1995), Venezuela, the Guianas, Brazil, and Peru (Loreto) at elevations of 150–1675 m.

Much early confusion surrounding this species was resolved by Ames (1922) who provided the first illustration of *O. brachystalix* based on a plant from Trinidad, where it was collected for the first time in the Aripo Savannah. Described by Reichenbach in 1861 as *Zygopetalum brachystalix*, this species is characterized by having a weakly three-lobed lip and a biseriate callus consisting of a low transverse ridge between the auriculate lip lobules supplemented by three small longitudinal keels in front. Figures 1 and 2 provide images of the habit, inflorescence, and flowers of *O. brachystalix*, courtesty of Dr. Julian Kenny. Pabst and Dungs (1977: 285) provided an illustration of a flower dissection of *O. brachystalix*.

According to Julian Kenny (2004, pers. comm.), *O. brachystalix* is known in eastern Trinidad from the Aripo Savannah, which is a 360-hectare bog-like grassland lying on a bed of quartz sand over a clay pan. The savannah is boggy during the rainy season and arid during the dry season. The dominant vegetation consists of grasses and sedges, as well as bog indicators, *Drosera* and *Sphagnum* species.

In the Aripo Savannah, *O. brachystalix* is more often seen on well-drained, slightly elevated patches. It flowers typically in the dry season from January to April (Kenny 1988). A mature plant grows to about 70 cm tall. Populations have declined significantly in the last 20 years (Kenny 2004, pers. comm.), presumably due to overcollecting, as it is the easiest to grow of the savannah orchids. A pot of sand and exposure to sun and proper watering is all that is necessary to cultivate this species (Kenny 2004, pers. comm.). Several other orchids exist in this habitat, such as *Cleistes tenuis* (Rchb.f.) Schltr., *Epistephium parviflorum* Lindl., *Habenaria leprieurii* Rchb.f., *H. mesodactyla* Griseb., and *Sarcoglottis simplex* (Griseb.) Schltr. *Cyrtopodium parviflorum* Lindl. also exists in the same habitat but according to Kenny (2004, pers. comm.) it is now rare due to overcollecting.

3. Otostylis lepida (Linden and Rchb.f.) Schltr., Orchis 12:40. 1918. *Aganisia lepida* Linden and Rchb.f., Beitr. Orchideenkunde 15, t. 5. 1869. TYPE: BRAZIL. AMAZONAS: Rio Negro, *G. Wallis s.n.* (HOLOTYPE: W!).

Pseudobulbs slender, fusiform, to 6 cm long, to 1 cm in diameter, subtended by nonfoliaceous bracts. Leaves 1–3, arching-erect, linear-lanceolate, petiolate, acuminate, to 65 × 6 cm, often half that size. Inflorescences erect long-pedunculate racemes, shorter than the leaves, to 25 cm long, the floral bracts inconspicuous, ovate, acute, to 0.4 cm long. Flowers 4–10, 2 mm across, white, the sepals and petals often suffused with pink toward the apices, the callus and surrounding field yellow. Sepals and petals subsimilar, elliptic, acute, the sepals to 2 × 1 cm, the petals to 1.8 × 0.8 cm. Lip unlobed, elliptic-suborbicular, slightly constricted above the base (= obscurely pandurate), obtuse-truncate with a minutely apiculate apex formed by conduplicate folding, to 1.8 × 1.8 cm,

FIG. 4. Inflorescence and flowers of *Otostylis paludosa* from Madre de Dios, Peru. (Photograph by Mathias Tobler, 2002)

Fig. 5. Palm swamp habitat of *Otostylis paludosa* in Madre de Dios, Peru. (Photograph by Mathias Tobler, 2002)

the callus loosely W-shaped, a transverse minutely warty ridge extending as two short arms. Column winged, to 1.2 cm long, 7 mm wide across the wings, 3 mm wide at the base, the wings quadrate, truncate. Fruits not seen.

Distribution.—Venezuela, Guiana, and Brazil at elevations of 750–1615 m.

This species is easily recognized by its minutely warty callus with arms that extend onto the blade of the lip.

4. Otostylis paludosa (Cogn.) Schltr., Repert. Spec. Nov. Regni Veg. 15:214. 1918. (**Figs. 3–5**). *Zygopetalum paludosum* Cogniaux, Comm. Linh. Tel. Est. Matto Grosso, Annex. 5, pt. 3:12, t. 64. 1912. TYPE: BRAZIL. MATTO GROSSO: Rio Juruena, May, *F.C. Hoehne (Comm. Rondon) 2000 & 2013* (SYNTYPE: BR!).

Pseudobulbs ovoid, to 2 cm long, completely concealed by leaf bases. Leaves 1–2, erect, linear-lanceolate, petiolate, acuminate, to 60.7 cm long, 2.3 cm wide. Inflorescences erect long-pedunculate racemes, longer than the leaves, the peduncle to 62.4 cm long, the rachis 10–15 cm long, the floral bracts lanceolate, acute, to 0.5 cm long. Flowers 10–20, to 3 cm across, white, the center of the lip yellow, the inner face of the column purple. Sepals and petals subsimilar, subequal, spreading, oblong-elliptic, obtuse, the dorsal sepal to 17 × 7 mm, the lateral sepals to 15 × 8 mm, the petals to 15 × 6 mm. Lip unlobed auriculate, the midlobe suborbicular to transversely kidney-shaped, broadly rounded, to 12 × 11 mm, the callus a transverse, lunate crest, incised forming ridges but not distinct teeth, to 2.5 mm long and 5 mm wide. Column stout, to 8 mm long, with obtuse, quadrangular wings, to 4 × 1.9 mm, the width at wings to 7 mm and at base to 3.5 mm. Fruits ellipsoid, smooth capsules.

Distribution.—Brazil (Matto Grosso) and Madre de Dios, Peru, in the hot, humid lowlands at ca. 230–250 m.

This somewhat obscure species, generally maintained in the synonymy of *O. lepida* (e.g., Pabst & Dungs 1977), has rather ironically been well illustrated in the literature. In particular, the drawing from *Flora Brasílica* (Hoehne 1948, 1953) was reproduced in the very widely available horticultural manual *Encyclopaedia of Cultivated Orchids* (Hawkes 1965: 348). In addition, a watercolor drawing of a flower, clearly showing the high callus without ancillary structures in front, was reproduced in Pabst and Dungs (1977: 229, as *O. lepida*).

A swamp dweller as the name implies, plants of *O. paludosa* are remarkable for their stature when in flower, being about twice as tall as the other species in the genus (Fig. 3). The flowers, however, are similar in size to other species of *Otostylis*. A photograph of a flowering plant *in situ* on the Parecis plateau and its habitat was given by Miranda (1996) as *O. lepida* but is probably *O. paludosa*. See Figure 4 for images of the inflorescence and flowers of *O. paludosa* from Madre de Dios, Peru.

We record this species as new to the flora of Peru based on a collection by Janovec et al. from the Department of Madre de Dios. It has only been found in bog-like savannah habitat associated with large swamps dominated by the palm

Mauritia flexuosa L. (Arecaceae), known commonly as the Aguaje palm. Figure 5 shows the habitat of *O. paludosa* from a study site in Madre de Dios, Peru.

Otostylis paludosa is the largest, most abundant, and conspicuous orchid growing in the open boggy savannahs of the Aguaje palm swamp habitat in the region. This species grows with ferns, grasses, rushes, sedges, and other plants on small moist raised areas of *Sphagnum* emerging like small islands from the bog water. Botanical and ecological studies in progress have documented hundreds of individuals of this species per hectare (Janovec et al., in prep.). Despite its abundance, this species has never been recorded in Peru, most likely due to a major lack of exploration of vast wetland habitats, especially of Madre de Dios, Peru.

The peak flowering season in Peru is July–September, when the white flowering inflorescences of this species can be observed in abundance, but flowers have also been observed in January–March. The plants can be seen holding fruits during March–July and September–February.

Collections examined: **PERU. Madre de Dios:** Manu Province, *Mauritia flexuosa* (Arecaceae) palm swamp 7 km up the Madre de Dios River from the Los Amigos River, 230 m, 19 Aug 2002, *J.P. Janovec et al. 2662* (USM, BRIT); same locality, *M.A. Chocce 277, 279, & 295* (USM).

EXCLUDED SPECIES

Otostylis hirtzii Dodson, Icon. Pl. Trop., ser. 1, t. 976. 1984. TYPE: ECUADOR: Pichincha, between San Juan and Chiriboga on old road from Quito to Santo Domingo, 1800–2200 m, 7 Mar 1982, *A. Hirtz & J. Leon 201* (HOLOTYPE: SEL) = *Warreopsis pardina* (Rchb.f.) Garay (see Senghas & Gerlach 1993).

Stems short, completely concealed by leaf bases. Leaves 3–5, lanceolate, long-petiolate, acuminate, to 75 × 8 cm. Inflorescences erect long-pedunculate racemes to 75 cm long, the floral bracts lanceolate, acute, to 0.5 cm long. Flowers 12–15, to 1.7 cm across, the sepals and petals yellow with purple spots, the lip pinkish-white. Sepals and petals subsimilar, subequal, oblong-elliptic, obtuse, to 1 × 0.5 cm, the dorsal sepal concave. Lip unlobed, auriculate, fan-shaped, notched at the apex, to 0.8 × 0.9 cm, the callus an inverted U-shaped crest. Column straight, without wings, to 0.6 cm long, the foot to 0.2 cm long. Fruits not seen.

Distribution.—Known from Colombia and Ecuador at elevations of 1800–2200 m.

This species has always been out of place in *Otostylis* by virtue of its column which is devoid of any wings and its boldly spotted yellow sepals and petals. With the removal of this species to *Warreopsis*, all species of *Otostylis* have the generic character of prominent column wings as well as unmarked white sepals and petals.

ACKNOWLEDGMENTS

We would like to thank the Gordon and Betty Moore Foundation, Beneficia Foundation, Upton Foundation, World Wildlife Fund, Winrock International, Amazon Conservation Association, and the Asociación para la Conservación de la Cuenca Amazónica, for supporting the studies that led to the discovery of *Otostylis paludosa* in Madre de Dios, Peru. Piher Maceda, Fernando Cornejo, Jorge Herrera, Juan Carlos Flores, and Fausto Espinosa deserve special thanks for supporting logistics and fieldwork. We thank Asunción Cano, Director of the San Marcos Herbarium, and Carlos Reynel, Professor and Director of the La Molina Forestry Herbarium, for their support of the project, and the Peruvian Ministry of Natural Resources (INRENA) for providing research and collection permits for studies of this and other plant species in Madre de Dios, Peru. Amanda Neill and Ted Barkley provided important comments on earlier versions of the manuscript. We thank Mathias Tobler for allowing us to use his photographs and for contributing as a major collaborator in studies of wetlands in Madre de Dios, Peru. We are grateful to Julian Kenny who kindly provided photographs and essential information from his studies of *Otostylis brachystalix* in in the Aripo Savannah of Trinidad-Tobago. Finally, we thank Leslie Garay for freely sharing critical information from his private research files.

UNDERSTANDING *PLATANTHERA CHAPMANII* (ORCHIDACEAE), ITS ORIGINS AND HYBRIDS

Paul Martin Brown

10896 SW 90th Terrace
Ocala, Florida 34481, U.S.A.

ABSTRACT

Platanthera chapmanii (Small) Luer emend. Folsom is a rare orchid endemic to the southern coastal plain of the southeastern United States. Since its original description by Small in 1902 as *Blephariglottis chapmanii*, *Platanthera chapmanii* has been recognized at various taxonomic levels. Folsom (1984) clarified this problem by once again recognizing it at the species level and also provided evidence for the hybrid origin of the species and a new contemporary hybrid, *P.* ×*channellii*. Because Folsom's work was not widely available, much misunderstanding still persists as to the correct identity and rank of *Platanthera chapmanii*. Several species and hybrids are involved in this complex and all have contributed to the confusion. Those misunderstandings and relationships are clarified here.

RESUMEN

Platanthera chapmanii (Small) Luer emend. Folsom es una orquídea rara endémica de la llanura costera del Sur de los Estados Unidos. Desde su descripción original por Small en 1902 como *Blephariglottis chapmanii*, *Platanthera chapmanii* ha sido reconocida en varios niveles taxonómicos. Folsom (1984) clarificó este problema reconociéndola una vez más a nivel específico y también aportó pruebas del origen híbrido de la especie y un nuevo híbrido contemporáneo, *P. _channellii*. Debido a que el trabajo de Folsom no estuvo ampliamente disponible, todavía persiste mucho malentendido para la correcta identidad y rango de *Platanthera chapmanii*. Varias especies e híbridos están implicados en este complejo y todos han contribuido a la confusión. Se clarifican estos errores y relaciones.

Although geographically restricted to the southern portion of the southeastern United States, Chapman's fringed orchis, *Platanthera chapmanii* (Small) Luer emend. Folsom, is an important component of the summer-flowering orchid flora of this area. No other complex within the Orchidaceae in the southeastern United States has the unique position of having a species with an ancestral hybrid origin: *P. chapmanii*, and also having a current, or contemporary, occurring hybrid: *P.* ×*channellii*, with the same parentage. Historically known from East Texas, much of northern Florida, and southern Georgia, today it can be best found in the Apalachicola and Osceola National Forests of Florida. A few other small sites in northern Florida persist. The species is absent from the eastern half of the Panhandle. The Marion and Polk County, Florida records appear to be Channell's hybrid fringed orchis, *P.* ×*channellii* Folsom. Few sites remain in East Texas (Liggio & Liggio 1999) and the Georgia locales are based upon historic collections. No collections have ever been made from the area between the Apalachicola National Forest and East Texas.

Although Correll cites the range for *Platanthera chapmanii* (as *Habenaria* ×*chapmanii*) from New Jersey to Georgia and Florida and west to Texas, he was basing his knowledge on plants of both *P. chapmanii* and *P.* ×*channellii*. True *Platanthera chapmanii* has always been, and continues to be, one of the rarest orchids found in North America and is endemic to this lower portion of the southeastern Coastal Plain (Fig. 1) (Brown & Folsom 2002).

Chapman's fringed orchis originally was described by Small (1903) as *Blephariglottis chapmanii*. Ames (1910), noting its intermediacy between *Habenaria ciliaris* and *H. cristata*, made a new combination as *Habenaria* × *chapmanii*. This hybrid status remained for many years, including the new combination of *Platanthera* ×*chapmanii* (Small) Luer made by Luer (1972). It was not until Jim Folsom's work in 1984 that the taxon was restored to its rightful status of full species and a new, contemporary, hybrid, *P.* ×*channellii*, was described (Folsom 1984).

Understanding *Platanthera chapmanii* and its relationships to the closely related orange fringed orchis, *P. ciliaris*, and orange crested orchis, *P. cristata*, is greatly simplified if the observer can see all three taxa in one field session. This can only be accomplished in the Osceola National Forest, because *P. ciliaris* is historically and apparently currently absent from any of the other known localities. Liggio and Liggio (1999) clearly state that *P. ciliaris* has never been found within any of the Texas locales for *P. chapmanii*. Although vouchered from the panhandle counties encompassing the Apalachicola National Forest, no records exist for *P. ciliaris* within the Apalachicola National Forest (Anglin, pers. comm.; Brown & Folsom 2002; Folsom 1984, 1985). Conversely, *P. cristata* is often found growing within or nearby many of the *P. chapmanii* sites, especially in eastern Florida.

Folsom (1984) clearly demonstrated that the origins of *Platanthera chapmanii* were most likely an ancient hybridization of *P. ciliaris* and *P. cristata*. Therefore *P. chapmanii* is intermediate in size and characters between the two ancestors. Over the years it has evolved into a stable, reproducing species with a very distinctive bent column. This evolution of the column shape is critical in the pollination of the species. At the same time the contemporary hybrid of *P. ciliaris* and *P. cristata*, Channell's hybrid fringed orchis, *P.* ×*channellii*, occurs in rare situations when both parents are present. It, too, is intermediate between the parents, but the column is unlike that of *P. chapmanii*. Folsom (1984) illustrates all of these characters in great detail. Because Folsom's original publication in *Orquidea* (Mex.) was not readily available to many interested orchidists, the article, with minor revisions, was reprinted in the *North American Native Orchid Journal* in 1995, and included all of Folsom's graphics (Folsom 1995).

One of the best aids in the initial determination of plants in the field is observing what predominates in the area. If both *Platanthera ciliaris* and *P. cristata* are present and only a few intermediates are to be found, then they in

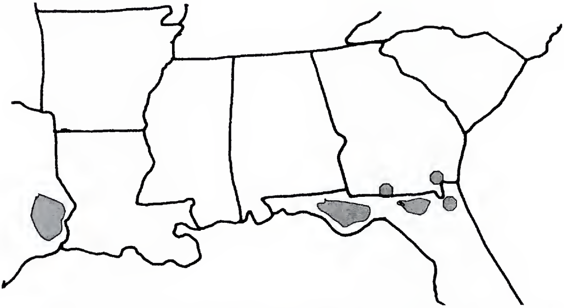

FIG. 1. Distribution of Chapman's fringed orchid (*Platanthera chapmanii*) in the southeastern United States.

all probability would be the hybrid *P.* ×*channellii*. If the majority of plants appear intermediate between *P. ciliaris* and *P. cristata* and only a few of either of the latter species are present then the observer needs to look carefully at the shape of the column, and most likely the majority of plants will be *P. chapmanii*. The rostellum lobes of the column in *P. chapmanii* have a prominent, distinctive, and characteristic hook that is clearly visible while the rostellum lobes of the columns of *P. ciliaris* are triangular and the tips pointing straight forward and those of *P. cristata*, are much shorter, nearly truncated, and with a very slight hook.

In addition, characters that help in determining which species are present may also include geographic location, diameter of raceme, size of flower, length and position of spur, and shape of orifice (Folsom 1984, 1995). To simply state that *Platanthera ciliaris* is larger, *P. chapmanii* intermediate in size, and *P. cristata* smaller has led to much confusion. For many orchid enthusiasts this, although not explicitly stated, implied overall size, especially height. That is not accurate and height should never be taken into account. All three species can grow from 10 or 15 cm to, in the case of *P. chapmanii* and *P. ciliaris*, over a meter in height! When size comparisons are made they refer to the diameter of the raceme and the measurements of the individual flowers. Even the overall height of the flowering raceme is not a good criterion for identification. Because of the ancestral parentage of *P. chapmanii* plants can easily favor the overall raceme shape of either parent, but the raceme diameter appears to remain constant. Spur length in the three species is helpful as well. Typically, in *P. ciliaris* the spur is 20–25 mm long, in *P. chapmanii* 10–14 mm long, and in *P. cristata* 5–

8 mm long. Figures 2 and 3 show the relationships of *P. cristata*, *P. chapmanii*, and *P. ciliaris* and will assist in understanding this comparison.

In addition to understanding the species orchid observers need to be aware of the hybrids that are involved in this complex include:

Platanthera ×*apalachicola* P.M. Brown & S. Stewart—(*P. chapmanii* × *P. cristata*)
Platanthera ×*channellii* Folsom—(*P. ciliaris* × *P. cristata*)
Platanthera ×*osceola* P.M. Brown & S. Stewart—(*P. chapmanii* × *P. ciliaris*)

Relationships among this group are best summed up in Figure 4. *Platanthera blephariglottis*, *P. conspicua*, and *P. integrilabia* are included in this diagram for completeness in the group (Brown 2003; Brown & Folsom 2004). These relationships and putative parentages are based upon morphological criteria. Artificially created hybrids, cytological, and molecular work has yet to be done on this entire complex.

Because hybrid swarms of some or all three species occur it may be difficult to determine individual plants. *Platanthera* ×*apalachicola* is locally common in northern Florida where both parents frequently grow together. They usually occur as individuals and may appear within stands of *P. chapmanii* as smaller flowered, more slender plants or within stands of *P. cristata* as larger flowered more robust individuals. The hooked column of *P. chapmanii* is usually dominant, but the spur length and position is intermediate (Brown & Stewart 2003).

Platanthera ×*channellii* and *P. chapmanii* can be difficult to tell apart. In the field one of the best ways is to look about and see which other species are growing nearby. If all the plants observed are the same, and within the range of *P. chapmanii*, it is most likely *P. chapmanii*, whereas if it is a colony of mixed species and only a few intermediate plants are present it is more likely to be *P.* ×*channellii*.

Platanthera ×*osceola* is known only from Osceola National Forest where it is the only place documented that both parents are found growing together. Plants of the hybrid usually occur as individuals and may appear within stands of *P. chapmanii* as larger flowered, more robust plants with decidedly longer spurs or within stands of *P. ciliaris* as smaller more compactly flowered individuals. The hooked column of *P. chapmanii* is not as dominant as in *P.* ×*apalachicola* (Brown & Stewart 2003).

Understanding both the history of *Platanthera chapmanii* and the hybrid swarms that may accompany plants in the wild hopefully will help in clarifying some of the mystery around this rare and spectacular orchid. Photographs and details of all of the taxa mentioned above are found in Brown and Folsom (2002, 2003, and/or 2004). All orange-flowered plants throughout the over-

BOOK NOTICE

Beautiful Peonies

Josef J. Halda and James W. Waddick (Botanical Illustrations by Jarmila Haldová). 2004. **The Genus Paeonia**. (ISBN 0-88192-612-4, hbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $34.95, 228 pp., 36 watercolors and 43 line drawings, 8 ×" × 11".

The Genus *Paeonia* by Josef J. Halda with James W Waddick, botanical illustrations by Jarmila Haldová, presents 36 watercolor paintings depicting the peony. Simply put, botanical art is a mixture of science and art. The more balanced the mix, the higher the chance of success The 22 color portraits here by book illustrator Jarmila, succeed more as art than science.

Grand flowers, dramatically lit, are posed against sophisticated taupe backgrounds. As art, the works are beautiful and haunting. The papery quality of the petals is convincing. The dark colored peonies so saturated in color as to appear satin-like. Veining on leaves is captured in rich detail. Delicate hairs on stems a virtuoso handling of the brush. But an inconsistent light source that cast bright to almost white coloring on flowers yet placed no shadow at all on some stems and leaves, disappointed. Given the rigid standards of botanical drawing, better to abandon dramatic lighting altogether and spend all available time on the accuracy of the live plant specimen placed in front of you. An uncomfortable shortening of leaves and twisting of some flower heads to fit the formatting of the paper resulted in perspective issues. Ideal positioning of flower placement on paper should be studied before the start of the drawing. While not strict botanical renderings of peonies, these are stunning portraits of peonies lovely enough to frame

In addition to the color paintings in The Genus *Paeonia*, are 43 stunning black and white line and stipple drawings. These are sure and confident Cooly devoid of illustrative styling. A PRELIMINARY ANALYSIS OF *CLEMATIS* (RANUNCULACEAE) IN SUB-SAHARAN AFRICA

Frederick B. Essig

Institute for Systematic Botany
Department of Biology SCA 110
University of South Florida
Tampa, Florida 33620 U.S.A.

ABSTRACT

Based on a survey of the literature and a representative sampling of herbarium material, it appears that the approximately 70 published binomials for *Clematis* in sub-Saharan Africa can be reduced to 10–13 distinct species or species complexes. A key to these species, along with a commentary on each, is provided as a preliminary guide for further floristic and taxonomic studies.

RESUMEN

Basado en una revisión de la literatura y una prueba representativa del material herbario, parece que los aproximadamente 70 binómenes publicados para las clemátides del África sub-Sahariana pueden ser reducidos a 10–13 complejos de especies, o especies distintas. Se proporciona una clave para estas especies, junto con un comentario para cada una, como una guía preliminar para estudios adicionales florísticos y taxonómicos.

INTRODUCTION

This report originated as part of an effort to develop tentative hypotheses about the number and distribution of the species of *Clematis* in various parts of the world. It was found, however, that the literature referencing *Clematis* in sub-Saharan Africa, in which approximately 70 species have been named, was confusing, patchy, inconsistent and often contradictory. The goal of this exercise was therefore to make the first continent-wide survey of sub-Saharan *Clematis* in Africa, combining study and synthesis of the diverse literature on the subject with a limited but representative herbarium study, in order to provide a preliminary overview of the number, correct names, and distribution of the species. North African species were excluded because they are more naturally a part of the Mediterranean flora. It is hoped that this preliminary report will provide a framework, some meaningful hypotheses, and a stimulus for regional African botanists to take up the detailed work that needs to be done. A comprehensive treatment of African *Clematis* will require extensive study in the herbaria of Europe and Africa, as well as a great deal of fieldwork in all parts of this large continent.

Since the study was initiated, global surveys of *Clematis*, including the African species, have been completed by Johnson (1997) and Grey-Wilson

SIDA 21(2): 861–877. 2004

(2000). Both authors have great familiarity with *Clematis* and each brings some interesting perspectives to the study of this genus, but neither addressed the many taxonomic and nomenclatural problems of the African *Clematis* in any depth. The relationship of the African species with those of other parts of the world is of great interest, but no definitive phylogenetic studies have been completed. Grey-Wilson considers the African species, with the exception of *C. grandiflora* and the species of section *Pseudanemone*, to constitute a subsection of the section *Meclatis*. This is an interesting and feasible hypothesis, but needs to be born out by formal phylogenetic studies. Other authors, such as Tamura (1967) and Johnson (1997) have considered the African species to be part of the subgenus or section *Clematis*, which includes similar white-flowered species in Eurasia and the Americas.

Even under the best of circumstances *Clematis* is a taxonomically difficult genus, due to great variability within species and minimal diagnostic differences in floral morphology between species, at least as can be seen in herbarium material. Previous work with North American *Clematis* (Essig 1990) had suggested that taxonomic problems in this genus might be largely resolved through careful analysis of existing herbarium material. In that study, the two widespread and frequently confused white-flowered species in eastern North America were found to be distinguishable by subtle morphological features plus differences in blooming season and substrate preferences. Such studies are feasible for taxa that are readily collected by generalists, and hence abundantly represented in herbaria. This study was initiated with the anticipation that this would be true of African *Clematis* as well.

MATERIALS AND METHODS

The survey of herbarium material was based on the collection of African *Clematis* at the Missouri Botanical Garden (MO), consisting of some 550 specimens. The Missouri Botanical Garden has a strong history and a sizeable ongoing program of fieldwork in Africa, and probably the best herbarium collection of African plants in North America. The collection includes sets of duplicates from important collectors in all parts of Africa, including Exell & Mendonca in Angola, deWilde, Ash, Westphal and Pichi-Sermolli in Ethiopia, Pawek, Phillips and Brass in Malawi, Reekmans in Burundi, Richards in Zambia and Tanzania, and countless other collectors who have collectively made a huge contribution. Table 1 shows the origin, by country, of the collections at Missouri. The best represented areas in the Missouri collections are the African upland areas stretching from South Africa to Ethiopia. Weakly represented areas include tropical west Africa from Senegal to Angola, the northern tier of the savanna belt running from Senegal to the Sudan, and the east coastal regions from Mozambique through Tanzania. These results probably reflect both the abun

TABLE 1. Collections in the Missouri Botanical Garden Hebarium (MO) by country of origin.

Ethiopia 45	Uganda 20	Kenya 20	Burundi /Rwanda 33

Tropical West Africa 36			

dance of *Clematis* and the intensity of botanical activity in these areas, but suggest a reasonably balanced coverage of the continent, sufficient for at least the preliminary survey undertaken here.

RESULTS

The collections of the Missouri Botanical Garden were readily sorted into 10 broadly distributed groups that can be interpreted as species or potentially as species complexes. These were identified using the earliest validly published name applicable to each group, as determined through examination of type materials, and/or original descriptions/diagnoses of the many species described in the literature. These widespread and variable taxa include *C. villosa*, *C. uhenensis*, *C. chrysocarpa*, *C. grandiflora*, *C. longicauda*, *C. dolichopoda*, *C. hirsuta*, *C. simensis*, *C. brachiata*, and *C. welwitschii*. This is a conservative interpretation, a hypothesis of what appears to be the minimum number of distinct species in Africa. Support for an additional three narrowly distributed species recognized by some authorities (*C. burgensis*, *C. sigensis*, and *C. viridiflora*), was weak or lacking in the Missouri collections, but are worth considering further and included in this treatment. In addition, the subspecies of *Clematis villosa* and *C. chrysocarpa* recognized by Brummitt (2000) are well-supported by this study, and may be nearly as distinct as the other species recognized. The preliminary nature of this study is stressed. Additional species may very well emerge after more exhaustive study.

The species have distinctive but overlapping geographic and altitudinal ranges. A number of intermediate specimens suggest hybridization or incomplete separation of the taxa, but most specimens fall clearly into one taxon or another. The taxa are defined primarily on the number, size, and shape of the leaflets, and in some cases by significant differences in flower size. Otherwise, flowers in African *Clematis* are relatively uniform with respect to morphology. All are bisexual and of a nodding habit (different from white-flowered species elsewhere, in which flowers are erect). Sepals vary only in size and slightly in texture, vestiture or color. Stamens are numerous, and all have hairy filaments. Carpels are numerous, all developing into achenes with long, plumose tails. Floral characters referred to by earlier authors (e.g. anther shape) have been found to vary as much within taxa as between taxa. Finally, ecological separation is suggested by some differences in blooming season and altitudinal range, but data on habitat and soil type were meager and inconsistent. Other subtle biological differences, such as differences in floral fragrance and flower color, are hinted at sporadically on labels, and need to be investigated in the field.

A key to these species, and discussion of each, follow.

KEY TO THE SPECIES OF *CLEMATIS* IN SUB-SAHARAN AFRICA

1. Plants erect, stiff-stemmed, perennial herbs; flowers with sepals imbricate in bud (species formerly segregated as the genus *Clematopsis*, key based on Brummitt, 2000).
  2. Achenes with golden-brown hairs; flowers solitary; leaves with 1–2 (very rarely 3) pairs of pinnae ____ **(C. chrysocarpa)**
    3. Leaves mostly trifoliolate; sepals 32–55 mm long; achenes (including plumose style) 55–70 mm long. Angola, Zaire ____ **C. chrysocarpa** subsp. **chrysocarpa**
    3. Leaves mostly 5–7-foliolate; sepals 20–32 mm long; achenes 35–50 mm long. Malawi, Tanzania and Mozambique ____ **C. chrysocarpa** subsp. **bijuga**
  2. Achenes with gray hairs; flowers 1-many per stem; leaves simple to tripinnate.
    4. Leaves simple; flowers solitary; sepals 32–60 mm long. Angola and Zaire to Tanzania ____ **C. uhehensis**
    4. Leaves trifoliate to tripinnate; flowers 1-many per stem; sepals 17–33 mm long ____ **(C. villosa)**
      5. Leaves trifoliolate or occasionally 5-foliolate, flowers 1–5 per stem. Cameroun and Nigeria to Tanzania ____ **C. villosa** subsp. **oliveri**
      5. Leaves pinnate to tripinnate, rarely trifoliolate; flowers 1–many per stem.
        6. Leaves tripinnae with segments 1–5(–8) mm broad; flowers 1–5 per stem; Zambia to Namibia and S. Africa ____ **C. villosa** subsp. **stanleyi**
        6. Leaves pinnate to bipinnate, with segments 5–40 mm broad; flowers 1-many per stem.
          7. Leaves densely sericeous beneath, pinnae lobes up to 15 mm broad and usually rounded at the apex; flowers 1–7(–13) per stem; W. Zaire, Angola, S. Uganda, W Tanzania ____ **C. villosa** subsp. **villosa**
          7. Leaves sparsely to densely appressed-pubescent beneath, pinnae lobes up to 40 mm broad and acute at apex; flowers 5–many per stem; S. Zaire, Tanzania, Mozambique, Malawi, Zambia ____ **C. villosa** subsp. **kirkii**
1. Plants vining or trailing; flowers with sepals valvate in bud.
  8. Flowers large, solitary or in clusters of 3, with sepals 15–45 mm long; carpels 50–200 per flower.
    9. Flowers campanulate, sepals strongly ribbed, greenish to yellowish or cream-colored, mostly more than 2.5 cm long (but with some specimens as short as 1.8 cm); leaves mostly 3–5-foliolate, with leaflets mostly more than 50 mm long.
      10. Leaves mostly 5-foliolate, leaflets lanceolate-ovate, rarely lobed, finely and regularly toothed; west equatorial Africa, from Guinea to Angola, 300–1600 m ____ **C. grandiflora**
      10. Leaves mostly 3-foliolate, leaflets broadly 3-lobed, irregularly toothed, foliage conspicuously reddish-golden pubescent; Ethiopia, 1350–2100 m ____ **C. longicauda**
    9. Flowers with spreading to reflexed sepals, sepals mostly 15–25 mm long; leaflets mostly less than 5 cm long.

11. Leaves 3–5-foliolate, leaflets broadly to narrowly ovate, abaxially reddish-golden pubescent; flowers white, reddish-golden pubescent externally, the sepals somewhat ridged; occurring in evergreen montane forest, Tanzania, Burundi, 1000–2500 m ______ **C. dolichopoda**
11. Leaves mostly twice pinnate, leaflets ovate-apiculate to linear-elliptic, subglabrous to moderately white-hirsute; flowers white to cream-colored or rarely tinged with pink, sepals not conspicuously ribbed; occurring in open woodland, Angola to Zaire, Tanzania, Malawi, & Zimbabwe, 400–1600 m ______ **C. welwitschii**

8. Flowers small, numerous, with sepals mostly less than 15 mm long (to 20 mm long in some populations of *C. hirsuta*), white, cream, greenish or yellowish; leaves mostly 5- or more foliolate, of various shapes; carpels fewer than 50 per flower.
    12. Leaves 3–5-foliolate with leaflets ovate-lanceolate, rarely lobed.
        13. Leaflets regularly and finely toothed. Ethiopia to Zaire and Nigeria ______ **C. simensis**
        13. Leaflets with margins essentially entire.
            14. Achenes with style 50–70 mm long; sepals 12–15 mm long. Kenya, Tanzania ______ **C. sigensis**
            14. Achenes with style to 33 mm long; sepals 10 mm long. Ethiopia ______ **C. burgensis**
    12. Leaves 5- or more foliolate with leaflets broadly ovate and frequently deeply lobed, irregularly or infrequently toothed.
        15. Flowers yellowish-green, coastal Mozambique and Tanzania ______ **C. viridiflora**
        15. Flowers white to cream or greenish.
            16. Leaves mostly once-pinnate, 5–9-foliolate, leaflets broadly ovate, irregularly lobed and toothed; tropical woodland and savanna, Angola to n.e. South Africa and Zimbabwe, northward to Ethiopia, and from there westward to Senegal, 220–2340 m ______ **C. hirsuta**
            16. Leaves mostly twice-pinnate, leaflets narrow, deeply lobed and infrequently toothed; temperate to subtropical grassland, South Africa to Zimbabwe, Botswana & Namibia; 400–2200 m ______ **C. brachiata**

TAXONOMIC SYNOPSIS AND COMMENTARY

Note: Three species of African *Clematis*, *C. chrysocarpa*, *C. uhehensis* and *C. villosa*, were formerly segregated in the genus *Clematopsis*, and not originally included in this survey. The recent paper by Brummitt (2000) provides a thorough treatment of those species, while providing the rationale for including them in *Clematis*. I am in full agreement with that decision, and include the species in this synopsis, but refer the reader to Brummitt's paper for more detail and discussion.

1. Clematis brachiata Thunb., Prod. pl. cap. 94. 1800. TYPE: not cited, but photos of authentic material from Uppsala have been seen.

Clematis oweniae Harv. in Harv. & Sond., Fl. cap. 1:2. 1860.
Clematis stewartiae Burtt Davy, Man. Flowering Pl. Ferns Transvaal. 1:37, 111. 1926.
Clematis thunbergii Steud., Nom., ed 2, 1:380. 1841, Harv. in Harv. & Sond., Fl. Cap 1:2. 1860.
Clematis triloba Thunb., Prod. pl. cap. 94. 1800 (non B. Heyne ex Roth, Nov. pl. sp. 251. 1851). TYPE: not cited.

The first species of *Clematis* described from sub-Saharan Africa, *C. brachiata* is similar to *C. hirsuta*, as both are widespread, variable species of open, disturbed habitats, and both produce numerous small white flowers. Exell and Milne-Redhead (1960), along with Thulin (1993), considered that *C. brachiata* and *C. hirsuta* would probably have to be combined, although earlier, Exell (1937) recognized *C. hirsuta* in Angola and *C. brachiata* in South Africa. White (1962) considered *C. hirsuta* and *C. inciso-dentata* as synonyms of *C. brachiata*. The two species can, however, be generally separated by the simply pinnate leaves of *C. hirsuta* compared with the doubly- (or more) compound leaves of *C. brachiata*. The geographic separation, with *C. brachiata* confined primarily to the subtropical grasslands of eastern South Africa and *C. hirsuta* occurring primarily in tropical savannas and woodlands, also suggests ecological differences.

Confusion between *C. hirsuta* and *C. brachiata* may have arisen in part because of a discrepancy between Thunberg's diagnosis of the latter species and his own specimens at the Uppsala Herbarium. Thunberg actually described two species from South Africa. One (*C. brachiata*) supposedly had simply pinnate leaves, and the other (*C. triloba*) had doubly compound leaves. Thunberg did not designate types, but authentic specimens have been found at Uppsala, one for each species, and apparently annotated by Thunberg. In contradiction to his diagnoses, both specimens have doubly compound leaves, as do the great majority of South African specimens. The specimen annotated as *C. triloba* has larger flowers (sepals 10 mm long vs 5 mm long) than the specimen annotated as *C. brachiata*. Both flower size and the dissection of the leaf are quite variable, and the differences between these two specimens of Thunberg become insignificant when a large number of specimens are examined. Because of its simply pinnate leaves, *C. hirsuta* may have been equated with Thunberg's diagnosis of *C. brachiata* by some authors. For them the species with doubly-compound leaves was *C. triloba* or one of the later names discussed below.

There was some additional confusion concerning the name *C. triloba* Thunb.. It was apparently assumed by some later authors that this name was anteceded by *C. triloba* Roth ex B. Heyne, which however was not published until 1821. The name *C. thunbergii* was published by Steudel in 1841, apparently as a new name for *C. triloba*, so the latter name has been little used. In 1860, Harvey published *C. oweniae* for some South African specimens with doubly-compound leaves, apparently unaware of *C. triloba*. Some authors have attempted to distinguish *C. oweniae* from *C. brachiata* on the basis of anther shape, with the former species possessing short ovoid anthers and the latter elongate anthers. These differences do not hold up when a broad range of specimens is examined. The same applies to the species *C. stewartiae*.

Johnson (1997) and Grey-Wilson (2000) recognized three South African species, *C. brachiata*, *C. triloba*, and *C. oweniae*. Grey-Wilson distinguished *C. oweniae* from *C. triloba* by its smaller flowers (sepals 10–12 mm long vs. 12–18 mm long). He also says that the latter has "deliciously scented" flowers, but does not mention scent for *C. oweniae*. Flowers of *C. brachiata* are simply described as "fragrant," and he appears to have misinterpreted *C. brachiata* as similar in foliage to *C. simensis*. Once again, variation in leaf form and flower size in South African *Clematis* are such that these kinds of lines are hard to draw without extensive field studies. Particular morphological combinations may indeed prove to be consistent within populations occupying specialized habitats or geographical areas. The issue of fragrance also needs to be examined more rigorously and consistently.

Hybridization between *Clematis brachiata* and *Clematis villosa* subsp. *stanleyi*, both of which are common in the Johannesburg area, has been noted in the literature (Letty 1962) and on some herbarium specimens. One specimen that is clearly intermediate in character between these two species is *Mogg 36528*. This underscores the close relationship between the species formerly segregated into *Clematopsis* and other African species, as well as the possibility that many unusual specimens in Africa could be the result of hybridization.

2. Clematis burgensis Engl., Bot. Jahrb. Syst. 45:272. 1910.

A distinct species according to Demel (1987), native to Ethiopia. Three of the specimens cited under *C. simensis* (*Ash 1294*, *J. deWilde 6224*, *Westphal & Westphal-Stevels 3062*) have smooth leaflet margins as indicated for this species, but lack flowers so the other traits could not be verified. I was unable to draw any conclusions about this species from the MO material.

3. Clematis chrysocarpa Welw. ex Oliv., Fl. trop. Afr. 1:5. 1865. *Clematis villosa* subsp. *chrysocarpa* (Welw. ex Oliv.) Kuntze, *Clematopsis chrysocarpa* (Welw. ex Oliv) Hutch. (see Brummitt, 2000).

a. Clematis chrysocarpa subsp. **chrysocarpa**
Brummitt (2000) places the following species in synonymy here: *Clematis chrysocarpoides* DeWilde., *Clematopsis speciosa* Hutch. (*Clematis angolana* M. Johnson, 1997, Släktet Klematis: 145, *nom. nov.*: replaced synonym: *Clematopsis speciosa* Hutch.)

b. Clematis chrysocarpa subsp. **bijuga** Brummitt, Kew Bull. 55:97–108. 2000.
Brummitt (2000) placed the following species in synonymy here: *Clematopsisineariloba* Hutch. & Summerh., *Clematopsis oliveri* forma *lineariloba* (Hutch. & Summerh.) Staner & Leonard. (*Clematis africolineariloba* W.T.Wang, Acta Phytotax. Sin. 39:336. 2001, replaced synonym: *Clematopsis lineariloba* Hutchinson & Summerhayes).

4. Clematis grandiflora DC, Syst. nat. 1:151. 1818. TYPE: not indicated.

Clematis pseudograndiflora Kuntze, Verh. Bot. Vereins Prov. Brandenburg 26:128. 1885. TYPE: ANGOLA: *Welwitsch 1218, 1219*.

Clematis kakoulimensis Schnell, Bull. Soc. Bot. France 96:223. 1949. TYPE: GUINEA: Mt. Kakoulima, 2000 ft, *Schnell 2461* (HOLOTYPE: n.v.)

Clematis chlorantha Lindl., Edward's Bot. Reg. 16, t. 1234. 1829. Belongs here according to Oliver (1868) and Johnson (1997).

A very distinctive species with very large, campanulate flowers. Leaves are 5-pinnate, with leaflets ovate, rarely lobed, and finely toothed, much like those of *C. simensis*. Material referred to as *C. kakoulimensis* and *C. pseudograndiflora* have somewhat smaller flowers, with sepals 18–20 mm long, and about 50 carpels per flower, but otherwise similar to the large-flowered specimens. They appear to represent extremes in the range of variation. A remarkable photograph of this species appears in Johnson (1997), showing large, pendant, yellowish flowers, reminiscent of Asian species in the section *Connatae*.

5. Clematis dolichopoda Brenan, Kew Bull. 1949:71. 1949. *Clematis hirsuta* var. *dolichopoda* (Brenan) Staner & J. Leonard, Bull. Soc. Roy. Bot. Belgique 82:36, 1950 and Flore du Congo Belge 2:187. 1951.

Clematis longipes Engl., Bot. Jahrb. Syst. 45:273. 1910. Illegitimate name, cf. *Clematis longipes* Freyn, 1890, from Madagascar.

Poorly represented in the MO collections, this species appears to be similar to *C. longicauda*, but with smaller flowers. the foliage has the same distinctive indumentum of golden hairs ("rusty ferrugineous"). Sepals are 13–20 mm long, variously described as white, golden-white, or yellowish, the latter perhaps due to the heavy external covering of golden hairs. Leaflets are essentially heart-shaped, with irregular teeth, or in some material from Burundi, the leaflets are narrow-elongate. It is possible that the latter material represents hybrids with *C. welwitschii*. The species occurs mostly in high mountains, up to 3500 m, but as low as 1000 m in some Burundi material. One specimen, *Williams 35*, is placed here questionably. It is a fruiting specimen, but the large number of fruiting heads in the inflorescence suggests that the flowers are much smaller than in the other specimens. The hairs are much sparser on the leaves, though still golden in color.

6. Clematis hirsuta Guill. & Perr. in Guill., A. Rich. & Perr., Fl. Seneg. tent. 1:1. 1831. TYPE: not cited, collected by Perrottet in 1829 at Cape Verde, Senegal near Kounoun and Rufisk.

Clematis inciso-dentata A. Rich., Tent. fl. abyss. 1:2, fig 1. 1847. TYPE: not specified, but collected by A. Petit in Shoa Province, Ethiopia, between 1838 and 1843; = *C. hirsute* fide Demel (1987) and Johnson (1997).

Clematis wightiana auct non Wall.

Clematis grata (non Wall.) sensu Oliv., Fl. trop. Afr. 1:7. 1868.

Clematis glaucescens Fresen., Beitr. Fl. Abyssin., in Mus. Senckenb. 2: 268. 1837. TYPE: Not cited; = *C. hirsuta* fide Demel (1987) and Johnson (1997).

Clematis djalonensis A. Cheval., Bull. Mus. Hist. Nat. (Paris), ser. 2. 4:1010. 1932. TYPE: FRENCH GUINEA: Fouta-Djalon, 1300 m, *Chevalier 34545* (n.v.) (= *C. hirsuta* fide Hutch. & Dalziel).

Clematis chariensis A. Cheval., Bull. Mus. Hist. Nat. (Paris), ser. 2. 4:1012. 1932. TYPE: CENTRAL AFRICAN REPUBLIC: Haut-Chari, between Dekoua and Nana, *Chevalier 6192;* said to be a cousin of *C. hirsuta* by Chevalier, described as a low-growing scrambler adapted to frequent bush fires, sprouting annually from the rootstock.

Clematis petersiana Klotsch in Peters, Naturw. Reise Mossambique 6(1):170. 1861. From the ambiguous description, this species appears to be indistinguishable from ordinary *C. hirsuta*. It is from the upland, interior province of Tete, and so not likely to be equated with *C. viridiflora*.

In the conservative treatment presented here, this is a widespread, variable species found throughout the tropical savannas and open woodlands of central Africa. It's distribution correlates roughly with that of *Acacia sieberana* in mid-elevation plains and plateaus in what is called the Sudano-Zambezian region (Brenan 1978). The correlated distribution of the two species includes disjunct populations of each in central Angola. The two other widespread species with numerous white flowers appear to be geographically and/or altitudinally separated: *C. simensis* at generally higher elevations, and *C. brachiata* further south in the warm-temperate to subtropical grasslands of South Africa. A fourth species that appears to be in this complex, *C. viridiflora* is a lowland species found along the coast of Mozambique and possibly Tanzania. There are morphological differences as well, but definitely gray areas between these species, both geographically and morphologically. *Clematis hirsuta* is distinguished from *C. simensis* by its lobed, irregularly toothed leaflets, as opposed to the unlobed, finely dentate leaflets of the latter, and from *C. brachiata* by its simply pinnate leaves, as opposed to the doubly compound leaves of *C. brachiata. C. viridiflora* is hard to distinguish from herbarium material, but its flowers are somewhat larger, with the sepals said to be thinner and more yellowish.

Clematis species with numerous, small, white flowers are found throughout the world, including the *C. virginiana/catesbyana/ ligustifolia* group in North America, *C. dioica* and its relatives in tropical America, *C. grata/ wightiana* and similar species in Asia, *C. vitalba* in Europe, and other species in New Guinea, Australia and New Zealand. All of these species are abundant, variable and widespread, occupying open, disturbed habitats, and can generally be described as "weedy." Species with larger, fewer, and often more colorful and/or fragrant flowers, on the other hand, tend to be less common and more restricted in both their distribution and habitat preferences. This pattern holds for Africa as well.

The species placed in synonymy here were based on one or a few variant specimens and appear to fall within the range of variation in the widespread species, although they do warrant further study. The vestiture of the leaves in *C. hirsuta* is variable. Some, as the name implies, are rather densely hirsute, while others are nearly glabrous. The greatest concentration of heavily hirsute specimens is in the Ethiopia/Uganda region. Some populations in Ethiopia have significantly larger flowers with rather attenuate sepals, as opposed to the more obtuse sepals in other specimens, suggesting some degree of subspecific differentiation. This appears to have been the basis for recognizing both *C. glaucescens* and *C. inciso-dentata*, neither of which were recognized by Demel Tekatay (1987) in his thorough study of *Clematis* in Ethiopia. The present study also suggests that there are numerous intermediate specimens, making such a distinction difficult. Grey-Wilson (2000) recognized *C. djalonensis* from southwest Mali and northern Guinea, on the basis of its smaller flowers that are more rounded in bud and said to be more fragrant, and with shorter pedicels. This again appears to fall within the range of variation for *C. hirsuta*, but needs to be investigated further. The photograph of *C. hirsuta* in Grey-Wilson appears to be misidentified. The flowers appear to be much larger than those of the many specimens examined in this study, and the leaves appear to be more deeply divided. The plant looks more like *C. welwitschii*.

One difficulty in verifying the proper application of the name *C. hirsuta* is the lack of authentic type material. The type should be at Paris, but it cannot be found, and the Missouri collection contains no specimens from Senegal at all. The protologue for that species indicates that the foliage is ternate to biternate, and densely villous. No dimensions were given for the flowers, which were said only to be in clusters of 1–3. Biternate leaves are rare in the species as currently understood, suggesting the possibility that the population at Cape Verde (near sea-level) is distinct at some level from the more widespread form. In his flora of Senegal, Berhaut (1967) describes the leaves as having two pairs of leaflets, and the white flowers produced in large panicles, which is consistent with *C. hirsuta* elsewhere in its range. It is not known whether Berhaut had material from the Cape Verde area, however. If the species still exists there, it needs to be studied in order to resolve any further doubts.

7. Clematis longicauda Steud. ex A. Rich., Tent. fl. abyss. 1:2. 1847. TYPE: ETHIOPIA: *Schimper 1284* (n.v.).

This taxon has large flowers similar to those of *C. grandiflora*. The 3-foliolate leaves differ conspicuously in the broader, lobed leaflets and the fine reddish-gold pubescence. It is found at higher elevations (1350–2100 m), and only in Ethiopia. Johnson (1997) and Grey-Wilson (2000) both misinterpret this very distinctive species as a synonym of *C. hirsuta*.

8. Clematis simensis Fresen., Beitr. Fl. Abyssin., in Mus. Senckenb. 2:267. 1837. TYPE: *Ruppell* (n.v.).

Clematis altissima Hutch. belongs here according to Hutchinson and Dalziel (1954) and Johnson (1997).

This is a distinctive species occurring throughout central and eastern Africa, generally at higher elevations than *C. hirsuta*, with which it overlaps geographically. Leaves are typically 5-foliolate, with the leaflets finely toothed and unlobed. Flowers tend to be numerous in elongate inflorescences, well exserted above the foliage. One specimen from Kenya, *Taylor 1455*, has unusually large flowers, representing perhaps a taxonomic variant or hybrid with a large-flowered species.

9. Clematis sigensis Engl., Bot. Jahrb. Syst. 45:271. 1910.

A distinct species according to Beentje (1989), found in Kenya and Tanzania; no matching specimens at MO.

10. Clematis uhehensis Engl., Bot. Jahrb. Syst. 28:387. 1900. *Clematopsis scabiosifolia* subps. *uhenensis* (Engl.) Brummitt, *Clematopsis villosa* subsp. *uhehensis* (Engl.) J. Raynal & Brummitt (see Brummitt, 2000).

Brummitt (2000) includes the following names in synonymy here: *?Clematis villosa* var. *teuszii* Kuntze, *Clematopsis teuszii* (Kuntze) Hutch.; *Clematis homblei* De Wild., *Clematopsis homblei* (DeWild) Staner & J. Leonard, *Clematopsis katangensis* Hutch., *Clematis katangensis* (Hutch.) M. Johnson, *Clematopsis simplicifolia* Hutch & Summerh., *Clematopsis grandifolia* Staner & J. Leonard, *Clematis grandifolia* (Staner & J. Leonard) M. Johnson.

11. Clematis villosa DC., Syst. nat. 1:154. 1818.

a. Clematis villosa subsp. **villosa**
Brummitt (2000) placed the following species in synonymy here: *Clematis scabiosifolia* DC., *Clematis villosa* var. *scabiosifolia* (DC.) Hiern., *Clematopsis scabiosifolia* (DC.) Hutch., *Clematis villosa* subsp. *argentea* Kuntze, *Clematis argentea* (Kuntze) Prantl, *Clematopsis argentea* (Kuntze) Hutch., *?Clematis mechowiana* Kuntze, *? Clematis villosa* var. *angolensis*, *Clematis stuhlmannii* Hieron. ex Engl., *Clematopsis stuhlmannii* (Hieron. ex Engl.) Hutch., *Clematis villosa* forma *obtusiloba* Hiern, *Clematis villosa* forma *stenophylla* Hiern, *Clematis sapinii* De Wild, *Clematopsis sapinii* (De Wild.) Staner & J. Leonard.

b. Clematis villosa subsp. **stanleyi** (Hook.) Kuntze, Verh. Bot. Vereins Prov. Brandenburg 26:172. 1885. *Clematis stanleyi* Hook., *Clematopsis scabiosifolia* subsp. *stanleyi* (Hook.) Brummitt, *Clematopsis stanleyi* (Hook.) Hutch. (see Brummitt, 2000).

Brummitt (2000) places the following species in synonymy here: *Clematis villosa* var. *tomentosa* (Kuntze) T. Durand & Schinz.

This is a very distinctive subspecies, with finely dissected leaves.

c. Clematis villosa subsp. **kirkii** (Oliv.) Brummitt, Kew Bull. 55:97–108. 2000. *Clematis kirkii* Oliv., *Clematis villosa* var. *kirkii* (Oliv.) Kuntze, *Clematopsis kirkii* (Oliv.) Hutch., *Clematopsis scabiosifolia* subsp. *kirkii* (Oliv.) Brummitt (see Brummitt 2000).

Brummitt (2000) places the following species in synonymy here: *Clematis villosa* var. *pubescens* Kuntze; *Clematis stanleyi* var. *pubescens* (Kuntze) T. Durand & Schinz; *Clematis goetzei* Engl.; *Clematis busseana* Engl.; *Clematis lugnignu* De Wild.

d. Clematis villosa subsp. **oliveri** (Hutch.) Brummitt, Kew Bull. 55:97–108. 2000.

Clematopsis scabiosifolia subsp. *oliveri* (Hutch.) Brummitt

Brummitt (2000) included the following species in synonymy here: *Clematopsis nigerica* Hutch.

12. Clematis viridiflora Bertol., Misc. bot. 19:7, pl. 3. 1830.

The number of specimens available for this species at MO are few, but it appears to be a distinct species ecologically as well as morphologically. The name suggests that the flowers are greenish. This is confirmed on one specimen (*Lemos & Balsinhas 37*) who describe the flower color as "amarelo-esverdeades." Exell and Milne-Redhead (1960), describe the sepals as "thin and membranous" as opposed to the thicker sepals of *C. brachiata*, which they equate with *C. hirsuta*. Ecologically, it appears to be a coastal species, apparently growing on dunes—a most unusual habitat for African *Clematis*, although in North America there are populations of *C. catesbyana* in a similar habitat (Essig 1990). A photograph of a cultivated plant attributed to this species in Grey-Wilson (2000) shows a plant with yellowish flowers. If accurately identified, it confirms a distinctly different species, and also strengthens the argument of a relationship with section *Meclatis*. One specimen from Zanzibar Island is tentatively placed here, though it has smaller flowers, reported to be white, and leaflets less lobed than the material from Mozambique. It may be represent *C. zanzibarensis* Bojer ex Loud., who found it similar to *C. vitalba* and *C. grata*, the latter a name widely misapplied to *C. hirsuta*. It has to be remembered also that Zanzibar has been a center of trade for centuries and that exotic species may have been brought in.

13. Clematis welwitschii Hiern ex Kuntze, Verh. Bot. Vereins Prov. Brandenburg 26:171. 1885. TYPE: *Welwitsch 1217* (photo seen, MO- Angola); see also Exell & Mendonca (1937).

Clematis antunesii Engl., Bot. Jahrb. Syst. 45:274. 1910. TYPE: ANGOLA. *Antunes A56* (BD, n.v.), belongs here according to Exell and Mendonca (1937).

Clematis commutata Kuntze, Verh. Bot. Vereins Prov. Brandenburg 26:128. 1885. TYPE: ANGOLA: *Welwitsch 1215a* (MO-photo seen).

Clematis prostrata Hutch., Botanist southern Africa. 484. 1946. TYPE: *Hutchinson 3504* (n.v.); appears to belong here from the description, placed here by Exell &Milne-Redhead, 1960.

Clematis thalictrifolia Engl., Bot. Jahrb. Syst. 45:270. 1910. Zaire, Zambia. Tanzania; close to *C. welwitschii* fide Exell & Milne-Redhead (1960), distinguished by larger, solitary flowers.

This taxon includes specimens with medium-large flowers (sepals 1.5–2 cm long) with spreading sepals. Flowers are reported to be white to cream-colored, but sometimes with a pink tinge on the outside. Foliage is extremely variable in this species. Leaves are pinnately to doubly pinnately compound, with leaflets coarsely toothed, deeply lobed, elongate, and sometimes very finely dissected. The types of both *C. welwitschii* and *C. commutata* were collected in Angola, and both names have been applied to specimens with moderately large flowers in a broad area from Angola, Zaire and Cameroon to Tanzania. Differences between them, primarily leaf shape and number of flowers, blur considerably when a large number of specimens are examined, and they appear at this point to be just forms of one variable species. Johnson (1997) and Grey-Wilson (2000) both recognize *C. commutata* and *C. thalictrifolia* as separate species, but the distinctions are not clear or convincing, and the ranges overlap. The Missouri collections did not contain any specimens with flowers as large as those reported for *C. thalictrifolia.* They are said to be up to 50 mm across, which put them in the range of *C. grandiflora* or one of the species of section *Pseudanemone*, such as *C. villosa.* This potential species is certainly worth investigating. A number of the specimens cited below have broad, cordate leaves and/or somewhat smaller flowers, strongly suggesting hybridization with a species such as *C. hirsuta.* These include *Exell & Mendonca 1076* from Angola, *Lacroix 3020*, *Tawakali & Kaunda 190*, and *Pawek's 6255, 12644*, and *13658* from Malawi.

ERRONEOUS AND UNRESOLVED NAMES IN AFRICAN *CLEMATIS*

The following names are either erroneous, invalid or require further research to determine their status. (note: IPNI = International Plant Name Index at www.ipni.org)

Clematis capensis Poir. Encyc. Suppl. 2, 298. (= *Anemone capensis* according to IPNI).

Clematopsis costata Weim., Bot. Not. 1936:28. Zimbabwe/Zambia.

Clematis friesiorum Ulbr., Notizbl. Bot. Gart. Berlin-Dahlem, 10:914. 1930. Kenya. (= *C. hirsuta* fide Johnson 1997)

Clematis intermedia Chiov., Ann. Bot. (Roma) 9:51. 1911. hybr, Ethiopia; said to be a natural hybrid between *C. simensis* and "*C. thunbergii*" (*C. hirsuta*?).

Clematis iringaensis Engl., Bot. Jahrb. Syst. 28:388. 1900. Zambia and Tanzania; resembles *C. welwitschi*, but flower buds covered with "yellow" indumentum, possibly as in *C. dolichopoda.*

Clematis kassneri Engl., Bot. Jahrb. Syst. 45:274. 1910; Zaire. (= *C. welwitschii* fide Grey-Wilson (2000).

Clematis keilii Engl., Bot. Jahrb. Syst. 45:273. 1910; Burundi. (= *C. welwitschii* fide Grey-Wilson (2000; but said by Engler to be "ferrugineo-pilosus" and similar to *C. longipes*, i.e. *C. dolichopoda*).

Clematis kerrii Steud., Nom. ed. 2. 1:379. 1840. South Africa.

Clematis kissenyensis Engl. in Wiss. Ergebn. Deutsch. Zentr. Afr.-Exped. 1907–8, 2:207. 1911. Tropical East Africa. (=*C. simensis* fide Johnson 1997)

Clematis massoniana DC., Syst. nat. 1:135. 1818. (= *C. brachiata* fide IPNI). Ethiopia? South Africa.

Clematopsis pulchra Weim., Bot. Not. 1936:27.

Clematis schinziana Engl. & Gilg ex Engl., Pflanzenw. Ost.-Afrikas 3:1. 1895. (Engl. & Drude, Veg. Erde 9:172. 1915, in obs.). Namibia.

Clematis spathulifolia (Kuntze) Prantl, Bot. Jahrb. Syst. 9:258. 1888, in obs. Zaire (cannot be determined fide Brummitt 2000).

Clematis stolzii Engl., Bot. Jahrb. Sys. 45:272 (1910), Malawi. (= *C. simensis* fide Johnson 1997, but has few, rather large flowers; could be a form of *C. welwitschii* or a hybrid).

Clematis tenuifolia Poir., Encyc. Suppl. 2, p. 298. 1786. (=*Anemone tenuifolia* fide IPNI).

Clematis teusczii (Kuntze) Engl., Pflanzenw. Ost.-Afrikas 3:1. 1895. (Engl. & Drude, Veg. Erde 9:170. 1915, in obs. (= *C. villosa* var. *teuszii* fide IPNI). Angola.

Clematis tibestica Quezel, Bull Soc. Hist. Nat. Afrique N. 48:86. 1957. Tibesti Mountains of Sudan (treated as a separate species by Johnson (1997) and Grey-Wilson (2000), who also indicated its close affinity with *C. simensis*).

Clematis zanzebarica Sweet, Hort. brit. ed. 2, 1. 1832. = C. *zanzibarensis* Loudon, fide IPNI (=*C. viridiflora?*).

Clematis zanzibarensis Bojer ex Loudon, Hort. brit.. ed 2, 228. 1832. (=*C. viridiflora?, similar to C. vitalba* or *C. grata* fide Exell & Mendonca 1937).

APPENDIX

Abbreviated listing of specimens examined (all from MO)

Clematis brachiata Thunb.—**Botswana:** *Skarpe 284.* **Namibia:** *Leistner et al. 194; Muller & Tilson 917; Seydal 2150, 4123, 4291.* **South Africa:** *Allardice 1572; Arnold 205; Balsinhas 2857, 3416; Bayliss 1188, 1331, 4674; Booi 32; Borle 508, 1110; Brink 596, 628; Buitendag 812; Burtt-Davy 15148; Codd 9648, Dahlstrand 2387, 2542, 3515, 3588; Davidse 6776; Drege s.n.* (6 specimens with meager label data); *Ecklon s.n.* (3 specimens with meager label data); *Edwards 175; Edwards & Vahrmeyer 4281, Germishuizen 225, 3168, 3924; Gibbs et al 234; Goldblatt 1688; Halliwell 5126; Hilliard & Burt 9836; Joffe 232; Kemp 864; Krause 1234; Leendertz 50; Liebenberg 7564, 8820; Madley-Wood 4733, s.n. (1900); McLean 331, 534, 829; Mogg 19347, 21053, 25264, 25832; Morley 377. Pillans 10910; Phillipson 551; Raymond s.n. (1972); Reardon 17; Retief & Germishuizen 286, Rodin 3685, 3874, Scheepers 1398, 1485, Sidey 683, 2432, Stinton 83; Strey 2542, 9745, 86411181, 11263; Vahrmeyer 2425; van Hoepen 1648; Welman 729, 801; Wild 5781; Zambatis 1182.* **Swaziland:** *Kemp.* **Zimbabwe:** *Davies 388, Ngoni 372; Norrgrann 103a.*

Clematis chrysocarpa subsp. **chrysocarpa** Welw. ex Oliv—**Angola:** *Exell & Mendonca 794, 1360, 2547; Homble 828bis* (photo, BR); *Welwitsch 1222* (photo, BM). **Zaire:** *Symoens 6060*

Clematis chrysocarpa subsp. **bijuga** Brummitt—**Malawi:** *Brummitt et al. 15601; Chapman & Chapman 7510; Lacroix 4257; Pawek 6256, 8044, 8415, 8894, 10797; Phillips 799, 1310; Reekmans 5527.* **Mozambique:** *Jansen & Boane 7882; Pereira et al. 1827.* **Tanzania:** *Bidgood & Congdon 147; Kayombo & Kayombo 166, Gereau & Kayombo 4363, Richards 15564. Stolz 2385* (type of *C. lineariloba* Hutch. & Summerhayes)

Clematis dolichopoda Brenan—**Tanzania:** *Williams 35, Verdcourt 275; Schlieben 3991.* **Burundi:** *Reekmans 2298, 2365, 8476.*

Clematis grandiflora DC—**Angola:** *Gossweiler 10311, Welwitsch 1218* (photo, BM, type of *C. pseudograndiflora*), *1219.* **Cameroon:** *Bates 1257, Guile 10, Latilo & Daramola FHI 28900, de Wilde & de Wilde-Duyfjes 1157.* **Côte d'Ivoire:** *Hepper & Maley s.n.* (1984). **Ghana:** *Vigne 2681.* **Guinea:** *Adam 3857, 7562.* **Liberia:** *Konnel 621.* **Nigeria:** *Dalziel s.n.* (1912). **Sierra Leone:** *Adam 22116, 22315, 22409, 22974.* **Zaire:** *Liben 3192.*

Clematis hirsuta Guill. & Perr—**Angola:** *Giess et al. 6612; Gossweiler 10285, 11379.* **Botswana:** *Smith 616, 3520.* **Burundi:** *Lewalle 4674; Reekmans 595, 3444, 5132, 5133, 5138, 6271, 8029, 8983, 9145, 10258, 10420.* **Cameroon:** *Thomas 3105; Baldwin 13852; de Wilde & de Wilde-Duyfjes 4332, 4117; Latilo & Dasabika 28773; Leeuwenberg 7561, 10497.* **Central African Republic:** *Fay 5562, 6084.* **Côte d'Ivoire:** *Gautier-Beguin 460.* **Ethiopia:** *Ash 652, 1279, 1343; de Wilde & de Wilde-Duyfjes 8693, 9277; J. de Wilde 5773, 5866, 6225, 7350, Mengeshu s.n.* (1958); *Nievergelt & Nievergelt 1227;* Pappi 4642, 507; *Pichi-Sermolli 2372; Schimper 212, 1481; Westphal & Westphal-Stevels 2476, 2876, 2951.* **Fernando Po:** Guinea 1876. **Guinea:** *Adam 2630, 7174, 7190.* **Kenya:** *Agnew et al. 10283; Mwangangi 77; Faden et al. 74/655, Harmsen & Agnew 6540; Paolo 541. Perdue & Kibuwa 8155; Williams 315.* **Malawi:** *Banda & Thera 2612; Brass 17112, 17119; Chapman & Chapman 7496, Kwatha & Balaka 139; LaCroix 4562; Pawek 5547, 5548, 7162, 11354; Phillips 1438, 2678, 2823; Salubeni 1536, 2799, 3156; Salubeni & Tawakali 4960, 5000;*

Stolz 206; LaCroix 4562; Willan 65. **Mozambique:** *de Konig 7436; Jansen et al. 301.* **Nigeria:** *Olorunfemi et al. OBB94, OBB501; Guile 13.* **Rwanda:** *Bouxin & Radoux 2216.* **Sierra Leone:** *Adam 22214, 22768, 22223, 23259, 22944; Morton SL2804.* **Somalia:** *Pichi-Sermolli 138.* **South Africa:** *Cooper 191; Galpin 14413, 14418; Hemm 596; Stalmans 441.* **Swaziland:** *Kemp 734, 847.* **Tanzania:** *Flock 423; Frame 149; Gereau & Mziray 1678; Gereau et al. 4600; Grant s.n.* (1928); *Greenway & Kanuri 15164; Jefford et al. 243; Kayombo 555; Lovett 2182; Lovett & Congdon 1852; Lovett & Kayambo 3458; Mathias et al. The Southern Appalachian Botanical Society, Dr. Patricia Cox, TVA Heritage Program, PO Box 1589, Norris, TN 37828, U.S.A. (Orders: same). Price not given, 142 pp., 6 3/4" × 10".

Abstract: "This paper lists published sources pertaining to the lives and work of seventy individuals who contributed to early botanical knowledge of the Southeastern United States. General sources, primarily biographical compilations and scientific bibliographies, are listed at the beginning of the paper, followed by entries for individual botanists. For each botanist, the listed information includes name (with any variants), place and year of birth and death, location of manuscripts and plant specimens, citations for published portraits and handwriting samples, lists of any plant or fungal genera named for the botanist, a brief summary statement about the person's significance to Southeastern botany, and entries for published sources pertaining to the botanist. Works both by and about each botanist are listed with annotations. All entries are cross-referenced parenthetically throughout the text."

ABSTRACT

As part of a search for DNA regions suitable for phylogenetic analysis in the genus *Clematis* (Ranunculaceae), the nuclear-encoded Actin I intron was employed in a preliminary sampling of a small number of species selected to represent the major subdivisions of the genus. This DNA region was found to be more informative and to provide a more robust phylogenetic tree than chloroplast DNA regions. Trees generated were consistent with phylogenetic hypotheses based on morphology and with published molecular analyses. Moreover, three species of the section Crispae (subgenus Viorna) native to Florida, considered closely related on morphological grounds, formed a well-supported clade, and were distinguishable from one another. This suggests that this DNA region might be a useful tool for distinguishing groups of closely-related species, individual species, and possibly hybrids.

RESUMEN

Como parte de una búsqueda de regiones de DNA apropiadas para análisis filogenéticos en el género *Clematis* (Ranunculaceae), se empleó el intrón Actin I nuclear en un muestreo preliminar de un pequeño número de especies seleccionadas para representar las grandes subdivisiones del género. Esta región de DNA se encontró que era más informativa y daba un árbol filogenético más consistente que las regiones de DNA plastidial. Los árboles generados eran consistentes con la hipótesis filogenética basada en la morfología y con los análisis moleculares publicados. Además, tres especies de la sección Crispae (subgénero Viorna) nativas de Florida, consideradas fuertemente emparentadas en aspectos morfológicos, formaron un clado muy coherente, y eran distinguibles una de otra. Esto sugiere que esta región del DNA puede ser un instrumento útil para diferenciar grupos de especies muy emparentadas, especies individuales, y posiblemente híbridos.

INTRODUCTION

The infrageneric classification of *Clematis* (Ranunculaceae), a genus of more than 300 species distributed worldwide, has been uncertain pending definitive phylogenetic studies. Traditional classifications have relied primarily on floral characters for the major divisions of the genus (as in Tamura 1967). However, characters of seedling and juvenile morphology have been cited in recent decades as supporting a fundamental division in the infrageneric classification of the genus (Tamura 1987; Essig 1991; Miikeda et al. 1999). A specialized syndrome of seedling and vegetative characters, featuring a suppressed hypocotyl

SIDA 21(2): 879–886. 2004

and opposite seedling leaves ("Type II," Essig 1991, "opposite" in Miikeda et al. 1999; see also Appendix 1) appears to have arisen from the more general Ranunculaceous type featuring an elongate hypocotyl and alternate seedling leaves ("Type I," or "alternate"), but it has been uncertain whether this morphological complex has arisen just once or more than once, as it is found in species formerly placed in different subgenera.

We have been seeking appropriate molecular tools with which to resolve these and other phylogenetic questions within *Clematis*. The use of DNA sequencing techniques has thus far been of limited success. Miikeda et al. (1999) utilized several chloroplast genes, including matK (maturase-encoding gene), trnK (UUU) intron, trnL (UAA) intron, the intergenic spacer between trnL and trnF (GAA), and the intergenic spacer between rbcL and atpB. Employing approximately 4,400 bp. of sequence for the eight taxa included in the study, the team produced a tree that was consistent with Essig's proposal, but was weakly resolved. Our own efforts with chloroplast DNA also produced weak results.

A search for alternative tools led us to consider some nuclear DNA regions, which are expected to be more informative than chloroplast non-coding regions in determining species level phylogenies because the nuclear genome has a substitution rate 5 to 10 times faster than the chloroplast genome (Li 1997). In particular, we have focused on a non-coding intron of the Actin I gene. Actin is one of the components of the cellular cytoskeleton, and is produced through the activity of a large multigene family (Moniz de Sa & Drouin 1996). The location of the Actin I intron is highly conserved across all angiosperm families, making the development of primers suitable for the PCR amplification of the intron possible. A preliminary test of this DNA region as a phylogenetic tool in *Clematis* was conducted using a small sampling of species representing the major subdivisions of the genus.

MATERIALS AND METHODS

Materials were obtained from the Chicago Botanical Garden and the University of South Florida Botanical Garden (Table 1). Samples were selected to represent the major subdivisions of the genus *Clematis*. They include several species with Type I vegetative morphology, and several with Type II vegetative morphology, while also representing the traditional sections *Clematis* and *Viorna* (as in Tamura 1967), and the rearranged sections (elevated to subgenera) of Tamura (1987) (Table1). The traditional sections each contained subsections with Type I and Type II morphologies, and in his revision, Tamura (1987) reorganized his classification to reflect those different morphologies. Note that two of the species included in this study were realigned in that taxonomic shift. *Clematis terniflora* in subsection *Rectae* was formerly included in section Clematis, while *C. stans*, in subsection *Tubiflorae* was formerly included in section *Viorna*. This analysis is thus a preliminary test of that taxonomic revision.

Table 1. Taxa included in the analysis (with seedling morphology type indicated as I or II).

Species	**Classification (Tamura 1987)**	**Voucher**
Clematis reticulata Walt.	(Viorna: Crispae II)	*Arias 71* (USF)
Clematis crispa L.	(Viorna: Crispae II)	*Essig 011001-6* (USF)
Clematis baldwinii Torr. & A. Gray	(Viorna: Crispae II)	*Essig 011001-7* (USF)
Clematis terniflora DC	(Flammula: Rectae II)	*Essig 860904-1* (USF)
Clematis virginiana L.	(Clematis: Dioicae I)	Chicago B. G. acc. # 356-81
Clematis stans Sieb. & Zucc.	(Campanella: Tubulosae I)	*Essig 011001-3* (USF)
Anemone pulsatilla var. vulgaris L.	(outgroup I)	*Essig 020305-2* (USF)

The samples for this study also includes three species native to Florida that on morphological grounds appear to be closely related. Their inclusion provides a test of the resolving power of the Actin I DNA sequence.

A species of *Anemone* (*A. pulsatilla* var. *vulgaris* L) was chosen as the outgroup. *Anemone* has traditionally been identified as closely related to *Clematis*, and *A. pulsatilla* shares with *Clematis* the very distinctive elongate styles of the mature achenes. A number of recent phylogenetic studies (Johansson & Jensen 1993; Hoot 1995, and Kosuge et al. 1995) have identified a clade that includes *Clematis* along with *Anemone, Pulsatilla* (sometimes treated as a segregate of *Anemone*), *Knowltonia, Hepatica*, and sometimes *Ranunculus* and/or *Trautvettaria*. A more comprehensive study will include more of these genera as outgroups. An unnamed species of *Anemone* was also used as the outgroup in the study by Miikeda et al. (1999).

Angiosperm Actin (ac1) gene sequences from a broad range of taxa were obtained from Genbank (*Arabidopsis, Zea, Oryza*, and *Glycine* (accession #'s M20016, J01238, X15865, and J01298, respectively). These sequences were aligned using Clustal X (Thompson et al. 1994; Higgins et al. 1996). The primer sequences were selected from the alignment by anchoring the forward primer in a highly conserved (relatively guanine and cytosine rich [48%]) coding region just downstream of the intron. The reverse primer was anchored in a highly conserved coding region just upstream of the intron (Table 2). This primer set corresponds to a region of approximately 300 nucleotides in the taxa listed above.

Some specimens were deep frozen at -80° C before use, others were prepared immediately for extraction. Total genomic DNA was extracted from leaf samples following the modified CTAB protocol developed by Doyle & Doyle (1987).

Polymerase chain reaction (PCR) was carried out on all extracted DNA samples using primers for the gene regions shown in Table 2. PCR reactions (amplification) were carried out in 100 μL volumes, using a taq polymerase kit from Enzypol (Boulder CO), following their instructions. Thermal cycling parameters were the same for all species: 1 min. initial denature at 95°C, followed by 35

Table 2. PCR primers for Actin genes.

Actin I forward:	CCC	GAA	TTC	CTT	GTT	TGC	GAC	AAT	GGA	AC
Actin I reverse:	CCC	GAA	TTC	ACA	ATT	CCA	TGC	TCA	AT	

cycles of 15 sec. at 95°C, annealing at 48 °C for 30 sec., a 90 sec. extension at 72°C, followed by a 10 min. hold at 72°C, and then a final hold at 4°C.

The ˜300 bp PCR product of the Actin I intron was gel purified and cloned into a pBluescript vector and transformed into DH5μ *Escherichia coli* cells (Gibco, Carlsbad CA). White colonies were picked from bacterial plates, grown in small cultures with ampicillin and sequencing template prepared using the alkaline lysis method (Ausubel 2000). After purification, cycle sequencing reactions were carried out in 200μL thin-walled capped tubes using a Perkin-Elmer (Foster City, CA) DYEnamic ET terminator cycle sequencing kit with an ABI Model 310 genetic analyzer.

Phylogenetic trees were constructed from DNA sequence alignments generated by Clustal X (Thompson et al. 1994; Higgins et al. 1996) and modified by hand using Genedoc (Nicholas et al. 1997). Neighbor-joining trees from molecular data were made using MEGA 2.1 software (Kumar et al. date) using Kimura 2-parameter distances with 1000 bootstrap replicates. For comparison, a brief morphological analysis incorporating vegetative and floral characters used in recent classifications was carried out (Fig. 1B, and Appendices 1 & 2). The morphological tree was recovered using PAUP 4.0b10 (Swofford 2001) using an heuristic search with default parameters and 200 bootstrap replicates.

RESULTS AND DISCUSSION

The Actin intron sequences yielded an alignment of 316 bp with 27 variable sites, 17 parsimony informative sites and 28 sites with gaps. The alignment was relatively unambiguous and resulted in a neighbor-joining tree (Fig. 1A) with two well-supported clades that coincide with Type I and Type II seedling morphology as described by Essig (1991). A maximum parsimony tree based on morphology (Fig. 1B) recovered the type II clade, and illustrates the plesiomorphic distribution of the Type I character syndrome. The molecular analysis produced a strongly supported (bootstrap value 100%) derived clade containing *Clematis crispa*, *C. reticulata* and *C. baldwinii*. These are morphologically similar species native to the southeastern U.S. belonging to the traditional group *Crispae* (variously designated as a section or subsection) in subgenus *Viorna*, and exhibiting type II morphology. There is a strong sister group relationship (97%) between this group and *C. terniflora*, a Eurasian species also with Type II morphology, but with panicles of small whitish flowers—a reproductive morphology syndrome it shares with Type I members of the traditional subgenus *Clematis*. *Clematis virginiana* and *C. stans* form a separate well-sup-

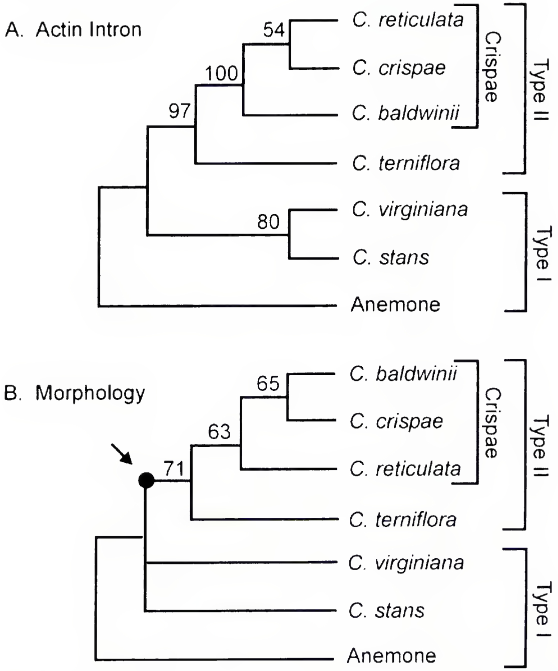

Fig. 1. **A.** Neighbor Joining tree from the Actin intron alignment. A maximum parsimony analysis (not shown) also found the Type II and *Crispae* nodes but with 90 and 99 percent bootstrap values respectively. **B.** Maximum parsimony tree from morphological data (see Appendices 1 and 2). Type I and Type II are syndromes of morphological characters, primarily of seedlings, as described in Essig (1991). The arrow on B indicates the origin of the Type II syndrome. *Crispae* is the sectional name for North American species of subgenus *Viorna* (Tamura 1987).

ported clade (80%) and both have Type I seedling morphology, despite having different floral morphologies.

The results of this preliminary analysis are consistent with those obtained by Miikeda et al. (1999). The species used in the two studies were different, but representative of the same infrageneric taxa. The results are also supportive of Tamura's (1987) revised classification, and Essig's (1991) proposal that taxa with type II seedling morphology represent a monophyletic clade and might be placed together in a major infrageneric division of the genus.

The results also confirm the close relationship of the 3 species of the subsection *Crispae* occurring in the southeastern U.S.A., and appear to resolve those species from one another. The relationship of the three species was slightly different in the DNA analysis from that in the morphological analysis, or from what one would expect through conventional taxonomic analysis. More extensive sampling within species is needed, along with analysis of additional DNA regions, to fully evaluate the resolving power of the Actin I intron region at this level.

Another discrepancy between the two analyses is the sister group relationship between *C. virginiana* and *C. stans* found in the molecular tree but not in the morphological tree. Too few taxa were included in this study to draw any conclusions about the deeper branches in the genus, however. A great many more taxa with both Type 1 and Type 2 morphologies exist. A more complete analysis will include a great many more of the species of this large genus, and in particular, as many of the recognized infrageneric taxa (sections, subsections) as possible, along with a comprehensive morphological analysis, in order to fully understand the phylogeny of this genus and develop a definitive infrageneric classification.

In conclusion, the results of this preliminary analysis are consistent with taxonomic concepts based on morphology and with other DNA-based analyses, and also appear to discriminate among fairly closely related species. Therefore, it appears that the Actin I gene region will be a very useful tool for the analysis of infrageneric relationships in *Clematis*, and likely in other angiosperm genera.

APPENDIX 1

Characters used in morphological analysis. Note: characters 1–4 are the primary features distinguishing the Type I (0) from the Type II (1) syndrome; characters 6–8 are the floral characters traditionally cited in distinguishing subgenus *Clematis* from subgenus *Viorna*.

1. Seedlings with hypocotyl elongate (0) vs hypocotyl suppressed (1)
2. Seedling leaves alternate (0) vs leaves opposite (1)

NEW COMBINATIONS IN NORTH AMERICAN CARYOPHYLLACEAE

J.K. Morton

Department of Biology
University of Waterloo
Waterloo, Ontario, CANADA N2L 3G1
jkmorton@sciborg.uwaterloo.ca

ABSTRACT

The following new combinations are proposed. *Cerastium velutinum* Raf. var. *villosissimum* (Pennell) J.K. Morton, *Silene drummondii* Hook. subsp. *striata* (Rydb.) J.K. Morton, *Silene laciniata* Cav. subsp. *californica* (Durand) J.K. Morton, *Silene ostenfeldii* (A.E. Porsild) J.K. Morton and *Stellaria cuspidata* Willd. ex Schlecht. subsp. *prostrata* (Baldw. ex Ell.) J.K. Morton.

RESUMEN

Se proponen las siguientes nuevas combinaciones. *Cerastium velutinum* Raf. var. *villosissimum* (Pennell) J.K. Morton, *Silene drummondii* Hook. subsp. *striata* (Rydb.) J.K. Morton, *Silene laciniata* Cav. subsp. *californica* (Durand) J.K. Morton, *Silene ostenfeldii* (A.E. Porsild) J.K. Morton y *Stellaria cuspidata* Willd. ex Schlecht. subsp. *prostrata* (Baldw. ex Ell.) J.K. Morton.

During the preparation of treatments of *Cerastium*, *Silene* and *Stellaria* for the Flora of North America, the need for the following new combinations became apparent.

NEW COMBINATIONS

Cerastium velutinum Raf. var. **villosissimum** (Pennell) J.K. Morton, comb. nov.
BASIONYM: *Cerastium arvense* L. var. *villosissimum* Pennell, Bartonia 12:11. 1931. TYPE: U.S.A: PENNSYLVANIA. Chester Co.: rocky cliff, serpentine below Lees Mills by Octoraro Creek, 21 Sep 1920, *Pennell 10767* (HOLOTYPE: PH; ISOTYPE: NY).

Cerastium arvense L. in North America consists of at least three species. One of these, *Cerastium velutinum* Raf., includes the plant that Pennell (1931) described as *Cerastium arvense* L. var. *villosissimum*. The new combination is required to accommodate this change.

Silene drummondii Hook. subsp. **striata** (Rydb.) J.K. Morton, comb. et stat. nov.
BASIONYM: *Lychnis striata* Rydb., Bull. Torrey Bot. Club 31:408. 1904. TYPE: COLORADO: Cameron Pass, 1000 ft, 30 Jul 1896, *Baker s.n.* (HOLOTYPE: NY; ISOTYPE: MO).

Silene drummondii contains two taxa, subsp. *drummondii* which is characteristically a prairie taxon, and subsp. *striata* which is associated with the Rocky Mountains from near the Canada border southwards. Though the two subspecies are clearly distinct in their extreme forms they intergrade where they come into contact.

SIDA 21(2): 887–888. 2004

Silene laciniata Cav. subsp. **californica** (Durand) J.K. Morton, comb. et stat. nov. BASIONYM: *Silene californica* Durand, J. Acad. Nat. Sci. Philadelphia, n.s. 3:83. 1855. TYPE: CALIFORNIA: *Pratten s.n.* (HOLOTYPE: P, n.v.).

The Mexican Pinks (*S. laciniata, S. californica and S. greggii* A. Gray) have frequently been regarded as distinct species. In the context of North America this is probably appropriate, for all three have clearly recognizable morphological characters. However, in Mexico, where their distribution is centred, many collections show intergrading characters and are not readily identifiable. For this reason, subspecific status is more appropriate.

Silene ostenfeldii (A.E. Porsild) J.K. Morton, comb. nov. BASIONYM: *Melandrium ostenfeldii* A.E. Porsild, Sargentia 4:37. 1943. TYPE: CANADA: Narakay Island, Dease Arm, Great Bear Lake, Northwest Territories, 1 Aug 1928, *A.E. & R.T. Porsild 4839* (HOLOTYPE: CAN).

Silene taimyrensis (Tolm.) Bocquet is the name that has been used for this species since Bocquet created the combination in 1967. Unfortunately, Bocquet did not have access to the type specimen on which the name is based (*Tolmatchew 762*; holotype, L). Recently Petrovsky & Elven (in the on-line Pan Arctic Flora- www.mun.ca/biology/delta/arcticf) reported that they had examined Tolmatchew's specimen and consider it to be a form of *Silene involucrate* (Cham. & Schlecht.) Bocquet. The combination *Silene ostenfeldii* has apparently not been validly published. Electronic publication is not acceptable under Article 29.1 of the International Code of Botanical Nomenclature (Greuter et al. 2000). Accordingly the combination is validated here.

Stellaria cuspidata Willd. ex Schlecht. subsp. **prostrata** (Baldw. ex Ell.) J.K. Morton, comb. et stat. nov. BASIONYM: *Stellaria prostrata* Baldw. ex Ell., Sketch Bot. S. Carolina 1:518. 1821. TYPE: FLORIDA: on the island of Fort George, East-Florida (Apalachicola), without date, *Baldwin s.n.* (HOLOTYPE: NY).

Stellaria cuspidata and *S. prostrata* frequently intergrade and hence are better treated as subspecies. The former tends to be montane and the latter to be a lowland weed.

ABSTRACT

Phylogenetic analysis of nrDNA (ETS and ITS) sequence data for 50 species of Astereae (Asteraceae) belonging to the *Eurybia-Machaerantherinae* clade show that *Tonestus kingii* and *T. aberrans* belong to this group. The genus *Herrickia* is reinstated and expanded to include *H. kingii* as well as members of *Eurybia* section *Herrickia* sensu Nesom (1994). A new genus, *Triniteurybia*, is established for *T. aberrans*, which is sister to the *Machaerantherinae*.

RESUMEN

El análisis filogenético de secuencia de bases de nrDNA (ETS y ITS) de 50 especies de Astereae (Asteraceae) pertenecientes al clado *Eurybia-Machaerantherinae* muestra que *Tonestus kingii* y *T. aberrans* pertenecen a este grupo. El género *Herrickia* se reinstaura y expande para incluir a *H. kingii* así como a miembros de *Eurybia* sección *Herrickia* sensu Nesom (1994). Se establece un nuevo género, *Triniteurybia*, para *T. aberrans*, que es "sister group" de *Machaerantherinae*..

INTRODUCTION

Several species of tribe Astereae in North America have proven difficult to assign taxonomically to genera or groups. Molecular phylogenetic studies, notably following the seminal paper of Noyes and Rieseberg (1999), have helped to solve the relationships of many of these taxa. Nevertheless, the disposition of some species still remain controversial, notably species recently included in *Tonestus* by Nesom and Morgan (1990), *T. aberrans* (A. Nelson) G.L. Nesom & Morgan (basionym *Macronema aberrans* A. Nelson), and by Nesom (1991), *T. kingii* (D.C. Eaton) G.L. Nesom (basionym *Aster kingii* D.C. Eaton). The basis for inclusion of these species in *Tonestus* were the woody caudices, leaf shape and anatomy, eglandular (or sparsely short-stipitate-glandular) herbage, mostly single-headed capitulescences and foliaceous outer phyllaries (not in *T. aberrans* however). Nesom and Morgan (1990) did not discuss the specific reasons for the inclusion of *Macronema aberrans* in *Tonestus*, but pointed out its similarities to *T. graniticus*. Nesom (1991) reviewed the detailed taxonomic history of *Aster kingii*, which has also been named *Machaeranthera kingii* (D.C. Eaton) Cronquist & Keck, and he pointed out that various authors had seen relationships of this species with genus *Aster* s.l., notably western members of *Eurybia* and *Oreostemma*. The similarities invoked to link this species to *Tonestus* are those cited above. The only discordant feature in the group would be its white rays in a yellow-rayed group. All species placed in *Tonestus* are n= 9, a primitive and frequent number in the tribe.

A recent molecular phylogeny of *Chrysothamnus* and related *Solidagininae* (Roberts & Urbatsch 2004) suggests, however, that *Tonestus* sensu Nesom is polyphyletic. Further investigations by Urbatsch and colleagues (unpublished) suggested that *T. aberrans* and *T. kingii* might better be placed near *Eurybia*. Likewise, a study of the position of the North American asters within tribe Astereae had suggested that *T. kingii* was better placed with *Eurybia* and *Oreostemma*, two North American segregates of *Aster* s.l. (see summarized phylogeny in Semple et al. 2002) that will be called henceforth the eurybioid lineage. Therefore, in preparation for the treatment of *Eurybia* and relatives (Asteraceae, Astereae) for the Flora of North America, we are using ITS and 3'ETS molecular phylogenetic data to investigate the taxonomic position of *T. aberrans* and *T. kingii* within the Astereae. These molecular markers have proved useful in determining the position of taxa in tribe Astereae (e.g., Noyes & Rieseberg 1999; Roberts & Urbatsch 2004). We show that these species belong to the eurybioid grade within the North American clade and are presenting the necessary combinations to reflect this phylogenetic position. Genus *Herrickia* is reinstated and *T. kingii* transferred to it as *H. kingii* (along with congeners *H. glauca* and *H. wasatchensis*), and a new monotypic genus is described to accommodate *T. aberrans*, *Triniteurybia*. These names are subsequently used in the paper.

MATERIAL AND METHODS

Samples were preserved either as frozen leaf material, in silica gel, or taken from herbarium specimens. Data for the Machaerantherinae were taken from Markos and Baldwin (2001). Extraction and molecular methods used here are as described in Roberts and Urbatsch (2004) (Urbatsch laboratory) and in Fougère-Danezan et al. (2003) (ITS, Brouillet laboratory). For ETS (Brouillet laboratory), the primers Ast-8 (Markos & Baldwin 2001) and 18S-2L (Linder et al. 2000) were used, with PCR conditions similar to ITS (above); this resulted in longer ETS sequences than those produced in the Urbatsch laboratory (*T. kingii* and *T. aberrans*).

Sequences were input into already aligned matrices of ITS and ETS for the Astereae and manually adjusted. All new sequences used in this study are deposited in GenBank under the accession numbers provided in Table 1. Sources for already published sequences are provided also.

Preliminary parsimony analyses were done on the full ITS (more than 500 taxa in Astereae) and ETS (106 taxa) matrices, using PAUP* 4.0b10 (Swofford 2002). Resulting trees (not shown) clearly indicate that *T. kingii* and *T. aberrans* are members of the *Eurybia* complex (eurybioids) at the base of the *Machaerantherinae* (see Semple et al. 2002), but the trees were unresolved (polytomy) in the current region of interest. Given that the trees were not in conflict, data were combined for 50 taxa for which both sets were available, in an attempt to better define the position of these species within the *Eurybia* complex. The total number of characters in the combined ETS + ITS matrix is 1149, of which 195 are parsimony informative; few phylogenetically informative indels are found in the reduced taxon matrix (mostly in the ITS portion) and they were not coded as distinct characters. The matrix was subjected to parsimony analysis using PAUP* 4.0b10 (TBR, characters unordered, unweighted, gaps as missing, random addition, Multrees in effect), and to Bayesian analysis using MrBayes3 (Ronquist and Huelsenbeck, 2003). For the latter, the following parameters were applied: 4 chains, 1,000,000 generations, burn in 100,000, every 10,000th tree saved, model GTR+ gamma+gamma inv, nst=6. Analyses were run to completion. Bootstrap and jacknife supports were calculated for the parsimony analysis (5000 replicates, TBR, random addition); for the jacknife, 50% of characters were deleted in each run. Strict and 50% majority rule consensus trees were drawn for the parsimony analysis, and posterior probabilities were input onto the 50% majority rule tree for the Bayesian analysis. Trees were rooted using *Chloracantha spinosa* and *Canadanthus modestus*.

RESULTS

Parsimony analysis of the ETS + ITS matrix yielded 6910 trees of length 687, CI 0.662, RI 0.812 and RC 0.538. In the strict consensus tree (not shown) the eurybioids + *Machaerantherinae* form a clade, within which *Oreostemma*, *Eurybia* and *Eurybia* sect. *Herrickia* form a polytomy sister to a *T. aberrans*-*Machaerantherinae* clade. The parsimony 50% majority rule tree is similar to that shown for the Bayesian analysis (Fig. 1), which resulted in 9002

TABLE 1. List of voucher specimens for the sequences generated for the current study, and sources of previously published data. Current species names (e.g., Morgan & Hartman 2003){ Sida 20:1403} are used and original published names are provided in parentheses when differing (as deposited in GenBank; Markos & Baldwin 2001). For eurybioids, names proposed here are used and formerly used ones are in parentheses.

Xylorhiza tortifolia (Torr. & A.Gray) Greene	Markos & Baldwin (2001)	AF251570	AF251628

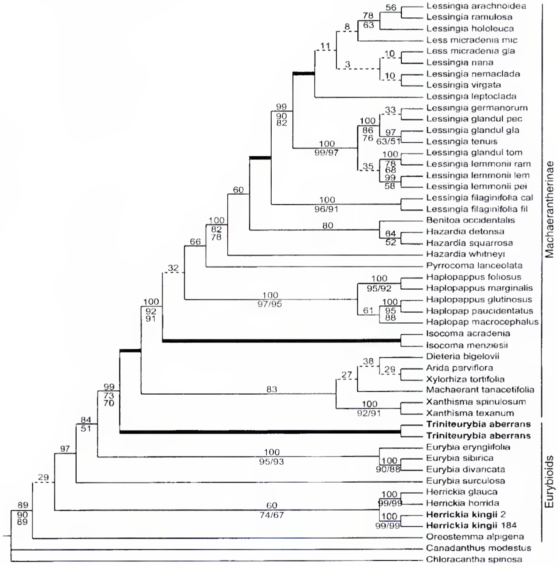

Fig. 1. 50% majority rule consensus tree of the Byaseian analysis of the eurybioids-*Machaerantherinae* (Asteraceae: Astereae); *T. aberrans* and *H. kingii* are in bold; dash lines indicate branches with less than 50% posterior probabilities, thick ones those that have 100% posterior probability, 100% parsimony bootstrap and 100% jacknife support. Posterior probabilities are indicated above the lines, bootstrap and jacknife (second figure) below.

trees. Posterior probabilities are shown on Figure 1, as well as the bootstrap and jacknife support values from the parsimony analysis.

DISCUSSION

Both the preliminary separate ITS and ETS parsimony analyses and the reduced combined analyses (Fig. 1) show that *Herrickia kingii* and *Triniteurybia aberrans* belong to the eurybioid-*Machaerantherinae* lineage of the Astereae. The basal branch of the eurybioid-*Machaerantherinae* receives strong support (posterior probabilities 89%, bootstrap 90%, jacknife 89%), a fact further reinforced by the possession of a non-homoplasic, synapomorphic 1-bp deletion at position 124 (ITS1). Such a relationship had been foreseen for *H. kingii* when described as a species of *Aster* s. l. (e.g., Welsh 1983) or when transferred to *Machaeranthera* section *Xylorhiza* (Cronquist and Keck 1957). Watson (1977), however, later excluded it from *Xylorhiza* when he segregated the section from *Machaeranthera*, pointing out instead similarities to *Aster* s.l. species (*Oreostemma alpigena*, *Eurybia conspicua* and *E. integrifolia*). Hartman (1990) likewise excluded *H. kingii* from *Machaeranthera*. Nesom (1991) mentioned that A. G. Jones (in pers. comm.) thought the species was associated with *Aster* sect. *Oreostemma* (*Oreostemma*), a basal group in the eurybioids. Nesom (1994), however, did not consider this possibility in his review of North American asters, though he did discuss *Tonestus* and the species studied here, noting that this (possibly polyphyletic) genus stood clearly outside *Machaerantherinae*. In transferring *H. kingii* to *Tonestus*, Nesom (1991) stressed its similarities to *T. aberrans*. A relationship to *Aster* s.l. was never envisioned for *T. aberrans*. However, the species was treated in *Macronema*, *Sideranthus* and *Haplopappus*, before its transfer to *Tonestus*, a yellow-rayed member of the *Solidagininae*, by Nesom and Morgan (1990). In all these genera, *T. aberrans* appeared unusual and aptly named.

The combined ETS + ITS analyses (Fig. 1) allow us to determine the position of *T. aberrans* and *H. kingii* within the eurybioid grade. In the parsimony strict consensus tree (not shown), the eurybioids are mostly polytomous, but *T. aberrans* emerges as sister taxon to the *Machaerantherinae*. This relationship is seen clearly in Figure 1 and receives high posterior probabilities (99%), as well as good bootstrap (73%) and jacknife (70%) support in the parsimony analysis (Fig. 1). In no analysis (Brouillet, unpublished data) is *T. aberrans* associated with *Eurybia* species. It occupies an isolated position between *Eurybia* and the *Machaerantherinae* and deserves recognition as a new monotypic genus, described below. Identification of this taxon as sister to the *Machaerantherinae* does not affect relationships previously determined within the subtribe (e.g., Morgan 2003; Markos & Baldwin 2001), and may shed light on the early evolution of this complex of mostly xeric, western species that have undergone a rapid diversification in ecology, morphology and karyology.

The position of *T. kingii* also appears resolved, but in a less striking manner. In all analyses (including a larger ITS study using different sequences for the species than those used here; Brouillet et al., in preparation), the species is sister to *Herrickia* (*Eurybia* sect. *Herrickia* of Nesom 1994; see below) (Fig. 1); it groups here with *H. glauca* and *H. horrida*, two of the three members of the genus. Support for this relationship, however, is not strong (posterior probabilities, 60%; bootstrap 74%, jacknife 67%), and is based on a single synapomorphy (in ETS) that is homoplasic due to parallel changes in the *Machaeranthera* complex. In all analyses done so far (including the large ITS parsimony study), *Herrickia* appears either in a polytomy or basal within *Eurybia* sensu Nesom

(1994). Its distinction from *Eurybia* receives 97% posterior probability, but this branch receives no support in parsimony analyses. Yet, it is defined by two synapomorphies (both from ITS1) without reversal or homoplasy. Another observation reinforces the conclusion that *Herrickia* may be best segregated from *Eurybia*, coming from cpDNA trnL-F sequence data (Brouillet, unpublished): while species of *Eurybia* s. str. have a 4-bp synapomorphic deletion, *Oreostemma*, *Herrickia*, *T. aberrans* and the *Machaerantherinae* all have the standard sequence, which suggests that *Eurybia* s. str. is a distinct clade. Despite this observation, one could advocate separating *E. surculosa* from other *Eurybia* on the basis of its position in Figure 1. The branch leading to this species is long, however. Furthermore, in analyses of ITS data using a larger set of eurybioids, *E. surculosa* groups with other *Euribia* species, though *Eurybia* and other eurybioidds globally are polytomous. The position of *E. surculosa* in the current tree appears the result of low taxon sampling and a long branch in the combined data. At the present time, relationships within and monophyly of *Eurybia* s. str. (including subgenera *Eurybia* and *Heleastrum* of Nesom 1994) cannot be tested appropriately. This is not the case for *Herrickia*, which forms a group in these analyses. Nevertheless, *Herrickia* as a genus appears monophyletic and worthy of reinstatement, with a new circumscription that includes the taxa grouped within section *Herrickia* by Nesom (1994) (i. e., *H. horrida*, *H. glauca* and *H. wasatchensis*), as well as *H. kingii*, as sister to the clade *Eurybia* s. str.-*Triniteurybia*-*Machaerantherinae*.

Triniteurybia Brouillet, Urbatsch & R.P. Roberts, gen. nov. TYPE: *Macronema aberrans* (A. Nelson) Brouillet, Urbatsch & R.P. Roberts

Ab *Eurybia* differt capitulae eradiatae et foliae stipitato-glandulosae. Differs from *Eurybia* by its eradiate capitula and stipitate-glandular leaves.

Herbs perennial, cespitose; caudices woody, ramified, from slender, creeping taproots. Stems erect, simple, slender, 0.5–2.5(–3) dm, stipitate-glandular. Leaves basal and cauline, alternate; basal mostly persistent, petiolate to subpetiolate, bases tapering, distal sessile; blades ascending, simple, obovate or oblong to broadly oblanceolate, distal usually gradually reduced, 1-nerved, margins sparsely serrate, apices obtuse to subacute, faces stipitate-glandular. Capitulescences of solitary heads or 2–4 in dense, ± corymbiform arrays, sessile or subsessile in axils of distalmost leaves. Heads discoid. Involucres cylindro-campanulate, 9–14 mm. Phyllaries in 3–4 series, imbricate, graduated, bases indurate, 1-nerved, green zones +/- basally truncate, occupying distal 1/2–1/3, apices acute, faces glandular-viscid (exposed parts). Receptacles slightly convex, alveolate, margins toothed, chartaceous, epaleate. Disc florets 25–60, bisexual, fertile; corollas yellow and often reddish (particularly in lobes), slenderly cylindric, barely ampliate, tubes shorter than throats, lobes 5, erect, lanceolate, ca. 0.8 mm, minutely and sparsely puberulent; style-branch 2–3 mm, moderately exserted, appendages linear-triangular, very acute, +/- equaling stigmatic portion, short-hairy. Cypselae fusiform, ca. 10-nerved, ca. 3 mm, faces sparsely strigillose, eglandular; pappi of few bristles in 1 series, unequal, soft, barbellate, barely exceeding disc corollas.

Etymology.—*Triniteurybia* is named for Trinity Lake, Idaho, the type locality, and the closely related genus *Eurybia*, to indicate its relationships.

The genus is known only from the Sawtooth Mountains of Idaho and the Bitterroot Mountains of Montana, where it is considered of conservation concern. It inhabits the crevices of cliffs and outcrops of the dry coniferous montane forest zone, sometimes at or above timberline. The chromosome number is yet unknown.

Triniteurybia aberrans (A. Nelson) Brouillet, Urbatsch & R.P. Roberts, comb. nov. BASIONYM: *Macronema aberrans* A. Nelson, Bot. Gaz. (Crawfordsville) 53:226. 1912. *Sideranthus* *aberrans* (A. Nelson) Rydb., Fl. Rocky Mts. 1067. 1917. *Haplopappus aberrans* (A. Nelson) H.M. Hall, Carnegie Inst. Washington Publ. 389:185. 1928. *Tonestus aberrans* (A. Nelson) G.L. NEW COMBINATIONS IN *EUTROCHIUM* (ASTERACEAE: EUPATORIEAE), AN EARLIER NAME THAN *EUPATORIADELPHUS*

Eric E. Lamont

Honorary Research Associate
Institute of Systematic Botany
The New York Botanical Garden
Bronx, New York 10458, U.S.A.

ABSTRACT

The following new combinations are proposed: *Eutrochium dubium, Eutrochium fistulosum, Eutrochium maculatum, Eutrochium maculatum* var. *bruneri, Eutrochium maculatum* var. *foliosum, Eutrochium purpureum, Eutrochium purpureum* var. *holzingeri*, and *Eutrochium steelei*.

RESUMEN

Se proponen las siguientes combinaciones nuevas: *Eutrochium dubium, Eutrochium fistulosum, Eutrochium maculatum, Eutrochium maculatum* var. *bruneri, Eutrochium maculatum* var. *foliosum, Eutrochium purpureum, Eutrochium purpureum* var. *holzingeri*, y *Eutrochium steelei*.

Plants known as Joe-Pye weeds have been long treated in *Eupatorium* L. (Lamont 1995). Sometimes, they have been treated as generically distinct, as members of *Eupatoriadelphus* R.M. King & H. Robinson (1970). Recent studies based on chloroplast DNA (cpDNA) restriction site analysis (Schilling et al. 1999) and nuclear internal transcribed spacer (ITS) sequence data (Schmidt & Schilling 2000) have been interpreted as providing support for recognizing *Eupatoriadelphus* as distinct. If treated as distinct at generic rank, an earlier name should be used for the group, *Eutrochium* Raf.

Eutrochium Raf., New Fl. 4:78. 1836 [1838]. TYPE: *Eutrochium purpureum* (L.) E.E. Lamont (LECTOTYPE, here designated).

The following new combinations are needed for treatment of Joe-Pye weeds as members of *Eutrochium* in a forthcoming volume of Flora of North America North of Mexico.

Eutrochium dubium (Willd. ex Poiret) E.E. Lamont, comb. nov. BASIONYM: *Eupatorium dubium* Willd. ex Poiret in J. Lamarck et al., Encycl. Suppl. 2:606. 1811. *Eupatoriadelphus dubius* (Willd. ex Poiret) R.M. King & H. Robinson, Phytologia 19:432. 1970.

Eutrochium fistulosum (Barratt) E.E. Lamont, comb. nov. BASIONYM: *Eupatorium fistulosum* Barratt, Eupatoria Verticillata no. 1. 1841; in A. Wood, Class-book Bot., ed. 10, 314. 1849. *Eupatoriadelphus fistulosus* (Barratt) R.M. King & H. Robinson, Phytologia 19:432. 1970.

Eutrochium maculatum (L.) E.E. Lamont, comb. nov. BASIONYM: *Eupatorium maculatum* L., Cent. Pl. I, 27. 1755. *Eupatoriadelphus maculatus* (L.) R.M. King & H. Robinson, Phytologia 19:432. 1970.

Eutrochium maculatum (L.) E.E. Lamont var. **bruneri** (A. Gray) E.E. Lamont, comb. nov. BASIONYM: *Eupatorium bruneri* A. Gray in A. Gray et al., Syn. Fl. N. Amer. 1(2):96. 1884. *Eupatoriadelphus maculatus* (L.) R.M. King & H. Robinson var. *bruneri* (A. Gray) R.M. King & H. Robinson, Phytologia 45:465. 1980.

Eutrochium maculatum (L.) E.E. Lamont var. **foliosum** (Fernald) E.E. Lamont, comb. nov. BASIONYM: *Eupatorium purpureum* L. var. *foliosum* Fernald, Rhodora 10:86. 1908. *Eupatorium maculatum* L. var. *foliosum* (Fernald) Wiegand, Rhodora 22:66. 1920.

Eutrochium purpureum (L.) E.E. Lamont, comb. nov. BASIONYM: *Eupatorium purpureum* L., Sp. Pl. 838. 1753. *Cunigunda purpurea* (L.) Lunell, Amer. Midl. Naturalist 5:35. 1917. *Eupatoriadelphus purpureus* (L.) R.M. King & H. Robinson, Phytologia 19:432. 1970.

Eutrochium purpureum (L.) E.E. Lamont var. **holzingeri** (Rydberg) E.E. Lamont, comb. nov. BASIONYM: *Eupatorium holzingeri* Rydberg, Brittonia 1:97. 1931. *Eupatorium purpureum* L. var. *holzingeri* (Rydberg) E.E. Lamont, Phytologia 69:468. 1990 [1991].

Eutrochium steelei (E.E. Lamont) E.E. Lamont, comb. nov. BASIONYM: *Eupatorium steelei* E.E. Lamont, Brittonia 42:279. 1990. *Eupatoriadelphus steelei* (E.E. Lamont) G.J. Schmidt & E.E. Schilling, Amer. J. Bot. 87:726. 2000.

ACKNOWLEDGMENTS

Appreciation is expressed to George Yatskievych for calling attention to *Eutrochium* Raf. being the oldest validly published generic name for the Joe-Pye weeds; Harold Robinson for sharing his insight into the taxonomy of *Eupatorium*, *Eupatoriadelphus*, and *Eutrochium*; John Strother and Guy Nesom for reviewing an earlier draft of this manuscript; and Barney Lipscomb for expediting publication of these new nomenclatural combinations.

NEW COMBINATIONS IN NORTH AMERICAN *SYMPHYOTRICHUM* SUBGENUS *ASTROPOLIUM* (ASTERACEAE: ASTEREAE)

Scott D. Sundberg

Department of Botany & Plant Pathology
Oregon State University
2082 Cordley Hall
Corvallis, Oregon 97331-2902, U.S.A.
sundbers@science.oregonstate.edu

ABSTRACT

Five new combinations in *Symphyotrichum tenuifolium* and *S. subulatum*, of subgenus *Astropolium* (Nutt.) Semple are presented. A selection of synonyms are listed for each taxon. Geographical ranges of each variety is presented and the characteristics and distributions of intermediate populations are discussed.

RESUMEN

Symphyotrichum subgenus *Astropolium* (Nutt.) Semple ha sido típicamente circunscrita usando los nombres de *Aster* subg. *Oxytripolium* (DC.) Torr. & A. Gray o *S.* sect. *Oxytripolium* (DC.) G.L. Nesom (Jones 1980; Semple & Brouillet 1980; Sundberg 1986; Nesom 1994). Todas las interpretaciones recientes han incluido un grupo central de taxa norteamericanos y se han incluido otros taxa principalmente en base a una morfología compartida o número cromosomático base.

INTRODUCTION

North American species of *Symphyotrichum* subgenus *Astropolium* (Nutt.) Semple have typically been treated as *Aster* subg. *Oxytripolium* (DC.) Torr. & A. Gray (Jones 1980; Semple & Brouillet 1980; Sundberg 1986). These references have included a core group of taxa with shared morphological characteristics and base chromosome number. Several additional taxa were included in the subgenus, but were excluded by Sundberg (1986). Nesom (1994) placed the core group of taxa in *Symphyotrichum* sect. *Oxytripolium* (DC.) G.L. Nesom and added seven South American species. Sundberg's (1986) treatment of the subgenus included eight taxa in three species, all of which were recognized at the species rank by Nesom (1994).

This paper presents five new combinations in *Symphyotrichum tenuifolium* and *S. subulatum*, making them available for use in an upcoming volume of the Flora of North America. No new combinations are proposed in the third North American species of subgenus *Astropolium*, *S. potosinum* (A. Gray) G.L. Nesom. A selection of synonyms are listed for each taxon. Data presented here are summarized from Sundberg (1986).

SIDA 21(2): 903–910. 2004

Symphyotrichum tenuifolium

Symphyotrichum tenuifolium consists of the two parapatric varieties, *tenuifolium* and *aphyllum*. Both varieties are diploids with $n = 5$ chromosomes (var. *tenuifolium*: Louisiana, St. Mary Parish, *Sundberg 2195*; var. *aphyllum*: Florida, Monroe Co., *Sundberg 2325*). The varieties can be distinguished using the following key:

1. Plants colonial, rhizomes long, not profusely branched; stems solitary, not wiry; midstem leaves (1.5–)3–6 mm wide; involucres 6–9.5(–11) mm; disc florets 25–45(–54), (4–)4.7–6(–6.5) mm; ray florets (12–)17–25; cypselae 2.8–4(–4.5) mm; pappus 5–6.1 mm _____ var. **tenuifolium**
1. Plants not colonial, rhizomes short, compact, profusely branched; stems clustered, slender, wiry, narrow; midstem leaves nearly filiform, (1–)1.5–2.7 mm wide; involucres 4.1–5.3 mm; disc florets (10–)13–23, 3.4–4.6 mm; ray florets 10–16 mm; cypselae 1.5–2(–2.5) mm; pappus 3–4.4 mm _____ var. **aphyllum**

Symphyotrichum tenuifolium var. *tenuifolium* is distributed along the Atlantic coast of the United States from Massachusetts to northern Florida, and along the Gulf of Mexico coast from northern Florida to Texas. It is not uncommon on dark-colored mud in coastal salt marshes.

Variety *aphyllum* has a more southern distribution and is known from dark mud or marl in coastal salt marshes of southern and central Florida, the Bahamas, and Cuba.

Intermediates between the two varieties are frequent along the Gulf of Mexico Coast, from Taylor to Pinellas counties, in northern and central peninsular Florida. In these populations varieties *tenuifolium* and *aphyllum* intergrade in nearly all distinguishing characters (Table 1, Table 2), especially in stem diameter, leaf width, and head size. The rhizome system of intermediates is generally more like that of var. *tenuifolium*. Individuals in the northern part of this zone of intergradation closely approach the morphology of var. *tenuifolium*, southern populations are more similar to var. *aphyllum*, but most populations combine features of both varieties. Observations of populations in the field suggest that the extreme forms are clonally-derived, peripherally divergent populations between the varieties.

Sundberg (1986) conducted hybridization experiments between two individuals of var. *tenuifolium* with var. *aphyllum*. Following sixteen attempts to cross the varieties, he reported a 31% hybridization success rate (based on recovery of mature cypselae). Hybrid plants exhibited a mixture of vegetative traits of the two varieties. When compared to the parent taxa, the hybrids were intermediate in leaf and stem widths and rhizome morphology. Only vegetative characters were assessed, as experiments were terminated before the hybrids flowered.

Symphyotrichum tenuifolium (L.) G.L. Nesom, Phytologia 77:293. 1994 (1995). BASIONYM: *Aster tenuifolius* L., Sp. Pl. 2:873–874. 1753. TYPE?: "in America septentrionale," without collector or date, specimen number 997.26 (LINN; photographs GH!, NY!, UC!). This specimen is annotated *A. tenuifolius* in Linnaeus' handwriting.

TABLE 1. Character states used to distinguish *Symphyotrichum tenuifolium* var. *tenuifolium*, var. *aphyllum*, and intermediates in Table 2.

Character	var. *tenuifolium*	var. *aphyllum*	intermediates
Habit	rhizomes creeping	stems clustered	na
Midstem leaf width	> 3mm	< 2 mm	2–3 mm
Involucre height	> 6 mm	< 5 mm	5–6 mm
Number of disk florets	> 25	< 22	22–25
Disk floret length	> 4.6 mm	< 4.3 mm	4.3–4.6 mm
Number of rays	> 17	< 14	14–17
Cypsela length	> 2.8 mm	< 2.4 mm	2.4–2.8 mm
Pappus length	> 4.5 mm	< 4.0 mm	4.0–4.5 mm

TABLE 2. Representative specimens of *Symphyotrichum subulatum* vars. *tenuifolium* and *aphyllum*, arranged from north to south along the Gulf coast of peninsular Florida. *Morphological characteristics of var. *tenuifolius* (T), var. *aphyllus* (A), or intermediate (-); characters are listed in the order used in Table 1.

Symphyotrichum subulatum

Symphyotrichum subulatum is widely distributed in moist habitats in the Americas, from southern and eastern states of the United States, through the Caribbean islands and Central America, to South America. Variety *ligulatum* is a widespread weedy annual on disturbed soils from Nebraska south to Tamaulipas, Mexico, and from Alabama to New Mexico. Variety *parviflorum* occurs in North America, West Indies, Mexico, and northern South America and has been introduced in other parts of the world. Variety *elongatum* grows in Florida, coastal Georgia, and the Bahamas. Variety *subulatum* is common in salt marshes and brackish areas along the Atlantic coast from New Brunswick to northern Florida. Variety *squamatum* is an introduced taxon in the United States and elsewhere, with a native habitat of saline and freshwater regions, especially in the southern half of South America.

The five varieties recognized here differ in chromosome number, ligule size, capitulescence morphology, number of disk and ray florets, head size, and presence of basal rosettes. Within a single population plants may be tall and with numerous capitula, or short and monocephalous. Within a variety it is typical for individual diagnostic characters to vary.

Symphyotrichum subulatum has a base chromosome number of $x = 5$. Varieties *ligulatum* (Texas, Travis Co., *Sundberg 1375*), *parviflorum*, (California, Kern Co., *Sundberg 2094*) and *subulatum* (Georgia, Glynn Co., *Sundberg 2342*) are diploids with $n = 5$, and varieties *elongatum* (Florida, Dade Co., *Sundberg 2324*) and *squamatum* (Argentina, Prov. Salta, *Lavin & Lavin 5809*) are tetraploids with $n = 10$ (for 79 more chromosome count citations, see Sundberg 1986). Greenhouse studies of the species (Sundberg 1986) showed that varieties *elongatum*, *parviflorum*, *squamatum*, and *subulatum* are self-compatible. This may facilitate the fixation of variant forms and result in greater infraspecific variability in these varieties. Variety *ligulatum* is not self compatible and is the least variable taxon.

The varieties intergrade morphologically where their distributions approach one another. This may be the result of past hybridization events and limited gene flow across reproductive barriers. Artificial hybrids produced in the greenhouse among the varieties are highly sterile, yet, for example, 2% of the pollen of the triploid hybrid, var. *parviflorum* × var. *elongatum* stains darkly with cytoplasmic stain, suggesting that a small fraction of the pollen may be viable (Sundberg 1986).

Varieties *ligulatum* and *parviflorum*: Populations intermediate in ligule length and width occur in trans-Pecos Texas, parts of New Mexico (including the type of *A. neomexicanus* Wooton & Standl., collected in Chaves Co.), Arizona, and Chihuahua, Mexico. These are fertile plants in stable populations and produce plump, apparently viable cypselae.

Varieties *elongatum* and *subulatum*: Intermediates between these varieties occur sporadically in northeastern Florida (Duval County) and along the coast of the Florida panhandle. Intergradation is demonstrated in the compactness of the capitulescence and the number of disk and ray florets.

Varieties *elongatum* and *parviflorum*: Although readily distinguishable over much of their ranges, similar forms of the two varieties are found in southern Florida, where their distributions approach. In this area individuals of var. *parviflorum* are more robust (to 1.5 m tall) than elsewhere and the ligules are often pink, instead of white. Variety *parviflorum* is usually more diffusely and more equally branched in the capitulescence than var. *elongatum*. The latter variety often has long branches in the capitulescence, with shorter peduncles that are often disposed toward the upper side of the branch. In addition, variety *parviflorum* has shorter heads, narrower phyllaries, fewer and shorter ray florets, and fewer disk florets than var. *elongatum*.

Symphyotrichum subulatum (Michx.) G.L. Nesom, Phytologia 77:293. 1994 (1995). *Aster subulatus* Michx.. Fl. Bor.-Amer. 2:111. 1803. TYPE: U.S.A. "Pensylvania:" *Michaux s.n.* (LECTOTYPE [Bosserdet 1970]: P, photograph TEX!).

Symphyotrichum subulatum (Michx.) G.L. Nesom var. **elongatum** (Boss.) S.D. Sundb., comb. nov. BASIONYM: *Aster subulatus* var. *elongatus* Boss., Taxon 19:250. 1970. TYPE: U.S.A. FLORIDA. Hillsborough Co.: Tampa, 20 Aug 1895, *Nash 2416* (LECTOTYPE [Jones & Lowry 1986]: P; photograph: TEX!).

Aster bahamensis Britton, Bull. Torrey Bot Club 41:14. 1914. *Aster subulatus* Michx. var. *bahamensis* (Britton) Boss., Taxon 19:249. 1970. *Symphyotrichum bahamense* (Britton) G.L. Nesom, Phytologia 77:276. 1994 (1995). TYPE: BAHAMAS. Great Bahama: Barnett's Point, 5–13 Feb 1905, *Britton & Millspaugh 2621* (HOLOTYPE: NY!, photograph TEX!; ISOTYPE: F!).

Symphyotrichum subulatum (Michx.) G.L. Nesom var. **ligulatum** (Shinners) S.D. Sundb., comb. nov. BASIONYM: *Aster subulatus* Michx. var. *ligulatus* Shinners, Field & Lab. 21:159. 1953. TYPE: U.S.A. TEXAS. Hill Co.: 6.9 mi SW of Hillsboro, bottom of dried-up pond, sandy clay, rays light lavender, 23 Oct 1949, *Shinners 12057* (HOLOTYPE: SMU; ISOTYPE: GH!).

Tripolium divaricatum Nutt., Trans. Amer. Philos. Soc. n.s. 7:296. 1841. *Aster divaricatus* (Nutt.) Torr. & A. Gray, Fl. N. Amer. 2:163. 1841. non L., Sp. Pl.: 873. 1753, *Symphyotrichum divaricatum* (Nutt.) G.L. Nesom, Phytologia 77:279. 1994 (1995). Type: Innundated [sic] banks of the Mississippi, *Nuttall s.n.* (HOLOTYPE: PH!, photograph TEX!).

Distinctive, localized forms of variety *ligulatum* occur in some areas. Collections from the Dallas-Fort Worth area of Texas have particularly small heads and florets. Along the coast of Texas and Tamaulipas, near the mouth of the Rio Grande and southward, plants are especially large, sometimes over two meters tall, and exhibit the largest capitula, with the most phyllaries, ray florets, and disk florets found in the variety. These forms intergrade gradually into more typical forms and are not deemed to be worthy of nomenclatural recognition.

Symphyotrichum subulatum (Michx.) G.L. Nesom var. **parviflorum** (Nees) S.D. Sundb., comb. nov. BASIONYM: *Tripolium subulatum* (Michx.) DC. var. β *parviflorum* Nees, Gen. sp. Aster.: 157, 286. 1833. TYPE: U.S.A. HAWAII: Oahu, 1816 or 1817, *Chamisso s.n.* (LECTOTYPE, here designated: G-DC; microfiche!, photograph!).

Erigeron expansus Poepp. ex Spreng., Syst. Veg. 3:518. 1826. *Symphyotrichum expansum* (Poepp. ex Spreng.) G.L. Nesom, Phytologia 77:281. 1994 (1995). TYPE: "En. pl. Cub. MSS. In siccis calidis Cubae. Octbr." (HOLOTYPE: W?; ISOTYPES: HAL!, MO!, NY, F!).

Aster divaricatus (Nutt.) Torr. & A. Gray var. *sandwicensis* A. Gray in H. Mann, Proc. Amer. Acad. Arts 7:173. 1867. *Aster sandwicensis* (A. Gray in H. Mann) Hieron., Bot. Jahrb. Syst. 29:20. 1901. *Aster subulatus* Michx. var. *sandwicensis* (A. Gray ex H. Mann) A.G. Jones, Brittonia 36:465. 1984. TYPE: U.S.A. HAWAII: Oahu, 1816 or 1817, *Chamisso s.n.* (LECTOTYPE: [Jones 1984]: G-DC; microfiche!, photograph!).

Jones (1984) designated a specimen in G-DC as the lectotype of *Aster divaricatus* var. *sandwicensis* and listed homotypic and heterotypic synonyms of the variety. She listed *Tripolium subulatum* (Michx.) DC. var. β Nees as "unnamed" in the list of homotypic taxa, but did not recognize, or explicitly lectotypify, the variety. Sundberg later examined high resolution photographs of the lectotype and identified the specimen as var. *parviflorum*, and not var. *squamatum*, as the name has been applied in earlier publications.

Nees (1833) cited *Tripolium subulatum* (Michx.) DC. var. β as "β. Parviflorus, caule supradecomposito, calathiis dimidio minoribus," which could be interpreted as a polynomial, or an informal description of a form. However, on page 286, in "synonyma addenda vel corrigenda" Nees writes, "Ad *Tripolium subulatum* var. β *parviflorum* p. 157, *Aster inconspicuus* Less. in Schlechtend. Lin. V. p. 143," which changed the "*parviflorus*" to "*parviflorum*" to agree in gender with *Tripolium*. He indicated that "β *parviflorum*" was based on *A. inconspicuus* Less., and associated "Var." with the varietal epithet. Thus, Nees' correction was to list *A. inconspicuus* Less as a synonym of his new variety. The lectotype of var. *parviflorum* is further selected on the basis of Nees' (1833) statements on p. 143 that "Var. β in O Wahu insula (Cham.)." and "Vidi exempla Americae borealis et O Wahu insulae," indicating that he had seen a specimen of the variety collected in Oahu by Chamisso.

Variety *parviflorum* varies in ligule length, ligule pigmentation (white or pink), head size, and vegetative characters. Populations with abnormally large heads and pigmented ligules occur sporadically in the states of Mexico and Veracruz, of central Mexico.

Symphyotrichum subulatum (Michx.) G.L. Nesom var. **squamatum** (Spreng.) S.D. Sundb., comb. nov. BASIONYM: *Conyza squamata* Spreng., Syst. Veg. 3:515. 1826; *Aster squamatus* (Spreng.) Hieron., Bot. Jahrb. Syst. 29:19. 1901. *Conyzanthus squamatus* (Spreng.) Tamamschjan, FL., U.R.S.S. 25:186. 1959. *Symphyotrichum squamatum* (Sprengel) G.L. Nesom, Phytologia 77:292. 1994 (1995). TYPE: URUGUAY: Montevideo, *Sello[w] s.n.* (HOLOTYPE: P).

Sprengel's Asteraceae specimens were sold to Schultz-Bipontinus, whose herbarium is now part of the Cosson herbarium at P (Stafleu & Cowan 1985). Because this is the only known collection by Friedrich Sellow from Montevideo in the Sprengel Herbarium, the P specimen (Sprengel Herb #1064) may be regarded as a holotype. Stafleu and Cowan note that Sello crossed out the letter "w" on many labels to reflect the original family name. Sprengel used the spelling, "Sello" in the original description.

The branching of the capitulescence, head size, and cypsela pubescence vary greatly in var. *squamatum*. Populations with glabrous cypselae, and narrow phyllaries and heads occur in the vicinity of Tucuman Province in Argentina, as well as around Buenos Aires. In other respects these plants are typical of the variety. In Chile a form with large involucres (8.5 mm high), ligules that extend 1.5 mm beyond the pappus, and cypselae ca. 3.2 mm long exist. These occur in proximity to populations of typical var. *squamatum*, which has shorter involucres, cypselae, and ligules. Similar large-headed forms, but with short ligules are found in Peru. Collections of these variants of var. *squamatum* are few and additional study may reveal that some of the populations represent distinct varieties.

Symphyotrichum subulatum (Michx.) G.L. Nesom var. **subulatum**

Aster subulatus Michx. var. *obtusifolius* Fernald, Rhodora 16:61. 1914. TYPE: CANADA. NEW BRUNSWICK. Gloucester Co.: Bathurst, brackish marsh along Middle River, 13 Aug 1913, *Blake* 5372 (HOLOTYPE: GH!; ISOTYPES: CAS!, LL!, NY!, US!).

Aster subulatus Michx. var. *euroauster* Fernald & Griscom, Rhodora 37:183. 1935. TYPE: U.S.A. VIRGINIA. Norfolk Co.: border of gum swamp near North Landing, 22 Sep 1933, *Fernald & Griscom 2919* (HOLOTYPE: GH!).

Aster ensifer Boss., Taxon 19:250. 1970. TYPE: U.S.A. MASSACHUSETTS: Cambridge, margin of salt marsh, 2 Oct 1901, *Robinson & Fernald 65* (HOLOTYPE: P, photograph TEX!; ISOTYPES: CAS!, DS!, GA!, GH!, ILL, LL!, MICH!, MO!, NY!, POM!, UC!, US!).

Plants of variety *subulatum* from the northern Atlantic coast are shorter, with fewer capitula, larger leaves in the capitulescence, and longer ligules than plants from the southern Atlantic coast of the United States. The form that occurs in New Brunswick has been treated as *Aster subulatus* Michx. var. *obtusifolius* Fernald. However, this represents an extreme form in a gradual cline, and one variable variety is recognized here.

ACKNOWLEDGMENTS

I thank Linda Hardison for assisting with the production of the manuscript, Laurent Gautier and Muriel Hecquet for sending high-resolution photographs of a type specimen at G-DC, Almut Jones for providing photographs of type specimens, Guy Nesom for his comments on the manuscript, and the curators of CAS, DS, F, FSU, GA, GH, HAL, K, LL, MICH, MO, NLU, NY, POM, RSA, TEX, and USF for specimen loans used for this study.

ABSTRACT

Seed and capsule characters of several species of *Arcytophyllum*, *Bouvardia*, and *Manettia* (Hedyotideae: Rubiaceae) are described and compared. Seed characters are illustrated by scanning electron microscopy. Morphological similarities and differences are emphasized and outlined by a descriptive key. All characters of *Arcytophyllum serpyllaceum* and *A. muticum* were compared in tabular format, and a strong similarity was noted. These results support previous work that considered A. *serpyllaceum* a member of the genus *Arcytophyllum*.

RESUMEN

Las semillas y frutos de algunas especies de *Arcytophyllum*, *Bouvardia* y *Manettia* (Hedyotideae; Rubiaceae) son descritas y comparadas. Los caracteres de las semillas son representados mediante imágenes producidas por un microscopio electrónico de barrido. Las semejanzas y diferencias morfológicas de estos géneros son enfatizadas y esquematizadas por medio de una clave descriptiva. Todos los caracteres de *Arcytophyllum serpyllaceum* y *A. muticum* fueron comparados en una tabla, mostrando éstos un alto grado de similitud. Los resultados obtenidos, apoyan la noción sugerida por estudios previos, de que *Arcytophyllum serpyllaceum* es en realidad un miembro del genero *Arcytophyllum*.

INTRODUCTION

This study of seeds and capsules of three genera belonging to the tribe Hedyotideae (Rubiaceae), follows the pattern of recent work on this tribe (e.g., Terrell 1996; Terrell & Robinson 2003). These studies involved examination of surface features of seeds by dissecting microscope and scanning electron microscopy (SEM). Revision of *Houstonia* (Terrell 1996) showed seed characters and chromosome numbers to be especially important in revealing relationships.

The three genera in the present study, *Arcytophyllum*, *Bouvardia*, and *Manettia*, are from Mexico, and Central and South America. These genera have largely escaped the past tendency to include many members of the tribe in a broad concept of the genus *Hedyotis*, and *Bouvardia* and *Manettia* have sometimes been placed in the tribe Cinchoneae because of the conspicuous papery winged seeds.

---

[1] Address for correspondence: 14001 Wildwood Drive, Silver Spring, Maryland 20905, U.S.A

Bremer and Manen (2000) in a molecular study placed *Manettia* and *Bouvardia* in the combined Hedyotideae/Spermacoceae where the older name Spermacoceae was adopted. Terrell and Wunderlin (2003) questioned this action on the basis of fundamental morphological differences between the two tribes. Here and elsewhere (e.g., Terrell & Robinson 2003) we continue to place the present genera in the tribe Hedyotideae sens. str.

All three of our studied genera have recorded chromosome numbers of $x = 9$ (Lewis 1965: 199), a number that is frequent in the Hedyotideae, but unusual in the family Rubiaceae that has mostly $x = 11$.

The purpose of this study is to present for comparison illustrations and/or data on the seeds and capsules of the three genera and to re-examine seed data published by Terrell (1999) and Andersson et al. (2002) for *Bouvardia* and *Arcytophyllum serpyllaceum*.

MATERIALS AND METHODS

Seeds were obtained from the U.S. National Herbarium (US), Smithsonian Institution, and from other herbaria including CHAPA, GH, NY, TENN. Seeds were examined by dissecting microscope and mature, well-formed seeds were viewed by scanning electron microscopy (SEM) at the Smithsonian Institution, and prior to 1985 at the Electronics Lab, U.S. Department of Agriculture, Beltsville, Maryland.

Seed descriptions for each species and inclusive descriptions for each species-group provide basic data.The nomenclatural authors and collection data are added to the seed descriptions for each species. Seed collections viewed by SEM are indicated by a designation such as B35, as e.g. for *Arcytophyllum lavarum*.

Light microscopy was used to observe pollen and some additional structures such as corollas, calyx lobes, and stipules in type species and other selected species of all three genera. Material was mounted on slides in Hoyer's solution (Anderson 1954).

RESULTS

The light microscope study included material of *Arcytophyllum nitidum*, *A. serpyllaceum*, *Bouvardia ternifolia*, and *Manettia alba* and *M. reclinata*. The first, third, and fifth of these species are the types of their respective genera. Pollen in *Arcytophyllum* and *Bouvardia* show essentially identical spherical, tricolporate pollen with minor variation in the granulation of the exine. Only *Manettia* differs by a sometimes more oblate shape with projecting pores. The grains of *M. reclinata* are commonly lying on their more flattened poles and seem almost triangular. The light microscope also showed prominent raphide bundles in stipules, calyx and sometimes the corolla of *Manettia* that were not seen in *Arcytophyllum* or *Bouvardia* slides.

A review of the genera and species for seed and capsule data is as follows:

Arcytophyllum Willd. ex Schult. in Roem.& Schult., Syst. Veg. Mant. 3:5. 1827. This Andean and Central American genus of 16 species of shrubs, subshrubs, and suffruticose herbs grows at higher elevations from Costa Rica to Bolivia (Mena 1990). Most species have rather restricted ranges. Mena found the most useful characters to be the shape of the stipules and the leaf and corolla shapes.

We examined seeds of nine of the sixteen species of *Arcytophyllum*, of which six species were treated by SEM. The seeds of the studied species fell into three groups, as outlined below.

Group A

This group includes the type of the genus. The species are *A. filiforme, A. lavarum, A. macbridei, A. muticum, A. nitidum*, and *A. serpyllaceum*. *Arcytophyllum lavarum, A. muticum*, and *A. serpyllaceum* have lenticular seeds, polygonal or suborbicular in outline, with centric punctiform or slightly raised hila (Fig. 1). *Arcytophyllum lavarum* may or may not be winged, but is shown in this figure as being winged. The remaining three species, *A. filiforme, A. macbridei*, and *A. nitidum* were not done by SEM, but their descriptions are included below. Descriptions of the seeds of the six species follow:

Arcytophyllum filiforme (Ruiz & Pav.) Standl.—Seeds 0.7–1.0 mm diam., black, moderately to strongly compressed, suborbicular in outline, lenticular, thickly to thinly concavo-convex, hilar area rounded or slightly raised, areoles not seen in detail. *Harling & Andersson 12638* (US), Ecuador (det. Boom); *Fosberg & Giles 23135* (US), Ecuador (det. L.B.Smith).

Arcytophyllum lavarum K. Schum.—Seeds 0.7–1.0 mm diam., black, strongly compressed, suborbicular or polygonal in outline, lenticular, biconvex, wing absent or partial, very narrow, fragile, hilum punctiform, areoles isodiametric or polygonal, their walls thick, testa smooth. *Cuatrecasas & Leon 26524* (US), Costa Rica, R8a; *Herrera & Robles 791* (US), Costa Rica, B35 (Fig. 2).

Arcytophyllum macbridei Standl.—Seeds 1.4–1.6 mm diam., black, strongly compressed, suborbicular in outline, lenticular, concavo-convex, wing partial, very narrow, fragile, hilum punctiform or slightly raised, areoles not seen in detail. *Wurdack 1273* (US), Peru (dupl.det. Steyermark).

Arcytophyllum muticum (Wedd.) Standl.—Seeds 1.0–1.4 mm diam., black, moderately to strongly compressed, suborbicular or polygonal in outline, lenticular, rather thickly biconvex or only convex dorsally, hilum punctiform, slightly raised, or a short ridge, areoles isodiametric or polygonal, small, their walls thick, testa smooth. *Fosberg 19196* (US), Colombia, (det. Mena), B36; *Haught 5803* (US), Colombia, R7; *Martin & Plowman 93* (US), Colombia (det. Mena) (Fig. 1).

Arcytophyllum nitidum (Kunth) Schltdl.—Seeds 0.7–1.0 mm diam., black, strongly compressed, polygonal to suborbicular in outline, lenticular, convex dorsally, flat or bent ventrally, hilum punctiform, areoles not seen in detail. *Fosberg & St. John 21880* (US), Colombia.

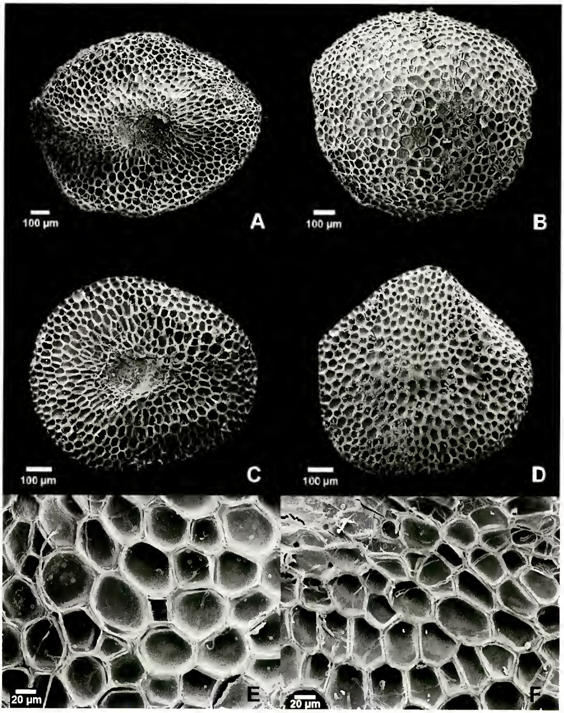

Fig. 1. Seeds of *Arcytophyllum* species examined by SEM. A, B, E, *Arcytophyllum muticum, Fosberg 19196* (US), Colombia. C, D, F, *Arcytophyllum serpyllaceum, Williams et al. 22771* (US), Guatemala. A, C, ventral views; B, D, dorsal views; E, F, areoles.

Arcytophyllum serpyllaceum (Schltdl.) Terrell—Seeds 0.6–1.2 mm diam., black, moderately to strongly compressed, suborbicular or polygonal in outline, lenticular, rather thickly biconvex or flat on one face, hilum punctiform, areoles isodiametric or polygonal, small, their walls thick, testa smooth. *Sharp*

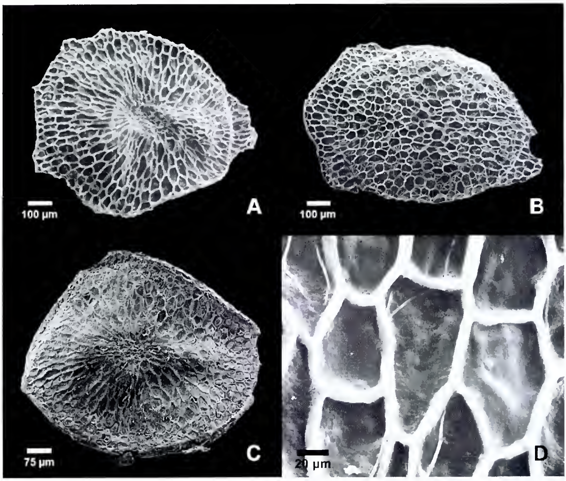

Fig. 2. Seeds of *Arcytophyllum lavarum* examined by SEM. **A, B, D,** *Cuatrecasas & Leon 26524* (US), Costa Rica; **C,** *Herrera & Robles 791* (US), Costa Rica. **A, C,** ventral views; **B,** dorsal view; **D,** areoles.

45143 (TENN), Guatemala, R12; *Williams et al. 22771* (US), Guatemala, B38; *Alexander 1063* (NY), Chiapas, Mexico (Fig. 1).

An inclusive description follows: Seeds 0.6–1.6 mm diameter, black, moderately to strongly compressed, suborbicular or polygonal in outline, thickly to thinly lenticular, faces (sides) flat, concave, convex, or biconvex, wings absent or present, partial, very narrow, fragile, hilum punctiform, rounded, or slightly raised, areoles isodiametric or polygonal, small, walls thick, testa smooth.

Group B

This group includes only *A. aristatum*. Seeds are polygonal in outline, lumpy, not lenticular, and have a strongly raised or ridged ventral face.

Arcytophyllum aristatum Standl.—Seeds 0.7–1.0 mm diam., black, moderately to slightly compressed, lumpy, polygonal in outline, dorsal face convex, ventral face with a strongly raised hilar area or a short to long hilar ridge, areoles small, isodiametric or polygonal, walls thick, testa smooth. *Cuatrecasas*

18976 (US), Colombia, B34; *Luteyn & Luteyn 6758* (US), Ecuador; *Steere 8034* (US), Ecuador (Fig. 3).

Group C

This group includes *Arcytophyllum rivetii* and *A. thymifolium* and has elliptical or oblong seeds with a low hilar ridge.

Arcytophyllum rivetii Danguy & Cherm.—Seeds 1.0–1.3 × 0.6–0.7 mm, black, strongly compressed, broadly elliptic or oblong in outline, biconvex, concavo-convex, or flat, wing none or very narrow at one end of seed, hilum a low linear ridge, areoles isodiametric or polygonal, their walls thick, testa smooth. *Wurdack 1288* (US), Peru, B37 (Fig. 3).

Arcytophyllum thymifolium (Ruiz & Pav.) Standl.—Seeds 0.8–1.2 × 0.5–0.7 mm, black or dark brown, strongly compressed, broadly elliptic or oblong in outline, rather thin, concavo-convex or flat, hilum a low linear or oblong ridge, areoles isodiametric or polygonal, their walls thick, testa smooth. *Firmin s.n., 5/12/27* (US), Ecuador, B39; *Fosberg 21196* (US), Colombia; *Schultes & Villarreal 7880* (US), Colombia (Fig. 3).

An inclusive description is as follows: Seeds 0.8–1.3 × 0.5–0.7 mm, black or dark brown, strongly compressed, broadly elliptic or oblong in outline, biconvex, concavo-convex, or flat, wing none or very narrow at one end of seed, hilum a low, linear or oblong ridge, areoles isodiametric or polygonal, their walls thick, testa smooth.

Summary of Arcytophyllum.—A general survey of *Arcytophyllum* seeds shows that they are strongly or moderately dorsiventrally compressed, with a ventral punctiform centric hilum or a hilar ridge. A few species may have very narrow, fragile, partial wings, but the more common state is wingless. The areoles (cells) are usually isodiametric or polygonal and rather thick-walled with smooth testa. There are three distinct kinds of seeds.

Group A seeds are polygonal or suborbicular in outline. The seeds are lenticular, varying thicker or thinner and biconvex or concavo-convex or flat on a face. The hilum is centric, i.e., on or near the center of the ventral face of the seed, and is often punctiform, appearing as a dot or a small round or raised area. (Figs. 1, 2). Group B has thicker, lumpy seeds with ventral face raised or a short to long hilar ridge. (Fig. 3). Group C has oblongoid or ellipsoid seeds which are slightly to strongly concave ventrally. A low narrow hilar ridge extends along part or most of the seed (Fig. 3).

Mena's (1990) description of *Arcytophyllum* seeds as irregularly patelliform (dish- or saucer-shaped) or cymbiform (boat-shaped) and coarsely alveolated (honeycombed) is somewhat misleading because it suggests that they have shallow or deep ventral cavities or concavities such as are typical of *Houstonia* (Terrell 1996). In *Arcytophyllum*, however, the seeds are in Group A lenticular, in Group B lumpy, and in Group C are ellipsoidal or oblongoid and longitudi-

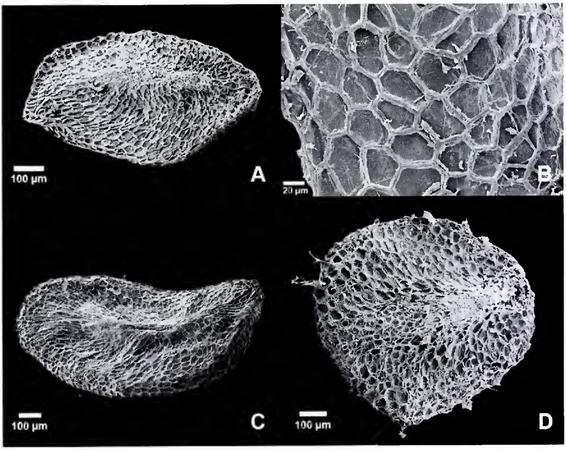

Fig. 3. Seeds of *Arcytophyllum* species examined by SEM. **A–B,** *Arcytophyllum rivetii, Wurdack 1288* (US), Peru. **C,** *Arcytophyllum thymifolium, Firmin s.n.*, 5/12/27, (US), Ecuador. **D,** *Arcytophyllum aristatum, Cuatrecasas 18976* (US), Colombia. **A, C, D,** ventral views; **B,** areoles.

nally concave or bent. The seed surfaces are never honey-combed, but are reticulate and like most seeds of Hedyotideae are made up of walled areoles or cells.

Capsules of *Arcytophyllum* were described by Standley (1921) as biloculate, turbinate to globose, and usually septicidally dehiscent to the base. Mena's description was "septicidal, sometimes only the beginning of the dehiscence loculicidal", crowned by the persistent calyx lobes and intercalycine teeth. For eight of our studied species Mena said that the capsules varied 1–3 mm in diameter, and were mostly subglobose. He found 2–15 seeds per locule (4–30 per capsule). For *A. thymifolium* Mena found 1.7–2 × 2–2.5 mm, which suggests a dimension wider than long. Terrell for *A. thymifolium* recorded 2 × 1 (ellipsoid or oblongoid) in one collection; in a second collection 1.5–2 × 1.0–1.7 (subglobose to oblongoid). Terrell found 5–12 seeds per capsule in *A. lavarum* and *A. thymifolium*. The capsules of *A. serpyllaceum* are 1.5–4 × 2–3.5 mm, turbinate, loculicidal, nerved, and have 8–29 seeds per capsule. This species is further discussed below and compared with *A. muticum*.

Bouvardia Salisbury, Parad. Lond. Pl. 88. 1805.
Blackwell (1968) recognized 31 species in three subgenera in *Bouvardia*. The species are primarily Mexican, with extensions into Central America and southwestern United States, and are shrubs except for four species in the third subgenus. The first subgenus recognized by Blackwell was *Bouvardiastrum* Schltdl. with 15 species, of which we examined *B. capitata*, *B. cordifolia*, *B. laevis*, and *B. multiflora*. The second subgenus, *Bouvardioides* Schltdl. has 8 species, none of which are represented in our study. The third subgenus, *Bouvardia* Schltdl., has 8 species of which we examined *B. ternifolia* and two recently described or transferred perennial herbs, *B. rzedowskii* and *B. xestosperm* (Terrell and Koch 1994), which are similar to and apparently related to the perennial herbs, *B. rosea* Schltdl. and *B. tenuifolia* Standl. Several additional *Bouvardia* species have been described in recent years, but our study utilizes mainly the species studied by Blackwell (1968).

Previous field work in Mexico provided a foundation for the present study. *Bouvardia rzedowskii* was collected and described and *B. xestosperma* was recollected in Oaxaca (Terrell and Koch 1994). Other species of *Bouvardia* were seen in Mexico during this work.

Individual descriptions of seeds are given as follows, with capsule data added from Blackwell (1968). Two groups of species are recognized for this genus.

Group A
The first group includes four shrubby species in subgenus *Bouvardiastrum* (*B. capitata*, *B. cordifolia*, *B. laevis*, *B. multiflora*) and one shrubby species in subg. *Bouvardia* (*B. ternifolia*). These species seem to be generally similar in seed morphology.

Bouvardia capitata Bull.—Seeds 2.5–3.5 mm diam., brown with tan wing, papery thin, orbicular in outline, ventral face concave, seed body 1.0–1.5 mm wide, wing 0.3–1.0 mm wide, its margin entire, undulate, hilum punctiform, often a raised point, areoles radially elongated, their walls thin, testa smooth. *Hinton 8600* (US), Tejupilco, Tepascaltepec (?), Mex. (det. Blackwell), B41 (Fig. 4).

Bouvardia multiflora (Cav.) Schult. & Schult.f.—Seeds 2–3 mm diam., dark brown or black with brown wing, papery thin, orbicular in outline, ventral face concave or almost flat, seed body 0.8–1.4 mm wide, wing 0.2–1.0 mm wide, its margin entire, undulate, hilum punctiform, sometimes a raised point, areoles radially elongated, their walls thin, testa smooth. *H.S. Gentry 8388* (US), Durango, Mexico, (det. Blackwell), B42; *E. Palmer 708* (US), Mexico (Fig. 4).

Bouvardia ternifolia (Cav.) Schltdl.—Seeds 2–3 mm diam., black with brown wing, papery thin, orbicular in outline, ventral face concave, seed body 1.0–2.2 mm wide, wing 0.2–0.6 mm wide, its margin entire, undulate, hilum punctiform, a slightly raised point or rounded area, areoles radially elongated, their walls thin, testa smooth. *Dziekanowski et al. 1860* (US), Hidalgo, Mexico, H52 (Fig. 4).

An inclusive description is as follows: Seeds 2–3.5 mm diam., brown, black,

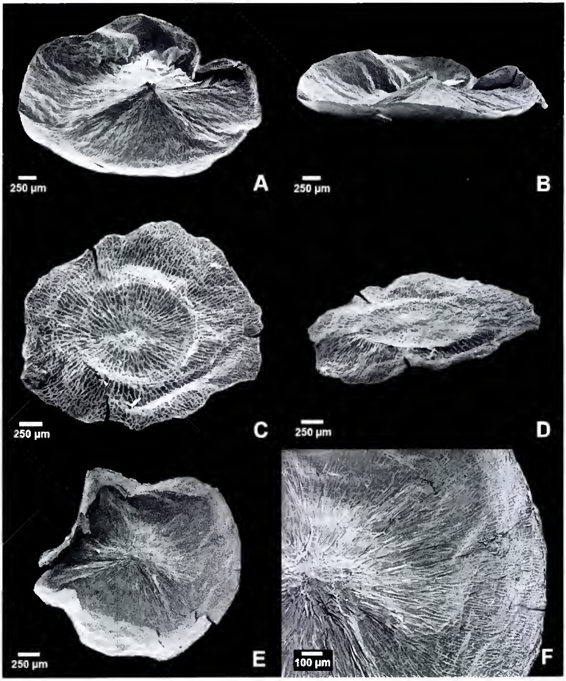

Fig. 4. Seeds of *Bouvardia* species examined by SEM. **A–B,** *Bouvardia capitata, Hinton 8600* (US), Mexico. **C, D,** *Bouvardia ternifolia, Dziekanavski et al. 1860* (US), Mexico. **E, F,** *Bouvardia multiflora, H.S. Gentry 8388* (US), Mexico. **A–F,** ventral views; **F,** enlarged section showing areoles.

or tan, papery thin, orbicular in outline, ventral face concave, seed body 0.8–2.2 mm wide, wing 0.2–1.0 mm wide, its margin entire, undulate, hilum punctiform, a raised point or rounded area, areoles radially elongated, their walls thin, testa smooth.

Capsules in group A have the following inclusive description: 3–9 × 3.5–11 mm., subglobose or slightly oblate, dehiscing loculicidally then septicidally (Blackwell). Standley (1921) recorded capsules as globose and loculicidally dehiscent.

Group B.

The second group includes two recently described or transferred perennial herbs in subg. *Bouvardia* (*B. rzedowskii* and *B. xestosperma*).

Bouvardia rzedowskii Terrell & S.D. Koch—Seeds 1–2 mm diam., dark brown with brown wing, papery thin, orbicular in outline, ventral face concave or flat, seed body 0.5–1.0 mm wide, wing 0.1–0.4 mm wide, its margin entire, undulate, hilum punctiform, sometimes a raised point, areoles radially elongated, their walls thin, testa smooth. *Koch & Koch 8935* (CHAPA), Oaxaca, Mexico, H51 (Fig. 5).

Bouvardia xestosperma (Rob. & Greenm.) Terrell & S.D. Koch—Seeds 1–2 mm diam., dark brown or black, thin, orbicular or oval in outline, ventral face flat or slightly concave, seed body 0.3–1.0 mm wide, wing partial or complete, 0.1–0.5 mm wide, entire, sometimes undulate, hilum punctiform, a slightly raised point, areoles radially elongated, their walls thin, testa smooth. *Koch & Koch 8934* (CHAPA), Oaxaca, Mexico, B45; *Conzatti & Gonzalez 248* (GH), Oaxaca, Mexico, H4 (Fig. 5).

Inclusive description: Seeds 1–2 mm diam., dark brown or black, papery thin, orbicular or oval in outline, ventral face concave or flat, seed body 0.3–1.0 mm wide, wing partial or complete, 0.1–0.5 mm wide, entire, undulate, hilum punctiform, sometimes a raised point, areoles radially elongated, their walls thin, testa smooth.

Capsules 3–5 × 3.5–4.5 mm in *B. rzedowskii*, and 2.5–4 mm long in *B. xestosperma*, with loculicidal dehiscence.(Terrell & Koch 1994).

Due to limited sampling summaries are not given for *Bouvardia* and *Manettia*; however, a comparison of *Bouvardia* groups A and B shows that group B of perennial herbs has smaller seeds and partial instead of complete wings. *Bouvardia ternifolia*, a shrubby species, seems more allied to *Bouvardiastrum* or *Bouvardioides* which have shrubby species.

Manettia Mutis ex L., Mant. Pl. 553, 558.1771, nom. cons.

The genus includes vines or herbs distributed in tropical America, principally in South America. Standley (1921) treated 10 species from West Indies, Mexico, and Central America. Chung (1967, 1968) studied five species in the section *Heterochlora* K. Schum. and six species in section *Pyrrhanthos* K. Schum. Steyermark (1974) estimated 140 species of *Manettia* altogether, and treated 19 species from Venezuela. *Manettia* has broadly winged seeds similar to those of *Bouvardia*. Our data on *Manettia* are limited, and our main purpose here is to present seed descriptions of five species and SEM illustrations of three species of *Manettia* for comparison with similarly-seeded *Bouvardia*. We do not reach any conclusions regarding possible relationships to *Bouvardia*.

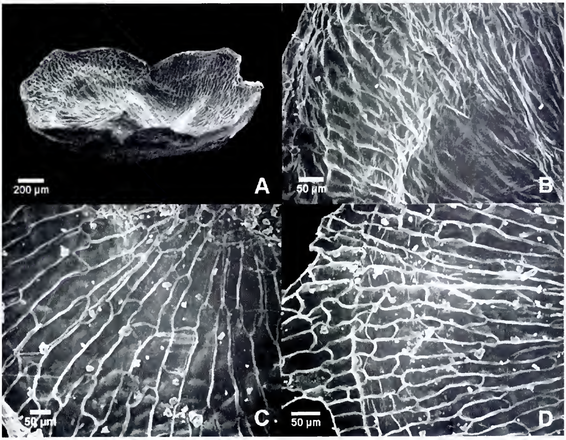

Fig. 5. Seeds of *Bouvardia* species examined by SEM. A–B, *Bouvardia rzedowskii, Koch & Koch 8935* (CHAPA), Mexico. C, D, *Bouvardia xestosperma, Conzatti & Gonzalez 248* (GH), Mexico. A, ventral view; B, C, D, areoles.

We examined the seeds of the following five species of *Manettia*: *M. calycosa* var. *karsteniana*; *M. divaricata*; *M. flexilis*; *M. meridensis*, and *M. reclinata*. Three of these were examined by SEM: *M. calycosa* var. *karsteniana*, *M. flexilis*, and *M. reclinata*.

Manettia calycosa Griseb.var. *karsteniana* K. Schum.—Seeds 0.8–1.1 mm diam., black with brown wing, thin, orbicular in outline, flat or slightly concave ventrally, seed body ca. 0.7 mm wide, wing 0.1–0.3 mm wide, its margin erose, hilum punctiform, areoles radially elongated, walls thin, testa smooth. *Steyermark & Wiehler 106576* (US), Venezuela, B47 (Fig. 6).

Manettia divaricata Wernham—Seeds 2–3 mm diam., black with brown wing, thin, orbicular in outline, flat or slightly concave ventrally, seed body 1.0–1.5 mm wide, wing 0.4–1.0 mm wide, its margin ornately erose or toothed, hilum depressed to slightly raised, areoles not seen in detail. *Schunke V. 838* (US), Peru, (det. D.R. Simpson).

Manettia flexilis Brand.—Seeds 2.0–3.5 mm diam., dark brown with light brown wing, thin, orbicular in outline, flat, seed body 0.6–1.5 mm wide, wing 0.4–1.2 mm wide, its margin erose, hilum punctiform or flat, areoles radially

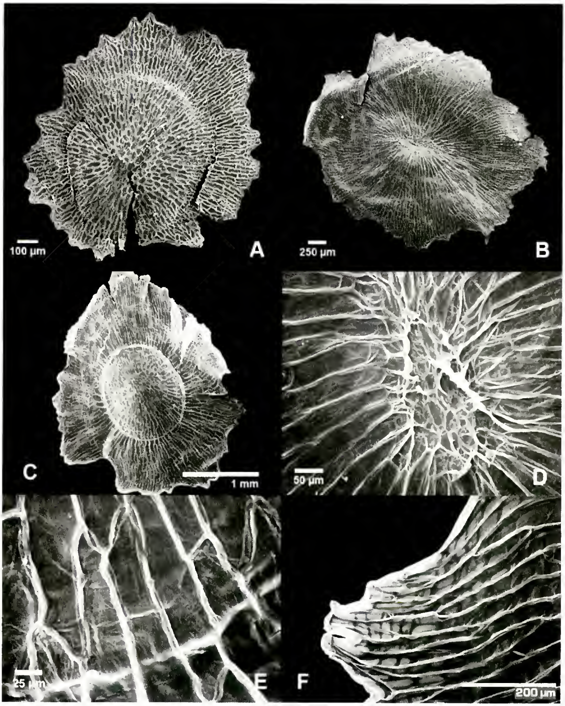

Fig. 6. Seeds of *Manettia* species examined by SEM. A, *Manettia calycosa* var. *karsteniana, Steyermark & Wichler 106576* (US), Venezuela. B, *Manettia reclinata, Hoover 161* (US), Mexico. C–F, *Manettia flexilis, Smith P2360* (US), Costa Rica. A–B, ventral views; C, dorsal view; D, hilar area; E, F, areoles and wing areoles.

elongated, walls thin, testa smooth. *A. Smith P2360* (US), Costa Rica, H32, (det. S. F. Blake) (Fig. 6).

Manettia meridensis K. Schum.—Seeds 2–3 mm diam., black with dark brown wing, thin, orbicular in outline, flat or slightly concave ventrally, seed body 0.5–1.5 mm wide, wing 0.4–0.8 mm wide, its margin entire or minutely erose, hilum punctiform, flat or a slightly raised point, areoles not seen in detail. *Bro. Daniel 1707* (US), Colombia.

Manettia reclinata Mutis ex L.—Seeds 2.5–3.0 mm diam., black with brown wing, thin, orbicular in outline, flat or slightly concave ventrally, seed body 0.7–1.2 mm wide, wing 0.5–1.2 mm, its margin erose, hilum area flat or slightly depressed, areoles radially elongated, walls thin, testa smooth. *Hoover 161* (US), Chiapas, Mexico, B46 (Fig. 6).

Inclusive description of the five species is as follows: Seeds 0.8–3.5 mm diam., black or brown, thin, orbicular in outline, flat or slightly concave ventrally, seed body 0.5–1.5 mm wide, wing 0.1–1.2 mm wide, its margin erose, coarsely toothed, or entire, hilum punctiform, flat or depressed, or slightly raised, areoles radially elongated, walls thin, testa smooth.

Seeds of *Manettia* have wings with margins erose or coarsely and irregularly toothed, much more ornate than *Bouvardia* wings.

Manettia capsules were described by Standley (1921) as septicidally dehiscent, obovoid or turbinate, and coriaceus or chartaceous. Steyermark (1974) also considered the capsules as septicidally dehiscent and described *M. calycosa* as subglobose to ellipsoid or turbinate and 4–7 mm long; for *M. reclinata* obconic and 10–12 × 7–9 mm.

In this study we found *M. divaricata* with capsules 10 × 5.5 and obovoid; *M. meridensis* 5 × 5 and obovoid; and *M. reclinata* 8 × 6.5–8 mm wide and subglobose or broadly ellipsoid. All capsules seen had septicidal dehiscence. Capsules often had two separated halves with each half having a slit or longitudinal opening into the locule reminescent of the diplophragmous capsules of *Hedyotis* subgenus *Hedyotis* (Terrell & Robinson 2003).

DISCUSSION

Capsule characters Capsules in *Arcytophyllum* and *Manettia* have septicidal dehiscence, whereas *Bouvardia* primarily has loculicidal dehiscence followed by septicidal dehiscence. Capsule thicknesses and sizes are much greater in *Bouvardia* and *Manettia* and more varied in shape, although a predominant shape in *Arcytophyllum* and *Bouvardia* is subglobose.

Seed characters The following descriptive key is based on the the present sample of species. *Bouvardia* and *Manettia* seeds are so similar that they are here treated as one unit.

1. Seeds 0.6–1.6 mm long or diam, orbicular or elliptical in outline, moderately or strongly compressed, lenticular, faces biconvex, concavo-convex, or flat or else somewhat concavo-convex, wings none or very narrow and partial, hila centric, flat or slightly depressed or slightly raised, or else a low ridge, areoles isodiametric or somewhat polygonal, their walls thick ______ **Arcytophyllum**
1. Seeds 0.8–3.5 mm diam, orbicular in outline, strongly compressed, flat, thin, most

species broadly winged, wing papery, fragile, seed body and wing often incurved or concave, wing margin entire and undulate (*Bouvardia*) or erose or toothed (*Manettia*), or else wing narrow, hila centric, flat or sometimes raised slightly to form a point, areoles radially elongated, their walls thin ________________ **Bouvardia, Manettia**

Relationships of Arcytophyllum serpyllaceum

The species long known as *Hedyotis serpyllacea* Schltdl. (Linnaea 9:599. 1834) occurs at higher elevations (usually 1500-3500 m) in southern Mexico (Veracruz, Chiapas, Oaxaca) and Guatemala. It is a prostrate, creeping, mat-forming, suffruticose herb that is often abundant in open, grassy places or fields. It produces small white flowers that tend to be purplish or greenish on their abaxial faces. During field work in Mexico (Terrell & Koch 1994) the species was observed and collected in Veracruz.

This species was long retained in *Hedyotis* but differed from other Mexican species that had been placed in that genus. Terrell (1999) described and discussed it in detail, transferred the name *Hedyotis serpyllacea* to *Arcytophyllum* (1827) and noted that there is a precedent for its placement in *Arcytophyllum*. John Donnell Smith (1893) described the species from Guatemala, placing it in *Mallostoma* (Karst. 1862), a synonym of *Arcytophyllum*, as *M. shannoni*. Smith provided a rather complete description of the entire plants, including the following: "capsule obovate ... 8-costate, loculicidal at apex, septicidal at base; seeds 8–20, compressed, roundish, ... finely punctate, black and shining." The "punctate" seed description apparently refers to the polygonal areoles, visible at lower power magnification as reticulations, a common feature of hedyotoid seeds. Standley (1916) transferred *M. shannoni* (without comment) to *Arcytophyllum* as *A. shannoni*, but included only *A. lavarum* in his treatment of Rubiaceae for the North American Flora (Standley 1921). (Apparently, *A. muticum* was not known from Panama and Costa Rica in 1921; see other comments below about *A. muticum*)

Although Mena (1990) in his revision of *Arcytophyllum* had merely listed *Hedyotis serpyllacea* in his category of Excluded and Dubious Names, nonetheless there are similarities to the prostrate, suffruticose species of *Arcytophyllum*, suggesting that *A. serpyllaceum* could be an extension of *Arcytophyllum* northward from Costa Rica into Guatemala and southern Mexico.

The transfer of this species to *Arcytophyllum* was questioned by Andersson et al. (2002) based on their Analysis 1, data from the *rps*16 intron. A phylogenetic tree indicated a close relationship to *Bouvardia* rather than *Arcytophyllum*. Their study of *A. serpyllaceum* was based on a Mexican collection from the MO herbarium, *Stafford et al. 203*. Hoping to examine this collection we corresponded with Charlotte Taylor, curator of Rubiaceae at MO. She has been unable to find this herbarium sheet either under *Hedyotis* or related genera, although Andersson has written to Terrell stating that the loan of MO specimens to GB was returned to MO. Presently, the location of this specimen remains unknown.

Table 1. Comparison of characters of *Arcytophyllum muticum* and *A. serpyllaceum*.

Characters	**muticum**	**serpyllaceum**
Roots and stems	"Subshrubs", prostrate, stoloniferous, mat-forming	Suffruticose herbs, prostrate, woody rhizomes, creeping, mat-forming
Stipules	Genus: interpetiolar, entire or with toothed projections, glabrous or with pustuliform papillae Species: Decurrent, deltate, with acuminate projections 0.4–0.7 mm long, scattered short hairs	Interpetiolar, to 2 mm long, ovate, with short to long narrow caudae, marginal teeth with apical glands, glabrous to ciliolate
Leaves	Sessile or subsessile, 2.5–4.5 × 0.8–1.8 mm, ovate, transversely falcate, coriaceous, glabrous	Sessile, 2–9 × 1–5 mm, ovate or elliptic, thickened, coriaceous, glabrous
Flowers	Solitary, sessile, apparently isostylous	Solitary, pedicels to 7 mm long, heterostylous
Calyces	1–2.5 mm long, trullate or triangular, glabrous, with intercalycine teeth	Lobes (1–)3–8 × 0.5–1.5 mm, lanceolate to ovate or obovate, glabrous, with intercalycine teeth
Corollas	6–9 mm long, salverform–funnelform, purple or bluish abaxially, white adaxially	(4–)6–10 mm long, funnelform, greenish or purple abaxially, white adaxially, thickish
Corolla lobes	2–4.5 × 2–3.5 mm, deltate, papillose, scattered hairs in margin and abaxially, scattered shiny scales adaxially	2.5–4.8 × 1.2–1.7 mm, ovate or elliptic, densely white pubescent adaxially
Corolla tubes	3–4.5 × 1–2 mm, glabrous	3–5 × 2–3 (at throat), glabrous abaxially, pubescent distally adaxially
Stamens	Anthers 1 × 0.3 mm, slightly exserted	Anthers ca. 1–2 mm long, oblong, slightly exserted (thrum flowers), included (pin flowers)
Stigmas	1 mm long, papillose adaxially	1–2.3 mm long (pin), 1–1.4 mm long (thrum)
Capsules	1–3 mm diam., globose, septicidal, 4–24 seeds/capsule	1.5–4 × 2–3.5 mm, broadly oblong or obovate, loculicidal, 8–29 seeds/capsule
Seeds	1.0–1.4 mm diam., often strongly compressed, often polygonal in outline, lenticular, often biconvex, hilum sl. raised, areoles often isodiametric, small.	0.6–1.2 mm diam., other characters very similar to those of *A. muticum*

In the absence of confirmation of the voucher for the study by Andersson et al. (2002), the present study follows the species placement based on structural features of the plants. Two species of *Arcytophyllum* occur in Central America and are of particular interest here. These are *A. lavarum*, endemic to Costa Rica and Panama, and *A. muticum*, native to Costa Rica and Panama and extending south to Ecuador. (Mena 1990 does not list *A. muticum* from Costa Rica except as the type for a synonym, but there are nine collections from Costa Rica in herbarium US). The two similar species, *A. muticum* and *A. serpyllaceum*, are compared in Table 1, listing all of the main characters. The flowers of the two species differ in styly, but this is not considered a generic difference (e.g., Terrell 1996 found both stylies in *Houstonia*).

The data on capsules suggest that *A. muticum* differs somewhat in size, shape, and number of seeds per locule (Table 1) from *A. serpyllaceum*. The two species differ also in *A. muticum* having septicidal dehiscence versus loculicidal dehiscence in *A. serpyllaceum*. Comparison of dehiscence in other genera of Hedyotideae shows considerable variation and the presence of septicidal (e.g., *Hedyotis* subg. *Hedyotis*) and loculicidal dehiscence (e.g., *Houstonia* and *Oldenlandia*).

Contrary to statements by Andersson et al. (2002) that *A. serpyllaceum* seeds resemble those of *Bouvardia*, we find that their seeds are distinctly different, not only in the presence or absence of conspicuous or inconspicuous wings, but also in the appearance of the often raised pointed hila and in the presence of thick-walled isodiametric areoles versus thin-walled radially elongate areoles.

Comparison of seeds of *A. muticum* and *A. serpyllaceum* show them to be so similar that we did not detect any differences in shape, position of hilum, or sizes and shapes of the areoles, and without identity data it would be impossible to distinguish them (Fig. 1). *Arcytophyllum lavarum* was also similar to the other two species (Fig. 2).

A more detailed study of additional species of Hedyotideae is needed in order to provide both molecular and morphological evidence concerning relationships. It is hoped that time will permit such a survey to be carried out with assistance from a person knowledgeable in molecular studies.

ACKNOWLEDGMENTS

We thank the herbarium curators for loans of specimens, Susann Braden for the SEM work, and Marjorie Knowles for formatting the illustrations. We also thank Charlotte Taylor, Curator of the Rubiaceae at MO, for her assistance in searching for a missing specimen needed to confirm an identity (see text), and Pedro Acevedo for providing the Spanish Resumen. Piero Delprete and an anonymous reviewer provided helpful comments on an earlier draft.

Mr. Orlando Alvarez-Fuentes

Michigan State University

Mr. Orlando Alvarez-Fuentes was awarded the 16th Annual Delzie Demaree Travel Award at the 51st Annual Systematics Symposium (8–10 Oct 2004) at the Missouri Botanical Garden.

Applications for the 2005 Delzie Demaree Travel Award should include a letter from the applicant telling how symposium attendance will benefit his/her graduate work and letter of recommendation sent by the major professor. Please send letters of application to: Dr. Donna M.E. Ware, P.O. Box 8795, Herbarium, Biology Department, The College of William and Mary, Williamsburg, VA 23185-8795, U.S.A. 1-757-221-2799; Email: ddmware@wm.edu. Applications need to be received 4 weeks ahead of the Symposium date. The Systematics Symposium dates for 2005 are 7–8 October.

Anyone interested in making a contribution to Delzie Demaree Endowment Fund, which supports the travel award, may make contributions by VISA or MasterCard or by a check, payable to Botanical Research Institute of Texas, to Barney Lipscomb, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A. 1-817-332-7432; Email: barney@brit.org. Thank you.

GENERIC PLACEMENT OF *CHAPTALIA HINTONII* (ASTERACEAE: MUTISIEAE)

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

ABSTRACT

Chaptalia hintonii, of south-central Mexico, was recently transferred to the otherwise essentially Old World genus *Gerbera* on the basis of the occurrence of staminodes in the pistillate flowers. No clear position within *Gerbera* was determined for the species. In contrast, *C. hintonii* also has been placed among the eight species of sect. *Chaptalia*, based on its similarity in a set of features including scape morphology, head behavior, ray corolla morphology, cypselar vestiture, flower biology, and geography. Other species of South American and Mexican *Chaptalia*, including one other from sect. *Chaptalia*, also are known to produce staminodes, a feature interpreted here as plesiomorphic, either as vestigial occurrence or as the result of developmental intermediacy between bisexual disc florets and outer, pistillate ray florets. The hypothesis that *C. hintonii* belongs with *Chaptalia* is stronger than that for positioning *C. hintonii* in *Gerbera*.

RESUMEN

Chaptalia hintonii, del centro-sur de México, fue transferida recientemente al género esencialmente del Viejo Mundo *Gerbera* en base a la presencia de estaminodios en las flores pistiladas. No se determinó una posición clara en *Gerbera* para la especie. Por contra, *C. hintonii* ha sido colocada entre las ocho especies de la sect. *Chaptalia*, en base a su similitud en un conjunto de características que incluyen la morfología del escapo, comportamiento del capítulo, morfología de los radios de la corola, indumento de las cipselas, biología floral, y geografía. Otras especies de *Chaptalia* de Sur América y México, incluida otra de la sect. *Chaptalia*, también se sabe que producen estaminodios, una característica interpretada aquí como plesiomórfica, tanto como ocurrencia vestigial o como resultado de desarrollo intermedio entre flósculos bisexuales del disco y flores radiadas pistiladas. La hipótesis que *C. hintonii* pertenece a *Chaptalia* es más fuerte que la que posiciona a *C. hintonii* en *Gerbera*.

In a recent discussion of the Mexican species *Chaptalia hintonii* Bullock and its relationship to other species groups of Mutisieae-Mutisiinae, Katinas (1998) concluded that *C. hintonii* should be placed in *Gerbera* rather than *Chaptalia*. In contrast, in a revision of the 12 North American and continental Central American species most recently considered to be *Chaptalia*, Nesom (1995) treated *C. hintonii* among the six species of sect. *Chaptalia*. Two additional species from Mexico were added to sect. *Chaptalia* by Cabrera and Nesom (2003). Indeed, the distinction between the New World *Chaptalia* Vent., 1802, and the Old World genus *Gerbera* L., 1758, is not sharply defined, as observed by Jeffrey (1967). Hansen (1990) provided additional perspective on taxonomic problems in the larger generic group of monocephalous, essentially scapose species of

SIDA 21(2): 929–933. 2004

Mutisiinae (the "*Gerbera*-complex") that includes these two genera and informally suggested a return to earlier positions of Schultz-Bipontinus (1856) and Baillon (1882), who believed that the limits of *Gerbera* should include New World species now treated in *Chaptalia*. Nesom (1995) also noted that recognition of the taxonomic boundary between *Chaptalia* and *Gerbera* is problematic but maintained *Chaptalia* as distinct.

In the observations by Katinas (1998), she did not deal directly with significant considerations pertinent to a judgement of generic placement of *Chaptalia hintonii*—it is among the species that constitute sect. *Chaptalia* (Nesom 1995), and cypselar vestiture suggests that *Chaptalia* has evolved apart from *Gerbera* (Hansen 1990).

Species of sect. *Chaptalia* are characterized by monocephalous, ebracteate or few-bracted scapes, heads nodding in bud, broad, cream-colored rays with a purple midstripe on the abaxial surface, and functionally staminate disc flowers. This set of features apparently does not consistently occur in any other group of Mutisiinae. *Chaptalia tomentosa* Vent., the type of the genus, is native to the Atlantic and Gulf coastal plains of the southeastern United States; the other seven species occur in montane habits in eastern and south-central Mexico. Within the section, three species groups can be recognized: (a) *C. tomentosa* and *C. madrensis* Nesom produce narrowly beaked cypselas and pistillate ray corollas without an inner lip; (b) *C. pringlei* Greene is alone in its heads without a zone of rayless pistillate flowers (all pistillate flowers produce conspicuous rays), and cypselas with a short neck; (c) *C. lyratifolia* Burkart, *C. hidalgoensis* Cabr. & Nesom, *C. mexicana* Burkart, *C. hintonii*, and *C. estribensis* Nesom are similar in their colonial habit from rhizomes, leaves with cordate blades and mucronulate margins, pistillate flowers with relatively short style branches, and unbeaked cypselas. *Chaptalia hintonii* differs from *C. lyratifolia C. hidalgoensis*, *C. mexicana*, and *C. estribensis* primarily in its thicker, more easily disconnected rhizomes, and thinner leaves, but the geographic and morphological coherence of these five species within sect. *Chaptalia* seems apparent. The transfer of *Chaptalia hintonii* to *Gerbera* implies that the species belongs to neither the *C. lyratifolia* group ("group c" above) nor sect. *Chaptalia*, but Katinas's observation on the implied non-cohesiveness of sect. *Chaptalia* is indirect—only through her removal of *C. hintonii*.

"The characteristic lack of staminodes in *Chaptalia* and their presence in *Gerbera*" led [Katinas] to place [*Chaptalia*] *hintonii* in the genus *Gerbera*" (Katinas 1998, p. 380). Also, "*Chaptalia hintonii* is much closer to *Gerbera* in its floral characteristics" (p. 382). She noted that for *C. hintonii*, "all florets bilabiate," "outer ray florets conspicuously surpass the involucre," and "ray florets possess staminodes" were features supporting its removal from *Chaptalia*. Numerous other species of *Chaptalia*, however, have all florets bilabiate, all species of sect. *Chaptalia* have large outer rays (e.g., see numerous published photographs of *C. tomentosa*), and staminodes also occur in the inner pistillate flowers of at least three other Mexican species: *C. estribensis* (sect. *Chaptalia*) from the locality in Oaxaca, but not from the localities in Hidalgo; *C. texana* Greene (sect. *Leria* (DC.) Burkart) in plants of Baja California Sur but apparently not from mainland localities; and *C. hololeuca* Greene (sect. *Leria*) from one locality in Coahuila but not from others. Similar staminodes also occur sporadically in both the outer and inner pistillate flowers of the South American species *C. incana* Cuatr., a species suggested by Cuatrecasas (1961) to belong in sect. *Leria* (DC.) Burkart. Finally, Burkart (1944) viewed a group of cordate-leaved South American *Chaptalia* species as better placed in *Trichocline* Cass. than *Chaptalia*, particularly in view of their production of staminodes in the outer pistillate florets. Jeffrey (1967) and Hansen (1990) found that pappus texture and cypselar vestiture refer these species to *Chaptalia* rather than to *Trichocline* or any group of the *Gerbera*-complex.

Parallel variation in the production of staminodes is found in Old World *Gerbera*. Katinas, following Hansen (1990), noted that a reduction to vestigial staminodes has occurred in several groups of *Gerbera* and that they are completely absent in *Gerbera* sect. *Parva* H.V. Hansen.

Hansen (1990) and Nesom (1995) have observed that the inner pistillate florets in *Chaptalia* are intermediate between the disc florets and the outer ray florets. "The inner pistillate flowers of *Chaptalia* appear to be transitional between the ligulate, outer, pistillate ones and the tubular, inner, bisexual flowers in two ways: 1) they usually are bilabiate, even if the outermost are not, and 2) in some species they sporadically produce small, abortive stamens [staminodes]" (Nesom 1995, p. 155). The occurrence of staminodes in *Chaptalia* and other entities of the *Gerbera*-complex is a plesiomorphic feature (Hansen 1990)—they may be interpreted as vestigial organs or as developmentally intermediate in origin (as above). A plesiomorphic similarity between Mexican *C. hintonii* and certain groups of Old World *Gerbera* does not imply closeness of relationship.

What genus?

Evidence at hand indicates that *Chaptalia hintonii* belongs in the same genus as *C. tomentosa*, the type species of *Chaptalia*. If *C. hintonii* is to become a species of *Gerbera*, then so also must the type and at least the other species of sect. *Chaptalia*. Most of *Chaptalia* as a genus holds together well. Species of sects. *Leria* (DC.) Burkart (*C. nutans* Polak., the type), *Archichaptalia* Burkart (*C. rotundifolia* D. Don, the type), and *Pseudotrichocline* Burkart (*C. isernina* Cuatr., the type) are similar to those of sect. *Chaptalia* in their nodding buds and cypselar vestiture, which provides evidence for the phylogenetic coherence of *Chaptalia* apart from Old World members of the *Gerbera*-group.

"Almost all taxonomic main groups [of the *Gerbera*-complex] can be circumscribed by having a special type of achene (cypsela) hair" (Hansen 1990, p.

471). *Chaptalia* has "achene hairs as in *Gerbera* sect. *Piloselloides* Less. but more narrow and either much smaller or much longer and then less inflated" (p. 476, Table 4). Katinas (p. 382) noted that "the species of section *Piloselloides* seem to be the most closely related [to *Chaptalia*] by virtue of the length of the outer ray florets and the type of pubescence on the cypselas ..." but her Table 1 and related comments do not indicate that the cypselar pubescence in these two groups is identical. There is slight variation among cypselar hairs within sect. *Chaptalia*, but I find the vestiture of *C. hintonii* indistinguishable from that of other species of the *C. lyratifolia* group.

Chaptalia sects. *Chaptalia*, *Leria*, and *Archichaptalia* are overlapping in morphological features—leaf shape, degree of elaboration of bracts on the scape, presence/absence of inner pistillate florets, style morphology, elaboration of the inner lip of pistillate florets, ray size, and degree of elaboration of cypselar beak. Especially in their long-petiolate, cordate leaves and broad rays, species of sect. *Archichaptalia* are similar to those of the *Chaptalia lyratifolia* group of sect. *Chaptalia*. Even the distinctive ovarian sterility of the central florets of sect. *Chaptalia* is not a totally exclusive feature. A Brazilian species (Dias de Moraes 1998) is said to be most closely similar to species of sect. *Archichaptalia*, but it apparently is anomalous there in its functionally staminate disc florets (as well as lack of inner pistillate florets, ebracteate scapes, all characters found in some species of sect. *Chaptalia*, where the Brazilian species might technically be placed). Cuatrecasas (1965) described variation in fertility between heads of different plants of the Peruvian *C. malcabalensis* Cuatr.: one head with outer radiate pistillate florets and bisexual fertile central florets, lacking inner rayless pistillate florets; another head with outer radiate pistillate florets, inner rayless pistillate florets, and central florets with sterile ovaries, except for two florets with fertile ovaries and sterile anthers.

Chaptalia sect. *Lieberkuhna* (Cass.) Burkart (*C. piloselloides* (Vahl) Baker, the type) and sect. *Loxodon* (Cass.) Burkart (*C. exscapa* (Pers.) Baker, the type), as a combined group, stand apart from all the rest of *Chaptalia* in production of erect buds, potential for cleistogamous heads, and distinctive cypselar vestiture, and it is possible that this small group of species will be separated at generic rank. This group apparently is the one underlying Hansen's notice (1990) that *Chaptalia* is separable into two groups, based on morphology of cypselar hairs. The Antillean group sect. *Microchaptalia* Burkart appears to be heterogeneous, but I agree with Burkart (1969) that all of it belongs with true *Chaptalia*, rather than being divided between *Chaptalia* and *Lieberkuhna*, as suggested by Jeffrey (1967).

Katinas found similarities between *Chaptalia hintonii* and *Gerbera* sects. *Lasiopus* (DC.) Schultz-Bip., *Pseudoseris* (Baillon) C. Jeffrey, and *Piloselloides* Less. (= *Piloselloides* (Less.) C. Jeffrey), although the species did not fit within any of them. In Hansen's strict consensus tree for the *Gerbera*-complex (1990), these three groups are most closely related to *Chaptalia* and phyletically separate from *Gerbera* sensu stricto, which is the basal OTU in the whole *Gerbera*-complex and separated from *Chaptalia* by *Leibnitzia* Cass., *Perdicium* L., and others. Thus the transfer of *C. hintonii* to *Gerbera* appears equivalent to a step toward recognizing the whole *Gerbera*-complex as a single genus rather than a precise hypothesis of relationship.

The ultimate fate of all of *Chaptalia* may be to join a much broadened *Gerbera*, as suggested by Hansen and earlier botanists, or it may be maintained (perhaps disjoined from *Lieberkuhna*) among a group of smaller genera, as suggested by Jeffrey, but the taxonomic decision in either case should be made in a broad perspective. The taxonomic segregation of *C. hintonii* has little support compared to the geographic and morphological coherence of this species with *Chaptalia* sect. *Chaptalia* and the apparent phylogenetic unity of most of the whole genus *Chaptalia*.

ACKNOWLEDGMENTS

I am particularly grateful to John Strother for various helpful comments on the manuscript.

COMMEMORATIVE

Raymond John Taylor Jr.

20 January 1930–9 November 2004

As this issue of *Sida* was going to press, I received the news that my good friend and colleague had just passed away. Dr. John Taylor retired from Southeastern Oklahoma State University, Durant in 1990 after a long and productive career in botany. I remember John as an excellent teacher and an accomplished botanist who enjoyed field work and collecting plant specimens.

A full memorial is forthcoming in *Sida.—Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

THE *GERBERA* COMPLEX (ASTERACEAE: MUTISIEAE): TO SPLIT OR NOT TO SPLIT

Museo de La Plata
Paseo del Bosque
1900 La Plata, ARGENTINA

ABSTRACT

The transfer of *Chaptalia hintonii* to the genus *Gerbera* was rejected by Nesom (this issue), who retains the species in *Chaptalia* sect. *Chaptalia*. *Chaptalia* and *Gerbera* belong to the *Gerbera*-complex, a group of scapose genera whose circumscriptions are still in flux and whose largest genera still lack complete revisions. Important morphological characters of the corollas, staminodes, and cypsela hairs are discussed, and a key to genera of the *Gerbera*-complex is provided. The short, filiform corollas of the inner ray florets and the lack of staminodes are characters that allow the circumscription of *Chaptalia*. Certain species must be excluded from this genus and the sections within it must be redefined. Staminodes and inner ray florets with bilabiate corollas that are longer than the style are two characters that confirm the transfer of *Chaptalia hintonii* into the genus *Gerbera*.

Key words: *Gerbera hintonii*, *Chaptalia*, *Gerbera*-complex, corollas, staminodes, cypsela hairs

RESUMEN

La transferencia de *Chaptalia hintonii* al género *Gerbera* fue rechazada por Nesom (este volumen), quien retiene esta especie en *Chaptalia* sect. *Chaptalia*. *Chaptalia* y *Gerbera* pertenecen al complejo *Gerbera*, un grupo de géneros de hábito herbáceo escaposo, cuya circumscripción no está definida y cuyos géneros más numerosos aún carecen de revisiones taxonómicas. Se discuten los caracteres morfológicos más importantes de corola, estaminodios y pelos de la cipsela, y se provee una clave de los géneros del complejo *Gerbera*. Las corolas cortas y filiformes de las flores más internas del radio y la ausencia de estaminodios son caracteres que permiten la circumscripción de *Chaptalia*. Ciertas especies deben ser excluidas de *Chaptalia*, y las secciones de este género deben ser redefinidas. La presencia de estaminodios y de flores internas del radio con corola bilabiada más larga que el estilo constituyen dos caracteres que confirman la transferencia de *Chaptalia hintonii* al género *Gerbera*.

In a recent paper (this issue), Nesom rejected Katinas' (1998) placement of the south-central Mexican species *Chaptalia hintonii* Bullock (Asteraceae, Mutisieae) in the Old World genus *Gerbera*. He argued that no clear position within *Gerbera* was given for the species in Katinas' paper and that the morphological evidence more strongly supports including *C. hintonii* within *Chaptalia* rather than in *Gerbera*. *Chaptalia* and *Gerbera* belong to the *Gerbera*-complex, a group of seven genera whose limits are as yet in flux.

I agree with Nesom's argument that a taxonomic decision should be made in a broad context. Therefore, I take this opportunity to clarify and extend my earlier remarks on *Gerbera hintonii* (Bullock) Katinas considering here the entire *Gerbera*-complex.

A revision of the genus *Chaptalia* in progress, led me to examine all the species of this taxon and many of the species of the other genera of the *Gerbera*-complex. This broad perspective allowed me to determine the potencial key characters that can be used to circumscribe the genera of the complex. Furthermore, I found ca. 15 species included in *Chaptalia* that are best excluded from this genus (Katinas, in prep.), some of which probably are better placed within *Gerbera*. The transfer of *C. hintonii* to *Gerbera* was a first step toward this goal.

It should be remarked that since the studies on this group are not finished yet (e.g., revisions of *Chaptalia*, *Gerbera*, and *Leibnitzia*), some conclusions presented here should be regarded as provisional. The main purpose of this presentation is to provide an overview of the transfer of *Chaptalia hintonii* to *Gerbera* in the broader context of the *Gerbera*-complex.

The problem

The *Gerbera*-complex or the scapose-complex (Jeffrey 1967; Hansen 1985a, 1990) belongs to Mutisiinae (tribe Mutisieae) a predominantly American subtribe with a few genera and species ocurring in Asia and Africa. The complex, with ca. 100 species characterized by monocephalous scapes, consists of the genera *Chaptalia* Vent. (ca. 35 species), *Gerbera* L. (29 species), *Leibnitzia* Cass. (six species), *Lulia* Zardini (one species), *Perdicium* L. (two species), *Trichocline* Cass. (22 species), and *Uechtritzia* Freyn (three species). Recently, Hind (2001) transferred *Trichocline spathulata*, the only Australian species of the South American genus *Trichocline*, to the genus *Amblysperma*. A re-examination of both genera however, led to return *Amblysperma* to the synonymy of *Trichocline* (Katinas 2004).

The circumscription of taxa within this morphologically homogeneous group, which lacks complete treatments for its largest genera, has been very problematic. Except for the small genera *Lulia*, *Perdicium* and *Uechtritzia*, the only complete systematic revision within the complex is for *Trichocline* (Zardini 1975). The remaining genera still need complete treatements. In the case of *Chaptalia*, Burkart (1944) focused on the Argentinian species, and Nesom (1995) treated the North and continental Central American species. In addition, Nesom (1983) revised the American species of *Leibnitzia*, whereas Hansen (1988) treated the Asiatic ones. Similarly, Hansen (1985a, b, 1988) treated separately the different sections of *Gerbera*, but he did not deal with the genus as a whole.

In all these studies, the authors stated the difficulties in circumscribing each genus due to the small differences among them. In many cases transfers were made from one genus to another, e.g., species from *Trichocline* to *Gerbera* (Zardini 1974), species from *Chaptalia* to *Leibnitzia* (Nesom 1983), species from *Chaptalia* to *Gerbera* (Katinas 1998). One caulescent species of *Trichocline* had the new genus *Lulia* (Zardini 1980) created for it (which may be excluded from the complex).

Contrasting potential solutions were proposed to deal with these conflicting treatments. Some would treat the entire *Gerbera*-complex as a single, large genus (e.g., Hansen 1990), and, then again, some would split the complex into smaller genera (e.g., Jeffrey 1967). Resolution of the problem will probably only be achieved when treatments of all the taxa are completed.

What character?

Nesom referred to some morphological characters when discussing the transfer of *Chaptalia hintonii* to *Gerbera*, and arguing for the inclusion of this species in *Chaptalia* sect. *Chaptalia*. Below I discuss these characters in the context of the entire *Gerbera*-complex.

Vegetative characters allow some distinction among genera of the *Gerbera*-complex, but reproductive ones, mainly florets (number of series per capitulum, type of corollas, style branches, staminodes) and fruits (cypsela apex, cypsela hairs) seem to be more useful for the delimitation of taxa.

A part of *Gerbera*, and the genera *Lulia*, *Trichocline*, and *Uechtritzia* have their capitula biseriate (two types of florets), i.e., ray florets bilabiate and disc florets bilabiate. *Leibnitzia* also has two types of florets, with ray florets ligulate or bilabiate, sometimes with a minute inner lip (e.g., *L. occimadrensis*), and disc florets tubular or bilabiate. *Perdicium* and a part of *Gerbera* have three types of florets, all bilabiate. *Chaptalia* also has triseriate capitula, with the outer ray florets mostly ligulate and in some species (e.g., *C. exscapa*, *C. tomentosa*) an inner lip is developed. The corolla of the inner ray florets is very reduced, filiform, with a narrow tube, and irregularly bilabiate, tubular or ligulate 3-lobed, shorter than the style. This short, reduced corolla separates *Chaptalia* from *Gerbera*. I have found only two species, *C. mandonii* and *C. tomentosa*, where longer corollas of the inner ray florets may exist, but here they are generally mixed with short ones in the same capitulum. I also found in *Gerbera* some specimens (e.g., *G. piloselloides* and *G. viridifolia*) with corollas that approach those of *Chaptalia* in that their inner ray florets are reduced and transitional between the outer ray florets and the disc florets, but here they are bilabiate and as long as the style or longer. This longer, more developed corolla is present in *G. hintonii* as I have already pointed out (Katinas 1998).

A point considered by Nesom is the presence and the degree of development of staminodes in *Chaptalia* and *Gerbera*. Hansen (1990) showed that there is a reduction series in the staminodes of the ray florets from well developed staminodes or sterile anthers (*Lulia*, *Trichocline*, *Uechtritzia*, part of *Gerbera*), vestigial (part of *Gerbera*, part of *Leibnitzia*, part of *Perdicium*) to absent (*Chaptalia*). *Gerbera parva* is the only species in the genus that lacks staminodes. Observations on different specimens of *G. piloselloides* show that staminodes can be present or absent (even in the same capitulum), the same situation that ocurrs in *G. hintonii*. Nesom pointed out that staminodes are found in species of *Chaptalia*, e.g., *C. estribensis*, *C. hololeuca*, *C. incana*, and *C.*

texana. The first three species, which have staminodes and lack the typical inner ray floret of *Chaptalia*, are included in the group that I would exclude from the genus. With respect to *C. texana*, Nesom (1995) reports that certain specimens (*Gentry & Fox 11768*) have staminodes. The approximately 55 specimens of this species that I have seen all lack staminodes. Moreover, the two sheets of *Gentry & Fox 11768* (MEXU, with the numbers 47607 and 132933) that I have seen lack staminodes as well. *Chaptalia texana*, in addition, is a species that has all the typical characters of *Chaptalia* (e.g., the corollas discussed above). Finally, unlike Nesom I do not consider that the vestigial staminodes, present in *G. hintonii* and other taxa, should be interpreted as a plesiomorphic similarity. As I previously pointed out (Katinas 1998: 381) the reduction of staminodes to thread like (or vestigial) structures as well as their complete absence represent apomorphic conditions.

Nesom also discusses cypsela hairs, in particular the twin hairs. According to him, the cypsela vestiture (together with nodding buds) is a synapomorphy (phylogenetic coherence) of *Chaptalia*. He also suggests that variation of the type of hairs (together with erect buds and cleistogamous heads) will allow the separation of a part of *Chaptalia* at generic rank. A complete classification of these hairs can be found in a work on Nassauviinae (Freire & Katinas 1995), the sister subtribe of Mutisiinae, and a discussion and description of the cypsela hairs in the *Gerbera*-complex is found in my previous paper (Katinas 1998: 381). The analysis of the cypsela twin hairs in most species of all genera of the complex led me to the same conclusion that Hansen (1990) came to, namely that this character is mainly useful in the distinction of *Uechtritzia*, with very long, filiform twin hairs (ca. 1 mm long). The type of twin hairs can differentiate *Chaptalia* and *Gerbera* to some degree, due to some sections of *Gerbera* having cypselas covered by filiform hairs, a type of hair that *Chaptalia* lacks. A distinction can also be made between the American *Leibnitzia* with divergent, radiate, and crenate twin hairs and the remaining genera of the *Gerbera*-complex. *Gerbera hintonii*, shares with many species of *Gerbera*, *Chaptalia* and other genera of the complex, the same type of hair (basic, rounded).

The following key delimits the genera of the *Gerbera*-complex using the characters discussed above, together with some others:

1. Caulescent herbs. Leaves parallel-nerved ____ **Lulia**
1. Acaulescent herbs. Leaves reticulate-nerved.
  2. Pappus bristles connate at the base ____ **Perdicium**
  2. Pappus bristles free.
    3. Plants dimorphic: A vernal generation with small leaves, sligthly developed, and chasmogamous capitula, and an aestival generation with large leaves, fully developed, and cleistogamous capitula ____ **Leibnitzia**
    3. Plants not dimorphic.
      4. Cypselas truncate at the apex.
        5. Cypselas shaggy, covered by long hairs, ca. 1 mm long ____ **Uechtritzia**

5. Cypselas papillose, covered by short hairs, 30–50 µm ______ **Trichocline**

4. Cypselas rostrate at the apex.
   6. Capitula dimorphic or trimorphic; when trimorphic, the inner ray florets with corolla bilabiate or filiform bilabiate, as long as the style or longer. Staminodes generally present ______ **Gerbera**
   6. Capitula trimorphic; the inner ray florets with corolla very reduced, filiform (irregularly tubular, ligulate or bilabiate), shorter than the style. Staminodes absent ______ **Chaptalia**

CONCLUSIONS

As mentioned above, these conclusions are provisional, depending on the completion of work on some genera of the *Gerbera*-complex. The exclusion of ca. 15 species currently included in *Chaptalia* will be crucial for the re-definition of this genus, as many of them have characters that approach those of *Gerbera* and may eventually be transferred to that genus.

With the removal of certain species, the sections within *Chaptalia* must be redefined. The controversial *C. hintonii*, which had been put in sect. *Chaptalia*, has already been excluded (Katinas 1998). Now it is necessary to study all the species of this genus to re-evaluate the traditional sections. For instance, the characters mentioned by Nesom defining section *Chaptalia* (monocephalous, ebracteate or few-bracted scapes, heads nodding in bud, broad, cream coloured rays with a purple midstripe, and funcionally staminate disc flowers) are present also in species belonging to other sections established by Burkart (1944), e.g., *C. denticulata* from Brazil (sect. Archichaptalia), *C. meridensis* from Venezuela (sect. Archichaptalia), *C. paramensis* from Colombia.

I agree with Nesom that *Chaptalia* is a natural group, although I disagree that the cypsela vestiture and nodding buds give coherence to the genus. The basic twin hairs differentiate *Chaptalia* and other taxa of the *Gerbera*-complex only to some degree, whereas nodding buds are not present in many species of *Chaptalia* (e.g., *C. dentata*, *C. exscapa*, *C. mandonii*, *C. piloselloides*, *C. runcinata*). The corolla morphology of the inner ray florets, on the other hand, seem to be the most consistent, apomorphic character for circumscribing the genus. The lack of staminodes, a condition found also (though uncommonly) in *Gerbera*, can also help to circumscribe *Chaptalia*.

In contrast, *Gerbera* has proved to be a non monophyletic genus (Hansen 1990). This situation and the potential addition of species from *Chaptalia* makes it necessary to completely revise the genus. For this reason, it is premature to consider if *Gerbera* could be splited in new, small, genera. I believe that at least some genera of the *Gerbera*-complex have characters that allow them to be mantained as independent taxa within the complex, i.e., the parallel-nerved leaves of *Lulia*, the long, filiform twin hairs on the cypselas of *Uechtritzia*, the alternating plant phases of *Leibnitzia*, and the morphology of the inner ray corollas of *Chaptalia*.

Finally, I conclude that the characters exhibited by *Gerbera hintonii*, i.e., bilabiate inner ray florets with corollas surpassing the style, and vestigial staminodes provide good support for positioning it in *Gerbera* rather than in *Chaptalia*.

ACKNOWLEDGMENTS

I thank Guy L. Nesom for access to his manuscript and for insightful comments during my work in this group of plants. I also thank Jorge V. Crisci and Bob Kowal for critical reading of this response. Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET) and the National Geographic Society (Grant n. 5776-96) are also acknowledged.

RESPONSE TO "THE *GERBERA* COMPLEX (ASTERACEAE: MUTISIEAE): TO SPLIT OR NOT TO SPLIT" BY LILIANA KATINAS

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

My view is that *Chaptalia hintonii* is artificially segregated from sect. *Chaptalia*, removed from its relatives *C. lyratifolia*, *C. hidalgoensis*, *C. mexicana*, and *C. estribensis*, which appear to me as inseparably close in both geography and morphology. *Chaptalia pringlei* (also of sect. *Chaptalia* in my treatment) has only two whorls of florets (completely lacking an inner series of pistillate florets with reduced corollas) and apparently also would be rejected from *Chaptalia*, following couplet 6 in Katinas's provisional key to genera of the *Gerbera*-complex. Only two other species are in sect. *Chaptalia*: the generitype *C. tomentosa*, and its putative sister species *C. madrensis*, both of which share significant features with the other six. The few South American species sharing morphological features characteristic of sect. *Chaptalia* are reasonably suspected of relationship with North American sect. *Chaptalia* as much as with South American groups that Burkart and others have hypothesized.

Katinas notes that the transfer of *Chaptalia hintonii* was but the first step in adjusting various taxonomic boundaries within the *Gerbera*-complex. She has "found ca. 15 species included in *Chaptalia* that are best excluded from this genus (Katinas, in prep.), some of which probably are better placed within *Gerbera*" (p. 000). Presumably none of these 15 is among the other seven of sect. *Chaptalia* as I have recognized it. Perhaps some of them are in *Chaptalia* sect. *Lieberkuhna* (sensu stricto, incl. *C. graminifolia*, *C. mandonii*, *C. piloselloides*, and *C. runcinata*) and sect. *Loxodon* (*C. exscapa*) as Katinas's key (couplet 3) appears to corroborate my observation that those sections (combined) might be segregated at generic rank—plants of these species are "dimorphic," alternately producing chasmogamous and cleistogamous heads, similar to those in the genus *Leibnitizia*. The first lead of couplet 3, however, separates only *Leibnitzia*, suggesting that this aspect of biology in the *Lieberkuhna* and *Loxodon* species is not given the same taxonomic weight (or does it imply that she views *Lieberkuhna* and *Loxodon* potentially as members of *Liebnitizia*?).

With further consideration, Katinas concludes that morphology of the inner pistillate florets is "the most consistent, apomorphic character for circumscribing [*Chaptalia*]," i.e., for distinguishing it from *Gerbera*, lack of staminodes of lesser significance. She observes that *C. hintonii* has the relatively "longer, more developed corolla" (as does *C. tomentosa*, where mixed with shorter ones) more characteristic of *Gerbera* (she also notes that only part of *Gerbera* has three types of florets, while the other part has two types). But if these inner pistillate corollas show features of developmental intermediacy between the inner, bisexual florets and the outer, ligulate pistillate florets (as noted in my earlier comments), more pronounced development of corolla lips would not be unexpected, nor would the occurrence of staminodes. In any case, hypotheses of homology in these variable features in species groups on different continents seem tenuous, especially when they play a significant role in decisions affecting generic status.

Apart from geographic and morphological evidence, what is gained by transferring *Chaptalia hintonii* or any species of *Chaptalia* to "*Gerbera*," when it is explicitly recognized that *Gerbera* is "non monophyletic," "necessary to completely revise," and has at least the possibility that it "could be split in new, small genera"? *Chaptalia hintonii* apparently is positioned by Katinas within *Gerbera* in the area of infrageneric groups that do not include *Gerbera* sensu stricto, suggesting that the species probably would soon be transferred again to some other genus. Of course, this is only a tangential comment, as evidence indicates to me that the closest relationship of *C. hintonii* is with sect. *Chaptalia*.

DESCRIPTION OF ASEXUAL REPRODUCTION IN A TEXAS SUCCULENT *SEDUM WRIGHTII* (CRASSULACEAE)

ABSTRACT

Sedum wrightii A. Gray, a west Texas native succulent, is one of a growing number of species known to reproduce by vegetative means. Detached leaves of *S. wrightii* produce plantlets on the basal portion of the adult leaf in association with callus tissue from what appears to be thinned-walled parenchyma and epidermal cells of the petiole. Shoot primordia appear first, emerging over lateral regions of the callus tissue by about day 5, with the roots emerging several days later.

RESUMEN

Sedum wrightii A. Gray, planta suculenta nativa de Texas, pertenece al creciente grupo de especies conocidas que se reproducen vegetativamente. Las hojas arrancadas de *S. wrightii* producen plántulas en la porción basal de la hoja adulta, en asociación con callo de lo que parece ser parénquima de paredes finas y células epidérmicas del pecíolo. Primero aparecen los primordios del vástago, emergiendo de las regiones laterales del callo sobre el quinto día, y las raíces emergen varios días más tarde.

INTRODUCTION

Survival of seeds and seedlings in shallow soils of rock outcrops (Sharitz & McCormick 1973) and on the desert soil surface is poor (Jordan & Nobel 1981), resulting in low sexual reproductive success and limiting the establishment of many desert perennials to certain favorable years. The development of young plantlets from vegetative buds borne on a parent plant, or on detached leaves occurs in several groups of plants including *Sedum*, *Bryophyllum* and *Crassula*, either normally or upon wounding (Stoudt 1934, 1938; Yarbrough 1934, 1936; McVeigh 1938). The propagative capacity of species of these genera have interested botanists, and its advantages have been exploited by horticulturists.

The development of plantlets from leaves is an efficient mechanism of vegetative reproduction in many plant families. These vegetative plantlets may be more successful than seedlings because of several factors, including greater water and carbon reserves (Holthe & Szarek 1985). In an examination of *Sedum wrightii* A. Gray, Clausen (1975) noted that after 11 weeks, 82% of detached leaves developed plantlets, each with a small rosette of leaves and well-developed roots. A later study (Gravatt 2003) showed that the additional source of water and

SIDA 21(2): 943–950. 2004

carbohydrates reserves, over an extended period provided by the detached leaf, was an added benefit for the developing propagule. By day 120 of the experiment, detached leaves remained physiologically active, whereas the propagules maintained constant growth. For succulents such as *S. wrightii*, drought survival of propagules may be determined by the amount of water-storing tissue in the detached leaf.

Gravatt (2003) found that detached leaves of *S. wrightii* readily developed propagules at the base of the leaves. Each propagule develops 2 to 3 roots and a small rosette of 3 to 5 leaves. By the end of the experiment nearly 80% (98% of surviving leaves) of the detached leaves had developed propagules. The morphological events associated with asexual reproduction in *S. wrightii* have not been previously characterized. The purpose of this investigation is to describe the development of young propagules from basal callus tissue of detached, adult leaves in this species using scanning electron microscopy.

MATERIALS AND METHODS

Sedum wrightii is a leaf-succulent perennial occurring in the semi-deserts of the southwestern USA and Mexico. Plants were collected on the limestone cliffs overlooking the Devils Arm of the Amistad Reservoir, Val Verde County, Texas at an elevation of 360 m in August 2001. Plants were potted in soil sand: perlite: topsoil (3 : 3 : 3) using plastic pots (10×10 cm) and placed in a plant growth chamber. Environmental conditions were as follows: photosynthetic photon flux density (PPFD) of 900 μmol $m^{-2} s^{-1}$, 25(±1) °C air temperature, and 1.9(±0.2) kPa vapor pressure deficit (vpd) during the day, and 20(±1) °C air temperature and 1.5(±0.2) kPa vpd at night. Environmental conditions were measured using an ADC (Hertfordshire, England) LCA4 CO_2 and H_2O analyzer. After transplanting, plants were kept well-watered and fertilized biweekly with 0.5-strength Peters Professional fertilizer (W.R. Grace and Co., Fogelsville, PA, USA) with trace elements, 15% each of total N, K_2PO_5, and K_2O.

Plants were allowed to grow until mature, as indicated by the presence of floral buds. A voucher specimen (*Gravatt s.n.*) was deposited in the Stephen F. Austin State University Herbarium (ASTC). Leaves were detached from whole plants ("parent leaves") and were placed on moist vermiculite in plastic pots (10×15 cm) and sampled on days 0, 1, 2, 5, 8, 10, and 14. The vermiculite was kept moist in the growth chamber for the duration of the experiment. Environmental conditions inside the chamber were the same as those described for the whole plants.

On each of the sampling days the basal third of *S. wrightii* leaves were excised using a razor blade, fixed in a 1:1 mixture of glutaraldehyde (5%) and 0.1M potassium phosphate buffer and refrigerated overnight. The specimens were rinsed in deionized water and dehydrated in a graded ethanol series to 100%

ethanol (Mims 1981). The leaf pieces were then critical point dried with carbon dioxide as the transitional fluid, mounted on aluminum stubs, and sputter coated with gold or gold-palladium. Basal ends of leaves were examined using a Hitachi S-405A scanning electron microscope operating at 15 KeV.

RESULTS

The leaves of *Sedum wrightii* are spirally arranged, elliptical or oblong and glabrous. Adult leaves are 8 to 12 mm long, 3.5 to 4.5 mm wide, and 1.5 to 2.5 mm thick. Petioles are much reduced, such that they give the appearance of the leaf being nearly sessile. Preliminary findings determined that leaves of *S. wrightii* contain a single leaf trace. The petioles are very brittle, so that the leaves fall from the stem with only slight pressure and take root from the base of the leaf, forming a new plant (Fig. 1).

Scanning electron microscopic examination of the basal portion of parent leaves revealed the sequence of events associated with propagule formation. After detachment from the stem, vascular tissue and the surrounding parenchyma, as well as the epidermis of the petiole can be seen (Fig. 2). Detached leaves lying on moist vermiculite showed signs of wound tissue formation after 24 hours (Fig. 3).

Within 48 to 60 hours, a cicatrate (scar left by a wound or by abscission) meristem forms at the base of the leaf under the region of the leaf trace. The cells of the wounded surface soon collapse, and the cells underneath these divide in a plane parallel to the surface. A small protuberance, visible under a binocular microscope, appears near the region of the petiole of the parent leaf by the second or third day. This region is identified as the zone of shoot emergence in Figure 3.

When detached leaves are maintained on moist vermiculite, young shoots typically emerge from the callus tissue after five to seven days (Fig. 4). The earliest observed emergence of shoots was three days, with the latest recorded emergence at ten days. The shoot primordium arises on the lateral surface of the callus tissue. The shoot apparently originates from peripheral tissue of the petiole, at the base of the leaf, not previously covered by callus. A single shoot arises by day 5, with two primordial leaves easily identifiable (Fig. 4).

The origination of root primordia within the callus tissue follows emergence of leaf primordia and usually occurs by the eighth day (Figs. 5 & 6). Thus, the development of growing points is as follows: callus tissue forms; the shoot appears before the root; and the roots appear as single root or in pairs.

Several root primordia may be organized within a given callus tissue (Fig 6), so that by day 14 the parent leaf may have three to four adventitious roots. The development of root hairs can be seen on leaves kept on moist vermiculite by about day 14 (Fig. 7).

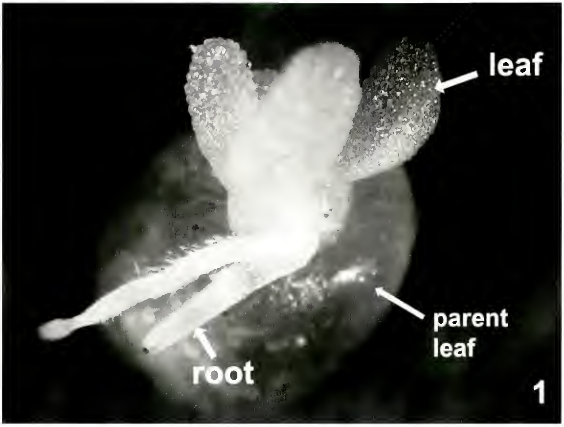

Fig. 1. Stereomicroscope image of *Sedum wrightii* leaf base with 14-day-old propagule (~30×).

DISCUSSION

In an earlier study, Gravatt (2003) found that after 11 weeks, 82% of detached leaves developed plantlets, each with a small rosette of leaves and well-developed roots. Furthermore, detached leaves survived for 120 d with a high rate of success for propagule formation, 89% of leaves from the start of the experiment (Gravatt 2003).

Scanning electron microscopic examination of the basal portion of parent leaves revealed a sequence of events associated with propagule formation comparable to that reported in *Crassula multicava* (McVeigh 1938), *Sedum stahlii* (Yarbrough 1936), and *Graptopetalum* (Green & Brooks 1978). The basipetal meristematic activity appears to link the propagule with the vascular system, as found in previous studies (McVeigh 1938; Yarbrough 1936; Green & Brooks 1978). Thus, the propagule is linked with the parent leaf for food and water reserves (see Fig. 4), allowing survival of the young plant (Gravatt 2003).

The origination of root primordia within the callus tissue follows emergence of leaf primordia and usually occurs by the eighth day (Figs. 5 & 6). These findings are in contrast to those found by Yarbrough (1936), who observed a different order of development for roots and shoots. In his study, detached leaves

of *S. stahlii*, left on a dry surface, gave rise to roots first and then shoots. Yarbrough (1936) further observed that in a moist chamber, as used in this study, shoots were not formed and roots only appeared occasionally.

Yarbrough (1936) concluded that production of roots and shoots from leaves of *Sedum stahlii*, which at the time of detachment clearly possess no residual meristem, clearly is an example of regeneration through the formation of adventitious structures. He further stated that the formation of callus tissue by the thinned-walled parenchyma cells of the short petiole involves differentiation. In this study, it appears that this is the case for *Sedum wrightii* as well, and compares well with the findings of Yarbrough (1936). The continued mitotic activity of the cells surrounding the callus makes possible the development of two fundamental growing points, the root and shoot primordia, and the subsequent development of a new plant from the detached leaf.

ABSTRACT

A literature search was conducted to determine the medicinal legume trees found in Pakistan and used as remedies for various human disorders or diseases. The taxonomic position of these trees is discussed and their distribution is described to facilitate their collection. There are 40 medicinal, legume tree species belonging to 25 genera of Fabaceae (Leguminosae). Most of these medicinal legume trees belong to Caesalpinioideae (10 genera and 16 species) followed by Mimosoideae (7 genera and 14 species) and Papilionoideae (8 genera and 10 species). This constitutes about half of the Pakistani legume trees possessing medicinal properties used for various ailments. The plant parts used for medicinal purposes included bark, roots, stem, leaves, flowers, fruits and seeds. These medicinal trees have good vegetative growth under cultivated conditions and are in ample supply for commercial exploitation. There is potential for growing medicinal plants in Pakistan as an income generating activity and for sustainable utilization of these medicinal legume trees. However, there is a need for systematic cultivation, commercial extraction using scientific methods and sustainable conservation of endemic medicinal legume trees for substantial utilization through community participation.

RESUMEN

Se realizó una búsqueda bibliográfica para identificar los árboles medicinales de las leguminosas que se encuentran en Pakistán y se usan como medicina para varias enfermedades humanas. Se discute la posición taxonómica de estos árboles y se describe su distribución para facilitar su recolección. Hay 40 especies medicinales de leguminosas arbóreas, pertenecientes a 25 géneros de Fabaceae (Leguminosae). La mayoría de estas leguminosas arbóreas medicinales pertenecen a las Caesalpinioideae (10 géneros y 16 especies) seguidas de Mimosoideae (7 géneros y 14 especies) y Papilionoideae (8 géneros y 10 especies). Esto constituye cerca de la mitad de las leguminosas arbóreas pakistanís que tienen propiedades medicinales usadas para varios remedios. Las partes de la planta usadas con propósitos medicinales incluyen la corteza, raíces, tallos, hojas, flores, frutos y semillas Estos árboles medicinales tienen buen crecimiento vegetativo en condiciones de cultivo y tienen amplio abastecimiento para la explotación comercial. En Pakistán hay potencial para el incremento de las plantas medicinales como actividad generadora de recursos económicos y para uso medicinal sostenible de estas leguminosas arbóreas. Pero, se necesita un cultivo sistemático, extracción comercial mediante métodos científicos y conservación sostenible de leguminosas arbóreas medicinales endémicas para una utilización importante mediante participación de la comunidad.

SIDA 21(2): 951–962. 2004

INTRODUCTION

Fabaceae (Leguminosae) is the third largest family of flowering plants comprising of 750 genera and 20,000 species with worldwide distribution (Sprent 2001). In Pakistan legumes form a considerable portion of the flora and are the third largest family in order of abundance (Kirkbride 1986). Ali (1973a, b; 1977) reported 107 genera and 539 species of legumes from Pakistan of which 68 genera have one or more native species (Kirkbride 1986). There are about 82 legume trees in Pakistan of which 27 tree species belong to Caesalpinioideae, 36 to Mimosoideae and 19 to Papilionoideae (Ali 1973a, b; 1977). These trees have considerable significance as source of timber, lumber and fire wood. They are also used as ornamental and shade trees in gardens, orchards and roadside plantations (Malik & Farooq 1984).

Classification of medicinal plants is organized in different ways depending on the criteria used. In general, medicinal plants are arranged according to their active principles in their storage organs, particularly roots, leaves, flowers, seeds and other plant parts (Athar & Nasir 2004; Athar & Siddiqi 2004; Foster & Duke 1990; Moerman 1986, 1991, 1996; Shaheen et al. 2003). These principles are valuable to human for treatment of different diseases (Borchers et al. 2000; Duke 1997; Shaheen et al. 2003; Shinwari & Khan 1998). Reports on the classification of many Pakistani medicinal plants that could be used for remedies and medicinal preparations are sporadic or lacking (Athar & Nasir 2004; Athar & Siddiqi 2004; Durrani et al. 2003; Saeed et al. 2004). Athar and Siddiqi (2004) described the taxonomy, distribution and flowering period of 95 species used as medicinal flowers in Pakistan. In another study, Athar & Nasir (2004) described the taxonomy of 78 plant species yielding vegetable oil used in cosmetics and skin and body care products. This third publication in the series presents the taxonomy of medicinal legume trees of Pakistan and their regional distribution, and summarizes the utilized tree parts and their principal method of application for various ailments.

MATERIALS AND METHODS

A literature search was conducted to determine the legume trees of Pakistan that are used as remedies for various disorders or diseases (Allen & Allen 1981; Athar & Siddiqi 2004; Bach 1994; Baquar 1989; Borchers et al. 2000; Duke 1997; Gunasena & Hughes 2000; Malik & Farooq 1984; Nasir & Rafiq 1995; Palaniswamy 2003; Rasool 1998; Rizvi 1998; Said 1969; Shaheen et al. 2003; Shinwari & Khan 1998; William & Ahmad 1999; Zaman & Khan 1970), and their taxonomic position was determined. The genera were arranged alphabetically within sub-families. The scientific and local names are provided that are commonly associated with these legume trees. Their distribution in various parts of Pakistan is also described to facilitate their collection. The nomenclature and classification followed Polhill and Raven (1994), and author citations followed Brummitt and Powell (1992).

RESULTS AND DISCUSSION

The taxonomic position of 40 species of medicinal legume trees is given in Table 1. These legume trees are distributed in 25 genera and all three sub-families of Fabaceae (Leguminosae). This constitutes about half of the Pakistani legume trees possessing medicinal properties used for various ailments. The list is comprehensive, yet not complete as more tree species could be investigated and added to the list. Most of these medicinal legume trees belong to Caesalpinioideae (10 genera and 16 species) followed by Mimosoideae (7 genera and 14 species) and Papilionoideae (8 genera and 10 species). The plant parts used for medicinal purposes included bark, roots, stem, leaves, flowers, fruits and seeds. Table 1 summarizes the ailments, tree parts and principal methods of application. Specific prescriptions, such as dosage and frequency, are not given, as these are rarely specified in literature and can vary considerably among users according to the recipe. Moreover, the table does not rank the order of the species importance as a medicinal source for the ailments, though this can be found in Hamdard Pharmacopoeia of Eastern Medicine (Said 1969).

Legume trees are amazing natural resources. These trees provide wood for home building, packaging that keeps food fresh during shipment, and natural products like cellulose that are found in everything from the instant soup that we eat to the fabrics that we wear. Legume trees give us food, fodder, fabric, furniture, fatty acids, oils, tannins, gums, medicines, even cosmetics (Allen & Allen 1981), and the list goes on and on expanding to their nitrogen-fixing properties (Allen & Allen 1981; Sprent 2001; Subba Rao & Rodriguez-Barrueco 1993). We get food, clothing and shelter from legume trees all in one environmentally friendly package. Essential oils have been extracted from legume trees for many years for their healing and nurturing properties (Athar & Nasir 2004). Today we use these same essential oils in aromatherapy to promote health, well-being and balance in body, mind and spirit. These plants are ever lasting, easily available and centuries old, tested sources for healing various ailments (Athar & Siddiqi 2004; Athar & Nasir 2004).

An estimated 80% of the rural population in Pakistan depends on traditional medicines for their primary healthcare needs using legumes and other plants or their active principles (William & Ahmad 1999). By trial and error, these people have learnt to employ certain plants, plant parts and extracts to cure diseases and ailments. In this context, certain legume trees also merit consideration for their therapeutic properties, which are being commercialized. It is worth mentioning that nomadic people and rural populations are much more familiar with the use of medicinal plants as compared to people living in the

TABLE 1. Taxonomy, distribution and medicinal uses of legume trees in Pakistan.

Species	Local Name	English Name	Distribution	Medicinal Use
Fabaceae (Leguminosae) Caesalpinioideae				
Bauhinia purpurea L.	Kaliar	Purple Bauhinia	Grown in Punjab, NWFP, Rawalpindi	Flowers are used as purgative. Flowers and buds used for indigestion. Stem bark decoction used for body pain and fever. Paste from bark is given for cancerous growths in stomach.
Bauhinia semla Wunderlin	Kandla	Bauhinia	Jowlian Reserve, Rawalpindi, Hazara	Bark is astringent; used in diarrhea and dysentery. Decoction of leaf is used for headache and malaria.
Bauhinia variegata L.	Kachnar	Mountain ebony	Grown in gardens of Punjab and Sindh	Flowers are aperient.
Caesalpinia bonduc (L.) Roxb.	Fevernut	Gray nicker bean	Grown in gardens of Pakistan	Leaf decoction taken for asthma and mental distress; pulverized seed infusion taken for fever and intestinal worms.
Caesalpinia pulcherrima (L.) Sw.	Gul-e-mohur	Paradise flower	Grown in gardens of Pakistan	Root decoction used for fevers; flowers used for asthma and bronchitis and as anti-pyretic and expectorant.
Cassia fistula L.	Amaltas	Golden shower, Indian laburnum	Naturalized throughout Pakistan	Flowers used for cough, diphtheria, constipation and edema.
Ceratonia siliqua L.	Kharnub	Carob	Introduced and naturalized in Punjab, Islamabad and NWFP	The pods are astringent and are used for coughs. Seed husk is astringent and purgative.
Chamaecrista absus (L.) H.S. Irwin & Barneby	Chasku	Cassia	Wild in open places in NWFP and Punjab	Seeds used for skin diseases.
Delonix regia (Bojer ex Hook.) Raf.	Gulmohar	Peacock flower	Planted in Karachi, Hyderabad and Lahore	Leaf decoction taken for constipation. Flowers are anthelmintic.

Table 1. continued

Species	Local Name	English Name	Distribution	Medicinal Use
Parkinsonia aculeata L.	Valaiti kikar	Jerusalem-thorn	Planted in Sindh, Karachi, Hyderabad, Punjab and Lahore	Leaf, fruit and stem decoctions taken for fever and also are abortive. Flowers and leaf poultice used for rheumatism.
Saraca indica L.	Ashok	Ashok tree	Cultivated in gardens in Punjab and Sindh	Bark is astringent; used in menorrhoea and uterine infections; also used for scorpion-sting.
Senna alata (L.) Roxb.	Dadmurdan	Ringworm cassia	Sometimes cultivated in Pakistan	Flowers are laxative and also useful for softening skin.
Senna alexandrina Mill.	Sennahindi	Indian senna	Wild in Punjab and Sindh	Stem, pods and leaves are useful in habitual costiveness. These lower bowels, increases peristaltic movements of the colon by its local action upon the intestinal wall. Plant is used as expectorant, wound dresser, antidysentric, carminative and laxative.
Senna italica Mill.	Kasordhi	Senna	Found in Punjab and Sindh	Plant useful for malaria and constipation. Pods used as laxative and seed for stomachace.
Senna siamea (Lam.) H.S. Irwin & Barneby	Kasood tree	Siamese shower	Cultivated in Karachi, Sindh	Flowers used as anthelmintic, anti-hypertensive, laxative, tranquilizer and sedative and for asthma, dandruff and insomnia.
Tamarindus indica L.	Imli	Tamarind	Grown in Sindh, Punjab, Jehlum, Karachi	Leaf decoction taken for throat infection, intestinal worms and liver ailments. Flowers used as anti-viral against new castle disease virus and are astringent and sedative. Fruits used for loss of appetite, constipation and rheumatism.

Table 1. continued

Species	Local Name	English Name	Distribution	Medicinal Use
Fabaceae (Leguminosae) Mimosoideae				
Acacia catechu (L.f.) Willd.	Khair, Katha	Black cutch	Distributed in the foothill zone of NWFP and Punjab	Bark is astringent. Root is made into paste and applied on joints for rheumatism.
Acacia farnesiana (L.) Willd.	Kabuli kikar	Sweet acacia	Grows in Sindh, Karachi, Punjab	Leaves used for fever, typhus, tuberculosis, gangrene, bladder infection and wounds; flower tea used for stomachache; crushed fruit juice used for diarrhea and eye and throat infections.
Acacia nilotica (L.) Delile	Kikar	Gum-arabic	Found in Sindh, Punjab, Baluchistan, NWFP	Flowers used for jaundice and palpitation. Leaf juice is taken with fennel for bloody dysentery. Powdered bark given for acute diarrhea. Extracts from root and bark are used as taenifuge, and gum is used as emollient.
Acacia senegal (L.) Willd.	Khor	Gum-arabic acacia	Karachi, Sindh, Balochsitan	Gum demulcent and emollient used internally for intestinal mucosa and externally applied on inflammations
Adenanthera pavonina L.	Barighumchi	Bead tree	Grown in Sindh, Karachi	Wood extract used for migraine and headache; bark and leaf decoction for diarrhea, dysentery and tonsillitis.
Albizia chinensis (Osbeck) Merr.	Ohi		Sub-Himalayan tract, Punjab	Infusion of the bark used as lotion for cuts, scabies and skin diseases.
Albizia julibrissin Durazz.	Ghulabi siris	Silk tree	Outer Himalayan zone	Flowers used for mild constipation, boils, carbuncles and swelling.

TABLE 1. continued

Species	Local Name	English Name	Distribution	Medicinal Use
Albizia lebbeck (L.) Benth.	Siris	Lebbek tree	Found in Sindh, Punjab, Bajaur, Malakand	Similar to *Albizia julibrissin*.
Albizia procera (Roxb.) Benth.	Sufaid-Siris	Lebbek tree	Cultivated and naturalized, Sindh, Karachi, Hasanabdal, Mirpur	Leaves used as poultice on ulcer. Plant has insecticidal properties.
Leucaena leucocephala (Lam.) de Wit	Ipil-Ipil	Ipil-Ipil	Introduced in Sindh, Punjab, NWFP	Root decoction taken for fever; leaf tea taken for typhoid and digestive tract ailment; root and twig decoction used for severe back pain; root and bark are abortive.
Pithecellobium dulce (Roxb.) Benth.	Jungle Jaleebi	Blackbead	Found in Sindh and Karachi	Root bark decoction taken for dysentery; leaf used for indigestion; leaf poultice used for convulsions, venereal lesions and pain; fruit pulp used for hemoptysis; seed used for nasal congestion and internal ulcer.
Prosopis cineraria (L.) Druce	Jhand	Mesquite	Found in Sindh, Baluchistan and Punjab	Flowers are beneficial against miscarriage.
Prospis juliflora (Sw.) DC.	Jhand	Mesquite	Found in Sindh, Baluchistan and Punjab	Eye drops made from leaf juice or cooked leaves and applied or taken orally for eye infections. Gum exudates from trunk used for colds and flu. Fresh root taken orally for diarrhea. Bark and fruit decoction taken for bronchial infection and sinus congestion.

Table 1. continued

Species	Local Name	English Name	Distribution	Medicinal Use
Samanea saman (Jacq.) Merr.	Siris	Lebbek tree	Grown in Sindh, Karachi	Fruit decoction used for anxiety, nervousness; fruit ingested for dysentery and hemorrhage; leaf tea or infusion used for constipation; seed chewed for throat infection.
Fabaceae (Leguminosae) Papilionoideae				
Butea monosperma (Lam.) Taub.	Dhak	Flame of the forest, Bengal Kino	Cultivated in Punjab and NWFP, sporadic in Rawalpindi district	Anti-pyretic, appetizer, aphrodisiac, blood purifier, diuretic, tonic, viral hepatitis. Seed is anthelmintic. Gum is astringent, used in diarrhea and dysentery. Leaves are tonic, astringent; flowers are astringent, diuretic, depurative and aphrodisiac. Bark and seeds are used for snakebites.
Dalbergia sissoo Roxb. ex DC.	Shisham	Sissoo	Widely distributed in Punjab, Sindh and NWFP	Leaves are bitter and stimulant; decoction is used in gonorrhea; root is astringent. Wood is also used in leprosy, boils, eruptions and to stop vomiting.
Erythrina stricta Roxb. var. *suberosa* (Roxb.) Niyomdham	Dhauldak	Coral tree	Sadiqpur Hills, Murree Road, Mirpur	The bark is laxative, diuretic, emmenagogue, expectorant, anthelmintic antibilious and febrifuge, and the decoction is given for dysentery and as a vermifuge and is effective as an eye lotion in ophthalmia. Leaves are anthelmintic, cathartic, glalactagogue and discutient. Leaf juice used externally as a dressing for ulcers and for killing maggots in sores.
Erythrina variegata L.	Pangar	Variegated coral tree	Cultivated as road side tree	Leaves contain a mixture of alkaloid, hyaphorine is present in leaves, seeds and bark. Apart from hyaphorine, betaine and choline are also found.

Table 1. continued

Species	Local Name	English Name	Distribution	Medicinal Use
Gliricidia sepium (Jacq.) Kunth ex Walp.	Sapium/Lal Tali	Madre tree	Only at experimental stations at Karachi and Islamabad	Leaf bath used for fever pain; leaf tea used for sinus inflammation and gonorrhea; root tea used for kidney ailments, edema and hepatitis; leaf poultice used for skin diseases and wounds.
Millettia pinnata (L.) Panigrahi	Karanja	Pongam	Cultivated in Sindh, Punjab	Flowers are used for diabetes.
Ougeinia oojeinensis (Roxb.) Hochr.	Sandan	Sandan	Cultivated in Punjab Gardens; Mirpur east (Sub-Himalayan tract)	The bark is febrifuge. The exudation obtained after incision is used in dysentery and diarrhea. The decoction is given to patients having highly colored urine; also used as fish poison.
Peltophorum pterocarpum (DC) Backer ex K. Heyne	Peela Gulmohar	Copperpod tree	Cultivated in Punjab as road side plantation	In traditional medicine, the bark used in various preparations as a tonic or as a astringent to cure or relieve intestinal disorders like constipation and ringworms, afterpain at childbirth, sprains, bruises and swellings, or as a lotion of eye troubles, muscular pains and sores. Leaves in form of decoction used to wash unhealthy skin.
Sesbania grandiflora (L.) Pers.	Bansa	Sesbania	Planted in Karachi, Kutch, Sindh, Punjab	Root paste used for rheumatism; root resin used for phlegm; bark decoction used for fever and diabetes; flower juice improves vision (as eye drops).
Sesbania sesban (L.) Merr.	Janter	Sesbania	Cultivated in Sindh, Punjab	Leaf compress applied to infected areas for suppuration. Anti-fertility activity of flowers also reported.

cities (Durrani et al. 2003; Saeed et al. 2004; William & Ahmad 1999). It is interesting to note that elderly people, particularly women, were more aware of the value of the medicinal flora than younger generations. Nomadic people and rural populations depend upon legume trees not only as medicinal plants but also for fuel wood and fodder and forage for their livestock. Some of the medicinally important plants are over-harvested due to their extensive use, which may lead to their extinction. Overgrazing and cutting of legume trees for fuel wood and commercial exploitation has also resulted in reduced vegetation cover, promoted soil erosion and deterioration of Pakistani rangelands. However, legume trees cultivated in the gardens, parks, and roadside and riparian plantations in Sindh and Punjab have good vegetative growth and are in ample supply for commercial exploitation.

Pakistan has the potential for sustainable utilization of its medicinal legume trees, and mainly exports crude plant materials that have a low value in the international market (Shaheen et al. 2003). On the other hand countries like China and India export value-added plant extracts standardized on the basis of their active ingredients. There is enormous price difference between crude plant material and properly processed plant extracts. Moreover, developed countries do not allow the import of unprocessed raw plant material due to rigorous phytosanitary regulations (Crockett & Khan 2003; FAH 2003). It is therefore important that Pakistani producers and traders of medicinal plants should consider adding value to their exports by carrying out the initial processing and quality evaluation in Pakistan. However, attention needs to be paid to the systematic cultivation, scientific extraction and sustainable conservation of endemic medicinal legume trees for substantial utilization through community participation.

A team from the Pakistan Forestry Institute, Peshawar has carried out an ethnobotanical study in northern areas of Pakistan (Rasool 1998). This study identified economically valuable trees that can be collected from the wild and medicinal plants that can be grown commercially on common or agricultural land. Several species are no longer found in the area, including *Taxus baccata*, the source of the anti-cancer agent Taxol. There is potential for cultivating medicinal plants as an income-generating activity (Athar & Nasir 2004; Athar & Siddiqi 2004). Further research should be carried out on the floristic composition of medicinal plants and the present status of medicinal cum economic plants, including their market potential within the country and in the international market. The study should also look at the prospects for conserving endemic medicinal and economic species for sustainable use through community participation.

ACKNOWLEDGMENTS

Special gratitude is expressed to Joseph H. Kirkbride, USDA, Agricultural Research Service, Beltsville, MD, for his help in checking the nomenclature and taxonomy of the plants and M. Akmal Siddiqi, Marshfield Clinic Research Foundation, Marshfield, WI, USA for valuable suggestions and helpful criticism on the manuscript. The authors are also grateful to M. Iqbal Choudhary, H. E. J. Research Institute of Chemistry, University of Karachi, Karachi, Pakistan for providing many original reprints used in the preparation of this paper.

ABOUT 450 MILES UP THE RED RIVER IN A LARGE PRAIRIE: PETER CUSTIS' SURVIVING BOTANICAL INFORMATION FROM THE RED RIVER EXPEDITION OF 1806

Michael H. MacRoberts and Barbara R. MacRoberts

Bog Research, 740 Columbia

Herbarium, Museum of Life Sciences and Red River Watershed Management Institute
Louisiana State University-Shreveport, Shreveport, Louisiana 71115, U.S.A.

ABSTRACT

In 1806 Peter Custis, botanist on the Red River Expedition, collected 26 plants mainly in the prairies in what is today Caddo and Bossier parishes, Louisiana. These were sent to Benjamin Smith Barton in Philadelphia. Two of the specimens are still in the Barton Herbarium. They are very unusual for the region today. We have looked for the other 24 specimens but without success. Those 24 specimens would certainly aid in understanding the ecology of the Red River area in 1806.

RESUMEN

En 1806 Peter Custis, botánico en la expedición del Red River, colectó 26 plantas principalmente el lo que hoy son los municipios de Caddo y Bossier, Louisiana. Fueron enviadas a Benjamin Smith Barton en Filadelfia. Dos de los especímenes están aún en el Barton Herbarium. Estas son muy raras en la región actualmente. Hemos buscado los otros 24 especímenes pero no hemos tenido éxito. Estos 24 especímenes ayudarían ciertamente a comprender la ecología del área del Red River en 1806.

INTRODUCTION

The first part of the title of this paper comes from an herbarium specimen label written by Benjamin Smith Barton for a plant collected by Peter Custis in 1806. The plant comes from "the forgotten expedition"—the ill-fated and suppressed Thomas Jefferson-sponsored 1806 Expedition to the Red River. This expedition was to have been a southern counterpart to the now famous Lewis and Clark expedition (Figs. 1, 2). The specimen, housed in the Barton Herbarium at the Academy of Natural Sciences, Philadelphia, is one of three Peter Custis plant specimens there. It is one of two known surviving plants of 26 that were collected by Custis on the expedition.

This paper has a twofold purpose. First, it makes the Freeman and Custis Red River Expedition of 1806 and its botanical contribution more familiar. The year 2006 will mark the bicentennial of the first botanical expedition into what is now northwestern Louisiana, southwestern Arkansas, and northeastern Texas (Anon 1807). Second, we call attention to an additional 24 collections made by Peter Custis in 1806 on the Red River that are not housed in the Barton Herbarium. These specimens, the identity of which is not known, might be crucial to under-

standing floristic changes that have occurred in the Red River region over the past two centuries.

THE EXPEDITION

Louisiana was purchased from France in 1803. Thomas Jefferson sent probes into the newly acquired territory, the most notable of which was the Lewis and Clark expedition begun in 1804. Other expeditions soon followed: Dunbar and Hunter up the Ouachita, Pike up the Arkansas, and Freeman and Custis up the Red (Jackson 1981). This latter expedition was to skirt the Spanish/United States border, follow the Red River to its source, and test the Spanish resolve to prevent American western expansion.

The Red River expedition, unlike other expeditions, was clearly politically motivated but was disguised as scientific by the inclusion of a naturalist in the company. The purpose was to probe, none too delicately, the resistance of the Spanish beyond the as yet unsettled boundary between Louisiana and Mexico. Peter Custis, a young naturalist and medical student trained at that time by the most knowledgeable American botanist Benjamin Smith Barton, accompanied Thomas Freeman, a surveyor and astronomer and leader of the expedition, during the spring and summer of 1806. They were accompanied by 45 soldiers, interpreters, and guides on the Red River some 615 miles in search of its headwaters, then thought to be in the vicinity of Santa Fe. The expedition entered the Red River on May 2 and left Natchitoches, the northernmost post on the Red River, a month later. Soon after leaving Natchitoches, they encountered the lowest logjam of the Red River raft and had to divert their course to the bayous, "raftlakes," and sloughs that surrounded the River (Figs. 3, 4, 5) (Humphreys 1971; Flores 1984; Triska 1984; Bagur 2001). They reentered the main River just above present day Shreveport to find themselves unobstructed in a land of prairies, cedar forests, river bottomlands, and pine-oak-hickory bluffs and uplands.

The Spanish reaction was immediate and in force far beyond the modest Freeman party. The expedition was stopped on July 28 by Captain Don Francisco Viana and a force of between 200 and 300 mounted soldiers and infantry at a point near what is today Spanish Bluff in Bowie County, Texas, and turned back (Fig. 6). The Red River expedition was a political failure and an embarrassment to President Jefferson, who quietly suppressed it. Knowledge of the expedition was lost to history for almost 200 years. The Red River, north of Bowie County, remained virtually unexplored until the Marcy and McClellan Expedition of 1852, almost fifty years later (Marcy & McClellan 1854).

PETER CUSTIS AND THE BOTANICAL ASPECT OF THE EXPEDITION

Since Jefferson had received some criticism for not including a naturalist on the Lewis and Clark expedition, the Red River expedition was to be the first American-sponsored exploring expedition to include a trained naturalist. Presumably Barton, at the University of Pennsylvania at the time, selected the list of candidates, and Freeman made the final choice. The nod was given to the 25-year old medical student, Peter Custis of Virginia, who had entered the University of Pennsylvania as a medical student in 1804 and was about a year away from his degree. His background for the position consisted in having attended Barton's inclusive lectures on natural history. He had no field experience and was not considered a "naturalist" in any real sense of the word. On this expedition no provision was made for proper scientific preparation to preserve and send specimens to Barton. Consequently, Custis attempted to identify and describe in the field the plants he encountered either by familiarity or by reference to the few floras he took with him, one of which probably was Linnaeus's *Systema Vegetabilium*. As might be expected, there were names of many for-

Fig. 3. Raft with vegetation growing on it on Red River, 1873. Archives Department, Noel Memorial Library, Louisiana State University in Shreveport, Shreveport, Louisiana. R.B. Talfor photographer.

eign species contained in the list of about 190 plants that Custis described (Morton 1967; MacRoberts et al. 1997). Because Custis could not identify all of the plants to his satisfaction, he collected 26 and sent or took them to Philadelphia where two of them are known to survive in the Barton collection (Flores 1984). Custis listed these 26 plants separately in his report, most of which were collected in the extensive prairies that then existed north of present day Shreveport (Fig. 7).

Both Freeman and Custis sent regular reports to President Jefferson, the Secretary of War Henry Dearborn, and to Professor Barton. These were drawn together, and Nicholas King was given the task of redacting the accounts. His redaction was published in a very limited edition in 1807, of which only about a dozen copies survive as stated in an extensive account of this publication by Flores (1984). The King redaction has many errors and some omissions, which Flores (1984), using primary material, has corrected. The redaction in a partial facsimile edition has been reprinted (Adams 1985).

While some historians were aware of the expedition (e.g., Jackson 1981), it did not get full attention until Flores (1984) published his detailed account. In anthropological circles, the expedition was known because of its descriptions of Native Americans encountered above the Great Red River Raft (Morton 1967).

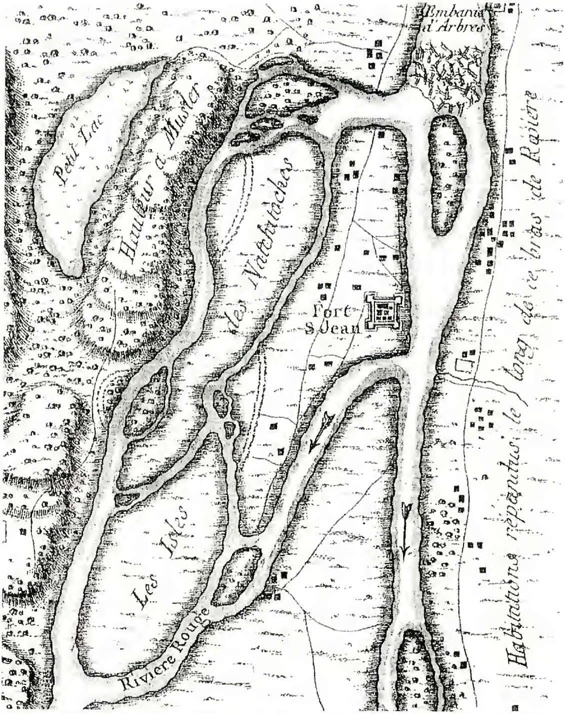

Fig. 4. Jacques Nicholas Bellin 1764 map of Natchitoches region of central Louisiana showing the lowest raft on the Red River in the 18th century. Archives Department, Noel Memorial Library, Louisiana State University in Shreveport, Shreveport, Louisiana.

In botanical, zoological, and ecological circles, the expedition remained unknown (e.g., McKelvey 1955; Ewan 1967; Sundell 1979; Lowery 1974a, 1974b). The expedition was unknown to Joseph Ewan (1952, 1969, 1988), Louisiana botanist and eminent historian of Bartonian Philadelphia. Morton (1967), using the

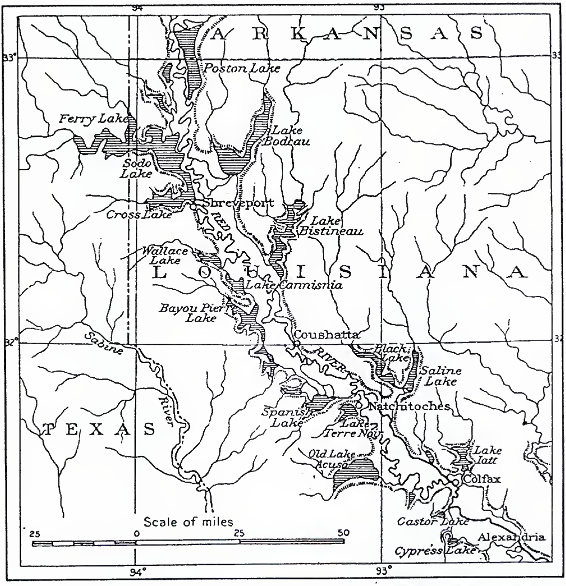

FIG. 5. Map of the "raft lakes" along the Red River created by overflow caused by the Raft. House Document 488, 59th Congress, 1st Session.

King redaction, published the first account of the plants observed by Custis. His aim was to interpret the Custis plant names and notes and provide modern identifications and nomenclature. Flores (1984) made the same attempt with the aid of Morton's (1967) paper. With the help of James Mears at the Academy of Natural Sciences in Philadelphia, Flores also located two of the Custis specimens and made photographic reproductions (Flores 1984:246–247). MacRoberts et al. (1997) reexamined the Custis accounts using, by that time, much better botanical information. Gilmore (2002) in his very important "Foundations of Southeastern Botany: An Annotated Bibliography of Southeastern American Botanical Explorers Prior to 1824" brought together the major works concerning the botanical aspects of the Freeman and Custis expedition. As Morton

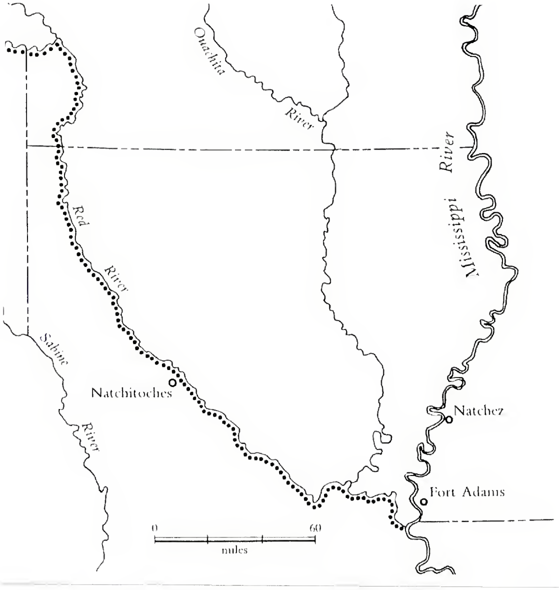

Fig. 6. Freeman-Custis route up the Red River. Modified from Jackson (1981, Fig. 10).

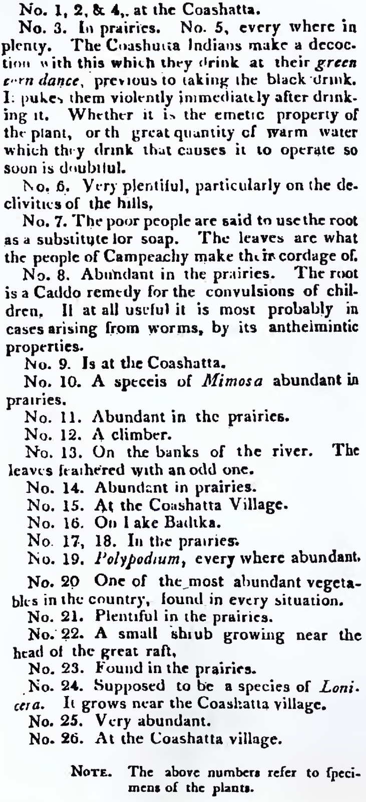
(1967) has rightly pointed out, the botanical part of the narrative is quite informative, being the first published information concerning the native plants of northwestern Louisiana and southwestern Arkansas, as well as the first descriptions of some of the plant communities, several of which have ceased to exist in the area, e.g., canebrakes, prairies, and cedar forests.

THE SPECIMENS

While it is possible to make informed guesses about the identity of the plants that Custis listed and described in his catalogues (Morton 1967; Flores 1984; MacRoberts et al. 1997), it is never possible to be certain without a specimen: thus the importance of the 26 plants collected by Custis that were forwarded to Barton.



No. 1, 2, & 4,. at the Coashatta.

No. 3. In prairies. No. 5, every where in plenty. The Coashutta Indians make a decoction with this which they drink at their *green corn dance*, previous to taking the black drink. It pukes them violently immediately after drinking it. Whether it is the emetic property of the plant, or the great quantity of warm water which they drink that causes it to operate so soon is doubtful.

No. 6. Very plentiful, particularly on the declivities of the hills,

No. 7. The poor people are said to use the root as a substitute for soap. The leaves are what the people of Campeachy make their cordage of.

No. 8. Abundant in the prairies. The root is a Caddo remedy for the convulsions of children. If at all useful it is most probably in cases arising from worms, by its anthelmintic properties.

No. 9. Is at the Coashatta.

No. 10. A speceis of *Mimosa* abundant in prairies.

No. 11. Abundant in the prairies.

No. 12. A climber.

No. 13. On the banks of the river. The leaves feathered with an odd one.

No. 14. Abundant in prairies.

No. 15. At the Coashatta Village.

No. 16. On Lake Badtka.

No. 17, 18. In the prairies.

No. 19. *Polypodium*, every where abundant.

No. 20 One of the most abundant vegetables in the country, found in every situation.

No. 21. Plentiful in the prairies.

No. 22. A small shrub growing near the head of the great raft,

No. 23. Found in the prairies.

No. 24. Supposed to be a species of *Lonicera*. It grows near the Coashatta village.

No. 25. Very abundant.

No. 26. At the Coashatta village.

Note. The above numbers refer to ſpecimens of the plants.

Fig. 7. Facsimile copy of the list of 26 plants collected by Custis from the King redaction of the Freeman-Custis reports.

The two known surviving specimens, which come from above the Great Raft in the prairies along the Red River, are unusual for the present flora. One, *Veronicastrum virginicum* (L.) Farw., is very rare, if extant, in Louisiana today, and the other, *Eustoma russellianum* (Hook.) G. Don, has never been found in the area since. What were the other "prairie" specimens collected by Custis; and, if they were extant, would it be possible to envision the type of prairie where they occurred? Unfortunately, the prairies from which these plants came have long ceased to exist and are now known only from old maps and place names (Fig. 8).

THE SEARCH

On June 12 and 13, 2003, we made a thorough search of all of the specimens in the Barton and Lambert Herbaria at the Academy of Natural Sciences in Philadelphia. The Barton Herbarium, kept separate at the Academy of Natural Sciences, consists of 1674 specimens originally housed at the American Philosophical Society but moved to the Academy in 1898 (Pennell 1926). It consists of many specimens only a few of which were collected by Barton himself. The majority were collected by Frederick Pursh (Barnhart 1926). Barton's collection was previously searched for the same material by James Mears in the early 1980's with the same idea in mind; he found both of the specimens mentioned above (Flores 1984). Our search located three Peter Custis specimens, the same two from the Red River and one apparently from Virginia. These three specimens may have been all that were there in 1926 when both Pennell (1926) and Barnhart (1926) examined the collections or they would have done more than very briefly mention Custis in their papers. We also examined the Aylmer Bourke Lambert collection, which is the remains of Lambert's large collection purchased by Edward Tuckerman and given to the Academy in 1842 (Miller 1970). It has a good deal of American material but no Custis collections. This leaves 24 specimens that have not been located.

We do not know what happened to the other 24 Custis specimens. We only know that two of them did get to Philadelphia, then the hub of American botany (Pennell 1950). If two did, then probably all of them did. If that is so, then, where are they now? It is unlikely they were discarded; collectors and curators prized their herbaria. But, the fragmentation and neglect of plant collections (including minimal labeling) in the early years of American botany is well known (Pennell 1950). For example, Frederick Pursh, Barton's part-time curator and collector between 1805 and 1809, took various specimens from the Barton collection, including a significant portion of the Lewis and Clark collection, first to New York and then to London, and many plants simply disappeared (Ewan 1952; McCourt & Spamer 2003). After Barton's death in 1815, his collections were warehoused for over 80 years at the American Philosophical Society before they were entrusted to the Academy of Natural Sciences (Mears 1981). Por-

tions of Pursh's collections that he took to England and left to Lambert were returned to the Academy in the mid-19th century (Miller 1970; Pennell 1950; McCourt & Spamer 2003). But as any browser of the *Index Herbariorum* learns, specimens collected by famous botanists are scattered worldwide. We would like to locate the missing specimens to better interpret the Red River ecology prior to the massive changes that occurred to the area during the subsequent two centuries.

ACKNOWLEDGMENTS

James Macklin, Lucinda McDade, Alfred Ernest Schuyler, and Earle Spamer, at the Academy of Natural Sciences, Philadelphia, aided with this study. Amanda Crnkovic, Jolene Long, Cran Lucas, Steve Lynch, and Glenda Sharbono, Louisiana State University in Shreveport, aided with the figures. Laura Conerly, Domenica Carriere, and Glenda Sharbono, Archives Department, Noel Memorial Library, Louisiana State University, aided with the maps. The research was partly supported by a J. Bennett Johnston Science Foundation Grant that Virginia Simons Lincove, Associate Vice Chancellor, Louisiana State University in Shreveport, was instrumental in securing for the research. Further support and assistance was provided by Gary Hanson and Patricia Peyton of the Red River Watershed Management Institute, Louisiana State University in Shreveport. Carolyn Harrington, Old Courthouse Museum, Natchitoches, Louisiana, allowed us to photograph the Custis specimens then on loan from the Academy of Natural Sciences, Philadelphia. Ron Looney, Clerk of Court Office, Caddo Parish, gave permission to photograph land plats. Reviews by Eric Sundell, University of Arkansas, Monticello, and Ronald L. Stuckey, Ohio State University, Columbus, are greatly appreciated.

Chapel Hill, North Carolina 27599-3280, U.S.A.

ABSTRACT

The Coker Arboretum at the University of North Carolina in Chapel Hill celebrated its centennial anniversary in the spring of 2003. The festivities began with a talk on botanist William C. Coker, which highlighted his humanistic traits. This paper briefly describes the events of the centennial celebration and provides the full text of the biographical presentation on Professor Coker.

RESUMEN

El Coker Arboretum en la Universidad de Carolina del Norte en Chapel Hill celebró su centenario en la primavera de 2003. Las festividades comenzaron con una charla sobre el botánico William C. Coker, que subrayó sus rasgos humanos. Este artículo describe brevemente los eventos de la celebración del centenario y aporta el texto completo de la presentación biográfica del Profesor Coker.

INTRODUCTION

William Chambers Coker (1872–1953) was a renowned botanist. His legacy includes important contributions in botany as well as in horticulture and landscaping. He arrived at the University of North Carolina at Chapel Hill in 1902 as the newly appointed associate professor of botany in the Department of Biology. When the Department of Botany was established in 1908, Coker became its first chair. He set forward two major objectives: to foster a knowledge and appreciation of nature among people and to advance the discipline of botany. Among Coker's lifelong scientific endeavors, mycology would occupy center stage and bring him international acclaim. Couch and Matthews (1954) described his life and scientific accomplishments.

Coker was regionally known for his expertise in planting trees in Chapel Hill and in landscaping school grounds. Among his efforts to beautify the UNC campus, he began in 1903 to develop a five-acre arboretum on the northeastern edge of campus (Fig. 1). Planting the site with trees, shrubs, and vines native in North Carolina, Coker envisioned the collection as a living laboratory for botany students. Later, he added Asian species of woody plants. Today, nearly 575 species of trees and shrubs provide an inviting refuge and a living tribute to Coker.

On the occasion of the centennial of the Coker Arboretum, the North Carolina Botanical Garden, the UNC Chapel Hill Libraries, and the Chapel Hill Museum hosted a series of events in the spring of 2003. From mid-March until mid-April, the UNC Libraries created several exhibits, all with a William Coker theme. The signature display was "W.C. Coker: Legacy of a Lifelong Botanist" (Fig. 2). On 11-12 April, a two-day celebration took place in Chapel Hill. On the morning of the first day, the staff of the UNC Herbarium presented a reception and gave tours of their facility. Noon-time tours of the arboretum were followed by a birthday party that drew a large group of attendees who watched several distinguished guests plant a seedling of *Crataegus marshallii*, one of Coker's favorites. Moving to the Morehead Planetarium, the group then listened to a number of distinguished speakers.

Later that day, the focus was the Chapel Hill Museum's exhibit "Coker Arboretum: The First Hundred Years." There, Mary Coker Joslin (Coker's niece) and illustrator Sandra Brooks Mathers signed copies of their book, *Essays on William Chambers Coker, Passionate Botanist* (Joslin 2003). Although Dr. Joslin had previously presented a talk on 20 March 2003 to mark the publication of the book, the signing was the official release date. Following this, Mary Jane and Woodrow Burns and Florence and James Peacock graciously opened their homes and gardens (formerly part of Coker's estate in Chapel Hill) with a reception. The first day of celebrations concluded with a formal dinner and a lecture. The next day, noted landscape gardener Chip Callaway entertained a large audience with the Evelyn McNeill Sims Native Plant Lecture entitled "North Carolina Natives—Gardeners and Their Gardens." To close the celebration, nearly 150 people enjoyed a luncheon at the North Carolina Botanical Garden. The festivities aptly commemorated not only the founding of the Coker Arboretum but also Coker's tangible record of service to the university and to botany.

The following commentary presents a humanistic view of William Chambers Coker, as related by Dr. Joslin at her 20 March talk. Filled with warmth, humor, and personal recollections of her uncle, the account provides a glimpse of Coker as a person.

WILLIAM CHAMBERS COKER, PASSIONATE BOTANIST

In these heartbreaking times of world violence and domestic threat to our environment, it is good to celebrate the contributions of someone who passionately loved our world, the real natural world, loved to learn of it, teach of it, and preserve it. It is also good for us to smile and laugh a little, which we may do in these next few minutes. Also, let's celebrate the first day of spring.

Thank you for allowing me to talk about William Chambers Coker (Fig. 3), lately one of my favorite subjects. My obsession with this topic has become so obvious that when I launch into an anecdote about him at a family meal, I hear comments like, "Oh, Oh! Uncle Will again." What a delight to have a captive au-

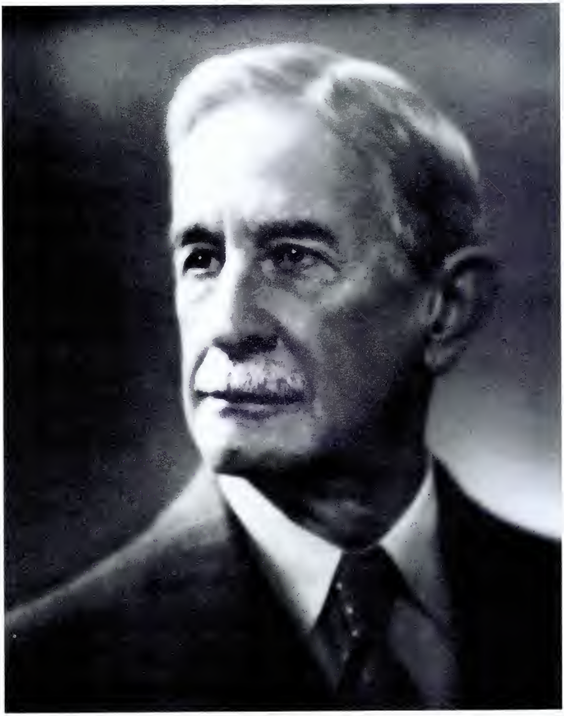

Fig. 3. William Chambers Coker, ca. 1940s. (Courtesy of the John N. Couch Biology Library, Botany Section, University of North Carolina, Chapel Hill).

dience this afternoon who will listen, I hope willingly, to a few stories about W.C. Coker, some of which are not recorded in our recently published *Essays on William Chambers Coker, Passionate Botanist* (Joslin 2003), where other tidbits may be found. Incidentally, I shall be referring to our subject in various ways according to context, using names such as William Chambers Coker, Will, Uncle Will, Professor Coker, Dr. Coker, etc. I hope this will be understandable and appropriate.

We South Carolinians have the reputation of idealizing selected ancestors or family members. I clearly remember an incident that lends some credence to that popular view. Some forty years ago, we were visiting my mother in Hartsville, South Carolina. Two of our young sons were bumbling about to the peril of various objects in their path. The younger child stopped, fixed his eyes on a somber portrait of my grandfather that hung over a fireplace. The artist had clothed him in a dark suit and posed him before an even darker background. His kindly face was bedecked with a flowing white beard. Our son grabbed his brother and asked, "Who is that?" Glancing up, the elder brother gave immediately what was for him a satisfactory answer before they dashed on: "Why that's God, I think."

True, my feelings toward my uncle, whom I knew and loved well, are tinted by admiration and affection. But maybe, even so, I can cast a realistic light on him. There was a real W.C. Coker; very human like ourselves. We need to remember this. His earthy humanity was a great part of his charm. One hundred and thirty years after his birth, Professor Coker has become an historic figure at the University of North Carolina, where he left his mark. What I hope to do today is to humanize him for you.

First, let's look at some of his character traits and then attempt to breathe life into them with anecdotes from family oral tradition and from my own memory's store. William C. Coker possessed a sense of humor that was quietly whimsical. He was brilliant, energetic, determined, tenacious, and even passionate in his work. He was a stickler for accuracy and he expected the same tenacity and accuracy of his students. In his determination to answer a botanical question, he went directly for it. He could ignore completely any inconvenience his floral quest might cause his colleagues, friends, or allies in the family. He took little note of the worldly rank of individuals on a societal scale. He was modest, even shy, not waiting for or even caring about recognition for his work. Rather, he directed his energies toward getting the work at hand done quickly and quietly and moving on to something else. He had no time or inclination to concentrate exclusively on the fields of botany in which he early became world-renowned, the Saprolegniaceae and the fleshy fungi. His interests were broader than these two fields. Nor did he have time regularly to attend meetings, where he would have periodically met with distinguished scholars and scientists.

Though he had no children of his own, he cared deeply about his greater family: his parents, aunts, uncles, cousins, siblings, nieces, and nephews. He was himself a poet and a collector of his favorite poet, Walt Whitman. He deeply appreciated natural beauty. He was a conservationist.

He was interested in literature and the visual arts. He had a good head for business. He was quietly generous. He had a succession of dogs and to each dog he gave his devoted affection.

Several anecdotes, which you may not yet have heard or read may serve to illustrate some of these character traits. Some are in our *Essays*; some are not. First, I will mention his whimsical sense of humor. Those of us who knew him remember his crooked smile and his chuckle, but no uproarious laughter. He could recognize his own foibles.

In recounting a rebellious incident of his early years, Uncle Will smiled at himself and at the same time paid tribute to the wisdom of his father. John Nathaniel Couch and Velma Matthews (1954), two of his former doctoral students, described one of their teacher's reminiscences. As there was no public school at the time, older children in Will's family were usually sent to live for a time with relatives in Society Hill, South Carolina, a community fifteen miles away. There, they prepared for a university education at Saint David's Academy, a good classical school incorporated in 1777 by the Saint David's Society of the Pee Dee River's Welsh Neck. Younger children were taught at home. There was for a time in Will's home in Hartsville, a live-in teacher from Virginia. Will recalled that in his early teens, he took a dislike to this inescapable lady under his roof. His reaction to her was so strong that he refused to pay attention to her instruction or even to do his assignments. The lady reported this rebellion to his father, who summoned Will and calmly offered him a choice: "Will, of course you may continue to pursue your studies respectfully, or, if you prefer, you may report at 6 A.M. tomorrow morning to our farm manager who needs your help in an area essential to our family's wellbeing." Will remained silent, but the next morning he reported for his studies and afterwards behaved himself.

Uncle Will had a way of softening a major personal loss with a whimsical comment. One summer, Professor Coker led a company of colleagues and students on a plant collecting excursion in western North Carolina. At a stop on their return to Chapel Hill, someone took from the expeditionary car a large box containing about one-third of the priceless botanical collection of their foray. Rather than bemoan an irreparable loss to the University Herbarium, Uncle Will chose to defuse the tragedy by understatement and by whimsically assuming the role of the disappointed robber. In 1923, Coker (1923) reported in the introduction of his book on clavarias that about one-third of the collection was lost through the activity of a misguided thief, who fancied he had found for himself something of value.

Professor Coker was a stickler for accuracy when plants were concerned. He had little patience with romantic ignorance. When asked to comment upon an article in the *New York Times* in praise of the Japanese honeysuckle that perfumes late-spring moonlit nights of the South, he waxed indignant, calling the invasive creeper a "first class pest, the worst pest since the chestnut blight." Noted botanist M. L. Fernald would later call it "the yellow peril of the South." The vine, Coker said, reaches out to throttle, not only shrubs but sometimes a considerable area of woodland, if left to its own devices. By this forceful reaction, he effectively dispelled for his interviewer the fanciful daydream of an urban journalist. What would he have said about kudzu? But that plant probably would have no romantic champion.

The native courtesy of Uncle Will was sometimes sorely strained by the inaccuracies of the botanically uninitiated. I remember a campus walk with Uncle Will on a lovely spring day. A talkative lady with our small party remarked several times on "funguses." Each time she used that expression Uncle Will, always a stickler for the correct use of botanical Latin, would mutter in a tone audible to most of us, if not to the lady in question, two clear syllables, "fun´-ji."

William Coker was a modest, even shy individual, avoiding attention to himself if at all possible. Family legends illustrate that this character trait was evident early in his life. Two incidences ring of truth.

When Will was a small boy, someone at the family breakfast table singled him out for praise for some accomplishment or other. There was no means of escape. A child then could not leave the family table unless excused by a parent. So Will picked up the large pancake on his plate to cover his face.

Another delicious family story deals with his arrival back home after receiving his Ph.D. degree from The Johns Hopkins University in Baltimore. That the son of a South Carolina farming region could and did earn a Ph.D. in 1901 was a rarity, a source of pride for the community. Young Dr. Will returned to Hartsville, his home village, by train on the railroad spur built by local citizens to carry manufactured products and supplies to and from the town. As the train slowed to stop, Will spied down the track, to his horror, a considerable crowd of friends and relatives gathered to greet him. He even caught the strains of the local brass band playing "Hail the Conquering Hero Comes." Though seemingly trapped, he quickly devised an escape. Grabbing his baggage, he descended from the train on the side away from the welcoming committee and temporarily vanished.

William Coker tried to ignore or to make light of honors that inevitably came his way and which he was obliged to acknowledge. In 1943, he received a letter informing him of his election as honorary curator of the Charleston (South Carolina) Museum. In his response, he avoided the traditional formula: an expression of gratitude, accompanied by a modest protest of unworthiness. He rather sidestepped the whole issue by diverting attention from himself to specimens in the museum's collection. He vividly recalled his youthful visits there with his father during the years when the family lived for four winters in

Charleston. During these Charleston years, from 1878 to 1882, Will was between five and nine years of age. The honoree simply remarked that on a recent visit to the museum he was struck by the remarkable fact that the expressions on the faces of the great deer and the giant buffalo had not changed at all in over 60 years.

Coker took little note of personal rank in the eyes of the world. He tackled his work in the chronological order of his commitment to it. People had to wait their turn. He had agreed to submit landscape plans for the factory buildings of a prominent industrialist in Durham, North Carolina. On 21 October 1915, the gentleman in question wrote asking him to run over and talk with him about his industrial park at his earliest convenience. Nine days later, the botanist-landscaper answered the letter telling the gentleman that, though he was able to leave the university only at irregular intervals, he hoped to see him on Thursday or Saturday of the following week "as he was going to La Grange for Arbor Day and may have a few minutes in Durham either coming or going." Later, as a volunteer extension agent for the university, he was to design the school grounds of this east Carolina farming community of La Grange.

While pursuing any current subject of his botanical research and writing, Coker left no stone unturned to collect all possible data. His eagle eye was sharp to detect a plant of particular interest. He recruited or pressed into service friends who could help him gather the specimens he needed. While causing these victims no little inconvenience, strangely enough, he often infected them with his own enthusiasm.

On family trips, when Uncle Will was along, we could plan for no rigid schedule, as we expected an abrupt halt along the way if he spotted something special. I well remember one particular occasion. We had traveled some distance across a seven-mile causeway over a marshy area where the driver was forbidden to stop or turn around. The eagle-eyed botanist called a halt and asked us to drive on and return for him presently, as he needed to get something on the edge of the swamp. He left the car, climbed over the guard rail and let himself down into the rich vegetation. On our return, he had not yet finished his collection. We caught sight of him at some distance waving us on. Obliged to continue, we anxiously attempted to note some landmark, such as an extra tall cypress tree, in the pristine vegetation, where we had last seen him. After we had made at least two seven-mile crossings, Coker, pleased with his collection and unapologetic, was ready to climb back over the guard rail and return to Hartsville with his trophies. He then pressed them for eventual addition to the herbarium in old Davie Hall at UNC.

During World War II, when Coker (1944) was preparing his classic article on "The Woody Smilaxes of the United States," gasoline rationing denied him ready access to the South Carolina low country, where he needed to round up some key specimens he lacked. He leaned heavily on good friends there to collect for him. Repeatedly and relentlessly, he wrote his friends G. Robert Lunz of the Charleston Museum and Frank Tarbox, master horticulturalist at Brookgreen Gardens on Pawley's Island, South Carolina, to seek, find, dig up, press, and send to him different species of smilax in various stages of development. This was no small favor to ask. The assignment involved constant vigilance for growth stages of the vines: male and female flowering and subsequent fruiting. It also meant innumerable sorties into a tangled woodland. Any woodsman knows that an encounter with some smilax thickets can be a very prickly experience. After the specimens were gathered, the collector had the time-consuming work of pressing the fresh plants, packing, and mailing them to Chapel Hill. These tasks, strangely enough, did not seem to turn Lunz and Tarbox against him—rather the contrary. Lunz was, during this period, an acting director of the Charleston Museum when Coker was made honorary curator and Tarbox shortly after his ordeal recommended Coker to Mr. Archer Huntington for appointment to a term as a trustee of Brookgreen Gardens, where he served for a period.

The Venus flytrap was another passion of Uncle Will's. He assumed a proprietary role in protecting this indigenous North Carolina carnivorous plant, whose habitat centers around Wilmington. In November of 1920, he sent to the *Georgetown Times*, Georgetown, South Carolina, an ad written in the urgent style of someone in pursuit of a criminal at large (Coker 1920b):

> Wanted: Information about Venus' Flytrap. One of the most remarkable plants in the world, called Venus' Flytrap because it catches and digests living insects, was reported from near Georgetown many years ago by [Stephen] Elliott in his 'Sketch of the Botany of South Carolina and Georgia.' No specimen from South Carolina is now known. Information in regard to the present occurrence of this plant in South Carolina is greatly desired. Address W.C. Coker, Professor of Botany, University of North Carolina, Chapel Hill, N.C.

Coker (1928) subsequently published an article on the "Distribution of Venus's Fly Trap" in 1928, and he was always investigating reports of an extended range.

There was something alluring about the passionate botanist's single-minded devotion to plants, something akin to the medieval Holy Grail spirit. One somehow felt honored to be invited to become a partner in an important quest that could involve discomfort, risk, or danger. On 23 April 1938, Coker wrote his friend, the South Carolina poet Archibald Rutledge, thanking him for his recent hospitality. Coker enclosed for Rutledge one of his own poems. His letter expressed concern at the news that Rutledge had been sick, but quickly moved to the main question. The intrepid botanist greatly needed to know whether the Venus flytrap was indeed to be found in the "big ocean," a local term for a botanically rich area near Rutledge's home, and was counting on his friend to find it. Rutledge wrote to Coker in Chapel Hill of his initial failure. He had indeed searched for the flytrap one day, but instead of his finding the plant, he himself had come face to face with a diamond-back rattler. He bravely assured Coker, though, that he was returning to the area presently, as he knew the plant was there. Though the poet had been sick, and though he had encountered a deadly serpent in his effort to help his friend, the tenacious botanist kept his friend focused on the most important matter at hand, the location and collection of specimens of this plant. In responding to Rutledge four days after the rattlesnake letter, Coker dutifully requested a word from Rutledge on whether or not he had been "bit." He ended the letter with the remark that he was looking forward with much interest to receiving the plants from Rutledge and that he greatly appreciated his continued interest.

In the effort to verify information that he needed for an article, Uncle Will at times demanded the well-nigh impossible of Miss Alma Holland, later Mrs. C. Dale Beers, for numerous years his able research assistant and coauthor. In 1919, he heard that a species of mountain rhododendron had been found growing naturally in sandhill country bordering North and South Carolina. Dr. Coker was then at his research desk in the New York Botanical Garden, where he worked from time to time during university vacations. Checking the report could not be delayed, as Coker's article on rhododendron had been thought to be complete and was already in the hands of the publisher. Hearing that Miss Alma had not yet succeeded in verifying the plant's location by correspondence, he urgently instructed her in a letter to visit the area personally. She was to take the train south to Rockingham, leaving Raleigh at 5 A.M. She was to find the plant, take specimens, and return the same day. Imagine the horror of that trip. The mere prospect of getting to Raleigh to take a train leaving at dawn, combined with the automobile transport of 1919, would have tempted a less dedicated botanist than Miss Alma simply to say, "I quit." The reflected August heat in the sandhills can be hard to take. You have to keep dumping your shoes as the hot sand sifts in. But our heroine succeeded in her quest and the article was published without error. Alan Weakley, our able herbarium curator at UNC, discovered the evidence. He reported two herbarium specimens of *Rhododendron minus* labeled "August 3, 1919, Richmond County, N.C., Collector, Alma Holland," thus providing ample proof of her strict obedience to orders and her success in accomplishing her mission. Weakley also checked the issue of the *Journal of the Elisha Mitchell Scientific Society*, where the article in question was published and found that Miss Holland's proof of the sandhills *Rhododendron minus* did indeed make the article before it was too late (Coker 1919). Our magnificent herbarium is a priceless archival research tool for solving all sorts of botanical mysteries.

Uncle Will was delighted to obtain a new plant and even to read about the wondrous plants of distant climes, epochs, and cultures. Dr. Paul Titman, a retired professor in Chicago who had studied with Coker in the late 1930s and had returned to earn a Master's degree in botany after his service in World War II, recorded for me in December 1998 his recollections of his old professor, which included the following incident illustrative of Coker's enthusiasm for plants.

Titman had described to Coker a particular kind of porcelain vine that grew in his grandmother's garden near Gastonia, North Carolina. Upon request, the student asked his grandmother to send a plant of this coveted vine for the Arboretum. Dr. Titman reminisced: "I still remember Miss Alma and Dr. Coker running through the Arboretum, where I was doing something, I don't know what, calling for me as if they were children at Christmas, to come quickly, that there was a package for me. And the gleam in his eye when that package was opened and he saw the anticipated vine was unforgettable." There is no more effective pedagogical tool than a teacher's own enthusiasm. Titman went on to earn his doctorate in botany at Harvard. He had planned to remain at Chapel Hill for his doctoral studies, but his professor advised him to seek instead, as he expressed it, "the cross-pollination of Harvard." Dr. Coker then pulled strings to assure that Titman was admitted to the doctoral program.

I myself shall never forget Uncle Will's excitement about the present William and I gave to him when he took the place of my late father at our wedding in May of 1946. By a stroke of good fortune, I found for him a beautifully illustrated book on an ancient Aztec herbal, reprinted under the title *The Badianus Manuscript* ([Cruz, Badiano, and Trueblood] 1940). The volume is America's earliest known book on herbal medicine. Ardently hoping that it would please him, I watched with bated breath as he unwrapped his gift. His unfeigned delight with our gift surpassed my wildest dreams. Ignoring the family hurly-burly swirling around us, he sat down to study it with total concentration. I believe that of all the gifts I have ever chosen for an adult, this book was the most appropriate and the most happily received.

Uncle Will had real affection for some of his colleagues on the faculty, and good relations with most of them. Dr. William De Bernière MacNider opened letters to Coker with "Dear Old Man." He closed them with "Affectionately," or "Devotedly," or "Bless your heart." Dr. Dey of Romance Languages and Coker addressed each other as "Colonel," with a complimentary close of "Very sincerely" or "Most sincerely yours." The more formal "Yours truly" was reserved for business-like letters. Among his close friends were Collier Cobb, John Booker, Archibald Henderson, George Coffin Taylor, and our great librarian, Louis Round Wilson.

With the renowned Professor Horace Williams, relations were somewhat less cordial. Professor Williams, it appears, was openly skeptical to his students of the laboratory method of the sciences and of the rigid demands for scholarly documentation in historical and literary research. "Oh those footnotes that Professor Greenlaw requires," he might casually remark. These methods of research he considered far less valuable as tools for learning than the Socratic method, which Professor Williams used so successfully to arouse the curiosity and stimulate the thinking of his students. Naturally this attitude caused some of his colleagues in science, history, and literature to bristle.

The farms of Professors Williams and Coker were adjacent. The Orange County (North Carolina) Register of Deeds records that Coker bought this land from an H.H. Williams in 1906. I feel sure that this is the very gentleman under consideration here, though I have not definitively nailed it down. It would be natural for Professor Williams to retain a proprietary feeling for his former acreage. The following letter from W.C. Coker (1920a) to Professor Horace Williams reveals quite a bit about their relationship. I'll read it for you.

February 21, 1920
Professor Horace Williams,
Chapel Hill, N.C.

Dear Professor Williams:

I find that two of your sheep have been grazing every day on my wheat field for at least a month, - in fact, spend nearly all of their time on my place. I ask that you have your sheep removed to some other pasture, where they will not do constant damage to my crops.

Yours truly,
[W.C. Coker]

When asked by the editor of the *Chapel Hill Weekly*, a local newspaper of Chapel Hill, for advice as to how to reach the ripe old age of seventy, one of Coker's answers was: "Marry the right woman and manage always to have around a congenial dog." Dogs were very important in his life. To each of an almost unbroken succession of canine friends, he gave his utter devotion. And it was amply returned. At their dinner table at "The Rocks," Aunt Louise sat at right angles to him, on his left. When she turned her head to address someone at the other end of the table, one could observe Uncle Will surreptitiously passing a tidbit from his plate to Tinkerbell lying at his feet. Could this dinner-sharing be one reason why Uncle Will remained so pencil slim?

One of his more colorful canine friends, Mickey, strongly resembled the famous Victrola dog of "His Master's Voice," according to our own Laurie Radford, one of Coker's former graduate students and coauthor of the history of the University of North Carolina Herbarium (L. Radford and A. E. Radford, [2000]). Mickey was as much a one-man dog, as his master was a one-dog man. Uncle Will proudly wrote a niece that Mickey was the only dog he had ever owned who would actually bite. This statement reminds me of James Thurber's delightful story, "The Dog that Bit People." Thurber captures Uncle Will's feeling toward Mickey, his beloved friend who could do no wrong. In Thurber's tale, a one-dog lady replied to each victim's complaint with the remark "Yes, he does love to bite but remember this, he never holds a grudge."

There is not enough time to tell other cherished tales and memories of my Uncle Will. I just hope that I have been able to humanize for you this very vital person who walked the paths of our University for more than fifty years and did what he could to make our campus more beautiful, to interest us in a great variety of plants, and to encourage us to understand and conserve the wonders of our native fields and forests. I never think of Uncle Will without a frisson of delight and gratitude for his infectious love for our natural world. He, of course, was but one of the considerable number of extraordinarily gifted faculty members at Chapel Hill during the first half of the twentieth century. If William Coker were magically to return to Chapel Hill this spring, he could scarcely avoid seeing himself prominently displayed. He would doubtless immediately descend from the wrong side of the train, so to speak, and disappear to botanize incommunicado in an unknown North Carolina field or forest, or to study in some remote herbarium until all of this nonsense blows over.

Please do forgive us, dear Uncle Will. We simply cannot help ourselves. You are irresistible.

ACKNOWLEDGMENTS

Many people, too numerous to cite, assisted us in preparing this paper. We particularly thank Laura Cotterman, Rogers McVaugh, and Peter S. White for reading the entire manuscript and providing useful comments for changes. We also acknowledge the expert advice and assistance of Brian Nalley and Susan Whitfield with the creation and preparation of the illustrations. The Southern Historical Collection, University of North Carolina at Chapel Hill kindly provided permission to quote two letters from the William Chambers Coker Papers. The North Carolina Botanical Garden funded this publication.

ABSTRACT

The widespread *Eleutherococcus senticosus* (Rupr. et Maxim.) Maxim. is threatened because of overharvesting of its root bark for medicinal uses. The geographically restricted *E. brachypus* becomes endangered due to habitat loss in the Loess Plateau of China. To facilitate the development of conservation strategies, genetic diversity of both species was measured at 26 isozyme loci (12 enzymes). *Eleutherococcus brachypus* had a low proportion of polymorphic loci (P_s=19.2%; P_p=13.1%) and low genetic diversity (H_{es}=0.063; H_{ep}=0.031). The genetic variability of the widespread *E. senticosus* was higher (P_s=26.9%; P_p=20.76%; H_{es}=0.094; H_{ep}=0.059) than that of the restricted *E. brachypus*. Population differentiation of *E. brachypus* (G_{st}=0.531) was greater than that of *E. senticosus* (G_{st}=0.383). Cluster analysis showed that populations of *E. senticosus* in Northeast or North China are genetically closer within each region than between the two regions. Populations of *E. senticosus* in Northeast China have a higher level of genetic diversity, and these populations need to be conserved with greater priority. Populations of *E. brachypus* in the Loess Plateau have been highly fragmented, and all populations of the species should be protected to maximize its genetic diversity.

CHINESE ABSTRACT

刺五加（*Eleutherococcus senticosus* (Rupr. et Maxim.）Maxim.）分布于华北和东北地区，由于人类的过度利用而使该物种受到威胁；短柄五加由于分布于黄土高原这一植被非常稀少的特殊地理地带同样有绝灭的危险。为了制定这些物种的有效保护措施，我们对这两个物种的遗传多样性进行了分析。我们每个物种各采集了5个居群的样品，共197份；分析了12个酶系统，共得到26位点。数据分析结果表明，短柄五加物种水平的多态位点为19.2%，居群水平的多态位点平均为13.1%；物种水平的期望杂合度为0.063，居群水平的期望杂合度平均为0.031。刺五加物种水平的多态位点为26.9%，居群水平的多态位点平均为20.76%；物种水平的期望杂合度为0.094，居群水平的期望杂合度平均为0.059。短柄五加居群间的分化系数(G_{st}=0.531)高于刺五加(G_{st}=0.383)。聚类分析结果显示，东北地区和华

SIDA 21(2): 993–1007. 2004

北地区的刺五加地区内部的居群之间具有更高的遗传相似性。东北地区的刺五加居群具有比华北地区的居群更高的等位酶多样性，从而更具有保护价值。短柄五加的遗传多样性没有明显的地理规律。考虑到黄土高原非常稀少的植被，短柄五加在水土保持中的重要作用，加上其居群数目少，遗传多样性低，建议保护所有自然群体以维持该物种的遗传多样性。

INTRODUCTION

Understanding of the levels of genetic diversity is important in designing conservation strategies for rare and endangered species (Holsinger & Gottlieb 1991; Hamrick & Godt 1996; Rieseberg & Swensen 1996; Newton et al. 1999; Gitzendanner & Soltis 2001). It is estimated that approximately 3000-4000 species (15%) of the vascular plants in China are endangered or threatened (Fu & Jin 1992). Since the 1970's, major efforts have been made to establish nature reserves to protect rare and endangered species and their communities. At present, few studies have been conducted to examine the genetic diversity of endangered species in China. Genetic data are needed from model plant groups in China to help design conservation efforts when resources are limited.

Eleutherococcus senticosus [= *Acanthopanax senticosus* (Rupr. et Maxim.) Harms] (Araliaceae) distributed in China, North Korea and Far East of Russia, is commonly known as Siberian ginseng (Soejarto & Farnsworth 1978; Farnsworth et al. 1985; Duke 1989) and is considered to be of high medicinal value. It has been used for hundreds of years in China as a tonic (Hu 1980). Studies have been conducted (e.g., Xu et al. 1983; Zhao et al. 1990, 1991, 1993) to analyze its chemical constituents. Polysaccharides extracted from its leaves and roots have been reported to inhibit tumor cell proliferation (Xie et al. 1989; Liang et al. 1994) and to have antiviral activity (Glatthaar-Saalmüller et al. 2001). Glucosides (such as liriodendrin) extracted from root or stem bark have also been reported to have an effect similar to those of that of ginseng (*Panax* spp.) (Slacanin et al. 1991), or as an adaptogen that exerts effects on both sick and healthy people by "correcting" any dysfunctions with no or few side effects (Davydov & Krikorian 2000). Industries have been developed to manufacture herbal products using *E. senticosus*. Herbal and pharmaceutical producers have been using material of the species collected from natural habitats, which has led to rapid destruction of natural populations. Although the species has a wide distribution in China, ranging from the North (Shanxi and Hebei provinces) to the Northeast (Liaoning, Jilin and Heilongjiang provinces) (Fig. 1), it is now listed in the "China Plant Red Data Book" as a vulnerable species (Fu & Jin 1992) for its economical importance.

Eleutherococcus brachypus (Harms) Nakai is a rare endemic species restricted to the Loess Plateau (southeastern Gansu and central Shaanxi provinces) of Northwest China (Fig. 1), which is heavily populated and has highly fragmented vegetation. *Eleutherococcus brachypus* is a clonal species with small populations (Wang et al., 1997), but has suffered from habitat loss, and is thus rare. Seeds of *E. brachypus* are usually not well developed, requiring 1.5 years of after-ripening (Tian et al. 1998). Wang et al. (1997) reported that insect visitation was necessary for seed set. Yan et al. (1997) investigated genetic diversity of this species using three populations from Yanán City, Shaanxi Province, and reported that the percentages of polymorphic RAPD bands were relatively low, 5.4%, 18.5%, and 27.7%, respectively.

Both *Eleutherococcus senticosus* and *E. brachypus* are shrubs with similar ecological preferences of sunny habitats, but different in geographic ranges. *Eleutherococcus senticosus* has a wide distribution, whereas *E. brachypus* is a rare endemic confined to the Loess Plateau of Northwest China (Fig. 1). This paper assesses the genetic diversity of these two congeneric species with allozyme markers using starch gel electrophoresis and discusses the implications for conservation.

MATERIALS AND METHODS

Sampling

Five populations of *E. senticosus* from five provinces in China and five populations of *E. brachypus* from North Shaanxi to South Gansu were sampled, covering nearly the full range of distribution of both species (Fig. 1, Table 1). Three populations of three other congeners: *E. giraldii* (Harms) Nakai, *E. gracilistylus* (W.W. Smith) S.Y. Hu, and *E. sessiliflorus* (Rupr. et Maxim.) S.Y. Hu (Table 1) were included in the UPGMA cluster analysis as comparisons.

One to two year old twigs were collected in the spring from about 20 individuals in each population. Populations of *E. brachypus* were small and the boundaries were easily determined. Samples were collected throughout the populations. Populations of *E. senticosus* were usually large with hundreds of individuals, and samples were collected at an interval of at lest 50 meters to minimize the possibility of collecting two samples from a single clone. The twigs were then kept in sealed moist plastic bags.

Electrophoresis

In the laboratory, the cut surface of each twig was immersed in water and incubated in a humid environment. When the first leaf appeared, the bud was removed and ground on ice with grinding buffer after removing bud scales. The grinding buffer (Tris-malate grinding buffer-PVP solution) was prepared following Soltis et al. (1983) with the substitution of sodium bisulfite for sodium metabisulfite. DMSO was added to the mixture to a final concentration of 10% before adjusting pH to 7.5. The enzyme solution was absorbed onto wicks, which were frozen (-80°C) until electrophoresis. Electrophoresis was carried out on horizontal starch (Sigma cat no. S4501) gels at 4°C. Four buffer systems (electrode buffer / gel buffer) were used to assay12 enzymes (Wang 1998): (1) 0.4M Citric acid trisodium salt (pH adjusted to 7.0 using 1.0M HCl) / 0.02M Histidine•HCl (pH adjusted to 7.0 using 1.0M NaOH) for aconitate hydratase

NADH-diaphorase (DIA, E. C. 1.6.2.2); and (4) 0.04M citric acid [pH adjusted to 7.5 using N-(3-aminopropyl)-morpholine] / 1:19 dilution of electrode buffer for isocitrate dehydrogenase (IDH, E. C. 1.1.1.42) and shikimate dehydrogenase (SKD, E. C. 1.1.1.25). Enzymes were visualized using stains in agar overlays except for AAT and AMP which were stained in buffer solutions.

Data analysis

Stained gels were photographed and the banding patterns were then drawn. The alleles at each locus were designated with letters a, b, and c, from the longest migration distance to the shortest. The resulting genetic data (genotypes) were analyzed with Biosys-1 (Swofford & Selander 1989) for each species. For each population, the allele frequencies, mean number of alleles per locus, percentage of polymorphic loci, heterozygosity observed and expected under Hardy-Weinberg equilibrium, F-statistics and unbiased genetic similarities/distances (Nei 1978) were computed. All the populations were analyzed to generate a dendrogram using UPGMA.

RESULTS

Twenty-six putative loci from 12 enzyme systems were interpretable on the basis of simple Mendelian genetics (Table 2). Nineteen loci exhibited polymorphisms in one or both species. The frequency of one allele often dominated over the others in a given population (Table 2).

Genetic diversity of *E. senticosus*

There were 13 polymorpic loci in *E. senticosus* (Table 2). The two regions of activity for AAT were designated as *Aat-1* and *Aat-2*. *Aat-1* had 2 alleles, the rare one *Aat-1b* and the common one *Aat-1c*. *Aat-2* had 3 alleles, *Aat-2a*, *Aat-2b*, and *Aat-2c* with *Aat-2b* being the common one. Only one locus was detected for ADH with 2 alleles, *Adh-a* and *Adh-b*, which were present in heterozygosity with low frequencies. Both *Amp-1* and *Amp-2* had 2 alleles, with the allele frequencies varying among populations. *Dia-1* exhibited polymorphism only in the S-JL population. Two alleles were detected on *G3pd-2* and *Hex-1*, respectively. The rare alleles on *Idh-2*, *Skd-1*, *Skd-2*, *Skd-3*, *Tpi-1*, and *Tpi-2* were unique to this species. Locus duplications were observed on PGM and TPI.

Eleutherococcus senticosus maintained a higher level of genetic diversity. The percentages of polymorphic loci ranged from 11.5% to 30.8% with a mean of 26.9% (Table 3). The mean number of alleles averaged over populations was 1.26, and the expected heterozygosity under Hardy-Weinberg equilibrium averaged over populations was 0.059. The population S-JL from Jilin Province (A=1.3; P=30.8%; H_e=0.073) and the population S-LN from Liaoning Province (A=1.3; P=23.1%; H_e=0.077) exhibited the highest genetic diversity. The southwest peripheral population S-SX from Shanxi Province had the lowest (A=1.2; P=11.5%; H_e=0.025).

At the species level, the mean number of alleles per locus was 1.7, and 26.9% of the loci were polymorphic. The expected heterozygosity was 0.094. The genetic diversity was maintained at 13 polymorphic loci, especially at *Amp-1*, *Amp-2*, *G3pd-2*, *Idh-2*, *Skd-3* and *Tpi-1* (Ht>0.2, Table 4). Among these loci only *Amp-1* and *Idh-2* contributed more to interpopulational than to intrapopulational variation (G_{st}>0.5). Of the mean total genetic diversity (H_t=0.094), only 38.3% was maintained within populations (H_s=0.058, D_{st}=0.036).

Genetic diversity of *E. brachypus*

There were 10 polymorphic loci detected in five populations of this species (Table 2). *Aat-1a* was unique to B-XY population. The alleles of *Aat-2a* and *Aat-2c* were infrequent. *Aco-1a* was common in B-XY population but rare or absent in the other populations. The unique allele *Adh-c* was present in heterozygosity with low frequencies. *Dia-2b* and *Dia-2c* were characteristic of this species, which exhibited intrapopulational variation. Nearly complete divergence of alternative allele fixation was found at the three loci of IDH between *E. brachypus* and *E. senticosus*. Locus duplication was not observed at PGM. Instead, both loci *Pgm-1* and *Pgm-2* were polymorphic.

The genetic diversity of *E. brachypus* at the populational level was relatively low compared to that of *E. senticosus* (Table 3). The percentage of polymorphic loci varied from 3.8% to 23.1% with a mean of 13.1%. The mean number of alleles

TABLE 2. Allele frequencies in 10 populations of *Eleutherococcus brachypus* and *E. senticosus* (N indicates sample size).

averaged over populations was 1.2, and the expected heterozygosity under Hardy-Weinberg equilibrium averaged over populations was 0.031. The population B-TS from Tianshui, Gansu Province, showed the highest genetic diversity (A=1.3; P=23.1%; H_e=0.048), while the population B-XY from Xunyi, Shaanxi Province, showed the lowest diversity (A=1.1; P=3.8%; H_e=0.008).

Eleutherococcus brachypus exhibited an average of 1.5 alleles per locus, and 19.2% of loci were polymorphic (Tables 3 & 4). The expected heterozygosity under Hardy-Weinberg equilibrium was 0.063. The genetic diversity was maintained at 10 polymorphic loci, notably at *Aco-1*, *Dia-2*, *G3pd-2* and *Pgm-1*. The mean total gene diversity (H_t) was 0.064. Nearly half of the total genetic diversity occurred within populations (H_s=0.030). Among the loci with high H_t values, *Dia-2* and *Pgm-1* showed most genetic variation within populations (G_{st}

was 0.254 and 0.151, respectively), while *Aco-1*(G_{st}=0.858) and *G3pd-2* (G_{st}=0.920) showed genetic variation primarily among populations.

Relationships among populations

Genetic identity between populations within each species was higher than 0.9, and the genetic distances were lower than 0.09 (Table 5). The average distances between the populations were 0.043 (±0.028) and 0.047 (±0.019) for *E. brachypus* and *E. senticosus*, respectively. The dendrogram generated from genetic identity data using UPGMA (Fig. 2) showed that populations of *E. senticosus* from Northeast China were more similar to one another than with those from North China. The population B-XY of *E. brachypus* differentiated most significantly from other populations of the species.

DISCUSSION

Overall genetic diversity within species

The levels of allozyme variation in *E. senticosus* and *E. brachypus* were relatively low at both species and populational levels in comparison with those of other species with similar attributes (Hamrick & Godt 1990). For example, P_s (26.9%) and H_{es} (0.094) of *E. senticosus* were about half the averages (64.7% and 0.177, respectively) of woody plants at the species level. Hamrick & Godt (1996) reported an average within species heterozygosity (H_{es}) for widespread and endemic species of 0.202 and 0.096, respectively. The H_{es} for the widespread *E. senticosus* was 0.094 and that of the restricted endemic species *E. brachypus* was 0.063. The allozyme heterozygosity within each of the two *Eleutherococcus* is thus considerably lower than the averages reported in the literature.

The percentages of polymorphic allozyme loci reported in this study correspond well to DNA-RAPD polymorphism in *E. brachypus* (3.8–23.1% vs 5.4–27.2%, Yan et al. 1997), but differ sharply from those of *E. senticosus* (11.5–30.8% vs 91.3–97.6%, Dai et al. 1998). However, the report of highly polymorphic RAPD bands in *E. senticosus* likely represents an overestimate because amplification failure from some individuals was interpreted as a lack of bands by Dai et al. (1998). Our allozyme data seem to be more reliable in presenting the overall genetic diversity of the species investigated.

Levels of genetic diversity between species

There is significant disparity between *E. brachypus* and *E. senticosus* in overall genetic diversity (Tables 3 & 4), with *E. senticosus* maintaining a higher level of genetic diversity than *E. brachypus*. These two species appears to be closely related, but not sister taxa. They differ in several characters that may influence genetic diversity. First, they have highly different distributional ranges. *Eleutherococcus senticosus* is widespread across several thousand kilometers, from North to Northeast China and adjacent countries (North Korea and Far East of Russia). By contrast, *E. brachypus* is restricted to the Loess Plateau of

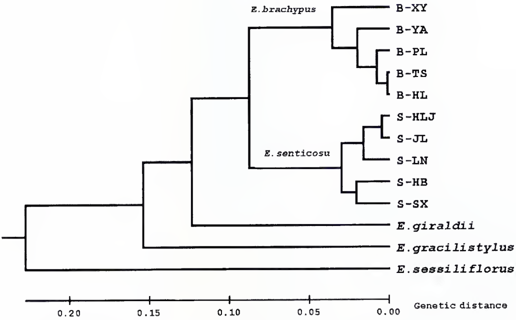

FIG. 2. Cluster analysis (UPGMA) of populations of *Eleutherococcus* based on Nei's unbiased genetic distance.

southeastern Gansu Province and central Shaanxi Province. Another major difference is the breeding system. *Eleutherococcus senticosus* is reported to be trioecious and protandrous (Liu et al. 1997a, 1998). But because individuals with hermaphroditic flowers are very rare (Liu et al. 1997b), this species is functionally dioecious with insect-mediated outcrossing (Liu et al. 1998a). *Eleutherococcus brachypus* has hermaphrodite flowers. Both selfing and insect-mediated outcrossing are important in its sexual reproduction. Similar to *E. senticosus*, anthers of *E. brachypus* start to shed pollen at least five days before the receptivity of stigmas of the same flower (Wang et al. 1997), suggesting outcrossing. Wang et al. (1997) proposed that "outcrossing" within local populations may represent selfing in a broad sense because local populations may be ramets of a single clone. But our study has shown that there is genetic variation within local populations. Thus the interpretation of a local population to be a group of ramets from a single clone is not supported (also see Yan et al. 1997).

The degree of human impact may also explain the difference in genetic diversity between these two species. The populations of *E. senticosus* assayed in this study have not suffered serious disturbance because they were mostly in nature reserves. In contrast, all populations of *E. brachypus* sampled were seriously disturbed, and they were finely fragmented due to land reclamation for farming.

Genetic diversity among populations

Considerable genetic variation was detected among populations (Table 3). The level of genetic diversity varies across localities in *E. senticosus*. The population S-LN in Liaoning Province is the center of the present distribution of this species, and the genetic diversity (*He*) is highest. The population S-SX in Shanxi Province is peripheral and its genetic diversity is the lowest. This pattern has also been reported in many other plant species (see Crawford 1990; Hamrick & Godt 1996).

In *E. brachypus*, however, the Tianshui population (B-TS) near the westernmost range of the species has the highest genetic diversity, whereas the Xunyi population (B-XY) near the distributional center shows the lowest level of genetic diversity. This unusual pattern may be due to a greater impact of human disturbance on *E. brachypus*.

Implications for conservation

In *Eleutherococcus senticosus* in China, populations near the distributional center have a higher level of genetic variation. From this center to the periphery, polymorphism decreases. The low genetic diversity in the populations of North China is expected due to their peripheral positions. When the entire distributional range (including the Far East of Russia) is considered, the population S-HLJ is also central. The relatively low genetic diversity of this population suggests that it may have suffered from genetic loss. Population destruction of *E. senticosus* has been serious in Heilongjiang Province.

Although the genetic structure of *E. senticosus* has not been seriously damaged, overharvesting should be prevented to maintain the sustainability of this species. Recent establishment of nature reserves in Northeast China (the center of genetic variation of this species in China) has been successful in protecting some populations of *E. senticosus*. Demographic investigation outside the reserves every few years is needed to determine the reduction rate of populations.

If it is rapid, use of this species should be controlled, and *ex situ* conservation of special genetic resources may be adopted in nearby nature reserves.

Conservation of *E. brachypus* is urgent because considerable genetic loss has occurred. No significant correlation has been found between genetic differentiation of populations and their geographical distances from the distributional center, suggesting that genetic structure has been altered. The vegetation of the Loess Plateau has been seriously fragmented. In order to maximize the conservation of genetic diversity, all natural populations should be protected. If nature reserves are to be established to conserve populations of this important species, priorities should be given to those in southern Gansu Province, where genetic diversity is high and habitat loss is serious.

ACKNOWLEDGMENTS

We thank Zheng Hongchun for assistance in sample collection, and Pete Lowry and Greg Plunkett for most helpful comments. This study was supported by grants from the National Natural Science Foundation of China (grant 3939150 to D.-Y. Hong), the Excellent Overseas Chinese Research Grant of the Chinese Academy of Sciences (to J. Wen), and the US National Science Foundation (DEB 0108536 to J. Wen).

ASBTRACT

Laboratory experiments were carried out in England to test the specificity and environmental requirements of a Peruvian isolate of the fungus *Puccinia lantanae* Farlow, known to attack the invasive plant *Lantana camara* L. a serious problem in Galapagos. Eight species of plants representing five families were inoculated with the fungus and kept in a dew chamber for 48 hours. *Lantana peduncularis* Andersson and *Lantana camara* were sourced from Galapagos; other species related to *Lantana* were sourced from other places. Dew periods of 5, 8, 11, 14, and 20 hours were tested to determine the period necessary for basidiospore formation and host infection. Only *Lantana camara* from Galapagos and Peru developed visible symptoms 6 days after inoculation and after 15 days sori were fully developed. No non-target species developed macroscopic symptoms. Most importantly the rust did not attack the closest host relative from Galapagos, the endemic *Lantana peduncularis*. Eight hours in the dew chamber was enough to induce basidiospore formation and host infection, but times up to 20 hours induced progressively more sori. Although we have not completed yet the experiments to determine the host range specificity, *P. lantanae* shows promise as a biocontrol agent for *Lantana camara* in Galapagos.

Key words: *Lantana peduncularis, Lantana camara, Puccinia lantanae*, rust, biocontrol, Galapagos

RESUMEN

Se realizaron experimentos de laboratorio en Inglaterra para determinar el nivel de especificidad y requerimientos ambientales del hongo *Puccinia lantanae* Farlow como potencial agente de control biológico de la especie invasora *Lantana camara* L. en Galápagos. Ocho especies de plantas pertenecientes a cinco familias relacionadas a *L. camara*, fueron inoculadas con pústulas del hongo y mantenidas durante 48 horas en la cámara de roció. *Lantana peduncularis* Andersson y *Lantana camara* fueron colectadas en Galápagos, las otras especies relacionadas con Lantana se obtuvieron en otros lugares. Para determinar el periodo de roció necesario para la producción de basidioesporas, las plantas de *L. camara* fueron inoculadas y sometidas a diferentes periodos de rocio (5, 8, 11, 14, 20 horas). *Puccinia lantanae* se desarrollo y afectó únicamente a *L. camara* proveniente de Galapagos y Perú. Los síntomas aparecieron seis días después de la inoculación y a los 15 días las pústulas estuvieron completamente desarrolladas. No se detectaron síntomas macroscopicos en las otras especies, principalmente en la endémica *L. peduncularis* que es la especie mas cercana. *Puccinia lantanae* fue capaz de esporular e infectar *L. camara luego* de ocho horas de roció; el mayor grado de infección y desarrollo de pústulas se obtuvo dentro de las 20 horas de roció. No se han realizado todas las pruebas necesarias para determinar si el nivel de especificidad es adecuado para liberar el agente, sin embargo hasta el momento, *P. lantanae* se muestra como un potencial agente de control biológico de *L, camara* para Galápagos.

SIDA 21(2): 1009–1017. 2004

INTRODUCTION

Lantana camara (Verbenaceae), an ornamental shrub, native to tropical America, is now found in most tropical and subtropical regions of the world. It is not only widespread but it is also generally considered to be a major pest of agricultural and natural areas (Thaman 1974). The *L. camara* complex will tolerate a wide range of climates. It can be found at altitudes between sea level and up to 2000 meters, and between 45° N to 45° S. It flourishes in both dry and wet regions, growing on mountain slopes, along coastal areas and in valleys. It is somewhat shade tolerant and thus can become the dominant understory plant in open forest and tropical tree crops in its weedy range (Holm et al. 1977). Reproduction is by seeds that are spread via frugivorous birds, and short distance spread is by the rooting of horizontal stems in contact with the soil.

Lantana camara was first introduced as an ornamental into Floreana Island in the Galapagos Archipelago in 1938 (Cruz et al. 1986), and has since spread or been carried to other islands, including Santa Cruz. The dense thickets created by this invasive weed impact not only the indigenous flora but also fauna (Hamann 1984; Cruz et al. 1986). There is evidence, for example, that it is affecting the nesting habitats of the endangered dark-rumped petrel, *Pterodroma phaeopygia* (Cruz et al. 1986).

Lantana camara was the first weed ever targeted for classical biological control at the turn of the century. The first attempt at the biological control of lantana began in 1902, when 23 insect species were imported into Hawaii from Mexico. Eight of these species were established (Perkins & Swezey 1924). A total of 36 insect species has since been released in 33 countries (Julien & Griffiths 1998), but control in Hawaii, as well as in other parts of the world, has only been partially successful (Taylor 1989). This has mainly been due to the genetic diversity, and hence environmental adaptability, of the weedy biotypes which outstrip those of its natural enemies. New biocontrol agents are still being evaluated and released, including pathogens. A broad range of pathogens has been recorded infecting *L. camara* in its native range (Barreto et al. 1995). Three fungal agents have been released so far: a species of *Septoria* was released in Hawaii, originally from Ecuador (Trujillo 1995), a rust *Prospodium tuberculatum* (ex Brazil) was released in Australia in 2001, and a leaf spot pathogen, *Mycovellosiella lantanae* var. *lantanae* (ex Florida, USA) was released in South Africa, also in 2001. The impact of these agents is still pending. *Puccinia tuberculatum* was screened against the invasive and native species of Lantana from the Galapagos at CABI Bioscience, but it was found to infect, albeit mildly, the native lantana, and was discounted as a potential agent. A number of other candidate pathogens have been identified with excellent potential, including a stem and leaf rust, *Puccinia lantanae* (Barreto et al. 1995).

Puccinia lantanae Farlow (Basidiomycotina, Uredinales) occurs in tropical and subtropical regions of America: From Mexico and Florida, through the Caribbean and as far South as Argentina. *Puccinia lantanae* has been recorded from a number of *Lantana* spp., but there is evidence of distinct races that are only capable of attacking single species, and are even specific to biotypes within that species. This rust is recorded as a microcyclic (only teliospores and basidiospores in the life cycle) and autoecious (completes life cycle on one host species) species. The teliospores remain in the sorus on the host plant, and are not released. Under conditions of high humidity, teliospores germinate and produce basidiospores that are released from the teliospores. These infect fresh plant material, from which more teliospores result, and hence complete the life cycle.

METHODS

Plant material and fungal inoculations

Plants species used in the experiment were grown from stem cuttings from the CABI Bioscience stock plant collection. *Lantana camara* and *Lantana peduncularis* were collected originally from the Galapagos Islands (Santa Cruz). Using rooting powder, stem cuttings were planted in pots containing substrate (John Innes no. 2). Plants were kept in a quarantine glasshouse set at a minimum temperature of 20 °C with 12 hours of artificial light and watered everyday.

The rust *Puccinia lantanae* used was taken from the CABI Bioscience specimen collection held on living plants (isolate reference number W1914). The fungus, like all rusts is a biotroph and therefore culturing can only be done *in vivo*.

To inoculate the experimental plants for host range testing and assessment of the minimum dew period requirement, sori of *Puccinia lantanae* were suspended over new shoots; between two to four shoots were targeted for each potted plant. The small piece of plant tissue containing the sori of teliospores, was attached to small Petri dish using petroleum jelly (Vaseline). Care was taken that no Vaseline was deposited on the fungal material. Petri dishes were attached to a small stick a distance of 2 cm above the young leaves, making sure that the teliospores were directly above the leaf, so the basidiospores are released onto the potentially susceptible part of the plant. (Koutsidou 2000). The target area was usually the four youngest leaves of any given stem. The inoculated stems were marked by tying a string to the stem. Target plants were watered and the leaves were wetted with a fine mist of sterile distilled water before putting them in the artificial dew chamber (Mercia Scientific, Birmingham, UK). All *in vivo* experiments were done in a quarantine greenhouse at CABI Bioscience, Ascot. United Kingdom.

There were two experiments described below:

Symptom Development and Host Range Specificity

For the host range specificity experiments, eight species from five families were used (Table 1). All test plants species were inoculated with the rust *Puccinia*

Table 1. Host range test species list and results of host specificity testing of *Puccinia lantanae*.

Family	Species	Provenance	Native in	Susceptibility rating
Bignonaceae	*Tecomanthe hilli*	Australia	Australia	0
Boraginaceae	*Cordia dichotoma*	Australia	Australasia	0
Lamiaceae	*Plectranthus parviflorus*	Australia	Australasia	0
Lamiaceae	*Vitex triflora*	Australia	South America	0
Lamiaceae	*Gmelina leichhardtii*	Australia	Australia	0
Verbenaceae	*Lantana camara*	Galapagos	South America	3
Verbenaceae	*Lantana camara*	Peru	South America	3
Verbenaceae	*Lantana montevidensis*	Australia	South America	0
Verbenaceae	*Lantana peduncularis*	Galapagos	Galapagos	0

lantanae using the method described above. At least three replicate plants were inoculated per species. Plants were incubated at 20° C for 48 hours in a dew simulation chamber to induce teliospore germination, basidiospores formation, and provide an optimum environment for potential plant infection.

Symptoms were recorded according to a rating system devised to assess the susceptibility of plant species to *P. lantanae* based on the visible symptoms (Koutsidou 2000): **0** No macroscopic symptoms; **1** Chlorosis on the leaf surface; **2** Restricted sporulation (sorus diameter <2mm), and; **3** Abundant sporulation (Sorus diameter >2mm).

Dew Period Requirements

Lantana camara plants (from Galapagos) were inoculated with the rust *Puccinia lantanae* using the method described above, although one sorus per shoot was used as the standard inoculum, of 5 mm diameter. Three or more shoots were inoculated per replicate plant and a mean number of sori per shoot taken for each plant. Dew period treatments of 5, 8, 11, 14, and 20 hours were compared, with two replicate plants per treatment. The dew chamber was set at 20° C. After this treatment, the inoculum was removed and plants moved into the quarantine glasshouse and pots watered normally avoiding the wetting of leaves. Plants were checked regularly for macrosymptoms and sorus development.

RESULTS

Symptom Development and Host Range Specificity

The first appearance of symptoms of *P. lantanae* infection on the *L. camara* from Galapagos, occurred 6-7 days after the inoculation, as small chlorotic spots. These spots enlarged, and after approximately 13-15 days the first symptom of sporulation i.e. sori became apparent. The size of the sori on leaves differed from between 1 mm to 6 mm in diameter. In general, the younger the leaves (approximately <5mm diameter) were at inoculation the larger the sori that formed. Leaves that had already partially expanded before infection produced the smaller sori. However, high densities of sori on a leaf also resulted in smaller average sorus size. No sporulation was observed on leaves that were fully expanded at inoculation. Sporulation occurred mainly on the lower surface of the leaf. When the density of sori was high, very premature leaf abscission was observed (around 13 days after inoculation). If the density of sori was lower, a necrotic area formed around them, which increased until earlier than normal leaf fall, but after full rust symptom expression. Infection often occurred on stems and petioles also.

Table 1 gives the results of the host specificity testing. Although this is a limited host range test, the results suggest that *P. lantanae* is host specific to *L. camara*. *Puccinia lantanae* was not able to infect nor sporulate on any of the other seven related species used in the experiments. Even the most closely related species *L. peduncularis* (Galapagos) and *L. montevidensis* were resistant to *P. lantanae*, suggesting strong host-specificity.

Dew Period Requirements

Puccinia lantanae was able to sporulate and infect *L. camara* plants after only 8 hours of dew. Maximum infection and sori development was obtained at or after 20 hours of dew (see Fig. 1).

Figure 2 shows the different levels of infection by *P. lantanae* after different lengths of dew period. Clearly, more basidiospores are released over a longer period of time in humid conditions.

DISCUSSION

Puccinia lantanae isolate W1914 from Peru seems to be significantly more destructive to *Lantana camara* than other pathotypes of *P. lantanae*, that are frequently observed throughout the native range of the plant. Previous records of isolates of *P. lantanae* report that the pathogen only infects leaves (Barreto et al. 1995). The fact that the isolate W1914 can also infect petioles and stem means that the rust is much more damaging to the weed and is therefore a better potential biological control agent than originally estimated. Whole branches may drop as a result of stem infection and infection of the leaves can be very severe. Disease symptoms start to appear 5-7 days after inoculation and sori can grow up to 6 mm in diameter suggesting a rapid and destructive infection of this rust. This rust is able to release the basidiospores that can infect fresh host tissue within the first 8 hours of a dew period however longer periods of humidity favor it.

Puccinia lantanae seems to be a promising biological control agent to target *L. camara* from the Galapagos Islands. Nevertheless it is necessary to continue with the host range specificity test using the related native and endemic species from Galapagos to avoid doubts about non-target species effects.

In addition, more collections of *L. camara* from Galapagos need to be made

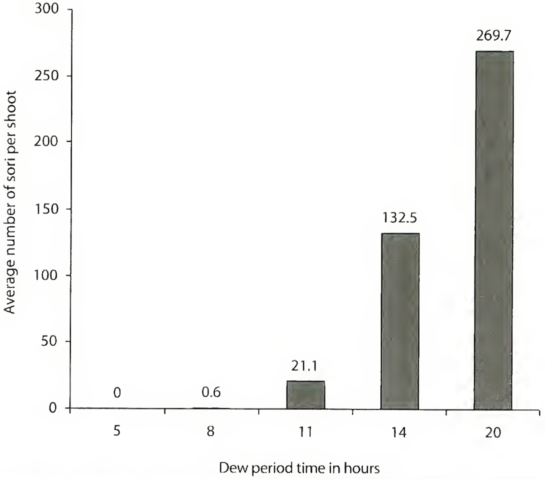

Fig. 1. Average number of sori per shoot developed within the five dew period time treatments.

to ensure that the rust is able to attack all the possible forms of the weed that may occur in Galapagos. There is evidence (from observations on flower color and plant growth form), that this weed has a narrow genetic base on the islands, and hence this rust is likely to infect all populations. Although only limited host specificity testing has been undertaken, the results suggest that this isolate is specific to *L. camara*.

Classical releases of rusts with the same type of life cycle as *P. lantanae* (e.g. microcyclic), show that such short-cycled rusts spread swiftly through and between plant populations (Morin et al. 1996.). The impact of successful classical biological control agents on woody weed species, such as *L. camara*, has tended to take a decade or more to be demonstrated, and often a suite of natural enemies is required. It is anticipated that due to the damaging nature of the rust and the short generation time, the impact may be observed sooner than is normal, and that this single agent may provide effective control.

In the subsequent glasshouse based tests of this agent, untreated (not inoculated) plants of *L. camara* should be compared with treated individuals, in

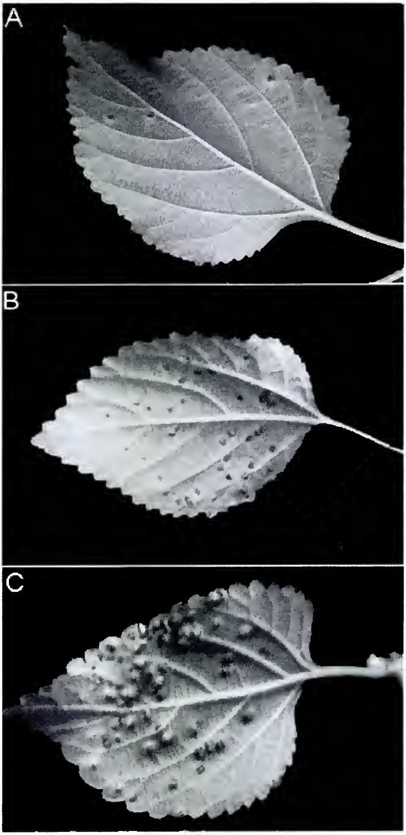

Fig. 2. Levels of infection of *Puccinia lantanae* as result of the different dew period treatments. A. eight hours, B. fourteen hours, C. twenty hours in the dew chamber.

order to investigate the effect of the rust on plant growth and survival. This may help give an indication of the possible level of impact of the agent in the field, although this is known to be quite difficult to study with woody species in controlled conditions.

Lantana camara is difficult to control and appears impossible to eradicate due to the wide range it occupies in the Galapagos. Biological control is a realistic management option. This weed has been studied for over a century as a classical biological control target. Although success has been limited, the rust *Puccinia lantanae* constitutes a new method and a potentially effective agent to try in Galapagos Islands.

ABSTRACT

Fifty-seven species of fungi belonging to 23 genera were isolated and identified from the rhizosphere and rhizoplane of 65 plant species, belonging to 58 genera and 19 families from Sindh and Baluchistan, (Pakistan). A greater number of fungi were isolated from the rhizosphere than from the rhizoplane. In the rhizosphere, *Fusarium solani* and *Aspergillus* spp. were dominant followed by *Drechslera australiensis*. In the rhizoplane, *Fusarium solani* was also dominant. Biocontrol agents like *Trichoderma harzianum, T. koningii, T. viride, V. chlamydosporium*, and *Stachybotrys atra* were isolated in low frequency suggesting their poor competence in the rhizosphere. *Memnoniella echinata* from *Zea mays* and *Sorghum bicolor* and *Stachybotrys parvispora* from *Zea mays* were reported for the first time from Pakistan. Microorganisms in agricultural soils are known to exert profound influences on the soil fertility status as well as on the suppression of soil-borne plant diseases. Multiple microbial interactions involving bacteria and fungi in the rhizosphere are shown to provide enhanced biocontrol in many cases in comparison with biocontrol agents used singly. Importantly, a soil that is suppressive to one pathogen is not necessarily suppressive to another, and so specificity in soil-plant-microbe interactions for disease suppression exists. Modern methods for analyzing microbial community structures may prove particularly valuable to help define the key organisms or groups of organisms responsible for such natural suppression as well as for monitoring the spread and impact of introduction of specific biocontrol agents or other management practices on natural microbial populations.

RESUMEN

Cincuenta y cinco especies de hongos pertenecientes a 23 géneros, fueron aisladas e identificadas en la rizosfera y rizoplana de 65 especies vegetales, pertenecientes a 58 géneros y 19 familias de Sindh y Baluchistan, (Pakistán). Fue aislado un número mayor de hongos en la rizosfera que en el rizoplana. En la rizosfera, *Fusarium solani* y *Aspergillus* spp. fueron los dominantes seguidos de *Drechslera australiensis*. En el rizoplana, *Fusarium solani* fue dominante también. Agentes de biocontrol como *Trichoderma harzianum, T. koningii, T. viride, V. chlamydosporium*, y *Stachybotrys* se aislaron en baja frecuencia lo que sugiere una competencia pobre en la rizosfera. *Memnoniella echinata* de *Zea mays* y *Sorghum bicolour*, y *Stachybotrys parvispora* de *Zea mays* se citan por primera vez de Pakistán. Los microorganismos de los suelos agrícolas ejercen profundas influencias en la fertilidad del suelo así

SIDA 21(2): 1019–1053. 2004

como en la supresión de enfermedades de las plantas originadas en el suelo Las interacciones microbianas múltiples que implican bacterias y hongos en la rizosfera se ve que ejercen un biocontrol incrementado en muchos casos en comparación con los agentes de biocontrol usados aisladamente. Es importante, que un suelo que es supresivo para un patógeno no es necesariamente supresivo para otro, y así la especificidad en las interacciones suelo-planta-microbio para la supresión de la enfermedad existe. Los métodos modernos para analizar la estructuras de la comunidad microbiana pueden ser muy valiosos para ayudar a definir los organismos clave o grupos de organismos responsables de tal supresión natural así como para la supervisión de la extensión y el impacto de la introducción de agentes de biocontrol específicos u otras prácticas de gestión de poblaciones microbianas naturales.

INTRODUCTION

The rhizosphere has become an important area to test and evaluate new opportunities being developed in biotechnology. The rhizosphere is the portion of soil directly influenced by substances issuing from roots into the soil solution, favoring certain microorganisms, harmful around roots of unthrifty plants and beneficial around roots of healthy plants (Atkinson & Watson 2000; Curl 1982). There is an exchange of materials between the plant root and the surrounding micro-population within the rhizosphere. These materials may inhibit or promote growth of the plant or the microorganisms (Bazin et al. 1990; Filion et al. 2004; Katan 2002). Rhizosphere is therefore the site where biological control of soilborne pathogens takes place. Pathogen population (inoculum density), growth and survival and infection or pathogenesis are all influenced by the rhizosphere (Abawi & Widmer 2000; Curl & Truelove 1986; Manka & Kacprzak 1999). Infection of roots by a soilborne plant pathogen is influenced by the physical and chemical properties of the rhizosphere environment and interaction of the pathogen with other microorganisms in that environment (Dix & Webster 1995; Tate 1995). Saprophytic fungi and bacteria in the rhizosphere and root surface create a competitive deterrent to the colonization of rhizoplane and invasion of the plant roots by pathogens (Abawi & Widmer 2000; Tate 1995). It has been reported that more competitive fungal species are found in rhizosphere than soil away from roots (Tate 1995).

Another special habitat or site of microbial activity is rhizoplane or the root surface which supports relatively high biologic activity than rhizosphere (Abawi & Widmer 2000; Atkinson & Watson 2000). It has been reported that legumes support larger rhizosphere population than non-leguminous plants (Subba Rao 1977). Similarly, rhizosphere of resistant cultivars of pigeon-pea (*Cajanus cajan*) harbored more *Streptomyces* and *Trichoderma* antagonistic to *Fusarium udum* causal agent of pigeon pea wilt, than susceptible cultivars and *Trichoderma viride* in the rhizosphere of varieties of tomato resistant to *Verticillium* wilt (Subba Rao 1977). *Trichoderma* spp. and *Paecilomyces lilacinus* are known as effective biocontrol agents against root infecting fungi and have shown promising results in microplot experiments (Boland & Kuykendall 1998; Burges 1998; Lewis et al. 1998; Whipps 1997, 2001). The opportunity to improve crop productivity by introduc-

ing organisms to the rhizosphere is highlighting a major need for the study of fungal community on and around the roots of plants. The present report describes the occurrence of fungal species on rhizosphere and rhizoplane of different plant species collected from different parts of Sindh and Baluchistan (Pakistan).

MATERIALS AND METHODS

Sites and Collection of Samples

Eight sites were chosen for the collection of samples; seven from Sindh and one from Baluchistan. Details of collection sites along with some of the soil characteristics are provided in Table 1. Overall rainfall of these areas is very scanty ranging from 25mm to 102 mm per year. Average summer temperature is 50° C (maximum) and 25° C (minimum), and average winter temperature 25° C (maximum) and 8° C (minimum).

Young healthy plants were carefully dug out up to a depth of 15 cm and root samples with adhering soil (25–50 g depending upon root size) were collected in polyethylene bags. Roots of cultivated crops were collected from agricultural fields. Roots of wild plants were collected from adjacent uncultivated fellow fields. Five replicates of each plant species were collected from each location. Samples were kept under refrigeration at 4° C until the isolation of fungi made within 24 hours. Potato dextrose agar was used for the isolation of fungi in this study, since it supports the growth of most of the fungi from rhizoplane and rhizosphere (van Elsas et al. 2002) and also for endophytes (Halleen et al. 2003), except obligate parasites and those which have special growth requirements.

Isolation of Fungi from Rhizosphere

Volume displacement technique was used for the isolation of fungi from rhizosphere soil as described by Reyes and Mitchell (1962). Root pieces with adhering soil were placed in a graduated cylinder containing 18 mL sterilized distilled water and shaken vigorously. The roots were removed and the process was repeated

Table 2. Fungi isolated from rhizoplane and rhiosphere of wild and cultivated plants growing in Sindh and Baluchistan, Pakistan.

1 = Karachi University Campus, **2** = Memon Goth, **3** = Darsano Chano, **4** = Shah Faisal Colony, **5** = Hub, **6** = Kathor, **7** = Gharo, **8** = Thatta with additional roots until the total volume of soil and water become 20 mL, assumed to be 1:10 dilution. From this other dilutions 1:100, 1:1000, 1:10,000, 1:100,000 were made. One mL aliquot from each of the last two highest dilutions were poured in sterilized petri plate containing potato dextrose agar (PDA) incorporated with penicillin (100,000 units/L) and streptomycin (0.2 g/L) to check bacterial growth. Plates were incubated for 5 days at room temperature (25–30° C) under 12 hours light and dark conditions. Fungi that grew and sporulated on plates were identified with reference to Barnett and Hunter (1998), Dix and Webster (1995), Domsch et al. (1993) and Nelson et al. (1983). Special attention was paid towards the occurrence of root infecting and well known biocontrol agents like *Trichoderma*, *Paecoilomyces lilacinus*, *Verticillium chlamydosporium*. Fungi that did not show morphological characters were included as unidentified.

Isolation of Fungi from Rhizoplane

Roots were washed under running tap water. Tap and lateral roots were cut into 1 cm long pieces, washed with sterilized water and transferred onto PDA plates containing penicillin (100,000 units/L) and streptomycin (0.2 g/L). Plates were incubated for 5 days at 28° C. Fungi grown on plates were identified as described above.

RESULTS AND DISCUSSION

The ecological relationships between host, pathogen and population of soil microbes have been represented by a triangle of interactions (Subba Rao 1977). Root infection by a parasite must be affected and often decisively by the microbial activity of the root surface and rhizosphere microflora (Abawi & Widmer 2000; Boland & Kuykendall 1998; Filion et al. 2004; Manka & Kacprzak 1999; Marschner et al. 2002; Subba Rao 1977; Whipp 2001). In the present study, 57 species of fungi belonging to 23 genera were isolated and identified from rhizoplane and rhizosphere of 65 plant species (Table 2). These comprised 58 genera within 19 families collected from from Sindh and Baluchistan (Table 2). Most of the fungi isolated from rhizosphere and rhizoplane belonged to ascomycota and fungi imperfecti. Few genera belonged to zygomycotina and mycelia sterilia. Host plants are arranged under their families and associated fungi.

A greater number of fungi was isolated from the rhizosphere than from the rhizoplane. In rhizosphere, *Aspergillus flavus* and *A. niger* were predominant along with *Fusarium solani* (Table 2). Population of aspergilli like *A. flavus*, *A. niger* and *A. terrus* was high as compared to other fungal species (data not presented). It is interesting to note that *A. niger* was found in the rhizosphere of the all the members of families Cucurbitaceae, Fabaceae, Solanaceae and Umbliferae. Various studies have also reported the occurrence of greater number of fungal species in rhizosphere than in rhizoplane (Abawi & Widmer 2000; Curl & Truelove 1986; Dix & Webster 1995; Frey et al. 1999; McLean & Huhta 2002)). It has been shown that microbial population is stimulated in rhizosphere (Manka & Kacprzak 1999). Organic and inorganic substances exuded from roots and sloughed off root cells enhanced the microbial population in the region (Tate 1995). Microorganisms in agricultural soils are known to exert profound influences on the soil fertility status as well as on the suppression of soil-borne plant diseases (Kennedy & Smith 1995). In fact, the health of soil can be defined in terms of its microbiological capacity to counteract (suppress) the activity of plant pathogenic or plant deleterious microorganisms (Katan 2002; van Bruggen & Semenov 2000). It is well known that some soils are naturally suppressive to some soil-borne plant pathogens such as *Fusarium oxysporum*, *Pythium* and *Phytophthora* species and this suppression relates to both physicochemical and microbiological features of the soil (Whipps 1997; 2001). Importantly, a soil that is suppressive to one pathogen is not necessarily suppressive to another, and so specificity in soil-plant-microbe interactions for disease suppression exists (Filion et al. 2004; Katan 2002; Marschner et al. 2002; Shiomi et al. 1999). Modern methods for analyzing microbial community structures may prove particularly valuable to help define the key organisms or groups of organisms responsible for such natural suppression as well as for monitoring the spread and impact of introduction of specific biocontrol agents or other management practices on natural microbial populations (Gamo & Shoji 1999; Smit et al. 1999; Postma et al. 2000; Whipps 2001).

In the rhizoplane, root-infecting fungi like *Fusarium solani*, *Drechslera australiensis*, *Macrophomina phaseolina* and *Rhizoctonia solani* were found to be predominant. *Aspergillus flavus* and *A. niger*, *Alternaria alternata*, *Chaetomium globosum*, *Curvularia clavata* and *Fusarium oxysporum* showed an intermediate frequency while remaining isolates were found in low frequency (Fig. 1; Table 2). Among the species of *Aspergillus* encountered frequency of *Aspergillus flavus*, *A. niger* was higher than for other fungi except *F. solani*. This is presumably due to their high sporulating ability and tolerance for different physico-chemical conditions of soil (Domsch et al. 1993). It is interesting to note that *Fusarium solani* was found predominant in both the rhizosphere and rhizoplane of most of the plant species reflecting their high competence in both rhizosphere and rhizoplane of different plant species in different ecological conditions. Characteristics like resistant nature, tolerance to a wide range of moisture, pH and temperature, and parasitic as well as saprophytic mode of life make *F. solani* ubiquitous (Hussain et al. 1966). *Fusarium solani* produces many antibiotics and mycotoxins (Whipps 1997, 2001). *Fusarium solani* is also reported to possess cytotoxic effect on root knot nematode *Meloidogyne javanica*, besides parasitizing its eggs (Hameed et al. 2001). These characteristics play a significant role in its establishment in the rhizosphere and rhizoplane. *Chaetomium*

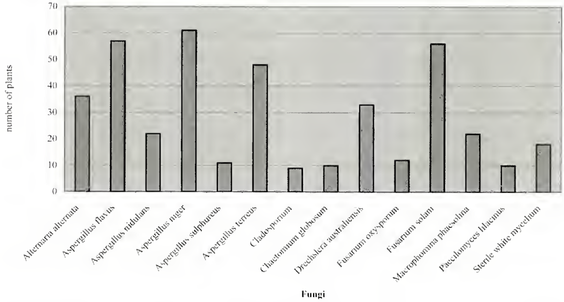

Fig. 1. Major fungi isolated from rhizosphere of 65 plants showing their incidence on hosts.

globosum, *C. indicum* and *Macrophomina phaseolina* had a moderate frequency while *Aspergillus fumigatus*, *A. nidulans*, *Fusarium moniliforme*, *F. oxysporum*, *F. semitectum*, *Penicillium* spp., showed low frequency (Table 2). *Penicillium* spp. are generally abundant in soil and are often among the readily isolated species (Qureshi & Khan 1971). There are reports that *Penicillium*, *Trichoderma*, and *Cladosporium* are most common genera associated with rhizosphere of resistant varieties of flex to *Fusarium* wilt, while *Alternaria*, *Cephalosporium*, *Fusarium*, *Helminthosporium* and *Verticillium* were relatively common in the rhizosphere of susceptible variety (Subba Rao 1977). Chesters and Parkinson (1959) reported that *Penicillium* spp. are abundant in the rhizosphere of very young roots while in older roots they are replaced by members of family Hypocreaceae (e.g. *Fusarium*) and family Dematiaceae (e.g. *Alternaria* and *Drechslera*). In this study six sterile mycelium and one ascomycetous fungi were not identified. Sterile mycelium did not produced reproductive structure on agar media. Might be they required special condition for reproduction. Oligonucleotide finger printing of rRNA genes for analysis of fungal community in soil (Valensky et al. 2002) would be helpful for their identification. It is interesting to note that, in general cultivated plants and common weeds of families Fabaceae and Compositae showed more fungi than wild plants. Presumably roots exudates of cultivated plants and common weeds are more attractive to microbes than exudates of wild plants.

In the present study well known biocontrol agents like *Trichoderma* spp., and *Paecilomyces lilacinus* were found in very low frequencies. Species of *Tri-*

choderma are known to produce antibiotics (Tate 1995; Domsch et al. 1993). Their fewer occurrences reflect their weak competence in the rhizosphere, presumably their sensitivity to metabolites of competeting microorganisms. There are reports that a bacterium with a high level of resistance to a range of antibiotics is more likely to be successful competitor in the rhizosphere than a bacterium producing large quantities of highly active antibiotics but has a marked sensitivity to even a single antibiotic molecules (Bazin et al. 1990). Multiple microbial interactions involving bacteria and fungi in the rhizosphere are shown to provide enhanced biocontrol in many cases in comparison with biocontrol agents used singly (Boland & Kuykendall 1998; Whipps 1997, 2000). A wide range of fungi with antagonistic activity against root pathogens are discovered each year. However, ecological success of the antagonist on the plant roots is governed by its ability to colonize and utilize substrates on plant root surface, allowing it to compete effectively with pathogens and other competitive microorganisms. Otherwise the success of a biocontrol agent with poor rhizosphere competence seems very remote.

ACKNOWLEDGMENTS

This work was carried out under a research grant from the Pakistan Science Foundation, Islamabad, Pakistan. We are thankful to William Campbell, Utah State University, Logan, Utah; M. A. Bari Mallik, Langston University, Langston, Oklahoma and Riaz Ahmad, University of Central Oklahoma, Edmond, Oklahoma for their critical comments and helpful suggestions on the manuscript.

ABSTRACT

The flora of 18 xeric limestone prairies in the Interior Low Plateaus physiographic province in Kentucky was surveyed and a checklist of vascular plants prepared for each site. Nine of the 18 sites are in the Knobstone Escarpment and Knobs, four in the Mammoth Cave Plateau, two in the Pennyroyal Plain and three in the Outer Blue Grass. Life form, photosynthetic pathway, geographic affinity, conservation status and presence were determined for each taxon. Community coefficients were calculated from site floristic lists, and the physiography, geology and soils associated with each site were documented. The flora of xeric limestone prairies in Kentucky was compared to that of limestone cedar glades of the southeastern United States and of deep-soil barrens of the southwestern Pennyroyal Plain in Kentucky and Tennessee. Three hundred and thirty-five taxa were identified in this plant community type, of which 20 are nonnative and 24 state-listed. Families with the highest number of taxa were Asteraceae (70), Poaceae (32) and Fabaceae (29); genera with the highest number of taxa were *Symphyotrichum* (15), *Panicum* sensu lato (=*Panicum* + *Dichanthelium*) (10), *Carex* (7), *Solidago* (7) and *Hypericum* (6). Intraneous C_3 hemicryptophytes make up the majority of the flora. Community coefficients indicate high similarity among all sites except those in the eastern outer Blue Grass, which belong to a second association or community type. Endemic species, a higher percentage of therophytes (i.e. annuals, especially winter annuals) and a higher number of taxa with western and northwestern geographic affinities distinguish the limestone cedar glade flora from those of xeric limestone prairies and deep-soil barrens.

RESUMEN

La flora de 18 praderas calcáreas xéricas en la provincia fisiográfica Interior Low Plateaus en Kentucky fue estudiada y se preparó un catálogo de plantas vasculares en cada lugar. Nueve de los 18 puntos están en el Knobstone Escarpment y Knobs, cuatro en el Mammoth Cave Plateau, dos en la Pennyroyal Plain, y tries en el Outer Blue Grass. Se determinó el tipo biológico, ruta fotosintética, afinidad geográfica, estado de conservación y presencia de cada taxon. Se calcularon los coeficientes de comunidad a partir de las listas florísticas del punto, y se documentó la fisiografía, geología y suelos asociados con cada punto. La flora de las praderas calcáreas xéricas en Kentucky se compara con la de los claros calcáreos de cedro del Sureste de los Estados Unidos y con la de los eriales de suelos profundos del Suroeste de la Pennyroyal Plain en Kentucky y Tennessee. Se identificaron trescientos treinta y cinco taxa en este tipo de comunidad vegetal, de los que 20 no son nativos y 24 están listados en el estado. Las familias con el mayor número de taxa fueron Asteraceae (70), Poaceae

---

SIDA 21(2): 1055–1079. 2004

(32) y Fabaceae (29), los géneros con el mayor número de taxa fueron *Symphyotrichum* (15), *Panicum* sensu lato (=*Panicum* + *Dichanthelium*) (10), *Carex* (7), *Solidago* (7) e *Hypericum* (6). Los hemicriptófitos C_3 característicos de la comunidad forman la mayor parte de la flora. Los coeficientes de comunidad indican alta similitud entre todos los puntos excepto los de Northeastern Blue Grass, que pertenecen a una segunda asociación o tipo de comunidad. Las especies endémicas, un alto porcentaje de terófitos (ej. anuales, especialmente anuales de invierno) y un alto número de taxa con afinidades geográficas occidentales y noroccidentales diferencian la flora de los claros calcáreos de cedro de la de las praderas calcáreas xéricas y eriales de suelos profundos

INTRODUCTION

Xeric limestone prairies are characterized by high cover of C_4 perennial grasses (*Schizachyrium scoparium*, *Andropogon gerardii*, *Sorghastrum nutans* and *Bouteloua curtipendula*), moderate to steep slopes with south to west aspects and shallow rocky soils derived from calcareous substrates (Baskin & Baskin 2000). In Kentucky, these herbaceous plant communities occur in the western mesophytic forest region (sensu Braun 1950) and are rare at the landscape scale. The flora of xeric limestone prairies in Kentucky has not been adequately characterized, and the soils, geology and physiography associated with this community type have not been documented systematically. Thus, the primary objectives of the present study were to: 1) provide a checklist of vascular plants in xeric limestone prairies in Kentucky based upon field work conducted by the first author; 2) determine the geographic relationships, life forms and photosynthetic pathways of the constituent taxa; and 3) document the soils, geology and physiography associated with xeric limestone prairies in Kentucky. A fourth objective was to further compare xeric limestone prairies to limestone cedar glades and deep-soil barrens, both of which also are developed on calcareous substrates and occur in the western mesophytic forest region.

In their comparison of xeric limestone prairies, limestone cedar glades and deep-soil barrens in the Kentucky Karst Plain and adjacent areas, Baskin et al. (1994) focused primarily on vegetation, edaphic characteristics and origins. Like xeric limestone prairies, deep-soil barrens are characterized by high cover of C_4 perennial grasses (*Schizachyrium scoparium*, *Andropogon gerardii* and *Sorghastrum nutans*). However, deep-soil barrens originated from periodic burning by Native Americans prior to European settlement, whereas xeric limestone prairies resulted from clearing of land for agricultural purposes, overgrazing and subsequent soil erosion (Baskin et al. 1994). Conversely, limestone cedar glades are an edaphic climax community and typically have high cover of the C_4 summer annual grass *Sporobolus vaginiflorus* (Baskin & Baskin 1999).

Baskin and Baskin (2003) published the flora of limestone cedar glades of the southeastern United States, and Chester et al. (1997) published the flora of deep-soil barrens in the southwestern Pennyroyal Plain of Kentucky and Tennessee. By providing a flora of xeric limestone prairies in Kentucky, the current study affords the opportunity for floristic comparisons among these three herb-dominated community types. Comparative data on species richness, geographic affinities, photosynthetic pathways, life form and taxonomic distribution of the three respective floras are essential for accurate characterization of these community types and will provide further insight into their ecological differences.

SITE CHARACTERISTICS

A site was defined as a single forest opening (Fig. 1), many of which contained small patches of woody vegetation. In two sample areas (Crooked Creek Barrens and Fort Knox Military Reservation), two forest openings occurred on the same land parcel. However, in both of these properties the two openings are separated by at least 100 m, and thus each opening was considered a site. An attempt was made to determine the exact area of each site using GIS software. However, the large perimeter to area ratios and patches of woody vegetation in many sites prevented accurate measurement. In general, sample sites ranged from less than 0.5 to approximately 2.25 hectares. Site characteristics are summarized in Table 1.

Physiography

In Kentucky, xeric limestone prairies occur in the Blue Grass, Shawnee and Highland Rim sections of the Interior Low Plateaus physiographic province (sensu Quarterman & Powell 1978) (Fig. 2). The Knobstone Escarpment and Knobs subsection of the Blue Grass supports the largest number of xeric limestone prairies in the state, containing nine of the 18 sites surveyed in this study. The relatively high number of xeric limestone prairies in this area is most likely due to the rugged terrain in the region, since moderate to steep slopes with fine-textured soils are particularly susceptible to soil erosion. Xeric limestone prairies also occur in the western (Pine Creek Barrens) and eastern (Crooked Creek Barrens 1 and 2) Outer Blue Grass. In the Shawnee Hills section, all four sample sites (Grayson County Barren, Knight's Barren, Lapland Barrens and Lapland Road Barrens) are located in the Mammoth Cave Plateau. Logan County Glade and Logan County Barrens also are shown in the Mammoth Cave Plateau on the map of Quarterman and Powell map (Fig. 1, page 30). However, we consider them to be in the Pennyroyal Plain subsection of the Highland Rim, which is in agreement with Fenneman (1938, Figure 123, page 436) and an unpublished map of the Pennyroyal Plain by Baskin and Baskin.

Geology

The xeric limestone prairies in Kentucky occur on Upper Silurian and Upper Mississippian calcareous substrates including limestone, dolomite and shale (Fig. 3). The sample sites in the Knobstone Escarpment and Knobs, Mammoth Cave Plateau and Pennyroyal Plain all occur on Upper Mississippian limestones, many of which also contain shale and/or dolomite. All nine xeric limestone prairies surveyed in the Knobstone Escarpment and Knobs are developed on

Fig. 3. Bedrock geology of xeric limestone prairies in the Outer Blue Grass (western and eastern), Pennyroyal Plain, Mammoth Cave Plateau, and Knobstone Escarpment and Knobs subsections of the Interior Low Plateaus physiographic province in Kentucky (from McDowell 1981). Numbers refer to site numbers in Table 1. The break between Upper Mississippian and Upper Silurian is for the Upper Devonian upon which xeric limestone prairies do not occur in Kentucky.

Salem Limestone, of the Meramecian Series (Keperfele 1966, 1967; Peterson 1966). Keperfele (1967) defines two main units within the Salem Limestone and describes the second unit in association with characteristic surface and vegetation features of xeric limestone prairies as follows: "an argillaceous limestone and shale" with a "surface marked by rounded gullied slopes barren except for scattered junipers."

All sample sites in the Mammoth Cave Plateau and Pennyroyal Plain occur on Upper Mississippian limestones of the Chesterian Series, many of which contain a significant shale component. Three of the four xeric limestone prairies in the Mammoth Cave Plateau (Lapland Road Barrens, Lapland Barrens and Knight's Barren) are on Reelsville Limestone, and two of the three sites (Lapland

Road Barrens and Lapland Barrens) extend onto Beech Creek Limestone (Amos 1972; Moore 1965). The fourth site in the Mammoth Cave Plateau (Grayson County Barren) is restricted to Glen Dean Limestone (Gildersleeve 1978). The two sites in the Pennyroyal Plain are developed on Paint Creek Limestone (Logan County Barrens) and Girkin Limestone (Logan County Glade) (Miller 1968; Rainey 1965).

The single sample site in the western Outer Blue Grass (Pine Creek Barrens) is on Louisville Limestone (Upper Silurian), which is composed of dolomite and dolomitic limestone (Keperfele 1968). The two xeric limestone prairies in the eastern Outer Blue Grass (Crooked Creek Barrens 1 and 2) are formed on the Upper Part of the Crab Orchard formation, a variegated clay-shale, and the Lower Part of the Crab Orchard and Brassfield formations (undivided, Upper Silurian), which is composed of dolomite, dolomitic limestone and interbedded clay-shale (Peck & Pierce 1966).

Soils

Soils of xeric limestone prairies in Kentucky have mixed mineralogy, are fine-textured (Table 2), moderately to severely eroded and shallow to moderately deep (0 to ca. 1 m, Baskin et al. 1994). Forty-two percent of 376 soil depth measurements in the 18 sites were $\leq$ 10 cm, 76% $\leq$ 30 cm, 91% $\leq$ 60 cm, and only 6% $>$ 1 m (Lawless, unpublished). Ten of the 13 soil series upon which xeric limestone prairies occur are Alfisols, and the remaining three series are Mollisols (Corydon), Ultisols (Gilpin) and Inceptisols (Garmon). Nine of the 18 sample sites are developed on the Caneyville series, a Typic Hapludalf (Fig. 4). In addition, many of the soil mapping units in xeric limestone prairies are rock outcrop complexes (e.g. Caneyville-Rock Outcrop Complex, Rock Outcrop-Corydon Complex and Rock Outcrop-Fredonia-Colbert Complex). All soil mapping units associated with sample sites in the Knobstone Escarpment and Knobs are members of the Garmon-Caneyville-Lenberg Soil Association, which in this region also includes the Corydon, Cumberland, Hagerstown and Vertrees series (Arms et al. 1979). Three of the four sites in the Mammoth Cave Plateau (Grayson County Barren, Lapland Road Barrens and Knight's Barrens) occur on the Caneyville series (Arms et al. 1979; Haagen 2001; Whitaker et al. 1972), and the fourth (Lapland Barrens) is the only site on the Rosine-Gilpin-Lenberg complex (Haagen 2001). Both sites in the Pennyroyal Plain (Logan County Barrens and Logan County Glade) are restricted to the Rock Outcrop-Fredonia-Colbert complex (Dye et al. 1975). The sample sites in the Outer Blue Grass occur on the Caneyville series (Pine Creek Barrens) (Whitaker & Waters 1986) and Beasley and Shrouts series (Crooked Creek Barrens 1 and 2) (USDA, NRCS, Soil survey of Lewis County, Kentucky. unpublished).

METHODS

In 2002 and 2003, each of 18 sites was visited a minimum of once per season in spring, summer and autumn. All vascular plant species were recorded and a

species list prepared for each site. Gleason and Cronquist (1991) was used for field identification, and taxa not identified in the field were collected and determined in the University of Kentucky Herbarium (KY) with the aid of a stereomicroscope. Each taxon was assigned a presence value based on the percentage of sites in which it was recorded and placed in one of the following five presence classes (Cain & Castro 1959): 1 (1–20%), 2 (21–40%), 3 (41–60%), 4 (61–80%) and 5 (81–100%) . *Sporobolus vaginiflorus* was treated as a single taxon, since the two varieties found in this study are primarily distinguished by microscopic characters in both vegetative and reproductive states (FNEC 2003). Community coefficients (CC) were calculated for all possible pair-wise site comparisons using PC-ORD (McCune and Mefford 1999). Community coefficients [CC= 2W/(A+B)] are based on the number of taxa shared between sample sites (W) and the total number of taxa in site A and in site B. The life form (sensu Raunkiaer 1934) of each taxon was obtained from Gibson (1961), Hansen (1952), Ennis (1928) and Baskin and Baskin (1978) and the photosynthetic pathway from Baskin and Baskin (2003) and Waller and Lewis (1978). Life form and photosynthetic pathway also were determined for each of the 342 taxa reported by Chester et al. (1997) in the deep-soil barrens of the southwestern Pennyroyal Plain of Kentucky and Tennessee for comparisons with the floras of xeric limestone prairies in Kentucky and limestone cedar glades of the southeastern United States (Baskin & Baskin 1999). We reviewed the list of state endangered, threatened and special concern species published by the Kentucky State Nature Preserves Commission (2002) and noted all state-listed taxa occurring in the xeric limestone prairies of Kentucky.

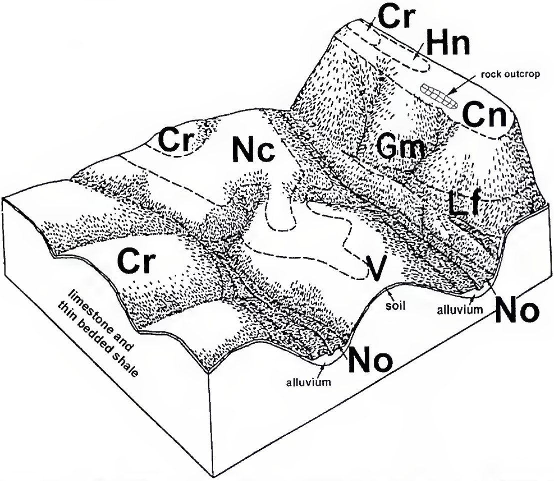

FIG. 4. A block diagram of the topography and soil series in the Knobs and Knobstone Escarpment section of the Interior Low Plateaus physiographic province in Hardin and Larue counties Kentucky. Soil series: **Cn**=Caneyville, **Cr**=Crider, **Gm**=Garmon, **Hn**=Hagerstown, **Lf**=Lenberg-Frondorf, **No**=Nolin-Newark-Melvin, **V**=Vertrees.

The geographic relationships of all taxa were determined by examining distribution maps obtained from Plants (USDA, NRCS 2004). Taxa in which Kentucky is in the central region of their current distribution were defined as intraneous, and those in which Kentucky is at the edge of their current distribution were defined as extraneous. When considering the geographic relationships of taxa in which Kentucky is near the edge of their range, the conservation status or rank and/or county distribution in the adjacent state was (were) considered, if available. If Kentucky is near the edge of the taxon's current distribution and the taxon is listed (endangered, threatened or special concern) in the adjacent state or only distributed in counties adjacent to the Kentucky border, the taxon was considered extraneous. The extraneous species were divided further into extraneous northern, southern, eastern and western groups in accordance with the position of Kentucky in relation to the center of distribution of the taxon of interest.

RESULTS

A total of 335 vascular plant taxa representing 333 species, 215 genera and 72 families were recorded in the 18 xeric limestone prairies surveyed (Appendix). The genera *Crataegus* and *Rubus* were each treated as a single taxon, because no flowering individuals were observed in either genus, both of which are characterized by intergradation of vegetative characters between/among species and high taxonomic diversity. Three hundred and fifteen (94.0%) of the 335 taxa are native to Kentucky, and the remaining 20 (6.0%) nonnative (Fig. 5). Asteraceae, Poaceae and Fabaceae had the highest richness values of all families, containing 70 (20.9%), 32 (9.6%) and 29 (8.7%) taxa, respectively. Genera with the largest number of taxa were *Symphyotrichum* (15), *Panicum* sensu lato (=*Panicum* + *Dichanthelium*) (10), *Carex* (7), *Solidago* (6) and *Hypericum* (6). The xeric limestone prairies in Kentucky support 24 state-listed taxa (9 endangered, 8 threatened and 7 special concern), including three species (*Delphinium carolinianum* ssp. *calciphilum*, *Leavenworthia exigua* var. *laciniata* and *Talinum calcaricum*) listed by Baskin and Baskin (1999) as cedar glade endemics. However, none of these state-listed taxa is federally listed, and none of the taxa recorded in this study is endemic to xeric limestone prairies in Kentucky. Furthermore, the three cedar glade endemics occur in areas of xeric limestone prairies that fit the description of limestone cedar glades when categorized at small spatial scales (Fig. 1).

The flora of xeric limestone prairies in Kentucky is composed primarily of native C_3 hemicryptophytes with broad geographical distributions encompassing Kentucky. Ninety-two and eight-tenths percent of the taxa are C_3 plants, and with the exception of *Manfreda virginica*, *Opuntia compressa* (CAM plants) and *Cuscuta cuspidata* (nonphotosynthetic), the remaining taxa are C_4 plants. The hemicryptophyte life form group contains more taxa (52.9% of native species) than all other life form groups combined (Fig. 5). Seventy-three and five-tenths percent of the native taxa in the xeric limestone prairie flora in Kentucky (230 taxa) is intraneous (Fig. 6), and taxa with southern geographic affinities (44 taxa, 14.1%) make up the largest extraneous component of the flora.

Although species richness values varied considerably across the 18 xeric limestone prairie sites surveyed, species composition among the sites was quite similar. Average site richness was 113 taxa (CV=13%) and ranged from 88 (Thompson Creek Glade) to 151 (Pine Creek Barrens) (Table 1). Calculation of community coefficients (CC's) for all possible pair-wise site comparisons determined that the majority of xeric limestone prairies surveyed form a single association or community type. Only 11 of the 153 CC's calculated were less than 0.50, the generally accepted association criterion (Barbour et al. 1999). Nine of the 11 CC's less than 0.50 included either site 1 or site 2 in Crooked Creek Barrens, and the CC resulting from comparison of Crooked Creek Barrens site 1 and site 2 is high

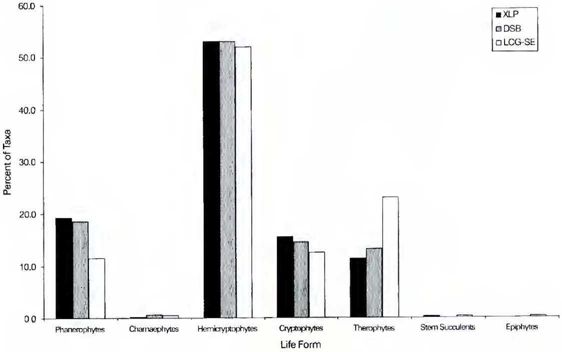

FIG. 5. Life form distribution of native species in the floras of xeric limestone prairies in Kentucky (XLP), deep-soil barrens of the southwestern Pennyroyal Plain (DSB) and limestone cedar glades of the southeastern U.S. (LCG-SE).

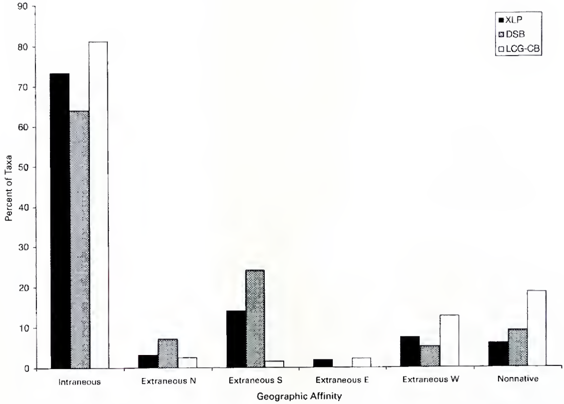

FIG. 6. Geographic affinities of the floras of xeric limestone prairies in Kentucky (XLP), deep-soil barrens of the southwestern Pennyroyal Plain (DSB) and cedar glades in the Central Basin of Tennessee (LCG-CB).

(0.71). These data suggest the two sites in Crooked Creek Barrens may belong to a second association or community type. Particularly noteworthy was the absence of *Echinacea simulata* and *Hypericum dolabriforme* in both Crooked Creek Barrens sites, since these taxa had high frequency values in the majority of the remaining sites (Lawless, unpublished). CC's ranged from 0.39 to 0.80, and the average CC (x=0.58) minus one standard deviation (s = 0.07) exceeds the generally accepted 0.50 association criterion.

As expected, the presence diagram for the xeric limestone prairie flora in Kentucky (Fig. 7) shows that the majority of species are in presence classes 1 and 2. However, the percentage of taxa in presence class four (15.3%) is similar to that in presence class two (18.0%), and thus class four approaches a second maximum (Oosting 1956). Only 13 taxa were present in all 18 sites, and all of them are native. Five of these 13 taxa are broadly distributed phanerophytes (*Cercis canadensis*, *Diospyros virginiana*, *Fraxinus americana*, *Juniperus virginiana* and *Rhamnus caroliniana*), two are dominant perennial (*Schizachyrium scoparium*) and annual (*Sporobolus vaginiflorus*) grass species in this community type (Baskin & Baskin 2000; Lawless, unpublished), and the remaining six species (*Euphorbia corollata*, *Helianthus hirsutus*, *Lobelia spicata*, *Physostegia virginiana*, *Ruellia humilis* and *Solidago nemoralis*) are relatively abundant forbs in the xeric limestone prairies in Kentucky (Lawless, unpublished).

DISCUSSION

The taxonomic distribution of the flora of xeric limestone prairies in Kentucky is very similar to that in the floras of cedar glades of the southeastern United States (Baskin & Baskin 1999) and of the deep-soil barrens of the Southwestern Pennyroyal Plain in Kentucky and Tennessee (Chester et al. 1999). However, the percentage of nonnative taxa in the xeric limestone prairie flora of Kentucky (6.0%) is considerably less than the percentages of nonnative taxa in the floras of the state of Kentucky (21.8%, Jones in press) of cedar glades of the Central Basin of Tennessee (18.7%, Baskin & Baskin 2003) and of southeastern United States (17.9%, Baskin & Baskin 1999) and of deep-soil barrens of the southwestern Pennyroyal Plain in Kentucky and Tennessee (9.1%, Chester et al. 1997) (Fig. 6). Furthermore, the vast majority of nonnative species in the xeric limestone prairie flora in Kentucky have low presence values. Nine of 20 taxa were present in only one site, and 18 occurred in four sites or less. The low percentage of nonnative taxa in the flora of xeric limestone prairies in Kentucky may be due to erosion of the organic horizon in these sites, which presumably has reduced nutrient availability in the surface layer. This reduction in surface layer nutrient availability may significantly decrease survivorship of nonnative seedlings, as these taxa typically are adapted to nutrient-rich sites (Grime 1974).

Asteraceae and Poaceae have the highest richness values of all families in the floras of xeric limestone prairies in Kentucky, cedar glades of the south-

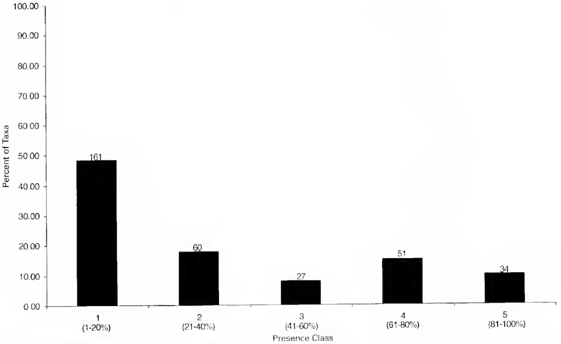

Fig. 7. Percent of taxa in each of five presence classes in 18 xeric limestone prairies surveyed in the Interior Low Plateaus physiographic province in Kentucky. Presence classes are as follows: 1=1–20%, 2=21–40%, 3=41–60%, 4=61–80% and 5=81–100%. Number of taxa in presence class above each bar.

eastern United States and deep-soil barrens of the southwestern Pennyroyal Plain, collectively accounting for 30.4%, 20.9% and 33.3%, respectively, of taxa in these floras. The Fabaceae ranks third in species richness in the floras of xeric limestone prairies in Kentucky and deep-soil barrens, whereas species richness in the Cyperaceae exceeds that in the Fabaceae in the flora of cedar glades of the southeastern United States. The flora of cedar glades also is distinguished by 19 endemic and two near-endemic taxa. The genus *Panicum* sensu lato contains the largest number of taxa in the floras of cedar glades (16 taxa) and deep-soil barrens (10 taxa). The flora of xeric limestone prairies in Kentucky also is rich in *Panicum* species sensu lato (10 taxa); however, *Symphyotrichum* had the highest richness of all genera (15 taxa).

The geographic affinities, photosynthetic pathway and life form distributions among the floras of xeric limestone prairies in Kentucky, limestone cedar glades and deep-soil barrens are similar. However, the flora of limestone cedar glades differs from that of the other two community types in three important aspects. The floras of xeric limestone prairies and deep-soil barrens contain a strong extraneous southern component (14.1 % and 24.0% of floras, respectively). In contrast, taxa with western or northwestern geographical affinities make up the largest percentage of extraneous taxa (12.6% of flora) in the limestone cedar glade flora (Baskin & Baskin 1999). The phanerophyte life form group contains a considerably smaller percentage of native taxa in the flora of limestone cedar glades (11.5%) in comparison with the floras of xeric limestone prairies in Kentucky (19.4%) and deep-soil barrens (18.6%) (Fig. 5). The flora of limestone cedar glades also is distinguished by a relatively high percentage of native therophytes (23.0%), many of which are winter annuals. The cedar glade flora contains eight winter annuals in the genus *Leavenworthia* alone, which partially accounts for the richness of the Brassicaceae (17 taxa) in this community type and for the near endemic status of the genus *Leavenworthia* in the southeastern United States (Baskin & Baskin 2003; Estill & Cruzan 1999). Conversely, the xeric limestone prairie flora in Kentucky contains only two native winter annuals, *Leavenworthia uniflora* and *Leavenworthia exigua* var. *laciniata*, both of which occur in cedar glade-like areas of the perennial grassland matrix (Fig. 1), and this life cycle type is absent in the deep-soil barrens flora.

The winter annual life cycle is an adaptive phenological strategy in limestone cedar glades. It assures completion of the life cycle prior to summer-dry conditions, which winter annuals pass in the drought-tolerant seed stage (Baskin & Baskin 1985). The paucity of winter annuals in the floras of xeric limestone prairies in Kentucky and deep-soil barrens of the southwestern Pennyroyal Plain suggest the edaphic conditions in these habitats are considerably less severe, and/or these communities have not existed for a sufficient period to allow for evolution of the annual life cycle in a comparable proportion of resident taxa.

Although the xeric limestone prairies surveyed support no endemic or federally listed taxa, this community type is the primary habitat in Kentucky for almost all of the 24 state-listed species recorded in the present study. Therefore, preservation of these species in Kentucky is dependent upon conservation of the xeric limestone prairie community type. Presently, nine of the 18 sites surveyed are owned by conservation organizations (Kentucky State Nature Preserves Commission and The Nature Conservancy) or by the federal government (Fort Knox Military Reservation). Three of the remaining nine sites (Hardin County Cedar Glade, Knight's Barrens and Lapland Barrens) are under management agreement with The Nature Conservancy, and the Logan County NRCS office is currently in the process of purchasing Logan County Barrens, one of the two sites surveyed in the Pennyroyal Plain. The most significant threat to xeric limestone prairie conservation is all terrain vehicle (ATV) usage, which damages or destroys vegetation, thus promoting further erosion of denuded soils.

Baskin et al. (1994) proposed the following sequence of events for the origin of xeric limestone prairies in Kentucky: clearing of marginal agricultural lands by European settlers → cultivation and/or grazing → significant erosion of the topsoil → abandonment → colonization of these degraded areas by the xeric limestone prairie flora → succession to hardwood forest in the absence of disturbance or maintenance of xeric limestone prairie with periodic management (i.e. disclimax). Forest succession is retarded by the highly eroded soils of these abandoned hillsides and by large heat loads (sensu McCune and Grace 2002) associated with the moderate to steep slopes with south to west aspects. However, succession to hardwood forest eventually occurs in the absence of management, which typically consists of mechanical removal of large trees, particularly *Juniperus virginiana*, and periodic prescribed fire (2-5 year burning interval, David Skinner, KSNPC Eastern Preserve Manager, personal communication).

The species composition of this community type is relatively consistent despite 1) their relatively recent origin, 2) the rarity of xeric limestone prairies at the landscape scale and 3) the small area occupied by these communities in the matrix of deciduous forests and agricultural lands. The richness of Asteraceae and Poaceae in the xeric limestone prairie flora of Kentucky is primarily responsible for the relatively high community coefficients (x = 0.58) observed in this study, since both of these families are characterized by large regional species pools and high proportions of wind-dispersed taxa. Furthermore, we have observed many taxa in the xeric limestone prairie flora (e.g. *Schizachyrium scoparium, Panicum flexile, Liatris squarrulosa, Ratibida pinnata, Croton monanthogynous, Hypericum dolabriforme*, etc.) in open forests with shallow rocky soils, on rock ledges and on rocky stream banks. These habitats, in addition to deep-soil barrens and limestone cedar glades, are the likely sources of the xeric limestone prairie flora in Kentucky, since they existed prior to European settlement.

CONCLUSIONS

Xeric limestone prairies are broadly distributed throughout the Interior Low Plateaus physiographic province in Kentucky and are most frequent in the Knobstone Escarpment and Knobs, where they primarily occur on eroded Alfisols derived from the Upper Mississippian Salem Limestone. The flora is rich in species of Asteraceae and Poaceae and contains 24 state-listed species, many of which are restricted to xeric limestone prairies in this part of their geographic range. Community coefficients suggest that all sample sites except those in the eastern Outer Blue Grass (Crooked Creek Barrens 1 and 2) belong to a single community type. Xeric limestone prairies are relatively well protected in Kentucky; the majority of sites are owned and/or managed by conservation organizations and the federal government.

The majority of taxa in the floras of xeric limestone prairies in Kentucky, limestone cedar glades of the southeastern United States and deep-soil barrens of the southwestern Pennyroyal Plain in Kentucky and Tennessee are intraneous C_3 hemicryptophytes. The very low percentage (6.0) of nonnative species in the xeric limestone prairie flora of Kentucky is noteworthy. Among xeric limestone prairies, limestone cedar glades and deep-soil barrens, the flora of limestone cedar glades is particularly unique due to 1) 21 endemic/near endemic taxa, 2) relatively high percentage of therophytes and 3) an extraneous component with strong western and northwestern affinities (Baskin & Baskin 1999).

In contrast, the floras of xeric limestone prairies in Kentucky and deep-soil barrens of the southwestern Pennyroyal Plain 1) contain no endemic taxa, 2) have higher percentages of phanerophyte taxa and 3) have an extraneous component with strong southern geographic affinities.

APPENDIX

Taxonomy is in accordance with USDA, NRCS (2004), with the exception of *Elymus glabriflorus* var. *australis*, which is based on the treatment by Campbell (1995). The name and authority for each taxon is followed, in parentheses, by the photosynthetic pathway (C3, C4 or CAM), life form (Ph=phanerophyte, Ch=chamaephyte, H=hemicryptophyte, Cr=cryptophyte and Th=therophyte; HP=holoparasite), geographic affinity (I=intraneous, EN=extraneous northern, ES=extraneous southern, EE=extraneous eastern, EW=extraneous western and X=introduced) and conservation status in the state of Kentucky (E=endangered, T=threatened and S=special concern) (KSNPC 2002) in bold-faced type. Number in bold-faced type following the final parenthesis refers to number of sites in which species was recorded.

ABSTRACT

Fort Matanzas National Monument, administered by the National Park Service, U.S. Department of the Interior, comprises 127 ha (313 acres) that includes portions of two barrier islands in St. Johns County, Florida: northern Rattlesnake Island, where the historic Fort Matanzas is located, and southern Anastasia Island. A floristic survey was conducted to provide Park Service personnel with a vouchered checklist of vascular plant species, supplemented with salient information such as relative abundance, locality data, and community type. Four intensive collecting trips conducted in 2003–2004 yielded 237 species of vascular plants in 189 genera of 73 families. The four largest families are Poaceae, Asteraceae, Fabaceae, Amaranthaceae, and Euphorbiaceae. A map, descriptions, and photographs of the various plant communities are also provided.

RESUMEN

El Monumento Nacional Fuerte Matanzas, administrado por el Servicio de Parques Nacionales del Departamento del Interior, tiene una extensión de 127 ha e incluye dos islas de barrera localizadas en el condado de St. Johns, Florida: al Norte la Isla Rattlesnake donde se encuentra el Fuerte Matanzas, y al Sur la Isla Anastasia. Fue realizado un monitoreo florístico por el personal del Servicio de Parques Nacionales, utilizando una lista de especies testigo, que presenta información sobre la descripción, abundancia relativa, localidad y el tipo de comunidad florística de las especies de plantas vasculares de la zona. Se realizaron cuatro viajes de colecta intensiva entre 2003 y 2004, de los cuales se obtuvieron un total de 237 especies de plantas vasculares, pertenecientes a 189 géneros y 75 familias. Las cinco familias más representadas son Poaceae, Asteraceae, Fabaceae, Amaranthaceae y Euphorbiaceae. Se presentan mapas, descripciones y fotografías de varias de las comunidades de plantas muestreadas.

SIDA 21(2): 1081–1106. 2004

INTRODUCTION

Study Area

Fort Matanzas National Monument, administered by the National Park Service (NPS; U.S. Department of the Interior), is located 14 mi (22.5 km) south of St. Augustine along State Road (S. R.) A1A in St. Johns County, Florida (Fig. 1A). The park comprises 313 acres (127 ha; Fig. 1B): the southern tip of Anastasia Island (138 acres, 56 ha) and the northern third of Rattlesnake Island (175 acres, 71 ha; NPS 2004). Both islands are separated from mainland Florida by the Matanzas River and the Intracoastal Waterway. These linear shaped barrier islands of quartz sand parallel the gently sloping Atlantic coastline and occur on underlying coquina (the Anastasia formation), a soft whitish limestone formed primarily of coarsely broken shells naturally cemented together (Waterbury 1993). The historic Fort Matanzas (discussed below), built from quarried coquina stone, is situated on northeast Rattlesnake Island overlooking the Matanzas River. A comprehensive and vouchered survey of the vascular flora had not previously been conducted for this NPS controlled land.

Anastasia Island.—The Anastasia Island portion of the park [1.0 mi (1.6 km) long; minimum width 0.02 mi (0.03 km), maximum width 0.4 mi (0.6 km)] consists of stabilized beach dunes rising as much as 27 ft (8.2 m) above sea level and is bisected by S. R. A1A that becomes a bridge over the southernmost tip of the island (Fig. 1B). Park property borders along A1A are 50 ft (15.2 m) from the center line of the highway on each side (east and west). The park is hemmed in by dense beachfront housing development to the north, and the Summer Haven community across the S. R. A1A bridge, to the south.

Most NPS land here is accessible to the public. Along southwest S. R. A1A are two entrance points to the Matanzas River (main visitor center and a dune boardwalk, numbered 1 and 4, respectively, in Fig. 1B), and across S. R. A1A to the east, two points of easy access to the Atlantic Ocean [beach ramp (2 in Fig. 1B) and dune boardwalk (5)]. The visitor center encompasses a parking lot/gift shop/picnic area, park headquarter offices/maintenance areas, boat dock, and a nature trail/boardwalk [through dense forest (3)]. A small parking lot for a boardwalk (4) through the dunes out to the Matanzas River is 0.35 mi (0.56 km) further south along west S. R. A1A. Directly across the highway to the east is another parking lot for the third, much longer boardwalk (5) over the fragile dune system, which terminates in an overlook of the Atlantic Ocean. Another parking area opposite the visitor center entrance (2) cuts through the dunes and allows vehicle access to the Atlantic Ocean. This popular beach even has traffic "lanes" along the shore (speed limit 10 mi/hr) policed by NPS personnel; however, only four-wheel drive vehicles are allowed along the southwest "hook" of the island bordering Matanzas Inlet where the sand is less compacted and where Least Terns nest for part of the year.

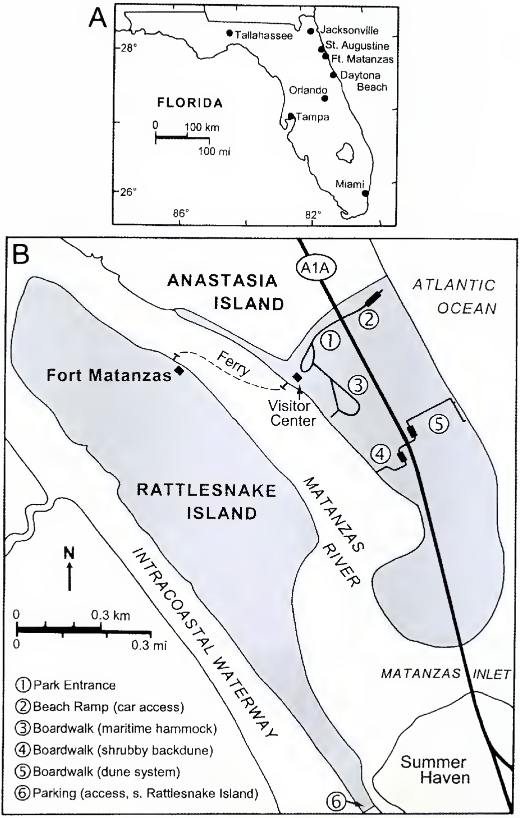

Fig. 1. Location and boundaries of Fort Matanzas National Monument. A. General location of Fort Matanzas, ca. 14 mi (22.5 km) south of St. Augustine, Florida. **B.** Fort Matanzas National Monument park property (shaded), comprising the northern third of Rattlesnake Island and the southern tip of Anastasia Island. Modified from NPS (2004).

Rattlesnake Island.—When Fort Matanzas was built in 1740, the island it occupied totaled less than two acres, and a soldier on the gun deck could look directly out over the ocean. Erosion and shifting tidal deposits have altered the inlet, and the fort is now about 0.5 mi (0.8 km) farther from the Atlantic Ocean (Fig. 2). In the early 1900's the Army Corps of Engineers dug the channel for the Intracoastal Waterway west of the fort (Fig. 1B), and the little island was joined with other islets, creating a much larger isle now called Rattlesnake Island (Chandler 2002).

The Rattlesnake Island park area [1.28 mi (2.1 km) long; minimum width 0.03 mi (0.05 km), maximum width 0.31 mi (0.50 km)] is bordered to the south by exclusive waterfront homes. The northern and southern ends of the park have been created mainly by dredged spoil from the Intracoastal Waterway, and tidal creeks and a labyrinth of mosquito control ditches fragment the low-lying central portion (Fig. 3). Most of the island is less than 5 ft (1.5 m) above sea level, although the central fill area at the northern end rises to ca. 17 ft (5.2 m).

The majority of NPS land on Rattlesnake Island is closed to the public. Fort Matanzas on the northeast coast is accessible for brief (ca. 45 min.) guided tours via a forty-two passenger boat that crosses the river eight times daily from the visitor center on Anastasia island. Annually, over 50,000 tourists visit the fort (NPS 2004). A parking area at the southeastern park border (6 in Fig. 1B) allows access for fishing, although we noted very little activity along the jetties, especially in comparison to the popular southwestern beaches of Anastasia island along the river and inlet.

Brief History of Fort Matanzas National Monument

Spanish colonial history in Florida (mid-sixteenth to early nineteenth centuries) involved crucial events around the Matanzas Inlet (Manucy 1943; Schesventer et al. 1980; Chandler 2002). The name Matanzas, the Spanish word for slaughters, reflects the violent history of the area – specifically, the massacre of 245 French soldiers in 1565 under the orders of Pedro Menéndez de Avilés. On two occasions, soldiers trying to reach Fort Caroline (near present-day Jacksonville) had shipwrecked in the inlet and surrendered to the Spanish. As "heretics" (Huguenots or Protestants) and a threat to Catholic Spanish colonization in Florida, they were subsequently executed behind the dunes on Anastasia Island.

A sentry post at Matanzas with no armament was erected by 1569 as part of a series of lookouts along the uninhabited Matanzas Inlet. The wooden watchtower was not optimal for weathering the warm temperatures and high humidity. The well preserved stone-masonry fort standing on present-day Rattlesnake Island (see photograph in lower right of Fig. 3) was constructed in 1740–1742. Fort Matanzas, designed by engineer Pedro Ruiz de Olano, is a simple, two-story, square structure: 49.5 ft (15.0 m) on each side with a 12 ft (3.7 m) gundeck with two 4 ft (1.2 m) tall parapets (east and west sides) and 30 ft (9.1

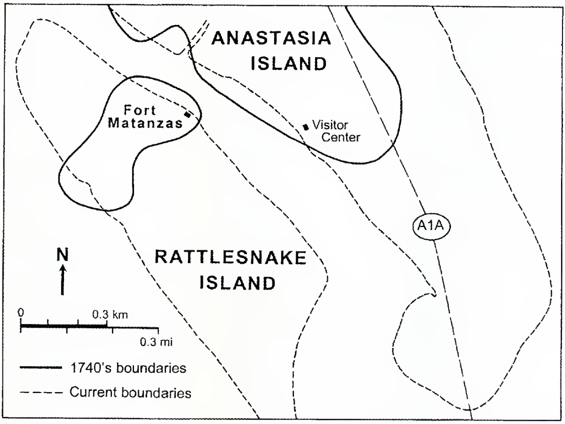

FIG. 2. Perimeter changes of Rattlesnake and Anastasia Islands over 250 years. Island boundaries in the 1740's (when Fort Matanzas was built) modified from Schesventer et al. (1980); present-day boundaries based on St. Johns County GIS Division (2002; also see Fig. 3).

m) tower (north side; Schesventer et al. 1980). The foundation originally comprised a system of closely-set pine pilings, driven deeply into the marshy substrate. The walls are coquina blocks comprising native shellstone (mainly *Donax variabilis*) probably quarried from El Peñón (within present-day Summer Haven) and originally were covered with mortar made of lime from burnt oyster shells, mixed with sand and water.

Fort Matanzas was armed with five cast iron cannon and usually manned by seven to 10 soldiers but could accommodate a planned maximum of 50 soldiers. The men were assigned to the fort for one-month duty tours as part of their regular rotation among the outposts and missions near St. Augustine. They had to bring supplies to last the whole month on small boats from St. Augustine; drinking water was either transported by boat or collected into a cistern as rainwater fell on the observation deck of the fort.

The strategic location of Fort Matanzas at the mouth of Matanzas Inlet helped maintain Spanish control of the waterway and served as a sentry to warn garrisons at St. Augustine about potential enemies approaching from the south

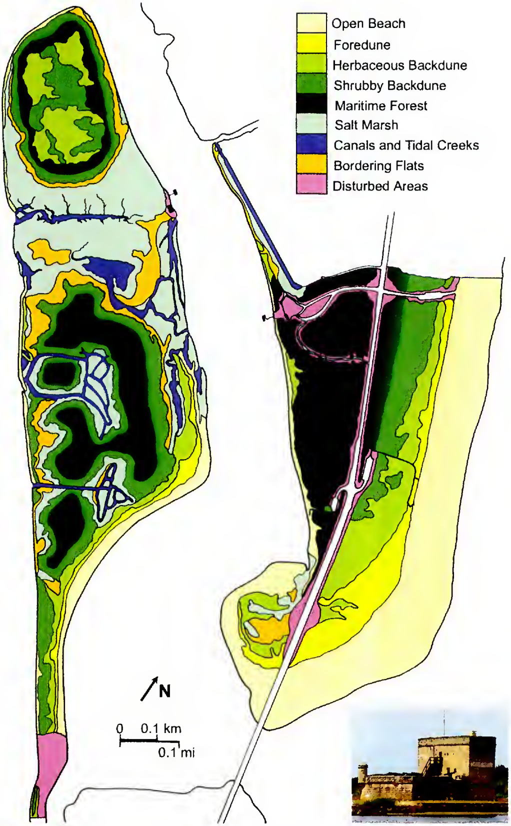

FIG. 3. General vegetation map of Fort Matanzas National Monument based on satellite imagery (St. Johns County GIS Division 2002) and field observations. Lower right: photograph of east face of Fort Matanzas. Photo credit: Wendy B. Zomlefer.

via the Matanzas River. The fort also functioned as a rest stop, coast guard station, and a place where Spanish vessels headed to St. Augustine could be advised on navigating the river. The inlet was close enough to Fort Matanzas that ships trying to enter the inlet came within range of the fort's guns. However, soldiers fired the fort cannons in battle only once, in 1742, thwarting two British vessels attempting to gain the inlet.

Over the next hundred years, Florida became a diplomatic pawn (Gold 1969). Fort Matanzas suffered periods of neglect during subsequent British (1763–1784) and second Spanish (1784–1821) occupations. The aging fort posed serious maintenance problems (Krakow 1986). By the late 1700's, the east foundation, facing the Matanzas River, was eroding. By the time Spain deeded Florida to the United States in 1819, the fort was so badly deteriorated that soldiers could no longer live inside.

The United States formally took possession in 1821 but never occupied the fort. At this time Fort Matanzas became the administrative property of the War Department as a national military park. By the turn of the twentieth century, the fort was overgrown with vegetation, including mature shrubs and trees, such as *Juniperus virginiana*, *Myrica cerifera*, and *Quercus virginiana* growing from the gundeck (Bryant 1872; Schesventer et al. 1980). The walls were cracked, and the south side leaned precariously on a weakened foundation undermined by the tides. In 1916, funds were granted by Congress for management and stabilization of the structure under a contract between the War Department and the St. Augustine Historical Society and Institute of Science (Krakow 1986). In 1924 President Calvin Coolidge proclaimed Fort Matanzas a national monument (Executive Proclamation No. 1713), and three years later the land around the fort was assigned to the Department of Agriculture as a bird refuge (Executive Order No. 4704).

President Franklin D. Roosevelt issued Executive Order No. 6166 in 1933, transferring Fort Matanzas (and other military parks and cemeteries) to the National Park Service, Department of the Interior. Over the past seventy years, the NPS has overseen extensive restoration, including installation of stainless steel rods that hold the upper portion of the fort together (Schesventer et al. 1980; Chandler 2002). As a result of these preservation efforts, Fort Matanzas, a unique relic of military architecture in the United States, retains its basic historic structure. Shoreline stabilization also requires constant vigilance. The original national monument site consisted of only the fort on Rattlesnake Island, but through the years, NPS has acquired additional land on both Rattlesnake and Anastasia Islands (see Krakow 1986), thereby preserving an intact (and imperiled) barrier island ecosystem.

MATERIALS AND METHODS

The first authors, PI Giannasi and coPI Zomlefer, lead four intensive field trips in 2003 (28–30 May, 29–31 July, 26–27 September) and 2004 (12–13 April) to collect vascular plant specimen vouchers in triplicate using standard field and herbarium techniques (under NPS collecting permit #FOMA-2003-SCI-0005) with assistance of the coauthors and other personnel listed in the acknowledgments. Plant associations were also assessed. A complete set of vouchers is deposited at GA, and one duplicate set at FLAS. The second duplicate set has not yet been distributed pending resolution of issues concerning NPS ownership of voucher specimens. The floras of Wunderlin & Hansen (2000, 2003) were primary sources for plant identification, supplemented by Godfrey & Wooten (1979, 1981). The majority of plants were identified by WBZ and DEG; coauthor LMK identified most ferns, grasses, and sedges; and coauthor WSJ confirmed other problematic determinations.

RESULTS AND DISCUSSION

Floristics

The 485 numbered collections (194 from Rattlesnake Island, 291 from Anastasia Island) comprise 237 species (plus two varieties): 125 species from Rattlesnake Island and 197 from Anastasia Island (see ANNOTATED CHECKLIST OF SPECIES below). Included in the list are 14 species planted around park headquarter buildings on Anastasia Island (indicated as "CULT"); *Zamia pumila*, a native species, occurs naturally in the park and is also cultivated there, and *Severinia buxifolia* is cultivated and has also escaped to the nearby hammock. The largest families are Poaceae (32 spp.), Asteraceae (28 spp.), Fabaceae (14 spp.), Amaranthaceae s.l. (9 spp.), Euphorbiaceae (9 spp.), and Rubiaceae (8 spp.). With completion of this survey, we have vouchered 57 new county records (53 species and four varieties) for St. Johns County, Florida, according to Wunderlin and Hansen (2004). No Florida endemics (Wunderlin & Hansen 2003) nor any state/federally listed endangered/threatened plants (Coile & Garland 2003; U.S. Fish and Wildlife Service 2004) were found. However, *Zamia pumila* (Florida arrowroot, coontie), which occurs naturally in the backdune/maritime hammock habitats (also planted around park headquarters), is a state listed "commercially exploited plant" (Coile & Garland 2003). In addition, harvesting *Uniola paniculata* (seaoats) is prohibited by Florida Statute 370.041 (State of Florida 2004) because of this species' crucial role as a dune builder and stabilizer.

Excluding the 12 cultivated exotics, the remaining 46 introduced species represent 20.4% of the total and include five listed as invasive exotics (FLEPPC 2004). Four (*Asparagus aethiopicus*, *Cinnamomum camphora*, *Nephrolepis cordifolia*, *Lantana camara*) are ranked as Category I (invasive exotics altering native plant communities by displacing native species, changing community structures/ecological functions, or hybridizing with natives), and one, *Pteris vittata*, as Category II (invasive exotics increasing in abundance/frequency but not yet altered Florida plant communities to the extent shown by Category I plants). In addition, *Schinus terebinthifolius* (Brazilian pepper), another Category I plant, had recently been extirpated by NPS personnel from the southern portion of Rattlesnake Island; reinvasion is possible, however, from fruiting plants observed by the authors near some homes adjacent to the park boundary. The one colony of *Nephrolepis cordifolia* (tuberous sword fern) growing on the edge of the forest near park headquarters (Anastasia Island) was sprayed by park personnel with herbicide the day after we collected vouchers; aggressive efforts to eradicate *Asparagus aethiopicus* (Sprenger's asparagus-fern) from the boat dock area were also underway. The relatively few plants of *Lantana camara* (lantana) occur sporadically in disturbed areas and occasionally in the backdune community. The one cultivated tree of *Cinnamomum camphora* (camphortree) is near maintenance buildings adjacent to the hammock. The cliff fern *Pteris vittata* (Chinese ladder brake), a significant arsenic hyperaccumulator (Ma et al. 2001), grows on the outer walls of Fort Matanzas and would require careful, probably mechanical, removal since the rhizomes deeply penetrate the precious coquina.

Plant Communities

The six major community types of the study area (open beach, foredune, backdune, maritime forest, salt marsh, and disturbed areas), discussed below and depicted in Figs. 3 to 5, are based upon satellite imagery (St. Johns County GIS Division 2002), our field observations, and classifications of similar areas by FNAI (1990), Johnson and Barbour (1990), Montague and Wiegert (1990), and Easley and Judd (1993). Barrier islands are dynamic habitats: zonation of species from the coast inland is controlled by the tolerance of plant growth habits to salt spray and sand burial, as well as wave-driven erosion and overwash (Leatherman 1988; Johnson & Barbour 1990). Overall species diversity is low, and several species may occur in more than one community. These maritime habitats are fairly uniform but may intergrade in the study area. We, therefore, have also designated several habitat subcategories to accommodate certain ecotones (Fig. 3): herbaceous backdune, shrubby backdune/maritime forest, and bordering flats (of the salt marsh).

Open Beach.—This area, also referred to as upper beach (e.g., Johnson & Barbour 1990), comprises exposed sandy beach up to the high tide line. High energy waves pound the shoreline and deposit sand grains, forming the beach. Anastasia Island has a well-developed open beach along the Atlantic Ocean, Matanzas Inlet, and the southwestern tip bordering Matanzas River (Figs. 3, 4A). The open beach along Rattlesnake Island, however, is more limited and is best developed along the southeastern shore along the river. Coastal perimeter and sandbar development varies with the tides and sand deposition, especially along the southern hook of Anastasia Island (Fig. 3). This habitat is generally

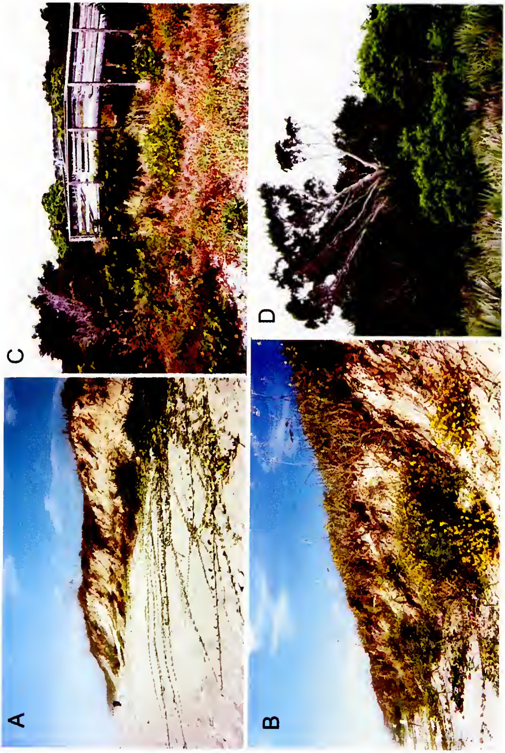

Fig. 4. Plant communities of Fort Matanzas National Monument Park. **A.** Open beach (eastern Anastasia Island): ramets of *Ipomoea pres-caprae* and *I. imperati* growing perpendicular to the ocean shore. **B.** Foredune (eastern Anastasia Island): *Ipomoea pes-caprae* and *Chamaecrista fasciculata* (below); *Croton punctatus*, *Heterotheca subaxillaris*, and *Uniola paniculata* (above). **C.** Herbaceous backdune (western Anastasia Island) at boardwalk entrance, west S. R. A1A: *Gaillardia pulchella*, *Helianthus debilis*, *Muhlenbergia capillaris*, and *Polypremum procumbens* (foreground); shrubby backdune vegetation (background). **D.** Shrubby backdune (eastern Rattlesnake Island): *Iva frutescens* and *Serenoa repens* (foreground); *Juniperus virginiana* and *Ilex vomitoria* (background). unvegetated with the exception of ramets of *Ipomoea imperati* and *I. pes-caprae* that may trail over the high tide line on Anastasia Island (Fig. 4A) where vehicles are allowed on the beachfront but not near inland dune vegetation.

Foredune.—This plant community, also called beach dune (FNAI 1990) or ocean beach (Easley & Judd 1993), includes terraces, overwash, and blowout sites adjacent to the beach itself (Johnson & Barbour 1990) and is a mobile and harsh environment sparsely to densely vegetated with pioneer species, especially seaoats ("seaoats zone," *Uniola paniculata*). The foredune forms as sand accumulates around plants. These sand particles, compared to those of the adjacent open beach, are smaller due to selective uplifting by wind. The vegetation must, therefore, tolerate burial by sand, as well as exposure to wind, salt spray, intense sunlight, and storms. Dune height is determined by wind strength and growth habits of certain dune-forming plants. Plants continuously recolonize the habitat due to periodic disturbance by waves from storms and high tides (Oertel & Larsen 1976). This community is particularly vulnerable to human impact: large gaps or blowouts in the foredune from footpaths or off-road vehicle trails destabilize the substrate, thereby providing opportunities for erosion by wind and water.

The foredune community is best developed as a distinct border between the open beach and much higher backdune (described below) along the Atlantic coast and southern hook of Anastasia Island (Figs. 3, 4B). The fragile system on Anastasia Island is protected from trampling by two boardwalks over the dunes (Fig. 1B); direct public access by foot or vehicle is forbidden. On Rattlesnake Island, this vegetation often intergrades with backdune and occurs mainly along the river beach (Fig. 3).

Foredune habitats in the study area have been usually built by *Uniola paniculata*, as well as two other dune grasses, *Panicum amarum* and *Spartina patens*. The growth of these species is stimulated by sand burial, with vertical growth keeping pace with burial, and lateral growth via runners forming a continuous dune ridge (Wagner 1964). The colonial and succulent morning-glories, *Ipomoea imperati* and *I. pes-caprae*, are usually the first invaders of foredune and beach after storm erosion. The plants produce long stolons that creep across the barren sands at right angles to the coast (Fig. 4A), ensuring ramets both on the old and newest foredunes (Johnson & Barbour 1990). Other pioneer species (often succulent), consistently found seaward of the foredune, include: *Atriplex cristata*, *Cakile edulenta*, *Cakile lanceolata*, *Cenchrus tribuloides*, *Chamaesyce bombensis*, *Gaillardia pulchella*, *Helianthus debilis*, *Iva imbricata*, *Salsola kali*, *Sesuvium portulacastrum*, and *Sporobolus virginicus*. *Croton punctatus*, *Hydrocotyle bonariensis*, *Oenothera humifusa*, *Phyllanthus abnormis*, and *Physalis walteri* are examples of wider-ranging species also characteristic of this zone. Several common weedy species, such as *Chenopodium ambrosioides*, *Chamaesyce maculata*, and *Heterotheca subaxillaris* also thrive on the foredunes; dense patches of *Distichlis spicata* occur in several wetter areas. Shrubby plants with lower salt tolerance, such as *Ilex vomitoria* and *Serenoa repens*, typically grow on the lee side of the foredunes where they are somewhat protected from sand burial and salt spray.

Backdune.—The backdune, also called the transitional zone (Johnson & Barbour 1990), coastal strand (FNAI 1990), open shrubby interior, maritime thicket, and coastal scrub (FNAI 1990; Easley & Judd 1993), is an ecotonal community generally occurring between foredune and maritime hammock and shares many species of both. These deep, stabilized, wind-deposited coastal dunes are covered with variable, often patchy, vegetation. Backdune communities are generally stable, and as prime beachfront real estate property, comprise one of the most rapidly disappearing community types in Florida (FNAI 1990). Originally a nearly continuous band along the Atlantic coast, backdune now occurs in isolated short stretches.

Along eastern Anastasia and Rattlesnake Islands, backdune comprises herbs to low shrubs (Fig. 4C, D) plus adjacent regions covered with low, dense, often impenetrable woody vegetation intergrading with maritime hammock community to the west (Fig. 5A). Therefore, the backdune habitat of the study area is here divided into two, more or less, well-demarcated subzones (discussed below), herbaceous backdune and shrubby backdune.

Herbaceous backdune zone.—This backdune zone, immediately bordering the foredune (Fig. 4C), is characteristically a broad flat area occupied by a mixture of herbs, often low-growing, including *Chamaecrista fasciculata*, *Gaillardia pulchella*, *Helianthus debilis*, *Heterotheca subaxillaris*, *Hydrocotyle bonariensis*, *Ipomopsis rubra*, *Iresine rhizomatosa*, *Opuntia pusilla*, *Opuntia stricta*, *Solanum chenopodioides*, and *Strophostyles helvola*, as well as several predominant grasses: *Andropogon glomeratus*, *Muhlenbergia capillaris*, *Spartina patens*, and *Uniola paniculata*. Some low shrubby plants, such as *Borrichia frutescens* and *Iva imbricata* may also occur. As in the foredune, many backdune species are succulent, have thickened cuticles, root readily from fragments, produce floating seeds, and/or spread by runners.

Shrubby backdune zone/maritime hammock.—Further inland, the backdune community commonly comprises a low, dense, often impenetrable thicket of salt-tolerant shrubs and small trees. The characteristic pruned and dwarfed form of these woody plants (see *Juniperus* in Fig. 4D) results from salt-spray laden winds that kill terminal buds on twigs facing the sea (Johnson & Barbour 1990). In the study area, this shrubby backdune zone (Figs. 3, 4D) gradually intergrades with maritime hammock, especially on the northwestern Anastasia Island portion of the park. Characteristic shrubby species (also often in forest understory) include: *Baccharis halimifolia*, *Ilex vomitoria*, *Iva frutescens*, *Myrica cerifera*, and *Sideroxylon tenax*; *Serenoa repens* commonly favors the

Fig. 5. Plant communities of Fort Matanzas National Monument Park, continued. **A.** Maritime forest (western Anastasia Island): *Serenoa repens* (understory); *Quercus virginiana* branches covered with *Tillandsia usneoides* and *Vitis* spp. vines (overstory). **B.** Salt marsh at high tide (central Rattlesnake Island): pure stand of *Spartina alterniflora*; Fort Matanzas (distant background). **C.** Tidal creek (central Rattlesnake Island) bordered by *Spartina alterniflora* (left) and *Batis maritima* (right). **D.** Bordering flats along salt marsh (east-central Rattlesnake Island): *Muhlenbergia capillaris* and *Eragrostis elliottii* (foreground); *Juniperus virginiana* (right background); Fort Matanzas (central background); *Avicennia germinans* in saltmarsh (small "shrubs," center and far left, distant background). Photo credits: **A,** Alexander Reynolds; **B–D,** Wendy B. Zomlefer.

protected lee slopes and flats behind steeply eroded dunes. *Juniperus virginiana, Persea borbonia, Prunus serotina, Sabal palmetto,* and *Zanthoxylum clava-herculis* are common tree associates. On the northwestern side of the Anastasia Island park area, portions of shorter shrubby backdune are almost completely covered by dense mats of tangled woody vines of *Ampelopsis arborea, Cissus trifoliata, Parthenocissus quinquefolia, Smilax auriculata, Vitis aestivalis,* and *Vitis rotundifolia,* as well as the herbaceous vine, *Mikania cordifolia.* Along the west border of the disturbed area comprising south Rattlesnake Island (see Fig. 3), a narrow strip of shrubby backdune vegetation includes species such as *Chiococca alba, Teucrium canadense, Vigna luteola,* and *Zamia pumila.*

Maritime Hammock.—This vegetation type, the terminal succession stage in these coastal areas, is defined as the impenetrable band of "hardwood" forest just inland of the dune community (Laessle & Monk 1961; Stalter & Dial 1984; FNAI 1990). The habitat is also referred to as coastal hammock (Easley & Judd 1993), stable dune zone, and maritime forest (Johnson & Barbour 1990). The dense wind-pruned canopy over the old, stabilized, white sand-dunes combined with humus buildup contributes to some moisture retention, but soils generally remain well-drained because of underlying deep sand. Many species overlap with those characteristic of the shrubby backdune. As with backdune, maritime hammock is prime resort and residential property and originally was an almost continuous band (with the dune system) along the coast of Florida but is now fragmented by development into short segments (FNAI 1990).

Typical mature maritime forest, best developed along the western coast of Anastasia Island (Figs. 3, 5A), forms a continuum with the shrubby backdune zone to the east (described above). The forest often covers relatively steep terrain, and sometimes the tops of large trees are near eye-level as one stands on the peak of an old dune. The dominant species are *Quercus virginiana* and *Q. geminata,* whose branches are characteristically covered with epiphytes *Pleopeltis polypodioides, Tillandsia recurvata,* and *Tillandsia usneoides. Persea borbonia* is a principal understory tree, along with *Asimina parviflora, Juniperus virginiana, Quercus myrtifolia, Prunus serotina,* and *Sabal palmetto. Callicarpa americana, Ilex vomitoria, Myrica cerifera, Sideroxylon tenax, Serenoa repens, Rhus copallinum,* and *Zamia pumila* are common understory shrubs (or shrubby trees). As in the backdune, woody vines are prevalent (i.e., *Parthenocissus quinquefolia, Smilax auriculata, Smilax bona-nox, Vitis aestivalis, Vitis rotundifolia*); herbaceous understory plants include *Galium hispidulum, Oplismenus hirtellus, Rivina humilis, Ruellia caroliniensis,* and *Teucrium canadense.*

The northern tip and western coastline of Rattlesnake Island, along the Intracoastal Waterway, support a much different maritime forest vegetation lacking oaks and dominated by *Celtis laevigata, Juniperus virginiana, Persea* *borbonia, Pinus elliottii*, and *Sabal palmetto. Pinus elliottii* (10–12 m tall) is more common on the northern portion of the island. Numerous snags of slash pine along the western coast indicate that this once dominant species has been declining and has been replaced by the more common juniper, cabbage palm, and large trees of *Celtis laevigata* that reach heights of over 12 m (0.5–1.0 m dbh). Common understory shrubs (to small trees) include *Ilex vomitoria* (4–5 m tall), *Myrica cerifera, Serenoa repens, Sideroxylon tenax, Zamia pumila*, and *Zanthoxylum clava-herculis. Smilax auriculata* is also common throughout the hammock. The dark forest floor supports little herbaceous understory except for occasional plants of species such as *Bacopa monnieri, Galium hispidulum*, and *Pilea microphylla* in exposed damp areas.

Salt Marsh.—The salt marsh system includes tidal marsh (FNAI 1990), tidal creeks, and bordering flats (Easley & Judd 1993) – distinguished as separate habitat subtypes in Fig. 3 for the study area. Salt marshes in Florida, most abundant north of the normal freeze line, are coastal communities of nonwoody salt-tolerant plants occupying intertidal zones at least occasionally inundated with salt water (Montague & Wiegert 1990). These plants must tolerate poorly aerated saline substrate, frequent submersion, and intense sunlight. Salt marshes develop at the land-marine water interface, especially in regions with low relief, high tidal range, and low wave energy. Therefore, the elevation varies from slightly below to slightly above sea level, with vegetation growing in intertidal and supertidal zones. Salt marsh ecotone functions in sediment stabilization and coastline storm protection. Dense stems and roots of colonizing plants trap sediments from upland runoff, and decaying marsh plant detritus accumulates to form anaerobic layered soils.

Within the park, the salt marsh system is best developed in the north-central portion of Rattlesnake Island, as well as some smaller areas along the east-central and south-central coastlines (Figs. 3, 5B). The salt marsh system here also includes a distinct network of drainage gullies, tidal creeks, and pools (Fig. 5C). Smaller salt marshes also occur within the southwestern tip of Anastasia Island (Fig. 3), as well as the northwestern most strip of the park property along the Matanzas River.

Salt marsh proper (tidal marsh).—Although salt marsh vegetation is often distinctively zoned in other locations (each zone dominated by a different species), large expanses of dense monotypic stands of *Spartina alterniflora* characterize the study area (Fig. 5B). *Juncus roemerianus*, another important indicator species in salt marshes elsewhere in Florida (Montague & Wiegert 1990), only occurs occasionally in a few small patches. *Spartina alterniflora* tends to grow along the deepest portions, grading subtly to other salt-tolerant plants, such as *Batis maritima* (Fig. 5C), *Distichlis spicata, Limonium carolinianum, Sarcocornia perennis (Salicornia perennis), Sesuvium portulacastrum*, and

Suaeda linearis along the edges. Small shrubby trees of *Avicennia germinans* (black mangrove) to 3 m tall (see background in Fig. 5D) also are well established within *Spartina* stands on both Rattlesnake and Anastasia Island. We observed little flowering and fruit set, however: our collections represent the northernmost limit of this tropical species along the east coast of Florida (Wunderlin & Hansen 2004).

***Bordering flats*.**—A distinct flora also characterizes the slightly elevated ridges bordering the salt marsh proper and associated tidal waterways in the study area (Fig. 3; Easley & Judd 1993). These flat sandy meadows (Fig. 5D) are vegetated with scattered herbs (mainly grasses and sedges), including: *Chamaecrista fasciculata, Cynanchum angustifolium, Cyperus esculentus, Cyperus polystachyos, Cyperus retrorsus, Distichlis spicata, Eragrostis elliottii, Fimbristylis spadicea, Juncus dichotomus, Limonium carolinianum, Muhlenbergia capillaris, Opuntia pusilla, Paronychia herniarioides, Pluchea odorata, Portulacca pilosa, Scleria triglomerata, Setaria parviflora, Solidago stricta, Sporobolus virginicus*, and *Triplasis purpurea*, as well as occasional woody species, such as *Borrichia frutescens, Iva frutescens, Juniperus virginiana, Pinus palustris, Prunus serotina*, and *Zanthoxylum clava-herculis*.

Disturbed areas (ruderal community).—On Anastasia Island, disturbed habitats have developed around public-access areas, and on Rattlesnake Island, consist of large Intracoastal Waterway dredge fill areas, land within the network of mosquito control ditches, and Fort Matanzas itself (see Fig. 3). Disturbed areas associated with construction and heavy human use on Anastasia Island (i.e., land bordering S. R. A1A, visitor center/picnic tables, parking lots, park headquarters/roads) have few species in common with the habitats discussed in the preceding sections. Common weedy plants occurring primarily in these disturbed areas include: *Acalypha graciliens, Andropogon glomeratus, Cenchrus spinifex, Chamaesyce hirta, Chamaesyce hyssopifolia, Conyza canadensis, Croton glandulosus, Cynodon dactylon, Dactyloctenium aegyptium, Indigofera spicata, Lepidium virginicum, Malvastrum corchorifolium, Paspalum setaceum, Phyla nodiflora, Pteridium aquilinum, Salvia lyrata, Sida rhombifolia, Sonchus asper, Spermacoce assurgens, Triodanis perfoliata, Verbena bonariensis*, and *Verbena officinalis*.

The sandy dune-like fill area comprising the northern tip of Rattlesnake island (Fig. 3) has a distinct ring of shrubby backdune/maritime hammock vegetation (e.g., *Celtis laevigata, Iva frutescens, Juniperus virginiana, Pinus elliottii, Sabal palmetto*; discussed above under maritime hammock) enclosing an open center of patchy, herbaceous to shrubby, backdune plants, including *Myrica cerifera, Baccharis halimifolia, Opuntia pusilla, Phyllanthus abnormis, Prunus serotina, Sideroxylon tenax, Uniola paniculata*, and *Zanthoxylum clava-herculis*. Small specimens of *Oxalis corniculata* and *Pteris vittata* were the only plants growing on the coquina walls of Fort Matanzas (northeastern coast) – a stark comparison to the varied and lush flora of 56 species we found covering the walls of Castillo de San Marcos in St. Augustine during the same study period (Zomlefer & Giannasi 2005). The small mowed lawn surrounding the fort comprises *Cynodon dactylon*, *Hydrocotyle bonariensis*, and *Stenotaphrum secundatum*.

The labyrinth of mosquito control ditches in the central southwest portion of the Rattlesnake Island park area (Fig. 3), excavated circa 1950–1960's (D. Parker, pers. comm.), drained large expanses of salt marsh, allowing growth of shrubby backdune and maritime forest (discussed above). The narrow fill area [ca 0.13 mi (0.21 km) long, 0.06 mi (0.10 km) wide, tapering to 0.03 mi (0.05 km); see Fig. 3] forming the southernmost portion Rattlesnake Island park property is an exposed flat ridge of very compact sand bordered by the Matanzas Inlet to the east and the Intracoastal Waterway to the west. This harsh, severely windblown habitat supports an odd flora of stunted plants (e.g., *Opuntia pusilla*, *O. stricta*) and compressed forms of normally upright plants (*Cnidoscolus stimulosus*, *Gaillardia pulchella*, *Oenothera humifusa*, *Phyllanthus abnormis*), as well as sand-hugging rosettes of *Chamaesyce bombensis* and *C. maculata*, large cushions of *Stenaria nigricans*, depauperate strings of *Galactia volubilis*, and hardy scattered tufts of grasses, such as *Cenchrus echinatus* and *Eragrostis secundifolia*.

ANNOTATED CHECKLIST OF VASCULAR PLANT TAXA

A list of 237 vascular plant species representing 189 genera in 73 families is here compiled from *Giannasi & Zomlefer* specimens (collection numbers in *italic*) in alphabetical order by family within three major groups (ferns, gymnosperms, and angiosperms). Genera, species, and infraspecific taxa are alphabetical within each family. Scientific nomenclature and common names follow Wunderlin & Hansen (2003); exceptions are vernacular names of a few horticultural plants (not included in their flora) that conform to Huxley (1992). Family circumscriptions for ferns and gymnosperms follow FNA (1993), and for the angiosperms, APG (2003).

Non-boldface collection number = collection from Anastasia Island; ***boldface collection number*** = collection from Rattlesnake Island; underlined taxa = new vouchered St. Johns County records according to on-line species list by Wunderlin & Hansen (2004); * = exotic (Wunderlin & Hansen 2003); invasive exotics (FLEPPC 2004): [CAT I] = Category I; [CAT II] = Category II; CULT = cultivated, i.e., planted on park grounds. Habitat data: DA = disturbed areas; FD = foredune; HB = herbaceous backdune; MH = maritime hammock; OB = open beach; SB = shrubby backdune; SB/MH = shrubby backdune/maritime hammock ecotone; SM = salt marsh; SM/BF = salt marsh/bordering flats. Relative abundance: c = common (generally abundant throughout a particular habitat; species easily found); o = occasional (locally common and/or several individuals distributed within a habitat; species not too difficult to locate); i = infrequent (sporadic occurrence of a small number of individuals; species relatively scarce and not easily found); r = rare (very few individuals encountered).

FERNS

DENNSTAEDTIACEAE

Pteridium aquilinum (L.) Kuhn var. *pseudocaudatum* (Clute) Clute ex A. Heller, Bracken fern, DA; o; *127*

NEPHROLEPIDACEAE

**Nephrolepis cordifolia* (L.) C. Presl, Tuberous sword fern, [CAT I], DA; o; *92*

POLYPODIACEAE

Wunderlin, pers. comm.), as in Wunderlin & Hansen (2003): The correct name for the species in the southeastern United States is clarified by Nesom (2004).]
Helianthus debilis Nutt. subsp. *debilis*, East coast dune sunflower, FD, HB; c; ***79***, *103*
Heterotheca subaxillaris (Lam.) Britton & Rusby, Camphorweed, DA, FD, HB; c; ***389***, *497*, *503*
Iva frutescens L., Bigleaf sumpweed, SB, SB/MH; c; ***267***
Iva imbricata Walter, Seacoast marshelder, FD, HB; o; ***246***, ***398***
Krigia virginica (L.) Willd., Virginia dwarfdandelion, HB; r; ***652***
Lactuca graminifolia Michx., Grassleaf lettuce, DA; r; ***634***
Mikania cordifolia (L. f.) Willd., Florida Keys hempvine, SB; o; *470*
Pluchea odorata (L.) Cass., Sweetscent, SM/BF; i; ***397***
Solidago odora Aiton var. *chapmanii* (A. Gray) Cronquist, Chapman's goldenrod, DA; r; *502*
Solidago stricta Aiton, Wand goldenrod, DA, SM/BF; i; *530*, ***560***
**Sonchus asper* (L.) Hill, Spiny sowthistle, DA; i; *510*, *607*
Sonchus oleraceus* L., Common sowthistle, DA; i; ***635*
**Taraxacum officinale* Weber ex F. H. Wigg., Common dandelion, DA; r; *663*, *672*
**Youngia japonica* (L.) DC., Oriental false hawksbeard, DA; i; *644*

BATACEAE

Batis maritima L., Saltwort, SM; c; ***20***, ***248***, *479*

BORAGINACEAE

Heliotropium curassavicum L., Seaside heliotrope, FD; r; ***245***

BRASSICACEAE

Cakile edulenta (Bigelow) Hook. subsp. *harperi* (Small) Rodman, American searocket, FD, HB, SM/BF; c; ***73***, *114*, *618*, *627*, ***661***
Cakile lanceolata (Willd.) O. E. Schultz, Coastal searocket, FD; i; *98*

**Coronopus didymus* (L.) Sm., Lesser swinecress, DA; r; *604*
Descurainia pinnata (Walter) Britton, Western tansymustard, DA; r; *606*
Lepidium virginicum L., Virginia pepperweed, DA, HB, SM/BF; i; ***24***, ***35***, ***548***, *620*

BROMELIACEAE

**Neoregelia spectabilis* (Moore) L.B Sm., Painted fingernail, CULT; *523*
Tillandsia recurvata (L.) L., Ballmoss, MH; o; *522*
Tillandsia usneoides (L.) L., Spanish moss, MH; c; *309*

CACTACEAE

Opuntia pusilla (Haw.) Haw., Cockspur pricklypear, DA, FD, SM/BF; c; ***48***, ***266***, *492*
Opuntia stricta (Haw.) Haw., Erect pricklypear, DA, HB, SB, SM/BF; c; ***71***, ***75***, *116*, *438*

CAMPANULACEAE

Triodanis perfoliata (L.) Nieuwl., Clasping Venus' lookingglass, DA; r; *605*

CANNABACEAE

Celtis laevigata Willd., Sugarberry, MH; c; ***660***

CARYOPHYLLACEAE

Paronychia baldwinii (Torr. & A. Gray) Fenzl ex Walp., Baldwin's nailwort, SM/BF; r; ***537***
Paronychia herniarioides (Michx.) Nutt., Coastalplain nailwort, SM/BF; i; ***259***
Stellaria media* (L.) Vill., Common chickweed, DA; o; ***637*, *643*, *665*

COMMELINACEAE

**Commelina diffusa* Burm. f. var. *diffusa*, Common dayflower, DA; r; *673*
Commelina erecta L., Whitemouth dayflower, DA, HB; i; ***61***, *96*, *243*
Tradescantia ohiensis Raf., Bluejacket, DA; o; *1*, *458*

CONVOLVULACEAE

Dichondra caroliniensis Michx., Carolina ponysfoot, HB; i; ***654***, *671*
Ipomoea batatas* (L.) Lam., Sweetpotato, DA; r; ***460*
Ipomoea cordatotriloba Dennst., Tievine, DA; i; *505*
Ipomoea imperati (Vahl) Griseb., Beach morning-glory, FD, OB; c; *95*
Ipomoea pandurata (L.) G. Mey., Man-of-the-earth, DA; r; *459*
Ipomoea pes-caprae (L.) R. Br., Railroad vine, FD, OB; c; *97*
**Merremia dissecta* (Jacq.) Hallier f., Noyau vine, DA; r; *101*, *289*

CYPERACEAE

Cyperus esculentus* L., Yellow nutgrass, SM/BF; o; ***29*, ***69***
Cyperus polystachyos Rottb., Manyspike flatsedge, DA, SM/BF; o; ***28***, ***419***, *455*
Cyperus retrorsus Chapm., Pinebarren flatsedge, HB, SM/BF; o; ***36***, ***37***, ***38***, ***260***, ***261***, ***557***
Cyperus tetragonus Elliott, Fourangle flatsedge, DA; i; *310*, *521*
Fimbristylis spadicea (L.) Vahl, Marsh fimbry, DA, SM/BF; o; ***31***, ***264***, *424*, ***540***
Scleria triglomerata Michx., Tall nutgrass, DA, SM/BF; r; ***263***, *312*

EBENACEAE

Diospyros virginiana L., Common persimmon, MH; r; *501*

ERICACEAE

**Rhododendron simsii* Planch., Indian azalea, CULT, *642*

EUPHORBIACEAE

Acalypha gracilens A. Gray, Slender threeseed mercury, DA; i; *526*
Chamaesyce bombensis (Jacq.) Dugand, Dixie sandmat, DA, OB, FD; c; ***62***, ***422***, *463*
Chamaesyce hirta (L.) Millsp., Pillpod sandmat, DA; i; *301*
Chamaesyce hyssopifolia (L.) Small, Hyssopleaf sandmat, DA, HB; o; *491*, *508*
Chamaesyce maculata (L.) Small, Spotted sandmat, HB; c; ***39a***
Cnidoscolus stimulosus (Michx.) Engelm. & A. Gray, Tread softly, DA, FD; c; ***76***, *106*
Croton glandulosus L. var. *glandulosus*, Vente conmigo, DA, HB; o; *302*, ***399***, *428*, *482*, *527*
Croton punctatus Jacq., Gulf croton, FD; c; ***45***, *112*, *441*
Poinsettia cyathophora (Murray) Bartl., Paintedleaf, DA, HB; i; *17*, *94*, *135*, ***406***, *447*, *493*

FABACEAE

Centrosema virginianum (L.) Benth., Spurred butterfly pea, DA, HB; o; *291*, ***405***
Chamaecrista fasciculata (Michx.) Greene, Partridge pea, FD, HB; c; ***65***, *105*, ***258***
**Desmodium tortuosum* (Sw.) DC., Dixie ticktrefoil, DA; r; *478*

Erythrina herbacea L., Coralbean, DA, HB; r; *430, 616, 628*

Galactia volubilis (L.) Britton, Downy milkpea, DA; o; ***81***, *288*, ***396***

**Indigofera hirsuta* L., Hairy indigo, DA; r; *481*

**Indigofera spicata* Forssk., Trailing indigo, DA; i; *303, 425*

Medicago lupulina* L., Black medick, DA; o; *601*, ***631*

Medicago polymorpha* L., Burrclover, DA; o; ***630*, *667*

Melilotus albus* Medik., White sweetclover, DA; o; ***82*, *617, 629*

Meliotus indicus* (L.) All., Indian sweetclover, DA; i; *614*, ***633*

**Senna obtusifolia* (L.) H.S. Irwin & Barneby, Coffeeweed, HB, r; *597*

Strophostyles helvola (L.) Elliott, Trailing fuzzybean, DA, FD, HB, SM/BF; c; ***32***, ***86***, *119*, ***390***, *437, 471, 487*

Vigna luteola (Jacq.) Benth., Hairypod cowpea, DA; o; ***388***, *483*

FAGACEAE

Quercus chapmanii Sarg., Chapman's oak; MH; i; *669*

Quercus geminata Small, Sand live oak, MH, SB/MH; c; *318, 644*

Quercus myrtifolia Willd., Myrtle oak, MH, SB/MH; o; *275, 316*

Quercus virginiana Mill., Live oak, MH, SB/MH; c; *317*

GERANIACEAE

Geranium carolinianum L., Carolina cranesbill, DA; i; *619*

HYPERICACEAE

Hypericum gentianoides (L.) Britton et al., Pineweed, SM/BF; r; ***534***

Hypericum hypericoides (L.) Crantz, St. Andrew's-cross, SB, MH, SM/BF; i; *277, 436*, ***536***

JUGLANDACEAE

**Carya illinoinensis* (Wangenh.) K. Koch, Pecan, CULT; *2*

JUNCACEAE

Juncus dichotomus Elliott, Forked rush, SM/BF; o; ***272***

Juncus roemerianus Scheele, Black rush, SM, SM/BF; o; ***27***, ***394***

LAMIACEAE

Callicarpa americana L., American beautyberry, MH; o; *6*

**Hyptis mutabilis* (Rich.) Briq., Tropical bushmint, DA; i; *296*

Monarda punctata L., Spotted beebalm, DA, HB; o; *283, 297, 472, 484*

Salvia lyrata L., Lyreleaf sage, DA; o; *5, 495, 594*

Stachys floridana Shuttlew. ex Benth., Florida hedgenettle, DA; i; *598*

Teucrium canadense L., Wood sage, SB, MH; o; *311*, ***423***

Trichostema dichotomum L., Forked bluecurls, HB, SM/BF; i; ***249***, ***421***, *485*

LAURACEAE

**Cinnamomum camphora* (L.) J. Presl, Camphortree, [CAT I], CULT; *638*

Persea borbonia (L.) Spreng., Red bay, MH, SB/MH; c; *7*, ***89***, *107*, ***255***, *322, 467, 486*

MAGNOLIACEAE

Magnolia grandiflora L., Southern magnolia, MH; r; *677*

MALVACEAE

Malvastrum corchorifolium (Desr.) Britton ex Small, False mallow, DA; i; *131*

**Malvastrum coromandelianum* (L.) Garcke, Threelobe false mallow, DA; i; *294, 512*

**Malvaviscus penduliflorus* DC., Turkscap mallow, CULT; *517* (Persisting after cultivation near maintanence road entrance.)

Sida rhombifolia L., Cuban jute, DA; o; *295, 511*

MORACEAE

Morus rubra L., Red mulberry, MH; r; *552*

MYRICACEAE

Myrica cerifera L., Southern bayberry, MH, SB, SB/MH; c; *279, 448, 514*, ***656***

NYCTAGINACAE

Boerhavia diffusa* L., Red spiderling, DA; o; *304

OLEACEAE

Forestiera segregata (Jacq.) Krug & Urb., Florida swampprivet, SB; i; ***416***

**Jasminum mesnyi* Hance, Japanese jasmine, CULT; *675*

ONAGRACEAE

Gaura angustifolia Michx., Southern beeblossom, DA, FD; c; *313*, ***395***

Oenothera humifusa Nutt., Seabeach eveningprimrose, DA, FD; c; *18*, ***87***, *124*

Oenothera laciniata Hill, Cutleaf eveningprimrose, DA; r; *609*

**Oenothera speciosa* Nutt., Pinkladies, DA; i; *595*

OXALIDACEAE

Oxalis corniculata L. (incl. *O. stricta* L.), Common yellow woodsorrel, DA, HB; c; ***56***, *461*

**Oxalis rubra* A. St.-Hil., Windowbox woodsorrel, DA; i; *596*, *674*

PHYLLANTHACEAE

Phyllanthus abnormis Baill., Drummond's leafflower, DA, FD, HB; c; ***39b***, ***88***, *104*, ***253***, *293*, *434*

**Phyllanthus tenellus* Roxb., Mascarene Island leafflower, DA, HB; i; *91*, *462*

PHYTOLACCACEAE

Phytolacca americana L. var. *rigida* (Small) Caulkins & Wyatt, American pokeweed, DA, HB; i; *15*, *429* [This distinct geographical race, previously included in the flora by Wunderlin (1998) but not in the recent edition (Wunderlin & Hansen 2003), merits recognition (see Caulkins & Wyatt 1990).]

Rivina humilis L., Rougeplant, MH; i; *282*

PLANTAGINACEAE

Bacopa monnieri (L.) Pennell, Herb-of-grace, SM/BF; o; ***400***, ***546***

Linaria canadensis (L.) Chaz., Canada toadflax, HB; i; ***74***, ***662***

Plantago virginica L., Virginia plantain, DA; i; *615*, ***649***

Scoparia dulcis L., Sweetbroom, HB, SM/BF; i; ***408***, *498*

PLUMBAGINACEAE

Limonium carolinianum (Walter) Britton, Carolina sealavender, SM, SM/BF; o; ***252***, ***539***

POACEAE

Andropogon glomeratus (Walter) Britton et al. var. *hirsutior* (Hack.) C. Mohr, Bushy bluestem, DA; c; *457*

Andropogon glomeratus var. *pumilus* (Vasey) Vasey ex L. H. Dewey, Bushy bluestem, DA, HB; c; *506*, ***658***

Andropogon virginicus L. var *virginicus*, Broomsedge bluestem, DA; i; *507*

Cenchrus echinatus L., Southern sandbur, DA, FD; i; ***66***, ***411***, *451*

Cenchrus gracillimus Nash, Slender sandbur, DA; o; ***53***, ***84***, *117*

Cenchrus spinifex Cav., Coastal sandbur, DA; o; *305*

Cenchrus tribuloides L., Sanddune sandbur, FD; i; *123*, *450*

**Cynodon dactylon* (L.) Pers., Bermudagrass, DA; c; *307*

Dactyloctenium aegyptium* (L.) Willd. ex Asch. & Schweinf., Durban crowfootgrass, DA; o; ***420*, *466*

Dicanthelium scabriusculum (Elliott) Gould & C. A. Clark, Woolly witchgrass, DA; o; *520*, *646*

**Digitaria bicornis* (Lam.) Roem. & Schult., Asia crabgrass, DA; i; *126*

Digitaria filiformis (L.) Koeler var. *filiformis*, Slender crabgrass, DA; o; ***417***

Distichlis spicata (L.) Greene, Saltgrass, HB; o; ***556***

**Eleusine indica* (L.) Gaertn., Indian goosegrass, DA; o; *286*

Eragrostis elliottii S. Watson, Elliott's lovegrass, SM/BF; o; ***562***

Eragrostis secundiflora J. Presl subsp. *oxylepis* (Torr.) S. D. Koch, Red lovegrass, DA, HB; o; ***77***, *121*

Eustachys petraea (Sw.) Desv., Pinewoods fingergrass, DA, HB; o; ***41***, ***83***, *499*

**Lolium perenne* L., Italian ryegrass, DA; i; *613*

Muhlenbergia capillaris (Lam.) Trin. var. *filipes* (M. A. Curtis) Chapm. ex Beal, Gulf hairawn muhly, HB; c; *488*, *489*, ***549***

Muhlenbergia capillaris var. *trichopodes* (Elliott) Vasey, Cutover muhly, SM/BF; o; ***561***

Oplismenus hirtellus (L.) P. Beauv., Woodsgrass, MH; o; *525*

Panicum amarum Elliott, Bitter panicgrass, FD, HB; c; *464*, *515*, ***551***

**Paspalum notatum* Flüggé var. *saurae* Parodi, Bahiagrass, DA; o; *265*

Paspalum setaceum Michx., Thin paspalum, DA; o; *287*, *308*, *528*

Poa annua* L., Annual bluegrass, DA; o; ***650*, *668*

Setaria parviflora (Poir.) Kerguélen, Yellow bristlegrass, SM/BF; o; ***22***, ***63***

Spartina alterniflora Loisel., Saltmarsh cordgrass, SM; c; *474*, ***542***, ***554***

Spartina patens (Aiton) Muhl., Marshhay cordgrass, FD; o; ***23***, ***393***, ***550***, ***555***

Sphenopholis obtusata (Michx.) Scribn., Prairie wedgescale, DA; o; *622*, ***636***

*_Sporobolus indicus_ (L.) R. Br. var. _pyramidalis_ (P. Beauv.) Veldkamp, West Indian dropseed, DA; i; _456_

Sporobolus virginicus (L.) Kunth, Seashore dropseed, FD, SM/BF; c; ***256***, ***271***, ***412***, _443_, ***558***

Stenotaphrum secundatum (Walter) Kuntze, St. Augustinegrass, SB; r; ***30*** [This common lawn grass is listed in Wunderlin & Hansen (2003) as native, and our collections in remote areas are likely not escapes from cultivation.]

Triplasis purpurea (Walter) Chapm., Purple sandgrass, DA, SM/BF; i; ***532***, ***559***

Uniola paniculata L., Seaoats, FD, HB; c; ***67***, ***68***, _125_, ***262***

POLEMONIACEAE

Ipomopsis rubra (L.) Wherry, Standingcypress, HB; r; _432_

POLYGALACEAE

Polygala incarnata L., Procession flower, SM/BF; i; ***533***

POLYGONACEAE

Rumex hastatulus Baldwin, Heartwing dock, DA, HB; i; _610_

PORTULACACEAE

Portulaca oleracea L., Little hogweed, DA, r; _298_

Portulaca pilosa L., Pink purslane, DA, SM/BF; i; ***273***, _299_, ***415***, _444_

ROSACEAE

*_Eriobotrya japonica_ (Thunb.) Lindl., Loquat, MH, r; _274_ (A colony of several saplings naturalized in the hammock.)

Prunus caroliniana (Mill.) Aiton, Carolina laurelcherry, DA; i; _640_

Prunus serotina Ehrh. var. _serotina_, Black cherry, MH, SB/MH; o; ***44***, ***541***, _641_, ***655***

*_Rhaphiolepis indica_ (L.) Lindl., Indian hawthorn, CULT; _676_

Rubus trivialis Michx., Southern dewberry, DA, HB, SB/MH; i; _612_, ***680***

RUBIACEAE

Chiococca alba (L.) Hitchc., Snowberry, HB; r; ***401***, ***531***

Diodia teres Walter, Poor joe, DA; r; _666_

Galium hispidulum Michx., Coastal bedstraw, DA, HB, MH; o; ***58***, ***414***, _433_, _524_

Houstonia procumbens (J.F.Gmel.) Standl., Innocence, HB; i; _442_, _473_, ***653***, ***679***

*_Oldenlandia corymbosa_ L., Flattop mille graines, DA; i; _300_

*_Richardia brasiliensis_ Gomes, Tropical Mexican clover, DA; i; _306_

Spermacoce assurgens Ruiz & Pav., Woodland false buttonweed, DA; r; _292_, _513_

Stenaria nigricans (Lam.) Terell var. _nigricans_, Diamondflowers, DA; o; ***57***

RUTACEAE

*_Severinia buxifolia_ (Poir.) Ten., Chinese boxorange, MH; _278_, _678_ [CULT] (Cultivated near park maintenance buildings and also escaped and apparently established in the nearby hammock.)

Zanthoxylum clava-herculis L., Hercules-club, MH, SB/MH; c; ***47***, ***257***, ***403***, _453_, ***632***

SANTALACEAE

Phoradendron leucarpum (Raf.) Reveal & M.C. Johnst., Oak mistletoe, MH; i; ***418***

SAPOTACEAE

Sideroxylon tenax L., Tough bully, MH, SB/MH; c; _9_, ***42***, _108_, ***270***, _435_, _469_

SMILACACEAE

Smilax auriculata Walter, Earleaf greenbrier, MH, SB, SB/MH; c; _4_, ***43***, _109_, _426_, _496_

Smilax bona-nox L., Saw greenbrier, o; MH, SB/MH; _8_

SOLANACEAE

Lycium carolinianum Walter, Christmasberry, SM/BF; r; ***553***, _625_

Physalis walteri Nutt., Walter's groundcherry, FD, HB; c; ***33***, ***60***, _111_

Solanum chenopodioides Lam., Black nightshade, HB; i; _445_

TETRACHONDRACEAE

Polypremum procumbens L., Rustweed, DA, HB; o; _118_, _134_, ***254***

URTICACEAE

Parietaria praetermissa Hinton, Clustered pellitory, DA; r; _93_

Pilea microphylla (L.) Liebm., Artillery plant, MH; i; ***681***

VERBENACEAE

*_Lantana camara_ L., Lantana, [CAT I], DA, HB; o; ***85***, _100_, _599_

Phyla nodiflora (L.) Greene, Turkey tangle fogfruit, DA, HB; o; _120_, _136_, _285_

**Verbena bonariensis* L., Purpletop vervain, DA; i; *132*

Verbena officinalis L. subsp. *halei* (Small) S. C. Barber, Texas vervain, DA; o; *99, 129*

VITACEAE

Ampelopsis arborea (L.) Koehne, Peppervine, DA, MH, SB; o; *14*, ***34***, ***250***

Cissus trifoliata (L.) L., Sorrelvine, SB; i; *314*

Parthenocissus quinquefolia (L.) Planch., Virginia creeper, DA, SB, MH; o; *12*, ***78***, *449*

Vitis aestivalis Michx., Summer grape, MH, SB; c; ***40***, *315*

Vitis rotundifolia Michx., Muscadine, MH, SB; o; *10, 320*

ZINGIBERACEAE

**Alpinia zerumbet* (Pers.) B.L. Burtt & R.M. Sm., Shellflower, CULT; *639*

ACKNOWLEDGMENTS

We thank William Carromero and Alexander Reynolds for enthusiastic assistance in the field. We greatly appreciate the invaluable support and cooperation of National Park Service personnel: Joe DeVivo, Network Coordinator; Gordon (Gordie) Wilson, Superintendent; David Parker, Site Supervisor and Chief of Resource Management; Andrew Rich, Park Ranger; and Ronnie Dean, Biological Science Technician. Park Guides Ray Hamel and Thomas Birmingham expertly commandeered the Matanzas Queen II around Rattlesnake Island, allowing our amphibious landings to otherwise inaccessible shores. Kent D. Perkins and Richard P. Wunderlin provided essential constructive criticisms of the manuscript; Kerik D. Cox created the electronic version of our vegetation map and assisted with the other figures; J. Steve Davis at the University of Florida generously lent us NPS structure study documents on Fort Matanzas; and Eric Fuchs translated the abstract into Spanish. We are also grateful to the Department of Plant Biology, University of Georgia, for the use of a departmental vehicle for three trips to transport supplemental field supplies and personnel. This survey was funded by National Park Service contract agreement J2114-03-0006 (PI D. E. Giannasi & coPI W. B. Zomlefer).

ABSTRACT

Despite the abundance of *Juniperus ashei* Buchholz in Texas, mature, intact stands are relatively rare. This study compares structural patterns and growth dynamics among three mature stands on the Edwards Plateau and documents relationships between structural changes and temporal development of these forests. Each stand has varied physiognomic characteristics and age-related structure. By identifying and comparing these properties, this study provides information relevant to conservation and management decisions relating to *J. ashei*.

RESUMEN

A pesar de la abundancia de *Juniperus ashei* Buchholz en Texas, las agrupaciones maduras e intactas son relativamente raras. Este estudio compara los modelos estructurales y la dinámica de crecimiento entre tres agrupaciones maduras en el altiplano Edwards y se documentan las relaciones entre los cambios estructurales y el desarrollo temporal de estos bosques. Cada agrupación tiene diversas características fisonómicas y una estructura relacionada con su edad. Al identificar y comparar estas propiedades, este estudio provee información pertinente para la conservación y decisiones de supervisión relacionadas con *J. ashei*.

INTRODUCTION

Background

Juniperus ashei Buchholz (Ashe juniper), one of the nine Texas species of the genus *Juniperus* (Correll & Johnston 1970; Simpson 1999), has dense populations from the Ozark Mountains in Missouri and Arkansas, to the Arbuckle Mountains of northeastern Oklahoma, and is found throughout central Texas particularly on southern and eastern portions of the Edwards Plateau where it is the dominant woody species and forms a significant component of the state's vegetation (Van Auken 1988; Diamond et al. 1995; Jackson & Van Auken 1997; Smeins et al. 1997). It also occurs in northeastern Mexico (Little 1992). Although

SIDA 21(2): 1107–1120. 2004

J. ashei has an overlapping distribution with both *J. virginiana* L. (eastern red cedar) and *J. pinchotii* Sudw. (redberry juniper), chemical analyses suggest that hybridization does not occur (Adams 1972, 1975; Kelley 1976; Flake et al. 1978).

Juniperus ashei is typically found on thin, calcareous limestone- or dolomite-derived soils (Vines 1960) and also grows in deeper, sandier soils often in association with *Quercus fusiformis* Small (plateau live oak), *Diospyros texana* Scheele (Texas persimmon), *Q. stellata* Wang. (post oak), *Q. sinuata* var. *breviloba* (Torr.) C.H. Müll. (scaly-bark oak) and *Q. buckleyi* Nixon & Dorr (Texas oak) (Van Auken et al. 1978; Riskind & Diamond 1986; Diggs et al. 1999). Co-occurrence of *J. ashei* with broadleaf trees constitutes prime habitat for *Dendroica crysoparia* (golden-cheeked warbler), an endangered species which nests solely in juniper/oak woodlands and uses the bark from mature (>30 yrs old) *J. ashei* trees as nesting material (Doughty & Parmenter 1989; Beardmore et al. 1995).

Mature, second-growth *J. ashei* stands are rapidly disappearing due to high rates of urban and suburban expansion (Doughty & Parmenter 1989; Diamond et al. 1995; Patoski 1999). Effective land and endangered species management must include an understanding and appreciation of *J. ashei*'s role in establishing and maintaining stable, mature communities (Diamond et al. 1995) and its importance to the endangered golden-cheeked warbler.

This study investigates the structure and dynamics of three mature *J. ashei* stands and provides information regarding the establishment and persistence of these stands. By identifying and comparing several structural and age-related characteristics, it provides information relevant to conservation and management decisions. Structural patterns and growth dynamics are compared among stands to document relationships between structural changes and temporal development of these forests.

METHODS

Study Areas

The three study areas are on the Edwards Plateau of central Texas (Fig. 1) where eroded marine sandstones, limestones, shales, and dolomites are covered by thin soil deposits (Riskind & Diamond 1988) on upland areas deeply dissected by streams. Precipitation, which averages 85 cm per year in the region of the study sites (Riskind & Diamond 1988), percolates downward to the water table, expands fissures in the limestone, and forms the sinkholes, caves, and underground drainages characteristic of 'karst' topography (Spearing 1991).

Two study sites are in Guadalupe River State Park, a 769 ha park in Comal and Kendall counties. The first site (hereafter Guadalupe South) is located south of the Guadalupe River on a 35 ha 'karst dome' (elevation = 385 m; N 29° 51' W 98° 30'). The second site (hereafter Guadalupe North) is north of the Guadalupe River atop the river's escarpment (elevation = 342 m; N 29° 52' W 98° 28').

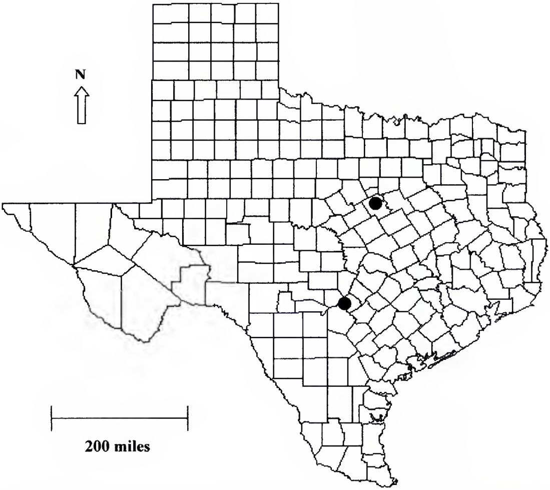

Fig. 1. Map of Texas with locations of study sites in Bosque and Comal counties.

Both stands are on undulating, well drained, cherty clay loam soils where chert and limestone cobbles cover >20 percent of the surface and subsoil layers below 15–20 cm are 75%, by volume, limestone fragments (U.S. Department of Agriculture 1984). Soils at both locations are typical of the region.

The third study site is on moderately deep, well-drained, loamy soil in Meridian State Park, a 204 ha reserve in Bosque County (elevation = 326 m; N 31° 53' W 97° 41'). Surface soil and subsoil layers are up to 38 and 94 cm deep, respectively, over a karst bedrock (U.S. Department of Agriculture 1980).

Sampling Procedures

Circular, 100 m^2 plots were established at 20 m intervals along transects in each stand. Transects differed in length according to stand dimensions. All trees were identified to species, mapped by their distance and bearing to the plot center, and their diameter breast height (dbh) recorded. Trees with dbh >8 cm were marked with individually numbered aluminum tags and cored at the base using a 4.3 mm diameter increment borer. Dead or unhealthy trees were not cored. Cores were glued to wooden mounting boards and sanded to a flat surface. Rings were counted under 37.5× magnification.

Because *J. ashei* forms false rings in response to environmental changes, ring number does not accurately reflect tree age. Therefore a formula for estimating age using ring counts was developed with cores from a separate set of trees of approximate known age from Meridian State Park. Photographs dating back to the park's development in 1933–34 were analyzed to isolate specific areas devoid of *J. ashei*. Trees now present in these areas were assumed to have germinated immediately after the park's establishment, giving them a maximum age (at the time of the study) of sixty-seven years. Cores from these trees were analyzed and a formula was derived by (1) counting rings of each tree, (2) dividing approximate age by ring count, and (3) pooling results and computing a mean. Approximate age of each *J. ashei* in this study was then calculated using the resulting formula: ring count × 0.67. Large rays and the diffuse porous nature of the deciduous hardwoods made it impossible to accurately determine ages of those trees. Ring count information was used to determine forest age structure.

Tree numbers, dbh, and height were used to determine mean height, mean basal area, size distribution, relative density (number of *J. ashei* as a proportion of the total number of individuals of all species), relative frequency (frequency of *J. ashei* as a proportion of the sum of the frequencies for all species), and relative basal area of each tree species. Importance values (Brower et al. 1998) were calculated.

Measurements for height, basal area, and age were tested for normality and homogeneity of variance (Sokal & Rohlf 1973) in order to determine the appropriate method of statistical analysis. All variables were normally distributed but displayed heterogeneity of variance, therefore non-parametric analysis of variance (ANOVA) was chosen to test for significant differences between stands.

RESULTS

Tree Species Identified and Importance Values

Table 1 provides numbers of each tree species found at each study site. Only *Juniperus ashei* was common to all three sites.

Relative density, frequency, and basal area of species may be summed to produce importance values (ranging from 0–3). Importance values integrate these separate measures to provide an indication of species influence in the community (Smith 1974). High importance values occurred for *J. ashei* at all three sites, with Guadalupe South at 2.70 and Meridian and Guadalupe North at 2.36 and 1.93, respectively (Table 2). These values indicate the dominance of this species in these communities.

TABLE 1. Summary counts of trees sampled.

Scientific Name	Common Name	Guadalupe South	Guadalupe North	Meridian
Juniperus ashei	Ashe juniper	138	131	86
Diospyros texana	Texas persimmon	3	38	0
Celtis laevigata	hackberry	0	5	0

Sideroxylon lanuginosum	.01	.05	.001	.06

Basal Area and Size Class Distribution

Mean basal area of *J. ashei* was calculated for each site. Data indicate 29.58 m^2ha^{-1} (±11.41), 33.89 m^2ha^{-1} (±12.13), and 39.30 m^2ha^{-1} (±10.63) for Guadalupe South, Guadalupe North, and Meridian, respectively. Analysis of variance (Table 3) showed no significant differences between basal area of the three stands.

TABLE 3. Kruskal-Wallace one-way multisample non-parametric ANOVA with ties correction and χ^2 approximation for tree basal area, height, and age at three sites. Mean sums of ranked scores are shown. Letters indicate significant differences at $p<0.05$ via Student-Newman-Keuls Multiple Range Test.

	Guadalupe South (n=84)	**Guadalupe North (n=77)**	**Meridian (n=66)**	
Basal Area (cm^2)	111.42 (a)	108.73 (a)	123.43 (a)	$\chi^2 = 1.99_{(2)}$, $p<0.3704$
Age (yrs)	128.2 (a)	134.5 (a)	72.0 (b)	$\chi^2 = 38.53_{(2)}$, $p<0.0001$
Height (m)	71.89 (a)	154.03 (b)	120.89 (c)	$\chi^2 = 63.89_{(2)}$, $p<0.0001$

Highest percentages of *J. ashei* at each site were in the smallest size class category (>30-300 cm^2) with Guadalupe South at 45.3%, Guadalupe North at 48.5%, and Meridian at 36.5% (Fig. 2). Fewer than 5% of *J. ashei* at each site were in each of the four largest size class categories.

Age Structure

Ages of cored *J. ashei* were calculated and divided into five equal groups, 27–56 years, 57–86 years, 87–116 years, 117–146, and 147–177 years. At all sites most trees were younger than 86 years and few were over 147 years (Fig. 3).

Mean ages for the stands ranged from 80.4 years at Guadalupe North to 55.5 years at Meridian (Table 4), and these differences were statistically significant (Table 3). There was no significant difference in mean ages between Guadalupe North and Guadalupe South. However, this result is believed to be due to the inability to determine ages of the many dead trees at Guadalupe North. Pattern for mean ages was reflected in the pattern for oldest trees (Table 4). The oldest trees at Guadalupe North and Guadalupe South sites were >150 years old. The oldest tree at Meridian was about the same age as the mean trees at both Guadalupe sites and was less than half the age of Guadalupe North's oldest tree.

Height

Mean heights were calculated for each tree species comprising >3 percent of each community. *Juniperus ashei* occupied the canopy at all three sites. At Guadalupe South and Guadalupe North, where the canopy was shared with other species, only *Ulmus crassifolia* (cedar elm) at Guadalupe North was taller than *J. ashei* (Table 5). Mean heights of *J. ashei* differed significantly among all sites with the greatest heights at Guadalupe North and the least at Guadalupe South (Table 3). Meridian had the highest rate of height increase (cm yr^{-1}), growing approximately 35% faster than Guadalupe South over the lifetime of the two stands (Table 6).

DISCUSSION

Mature *Juniperus ashei* dominated all three sites in this study; however, each stand had varied physiognomic characteristics and age-related structure.

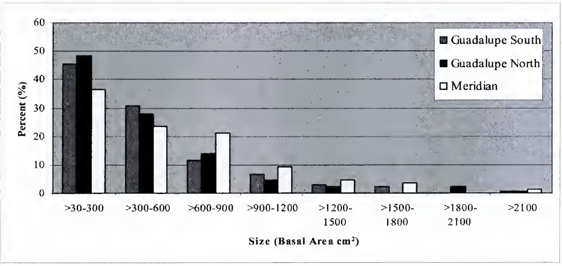

Fig. 2. Size class distribution of *Juniperus ashei* based on basal area.

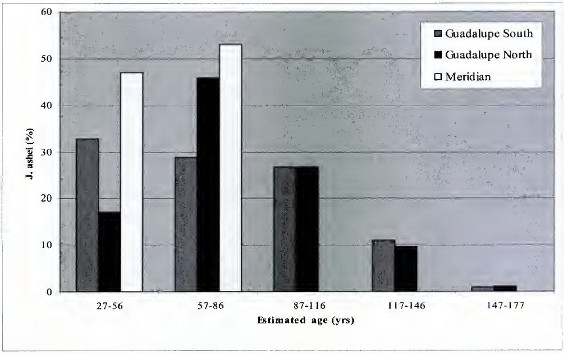

Fig. 3. *Juniperus ashei* estimated age class distribution.

Table 4. Mean *Juniperus ashei* ages and oldest trees.

Location	Mean Age *J. ashei* (yrs)	S.D.	Oldest *J. ashei* (yrs)
Guadalupe South	77.3	± 29.6	158
Guadalupe North	80.4	± 27.7	177
Meridian	55.5	± 12.4	82

Table 6. *Juniperus ashei* mean height increase (cm yr^{-1}).

Location	Mean Increase (cm yr^{-1})	S.D.
Guadalupe South	9.05	±4.17
Guadalupe North	11.57	±4.99
Meridian	13.81	±3.23

Tree Species Identified and Importance Values

Importance values were determined at all three locations (Table 2). The lowest *J. ashei* value occurs at Guadalupe North. Also present at this site is *Diospyros texana* (Texas persimmon), a small tree usually less than 12 m tall (Little 1992). *Diospyros texana* is exclusively an understory tree at this location, with the tallest individual measuring 4.7 m. At Guadalupe South, with the highest *J. ashei* importance value, *D. texana* is rare (Table 1). Shading conditions make no significant difference in germination rates of *D. texana* (Everitt 1984). However, *Diospyros* species are reported to require full sun for optimum growth (Crockett 1972). At Guadalupe North these trees are often found clustered near dead *J. ashei*. These gaps in the canopy appear to provide ideal locations for the continued growth of this species. Few *D. texana* occur under the canopy at Guadalupe South, but may become more abundant as the stand ages and gaps are opened by tree death.

Basal Area and Size Class Distribution

Van Auken (1988) reported *J. ashei* mean basal areas of 38.6, 21.4, 43.2, and 18.4 m^2 ha^{-1} in four mature, undisturbed, woodlands computed from diameters measured at 0.1 m above ground surface. These results are consistent with those for this study where mean basal areas of 29.6 (±11.4), 33.9 (±12.1), and 39.3 (±10.6)

m^2 ha^{-1} for *J. ashei* were measured at the Guadalupe South, Guadalupe North, and Meridian sites, respectively.

Analysis of variance (Table 3) showed no significant differences between basal areas of the three stands. However, since Meridian is a significantly younger stand (Table 4), this indicates a faster basal growth rate at that location. Some of this difference may be accounted for by the faster growth rate of younger trees. However, deeper surface soil with its associated greater moisture-holding capacity is probably the most important factor (Bockheim 1982) influencing tree growth and may have led to a faster growth rate at Meridian than at the two Guadalupe River State Park locations where soils are thinner and rockier.

Highest percentages of *J. ashei* were in the smallest size class category (>30-300 cm^2) at all three locations with Guadalupe South at 45.3%, Guadalupe North at 48.5%, and Meridian at 36.5% (Fig. 2). Less than 5% of *J. ashei* at each site were in each of the four largest size class categories. This arrangement results in a negative exponential size distribution, usually representing relatively early successional establishment (Van Auken 1993). However, size distribution does not necessarily reflect age distribution in forest age class studies. A generalization may be made that larger trees are likely to be old. However, it cannot be assumed that a small tree is young (Harper 1977). Many of the smaller *J. ashei* in this study were older than expected and size class distributions, in this case, do not indicate early successional stages, expanding populations, or relative youth of the majority of trees.

However, size class distribution is useful in describing the condition of a population in terms of its future and may offer insights into reproductive performance. While reproduction is often analyzed in terms of age structure, quite often it is a function of size and can best be studied using size distributions (Harper 1977). *Juniperus ashei* cone production is partially determined by environmental conditions, particularly rainfall, but is also dependent on tree size with trees reaching reproductive maturity at about 1.5 m height and about 50 cm^2 basal area. Results from this study indicate the majority of trees are reproductively mature and playing an important role in the reproductive dynamics of the population.

Age Structure

False rings formed by many species of *Juniperus* (Panshin & Dezeeuw 1964) cause considerable difficulty in age determination. Van Auken (1993) believes it is impossible to accurately determine ages of junipers from growth rings due to formation of several rings each year in response to fluctuating rainfall. Fuhlendorf (1992; pers. comm.) reported an inability to differentiate true and false annual rings while determining *J. ashei* ages from ring counts. Adams (pers. comm.) expressed doubt concerning dating method accuracy for *J. ashei* (Adams et al. 1998).

Methodology devised for age determination of *J. ashei* in this study is a novel approach based on ring counts of trees of known age. Although some conifers have a propensity to produce relatively more false rings when young and fewer when old, Grissino-Mayer has found no indication that Juniperus species have a tendency to do this (pers. comm.). Therefore, although the trees from Meridian were only 67 years old, the rate of false ring production should be similar to that of even the oldest trees in Guadalupe North. Although the trees were sampled at Meridian State Park, similar precipitation patterns at both parks also help validate use of the same formula constant for all three sites.

Forest populations often progress as a sequence of even-aged cohorts initiated by disturbance. However, the mixed-aged structure characterized in this study (Fig. 3) indicates rarity of disturbance and infers continuous recruitment over the life of the stands (Kelly & Larson 1997). These stands appear to have escaped the relatively frequent fires that historically occurred in Texas at the time of their establishment (Smeins et al. 1997) and apparently have been fire-free throughout their existence.

Interpreting age structure is complicated by the fact that there is no way to determine past mortality rates of a population. Age structure determination usually considers only survivors (as in this study) and does not utilize recruitment and mortality data (Harper 1977). However, accurate determination of stand age is dependent on mortality, as the oldest trees may be dead. This difficulty played a major role in determining the true age of Guadalupe North, where much of the forest was composed of dead trees. Despite these limitations, generalizations can be made concerning age structure of these stands.

Analysis of variance (Table 3) results indicated no significant differences between the ages of the two stands at Guadalupe River State Park. However, the stand at Meridian was significantly younger with a mean tree age of 55.5 years and no tree sampled older than 82 years (Table 4). All *J. ashei* at Meridian were in the two youngest age categories (Fig. 3). Stand age broadly corresponds to the establishment of the park in 1934. Much of the area now occupied by this stand was historically midgrass prairie (Riskind, pers. comm.), and the woodland's presence demonstrates the ability of *J. ashei* to colonize many terrain types in the absence of fire.

Mean ages for *J. ashei* were similar for Guadalupe South and Guadalupe North, with Guadalupe North results indicating a slightly (but not significantly) older stand (Table 4). Guadalupe South's age distribution is typical of an aging population, with trees in age categories of 27–56 yr, 57–86 yr, and 87–116 yr almost equally distributed (Fig. 3). Guadalupe North is the oldest stand with its establishment dating back to at least 170 years ago. Its greater age is reflected in the shift toward older trees (Fig. 3). It appears to be a declining population with relatively few individuals in the youngest 27–56 yr age category. Field observations indicated many large, old, dead trees for which ages could not be determined. This difficulty caused an underestimate of the stand's true age. Therefore, despite ANOVA results, Guadalupe North is believed to be older than Guadalupe South. Both Guadalupe North and Guadalupe South met some criteria for old-growth *J. ashei* stands as proposed by Diamond (1997) and perhaps could serve in refining the definition.

Height

Although *J. ashei* was the most abundant tree and dominated the canopy structure, other species, notably *Ulmus crassifolia*, *Quercus fusiformis*, and *Fraxinus texensis* were present in the canopy. At Guadalupe North the *J. ashei* canopy, at 7.93 m, is overtopped by a number of *U. crassifolia* (Table 5). Whether the taller *U. crassifolia* are older or whether they grow more quickly than *J. ashei* could not be determined. Presence of *Diospyros texana* is also significant at Guadalupe North. This species is primarily an understory tree as indicated by its mean height that is approximately half that of *J. ashei*.

Quercus fusiformis and *Fraxinus texensis* have mean heights shorter than *J. ashei* but still share the canopy at Meridian (Table 5). This stand developed in a grassland or savanna environment and records indicate that the area was a cotton field prior to establishment of the park (Riskind, pers. comm.). Therefore, trees sharing the canopy with *J. ashei* probably established concurrently.

ANOVA results indicated significantly different canopy heights between sites (Table 3). Although younger, Meridian had a greater mean height (7.19 m) than Guadalupe South (6.19 m). Reasons for this pattern are not known. However, deeper soils with greater moisture-holding capacity at Meridian could be one explanation for the observed height differences (Table 6). Tallest mean *J. ashei* height (7.93 m) is at Guadalupe North and differences between that site and Guadalupe South may be due to Guadalupe North's greater proportion of older trees.

Information is lacking concerning height growth rates of *J. ashei* but it is historically considered slow-growing (Blomquist 1990). Based on tree ring analysis, *J. pinchotii* grows in height an average of 6.01 cm yr^{-1} for the first thirty years (McPherson & Wright 1989; Ueckert 1997). *Juniperus ashei* height growth rates may be expected to be similar to those of *J. pinchotii* but data from this study indicated greater mean height increases at 9.05, 11.57, and 13.81 cm yr^{-1} for Guadalupe South, Guadalupe North, and Meridian, respectively (Table 6). If *J. ashei* height growth rates are similar to those of *J. pinchotii*, discrepancies may be due, in part, to previous studies overestimating tree age from faulty interpretation of annual ring counts.

Jackson and Van Auken (1997) recorded that *J. ashei* seedlings in edge habitats grow an average of 13.98 cm yr^{-1}. Their data are similar to height growth rates reported for Meridian. Deeper soils and the high light environment of open grassland during stand establishment may have resulted in relatively high rates of increase at this location.

Guadalupe South and Guadalupe North receive similar amounts of precipitation and have similar soil depths. Growth rate discrepancies between the two sites are probably due to underestimating the true age of Guadalupe North. If the Guadalupe North stand is older than data from this study indicate, an adjustment downward in height growth rate would result, giving Guadalupe North a growth rate more similar to that obtained for Guadalupe South.

ABSTRACT

Short's goldenrod (*Solidago shortii* Torr. & A. Gray) is an endemic species with a highly restricted distribution, the Kentucky populations occurring in and around the vicinity of Blue Licks in the northeastern portion of the state. The general occurrence of the species was first mapped in 1987, with several similar maps being published from 1989–2000. Due to changes in local land use practices the status of the populations has rapidly changed rendering these maps obsolete. A census of all populations was conducted and the precise topographic location and physical boundaries of each extant population was mapped using field reconnaissance techniques and GIS mapping technology. Between 1989 and 2003 four of the original populations were extirpated, eight declined in number of stems present, and one increased in both number of stems and area coverage.

RESUMEN

La "Espiga de oro de Short" (*Solidago shortii* Torr. & A. Gray) es una especie con poblaciones altamente restringidas en y a los alrededores de Blue Licks, al norteste de Kentucky. La distribución general de las poblaciones de esta especie fue cartografiada por primera vez en 1987 y varios mapas han sido publicados entre 1989-2000. Debido a cambios locales en el uso de tierra para cultivo, la distribución original de las poblaciones de la especie se han modificado en gran medida, y en consecuencia los mapas existentes están obsoletos. Un censo de todas las poblaciones, observaciones de campo, y técnicas del Sistema de Información Geográfica (SIG) han permitido la ubicación topográfica precisa y la delimitación física de cada población. De 1989 a 2003 cuatro de las poblaciones originales han desaparecido, ocho disminuyeron en número de tallos y una población aumentó en número de tallos y en área de cobertura

INTRODUCTION

Solidago shortii (Asteraceae) is listed as an Endangered Species in the Federal Register (Anonymous 1985). Charles Wilkens Short originally discovered specimens of the species growing on boulders at the Falls of the Ohio River in Jefferson County, Kentucky, in 1837. All remnants of those populations were either destroyed by inundation resulting from the construction of the McAlpine locks and dam to facilitate navigation on the Ohio River in 1925 (Buchele et al. 1989) or were extirpated in the latter half of the 19th century (Baskin et al. 2000). The species was "rediscovered" by E.L. Braun in 1939, in the vicinity of Blue Licks, KY (Braun 1941) (Fig. 1). The first map showing the spatial distribution of the Blue Licks populations was constructed in 1986 (Evans 1987). Several subsequent reports contained maps of similar resolution (e.g. Buchele et al. 1989), with a new population being noted in Baskin et al. (2000).

During the course of our field investigations from 1995-2003, we observed marked changes in the spatial size and occurrence of specific populations, due in part to local land-use practices and to local successional changes in several habitats. It became very clear that updated maps were needed to facilitate management practices involving this species.

This study was undertaken with two objectives in mind: 1) to develop higher resolution maps of each known Kentucky population of Short's goldenrod using Geographic Information Systems (GIS) cartographic technology; and 2) to update the status of each population first demarcated by Evans in 1987. Given the demonstrated utility of Geographic Information Systems technology in land use management (Longley et al. 1999) and species inventory applications (DeMers 1996), this application was a logical choice for developing accurate maps.

MATERIALS AND METHODS

Field Work-Population Census.—During the 2000 field season the boundary of each population first documented by Evans (1987) and Buchele et al. (1989) was defined through field surveys. Multiple transects through each population were established, dividing the population into parallel 3-meter-wide strips. The space between successive transects was then traversed, each individual *S. shortii* stem being counted. The majority of populations exhibit a linear rather than a polygonal distribution, which made this direct count approach technically feasible. This represents at best a minimal estimate, as undoubtedly some stems within the population boundaries escaped our detection, and some scattered plants do exist outside the demarcated boundaries.

Field Work-GPS Coordinates.—GPS Lat/Long coordinates, taken in the degrees/minutes/seconds format, were determined with a Magellan 2000 handheld GPS device at 50-meter intervals along the established perimeter of each population. Reference maps for each population were drawn in the field, using

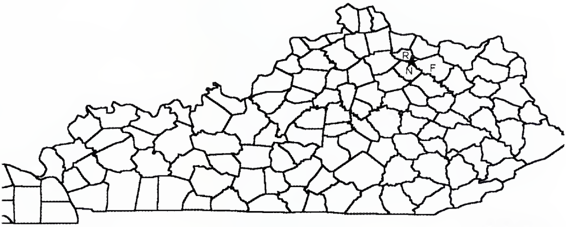

FIG. 1. Location of the populations of Short's goldenrod in Kentucky. The "star" indicated the approximate location of the majority of populations at the intersection of Fleming (F), Robertson (R), and Nicholas (N) counties.

measurements taken from local landmarks to orient field maps with aerial photographs and topographic maps (described below). Area estimates for each population were calculated from field measurements and combined with stem counts taken in 2001 to obtain density estimates for each population.

GIS Mapping.—An Event Theme using the GPS data points was created in ArcView 3.0. The X coordinate was set to Longitude, the Y coordinate to Latitude, and the Projection was set to Lambert Conformal Conic. Aerial and topographic images of the field research area were downloaded from the Kentucky Office of Geographic Information Systems (KYOGIS) website (ogis.state.ky.us/). The KYOGIS download included a file containing georeferencing information.

A Line Theme was created to show the plants' distribution. The plants' locations and their proximity to landmarks visible on the aerial photo were verified and corrected based on our field observations. Other data sets were combined with the images and population lines. For example, a State Highways theme and Counties theme from Environmental Systems Research Institute (ESRI) were added to show the locations of highways and county boundaries. Finally, we created the included maps (Fig. 2) using the ArcView Layout tool. All data and map files are available to appropriate scientific investigators and state and federal agencies upon request.

RESULTS

The ArcView system allows us to superimpose the GPS-derived data points for each population onto a number of high resolution cartographic interfaces, e.g., an aerial photograph (Fig. 2A) or a topographic map (Fig. 2B). Comparisons with earlier maps are not quantitative due to differences in cartographic methodologies. Likewise, exact comparisons of surface area coverage for each popu-

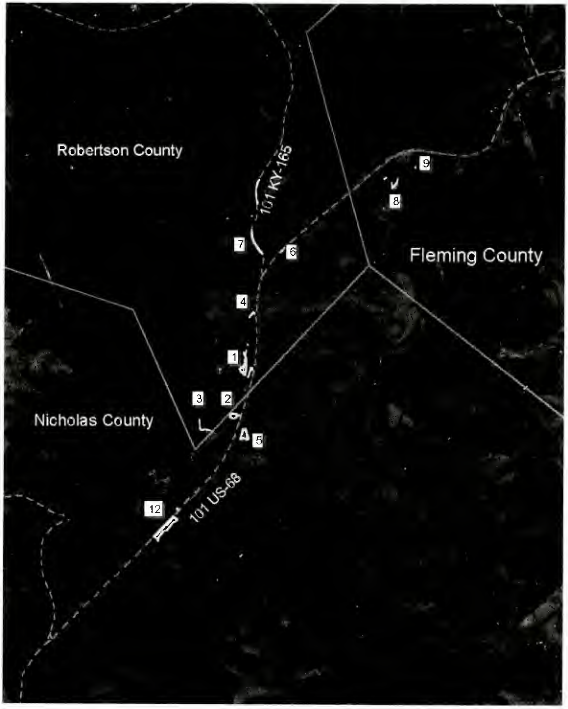

Fig. 2A. Example of a GIS-generated map showing the location of the known extant Kentucky populations of Short's goldenrod, with the exception of populations #11 and #15. Boxed numbering of populations follows Evans (1987). Solid white lines are county boundaries, dashed white lines are state and federal highways, the serpentine figure traversing the map is the Licking River, and population boundaries are shown in red. Only those populations found on properties in either state or federal agency ownership are shown.

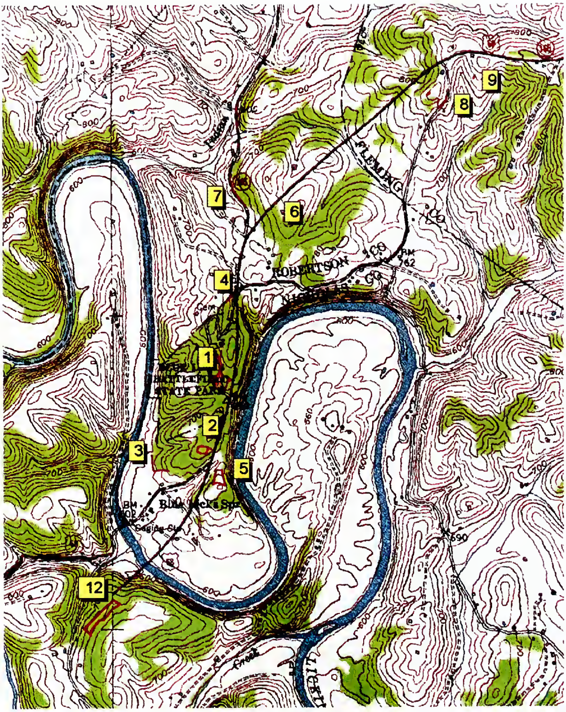

FIG. 2B. The identical shape file in figure 2A, now superimposed over a USGS topographic map.

lation relative to an earlier study (Buchele et al. 1989) are difficult due to differences in sampling techniques. However, we are confident that both sampling methodologies are of sufficient accuracy to allow for general comparisons. Two populations found on lands in private ownership (#11 and #15) are not shown on our maps to provide those populations with some measure of protection.

The census results, rather dramatic when compared to earlier stem counts, are summarized in Table 1. Based upon comparison with earlier stem counts and surface area estimates (Buchele et al. 1989) the populations cluster into the following categories.

Decline.—This is the status of populations #1–4, #7, #11 and #12, all having declined in stem numbers ranging from a 1.25-fold to 33-fold. Population #6 exhibits a larger fold decrease, now consisting of only one stem. We consider this population to be extirpated. A concomitant decrease in surface area is also seen in population #1–4, #7 and #8. While experiencing a slight decline in stem number (1.25-fold), population #12 has expanded its surface area by 13-fold. Census data for population #11 are not available for 2002, as we were unable to obtain permission from the private property owner to examine this site. GIS data were obtained for this population along a bordering road, and mapped from prior field observations.

Extirpated.—Population #6 occurs along a highway right-of-way, and is a remnant of a once larger population that was intentionally destroyed by a local landowner. There is now a single stem remaining. The original population #10 (Evans 1987) was destroyed by a local landowner (Mr. Allison, pers. comm.). We discovered a remnant set of eight plants in 1998, ca. 100 meters east of the original locality. This set is now extirpated due to local successional changes, e.g., increased canopy cover from arborescent species (primarily *Quercus* spp.).

Increase.—Population #5 is the only population that has increased in stem number, from 530 in 1989 to an estimated 3,488 in 2001. This is accompanied by an increase in coverage area from 870 m^2 in 1989 to 5,380 m^2 in 2001. This is now the largest Kentucky population of Short's goldenrod in terms of both area and stem number.

Doubtful reports.—Population #14, located on private property (the Kingsolver farm near Blue Licks Battlefield State Park) has been of doubtful determination since its "discovery". There are no voucher specimens from this site, and repeated efforts by the authors in 1998 and 1999 and by D. White (Kentucky State Nature Preserves Commission, pers. comm.) to locate *S. shortii* plants met with failure. This population, if ever extant, is now extirpated

Recently discovered population.—Population #15 was discovered by Mr. Nick Drozda of the KSNPC during a survey of a bison trace (trail) in 1998. This population was revisited in 2003 and found to have increased in number of stems and distribution.

Table 1. Summary of population census and area of coverage of all known verified populations of Short's goldenrod in Kentucky. Data from 1989 are those of Buchele et al. (1989), from 2001–2003 are from this study. The numbering of populations #1–13 is that of Evans (1987). Population #14 was designated and first mapped by Baskin et al. (2001), and #15 is the recent discovery by N. Drozda. The "First Report" entry refers to the earliest notation in status records maintained by the USFWS and provided by D. White of the KSNPC. KSNPC = Kentucky State Nature Preserves Commission; P = private ownership; KSPC = Kentucky State Parks Commission; KHC = Kentucky Highway Commission; ROW = Right-of-Way; USFWS = United States Fish and Wildlife Service. **extirpated* = population consisting of 1 plant, but in essence extirpated; **14 = dubious report; ***15 = stem number estimate provided by N. Drozda (pers. comm.).

DISCUSSION

Given the state of mapping technology in 1987 (and the passage of time) it is not surprising that maps derived through GIS applications are different from the original maps. What is of particular note is the general numeric decline in all but one population (#5) of *S. shortii*. Populations #1, 2, and 4 have been within the jurisdiction of the Kentucky State Parks Commission during this period of comparison, yet all three have suffered massive decline. An unequivocal cause for the decline of these three and/or any other populations under protection (i.e., populations #5 and 8, under the jurisdiction of the KSNPC, and population #12, under the USFWS) is not clear.

The spatial distribution patterns of the populations fall into two categories. The first we term "linear" (populations #1, 3–4, 6–9, 11 and 12). Several of these populations occur along either power line or highway rights-of-way (Table 1), but others occur in what appears to be uninterrupted habitat (e.g. #4) conforming to a linear pattern. This could be due to localized edaphic conditions, as the preferred habitat is one with shallow soils. The second category we refer to as "polygonal" (populations #2 and #5). These habitats are continuous areas uninterrupted by roads. The plants, however, are distributed discontinuously throughout the mapped area, the perimeter of the populations assuming an irregular geometric outline. The precise reasons for this difference in spatial distribution patterns is at present unknown but could be due to subterranean factors, e.g., rock shields underlying shallow soils and providing an unsuitable habitat for competing species. Alternatively, the plants' distribution could be due to seed dispersal patterns of those specific populations. At present both of these postulates remain untested.

The results of the stem count comparison are dramatic. Numbers of stems has decreased since 1989 for all observed populations except #5. This population exists in an old field that is currently under the management and ownership of the Kentucky State Nature Preserves Commission. The results of the area estimates are equally dramatic, since all of the observed populations except for #5 have decreased in area since 1989. Population #1 has experienced the most marked decline, most likely due to improper management and increased development and use of park recreation facilities by visitors. This population is now dissected into several distinct groups, each following either a road or a power line right-of-way or a former bison trace remnant. The glade area within the park where the plants were previously observed in abundance is now populated primarily by *S. nemoralis*. A similar situation exists in population #2. The impact of *S. nemoralis* on the long-term persistence of *S. shortii* is not known, although we have observed a steady decline in these two populations (Table 1).

Three populations have been extirpated, one by natural means and two by human intervention. Population #13 occurred in an open field and consisted of 180 stems in 1989 (Buchele et al. 1989). The field was subjected to mowing in the early years of the 1990s, but in the latter half of the decade the field was not cultivated. Competition from non-native grasses (e.g, *Festuca*) and forbs (e.g., *Lespedeza*) have contributed to the loss of this population. Population #6 grew in an actively grazed pasture and was removed by the landowner in 1988 by bulldozing the habitat (USFWS records and D. White, pers. comm.). In discussions with the local landowner it was revealed that population #10 was eliminated through extensive mowing of caulescent stems and the deposition of concrete debris on the persistent rosettes, beginning prior to 1995. Population #11 occurs along a woodland edge and appeared rather stable over the period of this study.

The status of a questionable population has also been resolved. Population #14 was first cited in Baskin et al. (2000). We were unable to locate plants in the field during 1998 and 1999, and there was confusion regarding the accuracy of the original species determination (D. White, pers. comm.). Records maintained by the USFWS indicated ca.15–20 stems of "Short's goldenrod" in 1989, but none was found in either 1997 or 1998. Independent efforts by D. White (pers. comm.) were also unsuccessful. If this population of Short's goldenrod ever existed, it is clear that it is now extirpated.

In 2000, a new population was discovered by N. Drozda of the KSNPC along a former bison trace (trail) in Fleming County. This population consisted of ca.25 stems, and the plants were described as "depauperate" (USFWS records). The population, designated as #15 in Table 1, persisted into 2003 and now consists of ca. 100 stems concentrated along the bison trace with a few individuals scattered in the adjacent woods.

In 1995 seven "clumps" of cultivated *S. shortii* (originally obtained from a Blue Licks population) were planted on the Indiana shoreline of the Ohio River, across from the type locality at the Falls of the Ohio River in an effort to reintroduce the species into suitable riparian habitat (Homoya 1996). These plants were lost in the following year due to increased water flow from winter runoff (D. White, pers. comm.). A recent report describes a population of Short's goldenrod in Indiana (www.in.gov/dnr/public/novdec01/news1.htm). This is the first verified record of Short's goldenrod outside of Kentucky (a voucher specimen has been deposited at MOBOT), the site occurring within a former migration pattern of the extinct eastern woodland bison (*Bison bison* L.). This could represent a very old population that has been genetically isolated from the Kentucky populations for perhaps several centuries. Alternatively, this population could consist of escaped colonizers from the 1995 effort to reintroduce the plants in Indiana, as the newly discovered population is ca. 50 nautical miles downstream from the attempted reintroduction. Genetic analyses of samples from both the Kentucky and Indiana populations are now underway in an effort to resolve this issue.

ACKNOWLEDGMENTS

Appreciation is extended to the Wilderness Road Girl Scout Council Troop #1265 for their mapping of population #4, and to Bruce Davis and the GIS Map Laboratory of Eastern Kentucky University for assistance with GIS software and map generation. Funding in support of field and computational activities was obtained through a Sigma Xi Grant-in-Aid of Research (JBB), through contracts #20379 and #99161405 from the Kentucky State Nature Preserves Commission and the US Fish and Wildlife Service, two EKU Faculty Research Awards and NIH/NCRR Award #P20 RR16481-S1 (PJC). Discussions with Marc Evans and Deborah White, and the field assistance of Tiffany Carpenter and Christina Shackleford are gratefully acknowledged. Nick Drozda escorted PC to population #15 and provided critical background information. The comments and reviews of Moriah Beck and Rob Naczi on the manuscript, and assistance from Sara Fuentes and Lupita Sanchez with Spanish translation are appreciated.

ABSTRACT

For the past five years, the Woodlot Forestry Research and Development Program at North Carolina State University has been assisting with the implementation of the Land Condition Trend Analysis (LCTA) program at Camp Butner. A plant inventory has been an ongoing aspect of associated research. This checklist represents a preliminary inventory of the flora of the site, comprising 78 families, 178 genera, and 241 species.

RESUMEN

En los cinco años anteriores, el Woodlot Forestry Research and Development Program de la Universidad del Estado de Carolina del Norte ha estado ayudando con la implementación del programa Land Condition Trend Analysis (LCTA) en Camp Butner. El inventario vegetal ha sido un aspecto de la investigación asociada. Este listado representa un inventario preliminar de la flora local, que comprende 78 familias, 178 géneros, y 241 especies.

The Camp Butner National Guard Training Site ('Camp Butner') in Durham and Granville counties, North Carolina comprises 1975 hectares and includes pine plantations, mixed pine-hardwood forests, and bottomland hardwood forests. For the past five years, the Woodlot Forestry Research and Development Program at North Carolina State University has been assisting with the implementation of the Land Condition Trend Analysis (LCTA) program at Camp Butner (WFRDP 2003). The Land Condition Trend Analysis (LCTA) inventory was instituted by the US Army Construction Engineering Research Laboratory (USACERL) in order to monitor the natural resources on military installations and to provide information for making sound training and land management decisions (Tazik et al. 1992). In association with annual vegetation monitoring, land use assessment, and wildlife monitoring, a plant inventory has also been an ongoing aspect of research at Camp Butner since 2001. This checklist represents a preliminary inventory of the flora of the site.

METHODS

To inventory the vascular plants of Camp Butner, the site was visited numerous times between 2001–2003. Principal collectors of the flora associated with our project include: C. Wiecek, V. Miller, C. Sheats, and K. Summitt. Batson (1952)

SIDA 21(2): 1131–1139. 2004

also collected in the area. Collected specimens were pressed and dried using standard herbarium techniques and identified using the collections of the North Carolina State University Herbarium (NCSC).

RESULTS AND DISCUSSION

Seventy-eight families, 178 genera, and 241 species are currently known from Camp Butner (Table 1). *Ruellia purshiana* Fern. (Acanthaceae) is known from the site (M. Franklin, pers. comm.), but has not been collected. Taxa are arranged alphabetically within the major subgroups of ferns, gymnosperms, dicots, and monocots. The number of genera, then species follows each family name. Brief habitat descriptions follow each species entry when available. Landscape features for the site are discussed by Hall (1995). Taxonomy follows APGII (APG 2003). Nomenclature primarily follows USDA, NRCS (2002). Specimens are deposited at NCSC, unless otherwise indicated.

The composition of the flora is typical for central North Carolina—the site hosts mixed second growth woodlands, pine plantations, and clearcuts (see also Palmer 1990; Hall 1995). However, compared to other near sites, the flora of Camp Butner is noticeably depauperate (Table 2). The flora of Umstead State Park, which is somewhat larger than Camp Butner, includes about three times as many species (Sawyer 1968). Even floras of sites smaller by an order of magnitude comprise 1.5 to 2 times as many species (Table 2). We suspect two main reasons to explain the relative species poorness of the Camp Butner flora. The majority of the site was not forested as late as 1950 based on black and white (1 to 60,000) photography flown by the US Army in November, 1950. The site now hosts forests that are under higher disturbance regimes from military land use than "nature preserves" such as Durant Park (Skean 1982) or Umstead State Park (Sawyer 1968). Prior to its current ownership, Camp Butner lands were in tobacco cultivation and pastures, as well as host to a WWII prisoner of war camp and artillery range.

Sampling intensity could also be an important factor. Based on comparisons with other floras (Table 3), it appears evident that several large families, including Asteraceae, Fabaceae, Cyperaceae, and Poaceae, remain undersampled in our study and that future efforts must concentrate on increasing representation.

FERNS AND ALLIES

ASPLENIACEAE 1/1

Asplenium platyneuron (L.) B.S.P. (*Sheats 106*; *Wiecek 68*) Pine-hardwood mix.

BLECHNACEAE 1/1

Woodwardia areolata (L.) T. Moore (*Sheats 107*) Pine-hardwood mix.

DENNSTAEDTIACEAE 2/2

Dennstaedtia punctilobula (Michx.) T. Moore (*Sheats 92*)

Pteridium aquilinum (L.) Kuhn (*Sheats 138*) Pine forest.

DRYOPTERIDACEAE 3/3

Athyrium filix-femina (L.) Roth ssp. *asplenioides* (Michx.) Hultén (*Summitt 148*) Near stream.

Table 1. Summary of numbers of families, genera, and species of Camp Butner.

	Ferns and allies	Gymnosperms	Dicotyledons	Monocotyledons	Total
Families	8	2	58	10	78
Genera	11	2	139	26	178
Species	11	4	192	34	241

Onoclea sensibilis L. (*Summitt 153*) Near stream.

Polystichum acrostichoides (Michx.) Schott (*Summitt 163*; *Wiecek 63*) Near stream; Pine plantation.

LYCOPODIACEAE 1/1

Lycopodium digitatum Dill. ex A. Braun (*Sheats 95*) Pine-hardwood mix.

OSMUNDACEAE 1/1

Osmunda cinnamomea L. (*Summitt 222*) Near stream.

POLYPODIACEAE 1/1

Pleopeltis polypodioides (L.) Andrews & Windham (*Sheats 203*) Bottomland hardwoods.

THELYPTERIDACEAE 1/1

Thelypteris noveboracensis (L.) Nieuwl. (*Summitt 223*) Near stream.

GYMNOSPERMS

CUPRESSACEAE 1/1

Juniperus virginiana L. (*Sheats 98*) Pine-hardwood mix.

PINACEAE 1/3

Pinus echinata P.Mill. (*Sheats 94*) Pine-hardwood upland mix.

Pinus taeda L. (*Sheats 136*) Pine forest.

Pinus virginiana P. Mill. (*Sheats 127*) Pine forest.

ANGIOSPERMS
BASAL ANGIOSPERMS AND EUDICOTS

ACANTHACEAE 1/1

Ruellia caroliniensis (J.F. Gmel.) Steud. (*Summitt 218*) Roadside.

ADOXACEAE 1/3

Viburnum acerifolium L. (*Summitt 213*) Near lake.

Viburnum prunifolium L. (*Batson 1274*, DUKE)

Viburnum rafinesquianum J.A. Schultes (*Sheats 147*) Bottomland hardwoods.

ALTINGIACEAE 1/1

Liquidambar styraciflua L. (*Sheats 77*) Upland hardwood mix.

ANACARDIACEAE 2/2

Rhus copallina L. (*Sheats 115*) Upland hardwoods.

Toxicodendron radicans (L.) Kuntze (*Sheats 101*) Pine-hardwood mix.

ANNONACEAE 1/1

Asimina parviflora (Michx.) Dunal (*Wiecek 15*) Bottomland hardwood forest.

APOCYNACEAE 2/2

Apocynum cannabinum L. (*Summitt 210*) Roadside.

Asclepias tuberosa L. (*Sheats 175*) Roadside/pine mix.

AQUIFOLIACEAE 1/2

Ilex decidua Walt. (*Batson 1029*, DUKE)

Ilex opaca Sol. (*Sheats 113*) Upland hardwoods.

ARISTOLOCHIACEAE 1/4

Hexastylis lewisii (Fern.) H.L. Blomq. & Oost. (*Batson s.n.*) Bluff.

Hexastylis minor (Ashe) H.L. Blomq. (*Wiecek 14*) Bottomland hardwood forest.

Hexastylis shuttleworthii (Britten & Baker f.) Small (*Summitt 131*) Lake edge.

Hexastylis virginica (L.) Small (*Sheats 75*)

ASTERACEAE 27/36

Achillea millefolium L. (*Sheats 125*, *Sheats 176*; *Summitt 125*) Roadside.

Ambrosia artemisiifolia L. (*Wiecek 39*) Upland hardwoods.

Antennaria plantaginifolia (L.) Richards (*Batson 1314*, DUKE)

Anthemis arvensis L. (*Sheats 212*) Roadside.

Bidens aristosa (Michx.) Britt. (*Miller 27*) Xeric site, near erosion monitoring plot.

Chrysogonum virginianum L. (Sheats 81; Summitt 81) Roadside slopes; near stream.

Chrysopsis mariana (L.) Ell. (*Miller 26*; *Wiecek 47*) Upland hardwoods; Xeric site, near erosion monitoring plot; clearing.

Cirsium horridulum Michx. (*Summitt 204*; *Sheats 126*) Roadside.

Conyza canadensis (L.) Cronq. (*Sheats 221*)

Coreopsis auriculata L. (*Sheats 86*) Alluvial forest.

Elephantopus tomentosus L. (*Batson 1290*, DUKE)

Erechtites hieracifolia (L.) Raf. ex DC. (*Sheats 222*)

Erigeron annuus (L.) Pers. (*Sheats 108*) Upland hardwoods.

Eupatorium capillifolium (Lam.) Small (*Wiecek 71*) Pine-hardwood mix.

Eupatorium hyssopifolium L. (*Batson 655*, DUKE)

Eupatorium rotundifolium L. (*Sheats 183*; *Wiecek 3*) Pine plantation/roadside.

Helenium amarum (Raf.) H. Rock (*Sheats 167*, *Sheats 179*; *Summitt 220*) Roadside, pine mix.

Helenium autumnale L. (Sheats 178) Roadside/pine-hardwood mix.

Hieracium gronovii L. (*Wiecek 5*, *Wiecek 48*) Loblolly pine plantation and clearings; Upland hardwoods.

Hieracium venosum L. (*Sheats 73*) Pine-hardwood mix.

Krigia virginica (L.) Willd. (*Summitt 206*) Roadside.

Leucanthemum vulgare Lam. (*Summitt 60*; *Wiecek 60*) Roadside; Pine plantation.

Liatris squarrosa (L.) Michx. (*Sheats 199*) Pine-hardwood mix/roadside.

Packera anonyma (Wood) W.A. Weber & A. Löve (*Summitt 166*) Roadside.

Pluchea foetida (L.) DC. (*Sheats 140*) Pine forest.

Pseudognaphalium obtusifolium (L.) Hilliard & Burtt (*Summitt 117*; *Wiecek 7*) Roadside; loblolly pine plantation

Sericocarpus asteroides (L.) B.S.P. (*Sheats 137*, *Sheats 172*; *Summitt 221*) Roadside/pine-mix.

Solidago caesia L. var. *curtisii* (Torr. & Gray) Wood (*Wiecek 52*) Upland hardwoods.

Solidago canadensis L. var. *scabra* Torr. & A. Gray (*Batson 640*, DUKE)
Solidago nemoralis Ait. (*Batson 625*, DUKE)
Solidago odora Ait. (*Sheats 207*) Roadside.
Solidago pinetorum Small (*Sheats 163*) Roadside.
Solidago roanensis Porter (*Miller 23*) Xeric site, near erosion monitoring plot.
Solidago speciosa Nutt. var. *erecta* (Pursh) MacM. (*Wiecek 58*) Slope near creek
Symphyotrichum dumosum (L.) Nesom (*Wiecek 44*) Upland hardwoods.
Taraxacum officinale G.H. Weber ex Wiggers (*Summitt 183*) Roadside.

BALSAMINACEAE 1/1

Impatiens capensis Meerb. (*Sheats 223*) Creekside.

BETULACEAE 5/5

Alnus serrulata (Ait.) Willd. (*Summitt 207*) Streamside.
Betula nigra L. (*Sheats 193*; *Summitt 211*) Bottomland hardwoods; streamside.
Carpinus caroliniana Walt. (*Sheats 91*) Pine-hardwood upland mix.
Corylus americana Walt. (*Miller 20*) Xeric site, near erosion monitoring plot
Ostrya virginiana (P. Mill.) K. Koch (*Summitt 214*) Near lake.

BIGNONIACEAE 1/1

Campsis radicans (L.) Seem. ex Bureau (*Sheats 103*, *Sheats 194*) Pine-mix.

BRASSICACEAE 4/4

Barbarea verna (P. Mill.) Aschers. (*Summitt 129*) Roadside.
Cardamine hirsuta L. (*Summitt 187*) Roadside near stream-crossing.
Draba verna L. (*Summitt 185*) Roadside.
Teesdalia nudicaulis (L.) Ait.f. (*Summitt 186*) Roadside.

CAMPANULACEAE 1/4

Lobelia cardinalis L. (*Wiecek 35*) Knap of Reeds Creek.
Lobelia inflata L. (*Wiecek 4*) Loblolly pine plantation.
Lobelia puberula Michx. (*Wiecek 38*) Knap of Reeds Creek
Lobelia spicata Lam. (*Sheats 109*) Upland hardwoods.

CAPRIFOLIACEAE 1/1

Lonicera japonica Thunb. (*Sheats 96*) Pine-hardwood mix.

CARYOPHYLLACEAE 2/2

Cerastium fontanum Baumg. ssp. *vulgare* (Hartman) Greuter & Burdet (*Summitt 179*) Roadside.
Scleranthus annuus L. (*Sheats 214*) Roadside/pine-mix.

CISTACEAE 1/1

Lechea pulchella Raf. (*Sheats 198*)

CLUSIACEAE 1/4

Hypericum gentianoides (L.) B.S.P. (*Sheats 197*) Quarry.
Hypericum hypericoides (L.) Crantz (*Sheats 144*, *Sheats 186*; *Wiecek 6*, *Wiecek 19*) Loblolly pine plantation; bottomland hardwood forests/roadside.
Hypericum nudiflorum Michx. ex Willd. (*Sheats 201*) Bottomland hardwoods.
Hypericum punctatum Lam. (*Sheats 189*; *Summitt 217*) Bottomland hardwoods; roadside.

CONVOLVULACEAE 1/1

Ipomoea pandurata (L.) G.F.W. Mey. (*Miller 32*; *Sheats 173*) Xeric site, near erosion monitoring plot; roadside/pine mix.

CORNACEAE 1/1

Cornus florida L. (*Sheats 80*; *Summitt 156*) Pine-hardwood mix; roadside.

EBENACEAE 1/1

Diospyros virginiana L. (*Sheats 218*) Pine mix.

ERICACEAE 6/8

Chimaphila maculata (L.) Pursh (*Sheats 111*; *Summitt 82*) Upland hardwoods.
Gaylussacia frondosa (L.) Torr. & Gray ex Torr. (*Summitt 215*)
Leucothoe racemosa (L.) Gray (*Wiecek 16*) Bottomland hardwood forest
Oxydendrum arboreum (L.) DC. (*Sheats 88*, *Sheats 142*, *Sheats 220*) Pine-hardwood upland mix; bottomland hardwoods.
Rhododendron periclymenoides (Michx.) Shinners (*Sheats 89*)
Vaccinium fuscatum Ait. (*Summitt 84*) Upland hardwoods.
Vaccinium pallidum Ait. (*Sheats 119*, *Sheats 209*) Pine forest.

Vaccinium stamineum L. (*Summitt 145*; *Wiecek 62*) Roadside; Pine plantation.

EUPHORBIACEAE 2/3

Chamaesyce maculata (L.) Small (*Sheats 165*) Upland hardwoods.

Euphorbia corollata L. (*Sheats 188*) Bottomland hardwoods.

Euphorbia marginata Pursh (*Wiecek 37*) Knap of Reeds Creek

FABACEAE 16/22

Albizia julibrissin Durazz. (*Sheats 177*) Roadside.

Amphicarpaea bracteata (L.) Fern. (*Wiecek 40*) Upland hardwoods.

Centrosema virginianum (L.) Benth. (*Sheats 211*)

Cercis canadensis L. (*Sheats 104*)

Chamaecrista fasciculata (Michx.) Greene (*Sheats 157*) Pine forest.

Chamaecrista nictitans (L.) Moench (*Miller 21*) Xeric site, near erosion monitoring plot.

Cytisus scoparius (L.) Link (*Sheats 168*) Pine mix.

Desmodium nudiflorum (L.) DC. (*Summitt 216*) Roadside near lake.

Desmodium paniculatum (L.) DC. (*Batson 929*, DUKE)

Desmodium rotundifolium DC. (*Wiecek 43*) Upland hardwoods.

Galactia volubilis (L.) Britt. (*Batson 980*, DUKE)

Gleditsia triacanthos L. (*Sheats 123*) Pine-hardwood mix.

Lespedeza bicolor Turcz. (*Sheats 174*, *Sheats 210*; *Wiecek 8*) Clearcut; roadside/pine-mix.

Lespedeza cuneata (Dum.-Cours.) G. Don (*Miller 22*; *Sheats 161*) Roadside; xeric site, near erosion monitoring plot.

Lespedeza procumbens Michx. (*Miller 31*) Xeric site, near erosion monitoring plot.

Lespedeza virginica (L.) Britt. (*Miller 30*) Xeric site, near erosion monitoring plot.

Pueraria montana (Lour.) Merr. (*Sheats 164*) Upland hardwoods.

Robinia pseudoacacia L. (*Sheats 192*) Bottomland hardwoods.

Strophostyles umbellata (Muhl. ex Willd.) Britt. (*Miller 28*; *Sheats 187*) Xeric site, near erosion monitoring plot; bottomland hardwoods/roadside.

Stylosanthes biflora (L.) B.S.P. (*Sheats 180*) Roadside.

Tephrosia virginiana (L.) Pers. (*Summitt 172*) Roadside.

Wisteria sinensis (Sims) DC. (*Summitt 89*) Roadside.

FAGACEAE 2/9

Fagus grandifolia Ehrh. (*Sheats 78*) Upland slopes.

Quercus alba L. (*Sheats 76*) Upland hardwood mix.

Quercus falcata Michx. (*Sheats 134*) Pine forest.

Quercus marilandica Muenchh. (*Sheats 181*) Pine-hardwood mix.

Quercus montana Willd. (*Sheats 87*) Dry oak-hickory mix.

Quercus phellos L. (*Sheats 128*) Pine forest.

Quercus rubra L. (*Sheats 79*) Upland hardwood mix.

Quercus stellata Wangenh. (*Sheats 135*) Pine forest.

Quercus velutina Lam. (*Sheats 213*)

GENTIANACEAE 1/1

Sabatia angularis (L.) Pursh (*Sheats 190*; *Wiecek 1*) Bottomland hardwoods; loblolly pine plantation.

HAMAMELIDACEAE 1/1

Hamamelis virginiana L. (*Wiecek 17*) Bottomland hardwood forest

JUGLANDACEAE 2/3

Carya alba (L.) Nutt. ex Ell. (*Sheats 97*, *Sheats 149*, *Sheats 225*) Upland forest; bottomland hardwood forest; pine forest.

Carya glabra (P. Mill.) Sweet (*Summitt 212*) Roadside near lake.

Juglans nigra L. (*Sheats 122*, *Sheats 151*) Pine forest; pine-hardwood mix.

LAMIACEAE 4/7

Prunella vulgaris L. (*Miller 24*; *Summitt 24*) Xeric site, near erosion monitoring plot; roadside.

Pycnanthemum muticum (Michx.) Pers. (*Sheats 185*) Bottomland hardwoods.

Pycnanthemum pycnanthemoides (Leavenworth) Fern. (*Wiecek 10*) Bottomland hardwood forest

Pycnanthemum tenuifolium Schrad. (*Sheats 184*) Pine plantation/roadside.

Salvia lyrata L. (*Summitt 209*) Roadside.

Scutellaria elliptica Muhl. ex Spreng. (*Sheats 110*) Upland hardwoods.

Scutellaria integrifolia L. (*Wiecek 69*) Pine-hardwood mix.

LAURACEAE 1/1

Sassafras albidum (Nutt.) Nees (*Sheats 112*, *Sheats 146*) Bottomland hardwoods; upland hardwoods.

LINACEAE 1/1

Linum sulcatum Riddell var. *sulcatum* (*Batson 1013*, DUKE)

MAGNOLIACEAE 1/1

Liriodendron tulipifera L. (*Sheats 83*) Upland oak-hickory mix.

MELASTOMATACEAE 1/1

Rhexia mariana L. (*Sheats 171; Summitt 171*) Pine mix; roadside.

MORACEAE 2/2

Maclura pomifera (Raf.) Schneid. (*Sheats 102*) Pine-hardwood mix.

Morus rubra L. (*Sheats 124*) Pine-hardwood mix.

NYSSACEAE 1/1

Nyssa sylvatica Marsh. (*Sheats 226; Summitt 219*) Pine hardwood mix; near stream.

OLEACEAE 1/1

Fraxinus americana L. (*Batson 1141*, DUKE)

ONAGRACEAE 2/3

Ludwigia decurrens Walt. (*Sheats 224*)

Oenothera biennis L. (*Summitt 132*) Ditch.

Oenothera fruticosa L. (*Sheats 93*) Roadsides.

OROBANCHACEAE 3/3

Agalinis purpurea (L.) Pennell (*Wiecek 46*) Upland hardwoods.

Aureolaria virginica (L.) Pennell (*Sheats 191*) Bottomland hardwoods.

Epifagus virginiana (L.) W. Bart. (*Wiecek 56*) Slope near creek

OXALIDACEAE 1/3

Oxalis corniculata L. (*Wiecek 54*)
Upland hardwoods.

Oxalis stricta L. (*Sheats 205; Summitt 170*) Roadside.

Oxalis violacea L. (*Summitt 191; Wiecek 36*) Knap of Reeds Creek; near stream.

PAULOWNIACEAE 1/1

Paulownia tomentosa (Thunb.) Sieb. & Zucc. ex Steud. (*Sheats 150*) Pine forest.

PHRYMACEAE 1/1

Mimulus alatus Ait. (*Sheats 200*) Bottomland hardwoods.

PHYTOLACCACEAE 1/1

Phytolacca americana L. (*Sheats 139*) Pine forest.

PLANTAGINACEAE 2/4

Nuttallanthus canadensis (L.) D.A. Sutton (*Summitt 195*) In clearcut.

Plantago aristata Michx. (*Sheats 152*) Pine forest.

Plantago rugelii Dcne. (*Sheats 206*) Roadside.

Plantago virginica L. (*Summitt 208*) Roadside.

PLATANACEAE 1/1

Platanus occidentalis L. (*Sheats 90*) Alluvial forest (streamside).

POLYGALACEAE 1/1

Polygala curtissii Gray (*Sheats 169; Summitt 9; Wiecek 9*) Clearcut; roadside.

PORTULACACEAE 1/1

Claytonia virginica L. (*Summitt 193*) Along creek.

RANUNCULACEAE 4/4

Hepatica nobilis Schreb. var. *obtusa* (Pursh) Steyermark (*Sheats 114; Summitt 188*) Upland hardwoods; along streambank.

Ranunculus abortivus L. (*Summitt 182*) Grass/pine border.

Thalictrum thalictroides (L.) Eames & Boivin (*Summitt 189*) Streambank

Xanthorhiza simplicissima Marshall (*Sheats 202*) Creekside.

ROSACEAE 10/12

Amelanchier arborea (Michx. f.) Fern. (*Summitt 114, Summitt 224*) Forest edge.

Crataegus flava Ait. (*Sheats 133*) Pine forest.

Fragaria virginiana Duchesne (*Batson 744*, DUKE)

Malus angustifolia (Ait.) Michx. (*Sheats 208*) Pine-hardwood mix.

Porteranthus trifoliatus (L.) Britt. (*Sheats 74*) Pine-hardwood mix.

Potentilla canadensis L. (*Sheats 84, Summitt 85*) Roadside.

Potentilla simplex Michx. (*Batson 738*, DUKE)

Prunus serotina Ehrh. (*Sheats 162*) Roadside.

Pyrus communis L. (*Sheats 154*) Pine forest.

Rosa carolina L. (*Batson 878*, DUKE)

Rubus argutus Link (*Summitt 137*) Roadside.

Rubus trivialis Michx. (*Sheats 82*)

RUBIACEAE 4/6

Diodia teres Walt. (*Miller 29; Sheats 204*) Roadside. Xeric site, near erosion monitoring plot

Galium circaezans Michx. (*Wiecek 11, Wiecek 41*) Bottomland hardwood forest; Upland hardwoods.

Galium pilosum Ait. (*Sheats 130*) Bottomland hardwoods.

Galium triflorum Michx. (*Wiecek 42*) Upland hardwoods.

Houstonia caerulea L. (*Summitt 180, Summitt 181*) Roadside.

Mitchella repens L. (*Wiecek 64*) Pine plantation.

SALICACEAE 1/1

Salix nigra Marsh. (*Sheats 141*) Bottomland hardwoods.

SAPINDACEAE 1/1

Acer rubrum L. (*Sheats 72*) Pine-hardwood mix.

SAXIFRAGACEAE 1/1

Heuchera americana L. (*Summitt 159*) Near streambank.

SIMAROUBACEAE 1/1

Ailanthus altissima (P. Mill.) Swingle (*Sheats 160*) Roadside.

SOLANACEAE 1/1

Solanum carolinense L. (*Sheats 116*) Pine forest.

SYMPLOCACEAE 1/1

Symplocos tinctoria (L.) L'Hér. (*Sheats 196*) Pine-hardwood mix/roadside.

ULMACEAE 1/1

Ulmus alata Michx. (*Batson 797*, DUKE)

VIOLACEAE 1/2

Viola × *primulifolia* L. (pro sp.) [*lanceolata* × *macloskeyi*] (*Summitt 143*) Roadside.

Viola tricolor L. (*Summitt 184*) Roadside.

VITACEAE 2/3

Parthenocissus quinquefolia (L.) Planch. (*Batson 1043*, DUKE)

Vitis aestivalis Michx. (*Batson 1044*, DUKE)

Vitis rotundifolia Michx. (*Wiecek 65*) Pine-hardwood mix.

MONOCOTS

ALLIACEAE 1/2

Allium ampeloprasum L. (*Sheats 159*)

Allium vineale L. (*Summitt 158*) Near streambank.

AMARYLIDACEAE 1/1

Narcissus sp. (*Summitt 75*) Roadside.

COMMELINACEAE 1/1

Commelina communis L. (*Wiecek 34*) Knap of Reeds Creek

CYPERACEAE 3/3

Carex crinita Lam. (*Wiecek 18*) Bottomland hardwood forest

Cyperus retrorsus Chapman (*Sheats 219*)

Scirpus cyperinus (L.) Kunth (*Wiecek 55*) Upland hardwoods.

IRIDACEAE 2/2

Iris verna L. (*Sheats 156, Sheats 182*) Pine plantation/roadside.

Sisyrinchium angustifolium P. Mill. (*Summitt 205*) Roadside.

LILIACEAE 1/1

Erythronium americanum Ker-Gawl. (*Summitt 190*) Lake edge.

MELANTHIACEAE 1/1

Trillium catesbaei Ell. (*Sheats 85*)

ORCHIDACEAE 2/3

Goodyera pubescens (Willd.) R. Br. ex Ait. f. (*Summitt 192*) Along creek.

Spiranthes cernua (L.) L.C. Rich. (*Wiecek 59*) Pine plantation.

Spiranthes praecox (Walt.) S. Wats. (*Wiecek 57*) Slope near creek

POACEAE 13/20

Andropogon ternarius Michx. (*Wiecek 70*) Pine-hardwood mix.

Chasmanthium latifolium (Michx.) Yates (*Wiecek 12*) Bottomland hardwood forest.

Chasmanthium laxum (L.) Yates (*Wiecek 49*) Upland hardwoods.

Chasmanthium sessiliflorum (Poir.) Yates (*Wiecek 53*) Upland hardwoods.

Danthonia sericea Nutt. (*Sheats 118*) Pine forest/roadside.

Danthonia spicata (L.) Beauv. ex Roemer & J.A. Schultes (*Batson 338*, DUKE)

Dichanthelium laxiflorum (Lam.) Gould (*Sheats 215; Batson 475*, DUKE)

Dichanthelium sphaerocarpon (Ell.) Gould (*Wiecek 2*) Loblolly pine plantation.

Echinochloa crus-galli (L.) Beauv. (*Sheats 227*)

Elymus hystrix L. (*Sheats 120*) Pine forest.

Holcus lanatus L. (*Sheats 153*)

Microstegium vimineum (Trin.) A. Camus (*Sheats 100; Wiecek 67*) Pine-hardwood mix; Pine-hardwood mix.

Panicum anceps Michx. (*Sheats 217; Wiecek 51*) Upland hardwoods; roadside.

Panicum dichotomiflorum Michx. (*Wiecek 61*) Pine plantation.

Paspalum floridanum Michx. (*Miller 33*) Xeric site, near erosion monitoring plot.

Paspalum notatum Flueggé (*Sheats 216*) Roadside.

Pennisetum glaucum (L.) R. Br. (*Wiecek 66*) Pine-hardwood mix.

ABSTRACT

Tributaries flowing into Kisatchie Bayou in southwestern Natchitoches Parish, Louisiana are characterized by clear flowing water and white sand bottoms. In places, sandstone or siltstone creek beds emerge during normal water levels but quickly become inundated during periods of rain. These emergent creek beds provide a unique microhabitat that hosts a distinctive flora. A total of 70 species representing 30 families and 52 genera were discovered in this base-line vascular plant survey of these emergent creek beds. With few exceptions, the plant species here appear to be well-adapted for life in this challenging microhabitat.

Key Words: Kisatchie Bayou, plant microhabitat, vascular flora survey

RESUMEN

Los afluentes que discurren por Kisatchie Bayou en el sudoeste de Natchitoches Parish, Luisiana se caracterizan por el agua clara que fluye y los fondos de arena blanca. En algunos lugares, los bancos de arenisca o aluviones emergen con niveles de agua normales pero se inundan rápidamente durante los períodos de lluvia. Estos bancos inesperados proporcionan un microhábitat único que alberga una flora distinta. Un total de 70 especies que representan a 30 familias y 52 géneros se descubrieron en un muestreo de la flora vascular de estos bancos inesperados, con pocas excepciones, estas especies parecen estar bien adaptadas para la vida en este microhábitat desafiante.

Tributaries flowing into Kisatchie Bayou in southwestern Natchitoches Parish, Louisiana are characterized by clear flowing water and white sand bottoms. In places, sandstone or siltstone creek beds emerge during normal water levels. Their surfaces are devoid of sand and soil except in small crevices and fissures. The emergent creek beds remain perpetually damp because water permeates these fissures.

The physiographic expression of the sector where Kisatchie Bayou and its tributaries reside reflects the lithologies of the Miocene Epoch (Andersen 1993). Andersen (1993) designates the physiography of the creeks draining the area as recent alluvium (undifferentiated) of the Holocene.

Martin et al. (1990) designated the soil along the stream banks, which ultimately washes into these tributaries as "Kisatchie-Oula." This soil type is broadly

SIDA 21(2): 1141–1147. 2004

defined as a very strongly acidic fine sandy loam occurring on 5–40% slopes. Additionally, this soil is low in fertility and runoff is rapid (Martin Jr. et al. 1990).

Some emergent creek beds are inhabited by a small number of vascular plants, bryophytes (mosses and liverworts) and lichens. Plants are rooted in the crevices and fissures. However, lichens are directly attached to the rock substrate. Only those plants that manage to remain rooted during periods of inundation survive in this unique and challenging microhabitat.

The purpose of this study is to survey the vascular flora of the emergent creek beds of Kisatchie Bayou tributaries. This survey provides a base-line inventory of this distinctive plant community that can be used for comparison to monitor changes that may occur due to natural or human perturbance.

METHODS

Several tributaries to Kisatchie Bayou were located by examining Natchitoches Parish aerial soil survey maps (Martin Jr. et al. 1990). Study sites were discovered by exploring these tributaries on foot.

Each study site was surveyed periodically throughout the entire year of 2002. At least one voucher specimen was collected for each species; voucher numbers are indicated in Table 1. All vouchers are housed at McNeese State University Herbarium (MCN). Nomenclature follows Kartesz (1999) with the exception of *Aletris lutea* (Narthecicaceae), where nomenclature follows Angiosperm Phylogeny Group (1998).

RESULTS

Vascular plants are not present in all emergent creek beds. However, they typically occur in areas where the creeks are broadened and the water levels are comparatively low. Additionally, these areas are often associated with small waterfalls and rippled currents. The forest canopy is more open in these broadened areas with consequent increased light levels. A detailed description of each study site follows. The location of each site is indicated in Figure 1.

Site 1 occurs in *Little Bayou Pierre*. This area is characterized by sandstone islets and peninsulas that lie just above the normal water level. Small waterfalls are present. The site is about 85 m long and about 18m at its widest point. The site is just south of the bridge along Hwy. 118 near Mink, 31° 23' 38" north and 93° 03' 52" west.

Site 2 occurs in *Little Sandy*. This area is characterized by islets and a few small peninsulas. The substrate here appears to be siltstone which is softer and darker than the sandstone found in the three other study sites. There are no waterfalls here; however, the creek bed topology produces turbulence and rippling. The area is about 73 m long and about 19m at its widest point. The site is about 1 km north of the bridge on Hwy. 118 and about 2.5 km east of the town of Kisatchie, 31° 24' 37" north and 93° 09' 7" west.

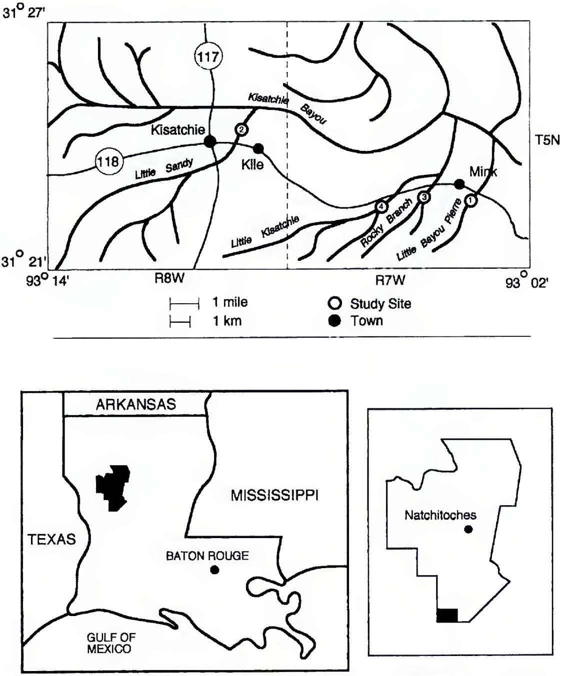

FIG. 1. Detailed map of the emergent creek bed study sites is depicted in the upper illustration; Louisiana State Highways 117 and 118 are indicated. The lower right illustration shows the study area in relation to Natchitoches Parish. The position of Natchitoches Parish within Louisiana is indicated in the lower left illustration.

Site 3 occurs in *Rocky Branch*. This area is characterized by a mixture of islets and peninsulas. A small waterfall is present. The area is about 38 m long and about 14 m at its widest point. The site is about 100 m south of the bridge on Hwy. 118 and about 3.6 km east of the town of Kisatchie, 31° 23' 50" north and 93° 05' 40" west.

Site 4 occurs in *Little Kisatchie Bayou*. The area is characterized by a mixture of peninsulas and islets. Rippled water flow occurs here but no waterfall is present. The area is about 49m long and about 9m at its widest point. The site is about 100 meters south of the bridge on Hwy. 118 about 3km east of the town of Kisatchie, 31° 23' 49" north and 93° 06' 29" west.

A total of 70 vascular plant species representing 30 families and 52 genera were discovered in this survey (Table 1). Of these, 32 species were found in two or more study sites. With a total of 57 species discovered, study site 1 was the most diverse. In study sites 2, 3 and 4, a total of 23, 20 and 21 species were discovered, respectively (Table 1).

DISCUSSION

Emergent creek beds within the Kisatchie Bayou tributaries provide a distinctive plant microhabitat. Observations made during this study suggest that this flora is stable. Periods of submergence had little impact on the overall health of the flora. For example, the effects of heavy rainfall from the remnants of hurricanes Lili and Kenna in October 2002 were minimal. Although larger plants were lodged by the strong force of rapidly moving water, they appeared to suffer no irreparable damage and recovered rapidly.

Although most species appeared to be thriving on the emergent creek beds, there were two notable exceptions. Of the several individuals of *Pinus taeda* that were discovered, all were seedlings or juveniles. It appears that the small fissures in which they were rooted had insufficient soil or space for plants to reach maturity. The one individual of *Baccharis halimifolia* appeared to have been repeatedly damaged by high water. Although individuals of these two species had managed to germinate and survive for a time, they do not appear to be adapted well for survival on the emergent creek beds.

Additionally, observations made during this study suggest that this flora is fertile. Specifically, all discovered species, with the exception of *Pinus taeda* and *Baccharis halimifolia*, produced spores or seeds during 2002.

ACKNOWLEDGMENTS

We thank Mark Paulissen for his review of an earlier version of this paper and the Kisatchie District of the U.S. Forestry Service.

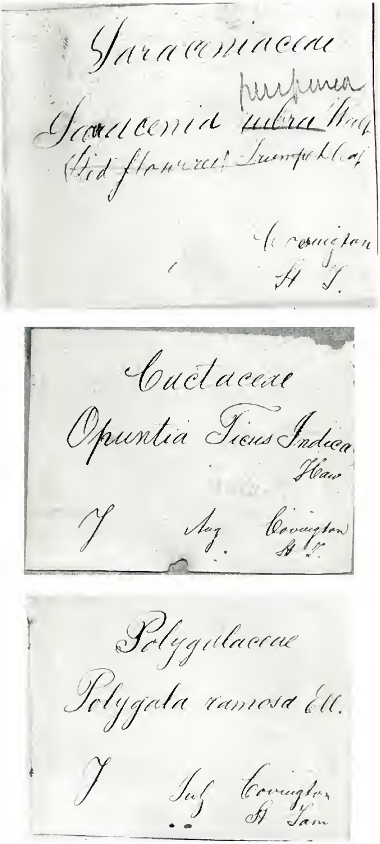
SARRACENIA PURPUREA (SARRACENIACEAE) IN LOUISIANA

Michael H. MacRoberts and Barbara R. MacRoberts

Bog Research, 740 Columbia
Shreveport, Louisiana 71104, U.S.A.
and
Herbarium, Museum of Life Sciences
Louisiana State University in Shreveport, Shreveport, LA 71115, U.S.A.

Sarracenia purpurea L. was once thought to extend from British Columbia along the Canadian-United States border to the Atlantic coast, down the coast to Georgia and Florida, and west along the Gulf Coastal Plain to Louisiana. However, Naczi et al. (1999) have recently separated the Gulf Coastal Plain population as a distinct species, *S. rosea* Naczi, F.W. Case & R.B. Case, which does not reach Louisiana but occurs in southwest Georgia, north Florida, south Alabama, and southeast Mississippi. However, two specimens—one collected in 1842 by William Marbury Carpenter (*s.n.* U.S.) and the other collected in 1870 by Americus Featherman (*s.n.* LSU)—both of which have been identified as *S. purpurea* by Naczi et al. (1999) and both reported from southeast Louisiana west of the range of *S. rosea*, are anomalous; they leapfrog *S. rosea* and are disjunct from the nearest *S. purpurea* population in eastern Georgia (see MacRoberts and MacRoberts [1988] for a detailed review of *S. purpurea* in Louisiana). Naczi et al. (1999) suggest possible labeling error to account for these anomalous specimens.

The label of the Featherman *Sarracenia purpurea* specimen, along with other Featherman collections from the same locality, is shown in Figure 1. MacRoberts and MacRoberts (1988) originally interpreted the script just below "Covington" on the *Sarracenia* specimen to read "AF," the collector's initials. Naczi et al. (1999:1200) question this interpretation: "The script leaves determination of the final pair of letters equivocal. Instead of ... Covington/AF. [Americus Featherman]' ... the label may actually read '... Covington/AL. [Covington, Alabama].'" According to this assessment, the specimen is from Covington Co., Alabama, not Covington, St. Tammany Parish, Louisiana. On reexamination, this interpretation fails for two reasons. First, the script following "Covington" is neither "AF" nor "AL," but "St T." Of the Featherman specimens with "Covington" on the label, some read "Covington" only, but others have something written below "Covington." We (and Diane Ferguson, pers. comm.) examined these and found that what was written was either "St Tam." or "St T.", abbreviations for "St. Tammany." Second, corroborative evidence that this specimen comes from Louisiana is to be found in Featherman's (1871) published description of



Sarraceniaceae

its provenance. In 1869 the Louisiana State Legislature passed Act. No. 72 in which professors of the Louisiana State Seminary of Learning and the Military College (later Louisiana State University) were to spend four months each year in survey work in their respective fields. Americus Featherman traveled extensively throughout Louisiana and produced three reports on the botany (Brown 1944). In his (Featherman 1871:78) list of species collected during his botanical survey of southern and central Louisiana in 1870, Featherman gives the following entry: "*Sarracenia rubra* Walt, [this is what Featherman called the species] Red Flowered, Trumpet-Leaf, Covington, St. Tammany," which, except for the abbreviation of St. Tammany, is exactly what is written on the specimen label. Reading Featherman's (1870, 1871, 1872) accounts of his extensive botanical surveys of Louisiana leaves no doubt of his competence as a careful botanist and researcher (see brief account of his Louisiana botanical career in MacRoberts [1984] and of his Louisiana botanical publications in Ewan [1967]).

The provenance of the Carpenter specimen is less certain. The original label reads "*Sarracenia purpurea*, wet pine woods, St. Helen, La." This was annotated by Charles Mohr who purchased Carpenter's collection some years after his death: "*Sarracenia purpurea* L., St Helena Parish, Carpenter 1842." Because in 1842 St. Helena Parish encompassed not only the present parish but also the northwestern quarter of Tangipahoa Parish, it is impossible to know from which present-day parish the specimen may have come. Carpenter was a prominent Louisiana botanist during the first half of the nineteenth century who collaborated with the leading botanists and naturalists of his time, including Charles Lyell and John James Audubon (Cocks 1914). He collaborated with J.L. Riddell and Josiah Hale on a work entitled "Plants of Louisiana," which, unfortunately, was never published and is now lost. However, J.L. Riddell in 1852 published an abridged version "Catalogus Florae Ludovicianae," and in his introductory remarks, Riddell writes: "The following systematic list, embodying the results of a great many years of observation, by Dr. Josiah Hale, by the late Professor W.M. Carpenter, and by the author, has been abridged from a manuscript work, contributed by the author, in 1851, to the Smithsonian Institution. The MS. work alluded to is entitled, 'Plants of Louisiana.' It comprises the technical and the vulgar names of the flowering and filicoid species of plants, well ascertained as growing within the limits of the State of Louisiana, [nearly all of which are represented by specimens in the author's herbarium],—with special localities, times of flowering, and full descriptions of the new species." Unfortunately, this manuscript no longer exists and we are simply left with the bare list, which contains about 1800 taxa and which remained the most extensive compilation for Louisiana until 1982 (MacRoberts 1984). As MacRoberts (1984:13) says: "an examination of Riddell's list leaves one with a feeling of confidence in his reports." Interestingly, *S. purpurea* is on the list but, of course, without provenance or collector identification. But it seems likely that this was the Carpenter specimen.

While labeling error, as Naczi et al. (1999) suggest, is always possible, there is no evidence of such in these cases, and there is strong corroborative evidence that the Featherman specimen came from Louisiana. As to the Carpenter specimen, there is corroborative evidence of its provenance, not strong but suggestive. Thus, there seems no reason to remove *Sarracenia purpurea* from the Louisiana flora.

ACKNOWLEDGMENTS

Diane Ferguson, Collections Manager, LSU Herbarium was instrumental in interpreting the Featherman labels and in providing scanned copies for our use. Amanda Crnkovic aided with the figure. Two anonymous reviewers provided useful comments.

ABSTRACT

Eleocharis mutata (L.) Roem. & Schult. is reported new to the flora of North America north of México based on recent collections from Brazoria Co., Texas, U.S.A. A key to separate *E. mutata* from other species of *Eleocharis* subg. *Limnochloa* in North America north of México as well as a technical description and ecological notes are provided.

RESUMEN

Se cita *Eleocharis mutata* (L.) Roem. & Schult. Nueva para la flora de Norte América al norte de México en base a recientes colecciones de Brazoria Co., Texas, U.S.A. Se ofrece una clave para separar *E. mutata* de otras especies de *Eleocharis* subg. *Limnochloa* en Norte América al norte de México así como una descripción técnica y notas ecológicas.

Recent field work in Texas produced collections of a member of *Eleocharis* R. Br. subg. *Limnochloa* (P. Beauv. ex T. Lestib.) Torr. (= *Eleocharis* ser. *Mutatae* Svenson) with triquetrous culms. These specimens keyed to *E. fistulosa* Schult. (= *E. acutangula* [Roxb.] Schult.) in *Manual of the Vascular Plants of Texas* (Correll & Johnston 1970) and *Aquatic and Wetland Plants of Southwestern United States* (Correll & Correll 1975). Correll and Johnston (1970) report *E. fistulosa* from the Rio Grande plains of Texas without mentioning any specific county. González-Elizondo et al. (2002) discussed the misapplication of *E. fistulosa* in North America, referring to Texas specimens as *E. obtusetrigona* (Lindl. & Nees) Steud. A review of pertinent manuals and treatments of subg. *Limnochloa* (Svenson 1929; Adams 1972; Hooper 1972; Kern 1974; Haines & Lye 1983; Koyama 1985; Wilson 1993; González-Elizondo 1994; Browning et al. 1997; González-Elizondo et al. 2002) and a critical examination of numerous herbarium specimens confirm our collections are of *Eleocharis mutata* (L.) Roem. & Schult.

Eleocharis subg. *Limnochloa* comprises over 20 species of perennial, rhizomatous, aquatic herbs distributed in tropical, subtropical, and warm temperate areas worldwide, and recognized by indurate and prominently to obscurely longitudinally many-veined scales and cylindrical spikelets (González-Elizondo & Peterson 1997; González-Elizondo 2002). Despite the usually coarse and conspicuous habit of this group, new species have recently been described from Venezuela (González-Elizondo & Reznicek 1996) and

SIDA 21(2): 1153–1160. 2004

México (Roalson 1999). *Eleocharis mutata* has not been previously reported for Texas (Hatch et al. 1990; Jones et al. 1997). In *Flora of North America*, González-Elizondo (2002) reports six species belonging to subg. *Limnochloa*: *E. cellulosa* Torr., *E. elongata* Chapm., *E. equisetoides* (Elliott) Torr., *E. interstincta* (Vahl) Roem. & Schult., *E. obtusetrigona* (Lindl. & Nees) Steud., *E. quadrangulata* (Michx.) Roem. & Schult., and *E. robbinsii* Oakes. A dichotomous key modified from Svenson (1929) and González-Elizondo (2002) and a technical description of *E. mutata* follow.

KEY TO *ELEOCHARIS* SUBG. *LIMNOCHLOA* IN NORTH AMERICA, NORTH OF MÉXICO

1. Culms without septa.
    2. Culms triquetrous to terete, not distinctly quadrangular.
        3. Culms relatively coarse, (2–)3–5(–8.5) mm thick at leaf sheath summit; spikelets 3.5–8 mm thick; achene 1.4–1.8 mm wide.
            4. Culms triquetrous (rarely distally obscurely 3 angled); achene apex slightly constricted at the summit into a hard annular thickening (see Fig. 1d); perianth bristles irregularly retrorsely spinulose **Eleocharis mutata**
            4. Culms more or less terete or distally obscurely 3–5-angled, never triquetrous; achene apex gradually to markedly constricted, but without hard annular thickening; perianth bristles smooth to coarsely retrorsely spinulose.
                5. Achene apex gradually narrowed into a stout spongy region; perianth bristles usually smooth or sometimes finely retrorsely spinulose (see Fig. 1e) **Eleocharis cellulosa**
                5. Achene apex markedly constricted to a short neck; perianth bristles coarsely retrorsely spinulose **Eleocharis obtusetrigona**
        3. Culms slender, 0.5–1.5 mm thick above leaf sheath summit; spikelets 3 mm or less thick; achene 0.5–1.4 mm wide.
            6. Achene 0.65–1.4 long × 0.5–0.8 wide; floral scales 3.5–4.5 mm long; tubers absent **Eleocharis elongata**
            6. Achene 1.9–2.6 long × 1–1.4 mm wide; floral scales 5–7.8 mm long; tubers sometimes present **Eleocharis robbinsii**
    2. Culms distinctly quadrangular (4-angled) **Eleocharis quadrangulata**
1. Culms septate.
    7. Perianth bristles longer than the achene, coarsely retrorsely spinulose; achenes conspicuously sculptured at 10–15×; culm septa extending up the culm to immediately below spikelet **Eleocharis interstincta**
    7. Perianth bristles much shorter than the achene, thin and soft, without teeth; achenes not conspicuously sculptured at 10–15×, appearing nearly smooth; culm septa extending up the culm to well short of spikelet **Eleocharis equisetoides**

Eleocharis mutata (L.) Roem. & Schult. (**Fig. 1 a–d**). *Scirpus mutatus* L., Syst. Nat. (ed. 10) 2:867. 1759. *Eleocharis mutata* (L.) Roem. & Schult., Sys. Veg. 2:155. 1817. *Limnochloa mutata* (L.) Nees, Fl. Bras. 2(1):101. 1842. Type: JAMAICA. (Lectotype, typified by Browning et al. [1997]: LINN photo!).

Eleocharis scariosa Steud., Syn. Pl. Glumac. 80. 1855. Type: BRASIL: Martius Herb. Fl. Bras. 229 (isotypes: GH!, M, NY!).

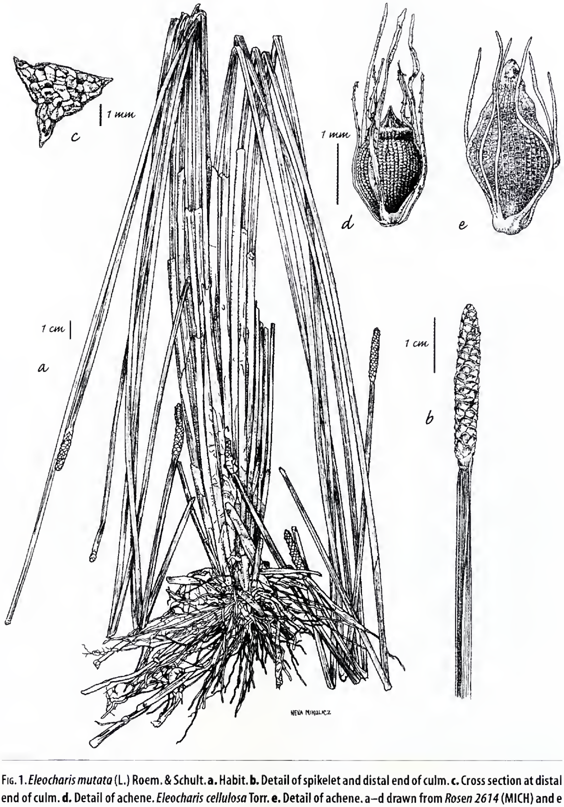

Fig. 1. *Eleocharis mutata* (L.) Roem. & Schult. **a.** Habit. **b.** Detail of spikelet and distal end of culm. **c.** Cross section at distal end of culm. **d.** Detail of achene. *Eleocharis cellulosa* Torr. **e.** Detail of achene. a–d drawn from *Rosen 2614* (MICH) and e drawn from *Rosen 2698* (SBSC) by Neva Mikulicz.

Plants perennial, rhizomes long, 2–5 mm thick, scales to 8 mm, tubers absent; roots coarse fibrous, gray-brown to maroon. **Culms** triquetrous, usually conspicuously so distally (rarely in the field Texas plants on dryer sites obscurely 3 angled), sometimes twisted, (31–)53.8–93(–116) cm × (2.2–)2.6–5.1(–8.5) mm, soft to hard, internally spongy, with incomplete transverse septa, longitudinally striate when dry, shinny and smooth when fresh, dark green. **Leaf sheaths** 2, apically notched, apex acute to acuminate, membranous, loose, friable, maroon-chestnut to cinnamon brown; blade reduced to a mucro to 5 mm long. **Spikelets** cylindric, obtuse (acute), proximal 2–3 scales empty, the first amplexicaul and appearing as a continuation of the culm, (12–)23–44(–66) × (3–)3.8–5.4(–8) mm; floral scales appressed to weakly spreading upon drying, ovate to broadly ovate, apex broadly rounded, the distal 0.2–0.3 mm hyaline-erose, central area broadly keeled from base for ca. 1/3–1/2 scale length, (2.8–)3.2–4(–4.8) × (1.9–)2.5–3.4(–4.8) mm, finely many veined, mid-vein evident only in adaxial view, cartilaginous, stramineous, abaxially red-maculate or more frequently with a dark band near apex, adaxially red-maculate. **Flowers** with (5–)6–8 perianth bristles, irregularly oriented, narrow to somewhat broad and strap-shaped proximally, irregularly retrorsely spinulose nearly to the base, mostly exceeding the achene, stramineous, the margins and spinules sometimes dark reddish; stamens 3; anthers 1.3–2.0 mm, reddish-brown; style trifid. **Achene** biconvex, more or less obpyriform, obovate, or sometimes broadly elliptic, the apex constricted to about 0.6 the width of the achene, broadening again into a hard annulus of the same texture and color as the achene, (1.2–)1.3–1.6(–1.9) mm (not including annulus or tubercle) × (1–)1.1–1.4(–1.8) mm, with ca. 20 longitudinal rows of deeply pitted horizontally rectangular cells visible through transparent periclinal layer on each achene face, dull, cream colored, maturing to lustrous olive-yellow (amber); annulus oblong or tapering apically, (0.05–)0.09–0.18(–0.3) mm high; tubercle dorsoventrally compressed, triangular, well formed to withered, distinct or sometimes appearing to merge with the annulus or shouldered by it, (0.15–) 0.3–0.5(–0.9) mm × 0.4–0.8 mm, dark brown.

Phenology and Ecology.—In Texas, flowering from early June through early November. *Eleocharis mutata* forms large monotypic colonies in dark gray, clay-loam soils of a shallow, semi-permanently flooded freshwater marsh near the coast, associated in the dryer fringes of the marsh with *Cyperus elegans* L., *C. oxylepis* Steud., *C. polystachyos* Rottb., *Eleocharis cellulosa*, *E. olivacea* Torr., *E. quadrangulata*, *Juncus roemerianus* G. Scheele, *Paspalum floridanum* Michx. *P. vaginatum* Sw., and *Spartina patens* (Ait.) Muhl. (Fig. 2). The nativity of *Eleocharis mutata* in Texas is uncertain; as we encountered it in Brazoria County, it was ecologically dominant, forming pure stands in a habitat usually more diverse.

Distribution.—In North America north of México, currently known from Brazoria County, Texas, on the eastern edge of the Gulf Prairies and Marshes.

Fig. 2. Fresh marsh in late August 2003 at Hoskins Mound near the Brazoria National Wildlife Refuge in Brazoria County, Texas, with *Eleocharis mutata* (L.) Roem. & Schult. in foreground.

Expected also in similar habitat from Jefferson County, SW to Goliad County, S through the Rio Grande Valley. There is an immature specimen at TAES with triquetrous culms (*Glazener s.n.*, collected 16 miles W of Goliad in 1941) annotated as *Eleocharis acutangula*. Unlike *E. acutangula*, however, this specimen has broadly ovate, finely many veined floral scales which fits our concept of *E. mutata*. It is possible that *E. mutata* is more widespread in southern Texas, and has been overlooked because of its affinity for aquatic habitats and its superficial similarity to *E. cellulosa* and *E. quadrangulata* with which it occurs. Coastal habitats in United States, México, Belize, Guatemala, Honduras, Nicaragua, Costa Rica, Panama, Cuba, Jamaica, Haiti, Dominican Republic, throughout the West Indies, tropical South America, and tropical Africa.

Vernacular name.—**scallion grass** (Adams 1972).

Representative specimens examined: **NORTH AMERICA. U.S.A.. TEXAS. Brazoria Co.:** Hoskin's Mound within the Brazoria National Wildlife Refuge, 3.8 km SE of the intersection of FM 2004 and Co. Rd 277, locally abundant in shallow water along roadside ditch and marsh S of perimeter oil-field service road, N of the mound, 21 Oct 2002, *Rosen & Jones 2382* (MO, TAES, TEX, VSC), 29 Aug 2003, *Rosen 2606* (GH, SBSC, NY, US, WIS, Z), *Rosen 2614* (CIIDIR, K, MICH). **Goliad Co.:** 16 mi. W of Goliad, in water, 23 Aug 1941, *Glazener s.n.*, (TAES). **BARBADOS. Christ Church:** Gruene Hill Swamp, dominant understory herb, forming a lawn throughout much of the swamp, 09 Nov 1996, *Rogers 96-128* (MICH). **BELIZE. Belize District:** roadside through mangrove swamp, 11 Mar 1933, *Lundell 1816* (MICH); Belize City, vacant lots, roadsides, disturbed sites about town, 1 m elev., swamp on S side of town, 09 Aug 1992, *Worthington 21439* (MO). **COSTA RICA. Limon:** Limon airport, beach at mouth of Rio Banano, near sand dunes and shallow ponds 35 m from shore, 07 Jul 1966, *Denton 1139a* (MICH). **Guanacasta:** Palo Verde National Park, swamp ca. 2 km from park headquarters at Catalina, along transect to Laguna Nicaragua, abundant, 07 Sep 1984, *Crow & Rivera 5981* (MO). **DOMINICAN REPUBLIC. Prov. Maria:** Llanura de Nagua, Trinidad Sanchez, Las Gordas, 18.7 km, Llanuras plantadas de arroz, zona pantanosa, con muchas malezas despues de la ultima cosecha (en el camino de Las Gordas a Mata Bonita), 19°25N, 70°00W, 05 Oct 1982, *Mejia & Pimentel 23601* (MO). **Prov. Peravia:** very common in muddy sites at roadside, Galeon, Bani, 29 Oct 1976, *Cicero 8276* (NY, TAES). **HAITI:** shallow pond and swamp area between Terrier Rouge and Fort Libertr, northeastern alluvial plain, 26 Jun 1941, *Bartlett 17480* (MICH, NY, US). **HONDURAS. Atlantida:** in boggy area near the seashore, vicinity of Ceiba, 06 Jul 1938, *Yuncker et al.* 8243 (MICH, NY); Sibun River, 28 Nov 1934, *Gentle 1429* (MICH, NY); Hector Creek, Sibun River, 28 Nov 1934, *Gentle 1432* (K, MICH, NY, US). **Toledo:** in wet area on river bank, Monkey River, 18 Oct 1941, *Gentle 3708* (MICH, NY, US); Monte Redondo lake, vicinity of Yeguare river, El Eamorano, 23 Jan 1970, *Molina 25403* (MO, NY); commonly found along the edge of brackish lagoons also thrives where it receives continuous sea spray, All Pines, 23 Jan 1970, *Schipp 786* (MICH, NY, Z). **JAMAICA.** St. Thomas, just N of Grant Pen, off of road A-4, a little above sea level, at edge of and growing in open water at roadside, 21 Jul 1963, *Crosby et al. 822* (MICH, NY, US); Port Antonio, Dec 1890, *Hitchcock s.n.* (MO). **MEXICO. Jalisco:** about 2 km N of Puerto Vallarta in cultivated areas west of the airport, near sea level, very common in wet depressions beside road, 13 Nov 1963, *Feddema 2533* (MICH); La Huerta, Rancho Cuixmala, Gargollo farm, on E side of Cerro de la Alborada, Lat. 19°24'N, Long. 104°59'W, elev. below 50 m, highly disturbed remnants of tropical semi-deciduous forest now used for cattle, locally common perennial with feet in water, mostly emergent, some plants recently exposed and in mud, 04 Nov 1991, *Lott et al. 4116* (K, MICH, NY, WIS); 3 km al N de Puerto Vallarta, sobre el camino al aeropuerto, terrenos planos, salobres, en suelo humedo, escaso, 16 Nov 1963, *Rzedowski 17829* (MICH). **Yucatan:** pequenta zona inundada a 8 kms al SE de Sisal, 11 Aug 1978, Lot 2582 (MO). **Montserrat:** dominant sedge in center of Chance's pond, alt. 2700 ft, 14–18 Jun 1950, *Howard 11894* (MICH). **NICARAGUA. Zelaya:** in wet sand, El Bluff near Bluefields, 14 Dec 1968, *Seymour 642* (BRIT); dense stands covering many acres, brackish inlet, Corn Island, 06 Mar 1971, *Svenson 4317* (BRIT). **Managua:** near the mouth of Rio El Carmen, 30 km NW of Masachapa, freshwater marsh 1 km from shore, 16 Nov 1976, *Neill 1276* (MO). **PANAMA. San Blas:** Comarca de San Blas, Rio Urgandi (Rio Sidra), elev. 0–30 m, in marsh by airport, 27 Jun 1986, *de Nevers & Herrera* 8105 (MO). **Canal Zone:** Farfan Beach road, growing in water, 03 Aug 1967, *Kirkbride & Elias* 69 (MO, NY). **Bocas del Toro:** out along road W Almirante, 17 Oct 1965, *Blum 1415* (MO). **PUERTO RICO:** 1.3 mi S on Rte 687 from junction with Rte 686, elev. 10 m, E end of Laguna Tortuguero, sandy soil in marsh, 31 Dec 1980, *Solomon 5749* (MO); Yabucoa, su paludosis justa flumen guayjanes, 10 Feb 1886, *Sintenis 4942* (GH, NY, Z-2 sheets, ZT).

SOUTH AMERICA. BRAZIL. Ceara: brackish marshes, Barra do Ceara, municipio de Fortalega, 25 Sep 1935, *Drouet 2503* (MICH, NY). **COLOMBIA. Antioquia:** swampy area on the peninsula approx. 1 km W of Turbo, probable lat. ca. 8° 5' N, long ca. 76° 43' W, elevation sea level, common growing in mud at edge of brackish slough in sun, 31 Mar 1962, *Feddema 2111* (MICH); Santa Marta, 100 ft, Sep 1898–1901, *Smith 245* (MICH, NY). **ECUADOR. Costa:** Prov. Esmeraldas, km 102, Esmeraldas-La Tola, a lado de la carretera, en pantano en un sabana grande, 27 Jul 1984, *Dodson et al.* 14564 (MO). **PARAGUAY:** no date, *Reugger s.n.* (ZT). **TOBAGO:** Buccoo Bay, 20 Apr 1939, *Elmore 510* (MICH). **TRINIDAD:** ca. 2–3 mi E of Trinidad along the Beetham Hwy., low lying sedge marshes, 04 Aug 1970, *Davidse 2546* (MO, NY). **VENEZUELA. Sucre:** Laguna La Bodega, inmediatamente al Este de Santa Fe, 17 Sep 1973, *Steyermark et al. 108552* (MO).

AFRICA. ANGOLA. Moxico: Ikula hot springs by R. Zambezi, plentiful in rock pools in 1–1.5 ft of water, tufted and stoloniferous perennial; lower sheaths pale brown; upper and stem green, triangular, glumes green, edged red-brown, turning pale brown, 17 Jan 1938, *Milne-Redhead 4195* (K). **LIBERIA:** Crew Town, Monrovia, in water, 27 Jun 1909, *Massey 82* (NY). **SENEGAL:** Lyndiane, 30 Sep 1956, *Jacques-Georges 12460* (MO); Ziguinchor, km 54-57 Cap Skiring-Bignona, vicinity of Nyassia, moist area in mangrove-area, 11 Sep 1994, *Laegaard et al. 16891* (K, US); Basse-Casamance, Fegroum, 08 Nov 1990, *Berghen 9301* (MO); 10 Apr 1946, *Roberty 6209* (Z). **SIERRA LEONE:** emplodered (sic) swamp, Rokupr, 03 Jul 1947, *Jordan 42* (K). **TANZANIA. Pemba:** Makongwe Is, in shallow water on the edge of a pond, leaves and stems (hand drawn triangle symbol) and flower spikes sessile at the apex of the stem, 16 Dec 1930, *Greenway 2730* (K). **TOGO:** Agwegan, entre route et lagune, depression sale, savane herbense inonde eau sale 9 gr Natt/litre, 26 Jun 1985, *Schafer 8629* (MO, US).

ACKNOWLEDGMENTS

We thank the curatorial staff at the herbaria listed. We thank Mark Spencer (LINN) for making excellent images of the type specimen available for study, Hajo Esser (M) for assisting with nomenclatural uncertainties of *E. scariosa*, and Mary Stiffler and Linda Oestry with the Missouri Botanical Garden Library for assistance locating certain literature items. We thank Richard Carter for providing many helpful suggestions and critical review of this manuscript, and for alerting the first author to certain important literature items. Thanks to Socorro González-Elizondo and Galen Smith for their critical review and many helpful comments. The first author is grateful to Brian Cain and Ron Brinkley (USFWS) for presenting specimens they discovered during their survey of Hoskins Mound, and to Mr. Tommy Thompson and Mr. Nathan Gutowsky with ChevronTexaco for facilitating access to the site which led to this discovery. Special thanks to Neva Mikulicz for preparing the illustration.

ABSTRACT

Cunila origanoides has been rediscovered in Texas based on recent herbarium and field studies.

RESUMEN

Cunila origanoides ha sido redescubierta en Texas mediante estudios recientes de herbario y campo.

Herbarium and field studies on the Texas flora have yielded the following records pertaining to the occurrence and distribution of *Cunila origanoides* within the state.

Cunila origanoides (L.) Britt. (Lamiaceae)—Small (1933), Cory and Parks (1937), Correll and Johnston (1970), Hatch et al. (1990), and Jones et al. (1997) attributed this species to Texas. Correll and Johnston (1970) cited the distribution as north central Texas, while Hatch et al. (1990) gave the distribution as the Post Oak Savannah, Blackland Prairies, and Cross Timbers and Prairies vegetational areas. The latter mentioned distribution was cited by Diggs et al. (1999) who included *Cunila* in the Flora of North Central Texas. Gould (1962, 1969) and Turner et al. (2003) did not include the species in their respective works. The exclusion from the latter work seems to have effectively removed *Cunila* from being known as a part of the state's flora. Most likely, the ambiguity in the literature is a consequence of no cited voucher specimen. Recently, we have uncovered the two specimens cited below, thus are able to resolve the matter.

Specimens examined. **Kaufman Co.:** vicinity of Terrell, 6 Sep 1904, *Tyler s.n.* (BAYLU (photo), US). **Lamar Co.:** 1.4 mi E of jct of St. Rt. 906 and Hwy 271 at Midcity on St. Rt. 906, slope forest below Pat Mayse Lake Dam, 18 Oct 2002, *Singhurst & Harris 11344* (BAYLU).

It may be assumed that Small (1933) had reference to a specimen, thus its inclusion in his manual, but under the genus *Mappia* House. The Kaufman County specimen was annotated by Donovan S. Correll in 1967, hence its inclusion in Correll and Johnston (1970). However, neither the Small (1933) nor Correll and Johnston (1970) reports give precise location data or indicate the source of their information. The other literature citations concerning the occurrence of the species in Texas seem to have originated from these two reports. Without loca-

SIDA 21(2): 1161–1163. 2004

tion data at least to county, it is understandable, and certainly correct, for Turner et al. (2003) to not include the species in the *Atlas of the Vascular Plants of Texas*.

Cunila is a New World genus of about 15 species native from eastern North America to Uruguay (Diggs et al. 1999). *Cunila origanoides* is a native to eastern North America that is distributed from New York, south to Georgia, west to Kansas and Texas (USDA, NRCS 2004). The occurrence of *C. origanoides* in Texas is very significant. In eastern Texas, calcareous disjuncts, such as *C. origanoides*, have been receding in distribution and are evidence of calciphile relics of an earlier cooler climate (Kral 1963). The real significance of the occurrence of *C. origanoides* is in the disjunct nature of the sites. It is not known what the 1904 location of *C. origanoides* in Kaufman County was like and whether such habitat still exists there. There are still a few remnant hardwood sites, such as Cedar Creek Island (the big island) in Cedar Creek Lake, in Kaufman County that contain old growth oak stands with eastern taxa like *Corallorhiza wisteriana*, *Erythronium albidum*, *Phryma leptostachya* and *Verbesina helianthoides*. In Lamar County, *C. origanoides* occurs in rich hardwoods on slopes along a spring fed creek where the Woodbine and Eagleford shale formations merge. This is cretaceous geology, which is of rather restricted occurrence in northeast Texas. It does, however, support other disjunct and peripheral species such as the rare [in Texas] *Prenanthes barbata* and the more eastern *Heuchera americana*. Therefore, the presence of *C. origanoides* in northeast Texas is significant as this native species is persisting in remnant mature hardwood habitat. This habitat type is dwindling from land use practices and the resulting fragmentation. Potential habitat for *C. origanoides* also occurs in Fannin, Hunt, Delta, Hopkins, Franklin, Titus, Red River, and Bowie counties. This information is valuable as an indicator of calcareous slope hardwood forests that may contain other peripheral and disjunct taxa and its discovery aids the understanding regional plant communities and their floristic make-up.

ACKNOWLEDGMENTS

We wish to thank the curators of GH, NY, TEX, and US for their search for and use of specimens that made this study possible. During the study, the junior author visited US and is grateful for the assistance and kindnesses extended. We are grateful to Margie Knowles of US who arranged to have a digital photo of the Kaufman Co. specimen sent to the authors. We are very grateful to Barney Lipscomb for his comments and suggestions in producing this manuscript.

ABSTRACT

Geocarpon minimum, a federally threatened species, is documented for the flora of Texas for the first time. Approximately 200 plants were found in an extensive saline prairie near the floodplain of the Neches River in Anderson County, Texas. Included is a general description of the habitat, known distribution of the species, and associated flora in Texas.

RESUMEN

Geocarpon minimum, una especie de la lista federal de plantas amenazadas de extinción se documenta para la flora de Texas por primera vez. Se encontraron aproximadamente 200 plantas en una llanura salada cerca de la llanura de inundación del Neches River (o Río Neches) en el condado de Anderson, Texas. Se incluye una descripción general del hábitat, la distribución conocida de la especie, y la flora asociada en Texas.

Geocarpon minimum MacKenzie (geocarpon, tiny Tim, earth fruit) is listed as a federally threatened species by the U.S. Fish and Wildlife Service and is currently known from Arkansas, northwestern Louisiana, and southwestern Missouri (MacKenzie 1914; Moore 1958; McInnis et. al. 1993; USDA, NRCS 2004; USFWS 1993). In Missouri, *Geocarpon minimum* occurs in glades and other open, sparsely vegetated areas on shallow soils over sandstone outcrops, often in shallow depressions (Morgan 1980; Palmer & Steyermark 1950; Steyermark, et. al 1959; Thurman 1989; USFWS 1993). In Arkansas it is typically found in sparsely vegetated areas on saline prairies (Moore 1958; Orzell & Bridges 1987; Pittman 1988; Rettig 1983; Shepherd 1987; USFWS 1993). Soils in both habitat types are high in magnesium or sodium (Rettig 1983). This species was brought to the attention of the former Texas Natural Heritage Program in 1993 by Peggy Horner of the Missouri Department of Conservation as potentially occurring in northeast Texas. Several surveys were then conducted on saline prairies in East Texas, including the Davy Crockett National Forest, Temple-Inland Forest Products Corp. (Temple) property, and other private lands.

In summer of 2003, we discovered a large saline prairie complex occurring on Temple property in Anderson County, Texas, just above the floodplain of the Neches River. This prairie was surveyed in the summer and fall of 2003 and found to contain several halophytes typically associated with *Geocarpon minimum*. In surveys conducted in early March 2004, approximately 200 plants of *Geocarpon minimum* were discovered at eight stations throughout the 75 acre saline barren complex. All of the plants occurred on the edge of sparsely vegetated areas commonly referred to a "slick spots" (USFWS 1993). These slick spots vary in size from one to approximately thirty square meters. They have very high sodium content and are typically devoid of any vegetation, with the exception of *Sibara virginica*, *Talinum parviflorum*, *Plantago pusilla*, and *Cleomella angustifolia*. This vegetative edge around the slicks is referred to as a "cryptogamic lip," where a spongy, leathery crust of moss protonemata, lichens, liverwort thalli, *Nostoc* sp., and the associated micro-flora interact to cement the lip in place (Shepherd pers. comm.; USFWS 1993). Woody species associated with *Geocarpon* adjacent to these slicks includes, *Celtis laevigata* spp. *laevigata*, *Crataegus* spp., *Juniperus virginiana*, *Opuntia macrorhiza*, *Pinus taeda*, *Quercus similis*, *Sabal minor*, *Smilax bona-nox*, *Vaccinium arboreum*, and *Ulmus crassifolia*. Associated herbaceous species include *Anagallis minima*, *Aphanostephus skirrhobasis*, *Astranthium integrifolium*, *Chaetopappa asteroides*, *Cleomella angustifolia*, *Coreopsis tinctoria*, *Crassula aquatica*, *Draba brachycarpa*, *Evolvulus sericeus*, *Gratiola flava*, *Houstonia rosea*, *Houstonia micrantha*, *Houstonia pusilla*, *Hypericum drummondii*, *Isolepis carinata*, *Krigia occidentalis*, *Lepuropetalon spathulatum*, *Ophioglossum crotalophoroides*, *Plantago pusilla*, *Portulaca* spp., *Rumex hastatulus*, *Sagina decumbens*, *Schoenolirion wrightii*, *Sedum nuttallianum*, *Sibara virginica*, *Sporobolus vaginiflorus*, and *Talinum parviflorum*. The surrounding topography also includes mima mounds with micro highs and lows. The Brimstone Silt Loam described in McInnis et. al. (1993) may be represented in this saline prairie. However, in Coffee (1975), this area is not differentiated from the surrounding bottomland soil type, and saline soils are not mentioned. The mapped soil series for the prairie area is classified as Nahatche-Wehadke Soil Series with typically loamy bottomland soils. However, in an older soil survey of Anderson County from 1890, the Anderson County saline areas are briefly described (Department of Agriculture, Insurance, Statistics, and History 1890). Collection data for *Geocarpon minimum* follow:

UNITED STATES. Texas. Anderson Co.: 120 m NE of a roadside park, 0.1 mi E of the jct. of U.S. Hwy 84 and Neches River; saline barren complex, 8 Mar 2004, *J. Singhurst 12921, E. Keith, S. Cook, & B. Shepherd* (BAYLU, TEX)

Fig. 2. Habitat of *Geocarpon minimum*. Plant found along edges of "slick spots."

TAXONOMIC DESCRIPTION

Glabrous winter annual, stems simple or branched at the base, the branches few, erect or spreading ascending, mostly 3–4 cm high and less than 0.5 mm thick, often a bright reddish or pale purplish color. **Leaves** simple, opposite, green or reddish in color, 3–4 mm long, narrowly oblong or ovate-oblong, the margins entire, and the apex acute. **Flowers** usually axillary, regular, funnelform-campanulate; sepals 5, 3–4 mm long, reddish or reddish-green; petals absent; stamens 5; staminodes 5; ovary superior, lance-ovoid, somewhat trigonous, about the length of the sepals. **Fruit** is a capsule containing numerous, funicular seeds, 0.5 mm long (NatureServe 2004; Steyermark 1963).

ACKNOWLEDGMENTS

Appreciation is given to Temple-Inland Forest Products Corp., which currently owns the entire saline prairie complex and is conserving the habitat. We would also like to thank Bill Shepherd, retired biologist from the Arkansas Natural Heritage Commission, for accompanying us on the collecting trip and sharing his expertise on *Geocarpon minimum* and its habitats. We would also like to thank Guy Nesom of the Botanical Research Institute of Texas and Monique Reed, Herbarium Botanist at Texas A&M University, for critical review of the paper.

ABSTRACT

Solanum viarum, Tropical Soda-Apple (Solanaceae), is an aggressive weed from South America. Since it is known from the southern U.S., including Louisiana, it has been watched for in Texas. A population has now been confirmed and vouchered from Jasper County, Texas. Other populations probably exist.

RESUMEN

Solanum viarum, manzana de soda tropical (Solanaceae), es una mala hierba agresiva de Sur América. Desde que es conocida del Sur de Estados Unidos, incluyendo Louisiana, ha sido buscada en Texas. Se ha confirmado ahora una población y se han tomado testigos del condado de Jasper, Texas.

Solanum viarum Dunal, Tropical Soda-Apple, is a perennial native to South America. It was first found in the U.S. in Florida in 1988 (Wunderlin et al. 1993), though it may have been present as early as 1981 (Coile 1993.) It can be aggressively weedy in warmer areas and is now also known from Alabama, Georgia, Mississippi, North Carolina, South Carolina, Pennsylvania, and Tennessee (USDA, NRCS 2004). It is also present in Louisiana and Arkansas (Medal et al. 2003). Medal et al. (2003) also listed the plant for Texas, but we have been unable to locate any voucher specimens or specific collection site information. (It is possible they were referring to the Jasper County population documented here.) The species was not listed for Texas by Correll and Johnston (1970) or by Jones et al. (1997).This is the first vouchered report of its occurrence in the state.

In 2002, plants were found growing in a cattle pasture in Jasper County. The land owner cleared as many of the plants as he could but left the dead plants (with mature fruit) on the property. By 2004, the infestation was much worse (hundreds of individuals on ca. 40 to 60 acres), and he sought identification of the weed. We determined that it was indeed *Solanum viarum*. The land owner suspects the seeds may have been introduced in a shipment of hay from Louisiana.

SIDA 21(2): 1171–1174. 2004

Voucher specimen: **U.S.A. TEXAS. Jasper Co:** Ranch, entrance on TX Hwy 63, ca. 1 mi N jct. TX Hwy 190, pasture. *Mary Ketchersid 5-2004-1*, 24 May, 2004 (TAMU).

Images of the Jasper County plants may be seen at www.csdl.tamu.edu/FLORA/cgi/gallery_query?q=solanum+viarum

In October, 2004, a live specimen was sent to Texas A&M from Edna in Jackson Co. This represents a second confirmed infestation and underscores the possibility that *S. viarum* is already more widespread in Texas than is currently known. We have also seen photographs of what appears to be another population *S. viarum* in Texas, but the property owner has declined to disclose the location of the plants.

Solanum viarum (Fig. 1) somewhat resembles *S. carolinense* L. or *S. dimidiatum* Raf., both native to North America, but it has unbranched rather than stellate hairs on the upper leaf surfaces. The plant may reach 1 m or more tall, with a branched, prickly stem. The leaves are ovate to ovate-triangular, to 15 cm long and 12 cm wide, sinuate, and with sharp prickles to 1 cm or longer on both the upper and lower surfaces. The flowers are white (vs. purple to white in *S. carolinense* or *S. dimidiatum*), with the corolla lobes proportionately narrow and strongly recurved. The fruit are globose, 1.5–2(–3) cm in diameter, striped light and dark green when young, becoming yellow at maturity. A full description can be found in Wunderlin et al. (1993) and Bryson and Byrd (1994.)

This plant has the potential to be a serious weed in Texas, and it has already been proposed for the Texas Noxious Weed List, as per Texas Agricultural Code rule 4TAC § 19.300(a.)(Texas Register 2004). Cattle avoid eating the foliage, allowing the plant to persist in grazed pastures. The fruit, however, is eaten by cattle and small mammals, which distribute the seeds in their feces. Small infestations may be controlled by herbicides, but this may be prohibitively expensive over large areas, where mowing before flowering stage is the first line of defense. Trials are underway in Florida to determine the efficacy of the beetle *Gratiana boliviana* as a biocontrol agent (Medal et al. 2003).

Anyone finding what they know or believe to be *Solanum viarum* in Texas should contact their county agent and/or Mary Ketchersid at the above address for confirmation of identification and specific control instructions.

ACKNOWLEDGMENTS

Thanks go to Rodney Young, National Plant Identifier for USDA-APHIS-PPQ, for his confirmation of the identification. We thank two anonymous reviewers for helpful comments.

NEW DISTRIBUTION RECORDS FOR *GAMOCHAETA* (ASTERACEAE: GNAPHALIEAE) IN THE UNITED STATES

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

ABSTRACT

Gamochaeta stagnalis is reported for the first time for the United States (Arizona and New Mexico). In Arizona these plants have previously been identified as *Gamochaeta purpurea* and *Gamochaeta falcata*. The species is common in Mexico and apparently is at the northern limit of its distribution in Cochise, Pima, and Santa Cruz cos., Arizona, and Hidalgo Co., New Mexico. *Gamochaeta purpurea* sensu stricto also occurs in Arizona, disjunct from its main range in the eastern U.S.A. Plants of the southeastern U.S.A. previously identified in some treatments as *Gamochaeta falcata* are separated into two species: *Gamochaeta calviceps* and *Gamochaeta antillana*. A lectotype is chosen for *G. antillana*. *Gamochaeta calviceps* is known primarily from the southeastern U.S.A. but is reported from two collections in California. *Gamochaeta coarctata* is first reported for Arkansas and Virginia and further documented for California. *Gamochaeta stachydifolia*, a South American native, is reported from two counties in California. For each of the 12 *Gamochaeta* species recorded for the U.S.A., a hypothesis of nativity is given, with a brief rationale.

RESUMEN

Se cita *Gamochaeta stagnalis* por primera vez para los Estados Unidos (Arizona y Nuevo México). En Arizona estas plantas han sido identificadas previamente como *Gamochaeta purpurea* y *Gamochaeta falcata*. La especie es común en México y aparentemente tiene su límite Norte de distribución en los condados de Cochise, Pima, y Santa Cruz, en Arizona, y condado de Hidalgo, en Nuevo México. *Gamochaeta purpurea* sensu stricto aparece también en Arizona, disyunta de su área principal en el Este de U.S.A. Las plantas del Sureste de U.S.A. a veces identificadas previamente como *Gamochaeta falcata* se separan en dos especies: *Gamochaeta calviceps* y *Gamochaeta antillana*. Se escoge un lectotipo para *G. antillana*. *Gamochaeta calviceps* se conoce primariamente del Sureste de U.S.A. pero se citan dos colecciones en California. *Gamochaeta coarctata* se cita por primera vez de Arkansas y Virginia, y se documentan otras citas para California. *Gamochaeta stachydifolia*, nativa de Sur América, se cita de dos condados de California. Para cada una de las 12 especies de *Gamochaeta* citadas para U.S.A., se ofrece una hipótesis de la posibilidad de ser nativas, con un informe razonado.

In connection with preparation of a taxonomic treatment of the genus *Gamochaeta* Wedd. for the developing Flora of North America volumes, various range extensions and new records have come to light.

***Gamochaeta purpurea* sensu stricto in Arizona**

Plants of *Gamochaeta* in Arizona have been identified as *G. purpurea* (L.) Cabr. (as *Gnaphalium purpureum* L.: Kearney & Peebles 1960; Lehr 1978) and *G. falcata* (Lam.) Cabr. (Nesom 1990). *Gamochaeta purpurea* sensu stricto does

SIDA 21(2): 1175–1185. 2004

indeed occur in Arizona, but further study shows that the more common plants are instead a species widespread in Mexico but previously unreported for the United States (see below). The native range of *G. purpurea* sensu stricto apparently is the eastern U.S.A., including eastern Texas, but it occurs as an adventive in many parts of the world. In the U.S.A., Arizona is the only other state in which *G. purpurea* is known to occur.

Specimens examined. **ARIZONA. Cochise Co.:** Chiricahua Mts., Rucker Canyon, streambank near upper road crossing, scarce, ca. 6300 ft, 8 Jun 1980, *Toolin 797* (ARIZ). **Pima Co.:** Rincon Mts., Speed Ranch, 7400 ft, 23 Aug 1909, *Blumer 3301* (GH, MO); Spud Rock Spring, wet meadow, 7200 ft, 17 Sep 1982, *Bowers R828* (ARIZ); Rincon Mts., 7500 ft, 1891, *Neally 230* (TEX, US); Santa Catalina Mts., Bear Canyon, near Tucson, 27 Apr 1930, *Cory s.n.* (ARIZ, GH); Mt. Lemmon, control road, 23 Aug 1931, *Harrison and Kearney 8128* (ARIZ, LL); Sabino Canyon, 26 Mar 1926, *Loomis 1410* (ARIZ); 10 mi NE of Tucson in Sabino Canyon, frequent along banks of small stream, 15 May 1965, *Matthews 387* (ARIZ, ASU); Sabino Canyon near Tucson, 26 March 1926, *Peebles et al. 1410* (US); old Sawmill on Apache Camp Trail, 6800 ft, 24 Jul 1914, *Shreve s.n.* (ARIZ); Sabino Canyon, moist alluvial soil, 2800 ft, 2 May 1903, *Thornber 416* (US), Sabino Canyon, moist alluvial soil, 3000 ft, 2 May 1903, *Thornber 468* (ARIZ, MO, NMC, US); Sabino Canyon, 5 May 1903, *Thornber s.n.* (ARIZ); Saw Mill, 24 Jul 1914, *Thornber 7303* (ARIZ).

The plant of *Harrison and Kearney 8128* (ARIZ; the LL specimen has a single stem with drawing of the habit) produced numerous decumbent, rhizome-like or caudex-like branches arising from a central axis and apparently was distinctly perennial. At least one of the plants collected by Shreve (s.n., ARIZ) also appears to have been perennial. It will be interesting to investigate whether the highly unusual modification of *Harrison and Kearney 8128* is phenotypic or whether a distinct genetic race might be present.

Gamochaeta purpurea probably is native to eastern North America (see below), where it is the least weedy of its congeners, but the species apparently occurs widely through the world as a adventive. Plants of *G. purpurea* in southern Arizona (Pima Co.) occur along sandy banks of perennial streams in Sabino Canyon and Bear Canyon at the base of the Santa Catalina Mountains east of Tucson. The first known collections were made in these long-popular recreation areas in 1903, perhaps accidentally established there through heavy visitation, as the same sites are heavily infested by other, more aggressive non-native species. On the other hand, collections of *G. purpurea* also have been made in the Rincon Mts. (Pima Co.) and the Chiricahua Mts. (Cochise Co.), where the species is less likely to have been introduced by human activity. It also seems unlikely that plants of *G. purpurea* sensu stricto in scattered Mexican localities were introduced there by human activity.

A record of *Gamochaeta purpurea* from New Mexico (Allred 2003) was attributed to documentation in McIntosh (1996), which instead reported records for *Pseudognaphalium leucocephalum* (A. Gray) Anderb. The voucher for the *Gamochaeta* record in New Mexico is identified here as *Gamochaeta stagnalis* (see citation below). Documentation for a report of *Gamochaeta purpurea* from

Montana (Dorn 1984, as *Gnaphalium purpureum*) has not been verified. Reports of *Gamochaeta purpurea* from California, Oregon, Washington, and British Columbia are primarily based on *G. ustulata* (Nutt.) Holub (a native and relatively common species), although three other species (non-native, relatively uncommon) of the genus are now known from California: *G. calviceps*, *G. stachydifolia*, and *G. coarctata*.

The status of *Gamochaeta stagnalis*

The present report documents the occurrence of *Gamochaeta stagnalis* in the U.S.A., where it occurs in Arizona and New Mexico. These plants have previously been identified in Arizona mostly as *Gamochaeta purpurea*. In the U.S.A., *G. stagnalis* does not geographically overlap with any other species and its identity should now be easily ascertained. A full description is given here, since one apparently does not exist elsewhere.

Gamochaeta stagnalis (I.M. Johnst.) Anderb., Opera Bot. 104:157. 1991. *Gnaphalium stagnale* I.M. Johnston, Contr. Gray Herb. ser. 2, 68:99. 1923. TYPE: MEXICO. SAN LUIS POTOSÍ: marshes about San Luis Potosí ("in palustris circa urbem"), Aug 1876, *J.G. Schaffner 225* (HOLOTYPE: GH!). A specimen at US, *Schaffner 666* (with "225" and "212" also written on the label), collected in Sep 1879, is the same species but apparently not a duplicate of the type.

Plants annual from a short, very slender to filiform taproot, less commonly from very shallow fibrous roots. **Stems** single and erect or 2–8 and decumbent-ascending, 2.5–20(–35) cm long, densely and loosely arachnoid-tomentose. **Leaves** mostly cauline, oblanceolate-spatulate to narrowly oblanceolate or nearly linear, 1–4 cm long, 2–6(–10) mm wide, basal usually not persistent, cauline oblanceolate, slightly reduced upward in size, equally loosely tomentose above and beneath or the adaxial surface glabrescent and greener. Capitulescence a capitate cluster (in smallest plants) of heads or an interrupted series of small glomerules subtended by divergent-ascending bracts similar to the upper cauline leaves, sometimes branching at lower nodes. **Involucres** campanulate, 2.5–3 mm high, conspicuously imbedded in loose tomentum, the outer bracts basally hairy; inner phyllaries narrowly oblong-lanceolate, with rounded-obtuse, whitish lamina, usually purple above the stereome and along proximal margins of the lamina, outer phyllaries ovate-triangular, translucent; receptacles deeply concave to crateriform. **Florets**: bisexual (2–)3(–4); all corollas purplish-tipped.

Flowering (Mar–)Apr(–May). Sandy, often moist soil, washes and permanent streams, canyon bottoms, flower beds, riparian, desert grassland, juniper-grassland, creosote bush-mesquite-cholla, oak woodland; 900–1750 m; Ariz., N.Mex.; Mexico (Sonora, Chihuahua, Coahuila, Nuevo León, Baja California Sur, Sinaloa, Durango, Zacatecas, San Luis Potosí, and other states to the south).

Specimens examined: **ARIZONA. Cochise Co.:** floodplain of Miller Canyon, 0.8 mi by road W of Hwy 92, under *Quercus emoryi* in open woodland, 14 Apr 1991, *Bowers 3426* (ARIZ); Dragoon Mts., Noonan Canyon, SE slope of S-facing saddle, 5080 ft, with *Fouquieria*, 29 Apr 1983, *Caffey-Moquin 396* (UNM) and 399 (UNM); Whetstone Mountains, rocky draw, 27 Apr 1952, *Goodding 58-52* (ARIZ); Huachuca Mountains, Coronado National Memorial, rocky bench in wash, E end of park, 5000 ft, 20 Apr 1991, *McLaughlin 6233* (ARIZ); San Bernardino Ranch, 18 mi E of Douglas, moist area around Middle Well, 3800 ft, 25 May 1981, *Marrs-Smith 561* (ASU); SW corner of Chiricahua National Monument, grassland, juniper, 5400 ft, 19 Apr 1975, *Reeves R2595* (ASU). **Pima Co.:** Rincon Mountains, along the Manning Camp trail, moist draws in desert grassland, 4500 ft, 27 Apr 1983, *Bowers R1124* (ARIZ); Rincon Mts., unnamed canyon at W base of Tanque Verde Ridge, 3200 ft, moist soil in streambed, 29 April 1984, *Bowers R1433* (ARIZ, LL); Altar Valley, 8 airline mi SSW of Robles Junction (Three Points), creosote bush-mesquite-cholla woodland, infrequent in disturbed areas, 2900 ft, 6 Apr 1973, *Holmgren 6668* (NY); Baboquivari Canyon, 11 Mar 1926, *Leding and Thackery 1123* (ARIZ); Forestry Cabin at W base of Baboquivari Peak, Papago Indian Reservation, permanent stream in oak-Sonoran desert zone, grazed, 6–7 Apr 1973, *Lehto et al. 10660* (NY, US); Pagago Indian Reservation, 0.3 mi E of Topawa, mesquite-cactus, bur-sage desert, roadside washes, 6 Apr 1973, *Lehto et al. 10749* (ARIZ); 22.0 mi S of Robles Jct. at Las Delicias Ranch Road along Hwy 286, desert grassland with mesquite, burroweed, *Opuntia* spp., 3200 ft, 14 May 1988, *McLaughlin 4568* (ARIZ); Buenos Aires National Wildlife Refuge, along Brown wash, with hackberry and mesquite, 3600 ft, 25 Apr 1991, *McLaughlin 6253* (ARIZ), Lower Bear Canyon, moist sand along stream, 3200 ft, 13 Apr 1961, *Mason 1908* (ARIZ); along Santa Cruz River at Cortaro Road, NW of Tucson, 5 Apr 1976, *Mason 3171a* (ARIZ); Little Tucson, Ascencio floodwater field section last plowed summer 1978, 17 Apr 1979, *Nabham 540* (ARIZ); Pima Co.: Coyote Mts., Mendoza Canyon, 3200 ft, abundant on canyon floor, 22 April 1945, *Parker 5797a* (ARIZ, BRIT, LL, NY); wet banks of the Rillita, 14 Apr 1881, *Pringle 13744* (GH, MO); Santa Catalina Mountains, Ventana Canyon, 1908, *Shreve s.n.* (ARIZ); Fort Lowell, Rillito, 23 Apr 1903, *Thornber s.n.* (ARIZ); Tucson, First Avenue at Roger Road, irrigated flower bed around parking lot, 14 Aug 1994, *Van Devender 94-444* (TEX). **Santa Cruz Co.:** Nogales-Lochiel Road, 6 mi from Ariz. Hwy 82, 9 airline mi E of downtown Nogales, sandy soil around oak tree, 4200 ft, 18 Apr 1973, *Holmgren 6866* (ARIZ, NY); Agua Caliente Canyon, along stream near road crossing, riparian vegetation with *Celtis*, *Baccharis*, *Fraxinus*, 3800 ft, 2 Apr 1978, *Reeves 6640* (ASU); Santa Rita Mountains, Gardner Canyon, 5700–5800 ft, 8 May 1975, *Van Devender s.n.* (ARIZ). **NEW MEXICO. Hidalgo Co.:** Peloncillo Mts., Granite Gap, occasional on W-facing granitic slope with *Ericameria laricifolia*, *Fouquieria splendens*, *Agave palmeri*, *Opuntia phaeacantha* var. *discata*, 21 Apr 1993, *McIntosh 2665* (NMC).

Localities for *Gamochaeta stagnalis* in Arizona and New Mexico are at the northwestern extremity of its overall range, where flowering is restricted to the end of the cool season. The species is common and widespread in Mexico, from Baja California Sur, Sonora, and Chihuahua southward and eastward to Jalisco and Colima, Nuevo León, San Luis Potosí, and Veracruz, where it occurs at elevations of 200–1800(–2600) meters in rocky or gravelly soil, including stream beds and other periodically wet sites, in areas of thorn-scrub, tropical deciduous, or oak woodland, usually in open or disturbed sites. In Mexico it flowers December through May but sometimes continues longer in wet seasons.

Plants of *Gamochaeta stagnalis* are recognized by their annual duration, usually from a filiform taproot, oblanceolate leaves equally tomentose on the lower and upper surfaces, interrupted capitulescence, small, basally tomentose heads, and phyllaries conspicuously purplish at the stereome/lamina junction and along the proximal margins of the lamina. It is similar to and probably closely related to *G. antillana* (below).

The status of *Gamochaeta antillana*

Gamochaeta antillana (Urb.) Anderb., a common species in the southeastern U.S.A., was combined in concept with *Gamochaeta calviceps* (Fern.) Cabr. and identified as *Gamochaeta falcata* (Lam.) Cabr. by Nesom (1990). Godfrey (1958) separated *G. calviceps* and identified the other species as *G. falcata*. It is now clear that two taxa occur in this region, and they are now known to be widely sympatric, countering Godfrey's notion that they might be treated as geographic varieties.

Gamochaeta antillana (Urb.) Anderb., Opera Bot. 104:157. 1991. *Gnaphalium antillanum* Urban, Repert. Spec. Nov. Regni Veg. 13:482. 1915. TYPE: CUBA. "In insula Saba ad Great Hill et Gumbeygut, m. April, fruct. delapsis, *Suringar*" (holotype: B, apparently destroyed). Two paratype collections cited by Urban (*Britton 10009*; *Britton 9619*) are at NY, with internet-posted photographs on the NY type database. Peter Michael, in May 1982, annotated *9619* as follows: "Urban designated a Suringar specimen as type and listed 2 additional specimens—*Britton 10009* and *Britton, Britton and Cowell 9619*. The Suringar specimen no longer exists; I believe that the fruiting specimen, *Britton, Britton and Cowell 9619* should be designated lectotype." It obviously is somewhat arbitrary, but I suggest that the features of the species are better shown by plants of *10009* and designate it here as the LECTOTYPE: Cuba. Prov. Pinar del Rio, Boca de Galafre, hillside, 15 Mar 1911, *N.L. Britton 10009* (NY).

Gnaphalium subfalcatum Cabr., Rev. Mus. La Plata (n.s.) Bot. 4:174. 1941. *Gamochaeta subfalcata* (Cabr.) Cabr., Bol. Soc. Argent. Bot. 9:383. 1961. TYPE: ARGENTINA. PROV. BUENOS AIRES: Pdo. Avellaneda, Isla Maciel, 12 Oct 1920, *Cabrera 944* (HOLOTYPE: LP).

Cabrera (1961) cited collections of *Gamochaeta subfalcata* from Texas and Florida, extending the range far from northeastern Argentina, as circumscribed by the original citations (Cabrera 1941). Freire and Iharlegui (1997) also identified this species in the U.S.A. as *G. subfalcata*, and it seems inescapable that *C. antillana* and *G. subfalcata* are synonyms. *Gamochaeta antillana* is known to occur in Alabama, Arkansas, Florida, Georgia, Louisiana, North Carolina, Oklahoma, Mississippi, South Carolina, Tennessee, Texas, and Virginia; also in South America, Europe, and New Zealand.

Gamochaeta antillana is closely similar to *G. stagnalis* but the plants often are generally taller (6–40 cm vs. 2.5–20(–35) cm in *G. stagnalis*) and the basal leaves are oblanceolate with the cauline quickly becoming linear (in *G. stagnalis*, the cauline leaves and those subtending the clusters of heads are oblanceolate). *Gamochaeta antillana* occurs in humid climates and habitats while *G. stagnalis* is a species of arid climate and habitat. Further study of the distinction between these two taxa is needed.

a. Involucres 3–3.5 mm, lightly arachnose only at the base or not at all; capitulescence interrupted at least distally, main axis visible to terminal heads; phyllaries in 5–7 series, outer and middle ovate-triangular with sharply acute-acuminate apices, 1/3–1/2 as long as the inner, none with purplish color; flowering May–Jul ________ **Gamochaeta calviceps**

a. Involucres 2.5–3 mm, seated in tomentum; capitulescence initially cylindric and uninterrupted, at least distally, main axis obscured by clustered heads; phyllaries in

3–4(–5) series, outer and middle ovate-lanceolate with narrowly to broadly acute apices, outer 1/2–2/3 as long as inner, at least innermost commonly tinged with purple at stereome-lamina junction; flowering (Feb–)Mar–May, sometimes later with moisture __________ **Gamochaeta antillana**

Gamochaeta calviceps in California

Gamochaeta calviceps occurs widely in the southeastern U.S.A. The first known North American records outside of that region are reported here. It is known to occur in Alabama, Arkansas, California, Florida, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Texas, Virginia, as well as South America, Europe, and New Zealand. As noted above, *G. calviceps* and *G. antillana* constitute the plants in the eastern U.S.A. most commonly identified in the past as *Gamochaeta falcata*.

CALIFORNIA. Contra Costa Co.: Tilden Regional Park Botanic Garden, Wildcat Canyon; a rapidly spreading weed [that] probably came with plant material from Delano, Kern Co., 27 Jun 1975, *True 7872A* (TEX). **San Diego Co.:** Peninsular Ranges, near Riverside Co. line, E of I-15 off Pala Road along Rancho Heights Rd, 1364 ft, chaparral, mostly past flower, 24 Jun 2003, *Spjut and Marin 15384* (BRIT, UCR).

Gamochaeta stachydifolia in California

This species is known to me by two collections from central California, the localities separated by about 200 kilometers. The 1990 collection suggests that it has probably is naturalized in that region and should be expected at more localities. The plants are recognized by their slender-taprooted habit (probably annual), oblanceolate and concolorous leaves, cylindric capitulescence, acute to acute-acuminate outer and middle phyllaries, inner phyllaries with brownish-hyaline, rounded-apiculate lamina, and yellowish-tipped florets. The GH collection (*Mason 6991*) was annotated by Peter Michael in 1990 as *Gamochaeta berteriana* (DC.) Cabr., but this identification is problematic, as *G. berteriana* apparently is perennial, thicker stemmed, and bears heads in capitate clusters; it is native to high elevation habitats in Chile (type: Chile, 1833, *Bertero 8222*, B, photo-TEX!). Freire and Iharlegui (1997) noted that the range of *G. stachydifolia* includes Argentina, Brasil, and Uruguay.

Gamochaeta stachydifolia (Lam.) Cabr., Bol. Soc. Argent. Bot. 9:382. 1961. *Gnaphalium stachydifolium* Lam., Encycl. 2:757. 1786. *Gnaphalium purpureum* L. var. *stachydifolium* (Lam.) Baker in Martius, Fl. Bras. 6(3):125. 1882. Probable HOLOTYPE (see comments by Cabrera 1961): Uruguay or Argentina. "Des environs de Montevideo et de Buenos Aires," without date, *Commerson s.n.* (P, photo-F, photo-LL). Lamarck noted that "Commerson a trouvé cette espèce à Monte-Video. (v.s.)."

Plants annual, slender taprooted. **Stems** 4–15 cm high, erect, single from the base, densely and loosely gray-white tomentose-arachnoid. **Leaves** basal and cauline, basal mostly withered and withering by flowering, oblanceolate, 1–2 cm long, 2–4 mm wide, cauline similar to basal, oblanceolate, commonly folded, subclasping but not auriculate, 2–3 cm long, 3–6 mm wide, continuing nearly unreduced into lower inflorescence but none longer than heads, dark apical mucro often evident, evenly gray-white tomentose-arachnoid on both surfaces. **Capitulescence** a continuous cylinder 2–3(–4) cm long, 10–12 mm wide (pressed). **Involucres** campanulate, 3.5–4 mm high; phyllaries in 4–5 gradate series, outer ca. 1/3 as long as innermost, outer and middle narrowly ovate-triangular, apically acute to acute-acuminate, lightly tomentose at the very base, innermost oblong, stereome ca. 1/2 length, lamina brownish-hyaline, apically rounded-apiculate; receptacles shallowly concave. **Florets:** bisexual 2–4; all corollas yellowish. **Cypselae:** mature fruits not seen.

Collections examined. **CALIFORNIA. Amador Co.:** Sierra Nevada foothills, hill above Ione, 25 Apr 1932, *Mason 6991* (GH, LL). **Butte Co.:** ca. 1/4 mi S of the Feather River, ca. 0.4 mi W of Pacific Heights Road, ca. 4.5 mi SW of Oroville, T18, R3E, ne/S3, riparian woodland (destroyed), 100 ft, uncommon, inconspicuous, growing on dry, bare disturbed, sandy soil in the borrow area, 28 Apr 1990, *Ahart 6466* (MO).

Gamochaeta coarctata in Arkansas, California, and Virginia

Gamochaeta coarctata (Willd.) Kerg. was previously noted to occur in California (Nesom 1990), but it was identified as *Gamochaeta americana*. In view of the rapid spread and pervasive occurrence of this species in the southeastern U.S.A., it seems likely that it also is becoming increasingly common in California. It is common throughout Louisiana, and its representation in southern Arkansas probably is already significantly greater in herbaria than the single record reported here. I have seen the following specimens.

ARKANSAS. Bradley Co.: "Southern Bluff" ca. 2.3 mi NW (by air) of the center of Warren, 26 Jun 1976, *Locke 2002* (BRIT). **CALIFORNIA. Humboldt Co.:** Canyon Creek, 6 mi SE of Blue Lake, hillside pasture in logged area, local and scarce, 1200 ft, 1 Aug 1936, *Tracy 15057* (NCU, TEX). **Sacramento Co.:** weed in irrigated alfalfa field, Aschwanden farm, 3 mi W of Galt, 10 Aug 1953, *Tucker 2674* (SMU). **Stanislaus Co.:** San Joaquin Valley, near Ceres and Turlock, 2 mi WSW of Keyes, uncommon annual weed in almond orchard, 80 ft, 8 Jul 2000, *Sanders 23532* (BRIT). **VIRGINIA. Northampton Co.:** north end of Hog Island, inner dune, 1 Jul 1996, *McAvoy 1603* (DOV).

Further comments on biology and nomenclature of *Gamochaeta coarctata* are given in two other papers in this issue (Nesom 2004; Pruski & Nesom 2004).

Nativity of North American *Gamochaeta* species

Assessment of the nativity of North American species of *Gamochaeta* is problematic. Most *Gamochaeta* species are native to South America, and most of the North American species characteristically occur in ruderal habitats, commonly in company of known non-native species of various families. Some, if not all, of the North American *Gamochaeta* species occur as weeds in parts of the world other than South America (although inconsistencies in identification and application of names make it difficult to accurately evaluate overall distributions of the widespread species). Thus by behavior and association, all ruderal *Gamochaeta* species in North America might also be expected to be non-native. The mode of introduction of those clearly non-native is not known.

Circumstantial evidence, however, suggests that some of the North American *Gamochaeta* species are native. *Gamochaeta purpurea* and *G. ustulata* were described from collections made early in the history of the U.S.A., presumably before non-native colonizers became abundant; others are known only from more recent collections. Several species are distributed over broad latitudinal and ecological range, suggesting that geographic differentiation may have occurred; the geographic range (and presumed genetic variability) of others is more restricted. Four of the species suggested as native on a geographic-ecological basis form two species pairs (the two of each pair with strong morphological similarities: *G. purpurea* and *G. sphacilata*, *G. argyrinea* and *G. ustulata*), suggesting that the evolutionary differentiation was autochthonous. *Gamochaeta pensylvanica*, *G. antillana*, and *G. stagnalis* are similar among themselves and possibly closely related; their nativity is uncertain, but at least it seems likely that *G. stagnalis* is native. For those non-native, evidence is strong that they are naturalized (sensu Nesom 2000a).

For each of the *Gamochaeta* species recorded for North America (north of Mexico), a hypothesis of nativity is given, with a brief rationale. Distribution maps for *G. purpurea*, *G. argyrinea*, *G. ustulata*, *G. chionesthes*, *G. simplicicaulis*, and *G. coarctata* are provided in Nesom (2004).

Gamochaeta purpurea (L.) Cabr.—Native: widespread in the eastern U.S.A. over a broad latitudinal and ecological range; early collections from known range in the U.S.A.; possibly closely related to *G. sphacilata*, which apparently occurs natively over a wide area, including South America and Mexico, into southwest Texas. *Gamochaeta purpurea* sensu stricto is found over a wide area of peninsular Florida, but *G. argyrinea* and *G. chionesthes*, both segregated from the concept of *G. purpurea* in the U.S.A., are restricted to the northern counties of the state (a loan of specimens from USF was extremely helpful in establishing this).

Gamochaeta sphacilata (Kunth) Cabr.—Native: widespread from South America to the U.S.A., occurs in essentially undisturbed habitats at mid and relatively high-elevation in Mexico and the northern extension of its range in trans-Pecos Texas; possibly closely related to *G. purpurea*, which apparently is native to the eastern U.S.A.

Gamochaeta argyrinea Nesom—Native(?): widespread in the eastern U.S.A. over a considerable latitudinal and ecological range and also known from Puerto Rico; early collections from known range in the U.S.A.; probably closely related to *G. ustulata*, which apparently is native to the western U.S.A.

Gamochaeta ustulata (Nutt.) Holub—Native: distinctive habitat and geographic range in Pacific coast states, over a wide latitude, mostly in coastal and near-coastal habitats; early collections from known range in the western U.S.A.; closely similar and probably closely related to *G. argyrinea*, which perhaps is native to the eastern U.S.A.

Gamochaeta chionesthes Nesom—Non-native: relatively scattered and recent collections in the southeastern U.S.A. (see Nesom 2004). It possibly has been identified in South America by a misapplied name (*G. americana*?); possibly closely related to *G. simplicicaulis*, a native of South America.

Gamochaeta simplicicaulis (Willd. ex Spreng.) Cabr.—Non-native: scattered and recent collections in the southeastern U.S.A., the earliest known in 1957–1959, when it was discovered in nine counties of North Carolina and South Carolina (Nesom 1999, 2000b). Widely distributed in South America and known from early collections there; recorded as adventive in other parts of the world before its discovery in North America.

Gamochaeta coarctata (Willd.) Kerg.—Non-native: collections from the U.S.A. before about 1970 are rare. Small (1933) did not include this distinctive species in his treatment of the Southeastern flora. Godfrey (1958) noted that he knew the species (as *Gnaphalium spicatum* Lam.) from collections from around Wilmington, North Carolina, and from Florida, "in and around Tallahassee, thence westward to Pensacola." Perhaps the earliest collection or one of the earliest was made in 1949 in Wilmington (*Godfrey 49341*, originally identified as *Gnaphalium purpureum*, SMU, NCU), where it was "abundant in vacant lots and weedy places"; it was collected again in Wilmington in 1950 (*Godfrey 50362*, SMU), identified as an "unusual form" of *Gnaphalium purpureum*. The range of *G. coarctata* in the southeastern U.S.A. is now apparently much more continuous than indicated by existing collections (personal observation), suggesting a recent and rapid expansion. The type of *Gnaphalium coarctatum* and its synonym *Gnaphalium spicatum* was described from Uruguay from a collection made in the 1700s (Pruski & Nesom 2004), and it seems likely that the species is native to South America. It is documented as adventive in other parts of the world.

Gamochaeta pensylvanica (Willd.) Cabr. (synonyms: *Gnaphalium spathulatum* Lam. [non Burm. f.], *Gnaphalium peregrinum* Fernald)—Non-native(?): common in the southeastern U.S.A. (nearly restricted to Atlantic Coast and Gulf Coast states); common in eastern South America and throughout the world as a weed. Similar and perhaps related to *G. antillana*, for which the nativity also is uncertain but suggested to be North American and Antillean. On balance, however, it seems likely that *G. pensylvanica* arrived early as an adventive in North America, especially in view of its apparent complete fidelity to ruderal habitats on this continent and its near-cosmopolitan occurrence as a weed. In Willdenow's proposal of the name *Gnaphalium pensylvanicum*, he noted that the 'habitat' was in Virginia and in Pennsylvania, north of its characteristic range in the U.S.A. My guess is that it was collected as a ballast waif in Philadelphia prior to 1809, the year of Willdenow's proposal. The species is shown only in Pennsylvania County by Wherry et al. (1979), who noted that it is "introduced" in the state; it was not included at all in a later summary of the

Pennsylvania flora (e.g., Rhoads & Block 2000). The type of *Gnaphalium spathulatum*, described by Lamarck in 1788, was from plants cultivated at the "Jardin du Roi" in Paris; Lamarck noted that he did not know the origin of the garden plants but that Commerson had found a similar form near Buenos Aires. In his description of *Gnaphalium peregrinum*, Fernald (1943) noted that *G. spathulatum* was a later homonym (non Burm. f. 1768) and probably the same species as *G. peregrinum*, but because of his uncertainty regarding the identity of the plant in the type photo (*G. spathulatum* Lam.), he chose a new type for the new name. Burman's name (Prodromus florae capensis 25. 1768) is validated by citation of a figure in Breyne's Prodromi (tab. 18, fig. 3. 1738) and accompanying legend (p. 29)—it apparently is a species of *Helichrysum*.

Gamochaeta antillana (Urb.) Anderb.—Native(?): common in the southeastern U.S.A., most in coastal states; described from Cuba in 1915, known from most islands of the Antilles, South America, and apparently weedy in other parts of the world. Closely similar to and possibly closely related to *G. stagnalis*.

Gamochaeta stagnalis (I.M. Johnst.) Anderb.—Native(?): common in northern Mexico and reaching southern Arizona and southwestern New Mexico, where it flowers in early spring in desert habitats. Probably closely related to *G. antillana* but different in geography and ecology.

Gamochaeta calviceps (Fern.) Cabr.—Native(?): described in 1935 from Virginia and known mostly from recent collections in eastern North America (states of the Atlantic Coast and Gulf Coast); apparently widespread in South America other parts of the world.

Gamochaeta stachydifolia (Lam.) Cabr.—Non-native: known in North America only from two counties in central California. Native to South America.

ACKNOWLEDGMENTS

I am grateful to Alan Weakley and Carol McCormick for checking locality data of NCU collections and to John Pruski and Susana Freire for reviews. Loans of specimens were studied from ARIZ, ASU, DOV, MO, NMC, and USF. Data also were obtained on visits to MO, NCU, NY, GH, TEX, and US.

ABSTRACT

This article reports the results of a vascular plant inventory of the Washita Battlefield National Historic Site in western Oklahoma. Two hundred and seventy-two species of vascular plants were collected from 201 genera and 62 families. The most specious families were the Poaceae (53), Asteraceae (48), Fabaceae (22) and Euphorbiaceae (22). One hundred and seventy-five species were perennials, ninety-five annuals, and 2 biennials. Twenty-eight woody plant species were present. Twenty-one species exotic to North America were collected representing 7.7% of the flora. Five species tracked by the Oklahoma Natural Heritage Inventory were found. This study reports 205 species previously not documented in Roger Mills County.

ABSTRACT

Este artículo presenta los resultados de un inventario de flora vascular del Washita Battlefield National Historic Site en el Oeste de Oklahoma. Se colectaron doscientas setenta y dos especies de plantas vasculares pertenecientes a 201 géneros y 62 familias. Las familias con más especies fueron Poaceae (53), Asteraceae (48), Fabaceae (22) y Euphorbiaceae (22). Ciento setenta y cinco especies eran perennes, noventa y cinco anuales, y 2 bianuales. Estaban presentes veintiocho especies leñosas. Se colectaron veintiuna especies exóticas para Norte América que representan el 7.7% de la flora. Se encontraron cinco especies seguidas por el Oklahoma Natural Heritage Inventory. Este estudio cita 205 especies no documentadas previamente en el condado de Roger Mills.

INTRODUCTION

The objectives of this study were twofold; to fill a gap in floristic data for western Oklahoma and provide resource managers at the Washita Battlefield National Historic Site (WBNHS) a comprehensive species list. Prior to 2002, when collecting began for this study, 446 specific and intraspecific taxa were reported from Roger Mills County (Hoagland 2004). *Erigeron bellidiastrum* Nutt., collected by J. Engleman on 3 July 1919, was the first botanical specimen gathered in Roger Mills County. There are no subsequent collection records until 1929.

SIDA 21(2): 1187–1197. 2004

Peak collecting years in Roger Mills County were 1939 (261 specimens), with the return of J. Engleman, and 1976 by Susan Barber and Rahmona Thompson (124 specimens) on behalf of the Robert Bebb Herbarium at the University of Oklahoma (Hoagland 2004). During the course of this research, Freeman et al. (2003) published a floristic list from the Thurman Ranch in Roger Mills County, located south of WBNHS, which documented 470 species from 85 families.

Study Area

The WBNHS was established on 12 November 1996 and encompasses 136 hectares in Roger Mills County (Fig. 1). Latitudinal extent ranges from 35.63°N to 35.62°N and longitudinal extent from 99.70°W to 99.71°W. The WBNHS is located within the subtropical humid (Cf) climate zone (Trewartha 1968). Summers are warm (mean July temperature = 27.7°C) and humid, whereas winters are relatively short and mild (mean January temperature = 1.9°C). Mean annual precipitation is 105.6 cm, with periodic severe droughts (Oklahoma Climatological Survey 2004). Physiographically, the study area is located in the Osage Plains section of the Central Lowlands province (Hunt 1974) and within the High Plains province of Oklahoma (Curtis & Ham 1979). Elevation in the study area ranges from 588 m along the Washita River to 610 m. The surface geology is primarily Permian red sandstone in the uplands to the south of the Washita River, and Quaternary silt, sand and clay adjacent to and north of the river (Branson & Johnson 1979). The primary soil association at WBFNHS is the Yahola-Port, which is composed of alluvial soils on bottomlands and terraces. The Woodward-Quinlan association occurs on uplands and is level to very steep loamy soils underlain by red sandstone (Burgess et al. 1959). The predominant potential vegetation types are mixedgrass prairie with a smaller component of bottomland forests and stabilized dunes (Duck & Fletcher 1943). Much of the Washita River bottomlands were cleared for agriculture and pasturage.

METHODS

Eight collection sites were established at WBNHS for intensive floristic sampling. Sites were selected following a review of US Geological Survey 1:24,000 topographic maps and field reconnaissance. The predominant vegetation association at these sites was classified according to Hoagland (2000). Collection effort was not limited to established sites. Collections were made on a monthly basis from March through October 2002. Vouchers for species exotic to North America were made from naturalized populations only, thus excluding cultivated and ornamental plants. Specimens were processed at the Robert Bebb Herbarium of the University of Oklahoma (OKL) following standard herbarium techniques. Manuals used for specimen identification included Correll and Johnston (1970), Gould (1975), Waterfall (1969) and Great Plains Flora Association (1986). Origin, whether native to introduced to North America, was deter-

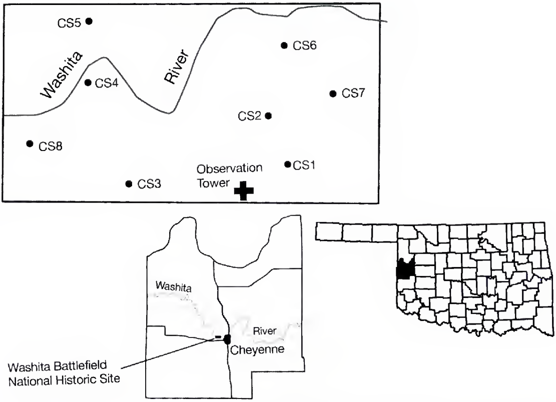

Fig. 1. Location of Washita Battlefield National Historic Site, Roger Mills County, Oklahoma.

mined using Taylor and Taylor (1991) and the United States Department of Agriculture-Natural Resources Conservation Service (USDA-NRCS 2004). The nomenclature used is in concordance with USDA-NRCS (2004). Voucher specimens were deposited at OKL.

RESULTS AND DISCUSSION

A total of 272 vascular plants in 201 genera and 62 families were collected (Table 1). Among the angiosperms, 66 were monocots and 205 were dicots. One gymnosperm was found. The most species were collected from the families Poaceae (53), Asteraceae (48), Fabaceae (22), and Euphorbiaceae (14). The genera *Chamaesyce* (5), *Eragrostis* (4), *Dalea* (4), and *Solanum* (4) had the most species. Ninety-seven species were annual or biennials, and 178 perennial.

Twenty-one exotic species from 14 families were collected, representing 7.7% of the flora. The greatest number of exotic species were in the families Poaceae (11) and Asteraceae (4). This is higher than the 10% exotic flora reported from the Thurman Ranch (Freeman et al. 2002), but is comparable to recent floristic inventories from other areas in Oklahoma. For example, a flora of the Chickasaw National Recreation Area reported 12% exotic species (Hoagland & Johnson

TABLE 1. Summary of floristic collections at the Washita Battlefield National Historic Site, Roger Mills County, Oklahoma. Table format follows Palmer et al. (1995).

Taxonomic Group	Species	Native spp.	Introduced spp.
Equisetophyta	0	0	0
Pteridophyta	0	0	0
Coniferophyta	1	1	0
Magnoliophyta			
Magnoliopsida	205	184	21
Liliopsida	66	56	10
Total	271	240	31

2001), 9% at Oologah Wildlife Management Area (Hoagland & Wallick 2003), 15% at Keystone Wildlife Management Area, and 11% for an inventory of Tillman County (Hoagland et al., in press). However, the percentage was lower, 6.6%, at Red Slough and Grassy Slough in southeastern Oklahoma (Hoagland & Johnson, in press).

Five species tracked by the Oklahoma Natural Heritage Inventory were found: *Argythamnia humilis* (G5S2S3), *Gaura brachycarpa* (G4G5 S1S2), *Solanum triflorum* (G5S1S2), *Sporobolus giganteus* (G5S1S3), and *Zinnia grandiflora* (G5S?). Species are ranked according to level of imperilment at the state (S) and global (G) levels on a scale of 1–5; 1 representing a species that is imperiled and 5 one that is secure (Groves et al, 1995).

As a result of this study, 651 species are now known to occur in Roger Mills County. Of the 361 species reported in this study, 156 had been previously collected in the county (Hoagland 2004). This study documented 205 species not previously reported from Roger Mills County. When compared with the Dempsey Divide site (Freeman et al. 2002), there were 219 species found at both sites. However, 53 species were documented at WBNHS that were not reported at Dempsey Divide. Two hundred and fifty-one additional species were found on the Dempsey Divide that were not found at the WBNHS. The difference in total area of the two sites may account for this discrepancy; the Thurman Ranch is 3,755 hecatres in area and contains 19 vegetation types whereas WABA is only 136 hectares with four vegetation types. (Freeman et al. 2002).

The 8 collection sites occurred within four vegetation associations. A brief description of each follows:

Sapindus saponaria woodland association

This association was limited to large sand dunes located on the northside of the Washita River. Although *S. saponaria* was abundant, dominance was locally variable. *Celtis laevigata* var. *reticulata* was a common woody species in this vegetation association, as was *Ulmus pumila*, a species introduced to western Oklahoma for shelterbelt plantings. Other common woody species included *Forestiera* *pubescens, Gymnocladus dioicus, Prunus angustifolia, Ribes aureum,* and *Sideroxylon lanuginosum.* Associated herbaceous species included *Andropogon hallii, Argemone polyanthemos, Asclepias arenaria, Cyclanthera dissecta, Dimorphocarpa candicans, Froelichia gracilis,* and *Funastrum cynanchoides.*

Schizachyrium scoparium—Bouteloua hirsuta herbaceous association

Occurred on Permian red sandstone in the uplands overlain by the Woodward-Quinlan soil association. Associated species included *Aristida oligantha, Ambrosia psiolstachya, Bouteloua curtipendula, Eriogonum annuum, Penstemon albidus, Sphaeralcea coccinea, Thelesperma megapotamicum,* and *Yucca glauca.*

Disturbed areas and old-field vegetation

This includes much of the Washita River floodplain, which had been under cultivation for many years. It also includes roadsides and areas visited by WBNHS visitors and other areas exhibiting signs of physical disruption. Common plants in disturbed areas and old fields included *Ambrosia trifida, Bothriochloa ischaemum, Chenopodium simplex, Cynodon dactylon, Digitaria ciliaris, Melilotus officinalis,* and *Sorghum halepense.*

APPENDIX 1

Annotated species list for the Washita Battlefield National Historic Site. The first entry indicates life history (**A**=annual, **P**=perennial), species not native to North America (designated with an asterisk), habitat (**DAOF**=disturbed area/old-field; **MGP**=mixed grass prairie; **RA**=riparian area; **SW**=sandy woodland), and collection number. Voucher specimens were deposited at the Robert Bebb Herbarium at the University of Oklahoma (OKL).

PINOPHYTA

Cupressaceae

Juniperus virginiana L.–P; SW; WAS193

MAGNOLIOPHYTA
MAGNOLIOPSIDA

Amaranthaceae

Amaranthus albus L.–A; MGP; WAS322
Amaranthus palmeri S. Wats.–A; DAOF; WAS093
Froelichia gracilis (Hook.) Moq.–A; SW; WAS103

Anacardiaceae

Rhus aromatica L.–P; MGP; WAS230
Rhus glabra L.–P; MGP; WAS044
Toxicodendron radicans (L.) Kuntze–P; RA; WAS183

Apiaceae

Chaerophyllum tainturieri Hook.–A; MGP; WAS222
Cymopterus macrorhizus Buckl.–P; MGP; WAS171

ABSTRACT

This paper reports the occurrence of two species previously unknown to the flora of Oklahoma. *Alternanthera paronichyoides* St. Hil., which occurs in Texas, was discovered in Pushmataha County in southeastern Oklahoma. *Rumex maritimus* L., a species found in all states adjoining Oklahoma, was collected in Washita County in western Oklahoma.

RESUMEN

Este artículo cita la ocurrencia de dos especies previamente desconocidas de la flora de Oklahoma. *Alternanthera paronichyoides* St. Hil., que vive en Texas, fue descubierta en el condado de Pushmataha en el Sureste de Oklahoma. *Rumex maritimus* L., una especie que se encuentra en todos los estados adyacentes de Oklahoma, se colectó en el condado de Washita en el Oeste de Oklahoma.

Alternanthera paronichyoides St. Hil.(Amaranthaceae) is a perennial plant species native to the old world tropics. It has been reported from Texas and several Gulf Coastal Plains and Atlantic Seaboard states (USDA-NRCS 2004). The population reported below was robust and growing in a ditch which drains into the Kiamichi River in southeastern Oklahoma. Associated species included *Arundinaria gigantea* (Walter) Muhl., *Eleocharis obtusa* (Willd.) Schult, and *Symphyotrichum subulatum* (Michx.) Nesom.

Voucher specimen: **OKLAHOMA. Pushmataha Co.:** 4.0 mi W of Rattan on Hwy. 3 at Rattan Landing on the Kiamichi River, T4S, R17E, sec 14, 5 May 2001, *Hoagland and Buthod hugo509* (OKL).

Rumex maritimus L. (Polygonaceae) is a native annual species that has been reported from all states adjoining Oklahoma (USDA-NRCS 2004). It was growing in the drawdown zone of a municipal reservoir. Associated species included *Ammannia coccinea* Rottb., *Cyperus setigerus* Torr. & Hook., *C. squarrosus* L., *Echinochloa crus-galli* (L.) Beauv., *Leptochloa fusca* (L.) Kunth ssp. *fascicularis* (Lam.) N. Snow, *Symphyotrichum subulatum* (Michx.) Nesom.

Voucher specimen: **OKLAHOMA. Washita Co.:** Clinton Lake, ca. 4.4 mi NE of Canute, shoreline habitat, T11N, R19W sec. 16, 23 Aug 2002, *Hoagland and Buthod AB-2867* (OKL).

ABSTRACT

Schoenoplectus hallii (A. Gray) S. Galen Smith, Hall's bulrush, has been discovered in the Lyndon B. Johnson National Grasslands, Wise County, Texas. Previous reports of this species in Texas were based on misidentified specimens, and the current report apparently represents the first record for the state.

RESUMEN

Schoenoplectus hallii (A. Gray) S. Galen Smith, ha sido descubierto en los Lyndon B. Johnson National Grasslands, Wise County, Texas. Las citas Previas de esta especie en Texas estaban basadas en especímenes mal identificados, y la presente cita es aparentemente la primera para el estado.

Schoenoplectus hallii (A. Gray) S. Galen Smith, Hall's bulrush, has been discovered during an extensive floristic survey of the Lyndon B. Johnson National Grasslands (LBJGL), 15.6 km north of Decatur, Wise County, Texas. The LBJGL are managed by the U.S. National Forest Service and comprise numbered "units" scattered throughout much of north-central Wise County. *Schoenoplectus hallii* grows in Unit 66 primarily along the moist sandy-clay margins of three small ponds that merge during periods of high water. The populations are approximately 100 meters apart and comprise about two hundred individuals each.

Specimens of *Schoenoplectus hallii* were collected in May 2003 through April 2004 and their identity was confirmed by Galen Smith of the University of Wisconsin. Earlier reports of the species in Texas (Correll & Johnston 1970; Hatch et al. 1990) and various herbarium vouchers (later correctly annotated) were based on misidentifications of *S. saximontanus* (Fern.) Raynal and *S. erectus* (Poir.) Palla ex Raynal (Schuyler 1969, Smith 1995). Because *S. hallii* had not been confirmed for Texas, it was not included in the recently published Illustrated Flora of North Central Texas (Diggs et al. 1999). Smith (2002) reported the occurrence of the species in Georgia, Illinois, Indiana, Kansas, Kentucky, Massachusetts, Michigan, Missouri, Oklahoma, and Wisconsin.

Schoenoplectus hallii (A. Gray) S. Galen Smith, Novon 5:101. 1995. *Scirpus hallii* A. Gray; *Scirpus supinus* L. var. *hallii* (A. Gray) A. Gray.

Identification of the Texas plants.—The following key to species of *Schoenoplectus* sect. *Supini* in Texas is modified from Smith (2002). *Schoenoplectus hallii* found elsewhere are usually annual, but in Texas many perennial plants have been observed.

1. Achenes in spikelets nearly equilaterally sharply trigonous; styles all 3-fid; from panhandle to central and far south Texas ____ **Schoenoplectus saximontanus**
1. Achenes in spikelets biconcave to plano-convex or obscurely compressed-trigonous; styles 2-fid or a few 3-fid.
   2. Achenes adaxially longitudinally convex or horizontally slightly convex with convex center; spikelet scale flanks often distally orange- or red-brown; in Texas known only from south coastal counties inland to Atascosa Co. ____ **Schoenoplectus erectus**
   2. Achenes adaxially concave or sometimes nearly plane; spikelet scale flanks pale orange to nearly colorless; known from one site in north central Texas ____ **Schoenoplectus hallii**

Habitat of the Texas plants.—*Schoenoplectus hallii* has a narrow habitat tolerance (Beatty et al. 2004). Although it is found in various soil types in other states, in Texas it is found along widely fluctuating margins of small sandy clay ponds where conditions apparently are more suitable for *S. hallii* than for many of its associates (Schuyler 1969). Many plant species occur with *S. hallii* in Texas (Table 1). These associates appear and disappear throughout the year as water levels fluctuate, but *S. hallii* can be found along pond margins from April to December. It is most closely associated nearly year-round with the rare *Pilularia americana* (Marsiliaceae). During periods of normal water levels *P. americana*

TABLE 1. Species associated with *Schoenoplectus hallii* in Texas, ranked by abundance.

Pilularia americana A. Braun
Eleocharis obtusa (Willd.) J.A. Schultes
Rotala ramosior (L.) Koehne
Cyperus acuminatus Torr. & Hook. ex Torr.
Fimbristylis vahlii (Lam.) Link
Ludwigia peploides (Kunth) Raven
Ammannia coccinea Rottb.
Eleocharis palustris (L.) Roem. & Schult.
Fuirena simplex Vahl
Eleocharis quadrangulata (Michx.) Roem.
Lindernia dubia (L.) Pennell var. *anagallidea* (Michx.) Cooperrider
Eleocharis coloradoensis (Britt.) Gilly
Callitriche heterophylla Pursh
Ammannia robusta Heer & Regel
Eleocharis engelmannii Steud
Najas guadalupensis (Spreng.) Magnus
Veronica peregrina L. var. *xalapensis* (Kunth) Pennell
Ludwigia glandulosa Walter
Heteranthera limosa (Sw.) Willd.
Eleocharis atropurpurea (Retz.) J.& K. Presl
Potamogeton diversifolius Raf.
Cyperus retrorsus Chapm. var. *cylindricus* (Ell.) Fern. & Grisc.
Cyperus squarrosus L.
Panicum rigidulum Nees
Juncus texanus (Engelm.) Coville
Echinodorus berteroi (Spreng.) Fassett
Juncus diffusissimus Buckl.
Spirodela polyrhiza (L.) Scheid.
Limnosciadium pinnatum (DC.) Mathias & Constance
Anagallis minima (L.) Krause
Marsilea vestita Hook. & Grev

is a submergent and can be conspicuous just below the surface around the entire margin of the pond. However, during periods of extended drawdown it becomes a marginal plant. The ponds occur in the West Cross Timbers of north central Texas at an elevation of 254 meters.

During the first year of our LBJGL survey, twelve other species undocumented for Texas, in addition to *S. hallii*, were discovered (O'Kennon et al. 2003; O'Kennon & McLemore in prep.). We believe that this probably reflects previous undercollecting rather than particularly unique habitats in this area.

Overall distribution.—*Schoenoplectus hallii* is a globally threatened species (Nature Conservancy ranking of G-2) known recently from only 8 states and fewer than 100 sites in the U.S.A. Texas Parks and Wildlife Department has assigned a ranking of S-1 (critically imperiled) for the species (Jackie Poole, pers. comm.), based on the discovery in Wise County. The closest populations of *S. hallii* to the Wise Co. populations are in Comanche Co., Oklahoma, about 190 kilometers northwest.

Prior to 1973, *Schoenoplectus hallii* was reported in 9 states, 15 counties, and 29 sites. During 1973–1997, it was reported in 8 states, 17 counties, and 46 sites. During 1993–1997, it was reported in only 6 states, 11 counties, and 37 sites (McKenzie 1998). Since not all sites are being monitored each year, it is difficult to ascertain the actual number of existing populations.

Plants in Massachusetts have not been seen since 1931 and are considered extirpated. *Schoenoplectus hallii* has not been collected in Georgia since 1966. It has not been confirmed in Iowa since 1890. There is a record from Iowa from 1960, but that specimen has not been seen nor confirmed (McKenzie 1998). Populations in these states are considered "possibly extirpated."

ACKNOWLEDGMENTS

We thank Guy Nesom of BRIT for assistance in identifying the original specimens and reviewing the manuscript. We gratefully acknowledge Galen Smith of the University of Wisconsin for assistance in confirming the identity of this plant. We thank James Crooks, Jimmy Dickerson, and Alfred Sanchez of the Lyndon B. Johnson National Grasslands and the U.S. Forest Service for assistance and cooperation in our work on this threatened species and for preserving the site.

ABSTRACT

Pseudognaphalium jaliscense is first reported from Nebraska, documented here from twelve counties; an earlier report of this species from California was based on collections of a form of *P. stramineum*. *Pseudognaphalium roseum* is first documented as occurring in the U.S.A., where it has been collected in southern California.

RESUMEN

Pseudognaphalium jaliscense se cita por primera vez de Nebraska, se documenta aquí de doce condados; una cita previa de esta especies de California estaba basada en colecciones de una forma de *P. stramineum*. *Pseudognaphalium roseum* se documenta por primera vez de U.S.A., donde ha sido colectado en el Sur de California.

In connection with taxonomic studies of Gnaphalieae, preparation of treatments for the Flora of North America volumes of Asteraceae, and floristic studies in Nebraska, we report new distribution records for two species of *Pseudognaphalium* Kirp.

Pseudognaphalium jaliscense in Nebraska

Pseudognaphalium jaliscense (Greenm.) Anderb. was recently reported for the U.S.A., based on collections from Arizona, New Mexico, Texas, and Colorado (Nesom 2001, including details of typification and description). The current report documents its occurrence in twelve counties of Nebraska. It was first collected in the state in 1968 by Steve Stephens (Custer Co.) but was not recollected until 1991 by Herb Karcher (Hayes Co.). It has since been recollected in both counties in addition to numerous other sites in the southwest and the Nebraska Sandhills in the north central part of the state. The recency of the collections and the common roadside habitat suggest recent introduction, but other collections are from apparently natural habitats, and the nativity of *P. jaliscense* in Nebraska is not clear.

Distribution of the species is shown in Figure 1 for northwestern Mexico and the U.S.A., based on the Nebraska citations below and those in Nesom (2001). Additional records for New Mexico also are cited below and suggest that the species may be even more common in that state, where habitats do not suggest that the species is a recent colonizer. If the distribution of *Pseudognaphalium*

SIDA 21(2):1205–1208. 2004

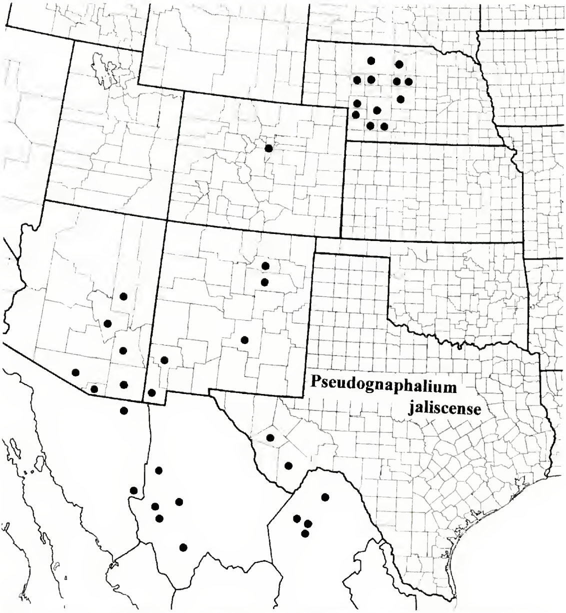

FIG. 1. Distribution of *Pseudognaphalium jaliscense* in the U.S.A. and northwestern Mexico. The species ranges further southward into Jalisco, Nayarit, and Aguascalientes, and localities in south-central Nuevo León are not shown. The records for Mexico are from collections studied by Nesom from various herbaria.

jaliscense is native in the U.S.A., it apparently should be expected in counties of northeastern Colorado and northwestern Kansas.

With further perspective, collections reported as *Pseudognaphalium jaliscense* from Mendocino, Marin, and Del Norte counties, California (Nesom 2001), prove to be the form of *Pseudognaphalium stramineum* (Kunth) A. Anderb. sometimes identified as *Gnaphalium stramineum* var. *confertifolium* Greene. These plants have larger heads with more numerous, more opaque phyllaries and often more florets than typical *P. stramineum*, which is abundant in California.

Pseudognaphalium roseum in California

Pseudognaphalium roseum (Kunth) A. Anderb. is widespread in Central America and Mexico, from Panama northward through Chiapas to Chihuahua, Veracruz, Nuevo Leon, Tamaulipas, and southeastern Coahuila. It occurs mostly above 1000 m elevation in a variety of habitats. The closest collections of *P. roseum* southward from California are from Sinaloa and southern Chihuahua, but the species is abundant only in eastern and southern Mexico. It is recognized by its persistently tomentose stems and leaves, the leaves subclasping and non-decurrent, weakly bicolored and sessile-glandular beneath the tomentum, often thick stems, large capitula with numerous, opaque-white or sometimes pink phyllaries, numerous florets, and smooth-surfaced cypselae. It has been confused with the smaller-headed *P. canescens* (DC.) A. Anderb., but plants of *P. roseum* with relatively few bisexual florets can be distinguished from *P. canescens* by their subclasping leaves commonly with closely wavy margins, broader and more numerous phyllaries, and smooth-surfaced cypselae. A key with diagnostic characters for these taxa is provided below. Collections of *P. roseum* cited from San Mateo Co. and Santa Barbara Co. may be atypical in their slightly smaller capitula.

U.S.A. CALIFORNIA. Orange Co.: Catalina Island, 16 Jun 1920, *Fisher s.n* (SMU). **San Diego Co.:** Border Field State Park, southwesternmost acre of continental U.S.A., 16 Mar 1989, *Turner 15925* (TEX); Tia Juana, 24 Apr 1913, *Eastwood 2918* (GH). **San Mateo Co.:** Pebble Beach, Pescadero, 29 June 1927, *Wolf 563* (TEX). **Santa Barbara Co.:** Purissima Canyon, 26 Mar 1925, *Munz 4737* (TEX). **Ventura Co.:** North Signal Street, Ojai, 8 Oct 1946, *Pollard 20331* (SMU).

a. Mid-cauline leaves mostly 3–7 cm long, (3–)6–15(–20) mm wide, subclasping, the margins often closely sinuate-wavy; pistillate florets 45–90(–110); bisexual florets (5–)6–12(–18); cypsela surfaces smooth (non papillate) _______ **Pseudognaphalium roseum**

a. Mid-cauline leaves mostly 1–4 cm long, 2–8(–15) mm wide, not clasping, the margins usually straight; pistillate florets (16–)24–44; bisexual florets (1–)2–5(–6); cypsela surfaces densely and minutely papillate _______________ **Pseudognaphalium canescens**

Pseudognaphalium roseum (Kunth) A. Anderb., Opera Bot. 104:148. 1991. *Gnaphalium roseum* Kunth in H.B.K., Nov. Gen. & Sp. 4 [folio]:63. 1818; 4 [quarto]:81. 1820. TYPE: MEXICO. GUANAJUATO: *Humboldt and Bonpland s.n.* (HOLOTYPE: P fiche!).

Taprooted annual to short-lived perennial herbs, the stems 5–20 dm tall, persistently woolly-tomentose. Leaves oblong-lanceolate to oblanceolate, the mid-cauline 3–7 cm long, (3–)6–15(–20) mm wide, subclasping to clasping but not basally ampliate, not decurrent, the margins often closely sinuate-wavy, persistently woolly-tomentose or sometimes tardily glabrescent above, with short-stipitate to sessile glands beneath the tomentum. Involucres 4–4.5 mm high; phyllaries ovate, in 5–6 graduate series, usually opaque-white but sometimes pink. Pistillate florets 45–90(–110). Bisexual florets (5–)6–12(–18), the corollas often pink on the lower half. Cypselae shallowly longitudinally ridged, smooth.

ACKNOWLEDGMENTS

We gratefully acknowledge loans from UNM, the staff at TEX for helps in visits there, staff at NEB and KANU for confirming collection data for specimens deposited there, and Caleb Morse for a review of the manuscript.

ABSTRACT

An unknown plant collected in 1998 at Fort Pulaski, Chatham County, Georgia has been identified as *Hybanthus parviflorus* (Violaceae), a South American native. The Georgia collection represents only the third report of this species in North America, and the first since the 1880s, when it was collected on ship's ballast at two port cities in New Jersey. It is possible that the introduction of the species to Georgia was also via ship's ballast, as Fort Pulaski would have been a port of call for ships going to and from Savannah, a major seaport in the 18th and 19th centuries; if the Georgia plant was introduced on ballast, it is apparently established. It is also possible that it is a more recent introduction; if so, however, the means of introduction of this species is obscure, as it is not typically an agricultural weed, nor of horticultural interest. The use of digital imagery and electronic mail facilitated the rapid and accurate identification of this alien species, which should now be considered an established, though rare, component of the North American flora.

RESUMEN

Una planta desconocida colectada en 1998 en Fort Pulaski, Chatham County, Georgia ha sido identificada como *Hybanthus parviflorus* (Violaceae), nativa de Sur América. La colección de Georgia es la tercera cita de esta especie en Norte América, y la primera desde los 1880s, cuando fue colectada en lastre de barcos en dos ciudades portuarias de New Jersey. Es posible que la introducción de la especie en Georgia haya sido también mediante lastre de barco, ya que Fort Pulaski podría haber sido un Puerto de llamada para barcos que van o regresan de Savannah, un gran puerto en los siglos XVIII y XIX; si la planta de Georgia fue introducida en el lastre, está aparentemente establecida. Es también posible que sea una introducción más reciente; en este caso, sin embargo, el sistema de introducción de esta especie no está claro, ya que típicamente no es una mala hierba agrícola, ni de interés hortícola. El uso de imágenes digitales y correo electrónico facilitó la identificación rápida y precisa de esta especie invasora, que podría ahora ser considerada como un componente establecido, aunque raro, de la flora de Norte América.

The University of Tennessee Herbarium (TENN) recently received a loan of selected *Gratiola* (Scrophulariaceae) from the University of Georgia Herbarium

(GA). Included within the loan were a few unidentified specimens of either unrequested *Gratiola* or the closely related *Lindernia*, and an undetermined specimen (Figs. 1, 2) collected by Govus (1998) from Ft. Pulaski National Monument, Chatham Co., Georgia, as part of a catalog of the vascular flora of that U.S. National Park Service unit (Govus 1998). At GA, this last specimen had been tentatively identified by an unknown individual as *Gratiola virginiana*, and then that identification had been crossed through, but the specimen was apparently left in a *Gratiola* folder and sent out with the *Gratiola* loan to TENN. Upon receipt of the loan at TENN, Wofford immediately eliminated this specimen as a member of Scrophulariaceae based on overall morphology. A few flowers were rehydrated and upon dissection its floral morphology unequivocally placed it in Violaceae, i.e., flowers zygomorphic, sepals 5, subequal, petals 5, unequal, the lower one slightly spurred at the base and wider than the others; stamens 5, the lower two provided with nectariferous appendages, the connective prolonged into a membranous appendage; ovary superior, unilocular, 3-valved, placentation parietal.

TENN houses only two genera of Violaceae (*Viola* and *Hybanthus*); this specimen obviously was not a *Viola* but the flowers were strikingly similar to the common eastern North American *Hybanthus concolor* (T.F. Forst.) Spreng. and the southwestern North American *H. verticillatus* (Ortega) Baill. Wofford developed the hypothesis that this might be an introduction of an extracontinental species of *Hybanthus*, a pantropical genus (extending into warm temperate areas, as in eastern North America) of about 85 species (Ballard, in press), though sometimes credited with as many as 150 species (Mabberley 1997). Additional specimens from Mexico and Cuba available at TENN were examined, but none remotely fit the overall morphology of this specimen.

Digital images of the unknown plant were then sent to Weakley at the University of North Carolina Herbarium (NCU). Two NCU specimens of *Hybanthus* (from Paraguay and Argentina) closely resembled the unknown from Georgia; unfortunately, both specimens were labeled only "*Hybanthus*" and lacked an identification to the species level.

Finally, an electronic image of the Georgia specimen was sent to Paula-Souza, who has research interests in Violaceae, especially *Hybanthus*. She immediately responded that "this plant is *Hybanthus parviflorus* (Mutis ex L.f.) Baill. This is a very common plant here in South America, and although it is considered a weed in some places, I have never seen a record of it from the United States."

Further investigation revealed that *H. parviflorus* had indeed been reported previously from North America, by Dowell (1906), as *Calceolaria glutinosa* (Vent.) Kuntze, based on several specimens collected "on ballast at Communipaw Ferry," New Jersey, in July and September 1880 (see specimens cited below). *H. parviflorus* is additionally represented by a specimen at the Academy of Natural Sciences in Philadelphia (PH), identified as *Ionidium glutinosum* Vent.

Fig. 1. Image of Govus collection of *Hybanthus parviflorus* from Fort Pulaski, Georgia. Photograph by Gene Wofford.

Fig. 2. Closeup of portion of Govus collection of *Hybanthus parviflorus* from Fort Pulaski, Georgia. Photograph by Gene Wofford.

and labeled "Herbarium of Isaac Burk, Philadelphia; Pa., on ballast, Kaigns Pt., N.J., October 1885." However, catalogs of the flora of New Jersey (Britton 1889), and the various manuals covering the Northeastern United States (Fernald 1950; Gleason 1952; Gleason & Cronquist 1991) do not include this taxon, presumably considering it a ballast waif, and it is also not included in the recent checklist of the Flora of North America (Kartesz 1999).

Hybanthus parviflorus is widely distributed over South America, from Venezuela through southern Brazil (Figs. 3, 4), Chile, and Argentina, occurring preferentially in cold regions and at higher altitude places in warmer regions. The species is commonly found in open sites, frequently behaving as a weed in pastures and roadsides, though not as a weed of cultivated crops. The 1880 New Jersey specimens came from ship's ballast, at the ferry landing of the Communipaw Ferry, one of several busy ferries between Jersey City and New York City. The 1885 specimen also came from ballast, at Kaighn's Point on the Delaware River in Camden, also a busy ferry landing serving Camden, New Jersey and Philadelphia, Pennsylvania, in operation from 1806 until at least 1926. It seems plausible that *H. parviflorus* was introduced to Fort Pulaski, Georgia, via ballast as well. Fort Pulaski has been actively used by ships since at least the mid 1700s, and would have been a regular docking area for sailing ships through much of the late 18th and early 19th centuries, including use by ships going to and from the large and active port city of Savannah, Georgia (ca. 20 miles away) to destinations around the world. If *H. parviflorus* were introduced to Georgia on ballast, it is apparently established, as the 1998 collection is long after the use of solid ballast material was discontinued. It is also possible that this represents a more recent introduction, but how and why this species would have arrived at Fort Pulaski is obscure, as the species in neither typically a weed of agricultural crops nor an object of horticultural interest.

Fig. 3. Habit of *Hybanthus parviflorus*. Photograph by Juliana de Paula-Souza, from live material in Itararé, São Paulo, Brazil.

Given this more recent occurrence of *H. parviflorus*, found 118 years after its initial collection in North America, it appears that *H. parviflorus* should be considered a rare, alien component of the North American flora, and collectors should be aware of its potential occurrence, especially in the vicinity of old seaports. It does not appear, at least at this time, that it is likely to be an aggres-

Fig. 4. Detail of flower of *Hybanthus parviflorus*. Photograph by Juliana de Paula-Souza from live material in Itararé, São Paulo, Brazil.

sive alien weed. Below, we present a description to aid in its recognition, should it occur elsewhere in North America. We also note that the increased use of digital imagery and electronic mail in herbarium work greatly facilitates international collaboration and the identification of an unknown, extracontinental, and potentially invasive species; "virtual annotation" can provide rapid results without the expense and risk of loaning uniquely valuable specimens.

Hybanthus parviflorus (Mutis ex L.f.) Baill., Bot. Med. 2:841. 1884.

Herbs up to 30 cm high, branched, erect or suberect, internodes (1.7–)4–20 mm long; leaves alternate or opposite, frequently opposite only at the base of the branches, petiole ca. 0.5–4 mm long, blade (3.5–)6–30 mm long × 2–10(–15) mm wide, elliptic, lanceolate or oblong, less frequently oblanceolate, widely elliptic, ovate or obovate, acute to obtuse at apex, margin serrate, base acute, attenuate, rounded or obtuse, glabrous to pubescent or puberulent on the midrib; stipules narrowly lanceolate; flowers white, frequently with purplish lines on the anterior petal, solitary, axillary or arranged in poorly defined racemose inflorescences; floral pedicel 3–11(–24) mm long, bracteoles absent; sepals equal or subequal, ca. 1–1.7 mm long × ca. 0.5 mm wide, narrowly lanceolate or rarely ovate to suborbicular, subfalcate, acuminate or rarely round or obtuse at apex, margin entire; posterior petals ca. 1 mm wide × ca. 0.5 mm long, oblong, lateral petals ca. 1.5–1.8 mm long × ca. 0.7 mm wide, oblong to lanceolate, falcate, anterior petal (1.5–)3–3.7 mm long × 1.2–1.4 mm wide, clawed; stamens subsessile, anthers ca. 0.5 mm long, connective appendages orange-brown, ca. 0.3 mm long, frequently asymmetric, anterior stamens provided with noduliform nectariferous appendages; style 0.6–0.8 mm long, straight or subsigmoid, ovary ca. 0.6 mm long, glabrous, capsule 3–4 mm long × 3.5 mm wide, ovoid to globose, seeds ca. 1.5 mm long × ca. 1–1.2 mm wide.

Voucher specimens: **GEORGIA. Chatham Co.**: growing in grassy area along road near the picnic area, south central Cockspur Island, 7 Apr 1998, *Govus 946* (GA!). **NEW JERSEY. Camden Co.**: on ballast, Kaigns Pt., N.J., Oct 1885, *Isaac Burk s.n* (PH!). **Hudson Co.**: ballast, near Communipaw Ferry, N.J., Sep 1880, *Addison Brown s.n.* (GH!, NY!, US!), Communipaw, N.J. (ballast), 20 Jul 1880, *Jos. Schrenk s.n.* (NY!).

ACKNOWLEDGMENTS

We thank the curators of GA, GH, NY, PH, and US for access to collections. We thank Harvey Ballard for pointing out the existence of the 1885 PH collection, and Harvey Ballard and Julie Ballenger for helpful reviews of the manuscript.

ASTERACEAE FROM WOOL MILL SITES IN SOUTH CAROLINA, INCLUDING NEW RECORDS FOR NORTH AMERICA

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

ABSTRACT

Documentation is given for 73 taxa of Asteraceae collected in 1957–1960 from wool mill sites in Berkeley County and Florence County, South Carolina. Twenty-eight (28) of these taxa are first reports for the flora of South Carolina; seventeen (17) others represent the first documentation for earlier reports for the state. Six (6) are first reports for North America: *Chevreulia sarmentosa*, *Gamochaeta argentina*, and *Panphalea heterophylla* (native to South America), and *Peripleura arida*, *Stuartina hamata*, and *Vittadinia sulcata* (native to Australia). *Calotis cuneifolia* (native to Australia) is reported for North America for the second time. Fifty-nine (59) of the 73 taxa are not native to South Carolina; of these, 29 are native to continents other than North America, while 30 are native to North America but from regions outside of the state.

RESUMEN

Se ofrece documentación de 73 taxa de Asteraceae colectados en el intervalo 1957–1960 en los condados de Berkeley y Florence County, Carolina del Sur. Veintiocho (28) de estos taxa son primeras citas para la flora de Carolina del Sur; otros diez y siete (17) representan los primeros testigos para citas previas en el estado. Seis (6) son primeras citas para Norte América: *Chevreulia sarmentosa*, *Gamochaeta argentina*, and *Panphalea heterophylla* (nativa de Sur América), y *Peripleura arida*, *Stuartina hamata*, y *Vittadinia sulcata* (nativa de Australia). *Calotis cuneifolia* (nativa de Australia) se cita para Norte América por segunda vez. Cincuenta y nueve (59) de los 73 taxa no son nativos de Carolina del Sur; de estos, 29 son nativos de otros continentes diferentes de Norte América, mientras que 30 son nativos de Norte América pero de regiones fuera del estado.

In the years 1957 through 1960, as part of the Flora of the Carolinas project and working from the University of North Carolina-Chapel Hill herbarium, Harry Ahles and companion John Haesloop made repeated collecting trips to two 'wool combing mills' in South Carolina. One of these was in Jamestown in Berkeley Co., the other north of Johnsonville in Florence Co.; both sites are located on the coastal plain, 40–50 kilometers from the coast and about 60 kilometers from each other. Some of the collections were identified and incorporated into the general collections at NCU several decades ago; others were mounted but were not identified or inserted into the general collections until 2001. Only a few of these were included in the account of the Flora of the Carolinas (Radford et al. 1968). Some have been the basis of recent reports (without documentation) for distribution records (Kartesz 1999 and others).

SIDA 21(2): 1215–1223. 2004

The wool combing mills received raw fleece and processed it toward production of clean wool for spinning. Early stages in the process are mechanical shaking (removes dirt and some plant matter), "scouring" (removes chemical substances and sand), and "combing" (removes finer plant material as well as shorter, weaker fibers). Waste from these processes at the South Carolina mills was the source of propagules for species collected by Ahles and Haesloop. Delivery of the raw wool probably was by railroad, because both of the sites are along the CSX Railroad, which runs roughly parallel to the coast. Both mills apparently are still in operation.

Seventy-three taxa (73) of Asteraceae in 54 genera are represented in the collections identified here. Twenty-eight (28) of these are first reports for the flora of South Carolina; seventeen (17) others represent the first documentation for earlier reports for the state. Six (6) are first reports for North America: *Chevreulia sarmentosa*, *Gamochaeta argentina*, and *Panphalea heterophylla* are native to South America; *Peripleura arida*, *Stuartina hamata*, and *Vittadinia sulcata* are native to Australia. *Calotis cuneifolia* (native to Australia) is reported for North America for the second time. Fifty-nine (59) of the species are not native to South Carolina; of these, 29 are native to continents other than North America, while 30 are native to North America but from regions outside of the state.

It would be useful to reinvestigate the status of these taxa in South Carolina, in order to determine which have persisted or increased their distribution. A number of the taxa reported here may have the potential to spread and become damaging weeds, or they may simply be waifs (sensu Nesom 2000).

Collections by Ahles and Haesloop were made in 1957 (April, May, July, September, October), 1958 (April, May, June, July, September), 1959 (May, July), and 1960 (May, July). From each of the two wool mill sites, collections were provided with essentially the same label data, except for the collection number and date.

SOUTH CAROLINA. Berkeley Co.: waste ground around Santee Wool Combing Mill, Jamestown on S.C. Rte. 45, [**Apr–Oct 1957–1960**], *H.E. Ahles* [**collection number**] with J.G. Haesloop.

SOUTH CAROLINA. Florence Co.: waste ground around the Wellman Wool Combing Mill, north of Johnsonville on S.C. Rte. 41, [**Apr–Oct 1957–1960**], *H.E. Ahles* [**collection number**] with J.G. Haesloop.

PLANT LIST

The genera and species are arranged alphabetically. If more than one collection was made for a single species, the citations are arranged chronologically. Vouchers are located at NCU, unless otherwise indicated.

Achillea millefolium L.
Berkeley Co.: 13 Jun 1958, *Ahles 42939*
Berkeley Co.: 27 May 1959, *Ahles 52717*
Native to western Asia, widely naturalized in the U.S.A.; previously known from South Carolina (Radford et al. 1968).

Amblyolepis setigera DC.
Berkeley Co.: 8 Apr 1957, *Ahles 22614*

Native to Texas and Mexico; first report for South Carolina.

Ambrosia artemisiifolia L.
Berkeley Co.: 27 May 1959, *Ahles 52805*
Native to North America and widely distributed; previously known from South Carolina (Radford et al. 1968).

Amphiachyris dracunculoides (DC.) Nutt.
Berkeley Co.: 28 Sep 1957, *Ahles 35585*
Berkeley Co.: 30 Oct 1957, *Ahles 38195*
Berkeley Co.: 22 Sep 1958, *Ahles 49216*
Native to the south-central U.S.A. as far east as Alabama and Tennessee; reported for South Carolina by Kartesz (1999), documented here.

Anthemis cotula L.
Berkeley Co.: 20 May 1957, *Ahles 25827*
Florence Co.: 28 May 1957, *Ahles 26690*
Berkeley Co.: 27 May 1959, *Ahles 52797*
Florence Co.: 11 Jul 1960, *Ahles 53756*
Native to Europe and Asia, widely naturalized in the U.S.A.; previously known from South Carolina (Radford et al. 1968).

Arctium minus Bernh.
Berkeley Co.: 11 Jul 1960, *Ahles 53824*
Native to Europe, widely naturalized in the U.S.A.; previously known from South Carolina (Radford et al. 1968).

Artemisia annua L.
Berkeley Co.: 11 Jul 1960, *Ahles 53848*
Native to eastern Europe and Asia, naturalized in various states of the USA; first report for South Carolina.

Artemisia biennis Willd. var. **biennis**
Berkeley Co.: 20 May 1957, *Ahles 25897*
Berkeley Co.: 27 May 1959, *Ahles 52762*
Berkeley Co.: 11 Jul 1960, *Ahles 53814*
Native to western and northern U.S.A. and Canada; first report for South Carolina.

Artemisia vulgaris L. var. **vulgaris**
Berkeley Co.: 25 May 1960, *Ahles 53402*
Berkeley Co.: 25 May 1960, *Ahles 53403*
Native to Europe and Asia, widely naturalized in Canada and the eastern U.S.A.; previously known from South Carolina (Radford et al. 1968).

Bidens bipinnata L.
Berkeley Co.: 20 May 1957, *Ahles 25836* (NCU, SMU)
Berkeley Co.: 14 May 1958, *Ahles 40488*
Native to the southern and eastern U.S.A. and Mexico; previously known from South Carolina (Radford et al. 1968).

Bidens pilosa L.
Florence Co.: 14 May 1958 *Ahles 40446*
Florence Co.: 30 Oct 1957, *Ahles 38153*
Florence Co.: 28 May 1957, *Ahles 26699*
Florence Co.: 22 Sep 1958, *Ahles 49139*
Native to Mexico and Central America, naturalized in the southwestern and southeastern U.S.A. and a few other states; previously known from South Carolina (Radford et al. 1968).

Bidens polylepis Blake
Berkeley Co.: 5 Jul 1957, *Ahles 30809*
Native to the eastern U.S.A.; previously known from South Carolina (Radford et al. 1968).

Bidens frondosa L.
Berkeley Co.: 22 Sep 1958, *Ahles 49204*
Native and widespread in North America; previously known from South Carolina (Radford et al. 1968).

Calotis cuneifolia R. Br.
Berkeley Co.: 8 Apr 1957, *Ahles 22537*
Berkeley Co.: 14 May 1958, *Ahles 40564*
Berkeley Co.: 13 Jun 1958, *Ahles 42935, 42973*
Native to Australia, reported in the U.S.A. only for Massachussetts (Sorrie 1992); first report for South Carolina.

Carduus pycnocephalus L.
Berkeley Co.: 8 Apr 1957, *Ahles 22550*
Native to northern Africa and western Asia, naturalized in scattered states of western and Gulf coast U.S.A.; reported for South Carolina by Kartesz (1999), documented here.

Carthamus baeticus (Boiss. & Reut.) Lara (syn = *Carthamus lanatus* L. subsp. *baeticus* (Boiss. & Reut.) Nyman
Berkeley Co.: 13 Jun 1958, *Ahles 42899*
Berkeley Co.: 27 May 1959, *Ahles 52774* (det. D.J. Keil 1997)
Berkeley Co.: 27 May 1959, *Ahles 52854*
Berkeley Co.: 25 May 1960, *Ahles 53372*
Native to southern Europe and northern Africa,

naturalized in scattered states, mostly along the Pacific coast; reported for South Carolina by Kartesz (1999), documented here.

Centaurea americana Nutt.
Berkeley Co.: 27 May 1959, *Ahles 52776*
Berkeley Co.: 27 May 1959, *Ahles 52843*
Berkeley Co.: 25 May 1960, *Ahles 53492*
Native primarily to the central U.S.A.; reported for South Carolina by Kartesz (1999), documented here.

Centaurea melitensis L.
Berkeley Co.: 8 Apr 1957, *Ahles 22624*
Berkeley Co.: 14 May 1958, *Ahles 40542* (det. L. Shinners)
Berkeley Co.: 13 Jun 1958, *Ahles 42919*
Native to southern Europe and northern Africa, naturalized in the western U.S.A. and various other states; reported for South Carolina by Cronquist (1980), documented here.

Centaurea solstitialis L.
Berkeley Co.: 25 May 1960, *Ahles 53487*
Berkeley Co.: 11 Jul 1960, *Ahles 53846* (det. L. Shinners)
Native to western Asia and the Mediterranean region of Europe, naturalized and weedy in most of the U.S.A.; reported for South Carolina by Hill and Horn (1997).

Chaetopappa asteroides (Nutt.) DC. var. **asteroides**
Berkeley Co.: 8 Apr 1957, *Ahles 22551*
Native to northern Mexico and the south-central U.S.A.; first report for South Carolina.

Chevreulia sarmentosa (Pers.) Blake
Berkeley Co.: 14 May 1958, *Ahles 40509*
Native to South America (Brazil, Paraguay, Uruguay, Bolivia, Argentina); first report for the U.S.A. and South Carolina.

Conyza bonariensis (L.) Cronq.
Berkeley Co.: 14 May 1958, *Ahles 40568*
Berkeley Co.: 21 Jul 1958, *Ahles 46996*
Native to South America, naturalized in most southern states of the U.S.A.; previously known from South Carolina (Radford et al. 1968).

Coreopsis tinctoria Nutt. var. **tinctoria**
Berkeley Co.: 27 May 1959, *Ahles 52825*
Berkeley Co.: 11 Jul 1960, *Ahles 53822*
Native and widespread in North America; previously known from South Carolina (Radford et al. 1968).

Coreopsis verticillata L.
Berkeley Co.: 13 Jun 1958, *Ahles 42900*
Native to the southern U.S.A.; previously known from South Carolina (Radford et al. 1968).

Cotula australis (Sieber) Hook. f.
Berkeley Co.: 8 Apr 1957, *Ahles 22592*
Native to Australia and New Zealand; naturalized in various western U.S.A. states and Florida; first report for South Carolina.

Dittrichia graveolens (L.) W. Greuter
Berkeley Co.: 28 Sep 1957, *Ahles 35595*
Native to the Mediterranean region, naturalized in various regions, including Australia, New Zealand, and California (Preston 1997), and reported from various other localities in the U.S.A. (Gleason & Cronquist 1991; Mitchell & Tucker 1997; Preston 1997; Tucker 1995); first report for South Carolina. In view of the other species reported here from Australia, it seems likely that the wool mill plants of *Dittrichia graveolens* also originated from there rather than from the native region of the species.

Dracopis amplexicaulis (Vahl) Cass.
Berkeley Co.: 20 May 1957, *Ahles 25840*
Berkeley Co.: 25 May 1960, *Ahles 53369*
Native primarily to the south-central U.S.A.; reported for South Carolina by Kartesz (1999), documented here.

Dyssodia papposa (Vent.) A.S. Hitchc.
Berkeley Co.: 8 Apr 1957, *Ahles 22620*
Berkeley Co.: 20 May 1957, *Ahles 25892*
Berkeley Co.: 14 May 1958, *Ahles 40483*
Berkeley Co.: 14 May 1958, *Ahles 40553*
Native to the southwestern and central U.S.A.; first report for South Carolina.

Eupatorium dubium Willd.
Berkeley Co.: 15 Jul 1959, *Ahles 52950*
Native to Atlantic coast states of the U.S.A., from South Carolina northward; previously known from South Carolina (Radford et al. 1968).

Evax multicaulis DC.
Berkeley Co.: 8 Apr 1957, *Ahles 22591*
Berkeley Co.: 14 May 1958, *Ahles 40511*

Native to Mexico and various states of the southern U.S.A.; reported for South Carolina by Cronquist (1980), documented here.

Evax prolifera Nutt. ex DC.
Berkeley Co.: 14 May 1958, *Ahles 40512, 40513*
Berkeley Co.: 27 May 1959, *Ahles 52737*
Native to Mexico and various states of the Great Plains and southern U.S.A.; first report for South Carolina.

Facelis retusa (Lam.) Schultz-Bip.
Berkeley Co.: 27 May 1959, *Ahles 52731*
Berkeley Co.: 27 May 1959, *Ahles 52858*
Native to South America and naturalized in states of the Gulf coast and southern Atlantic coast; previously known from South Carolina (Radford et al. 1968).

Flaveria trinervia (Spreng.) Mohr
Berkeley Co.: 28 Sep 1957, *Ahles 35584*
Berkeley Co.: 21 Jul 1958, *Ahles 47035*
Berkeley Co.: 22 Sep 1958, *Ahles 49172*
Berkeley Co.: 22 Sep 1958, *Ahles 49215*
Native to northwestern Mexico and the southwestern United States, naturalized in a few states of eastern U.S.A.; first report for South Carolina.

Gaillardia pulchella Foug. var. **drummondii** (Hook.) B.L. Turner
Berkeley Co.: 8 Apr 1957, *Ahles 22528*
Berkeley Co.: 20 May 1957, *Ahles 25852*
Berkeley Co.: 14 May 1958, *Ahles 40460*
Berkeley Co.: 13 Jun 1958, *Ahles 42902*
Berkeley Co.: 13 Jun 1958, *Ahles 42950*
Berkeley Co.: 13 Jun 1958, *Ahles 42969*
Berkeley Co.: 25 May 1960, *Ahles 53367*
Native primarily to the south-central U.S.A. but naturalized in various other states; reported for South Carolina by Kartesz (1999), documented here. The collections were determined by annotation as var. *drummondii* by B.L. Turner & T.J. Watson in 1995.

Gamochaeta antillana (Urb.) Anderb.
Berkeley Co.: 8 Apr 1957, *Ahles 22529*
Florence Co.: 8 Apr 1957, *Ahles 22628*
Probably native to the Caribbean region and perhaps South America, perhaps southeastern USA; first recognized by this name and circumscription in the U.S.A. by Nesom (2004).

Gamochaeta argentina Cabr.
Berkeley Co.: 8 Apr 1957, *Ahles 22594*
Native to South America (Argentina and Uruguay); first report for the U.S.A. and South Carolina.

Gamochaeta calviceps (Fern.) Cabr.
Berkeley Co.: 27 May 1959, *Ahles 52842*
Perhaps native to the southeastern USA, apparently naturalized worldwide; recognized by this name and circumscription in the U.S.A. by Nesom (2004).

Gamochaeta pensylvanica (Willd.) Cabr.
Berkeley Co.: 8 Apr 1957, *Ahles 22590*
Probably native to South America (Nesom 2004), naturalized in the southern U.S.A. and throughout the world; previously known from South Carolina (Radford et al. 1968).

Gamochaeta simplicicaulis (Willd. ex Spreng.) Cabr.
Berkeley Co.: 5 Jul 1957, *Ahles 30825*
Berkeley Co.: 21 Jul 1958, *Ahles 47038*
Berkeley Co.: 15 Jul 1959, *Ahles 52959*
Berkeley Co.: 11 Jul 1960, *Ahles 53783*
Native to South America, naturalized in a few states of Atlantic gulf coast U.S.A.; previously known from South Carolina, first reported by Nesom (1999).

Grindelia lanceolata Nutt. var. **lanceolata**
Berkeley Co.: 13 Jun 1958, *Ahles 42920*
Native to the south-central U.S.A.; first report for South Carolina. The plant is sterile, but the identification is probably correct. The plant has relatively broad leaves like plants from east Texas.

Gutierrezia sarothrae (Pursh) Britt. & Rusby
Berkeley Co.: 28 Sep 1957, *Ahles 35269*
Native to Mexico and the western U.S.A.; first report for South Carolina.

Gutierrezia texana (DC.) Torr. & A. Gray var. **texana**
Berkeley Co.: 11 Jul 1960, *Ahles 53821*
Berkeley Co.: 22 Sep 1958, *Ahles 49193*
Native to Mexico and Texas, naturalized or possibly native in a few other states of central U.S.A.; first report for South Carolina.

Helenium amarum (Raf.) H. Rock var. **badium** (A. Gray ex S. Wats.) Waterfall

Berkeley Co.: 20 May 1957, *Ahles 25829*
Berkeley Co.: 20 May 1957, *Ahles 25834*
Berkeley Co.: 14 May 1958, *Ahles 40478*
Berkeley Co.: 13 Jun 1958, *Ahles 42936*
Berkeley Co.: 27 May 1959, *Ahles 52727*
Native to Texas and Oklahoma; reported for South Carolina by Kartesz (1999), documented here.

Helenium elegans DC. var. **elegans**
Berkeley Co.: 25 May 1960, *Ahles 53357*
Native to Texas, Oklahoma, and Louisiana; reported for South Carolina by Kartesz (1999), documented here.

Helenium microcephalum DC. var. **microcephalum**
Berkeley Co.: 20 May 1957, *Ahles 25844* (NCU, SMU)
Berkeley Co.: 5 Jul 1957, *Ahles 30803*
Berkeley Co.: 21 Jul 1958, *Ahles 47002*
Berkeley Co.: 27 May 1959, *Ahles 52719*
Berkeley Co.: 25 May 1960, *Ahles 53405*
Florence Co.: 26 May 1960, *Ahles 53560*
Florence Co.: 11 Jul 1960, *Ahles 53750* (NCU, SMU)
Berkeley Co.: 11 Jul 1960, *Ahles 53816*
Native to Texas, Oklahoma, New Mexico, and Colorado; reported for South Carolina by Kartesz (1999), documented here.

Helianthus annuus L.
Berkeley Co.: 20 May 1957, *Ahles 25862*
Berkeley Co.: 13 Jun 1958, *Ahles 42987*
Florence Co.: 22 Sep 1958, *Ahles 49145*
Berkeley Co.: 27 May 1959, *Ahles 52777*
Berkeley Co.: 25 May 1960, *Ahles 53456*
Berkeley Co.: 11 Jul 1960, *Ahles 53770*
Berkeley Co.: 11 Jul 1960, *Ahles 53820*
Native or naturalized across the entire U.S.A., previously known from South Carolina (Radford et al. 1968).

Heliomeris multiflora (Nutt.) Blake var. **multiflora** (syn = *Viguiera multiflora* (Nutt.) Blake)
Berkeley Co.: 14 May 1958, *Ahles 40541*
Berkeley Co.: 27 May 1959, *Ahles 52778*
Native to the western USA and Mexico; first report for South Carolina.

Hymenoxys odorata DC.
Berkeley Co.: 8 Apr 1957, *Ahles 22512*
Berkeley Co.: 8 Apr 1957, *Ahles 22603*
Native to the southwestern U.S.A.; first report for South Carolina.

Hypochaeris brasiliensis (Less.) Griseb. var. **tweedei** (Hook. & Arn.) Baker
Berkeley Co.: 8 Apr 1957, *Ahles 22623*
Berkeley Co.: 28 Sep 1957, *Ahles 35593*
Berkeley Co.: 27 May 1959, *Ahles 52730*
Native to South America, naturalized in states along the Gulf coast and southern Atlantic; previously known from South Carolina, first reported by Shinners (1966) from a wool mill collection.

Hypochaeris glabra L.
Berkeley Co.: 14 May 1958, *Ahles 40469*
Berkeley Co.: 13 Jun 1958, *Ahles 42954*
Berkeley Co.: 27 May 1959, *Ahles 52738*
Native to South America, naturalized in states along the Gulf coast and southern Atlantic and various others; previously known from South Carolina (Radford et al. 1968).

Iva annua L.
Berkeley Co.: 28 Sep 1957, *Ahles 35606*
Berkeley Co.: 30 Oct 1957, *Ahles 38194*
Probably native to the central and eastern U.S.A.; previously known from South Carolina (Anonymous 1997), documented here.

Iva axillaris Pursh
Berkeley Co.: 13 Jun 1958, *Ahles 42961*
Native to western North America; first report for South Carolina.

Iva xanthifolia Nutt.
Berkeley Co.: 14 May 1958, *Ahles 40531*
Berkeley Co.: 27 May 1959, *Ahles 52803*
Native to most states of the U.S.A. except the Southeast; first report for South Carolina.

Krigia virginica (L.) Willd.
Berkeley Co.: 8 Apr 1957, *Ahles 22627*
Florence Co.: 8 Apr 1957, *Ahles 22546*
Florence Co.: 9 Apr 1958, *Ahles 38274*
Native to the eastern U.S.A.; previously known from South Carolina (Radford et al. 1968).

Lactuca graminifolia Michx.
Berkeley Co.: 13 Jun 1958, *Ahles 42968*
Native to coastal states of the southeastern U.S.A.; previously known from South Carolina (Radford et al. 1968).

Panphalea heterophylla Less. (identification by John Pruski)
Berkeley Co.: 8 Apr 1957, *Ahles 22585*
Native to South America (Brazil, Uruguay, Argentina); first report for the U.S.A. and South Carolina (Pruski & Nesom 2004).

Parthenium hysterophorus L.
Berkeley Co.: 20 May 1957, *Ahles 25850*
Berkeley Co.: 5 Jul 1957, *Ahles 30810*
Berkeley Co.: 22 Sep 1958, *Ahles 49161*
Berkeley Co.: 15 Jul 1959, *Ahles 52960*
Apparently native to the West Indies and adjacent North America and South America, naturalized in various states of south-central U.S.A. and elsewhere; first report for South Carolina.

Peripleura arida (Burbidge) Nesom (syn = *Vittadinia arida* Burbidge)
Berkeley Co.: 14 May 1958, *Ahles 40547*
Native to Australia; first report for the U.S.A. and South Carolina.

Pseudognaphalium stramineum (Kunth) Anderb.
Berkeley Co.: 11 Jul 1960, *Ahles 53825*
Native to Mexico and the western U.S.A., naturalized in Virginia, North Carolina, and South Carolina; previously known from South Carolina (Radford et al. 1968).

Ratibida columnifera (Nutt.) Woot. & Standl.
Berkeley Co.: 20 May 1957, *Ahles 25830*
Berkeley Co.: 14 May 1958, *Ahles 40468*
Berkeley Co.: 27 May 1959, *Ahles 52712*
Berkeley Co.: 27 May 1959, *Ahles 52801*
Berkeley Co.: 27 May 1959, *Ahles 52860*
Berkeley Co.: 25 May 1960, *Ahles 53370*
Berkeley Co.: 25 May 1960, *Ahles 53371*
Berkeley Co.: 25 May 1960, *Ahles 53491*
Florence Co.: 11 Jul 1960, *Ahles 53753*
Native to Mexico and the central U.S.A., widely naturalized; reported for South Carolina by Kartesz (1999), documented here.

Rudbeckia hirta L. var. **angustifolia** (T.V. Moore) Perdue
Berkeley Co.: 20 May 1957, *Ahles 25863*
Berkeley Co.: 13 Jun 1958, *Ahles 42916*
Berkeley Co.: 27 May 1959, *Ahles 52830*
Native to the coastal states of southeastern U.S.A.; previously known from South Carolina (Anonymous 1997), documented here.

Soliva sessilis Ruiz & Pavon (syn = *Soliva pterosperma* (Juss.) Less.)
Berkeley Co.: 27 May 1959, *Ahles 52718*
Native to South America, naturalized in the southeastern U.S.A.; previously known from South Carolina (Radford et al. 1968).

Sonchus oleraceus L.
Berkeley Co.: 8 Apr 1957, *Ahles 22615*
Native to Europe, northern and western Asia, and northern Africa, widely naturalized in North America; previously known from South Carolina (Radford et al. 1968).

Stuartina hamata Philipson
Berkeley Co.: 8 Apr 1957, *Ahles 22593*
Native to Australia; first report for the U.S.A. and South Carolina.

Symphyotrichum divaricatum (Nutt.) Nesom (syn = *Aster subulatus* Michx. var. *ligulatus* Shinners)
Berkeley Co.: 30 Oct 1957, *Ahles 38169*
Native to northern Mexico and the south-central U.S.A.; first report for South Carolina.

Tagetes minuta L.
Berkeley Co.: 20 May 1957, *Ahles 25845*
Berkeley Co.: 28 Sep 1957, *Ahles 35609*
Berkeley Co.: 22 Sep 1958, *Ahles 49188*
Native to South America, in the U.S.A. naturalized mainly in Atlantic coastal states; previously known from South Carolina (Radford et al. 1968).

Tetraneuris linearifolia (Hook.) Greene var. **linearifolia** (syn = *Hymenoxys linearifolia* Hook.)
Berkeley Co.: 8 Apr 1957, *Ahles 22513*
Native to Texas, New Mexico, Oklahoma, and Kansas; first report for South Carolina.

Thymophylla tenuiloba (DC.) Small var. **tenuiloba**) (syn = *Dyssodia tenuiloba* (DC.) B.L. Robins. var. *tenuiloba*)
Berkeley Co.: 8 Apr 1957, *Ahles 22580*
Native to Mexico and Texas, naturalized in a few Gulf coast states (e.g. Florida and Mississippi, Cronquist 1980; Alabama, Lelong 1988); first report for South Carolina.

Uropappus lindleyi (DC.) Nutt.
Florence Co.: 26 May 1960, *Ahles 53543*
Native to the southwestern U.S.A.; first report for South Carolina.

Verbesina encelioides (Cav.) var. **encelioides**
Berkeley Co.: 20 May 1957, *Ahles 25548*
Florence Co.: 28 May 1957, *Ahles 26719*
Berkeley Co.: 5 Jul 1957, *Ahles 30812*
Berkeley Co.: 14 May 1958, *Ahles 40486, 40554*
Florence Co.: 21 Jul 1958, *Ahles 46950*
Berkeley Co.: 22 Sep 1958, *Ahles 49180*
Berkeley Co.: 27 May 1959, *Ahles 52810*
Berkeley Co.: 15 Jul 1959, *Ahles 52945*
Florence Co.: 26 May 1960, *Ahles 53546*
Florence Co.: 11 Jul 1960, *Ahles 53762*
Native to Mexico and the western U.S.A., naturalized in several states of the southeastern U.S.A.; previously known from South Carolina, reported by Coleman (1974), documented here.

Vittadinia sulcata N. Burbidge
Berkeley Co.: 8 Apr 1957, *Ahles 22538*
Native to Australia; first report for the U.S.A. and South Carolina.

Xanthium spinosum L.
Berkeley Co.: 8 Apr 1957, *Ahles 22608*
Berkeley Co.: 20 May 1957, *Ahles 25872*
Florence Co.: 28 May 1957, *Ahles 26689*
Berkeley Co.: 30 Oct 1957, *Ahles 38199*
Berkeley Co.: 13 Jun 1958, *Ahles 42924*
Native to South America, widely naturalized in North America; reported for South Carolina by Kartesz (1999), documented here.

Xanthium strumarium L. var. **canadense** (P. Miller) Torr. & A. Gray
Berkeley Co.: 5 Jul 1957, *Ahles 30848*
Native to North America and widely distributed as a weed; previously known from South Carolina (Radford et al. 1968).

ACKNOWLEDGMENTS

I am grateful for help from the staff of herbarium NCU and for comments on the manuscript by Linda Lee (USCH). John Pruski (MO) provided the identification of *Panphalea heterophylla*.

PANPHALEA HETEROPHYLLA (COMPOSITAE: MUTISIOIDEAE: NASSAUVIEAE), A GENUS AND SPECIES NEW FOR THE FLORA OF NORTH AMERICA

John F. Pruski

Missouri Botanical Garden
P.O. Box 299
St. Louis, Missouri 63166-0299, U.S.A.

ABSTRACT

Panphalea heterophylla (Compositae) is a new genus and species for the United States. This also is the first known occurrence of the genus from outside of its native range in southern South America.

RESUMEN

Panphalea heterophylla (Compositae) es un género y especie nueva para los Estados Unidos. Este es también el primer reporte del género fuera de su área de ocurrencia nativa en Sur América.

Determinations of Compositae in conjunction with the study of Nesom (2004) identify *Ahles & Haesloop 22585* (NCU) as *Panphalea heterophylla* Less. (Compositae: Mutisioideae: Nassauvieae), a genus and species new for the flora of North America. This is the first known occurrence of *Panphalea* Lag. from outside of its native range in Argentina, Brazil, Paraguay, and Uruguay and increases to three the number of genera of Nassauvieae known in North America. In this paper I amplify comments on the taxonomic significance of the record, past the summary provided in Nesom (2004), with a description and typification of the species, U.S.A. voucher, and a key to the genera of Mutisioideae that occur in North America north of Mexico.

Nassauvieae Cass. were treated as Mutisieae subtribe Nassauviinae (Cass.) Benth. & Hook.f. by Bentham and Hooker (1873) and placed in Compositae subfamily Mutisioideae (Cass.) Lindl. [syn. Nassauvioideae (Cass.) Lindl.] by Pruski and Sancho (2004). Nassauvieae were resurrected from synonymy of Mutisieae and reinstated at the tribal level by Pruski (2004). Nassauvieae differ from Mutisieae Cass. by longer style branches with truncate tips commonly covered by a tuft of collecting hairs, by anthers with a well-defined appendage and shorter broader thecae, but they have bilabiate corollas and caudate anthers typical of most Mutisioideae [tribe Stifftieae D. Don is characterized by discoid capitula with short, abaxially rugulose style branches and mutisioid anthers (Pruski 2004)]. Nassauvieae are centered in South America, but two genera were previously known to occur in North America (Simpson & Anderson 1978): *Trixis* P. Browne is largely South American, but extends northward into the West Indies, Mesoamerica, Mexico, and the southwestern United States; *Acourtia* D. Don occurs from Mesoamerica northwards into the southwestern United States.

Panphalea heterophylla differs by epappose cypselae from the species of the five genera of Mutisioideae treated by Simpson and Anderson (1978) in North America north of Mexico [*Acourtia* D. Don (5 spp.), *Chaptalia* Vent. (4 spp.), *Gochnatia* H.B.K. (1 sp.), *Hecastocleis* A. Gray (1 sp.), and *Trixis* P. Browne (2 spp.)]. Additionally, the combination of the following features serves to further distinguish *Panphalea heterophylla* from these 13 species of Mutisioideae: annual herbaceous habit; glabrous herbage; leaves basal and cauline, lyrate to sharply lobed; corymbiform capitulescences; few-flowered, bilabiate capitula; thinly chartaceous, apiculate phyllaries; homogamous florets; and bilabiate, isomorphic corollas with an apically shortly bidentate inner lip.

KEY TO MUTISIOIDEAE IN NORTH AMERICA NORTH OF MEXICO

1\. Style branches short, apically rounded, glabrous or sparsely papillose; cypselae pappose (Mutisieae).

  2\. Plants rosulate herbs; capitula bilabiate-heteromorphic ________ **Chaptalia** Vent.

  2\. Plants subshrubs to shrubs; capitula discoid.

    3\. Leaves abaxially tomentose, entire; capitula many-flowered, not glomerate, not subtended by spiny subinvolucral bracts; pollen tricolporate ________ **Gochnatia hypoleuca** (DC.) A. Gray

    3\. Leaves not abaxially tomentose, at least some leaves with spiny margins; capitula uniflorous, glomerate, subtended by spiny subinvolucral bracts; pollen tricolpate ________ **Hecastocleis shockleyi** A. Gray

1\. Style branches elongate, apically truncate, crowned by a tuft of collecting hairs; cypselae pappose or epappose (Nassauvieae).

  4\. Glabrous annual herbs; inner corolla lip undivided proximally, bidentate apically; cypselae epappose ________ **Panphalea heterophylla** Less.

  4\. Perennial pubescent herbs to shrubs; inner corolla lip bifid, divided to base; cypselae pappose.

    5\. Rosulate perennial herbs, caudex commonly tomentose; corollas violet, pinkish, or white ________ **Acourtia** D. Don

    5\. Subshrubs to shrubs, corollas yellow ________ **Trixis** P. Browne

Panphalea heterophylla Less., Linnaea 5:8. 1830. TYPE: BRAZIL: In humidis Brasiliae meridionalis. 1823–1828 [sic], *Sello 1328* (HOLOTYPE: B, destroyed, photographs. MO!, NY!, US!, all photographs from C.B.G.N. negative 16096).

Glabrous annual herbs; stems slender, few to several, branched at base, spreading to ascending, 5–17 cm long. **Leaves** basal and cauline, alternate, chartaceous; basal leaves petiolate, oblong to oblong-lyrate, petiole 7–12 mm long, blade orbicular or more commonly lyrate with about 3 pairs of lobes, 4–15 mm long, 4–7 mm wide, margins entire; cauline leaves commonly sessile and clasping, ovate-lyrate, palmatifid, pedate, or lanceolate, 4–12 mm long, 4–6 mm wide. **Capitulescence** corymbiform, few-headed; peduncles 10–30 mm long. **Capitula** 8–12-flowered, bilabiate, homogamous; involucre 1–2-seriate, ca. 2.2 × 2 mm; phyllaries subequal, ovate-lanceolate, thinly chartaceous, apically truncate-apiculate, apiculum to ca. 0.5 mm long, margins broad, hyaline; receptacle epaleate. **Florets** bisexual; corollas bilabiate, isomorphic, white, ca. 5 mm long, weakly puberulent with scattered uniseriate, 5–7-celled trichomes, apical cell larger but neither bulbous nor inflated, tube ca. 2 mm long, outer lip ovate, ca. 3 × 1.5 mm, minutely tridentate apically, adaxial epidermal cells longitudinally elongated (mutisioid epidermal pattern), outer wall acute-ridged in transverse section, inner lip ca. 1.2 mm long, coiled, undivided proximally, shortly bidentate apically; style branches ca. 0.7 mm long, apically truncate, papillate with many collecting hairs; anthers ca. 2 mm long, caudate, apical appendage well-defined, obtuse, ca. 0.5 mm long, tails broadly lanceolate, ca. 0.4 mm long, smooth, tips rounded, not tapered. **Cypselae** obconical, ca. 1.5 mm long, densely pubescent, apically truncate; pappus absent. **Pollen** spheroidal, tricolporate, tectum minutely granular (subpsilate).

Specimen examined: UNITED STATES. **South Carolina. Berkeley Co.:** Jamestown on SC route 45, waste ground around the Santee Wool Combing Mill, 8 Apr 1957, *Ahles & Haesloop 22585* (NCU!).

Panphalea contains nine species (Cabrera 1953; Cabrera & Klein 1973) found in northeastern Argentina, adjacent Brazil, Paraguay, and Uruguay. Three species are annual herbs, and among these only the smallest, *Panphalea heterophylla*, is glabrous. Cypselae of this species were presumably imported into the United States in fleece brought from South America for processing. Species of tribe Nassauvieae are not commonly weedy, and it is unlikely that this subtropical species will become a pest, if it has persisted at all in South Carolina.

ACKNOWLEDGMENT

I would like to thank Dra. Gisela Sancho (LP) for helpful discussion.

Cuscuta indecora Choisy is frequent in southern U.S.A. (Yuncker 1932, 1965) and extends northward to Michigan, Minnesota, North Dakota, Montana and Idaho (USDA NRCS 2004). The species also occurs in Mexico, Central and South America (Yuncker 1932, 1965). We are reporting here the first record of this species for southern Saskatchewan, Canada. Its presence in the Canadian Provinces adjacent to its northern range was to be expected, and further floristic research may reveal its occurrence in southern Alberta, Manitoba and Ontario. Although *C. indecora* has definite weedy tendencies (Parker & Riches 1993), taking into account the natural habitats it was found in, the species may be considered native to southern Canada as well. The species was cultivated experimentally in Ontario and Alberta (vouchers at DAO and ALTA, respectively), but it has never spread (see also Crins & Ford 1988). The host range of *C. indecora* is wide, including numerous herbaceous and woody plants (Yuncker 1965).

Cuscuta indecora and *C. coryli* Engelm from subsection *Indecorae* Yuncker are probably sister species (Costea et al. unpublished). *Cuscuta coryli* in Canada, is rare in Saskatchewan, Manitoba, Ontario and Québec (Argus & Pryer 1990). Both species have in common the fleshy, papillate flowers with corolla lobes acute and inflexed. *Cuscuta indecora* differs from *C. coryli* mainly through the 5-merous flowers, 2–5 mm long, having usually large and abundantly fringed intrastaminal scales. *Cuscuta coryli* has flowers commonly 4-merous, ca. 2 mm long, and infrastaminal scales are reduced to winged or toothed ridges. Descriptions, identification keys and iconography can be found in Yuncker (1932, 1965).

ABSTRACT

A recent collection of mosses from the Department of Madre de Dios in the lowlands of southeastern Peru contains 58 different species. Fifty-four taxa are new to the district and four species are reported new to Peru. Previous collections from the district are listed which brings the total species known from the area to 74. This is the first major study of mosses from Madre de Dios, Peru, and it provides a foundation for continued work and production of a field guide for the region.

RESUMEN

Una colección reciente de musgos del Departamento de Madre de Dios en la zona baja del Sureste de Perú contiene 58 especies diferentes. Cincuenta y cuatro taxa son nuevos para el distrito y se citan cuatro especies nuevas para Perú. Se listan las colecciones previas del distrito que elevan el total de especies conocidas del área a 74. Este es el primer estudio amplio de musgos de Madre de Dios, Perú, y aporta un inicio para la continuación del trabajo y la producción de una guía de campo para la región.

INTRODUCTION

The southwestern Amazon of the trinational corner of SW Brazil, NW Bolivia, and SE Peru contains what is probably the largest and least disturbed area remaining of Upper Amazonian and Lower Andean ecosystems (Foster et al. 1994). Threats to the forest occur in the form of hunting, gold mining, timber extraction, impending road construction, and slash and burn agriculture. The Department of Madre de Dios (12°–14.5°S), Peru, dominated by the Madre de Dios River basin and tributaries, is an important geopolitical region in the pristine SW Amazon, which is divided equally between lowland, premontane, and montane forest (Davis et al. 1997). Madre de Dios is located at the southwestern edge of the Amazon basin near the Andean foothills and is covered primarily by lowland tropical/subtropical moist forest (Gentry & León 1997). The region has a distinct six month dry season and receives 2000–2500 mm of rain annually (Gentry & León 1997). Madre de Dios has been recognized as an epicenter of botanical diversity and holds world record numbers of other organisms, such as birds, tabanid flies, tiger beetles, damselflies and dragonflies, and butterflies (Stewart 1988).

Botanical research over the past 25 years in Madre de Dios, Peru, has been

SIDA 21(2): 1231–1238. 2004

important for identifying the extent and significance of the region's plant diversity, producing various publications and datasets (e.g., Gentry 1982; Phillips & Gentry 1993a–b; Foster et al. 1994; Terborgh & Andersen 1998; Pitman et al. 1999, 2001). There have been two geographic areas of botanical investigations in Madre de Dios, with most of the resources focused on quantitative inventory of trees (trunk diameter > 10 cm) in scattered one-hectare forest plots and 0.1-hectare transects. The Cocha Cashu Biological Station in Manu National Park has been the focus of significant field research during the last three decades (Terborgh 1994), producing one of the most comprehensive plant checklists for the region. The Tambopata-Candamo Reserved Zone (Foster et al. 1994) in lower Madre de Dios near the Peru-Bolivian border has been the focus of long-term monitoring of one-hectare forest plots and complementary 0.1-hectare transect work (Phillips et al. 2003), plus associated programs of general botanical collection.

Despite the research that has been focused on these selected areas, there has been no major, long-term systematic inventory of plants and habitats, and no flora has been published for the region. Between July 11 and August 19, 2002, as part of a long-term program of botanical inventory and monitoring, the authors conducted expeditions in the Amazonian lowlands of the Department of Madre de Dios. Led by the first author, cryptogamic collections were made from several localities in the region (Table 1, Fig. 1). Fifty-eight species of mosses were identified from approximately 226 collections. Of the 58 taxa identified, 54 are new records for the district and four of these are new records for Peru (Table 2).

The only previously published records of moss collections for Madre de Dios, as far as we know, were made by Vargas (1974) and recorded in a checklist of mosses for Peru by Menzel (1992). Vouchers of the Vargas material were searched for but not located in either of the two larger Peruvian herbaria—the Herbarium of the Museo de Historia Natural, Universidad Nacional Mayor de San Marcos (USM) and the Herbario Vargas, Facultad de Ciencia Biológicas, Universidad Nacional San Antonio Abad del Cuzco (CUZ).

We conclude that future work should be focused on comparative studies of the diversity of mosses and other bryophytes in time and space between different sites in the lowlands of Madre de Dios, and along the altitudinal gradient from the lowlands up the slopes of the Andes into the Department of Cusco. This work is produced as a component of long-term botanical exploration and collaboration in the Andes-Amazon region of southeastern Peru and it will serve as a foundation for the production of field guides to serve the multidisciplinary science, education, and conservation programs that are ongoing in the region.

ANNOTATED LIST OF SPECIES

Species are listed alphabetically by family. New records for the country are marked with an asterisk (*). The nomenclature for the species follows Crosby et al. (2000). Voucher collections are deposited at NY. Duplicates of some taxa are

Table 1. Summary of nine collection sites in Madre de Dios, Peru, and the corresponding moss collections made between July 11 and August 19, 2002.

Locality	Elevation	Geographic Coordinates (P. Majestyk)	Collection Numbers
1. Manu Province, Puerto Maldonado	300 m	12°36' S, 69°11' W	3720-3727

Sastre, *Sematopyllum subpinnatum* (Bridel) E. Britton, *Sphagnum subsecundum* Nees in Sturm, *Squamidium nigricans* (W.J. Hooker in Kunth) Brotherus.

Taxa listed as occurring in Madre de Dios in the Tropicos database with collector and collection number (mobot.mobot.org/W3T/Search/most.html):

Fissidens allionii Brotherus (*Matthews B-86580*, MO); *Fissidens lagenarius* Mitten (*Matthews B-86577*, COLO, PAC); *Fissidens perfalcatus* Brotherus (*Matthews B-85860*, MO); *Phyllogonium viscosum* (P. Beauv.) Mitten (*Chavez 857*, MO).

ACKNOWLEDGMENTS

We would like to thank the Gordon and Betty Moore Foundation and the Beneficia Foundation for their support of botanical studies in Madre de Dios, Peru. The first author thanks William Buck and the New York Botanical Garden for financial assistance which made this trip possible. The second author thanks Scott Mori for support during postdoctoral studies at the New York Botanical Garden. For aiding in the identification of several collections we thank William Buck, Robert Ireland, and Ron Pursell. We thank Asha McElfish for her assistance in preparation of tables and for helpful comments to improve the original manuscript. And we thank Barney Lipscomb for his excellent editorship and the two reviewers (Robert E. Magill and William R. Buck) who helped us improve the manuscript. Fieldwork would not have been possible without the logistical support provided by the Amazon Conservation Association (ACA), the Asociación para la Conservación de la Cuenca Amazonica (ACCA), and the staff of the Los Amigos Biological Station, including Jorge Herrera, Juan Carlos Flores, Giovana Espino, and Sonia Guerra. We also thank Asunción Cano of USM, Carlos Reynel of MOL, and staff of the Peruvian Ministry of Natural Resources (INRENA) for their support of our ongoing botanical research in Peru. Fernando Cornejo, Piher Maceda, Mathias Tobler, and Euridice Honorio provided essential assistance and collaboration during the field expeditions that made moss collections possible.

ABSTRACT

Kathleen M. Peterson (1948–2003) is remembered as a student, gifted teacher, skilled botanist, lawyer, and friend all as an introduction of a new species of *Scutellaria* (*Lamiaceae*) from Mexico named in her honor.

KEY WORDS: *Scutellaria*, Lamiaceae, Mexico, obituary

RESUMEN

Kathleen M. Peterson (1948–2003) es recordada como una estudiante, profesora con talento, botánica de pericia, abogada, y amiga, todo como una introducción de una nueva especie de *Scutellaria* (*Lamiaceae*) de México nombrada en su honor.

The notice in the Harrisburg, Pennsylvania, paper, the *Patriot-News*, published on November 26, 2003 was short: "Kathleen M. Peterson, 55, of Camp Hill, died Monday, November 24, 2003 at Hospice of Central Pennsylvania, Carolyn Croxton Slane Residence. She was an attorney for the Pennsylvania Treasury Department. Services will be held at the convenience of the family. Arrangements are by the Cremation Society of Pennsylvania, Harrisburg." Nothing was mentioned of the person or her life as a botanist; we hope our words and actions in proposing *Scutellaria petersoniae* (Turner & Reveal 2004) in some way, will rectify the oversight for it is with sadness that we note to the botanical community the passing of Kathy Margaret Peterson.

Kathy Peterson was a graduate student at the University of Maryland from 1973 until 1978, where she received her doctoral degree, working on a portion of the mint genus *Salvia*. Her master's thesis was done with Dr. Willard Payne (The genus *Hymenoclea* (*Compositae: Ambrosieae*), *Brittonia* 25:243–256. 1973) at the University of Illinois (1969–1971) where she took her undergraduate degree in 1969. The two of them also published "Observations of the hypodermises of ferns" in the *American Fern Journal* (63:34–42. 1973). Based on her work at Maryland, she published "*Salvia reptans. Labiatae*" with Raymond M. Harley of the Royal Botanical Garden, Kew, England, in *Curtis's Botanical Magazine*

(182:13–16. 1978). As in all papers published in that journal, their comments were accompanied by a beautiful, full-page colored painting of the species.

Her research on *Salvia* was supported by a grant from the National Geographic Society and a Doctoral Dissertation Improvement Grant from the National Science Foundation. Together, she and Reveal presented a report entitled "Biosystematic and evolutionary studies of *Salvia* subgenus *Calosphace*" that was published in the Society's *Research Reports* (15:557–564. 1983). Of a more personal nature was an article of their travels in Mexico ("Exploring the green frontier" by Broome, Reveal and Peterson published in the *University of Maryland's Graduate School Chronicle* 10(4):3–6. 1977). C. Rose Broome and Kathy spent a month collecting prior to being joined by Reveal and Harley at the silver mining town of Toluca. Together they explored a portion of Guerrero that had not been visited botanically for several decades. The new finds were numerous. Among them were *Bouvardia hintoniorum*, *Galium iltisii*, *Hansteinia harleyi*, *Montanoa revealii*, *Salvia turneri*, *Sinclairia broomeae*, *Tibouchina patens*, and a new genus *Revealia*.

The most beautiful addition made during their joint trip across the Sierra Madre del Sur was a wonderful new species named *Utricularia petersoniae* by Peter Taylor (*Kew Bull.* 41:8.1986). It was a fitting tribute to Kathy, tall and slender yet graceful with an elegant beauty.

Kathy was born in Oak Park, Illinois, on March 10, 1948. Here she spent her youth, attending local grade and high schools before entering the University of Illinois in 1965. There she majored in botany with minors in chemistry and geology. As a youngster she was tall, taller than most boys her age, and this would continue to be the case throughout her life. She had elegance about her, borne by her height so that in the classroom she was a presence. At Maryland she tutored struggling athletes, and was most effective as she could intimidate the largest football player and look many a basketball player in the eye. Her wit was appreciated but her strength was as a teacher. In 1978 she received the Carroll E. Cox award as the outstanding graduate student; during the 1978–1979 academic year she was appointed an instructor at College Park. She departed soon thereafter to accept a position as an assistant professor at the University of Montana. Her skill in the classroom continued, for Kathy taught a variety of classes and soon had a small group of students working on graduate degrees, being named "KP" to distinguish her from the other Kathys in the group. Augmented by grants from the National Science Foundation and National Geographic Society she continued her work on *Salvia*. Other funding allowed her and her students to work on various rare and endangered species in Montana. Among her students were Jeffrey Strachan now with the Plant Variety Protection Office, U.S. Department of Agriculture, Lisa Campbell of The New York Botanical Garden, Jennifer Ramstetter, a professor of biology at Marlboro College, and Kathy Ahlenslager of the U.S. Forest Service who wrote a recent obituary (Ahlenslager 2004). Perhaps her greatest contribution to the University of Montana came in the form of her effort to upgrade the herbarium by hiring a collections manager, finding volunteers to mount and file thousands of plant specimens, and to distribute a large backlog accumulated over the decades.

Professionally Kathy moved upward. Besides her teaching duties she directed the operations of the University's natural history museum, wrote several research papers, served on the editorial board of *Systematic Botany*, and was president of the University of Montana Sigma Xi chapter. In 1984 she was promoted to the rank of associate professor, and in 1986 she received tenue. Along with tenure the University awarded her a "meritorious teaching and research salary increase." Most of her publications at this time dealt with rare plant species in Montana. They include "Vascular plants of limited distribution in Montana" (Lesica, P., G. Moore, K.M. Peterson, and J.H. Rumley, *Montana Acad. Sci. Monogr.* 2:1–61. 1984) and a summary report on rare plants in the state (Peterson, K.M., P. Lesica & J.S. Shelly, *Proceedings of the 1986 Natural Areas Conference*, pp. 97–113).

Then, in 1987, she suddenly resigned her position, left Montana, and botany as well, all for what proved to be an unfortunate, short-lived marriage which ended formally in divorce in 1994.

Finding herself in Pennsylvania, Kathy began a new career. She was certified as a paralegal by Pennsylvania State University in March of 1989 and then attended The Dickinson School of Law where she was awarded her J.D. in 1992. During this time she was a member of the *Dickinson Law Review* and the Appellate Moot Court Board; she also served on the editorial board of the *Dickinson Journal of Environmental Law and Policy*. In the *Review* she published an article entitled "Federal regulation of artificial insemination donor screening practices: An opportunity for law to co-evolve with medicine," a title only a biologist would think of. Her interest initially was in environmental law, working as an intern for the Department of Environmental Resources (1991–1992) and as a law clerk for the state's Treasury Department. In August of 1992, two months before being admitted to the Pennsylvania Bar, she became the Assistant General Counsel for Treasury.

As a lawyer, Kathy drafted banking service contracts between the Treasury and banks, prepared white papers on State Workers' Insurance Fund and the Federal Reserve System, did general legal research on banking and ethics issues, and provided litigation support for the General Counsel. In September of 1995 she was promoted to the Department's Associate General Counsel. In this position, she represented the State Treasurer on various committees, including the Board of Directors of Pennsylvania's chapter of The Nature Conservancy.

In 1999, Kathy discovered that she had ovarian cancer. Initially the combination of chemotherapy and radiation was successful, and during most of this time she continued to serve the citizens of Pennsylvania. In 2001 her doctors

Kathleen M. Peterson (1948–2003).

found a lesion on the brain. It was removed surgically, and she returned to work determined to beat the newly found cancer. Two weeks after surgery she fell and a MRI found more lesions. A second round of surgery was performed, but her chances of survival were greatly diminished. Up to the end, Kathy was a strong, stalwart woman, loosing a battle to cancer that two and half years early claimed her brother, and months before her own death, took her mother. It is in Kathy's memory that we dedicate the following new species.

ACKNOWLEDGMENTS

We are grateful to Carl Peterson, Kathy Ahlenslager and Jeff Strachan for providing us with insights into Kathy's life.

BOOK REVIEWS

ANDREW PARKER. 2003. **In the Blink of an Eye**. (ISBN 0-465-05438-2 pbk.). Basic Books, 387 Park Avenue S., New York, N.Y. 10016, U.S.A. (Orders: 800-255-1514 or special.markets@perseusbooks.com). $15.00, 316 pp., b/w figures, index, 5" × 8".

In the new book *In The Blink Of An Eye*, author Andrew Parker puts a new spin on why animals first developed body armor during the Cambrian era. Parker contends that the discernable and sudden development of hard body coverings about 543 million years ago occurred to take advantage of the simultaneous development of higher-order vision in some animals. It was useful in attracting mates, and fighting off enemies, and being an effective predator.

This book takes the reader on an interesting expedition, through numerous fossil beds and to examine creatures living today throughout the world to discover the role of color and light in the evolution of Cambrian-era organisms. Parker presents a powerful and evidence-packed argument suggesting the cause of the Cambrian explosion, the sudden formation of body coverings, armament and distinct shapes around 543 million years ago, as the onset of organisms producing true vision and the ability to pursue prey.

The opening chapters present a well-organized mini "history of life" book and discussion of how fossils are investigated to give researchers clues on the appearance of and the living environment of those fossil organisms. These introductory chapters are helpful for the reader to get a good understanding of the argument about to be discussed. Following the background chapters, a good deal of information and numerous interesting examples are presented on the importance of visual appearance and behavior of various creatures as a response to light. For instance, examples included multilayer reflectors of Messel fossil beetles and Hercules beetles that alter the color of their appearance as humidity conditions change within layers of their body. Adaptations discussed included pigments, structural colors (such as iridescent film on wings), natural liquid crystals, diffraction, reflection layers and bioluminescence, all of which cause specific visual appearances. The uses of these visual appearances include camouflage, warning coloration, defense, and mating attractants. Information and examples presented included both fossil and extant organism evidence. Many of the adaptations discussed can only be seen if light is present. Therefore, many of the color, shape and behavior adaptations presented give clues as to the environment an organism could be found.

Vision as the cause of the Cambrian explosion is supported by evidence of the potential evolution of the eye in a short period of time (geologically speaking), and the ability of organisms to see their environment and more importantly (their) prey. It was determined possible for true eyes, eyes which not only vaguely perceive light and darkness, but form a true visual image in which the organism can "see" its surroundings, could evolve over less than half a million years. In addition, the strongest evidence for the author's theory is the occurrence of soft-bodied trilobites with no eyes in the Pre-Cambrian, then the abundance of trilobites with eyes and body armor in the Cambrian. The development of the first true eyes was followed by a rapid evolution of body color, body structure and behavior; all of these increased the capacity to be a predator and the avoidance of becoming prey through the formation of body armor and deterrents such as spines. The author does leave the reader with a parting question: "What prompted the development of the eye in the first place?"

Andrew Parker has presented a well-organized argument for vision as a trigger for the Cambrian explosion. He managed to explain the theory in a logical pattern while using both an educational and entertaining writing style. However, because each chapter entails so many details, I recommend you read each chapter beginning to end nonstop; doing so helps keep the ideas together.

One small complaint is the occasional reference to image plates that are not in the book. These plates would have enhanced the understanding of the information presented. This book is recommended for those interested in the Cambrian age, evolution, the development of vision, and body structural colors in insects and aquatic life.—*Lee Luckeydoo, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

Grape Man of Texas

SHERRIE S. MCLEROY and ROY E. RENFRO, JR. 2004. **Grape Man of Texas: The Life of T.V. Munson.** (ISBN 1-57168-819-6, hbk.) Eakin Press, P.O. Drawer 90159, Austin, Texas 78709-0159, U.S.A. (Orders: 512-288-1771; 800-880-8642; 512-288-1813 fax; Service and Sales: sales@eakinpress.com). $39.95, 296 pp., color and b/w figures, 7" × 10".

Grape Man of Texas: The Life of T.V. Munson is the first biography written about this eminent Texas horticulturist. He became one of the leading experts in native American grape species, and his studies were instrumental in saving the European grape and wine industry from disaster in the late nineteenth century. Munson developed over 300 new grapes but is perhaps best known for his efforts in fighting the phylloxera epidemic of the late 19th century, for which he received the Chevalier du Merite Agricole and inducted into the French Legion of Honor. He was also a leader in the viniculture movement of the period for his cutting-edge work in breeding new grape and plant varieties. His articles, experiments, correspondence, speeches, exhibits, grape classifications, and numerous inventions reveal his scientific thirst for knowledge and his wide-ranging interests.

Over 100 years ago Cognac, France and Denison, Texas shared two of it's citizens with the world to solve a major destructive force—the grapevine destroyer, phylloxera. It was 1880 and the phylloxera plague was rampant in France, especially in the Charante Region where Cognac is located. The phylloxera root louse was destroying the prestigious French winegrapes and therefore, destroying the economy of France. France assigned the preeminent French scientist, Pierre Viala the task of finding a cure for the phylloxera plague. This investigation brought him to the United States and to the home of Thomas Volney Munson in Denison, Texas. The two scientists collaborated on the problem for several days in Denison and various other locations in Texas to view the native grapes of Texas in their natural habitat. The soils of the Charante, in France, and Denison are very similar and therefore should support grape species capable of growing in either location. T.V. Munson suggested that the only way to save the French vineyards was to graft the *Vitis vinifera* varieties to resistant rootstocks. Munson knew that the Texas rootstocks were resistant to phylloxera and at his suggestion, Pierre Viala agreed that it was a good plan of action. Thousands of bundles of Texas rootstocks were shipped to France where Pierre Viala and other French scientists started educating the French winegrowers on the enormous grafting tasks that lay ahead. The grafting literally continues to this day.

For his monumental contributions to France, T.V. Munson was awarded the highest award that could be given a foreign civilian, the Chevalier du Merite Agricole and was inducted into the Legion of Honor in 1888. In 1898 he was elected as a foreign corresponding member of the Societe Nationale d'Agriculture de France and as an honorary member in the Societe des Viticulteurs de France. Several statues honoring Munson have been erected in France.

Nearly 300 pages long, the *Grape Man of Texas* includes more than 100 illustrations, many never before published; the first listing compiled since Munson's death of his 300+ grape hybrids and their parentages; a list of his wild grape discoveries, several of which remain important in modern viticulture and research; and a list of all of Munson's known speeches and publications.

Released in June 2004, *Grape Man of Texas* soon received its first international accolade when it was awarded a prestigious three stars from the Gourmand World Cookbook Awards, which recognize the finest in international food and wine books. The organization inaugurated the rating system this summer to rank the 4,000-plus books entered each year in its "Best in the World" competition. Gourmand defines these 3-star books as "masterpieces—buy and read immediately." *Grape Man*, the Gourmand press release states, is "a very important book for wine history." It is one of only four American books and 19 worldwide to be honored on the inaugural list.

The book was co-written by award-winning Texas author and historian Sherrie S. McLeRoy and by Dr. Roy E. Renfro, Jr., director of the T.V. Munson Viticulture and Enology Center in Denison, Texas.—*Gary L. Jennings, Librarian, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

Preservation of the Big Thicket

James J. Cozine, Jr. 2004. **Saving the Big Thicket: From Exploration to Preservation, 1685–2003.** (ISBN 1-57441-175-6, hbk.). University of North Texas Press, P.O. Box 311336, Denton, TX 76203-1336, U.S.A. (Orders: 1-800-826-8911, 940-565-4590 fax, rchrisman@unt.edu, www.unt.edu/untpress). $34.95, 272pp, 5 maps, 25 illustrations, 6" × 9".

Saving the Big Thicket: From Exploration to Preservation, 1685-2003 is the fourth in the Temple Big Thicket Series published by University of North Texas Press. Originally written by Cozine in 1976 as part of a dissertation literature entitled *Assault on a Wilderness*, the work has been updated to the present time and now includes a foreword and afterword by Pete A.Y. Gunter, author of another book in this series, *The Big Thicket: An Ecological Reevaluation*. *Saving the Big Thicket* is an account of the regional history and "play-by-play" of the political fight for the Big Thicket National Preserve (BTNP) with the afterword by Gunter detailing the more recent issues in the area since Cozine's original 1976 manuscript was published.

The foreword by Gunter describes the work of the author and his involvement and perseverance on this work, presents a general construction of the book and provides some insight into the process of constructing an overview of a region with such a long and complicated history. Introductory material gives a brief description of the units that make up the preserve, general ecosystems and plant diversity found in each, along with information about the creation of the units, trails and structures. Two maps from Cozine's original work accompany this first section. Cozine divides the history of the region into six time periods of human involvement: early Native American use, French and Spanish arrival and attempted settlement, the coming of early American backwoods settlers, initiation of logging railroads (for large-scale timbering) and oil exploration, the beginning of an early conservation movement and finally the formation of the second Big Thicket Association and creation of BTNP. Each section provides great detail and historical information on the people, organizations and industries that became involved with the land, how they used it, settled it (or attempted to), helped destroy it and eventually helped save it. The first few chapters involve pre-industry human effects on the Big Thicket, outlining the Native American tribes that lived in the area leaving a minimal impact, the arrival of the Spanish and French explorers that interacted with the Native American tribes, and finally the greater impact of backwoodsmen, escaped slaves, criminals and hunters seeking refuge in the Big Thicket. The following chapters address the arrival of timber railways, oil exploration and the incredible environmental damage to the region that came with them, the rise and fall of the original East Texas Big Thicket Association who first raised the environmental flag in the Big Thicket and the eventual creation of the Big Thicket National Preserve with the aid of the second (and successful) Big Thicket Association in 1974. Each of these chapters is riddled with political and social struggles among the groups involved and with the tale of destruction and human impact on the region's incredible biodiversity.

Throughout the book there are a total of 5 maps from Cozine's 1976 publication. The quality of these maps is that of the original publication era and they are somewhat difficult to interpret. There is also a central section containing 19 black and white photographs from Cozine's original work These photographs depict scenes from the early 1900's of bear hunts and early scenes in the big thicket, but the section mostly contains portraits and casual photographs of prominent politicians, activists, industry representatives and other people involved in the history of the area. These photographs are of poor quality and add little useful information or perspective to the book, besides presenting a pictorial record of the prominent figures in the Big Thicket's history.

The afterword by Gunter is a well-written account of the political, environmental and park management struggles since the creation of the park. It is a detailed account of complications that have arisen since the initial creation of the BTNP. Gunter divides this afterword into five sections addressing the bureaucratic beginnings of the park, the acquisition of new units and river property, further development of the park and facilities, and what Gunter calls a "New Big Thicket Crisis" about a struggle to add controversial new tracts of land, and finally what he calls a "postscript to a postscript" introducing, but not expounding on, peripheral issues affecting the Big Thicket.

Each section discussed above ends with a set of notes and references and a thorough index makes for easy location of subjects, organizations and persons mentioned in this book. *Saving the Big Thicket* provides a well-written historical account of the Big Thicket and is a good addition to the UNT Press series on the region. This work could be useful to historians, scientific researchers, restoration project managers, students, and the casual reader alike interested in the region's complex and "entangled" history.—*J. Hayley Gillespie, University of Texas at Austin, Integrative Biology, Austin, TX 78712, U.S.A., hayleygillespie@mail.utexas.edu*

This illustrated monograph is the most comprehensive generic treatment of legumes for any geographical area of Mexico. The book covers the genera of legumes known to be present in northern Mexico from Tamaulipas to Baja California Sur. The introductory material covers topography, climate, and vegetation types of northern Mexico. Included are 121 genera treated in three families: Fabaceae, Mimosaceae, and Caesalpiniaceae. The Fabaceae is the most abundant family with 87 genera followed by Mimosaceae (19) and Caesalpiniaceae (15). Keys to the families, tribes (only in Fabaceae), genera, and detailed line drawings of distinguishing characteristics are included for most of the genera to facilitate identification. Each genus is provided with a description, followed by distributional information, species number, chromosome number, and economic, ecological, and potential food importance.

The Atlas of Texas covers about 6000 taxa. This is the result of 54 years of herbarium and fieldwork by B.L. Turner, beginning in 1948 at Sul Ross State University, Alpine, Texas. In short, the senior author has examined personally, touched, or "pored over" an estimated several hundred thousand sheets in the preparation of the forthcoming Atlas volumes. Contents include an introduction, atlas of Texas plants arranged alphabetically by family, by genus, by species, and an index.

ABSTRACT

Sabatia arkansana, a new species from shale and igneous glades in central Arkansas, is described. It differs from *S. campestris* in its narrower leaves and narrower, more deeply colored corolla lobes rounded at the apex.

RESUMEN

Se describe **Sabatia arkansana,** especie nueva de claros de esquistos y de rocas ígneas en Arkansas central. Se diferencia de *S. campestris* por las hojas más angostas y por los lóbulos de la corola más angostos, coloreados más intensamente, y redondeados en el ápice.

HISTORY OF THE DISCOVERY

In June 2001, while collecting plants for the Flora of Arkansas Project and for his Master's thesis, the junior author was shown a small shale glade (Womble Formation) northwest of Owensville, Saline County, Arkansas, by nature photographer and amateur botanist John Pelton. Pelton, a long-time student of the flora of Arkansas and of Saline County in particular, was especially interested in showing Witsell plants of a *Sabatia* that he was unable to identify to species. Witsell collected specimens of this plant, as well as specimens of *Sabatia campestris* Nutt., which occurred in the same area.

Studies using all relevant botanical references available at the Arkansas Natural Heritage Commission and the University of Arkansas at Fayetteville Herbarium (UARK) supported the idea that this species was significantly different from any described in the literature. In any of the regionally appropriate keys, specimens of this plant keyed out to *S. campestris*. However, seeing *S. campestris* and this new species occurring at the same site made the differences between the two obvious (Fig. 3).

Conversations with the landowner at this site revealed the existence of another, larger glade opening 0.2 mile (0.3 km) northwest of the known glade. This glade was impressive in its botanical diversity and in that two intermittent spring-fed streams flow into the glade and join before flowing out of the glade downslope. More plants of this new *Sabatia* were found in this opening, which should be considered part of the same complex rather than a completely separate site.

In June 2002, while conducting surveys for the rare small-headed pipewort (*Eriocaulon kornickianum*) on igneous glades near Bauxite, Saline County, Arkansas, Witsell and Pelton located several more populations of this *Sabatia*.

Witsell compared the Saline County specimens with *Sabatia* specimens from a broader region at the herbarium of the Missouri Botanical Garden (MO) in July 2002. When no matches were found at MO, the Saline County specimens were sent to the senior author for confirmation that this was indeed a species new to science.

DESCRIPTION OF THE SPECIES

Sabatia arkansana J.S. Pringle & C.T. Witsell, sp. nov. **(Figs. 1–5)**. TYPE: ARKANSAS: Saline Co.: Alcoa Lake Glades Natural Area, 3.5 mi (5.6 km) SE of Bauxite, NE 1/4 of SW 1/4 of Section 26, T2S R14W, northernmost glade opening on W shore of lake, 18 Jun 2002, *Witsell 02-0832* (HOLOTYPE: UARK; ISOTYPE: MO).

Sabatia campestri affinis sed foliis linearibus vel anguste lanceolatis et corollis atroroseis lobis anguste spathulatis apicem versus rotundatis differens.

Annuals; roots fibrous. Plants 7–25 cm tall, single-stemmed at base. Stems ± terete but narrowly 4-winged; proximal diameter 0.4–1.3 mm, wings ca. 0.1–0.2 mm high; branching generally alternate (rarely opposite proximally), mostly at 30–50°, lowest branching ca. mid-height. Proximal internodes 0.8–2× as long as subtending leaves, distal internodes 0.6–1× as long. Leaves all cauline, bright green, membranous, spreading, linear to lanceolate; most leaves 7–30 × 1–4.5(–6) mm; bases narrowed, not clasping, apices obtuse (proximal leaves) to acute or acuminate (mid-stem and distal leaves); leaves smaller near base of stem, lowermost leaves minute. Inflorescence a ± corymboid, monochasial cyme; flowers 1–12(–18) per plant. Pedicels (2–)10–40 mm. Perianth and androecium pentamerous. Calyx (0.7–)1.0–1.4× as long as corolla; tube turbinate, green along commissural veins, otherwise whitish and nearly hyaline, 2.8–5.5 mm, 0.7–0.9× as long as corolla tube; ridges present along commissural veins of tube, triangular in cross-section, rounded or distally acute along apex but not winged, widening from 0.2–0.5 mm at base to 0.5–0.8 mm at summit of tube, where there is sometimes a minute protuberance, dividing into lower ridges along submarginal veins of lobes; lobes green, spreading at 60–90°, nearly filiform to linear, 9–13 × 0.6–1.2 mm, apices acute. Corolla deep but bright magenta-pink, with an oblong-triangular, sometimes apically notched yellow zone extending from tube into each lobe along midrib, alternating with shorter, yellowish-white zones flanking sinuses; tube 3–7 mm; lobes narrowly spatulate-obovate, 8–18 × 3–6 mm, apices rounded. Filaments (3–)4–5.5 mm, ca. 1.5× as long as uncoiled anthers; anthers yellow, 2.3–3.5 mm long before coiling. Pollen grains subprolate, 33–38 µm long, 27–34 µm in diameter. Uncleft portion of style 2–3.5 mm, style

Fig. 1. ***Sabatia arkansana*, holotype.**

branches plus stigmas when uncoiled (3–)4.5–6 mm, 1.7–2.5× as long as uncleft portion.

Paratypes: **ARKANSAS: Saline Co.:** Bauxite, sandy outwash on rock outcrop, 6 Jun 1950, *Moore 50-0161* (UARK); locality and date uncertain (see note below), *Moore 50-0168* (UARK); Womble Shale glade on W side of Burk Rd. NW of Owensville, 21 Jun 2001, *Witsell 01-0474*; Alcoa Clear Lake Glade, 2.5 mi (4.0 km) ESE of Bauxite, N 1/2 of NW 1/4 of NW 1/4 of Section 23, T2S R14W, 18 Jun 2002, *Witsell 02-0829*; Womble Shale glade E of Burk Road and W of the Middle Fork of the Saline River, NW of Owensville, NE 1/4 of SE 1/4 of Section 17, T1S R17W, 18 Jun 2002, *Witsell 02-0825*; International

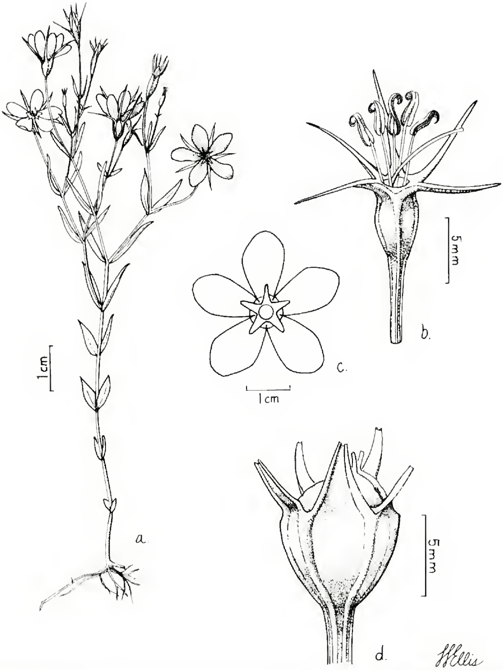

Fig. 2. ***Sabatia arkansana*****. A.** Plant (*Witsell 02-0829*, UARK). **B.** Flower, lateral view with petals removed, anthers newly dehisced and the stigma not yet receptive (*Witsell 02-0832*, UARK). **C.** Flower, adaxial view with stamens and sepals removed (*Witsell 02-0832*, UARK). **D.** Capsule, largely enclosed in persistent calyx (*Witsell 02-1125*, UARK).

Paper Pipewort Glades Preserve [now Dunnahoo Preserve, The Nature Conservancy], 3.5 mi (5.6 km) SE of Bauxite, NE 1/2 of NE 1/4 of Section 34, T2S R14W, 19 Jun 2002, *Witsell 02-0838*; Dry Lost Creek Glades, 1.75 mi (2.8 km) SE of Bauxite, E 1/2 of SE 1/4 of Section 21, T2S R14W, 19 Jun 2002, *Witsell 02-0840*, Womble Shale glades E of Burk Road and W of the Middle Fork of the Saline River, NW of Owensville, NE 1/4 of SE 1/4 of Section 17, T1S R17W, 10 Aug 2002, *Witsell 02-1125*. Unless otherwise indicated, specimens are in the herbarium of the Arkansas Natural Heritage Commission

The two specimens collected by D.M. Moore in 1950 were originally identified as *Sabatia campestris*. *Moore 50-0161* was labeled as being collected at Bauxite 6 June. *Moore 50-0168*, although bearing a higher number, was labeled as being collected 15 miles south of Little Rock, near Ferguson Lake, the previous day. Ferguson Lake is in extreme southeastern Saline County, on unconsolidated Tertiary and Quaternary sediments (Haley et al. 1976). No rock outcrops or glades—that is, no suitable habitats for *S. arkansana*—are known from the area. It is unlikely that *S. arkansana* actually occurred at this site, and it may be that specimens from the two sites were mixed up.

The genus *Sabatia* Adans. and its sections and subsections have been described by Wilbur (1955). *Sabatia arkansana* is unequivocally a species of sect. *Campestria* J.D. Perry. This section, which is well defined morphologically and isolated genetically, is most readily recognizable by its calyx morphology (Wilbur 1955; Perry 1971). In all species in the section, prominent ridges extend along the commissural (fused lateral) veins from the base of the calyx to the sinuses between the lobes. At the sinuses they divide and extend along the submarginal veins of the adjacent lobes. The commissural and submarginal veins, therefore, are more prominent than the midveins, which are not ridged. In the other sections the calyx tubes either lack ridges along the veins or have low-ridged commissural veins that are no more prominent than the midveins. Plants in sect. *Campestria* are annuals, and the branching is entirely or predominantly alternate. The flowers are pedicellate and are pentamerous except for the carpels. Except in *S. arenicola*, the eye of the corolla is of the shape and pattern described above for *S. arkansana*, as contrasted with the more widely triangular yellow zones of most species with pink corollas in the other sections. The stamens are inserted immediately below the sinuses of the corolla. The combinations of style branches plus stigmas are linear. The morphology of *S. arkansana* is consistent with that of the section in all of these respects.

Sabatia arkansana exhibits the syndrome of floral morphology associated with predominantly allogamous pollination in *Sabatia* (Hill 1891; Perry 1971). The corollas are showy and brightly colored, with sharply contrasting eyes. The flowers are protandrous. Initially the styles and stigmas are bent nearly horizontally to one side, and the style branches are helically coiled around each other, so that the stigmatic surfaces are not exposed. At this stage the stamens are nearly erect. The anthers, when mature, coil circinately at the tip, with the rest of the anther still being straight and nearly erect when the pollen sacs dehisce. Subsequently the stamens diverge and the whole anther curves into a bass-clef shape. The stigmas then become receptive. The uncleft portion of the style becomes erect, and the branches diverge and uncoil more or less completely.

Etymology and common name.—We name this new species *Sabatia arkansana* for the state to which it is apparently endemic. We propose the common name

Fig. 3. *Sabatia arkansana* (right), with *Sabatia campestris* (left) at the Womble Shale glade site. Photo by John Pelton.

"Pelton's rose-gentian" in honor of John Pelton, who first noticed that this species was distinct from *S. campestris*, but was too humble to allow a scientific name to be given in his honor. He has done much to further our knowledge and appreciation of the flora of Arkansas through his insight, his photography, and his encouragement and tutelage of younger students of the flora.

COMPARISON WITH RELATED SPECIES

Only three species, or in some treatments only two, have generally been recognized in sect. *Campestria* (Wilbur 1955; Perry 1971; Bell & Lester 1980). The leaves of *S. arkansana* are narrower than those of any other species in the section. The mid-stem leaves of the largest plants of *S. arkansana* are linear to narrowly lanceolate, 4–8× times as long as wide, with three primary veins. Except for one pair of leaves on one plant that were 6 mm wide, the maximum width of any leaf seen was 4.5 mm. All leaves of the smaller plants are linear, 1–2 mm wide, with one primary vein. Also uniquely in the section, the corolla lobes of *S. arkansana* are narrowly spatulate-obovate, generally more than 1.8× and often more than 2.2× as long as wide. They are widest at ca. 0.8× their length. The apex is rounded.

Sabatia campestris Nutt., the most widespread species in sect. *Campestria*, is the most similar to *S. arkansana*. Both *S. arkansana* and *S. campestris* (*Witsell 01-0473*) were found at the locality where *Witsell 01-0474* was collected. At this

Fig. 4. *Sabatia arkansana*, habit. Photo by John Pelton.

Fig. 5. *Sabatia arkansana*, detail of inflorescence. Photo by John Pelton.

site as elsewhere *S. arkansana* appears distinctly different in the field, and does not intergrade with *S. campestris*. Plants of *S. campestris* are larger than those of *S. arkansana* in nearby sites. Its leaves are ovate to lance-elliptic, 8–40 mm long × 5–20 mm wide, with clasping, rounded to subcordate bases. The ridges on its calyx tube have a distinct wing or keel along the apex, ca. 1.0 mm high, which projects slightly above the sinus. Its corollas are a paler, less purplish shade of pink. Its corolla lobes are obovate, less than 1.8× as long as wide, and are widest at ca. 0.6× their length. The apex is usually abruptly acute, occasionally obtuse.

The pollen grains of *Sabatia* are tricolporate, with a finely reticulate exine. Perry (1971) concluded that pollen size was not useful as an indicator of ploidy or as a species characteristic, and that neither shape nor exine sculpturing differed significantly among the species. The pollen of *S. arkansana*, however, is subprolate, and grains in equatorial view are as numerous as those in polar view or more so on a microscope slide. That of *S. campestris*, as seen in the present study, is more nearly spherical, 26–30 μm in diameter, i.e., slightly smaller than that of *S. arkansana*, and, as noted by Perry (1971), nearly always appears in polar view when placed on a slide.

At the Womble Formation locality near Owensville, *S. arkansana* is confined to open, flat, seasonally wet, narrow floodplains and seepage areas, whereas *S. campestris* grows in better-drained, steeper, drier microhabitats. Each of the two species occupies a distinct zone within the glades. Occasional plants of *S. campestris* occur within the microhabitat occupied by *S. arkansana* (Fig. 3) and, as noted above, no intergradation has been observed. *Sabatia campestris* is apparently absent from all of the glades on the nepheline syenite batholith near Bauxite. The two species also differ distinctly in phenology. Based on observations from 2001 through 2004, *S. arkansana* typically begins flowering 7 to 10 days before *S. campestris*, and *S. campestris* continues flowering at least 7 days after *S. arkansana*.

Sabatia formosa Buckley is known from Louisiana, Oklahoma, and Texas. It is recognized here following Bell and Lester (1978, 1980), but has often been included in *S. campestris* (Wilbur 1955). *Sabatia arkansana* is more similar to *S. formosa* than to *S. campestris* in its corolla color and markings but not in other respects. *Sabatia formosa* has closely spaced basal and near-basal leaves, which are larger than the mid-stem leaves and are generally present at flowering time, whereas in *S. arkansana* there is no evidence from crowded leaf-scars that a basal rosette is present at any stage. The proximal and mid-stem leaves of *S. formosa* are lanceolate to ovate, 8–25 × 3–13 mm. Its calyces are usually shorter than the corollas. Its corolla lobes are elliptic-rhombic, less than 1.8× as long as wide, and are widest near the middle, tapering to an obtuse to acute apex.

Sabatia arenicola Greenm. (including *S. carnosa* Small) is a seabeach species, native along the Gulf Coast from Louisiana to Tamaulipas. Unlike *S.*

arkansana it frequently branches from near the base, and its relatively copious and dense branching is proximally more often opposite than that of the other species in section *Campestria*. Its leaves are succulent when fresh and blacken upon drying. They are elliptic to ovate or obovate, 6–27 × 2–13 mm. Its calyx lobes are oblong-lanceolate to narrowly ovate-triangular. It differs further in exhibiting the floral morphology associated with autogamy in *Sabatia*. It has relatively small corollas, which are white or light pink with the eyes whitish and less sharply defined than those of the allogamous species. The styles are nearly erect when the flowers open, and the stigmas are receptive concurrently with rather than after the dehiscence of the anthers.

Only two other validly published names have been associated with sect. *Campestria*, and it is evident that neither was based on specimens of *S. arkansana*. *Sabatia nervosa* Raf. was included in *S. campestris* by Wilbur (1955). Its leaves were described as ovate-lanceolate and its corolla lobes as broadly obovate. The identity of *S. concinna* Alph.Wood, which presumably was based on specimens from Indiana, is uncertain. It was described as having opposite branching, which would be inconsistent with its inclusion in sect. *Campestria*, and calyces only half as long as the corollas.

Small plants of *S. campanulata* (L.) Torr., in sect. *Sabatia* subsect. *Campanulatae* S.F.Blake, are somewhat similar to *S. arkansana* in aspect. *Sabatia campanulata* is an extremely rare (S1) species in Arkansas. It has narrow leaves and calyx lobes, but the plants are perennial, usually with clustered stems, and the pedicels are mostly 40–70 mm. The calyx tube of *S. campanulata* is obconic, only 1–3 mm long and less than 0.5× as long as the corolla tube. Ridges along the commissural veins are absent or low and no more prominent than those along the midveins.

Sabatia arkansana cannot plausibly be interpreted as a recurrently produced interspecific hybrid. In most populations it is the only *Sabatia* species present. Other than *S. campestris*, the only *Sabatia* that has been found in the vicinity of *S. arkansana* is *S. angularis* (L.) Pursh, in sect. *Sabatia* subsect. *Angulares* S.F.Blake. *Sabatia angularis* does not intergrade with *S. arkansana*, and its morphology, which includes opposite branching, stem wings 0.2–0.3 mm high, and lanceolate to ovate leaves 5–30(–40) mm wide, does not suggest that it might be a parent of *S. arkansana*. The only other *Sabatia* species known from Arkansas are *S. brachiata* Ell., in sect. *Sabatia* subsect. *Angulares*, and *S. gentianoides* Ell., in sect. *Pseudochironia* Griseb. The first is uncommon in Arkansas, and the latter is extremely rare (S1) in the state. No intersectional hybrids in *Sabatia* are known in nature (Wilbur 1955; Perry 1971). All of Perry's (1967) attempts to make intersectional crosses involving species in sect. *Campestria*, including *S. campestris* × both *S. angularis* and *S. campanulata*, were unsuccessful.

KEY TO THE SPECIES OF *SABATIA* SECT. *CAMPESTRIA*

1. Leaves succulent when fresh, blackening in drying, elliptic to ovate or obovate; corolla lobes 4–10(–13) mm ____ **Sabatia arenicola**
1. Leaves not succulent nor blackening, linear to ovate; corolla lobes 8–25 mm.
  2. Basal leaves usually present at flowering time; calyces usually shorter than corollas; corolla lobes elliptic-rhombic, widest near mid-length ____ **Sabatia formosa**
  2. Basal leaves absent at flowering time; calyces usually as long as or longer than corollas; corolla lobes spatulate to obovate, widest distally.
    3. Leaves all lanceolate to linear, generally less than 5 (rarely to 6) mm wide; corolla lobes deep magenta-pink, more than 1.8× as long as wide, widest at ca. 0.8× or more of their length, rounded at apex ____ **Sabatia arkansana**
    3. Leaves except in distal portions of inflorescence lance-elliptic to ovate, more than 5 mm wide; corolla lobes light pink or occasionally white, less than 1.8× as long as wide, widest at ca. 0.6× their length, ± acute at apex ____ **Sabatia campestris**

HABITAT AND ASSOCIATED SPECIES

Sabatia arkansana is a plant of flat, seasonally wet microhabitats in shale and igneous glades in the eastern Ouachita Mountains and igneous batholiths of the Upper West Gulf Coastal Plain of central Arkansas. It appears to be restricted to small flat areas along the narrow floodplains of intermittent streams or along seepage areas within these glades. These habitats are typically wet in the winter and spring but usually become dry by July and remain so until the late fall. The substrate consists of thin soil over bedrock and of loose, weathered fragments of the same type as the local bedrock. No standing water was observed around the plants at the time of flowering.

Sabatia arkansana is known from glades with two different geologic substrates: shale from the Womble Formation and the igneous rock nepheline syenite (Fig. 6). The Womble Formation was deposited during the Middle Ordovician and consists of mostly black shale with thin layers of limestone, silty sandstone, and some chert (McFarland 2004). It is confined to the Central Ouachita Mountains physiographic province, a subsection of the Ouachita Mountains (Foti & Bukenhofer 1998). Large igneous intrusions of Late Cretaceous age outcrop in the Upper West Gulf Coastal Palin (Saline and Pulaski counties) and consist largely of nepheline syenite. These intrusions consist of light gray or bluish feldspathic and feldspathoidal igneous rocks in a batholith containing pendants of altered rocks of Paleozoic age, and are weathered locally to kaolin or bauxite (Haley et al. 1976; Gordon et al. 1958). These are the largest outcroppings of igneous rocks in Arkansas and are located within the Upper West Gulf Coastal Plain physiographic province, an area consisting of mostly unconsolidated surface geology of Cretaceous age and younger (McFarland 2004).

Associated species include *Talinum calycinum*, *Croton wildenowii*, *Croton capitatus*, *Croton monanthogynus*, *Euphorbia cyathophora*, *Bulbostylis capillaris*, *Fimbristylis autumnalis*, *Valerianella nuttallii*, *Calamintha arkansana*, *Allium*

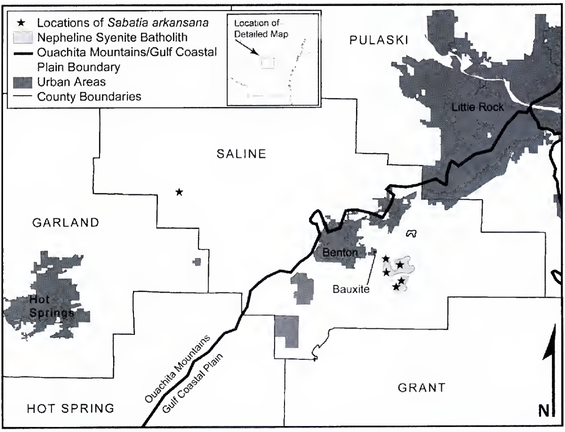

Fig. 6. Map showing the locations of collections of *Sabatia arkansana* in Saline County Arkansas and the nepheline syenite batholith southeast of Bauxite.

canadense var. *mobilense*, *Hedyotis nigricans*, *Asclepias longifolia* var. *hirtella*, *Sedum pulchellum*, *Polygonum tenue*, *Aristida dichotoma* var. *curtissii*, *Digitaria cognata*, *Sporobolus ozarkanus*, *Panicum flexile*, *Chamaesyce missurica*, *Nemastylis nuttallii*, *Silphium laciniatum*, *Ptilimnium nuttallii*, *Amsonia hubrichtii*, *Aster oblongifolius*, *Eriocaulon kornickianum*, *Isoetes butleri*, *Grindelia lanceolata*, *Mimosa quadrivalis* var. *nuttallii*, *Astragalus distortus* var. *engelmannii*, *Selenia aurea*, *Ranunculus pusillus*, *Astranthium integrifolium*, *Minuartia patula*, *Eryngium yuccifolium*, *Spiranthes vernalis*, and *Nostoc* sp. (Nomenclature follows Kartesz 1999).

Of these associates, the following (given with their conservation status ranks) are tracked as elements of special concern by the Arkansas Natural Heritage Commission: *Valerianella nuttallii* (G1G2S1), *Nemastylis nuttallii* (G4S2), *Amsonia hubrichtii* (G3S3), *Eriocaulon kornickianum* (G2S2), *Chamaesyce missurica* (G5S2), and *Bulbostylis capillaris* (G5S3) (Arkansas Natural Heritage Commission 2002). *Valerianella nuttallii* and *Amsonia hubrichtii* are endemic to the Ouachita Mountains and Arkansas Valley of Arkansas and Oklahoma.

This new species of *Sabatia* is one of more than 15 endemic plant taxa from the Ouachita Mountains (including upland portions of the Arkansas River Valley and the igneous batholith that outcrops in the Upper West Gulf Coastal Plain near the edge of the Ouachita Mountains in Saline and Pulaski counties, Arkansas). In addition to *V. nuttallii* and *A. hubrichtii*, these endemic taxa include *Amorpha ouachitensis*, *Carex latebracteata*, *Galium arkansanum* var. *pubiflorum*, *Liatris compacta*, *Hydrophyllum brownei*, *Polymnia cossatotensis*, *Monarda stipatoglandulosa*, *Houstonia ouachitana*, and *Quercus acerifolia* (Zollner et al. 2005).

CONSERVATION STATUS

Though *S. arkansana* has been collected from a number of glade openings, all of these are components of only two larger glade complexes, the nepheline syenite complex near Bauxite and the Womble Formation (shale) complex near Owensville. Therefore it can accurately be stated that this species is known from just two sites in the world, both in Saline County, Arkansas. Glades with appropriate microhabitat in adjacent counties (Pulaski, Garland, and Montgomery) were searched in 2003 and 2004 and no new sites for *S. arkansana* were found. Because *S. arkansana* is an annual, population size fluctuates from year to year. Two shale glade openings at the Womble Formation site support populations of *S. arkansana*, which ranged from approximately 200 to more than 1000 individuals per opening from 2001 to 2004. Five glade openings in the nepheline syenite complex support populations on *S. arkansana*, which ranged from hundreds to thousands of plants per opening from 2001 to 2004.

These glades have historically been the sites of mines (in the case of the economically important nepheline syenite) and borrow pits for road fill material (in the case of the shale glades). The absence of significant past mining at the Womble Formation locality makes it an especially rare site among shale glades in the Ouachita Mountains. The open character of these glades is maintained in part edaphically by the thin soil and in part, at least historically, by fire. The absence of fire in recent years has allowed glades throughout the region to be invaded by woody plants, particularly eastern redcedar (*Juniperus virginiana*). This encroachment has led to the decline of many plant species dependent upon open glade habitat.

These factors, along with significant pressure from encroaching residential development, make these glades a high conservation priority. Several glades immediately west of the Womble Formation locality (and part of the same glade complex) have recently been destroyed for an addition to a large gated residential golf course community. Fortunately, the Arkansas Natural Heritage Commission was recently able to acquire and protect 136 acres (55 ha) that include the *S. arkansana* locality, several other glades, and associated woodlands and forest. Meanwhile, all of the known *S. arkansana* sites on the nepheline syenite batholith are being protected by joint efforts of the Arkansas Field Office of The Nature Conservancy and Alcoa Corporation.

ACKNOWLEDGMENTS

Theo Witsell extends special thanks to John Pelton for sharing his enthusiasm and knowledge of the flora of Arkansas, and for showing him that beautiful pink flower in the glade back in the summer of 2001. Thanks also to Linda Ellis for the illustration and to Tanya Miller-Witsell for spending a day of our honeymoon in the herbarium at the Missouri Botanical Garden. Jim Peck (LRU), Johnnie Gentry (UARK), and George Yatskievych (MO) all helped facilitate this research. Seth Young, Chris Tracey, and Bill Shepherd reviewed and improved earlier versions of this manuscript. Thanks also to Meryl Hattenbach, Scott Simon, and Doug Zollner of the Arkansas Field Office of The Nature Conservancy, Jarvis Harper of Alcoa Corporation, and the staff of the Arkansas Natural Heritage Commission. Special recognition should go to Hugh and Steve Davis for granting permission to collect on their land at the Womble Formation site and for agreeing to sell a portion of that land for dedication as the Middle Fork Barrens Natural Area. James S. Pringle thanks the curators and staff of the herbaria of the Arkansas Natural Heritage Commission and the University of Arkansas at Fayetteville for the loan of specimens, and those at Harvard University and the Missouri Botanical Garden for the opportunity to study and compare specimens at those institutions.

ABSTRACT

A new species, **Aulonemia nitida** Judz., is described from the Pakaraima Mountains of Guyana, South America. It is a large-leaved species that differs from the Mesoamerican species *A. laxa* and *A. patriae* in its smooth, shining, non-striate, non-maculate foliage leaf sheaths. An illustration of the new species and a key to the species of *Aulonemia* from the Guayana Highlands are provided.

RESUMEN

Se describe una especie nueva, **Aulonemia nitida** Judz., de las montañas de Pakaraima, Guyana, América del Sur. Es una especie con láminas foliares grandes y anchas parecida a las especies Mesoamericanas *A. laxa* y *A. patriae*, pero se distingue por sus vainas foliares lisas y lustrosas, sin estriaciones o manchitas. Se incluyen una ilustración de la nueva especie y una clave de las especies de *Aulonemia* de las montañas de Guayana.

Since the publication of the grass treatment for the "Flora of the Guianas" project (Judziewicz 1991), several more specimens of a new bamboo (Poaceae: Bambusoideae: Bambuseae: Arthrostylidiinae) species from the Guayana Highlands have come to light. The name *Aulonemia nitida* has long been in print, appearing as a *nomen nudum* in Boggan et al. (1997: 168) checklist of Guianas plants, and, based on the Boyan specimen, was recognized as a likely new species as long ago as 1988. Even though all five known collections are sterile, the taxon is so distinctive that I have chosen to propose it here as a new species, following the example of Clark (1989, 1992) who has named several distinctive species in the bamboo genus *Chusquea* Kunth based on material lacking inflorescences. Specimens were examined from the following herbaria: F (2002), FDG (1988), K (1989), MO (2004), NY (1989), US (2004), UWSP (2004), and WIS (2004).

Aulonemia nitida Judz., sp. nov. (**Fig. 1**). Type: GUYANA. Potaro-Siparuni Region: upper slopes of Mt. Wokomung, 5°05'N-59°50"W, 1530 m, *Hedyosmum*-bamboo dominated moist forest, bamboo with culms at base to 2 cm diam., overall height 4 m, common and at times dense on upper slopes, sterile, 14 Jul 1989, *B.M. Boom & G.J. Samuels 9224* (holotype: FDG!; isotypes: MO-3 sheets!, NY!).

Graminum cespitosum. Culmi usque ad 5 m longi, 2.5 cm lati. Vaginae foliorum glabrae, nitidae, fimbriatae ad apicem tantum; fimbriae 7–10 cm longae; laminae foliorum 25–37 cm longae, 7–10.5 cm latae, lanceolatae-ovatae. Inflorescentia non vidi.

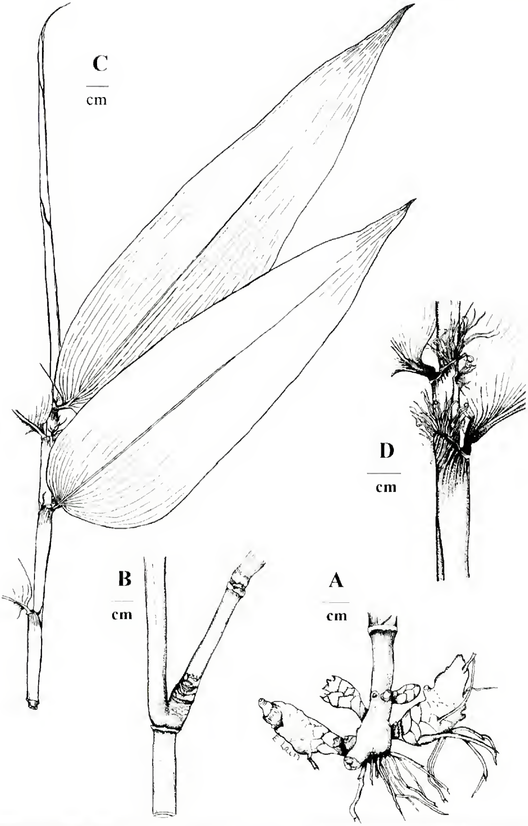

Fig. 1. A. Base of plant showing sympodial rhizomes (nodes and internodes decayed or indistinct in available material). **B.** Culm and branch. **C.** Branch with foliage leaves. **D.** Detail of ligular area. Scale bar = 1 cm. Illustration by Emily Lain. A and B based on *Boom & Samuels 9224* (MO), C and D based on *Henkel, Williams, Fratello & Williams 4493* (WIS).

Cespitose perennial, thicket-forming woody bamboo from short, sympodial rhizomes; glabrous throughout. Culms up to 5 m long and at least 2.5 cm in diameter, shiny, hollow, the walls only ca. 1 mm thick with a 1–1.5 mm thick annular ring present at the lower nodes; buds and branches one per node. Culm leaves not seen, perhaps not differentiated from foliage leaves. Foliage leaves at least 5 per complement; sheaths glabrous, smooth, shiny, and stramineous throughout most of their length, strongly keeled 3–5 cm below the apex, striate only in the area 0.5–1 cm below the apex; fimbriae ca. 12–20, each 7–10 mm long, pale, flexuous and spreading, confluent basally and forming an indurate rim at the summit of the leaf sheath; outer ligules ca. 0.2 mm long, indurate, rim-like; inner ligules 1–1.5 mm long, membranous; pseudopetioles 7–10 mm long, pale; blades 25–37 × 7–10.5 cm, narrowly ovate to broadly lanceolate, rounded to very slightly oblique or subcordate at the base, acuminate at the apex, not evidently tessellate, the abaxial surface slightly whitened or bluish green. Inflorescence not seen.

Additional collections examined (PARATYPES): **GUYANA Cuyuni-Mazaruni Region:** Ayanganna [a sandstone mountain with a summit elevation of over 2100 m] slope, among rocks in low forest, sterile, 2 Mar 1960, *R. Boyan 120* [= FD7944] (FDG, NY); Pakaraima Mts., 2 km transect along summit ridge of Mt. Ayanganna, 5°23'N-59°59'W, 1800–2000 m, low sclerophyllous community, organic soils on sandstone, 3 Nov 1992, *B. Hoffman & T. Henkel 3209* (US, WIS). **Potaro-Siparuni Region:** Mt. Wokomung, E-most pinnacle of massif, 5°05'34"N-59°50'13"W, 1524 m, coarse herb 4 m, sterile, 13 Jul 2003, *H.D. Clarke, R. Williams, C. Perry, E. Tripp, D. Gittens & S. Stern 10808* (US, WIS); Mt. Wokomung, summit ridge of Ka-mie-wah pinnacle NE to S pinnacle, "Little Ayanganna," 5°04'N-59°52'W, 1550–1650 m, mixed hardwood cloud forest grading to Guyana scrub forest on pinnacle escarpments; on sandstone, stout bambusoid grass from 1–5 m tall, forming thickets on rocky ridges, sterile, 17 Nov 1993, *T.W. Henkel, R. Williams, S. Fratello, L. Williams 4493* (FDG, MO, US, WIS).

DISCUSSION

Aulonemia nitida is endemic to elevations of 1500–2100 m in cloud forests on sandstone tepuis in the Pakaraima Mountains (Mt. Ayanganna and Mt. Wokomung; all collections come from an area of about 30 km in length) of Guyana near the Brazilian frontier. The species epithet derives from the nitid or shiny foliage leaf sheaths. A vernacular name is "reroballi" (*Boyan 120*).

There are 35 described species of *Aulonemia* throughout tropical America (Clark et al. 1997; Judziewicz et al. 1999, 2000) and I am currently working on a revision of the genus. *Aulonemia nitida* appears to be most closely related to the Mesoamerican species *A. laxa* (F. Maek.) McClure and *A. patriae* R. Pohl (Pohl & Davidse 1994). All three taxa have broad, fimbriate foliage leaves with distinctive keeled sheaths, but *A. laxa* and *A. patriae* have sheaths that are striate and maculate their entire lengths. *Aulonemia nitida* differs in its smooth, shiny, non-maculate sheaths that are striate, if at all, only in the final 1 cm or so below the ligular area. The two Mesoamerican species also differ in their generally longer (10–32 mm) fimbriae; those of *A. laxa* are straight and appressed to the culm, not spreading as in *A. nitida* and *A. patriae*.

There are eight species of the *Aulonemia* in the Guayana Highlands (Judziewicz 2004). In the "Flora of the Venezuelan Guayana" (Judziewicz et al. 1991; Judziewicz 2004) *Aulonemia nitida* would key to either *A. deflexa* (N.E. Brown) McClure, *A. chimantaensis* Judz. & Davidse, or *A. jauaensis* Judz. & Davidse. However, these three taxa have smaller foliage leaf blades (a maximum of 22 × 4.5 cm versus at least 25 × 7 cm in *A. nitida*), longer fimbriae (10–20 mm long versus 7–10 mm in *A. nitida*), and completely striate foliage leaf sheaths. *Aulonemia deflexa*, the only other species known from Guyana, is present at higher elevations on Mt. Roraima (ca. 2800 m), as well as on several Venezuelan tepuis. *Aulonemia patula* (Pilg.) McClure from Andean Colombia and Ecuador has similarly large foliage leaves, but the sheaths are non-keeled, non-striate, and the fimbriae are conspicuous all along the sheaths margins as well as at the sheath summit. A key differentiating the species of *Aulonemia* found in the Guayana Highlands follows.

KEY TO THE SPECIES OF *AULONEMIA* FROM THE GUAYANA HIGHLANDS

1. Foliage leaf sheaths with marginal fimbriae.
  2. Foliage leaf blades with midrib excentric, placed 5–7 mm from one margin of a blade 22–25 mm wide; 600–700 m, Cerro Huachamacari, Amazonas, Venezuela ____ **A. sp. A** (Judziewicz 2004)
  2. Foliage leaf blades with midrib placed centrally on a blade 30–60 mm wide; 2200 m, Bolívar and Amazonas, Venezuela ____ **A. aff. subpectinata** (Kuntze) McClure
1. Foliage leaf sheaths lacking marginal fimbriae.
  3. Foliage leaf sheath summits prominently auriculate; 1000–2000 m, Cerro Duida, Amazonas, Venezuela ____ **A. sp. B** (Judziewicz 2004)
  3. Foliage leaf sheath summits lacking auricles.
    4. Dwarf plants ca. 0.5 m tall; foliage leaf blades ca. 4 cm long, 0.7 cm wide; 2600 m, Cerro Marahuaka, Amazonas, Venezuela ____ **A. sp. C** (Judziewicz 2004)
    4. Plants 1–3 or more m tall; foliage leaf blades 11—37 cm long, 1.8–10.5 cm wide.
      5. Foliage leaf sheaths smooth and shiny, the blades 25–37 cm long, 7–10.5 cm wide; fimbriae 7–10 mm long, 1500–2100 m, Guyana ____ **A. nitida** Judz.
      5. Foliage leaf sheaths striate and dull, the blades 11–20 cm long, 1.8–4.5 cm wide; fimbriae 10–20 mm long.
        6. Spikelets 12–20 mm long, 4–5-flowered; 2100–2800 m, Bolívar, Venezuela and adjacent Guyana ____ **A. deflexa** (N.E. Brown) McClure
        6. Spikelets 22–70 mm long, 9–23-flowered.
          7. Spikelets 22–40 mm long, 9–15-flowered; lemmas 8–10 mm long, obtuse, slightly tridentate at apex, glabrous to sparsely puberulent on the back, the margins short-ciliate; 2100–2200 m, Macizo de Chimantá, Bolívar, Venezuela ____ **A. chimantaensis** Judz. & Davidse
          7. Spikelets (20–)40–70 mm long, 11–23-flowered; lemmas 10–13 mm long, acute, densely puberulent throughout with prickle-like hairs; 1900–2100 m, Cerro Jaua, Bolívar, Venezuela ____ **A. jauaensis** Judz. & Davidse

ACKNOWLEDGMENTS

I thank Lynn G. Clark for encouraging me to publish this paper; the curators of MO, US, and WIS for loans; Emily Lain for the illustration; and Paul M. Peterson for a thorough and helpful review.

BOOK REVIEWS

ROLAND H. WAUER. 2001. **Naturally…South Texas: Nature Notes from the Coastal Bend.** (ISBN 0-292-79144-5, hbk.). The University of Texas Press, P.O. Box 7819, Austin, TX 78713-7819, U.S.A. (**Orders:** 800-252-3206, fax 800-687-6046, www.utexas.edu/utpress). $22.95, 240 pp., 6" × 9".

This is a collection of brief essays arranged chronologically as a "natural history calendar" and sorted into 12 chapters, January through December. All were originally published in the Victoria Advocate, the regional newspaper. After the author retired from the National Park Service, he moved to Victoria (about halfway between Houston and Corpus Christi) in south Texas, which "undoubtedly is the best birding area anywhere in the United States." This region "encompasses four rather distinct ecosystems, all within a mile circle of Victoria: the northeastern edge of the South Texas Plains, the southern edges of the Post Oak Savannah and Blackland Prairie, and the heart of the Gulf Prairie and Marshes." Wauer's attention is strongly turned to birds, but various plants, insects, and other animals are highlighted. The essays are built around his own observations and interpretations and are supported by "technical" insertions from various sources—all easily readable and enjoyable.—*Guy Nesom, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

JASON F. SHOGREN (Ed.). 2005. **Species at Risk: Using Economic Incentives to Shelter Endangered Species on Private Lands.** (ISBN 0-292-70597-2, pbk.). The University of Texas Press, P.O. Box 7819, Austin, TX 78713-7819, U.S.A. (**Orders:** 800-252-3206, fax 800-687-6046, www.utexas.edu/utpress). $21.95, 271 pp., 6" × 9".

Regarding the rapid decline and loss of species: "The stakes are high, and they go to the heart of our collective responsibility to leave this land a better place than we found it. This book is an attempt to develop and refine a workable, practical, and equitable set of incentives for preserving species and the habitat they need for survival" (from the Foreword). About half of all endangered species rely on private land for their habitat, but private landowners have often opposed the regulations of the Endangered Species Act, which, they argue, unfairly limits their right to profit from their property. "In this book, lawyers, economists, political scientists, historians, and zoologists come together to assess the challenges and opportunities for using economic incentives as compensation for protecting species at risk on private property."

1. Introduction

Part I. Current and proposed incentive options for species protection on private lands.

2. The Endangered Species Act and its current set of incentive tools for species protection.

3. An economic review of incentive mechanisms to protect species on private lands.

Part II. Challenges to using economic incentives for species protection

4. Endangered species protection and ways of life: Beyond economy and ecology.

5. A critical examination of economic incentives to promote conservation

6. Appraising the conservation value of private lands.

7. Markets for conserving biodiversity habitat: Principles and practice.

8. The role of private information in designing conservation incentives for property owners.

Part III. Economic incentives for ESA reauthorization

9. Evaluating the incentive tools

FOUR NEW SPECIES OF ERICACEAE (VACCINIEAE) FROM ECUADOR

James L. Luteyn

Institute of Systematic Botany

jluteyn@nybg.org

ABSTRACT

Four new species of endemic blueberries from montane Ecuador, **Ceratostema oyacachiensis, Ceratostema pendens, Ceratostema pubescens**, and **Disterigma bracteatum**, are described, illustrated, and their relationships discussed.

RESUMEN

Se describen y se discuten cuatro especies nuevas endemicas de mortiños de la sierra del Ecuador, **Ceratostema oyacachiensis, Ceratostema pendens, Ceratostema pubescens**, y **Disterigma bracteatum**, con sus ilustraciones y relaciones.

INTRODUCTION

In Ecuador, the Ericaceae, with 21 genera and about 222 species, are one of the largest and most conspicuous montane, flowering plant families (Luteyn 1996, 1998, 2002). Despite the recent treatment of the family in the *Flora of Ecuador* series, the number of new species continues to increase due to additional collecting efforts in previously unexplored or underexplored regions. This paper documents some of these new species and emphasizes, once again, that our basic knowledge of the numbers of species in this family, even in a country as well collected and studied as Ecuador, is still uncertain.

CERATOSTEMA Jussieu

Ceratostema is a montane genus of about 35 species of blueberries that is characterized by stamens usually as long as the corolla and of equal lengths, pedicels usually articulate with the calyx, anther thecae that are coarsely papillate, anther tubules that are elongate and about half the diameter of the thecae, and large corollas with lobes that are proportionately elongate. It ranges from Venezuela and Guyana south through the Andes to northern Peru. Luteyn (1984, 1986) considered the genus morphologically related to *Semiramisia* Klotzsch, although recent molecular studies (Powell & Kron 2003) place it in a clade with *Macleania* Hook. and *Psammisia* Klotzsch. The genus is currently being investigated by the author.

Ceratostema oyacachiensis Luteyn, sp. nov. **(Fig. 1).** TYPE: ECUADOR. NAPO: Río Chalpi at confluence with Río Oyacachi, 00°15'S, 77°58'W, 2500–2550 m, 21 May 1996 (fl), *B. Ståhl, P. Asimbaya & H. Navarrete 2512* (HOLOTYPE: NY; ISOTYPES: AAU, K n.v., MO n.v., QCA n.v., QCNE n.v.).

Species nova ab congeneribus differt foliis quoad venationem plinerviis, base late cuneatis vel obtusis, calycibus ad pedicellos articulatis, tubo calycino 10-costato, limbo calycino inconspicuo, rotato, lobis calycinis brevibus ad basem glandulis circularibus carentibus sed ad margines lacerato-glandulosis, atque corollis magnis crasso-carnosis lobis earum brevibus latisque.

Epiphytic **shrubs**; mature stems terete or subterete and bluntly angled, glabrous, the bark grayish, cracking longitudinally and exfoliating in thin strips; twigs terete to subterete, striate, glabrous, reddish-brown; axillary buds arising up to 3. 5 mm above leaf-nodes, the outer pair of scales 2, valvate, relatively obscure, narrowly triangular, acuminate, up to 2.5 mm long. **Leaves** alternate, flat, the blades thick-coriaceous, lanceolate, 5.2–11 × 1.2–2.4 cm, basally broadly cuneate to obtuse, apparently decurrent onto petiole, apically long-acuminate, glabrous, the venation weakly 3–5-plinerved from near base, the midrib thickened and raised in proximal ca. 5 mm then plane to weakly impressed distally adaxially, raised and conspicuous abaxially, the lateral nerves plane to very weakly impressed adaxially and raised abaxially, the reticulate veinlets obscure adaxially and weakly raised abaxially; petioles subterete, slightly flattened adaxially, slightly winged to blade, ca. 4–11 mm long, glabrous. **Inflorescences** axillary, sometimes located along tips of branches where leaves have fallen, racemose, 2–8-flowered, somewhat short-pedunculate with flowers congested distally; rachis subterete, striate, 1.5–2.5 cm long, glabrous; floral bract caducous, not seen; pedicel terete, striate, 15–18 mm long, glabrous, articulate with calyx; bracteoles 2, located near base, caducous, ovate, ca. 2.2 mm long, apically long-acuminate, marginally glandular-fimbriate. **Flowers** 5-merous, pendent; calyx 6–9 mm long, glabrous, the tube obconic, truncate, terete to bluntly 10-ribbed, 2.5–3 mm long, the limb open, spreading to rotate, 5–6 mm long, the lobes broadly ovate, short-acuminate, 3–4 × 5 mm, with margins thin and seemingly lacerate-glandular, the sinuses acute; corolla thick-carnose, bistratose, cylindrical but slightly broadening distally, terete in cross-section, ca. 37–46 mm long, 7–9 mm basal diam. and 9–14 mm diam. at throat, orange, glabrous externally, the lobes broadly deltate, bluntly acute, 4–7 × 6–7 mm, green, densely floccose internally with flat, translucent trichomes to 2 mm long; **stamens** 10, ± equaling corolla in overall length, equal with each other, ca. 36–43 mm long, the filaments distinct, glabrous, ca. 4–6 mm long, the anthers ca. 33-39 mm long, the thecae ca. 9.5–11 mm long, basally conspicuously granular-papillate, the tubules ca. 24–28 mm long, seemingly connate in proximal 2/3, dehiscing by terminal pores ca. 0.2 mm diam.; style exserted, to 56 mm long, glabrous. **Fruit** not seen.

Distribution.—Endemic to northeastern Ecuador, where it occurs in both primary and disturbed forest, at ca. 1500–2550 m.

Ceratostema oyacachiensis is characterized by having leaf blades that are basally broadly cuneate to obtuse with plinerved venation, calyces that are articulate with the pedicels, calyx tubes that are terete to 10-ribbed, calyx limbs that are inconspicuous and rotate, calyx lobes that are short and lack basal, circular glands but do possess instead lacerate-glandular margins, corollas that are large and thick-carnose, broadening slighty distally and having short and broad lobes. In Luteyn's (1996) key to the Ecuadorean species of *Ceratostema*, this new species would be found in the vicinity of *C. pedunculatum* Luteyn, *C. prietoi* A.C. Sm., *C. nubigenum* (A.C. Sm.) A.C. Sm., and *C. ventricosum* Luteyn. It is distinct from all those species, however, based on its combination of characters mentioned above. If it were not for the articulate calyx/pedicel, this new species might be placed in the genus *Semiramisia* due to its rotate calyx limb and corolla that broadens slightly distally with relatively short, broad lobes. Additional collections of this species are needed to determine its morphological range of variation and relationships.

Additional collections examined: **ECUADOR. Sucumbíos:** Sinangoe Station, Shishicho Ridge, Alto Aguarico drainage, above (south of) Río Cofanes, W of Puerto Libre, NW of Lumbaqui, 00°12'N, 77°32'W, 1500–1570 m, 13 Aug 2001 (fl), *Aguinda, Pitman & Foster 1673* (F, QCA n.v., QCNE n.v.).

Ceratostema pendens Luteyn, sp. nov. **(Fig. 2).** TYPE: ECUADOR. MORONA-SANTIAGO: Limón-La Unión road, trail beyond end of road (beginning at 13.6 km from Limón) towards La Unión, ca. 2°59'S, 78°25'W, 1340–1370 m, 18 Nov 1998 (fl, fr), *J.L. Luteyn & H. Mogollón 15376* (HOLOTYPE: NY; ISOTYPES: AAU, CAS, MO, QCA, QCNE, US).

Ab *C. auriculato* Luteyn foliis breve pilosis (non glabris), calice breviore 8–9 mm longo (non 12–14 mm), tubo calycis tereti vel quinquangulo (non 5-alato), limbo calycis pro ratione inconspicuo lobis calycinis brevioribus 4.8–5 mm longis (non 9–10 mm) fimbriis eorum glanduliferis carentibus differt.

Epiphytic **shrubs**, arising from lignotubers; mature stems long-pendent, terete, striate, glabrous, the bark thin, reddish, cracking longitudinally; twigs subterete to terete, striate, brownish, densely spreading short-pilose with simple (uniseriate, unicellular) trichomes ca. 1–1.3 mm long, glabrate; axillary buds not seen. **Leaves** alternate, petiolate, flat, amplexicaul, involute at base so as to conceal flowers and fruits, the blades broadly ovate, 7–10 × 4–7 cm, basally deeply cordate and slightly auriculate with the lobes imbricate when fresh, apically acuminate to short-acuminate, densely soft, white, short-pilose on both surfaces with simple trichomes ca. 1 mm long, the venation pinnate with 2–4 lateral veins **or** weakly 5(–7)-plinerved with inner pair of lateral nerves arising in the proximal 1 cm, the midrib thickened and raised in proximal 1 cm then plane to weakly impressed distally adaxially, weakly raised abaxially, the lateral nerves anastomosing distally and along with reticulate veinlets weakly raised but obscure on both surfaces; petioles terete, rugose, 2–3 mm long, densely short-white-pilose with simple trichomes. **Inflorescences** axillary, racemose,

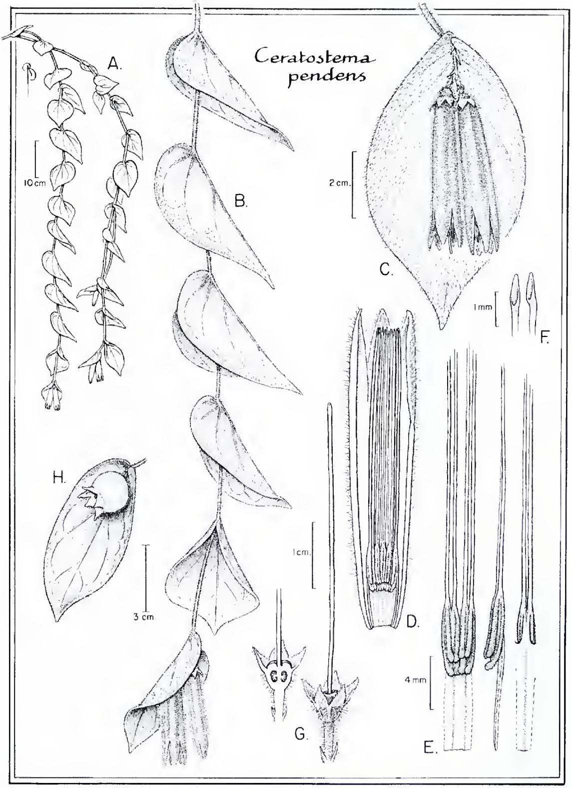

FIG. 2. *Ceratostema pendens*. A, habit. B, portion of stem showing involute leaves and two flowers. C, leaf spread open to show flowers. D, longitudinal section of corolla showing relative position of stamens. E, stamens in ventral, lateral, and dorsal views. F, close up of staminal dehiscence pores. G, calyx whole and in longitudinal section showing bracteoles and style. H, leaf spread open to show mature fruit (drawn from holotype, *Luteyn & Mogollón 15376*).

1–4-flowered but evidently only 1–2 flowers develop per rachis; rachis subterete, ca. 8–10 mm long, short-pilose with white, simple trichomes; floral bract 1, triangular, acuminate, ca. 2 mm long, densely short-pilose with simple trichomes; pedicel subterete, 5–6 mm long, articulate with calyx, short-pilose with simple trichomes; bracteloles 2, located near base, ovate, acute, ca. 1.3 mm long, short-pilose with simple trichomes. **Flowers** 5-merous; calyx ca. 8–9 mm long, short-pilose with white, simple trichomes, the tube terete to slightly pentagonal in cross-section, obconic, ca. 2.7–3.5 mm long, densely matted short-pilose, the limb spreading, ca. 5.3–5.5 mm long, moderately short-pilose, the lobes triangular-ovate, short-acuminate, ca. 4.8–5 mm long, striate, eglandular, moderately short-pilose externally and weakly so internally, the sinuses acute; corolla carnose, bistratose, cylindric to broadly and bluntly pentagonal in cross-section, slightly widening distally, ca. 45–48 mm long and 11 mm diam. at throat, dark maroon-red to pinkish-red, densely short-pilose with white, simple trichomes ca. 1 mm long, the lobes narrowly triangular, long-acuminate, ca. 12–13 × 3 mm; **stamens** 10, ± equaling corolla in overall length, alternately slightly unequal with each other, ca. 45 mm and 46.5 mm, the filaments equal, connate into a tube ca. 8–8.5 mm long, glabrous, the anthers 39.5 mm and 41 mm long, the thecae equal, ca. 7 mm long, conspicuously papillate, the tubules 2, alternately slightly unequal, distinct to base, ca. 34 mm and 35.5 mm long, dehiscing by introrse, oblique, oval pores ca. 0.6–0.8 mm long. **Fruit** a spherical, translucent cream-colored to waxy white, juicy berry, 15–22 mm diam., weakly short-pilose; seeds numerous, surrounded by translucent, mucilaginous sheath.

Distribution.—Endemic to Ecuador, where it occurs in primary forest on sandstone substrates, at 1000–1600 m.

Ceratostema pendens is characterized by its long-pendent, epiphytic habit with generally short-pilose vegetative and floral organs, amplexicaul leaves with cordate blades that are basally involute thus concealing the flowers and fruits when living, short floral bracts, terete to slightly pentagonal calyx tube, relatively inconspicuous calyx limb and lobes, and translucent whitish berry. In Luteyn's (1996) key to the Ecuadorean species of *Ceratostema*, this new species would be found in the final couplet containing *C. silvicola* and *C. amplexicaule*. It may be easily distinguished from those species by its involute leaves, fewer-flowered inflorescences, connate staminal filaments, and white berry (although berry color is unknown for *C. silvicola*). It is morphologically most similar to *C. auriculatum* Luteyn, having in common a long-pendent, epiphytic habit, amplexicaul leaves with blades that are cordate and pinnately-nerved, and few-flowered inflorescences that are hidden by the leaves. *Ceratostema pendens* differs from *C. auriculatum*, however, by having leaves that are short-pilose (vs. glabrous), shorter calyces (8–9 mm vs. 12–14 mm long), terete to pentagonal calyx tubes (vs. conspicuously 5-winged), and calyx limbs that are relatively inconspicuous possessing shorter lobes (4.8–5 mm vs. very conspicuous and 9–10 mm long) that lack glandular fimbriae. There are very few collections of these species, however, and so interspecific relationships are uncertain at this time.

In *Flora of Ecuador* (Luteyn 1996), the sterile collection *van der Werff & Palacios 10428* (MO, NY) was determined as *Ceratostema macbrydiorum* Luteyn, but the pubescence of its young leaves now characterizes it as an example of this new species. This points out further that sterile material of *C. pendens*, *C. auriculatum*, and maybe *C. cutucuense* Luteyn may be confused, due primarily to their having in common amplexicaul leaves with blades that are rounded to broadly ovate and deeply cordate basally, and short-acuminate apically. Table 1 compares and contrasts these species.

Additional collections examined: **ECUADOR. Morona-Santiago:** Limón Indanza, Cordillera de Huaracayo, E of Cordillera del Cóndor and Río Coangos, E of Shuar village of Tinkimints, 3°15'S, 78°11'W, 1600 m, 24 Mar 2001 (fl, fr), *Neill & Manzanares 13192* (MO, NY); along unfinished road E of Limón, 1000 m, 5 Feb 1989 (ster), *van der Werff & Palacios 10428* (MO, NY).

Ceratostema pubescens Luteyn, sp. nov. **(Fig. 3).** TYPE: ECUADOR. EL ORO: Manu-Chilla road, Km 36, 10 km W of Guanasan, 3°28'S, 79°33'W, 2600 m, 4 Oct 1996 (fl), *G.P. Lewis, P. Lozano, N. Aguirre & I. Aldaz 2640* (HOLOTYPE: NY; ISOTYPES: AAU n.v., E n.v., K n.v., LOJA n.v., QCNE n.v.).

Ab *C. fasciculato* Luteyn foliis ad basem cuneatis breve attenuatisque (non rotundatis vel subcordatis), inflorescentia e fasciculis 4–6-floris (non e racemis usque 30-floris) composita, bracteis floralibus longioribus 20–26 mm longis (non 17–20 mm), corolla breviori 38–43 mm longa (non 45–57 mm), staminibus brevioribus 36–40 mm longis (non 45–51 mm) differt.

Coarse, terrestrial **shrubs**, sometimes semi-scandent, 2–3 m tall with stems to 10–12 cm diam., arising from lignotubers; mature stems somewhat contorted, erect or pendulous, subterete, coarsely and bluntly angled, densely short-pilose with whitish, simple trichomes, the bark grayish; twigs subterete, bluntly angled, striate, reddish-brown, densely pilose with whitish, simple trichomes to ca. 2 mm long; axillary buds with outer scales 2, valvate, pseudostipular, narrowly lanceolate, long-acuminate, 6–11.5 × 1.5–2 mm, carinate, short-pilose with whitish, simple trichomes. **Leaves** alternate, congested, petiolate, the blades coriaceous, flat to slightly revolute, sometimes slightly bullate, ovate, 4–10.5 × 2.5–6.5 cm, basally rounded and often subcordate, apically short-acuminate, glabrous to weakly short-pilose with whitish, simple trichomes adaxially and there also bearing multicellular-multiseriate, reddish, glandular-fimbriate trichomes, densely white pilose abaxially and there also reddish, glandular-fimbriate, discolorous (when fresh dark to yellowish-green adaxially and whitish-green abaxially, when dry olive-green adaxially and reddish-brown abaxially), the venation 3–5(–7)-plinerved with inner lateral nerves arising 1–2 cm above the base, the midrib thickened and raised in proximal 1 cm then plane to slightly impressed distally adaxially, raised and conspicuous abaxially, the lateral nerves plane to impressed adaxially and raised abaxially, the reticulate

proximal several (to 4) nodes bearing sterile bracts; floral bract 1, lanceolate, long-acuminate, 11–16 × 3–5 mm, the venation conspicuous, moderately short-pilose with simple trichomes, marginally glandular-fimbriate with multicellular, multiseriate trichomes; pedicel subterete, striate, 10–14 mm long, densely short-pilose with simple trichomes and also short-glandular-fimbriate with multicellular, multiseriate trichomes, articulate with calyx; bracteoles 2, alternate, located basally to distally along pedicel, similar to floral bract but 6–16 × 2.5–3 mm. **Flowers** 5-merous, pendulous; calyx 17–20 mm long, short-pilose with simple trichomes and also sometimes short-glandular-fimbriate with multicellular, multiseriate trichomes, the tube cylindric to obconic, terete in cross-section, 4–6 mm long, densely short-pilose with white to yellowish trichomes, the limb slightly spreading, 13–17 mm long, moderately short-pilose, the lobes membranous, concave, ovate, acuminate, 11–13 × 4–5 mm with venation conspicuous, the sinuses acute; corolla membranous (fleshy when fresh), weakly bistratose, broadly and bluntly pentagonal in cross-section, cylindric and only slightly expanded basally, 45–57 × 6–9 mm, red to scarlet when fresh, short-pilose with whitish to reddish simple trichomes, also short-glandular-fimbriate with multicellular, multiseriate trichomes, the lobes wide-spreading and slightly reflexed exposing the stamens, lanceolate, bluntly acute, 7.5–13.5 × 2–5 mm, green when fresh; **stamens** 10, nearly equaling corolla in overall length, alternately slightly unequal with each other, 45–51 mm and 46.5–53.5 mm long, the filaments distinct, alternately 9–11 mm and 9.5–13 mm long, glabrous, the anthers alternately 38–42 mm and 40–44 mm long, the thecae alternately 12–13 mm and 13–14 mm long, the tubules 2, alternately 25–29 mm and 28–31 mm long, distinct in distal 1/2–1/3, dehiscing by introrse, oblique, short clefts ca. 1.5–2 mm long; style shortly exserted, 48–59 mm long, glabrous, red to pink with green apex when fresh. **Fruit** a spherical, short-pilose berry at least 13 mm diam., apparently translucent pale greenish when mature.

Distribution.—Endemic to Ecuador, where it occurs in rocky outcrops of "Southern Ecuadorean Scrub" vegetation along a very narrow and local cloud belt zone, at ca. 2600–3100 m. Common associates include *Puya* and *Pitcairnia* (Bromeliaceae), *Macleania* (Ericaceae), and lichen-covered boulders. Some corollas have holes at their bases made by nectar robbing birds. The fruit is said to be edible and a local common name is "salapa blanca grande."

Ceratostema pubescens is characterized by having a coarsely shrubby habit, densely pubescent leaf blades, long and narrow bud scales that appear pseudostipular, multi-flowered and racemose inflorescences, elongate bracteoles, large calyces and corollas, terete calyx tubes, conspicuously veined calyx lobes, and bluntly 5-angled corollas with proportionately short lobes. In Luteyn's (1996) key to the Ecuadorean species of *Ceratostema*, this new species would be found nearest *C. fasciculatum* Luteyn, which differs morphologically by its basally cuneate and short-attenuate leaf blades (vs. rounded to subcordate), fasciculate and

4–6-flowered inflorescences (vs. racemose and to 30-flowered), longer floral bracts (20–26 mm vs. 11–16 mm), longer bracteoles (15–24 mm vs. 6–16 mm), overall longer calyx (20–27 mm vs. 17–20 mm), shorter corolla (38–43 mm vs. 45–57 mm), shorter stamens (36–40 mm vs. 45–51 mm), and eastern slope geographical distribution (i.e., Zamora-Chinchipe vs. western slope El Oro). The exact phylogenetic relationship of the new species awaits further study.

Additional collections examined: **ECUADOR. El Oro:** same as type, 6 Nov 1997 (fl), *Lewis et al. 3687* (AAU, E n.v., GB n.v., K n.v., LOJA n.v., MO n.v., NY, P n.v., QCA n.v., QCNE n.v., US n.v.), 1 May 1997 (ster), *Luteyn et al. 15066* (NY, QCA); Chilla, Km 7, track to the antennas and páramo, 3°27'S, 79°36'W, 3100 m, 7 Nov 1997 (fl), *Lewis et al. 3700* (AAU, E n.v., GB n.v., K n.v., LOJA n.v., MO n.v., NY, QCA n.v., QCNE n.v., US n.v.); Chilla-Pueblo Viejo road, trail above Pueblo Viejo, 3°28'S, 79°36'W, ca. 2800 m, 2 May 1997 (im fr), *Luteyn et al. 15071* (NY, QCA); Chilla-Pueblo Viejo, 3°28'S, 79°43'W, 2780 m, 28 Feb 1996 (fr), *Van den Eynden & Cueva 630* (LOJA n.v., NY).

DISTERIGMA (Klotzsch) Niedenzu

Disterigma is a montane genus of about 35 species that is characterized by its usually small leaves, sessile to subsessile flowers, and pedicellary bracteoles that are apical and surround (sometimes tightly clasp) the calyx and sometimes the proximal parts of the corolla. It ranges from Guatemala south to Bolivia and east to Guyana. The genus has been considered related to *Vaccinium* on the basis of morphology, although recent molecular studies (Powell & Kron 2003) place it in a clade with *Sphyrospermum*. The genus is currently being monographed by graduate student Paola Pedraza at The New York Botanical Garden.

Disterigma bracteatum Luteyn, sp. nov. **(Fig. 4).** TYPE: ECUADOR. AZUAY: Jesus María-Molleturo-Cuenca road, 22.3–25.2 km E of Coastal Highway at Jesus María, ca. 2°37'S, 79°14'W, 975–1160 m, 23 Nov 1998 (fl), *J. L. Luteyn & H. Mogollón 15401* (HOLOTYPE: NY; ISOTYPES: AAU, CAS, G, K, MO, QCA, QCNE, S, US).

Species nova congeneris omnibus distinguenda in combinatione notarum sequente: foliis succulentis, bracteis inflorescentiae numerosis, circa 23, lanceolatis brunneolis persistentibus usque 11 mm longis, lobis calycinis anguste lanceolatis usque 5–6 mm longis atque staminibus 5 geniculatis.

Terrestrial to epilithic, spreading **shrubs** with branches somewhat pendent to 3 m long; mature stems terete, striate, glabrous, brownish, the bark cracking longitudinally into parallel strips; twigs subterete, bluntly and broadly angled, glabrous to weakly puberulent, grayish-brown; axillary buds with outer pair of scales 2, valvate, ovate, acuminate, glabrous, ca. 2.5 mm long, the inner series of scales numerous, lanceolate to ovate-lanceolate, acuminate, striate, glabrous, brown, to 20 × 7 mm, persistent at base of stems for at least three seasons. **Leaves** alternate, congested, the blades succulent and thick-coriaceous when fresh, wrinkled when dry, slightly revolute, elliptic to ovate-elliptic, 1.8–3.5 × 1.2–2.5 cm, basally rounded to broadly obtuse, apically rounded to broadly acute, glabrous on both surfaces, the venation obscurely 3–5-plinerved from the base with only the midrib scarcely visible adaxially; petioles terete, rugose, 2.5–5 mm long, weakly

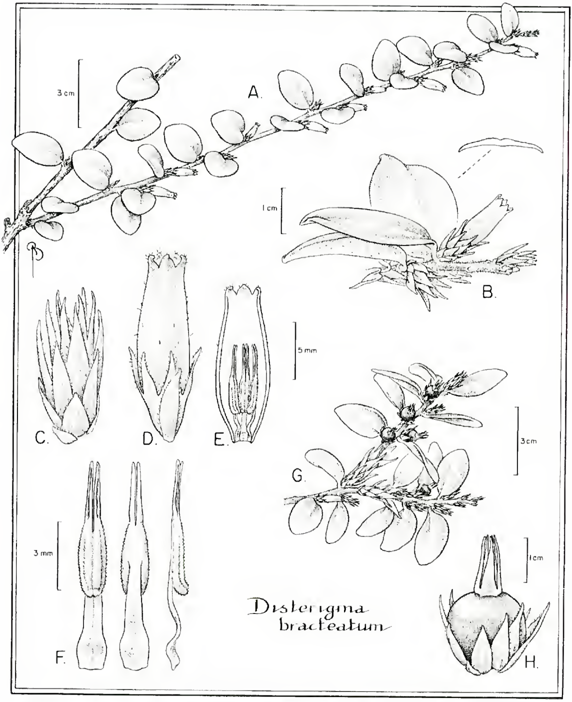

Fig. 4. *Disterigma bracteatum*. **A,** habit. **B,** portion of stem showing leaves and inflorescences, with detail of leaf cross-section. **C,** inflorescence bud. **D,** flower showing one bracteole, calyx and corolla. **E,** longitudinal section of corolla showing geniculate stamens. **F,** stamens showing ventral, dorsal, and lateral views. **G,** portion of stem showing fruits and immature inflorescences. **H,** details of mature berry showing persistent bracts and calyx lobes (drawn from *Luteyn & Magollón 15401* & *15404*).

puberulent. **Inflorescences** fusiform in shape, of solitary flowers, seemingly arising from the axils of each leaf of a current season's growth, circumscribed by a series of numerous (ca. 23), ovate to lanceolate, acuminate to long-acuminate, weakly striate, scarious or brownish, glabrous but deciduously fimbriate-margined bracts up to ca. 11 × 4 mm that cover the calyx and lower ca. half of the corolla and persist at least until the fruits mature, the third innermost bract (i.e., the floral bract) morphologically indistinguishable from the other inflorescence bracts ca. 11 × 4 mm, the two innermost bracts (i.e., the bracteoles) also morphologically indistinguishable from the other inflorescence bracts ca. 7–9 × 3–4 mm; pedicel none, replaced by a series of overlapping nodes covering <0.5 mm length. **Flowers** 5-merous; calyx ca. 8–11.5 mm long, glabrous or sometimes weakly short-pilose (especially the lobe tips), the tube barrel-shaped, ca. 2–4.5 mm long, the limb cylindric, ca. 6–7 mm long, the lobes narrowly lanceolate, long-acuminate, ca. 5–6 mm long, marginally fimbriate, the sinuses acute; corolla cylindric, narrowing at base and to throat, somewhat pentagonal to 5-angled in cross-section, ca. 7.7–15 × 6.5 mm, bright red, glabrous, the lobes deltate, ca. 1.2–2 mm long, bluntly acute; **stamens** 5, shorter than corolla in overall length, equal with each other, ca. 10–11 mm long, the filaments geniculate, distinct, ca. 4–4.5 mm long, glabrous, the anthers ca 7–7.4 mm long, the thecae ca. 3.6–3.9 mm long, the tubules 2, distinct to base, ca. 3.4–3.5 mm long, dehiscing by introrse, elongate clefts ca. 2.5–3 mm long; style included, ± equaling corolla. **Fruit** a spherical, dark purple berry, 7–8 mm diam., crowned by persistent calyx lobes.

Distribution.—Endemic to Ecuador, where it occurs on rocks and rock outcrops as a low, spreading shrub within montane cloud forest habitats, at ca. 975–2600 m.

Disterigma bracteatum is characterized by having succulent leaves, numerous (ca. 23), lanceolate, brownish, persistent bracts to 11 mm long that surround the vegetative branches, inflorescences and fruits, calyx lobes that are narrowly lanceolate to 5–6 mm long, and five geniculate stamens. In Luteyn's (1996) key to the Ecuadorean species of *Disterigma*, this new species would be found near *D. pentandrum* S.F. Blake and *D. rimbachii* (A.C. Sm.) Luteyn, all three species characterized by possessing succulent leaves, solitary flowers surrounded by a series of brownish bracts, and five stamens. *Disterigma bracteatum* differs from *D. rimbachii*, which has few, caducous bracts to 2 mm long, calyx lobes deltate ca. 1 mm long, and bracteoles 1–2 mm long, and from *D. pentandrum*, which has about six persistent bracts to 7 mm long, calyx lobes ca. 3.5 mm long, and bracteoles ca. 7 mm long.

Additional collections examined: **ECUADOR. Azuay:** Jesus María-Molleturo-Cuenca road, 0.9 km towards Molleturo from turn-off from highway that is 56 km E of Jesus María, ca. 2°42'S, 79°13'W, ca. 2438 m, 23 Nov 1998 (fr), *Luteyn & Mogollón 15404* (AAU, COL, GB, NY, QCA, QCNE, W), 2600 m, 27

Dec 2003 (fl), *Pedraza & Pedraza 1016* (COL, NY, QCA, QCNE), 10 kms before Molleturo, ca. 2°46'N, 79°24'W, 2600 m, 27 Dec 2003 (fl), *Pedraza & Pedraza 1017* (NY, QCA, QCNE).

ACKNOWLEDGMENTS

I wish to thank Gwilym P. Lewis and Veerle Van den Eynden for making special efforts to collect *Ceratostema pubescens* for me and guiding me to its location; Bertil Ståhl for providing pickled floral material; Robin B. Foster for providing beautiful photos of *C. oyacachiensis*; Bobbi Angell for the wonderful illustrations; and Patricia Eckel for providing the Latin diagnoses. The National Science Foundation (grants BSR-9024221 and DEB 9628841) provided funds for field work in Ecuador, and the Missouri Botanical Garden provided facilities to write portions of this paper. Thanks to Walter Judd and Larry Dorr who made helpful review comments.

ABSTRACT

Ipomoea arborescens (tree morning glory) has two varieties in the state of Sonora, Mexico. Author citation of *I. arborescens* var. *glabrata* (a nomenclatural synonym of *I. arborescens* var. *arborescens*) is corrected. The second taxon, *I. arborescens* var. *pachylutea*, was named by Howard Scott Gentry from the Río Mayo region. These plants differ considerably from *I. arborescens* var. *arborescens* in having different bark morphology and corolla tube colors.

RESUMEN

En el estado de Sonora, México, *Ipomoea arborescens* (palo santo) tiene nombres para dos variedades. Se corrige la citación del autor de *Ipomoea arborescens* var. *glabrata*, sinónimo de *Ipomoea arborescens* var. *arborescens*. Howard Scott Gentry nombró *I. arborescens* var. *pachylutea* de la región del Río Mayo, la cual se distingue principalmente de la var. *arborescens* por su corteza amarillenta y corolas con tubos morados.

During studies of the Convolvulaceae for both the *Flora Mesoamericana* (Austin et al. in prep.), and the *Trees of Sonora, Mexico* (Felger et al. 2001), it became apparent that there is nomenclatural confusion with plants called *Ipomoea arborescens*. In addition, there is biological uncertainty about the taxonomic delimitations of these Mexican trees. This paper will address the nomenclatural problems.

When Gentry (1942) was studying the plants of the Río Mayo region of southern Sonora, he encountered two different varieties of this tree. One of these he called *I. arborescens* var. *glabrata*, and the other he named *I. arborescens* var. *pachylutea*. Although the most recent revision of the group by McPherson (1981) does not mention either variety, subsequent field studies by various botanists (e.g., Martin et al. 1998; Van Devender et al. 2000; Felger et al. 2001) make it clear that in Sonora there are indeed two distinct morphotypes subsumed by the binomial *I. arborescens*. There is as well a third morphotype farther south for which we have insufficient data to completely compare with Sonoran plants.

SIDA 21(3): 1283–1292. 2005

The species is widespread and may be characterized by the following:

Ipomoea arborescens (Humb. & Bonpl. ex Willd.) G. Don, Gen. Syst. 4:267. 1838. *Convolvulus arborescens* Willd., Enum. Pl. 1:204. 1809. TYPE: MÉXICO. GUERRERO: between Acaguisotla and Chilpancingo, *Humboldt & Bonpland 3927* (HOLOTYPE: P; microfiche seen).

Trees 5–15 m tall; the trunk thick, often 50–70 cm diameter, the bark gray, whitish or pale yellowish, stems with abundant latex, tomentose when young with trichomes 0.1–2.5 mm long, glabrescent. **Leaves** 9–27 cm long, 6–9+ cm wide, ovate to lanceolate, glabrescent, the apex acuminate, the base cordate, with trichomes longer that those on the branches, velvety at least below, the midrib base (just above the petiole) with a pair of blisterlike glands 1–3 mm in diam., turgid on young, enlarging leaves (these glands are the same color as the midrib and may be difficult to see, especially on older or dried specimens). **Inflorescences** terminal or axillary, monochasial, racemose. **Flowers** 1(–2); sepals 6–14 mm long, ovate to rarely orbicular, more or less equal, tomentose, the apex obtuse to obtuse-mucronate; corollas 4–4.3 cm long, often 6.5–9.5 cm wide, funnelform, tomentose at least on the lobes, white, tube green without. Fruits 17–25 mm long, capsular, 4-valvate, brown, glabrous; seeds 1–4, 9–16 mm long, brown, pilose on the margins with trichomes 10–15 mm long.

Illustrations.—Martínez (1969: 237), Felger et al. (2001: 139–141).

Common names.—Tree morning glory; *cazahuate* (from Distrito Federal to Oaxaca), *jútuguo* (Mayo, southern Sonora), *osí* (Tarahumara, Chihuahua), *palo blanco* (Sonora), *palo santo* (Sonora), *patancán blanco* and *rosí* (Durango, Jalisco, Michoacán, Guerrero), *tochiyó* (Guarijío, SE Sonora).

Flowering November–April; near sea level–1800 m; Sonoran desertscrub, thornscrub, tropical deciduous forest, and oak woodland or rarely at the lower edge of "tropical" pine-oak forest (Fig. 1).

The type locality is between Acapulco and Cd. México, in a mid-elevation seasonally dry tropical zone. The original vegetation at the type locality was probably tropical deciduous forest. That region is the southern part of the "typical" habitat of the modern known range of *I. arborescens*, although the species ranges into the highlands of Edo. México, Michoacán, and Morelos.

Gentry (1942) called the "smaller, less pubescent-leaved form characteristic of the species throughout the foothill regions of southern and central Sonora" var. *glabrata*. The trees that extend into the Sonoran Desert North of Hermosillo are probably the same taxon as Gentry's variety *glabrata*. Trees of the lowland and northern Sonora populations have conspicuously lighter-colored (whiter) bark, and flowers with the purple coloration much reduced or lacking when compared with var. *pachylutea*.

Fig. 1. Distribution of *Ipomoea arborescens* in Mexico. **Dots** = herbarium specimens; squares = sight records reported by Turner et al. 1995; **R** = report by Torres-R. (2004). Based on Rose (1894), Matuda (1963, 1966), McPherson (1981), Cowan (1983), Torres-R. (2004), and herbarium specimens at MEXU, MO, and ARIZ.

KEY TO SYNOPTIC TRAITS

Habitat Sonoran desert-scrub to tropical deciduous forest and lower oak woodland. Bark white. Flowers white with yellow or diffuse pale purple dots and short bands within the tube (Figs. 2, 3). Flowers in Sonora visited by bees, hawkmoths, and hummingbirds, south of Sonora by bats ______ **Ipomoea arborescens** var. **arborescens**

Habitat humid tropical deciduous forest and oak woodland. Bark yellowish. Flowers solid or almost solid dark-purplish within the tube. Flower visitors unknown ______ **Ipomoea arborescens** var. **pachylutea**

NOMENCLATURE

Ipomoea arborescens (Humb & Bonpl. ex Willd.) G. Don var. **arborescens.** *Ipomoea arborescens* (Humb & Bonpl. ex Willd.) G. Don var. *glabrata* Gentry, Carnegie Inst. Wash. Publ. 527:212. 1942. TYPE: MÉXICO. SONORA: Arroyo Cuchijaqui, *Gentry 870* (SYNTYPE: DS, n.v., cited by McPherson); San Bernardo, *Gentry 1158* (LECTOTYPE, here chosen: ARIZ!; ISOLECTOTYPE: MO!).

Ipomoea murucoides var. *glabrata* Rose, Contr. U.S. Natl. Herb. 1:107. 1891, non A. Gray (1887). TYPE: MÉXICO. SONORA: Alamos, *Palmer 316* (HOLOTYPE: US!).

FIG. 2. Corollas of *Ipomoea arborescens* var. *arborescens* as they are in plants in Sonora. The small and spotted areas of purple in the corolla throats are distinctive.

FIG. 3. Corollas of *Ipomoea arborescens* var. *pachylutea* in Sonora. The large and almost continuous areas of purple in the corolla throats are distinctive.

When Gentry made this combination, he cited the correct protologue by Rose, but incorrectly listed Gray as the author. Since the varietal name by Rose was a later homonym of var. *glabrata* A. Gray, we are interpreting Gentry's action as creation of a new name (Article 58). Tentatively, we consider this a nomenclatural synonym of *I. arborescens*. McPherson (1981) also considered the glabrous forms of the plants as a synonym, because he cited the type of *I. murucoides* var. *glabrata* Rose in synonymy with *I. arborescens*. As pointed out by Gentry (1942), there are differences between these northern plants and those farther south, but we do not have enough data on the southern populations to determine if the two should be considered nomenclaturally distinct.

These are the plants that Soderholm and Gaskins (1963) called *I. wolcottiana*. The USDA collection forming the basis of their report grows in Miami at both the Plant Introduction Station and the Fairchild Tropical Garden and its identity has been verified as *I. arborescens* var. *glabrata*. Presumably that report is also the basis of the incorrect report of *I. wolcottiana* from Sonora. That species has not been documented in Sonora.

Ipomoea arborescens (Humb & Bonpl. ex Willd.) G. Don var. **pachylutea** Gentry, Carnegie Inst. Wash. Publ. 527:213. 1942. TYPE: MÉXICO. SONORA: Sierra de Alamos. *Gentry 3000* (LECTOTYPE: ARIZ!, ISOTYPES: MO!, UC, n.v., US!). PARATYPE: MÉXICO. SONORA: Algodones, Sierra Charuco, *Gentry 2299* (ARIZ!).

Selected additional specimens seen: Sonora, Sierra de Alamos, rocky slopes and canyon bottoms, 2000–3000 ft [610–915 m]. Vernacular: *palo santo amarillo*. Large trees with massive trunks & yellowish bark browning with age; 8–15 m high. Petioles and twigs with milky juice, *Gentry 4888* (ARIZ); Sinaloa, Las Mesas, Sierra Surotato, 25 Aug 1941. Oak-*Ipomoea* savanna; volcanic ash, elev. ca. 3000 ft [915 m]. Vernacular: *palo blanco*. Tree with yellow bark. Co-dominant with oak. *Gentry 6144* (ARIZ). Additional specimens were cited by Martin et al. (1998), McPherson (1981), and Turner et al. (1995) mapped the species.

Common name.—Palo santo amarillo.

Gentry (1942) named the higher elevation or montane populations in southeastern Sonora and adjacent southwestern Chihuahua var. *pachylutea*, and distinguished these trees from *I. arborescens* var. *glabrata* in having "...yellowish bark, larger and more pubescent leaves, longer and stouter pedicels, larger and more numerous flowers, larger sepals, and generally heavier inflorescences." Other differences include wood that is apparently not as soft, corollas with a prominently maroon-purple throat, and pale lavender filaments. *Ipomoea arborescens* var. *pachylutea* occurs at ca. 500–1220 m in tropical deciduous forest and the lower oak zones. To date, variety *pachylutea* is known only from Sonora and Chihuahua, but no comparison has been made with living plants farther south.

The southern limits of var. *pachylutea* remain unknown. Both varieties occur in southeastern Sonora, but do not occur intermixed with minor exceptions. Near Alamos, Sonora, a single tree of var. *pachylutea* was found in an area of var. *arborescens* trees. Such trees, however, are in disturbed, partially cleared areas at elevations near the usual lower elevational limits of var. *pachylutea*. Trees of intermediate character are not known, and the varieties abruptly replace each other. We suspect that the two "varieties" are actually cryptic species.

Grown side-by-side at the Arizona-Sonora Desert Museum in Tucson from seed collected in Sonora, plants of var. *pachylutea* bear leaves nearly twice as large as those of var. *arborescens* (var. *glabrata* sensu Gentry 1942). In the field, Sonoran populations of these varieties exhibit overlap in leaf sizes. In Arizona plantings, variety *pachylutea* tends to branch near the base of the plant with large horizontal branches, while living specimens of var. *arborescens* generally do not share these features and develop a thick trunk at an earlier age. However, in dense forests near Alamos, *Ipomoea arborescens* var. *pachylutea* is an upright tree.

One of the difficulties in applying these names to herbarium specimens is that there typically are few obvious traits retained that can be used in distinguishing the two taxa, even though living trees are quite distinctive. When flowers are present, dissection of the corollas will reveal the needed 'comparative' differences in purple within the base of the tube. Even when both forms are not available, the two may be separated relatively easily. The inside of the tube of var. *pachylutea* is solid or nearly solid purple throughout; tubes of var. *arborescens* are variable but usually lighter in color—diffusely colored with bands and dots of light purple. Beyond that trait, we have found no consistent herbarium differences in the sizes of leaves or flowers that Gentry noted, as there is considerable variation throughout the range of the species.

Although no field phenology data are available for Sonora, trees grown in Tucson flower at different times. Data taken over 10 seasons on var. *arborescens* indicate that its beginning flowering dates vary from the third week in October to the third week in January. However, the trees cease flowering before the third week in February. By contrast, two season's data show that var. *pachylutea* does not begin flowering until the second week in March. Thus, a full two weeks separate the flowering periods. Based on herbarium specimens at ARIZ, these differences do not hold for wild plants in Sonora where flowering seasons of both varieties overlap.

The floral biology is variable and is largely temperature-dependent (Alberto Búrquez M., pers. comm. 1998; Francisco Molina F., pers. comm. 2001). The flowers commonly open in the late afternoon. During warmer weather, the corollas fall the next morning with warming daytime temperatures, but on cooler days they often do not fall until the second night. This is consistent with a number of matinal and/or nocturnal species in the family (Austin, unpubl. data). The trees are self-incompatible (Alberto Búrquez M., pers. comm. 1998); buds attract both red and black large ants (Felger et al. 2001), perhaps *Camponotus*.

In Sonora, *Hyles lineata* (white-lined sphinx moth) and perhaps other hawkmoths and hummingbirds are the primary pollinators of var. *arborescens* (Felger et al. 2001). The flowers are visited by hummingbirds in tropical deciduous forest and foothills thornscrub from the Alamos area north to Santa Ana de Yécora and Tepoca, and northwest to the Hermosillo area in the Plains of Sonora subdivision of the Sonoran Desert (Van Devender et al. 2004). *Cynanthus latirostris* (broad-billed hummingbird) and *Calypte costae* (Costa's hummingbird) are the most common visitors to *I. arborescens* while *Calpyte anna* (Anna's hummingbird) are sporadically seen. Other avian visitors such as montane species that come down from the pine-oak forest and oak woodland of the Sierra Madre Occidental into the tropical deciduous forest for the winter, include *Amazilia beryllina* (berylline hummingbird), *Heliomaster constantii* (plain-capped starthroat), and *Hylocharis leucotis* (white-eared hummingbird). Bees also visit the plants near Hermosillo (Francisco Molina, pers. comm., 2004).

While agaves (*Agave* spp.), ceibas (*Ceiba grandiflora*), yuccas (*Yucca* spp.), saguaros (*Carnegiea gigantea*), organ pipe cactus (*Stenocereus thurberi*), cardón (*Pachycereus pringlei*), and other cacti are famous for being pollinated by bats (Arizaga et al. 2000; Casas et al. 1999; Fleming et al. 1998; Nassar et al. 1997; Quesada et al. 2003; Stoner et al. 2003; Valiente-B. et al. 1997), these flying mammals do not visit only these plants exclusively. Indeed, flowers on tree *Ipomoea* may supply nectar during the season when few other bat-pollinated plants are in bloom (Hevly 1979; Turner et al. 1995).

Pollinators of *Ipomoea arborescens* var. *pachylutea* are not known, although the white limb and lavender throat may suggest bat-pollination, but bats have not been seen visiting the flowers of *I. arborescens* in Sonora. Farther south in Guerrero, México (Baker et al. 1977; Butanda C. et al. 1978), *I. arborescens* and some other species of tree morning glory are visited and presumably pollinated by *Choeronycteris mexicana* (Mexican long-tongued bat), *Glossophaga soricinia* (long-tongued bat; Villa R. 1966), and *Leptonycteris curasoae* (lesser long-nosed bat). Although *L. curasoae* is reported feeding from '*I. arborescens*' in Hidalgo (Baker et al. 1977), that species does not occur there (Carranza-G. et al. 1998); instead the plants probably are *I. rzedowskii*, although *I. murucoides* also grows there. *Leptonycteris curasoae* is known to consume *Ipomoea* pollen in Sonora (Hevly 1979) and *I. arborescens* is one of the few species of *Ipomoea* sturdy enough for bats in the state.

Because the mammals migrate north from central and southern Mexico to southern Arizona and back south during different seasons (Moreno-Valdez et al. 2000; Newton et al. 2003; Wilkinson et al. 1996), a variety of food sources are critical for their survival and reproduction. It is noteworthy that the flowering seasons of the two varieties of *I. arborescens* are different in the Arizona-grown plants because they correspond with the migration dates of the bats. *Leptonycteris* arrives in Organ Pipe Cactus National Monument in April and

May (Hoffmeister 1986; K. Krebbs & T. Tibbitts pers. comm., Sep 2004) just after var. *pachylutea* has flowered in Sonora. Adult female *Leptonycteris* have left Arizona by late September, and the juveniles leave later (K. Krebbs pers. comm., Sep 2004). *Ipomoea arborescens* var. *arborescens* in Sonora is in flower from October through the end of the year. Therefore, when the bats leave Arizona and fly through northern Sonora, the tree *Ipomoea* are not in flower.

However, in about the southern half of Sonora, there are at least a few animals present during the winter. Francisco Molina (pers. comm., 2004) informed us that "we have captured *Leptonycteris* in Hermosillo (Centro Ecológico) in mid-February visiting Agaves. We have also captured *Leptonycteris* in February at Rancho San Francisco (between San Jose de Pimas and Tecoripa) visiting etchos [*Pachycereus pecten-aboriginum*]." These winter resident *Leptonycteris* apparently are not present much north of Hermosillo (K. Krebbs, pers. comm. 2004); hence they are absent from most of the October to January flowering period of *I. arborescens* var. *arborescens*. On the other hand, *Choeronycteris* is present throughout the year in northern Sonora.

Much less is known about *Choeronycteris* because it is not a colonial species gathering in maternity colonies like *Leptonycteris* (Hoffmeister 1986; K. Krebbs, pers. comm., Sep 2004). Some individuals remain in Arizona and northern Sonora throughout the winter (K. Krebbs, pers. comm., Nov 2004), although it appears that the majority migrate southward. Their young are born in late June (Hoffmeister 1986), and presumably the migrants arrive from Mexico near the same time as *Leptonycteris*. Thus, bats may utilize *I. arborescens* on their migration north through Sonora, but do not appear to do so when going south.

ACKNOWLEDGMENTS

We thank Alberto Búrquez M., Karen Krebbs, Ana Lilia Reina-G., Curtis McCasland, Rodrigo A. Medellín, Francisco Molina F., Guillermina Murguía S., Yar Petryszyn, Tim Tibbitts, and Michael F. Wilson for information and aid in examining these plants, herbarium material, and photographs. RSF thanks the Wallace Research Foundation for support. Ana Lilia Reina G. kindly provided the Spanish abstract. Andrew McDonald and an anonymous reviewer provided helpful comments on an earlier draft of the manuscript.

ABSTRACT

Ipomoea seaania is described as a new species from the vicinity of Guaymas, Sonora. These plants are confined to the Sierra El Aguaje, although they perhaps grow in other nearby unexplored mountains. The relationships of this species to the other members of *Ipomoea* series *Arborescentes* are discussed, and all taxa in the group are listed and ranges given. *Ipomoea seaania* brings the total number of taxa in the series to 13 species, with *I. arborescens* having two varieties and *I. pauciflora* and *I. wolcottiana* each having two disjunct subspecies.

RESUMEN

Se describe **Ipomoea seaania** de las cercanías de Guaymas, Sonora, como una especie nueva. Estas plantas se encuentran restringidas a la Sierra El Aguaje, aunque quizás se encuentren en otras sierras cercanas sin explorar. Se discuten las relaciones de esta especie con otros miembros de *Ipomoea* serie *Arborescentes*; del mismo modo se listan todos los taxa del grupo y se proporcionan sus rangos de distribución. Con el reconocimiento de *Ipomoea seaania* como nueva especie, se reconocen un total de 13 especies en el grupo, de las cuales *Ipomoea arborescens* presenta dos variedades e *I. pauciflora* e *I. wolcottiana* dos subespecies.

When Old World botanists began discovering morning glories in the New World, most species they found had life forms like the twiners *Calystegia*, *Convolvulus*, and *Cuscuta* they knew at home. Their concept of the family was somewhat broadened when they found erect and sprawling herbs in the Americas, and they were amazed when they found morning glory trees (Austin 2004). In 1809, Humboldt, Bonpland and Willdenow called the first known tree species *Convolvulus arborescens*, the distinctions between *Convolvulus* and *Ipomoea* being unclear at the time. These trees still are considered "odd" or "unusual" in the family, and the only other genus in the family that achieves tree stature is the Malagasian *Humbertia* (cf. Pichon 1947; Deroin 1992). Anatomically, these American trees are distinct from other shrubby and woody members of the family (Austin 1971; Carlquist & Hanson 1991; McDonald 1992; Deroin 2001).

The arborescent species of *Ipomoea* in the New World have long been of interest to the people who lived with them. Indigenous people use several species (Hersch-M. 1995; Yetman & Felger 2002; Yetman & Van Devender 2001), and the chemistry of the group is somewhat distinctive (Pérez-A. et al. 1982, 1983, 1992a, b). Three of these alkaloids (3a-(4-hydroxybenzoyloxy)tropane, 3a-

(4-methoxybenzoyloxy)nortropane, phyllalbine) are considered rare constituents, especially in the genus *Ipomoea* (E. Eich, pers. comm., 26 Jul. 2004). Of additional interest was the discovery that nectar-feeding bats are at least seasonal flower-visitors and pollinators in some species (Butanda-C. et al. 1978; Carranza-G. et al. 1998; Casas et al. 1999; Fleming et al. 1998; Hevly 1979; Moreno-V. et al. 2000; Nassar et al. 1997; Newton et al. 2003; Quesada et al. 2003; Stoner et al. 2003; Turner et al. 1995; Valiente-B. et al. 1997; Wilkinson et al. 1996). These bats are *Choeronycteris mexicana*, *Glossophaga soricina*, and *Leptonycteris curasoae* (= *L. sanborni*, *L. yerbabuenae*). The *Leptonycteris* has been listed as endangered in the United States (Reid 1997; U.S. Fish and Wildlife Service 1997) since 30 September 1988. (See accompanying paper by Austin, Felger & Van Devender p. 1283–1292 for discussion.)

As summarized in Table 1, there are 13 species in the American series *Arborescentes* (Austin & Huaman 1996; McDonald 1991; McPherson 1981; Murguía-S. et al. 1995; Carranza-G. & McDonald 2004). Most of the species are confined to Mexico and nearby Mesoamerica (Austin 2001; Austin & Huaman 1996, Austin et al. in preparation), but there are two with disjunct subspecies in western South America (Austin 1982; McPherson 1981).

The first author found *I. seaania* in Sonora during 1980 and again in 1985 and located additional herbarium specimens. Although we talked about the plants in 1989, neither of us had the opportunity to pursue them further. Finally, we have been able to compare the known taxa with these plants.

Regarding morphology and range, this is a markedly distinct species (Table 1). Using the key in McPherson (1981) these plants come out at *I. chilopsidis*. Leaves on the two are the most obvious distinction on herbarium specimens. Both have narrow leaves, often less than one cm wide, but they are 10–20 cm long in *I. chilopsidis* and only 4–8 cm in *I. seaania*. Flowers are large (8–9.5 cm long) in *I. chilopsidis*, but only 4–6 cm in *I. seaania*. Furthermore, the overall architecture of the plants is profoundly different.

Ranges and altitudinal differences also are pronounced. *Ipomoea chilopsidis* is a plant of "high and arid craigs" (*Gentry 2391*, ARIZ) of the Sierra Madre Occidental, ranging from the eastern border of southeastern Sonora through about half of the southern end of Chihuahua. Near the border between Chihuahua and Sonora *I. chilopsidis* grows at 1100–1800 m in oak and pine-oak forest (Gentry 1942, Martin et al. 1998). On the other hand, *I. seaania* is known only from the vicinity of Guaymas in west-central Sonora where it grows near the southern margin of the desert on rocky slopes near the Gulf of California. The Guaymas region uplands are more than 1,000 m lower than those of Chihuahua.

All records for *I. seaania* are from essentially the same locality, below ca. 20 m elevation and near a road, except one collection (*Felger 80-36 et al.*) which is from a nearby canyon probably one kilometer eastward. The rugged slopes immediately above this area have yet to be explored. The canyons where the

TABLE 1. Taxa in series *Ipomoea* series *Arborescentes* and their geographic distributions.

Ipomoea arborescens (Humb. & Bonpl. ex Willd.) G. Don var. *arborescens*	Mexico (Chiapas, Colima, Durango, Guerrero, Jalisco, México, Michoacán, Morelos, Nayarit, Oaxaca, Puebla, Querétaro, Sinaloa, Sonora)
Ipomoea arborescens var. *pachylutea* Gentry	Mexico (Chihuahua, Sonora)
Ipomoea chilopsidis Standley	Mexico (Chihuahua, Sonora)
Ipomoea cuprinacoma E. Carranza & J.A. McDonald	Mexico (Guerrero, Jalisco, Michoacán)
Ipomoea intrapilosa Rose	Mexico (Jalisco, Nayarit, Sinaloa, Zacatecas)
Ipomoea murucoides Roemer & Schultes	Mexico (Aguascalientes, Chiapas, Distrito Federal, Distrito Federal, Durango, Guanajuato, Jalisco, Edo. México, Michoacán, Morelos, Nayarit, Oaxaca, Puebla, Queretaro, Zacatecas), Guatemala
Ipomoea pauciflora Martens & Galeotti ssp. *pauciflora*	Mexico (Guerrero, Edo. México, Michoacán, Morelos, Oaxaca, Pubela, Veracruz), Guatemala, Honduras, Nicaragua
Ipomoea pauciflora ssp. *vargasiana* (O'Donell) McPherson	Ecuador (Loja), Peru (Apurimac, Ayacucho, Cuzco), Bolivia?
Ipomoea populina House	Mexico (Chiapas, Guerrero, Oaxaca), Guatemala, Honduras, Nicaragua
Ipomoea praecana House	Mexico (Chiapas, Colima, Guerrero, Edo. México, Michoacán, Morelos, Oaxaca), Guatemala, Honduras, Nicaragua
Ipomoea pulcherrima van *ooststrstroom* (perhaps not a member of series Arborescentes)	Peru (Apurimac)
Ipomoea rzedowskii Carranza, Zamudio & Murguía	Mexico (Guanajuato, Hidalgo, Querétaro)
Ipomoea seaania Felger & D.F. Austin	Mexico (Sonora)
Ipomoea teotitlanica McPherson	Mexico (Oaxaca)
Ipomoea wolcottiana Rose var. *wolcottiana*	Mexico (Chiapas, Colima, Guerrero, Hidalgo, Jalisco, Michoacán, Morelos, Oaxaca, Puebla, Sinaloa, Tabasco, Veracruz), Guatemala, El Salvador, Honduras
Ipomoea wolcottiana ssp. *calodendron* (O'Donell) McPherson	Peru (Piura, Tumbez)

new species occurs are at the lower, southwestern flanks of the extremely rugged Sierra El Aguaje (Gentry 1949 called it the Guaymas Monadnoc, see Felger 1999). Although there has been extensive botanical exploration in the region (e.g., Felger 1999; Felger et al. 2001; Gentry 1949), the higher elevations are difficult to access and remain nearly unexplored botanically. These higher elevations, as well as the nearby and vegetationally similar Sierra Libre and Sierra El Bacatete, contain extensive areas of non-desert vegetation resembling tropical deciduous forest (Búrquez et al. 1999; Felger & Lowe 1976).

In general appearance, *I. seaania* is most similar to *I. wolcottiana* and *I. intrapilosa*, even though the latter two species are trees and *I. seaania* is a multi-stemmed shrub to 4 m. *Ipomoea wolcottiana* grows to 13 m tall, and ranges from Jalisco to El Salvador, whereas *Ipomoea intrapilosa* reaches 10 m tall, and grows from southern Sinaloa to Jalisco. McPherson (1981) pointed out that *I. wolcottiana*, *I. pauciflora*, and *I. populina* have unusual cylindrical stigmas. Murguía-S. (1995) confirmed only the presence of cylindrical stigmas (longer than wide) in only *I. pauciflora* and *I. populina*. Instead of having two appressed lobes that create an elongate stigma like the other two species, *I. wolcottiana* has lobes that are elongated laterally. Thus, while technically "cylindrical," it is wider than long. *Ipomoea seaania* exhibits two globose stigmatic lobes, which is typical of the genus, and other members of series *Arborescentes*. The cylindrical stigmas of *I. wolcottiana* and *I. pauciflora* seem to indicate a more distant relationship.

As Búrquez et al. (1999) and Felger (1999) have pointed out, the Sierra El Aguaje is notable for containing endemic species largely allied with, and presumably derived from, taxa farther south. Climatic variations and isolation were probably the driving forces behind divergence of those numerous endemic species. In addition, many species in the Sierra El Aguaje region are otherwise known only from the Baja California peninsula (Felger 1999). However, no arborescent *Ipomoea* are known from Baja California.

There are four taxa of arborescent *Ipomoea* in the state of Sonora (Table 1), which is the northernmost extension of the series (Búrquez et al. 1999; Felger 1999; Felger et al. 2001; Felger & Lowe 1976; Gentry 1949). *Ipomoea seaania* and *I. arborescens* are the only two taxa growing in the Sonoran Desert, primarily at the southern and southeastern "subtropical" margin of the desert.

Ipomoea seaania Felger & Austin, sp. nov. (**Fig. 1**). TYPE: MEXICO. SONORA: Municipio de Guaymas, broad canyon, ca. 1 km N of Bahía San Carlos on old road to Bahía Algodones; 27°57'32"N, 111°03'45"W, rhyolitic hillside, ca. 5 m above canyon bottom with riparian vegetation; shrub 2 to 3 m tall; in full flower, corollas white; locally common on steep rock hillsides, 27 Feb 1985, *Felger with Robert S. Devine 85-301* (HOLOTYPE: UA, ISOTYPES: ARIZ, ASU, BRIT, CAS, HCIB, IEB, K, MEXU, MO, NY, RSA, SD, TEX, UC, US, USON).

Frutex ad 4 m altus, ramulis dense vel sparsim breve-pilosis vel glabris. Folia ovato-lanceolata vel ovata, 2–8 cm longa, 1.5–2 cm lata, basi obtusa vel subtruncata, apice obtusa vel emarginata, margine integra, glabra. Inflorescentiae a brachyblastis lateralis productae, uniflorae rarus biflorae vel triflorae, pedunculis ad 5 mm longis, pedicellis florum 8–22 mm longis. Sepalis 12–17 mm longis, 6–8 mm latis. Corolla alba, infundibiliformis, glabra, 4–6(–7) cm longa, 7–8 cm diametro; stamina 5, antheris oblongis, sagittiformibus, 6–7 mm longis, stylus glaber, 3.6–4 cm longus, stigma biglobosum.

Openly-branched **shrubs** 1–4 m tall, with many woody stems branching from the base, the upper twigs sometimes sinuous or moderately spiraling, sometimes becoming extremely slender. Herbage largely glabrous or glabrate except newest growth densely to sparsely short-pilose, the trichomes mostly spreading.

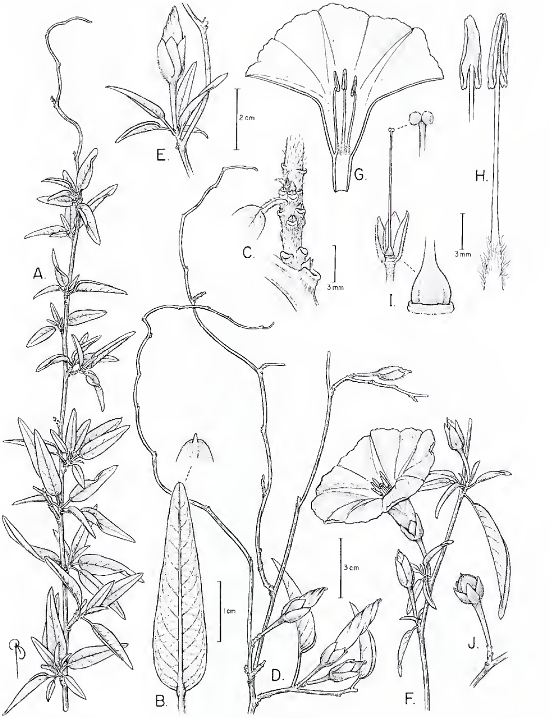

Fig. 1. *Ipomoea seaania.* **A.** Distal branch. **B.** A spur-branch leaf. The usual long-shoot leaves, lower on the stems and present during the summer rainy season, are usually broader, more ovate rather than lanceolate. **C.** Detail of spur-branch. **D.** Flowering branch. **E.** Detail of bud on spur-branch. **F.** Detail of open flower on spur-branch. **G.** Open corolla. **H.** Detail of stamen. **I.** Details of gynoecium. **J.** Young fruit. Drawn from the Holotype (*Felger with Robert S. Devine 85-301*).

Leaves drought deciduous, lanceolate to ovate, long-shoot leaves often 2–8 cm long, the blades lanceolate to ovate, 1.5–2 cm wide, with 6–8(–10) lateral pairs of primary veins, the base obtuse to subtruncate, the apex obtuse to emarginate, the midrib often ending in a short mucrone, blade glabrous; petioles 8–15(–20) mm long, with a pair of glands, usually conspicuous, at junction of petiole and blade on the lower leaf surface. Spur-branch leaves linear to linear lanceolate, often 4–8 cm long, to 4–11 mm wide, with 6–10 lateral pairs of primary veins, base obtuse to subtruncate, the apex obtuse or blunt, or sometimes shallowly emarginate, the midrid often ending as a short mucrone, the petioles to 2–9(–13.5) mm long. **Inflorescences** of 1–2(–3) flowers, appearing solitary but cymose on short-shoots 2–5 mm long, these sometimes with a few small leaves; bracts 5–8 mm long, quickly deciduous, broadly oblong with an obtuse tip; peduncles very short, to 5 mm, the pedicel 8–22 mm long. **Sepals** 12–17 mm long, 6–8 mm wide, broadly lanceolate to mostly ovate, puberulous to villous, the inner surfaces generally more densely hairy than the outer surfaces, the trichomes white, appressed to mostly ascending, and curly to straight. Inner (adaxial) sepals obtuse, the surfaces with trichomes 0.15–0.6 mm long; outer (abaxial) 2 sepals acute, slightly narrower and more sparsely pubescent than the inner 3, the trichomes 0.1–0.5 mm long, the sepal margins scarious and glabrous or glabrate. **Corollas** showy, funnelform, glabrous, 4–6 cm long and 7–8 cm wide, white with yellowish interplicae and a maroon band at inside base of the tube. **Stamens** 5, with 4 filaments 25–26 mm long, the fifth stamen 23–24 mm long, basal 4 mm of filaments pubescent, anthers oblong, sagittitate, 6–7 mm long, pollen spheroidal, spinulose. **Ovary** glabrous, 3 mm long, the style glabrous, 37–38 mm long, the stigma 2-globose. Flowering January–March.

Other specimens examined: **Municipio de Guaymas:** Along partially paved road between San Carlos Bay and Catch-22 airstrip NW of Guaymas, desert scrub with *Stenocereus, Bursera, Pachycereus, Jatropha*, and *Acacia*, elevation near sea level, shrub to 3 m, corolla white, infrequent, 5 Jan 1983, *T.F. Daniel 2360* (ASU 128321); on road outside Bahía San Carlos, open shrub, 1–1.5 m tall, cliff base in hardened volcanic soil, NW slope in association with *Euphorbia ceroderma, Mascagnia macroptera, Acacia willardiana*, elevation 10 m, 21 Feb 1977, *Ames 77-60* (ARIZ 211499); 0.1 mi N of north end of San Carlos Bay, west-facing slopes above bay, elevation 15 m, 27°57'N, 111°03'W, Sonoran Desertscrub, shrub 2–3 m tall, 10 Oct 1985, *Felger 85-1232, with Frank W. Reichenbacher* (ARIZ 332087); San Carlos Bay, W of Guaymas; a canyon one mi N of the bay near Cerro Los Algodones, along the road to Rancho La Manga, near 27°58'N, 111°04'W, rocky volcanic ridge and adjacent stony canyon bottom, associated with *Bursera, Prosopis, Jatropha, Croton sonorae, Acacia willardiana*, etc., scarce large shrub about 12 ft high with many stems from base, on floor of canyon above wash, fls white with yellowish star pattern and maroon band in throat, ± 300 ft, 22 Mar 1983, *A.C. Sanders 3616* (ARIZ 245472, TEX); canyon, ca. 4 km NW of Bahía San Carlos, steep rocky canyon with dense desertscrub, shrub 1.8 m tall, scattered, not common, 6 Sep 1980, *Felger 80-36, with L. Findley, S. Findley* (ARIZ 200443); road between San Carlos Bay and Catch-22 airstrip, collected in desertscrub with *Stenocereus, Bursera, Pachycereus, Jatropha, Acacia, Fouquieria, Opuntia, Ferocactus*; elevation near sea level, small tree to 3 m, corolla white, rare, 8 Mar 1985, *Daniel 3986* (CAS).

The plants are locally common on rugged, lower slopes of the Sierra El Aguaje just North of Bahía San Carlos; on rocky volcanic ridges, steep colluvium, and rhyolite slopes of canyon sides and cliff bases. The San Carlos region is undergoing rapid tourist development and extensive areas of natural vegetation are being destroyed. The canyon bottom immediately below the *Ipomoea seaania* population once supported a dense stand of subtropical riparian vegetation; this was destroyed several decades ago to build a road to the site for the filming of "Catch 22." There are no other records for this unusual shrub.

These plants grow in dense desertscrub with ca. 60% cover of perennials. Species associated with the type collections include *Abutilon incanum, Acacia willardiana, Agave angustifolia, Antigonon leptopus, Ayenia jaliscana, Bursera laxiflora, B. microphylla, Cardiospermum corindum, Colubrina viridis, Cordia parvifolia, Coursetia glandulosa, Croton sonorae, Cylindropuntia versicolor, Desmanthus covillei, Diphysa occidentalis, Euphorbia ceroderma, Ferocactus emoryi, Fouquieria diguetii, Haematoxylon brasiletto, Hechtia montana, Holographis virgata, Ibervillea sonorae, Jatropha cuneata, Krameria sonorae, Lantana velutina, Lippia palmeri, Mammillaria johnstonii, M. swinglei, Manihot* sp., *Melochia tomentosa, Mimosa distachya, Nissolia schottii, Opuntia gossiliniana, Randia thurberi, Ruellia californica, Sebastiania bilocularis, Stenocereus thurberi,* and *Trixis californicus.*

Ipomoea seaania plants are generally leafy and produce vegetative growth only during the brief summer-early fall monsoonal rainy season, when sporadic thunderstorms occur. Occasional late summer and fall hurricane-fringe storms extend the growing season. Otherwise the plants are leafless or nearly so. As with *I. arborescens* in the Sonoran Desert, flowering occurs when the plants are essentially leafless. Other species in the series typically retain their leaves while flowering.

Summer monsoon rains and occasional hurricane-fringe rains at the end of summer and early fall come at a time of hot weather, but these hot-weather rains are highly variable. It is during the monsoon season when most long-shoot growth occurs, and leaves on the long-shoots are the largest, broadest, and have the longest petioles (even relative lengths). Other arborescent *Ipomoea* in Sonora likewise do not flower during this season (Table 1). Also during the wet season, abundant leaf production of *I. seaania* occurs on numerous short-shoots, and these leaves are smaller, narrower, and with shorter petioles in comparison to leaves on long-shoot branches.

Winter-spring rains are unpredictable, and if they occur when the weather is warm enough, short-shoots and leaves and some long-shoot development may occur. However, these long-shoots are generally small in comparison to those of monsoon-season growth. Flowering may occur from fall (October and November) through spring (late March, perhaps April).

Although minor frosts may occur in the region, the habitat on the rocky slopes where *I. seaania* grows is undoubtedly frost free. The weather is very hot during the long summer, and very mild even in winter, and warm to even hot during the rest of the year. Mean annual rainfall for the nearby city of Guaymas is around 275 mm, based on data taken from September 1968 to February 1987. However, as is usual in deserts, there is considerable variation in annual rainfall. Maximum temperature occurs in August (mean 40°C) and minimum temperature is in January (mean 7°C, with absolute minima of 1°C in 1973 and 1987) (Comisión Nacional de Agua, Hermosillo).

Some herbarium curators have the view that non-flowering specimens lack value. For the general user, perhaps the curators are correct, but for the specialist, sterile specimens often provide data that otherwise are available only on living plants at specific seasons. Without preserved examples of these temporal variations the data derived from fertile herbarium specimens is often limited at best. We lament the general lack of good vegetative specimens of arborescent morning glories.

The new species occurs at the northern boundary of the original homelands of the Yoeme (Yaqui) people. The species name derives from *Sea Ania*, the Yoeme concept of the Flower World, the place where life begins. *Sea Ania* was created after *Yo Ania* (the Enchanted World) and after people. *Sea Ania* is in all life, in all creatures, overseeing nature, including the rivers, the wind, the clouds, ocean, rain, sun, moon, sky, and stars. *Sea Ania* is *Huya Ania* (Wilderness World) in flower. The Flower World is the living beauty of this world, the natural world. *Sea Ania* is the final resting place of the Yoemen (Yaqui people). Yoeme artists use flowers in their artwork to represent *Sea Ania* (Evers & Molina 1987).

ACKNOWLEDGMENTS

We thank Phil Jenkins at ARIZ, Shannon Doan at ASU, Lloyd Findley, Francisco Molina F., Ana Lilia Reina G., Tom Van Devender, and Michael Wilson for herbarium material, comments, and other support. RSF thanks the Wallace Research Foundation for support. Ana Lilia Reina G. kindly provided the Spanish abstract. Andrew McDonald provided helpful comments on an earlier draft of the manuscript. We thank Bobbi Angell for the magnificent drawing.

BOOK REVIEWS

ROY L. LEHMAN, RUTH O'BRIEN, and TAMMY WHITE drawings by EVELINE MAY JACKSON and KIM KEPLAR. 2005. **Plants of the Texas Coastal Bend.** (ISBN 1-58544-408-1, hbk.). Texas A&M University Press, John H. Lindsey Bldg., Lewis St. 4354 TAMU, College Station, TX 77843-4354, U.S.A. (**Orders:** wlawrence@tamu.edu, http://www.tamu.edu/upress, 800-826-8911). $40.00 hbk., 352 pp., ca. 70 b/w line drawings, CD with over 750 color photos, index, 6 1/8" × 9 1/8".

This is an update of Fred Jones' "*Flora of the Texas Coastal Bend*" (Edition 2, 1977)—additional species are included and nomenclature is amended to follow more recent taxonomic concepts. "About 1,150 species and varieties, exclusive of the grasses, are included," users are referred to three recent volumes treating the Poaceae from the Coastal Bend region. Many recent generic segregates are recognized, following the 1997 Texas checklist and overview by [Stan] Jones, Wipff, and Montgomery, but others are not (e.g., why not *Thymophylla* and *Rayjacksonia*?). Families, genera, and species are now treated alphabetically. Keys remain highly abbreviated but are no longer indented. More intense botanical editing could have avoided various small errors.

Copyright of the publication is held by the Welder Wildlife Foundation (as with the original Jones volumes), perhaps because the keys and descriptions are identical in large part to the first. The book is dedicated to the memory of Fred Jones, and it is curious that Lehman, O'Brien, and White changed the title slightly, included updates and changed formats, and supplanted Jones's authorship. Legal necessities with change of press?

Accompanying the volume is a CD with many hundreds of photos of Coastal Bend species. They vary in quality and a surprising number are not identified to species, but at least the latter are useful for confirming identities at generic level.—*Guy Nesom, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

JAMES A. FOWLER. Introduction by PAUL MARTIN BROWN. 2005. **Wild Orchids of South Carolina: A Popular Natural History.** (ISBN 1-57003-566-0, hbk.). University of South Carolina Press, 718 Devine St., Columbia, SC 29208, U.S.A. (**Orders:** 800-768-2500, www.sc.edu/uscpress/). $39.95, 242 pp., color photos, 6" × 9".

"Although this work is neither intended to be a comprehensive treatise nor a technical, scientifically oriented field guide, it is a popular account of one man's intoxicating obsession with wild orchids. As such, it becomes a valuable contribution to the knowledge of the orchids of South Carolina and an aesthetic presentation of the beauty and intricacies of these captivating flowers" (from the introduction by Paul Martin Brown (author of "Wild Orchids of the southeastern United States, north of peninsular Florida," 2004). The forte of this book surely is the photography—for each of the 55 species currently known from the state, there is a full page color photo—details and variants are often included. For each species, there also is a county-level map and notes on pollinators, flowering time, and habitat. Because the county maps seem to be identical or nearly so with those shown by the South Carolina Plant Atlas <http://cricket.biol.sc.edu/herb/>, Fowler's maps probably are taken from the former—there is no formal attribution or acknowledgement, although the SC Plant Atlas is listed in the Bibliography.—*Guy Nesom, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

INFRAGENERIC CLASSIFICATION OF *LIATRIS* (ASTERACEAE: EUPATORIEAE)

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

ABSTRACT

The 37 currently recognized species of *Liatris* are placed in formal positions within an infrageneric taxonomic system modified from one proposed by Gaiser in 1946. Five sections are recognized: (1) sect. *Liatris* (including ser. *Liatris*, ser. *Punctatae*, and ser. *Elegantes*), (2) sect. **Vorago** Nesom, sect. nov., (3) sect. *Suprago* (Gaertner) DC., (4) sect. **Pilifilis** Nesom, sect. nov., and (5) sect. **Graminifolium** Nesom, sect. nov. (including ser. *Garberae*, ser. *Pauciflorae*, ser. *Virgatae*, ser. *Graminifoliae*, and ser. *Scariosae*).

RESUMEN

Las 37 especies usualmente reconocidas de *Liatris* se colocan en posiciones formales en un sistema taxonómico infragenérico modificado a partir del propuesto por Gaiser en 1946. Se reconocen cinco secciones: (1) sect. *Liatris* (que incluye las ser. *Liatris*, ser. *Punctatae*, y ser. *Elegantes*), (2) sect. **Vorago** Nesom, sect. nov., (3) sect. *Suprago* (Gaertner) DC., (4) sect. **Pilifilis** Nesom, sect. nov., y (5) sect. **Graminifolium** Nesom, sect. nov. (including ser. *Garberae*, ser. *Pauciflorae*, ser. *Virgatae*, ser. *Graminifoliae*, y ser. *Scariosae*).

Gaiser (1946) provided the only taxonomic overview of the genus *Liatris* since reviews by de Candolle (1836) and Gray (1884). Regional treatments by Alexander (1933), Fernald (1950), and Cronquist (1980) included most or many of the species, and recent studies have investigated various taxonomic problems (Godfrey 1948; Menhusen 1963; Cruise 1964; Johnson 1971; Thomas 1975; Bowles et al. 1988; Pyne & Stucky 1990; Stucky & Pyne 1990; Stucky 1991, 1992; Godt & Hamrick 1996; Allison 2001; Nesom & O'Kennon 2001; Anderson 2002; Mayfield 2002; Kral & Nesom 2003; Gandhi et al. 2003; Nesom & Stucky 2004; Ward 2004; Nesom 2005a, 2005b). Apart from Gaiser's monograph, however, only Alexander and Fernald formally arranged species into infrageneric groups. King and Robinson (1987) offered pertinent observations regarding possible relationships within the genus but did not attempt to provide a formal infrageneric taxonomic structure. Observations made in connection with preparation of a species-level taxonomic treatment of *Liatris* (Nesom 2005a) for the Flora of North America volumes are formalized here toward additional perspective on interrelationships within the genus.

The closest relatives of *Liatris* are *Carphephorus* Cass. (7 species; including *Litrisa* Small—1 species and *Trilisa* (Cass.) Cass.—2 species), *Garberia* A.

SIDA 21(3): 1305–1321. 2005

Gray (1 species), and *Hartwrightia* A. Gray ex S. Wats. (1 species), which (with *Liatris*) constitute subtribe Liatrinae King & H. Robinson of tribe Eupatorieae Cass. (King & Robinson 1987). Specializations of *Hartwrightia* apparently obscured an understanding of its relationship until the study of Robinson and King (1977). The Liatrinae is essentially restricted to the eastern and southeastern U.S.A.; one species (*Liatris garberi*) occurs on the Bahama islands as well as in Florida and several species are essentially Great Plains entities, one of them reaching into northern Mexico. The subtribe is a well-defined group, characterized by the following features: base chromosome number of $x = 10$; leaves alternate, usually in a basal rosette, at least in early stages (fide King & Robinson 1987); corollas rose-purple, with cells laxly subquadrate to short-oblong and usually without sinuous walls, lobes mamillose or papillose on inner surfaces; carpopodium indefinite or lacking; cypselar duplex trichomes with cells diverging from near the base; and pappus bristles with barbels indefinitely (vs. linearly) arranged. Within the Liatrinae, *Liatris* is characterized by its usually cormose habit, usually spiciform to racemiform capitulescence, relatively long corolla lobes (long lobes also are characteristic of *Garberia*), and oblong-ovate and apically rounded (non-retuse) anther appendages (also found in *Trilisa*). Concepts of the other genera have been generally accepted, except for *Carphephorus*.

Most recent authors (e.g., Hebert 1968; Correa & Wilbur 1969; Cronquist 1980) have treated *Carphephorus* broadly to include *Litrisa* and *Trilisa*. Radford et al. (1968), in contrast, treated *Carphephorus* and *Trilisa* separately, and King and Robinson (1987) opted for narrower generic concepts, observing that (p. 279) "the broader concept of *Carphephorus* [sensu lato], though natural, is difficult to define in contrast to *Liatris*" and that "actual differences between *Carphephorus*, *Trilisa*, and *Litrisa* have been underestimated by the various authors favoring synonymy." A molecular-phylogenetic study (Schmidt & Schilling 2000), which included two species of *Trilisa* (*C. odoratissimus* and *C. paniculatus*), two of *Carphephorus* sensu stricto (*C. pseudoliatris* and *C. corymbosus*), and three of *Liatris*, suggests that *C. pseudoliatris* is more closely related to *Liatris* than to the others, but too few species of Liatrinae were included to make this a reliable conclusion. A preliminary report on Liatrinae phylogeny (Schilling & Cox 2000) appears to confirm the phylogenetic distinction of *Trilisa* and *Litrisa*. King and Robinson (1987, p. 272), observed that "the genus *Liatris* stands unmistakably outside of the complex including *Carphephorus*, *Litrisa*, and *Trilisa*."

The evolutionary and taxonomic coherence of *Liatris* is supported by the apparent ease with which hybrids are formed between species. A pattern of occurrence is not evident. Interspecific hybrids within *Liatris* have been reported across sectional boundaries (as delimited here) within *Liatris*: *Suprago-Graminifolium* (Gaiser 1946; Hadley & Levin 1967; Levin 1967); *Liatris-Graminifolium*, *Liatris-Pilifilis*, and *Liatris-Suprago* (Gaiser 1951; Hadley &

Levin 1967; Levin 1973); and *Liatris-Vorago* (Allison 2001; Mayfield 2002; Hardig et al. submitted). A list of *Liatris* interspecific hybrids and their putative parents is given in the FNA treatment (Nesom 2005a). There is no readily apparent morphological evidence, however, that hybridization has occurred between species of any of the generic-level taxa of Liatrinae, including the segregates of *Carphephorus*.

Overview of *Liatris* infrageneric taxonomy

Alexander (1933) did not assign rank to species groups that he recognized for *Laciniaria* (= *Lacinaria* = *Liatris*). Gaiser (1946) used the conventions initiated by Alexander (plural adjectives for group names) but modified the species constitution for some of the groups. Although she specifically referred to the species groups as "series" (placed within two sections) (Table 1), Gaiser did not validate the infrageneric nomenclature by providing Latin diagnoses for the groups, nor did she make direct or indirect reference to Alexander's names. Fernald (1950) credited Gaiser as combining author of the names she had proposed at the rank of series, using unranked basionyms of Alexander from 1933.

The current study arranges 37 species of *Liatris* in five sections. Figure 1 is essentially a diagrammatic representation of the classification presented below, or it might be read as an essentially unresolved cladogram. A few phyletic generalizations are noted in the following discussion, but lack of morphological evidence limits resolution of relationships.

Among the five sections, sects. *Liatris* and *Vorago* have a more western distribution (essentially extra-Floridian, extra-Atlantic) and constitute a lineage characterized by a distinctive foliar feature—the margins are distinctly whitish-thickened and the surface of this tissue is minutely pebbly-scabrous, an apparently specialized feature not occurring elsewhere in the genus or Liatrinae. Sect. *Liatris* is the only group within the Liatrinae with plumose pappus bristles and is interpreted here as monophyletic on the basis of this apparent synapomorphy. The level of morphological differentiation among the three series of sect. *Liatris*, however, is greater than among the groups treated here as series within sect. *Graminifolium*.

Sects. *Graminifolium*, *Suprago*, and *Pilifilis* have been considered together to constitute sect. *Suprago* (Gaiser 1946; King & Robinson 1987; presumably characterized by the shared plesiomorphy of barbellate pappus bristles), but no specialized morphological feature is evident that would link these groups as a single clade. Gaiser recognized ser. *Pycnostachyae*, ser. *Spicatae*, and ser. *Tenuifoliae* as distinct groups, but the first two are treated here without formal rank within sect. *Suprago*. The two species of ser. *Tenuifoliae* are treated here as sect. *Pilifilis*. Sect. *Graminifolium* includes the species that have an internally pilose corolla tube (with exceptions, as noted below): within the section, ser. *Scariosae* and ser. *Graminifoliae* were recognized as formal groups by Gaiser,

Table 1. Gaiser's classification (1946) of *Liatris*.

Section **Euliatris**
    Ser. **Elegantes**: *L. elegans*
    Ser. **Punctatae**: *L. punctata, L. densispicata, L. mucronata, L. angustifolia, L. bracteata*
    Ser. **Cylindraceae**: *L. cymosa, L. ohlingerae, L. cylindracea*
    Ser. **Squarrosae**: *L. squarrosa*

Section **Suprago**
    Ser. **Spicatae**: *L. spicata, L. lancifolia, L. microcephala, L. acidota, L. garberi*
    Ser. **Pycnostachyae**: *L. pycnostachya*
    Ser. **Graminifoliae**: *L. graminifolia, L. helleri, L. regimontis, L. gracilis, L. turgida*
    Ser. **Pauciflorae**: *L. chapmanii, L. pauciflora, L. secunda*
    Ser. **Tenuifoliae**: *L. tenuifolia, L. laevigata*
    Ser. **Scariosae**: *L. scariosa, L. aspera, L. scabra, L. ligulistylis, L. borealis, L. earlei*

although the species compositions of both are modified here; additionally, ser. *Virgatae*, ser. *Pauciflorae*, and ser. *Garberae* are recognized as constituents of sect. *Graminifolium* in the current classification.

Morphological trends

Parallel trends in morphological specialization can be observed within *Liatris*. Although the other genera of Liatrinae produce heads in corymbiform arrangements, the ancestral arrangement within *Liatris* apparently is spiciform to racemiform, and the open, broadly corymbiform capitulescences of *L. ohlingerae* (sect. *Graminifolium*) and *L. cymosa* (sect. *Liatris*) are interpreted here as independently and secondarily derived. As observed by King and Robinson (1987), a nearly complete reduction of the anther appendages seems to have been correlated with these modifications in head arrangement (appendage reduction also has occurred in *L. elegans*); increase in head size also has been a concomitant. Marked increase in head size also has occurred in ser. *Punctatae*, and size of heads (especially as gauged by number of florets) often varies widely among species, particularly in sect. *Graminifolium*. Parallel foliar venation apparently has developed independently in sect. *Liatris* and sect. *Suprago*. Reduction or loss of glandular punctation has occurred in sect. *Suprago*, several groups of sect. *Graminifolium*, sect. *Liatris*, and sect. *Vorago*. Elongation of the putatively primitive corm has occurred independently in sect. *Liatris* (e.g., L. *elegans*, L. *punctata*), sect. *Suprago* (e.g., *L. pycnostachya* var. *lasiophylla*, *L. spicata*), and sect. *Graminifolium* (e.g., *L. garberi*, *L. savannensis*). Chromosome numbers in *Liatris* and Liatrinae are mostly $2n = 20$ (Gaiser 1949, 1950a, 1950b); within *Liatris*, polyploidy occurs in ser. *Punctatae* (see below) and perhaps other groups.

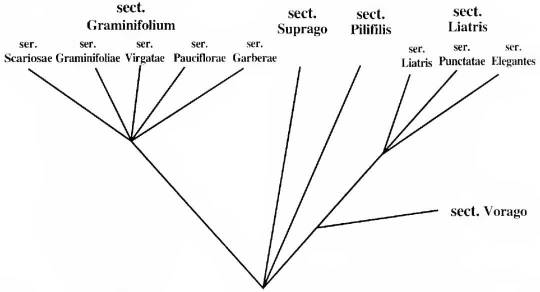

Fig. 1. Infrageneric taxonomic structure of *Liatris*.

Corms or roots?

Interpretation of the morphological nature of the perennating structures of *Liatris* and their descriptive terminology have been inconsistent. Gaiser (1946, p. 168–169) interpreted them as thickened underground stems and referred to them as corms. She noted that "During the first summer of the seedling's growth there develop a few radical leaves above what appears as a slightly thickened tap-root, but at the end of the season an apical bud is developed from a small crown and this, in the second year, produces the first flowering stalk. During successive summers the stem thickens, becoming globular or remaining ovoid in most species. ..." She referred to the more elongate structures, such as produced by *L. punctata*, both as "rhizomes" and as "rootstocks" and also was inconsistent in description of the globose structures: for example, she noted for *L. spicata* (p. 178) "Rootstock globose in young plants, enlarged and shallow in old plants by separation of parts permitting considerable vegetative propagation." Other botanists also have described them variously: Gray (1884), "a tuberous or mostly globose and corm-like stock;" Fernald (1950), "a roundish corm or tuber ... ;" Bailey and Bailey (1976), "a corm, or less often ... a rhizome or an elongated root crown;" Cronquist (1980), "a thickened, usually cormlike rootstock" but noting that they appear to have characteristics of both corm and root; King and Robinson (1987), "a thickened, usually corm-like, penetrating rootstock ..." Kerster (1968) and Levin (1973) made age estimates of *Liatris* individuals by counting annual growth rings from radial sections of "corms," but they did not detail their interpretation of them as stems rather than roots; annular secondary growth may occur in both kinds of organs.

While these structures quickly become woody and nodes are difficult to discern, they are here regarded as corms and rhizomes, rather than roots with adventitious buds, because of several reasons. (1) New, ascending-erect stems may be produced from various lateral points (nodes) of somewhat elongated, vertically oriented corms. From the somewhat flattened tops of older, much enlarged corms (e.g., in *L. punctata* var. *mucronata*), up to 30 buds (stems) are sometimes produced. (2) In some taxa there are various stages of transition between the globose structures and much-elongated structures, which appear to function as horizontal rhizomes. Such elongation can be observed in *Liatris pycnostachya* var. *lasiophylla* and *L. punctata* var. *punctata*. Some of the longer rhizomes produce new erect stems at intervals; the lowermost portions of such new stems may expand in circumference, become woody, and appear like caudex branches. (3) All of the other Liatrinae (except perhaps the shrubby *Garberia*) apparently produce rhizomes with fibrous roots. In some species of *Carphephorus*, there is little if any rhizome and the stems and fibrous roots originate from the highly condensed crown area. A taproot is never evident, except perhaps very early in ontogeny, as noted above by Gaiser for *Liatris*.

CLASSIFICATION

Liatris Gaertner ex Schreb., Gen. Pl. 2:542. 1791 (nom. cons.). Type species: *Liatris squarrosa* (L.) Michx. = *Serratula squarrosa* L. (typ. cons.)

Lacinaria J. Hill, Veg. Syst. 4 (ed. 2):49, t. 46. 1762 (nom. rej.), non *Laciniaria* J. Hill (1769), an orthographic variant. Lectotype (J. Hill, Hort. Kew. 70. 1769), *Liatris squarrosa* (L.) Michx.

Psilothamnus Necker, Elem. Bot. 1:69. 1790 (nom. inval.).

Suprago Gaertner, Fruct. Sem. Pl. 2(3):402. 1791. Lectotype. (Cassini, Dict. Sci. Nat. 51:384. 1827), *Liatris spicata* (L.) Willd.

Calostelma D. Don in Sweet, Brit. Flower Gard. ser. 2, 2:184. 1833. Type species: *Liatris elegans* (Walter) Michx.

Ammopursus Small, Bull. Torrey Bot. Club 51:392. 1924. Type species: *Liatris ohlingerae* (Blake) B.L. Rob.

KEY TO THE SECTIONS

1\. Leaf margins whitish, thickened, and minutely scabrous; phyllaries foliaceous and subequal to weakly or strongly graduate, hyaline margins absent or extremely narrow (apices hyaline in ser. *Elegantes*); pappus bristles plumose or barbellate.

    2. Pappus bristles plumose. **1.** Sect. **Liatris**

    2. Pappus bristles barbellate. **2.** Sect. **Vorago**

1\. Leaf margins greenish, slightly thickened or not, smooth; phyllaries not foliaceous, usually strongly graduate, usually completely bordered by purplish, hyaline margins; pappus bristles barbellate.

    3. Basal and lower cauline leaves 3–5-veined, parallel venation of basal leaf bases persistent as fibrous vestiges; corolla tubes glabrous within. **3.** Sect. **Suprago**

    3. Basal and lower cauline leaves 1-veined, parallel venation of leaf bases usually not persistent-fibrous; corolla tubes glabrous or pilose within.

        4. Corolla tubes glabrous within, stems glabrous; staminal filaments pilose. **4.** Sect. **Pilifilis**

4. Corolla tubes pilose within, or if glabrous (in *L. ligulistylis*, *L. scariosa*, *L. microcephala*, *L. ohlingerae*, and *L. garberi*) then stems puberulent to puberulent-pilose; staminal filaments glabrous. ____________ **5.** Sect. **Graminifolium**

1. Section **Liatris.** Type species: *Liatris squarrosa* (L.) Michx.

Leaves 3–5-veined; leaf margins thickened, whitish, and minutely pebbly-scabrous; parallel venation of leaf bases not fibrous-persistent; laminae punctate-glandular to weakly punctate-glandular. Capitulescence mostly racemoid-spiciform, cymoid in one species of ser. *Punctatae* (heads commonly solitary in *L. compacta*). Heads sessile to subsessile or pedunculate. Involucres cylindric to campanulate-cylindric; phyllaries indurate to thin-herbaceous, appressed to loose or spreading, apices rounded to acute or acuminate, green or petaloid, margins usually without a scarious border. Corolla lobes hispid-hirsute or glabrous on adaxial surface; corolla tubes glabrous within; staminal filaments glabrous. Pappus bristles plumose.

Species of sect. *Liatris* are characterized by white-indurate, minutely scabrous leaf margins, cylindric heads with foliaceous, subequal phyllaries (strongly to weakly graduate in ser. *Punctatae*), plumose pappus bristles, and a primarily central North American distribution.

KEY TO THE SERIES

1. Leaves with 3–5 parallel nerves; leaves and phyllaries weakly glandular-punctate or not at all; phyllaries weakly graduate to subequal, usually loose and spreading (strongly graduate and appressed in *L. cylindracea*), apices green; corolla lobes hispid on adaxial surface. ____________ **1a.** Ser. **Liatris**
1. Leaves 1-nerved; leaves and phyllaries glandular-punctate; phyllaries strongly graduate and appressed or subequal and loose or spreading; corolla lobes glabrous.
    2. Phyllaries not foliaceous, strongly to weakly graduate, mostly appressed, apices green. ____________ **1b.** Ser. **Punctatae**
    2. Phyllaries somewhat foliaceous, weakly graduate to subequal, loose or spreading, apices petaloid. ____________ **1c.** Ser. **Elegantes**

1a. Series **Liatris.** Type species: *Liatris squarrosa* (L.) Michx.

Lacinaria unranked *Squarrosae* Alexander in Small, Man. Southeastern Fl. 1331. 1933. *Liatris* ser. *Squarrosae* (Alexander) Gaiser ex Fernald, Gray's Man. ed. 8, 1375. 1950. Type species: *Liatris squarrosa* (L.) Michx.

Liatris sect. *Euliatris* series *Squarrosae* Gaiser, Rhodora 48:393. 1946 (nom. nud., without Latin descr.).

Liatris sect. *Euliatris* series *Cylindraceae* Gaiser, Rhodora 48:373. 1946 (nom. nud., without Latin descr.).

Liatris ser. *Cylindraceae* Gaiser ex Fernald, Gray's Man. ed. 8, 1375. 1950 (nom. nud., without Latin descr.).

Leaves 3–5-nerved. Phyllaries foliaceous, weakly graduate to subequal, loose or spreading, apices green. Corolla lobes hispid on adaxial surface.

Species included.—*Liatris compacta* (Torrey & A. Gray) Rydb., *L. cylindracea* Michx., *L. hirsuta* Rydb., *L. squarrosa* (L.) Michx.

The strongly graduate, appressed phyllaries of *Liatris cylindracea* are similar to those of ser. *Punctatae*, but the 3–5-veined leaves and hirsute corolla lobes of ser. *Liatris* make this a strongly defined and easily recognizable group within the 'western' clade (which has white-indurate, minutely scabrous leaf margins and plumose pappus bristles).

1b. Series **Punctatae** (Alexander) Gaiser ex Fernald. *Lacinaria* unranked *Punctatae* Alexander in Small, Man. Southeastern Fl. 1331. 1933. *Liatris* ser. *Punctatae* (Alexander) Gaiser ex Fernald, Gray's Man. ed. 8, 1375. 1950. TYPE: *Liatris punctata* Hook.

Liatris sect. *Euliatris* series *Punctatae* Gaiser, Rhodora 48:346. 1946 (nom. nud., without Latin descr.).

Leaves 1-nerved. Phyllaries not foliaceous, strongly to weakly graduate, appressed to slightly loose, apices green. Corolla lobes glabrous.

Species included.—*Liatris aestivalis* Nesom & O'Kennon, *L. bracteata* Gaiser, *L. cymosa* (H. Ness) K. Schum., *L. glandulosa* Nesom & O'Kennon, *L. punctata* Hook. (including *L. mucronata* DC. and *L. densispicata* [Bush] Gaiser).

Ser. *Punctatae* apparently is the only group of Liatrinae in which polyploidy is prevalent (Gaiser 1950b, 1954). Except for *L. punctata*, which ranges from Canada into northern Mexico, the species are largely Texas-centered. Several taxonomic problems remain to be resolved within *L. punctata* sensu lato.

1c. Series **Elegantes** (Alexander) Gaiser ex Nesom, comb. et stat. nov. BASIONYM: *Lacinaria* unranked *Elegantes* Alexander in Small, Man. Southeastern Fl. 1331. 1933. TYPE SPECIES: *Liatris elegans* (Walter) Michx.

Liatris sect. Euliatris series Elegantes Gaiser, Rhodora 48:340. 1946 (nom. nud., without Latin descr.).
Calostelma D. Don in Sweet, Brit. Flow. Gard. ser. 2, 2:184. 1833. TYPE SPECIES: Liatris elegans (Walter) Michx.

Leaves 1-nerved. Phyllaries foliaceous, weakly graduate to subequal, loose or spreading, apices petaloid. Corolla lobes glabrous.

Species included.—*Liatris elegans* (Walter) Michx.

2. Section **Vorago** Nesom, sect. nov. TYPE SPECIES: *Liatris oligocephala* J. Allison.

Folia 1-nervia (*L. oligocephala*) vel leniter 1–3-nervia (*L. tenuis*); margines incrassati, candidi, scabrelli; nervatura parallella basium foliorum non fibrosi-persistens. Capitulescentia spiciformis (*L. tenuis*) aut cymiformis capitulis 1-aliquot (*L. oligocephala*). Capitula sessiles vel subsessiles vel pedunculata. Involucra campanulati-cylindrica; phyllaria indurata, virida, plerumque incohaerentia vel patentia, sine marginibus angustis hyalinis, apicibus acutis vel acuminatis. Corollae lobis glabris, tubis glabris interne; stamina filamentis glabris. Pappus setis plerumque barbellatis.

Leaves 1-veined (*L. oligocephala*) or 1- to weakly 3-veined (*L. tenuis*); leaf margins thickened, whitish, and minutely pebbly-scabrous; parallel venation of leaf bases not fibrous-persistent; lamina not punctate-glandular or only weakly punctate. Capitulescence spiciform (*L. tenuis*) or heads solitary to few and in a cymoid arrangement (*L. oligocephala*). Heads sessile to sessile or pedunculate. Involucres campanulate-cylindric; phyllaries indurate, green, usually loose or spreading, apices acute to acuminate, margins without a hyaline border. Corolla lobes glabrous; corolla tubes glabrous within; staminal filaments glabrous. Pappus bristles mostly barbellate.

Species included.—Liatris oligocephala J. Allison, *L. tenuis* Shinners.

These species are similar to some in sect. *Liatris* in their whitish, thickened, and minutely scabrous leaf margins, cylindric heads, and indurate and loose or spreading, subequal to weakly graduate, somewhat foliaceous, triangular phyllaries with acute to acuminate apices and without hyaline margins. Their generally western (non-Floridian) geographical position within the genus also suggests ancestry similar to sect. *Liatris*. Pappus bristles of both species, however, are barbellate.

In the original description of *Liatris tenuis*, Shinners (1959) noted its general similarity to *L. squarrosa* (ser. *Liatris*) but rejected a hypothesis of close relationship because of the disparity in pappus bristle morphology. Still, the weakly 3-veined leaves of *L. tenuis* suggest that it may be closest to species of ser. *Liatris*, perhaps as a sister element.

Liatris oligocephala is similar to *L. tenuis* in features of the involucre, corolla, and pappus, but because no synapomorphy is evident, it seems likely that these two species originated independently from the ancestral stock of sect. *Liatris*. Thus, sect. *Vorago*, as delimited here, may not be monophyletic. As noted by Allison (2001), the glabrous achene surfaces of *L. oligocephala* represent a specialized state unique in the genus. Leaf margins are thickened and whitish but vary from "pebbly" (*Allison 7817*, VDB) to smooth (*Allison 8134*, VDB). Phyllary margins are mostly without a hyaline border, but a weakly developed proximal border sometimes is evident.

The name of the section ("vorago," Latin, gulf) alludes to the range of the two species on the Gulf Coastal Plain as well as to the considerable morphological "gulf" between them.

3. Section **Suprago** (Gaertner) DC. *Suprago* Gaertner, Fruct. Sem. Pl. 2(3):402. 1791. *Liatris* section *Suprago* (Cass.) DC., Prodr. 5:129. 1836. LECTOTYPE: (Cassini, Dict. Sci. Nat. 51:384. 1827), *Liatris spicata* (L.) Willd.

Lacinaria unranked *Spicatae* Alexander in Small, Man. Southeastern Fl. 1332. 1933. *Liatris* ser. *Spicatae* (Alexander) Gaiser ex Fernald, Gray's Man. ed. 8, 1372. 1950. TYPE SPECIES: *Liatris spicata* (L.) Willd.

Liatris sect. *Suprago* series *Spicatae* Gaiser, Rhodora 48:177. 1946 (nom. nud., without Latin descr.).

Lacinaria unranked *Pycnostachyae* Alexander in Small, Man. Southeastern Fl. 1331. 1933. *Liatris* ser. *Pycnostachyae* (Alexander) Gaiser ex Fernald, Gray's Man. ed. 8, 1373. 1950. TYPE SPEICES: *Liatris pycnostachya* Michx.

Liatris sect. *Suprago* series *Pycnostachyae* Gaiser, Rhodora 48:237. 1946 (nom. nud., without Latin descr.).

Leaves 3–5 veined; leaf margins slightly thickened, green, smooth; parallel venation of bases of basal leaves conspicuously persisting as fibrous vestiges;

lamina punctate-glandular to weakly punctate-glandular. Capitulescence spiciform to narrowly racemiform. Heads sessile to subsessile. Involucres cylindric; phyllaries thin-herbaceous, appressed to loose or spreading, apices rounded to acute, green (petaloid-recurving in *L. pycnostachya*), margins usually with a narrow scarious border. Corolla lobes glabrous; corolla tubes glabrous within; staminal filaments glabrous. Pappus bristles barbellate (subplumose in *L. acidota*). Type species: *Liatris spicata* (L.) Willd.

Species included.—*Liatris acidota* Engelm. & A. Gray, *L. lancifolia* (Greene) Kittell, *L. pycnostachya* Michx., *L. spicata* (L.) Willd.

Sect. *Suprago* is distinct in its 3–5-veined leaves, parallel veins at the bases of the basal leaves conspicuously persisting as fibers, and internally glabrous corolla tubes. The species are relatively scattered in geographic distribution but are mostly "western" like those of sect. *Liatris*; none are primarily "Floridian." In addition to features of sect. *Suprago* noted in the description, cauline leaves tend to be abruptly reduced to bracts above midstem. Even within *L. spicata*, however, the distal cauline leaves of *L. spicata* var. *resinosa* are abruptly reduced while those of var. *spicata* are only gradually reduced. Similar reduction of distal cauline leaves also occurs in other groups of *Liatris*.

4. Section **Pilifilis** Nesom, sect. nov. *Lacinaria* unranked *Tenuifoliae* Alexander in Small, Man. Southeastern Fl. 1331. 1933. Type species: *Liatris tenuifolia* Nutt.

Liatris sect. *Suprago* series *Tenuifoliae* Gaiser, Rhodora 48:286. 1946 (nom. nud., without Latin descr.).

Folia 1-nervia; margines leniter incrassati, virides, laeves; nervatura parallella basium foliorum plerumque non fibrosi-persistens. Capitulescentia spiciformis vel leniter racemiformis. Capitula sessiles vel subsessiles vel pedunculata. Involucra cylindrica; phyllaria tenuiter herbacea, virida (non petaloidea), appressa, apicibus obtusis vel retusis plerumque apiculatis, marginibus angustis hyalinis. Corollae lobis glabris, tubis glabris interne, stamina filamentis pilosis. Pappus setis barbellatis.

Leaves 1-veined; leaf margins slightly thickened, green, smooth; parallel venation of leaf bases usually not fibrous-persistent but sometimes weakly so; lamina punctate-glandular to weakly punctate-glandular. Capitulescence spiciform to slightly racemiform. Heads sessile to subsessile or pedunculate. Involucres cylindric; phyllaries thin-herbaceous, green (not petaloid), appressed, apices obtuse to retuse and usually apiculate, margins with a narrow scarious border. Corolla lobes glabrous; corolla tubes glabrous within; staminal filaments pilose. Pappus bristles barbellate.

Species included.—*Liatris laevigata* Nutt., *L. tenuifolia* Nutt.

The pilose staminal filaments of these two species set them apart from others in the genus. It seems reasonable to speculate that this is homologous with production of hairs from internal petal tissue near the corolla base in sect. *Graminifolium*. Basal leaves of *L. laevigata* and *L. tenuifolia* show a tendency to be fibrous-persistent, like those in sect. *Suprago*, but the leaves are 1-veined.

5. Section **Graminifolium** Nesom, sect. nov. TYPE SPECIES: *Liatris pilosa* (Aiton) Willd. (= *Liatris graminifolia* Willd.).

Folia 1-nervia. (leniter 3–5-nervia in *L. savannensi*); margines leniter incrassati, virides, laeves; nervatura parallella basium foliorum non fibrosi-persistens. Capitulescentia racemi-spiciformis, raro cymiformis. Capitula sessiles vel subsessiles vel pedunculata. Involucra cylindrica vel campanulata; phyllaria tenuiter herbacea, virida, appressa, apicibus rotundatis vel acutis, marginibus angustis hyalinis Corollae lobis glabris, tubis plerumque pilosis interne (glabris in *L. garberi*, *L. ligulistyli*, *L. microcephala*, ac *L. ohlingerae*); stamina filamentis glabris. Pappus setis barbellatis.

Leaves 1-veined (weakly 3–5 veined in *L. savannensis*); leaf margins slightly thickened, green, smooth; parallel venation of leaf bases not fibrous-persistent; lamina punctate-glandular to weakly punctate-glandular. Capitulescence racemoid-spiciform, rarely cymoid. Heads sessile to subsessile or pedunculate. Involucres cylindric to campanulate; phyllaries thin-herbaceous, green, appressed, apices rounded to acute, margins with a narrow scarious border. Corolla lobes glabrous; corolla tubes usually pilose within (glabrous in *L. ligulistylis*, *L. ohlingerae*, *L. microcephala*, and *L. garberi*); staminal filaments glabrous. Pappus bristles barbellate.

Section *Graminifolium* is characterized by the distinctive pilose vestiture produced within the corolla tubes in the region of filament insertion. This vestiture is hypothesized to have been lost in four species, each of which apparently is specialized in other features: *Liatris ohlingerae* and *L. ligulistylis* produce particularly large heads; *L. microcephala* has exceptionally short pappus bristles and short corollas, mostly due to loss of tube length; *L. garberi* is hypothesized to have reverted to a characteristically primitive root system (see comments below).

KEY TO THE SERIES

1. Phyllaries acute to obtuse (angular) at the apex.
2. Stems glabrous; phyllaries oblong-triangular. **5c.** Ser. **Virgatae**
2. Stems hirtellous or pilose-puberulent (usually glabrous in *L. pauciflora*); phyllaries usually obovate.
3. Corms globose; stems hirtellous or glabrous; corolla tubes pilose within. **5a.** Ser. **Pauciflorae**
3. Corms irregularly shaped, short-rhizomiform with tuberous-thickened fibrous roots; stems pilose-puberulent; corolla tubes glabrous within. **5b.** Ser. **Garberae**
1. Phyllaries rounded to obtuse-rounded at the apex.
4. Stems glabrous or uncommonly sparsely pilose; basal leaves mostly oblanceolate; heads sessile to short-pedunculate in a spiciform capitulescence. **5d.** Ser. **Graminifoliae**
4. Stems puberulent; basal leaves obovate-spatulate; heads usually pedunculate in a racemiform to corymbiform capitulescence. **5e.** Ser. **Scariosae**

5a. Series **Pauciflorae** (Alexander) Gaiser ex Nesom, comb. et stat. nov. BASIONYM: *Lacinaria* unranked *Pauciflorae* Alexander in Small, Man. Southeastern Fl. 1331. 1933. TYPE SPECIES: *Liatris pauciflora* Pursh.

Liatris sect. *Euliatris* series *Pauciflorae* Gaiser, Rhodora 48:279. 1946 (nom. nud., without Latin descr.).

Corms globose. Stems hirtellous or glabrous. Basal leaves mostly oblanceolate. Heads sessile to short-pedunculate in a spiciform capitulescence. Phyllaries obovate, apically acute to obtuse (angular). Corolla tubes pilose within.

Species included.—*Liatris chapmanii* Torrey & A. Gray, *L. pauciflora* Pursh (including *L. secunda* Ell.), *L. provincialis* Godfrey

5b. Series **Garberae** Nesom, ser. nov. TYPE: *Liatris garberi* A. Gray

Cormi forma irregulares, brevi-rhizomiformes radicibus fibris crassis. Caules pilosi-puberuli. Folia basalia plerumque oblanceolata. Capitula sessiles vel brevipedunculata capitulescentia spiciformis. Phyllaria obovata, ad apices angulata, acuta vel obtusa. Corollae tubis interne glabris.

Corms irregularly shaped, short-rhizomiform with tuberous-thickened fibrous roots. Stems pilose-puberulent. Basal leaves mostly oblanceolate. Heads sessile to short-pedunculate in a spiciform capitulescence. Phyllaries obovate, apically acute to obtuse (angular). Corolla tubes glabrous within.

Species included.—*Liatris garberi* A. Gray

The thickened, fibrous roots of *Liatris garberi*, arising from an abbreviated crown or short and irregular rhizome, are distinct in the genus and are similar to those of *Carphephorus* and *Hartwrightia*, presumably a primitive feature for the Liatrinae. If corms are an ancestral feature of *Liatris*, as seems to be the case, then the root system of *L. garberi* may be secondarily derived. The internally glabrous corolla tubes of *L. garberi*, in the interpretation here, also are specialized (loss of pubescence). *Liatris garberi* is more similar in stem vestiture to *L. pycnostachya* and *L. acidota* of sect. *Suprago* than to any species of sect. *Graminifolium*. Leaf bases of *L. garberi*, however, are not like those of sect. *Suprago* and the phyllaries are similar to those of ser. *Pauciflorae*. The restricted Floridian geography of *L. garberi* also suggests that its closest relatives are more likely found in the same area (i.e., ser. *Pauciflorae*, especially).

5c. Series **Virgatae** Nesom, ser. nov. TYPE SPECIES: *Liatris virgata* Nutt.

Cormi globosi. Caules glabres. Folia basalia plerumque oblanceolata. Capitula sessiles vel brevipedunculata capitulescentia spiciformis. Phyllaria oblongi-triangulares, ad apices angulata. Corollae tubis interne pilosis.

Corms globose. Stems glabrous. Basal leaves mostly oblanceolate. Heads sessile to short-pedunculate in a spiciform capitulescence. Phyllaries oblong-triangular, apically acute to obtuse (angular). Corolla tubes pilose within.

Species included.—*Liatris cokeri* Pyne & Stucky, *L. virgata* Nutt.

As suggested by Nesom and Stucky (2004), *Liatris cokeri* and *L. virgata* may be sister taxa. Their angular phyllary apices possibly indicate relatively close ancestry with ser. *Pauciflorae*, although some plants in the northern range of *L. pilosa* also produce angular phyllaries. The glabrous stems of *L. cokeri* and *L. virgata* are similar to those of ser. *Graminifoliae*.

5d. Series **Graminifoliae** Gaiser ex Nesom, ser. nov. *Liatris* sect. *Suprago* series *Graminifoliae* Gaiser, Rhodora 48:246. 1946 (nom. nud., without Latin descr.). *Liatris* ser. *Graminifoliae* Gaiser ex Fernald, Gray's Man. ed. 8, 1373. 1950 (nom. nud., without Latin descr.). Fernald attributed the basionym to Alexander, but "Graminifoliae" was not among the group-names used by Alexander. TYPE SPECIES: *Liatris pilosa* (Aiton) Willd. (= *Liatris graminifolia* Willd.).

Cormi globosi. Caules glabres vel sparsim pilosi. Folia basalia plerumque oblanceolata. Capitula sessiles vel brevipedunculata capitulescentia spiciformis. Phyllaria oblongi-triangulares, ad apices rotundata vel obtusi-rotundata. Corollae tubis interne pilosis.

Corms globose. Stems glabrous to sparsely pilose. Basal leaves mostly oblanceolate. Heads sessile to short-pedunculate in a spiciform capitulescence. Phyllaries oblong-triangular, apically rounded to obtuse-rounded. Corolla tubes pilose within.

Species included.—*Liatris elegantula* (Greene) K. Schum., *L. helleri* Porter (synonym = *L. turgida* Gaiser), *L. microcephala* (Small) K. Schum., *L. pilosa* (Aiton) Willd. (synonym = *L. graminifolia* Willd.), *L. savannensis* Kral & Nesom.

Prior to recent recognition of *Liatris savannensis* (Kral & Nesom 2003), plants of that species had been identified mostly as *L. spicata* (sect. *Suprago*). The leaves of *L. savannensis* are weakly 3-nerved, a feature of *L. spicata* and its close relatives but one not otherwise found in sect. *Graminifolium*, and *L. savannensis* might be investigated toward the possibility that genes from sect. *Suprago* were involved in its evolutionary origin.

Basal leaves of *Liatris helleri* (sensu lato, Nesom 2005b) range to relatively large size, similar to those of ser. *Scariosae*. *Liatris helleri*, however, is most similar overall to *L. pilosa*, and the geographic juxtaposition of *L. virgata* between *L. pilosa* and *L. elegantula* (Nesom & Stucky 2004) is perhaps indicative of a more distant relationship of the the latter two species.

Liatris microcephala is very similar to other species of ser. *Graminifoliae* but lacks the diagnostic pilose vestiture within the corolla tube. The tube, however, is much shortened (the whole head is shortened), and it is assumed here that loss of the vestiture accompanied other specializations toward reduction in corolla size. The characteristic tendency for short pappus bristles in *L. microcephala* also occurs in some populations of *L. helleri* (Nesom 2005b) but not elsewhere in the genus.

5e. Series **Scariosae** (Alexander) Gaiser ex Fernald. *Lacinaria* unranked *Scariosae* Alexander in Small, Man. Southeastern Fl. 1332. 1933. *Liatris* ser. *Scariosae* (Alexander) Gaiser ex Fernald, Gray's Man. ed. 8, 1374. 1950. TYPE SPECIES: *Liatris scariosa* (L.) Willd.

Liatris sect. *Euliatris* series *Scariosae* Gaiser, Rhodora 48:293. 1946 (nom. nud., without Latin descr.).

Ammopursus Small, Bull. Torrey Bot. Club 51:392. 1924. TYPE SPECIES: *Liatris ohlingerae* (Blake) B.L. Rob.

Corms globose. Stems hirtellous or pilose-puberulent (variably glabrous in *L. squarrulosa*). Basal leaves mostly obovate-spatulate. Heads sessile to short-pedunculate in a spiciform capitulescence or usually pedunculate in a racemiform to corymbiform capitulescence. Phyllaries oblong-triangular, apically rounded to obtuse-rounded. Corolla tubes usually pilose within (glabrous in *L. ligulistylis* and *L. ohlingerae*).

Species included (in three informal groups): **1)** southern range, linear basal leaves, large heads: *L. ohlingerae* (Blake) B.L. Rob.; **2)** southern range, smaller basal leaves, smaller heads: *Liatris gholsonii* L. Anderson, *L. gracilis* Pursh, *L. patens* Nesom & Kral; **3)** northern range, larger basal leaves, large heads: *Liatris aspera* Michx., *L. ligulistylis* (A. Nels.) K. Schum., *L. scariosa* (L.) Willd. (including *L. borealis*), *L. squarrulosa* Michx. (including *L. scabra* (Greene) K. Schum.)

Series *Scariosae* is separated here into three subgroups, generally differing in head size and in basal leaf morphology. Addition of *L. ohlingerae* and the apparently interrelated *L. gracilis*, *L. gholsonii*, and *L. patens* expands Gaiser's concept of ser. *Scariosae*. The latter three species range widely in head size (3–6[–9], 3–5[–6], and 7–12 florets, respectively). *Liatris ohlingerae* has 20–30 florets, glabrous corolla tubes, basal leaves hardly wider than the cauline, and may not belong with ser. *Scariosae*. Heads of *L. squarrulosa* also are markedly variable—11–26(–28) florets. *Liatris scariosa*, *L. ligulistylis*, and *L. aspera* are larger-headed—ca. 19–ca. 80, ca. 30–70, and (14–)18–24(–30) florets, respectively—and have more northern geographic distributions. *Liatris scariosa* and *L. ligulistylis* usually produce heads on long peduncles, as in *L. ohlingerae* and *L. patens*, and there is a tendency in the first three species for the corolla tubes to be glabrous.

Liatris ohlingerae is distinct in its relatively few, broadly campanulate heads in a cymiform arrangement. Small (1924, 1933) considered the species so remarkable that he treated it as the monotypic genus *Ammopursus*, emphasizing (1924, p. 393) the "succulent foliage, the open inflorescence, the somewhat zygomorphic corollas with inflated throats, and the short pappus." Gaiser placed *L. ohlingerae* in "series *Cylindraceae*" (a group treated here within sect. *Liatris*) because of its similarity in habit (mostly the arrangement of heads) to *L. cymosa*, but the pappus bristles of *L. ohlingerae* are barbellate rather than plumose as in sect. *Liatris*. Blake's original description (1923) of the species apparently emphasized the campanulate heads, noting that the species was nearest *L. scariosa*. The puberulent vestiture and long-pedunculate heads of *L. ohlingerae* also are shared similarities with ser. *Scariosae*, but the internally glabrous corolla tubes are unusual for sect. *Graminifolium*.

ACKNOWLEDGMENTS

Reviews and nomenclatural advice from K.N. Gandhi, Dick Wunderlin, and Ed Schilling are greatly appreciated—the manuscript has been much improved by their input.

ANNOUNCEMENT

THE RUPERT BARNEBY AWARD

The New York Botanical Garden is pleased to announce that Vidal de Freitas Mansano, of the Instituto de Pesquisas Jardim Botânico do Rio de Janeiro, and Benjamin M. Torke, currently a graduate student in the Department of Biology, Washington University, St. Louis, are the joint recipients of the Rupert Barneby Award for the year 2005. They will be studying the systematics and diversification of *Swartzia* (Leguminosae, Papilionoideae, Swartzieae), a prominent neotropical tree genus of approximately 140–180 species, with species diversity concentrated in lowland rainforests of the Guianas and Amazonia.

The New York Botanical Garden now invites applications for the Rupert Barneby Award for the year 2006. The award of US$ 1,000.00 is to assist researchers to visit The New York Botanical Garden to study the rich collection of Leguminosae. Anyone interested in applying for the award should submit their curriculum vitae, a detailed letter describing the project for which the award is sought, and the names of 2–3 referees. Travel to the NYBG should be planned for sometime in the year 2006. The application should be addressed to Dr. James L. Luteyn, Institute of Systematic Botany, The New York Botanical Garden, 200th Street and Kazimiroff Blvd., Bronx, NY 10458-5126 USA, and received no later than December 1, 2005. Announcement of the recipient will be made by December 15.

Anyone interested in making a contribution to THE RUPERT BARNEBY FUND IN LEGUME SYSTEMATICS, which supports this award, may send their check, payable to The New York Botanical Garden, to Dr. Luteyn.

BOOK REVIEWS

Tree Books

Owen Johnson (text) and David More (illustrations). 2004. **Collins Tree Guide.** (ISBN 0-00-71963-4, hbk.). HarperCollins*Publishers*, Ltd., 77-85 Fulham Palace Road, London W6 8JB, UK. (**Orders:** HarperCollins UK, Trafalgar Square, No. Pomfret, Vermont 05053, U.S.A.; www.trafalgarsquarebooks.com). $65.00, 464 pp., 8 1/2" × 12 1/2".

For those interested in cultivated trees in the U.S.A., this is a prime reference. In fact, as far as I know from the BRIT library, this is among the best, even though the book is aimed primarily at a different continent. Up front is a list of "the 63 species and microspecies that seem most likely to have got [to Britain and northern Europe] without human agency," but the book covers nearly 1600 taxa of "trees in the countryside, parks, and gardens of Britain and of non-Mediterranean Europe"—"those trees which, however rarely, may be found in the general run of gardens." Realistic color paintings show growth habits, bark, fruits, and close-ups of branches and leaves. Distinctive hybrids and cultivars abound. For example, illustrations are provided for 18 distinctively shaped cultivars of Lawson Cypress (*Chamaecyparis lawsoniana*)—"a uniform tree in the wild, but after its arrival in Europe it immediately began to throw more 'sports' than any other species."

In a review (Sida 19:642. 2001) of the "field guide-sized" (but thick) *A photographic guide to the Trees of Britain and Europe* (Keith Rushforth 1999, also published by HarperCollins), with color photos of many taxa and small-print descriptions and commentaries, I found it extremely useful for North American identifications. The Johnson and More volume, with larger format, less technical descriptions, narrower geographic scope, and greater emphasis on cultivars, is an exceptionally good complement to the Rushforth book.—*Guy Nesom, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

Fred Wampler (text) and Maryrose Wampler (paintings). 2001. **Trees of Indiana.** (ISBN 0-253-32885-3, hbk.). Indiana University Press, 601 North Morton Street, Bloomington, IN 47404-3797, U.S.A. (**Orders:** 800-842-6796, 812-855-7931 fax; iuporder@indiana.edu, www.indiana.edu/~iupress). $49.95, 152 pp., 72 watercolor paintings, 11 1/4" × 13 1/4".

A showcase of watercolor paintings of Indiana trees by Maryrose Wampler, in large ('coffee table') format—11 1/4 _ 13 1/4 inches—with brilliant greens, reds, oranges, and yellows. For each of the 72 species, a full tree is shown along with details of stems, leaves, flowers, and fruits.

"First and foremost, this is an art book." "While care has been taken to be as scientifically accurate as possible, we are not botanists, but generalists interested in trees. Our selection policy was somewhat subjective. We have covered most common trees and also others that 'lit the light,' ... including at least one representative of each genus that grows naturally in the state, commonly reaches a height of 20 feet or more, and has a single trunk."

Commentaries were researched "from secondary sources in order to give Hoosiers an appropriate introduction and background."—*Guy Nesom, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

BROADENED CONCEPT OF *LIATRIS HELLERI* (ASTERACEAE: EUPATORIEAE)

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, Texas 76102-4060, U.S.A.

ABSTRACT

Liatris helleri T.C. Porter (1891) previously has been regarded as a rare, narrowly distributed endemic of North Carolina. The present investigation, in the context of a study of the whole genus, presents a broadened concept of *L. helleri*, including plants in West Virginia, Virginia, and North Carolina previously identified as *L. turgida* Gaiser (1946) and many from the same region misidentified as *L. graminifolia* var. *smallii*. A lectotype (NY) is selected for *L. helleri*. The diagnostic feature of *L. helleri* sensu stricto, a shortened pappus, has been the primary distinction between it and *L. turgida*, but pappus length varies among populations in the small region of *L. helleri* sensu stricto and a short pappus also occurs in some populations of *L. turgida*. If this broadened concept is followed, it may have the effect of lessening legal protections for *L. helleri*, but some of the North Carolina populations occur with other rare species in a rare natural community, and the species and habitat are a focus of continuing conservation concerns.

RESUMEN

Liatris helleri T.C. Porter (1891) ha sido vista previamente como un endemismo raro escasamente distribuido en Carolina del Norte. En la presente investigación, en el contexto de un estudio de todo el género, se presenta un concepto más amplio de *L. helleri*, incluyendo plantas del Oeste de Virginia, Virginia, y Carolina del Norte identificadas previamente como *L. turgida* Gaiser (1946) y muchas de la misma región identificadas incorrectamente como *L. graminifolia* var. *smallii*. Se ha seleccionado un lectotipo (NY) para *L. helleri*. El carácter diagnóstico de *L. helleri* sensu stricto, un vilano corto, ha sido la diferencia principal entre éste y *L. turgida*, pero la longitud el vilano varía entre poblaciones de la pequeña región de *L. helleri* sensu stricto y un vilano corto se da también en algunas poblaciones de *L. turgida*. Si se sigue este concepto ampliado, puede tener como efecto la pérdida de protecciones legales de *L. helleri*, pero algunas de las poblaciones de Carolina del Norte conviven con otras especies en una comunidad natural rara, y tanto las especies como el hábitat tienen implicaciones permanentes en la conservación.

Liatris helleri T.C. Porter previously has been regarded as a endemic of montane habitats in North Carolina, restricted to a few populations in Avery, Burke, Caldwell, Mitchell, and Watauga (the type) counties. It has been said to be characterized by high-elevation habitats, although within its restricted range, it occurs over a range of 1020–1750 meters elevation. Because of its perceived rarity, *L. helleri* is federally listed as a threatened species (G1, critically imperiled), and a recovery plan (USF&WS 1989, 1999 First Revision) is available. It is listed as threatened in North Carolina (NCDA&CS 2005). Comprehensive information on the species (sensu stricto), including conservation and management summaries, protective rankings, and references and technical reports, is provided on the Center for Plant Conservation website (CPC 2005). Studies of the mating system (Godt & Hamrick 1995) and genetic diversity (Godt & Hamrick 1996) of *L. helleri* have been published. Photographs and illustrations of the species can be found on the CPC website and others.

A markedly shortened pappus has been used as the primary diagnostic feature of *Liatris helleri* to distinguish it from taxa of the *L. pilosa* (Ait.) Willd. (synonym = *L. graminifolia* Willd.; Nesom & Stucky 2004) group. Pappus bristles of typical *L. helleri* are about half to two-thirds the length of the corolla tube, compared to the characteristic condition in the *L. pilosa* group and most of the rest of the genus, where the bristles are as long or slightly longer than the corolla tube.

Pappus length, however, is variable in *Liatris helleri*. In conservation-oriented surveys of the species, Sutter and Murdock (1984) observed that pappus length was not consistent among populations, and they subsequently undertook a more detailed taxonomic analysis to compare various features of *L. helleri* (3 native populations) with *L. pilosa* (4 native populations, localities noted only as "across North Carolina," identified as *L. graminifolia*). Data were taken from field measurements and common garden studies, augmented by specimens from four herbaria. They found that for stem height, number of leaves, capitulescence length, and number of heads per plant, *L. helleri* (all populations) differed from *L. pilosa*. In pappus length and pappus/corolla length ratios, however, Linville and Blowing Rock populations of *L. helleri* had significantly shorter pappus, while the Grandfather Mountain population of *L. helleri* was not different from *L. pilosa*. Sutter and Murdock (1984, p. 8) concluded that "the Grandfather Mountain population of *L. helleri* should be considered an infraspecific taxon within *L. graminifolia*." Neither their taxonomic study or its conclusion, however, is cited or mentioned in recovery plans written by the same authors (USF&WS 1999, 1989), which is surprising, since the Grandfather Mountain plants have continued to be recognized within *L. helleri*.

Pappus variation in *Liatris helleri* also was observed in the genetic study by Godt and Hamrick (1996), who noted (p. 467) that the populations sampled in their work were "recognized by the U.S. Fish and Wildlife Service and by the North Carolina Heritage programme as populations of *L. helleri*, although they cannot all be keyed to *L. helleri* on the basis of pappus length." Observations of the present study, corroborating Kral (1983), indicate that pappus length varies from about half to two-thirds the corolla tube length among populations of typical *L. helleri*, apart from the longer pappus in the Grandfather Mountain series.

Liatris turgida and *L. helleri* compared

Liatris turgida Gaiser has been considered to be an Appalachian species primarily at low elevations in montane Virginia and West Virginia (e.g., Johnson

1971; Strausbaugh & Core 1977), with rare populations in North Carolina (Godfrey 1948; Ahles 1968) and perhaps in northern Alabama and Georgia (Cronquist 1980; Duncan & Kartesz 1981; Gleason & Cronquist 1994). In a taxonomic study of the whole genus (Nesom 2005a), the only difference between *L. turgida* and *L. helleri* is one of pappus length. Over most of the geographic range of *L. turgida*, pappus bristles equal or slightly surpass the corolla tubes in length. In several areas of Virginia, however, the pappus sometimes is shortened to a length approaching typical populations of *L. helleri* (e.g., Amherst Co., *Freer 2007*; Bedford Co., *Freer 12226*; Roanoke Co., *Uttal 10883*; full citations below). The Grandfather Mountain population series (Avery Co., North Carolina) of *Liatris helleri*, as included in the study by Sutter and Murdock (1984), technically would be identified as *L. turgida*.

Gaiser (1946, p. 263) noted that *Liatris helleri* (sensu stricto) was distinguished from *L. turgida* by "the short pappus, the few, though closely spaced heads, and usually quite glabrous leaves" (the same contrast repeated almost identically on p. 259). Species descriptions by Cronquist (1980) contrast *L. helleri* with *L. turgida* by shorter pappus and otherwise only by several, strongly overlapping features: stems shorter, vestiture consistently glabrous, leaves shorter and narrower and eciliate, heads fewer, and florets fewer per head. Length of pappus was the only difference noted by Ahles (1968, p. 1049, 1050). In the present study, I find that no character or combination of characters is able to separate the two taxa. As variability of the single character defining *L. helleri* (pappus length) has become apparent, recent practice has been to continue to recognize the species primarily on the basis of its short stature and its occurrence in exposed rock outcrop situations at high elevations in northwestern North Carolina, in association with other narrow endemics and arctic-alpine disjuncts, notably *Geum radiatum*, *Huperzia appalachiana*, *Trichophorum caespitosum*, *Houstonia montana*, *Hudsonia montana*, *Juncus trifidus*, *Carex misera*, and *Solidago spithamaea* (Weakley pers. comm.). This distinctive assemblage of species has been described as a rare plant community, called High Elevation Rocky Summit by Schafale and Weakley (1990) and studied in detail by Wiser (Wiser 1994; Wiser et al. 1996).

While ecological and distributional considerations can help make the case for the taxonomic distinction of two entities when morphological characters are weak, *Liatris helleri* and *L. turgida* are not separable by any reliable characters. I am simply unable to recognize more than a single entity, as documented by the technical description below. Plants of *L. turgida* may be relatively short and the heads few and distantly spaced or taller with up to 40 heads borne in a relatively dense spike. Leaves of *L. turgida* vary from sparsely pilose to glabrous. Other features, including leaf morphology, head size, and floret number, also are broadly or completely overlapping.

Gaiser's direct and repeated comparisons (1946) of *Liatris helleri* and *L.*

turgida imply that she regarded these two taxa as most similar to each other. Comparison of species descriptions by Cronquist (1980) also indicate that he found *L. helleri* and *L. turgida* most similar between themselves. Ahles (1968, p. 1050) observed that *L. helleri* is "Similar to no. 5 [*L. turgida*] and perhaps not specifically distinct from it." Sutter and Murdock (1984) and Godt and Hamrick (1996) encountered difficulties in the definition of *L. helleri*, but the taxonomic study by Sutter and Murdock compared *L. helleri* with *L. pilosa*, noting (without other comment) that *L. turgida* was "obviously unrelated to the *L. helleri* complex."

Godt and Hamrick (1996) found that local populations of *Liatris helleri* sensu stricto are genetically isolated and significantly differentiated among themselves. Common garden experiments suggested to Sutter and Murdock (1984, p. 6) that "strong selection for short stature and size" in the Grandfather Mountain and Linville area plants may be effected by the "exposed nature of the habitats ... and the intensity of wind at these elevations." They also noted (p. 8) that "many of the characters that relate *L. helleri*—Grandfather to *L. helleri*—Linville appear to have a genetic basis but also may have arisen several times under the selective forces of the environment at high elevations."

Broadened concept of *Liatris helleri* to include *L. turgida*

In view of the lack of distinction between the two taxa, the concept of *Liatris helleri* (described in 1891) is expanded here morphologically and geographically (Fig. 1) to include plants in West Virginia, Virginia, and North Carolina identified as *L. turgida* (described in 1946). Details regarding the nomenclatural priority of *L. helleri* are given below. Additionally, a number of collections previously identified by the misapplied names *L. graminifolia* Willd. (= *L. pilosa*) and *L. graminifolia* var. *smallii* (Britton) Fern. & Grisc. (= *L. virgata* Nutt.) also have been recognized as *L. helleri* in the present study.

A study of allozymic variation of *Liatris helleri* sensu stricto (Godt & Hamrick 1996) supports the broadened concept of the species. Based on samples from nine North Carolina populations occurring within a 30 kilometer radius, Godt and Hamrick found relatively high levels of genetic diversity in *L. helleri*, in exception to a general trend for reduced diversity in geographically restricted species. The diversity in *L. helleri* is "about three times the mean genetic diversity found for endemic plants" (p. 466) and is comparable to that found in the widespread *Liatris cylindracea* (Schall 1975, 1976). In the present interpretation of broadened geographic range and greater abundance of *L. helleri*, the allozymic variability observed by Godt and Hamrick no longer appears unusual.

Taxonomic rank and relationships of *Liatris helleri* sensu lato

Quantitative variation in a single character (pappus length, in this case) might justify recognition of a varietal taxon if the variant feature were consistent and geographically coherent. In *Liatris helleri*, however, these conditions do not hold

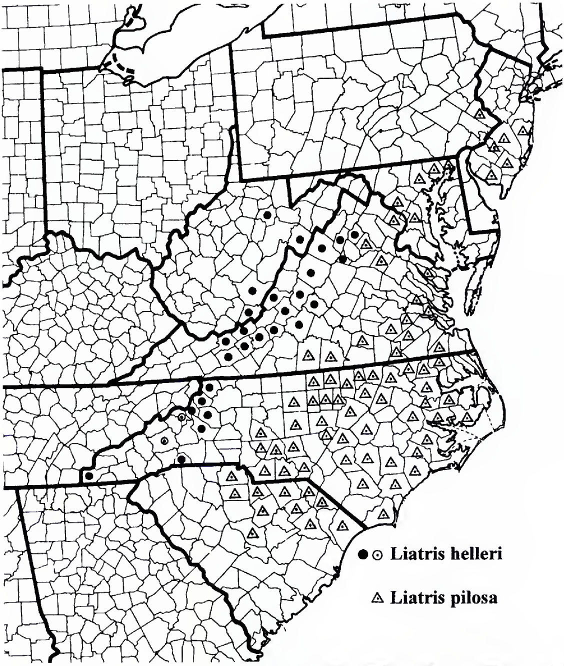

Fig. 1. Geographic distribution of *Liatris helleri* and *L. pilosa*. Localities for *L. pilosa* are from Nesom and Stucky (2004). Open circles represent collections cited by Gaiser (1946) but not seen in the present study.

and it is more consistent with taxonomic practice to informally recognize the North Carolina cluster of short-pappus populations. In fact, in view of the close similarity and presumed relationship of *L. helleri* sensu lato with *L. pilosa*, it would not be unreasonable to treat *L. helleri* sensu lato at varietal rank within *L. pilosa*.

Recognition of *Liatris helleri* at specific rank, apart from *L. pilosa*, emphasizes their distinct geography and habitat and their generally consistent, though small, differences in morphology (see key below). The two varieties of *L. spicata* (L.) Willd. have an essentially allopatric distribution (coastal plain and montane/inland) nearly analogous to that of *L. helleri* and *L. pilosa*, but the morphological overlap between the varieties of *L. spicata* is greater than between *L. helleri* and *L. pilosa*.

Liatris helleri is a member of *Liatris* ser. *Graminifoliae* (sensu Gaiser 1946; sect. *Graminifolium* ser. *Graminifoliae* sensu Nesom 2005b)—this species would have been appropriately treated by Nesom and Stucky (2004) as a member the *L. pilosa* group. In fact, *L. pilosa* and *L. helleri* (sensu lato) are more similar to each other than *L. pilosa* is to *L. elegantula* (Greene) K. Schum. (the latter two were regarded as most closely related to each other by Nesom and Stucky 2004). *Liatris microcephala* (Small) K. Schum. also is treated as a member of ser. *Graminifoliae* (Nesom 2005b); it is the only other species of *Liatris* with short pappus, but in contrast to *L. helleri*, bristle length in *L. microcephala* is relatively consistent over the range of the species.

Distinctions among these closely related taxa of ser. *Graminifoliae* are given in the key and comments below.

1. Stems glabrous; heads loosely arranged, on internodes (2–)5–10(–14) mm; peduncles 0–2(–7) mm; involucres 6–8 mm; phyllaries in 3–4(–5) series ____ **Liatris elegantula**
1. Stems glabrous to sparsely or moderately pilose; heads densely arranged, on internodes (1–)2–5(–7) mm; peduncles 0–10(–17,–80 in proximal part of capitulescence) mm; involucres (7–)8–10 mm, phyllaries in (3–)4–5(–6) series.
    2. Stems 15–55 cm; leaves and phyllaries not at all punctate-glandular or weakly so, the punctations evident only as tiny black dots (no glandular hairs evident); involucres 6–8(–10) mm wide; pappus bristles 1/2–2/3 to equal the corolla tube length; montane, 650–1600(–1850) m ____ **Liatris helleri**
    2. Stems 40–120 cm; leaves and phyllaries usually weakly punctate-glandular, phyllaries sometimes eglandular or the glands weakly developed and superficial; involucres 5–6 mm wide; pappus bristles equal the corolla tube length; coastal plain and piedmont, ca. (0–)10–500 m ____ **Liatris pilosa**

Also, compared to *L. pilosa*, stems of *L. helleri* are shorter, basal leaves average larger and cauline leaves tend to be more abruptly reduced distally, heads tend to be slightly more separated, and cypselae are slightly larger (Nesom 2005a). It would be useful to study these taxa in detail where their ranges closely approach each other in northern Virginia and Maryland (Fig. 1). Rare plants in the northernmost geographic range of *Liatris pilosa* might be identified as *L. helleri* (e.g., DELAWARE, Newcastle Co., Saint Georges, no collector or date, DOV; NEW JERSEY, Cape May Co., Belleplain, dry sandy pinewoods, 20 Sep 1974, *Moldenke 29024*, MO). Presumably, this could be interpreted as incomplete differentiation or as the result of gene flow in this area where the mountains closely approach the coastal plain.

Liatris helleri T.C. Porter, Bull. Torrey Bot. Club 18:147. 1891. *Lacinaria helleri* (T.C. Porter) T.C. Porter ex Heller, Muhlenbergia 1:6. 1900. TYPE: U.S.A. NORTH CAROLINA. Watauga

Co.: Blowing Rock Mt., 18 Aug 1890, *A.A. Heller 81* (LECTOTYPE, designated here: NY 180685!; ISOLECTOTYPES: MO! ND, NY 180687!). Porter (1891) did not specify the herbarium of deposition for the type; Gaiser (1946) noted that the "type" was at NY, but neither of the NY sheets cited here was annotated by her. Both of the NY sheets have recently been annotated as isotypes.

Liatris turgida Gaiser, Rhodora 48:261. 1946. TYPE: U.S.A. VIRGINIA. Nelson Co.: vicinity of Afton in the Blue Ridge Mts., road to Royal Orchard, rocky woods, 600 m, 31 Aug 1912, *E.S. Steele 24* (HOLOTYPE: US internet image!).

Corms globose, sometimes knotty. **Stems** 15–55 cm tall, glabrous. **Leaves**: basal and lower cauline spatulate-oblanceolate to narrowly lanceolate or linear-oblanceolate, 1-nerved, (5–)6–10(–18, –22) cm long (usually at least reaching the level of the heads), 3–8(–15) mm wide, usually quickly to gradually reduced in size above midstem, glabrous to sparsely pilose abaxially (especially in Va.), not glandular-punctate or only weakly so and without evident glandular hairs. **Heads** sessile to subsessile, peduncles rarely to 12 mm long, usually in a densely to loosely spiciform arrangement. **Involucres** turbinate-campanulate, 7–10 mm long, 6–8(–10) mm wide; phyllaries in 3–4(–5) graduate series, oblong, apically rounded, margins with a hyaline border, ciliolate, otherwise glabrous, without glandular punctations. **Florets** 7–13(–17) per head; corolla tubes sparsely pilose within in the region of filament insertion. **Cypselae** (2.5–)3.5–5 mm long, hairy; pappus bristles 1/2–2/3 or equaling the corolla tube length, barbellate. Chromosome number, $2n = 20$.

Flowering July through mid September. Rock outcrops (often shale in Virginia and West Virginia), cliff faces and ledges, ridges, shallow soil pockets, rocky openings in heath balds, roadside banks, oak, dry pine-oak, and pitch pine woods; 650–1600(–1850) m. North Carolina, Virginia, and West Virginia. Reported from Alabama and Georgia as *L. turgida* (Cronquist 1980; Duncan & Kartesz 1981; Gleason & Cronquist 1994) but not confirmed in this study; more intensive study of collections may corroborate the reports.

Additional collections examined: **NORTH CAROLINA. Ashe Co.:** summit of Paddy Mountain, E of Bluff Mountain, 22 May 1994, *Sorrie 7971* (NCU); summit of Paddy Mountain, E of Bluff Mountain, 22 May 1994, *Weakley s.n.* (NCU). **Avery Co.:** seepage area on bluffs of Big Lost Cove Cliffs, 3400 ft, 1 Aug 1986, *Bradshaw s.n.* (SMU); summit of Grandfather Mountain, 25 Sep 1898, *Canby 70* (MO); soil pockets in granitic summit of Grandfather Mt., by observatory, 3 Aug 1977, *Kral 60747* (VDB); summit of Four Diamond Ridge, grass-forb bald, 4800 ft, 25 Jul 1978, *Rohrer 2188* (NCU); Grandfather Mt., NW corner of swinging bridge away from visitor's center, upper slope of rock outcrop, meta-arkose, bordering Spruce-Fir Forest, 30 degree slope facing NNW, 1611 m, 10 Sep 1989, *Wiser 89-2* (NCU); Hanging Rock, NW-facing slope of highest peak, lower slope of rock outcrop, meta-basalt, 1562 m, 27 Jun 1989, *Wiser 89-30* (NCU); 20 m ESE of highest peak of Ship Rocks, Rough Ridge, adjacent to Tanawha trail, top of rock outcrop, 1426 m, 15 Sep 1990, *Wiser 90-175* (NCU); Grandfather Mt., Linville Bluffs, mid slope of rock outcrop, on 42 degree slope facing NNW, 1427 m, 18 Sep 1990, *Wiser 90-180* (NCU). **Burke Co.:** Hawk's Bill Mountain, 11 Sep 1982, *Frizzell 229* (NCU); vicinity of Table Rock Mountain, 3 Aug 1890, *Heller 81* (MO); gneissic summit of Table Rock Mt., above Linville gorge, 2 Aug 1977, *Kral 60704* (VDB); Shortoff Mt., dry pine-oak woods, 18 Aug 1949, *Radford 4888* (NCU); bald on Table Rock, 24 Aug 1952, *Radford 6515* (NCU); Table Rock, 29 Aug 1936, *Wherry s.n.* (LL).

Two collections cited by Gaiser (1946) probably represent additional North Carolina counties for *Liatris helleri*. These are mapped on Figure 1 with open symbols.

North Carolina. Buncombe Co.: near Black Mt., rocky roadside banks, 23 Aug 1927, *Wiegand & Manning 3176* (GH, cited by Gaiser as *Liatris turgida*, not seen in present study). **Mitchell Co.:** Roan Mt., mountain meadows, 10 Jul 1894, *Mohr s.n.* (US, cited by Gaiser as *L. helleri*, not seen in present study). It is likely that at least some collections cited by her as *L. graminifolia* var. *dubia* (W.P.G. Barton) Gray from Avery, Buncombe, Burke, and McDowell counties, North Carolina, also are *L. helleri*.

CONSERVATION IMPLICATIONS

The taxonomic hypothesis forwarded here presumably may have the effect of lessening legal protections for *Liatris helleri*. In this broadened concept, the species probably will not call for such urgent conservation measures (e.g., Kral 1983; Massey et al. 1983; USF&WS 1999) as might be accorded more threatened taxa. I have not taken this lightly, especially in view of the good will and generosity of many in efforts to conserve and restore populations of this beautiful species. The biological and taxonomic realities, however, seem unequivocal, and it is possible to see the wider distribution of the species and its conceptual escape from threat and endangerment as a happy consequence. Even so, *L. helleri* apparently is nowhere common and it remains a rare species within North Carolina. Commercial and recreational development, and especially trampling by outdoor enthusiasts, pose immediate threats to the species and the natural communities in which it occurs. Efforts toward ensuring its continued existence are critical. As mentioned above, some of the North Carolina populations of *L. helleri* occur with other rare species in a rare natural community, and the species and habitat remain a focus of conservation concern and activity.

ACKNOWLEDGMENTS

Specimens were studied from DOV, NCU, and WVA (loans), MO, NCU, NY, and TEX,LL (visits), and BRIT/SMU and VDB. I am grateful to Carol Ann McCormick (NCU) for assistance with specimen data, Nancy Cole (USFWS, Asheville) for sending a copy of the study by Sutter and Murdock, and Rob Sutter, Alan Weakley, and Zack Murrell for comments and review of the manuscript.

MEETING ANNOUNCEMENT

To celebrate the 25th Anniversary of the herbarium CIIDIR and the starting of our graduate program, the CIIDIR Unidad Durango of the National Polytechnic Institute, in conjunction with the Sociedad Botánica de México, will present the Symposia:

1) The Role of the Botany in the Management and Conservation of Ecosystems

2) 2nd Botanical Symposium of Northern Mexico

The Symposia will be held on September 13-14, 2005 in Durango, México. The event includes a meeting of the Sociedad Botánica de México with Dra. Laura Arriaga Cabrera giving the keynote lecture.

On the 15th there is an optional field trip to the Sierra Madre Occidental, along the Durango-Mazatlán Hwy.

BOOK REVIEW

RON LANCE. 2004. **Woody plants of the Southeastern United States: A Winter Guide.** (ISBN 0-8203-2524-4, hbk.). University of Georgia Press, Athens, GA 30602, U.S.A. (**Orders:** 800-266-5842, books@ugapress.uga.edu, www.ugapress.org). $54.95, 441 pp., 587 b/w line drawings, 6" × 9 1/4".

For anyone identifying woody plants from the southeastern U.S.A., this book ought to be at hand. There are so many 'tree books' but Lance's volume is extraordinary—so many taxa, excellent illustrations, good keys, and useful comments from someone obviously with deep first-hand experience. It's hard to imagine how it could be improved, much less approached by a competing facsimile. It's a classic and surely will be in use for a long time—perhaps to be used as companion to the Duncans' "Trees" and "Woody Vines" of the southeastern United States and Carl Hunter's "Trees, Shrubs, and Vines of Arkansas," personal favorites of mine.

The volume treats "native plants, as well as naturalized exotic species known to occur in at least two locations in the Southeast," from east Texas and northern Florida (excluding peninsular Florida) to southeastern Kansas and southern Delaware. "Some 900 species" are included; about 600 original illustrations by the author show distinguishing characteristics of twigs and buds. These are "all the trees, shrubs, and woody ground covers that grow without the aid of cultivation"—the last category is broad, including species of *Calamintha*, *Euonymus*, *Hypericum*, *Ilex*, *Iva*, *Parthenocissus*, *Rubus*, *Ribes*, *Vaccinium*, and *Vitis* (for a few examples among many). For species without reliable winter diagnostic features, spring and summer features are shown and described.

With that brief overview and unqualified recommendation, here are wonderful comments from the author's own preface. "For many years, botanical bait has lured me across the southeastern United States. This pull has been on many occasions a consuming quest to find and inspect, to collect and study, to photograph, illustrate, and record, as nearly as personally possible the totality of our native woody flora. Doing this amid and between jobs, during vacations, and at nearly every other available opportunity, I ultimately came to the realization that this assignment would have no end. Therefore, to see finally at least part of a lifelong interest rendered into this publication is a joy and a relief.... For that minority of people that marvel and cheer internally each time they see a species in its place in the world for their very first time, this book is presented not only as a guide of what can be seen but also as an enticement to see differently.... Bare twigs and dormant buds are merely another dimension in the appearance of our woody plants, a dimension often overlooked yet perfectly distinctive if viewed with an eye for detail."—*Guy Nesom, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

BOOK NOTICE

SUSAN L. WOODWARD. 2003. **Biomes of Earth: Terrestrial, Aquatic, and Human-Dominated.** (ISBN 0-313-31977-4, hbk.). Greenwood Press, 88 Post Road West, Westport, CT 06881, U.S.A. (**Orders:** 800-225-5800, fax 603-431-2214, www.greenwood.com). $79.95, 435 pp., b/w figs, maps, 7" × 10".

In this *Biomes of the Earth* book, Woodward divides the world's biomes into four principal types: **Terrestrial, Freshwater, Marine,** and **Human-dominated.** "Comprehensive discussions enable readers to obtain a thorough understanding of each biome, and the convenient one-volume format allows easy comparison between aspects of each region."

A REVISION OF THE *PSIDIUM GRANDIFOLIUM* COMPLEX (MYRTACEAE)

Leslie R. Landrum

School of Life Sciences
Arizona State University
Tempe, Arizona 85287-4501, U.S.A.
les.landrum@asu.edu

ABSTRACT

The *Psidium grandifolium* complex is revised with keys, descriptions, maps, and illustrations and is considered to consist of *P. grandifolium*, *P. missionum*, and *P. australe*, the last with three varieties. The complex is mainly confined to eastern interior South America, ranging from Venezuela to Argentina. Lectotypes for the following taxa are chosen: *Psidium argenteum* O. Berg, *Psidium argenteum* var. *purpureum* O. Berg, *Psidium cinereum* var. *grandifolium* O. Berg, *Psidium cinereum* var. *intermedium* O. Berg, *Psidium grandifolium* var. *intermedium* O. Berg, *Psidium mucronatum* Barb. Rodr. ex Chodat et Hassl., *Psidium sericeum* O. Berg, *Psidium suffruticosum* O. Berg, *Psidium incanescens* var. *rotundifolium* O. Berg. Two new combinations are made: *Psidium australe* var. *argenteum* (O. Berg) Landrum and *Psidium australe* var. *suffruticosum* (O. Berg) Landrum

RESUMEN

Se hace una revisión del complejo *Psidium grandifolium* con claves, descripciones, mapas, e ilustraciones. El complejo incluye *P. grandifolium*, *P. missionum*, y *P. australe*, la última con tres variedades. El complejo crece principalmente en el interior del este de Sud América, desde Venezuela hasta Argentina. Se seleccionan lectotipos para los siguientes taxa: *Psidium argenteum* O. Berg, *Psidium argenteum* var. *purpureum* O. Berg, *Psidium cinereum* var. *grandifolium* O. Berg, *Psidium cinereum* var. *intermedium* O. Berg, *Psidium grandifolium* var. *intermedium* O. Berg, *Psidium mucronatum* Barb. Rodr. ex Chodat et Hassl., *Psidium sericeum* O. Berg, *Psidium suffruticosum* O. Berg, *Psidium incanescens* var. *rotundifolium* O. Berg. Se hacen las siguientes combinaciones nuevas: *Psidium australe* var. *argenteum* (O. Berg) Landrum y *Psidium australe* var. *suffruticosum* (O. Berg) Landrum.

The *Psidium grandifolium* complex is a group of small, fire resistant shrubs of the grasslands (campos) and shrubby vegetation (cerrado) of central Brazil and northeastern Argentina, Paraguay, eastern Bolivia, Venezuela, and Guyana. It presents some of the most difficult taxonomic problems in the genus due to variation within species, apparent hybridization between species in the complex, and hybridization of *P. grandifolium* and *P. australe* with *P. guineense* Sw. Especially perplexing is the fact that there exist regions in which species limits are well-defined and other areas where they breakdown. The species have in common a shrubby habit, ability to resprout from underground stems after fires; young twigs that are usually square or 4-winged in cross-section; leaf venation that is usually eucamptodromous proximally to brochidodromous distally with a poorly defined marginal vein; a placenta that protrudes little and that is com-

SIDA 21(3): 1335–1354. 2005

pletely hidden by numerous ovules at anthesis; and seeds that are relatively smooth and rounded. A similar group, the *P. salutare* complex (Landrum 2003), has the same habit and ability to resprout vigorously after fires, and smooth, round seeds, but the twigs are not winged, the venation is entirely brochidodromous and the peltate placenta is clearly visible in dissections with one or two rows of ovules on each side.

Calyx structure is often taxonomically important in *Psidium*, but in the *P. grandifolium* complex it is quite variable and not useful in defining the group. The calyx may be fused and closed except for a terminal pore or it can be quite open in the in the flower bud. The calyx-lobes may be scarcely developed, or quite evident. Calyx structure is generally helpful at the specific level in the complex.

There is considerable variation among members of the *Psidium grandifolium* complex and two or three distinct morphological entities may grow together or near to one another. For instance I have seen *P. grandifolium*, *P. australe* var. *australe* and *P. missionum* growing together at two localities in southern Paraguay. In the municipality of Mogi-Guaçu of São Paulo quite distinct forms of *P. grandifolium*, *P. australe* var. *australe* and *P. australe* var. *suffruticosum* all grow. Unfortunately intergradation among these typical forms is common, and in some areas distinctions seem to disappear. Thus, drawing species limits is quite difficult. I have chosen to accept three species, but all can be expected to intergrade with at least one other in the complex. *Psidium australe* I divide into three varieties, but others might consider these entities species. Intergradation between *P. australe* and *P. grandifolium* is common and I have found it expedient to accept numerous specimens between these species as "intermediates" without applying one name or the other to them. It is possible that the group that I accept as *P. australe* var. *argenteum* has originated through introgression from *P. grandifolium*.

Hybridization with the more distantly related *Psidium guineense* also seems to be common and further complicates taxonomy. Therefore a key is provided that distinguishes that species from the *P. grandifolium* complex.

1. Anthers elongate, 1–3 mm long, usually 3–6 times as long as wide; placenta laminar, sometimes peltate; tertiary veins often producing a ladder-like pattern; calyx closed or nearly so; hairs of lower leaf surface usually more or less erect, mostly nearly straight, usually reddish brown ____ **P. guineense**
1. Anthers not elongate, 0.5–1 mm long, about 2 times as long as wide; placenta mound-like, not laminar or peltate; tertiary veins reticulate; calyx closed or open; hairs of lower leaf surface generally appressed and straight to densely tangled, usually gray to white ____ **P. grandifolium** complex

When studying the *Psidium grandifolium* complex it is important to consider the following characteristics: 1) type and density of hair covering or its absence; 2) peduncle length; 3) calyx-lobe shape and degree of calyx closure; 4) presence or absence of dichasia; 5) leaf size and shape; 6) leaf texture. The differences are outlined in the key below. Not one of the characteristics is entirely reliable, but consideration of them all seems to work well in distinguishing these species in Argentina, Paraguay, and usually in Paraná, São Paulo, and Bahia, Brazil. In Minas Gerais, Goiás and the Distrito Federal, Brazil distinctions are less clear.

Perret (1999) proposed that the numerous names published by Chodat and Hassler (1907) and attributed to Barbosa Rodrigues, some of which appear as synonyms in this paper, should not be accepted because their original descriptions are brief and appear to be a mere list of names with minimal information. I believe that these descriptions, although brief, are in accordance with the International Code of Botanical Nomenclature (Greuter et al. 2000). Fortunately they are usually represented by good type collections and may be identified accurately.

For illustrations I have used portions of scanned herbarium specimens. These images can be viewed in their entirety in color in the Image Library on the ASU Herbarium website http://lifesciences.asu.edu/herbarium/. A list of exsiccatae will also be made available at the same website once this paper is published.

Ecology.—The species of *Psidium* vary from forest trees to savanna shrubs and grow in coastal vegetation to mountainous habitats. The great majority of the collections of the *P. grandifolium* complex have been made below 1200 m elevation and in the interior of South America. Species of the complex are shrubs and subshrubs and grow in grasslands or in shrubby vegetation (cerrado) and are resistant to fires or other disturbance (but perhaps not grazing), resprouting from underground or surface level stems, being similar to the *P. salutare* complex in ecology (Landrum 2003). During field studies in Argentina and Paraguay I have noticed that these species persist in the narrow strip of natural vegetation between roads and pastures, but do not do well in the pastures themselves.

The climates in which the *P. grandifolium* complex grows often have distinct dry and wet seasons, with freezing temperatures being rare or non-existent. Commonly associated with them are other genera of Myrtaceae (e.g., *Campomanesia, Eugenia,* and *Myrcia*); Poaceae, Fabaceae, and Asteraceae often dominate the vegetation.

Suggestions for future work.—Why do these species seem to merge in some areas and remain distinct in others? In areas where the distinctions continue, some sort of isolating mechanisms must exist. What are the barriers to hybridization and under what circumstances do they break down? What are the pollinators, the phenological patterns, and breeding systems of these species? These are all questions that can best be answered by field studies and perhaps concurrent laboratory work in South America and offer interesting opportunities for biologists. The habitats supporting species of the *P. grandifolium* complex are unfortunately rapidly being converted to pasture and agriculture. A better understanding of their biology is urgently needed for the long-term conservation of these species.

KEY TO THE SPECIES OF THE *PSIDIUM GRANDIFOLIUM* COMPLEX

1. Calyx of flower bud with lobes about triangular, 2–5 mm long, about as long as wide.
    2. Leaves thinly pubescent to glabrous ____ **P. missionum**
    2. Leaves densely tomentose below ____ **P. grandifolium** (populations of southern Paraguay and Argentina)
1. Calyx of flower bud nearly closed or the lobes truncate to broadly triangular, about 2 times wider than long.
    3. Flower bud just before anthesis 6–15 mm long, densely lanate, the underlying surface of hypanthium hidden, the calyx usually nearly closed; leaves whitish lanate below, generally at least some widest near the middle ____ **P. grandifolium**
    3. Flower bud just before anthesis 5–10 mm long, moderately covered with hairs to glabrous, the underlying surface of hypanthium visible through hairs (if present), the calyx open or nearly closed; leaves glabrous to densely short pubescent below, generally widest above the middle ____ **P. australe**

Psidium australe Cambess., in A. St.-Hil., Fl. Bras. Merid. 2: 283. 1833. *Guajava australis* Kuntze, Revis. Gen. Pl. 1: 239. 1891. Type: BRAZIL: "Prope vicum vulgo Capella de Sta. Maria ad fines provinciarum Rio Grande de S. Pedro do Sul et Missionum," *Saint-Hilaire s.n.* (holotype: P!, =F-36406!, =ASU photo!).

Shrub or subshrub to ca. 1(–1.5) m high, essentially glabrous (except for inner calyx-lobe surface), subglabrous to densely hairy on young growth, sometimes densely covered with appressed hairs on lower leaf surfaces, arising from a fire resistant underground stem; hairs whitish, appressed, to ca. 0.5 mm long; young twigs square in cross section, with four wings, reddish-brown to gray-green, glabrous to moderately pubescent, glandular, with age the bark becoming gray to light brown, the bark flaking off to reveal smooth reddish-brown to gray bark. **Leaves** obovate, oblanceolate, narrowly elliptic, or elliptic, 3.5–11 cm long, 1.3–6 cm wide, 1.6–5.4 times as long as wide, glabrous to moderately pubescent, sometimes densely pubescent below; apex round, truncate, to acute, less often with a cuspidate tip; base cuneate, acute, acuminate, or rounded; petiole shallowly channeled, 0–4 mm long, 1.2–2 mm wide; midvein impressed to flat above, prominent below, the venation usually eucamptodromous proximally to brochidodromous distally, the lateral veins usually 4–8, a clear marginal vein not present, the tertiary veins obscure or forming an irregular reticulate pattern; blades coriaceous to subcoriaceous, drying light to dark olive green to dark reddish brown, usually darker above than below, lustrous or dull above. **Flower buds** pyriform, 5–10 mm long; peduncles sparsely hairy, 1-flowered or 3-flowered, 0.1–3.7 cm long, 0.8–1.5 mm wide, the arms of the dichasia 2–13 mm long; bracteoles narrowly deltoid-lanceolate, 1–3 mm long, clasping the hypanthium, usually falling before anthesis; calyx glabrous to sparsely pubescent without, apically pubescent within, connate as a cup-like tube for 2–4 mm, with deltoid lobes along the edge of the tube or merely with a sinuate margin, or nearly (rarely completely) closed, tearing more or less irregularly between the lobes to the staminal ring at anthesis, the lobes before anthesis to ca. 1 mm long, to ca. 3 mm wide; petals obovate to suborbicular, elliptic, oblanceolate, 7–10 mm long, glabrous; hypanthium obconic to subhemispheric, 2.5–4 mm long; disk 5–10 mm across, glabrous to pubescent; stamens 100–300, 6–10 mm long, reflexed in bud so that anthers reach the disk; anthers 0.5–0.8 mm long, with 1 apical gland in the connective; style 5–8 mm long, the stigma somewhat peltate; ovary 3–4-locular, usually with a central hollow area; ovules 20–95 per locule, the placenta hidden by ovules. **Fruit** globose to subpyriform, 1.5–3 cm long; seeds subreniform, 3–5 mm long, rounded, 6–50.

Psidium australe may be divided into three more or less distinct varieties distinguished in the key below.

1. Leaves densely covered with hairs beneath, the underlying leaf surface (except for larger veins) hidden by hairs ________ **P. australe** var. **argenteum**
1. Leaves sparsely covered with hairs to glabrous beneath
    2. Leaves often 3 or more times as long as wide, lustrous above; peduncles usually more than 2 cm long, usually 3-flowered; calyx usually nearly closed in young bud; seeds up to ca. 10. ________ **P. australe** var. **suffruticosum**
    2. Leaves usually less than 3 times as long as wide, usually dull above; peduncles commonly all less than 2 cm long, usually 1-flowered; calyx usually open in young bud; seeds up to ca. 50 ________ **P. australe** var. **australe**

Psidium australe Cambess var. **australe**

Psidium australe Cambess in A. St.-Hil., Fl. Bras. Merid. 2: 283. 1833, as to type. (**Figs. 1, 2**).

Psidium triphyllum Barb. Rodr., Myrt. Paraguay 12. 1903. TYPE: PARAGUAY. "Ipê-hú... Sierra de Maracayu," *Hassler 4990* (HOLOTYPE: G, =ASU photo!)

Psidium mucronatum Barb. Rodr. ex Chodat & Hassl., Bull. Herb. Boissier 7: 798. 1907. TYPE: PARAGUAY. "Ipé-hu Sierra de Maracayu," *Hassler 5082* (HOLOTYPE: G [4 sheets], =ASU photos!; sheet in G photo 105 [LECTOTYPE, here designated]; ISOLECTOTYPE: NY!).

Psidium piribebuiense Barb. Rodr. ex Chodat & Hassl., Bull. Herb. Boissier 7:797. 1907. TYPE: PARAGUAY: "Cordillera de Piribebuy," *Hassler 6632* (HOLOTYPE: G [2 sheets], =ASU photos!).

Psidium submetrale McVaugh, Mem. New York Bot. Gard. 18:261. 1969. TYPE: VENEZUELA. "Bólivar: Entre San Félix y Puerto Ordaz ... elev 20 m, 26-27 Jun 1964 (fl)," *Steyermark 94275* (HOLOTYPE: MICH!).

Shrub or subshrub ca. 1(-1.5) m high; leaves mainly obovate to oblanceolate, 1.6–3.5 times as long as wide, glabrous to sparsely pubescent beneath, the upper surface usually dull; peduncles mostly under 2 cm long, 1(–3)-flowered; calyx usually quite open in the flower bud before anthesis and before tearing between lobes begins; fruit 1.5–3 cm long; seeds up to ca. 50.

The four specimens of *Psidium mucronatum* at G of *Hassler 5082* are a mixture of entities. The one specimen most certainly belonging to *P. australe* is chosen as the lectotype. The type of *Psidium triphyllum* might best be placed under *P. australe* var. *suffruticosum*, but I cannot say with certainty based on the photo I have.

Psidium australe var. **argenteum** (O. Berg) Landrum, comb. nov. (**Fig. 3**). *Psidium argenteum* O. Berg, in Mart., Fl. Bras. 14(1):388. 1857. *Psidium argenteum* var. *purpureum* O. Berg, in Mart., Fl. Bras. 14(1):388. 1857, inadmissible name to be replaced by *P. argenteum* var. *argenteum*, the type serving to typify the species. *Guajava argentea* (O. Berg) Kuntze, Revis. Gen. Pl. 1:239. 1891. Type: BRAZIL: Isotype of *P. argenteum* var. *purpureum* O. Berg, here designated as LECTOTYPE of species, "in campis prov. Rio Grande do Sul," *Sellow s.n.* (SYNTYPE: B, lost; ISOSYNTYPE: P! [LECTOTYPE, here designated], =F-36405!, =ASU photo!).

Psidium cuneatum Cambess., in A. St.-Hil., Fl. Bras. Merid. 2:283. 1833. *Psidium cuneatum* var. *niveum* O. Berg, in Mart., Fl. Bras. 14(1):405. 1857, inadmissible name to be replaced by *P. cuneatum* var. *cuneatum*. *Guajava cuneata* Kuntze, Revis. Gen. Pl. 1:239. 1891. Type: BRAZIL: "Prope urbem S. João del Rey in provincia Minas Geraes," *Saint-Hilaire s.n.* (HOLOTYPE: P!, =F-36409!, =ASU photo!).

Psidium argenteum var. *angustifolium* O. Berg, in Mart., Fl. Bras. 14(1):388. 1857. Type: BRAZIL: "ad pagum Formigas in parte deserta prov. Minarum," *Pohl [287, 534]* (SYNTYPES: W, B, M; syntype at W, =F-31417!).

?*Psidium argenteum* var. *grandifolium* O. Berg, in Mart., Fl. Bras. 14(1):388. 1857. Type: BRAZIL: "in campis prov. S. Pauli," *Sellow s.n.* (HOLOTYPE: B, lost).

?*Psidium argenteum* var. *pumilum* O. Berg, in Mart., Fl. Bras. 14(1):388. 1857. Type: BRAZIL: "ad S. Ignacio," *Sellow s.n.* (HOLOTYPE: B, lost).

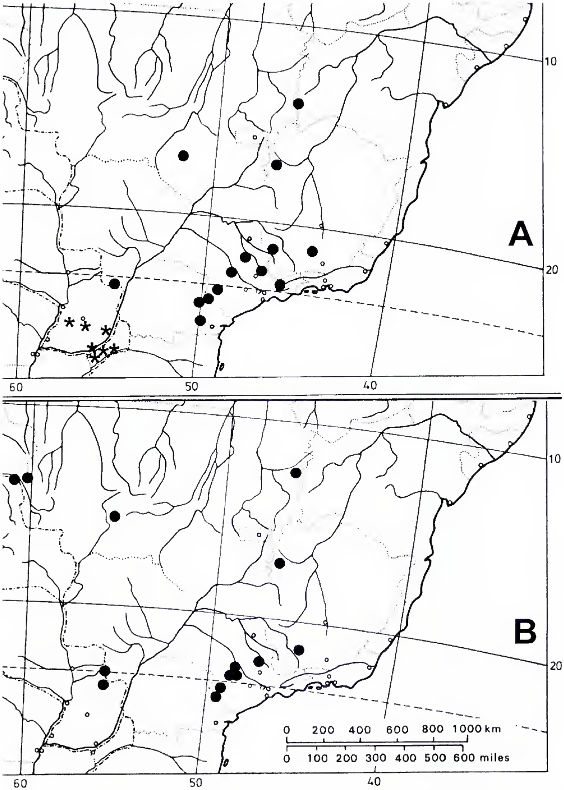

Fig. 3. **A.** Distribution of *P. australe* var. *argenteum* (dots) and *P. missianum* (stars). **B.** Distribution of *P. australe* var. *suffruticosum*.

Shrub or subshrub ca. 1(–1.5) m high; leaves mainly obovate to oblanceolate, 1.6–3.5 times as long as wide, densely pubescent beneath, the hairs hiding the underlying surface except for larger veins, the upper surface usually dull; peduncles mostly under 2 cm long, 1(–3)-flowered; calyx usually quite open in the flower bud before anthesis and before tearing between lobes begins; fruit 1.5–3 cm long; seeds up to ca. 50.

BRAZIL. Goias: Serra do Caiapó, ca. 60 km S of Caiaponia on road to Jatai (17°12'S, 51°47'W), 800–1000 m, 27 Oct 1964 (fl), *Irwin & Soderstrom 7432* (MICH, MO, NY); Serra Geral de Goiás, ca. 6 km S of Posse (14°S, 46°W), 800 m, 5 Apr 1966 (fr), *Irwin et al. 14393* (NY); Contraforte Central, ca. 26 km NE of Catalão, 875 m, 23 Jan 1970 (fr), *Irwin et al. 25224* (NY). **Minas Gerais:** Serinha, (fl), *Chiea 480* (ASU, SP); Mun. De Candolle (1828) simultaneously described three species of *Psidium* in his Prodromous based on Martius collections and using names applied by Martius in his herbarium: *P. grandifolium*, *P. cinereum*, and *P. incanescens*. De Candolle expressed doubt that *P. incanescens* and *P. cinereum* were distinct. In fact all three type specimens are similar and I think it is best to consider them a single species. Legrand (Legrand & Klein 1977) united *P. cinereum* with *P. incanescens* [i.e., *Psidium cinereum* var. *incanescens* (O. Berg) D. Legrand], but no one has united *P. grandifolium* with either of the others. As I discussed before there are a continuum of forms of *Psidium* in this complex and I choose the name *P. grandifolium* because the type is most clearly distinct from its relatives *P. australe*, *P. missionum* and intermediates. The name *P. cinereum*, the other alternative, has been applied to a wide variety of forms, some of which I now include in *P. australe*.

Psidium grandifolium is a variable species. In the southern part of its range (Argentina and southern Paraguay) there are individuals with clearly deltoid triangular calyx-lobes 2–5 mm long that are longer than wide and longer than the calyx-tube (Fig. 5C). These often have narrowly elliptic leaves that are subcoriaceous. Mixed with these are others with broader subcoriaceous leaves and shorter, broader calyx-lobes. Towards the north of Paraguay and into Brazil the leaves become more coriaceous and the calyx-lobes less prominent, in some cases being scarcely perceptible along the rim of the calyx-tube, and the calyx-tube becomes longer (Fig. 5B). These forms may warrant recognition at a subspecific level.

The name *Psidium cuneatum* Cambess. has been applied to this species in Argentina by Rotman (1976) who was apparently following the opinions of Legrand and Kausel (both cited in Rotman). I have been able to carefully study the type of *P. cuneatum* and believe that it is a synonym of *P. australe* var. *argenteum*.

From a broad area of Brazil (Bahia to Paraná), there exist collections of plants intermediate between *P. australe* and *P. grandifolium*. In other areas these species remain quite distinct and do not intermix. After several years of consideration of this situation I believe that it is best to simply accept some specimens as belonging to the complex but as intermediates. The alternative would be to unite the whole group in to one extremely variable species with subspecific groups that act as separate species over much of their distribution. Intermediates include types of the following taxa:

Psidium microcarpum Cambess., in A. St.-Hil., Fl. Bras. Merid. 2:284. 1833. TYPE: BRAZIL: "Prope urbem S. João del Rey in provincia Minas Geraes," *Saint-Hilaire s.n.* (HOLOTYPE: P!, =F-36416!, =ASU photo!).

Psidium sericeum O. Berg, in Mart., Fl. Bras. 14(1):389. 1857. TYPE: BRAZIL: "in campis ad Carambey in prov. S. Pauli," *Sellow s.n.* (HOLOTYPE: B, lost; ISOTYPES: LE, =ASU photo!, P! [LECTOTYPE, here designated], =F-36421!, =ASU photo!).

Psidium grandifolium var. *parvifolium* O. Berg, in Mart., Fl. Bras. 14(1):407. 1857. TYPE: BRAZIL: "prov. Minarum," *Regnell I-129* (HOLOTYPE: MEL; ISOTYPE: P!, = ASU photo!).

Psidium cinereum var. *grandifolium* O. Berg, in Mart., Fl. Bras. 14(1):404. 1857. TYPE: BRAZIL: "in prov. S. Pauli," *Sellow s. n.* (HOLOTYPE: B, lost; ISOTYPE: P! [LECTOTYPE, here designated], = ASU photo!, W!,= ASU photo!).

Specimens that I consider intermediate between *Psidium grandifolium* and *P. australe* include the following.

BRAZIL. Bahia: Serra da Agua de Rega, 23 km N of Seabra, road to Agua de Rega, ca. 1000 m, 24 Feb 1971 (fr), *Irwin et al. 30894* (HB, MBM, MO, NY). **Distrito Federal:** Horto do Guará, Brasilia, 15 Dec 1961 (fl), *Heringer 8773* (ASU, HB); na Rod. da RECOR no trecho entre a RECOR e DNER, 20 Nov 1978 (fl), *Heringer et al 17180* (ASU, HB); Brasilia, Bacia do São Bartolomeu, alto do Ribeirao Papuda, 18 Feb 1981 (fr), *Heringer et al. 6221* (MO, NY); near Sobradihno, 1100 m, 27 Sep 1965 (fl), *Irwin et al. 8717* (CAS, MICH, MO, NY); ca. 12 km W of Taguatinga on road to Brasilandia, 1250 m, 26 Nov 1965 (fl), *Irwin et al. 10692* (NY); Chapada da Contagem, ca. 15 km E of Brasilia, 1050 m, 30 Jan 1966 (fr), *Irwin et al. 12154* (MICH, MO, NY). **Goiás:** São Gabriel, arredores, 7 Nov 1991 (fl), *Hatschbach 55874* (ASU, MBM); Luziânia, 11 Feb 1982 (fl), *Heringer 18279* (MO, NY); Serra dos Cristais, 5 km W of Cristalina (17°S, 48°W), 1175 m, 2 Nov 1965 (fl), *Irwin et al. 9766* (MICH, NY); Serra do Rio Preto, ca. 10 km E of Cabeceiras (16°S, 47°W), 1000 m, 17 Nov 1965 (fl), *Irwin et al. 10377* (HB, MICH, MO, NY, SP); Serra do Pirineus, ca 12 km S of Corumbá de Goiás (16°S, 49°W), 1000 m, 1 Dec 1965 (fl), *Irwin et al. 10855* (MICH, MO, NY); Mun. de Alexania, 5–7 km from BR060 on road to Rio Corumbá, ca. 12 km W of Alexania, 1000 m, 21 Jul 1984 (fl), *Mori et al. 16920* (NY); Morrinhos, fazenda proxima da cidade (17°49'22"S, 49°3'39"W), 6 Sep 1998 (fr), *Proença 1987* (ASU). **Mato Grosso do Sul:** Rod. Psidium missionum D. Legrand, Darwiniana 9:284. 1950. (**Fig. 7**). TYPE: ARGENTINA. "Misiones, Depto. Candelaria, Santa Ana," *Rodriguez 16* (HOLOTYPE: MVM; ISOTYPES: F!, = ASU photo!, LIL!, SI).

Shrub or subshrub to ca. 1 m high, with a persistent underground stem from which shorter lived above ground shoots arise, resprouting after being burnt or cut to the ground, glabrous to moderately pubescent on young growth; hairs when present whitish, up to ca. 1 mm long but usually shorter; young twigs reddish brown, glabrous to pubescent, less often pubescent, reddish-brown, smooth, the older twigs at first scaly, later smooth, gray. **Leaves** oblanceolate, obovate, or elliptic, 2.5–8.8 cm long, 1.1–4 cm wide, 1.8–3.5 times as long as wide; apex abruptly acuminate to acute; base cuneate to acute; petiole 1–2 mm long, 1–1.5 mm thick, flat or channeled above; midvein flat to slightly impressed above, prominent below; lateral veins usually 4–6 pairs ascending and arching upwards, connecting to form a weaker marginal vein in the upper half, the smaller tertiary veins between the laterals forming a reticulate pattern; blades lustrous or not above, drying olive green, gray-green, to blackish brown, nearly concolorous, coriaceous. **Flower buds** pyriform, 7–12 mm long; peduncles 1(–3)-flowered, 1–2.3 cm long, ca. 1 mm wide, flattened, pubescent to glabrous; bracteoles linear to narrowly lanceolate, 3–8 mm long, ca. 1 mm wide, glabrous to pubescent, deciduous at about anthesis; calyx open in the bud, tearing up to ca. 1 mm between the lobes after anthesis, the lobes triangular, 2–4 mm long, 3–4 mm wide, subglabrous to pubescent, the apex acute to acuminate; petals obovate to oblanceolate, ca. 9 mm long, glabrous to subglabrous; hypanthium obconic, 3–5 mm long, glabrous to pubescent; disk 4–6 mm across, the staminal ring pubescent; stamens 130–235, 9–11 mm long; anthers subglobose to oblong, ca. 0.5–1 mm long; style 7–9 mm long, usually with a few scattered hairs, the stigma only slightly wider than style; ovary 3–4-locular; ovules 43–70 per locule, about 8-seriate, the placenta not peltate, hidden by ovules. **Fruit** globose, ca. 1–1.5 cm long; seeds 14–20 in fruits seen, ca. 5 mm long, the seed coat several cells thick.

ARGENTINA. Misiones: San Ignacio, ca. 3 km along road to Peña Victoria, Teyu Cuaré (ca. 27°15'S, 55°35'W), 10 Dec 1987 (fr), *Landrum 5718* (ASU, CTES), Candelaria, 4 km S of Santa Ana on ruta 12 (27°25'S, 55°40'W), 11 Dec 1987 (fl), *Landrum 5735* (ASU); San Ignacio, new road to Loreto, ca. 1 km from ruta 12, 11 Dec 1987 (fr), *Landrum 5738* (ASU); Candelaria, 3 km S of Arroyo Yabebiry, 4 km S of San Ignacio on ruta 12 (27°15'S, 55°35'W), 11 Dec 1987 (st), *Landrum 5740* (ASU, CTES); Cainguás, Monte Carlo, 205 m, 2 Feb 1955 (fr), *Montes 14806* (CAS, NY).

PARAGUAY. Caazapá: Tavai, destacamento militar (26°10'S, 55°20'W), 1988 (fl), *Basualdo 2076* (FCQ). **Guairá:** Del Guaira Iturbe, 0.50–0.80 m, 3 Oct 1952 (fl), *Montes 1260* (CTES). **Itapua:** Capitán Miranda, 4.2 km N of entrance to Hotel Tirol, behind CONAVI project (27°12'S, 55°45'W), 9 Nov 1995

(fl), *Landrum 8808* (ASU, FCQ); Capitán Miranda, road to Jesús ca. 0.6 km from main highway (ca. 27°12'S, 55°45'W), 9 Nov 1995 (fl), *Landrum 8812* (ASU, FCQ); **Paraguari:** road to Lago Ypoa, ca. 23 km N of Caapucú, 3.5 km W of main Asunción-Encarnación highway, ca. 250 m, 10 Nov 1995(fl), *Landrum 8838* (ASU, FCQ).

Psidium missionum frequently grows with *Psidium salutare* var. *mucronatum* (Cambess.) Landrum [=*Psidium luridum* (Spreng.) Burret] and can be confused with that entity. The two are contrasted in the key below.

1. Leaves 2–4.5 cm long, 0.7–2.3 cm wide, 1.5–5 times as long as wide; marginal vein distinct, closely following the margin; placenta protruding, peltate; style 5–6 mm long, glabrous __________ **P. salutare** var. **mucronatum**
1. Leaves 2.5–8.8 cm long, 1.1–4 cm wide, 1.8–3.5 times as long as wide; marginal vein evident only in distal portion of leaf, arching broadly between laterals; placenta protruding only slightly, not peltate; style 7–9 mm long, usually with a few scattered hairs __________ **P. missionum**

ACKNOWLEGMENTS

I am grateful to the curators of the following herbaria who kindly allowed me to study their specimens on loan, as images, or as a visitor (ALCB, BR, CAS, CEPEC, CTES, F, FCQ, G, GH, HB, K, LE, LIL, MBM, MEL, MICH, MO, NY, OXF, P, R, RB, SP, UB, UC, US, USP, VEN, WIS). Alexander N. Sennikov has been especially helpful in providing images of types at LE. My Latin American colleagues I. Basualdo, E. Zardini, C. Proença, M. L. Kawasaki, A. Krapovickas, G. Hatschbach, and M. Sobral have helped in many ways. A Fulbright American Republics grant supported herbarium visits and fieldwork. Many thanks to my wife Sonia S. Landrum for her help in the field and at home. B. Holst and J. Salazar reviewed this paper and offered many helpful suggestions.

PEOPLE'S REPUBLIC OF CHINA

ABSTRACT

Ptilagrostis luquensis P.M. Peterson, Soreng & Z.L. Wu from the People's Republic of China is described and illustrated. The new species was found in dense thatch, mollisol soils on nearly level grassy plains surrounded by low hills in Gansu Province. *Ptilagrostis luquensis* is morphologically similar to *P. dichotoma* but differs by having glabrous anthers (1–1.4 mm long), shorter spikelets (2.6–3.5 mm long), shorter glumes (2.6–3.5 mm long), shorter lemmas (2.2–2.7 mm long), shorter and narrower panicles (2–5.2 x 1–3 cm), and lower nodes with 1 or 2 sheathing lanceolate hyaline bracts (1–5 mm long) on the culm inserted immediately below the lowest branches. A key to the species of *Ptilagrostis* in China is provided.

摘 要 (CHINESE ABSTRACT)

本文描述了采自中国的一新种短花细柄茅*Ptilagrostis luquensis* P.M. Peterson, Soreng & Z.L. Wu。该新种采自甘肃省碌曲县，生长在山间草地的密集草丛中。短花细柄茅*Ptilagrostis luquensis*与双叉细柄茅*P. dichotoma*在形態上相似，但区别在于光滑的花藥，长1–1.4毫米，短的小穗，长2.6–3.5毫米，短的颖，长2.6–3.5毫米，短的外稃，长2.2–2.7毫米，短而狭窄的圆锥花序，长2–5.2厘米，宽1–3厘米，在杆上紧接最下部分枝处具1或2枚鞘状的、披针形、透明的苞片，长1–5毫米。本文同时作出细柄茅属的分种检索表。

Ptilagrostis Griseb. is characterized as having chartaceous lemmas with awns that are geniculate and plumose throughout their length, lemma apices with two lobes or teeth, non-overlapping lemma margins, an obtuse callus (≤6 mm long), caryopses with non-glossy surfaces, and shoots arising intravaginally (Barkworth 1983; Freitag 1985; Lomonosova 2001; Tzvelev 1983, 2001). There has been much controversy over the interpretation of the taxonomic status and generic limits among species of *Achnatherum* P. Beauv. (syn. *Lasiagrostis* Link), *Ptilagrostis*, and *Stipa* L. *Achnatherum* can be separated from *Ptilagrostis* by having lemmas with awns that are scabrous at least in the terminal portion. *Stipa* generally has florets with a sharp-pointed cylindrical callus (≥0.7 mm long) and lemmas that have completely overlapping margins (Tzvelev 1983, 2001). There are approximately 11 species of *Ptilagrostis* currently recognized worldwide and the following six species are treated in the Chinese Floras: *P. concinna* (Hook. f.) Roshev., *P. dichotoma* Keng ex Tzvelev, *P. junatovii*, Grubov,

SIDA 21(3): 1355–1362. 2005

mongholica (Turcz. ex Trin.) Griseb., *P. pelliotii* (Danguy) Grubov, and *P. yadongensis* Keng f. & J.S. Tang (Cui 1996; Keng 1965; Lu 1987; Lu & Kuo 1987; Qian 2002; Wu & Phillips, In prep.). In addition to these six species the following three species, described from outside China, have been reported in China and adjacent regions: *Ptilagrostis alpina* (F. Schmidt) Sipliv. from northeastern China (Liaoning), Japan, and Russia (Eastern Siberia and Far East); *P. malyschevii* Tzvelev from Xinjiang (Tien Shan), Kazakhstan, Kyrgystan, Tajikistan (Tien Shan and central Pamirs); and *P. schischkinii* (Tzvelev) Czer. (= *P. concinna* subsp. *schischkinii* Tsvelev) from Xinjiang (Tien Shan and Pamirs), Kazakhstan, Kyrgystan (Tien Shan) [Lomonosova 2001; Probatova 2003; Tzvelev 1983].

While collecting grasses on an extended trip to China in 1997 RJS and PMP found this small *Ptilagrostis* and were unsuccessful finding other specimens with similar morphological features while reviewing specimens at KUN and PE. Recently, RJS sent *Soreng, Peterson & Sun 5383* to Sylvia Phillips at Kew who was preparing (with Wu Zhen-Lan) the treatment of *Ptilagrostis* for the Flora of China. We conclude this specimen represents an undescribed species. The new species is clearly a member of the subtribe Stipinae, tribe Stipeae, and subfamily Pooideae (Soreng et al. 2003, 2004).

Ptilagrostis luquensis P.M. Peterson, Soreng & Z.L. Wu, sp. nov. (**Fig. 1**). TYPE: CHINA. GANSU PROVINCE. Luqu Co. Ca. 30–40 km N of Gansu/Sichuan border on road from Chengdu to Lanzhou, ca. 20 km S of Waxu and 10 Km E of Gahai, ca. 230 km SSW of Lanzhou at kilometer post 394 [34°24'N-102°17'E (corrected from original estimate)], 3440 m, 18 Sep 1997, *R.J. Soreng, P.M. Peterson & H. Sun 5383* (HOLOTYPE: US!, ISOTYPES: HNWP!, K!, KUN!, MO!, PE!).

A *Ptilagrostis dichotoma* Keng ex Tzvelev antheris apice glabris 1–1.4 mm longis, spiculis 2.6–3.5 mm longis, glumis 2.6–3.5 mm longis, lemmatibus 2.2–2.7 mm longis, paniculis 2–5.2 cm longis 1–3 cm latis apertis, nodis inferioribus (1)2 lanceolatis hyalinis bracteis 1–5 mm longis differt.

Caespitose perennial with intravaginal shoot initiation; roots 0.2–0.3 mm diameter. Culms 5–23 cm tall, 0.5–0.8 mm diameter near base, erect, smooth, glabrous, 1-noded, nodes basal, not visible. Sheaths (0.5–)2–8 cm long, shorter than the internodes, glabrous, smooth, the old sheaths forming tight clusters at base; margins hyaline near summit, often excurrent. Blades 2–6 cm long, 0.2–0.5 mm wide, involute, filiform, glabrous, abaxially smooth or scaberulous along keel; margins scabrous; flag blades 1–2 cm long. Ligules 0.4–1.2 mm long, hyaline, purplish to brownish below; apex truncate, obtuse or retuse, usually ciliate, the cilia ca. 0.1 mm long; flag ligules 0.7–1.2 mm long. Panicles 2–5.2 cm long, 1–3 cm wide, open, exerted with 10–15 spikelets; lowest internodes 0.9–1.7 mm long; branches 0.7–2.8 cm long, capillary, loosely ascending to sinuous, spreading 10–50° from the culm axis, smooth, glabrous, purplish; lower nodes usually with 1 or 2 sheathing linear-lanceolate hyaline bracts 1–5 mm long on the culm inserted immediately below the lowest branches, the lowest node with (1)2 branches, each branch often twined or immediately re-branched at the base on the lower nodes; pulvini inflated, smooth, glabrous, present at all branching

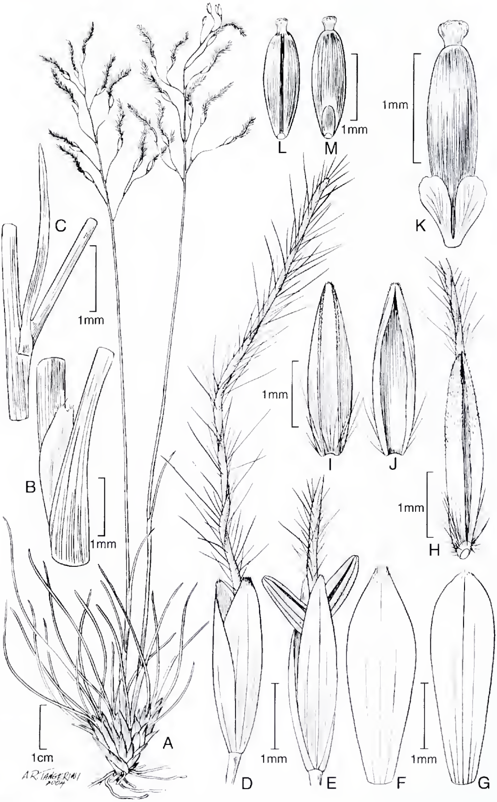

Fig. 1. *Ptilagrostis luquensis* (*Soreng, Peterson & Sun 5383*). **A.** Habit. **B.** Blade, ligule, and sheath. **C.** Lowest panicle node with hyaline bract. **D.** Spikelet. **E.** Spikelet with anthers. **F.** Lower glume, dorsal view. **G.** Upper glume, dorsal view. **H.** Lemma, ventral view. **I.** Palea, dorsal view. **J.** Palea, ventral view. **K.** Lodicules and caryopsis. **L.** Caryopsis, ventral view. **M.** Caryopsis, dorsal view.

points. Spikelets 2.6–3.5 mm long, 1-flowered; pedicels 3–12 mm long, mostly longer than the spikelets, smooth, glabrous or with a few scattered hairs. Glumes 2.6–3.5 mm long, oblanceolate to elliptic-oblong, subequal, longer than the floret, glabrous and smooth below, whitish with the base purplish; apex obtuse, usually erose and ciliate; lower glume faintly1–3-veined, slightly broader than the upper; upper glume faintly 3–5-veined. Floret callus short, obtuse, shortly bearded, the white hairs 0.5–1 mm long. Lemmas 2.2–2.7 mm long, lanceolate, chartaceous, terete, 5-veined, awned, scattered pilose on lower 1/4–1/3, the hairs 0.2–0.6 mm long, smooth in the middle, densely scaberulous above; apex acute with lateral triangular lobes ca. 0.6 mm long; awn 6–10 mm long, 1-geniculate, column twisted, sometimes sinuous above, plumose with hairs 1.2–2 mm long throughout, the hairs slightly shorter near apex. Paleas 2.2–2.7 mm long, slightly shorter or equal to the lemma, not overlapped by the lemma margins, distinctly 2-veined, with a few hairs below, scaberulous along the nerves above; apex acute. Stamens 3, anthers 1–1.4 mm long, yellowish; apex glabrous. Lodicules 3, obovate, unequal; abaxial lodicules ca. 0.7 mm long; adaxial lodicule ca. 1 mm long. Ovary 0.5–1 mm long, glabrous; styles 2, separate; stigmas 2 feathery. Caryopses 1.6–1.9 mm long, fusiform, terete, minutely-beaked, grayish, translucent; hilum linear nearly as long as the grain; embryo ca. 1/4 as long as the grain.

Phenology.—Flowering in August through September.

Distribution.—*Ptilagrostis luquensis* is known from Gansu, Qinghai, Xizang, and Sichuan Provinces between 3350–4800 m. At the type locality the new species was found in dense thatch, mollisol soils on nearly level grassy plains surrounded by low hills, associated with *Poa*, *Calamagrostis*, and *Koeleria*.

Etymology.—The specific epithet 'luquensis' is given to this species since the type was found growing in this county.

Additional specimens examined (PARATYPES): **CHINA. Qinghai:** Maduo, 4600m, 7 Jul 1980, *Y.H. Wu 1108* (HNWP), Qumalai, 4400m, 8 Aug 1966, *S.W. Liu 00765* (HNWP); Zhiduo, 4700m, 15 Aug 1966, *L.H. Zhou 322* (HNWP). **Xizang:** Zhongba, 4800m, 14 Aug 1975, *Qinghai-Xizang Exped. 6758* (HNWP). **Sichuan:** Ruoergai, 3350 m, Jul 1975, *Sichuan Exped. 10225* (HNWP).

DISCUSSION

Species delimitation within *Ptilagrostis* is problematical and authors have had difficulty differentiating *P. mongholica*, *P. dichotoma*, and *P. concinna*. Noltie (2000) and Cope (1982) may have misapplied *P. mongholica* (treated as *Stipa mongholica* Turcz. ex Trin.) for *P. dichotoma*. Their descriptions include small-flowered (lemmas 3.7–5.5 mm long) and short-awned (12–30 mm long) with short hairs (0.75–2 mm long) forms. Wu & Phillips (In prep.) placed *P. tibetica* (Mez) Tzvelev, a form with lemmas hairy throughout, as a synonym of *P. mongholica*. Noltie (2000) also reduced *P. concinna* (*Stipa concinna* Hook.f.) to a synonym of *P. mongholica*.

Ptilagrostis schischkinii is morphologically similar with *P. luquensis* since it is a diminutive plant with glabrous anthers. However, from Roshevitz (1963) description, the spikelets are 5–7 mm long (verses 2.6–3.5 mm) and the lemmas are 3–5 mm long (verses 2.2–2.7 mm). *Ptilagrostis concinna* sensu stricto, is more southern in its distribution (type from Sikkim Himalaya) and differs from *P. luquensis* by having longer glumes (4–6.3 mm), longer lemmas (3.5–5 mm), and longer anthers (1.5–2.2 mm) with a tuft of hairs at the apex. *Ptilagrostis mongholica* subsp. *minutiflora* (V.S. Titov ex Roshev.) Tzvelev [= *P. minutiflora* (V.S. Titov ex Roshv.) Czer.] is another small form from Central Siberia that has small spikelets 4.5–5 mm long and lemmas 3.3–4 mm long with awns 15–20 mm long (versus 6–10 mm in *P. luquensis*) [Tzvelev 1983].

Ptilagrostis alpina is another species with small spikelets (3.6–4.5 mm long) and short culms (15–35 cm tall). However, it differs from *P. luquensis* by having scabrous panicle branches, hairy anthers, and longer lemma awns [15–20 (–30) mm long].

Much confusion has also surrounded the use of *Ptilagrostis dichotoma* var. *roshevitsiana* Tzvelev since this too has small spikelets 3.2–4 mm long. However, Tzvelev (2001) indicates that the panicles have dense, short hairs (spinules) on the branches (glabrous in *P. luquensis*), the anthers are hairy, and the plants are large. It is possible that *P. alpina* and *P. dichotoma* var. *roshevitisiana* represent the same entity since both have small spikelets, scabrous panicles, and hairy anthers. The illustration in Lu and Kuo (1987) of *P. dichotoma* var. *roshevitsiana* shows the anthers as having tufts of hairs at the apex. A specimen at Kew (Y.L. *Keng & Keng f. 5468* from Qinghai Province, Hüang-yuan Hsien, Harakutur) is problematical since it has glabrous anthers and smooth panicle branches but otherwise seems to match the description of *P. dichotoma* var. *roshevitsiana*. Since this specimen does not have short hairs (spinules) on the panicle branches and does not have inflated pulvini, i.e., it has contracted panicles, we think it falls within the range of variation of *P. schischkinii* (with glabrous anthers). If the *Keng and Keng f. 5468* specimen is included within the range of variation of *P. schischkinii* then one must allow for smaller spikeleted forms ranging from (3.8–)4–7 mm long.

Two herbarium specimens from Qinghai: *P.C. Kuo 12317* (HNWP) and *P.C. Kuo et al. 331* (HNWP) are problematical since they both have hairy anthers but otherwise seem to exhibit the morphology of *P. luquensis*. It is possible that only a few genes control the expression of this trait and that these specimens represent different populations of *P. luquensis*. At this time we do not have enough information to make this distinction and prefer to recognize the new species as only having anthers that are glabrous at the apex.

The North American disjunctions, *Ptilagrostis kingii* (Bol.) Barkworth from the Californian Sierra Nevada and *P. porteri* (Rydb.) W.A. Weber [syn. *P. mongholica* subsp. *porteri* (Rydb.) Barkworth] from the central Rocky Mountains in Colorado are the only other two species in this genus. *Ptilagrostis porteri* has open, smooth-branched panicles, larger spikelets (4.5–6 mm long), and glabrous anthers, whereas *P. kingii* has contracted, scabrous-branched panicles, smaller spikelets (3.2–4.5 mm long), hairy anthers, and lemmas that are hairy throughout with short-pubescent awns (Barkworth 1983).

A key for separating the new species from all other reported species of *Ptilagrostis* in China follows:

KEY TO THE SPECIES OF *PTILAGROSTIS* IN CHINA

1. Lemmas 2.2–2.7 mm long; glumes 2.6–3.5 mm long; anthers 1–1.4 mm long, glabrous at the apex ____ **Ptilagrostis luquensis**
1. Lemmas 3.0–8 mm long, glumes 4–12.5 mm long, anthers 1.3–4 mm long, glabrous or hairy at the apex.
    2. Ligules truncate, ca. 1 mm long, ciliate; leaf blades fairly stiff; glumes lanceolate, sharply acuminate; gravelly and rocky places on desert plains ____ **Ptilagrostis pelliotii**
    2. Ligules oblong or lanceolate, rounded, 0.5–6 mm long, glabrous rarely ciliate; leaf blades softer; glumes elliptic or oblong lanceolate, obtuse to acute; alpine meadows and high hilly steppe.
        3. Panicles contracted, 0.7–2 cm wide; branches 0.3–2.8 cm long, suberect or narrowly ascending.
            4. Spikelets 8–12 mm long; glumes unequal ____ **Ptilagrostis yadongensis**
            4. Spikelets (3.8–)4–7 mm long; glumes subequal.
                5. Anthers glabrous or with a solitary hair at the apex; lemma awns 6–10 mm long ____ **Ptilagrostis schischkinii**
                5. Anthers with a tuft of hairs at the apex; lemma awns 1–2 mm long.
                    6. Panicles with sheathing membranous bracts at base of lowest branches; spikelets purple; lemmas 3.5–5 mm long; awns 1–1.5 cm long ____ **Ptilagrostis concinna**
                    6. Panicles without membranous bracts at base of lowest branches; spikelets brownish mauve; lemmas 4.5–6 mm long; awns 1.5–2 cm long ____ **Ptilagrostis junatovii**
        3. Panicles open, 3–5 cm wide; branches up to 6 cm long, spreading.
            7. Anthers 1.8–4 mm long, glabrous at the apex ____ **Ptilagrostis mongholica**
            7. Anthers 1–2 mm long, with a tuft of hairs at the apex.
                8. Lemma awns 23–42 mm long; ligules 2.5–6 mm long ____ **Ptilagrostis malyschevii**
                8. Lemma awns 1–20(–30) mm long (if over 20 mm long then branches scabrous); ligules 1–3 mm long.
                    9. Panicle branches scabrous; 7–13 spikelets per panicle; plants 15–35 cm tall ____ **Ptilagrostis alpina**
                    9. Panicle branches smooth; 15–25 spikelets per panicle; plants 15–50 cm tall ____ **Ptilagrostis dichotoma**

ACKNOWLEDGMENTS

We wish to thank curators at the following herbaria for their help: HNWP, K, KUN, PE; and the Smithsonian Institutions, National Museum of Natural History, Biodiversity and Inventory Program for supporting the fieldwork. Appreciation is extended to Alice R. Tangerini for providing the illustration; Alain Touwaide for correcting the Latin diagnosis; Sylvia M. Phillips for providing us with an annotated copy of her unpublished Flora of China account and key; and SMP and William A. Weber for reviewing the manuscript.

ABSTRACT

A taxonomic treatment of *Eragrostis* Wolf for northeastern México (Coahuila, Nuevo León, and Tamaulipas), is given. Twenty-six species and four varieties or subspecies of *Eragrostis* are recognized in the study area. Twenty of these species are native to the Flora region and six are introduced and adventive. Keys for determining the species, descriptions, distributions, specimens examined, illustrations, synonymies, and a brief discussion indicating relationships among all native and adventive species of *Eragrostis* in northeastern México are provided.

RESUMEN

Se presenta un estudio taxonómico de *Eragrostis* Wolf para el noreste de México (Coahuila, Nuevo León y Tamaulipas). Un total de veintiséis especies y cuatro variedades o subespecies de *Eragrostis* se reconocen en el área del estudio. Veinte de estas especies son nativas de la flora de la región y seis son introducidas y adventicias. Se incluyen claves para determinar las especies, descripciones, distribuciones, especimenes examinados, ilustraciones, sinonimias, y una discusión breve indicando las relaciones entre todas las especies nativas y adventicias de *Eragrostis* para el noreste de México.

Coahuila, Nuevo León, and Tamaulipas or northeastern México covers an area of 291,955 km^2 or 15 % of the total land of México. This area includes portions of two natural regions known as the Chihuahuan and Tamaulipan Deserts. These regions are considered a center of origin and diversification of arid and semi-arid plant species (Dávila-Aranda et al. 2004; Peterson et al. 2005). As part of the current revision of the grass flora of northeastern México, an examination of the taxonomy and distribution of the species of *Eragrostis* was begun to aid the agriculture and livestock industries. This study treats 26 species and four varieties or subspecies, for a total of 30 taxa.

Eragrostis is a large genus of more than 350 species occurring in tropical, subtropical, and warm temperate regions throughout the World (Clayton & Renvoize 1986; Peterson et al. 1995, 1997, 2001; Watson & Dallwitz 1992). There are 111 species of *Eragrostis* found in North, Central, and South America; 25 native in the United States and Canada; and 36 native in México (Beetle et al. 1991; Espejo-Serna et al. 2000; Peterson et al. 2001, 2003, 2005). The genus is charac-

SIDA 21(3): 1363–1418. 2005

terized by having many-flowered spikelets where the disarticulation of the lemma and palea occurs separately, lemmas that are usually 3-nerved and unawned, longitudinally bowed-out paleas with ciliolate keels, paniculate inflorescences, and leaves with ciliate ligules (Peterson et al. 1997). Most species of *Eragrostis* occupy open habitats with poor soils and many occur in disturbed localities (Clayton & Renvoize 1986; Van den Borre & Watson 1994).

All species of *Eragrostis* that have been examined anatomically exhibit "kranz" or C_4 leaf anatomy [except the C_3, *E. walteri* Pilg from South Africa, see Ellis (1984)] and species have either chloridoid bicellular microhairs (broad, short terminal cell the same thickness as the basal cell) or panicoid bicellular microhairs-like (long, thin-walled terminal cell) [Amarasinghe & Watson 1990]. Apparently three C_4 biochemical types exist in *Eragrostis*: NAD-ME (nicotinamide adenine dinucleotide co-factor malic enzyme), PCK (phosphoenolpyruvate carboxykinase), and intermediates (Prendergast et al. 1986).

The classification of the tribe Eragrostideae has been problematic, primarily because no one has been able to define this group and select diagnostic characters that exclusively delimit this tribe from other tribes in the Chloridoideae (Hilu & Alice 2000; 2001; Van den Borre & Watson 1997; 2000). Historic accounts of the ever changing opinions of systematists on the classification of the Eragrostideae can be found in Peterson et al. (1995) and Van den Borre and Watson (1994). Peterson et al. (1997) recognized 38 Eragrostideae genera occurring in the New World, then later placed many of these same genera in the tribe Cynodonteae without delineating an Eragrostideae. Based on results of a DNA sequence study of the Chloridoideae (Columbus et al. 2005), Peterson et al. (2005) has proposed a completely new classification of the New World Chloridoideae. Here, the Eragrostideae is narrowly interpreted to include only three small subtribes (Cotteneinae, Uniolinae, and the Eragrostidinae) that diverge as a clade at the base of the chloridoids (Peterson et al. 2005). Character trends in the Eragrostideae include spikelets with many florets, lemmas with 3–13-nerves, and many species adapted to xeric habitats.

The subtribe Eragrostidinae as treated here includes three genera: *Cladoraphis cyperoideae* (Thunb.) S.M. Phillips introduced from Africa; *Eragrostis* with 112 species (86 native NW spp.); and *Steirachne* with two species (Peterson 2003; Peterson et al. 2005). The Eragrostidinae is characterized by having hairy or glabrous culm nodes; hairy or glabrous rachillas; entire lemma apices that are awnless, mucronate or short-awned (only in the latter two genera); glabrous or scabrous lemmas that are (1) 3 (5)-nerved lemmas; and short basal microhair cells (15–75 microns) on the abaxial epidermis of the leaf blade.

Recent systematic treatments of *Eragrostis* from Argentina (Nicora 1998), Australia (Lazarides 1997), Brazil (Boechat & Longhi-Wagner 2001), Ecuador (Peterson 2001), Mesoamerica (Davidse 1994), México (Beetle et al. 1991), the United States and Canada (Peterson 2003), and Zambesiaca (Cope 1998) have given us a good understanding of the species limits and their distribution. Based on nuclear and plastid DNA sequences, Ingram and Doyle (2004, 2005) tested the monophyly of *Eragrostis* and found that with inclusion of *Acamptoclados* Nash (*E. sessilispica* Buckley), *Diandrochloa* de Winter, *Neeragrostis* Bush, and *Pogonarthria* Stapf the genus is indeed monophyletic. However, only 37 species of *Eragrostis* were included in their analysis so any subgeneric interpretations were beyond the scope of their work. What is lacking is a definitive treatment of the subgeneric classification of the entire genus. Based on spikelet disarticulation Clayton (1974) and Clayton and Renvoize (1986) have arrived at a "first approximation to natural groups" and have presented a key to sections *Psilantha*, *Eragrostis*, *Lappula*, and *Platystachya*. In most native New World species the lemmas fall acropetally (from the base towards the apex) from the persistent rachilla, and with the paleas persistent on the rachilla. The other major pattern of spikelet disarticulation in *Eragrostis* is when the lemmas fall basipetally (from the apex towards the base). Van den Borre and Watson (1994) investigated 53 species of *Eragrostis* and found that anatomical characters, among others, support the recognition of two distinct groups: subgenus *Eragrostis* and subg. *Caesiae*. The most comprehensive attempt so far is Lazarides (1997) treatment of the Australian *Eragrostis* where he recognized six groups primarily based on spikelet disarticulation. Lazarides (1997) correlates his classification with Van den Borre and Watson (1994) who recognized subgenus *Eragrostis* and subg. *Psilantha*, and with Amarasinghe and Watson (1990) who investigated microhair morphology within the genus. Cope's (1998) subgeneric treatment of *Eragrostis* for the flora of Zambesiaca is also comprehensive since he delineates nine groups based on panicle, lemma, and palea morphology in addition to spikelet disarticulation.

The following taxonomic treatment contains a key for determining the species, descriptions, distribution, specimens examined, illustrations, synonymies, and a brief discussion indicating hypothesized relationships among all native and adventive species of *Eragrostis* in northeastern México. This study is based on the examination of herbarium specimens from ANSM, COCA, MEXU, MO, TEX, UAT, and US, including the type specimens of most of the species studied.

TAXONOMIC TREATMENT

Eragrostis Wolf, Gen. Pl. 23. 1776. TYPE: *Eragrostis minor* Host (LECTOTYPE: designated by R. Ross, Acta Bot. Neerl. 15:157. 1966).

Plants annual or perennial; usually synoecious, sometimes dioecious; caespitose, stoloniferous, or rhizomatous. Flowering culms (2–)5–170 cm tall, not woody, erect, decumbent, or geniculate, sometimes rooting at the lower nodes, simple or branched; internodes solid or hollow; bud initiation intravaginal, rarely extravaginal. Leaf sheaths open, often with tufts of hairs at the apices, hairs 0.3–8 mm long; ligules usually membranous and ciliolate or ciliate, cilia sometimes longer than the membranous base, occasionally of hairs or membranous and non-ciliate; blades flat, folded, or involute. Inflorescences terminal, sometimes also axillary, simple panicles, open to contracted or spike-like, terminal panicles usually exceeding the upper leaves; pulvini in the axils of the primary branches glabrous or hairy; branches not spike-like, not disarticulating. Spikelets 1–18(–23) mm long, 0.6–9 mm wide, laterally compressed, with 2–45 florets; disarticulation below the fertile florets, sometimes also below the glumes, acropetal with deciduous glumes and lemmas but persistent paleas, or basipetal with the glumes often persistent and the florets usually falling intact; glumes usually shorter than the adjacent lemmas, (1)3(5)-veined, not lobed, apices obtuse to acute, unawned; calluses glabrous or sparsely pubescent; lemmas usually glabrous, obtuse to acute, 3(5)-veined, usually keeled, unawned or mucronate; paleas shorter than the lemmas, longitudinally bowed-out by the caryopses, 2-keeled, keels usually ciliate, intercostal region membranous or hyaline; anthers 2 or 3; ovaries glabrous; styles free to the bases. Cleistogamous spikelets occasionally present, sometimes on the axillary panicles, sometimes on the terminal panicles. Caryopses variously shaped; hilum short; embryo with an epiblast, scutellar tail, and elongated mesocotyl internode (formula P+PF), endosperm hard. Base chromosome number, $x = 10$.

The origin of the name is somewhat obscure. Nathaniel Wolf (1776), who first named *Eragrostis*, made no statement concerning the origin of its name. Clifford (1996) provides three possible derivations: from eros, 'love', and *Agrostis*, the Greek name for an indeterminate herb; from the Greek er, 'early' and *agrostis*, 'wild', referring to the fact that some species of *Eragrostis* are early invaders of arable land; or the Greek eri-, a prefix meaning 'very' or 'much', suggesting that the name means many-flowered *Agrostis*. Watson and Dallwitz (2003) indicate that the derivation of *Eragrostis* is "from the Greek *eros* (love) or *era* (earth) and *agrostis* (a grass), probably alluding to the characteristic, earthy (human) female aroma of the inflorescences of many species."

Comments.—As taxonomists we know little about the true limits or boundaries among species of *Eragrostis* but hope our treatment using gross morphological features will allow determination of most of the 26 species. We also want to familiarize the user with the morphological features that are used to infer relationships among this group of grasses. Therefore, we present a review of the affinities or "hypothesized relationships" of the 26 species of *Eragrostis* from Northeastern México for readers to more thoroughly understand their classification and to point out problem areas that will require further analysis. The following four paragraphs outline our current thoughts on four hypothesized lineages within these 26 species of *Eragrostis*: the Old World group, *Eragrostis intermedia* complex, *E. pectinacea* complex, and *E. spectabilis*-*E. secundiflora* group.

The Old World group consists of *E. barrelieri*, *E. cilianensis*, *E. curvula*, and *E. lehmanniana*. Based on acropetal floret disarticulation, persistent rachillas, deciduous lemmas, persistent paleas, and the presence of laterally compressed spikelets, Lazarides (1997) placed: *E. barrelieri, E. cilianensis, E. curvula*, and *E. mexicana* in his"group 2." In addition to these species, Cope (1998) placed *Eragrostis lehmanniana* in his "group 9" which corresponds to sect. *Eragrostis*. It is also interesting to note that two (*E. curvula* and *E. lehmanniana*) of these five species have dorsally compressed caryopses while the others have laterally compressed caryopses. The only species native to the New World in this assemblage is *E. mexicana*, a weedy taxon naturalized in Australia and South Africa.

Preliminary DNA sequence evidence suggests that *E. mexicana* might be aligned with some members of the subsect. *Hirsutae* (Ingram & Doyle 2004) as proposed by Harvey (1948) and later investigated and expanded by Witherspoon (1975) as the "*Eragrostis intermedia* complex." Based on having wide, open panicles with spreading branches, disarticulating rachillas, and caryopses with surface reticulations, Witherspoon included the following species from the Flora region in the *E. intermedia* complex: *E. erosa, E. intermedia, E. hirsuta, E. hirta, E. lugens*, and *E. palmeri*. We feel the *Eragrostis intermedia* complex is a young assemblage of species that is rapidly evolving since the morphological limits among the species are small.

We feel that *E. mexicana* is perhaps better aligned with *E. pectinacea* and *E. pilosa* in the *E. pectinacea* complex as proposed by Harvey (1948) who emphasized the deeply-grooved ventral surface of the caryopses and the presence of glandular tissue below the nodes in his subsect. *Pectinaceae*. Harvey also included *E. tef* (Zucc.) Trotter, the economically important cereal crop grown primarily in Ethiopia, in the *Pectinaceae* group. Ingram and Doyle (2003) recently investigated the origin and evolution of *E. tef* and presented evidence that supports *E. pilosa* as a close relative and potential progenitor to the tef genome.

Based on the presence of stiffly spreading panicle branches and flattened, coriaceous spikelets that usually appear distant, Harvey (1948) recognized the following four species in subsect. *Spectabiles*: *E. curtipedicellata, E. elliottii, E. silveana*, and *E. spectabilis*. Three of these species (excluding *E. elliottii*) have short, knotty rhizomes. *Eragrostis secundiflora*, also with coriaceous spikelets, was placed by Harvey (1948) in subsect. *Oxylepides* based on densely flowered panicles, conspicuous lateral nerves on the lemma, and spikelets several times wider than thick. We feel these five species in the *E. spectabilis-E. secundiflora* group perhaps represent a lineage within the New World *Eragrostis*.

Other species in the Flora region without immediate sisters include *E. spicata* in sect. *Sporoboloides* with spiciform panicles with short branches, small 2–4-flowered spikelets, and grains falling free like the dropseeds (*Sporobolus*); *E. capillaris* in subsect. *Capillares* with large robust panicles 1/2 or more the length of the culm, capillary branches, and hyaline, few-flowered spikelets; *E. ciliaris* in subsect. *Amabiles* with ciliate (tuberculate) paleas ["group 6" of Lazarrides (1997); "group 3" of Cope (1998)]; *E. sessilspica* in sect. *Acamptocladus* with sessile or nearly so spikelets, stiffly spreading panicle branches, and appressed spikelets; and *E. superba* in sect. *Platystachya* with the entire spikelets that fall with the glumes and florets attached ["group 5" of Lazarides (1997); "group 6" of Cope (1998)] (Harvey 1948). The enigmatic, *Eragrostis obtusiflora* is currently being investigated by Travis Columbus (per. comm.) and Maricela Sanchez, where it appears members of the Monanthochloinae are more closely related than other species of *Eragrostis* (see comments under this species).

KEY TO THE SPECIES OF *ERAGROSTIS* IN NORTHEASTERN MÉXICO

1\. Plants annual, caespitose or mat-forming, without innovations at the basal nodes.

  2\. Palea keels prominently ciliate, the cilia 0.2–0.8 mm long.

    3\. Spikelets 1.8–3.2 mm long, 1–2 mm wide, with 6–11 florets; lemmas 0.8–1.3 mm long without glands on the keels; anthers 2 ____ **1. E. ciliaris**

    3\. Spikelets 6–20 mm long, 2–4 mm wide, with 10–40 florets; lemmas 2–2.8 mm long with 1–3 crateriform glands on the keels; anthers 3 ____ **3. E. cilianensis**

  2\. Palea keels smooth or scabrous, the cilia less than 0.2 mm long.

    4\. Plants mat-forming; panicles 1–3.5 cm long; erect portion of culms (2–)5–20 cm tall, the basal portion prostrate and rooting at the nodes.

      5\. Spikelets bisexual; anthers 2, 0.2–0.3 mm long ____ **11. E. hypnoides**

      5\. Spikelets and plants unisexual; anthers 3, 1.4–2.2 mm long ____ **20. E. reptans**

    4\. Plants usually not forming mats; panicles 3–55 cm long; culms (5–)8–130 cm tall, not prostrate or rooting at the lower nodes.

      6\. Caryopses with a shallow or deep ventral groove, ovoid to rectangular-prismatic, the surface striate.

        7\. Spikelets 4–11 mm long, with 5–11(–15) florets; pedicels 1–6(–7) mm long, somewhat divergent to appressed; panicles less than 1/2 the height of the plant ____ **15. E. mexicana**

        7\. Spikelets (1.4–)2–5 mm long, with 2–5(–7) florets; pedicels (4–)5–25 mm long, divergent; panicles 2/3 or more the height of the plant ____ **2. E. capillaris**

      6\. Caryopses without a ventral groove, usually globose, pyriform, ovoid to prism-shaped, or ellipsoid, the surface smooth to faintly striate.

        8\. Plants without glandular pits or bands.

          9\. Lower glumes 0.5–1.5 mm long, at least 1/2 as long as the lowest lemmas; spikelets 1.2–2.5 mm wide; panicle branches solitary or paired at the lowest 2 nodes; lemmas with moderately conspicuous lateral veins ____ **18. E. pectinacea**

          9\. Lower glumes 0.3–0.6(–0.8) mm long, usually less than 1/2 as long as the lowest lemmas; spikelets 0.6–1.4 mm wide; panicle branches usually whorled at the lowest 2 nodes; lemmas with inconspicuous lateral veins ____ **19. E. pilosa**

        8\. Plants with glandular pits or bands somewhere, the location(s) various, including any or all of the following: below the cauline nodes, on the sheaths, blades, rachises, panicle branches, or pedicels, or on the keels of the lemmas.

          10\. Spikelets 0.6–1.4 mm wide; pedicels 1–10 mm long, lax, appressed or divergent ____ **19. E. pilosa**

          10\. Spikelets 1.1–4 mm wide; pedicels 0.2–4 mm long, stiff, straight, usually divergent.

            11\. Lemmas 2–2.8 mm long, with 1–3 crateriform glands along the keels; spikelets 6–20 mm long, 2–4 mm wide, with 10–40 florets;

disarticulation below the florets, the rachillas persistent; anthers yellow ____________ **3. E. cilianensis**

11. Lemmas 1.4–1.8 mm long, without crateriform glands along the keels; spikelets 4–7(–11) mm long, 1.1–2.2 mm wide, with 7–12(–20) florets; disarticulation below the lemmas, both the paleas and rachillas usually persistent; anthers reddish-brown ____________ **1. E. barrelieri**

1. Plants perennial, sometimes rhizomatous, forming innovations at the basal nodes.

12. Paleas with a broad lower portion forming a wing or tooth on each side, these often projecting beyond the lemmas ____________ **26. E. superba**

12. Paleas without a broad lower portion forming a wing or tooth, the bases never projecting beyond the lemmas.

13. Plants rhizomatous; disarticulation always below the florets, the paleas falling with the lemmas and caryopses.

14. Plants with long, scaly rhizomes, 4–8 mm thick; spikelets 8–14 mm long; lemmas 3.8–4.5 mm long, 3–5-veined, the apices acute to obtuse, usually erose; caryopses 1.6–2 mm long ____________ **16. E. obtusiflora**

14. Plants with short, knotty rhizomes less than 4 mm thick, often stout but never elongated; spikelets 2.5–7.6 mm long; lemmas 1–2.5 mm long, 3-veined, the apices acute, usually entire; caryopses 0.5–0.8 mm long.

15. Sheaths, blades, and culms not viscid or glandular; caryopses strongly flattened, the ventral surface with 2 prominent ridges separated by a groove; anthers 0.3–0.5 mm long; lemmas leathery ____________ **24. E. spectabilis**

15. Sheaths, blades, and/or culms often viscid, sometimes glandular; caryopses terete, the ventral surfaces without 2 ridges separated by a groove; anthers 0.2–0.4 mm long; lemmas membranous.

16. Pedicels 0.2–1.2 mm long, appressed; lemmas 1.5–2.2 mm long; caryopses 0.6–0.8 mm long ____________ **5. E. curtipedicellata**

16. Pedicels (1–)1.5–12 mm long, divergent or appressed; lemmas 1.1–1.4 mm long; caryopses 0.5–0.6 mm long ____________ **23. E. silveana**

13. Plants not rhizomatous; disarticulation often below the lemmas, the paleas persistent, sometimes below the florets and the paleas falling with the lemmas and caryopses.

17. Panicles 0.3–0.6 cm wide, spicate, dense; spikelets with 2 or 3 florets ____________ **25. E. spicata**

17. Panicles 1–45 cm wide, ovate to obovate or elliptic, open to somewhat condensed and glomerate; spikelets with 1–45 florets.

18. Caryopses with shallowly to deeply grooved adaxial surfaces, rectangular-prismatic to ellipsoid, ovoid, or obovoid in overall shape.

19. Caryopses strongly dorsally compressed, translucent, mostly light brown, bases sometimes greenish.

20. Lemmas 1.8–3 mm long; panicles 16–35(–40) cm long, (4–)8–24 cm wide; blades 12–50(–65) cm long; caryopses 1–1.7 mm long; ligules 0.6–1.3 mm long ____________ **6. E. curvula**

20. Lemmas 1.5–1.7 long; panicles 7–18 cm long, 2–8 cm wide; blades 2–12 cm long; caryopses 0.6–0.8 mm long; ligules 0.3–0.5 mm long ____________ **13. E. lehmanniana**

19. Caryopses laterally compressed, terete, or slightly dorsally compressed, usually opaque, usually reddish-brown.

21. Lemmas 1.2–1.6 mm long; culms (20–)30–50(–60) cm tall; sheaths usually glabrous **14. E. lugens**

21. Lemmas 1.6–3 mm long; culms (30–)40–170 cm tall; sheaths usually hairy.

22. Sheaths with papillose-based hairs near the apices and margins.

23. Spikelets with 2–4 florets, 1–1.5 mm wide, lanceolate, greenish with a purplish tinge; bud initiation usually intravaginal **9. E. hirsuta**

23. Spikelets with 4–7 florets, 1.4–2.0 mm wide, ovate to linear-ovate, plumbeous to reddish-purple; bud initiation usually extravaginal **10. E. hirta**

22. Sheaths without papillose-based hairs near the apices and margins.

24. Lemmas 1.6–2.2 mm long; anthers 0.5–0.8 mm long, purplish **12. E. intermedia**

24. Lemmas 2–3 mm long; anthers 0.6–1.7 mm long, purplish to yellowish.

25. Caryopses 0.8–1.6 mm long; lemmas 2.4–3 mm long **8. E. erosa**

25. Caryopses 0.6–0.8 mm long; lemmas 2 2.6mm long **17. E. palmeri**

18. Caryopses not grooved on the adaxial surfaces, ellipsoid, ovoid, obovoid, globose, to pyriform, prism-shaped, and rectangular-prismatic in overall shape.

26. Anthers 2.

27. Panicles 15–45 cm wide, diffuse, broadly ovate to obovate, open, diffuse; primary branches lax; pedicels (4–)10–35 (–50) mm long, the pedicels longer than the spikelets; spikelets 1.4–3 mm wide **7. E. elliottii**

27. Panicles 1–15 cm wide, narrowly oblong to ovate and open; primary branches stiff; pedicels absent or 0–1(–3) mm long, always shorter than the spikelets; spikelets 2.4–5 mm wide **21. E. secundiflora**

26. Anthers 3.

28. Primary panicle branches not rebranched; proximal spikelets on each branch sessile or subsessile, the pedicels shorter than 0.4 mm **22. E. sessilispica**

28. Primary panicle branches with secondary branches; proximal spikelets on each branch pedicellate, the pedicels longer than 0.4 mm.

29. Spikelets 2–5.5 mm long.

30. Lemmas 1.2–1.6 mm long; culms (20–)30–50(–60) cm tall **14. E. lugens**

30. Lemmas 1.6–3 mm long; culms (30–)40–170 cm tall.

31. Spikelets with 2–4 florets, 1–1.5 mm wide, lanceolate, greenish with a purplish tinge; bud initiation usually intravaginal **9. E. hirsuta**

31. Spikelets with 4–7 florets, 1.4–2.0 mm wide, ovate to linear-ovate, plumbeous to reddish-

purple; bud initiation usually extravaginal ______ **10. E. hirta**

29. Spikelets 4–12 (–14) mm long.
    32. Lemmas 1.8–3 mm long; panicles 16–35(–40) cm long, (4–)8–24 cm wide; blades 12–50(–65) cm long; caryopses 1–1.7 mm long; ligules 0.6–1.3 mm long ______ **6. E. curvula**
    32. Lemmas 1.5–1.7 long; panicles 7–18 cm long, 2–8 cm wide; blades 2–12 cm long; caryopses 0.6–0.8 mm long; ligules 0.3–0.5 mm long ______ **13. E. lehmanniana**

1. Eragrostis barrelieri Daveau, J. Bot. (Morot) 8:289. 1894. (**Fig. 1, A & B**). *Eragrostis poaeoides* var. *barrelieri* (Daveau) Fiori, F. Italia 1:82. 1908. *Eragrostis vulgaris* ssp. *barrelieri* (Daveau) R.C.V. Douin, Fl. Ill. France 12:32. 1927–1932. TYPE: Plantae per Galliam, Hispaniam et Italiam observatae (type not indicated in the prologue): EGYPT: *Ascheron s.n.* (SYNTYPE: P; ISOSYNTYPE: K); ALGERIA. *Balansa 734* (SYNTYPE: P; ISOSYNTYPE: K); ITALY. SICILY: *Todaro s.n.* (SYNTYPE: P; ISOSYNTYPE: K); SOUTH EUROPE: *Barrelier s.n.* (SYNTYPE: ?).

Caespitose annuals, without innovations. Culms (5–)10–60 cm tall, erect or sprawiling to decumbent and prostrate, much-branched near the base, somewhat glaucous, with a ring of glandular tissue below the nodes, rings often shiny or yellowish. Leaf sheaths1/2–7/8 the length of the internodes, hairy at the apices, hairs to 4 mm long; ligules 0.2–0.5 mm long, ciliate; blades 1.5–10 cm long, 1–3(–5) mm wide, flat, abaxial surfaces glabrous, adaxial surfaces glabrous, sometimes scabridulous, occasionally with white hairs to 3 mm long, margins without crateriform glands. Panicles 4–20 cm long, 2.2–8(–10) cm wide, ovate, open to contracted, rachises with shiny or yellowish glandular spots or rings below the nodes; primary branches 0.5–6 cm long, diverging 20–100° from the rachises; pulvini glabrous; pedicels 1–4 mm, stout, stiff, divergent, without glandular bands. Spikelets 4–7(–11) mm long, 1.1–2.2 mm wide, narrowly ovate, reddish-purple to greenish, occasionally grayish, with 7–12(–20) florets; disarticulation acropetal, paleas persistent; glumes broadly ovate, membranous, 1-veined; lower glumes 0.9–1.4 mm long; upper glumes 1.2–1.6 mm long; lemmas 1.4–1.8 mm long, broadly ovate, membranous, lateral veins evident, apices acute to obtuse; paleas 1.3–1.7 mm long, hyaline, keels scabrous, scabridities to 0.1 mm long, apices obtuse to acute; stamens 3; anthers 0.1–0.2 mm long, reddish-brown. Caryopses 0.4–0.7 mm long, ellipsoid, not grooved, smooth to faintly striate, light brown. $2n = 40, 60$.

Distribution and habitat.—*Eragrostis barrelieri* is an introduced European species that is now naturalized in the Flora region. It grows on gravelly roadsides, in gardens, and other disturbed, sandy sites, especially near railroad yards, at 10–1800 m.

Comments.—The ring of glandular tissue is most conspicuous below the upper cauline nodes.

Contr. U.S. Natl. Herb 12:121. 1908.).

Aira capillacea Lam., Tabl. Encycl. 1:177. 1791. TYPE: U.S.A. E. Carolina, *D. Fraser s.n.* (HOLOTYPE: P-LAM; ISOTYPE: US-76301 fragm. ex P-LAM!).

Poa tenuis Elliott, Sketch Bot. S. Carolina 1(2):156. 1816, nom. illeg. hom. *Eragrostis tenuis* Steud., Syn. Pl. Glumac. 1:273. 1854, nom. nov. as comb. TYPE: U.S.A. SOUTH CAROLINA. Greenville Co.: Aug, *Moulins s.n.* (HOLOTYPE: CHARL-3985).

Caespitose annuals, without innovations. Culms (15–)20–50(–60) cm tall, erect, glabrous, often shiny below the nodes. Leaf sheaths overlapping, 1–2 1/2 as long as the internodes, pilose along the margins, apices hirsute, hairs to 7 mm long; ligules 0.2–0.5 mm long, ciliate; blades (6–)8–20(–30) cm long, (1–)2–5 mm wide, flat, abaxial surfaces smooth, glabrous, adaxial surfaces scabridulous, with long scattered hairs. Panicles (10–)15–45(–55) cm long, (7–)10–25 cm wide, to 2/3 the height of the plants, elliptic to ovate, open, rachises without glandular pits; primary branches (2–)5–15 cm long, diverging 20–90° from the rachises, capillary, naked basally; pulvini glabrous; pedicels (4–)5–25 mm long, divergent, scabridulous. Spikelets (1.4–)2–5 mm long, 1–1.3(–1.4) mm wide, ovate to lanceolate, plumbeous, occasionally reddish-purple, with 2–5(–7) florets; disarticulation acropetal, paleas persistent; glumes narrowly lanceolate to lanceolate, hyaline; lower glumes 1–1.2 mm long, narrower than the upper glumes; upper glumes 1.2–1.4 mm long; lemmas 1.2–1.7 mm long, broadly ovate, membranous, keels scabridulous, lateral veins inconspicuous, apices acute; paleas 1.2–1.6 mm long, hyaline, keels almost smooth to scabrous, scabridities to 0.1 mm long, apices acute to obtuse; stamens 3; anthers 0.2–0.3 mm long, reddish-brown. Caryopses 0.4–0.7 mm, ovoid to rectangular-prismatic, adaxial surfaces deeply grooved, striate, bases reddish-brown, distal 2/3 opaque. $2n = 50, 100$.

Distribution and habitat.—*Eragrostis capillaris* is native to the eastern portion of the Flora region. It grows in open, dry, sandy riverbanks, floodplains, rocky roadsides, and gravel pits, usually in association with *Pinus*, *Quercus*, *Carrya*, and *Liquidambar styraciflua*. Its range extends into the eastern United States; 300–600 m.

Comments.—Distinguishing features of *E. capillaris* include the panicle which is often 2/3 or more the height of the plant and the pedicels that are widely divergent and longer than the spikelets.

Specimen examined. **MEXICO. Tamaulipas:** Municipio de Casas, El Pirulí, *J.F. Iribe-Duarte 238* (COCA).

Caespitose annuals, without innovations. Culms 15–45(–65) cm tall, erect or decumbent and prostrate, sometimes with crateriform glands below the nodes. Leaf sheaths overlapping below, 2/3 the length of the internodes above, glabrous, occasionally glandular, apices hairy, hairs to 5 mm long; ligules 0.4–0.8 mm long, ciliate; blades (1–)5–20 cm long, (1–)3–5(–10) mm wide, flat to loosely involute, abaxial surfaces glabrous, sometimes glandular near margins, adaxial surfaces scabridulous, occasionally also hairy. Panicles (3–)5–16(–20) cm long, 2–8.5 cm wide, oblong to ovate, condensed to open; primary branches 0.4–5 cm long, appressed or diverging 20–80° from the rachises; pulvini glabrous or hairy; pedicels 0.2–3 mm long, stout, straight, stiff, usually divergent, occasionally appressed. Spikelets 6–20 mm long, 2–4 mm wide, ovate-lanceolate, plumbeous, greenish, with 10–40 florets; disarticulation below the florets, each floret falling as a unit, rachillas persistent; glumes broadly ovate to lanceolate, membranous, usually glandular; lower glumes 1.2–2 mm long, usually 1-veined; upper glumes 1.2–2.6 mm long, often 3-veined; lemmas 2–2.8 mm long, broadly ovate, membranous, keels with 1–3 crateriform glands, apices obtuse to acute; paleas 1.2–2.1 mm long, hyaline, keels scabrous, sometimes also ciliate, cilia to 0.3 mm long, apices obtuse to acute; stamens 3; anthers 0.2–0.5 mm long, yellow. Caryopses 0.5–0.7 mm long, globose to broadly ellipsoid, smooth to faintly striate, not grooved, reddish-brown or translucent. $2n = 20$.

Distribution and habitat.—*Eragrostis cilianensis* is an introduced European species that now grows in disturbed sites such as pastures and roadsides through most of the North America; 0–2300 m.

Comments.—The nomenclature of *E. cilianensis* has been a bit chaotic, and the conclusions of Simon (1983) have been adopted. The most prominent feature of this species is the presence of 1–3 crateriform glands on the keel of the lemma.

TYPE: JAMAICA: *Browne s.n.* (LECTOTYPE: LINN-87.66, designated by Hitchcock, Contr. U.S. Natl. Herb. 12:121. 1908.).

Caespitose annuals, without innovations. Culms (3–)9–75 cm tall, erect or geniculate in the lower portion, not rooting at the lower nodes, glabrous. Leaf sheaths 1/2–3/4 as long as the internodes, hairy on the margins and at the apices, hairs to 4 mm long; ligules 0.2–0.5 mm long; blades 1.8–12(–15) cm long, 2–5 mm wide, usually flat, occasionally involute, glabrous or ciliate basally. Panicles 1.7–17 cm long, 0.2–5 cm wide, cylindrical, contracted or open, spike-like, branches forming glomerate lobes or sometimes more open, often interrupted in the lower portion; primary branches 0.4–4 cm, appressed or diverging up to 50° from the rachises; pulvini usually glabrous, occasionally sparsely pilose; pedicels 0.1–1 mm long, erect, shorter than the spikelets, glabrous. Spikelets 1.8–3.2 mm long, 1–2 mm wide, elliptical-ovate to ovate-lanceolate, yellowish-brown, sometimes with a purple tinge, with 6–11 florets, densely packed next to one another or widely separated; disarticulation basipetal, glumes persistent; glumes ovate to lanceolate, keels scabridulous, veins commonly green, apices acute; lower glumes 0.7–1.2 mm long; upper glumes 1–1.6 mm long; lemmas 0.8–1.3 mm long, elliptical-ovate to lanceolate, membranous, keels scabridulous, lateral veins evident, apices obtuse to acute; paleas 0.8–1.3 mm long, membranous, keels prominently ciliate, cilia 0.2–0.8 mm long, apices obtuse to acute; anthers 2, 0.1–0.3 mm long, purplish. Caryopses 0.4–0.5 mm long, ovoid, reddish-brown. $2n = 20, 40$.

Distribution and habitat.—*Eragrostis ciliaris* is apparently native to the paleotropics and introduced and naturalized in México and the United States, growing along roadsides, on waste sites, in xerothermic vegetation, and sometimes in saline habitats; 0–1950 m. It may be more widespread than indicated. *Eragrostis ciliaris* var. *ciliaris* is more common than *E. ciliaris* var. *laxa* in the *Flora* region.

KEY TO THE VARIETIES OF *ERAGROSTIS CILIARIS*

1. Panicles 0.2–1.5 cm wide, contracted, the branches mostly appressed to the rachises, congested, forming glomerate lobes; spikelets densely packed _____ **4a. E. ciliaris** var. **ciliaris**
1. Panicles 1.5–5 cm wide, open, the branches spreading 20–50° from the rachises; spikelets widely separated from each other _____ **4b. E. ciliaris** var. **laxa**

4a. Eragrostis ciliaris (L.) R. Br. var. ciliaris (Fig. 3, D–F).

Panicles 0.2–1.5 cm wide, contracted; primary branches mostly appressed to the rachises, forming glomerate lobes. Spikelets densely packed.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Arteaga, Sierra de Arteaga, 50 km SE de Saltillo, *M.A. Madrigal-A. s.n.* (ANSM). **Tamaulipas:** Municipio de Aldama, between La Concepcion and Aldama, *F. Martínez-Martínez & G. Borja L. F-2176*; Municipio de Bustamante, El Capulín, *C.R. López-Aguilar 197* (COCA); Municipio de Gonzalez, Sierra de Tamaulipas between La Chona and Rio Santa Olaya, *F. Martínez-Martínez & G. Borja L. F-2148* (US); Municipio de Mante, El Mante to Limon, *J.R. Swallen 1614* (US); Municipio de Nuevo Laredo, 20 km W of Ciudad Guerrero, *F. González-Medrano et al. 6320* (MEXU); Municipio de Palmillas, Las Enramadas, *C.R. López-Aguilar 194* (COCA); Municipio de Soto La Marina, Chamal, *J.R. Swallen 1643* (US); Municipio de Tampico, vicinity of Tampico, *E. Palmer 147* (US); Tampico, *A.S. Hitchcock 5791* (US); 8 km E of Tampico, *E. Palmer 591* (US); Municipio de Victoria, Ejido La Libertad, *J.F. Iribe-Duarte 404* (COCA); vicinity of Victoria, *E. Palmer 481* (US).

4b. Eragrostis ciliaris var. laxa Kuntze (Fig. 3, G).

Panicles 1.5–5 cm wide, open; primary branches spreading 20–50° from the rachises. Spikelets widely separated from each other.

Specimens examined. **MÉXICO. Tamaulipas:** Municipio de Soto La Marina, San José de las Rusias, *M.H. Cervera-Rosado 85* (COCA); Municipio de Victoria, Ciudad Victoria, *M.H. Cervera-Rosado 287* (COCA).

5. Eragrostis curtipedicellata Buckley, Proc. Acad. Nat. Sci. Philadelphia 14:97. 1862. (Fig. 4, A & B).

Eragrostis brevipedicellata A. Gray, Proc. Acad. Nat. Sci. Philadelphia 14:336. 1862, *nom. inval.* TYPE: U.S.A. NORTHERN TEXAS: *Buckley s.n.* (LECTOTYPE: PH, designated by Hitchcock, Man. Grasses U.S. 849. 1935, but without citing a specific sheet in a specific herbarium).

Eragrostis viscosa Scribn., Bull. Div. Agrostol., U.S.D.A. 11:51, t. 7. 1898, nom. illeg. hom. TYPE: U.S.A. TEXAS: Midland, 2 Aug 1897, *J.G. Smith s.n.* (SYNTYPE: US-1768944!); Laredo, *Mrs. Anna B. Nickels s.n.* (SYNTYPE: US!).

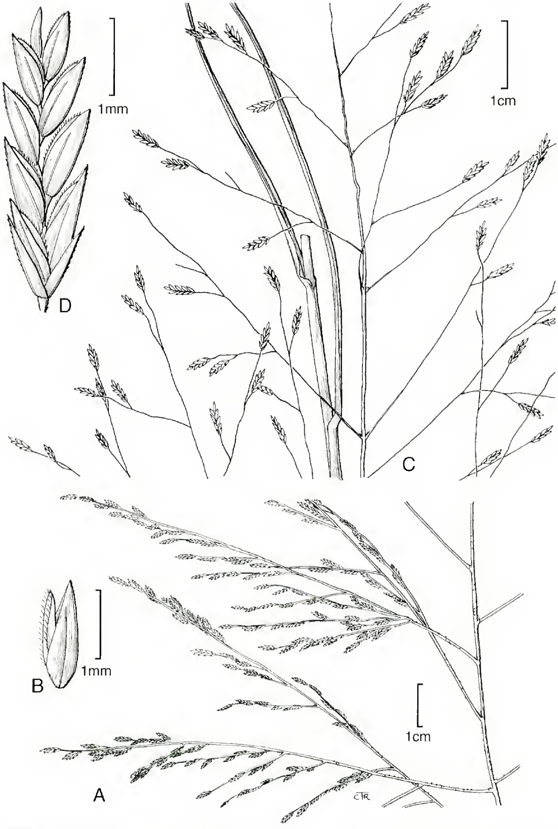

Fig. 4. *Eragrostis curtipedicellata*. **A.** Inflorescence. **B.** Floret. *Eragrostis silveana*. **C.** Inflorescence with portion of culm. **D.** Spikelet.

Caespitose perennials with innovations and short, knotty rhizomes less than 4 mm thick. Culms 20–65 cm tall, erect, viscid or gummy below the nodes, usually with particles of soil adhering to the surface. Leaf sheaths overlapping, 1-1/2 times as long as the internodes, usually viscid, hairy at the apices and on the collars and margins, hairs to 6 mm long; ligules 0.1–0.3 mm long; blades 5-18 cm long, 2–4(–5) mm wide, flat to involute, sometimes viscid, densely hairy behind the ligules, hairs to 8 mm long. Panicles 18–35 cm long, 10–30 cm wide, broadly ovate, open, sometimes partly enclosed by the sheath below; primary branches 3–18 cm long, diverging 10–90° from the rachises, stiff, viscid, naked basally; pulvini hairy, hairs to 6 mm long; pedicels 0.2–1.2 mm long, appressed. Spikelets 3.5–6(–7.6) mm long, 1–1.5 mm wide, linear-lanceolate, stramineous to reddish-purple, with 4–10 florets; disarticulation basipetal, glumes persistent; glumes lanceolate, membranous; lower glumes 0.9–1.8 mm long; upper glumes 1.2–2 mm long, 1–3-veined; lemmas 1.5–2.2 mm long, ovate to lanceolate, membranous, 3-veined, lateral veins evident, apices acute; paleas 1.2–2 mm long, hyaline, not wider than the lemmas, apices obtuse; stamens 3; anthers 0.2–0.4 mm long, purplish. Caryopses 0.6–0.8 mm long, ellipsoid, terete in cross section, neither ridged nor grooved, faintly striate, reddish-brown. $2n = 40$.

Distribution and habitat.—*Eragrostis curtipedicellata* extends from southern Colorado, Kansas, and Missouri, to northeastern Mexico. It is native to the Flora region and grows near fields, along roadsides, and in the margins of woods; 10–1525 m.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Juárez, 2 mi NW of Juárez on road to Sabinas, *L.H. Harvey & J.T. Witherspoon 9190* (US, TEX-LL); Don Martín Dam, *L.H. Harvey 932* (US). **Nuevo León:** Municipio de General Bravo, 23 mi E of General Bravo on the Reynosa highway, *M.C. Johnston 6063* (TEX-LL); Municipio de Lampazos de Naranjo, Rancho Santa Elena, *G. Nava-Villarreal s.n.* (ANSM, MEXU); Municipio de Montemorelos, near Río Ramos, 2 km NW of Montemorelos, *N.J. Weaver 1024* (TEX-LL).

6. Eragrostis curvula (Schrad.) Nees, Fl. Afr. Austral. Ill. 397. 1841. (**Fig. 5, A–C**). TYPE: SOUTH AFRICA. CAPE PROVINCE: Cape of Good Hope, *Hesse s.n.* (HOLOTYPE: LE; ISOTYPE: LE-TRIN-2327.01, lower middle specimen!).

Caespitose perennials forming innovations at the basal nodes. Culms (45–)60–150 cm tall, erect, glabrous or glandular. Leaf sheaths 1/3–2/3 the length of the internodes, with scattered hairs, hairs to 9 mm long; ligules 0.6–1.3 mm long; blades 12–50(–65) cm long, 1–3 mm wide, flat to involute, abaxial surfaces glabrous, sometimes scabridulous, adaxial surfaces with scattered hairs basally, hairs to 7 mm long. Panicles 16–35(–40) cm long, (4–)8–24 cm wide, ovate to oblong, open; primary branches 3–14 cm long, diverging 10–80° from the rachises; pulvini glabrous or not, the hairs up to 3 mm long; pedicels 0.5–5 mm long, appressed, flexible. Spikelets 4–8.2(–10) mm long, 1.2–2 mm wide, linear-lanceolate, plumbeous to yellowish, with 3–10 florets; disarticulation irregular to acropetal, proximal rachilla segments persistent; glumes lanceolate, hyaline;

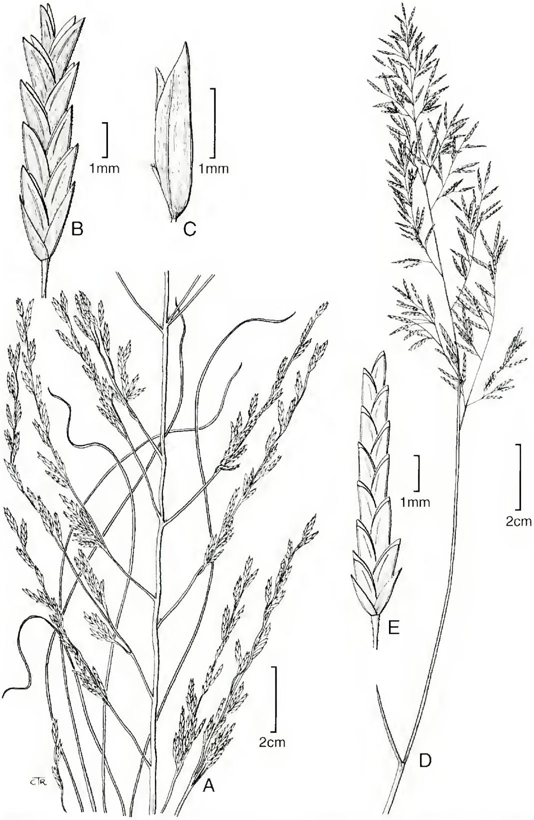

Fig. 5. *Eragrostis curvula*. **A.** Inflorescence with blades. **B.** Spikelet. **C.** Floret. *Eragrostis lehmanniana*. **D.** Inflorescence and culm. **E.** Spikelet.

lower glumes 1.2--2.6 mm long; upper glumes 2–3 mm long; lemmas 1.8–3 mm long, ovate, membranous, lateral veins conspicuous, apices acute; paleas 1.8–3 mm long, hyaline to membranous, apices obtuse; stamens 3; anthers 0.6–1.2 mm long, reddish-brown. Caryopses 1–1.7 mm long, ellipsoid to obovoid, dorsally compressed, adaxial surfaces with a shallow, broad groove or ungrooved, smooth, mostly translucent, light brown, bases often greenish. $2n = 40, 50$.

Distribution and habitat.—*Eragrostis curvula* is native to southern Africa and introduced in the Flora region. It is often used for reclamation because it provides good ground cover but, once introduced, it easily escapes. In the Flora region, it grows on rocky slopes, at the margins of woods, along roadsides, and in waste ground, usually in pine-oak woodlands, and yellow pine and mixed hardwood forests; 10–2000 m.

Comments.—*Eragrostis curvula* is one of two species in the Flora region that has strongly dorsally compressed and translucent caryopses. It can be separated from *E. lehmanniana* (also with dorsally compressed and translucent caryopses) by having longer lemmas (1.8–3 mm verses 1.5–1.7 mm) and taller culms (60–150 cm verses 40–80 cm).

Specimens examined. **MÉXICO. Coahuila:** Municipio de Cuatrociénegas, Rancho La Zacatosa, *M.A. Carranza-Pérez & L. García S. 996* (ANSM); Municipio de Muzquiz, 138 km NW of Muzquiz on Hwy 53 towards Boquilla del Carmen, *P.M. Peterson & C.R. Annable 10592* (US); Municipio de Saltillo, Rancho experimental Los Angeles, 48 km S de Saltillo, carretera 54 Saltillo-Concepción del Oro, Zacatecas, *S.L. Hatch 4549* (ANSM); Buenavista, 7 km S de Saltillo, carretera 54 Saltillo-Concepción del Oro, Zacatecas, *J. Valdés-Reyna & M. A. Carranza P. 922* (ANSM); **Nuevo León:** Municipio de Juárez, Rancho San Marcos, km 7 camino a San Mateo, carretera Villa de Juárez-Cadereyta, *J. Garza-Covarrubias 32* (COCA). **Tamaulipas:** Municipio de Ciudad Madero, Carretera al recreativo, km 1.5, *M.G. Torres-Guzmán s.n.* (ANSM).

7. Eragrostis elliottii S. Watson, Proc. Amer. Acad. Arts 25:140. 1890. (**Fig. 6, A–C**). *Poa nitida* Elliott, Sketch Bot. S. Carolina 1(2):162. 1816, *nom. illeg. hom. Eragrostis nitida* (Elliott) Chapm., Fl. South. U.S. 564. 1860, nom. illeg. hom. TYPE: U.S.A. SOUTH CAROLINA: Paris Island, *Elliott s.n.* (HOLOTYPE: CHARL; ISOTYPE: LE).

Eragrostis macropoda Pilg., Symb. Antill. 4:106. 1903. TYPE: PUERTO RICO: CATAÑO. Bayamón, 27 Mar 1885, *P.E.E. Sintenis 1233* (HOLOTYPE: B?; ISOTYPES: NY-70977!, US-821975!, US-2941525 fragm!).

Eragrostis acuta Hitchc., Proc. Biol. Soc. Wash. 41:159. 1928. TYPE: U.S.A. FLORIDA: Punta Rassa, Jul-Aug 1900, *A.S. Hitchcock 263* (HOLOTYPE: US-731236!; ISOTYPE: US-1503824!).

Caespitose perennials, with innovations. Culms 25–80 cm tall, erect, glabrous and shiny below the basal nodes. Leaf sheaths overlapping, 1.3–3 times as long as the internodes below, sparsely hairy at the apices, hairs to 6 mm long; ligules 0.2–0.4 mm long; blades 6–30(–52) cm long, 2–4.5 mm wide, flat, abaxial surfaces glabrous, adaxial surfaces scabridulous, sometimes with a few scattered hairs near the base. Panicles (25–)30–60 cm long, 15–45 cm wide, broadly ovate to obovate, open, diffuse; primary branches mostly 5–25(–32) cm long, diverging 20–90° from the rachises, capillary, lax; pulvini sparsely hairy; pedicels (4–)

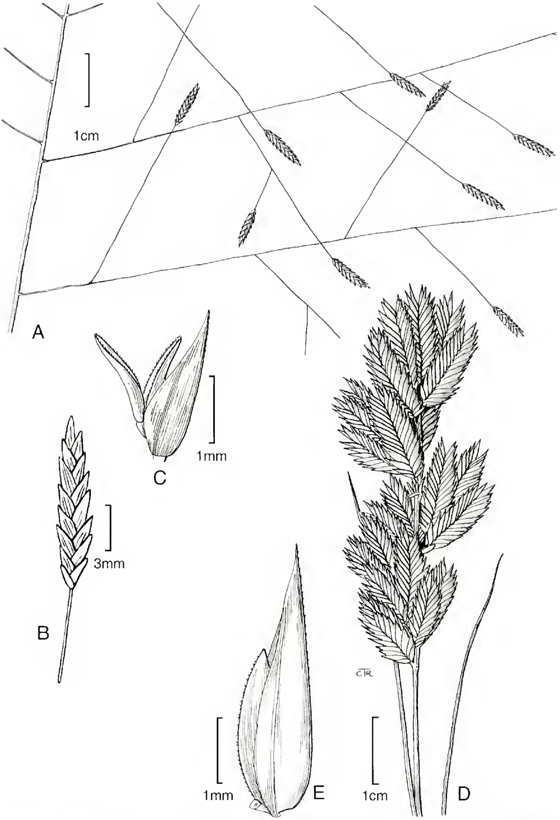

Fig. 6. *Eragrostis elliottii*. **A.** Inflorescence. **B.** Spikelet. **C.** Floret with palea below. *Eragrostis secundiflora* subsp. *oxylepis*. **D.** Inflorescence with blades. **E.** Floret.

10–35(–50) mm long, widely diverging, capillary, all the pedicels on each branch longer than the spikelets. Spikelets 4–18 mm long, 1.4–3 mm wide, linear-lanceolate, grayish-green or stramineous to purplish, with (6–)9–30 florets; disarticulation acropetal, below the lemmas, paleas persistent; glumes narrowly lanceolate, membranous; lower glumes 1.1–3.4 mm long; upper glumes 1.6–3.4 mm long, apices acuminate; lemmas 1.8–4.4 mm long, lanceolate, membranous, lateral veins evident to inconspicuous, sometimes greenish, apices acute to acuminate; paleas 1.1–3.5 mm long, hyaline to membranous, narrower than the lemmas, apices obtuse; stamens 2; anthers 0.3–0.8 mm long, purplish or brownish. Caryopses 0.6–0.8 mm long, ovoid to ellipsoid, finely striate, reddish-brown.

Distribution and habitat.—*Eragrostis elliottii* is native to the Flora region and grows in sandy pinelands and live-oak woodlands on the coastal plain; 0–150 m. Its range extends from the southeastern United States through the West Indies and Gulf coast of Mexico to Central and South America.

Comments.—*Eragrostis elliottii* is characterized by diffuse panicles 15–45 cm wide, lax primary branches, and pedicels longer than the spikelets.

Specimens examined. **MÉXICO. Tamaulipas:** Municipio de Tampico, Tampico, *A.S. Hitchcock 5799* (US-911146).

8. Eragrostis erosa Scribn. ex Beal, Grass. N. Amer. 2:483. 1896. (**Fig. 7, A–C**). TYPE: MÉXICO. CHIHUAHUA: Santa Eulalia Mountains, Oct 1885, *C.G. Pringle 415* (HOLOTYPE: MSC; ISOTYPES: MO-3728015!, US-821925!, US-1749578!).

Caespitose perennials with innovations, not glandular. Culms 70–110 cm tall, erect, glabrous below the nodes. Leaf sheaths overlapping, 1/2 to about as long as the internodes below, hairy at the apices and sometimes on the upper margins, hairs to 4 mm long, not papillose-based; ligules 0.2–0.4 mm long; blades (8–)12–30 cm long, 1.5–3.8 mm wide, flat to involute, abaxial surfaces glabrous, adaxial surfaces scabridulous, glabrous or sparsely hairy, hairs to 4 mm long. Panicles 25–45 cm long, (5–)12–30 cm wide, broadly ovate, open; primary branches mostly 4–20 cm long, diverging 20–90° from the rachises, capillary, sinuous; pulvini glabrous or hairy; pedicels 1–18 mm long, appressed or divergent, proximal spikelets on each branch usually with pedicels shorter than 5 mm long. Spikelets 5–9 mm long, 1–3 mm wide, lanceolate, plumbeous, with 5–12 florets; disarticulation acropetal, glumes first, then the lemmas, paleas persistent; glumes lanceolate to ovate, membranous; lower glumes 1.3–2.4 mm long; upper glumes 1.6–2.6 mm long; lemmas 2.4–3 mm long, ovate, mostly membranous, hyaline near the margins and apices, lateral veins inconspicuous, apices acute; paleas 1.5–3 mm long, hyaline, narrower than the lemmas, apices obtuse to truncate; stamens 3; anthers 0.6–1.7 mm long, purplish. Caryopses 0.8–1.6 mm long, subellipsoid, terete to somewhat laterally compressed, with a well-developed adaxial groove, faintly striate, opaque, reddish-brown.

Distribution and habitat.—*Eragrostis erosa* is native to the Flora region and

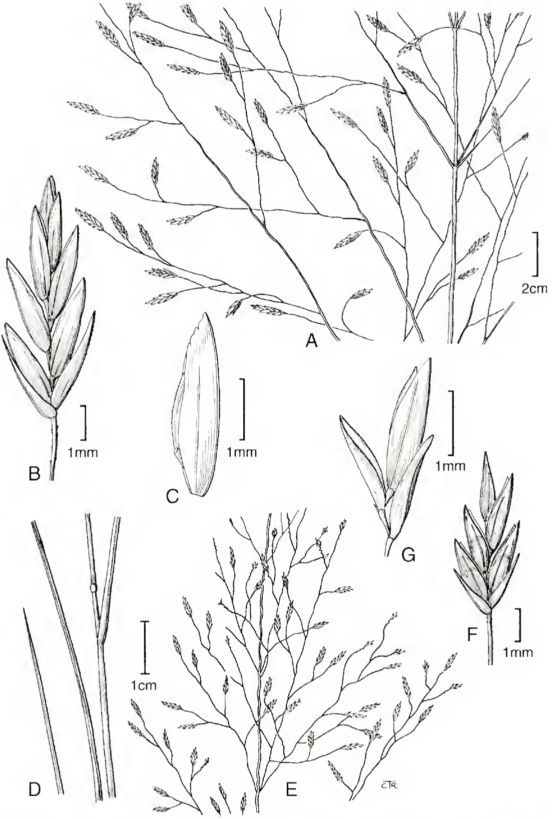

FIG. 7. *Eragrostis erosa*. **A.** Inflorescence. **B.** Spikelet. **C.** Floret. *Eragrostis palmeri*. **D.** Portion of culm and blades. **E.** Inflorescence. **F.** Spikelet. **G.** Floret with two paleas below.

grows on rocky slopes and hills, often in association with *Pinus edulis*, *Juniperus monosperma*, and *Bouteloua gracilis*; 1100–2300 m. Its range extends from northern México to New Mexico and western Texas.

Comments.—*Eragrostis erosa* is morphologically similar to *E. palmeri* but differs from the latter by having longer caryopses (0.8–1.6 mm verses 0.6–0.8 mm) and longer lemmas (2.4–3 mm verses 2–2.6 mm). These two species are sometimes very hard to differentiate; apparently *E. erosa* is much more restricted since it is known from only four locations in the Flora region.

Specimens examined. **MÉXICO. Coahuila:** western base of Picacho del Fuste, NE of Tanque Vaionetta, *I.M. Jonston 8413* (MEXU, US). **Nuevo León:** 3 km S of El Salero, *P.M. Peterson et al. 17832* (US). **Tamaulipas:** Municipio de Llera, La Gloria II, *J.L. Ramos-Delgado 249* (COCA); Municipio de San Carlos, Cerro del Diente, *J.A. Barrientos-B. 81* (COCA).

9. Eragrostis hirsuta (Michx.) Nees, Fl. Bras. Enum. Pl. 2:508. 1829. (**Fig. 8, A–D**)
Poa hirsuta Michx., Fl. Bor.-Amer. 1:68. 1803. TYPE: U.S.A. SOUTH CAROLINA: *Michaux s.n.* (HOLOTYPE: P!, ISOTYPE: US-77389 fragm!).

Eragrostis hirsuta var. *laevivaginata* Fernald, Rhodora 41(490):500–501. 1939. TYPE: U.S.A. VIRGINIA. Southhampton Co.: from wooded alluvial bottomland of Meherrin River, near Haley's Bridge, *M.L. Fernald & B.H. Long 9273* (HOLOTYPE: GH; ISOTYPE: PH).

Eragrostis sporoboloides J.G. Sm. & Bush, Annual Rep. Missouri Bot. Gard. 6:116, t. 54. 1895. TYPE: U.S.A. OKLAHOMA: Sapula, Indian Territory, Jul 1894, *B.F. Bush 766* (HOLOTYPE: ?).

Caespitose perennials with innovations and hardened bases, not glandular. Culms (30–)45–100 cm tall, erect, glabrous below the nodes; bud initiation usually intravaginal. Leaf sheaths overlapping, 1/2–1.5 times as long as the internodes below, rarely glabrous, apices and distal margins usually hairy, sometimes also densely hairy basally, dorsally, and on the collars, hairs to 6 mm long, papillose-based; ligules 0.2–0.4 mm long; blades 25–60 cm long, 4–8(–11) mm wide, flat to loosely involute, usually glabrous, adaxial surfaces sometimes hairy basally. Panicles 25–85 cm long, 15–40 cm wide, broadly ovate, open; primary branches mostly 4–35(–45) cm long, diverging 20–90° from the rachises, capillary; pulvini glabrous or hairy; pedicels 2–28 mm long, divergent. Spikelets 2–4(–5) mm long, 1–1.5 mm wide, lanceolate, greenish with purplish tinges, with 2–4 florets; disarticulation acropetal, paleas persistent; glumes lanceolate, hyaline to membranous; lower glumes 1.1–2 mm long; upper glumes 1.5–2.8 mm long, apices acuminate to acute; lemmas 1.6–2.4 mm long, ovate, membranous, hyaline near the margins, lateral veins inconspicuous, apices acute; paleas 1.2–2.2 mm long, hyaline, bases not projecting beyond the lemmas, apices acute to obtuse; stamens 3; anthers 0.3–0.8 mm long, purplish. Caryopses 0.8–1 mm long, rectangular-prismatic, somewhat laterally compressed, with or without a well-developed adaxial groove, striate, opaque, reddish-brown. $2n = 100$.

Distribution and habitat.—*Eragrostis hirsuta* is native to the Flora region and grows in sandy clay loams on the coastal plain and along roadsides, usually in association with *Pinus* and *Quercus*; 1–1750 m. Its range extends from

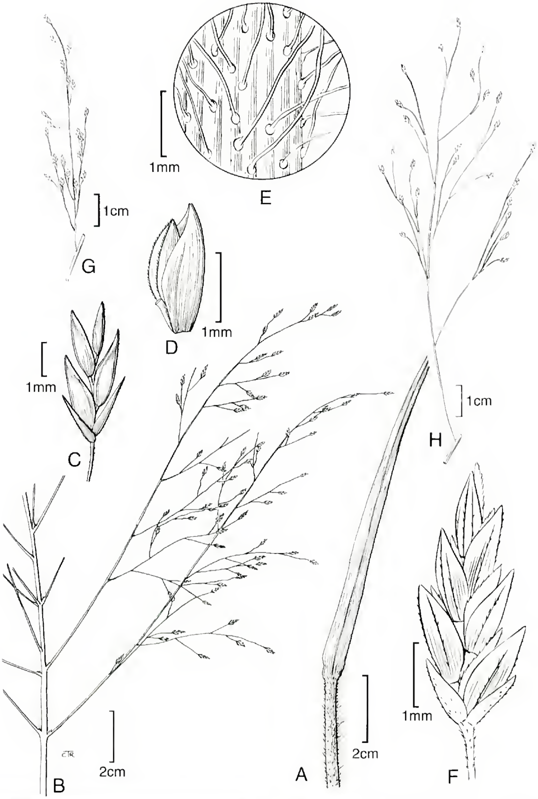

Fig. 8. *Eragrostis hirsuta*. **A.** Sheath and blade. **B.** Inflorescence. **C.** Spikelet. **D.** Floret. *Eragrastis hirta* var. *hirta*. **E.** Portion of the sheath. **F.** Spikelet. **G.** Primary panicle branch. *Eragrostis hirta* var. *longiramea*. **H.** Primary panicle branch.

the southeastern United States through eastern Mexico to Guatemala and Belize.

Comments.—*Eragrostis hirsuta* (along with *E. hirta*) is characterized by having papillose-based hairs near the apices and margins of the sheaths. The distinction between *E. hirsuta* and *E. hirta* is tentative and depends on the number of florets (2–4 in the former verses 4–7 in the latter), floret width (1–1.5 mm verses 1.4–2.0 mm), and floret color (greenish with a purplish tinge verses plumbeous to reddish-purple).

Specimens examined. **MÉXICO. Nuevo León:** Municipio de Bustamante, km 2 carretera Bustamante, *A. Bendeck s.n.* (ANSM). **Tamaulipas:** Municipio de Abasolo, Ejido La Esperanza, *J.F. Iribe-Duarte 48* (COCA); Municipio de Guémez, Ejido Los San Pedros, *G. Bores-Kulman 66* (COCA); Municipio de Hidalgo, El Chorrito, *G. Bores-Kulman 20* (COCA); Municipio de Jaumave, Sierra Madre rumbo a Jaumave, *J. Brito 43* (COCA); Municipio de Mainero, Adelante de Charco Dicha, Ejido Camarones, *M.H. Cervera-Rosado 359* (COCA); Municipio de Soto La Marina, Rancho El Saúz, *A. Brito 170* (COCA); Municipio de Victoria, Ejido Vicente Guerrero, *P. Moya-Salgado 139* (COCA); El Asbesto, *G. Bores-Kulman 80* (COCA).

10. Eragrostis hirta E. Fourn., Mexic. Pl. 2:115. 1886. TYPE: MEXÍCO. SAN LUIS POTOSÍ: Aug 1851, *Virlet de Aoust 1390* (HOLOTYPE: P!; ISOTYPE: US-77382 fragm. & photostat ex P!).

Eragrostis praetermissa L.H. Harv., Bull. Torrey Bot. Club 81:408. 1954. *Eragrostis intermedia* var. *praetermissa* (L.H. Harv.) Witherspoon, Ann. Missouri Bot. Gard. 64:327. 1977. TYPE: GUATEMALA. BAJA VERAPAZ: Santa Rosa, Jul 1887, *H. von Tuerckheim 1292* (HOLOTYPE: US-821939!).

Caespitose perennials, with innovations. Culms 60–170 cm tall, erect or ascending, glabrous or hairy below the nodes, internodes mostly glabrous; bud initiation usually extravaginal. Leaf sheaths overlapping below, 2/3 the length of the internodes above, pilose along the margins and at the apices, hairs to 4 mm long, papillose-based; ligules 0.2–0.4 mm long; blades 20–65 cm long, 2–8(–9) mm wide, flat to loosely folded or involute, mostly glabrous, scabrous above, sometimes with papillose-pilose near the base, the hairs up to 5 mm long; margins scabrous. Panicles 26–70 cm long, 4–40 cm wide, somewhat condensed or open, ovate, elliptic to lanceolate, branches whorled below, solitary or opposite above; primary branches mostly 4–25 cm long below, appressed, ascending and spreading up to 80° from the rachises; pulvini glabrous or pilose; pedicels 2.5–15 mm long, erect, longer than the spikelets, glabrous. Spikelets 3–5.5 mm long, 1.4–2.0 mm wide, ovate to linear-ovate, plumbeous to reddish-purple, with 4–7 florets; disarticulation acropetal with deciduous glumes and lemmas; glumes lanceolate, keel scabridulous, apices acute; lower glumes 1–1.8 mm long; upper glumes 1.6–2.2 mm long; lemmas 1.6–2.2 mm long, ovate, membranous, glabrous or with a few scattered hairs along the margins, lateral veins inconspicuous, keels scabridulous towards apex, apices acute; paleas 1.5–2.0 mm long, membranous, keels scabridulous; stamens 3; anthers 0.5–0.8 mm long, purplish. Caryopses 0.6–0.9 mm long, rectangular-prismatic, laterally compressed, striate, adaxially grooved, reddish-brown.

Distribution and habitat.—*Eragrostis hirta* is native to the Flora region.

KEY TO THE VARIETIES OF *ERAGROSTIS HIRTA*

1. Panicles 26–45(–50) cm long, 4–10 cm wide, somewhat condensed; primary branches 4–10 cm long below, appressed to ascending spreading; leaf blades 2–5 mm wide, mostly involute; culms 60–100 cm tall __________ **10a. E. hirta var. hirta**
1. Panicles 50–70 cm long, 18–40 cm wide, open; primary branches 15–25 cm long below, ascending spreading to reflexed; leaf blades 4–8(–9) mm wide, flat or loosely folded; culms (95–)110–170 cm tall __________ **10b. E. hirta var. longiramea**

10a. Eragrostis hirta var. **hirta** (**Fig. 8, E–G**).

Culms 60–100 cm tall. Leaf blades 20–45 cm long, 2–5 mm wide, mostly involute. Panicles 26–45(–50) cm long, 4–10 cm wide, somewhat condensed; primary branches 4–10 cm long below, appressed to ascending spreading.

Distribution and habitat.—*Eragrostis hirta* var. *hirta* occurs in rocky of sandy soils in oak-pine forests and along ravines and streams; 0–2100 m.

Specimens examined. **MEXICO. Tamaulipas:** Municipio de Casas, Sierra de Tamaulipas, Santa María de Los Nogales, *F. Martínez-Martínez 1949* (TEX-LL), *2081* (TEX-LL, US); Municipio Nuevo Laredo, 3 km S of El Huisachal, Standlford et al. 2115 (US); Municipio de Soto La Marina, Rancho Enramadas, *G. Villegas-Durán 499* (COCA); without Municipio, between Ciudad Victoria and Soto La Marina, *A.A. Beetle M-4437* (COCA).

10b. Eragrostis hirta var. **longiramea** (Swallen) Witherspoon, Ann. Missouri Bot. Gard. 64:328. 1977. (**Fig. 8, H**). *Eragrostis longiramea* Swallen, J. Wash. Acad. Sci. 21:437. 1931. TYPE: MÉXICO. TAMAULIPAS: Sierra de San Carlos, Pico del Diablo, vicinity of Marmolejo, 12 Aug 1930, *H.H. Bartlett 10910* (HOLOTYPE: US-1501524!; ISOTYPES: GH!, MICH!, US-1611156!, US-3160925!).

Culms (95–)110–170 cm tall. Leaf blades 25–64 cm long, 4–8(–9) mm wide, flat or loosely folded. Panicles 50–70 cm long, 18–40 cm wide, open; primary branches 15–25 cm long below, ascending spreading to reflexed.

Distribution and habitat.—*Eragrostis hirta* var. *longiramea* occurs in dry, rocky soils along oak forest borders and streams known only from Tamaulipas, Nuevo León, and San Luis Potosí; 50–2300 m.

Specimens examined. **MEXICO. Nuevo León:** Municipio de Galeana, Sierra Madre Oriental, Pablillo, *F.W. Pennell 17033* (MEXU), Municipio de Garza García, road to Chipinque Mesa, *I.K. Langman 2855* (MEXU, PH, US). **Tamaulipas:** Municipio de Casas, road to Rancho "Las Yucas" and Santa María de Los Nogales, *F. Martínez Martínez & G. Borja Luyando F-1938* (TAES, US); Municipio de Soto La Marina, Ejido Verde Grande, *J.F. Iribe-Duarte 330* (COCA).

11. Eragrostis hypnoides (Lam.) Britton, Sterns & Poggenb., Prelim. Cat. 69. 1888. (**Fig. 9, A–C**). *Poa hypnoides* Lam., Tabl. Encycl. 1: 185. 1791. *Megastachya hypnoides* (Lam.) P. Beauv., Ess. Agrostogr. 74, 167, 175. 1812. *Neeragrostis hypnoides* (Lam.) Bush, Trans. Acad. Sci. St. Louis 13:180. 1903. *Erosion hypnoides* (Lam.) Lunell, Amer. Midl. Naturalist 4:221. 1915. TYPE: Tropical America, *D. Richard s.n.* (HOLOTYPE: P-LAM!; ISOTYPES: BAA-1041!, NY fragm. ex P, US-2850742 fragm. ex P!).

Stoloniferous annuals, mat-forming, without innovations, without glands. Culms decumbent and rooting at the lower nodes, erect portion (2–)5–12(–20) cm tall, often branched, glabrous or hairy on the lower internodes. Leaf sheaths

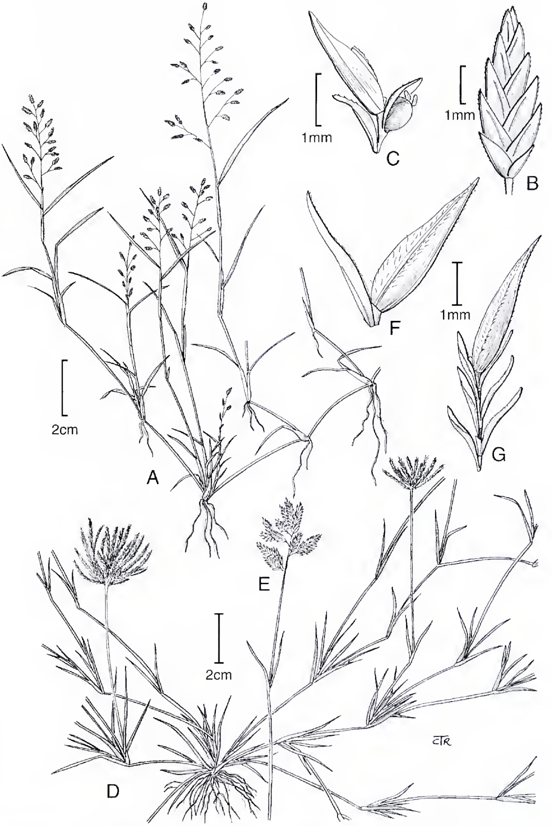

Fig. 9. *Eragrostis hypnoides*. **A.** Habit. **B.** Spikelet. **C.** Floret with two paleas below and caryopsis. *Eragrostis reptans*. **D.** Habit (female). **E.** Inflorescence (male) and culm. **F.** Floret (male) with palea below. **G.** Floret (female) with paleas below.

overlapping below, usually 1/3–1/2 as long as the internodes above, pilose on the margins, collars, and at the apices, hairs 0.1–0.6 mm long; ligules 0.3–0.6 mm long; blades 0.5–2.5 cm long, 1–2 mm wide, flat to involute, abaxial surfaces glabrous, adaxial surfaces appressed pubescent, hairs about 0.2 mm long. Panicles 1–3.5 cm long, 0.7–2.5 cm wide, terminal and axillary, ovate, open to somewhat congested; primary branches 0.1–0.5 cm long, appressed to strongly divergent, glabrous; pulvini sparsely pilose or glabrous; pedicels 0.2–1 mm long, ciliate. Spikelets 4–13 mm long, 1–1.5 mm wide, linear-oblong, often arcuate, loosely imbricate, greenish-yellow to purplish, with 12–35 florets; disarticulation acropetal, paleas persistent; glumes linear-lanceolate to lanceolate, hyaline; lower glumes 0.4–0.7 mm long; upper glumes 0.8–1.2 mm long; lemmas 1.4–2 mm long, ovate, strongly 3-veined, veins greenish, apices acuminate; paleas 0.7–1.2 mm long, hyaline, keels scabridulous, apices acute to obtuse; stamens 2; anthers 0.2–0.3 mm long, brownish. Caryopses 0.3–0.5 mm long, ellipsoid, somewhat translucent, light brown. $2n = 20$.

Distribution and habitat.—*Eragrostis hypnoides* grows along muddy or sandy shores of lakes and rivers and in moist, disturbed sites; 10–1600 m. It is native to the Americas, extending from southern Canada to Argentina.

Comments.—*Eragrostis hypnoides* is characterized by having a mat-like growth form only 5–20 cm tall with stoloniferous branches that root at the nodes. It is morphologically similar to *E. reptans* but differs by having bisexual florets and only two anthers 0.2–0.3 mm long.

Specimens examined **MÉXICO. Coahuila:** Municipio de Castaños, Presa Rodríguez, *E. Pérez-Torres* (COCA). **Nuevo León:** Municipio de Linares, Presa El Porvenir, *J.J. Ortíz-Díaz 8* (ANSM). **Tamaulipas:** Municipio de Aldama, km 15 carretera Estación Manuel-Aldama (Instituto Nacional de Investigaciones Forestales Agropecuarias y Pesqueras-Secretaria de Agricultura y Recursos Hidráulicos), *A. Brito s.n.* (UAT); Municipio de Soto La Marina, Chamal, *J.R. Swallen 1723* (US), Municipio de Tula, Joya de la Escondida, *G. Bores-Kulman 74* (COCA); Municipio de Victoria, area de la Torre de la Forestal, *J.G. Galván-Infante 307* (COCA).

12. Eragrostis intermedia Hitchc., J. Wash. Acad. Sci. 23:450. 1933. (**Fig. 10, A–C**). TYPE: U.S.A. TEXAS: Bexar Co.: San Antonio, 3 Jul 1910, *A.S. Hitchcock 5491* (HOLOTYPE: US-1535749!; ISOTYPES: US-908993!, US-1535750!).

Caespitose perennials, with innovations, not glandular. Culms (30–)40–90(–110) cm tall, erect, glabrous below the nodes. Leaf sheaths overlapping, 1/2 to about as long as the internodes below, sparsely pilose on the margins, apices hairy, hairs to 8 mm long, not papillose-based; ligules 0.2–0.4 mm long; blades (4–)10–20(–30) cm long, 1–3 mm wide, flat or involute, abaxial surfaces glabrous, adaxial surfaces densely hairy behind the ligules, elsewhere usually glabrous, occasionally sparsely hairy. Panicles 15–40 cm long, (8.5–)15–30 cm wide, ovate, open; primary branches 4–25 cm long, diverging 20–90° from the rachises, capillary; pulvini hairy or glabrous; pedicels 2–14 mm long, divergent. Spikelets 3-

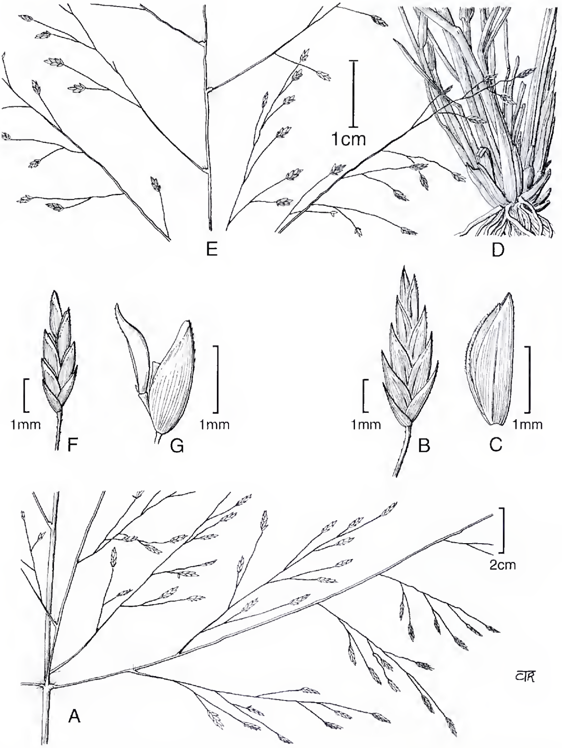

Fig. 10. *Eragrostis intermedia*. **A.** Inflorescence. **B.** Spikelet. **C.** Floret. *Eragrostis lugens*. **D.** Base of plant. **E.** Inflorescence. **F.** Spikelet. **G.** Floret with palea above.

7 mm long, 1–1.8 mm wide, narrowly lanceolate, olivaceous to purplish, with (3–)5–11 florets; disarticulation acropetal, paleas persistent; glumes lanceolate to ovate, hyaline to membranous; lower glumes 1.1–1.7 mm long, narrower than the upper glumes; upper glumes 1.3–2 mm long, apices acuminate to acute; lemmas 1.6–2.2 mm long, ovate, membranous, hyaline near the margins, lateral veins inconspicuous, apices acute; paleas 1.4–2.1 mm long, hyaline, narrower than the lemmas, apices obtuse to acute; stamens 3; anthers 0.5–0.8 mm long, purplish. Caryopses 0.5–1.0 mm long, rectangular-prismatic, somewhat laterally compressed, with a well-developed adaxial groove, striate, opaque, reddish-brown. $2n$ = ca. 54, 60, 72, ca. 74, 80, 100, 120.

Distribution and habitat.—*Eragrostis intermedia* is native to the Flora region and grows in clay, sandy, and rocky soils, often in disturbed sites; 0–2500 m. Its range extends from the United States through Mexico and Central America to South America. *Eragrostis intermedia* is similar to the more widespread *E. lugens*, but differs from that species in having wider spikelets, longer lemmas, and caryopses with a prominent adaxial groove.

Comments.—A numerical taxonomic study of the *Eragrostis intermedia* complex was completed by Witherspoon (1975) where he found much phenotypic overlap of individuals in his principal component and UPGMA cluster analyses of *E. intermedia* with *E. palmeri*, *E. erosa*, and *E. hirta*. Determination of these species is often problematic and examination of this group, which additionally includes *E. lugens* and *E. hirsuta*, is needed to clarify species boundaries. Presence or absence of papillose-based hairs near the apices and margins of the sheaths is the most reliable character to separate *E. hirta* and *E. hirsuta* from the others in this complex. Even though our key emphasizes the length of the lemma to separate *E. intermidia* (1.6–2.2 mm long), *E. erosa* (2.4–3 mm long), and *E. palmeri* (2–2.6 mm long), this character is somewhat variable in these species, and without the use of anther and caryopses length, it can be misleading. Our treatment is still very tentative and we encourage other agrostologists to investigate the evolutionary history within this group of species.

Specimens examined. **MEXICO. Coahuila:** Municipio de Acuña, Acuña, without collector (MEXU); near Santo Dominigo, *L.F. Wynd & C.H. 13. **Eragrostis lehmanniana** Nees, Fl. Afr. Austral. Ill. 402. 1841. (**Fig. 5, D & E**).

TYPE: SOUTH AFRICA: Cabo de Buena Esperanza, *J.F. Drège s.n.* (ISOTYPES: BM, LE).

Caespitose perennials, forming innovations at the basal nodes, without glands. Culms (20–)40–80 cm, erect, commonly geniculate, sometimes rooting at the lower nodes, glabrous, lower portions sometimes scabridulous. Leaf sheaths 1/3–2/3 the length of the internodes, sometimes shortly silky pilose basally, hairs less than 2 mm long, apices sparsely hairy, hairs to 3 mm long; ligules 0.3–0.5 mm long, ciliate; blades 2–12 cm long, 1–3 mm wide, flat to involute, glabrous, abaxial surfaces sometimes scabridulous, adaxial surfaces scabridulous. Panicles 7–18 cm long, 2–8 cm wide, oblong, open; primary branches 1–8 cm long, appressed or diverging to 40° from the rachises; pulvini glabrous; pedicels 0.5–4 mm long, diverging or appressed, flexible. Spikelets 5–12(–14) mm long, 0.8–1.2 mm wide, linear-lanceolate, plumbeous to stramineous, with 4–12(–14) florets; disarticulation irregular to basipetal, paleas usually persistent; glumes oblong to lanceolate, membranous; lower glumes 1–1.5 mm long; upper glumes 1.3–2 mm long; lemmas 1.5–1.7 mm long, ovate, membranous, lateral veins inconspicuous, apices acute to obtuse; paleas 1.4–1.7 mm long, obtuse; stamens 3; anthers 0.6–0.9 mm long, yellowish. Caryopses 0.6–0.8 mm long, ellipsoid to obovoid, dorsally compressed, sometimes with a shallow adaxial groove, smooth, translucent, mostly light brown, embryo region dark brown with a greenish ring. $2n = 40, 60$.

Distribution and habitat.—*Eragrostis lehmanniana* is introduced in the Flora region and native to southern Africa, where it grows in sandy, savannah habitats. In the Flora region, it grows in sandy flats, along roadsides, on calcareous slopes, and in disturbed areas; 1500–1830 m. It is commonly found in association with *Larrea tridentata*, *Opuntia*, *Quercus*, *Juniperus*, and *Bouteloua gracilis*.

Comments.—*Eragrostis lehmanniana* was introduced for erosion control in the southern United States, and now it often displaces native species throughout the New World.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Ramos Arizpe, Estación Experimental Forestal Z. A. "La Sauceda", *J.A. De la Cruz-Breton s.n.* (MEXU); Ramos Arizpe, *R. Palomo-Garza s.n.* (ANSM); Municipio de Saltillo, Buenavista, 7 km S de Saltillo, carretera 54 Saltillo-Concepción del Oro, Zacatecas, *J. Valdés-Reyna & M. A. Carranza P. 912, 915, 1819* (ANSM); 6 km S de Saltillo, entrada a la Universidad Autonoma Agraria Antonio Narro, J. Valdés-Reyna 2337 (US). **Nuevo León:** Municipio de Galeana, Navidad, carretera 57, km 85 al N de Saltillo, *F. Cárdenas & M. A. Bernal s.n.* (MEXU).

14. Eragrostis lugens Nees, Fl. Bras. Enum. Pl. 2:505-506. 1829. (**Fig. 10, D–G**). *Poa lugens* (Nees) Kunth, Enum. Pl. 1:331. 1833. *Eragrostis pilosa* var. *lugens* (Nees) Griseb., Abh. Königl. Ges. Wiss. Göttingen 24:290. 1879. TYPE: URUGUAY: Montevideo, *F. Sellow s.n.* [LECTOTYPE: US-732957!, designated by Witherspoon (1975) and not effectively published, accepted by Davidse (1994), and clarified by Boechat & Longhi-Wagner (2001); ISOLECTOTYPES: B, BM?, BAA-2932].

Caespitose perennials, with innovations, not glandular. Culms (20–)30–50 (–60) cm tall, erect, sometimes geniculate, glabrous below the nodes. Leaf sheaths overlapping, 1/2–2/3 as long as the internodes above, mostly glabrous, apices hairy, hairs 2–5 mm long, papillose-based, this sometimes not readily seen; ligules 0.2–0.3 mm long; blades (4–)8–22 cm long, 1–3.5 mm wide, involute to flat, both surfaces glabrous, margins sometimes with scattered hairs, hairs to 7 mm long. Panicles 16–28 cm long, 10–21 cm wide, ovate, open; primary branches 0.6–15 cm, diverging up to 100° from the rachises, naked basally; pulvini hairy; pedicels 1.4–5(–7) mm long, diverging, wiry, present on all spikelets. Spikelets 2–4.5(–5) mm long, 0.5–1(–1.3) mm wide, narrowly lanceolate, plumbeous to reddish-purple, with 2–7 florets; disarticulation acropetal, paleas persistent; glumes broadly ovate to narrowly lanceolate, hyaline, sometimes reddish-purple; lower glumes 0.6–1 mm long; upper glumes 1.1–1.4 mm long, usually broader than the lower glumes; lemmas 1.2–1.6 mm long, broadly ovate, mostly membranous but the distal margins hyaline, lateral veins inconspicuous, apices acute; paleas 1.1–1.7 mm long, membranous to hyaline, apices obtuse; stamens 3; anthers 0.2–0.7 mm long, reddish-purple. Caryopses 0.5–0.6 mm long, obovoid to somewhat prism-shaped, terete to somewhat laterally compressed, with an adaxial groove, finely striate, usually opaque, faintly reddish-brown to whitish. $2n = 40, 80$, ca. 108.

Distribution and habitat.—*Eragrostis lugens* is native to the Flora region and grows in montane areas along roadsides and waste places; 0–2500 m. Its range extends from the southern United States to Peru and Argentina.

Eragrostis limbata E. Fourn., Mexic. Pl. 2:116. 1886. TYPE: MÉXICO. 1833, *A.J.A. Bonpland 4573* [LECTOTYPE: P, designated by McVaugh (1983) but a specific herbarium not indicated!; ISOLECTOTYPE: US-2941517 fragm!].

Eragrostis neomexicana Vasey ex L.H. Dewey, Contr. U.S. Natl. Herb. 2(3):542. 1894. TYPE: U.S.A. NEW MEXICO: Organ Mountains, 1881, *G. Vasey 474* [LECTOTYPE: US-176631, designated by Koch and Sánchez-Vega (1985)!; ISOLECTOTYPES: K, US-822049!, US-909912!].

Caespitose annuals, without innovations. Culms 10–130 cm tall, erect, sometimes geniculate, glabrous, sometimes with a ring of glandular depressions below the nodes. Leaf sheaths 1/2–2/3 as long as the internodes, sometimes with glandular pits, pilose near the apices and on the collars, hairs to 4 mm long, papillose-based; ligules 0.2–0.5 mm long, ciliate; blades 5–25 cm long, 2–7(–9) mm wide, flat, abaxial surfaces glabrous, adaxial surfaces scabridulous, occasionally pubescent near the base. Panicles (5–)10–40 cm long, (2–)4–18 cm wide, less than 1/2 the height of the plant, ovate, rachises angled and channeled; primary branches 3–12(–15) cm, solitary to whorled, appressed or diverging to 80° from the rachises; secondary branches somewhat appressed; pulvini glabrous; pedicels 1–6(–7) mm long, almost appressed to narrowly divergent, stiff. Spikelets (4–)5–10(–11) mm long, 1.5–2.4 mm wide, ovate to oblong, gray-green to purplish, with 5–11(–15) florets; disarticulation acropetal; glumes subequal, 1.2–2.3 mm long, ovate to lanceolate, membranous; lemmas 1.2--2.4 mm long, ovate, membranous, glabrous or with a few hairs, gray-green, lateral veins evident, often greenish, apices acute; paleas 1–2.2 mm long, hyaline, keels scabrous, apices obtuse to truncate; stamens 3; anthers 0.2–0.5 mm long, purplish. Caryopses 0.5–0.8(–1) mm long, ovoid to rectangular-prismatic, laterally compressed, shallowly to deeply grooved on the adaxial surface, striate, reddish-brown, distal 2/3 opaque. $2n = 60$.

Distribution and habitat.—*Eragrostis mexicana* is native to the Flora region and grows along roadsides, near cultivated fields, and in disturbed open areas; 100–3000 m. *Eragrostis mexicana* subsp. *mexicana* grows from Ontario through the midwestern United States to California, South Carolina, and Texas and southwards to México, Central America, and northern South America to Argentina (Sanchéz Vega & Koch 1988).

Comments.—We follow Koch and Sánchez-Vega (1985) in the placement of *E. neomexicana* as a synonym of *E. mexicana* subsp. *mexicana*.

16. Eragrostis obtusiflora (E. Fourn.) Scribn., Bull. Div. Agrostol. U.S.D.A. 8:10, t.5. 1897. (**Fig. 11, A–C**). *Brizopyrum obtusiflorum* E. Fourn., Mexic. Pl. 2:120. 1886. MÉXICO. VERACRUZ: Orizaba (in ora occidentali), *Émy s.n.* (HOLOTYPE: P!).

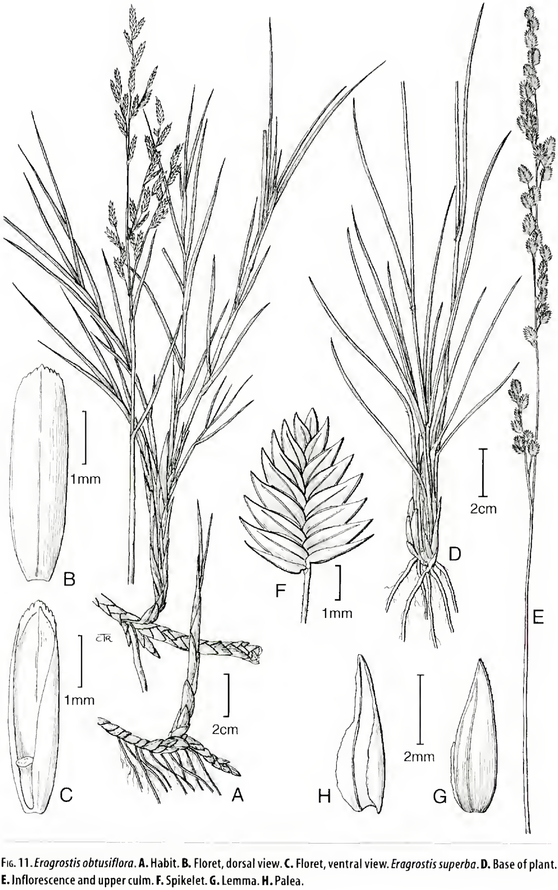

Fig. 11. *Eragrostis obtusiflora*. **A.** Habit. **B.** Floret, dorsal view. **C.** Floret, ventral view. *Eragrostis superba*. **D.** Base of plant. **E.** Inflorescence and upper culm. **F.** Spikelet. **G.** Lemma. **H.** Palea.

Perennials with scally, sharp-pointed rhizomes, with innovations, sometimes stoloniferous, the sharp-tipped rhizomes 4–8 mm thick. Culms 15–40(–50) cm tall, erect, stiff, hard, glaucus below the nodes. Leaf sheaths hairy at the apices, hairs to 2 mm long; ligules 0.2–0.4 mm long, membranous, ciliate; blades 2–15 cm long, (1–)2–4 mm wide, involute, arcuate, glabrous abaxially, scabrous adaxially, apices sharply pointed. Panicles 6–20(–24) cm long, 2–8(–12) cm wide, ovate, open or contracted; primary branches 1–8(–15) cm long, appressed or diverging up to 50° from the rachises; pulvini glabrous or not; pedicels 0–8 mm long, appressed, lower pedicels on each branch shorter than 1 mm long. Spikelets 8–14 mm long, 1.4–3 mm wide, ovate to lanceolate, stramineous with a reddish-purple tinge, with 5–10 florets; disarticulation basipetal, glumes persistent; glumes unequal, chartaceous; lower glumes 2.4–3.6 mm long; upper glumes 3–4.5 mm long, sometimes 3-veined; lemmas 3.8–4.5 mm long, ovate, leathery, 3–5-veined, lateral veins evident, greenish, upper margins hyaline, apices acute to obtuse, usually erose; paleas 3.8–4.5 mm long, membranous, keels scabridulous, apices obtuse to truncate; stamens 3; anthers 2–2.4 mm long, purplish to yellowish. Caryopses 1.6–2 mm long, ellipsoid, dorsally flattened, with a shallow adaxial groove, striate, reddish-brown. $2n = 40$.

Distribution and habitat.—*Eragrostis obtusiflora* is native to the southwestern United States and México. It grows in dry or wet alkali flats, often in association with *Distichlis* and *Sarcobatus*; 900–1400 m.

Comments.—*Eragrostis obtusiflora* was first described by Fournier (1886) in the genus *Brizopyrum* Link along with other species that are now included in *Distichlis* (*D. spicata* ssp. *stricta* Thorne), *Jouvea* [*J. pilosa* (J. Presl) Scribn.], and *Uniola* (*U. pittieri* Hack.). Ogden (1896) performed an anatomical survey of four grasses, *E. obtusiflora*, *Jouvea pilosa*, *J. straminea* E. Fourn., and *Distichlis spicata* (L.) Greene, all inhabitants of saline environments in southwestern North America. Ogden had originally thought that *E. obtusiflora* was conspecific with *Jouvea*. While all three of these species appear to be C_4 NAD-ME grasses, there are few unique anatomical features among each of these species. *Eragrostis obtusiflora* has a crown of colorless cells above each vein that separates it from the other three species. Even though Fournier (1886) and later Ogden (1896) noticed affinities of *E. obtusiflora* with *Distichlis*, *Jouvea*, and *Uniola*, all American agrostologists have followed Scribner's placement of this species in *Eragrostis*. Travis Columbus (per. comm.) has preliminary molecular sequence data that suggests *E. obtusiflora* is closely related to members of the Monanthochloinae that currently includes: *Distichlis*, *Monanthochloe*, and *Reederochloa* (Peterson et al. 2005).

Specimens examined. **MÉXICO. Coahuila:** Municipio de Ramos Arizpe, Predio La Esmeralda, *P. Moya-Salgado 440* (COCA); Municipio de Sierra Mojada, 80 (air) mi E of Saucillo, Chihuahua, W side of Laguna Jaco, *J. Henrickson 14202* (TEX-LL).

17. Eragrostis palmeri S. Watson, Proc. Amer. Acad. Arts 18:182. 1883. (**Fig. 7, D–G**). Type: MÉXICO. Coahuila: Juárez, on the Sabinas River, Sep-Oct 1880, *E. Palmer 1368* (holotype: GH; isotypes: US-1761635!, US-821984!).

Eragrostis caudata E. Fourn., Mexic. Pl. 2:115. 1886, nom. illeg. hom. Type: MÉXICO: Consoquitla, Aug 1841, *F.M. Liebmann 520* (syntypes: C, US-207543 fragm!); near Matamoras, Sep 1851, *J.L. Berlandier 2345* (syntypes: MO-129490!, US-911405 fragm!, US-77390 fragm!).

Caespitose perennials, with innovations and knotty bases, not glandular. Culms 50–90(–120) cm tall, glabrous below the nodes. Leaf sheaths overlapping, 1/2 to about as long as the internodes below, villous and the hairs not papillose-based, or mostly glabrous, apices hairy, hairs to 5 mm long, not papillose-based; ligules 0.2–0.4 mm long; blades (14–)20–35 cm long, 1–2.4 mm wide, involute, abaxial surfaces glabrous, adaxial surfaces scabridulous, sometimes sparsely hairy. Panicles 12–40 cm long, 4–20 cm wide, oblong, open; primary branches 2–20 cm long, diverging 20–70° from the rachises, capillary; pulvini glabrous or sparsely hairy; pedicels (0.4–)1–4(–14) mm long, appressed or diverging, only the terminal pedicels on each branch longer than 4 mm. Spikelets 4–6(–7.3) mm long, 1–2 mm wide, linear-lanceolate, plumbeous, with 5–12 florets; disarticulation acropetal, paleas persistent; glumes lanceolate to ovate, hyaline; lower glumes 1.1–1.8 mm long; upper glumes 1.2–2.2 mm long, exceeded by the basal lemmas; lemmas 2–2.6 mm long, ovate, membranous, hyaline towards the apices and margins, keels weak or strong, without glands, lateral veins from inconspicuous to conspicuous, apices acute; paleas 1.7–2.4 mm long, hyaline, bases not projecting beyond the lemmas, apices truncate, often notched; stamens 3; anthers 0.6–1.3 mm long, yellowish to purplish. Caryopses 0.6–0.8 mm long, rectangular-prismatic to subellipsoid, laterally compressed, with a well-developed adaxial groove, faintly striate, opaque, reddish-brown. $2n = 40$.

Distribution and habitat.—*Eragrostis palmeri* is native to the Flora region and grows on rocky slopes and hills generally in association with *Pinus edulis*, *Juniperus monosperma*, *Bouteloua gracilis*, and *Prosopis*; 300–2150 m. Its range extends from the Oaxaca to the southwestern United States.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Canstaños, Paso de San Lázaro, Sierra de la Gavia, 37.6 mi S of Monclova on Hwy 57, *P.M. 18. Eragrostis pectinacea (Michx.) Nees, Fl. Afr. Austral. Ill. 406. 1841. *Poa pectinacea* Michx., Fl. Bor.-Amer. 1:69. 1803. *Eragrostis pectinacea* (Michx.) Steud., Syn. Pl. Glumac. 1:272. 1854, *isonym*. TYPE: U.S.A. ILLINOIS: *Michaux s.n.* (HOLOTYPE: P-MICH!; ISOTYPE: US-2851264 fragm. ex P!).

Caespitose annuals, without innovations, without glandular pits. Culms 10–80 cm tall, erect to geniculate or decumbent below, glabrous. Leaf sheaths overlapping below, 1/2–3/4 as long as the internodes above, hirsute at the apices, hairs to 4 mm long; ligules 0.2–0.5 mm long; blades 2–20 cm long, 1–4.5 mm wide, flat to involute, abaxial surfaces glabrous and smooth, adaxial surfaces scabridulous. Panicles 5–25 cm long, 3–12(–15) cm wide, ovoid to pyramidal, usually open, sometimes contracted; primary branches 0.6–8.5 cm long, appressed or diverging to 80° from the rachises, solitary or paired at the lowest 2 nodes; pulvini glabrous or sparsely hairy; pedicels 1–7 mm long, flexible, appressed to widely divergent, sometimes capillary. Spikelets 3.5–11 mm long, 1.2–2.5 mm wide, linear-oblong to narrowly lanceolate, plumbeous, yellowish-brown, or dark reddish-purple, with 6–22 florets; disarticulation acropetal, paleas persistent; glumes subulate to ovate-lanceolate, hyaline; lower glumes 0.5–1.5 mm long, at least 1/2 as long as the adjacent lemmas; upper glumes 1–1.7 mm long, usually broader than the lower glumes; lemmas 1–2.2 mm long, ovate-lanceolate, hyaline to membranous, grayish-green proximally, reddish-purple distally, lateral veins moderately conspicuous, apices acute; paleas 1–2 mm long, hyaline to membranous, keels scabridulous, apices obtuse; stamens 3; anthers 0.2–0.4 mm long, purplish. Caryopses 0.5–1.1 mm long, pyriform, slightly laterally compressed, smooth, faintly striate, brownish. $2n = 60$.

Distribution and habitat.—*Eragrostis pectinacea* is native from southern Canada to Argentina. In the Flora region, it grows in disturbed sites such as roadsides, railroad embankments, gardens, and cultivated fields; 0–2400 m.

KEY TO THE VARIETIES OF *ERAGROSTIS PECTINACEA*

1. Pedicels appressed, rarely diverging to 20° from the rachises ____________ **18a. E. pectinacea** var. **pectinacea**
1. Pedicels widely divergent, usually diverging 20–60° from the rachises ______ **18b. E. pectinacea** var. **miserrima**

18a. Eragrostis pectinacea (Michx.) Nees var. **pectinacea (Fig. 12, A–C)**.

Eragrostis diffusa Buckley, Proc. Acad. Nat. Sci. Philadelphia 14:97. 1862. *Eragrostis purshii* var. *diffusa* (Buckley) Vasey, Contr. U.S. Natl. Herb. 1:59. 1890. Type: U.S.A. Texas: *S.B. Buckley* (lectotype: PH; isolectotype: US-91621, designated by Hitchcock, Man, Grasses U.S. 849. 1935 without citing a specific sheet or a specific herbarium!).

Pedicels appressed or diverging to 20° from the branch axes.

Distribution and habitat.—*Eragrostis pectinacea* var. *pectinacea* grows throughout the range of the species, including most of the states within México.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Cuatrociénegas, Sierra de San Marcos, áreas cercanas a la Poza de La Becerra, *A. Inflorescence. *Eragrostis pilosa* var. *pilosa*. **E.** Inflorescence and upper culm with a blade. **F.** Rachis just below first inflorescence branch showing glandular band. **G.** Inflorescence. **H.** Spikelet. *Eragrostis pilosa* var. *perplexa*. **I.** Sheath and blade with glands. **J.** Portion of the blade with glands.

Pedicels widely divergent, usually spreading 20–60° from the branches.

Distribution and habitat.—*Eragrostis pectinacea* var. *miserrima* grows in the southern United States, from Texas to Florida, and south throughout México to the lowland tropics of Brazil.

Comments.—We follow Reeder (1986) in the placement of *E. arida*, *E. delicatula*, and *E. tephrosanthos* as synonyms of *E. pectinacea* var. *miserrima*.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Arteaga, 1 mi SE of San Antonio de las Alazanas, *F.W. Gould & D. 19. Eragrostis pilosa (L.) P. Beauv., Ess. Agrostogr. 71:162, 175. 1812. *Poa pilosa* L., Sp. Pl. 1:68. 1753. TYPE: ITALY. 9–10 Aug 1902, *A. Kneucker, Gram. Exsicc. XII, 344* (EPITYPES: B, designated by H. Scholz in Cafferty et al., Taxon 49:256. 2000; US-557051!).

Poa eragrostis Walter, Fl. Carol. 80. 1788, nom. illeg. hom. TYPE: U.S.A. SOUTH CAROLINA.

Eragrostis filiformis Link, Hort. Berol. 1:191. 1827. *Poa linkii* Kunth, Révis. Gramin. 1:113. 1829. *Eragrostis linkii* (Kunth) Steud., Syn. Pl. Glumac. 1:273. 1854, nom. illeg. superfl. TYPE: America Boreali (ISOTYPE: US-91380 fragm. ex herb. Elliott!).

Caespitose annuals, without innovations. Culms 8–45(–70) cm tall, erect or geniculate, glabrous, occasionally with a few glandular depressions. Leaf sheaths overlapping below, about 1/2 as long as the internodes, mostly glabrous, occasionally glandular, apices hirsute, hairs to 3 mm long; ligules 0.1–0.3 mm long, ciliate; blades 2–15(–20) cm long, 1–2.5(–4) mm wide, flat, abaxial surfaces glabrous, occasionally with glandular pits along the midrib, adaxial surfaces scabridulous. Panicles 4–20(–28) cm long, 2–15(–18) cm wide, ellipsoid to ovoid, diffuse; primary branches 1–10 cm long, diverging 10–80°(–110°) from the rachises, capillary, whorled on the lowest 2 nodes, rarely glandular; pulvini glabrous or hairy; pedicels 1–10 mm long, flexible, appressed or divergent. Spikelets (2–)3.5–6(–10) mm long, 0.6–1.4 mm wide, linear-oblong to narrowly ovate, plumbeous, with (3–)5–17 florets; disarticulation acropetal, paleas tardily deciduous, rachillas persisting longer than the paleas; glumes narrowly ovate to lanceolate, hyaline; lower glumes 0.3–0.6(–0.8) mm long; upper glumes 0.7–1.2(–1.4) mm long; lemmas 1.2–2 mm long, ovate-lanceolate, membranous to hyaline, grayish-green proximally, reddish-purple distally, lateral veins inconspicuous, apices acute; paleas 1–1.6 mm long, membranous to hyaline, keels scabridulous to scabrous, apices obtuse; stamens 3; anthers 0.2–0.3 mm long, purplish. Caryopses 0.5–1 mm long, obovoid to prism-shaped, adaxial surfaces flat, smooth to faintly striate, light brown. 2*n* = 40.

KEY TO THE VARIETIES OF *ERAGROSTIS PILOSA*

1. Plants with numerous glandular pits scattered over the whole plant, especially on the midribs of the sheaths and blades; lemmas 1.8–2 mm long ____________ **19a. E. pilosa** var. **perplexa**
1. Plants with a few glandular pits scattered on the culms or without any glandular pits; lemmas 1.2–1.8 mm long ______________________________ **19b. E. pilosa** var. **pilosa**

19a. Eragrostis pilosa var. **perplexa** (L.H. Harv.) S.D. Koch, Illinois Biol. Monogr. 48:28. 1974. (**Fig. 12, I & J**). *Eragrostis perplexa* L.H. Harv., Bull. Torrey Bot. Club 81:409. 1954. TYPE: U.S.A. SOUTH DAKOTA. Mellette Co.: 30 Aug 1935, *W.L. Tolstead s.n.* (HOLOTYPE: US-1645027!; ISOTYPE: US-1649186!).

Culms with numerous glandular pits. Leaf sheaths with glandular pits; blades with glandular pits. Spikelets 0.6–1.4 mm wide; upper glumes 1–1.4 mm long; lemmas 1.8–2 mm long. Caryopses 0.8–1 mm long.

Distribution and habitat.—*Eragrostis pilosa* var. *perplexa* is a native variety known from widely scattered locations on moist soils in Wyoming, North Dakota, Nebraska, Colorado, northwestern Texas, and Tamaulipas; 10–300 m.

Specimens examined. **MÉXICO. Tamaulipas:** Municipio de Victoria, Camino a Santa Clara y Santa Rosa, *J.F. Iribe-Duarte 188* (COCA).

19b. Eragrostis pilosa var. **pilosa** (**Fig. 12E–H**).

Culms with few or no glandular pits. Leaf sheaths and blades without glandular pits. Spikelets 0.6–1.3 mm wide; upper glumes 0.7–1.2 mm long; lemmas 1.2–1.8 mm long. Caryopses 0.5–0.9 mm long.

Distribution and habitat.—*Eragrostis pilosa* var. *pilosa* is native to Eurasia but has become naturalized in many parts of the world. It is more common than *E. pilosa* var. *perplexa* in the Flora region and occurs along forest margins and disturbed sites such as roadsides, railroad embankments, gardens, and cultivated fields; 0–2100 m.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Saltillo, Poblado Los Ramones, *F. Pérez-Torres 32* (COCA); Terrenos de la Secretaría de Agricultura y Recursos Hidráulicos, *M.E. Megastachya fasciculata E. Fourn., Mexic. Pl. 2:120. 1886. Type: MÉXICO: Matamoros, *J.L. Berlandier 2325* (isotype: US-2821451 fragm!).

Neeragrostis weigeltiana Bush, Trans. Acad. Sci. St. Louis 13(7):178. 1903. *Eragrostis weigeltiana* Bush, Trans. Acad. Sci. St. Louis 13: 180. 1903, *nom. altern.* Type: SURINAM: 1827, *Weigelt s.n.* (isotype: MO-116197 fragm. ex herb Bernhardi!).

Eragrostis capitata (Nutt.) Nash, Man. Fl. N. States 1042. 1901. *Poa capitata* Nutt., Trans. Amer. Philos. Soc., n.s., 5:146. 1835. Type: U.S.A. Arkansas: sand beaches of the Arkansas, *N. Nuttall* s.n. (isotype: US-2821449 fragm!).

Annuals; unisexual, pistillate and staminate plants morphologically similar; mat-forming, without innovations, without glands. Culms 5–20 cm tall, rooting at the lower nodes, erect or decumbent, glabrous, pilose, or villous, particularly below the panicles. Leaf sheaths mostly scabrous, margins sometimes with hairs 0.1–0.4 mm long; ligules 0.1–0.6 mm long; blades 1–4 cm long, 1–4.5 mm wide, flat or conduplicate, abaxial surfaces glabrous, adaxial surfaces appressed pubescent, hairs about 0.2 mm long. Panicles 1–3 cm long, 0.6–2.5 cm wide, terminal, ovate, contracted, exerted or partially included in the upper leaf sheaths, rachises somewhat viscid, pilose or glabrous; primary branches 0.5–1.5 cm long, appressed to the rachises, each terminating in a spikelet; pulvini sparsely pilose or glabrous; pedicels 0.2–2 mm long, shorter than the spikelets, glabrous or hairy. Spikelets 5–26 mm long, 1.5–4.7 mm wide, linear to ovate, greenish to stramineous, with 16–60 florets; disarticulation in the pistillate florets basipetal, the lemmas falling separately, staminate spikelets not or tardily disarticulating; glumes unequal, ovate, hyaline, glabrous or sparsely hirsute; lower glumes 0.8–1.6 mm long, 1-veined; upper glumes 1.5–2.5 mm long, 1–3-veined; lemmas (1.5–)1.8–4 mm long, ovate, hyaline to membranous, lateral veins conspicuous, greenish, apices acute to acuminate, sometimes prolonged into a mucro, mucros to 0.4 mm long; paleas 0.7–3.8 mm long, hyaline, about 1/2 as long as the lemmas in pistillate florets, as long as the lemmas in staminate florets, keels scabridulous; stamens 3; anthers 1.4–2.2 mm long, reddish to yellowish. Caryopses 0.4–0.6 mm long, ellipsoid, somewhat laterally compressed, smooth, light reddish-brown. $2n = 60$.

Distribution and habitat.—*Eragrostis reptans* is native to the Flora region and grows in wet sand, gravel, and clay soils along rivers and lake margins from southcentral United States to northeastern México, frequently with *Cynodon dactylon* and *Heliotropium*; 0–1350 m.

Comments.—*Eragrostis reptans* is unique among the species of *Eragrostis* in the Flora region because it is unisexual with male and female plants that can easily be mistaken for two separate species. The male plants have florets with well developed anthers (1.4–2.2 mm long), lack caryopses, and have spikelets that are arranged in a loose panicle. The female plants have florets that lack stamens or have stamens with rudimentary anthers, develop mature caryopses, and have spikelets that are arranged in a tight panicle, at first glance appearing to be inserted digitately.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Juárez, Presa Don Martín, *L.H. Harvey 927 & 929*(US), *F.W. Gould 11242* (TEX-LL), *Valdés-Reyna & L.E. Rodríguez G. 1926* (ANSM); Municipio de Progreso, 38 mi SE of Sabinas along Hwy 22, NE side of Venustiano Carranza Lake, *P.M. Peterson & J. Valdés-Reyna 8375* (ANSM, US). **Nuevo León:** 48 km S of Nuevo Laredo on road to Monterrey, *T.C. & E.M. Frye 2345* (US). **Tamaulipas:** Municipio de Matamoros, Ejido El Soliseño, *J. Cantu 32* (COCA).

21. Eragrostis secundiflora subsp. **oxylepis** (Torr.) S.D. Koch, Rhodora 80(823):397. 1978. (**Fig. 6, D & E**). *Poa interrupta* Nutt., Trans. Amer. Philos. Soc., n.s., 5:196. 1837, *nom. illeg. hom. Poa oxylepis* Torr., Explor. Red River Louisiana 301, t. 19. 1853. *Eragrostis oxylepis* (Torr.) Torr., Pacif. Railr. Rep. 4:156. 1857. *Megastachya oxylepis* (Torr.) E. Fourn., Mexic. Pl. 2:118. 1886. TYPE: U.S.A. ARKANSAS: near the sandy banks of the Arkansas River, *Nuttall s.n.* (HOLOTYPE: PH).

Caespitose perennials, with innovations, not glandular. Culms 30–75 cm tall, erect, glabrous below. Leaf sheaths overlapping below, 1/2 as long as the internodes above, mostly glabrous, hairy at the apices, hairs to 4 mm long; ligules 0.2–0.3 mm long; blades 10–25(–40) cm long, 1–5 mm wide, involute, glabrous abaxially, scabridulous adaxially, sometimes also sparsely pilose. Panicles (3–) 5–30 cm long, 1–15 cm wide, from narrowly oblong, glomerate, and interrupted below to ovate and open; primary branches 0.5–12(–16) cm, appressed or diverging up to 40° from the rachises, stiff; pulvini glabrous or sparsely hairy; pedicels 0–1(–3) mm, appressed, flattened. Spikelets 6–16(–23) cm long, 2.4–5 mm wide, ovate to linear-elliptic, flattened, stramineous, with reddish-purple margins or completely reddish-purple, with 10–45 florets; disarticulation basipetal, florets falling intact and before the glumes; glumes ovate-lanceolate to lanceolate, membranous; lower glumes 1.7–3 mm long; upper glumes 2.2–4 mm long, apices acuminate; lemmas 2–6 mm long, ovate, membranous to leathery, apices usually acuminate or attenuate, sometimes acute; paleas 1.5–3 mm long, membranous to leathery, narrower than the lemmas, apices obtuse, sometimes bifid; stamens 2; anthers 0.2–0.5 mm long, brownish. Caryopses 0.8–1.3 mm long, ellipsoid, somewhat laterally flattened, smooth, reddish-brown. $2n = 40$.

Distribution and habitat.—There are two subspecies of *E. secundiflora*; plants from the Flora region belong to *E. secundiflora* subsp. *oxylepis* (Torr.) S.D. Koch. It is native to the Flora region and grows in sandy soils, dunes, grasslands, beaches, and roadsides; 0–300 m. The range of *E. secundiflora* extends into southern United States.

Caespitose perennials, with innovations, not glandular. Culms 30–90 cm tall, erect or decumbent, glabrous below the nodes. Leaf sheaths overlapping below, 1/2 to as long as the internodes above, hairy at the apices and on the collars, sometimes also on the distal portion of the margins, hairs to 5 mm long; ligules 0.4–0.5 mm long; blades 5–30 cm long, 1–3 mm wide, usually involute, sometimes flat, abaxial surfaces glabrous or sparsely pilose, hairs to 5 mm long, adaxial surfaces scabridulous. Panicles 20–65 cm long, 10–35 cm wide, ovate, open; primary branches 2–20(–24) cm long, widely spaced, diverging 20–100° from the rachises, not rebranched, naked basally; pulvini hairy; pedicels 0–12 mm long, appressed, proximal spikelets on each branch sessile or subsessile, the pedicels shorter than 0.4 mm long. Spikelets 5–13 mm long, 1.4–3 mm wide, oblong to oblanceolate, stramineous to reddish-purple, with 3–12 florets; disarticulation tardy, basipetal, in the rachilla below the florets, glumes persistent; glumes lanceolate, broad basally, indurate; lower glumes 2.5–6 mm long; upper glumes 3–6 mm long, apices acuminate; lemmas 3–5 mm long, narrowly ovate to lanceolate, indurate, apices acuminate; paleas 2.4–4.6 mm long, indurate, gibbous basally but the sides not projecting beyond the lemmas, keels ciliolate, apices obtuse; stamens 3; anthers 0.3–0.5 mm long, reddish-brown. Caryopses

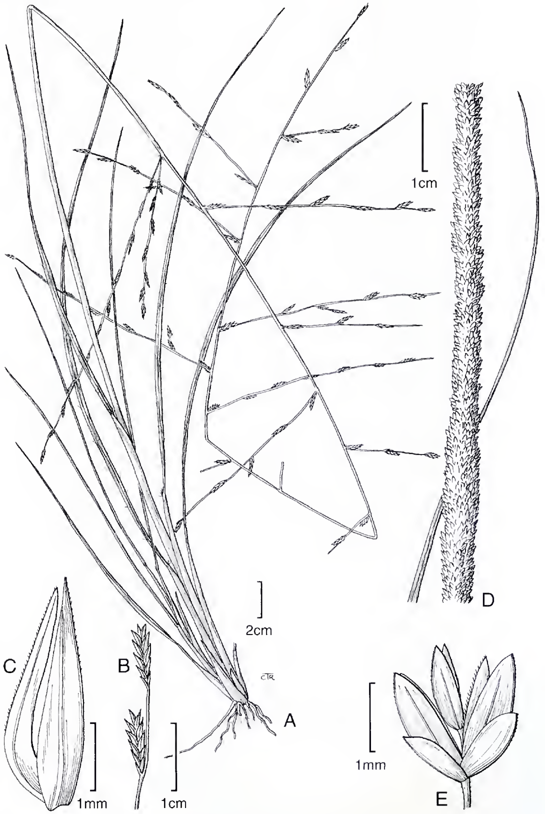

Fig. 13. *Eragrostis sessilispica*. **A.** Habit. **B.** Panicle branch with two spikelets. **C.** Floret. *Eragrostis spicata*. **D.** Infloresence (portion) and blade. **E.** Spikelet.

0.9–1.5 mm long, ovoid to pyriform, laterally flattened, tapering distally, smooth to faintly striate, brownish. $2n = 40$.

Distribution and habitat.—*Eragrostis sessilispica* is native to the Flora region and grows in prairies, limestone mesas, thorn forest openings, and grasslands, generally in sandy soils, at 0–300 m, often in association with *Prosopsis* and *Quercus*. Its range extends into Texas, New Mexico, Oklahoma, and Kansas.

Comments.—*Eragrostis sessilispica* is characterized by having panicle branches that are not rebranched and sessile or subsessile spikelets on the lower portions of each branch.

Specimens examined. **MÉXICO. Tamaulipas:** Municipio de Soto La Marina, Chamal, *J.R. Swallen 1739* (US-1502972); unknown Municipio, Buena Vista Hacienda, *E.O. Wooton s.n.* (US-1061799).

23. Eragrostis silveana Swallen, Amer. J. Bot. 19(5):438, f. 3. 1932. (**Fig. 4, C & D**).
TYPE: U.S.A. TEXAS Bexar Co.: 1–31 Oct 1931, *W.A. Silveus 360* (HOLOTYPE: US-1501596!; ISOTYPES, US-1501597!, US-1501598!, US-1501599!, US-1501600!).

Caespitose perennials, with innovations and short, knotty rhizomes less than 4 mm thick. Culms 45–60 cm tall, erect, often glandular below the nodes, sometimes viscid. Leaf sheaths overlapping, 1–2 times as long as the internodes, often viscid, sometimes sparsely pilose, hairy at the apices, hairs to 6 mm long; ligules 0.2–0.3 mm long; blades 8–25 cm long, 2–4 mm wide, flat to involute, glabrous, sometimes viscid. Panicles 20–35(–42) cm long, 10–22 cm wide, broadly ovate, open, bases included in the uppermost leaf sheaths; primary branches 5–14 cm long, diverging 20–90° from the rachises, capillary, sometimes viscid, naked basally; pulvini hairy, hairs to 6 mm long; pedicels (1–)1.5–12 mm, diverging or appressed. Spikelets (2.5–)3–4.8 mm long, 0.9–1.4 mm wide, linear-lanceolate, reddish-purple, with 4–9 florets; disarticulation basipetal, glumes persistent; glumes lanceolate, membranous; lower glumes 0.9–1.2 mm long; upper glumes 1–1.3 mm long; lemmas 1.1–1.4 mm long, ovate to lanceolate, membranous, lateral veins conspicuous, apices acute; paleas 1–1.4 mm long, hyaline, not wider than the lemmas, apices obtuse; stamens 3; anthers 0.2–0.3 mm long, purplish. Caryopses 0.5–0.6 mm long, ellipsoid, terete in cross section, neither ridged nor grooved, faintly striate, reddish-brown.

Distribution and habitat.—*Eragrostis silveana* is native to the Flora region and grows in various open habitats, from sandy prairies to clay loam flats, near roadsides, railroads, and fields; 0–1310 m. Its range is limited to the coastal plain of Texas and higher plains of eastern México.

Comments.—Morphologically, *E. silveana* is somewhat intermediate between *E. spectabilis* and *E. curtipedicellata*, and grows where the distribution of these two species overlaps. *Eragrostis silveana* can be separated from *E. curtipedicellata* by having long pedicels (1.5–12 mm long in the former verses 0.2–1.2 mm long in the latter), shorter lemmas (1.1–1.4 mm long verses 1.5–2.2 mm long), and shorter caryopses (0.5–0.6 mm long verses 0.6–0.8 mm long).

Eragrostis silveana differs from *E. spectabilis* by having viscid to glandular sheaths or blades, terete caryopses, and leathery lemmas.

Specimens examined. **MÉXICO. Nuevo León:** Municipio de Linares, 11 mi N of Linares, *M.C. Johnston & A.J. Graham 4642* (TEX-LL). **Tamaulipas:** Municipio de Casas, 64 km from Soto La Marina towards Casas and Victoria, *F. Martinez Martinez & G. 24. Eragrostis spectabilis (Pursh) Steud., Nomencl. Bot. (ed. 2) 1:564. 1840. (**Fig. 1, C–E**). *Poa amabilis* Walter, Fl. Carol. 80. 1788, nom. illeg. hom. *Poa spectabilis* Pursh, Fl. Amer. Sept. 1:81. 1814. *Megastachya spectabilis* (Pursh) Roem. & Schult., Syst. Veg. 2:589. 1817. *Poa hirsuta* var. *spectabilis* (Pursh) Torr., Fl. N. Middle United States 1(1):114. 1823. *Eragrostis pectinacea* var. *spectabilis* (Pursh) A. Gray, Manual (ed. 2) 565. 1856. *Erochloe spectabilis* (Pursh) Raf. ex B.D. Jacks., Index Kew. 1:886. 1893. TYPE: U.S.A. SOUTH CAROLINA: *Clayton 580* (ISOTYPE: US-2891488 fragm!).

Eragrostis geyeri Steud., Syn. Pl. Glumac. 1:272. 1854. *Poa pectinacea* Geyer ex Steud., Syn. Pl. Glumac. 1:272. 1854, hom. illeg. et nom. inval. TYPE: U.S.A. ILLINOIS: *C.A. Geyer s.n.* (ISOTYPE: US-2891474 fragm!).

Eragrostis spectabilis var. *sparsihirsuta* Farw., Amer. Midl. Naturalist 10:306. 1927. TYPE: U.S.A. MICHIGAN.

Eragrostis velutina Schrad., Linnaea 12:451. 1838. *Poa villosa* Beyr. ex Schrad., Linnaea 12(4):451. 1838, *nom. inval.* TYPE: U.S.A. CAROLINA: *Beyrich s.n.*

Caespitose perennials, with innovations and short, knotty rhizomes less than 4 mm thick. Culms 30–70(–85) cm tall, erect to ascending, often sprawling, glabrous. Leaf sheaths overlapping, hairy on the margins and at the apices, hairs to 7 mm long; ligules 0.1–0.2 mm long; blades 10–32 cm long, 3–8 mm wide, flat to involute, both surfaces usually pilose, sometimes glabrous on both surfaces or glabrous abaxially and sparsely pilose adaxially, often with a line of hairs behind the ligules, hairs to 8 mm long. Panicles (15–)25–45(–60) cm long, 15–35 cm wide, broadly ovate to oblong, open, basal portions sometimes included in the uppermost leaf sheaths; primary branches (6–)12–20 cm long, diverging 20–90° from the rachises, capillary, naked below; pulvini hairy, hairs to 6 mm long; pedicels 1.5–17 mm long, divergent or appressed. Spikelets 3–7.5 mm long, 1–2 mm wide, linear-lanceolate, reddish-purple, sometimes olivaceous, with (4–) 6–12 florets; disarticulation basipetal, glumes persistent; glumes (1–)1.3–2.3 mm long, subequal to equal, lanceolate, membranous to chartaceous; lemmas (1–) 1.3–2.5 mm long, ovate to lanceolate, leathery, 3-veined, apices acute; paleas (1–) 1.2–2.4 mm long, membranous, keels sometimes shortly ciliate, apices obtuse to truncate; stamens 3; anthers 0.3–0.5 mm long, purplish. Caryopses 0.6–0.8 mm long, ellipsoid, strongly flattened, adaxial surfaces with 2 prominent ridges separated by a groove, reddish-brown. $2n = 20, 40, 42$.

Distribution and habitat.—*Eragrostis spectabilis* is native in the Flora region, extending from southern Canada through the United States, México, and Belize.

It grows in fields and on the margins of woods, along roadsides, and in other disturbed sites, usually in sandy to clay loam soils, and is associated with hardwood forests, *Prosopsis-Acacia* grasslands, and shortgrass prairies; 0–1000 m.

Comments.—A showy species, *E. spectabilis* is available commercially for planting as an ornamental.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Nava, Río Grande Valley, just N of Río Escondido, 18 km SW of Piedras Negras on México Hwy 57, *H.H. Iltis & A. Lasseigne 16* (COCA); Municipio de Saltillo 18 km W of Saltillo, *A.A. Beetle M-418* (COCA). **Nuevo León:** Municipio de General Bravo, General Bravo, *J.A Ochoa-Guillemar 1166* (COCA); Municipio de Linares, Cañón Los Pinos, *T.S.P. s/n* (ANSM); without Municipio, Lampazos-Bustamante, *J.A. Ochoa-Guillemar 1224* (COCA). **Tamaulipas:** Municipio de Aldama, Ejido Lauro Aguirre, *P. Moya-Salgado 253* (COCA); km 10 a Barra del Tordo, *M.H. Cervera-Rosado 30* (COCA); Municipio de Casas, Predio González, *M.H. Cervera-Rosado 303* (COCA); Municipio de Victoria, Colonia La Estrella, Ciudad Victoria, *M. Cisneros 52* (COCA).

25. Eragrostis spicata Vasey, Bot. Gaz. 16(5):146. 1891. (**Fig. 13, D & E**). TYPE: MÉXICO. BAJA CALIFORNIA SUR: San José del Cabo, 12 Sep 1890, *T.S. Brandegee 10* (HOLOTYPE: US-1761638!).

Sporobolus tenuispica Hack., Repert. Spec. Nov. Regni Veg. 6(21–26):344. 1909. TYPE: PARAGUAY. GRAN CHACO: Pilcomayo, Jun, *T. Rojas 258* (HOLOTYPE: W; ISOTYPES: BAA-2931 fragm. ex herb. Hassler; US-2891485 fragm!).

Caespitose perennials, with innovations. Culms 75–100 cm tall, erect, glabrous. Leaf sheaths overlapping, about as long as the internodes above, hirtellous on the margins when immature, apices glabrous or hairy, the hairs shorter than 0.5 mm long; ligules 0.2–0.3 mm long; blades 20–40 cm long, 2–5(–6) mm wide, flat to involute, glabrous abaxially, scabrous adaxially. Panicles 22–40 cm long, 0.3–0.6 cm wide, spike-like, dense; primary branches shorter than 1.2 cm long, closely appressed, spikelet-bearing to the base; pulvini glabrous; pedicels 0.1–0.6 mm long, mostly appressed, hirtellous. Spikelets 1.4–2.2 mm long, 0.9–1.2 mm wide, ovate, stramineous to light greenish, with 2 or 3 florets; disarticulation basipetal, in the rachilla below the individual florets or at the base of the florets, glumes persistent; glumes elliptic to ovate, hyaline, keels ciliolate; lower glumes 0.7–1 mm long; upper glumes 0.9–1.3 mm long, apices obtuse; lemmas 1.5–2.1 mm long, ovate, membranous to hyaline, apices acute to obtuse; paleas 1.1–1.6 mm long, hyaline, not wider than the lemmas, apices obtuse; stamens 2; anthers 0.3–0.4 mm long, reddish-brown. Caryopses 0.7–1 mm long, ellipsoid, somewhat ventrally flattened, smooth to faintly striate, reddish-brown. $2n = 40$.

Distribution and habitat.—*Eragrostis spicata* is native to the Flora region and grows in moist areas in prairies, usually in deep, sandy, clay loam soils; 0–130 m. It is native from southern Texas to México and also found in Paraguay and Argentina. In North America, *E. spicata* grows with *Andropogon*, *Quercus stellata*, *Prosopsis glandulosa*, and *Acacia*.

Comments.—*Eragrostis spicata* is characterized by having a spike-like, narrow panicle (0.3–0.6 mm wide) with short closely appressed branches and 2- or 3-flowered spikelets.

Specimens examined. **MÉXICO. Tamaulipas:** Municipio de San Fernando, 23 mi from San Fernando-Matamoros Hwy, at Junction of road to Reynosa, *M.C. Johnston & A.J. Graham 4714* (TEX-LL); near Santa Teresa, 50 mi S of Matamoros, *M.C. Johnston & J. Crutchfield 5495* (TEX-LL, US); Municipio de Tampico, Tampico, *M.A. Madrigal-A. s.n.* (ANSM).

26. Eragrostis superba Peyr., Sitzungsber. Kaiserl. Akad. Wiss., Math.-Naturwiss. Cl. 38:584. 1860. (**Fig. 11, D–H**). TYPE: ANGOLA. Benguela, *Wawra 244* (HOLOTYPE: W).

Caespitose perennials, with innovations, without glands. Culms 45–95 cm tall, erect, glabrous. Leaf sheaths overlapping below, 1/3–1/2 the length of the internodes above, hairy at the apices and on the margins, hairs to 6 mm long; ligules 0.5–1.2 mm long; blades 7–30 cm long, 2.5–7 mm wide, flat to loosely involute, glabrous abaxially, scabrous adaxially, margins sharply scabrous. Panicles 10–30 cm long, 1–6 cm wide, oblong, condensed, interrupted below; primary branches 1–11 cm long, appressed or diverging to 40° from the rachises, naked basally; pulvini glabrous; pedicels 0.5–25 mm long, with a narrow band or abscission line below the apices. Spikelets 5.5–16 mm long, 2.7–9 mm wide, ovate, flattened, greenish to stramineous, sometimes with a reddish-purple tinge, with 4–22 florets; disarticulation below the glumes, spikelets falling intact; glumes equal, 3–4.5 mm long, ovate, chartaceous; lemmas 3–5 mm long, broadly lanceolate, chartaceous to leathery, lateral veins green, apices acute; paleas 3–5 mm long, chartaceous to hyaline, keels broadly winged below, forming a' wing or tooth on each side that often projects beyond the lemma bases, apices acuminate; stamens 3; anthers 1.4–2.8 mm long, golden-yellow. Caryopses 1–2 mm long, ellipsoid, adaxial surfaces flattened, reddish-brown. $2n = 40$.

Distribution and habitat.–*Eragrostis superba* is introduced to the Flora region and native to Africa, where it is grown for hay, being fairly palatable and drought resistant. It is also used for erosion control and re-vegetation. In the Flora region, *E. superba* grows on rocky slopes, in sandy flats, and along roadsides, often with *Acacia, Prosopsis, Fouquieria splendens, Juniperus*, and *Quercus*; 480–1900 m.

Comments.—In addition to having very large spikelets (5.5–16 mm long and 2.7–9 mm wide), *Eragrostis superba* has winged paleas that often project beyond the lemmas when viewed laterally.

Specimens examined. **MÉXICO. Coahuila:** Municipio de Ramos Arizpe, Campo experimental de Zonas Áridas La Sauceda, *L. Luan-Olague s.n.* (ANSM); Municipio de Saltillo, Buenavista, 7 km S de Saltillo, *Valdés-Reyna s.n.* (ANSM); Cañón de San Lorenzo, 5 km de Saltillo hacia Zacatecas, *M.A. Madrigal-A. s.n.* (MEXU). **Tamaulipas:** Municipio de Llera, La Angostura, Llera-Victoria, *J.F. Iribe-Duarte 376* (COCA).

EXCLUDED SPECIES

Eragrostis swallenii Hitchc. has been reported from the Flora region (Beetle et al. 1991; Espejo-Serna et al. 2000), but no specimens supporting its presence have been located.

ACKNOWLEDGMENTS

We wish to thank the curators at the following herbaria for help locating specimens: COCA, MEXU, MO, TEX, UAT; the Smithsonian Institutions, Fellowships and Grants for supporting research visits by JVR to the United States National Herbarium; the Scholarly Studies Program, Research Opportunities, Atherton Seidell Foundation, and Biodiversity Surveys and Inventories Program all at the Smithsonian Institution for financial support; Utah State University for permission to use illustrations that appeared in Flora of North America, Volume 25, prepared by Linda A. Vorobik and Cindy Roché; Alice R. Tangerini for preparing illustrations for *Eragrostis hirta* and for preparing all the plates; Miguel Carranza for help preparing the specimens examined; and Kelly W. Allred, Yolanda Herrera Arrieta, and Barney Lipscomb for reviewing the manuscript.

ABSTRACT

A taxonomic treatment of *Trisetum* Pers. and *Graphephorum* Desv. in North America north of México is given. Eight species of *Trisetum* are recognized. Two species are endemic to the United States: *T. orthochaetum* (Montana) and *T. projectum* (California, Montana, and Nevada); *Trisetum cernuum* subsp. *cernuum*, *T. cernuum* subsp. *canescens*, *T. montanum*, *T. sibiricum*, *T. spicatum* var. *spicatum*, and *T. spicatum* var. *pilosiglume* are found in Canada and the United States; and *T. spicatum* var. *spicatum* and *T. spicatum* var. *pilosiglume* are found in Greenland. Two species, *T. aureum* and *T. flavescens*, are introduced. *Trisetum floribundum* Pilg. is chosen as a lectotype for *Trisetum* sect. *Aulacoa* Louis-Marie. The genus *Graphephorum* comprises only two species: *G. melicoides* ranging from Canada to the United States and *G. wolfii* endemic to the United States.

RESUMEN

En el presente artículo se presenta un tratamiento taxonómica para *Trisetum* Pers. y *Graphephorum* Desv. en Norteamérica norte de México. Se reconocen ocho especies de *Trisetum*. Dos de estas especies son endémicas de los Estados Unidos: *T. orthochaetum* (Montana) y *T. projectum* (California, Montana y Nevada). *Trisetum cernuum* subsp. *cernuum*, *T. cernuum* subsp. *canescens*, *T. montanum*, *T. sibiricum*, *T. spicatum* var. *spicatum* y *T. spicatum* var. *pilosiglume* se encuentran en Canadá y los Estados Unidos; y *T. spicatum* var. *spicatum* y *T. spicatum* var. *pilosiglume* se encuentran en Groenlandia. Dos especies, *T. aureum* y *T. flavescens*, han sido introducidas. *Trisetum floribundum* Pilg. se elige como lectotipo para *Trisetum* secc. *Aulacoa* Louis-Marie. El género *Graphephorum* comprende sólo dos especies: *G. melicoides*, que se encuentra desde Canadá hasta los Estados Unidos y *G. wolfii*, endémico de los Estados Unidos.

Trisetum includes approximately 40 species and several infraspecific taxa in the Americas and is distributed from Greenland (70°N) to southern South America (55°S) [Clebsch 1960; Hultén 1959; Nicora 1978, Finot 2003a, Finot et al. 2004). There are two endemic species of *Trisetum* in the Hawaiian Islands: *T. glomeratum* (Kunth) Trin. ex Steud. and *T. inaequale* Whitney (O'Conner 1990). We recognize eight species and two varieties in North America (excluding México), 17 species in México and Central America, and 18 species and seven varieties in South America (Finot 2003a; Finot 2004; Finot et al. 2004). *Trisetum* is also present in Europe, Asia, Australia, and New Zealand (Jonsell 1980; Tsvelev 1983; Clayton & Renvoize 1986; Pohl & Davidse 1994; Tucker 1996; Edgar 1998; Soreng et al. 2003; Finot et al. 2004, 2005). The genus seems to be absent in Africa (Clayton & Renvoize 1986). Although several species were described for Africa (Steudel 1854), they were later transferred to *Helictotrichon* Besser ex Schult. & Schult. f. (Hubbard 1936; Schweickerdt 1939).

TAXONOMIC HISTORY OF NORTH AMERICAN SPECIES

One of the earliest treatments of *Trisetum* was made by Steudel (1854), who recognized five North American taxa: *T. cernuum* Trin., *T. groenlandicum* Steud. [=*T. spicatum* (L.). K. Richt. var. *spicatum*], *T. labradoricum* Steud. (*T. spicatum* var. *spicatum*), *T. molle* Kunth (*T. spicatum* var. *spicatum*), and *T. palustre* (Michx.) Torr. [=*Sphenopholis pensylvanica* (L.) Hitchc.]. Buckley (1862) described three new species for North America: *Trisetum glabrum* Buckley [= *Deschampsia danthonioides* (Trin.) Munro], *T. interruptum* Buckley [= *Sphenopholis interrupta* (Buckley) Scribn.], and *T. canescens* Buckley, sometimes referred to as a variety or subspecies of *T. cernuum* (Beal 1896; Calder & Taylor 1965), or to *Helictotrichon canescens* (Buckley) Clayton. A new species described by Scribner (1884), *T. hallii* Scribn., is now considered a synonym of *Sphenopholis interrupta* (Buckley) Scribn. (Finot et al. 2004). Beal (1896) presented a treatment of *Trisetum* in North America (those found only in México and/or countries south are marked with an asterisk) that included the following 15 species: *T. cernuum*, *T. deyeuxioides* (Kunth) Kunth*, *T. elongatum* (Kunth) Kunth, *T. filifolium* Scribn. ex Beal*, *T. hallii* Scribn., *T. ludovicianum* Vasey, *T. montanum* Vasey, *T. palustre*, *T. paniculatum* E. Fourn. [= *Trisetum viride* (Kunth) Kunth]*, *T. pratense* Pers. [= *Trisetum flavescens* (L.) P. Beauv.], *T. sandbergii* Beal, *T. sesquiflorum* Trin., *T. spicatum*, *T. tolucense* (Kunth) Kunth (= *Trisetum spicatum* var. *spicatum*), and *T. virletii* E. Fourn.* Five of these species included in Beal's treatment were later transferred to other genera: *Trisetum palustre*, *T. ludovicianum*, and *T. hallii* to *Sphenopholis* (Scribner 1906; Erdman 1965); *T. deyeuxioides* to *Peyritschia* (Finot 2003b); and *T. sesquiflorum* to *Calamagrostis* (Rozhevits 1962; Soreng & Greene 2003). Beal (1896) also described a new species, *T. sandbergii* from Mt. Stuart, Washington, now considered a synonym of *T. cernuum* Trin. (Hitchcock 1939; Hitchcock 1950; Finot 2003a). Beal (1896) recognized *T. montanum* as a valid species. It was later treated, however, as a synomym of *T. spicatum* by several authors (Hitchcock 1928; Weber 1976).

Karl Richter (1890), an Austrian botanist recognized that *Trisetum* *subspicatum* (L.) P. Beauv. was an illigitimate homonym since it was based on *Aira spicata* L., and therefore, made the combination, *Trisetum spicatum*. Beal (1896) was the first North American agrostologist to use *Trisetum spicatum*. Scribner and Merril (1902) described a new species for the flora of North America, *T. congdonii* Scribn. & Merr., a synonym of *T. spicatum* in modern treatments. Several differences between *T. congdonii* and *T. spicatum* listed by the authors included more rigid leaves, narrower glumes, more scabrous lemmas and longer awns. Since the extent of variation of *T. spicatum* is great, we feel these differences do not warrant recognition at the species level. For the central Rockies (Colorado) three species: *T. spicatum* (as *T. subspicatum*), *T. majus* Vasey ex Rydb. (= *T. spicatum*), and *T. montanum* Vasey, were reported by Rydberg (1906).

Louis-Marie (1928-29) in his taxonomic revision of *Trisetum* in America, included 15 species with several varieties in North America. In *Trisetum* subgen. *Heterolytrum* Louis-Marie sect. *Anaulacoa* Louis-Marie subsect. *Trisetum* (as "*Eutriseta*"), he included *Trisetum montanum* [including two varieties: *T. montanum* var. *pilosum* Louis-Marie and *T. montanum* var. *shearii* (Scribn.) Louis-Marie], *T. cernuum* [including *T. cernuum* var. *luxurians* Louis-Marie, *T. cernuum* var. *luxurians* fo. *pubescens* Louis-Marie, and *T. cernuum* var. *sandbergii* (Beal) Louis-Marie], *T. canescens* Buckley (including *T. canescens* fo. *tonsum* Louis-Marie and *T. canescens* fo. *velutinum* Louis-Marie), *T. projectum* Louis-Marie, *T. sesquiflorum*, *T. bongardii* Louis-Marie [= *Calamagrostis sesquiflora* (Trin.) Tzvelev], *T. williamsii* Louis-Marie [= *Danthonia intermedia* Vasey], *T. spicatum* [including *T. spicatum* var. *laxius* (Lange) Louis-Marie, *T. spicatum* var. *majus* Farwell, *T. spicatum* var. *molle* (Michx.) Piper, *T. spicatum* var. *brittonii* (Nash) Louis-Marie, *T. spicatum* var. *pilosiglume* Fern., *T. spicatum* var. *alaskanum* (Nash) Malte ex Louis-Marie, *T. spicatum* var. *villosissimum* Lange], and *T. congdonii*. In *Trisetum* subsect. *Sphenophoidea* Louis-Marie he included *T. pennsylvanicum* (L.) P. Beauv. ex Roem. & Schult., *T. interruptum*, and *T. hallii*, now transferred back to *Sphenopholis* by Erdman (1965). In *Trisetum* subsect. *Graphephorum* (Desv.) Louis-Marie, Loius-Marie included *T. melicoides* (Michx.) Scribn. and *T. wolfii* Vasey [including *T. wolfii* var. *brandegei* (Scribn.) Louis-Marie and *T. wolfii* var. *brandegei* fo. *muticum* (Boland.) Louis-Marie], and in *Trisetum* Sect. *Aulacoa* Louis-Marie he included *T. floribundum* Pilg. [Lectotype here designated: = *Dielsiochloa floribunda* (Pilg.) Pilg.], and *T. trinii* (Trin.) Louis-Marie [= *Bromus berteroanus* Colla].

Hitchcock (1934) described a new species from Montana, *T. orthochaetum*. Later, Hitchcock (1939) gave a detailed account of the genus for the North American flora (including México), where 19 species were recognized under *Trisetum*. Eleven of the species listed by Hitchcock are from México and Central America, and the following eight range from the United States, Canada, and Greenland: *T. melicoides* and *T. wolfii* (here treated under genus *Graphephorum*), *T. spicatum*, *T. orthochaetum*, *T. canescens*, *T. cernuum*, *T. flavescens*, and *T.*

montanum. Finot et al. (2004) recognized 17 species of *Trisetum* in México and Central America: *T. angustum* Swallen, *T. barbatipaleum* (Hultén ex Veldkamp) Finot, *T. curvisetum* Morden & Valdes-Reyna, *T. durangense* Finot, P.M. Peterson, *T. filifolium*, *T. irazuense* (Kuntze) Hitchc., *T. ligulatum* Finot & Zuloaga, *T. martha-gonzaleziae* P.M. Peterson & Finot, *T. palmeri*, *T. pinetorum* Swallen, *T. pringlei* (Scribn. ex Beal) Hitchc., *T. rosei* Scribn. & Merr., *T. spellenbergii* Soreng, Finot & P.M. Peterson, *T. spicatum*, *T. tonduzii* Hitchc., *T. viride*, and *T. virletti*.

Hultén (1959) studied the *Trisetum spicatum* complex on a world-wide basis, and recognized several North American infraspecific taxa: *T. spicatum* subsp. *alaskanum* (Nash) Hultén, *T. spicatum* subsp. *pilosiglume* (Fernald) Hultén, *T. spicatum* subsp. *molle* (Michx.) Hultén, *T. spicatum* subsp. *majus* (Vasey) Hultén, *T. spicatum* subsp. *congdonii* (Scribn. & Merr.) Hultén, and *T. spicatum* subsp. *congdonii* var. *spicatiforme* Hultén. Later authors concluded that *T. spicatum* is polymorphic (Randall & Hilu 1986), and most of the infraspecific taxa were placed in synonymy.

Graphephorum is a small genus endemic to North America, closely related to *Trisetum*. It differs from this genus in having the apex of the lemma entire and the dorsal awn reduced to a subapical mucro. *Graphephorum* comprises only two species, *G. melicoides* (Michx.) Desv. and *G. wolfii* (Vasey) Vasey (Finot & Soreng 2003), sometimes treated under *Trisetum*. Clayton and Renvoize (1986) indicate *Graphephorum* has three species but only the type species was given. One species from México, originally described as *Graphephorum altijugum* E. Fourn. is currently accepted as *Peyritschia koelerioides* (Peyr.) E. Fourn. (Finot 2003b; Finot et al. 2004). *Graphephorum pringlei* Scrib. ex Beal, from México, Guatemala, Costa Rica, and Panamá, was transferred to *Trisetum* by Hitchcock (1927).

MATERIAL AND METHODS

Type specimens and general collections from the following herbaria were studied: BA, BAA, BAF, C, CR, CIIDIR, CONC, F, LP, MERL, P, PR, QCA, SGO, S, SI and US. For micromorphological studies, ligules were collected from upper and basal culm leaves with a sharp razor blade and mounted in lactophenol. For leaf anatomical studies, hand cross sections and abaxial epidermis preparations were made following Metcalfe (1960). The terminology for ligule description is based mainly on Chaffey (1983, 1984). Transverse sections and abaxial epidermis of leaves were described following the terminology proposed by Ellis (1976, 1979). Observations were made with a Zeiss MC-80 microscope equipped with objectives 20×, 40×, 63×, and 100×. All grass names mentioned in this manuscript, including those in the introduction are treated in Appendix 2.

In the morphological descriptions the length given for florets was usually taken from the first or lowest floret. If there were three or more florets per spikelet then the second floret was sometimes used to calculate the range. Therefore, when using our keys to determine North American specimens of *Trisetum* it is best to measure only the first or lowest floret.

TAXONOMIC TREATMENT

KEY FOR DISTINGUISHING THE GENERA *TRISETUM* AND *GRAPHEPHORUM* IN NORTH AMERICA

1. Lemma with lateral nerves not prolonged into apical setae, the apex entire to slightly bilobate; dorsal awn absent or reduced to a short subapical mucro; palea not gaping (palea tightly enclosed by the margins of the lemma); panicle lax, open or contracted, never spiciform ________ **Graphephorum**
1. Lemma with lateral nerves prolonged into 2(4) apical setae, the apex bidentate; dorsal awn well developed, borne on the upper half or third of the lemma; palea gaping (palea not tightly enclosed by the margins of the lemma); panicle lax or densely-flowered, contracted or open, and ovate or pyramidal, often spiciform ________ **Trisetum**

Graphephorum Desv., Nouv. Bull. Sci. Soc. Philom. Paris 2:189. 1810. Type: *Graphephorum melicoides* (Michx.) Desv.

Perennials, loosely caespitose or with short rhizomes. Culms 50–100 cm tall, glabrous or pilose. Leaf sheaths glabrous, scabrous, and/or pilose; blades flat, glabrous or pilose; ligule membranous. Inflorescence in panicles open or contracted, glabrous below the panicle. Spikelets 2- or 3-flowered; rachilla pilose; disarticulation above the glumes and between the florets; glumes slightly unequal, slightly shorter than the spikelet; first glume 1-nerved, lanceolate to linear-lanceolate; second glume 1- or 3-nerved, lanceolate to oval-lanceolate; lemmas with apex entire to slightly bilobate, muticous or with a reduced awn (mucro), borne inmediately below the apex, the mucro not reaching the apex of the lemma; palea not gaping; stamens 3; ovary glabrous or with short apical hairs.

KEY TO THE SPECIES OF *GRAPHEPHORUM* IN NORTH AMERICA

1. Panicles 2–4 cm wide, open, lax; ovary glabrous; callus hairs about 2.5 mm ____ **1. G. melicoides**
1. Panicles 1–1.5 cm wide, contracted; ovary glabrous or with short hairs at the apex; callus hairs 0.5 mm long ________ **2. G. wolfii**

1. Graphephorum melicoides (Michx.) Desv., Nouv. Bull. Sci. Soc. Philom. Paris 2:189. 1810. *Aira melicoides* Michx., Fl. Bor. Amer. 1:62. 1803. *Poa melicoides* (Michx.) Nutt., Gen. N. Amer. Pl. 1:68. 1818. *Triodia melicoides* (Michx.) Spreng., Syst. Veg. 1:331. 1825. *Trisetum melicoides* (Michx.) Scribn., Bot. Gaz. 9:169. 1884. Type: CANADA. America Boreal, *Michaux* s.n. (HOLOTYPE: P!; ISOTYPE: LE-TRIN 1864.01!).

Arundo airoides Poir., Encycl. 6:270. 1804. *Deyeuxia airoiodes* (Poir.) P. Beauv., Ess. Agrostogr. 44, 152, 160. 1812. *Agrostis airoides* (Poir.) Raspail, Ann. Sci. Nat. (Paris) 5: 449. 1825, *nom. illeg. hom. Calamagrostis airoides* (Poir.) Steud., Nomencl. Bot. (ed. 2) 1:249. 1840. Type: U.S.A. America Septentrionalis, *Michaux* s.n. (HOLOTYPE: Herb. Juss., not seen).

Dupontia cooleyi A. Gray, Manual (ed. 2) 556. 1856. *Graphephorum melicoides* var. *majus* A. Gray, Proc. Amer. Acad. Arts 5:191. 1861. *Graphephorum melicoides* var. *cooleyi* (A. Gray) Scribn., Mem. Torrey Bot. Club 5(4):53. 1894. *Trisetum melicoides* subsp. *cooleyi* (A. Gray) Scribn., Rhodora 8(89):87. 1906. *Trisetum melicoides* var. *majus* (A. Gray) Hitchc., Rhodora 10(112):65. 1908. *Graphephorum cooleyi* (A. Gray) Farw., Pap. Michigan Acad. Sci. 1:88. 1923. TYPE: U.S.A. MICHIGAN: (HOLOTYPE: not found).

Perennials. Culms 50–100 cm tall, glabrous. Leaf sheaths scabrous or pubescent; ligules 1.3–2 mm long, oval, glabrous dorsally, apex dentate with short cilia; blades 80–150 × 2–8 mm, flat, glabrous, sometimes pubescent adaxially. Panicles 8–20 × 2–4 cm, lax, open, nodding; branches ascending; rachis scabrous. Spikelets 6–7 mm long; rachilla hairy; the hairs 1–1.5 mm long; glumes unequal, shorter than the spikelet; keel smooth or scabrous on the upper half; first glume 4–4.5 × 0.5 mm, shorter and narrower than the second glume, lanceolate, 1-nerved; second glume 6–7 × 0.8 mm, oval-lanceolate, 3-nerved; lemmas with short and straight subapical awn (mucro), intermediate nerves not reaching the apex; apex acute, entire, not setulate or aristulate; callus hairy, the hairs about 2.5 mm long; palea shorter than the lemma, 2-nerved; apex entire; lodicules about 0.6 mm long, with the apex entire to slightly bilobate; ovary glabrous. Caryopses 3.2–3.8 mm long, glabrous; endosperm semi-liquid.

Anatomy and Micromorphology.—Ligule apices without hairs or papillate cells, composed of long cells with rounded ends; ligule epidermis composed of rectangular long cells with straight side walls, without prickle hairs or macrohairs; blades in transverse section flat to weakly keeled; adaxial face with rounded ribs, the ribs not very prominent; furrows wider than the adjacent ribs; abaxial face with ribs similar in size and shape to the adaxial ribs; vascular bundles 15, rounded, situated in the median portion of the blade; vascular bundles with adaxial and abaxial girders; marginal sclerenchyma present, small; epidermis in transverse section larger than the mesophyll, the adaxial epidermis with epidermal cells more or less rounded, thin; bulliform cells inconspicous; prickles scarce, present only in the adaxial epidermis; stomata present in both adaxial and abaxial surfaces; abaxial epidermis with costal-intercostal zones well differentiated; intercostal zones with long cells rectangular to fusiform, with straight side walls and vertical to oblique terminal walls; intercostal short cells absent; stomata in two intercostal rows; prickles scarce; macrohairs absent; costal zone 2 or 3 cells wide, with long cells similar to the intercostal epidermal cells but shorter and narrower; short cells rectangular, with sinuous walls; prickles in rows on the costal zones.

Distribution.—Canada (Newfoundland, Ontario, Québec) and United States (Maine, Michigan, New Hampshire, New York, Vermont, Wisconsin) [Hitchcock 1939; Kartesz 1998].

Specimens examined. **CANADA. Ontario:** Township, 20 mi S of Moonbeam, 14 Aug 1959, *Morton 11449* (US). **Newfoundland:** Valley of Exploits River, Grand Falls, 12 Aug 1911, *M.L. Fernald & Wiegand 4591* (US). **U.S.A. Maine: Aroostook Co.:** along St. John River, St. Francis, 5 Aug 1893, *M.L. Fernald 187* (P); Northern Maine, St. Francis River, Aug 1902, *Eggleston 3136* (P); Woosehead Lake, 1 Sep 1868, *A.E. Smith & C.E. Smith s.n.* (P).

2. Graphephorum wolfii (Vasey) Vasey ex Coult., Man. Bot. Rocky Mt. 423. 1885. *Trisetum wolfii* Vasey, Monthly Rep. Dept. Agric. 1874:156. 1874. TYPE: U.S.A. Colorado: Lake Co.: Twin Lakes, 1873, *J. Wolfe s.n.* (ISOTYPES: NY-232367!, US-81781!).

Trisetum subspicatum var. *muticum* Bol., Bot. California 2:296. 1880. TYPE: U.S.A. California: on the upper Tuolumne, 7500 ft, 1866, *H.N. Bolander 5019* (ISOTYPES: NY-232371!, US-867860!, US-344201!).

Perennials. Culms 50–100 cm tall, with short rhizomes. Leaf sheaths glabrous or pilose; ligules 1.5–2 mm long, truncate, glabrous dorsally, apex dentate; blades 60–200 × 3–7 mm, flat, soft; lower blades pilose abaxially, sparsely pilose adaxially; upper blades glabrous to sparsely pilose abaxially, sparsely pilose adaxially. Panicle 8–15 × 1–1.5 cm, contracted, dense, erect, tinged with purple; rachis strongly scabrous. Spikelets 6–7.5 mm long, 2- or 3-flowered; rachilla 1.5 mm long, hairy, the hairs 0.5–1.5 mm long; glumes unequal, nearly as long as the spikelet; keel scabrous towards the apex; apex acute; first glume 4.2–6 × 0.5–0.7 mm, shorter and narrower than the second glume, lanceolate, 1-nerved; second glume 5–6.5 × 0.8–0.9 mm, as long or shorter than adjacent floret, 3-nerved; lower floret 5–5.5 mm long,; upper florets shorter; lemma glabrous to slightly scabrous towards the apex; apex acute to slightly bidentate, hyaline, muticous or with a short subapical mucro 1–2.2 mm long, borne at 1–1.3 mm below the apex; callus short hairy, the hairs about 0.5 mm long; palea about 4 mm long, shorter than the lemma, 2-nerved, the nerves scabrous; lodicules 0.7–0.8 mm long; apex with two 2 teeth, sometimes with a third smaller tooth between them; anthers 0.7–0.8 mm long; ovary glabrous, sometimes with hairs near the apex. Caryopses 2.4–3 mm long, with or without hairs at the apex; endosperm solid.

Anatomy and *micromorphology.*—Ligule apices with stiff hairs and papillate cells; ligule epidermis composed of rectangular long cells; short cells present; prickle hairs scarce; stomata and macrohairs absent; blades in transverse section V-shaped, symmetric, keeled, the keel with a well developed sclerenchymatic tissue; adaxial ribs absent; central vascular bundle free, without adaxial sclerenchyma; second order vascular bundles with I-shaped sclerenchyma girders; third order vascular bundles free, with small strands of adaxial or abaxial sclerenchyma; marginal sclerenchyma small; bulliform cells conspicuous, in fan-shaped groups; macrohairs absent; abaxial epidermis with costal-intercostal zonation present; intercostal zones with fusiform to rectangular long cells, with lateral walls straight; short cells and stomata present; prickles and macrohairs absent; costal zones with long cells rectangular, narrower than the intercostal cells; short cells rectangular, with sinuous side walls.

Distribution.—A species endemic to western United States (California, Colorado, Idaho, Montana, New México, Nevada, Oregon, Utah, Washington, and Wyoming) [Hitchcock 1939; Kartesz 1998).

Specimens examined. **U.S.A. CALIFORNIA: Mono Co.:** Ravine Creek, 3200 m, 21 Aug 1954, *Krapovickas 8102* (SI); Yosemite National Park, 9600 ft, 1 Aug 1934, *Bartholomew s.n.* (US); *J.R. Swallen 1937* (P). **COLORADO: Sequachi Co.:** Marshall Pass, 10800 ft, 27 Jul 1896, *Clements 200* (US); Buffalo Pass, 10500 ft, 14 Aug 1898, *Shear & Bessey 1482* (US). **NEVADA: Elko Co.:** just above Angel Lake, East Humboldt Mountain, 8000 ft, 24 Jun 1958, *P.H. Raven & O.T. Solbrig 1340* (SI); Ponderosa Mountain, above Leiglis Lake, 7000 ft, 26 Jul 1901, *Merril & Wilcox 348* (P). **NEW MÉXICO:** Castilla Valley, 4 Sep 1913, *E.O. Wooton s.n.* (US). **WASHINGTON: Spokane Co.:** 21 Jun 1889, *W. Suksdorf s.n.* (P); *W. Suksdorf 949* (P).

Trisetum Pers., Syn. Pl. 1:97. 1805. *Trisetarium* Poir., Encycl. Suppl. 5: 365. 1817, *nom. superfl.*, *Rebentischia* Opiz, Lotos 4:104. 1854, *nom. superfl.*, non P.A. Karsten 1869. TYPE: *Trisetum flavescens* (L.) P. Beauv., Ess. Agrostogr. 88, 153, t. 18, f. 1. 1812.

Acrospelion Besser ex Schult. & Schult. f., Syst. Veg. Mant. 3:526, 1827. LECTOTYPE (designated by L.K.G. Pfeiffer, Nom. 1:38. 8 Dec. 1781.): *Avena distichophylla* Vill. [= *Trisetum distichophyllum* (Vill.) P. Beauv.]

Rupestrina Prov., Fl. Canad.:689. 1862. TYPE: *Rupestrina pubescens* Prov. [= *Trisetum spicatum* (L.) Richt.].

Perennials and annuals, caespitose, sometimes shortly rhizomatous and/or stoloniferous. Culms 16–120 cm tall, erect to geniculate at base, glabrous or pubescent. Leaf sheaths glabrous or pubescent, longer or shorter than the internodes; blades flat, conduplicate, convolute or involute, soft rarely rigid; ligule membranous. Inflorescence in panicles contracted or open, lax or densely-flowered, spiciform, ovate, or pyramidal; the rachis glabrous, scabrous or pubescent. Spikelets (1-)2- to 4-flowered, short pedicellate; rachilla pubescent or glabrous, usually prolonged beyond the upper floret; disarticulation above the glumes and between the florets; glumes heteromorphic, lanceolate to ovate-lanceolate, equal or unequal, first glume 1-nerved, usually shorter and narrower than the second, second glume 1- or 3-nerved; lemmas lanceolate, (3-)5-(7-) nerved, usually awned dorsally or muticous, with apex and margins hyaline, glabrous or pubescent, slightly keeled and compressed, rarely terete; apex with 2- to 4 apical setae or short awns, bidentate, or 2-toothed; central awn from the upper third, rarely the middle, of the subapical portion of the lemma; awn exserted, geniculate or merely divaricate; callus short pilose; palea not tightly enclosed by the margins of the lemma (gaping), 2-keeled, hyaline, usually shorter than the lemma; stamens 3, anthers 0.5–3 mm long; lodicules 2, membranous, often apically lobed; ovary glabrous or with short and shining trichomes near the apex; endosperm solid or liquid, soft or hard. Caryopses compressed, soft; hilum short, punctiform. Basic chromosome number $x = 7$.

KEY TO SPECIES OF *TRISETUM* IN NORTH AMERICA

1. Plants delicate annuals; known only from a single introduction in Camden, New Jersey ____ **3. T. aureum**
1. Plants perennial; widespread.
    2. Panicles lax, open; glumes shorter than the spikelet (Sect. *Trisetum*).
        3. Ovary and caryopsis hairy near the apex.

4. Awns 3.5–4 mm long, straight, shorter than the lemma; apex of the lemma shortly bidentate; first glumes 4–6 mm long, never rudimentary ______ **7. T. orthochaetum**
4. Awns 6–16 mm long, geniculate, one to three times as long as the lemma; apex of the lemma ending in two setae 0.5–1.5 mm long; first glumes 0.5–5 mm long, sometimes rudimentary.
    5. Panicles few-flowered, loose; branches capillary, the lower ones usually naked on the lower third; leaf blades glabrous ______ **4a. T. cernuum** subsp. **cernuum**
    5. Panicles densely-flowered, narrow; branches closely appressed, the lower ones with spikelets to near base; leaf blades canescent to sparsely pilose ______ **4b. T. cernuum** subsp. **canescens**

3. Ovary and caryopsis glabrous near the apex
    6. Spikelets 2–4-flowered; panicles usually gold-yellowish, somewhat contracted; spikelets 5–9 mm long; lemmatal awns 5–9 mm long; anthers 2–3 mm long.
        7. Lemmas only dorsally scabrous ______ **9. T. sibiricum**
        7. Lemmas uniformily scabrous ______ **5. T. flavescens**
    6. Spikelets 2- or 3-flowered; panicles green sometimes tinged with purple, loose; spikelets 4.5–6 mm long; lemmatal awns 3.5–4 mm long; anthers 0.8–1.2 mm long ______ **6. T. montanum**

2. Panicles contracted, spiciform to narrow but always densely-flowered; glumes only a little shorter than the spikelet (Sect. *Trisetaera*, in part).
    8. Panicles 2.5–7(–10) cm long, densely spiciform ______ **10. T. spicatum**
    8. Panicles 8–23 cm long, open, loose, few-flowered to spiciform and interrupted with short ascending branches.
        9. Lemmatal awns 7–12 mm long, weakly twisted, geniculate; ligules about 2.5 mm long, glabrous or scabrous dorsally; ovary hairy near apex ______ **4b. T. cernuum** subsp. **canescens**
        9. Lemmatal awns about 5.5 mm long, not twisted or geniculate, diversely curved; ligules 0.35–1.5 mm long, densely pilose dorsally; ovary glabrous ______ **8. T. projectum**

3. Trisetum aureum (Ten.) Ten., Fl. Napol. 2:378. 1820. *Koeleria aurea* Ten., Tratt. Fitogn. 1:58. 1806. *Trisetaria aurea* (Ten.) Pignatti, Arch. Bot. (Forli) 31: 51. 1955. Type: (holotype: NAP?).

Delicate annuals, caespitose; culms 18–30 cm tall, erect, spreading or geniculate at base, glabrous. Leaf sheaths glabrous or pubescent, shorter than the internodes; ligule 0.8–1.3 mm long, hyaline, apex obtuse, margins decurrent; blades 2–8 cm long, 1.2–3 mm wide, glabrous to pubescent, the hairs less than 0.2 mm long. Panicles 1–5 × 0.8–3 cm, pyramidal to ovoid, contracted, densely flowered, often lobed, shining yellowish or light brownish; branches 0.6–3 cm long, closely appressed and ascending, naked below; rachis glabrous. Spikelets 2.6–3.3 mm long, 2- or 3-flowered; pedicels 0.2–1.6 mm long; rachilla 0.6–1.5 mm long, covered with stiff hairs, the hairs 0.3–1.2 mm long; glumes unequal, the second glume longer than the spikelet, scaberulous on the keel; first glume 2.1–2.6 mm long, linear-lanceolate, shorter and narrower than the second glume, 1-nerved, apex acuminate; second glume 2.8–3.3 mm long, ovate-lanceolate, 1- or

3-nerved, apex acute; lemmas 1.8–3 mm long, glabrous or scattered pilose, rarely scaberulous, ovate, hyaline, the apex bidentate with two setae 0.1–0.3 mm long; awn 1.3–3.5(–6) mm long, slightly bent, scaberulous, borne just above the middle; callus obtuse, mostly glabrous; paleas 1.5–2.8 mm long, shorter than the lemma, hyaline, 2-nerved, the apex bidentate with two teeth 0.2–0.4 mm long; anthers 1.2–1.6 mm long; ovary with a few short hairs near the apex. Caryopsis not seen.

Distribution.—*Trisetum aureum* is introduced in North America and occurs natively in the Mediterranean Region of Europe in Greece, Italy, Jugoslavia, and Sicilia.

Comments.—We are not in a position to critically evaluate the generic status of the assemblage of approximately 15 species that are sometimes segregated as *Trisetaria* Forssk. (sensu Clayton & Renvoize 1986). This taxon is treated as *Trisetum aureum* in the Flora of France by Kerguélen (1999) and as *Trisetaria aurea* by Doğan (1985) in the Flora of Turkey.

Specimens examined. **U.S.A. New Jersey:** Camden, ballast, *I.C. Martindale s.n.* (US)

4a. Trisetum cernuum Trin. subsp. **cernuum**, Mém. Acad. Imp. Sci. St.-Pétersbourg, Sér. 6, Sci. Math. 1:61. 1830. *Avena cernua* (Trin.) Kunth, Rev. Gen. 1, suppl. 26, 1833. TYPE: U.S.A. ALASKA: Sitka, 1826, *J.F.G. von Eschscholtz s.n.* (HOLOTYPE: LE-TRIN 1889-01!; ISOTYPES: BAA-3366!, NY-232366!, P!, US-81779 fragm. ex LE-TRIN!).

Avena nutkaensis J.Presl, Reliq. Haenk. 1(4–5):254. 1830. *Trisetum nutkaensis* (J.Presl) Scribner & Merr. ex Davy, Univ. Calif. Publ. Bot. 1:63. 1902. TYPE: CANADA. BRITISH COLUMBIA: Vancouver Island, Nootka, *T. Haenke s.n.* (ISOTYPES: LE-TRIN-1929.01!; US- 865598 fragm.!).

Trisetum sandbergii Beal, Grasses N. Amer. 2:378. 1896. *Trisetum cernuum* var. *sandbergii* (Beal) Louis-Marie, Rhodora 30:214. 1928. TYPE: U.S.A. WASHINGTON: Mt. Stuart, 7000–8000 ft, *Sandberg & Leiberg 823* (HOLOTYPE: MSC?; ISOTYPES, NY-431712!, GH, WS).

Trisetum cernuum var. *luxurians* Louis-Marie, Rhodora 30:213. 1928. TYPE: U.S.A. OREGON: Seaside, 11 Aug 1899, *C.L. Shear & F.L. Scribner 1705* (HOLOTYPE: US-867917!).

Trisetum cernuum fo. *pubescens* Louis-Marie, Rhodora 30:213. 1928. *Trisetum cernuum* fo. *pubescens* G. Jones, Univ. Wash. Publ. Biol. 5:108. 1936, hom. illeg. superfl. TYPE: U.S.A. CALIFORNIA: Humboldt Co.: Eureka, 30 May 1920, *Anonymous s.n.* (HOLOTYPE: UC-212883).

Perennials, with stolons and rhizomes. Culms 35–85 cm tall, glabrous, sometimes geniculate, with 2–4 nodes. Leaf sheaths longer or shorter than the internodes, glabrous or rarely pilose; ligules 1.3–7 mm long, membranous, longer in the upper leaves, oval, fimbriate, ciliate at the apex, glabrous or pilose dorsally; blades 100–220 × 3.5–12 mm, flat, soft, glabrous or sparsely pubescent on the adaxially. Panicles 6–30 × 2–5 cm, lax, open, loose, few-flowered, green or purplish; branches capillary, the lower ones usually naked on lower third; rachis glabrous. Spikelets 4.5–12 × 2–4 mm, 2- or 3-flowered, not overlapping; pedicels 1–4.5 mm long, capillary, flexuous, glabrous or scabrous; rachilla 1.5–2 mm long, covered with stiff hairs, the hairs 1–2 mm long; glumes shorter than the spikelet, very unequal to subequal in length and very unequal in width; first glumes 0.5–5 × 0.1–0.5 mm, linear-lanceolate, attenuate, 1-nerved, sometimes rudimentary, narrower than the second glume, the margins hyaline; second glumes 3–7.5 × 0.5–1 mm, oval-lanceolate, 3-nerved; first florets 5–8.5 × 0.7–1 mm; lemma linear-lanceolate, glabrous, scabrous towards the apex, sometimes tinged with purple; apex with two setae 0.5–1.5 mm long; awns 6–16 mm long, curved, not twisted nor geniculate, scabrous, borne on the upper third at 2–2.5 mm below the apex; callus obtuse, hairy, the hairs 0.2–0.7 mm long; paleas 4–5.7 mm long, shorter than the lemma, hyaline, 2-nerved, the nerves scabrous; apex bidentate; lodicules 0.7–0.8 mm long, bilobulate at the apex; anthers 0.5–1.5 mm long; ovary with short, curved and shining hairs near the apex; ovary hairy near the apex. Caryopses 3.5–5 × 1 mm, hairy at the apex; endosperm semi-liquid.

Anatomy and micromorphology.—Ligule apices composed of hairs and papillate cells; ligule epidermis composed of rectangular long cells, rarely fusiforms, with straight walls; short cells present; prickle hairs present; stomata absent; blades in transverse section flat, keeled; adaxial side with rounded ribs; furrows less than one half the leaf thickness; sclerenchyma as adaxial and abaxial I-shaped girders in the first and second order vascular bundles; marginal sclerenchyma present; bulliform cells in fan-shaped groups between vascular bundles; abaxial leaf epidermis composed of fusiform to hexagonal long cells, with straight side walls; short cells present in intercostal zones; prickle hairs absent to very few, often limited to the costal zones; macrohairs absent; stomata in 0–2 intercostal rows.

Distribution.—*Trisetum cernuum* subsp. *cernuum* is found in North America and southern South America (southern Chile and Argentina, from 38°S to 55°S south of the Strait of Magellan). In North America it is found in southern Alaska (Chicagof Islands, Yakutat Bay, 59°32'N,139°37'W), Canada (Alberta, British Columbia) and the continental United States (Washington, Oregon, Idaho, Montana and northern California, 36°N).

Specimens examined. **CANADA. Alberta:** 10 mi SW of Pincher Creek, 9 Aug 1950, *W.G. Dore 12479* (US); Waterton Lakes National Park, 5500 ft, 20 Aug 1939, *Mosg 555* (US); Waterton Lakes National Park, Spruce trail to Carthew Pass, 5500 ft, E shore of Cameron Lake, 1 Aug 1956, *Hermann 13048* (US); moist coniferous woods near Cameron Lake, 5450 ft, 26 Jul 1953, *Breitung 16778* (US). **British Columbia**: Mainland opposite Kaien Island, 19 Jun 1937, *McLake 4329* (US); Mts. near Ainsworth, Kootenay Lake, 2800 ft, 7 Jul 1890, *Macoun 107* (US); Mt. Revelstoke Road, 3 mi NE Revelstoke, 22 Jul 1956, *Hermann 12914* (US); Stikine Glacier, 8 Aug 1916, *Cooper 16* (US); Galloway Rapids a few miles S of Prince Rupert, 18 Jul 1954, *Calder, Saville & Ferguson 13166* (US); Maroon Mountain Trail, 54°48'24.1"N, 128°44'01.8"W, 600–1600 m, 23 Jul 2004, *Peterson, Saarela & Smith 18723* (US); Cypress Provincial Park, N of Vancouver, 49°23'37.3"N, 123°11'43.9"W, 896 m, 29 Jul 2004, *Peterson & Saarela 18754* (US); Vancouver Island, vicinity of Ucleulet, 13 Jul 1909, *Macoun s.n.* (US); vicinity of Namaimo, 23 Jun 1908, *Macoun s.n.* (US); Vancouver Island, *Macoun 28* (US); Jun-Jul 1901, *Rosendahl & Brand 129* (US); Queen Charlotte Islands, Skidigate, 29 Jul 1910, *Spreadborough s.n.* (US). **U.S.A. Heller 3904* (US). **Clallam Co.:** Olympic Mts., Jun 1900, *Elmer 1946* (US).

KEY TO SUBSPECIES OF *TRISETUM CERNUUM*

1. Panicles few-flowered, loose; branches capillary, the lower ones usually naked on the lower third; leaf blades glabrous ______ **4a. T. cernuum** subsp. **cernuum**
1. Panicles densely-flowered, narrow; branches closely appressed, the lower ones with spikelets to near base; leaf blades canescent to sparsely pilose ______ **4b. T. cernuum** subsp. **canescens**

4b. Trisetum cernuum subsp. **canescens** (Buckley) Calder & R.L. Taylor, Canad. J. Bot. 43:1389. 1965. *Trisetum canescens* Buckley, Proc. Acad. Nat. Sci. Philadelphia 1862:100 1862. *Trisetum elatum* Nutt. ex A. Gray, Proc. Acad. Nat. Sci. Philadelphia 14:337 1862, *nom. inval. Trisetum cernuum* var. *canescens* (Buckley) Beal, Grass. N. Amer. 2:380. 1896 *Helictotrichon canescens* (Buckley) Clayton, Kew Bull. 40:728. 1985. Type: U.S.A. Oregon: Columbia Plains, *T. Nuttall s.n.* (holotype: PH).

Trisetum canescens fo. *tonsum* Louis-Marie, Rhodora 30:216. 1928. Type: U.S.A. California: Trinity Co.: Buckeye Mt., 15 Jul 1914, *H.S. Yates 522* (holotype: UC; isotype: US-893773!).

Trisetum canescens fo. *velutinum* Louis-Marie, Rhodora 30:216. 1928. TYPE: U.S.A. CALIFORNIA: Lassen's Peak, Jul 1879, *R.M. Austin s.n.* (HOLOTYPE: GH).

Perennials. Culms 40–120 cm tall, glabrous, nodes 3. Leaf sheaths pubescent or upper portions glabrous; ligules about 2.5 mm long, dentate, glabrous or scabrous dorsally; blades 45–300 × 2–8 mm, flat, scabrous or canescent, sometimes sparsely pilose and ciliate on the margins. Panicles 8–23 × 1–3 cm, contracted, narrow, densely-flowered; rachis scaberulous; branches closely appressed, the lower ones with spikelets to near base. Spikelets 7.5–9 mm long, 2- or 3-flowered; pedicels scaberulous; rachilla 1.5–2 mm long, covered with stiff hairs, the hairs 1.5–2 mm long; glumes shorter than the spikelet, unequal, green or tinged with purple; first glumes 3.2–6 × 0.2–0.4 mm, linear-lanceolate, subulate, usually × as long as than the second glume, narrower than second, 1-nerved; second glumes 4.5–7 × 0.8–1 mm, oval to oval-lanceolate, 3-nerved; first floret 5–9 mm long; lemma glabrous, minutely scabrous towards the apex, with the margins and apex hyaline; apex 2-awned, the apical awns 0.7 mm long; awns 7–12 mm long, weakly twisted, geniculate, borne on the dorsal upper third, at 2–3 mm from the apex; callus pilose, the hairs 0.5–1 mm long, rachilla 1.7–3 mm long, pilose; paleas about 6.5 mm long, 2-nerved, the nerves scabrous; anthers 1.2–1.8 mm long; ovary hairy near the apex. Caryopses hairy at the apex.

Anatomy and micromorphology.—Ligule apices truncate, minutely dentate with hairs and papillate cells, the epidermis is composed of rectangular to fusiform long cells, with straight side walls; short cells present; dorsal surface of the ligule densely covered with hooks; macrohairs absent; blades V-shaped in transverse section, symmetric, slightly keeled; bulliform cells in fan-shaped groups; adaxial side with rounded ribs and furrows less than one half of the blade thickness; vascular bundles with adaxial and abaxial I-shaped girders; marginal sclerenchyma not well developed; abaxial epidermis with fusiform long cells and straight side walls; short cells on the costal zones with rectangular and sinuose side walls; stomata in two rows near the costal zones; hooks present; macrohairs present only on the adaxial epidermis.

Distribution.—Western Canada and United States. It reaches its boreal distribution at Vancouver (50° 55'N) and its austral distribution in California, U.S.A. (34°N). In the United States it is found in the states of Washington, Montana, Oregon, Idaho, Nevada, Utah, Arizona, and California, primarily between 47° N in Washington St. and 34° N in California.

Comments.—Clayton (1985) transferred *T. canescens* to *Helictotrichon*, probably because of the presence of hairs at the apex of the ovary. This character, however, is also present in the following species of *Trisetum*: *T. ambiguum* Rúgolo & Nicora, *T. cernuum* subsp. *cernuum*, *T. caudulatum* var. *correae* Nicora, *T. durangense*, and *T. longiglume* Hack. var. *longiglume*. All other characters in *Trisetum cernuum* subsp. *canescens* (hilum punctiform, lodicules apically lobed) distinguish it from *Helictotrichon* (hilum linear, lodicules acute at the apex).

The strong affinity between *T. cernuum* and *T. canescens* was first noticed by Beal (1896), who subordinated *T. canescens* to *T. cernuum* with the varietal rank. Louis-Marie (1928-29) did not accept Beal's treatment and suggested *T. canescens* was allied with *T. flavescens* rather than with *T. cernuum*. Nevertheless, *T. flavescens* has glabrous ovaries and caryopses whereas *T. cernuum* subsp. *cernuum* and *T. cernuum* subsp. *canescens* both have short hairs near the apex of the ovaries and caryopses.

Specimens examined **CANADA. British Columbia:** Kaslo, Kootenay, 27 Jun 1914, *McHenry 9130* (US); 15 May 1889, *Macoun 42* (US); Vancouver Island, 27 Jun 1887, *Macoun 141* (US); Vicinity of Victoria, 2 Jul 1908, *Macoun 80985* (US); on damp soil, 13 Jun 1887, *Macoun 50* (US); Vicinity of Victoria, 18 Jun 1908, *Macoun s.n.* (US). **U.S.A. Afrique N. 33(4):92. 1942, *nom. illeg. hom.* TYPE: *Herb. A. Van Royen no. 913.7-458* (LECTOTYPE: LINN-97.14, designated by Cope in Cafferty et al., Taxon 49:247. 2000).

Trisetum pratense Pers., Syn. Pl. 1:97. 1805. *Trisetum flavescens* subsp. *pratense* (Pers.) Asch. & Graebn., Syn. Mitteleur. Fl. 2:265. 1899. TYPE: Europe.

Perennials. Culms (20–)80–110 cm tall, glabrous, with 2–5 nodes. Leaf sheaths shorter than the internodes, glabrous or the lower ones sparsely pilose; ligules 0.5–2 mm long, minutely dentate, ciliate, glabrous dorsally, truncate; blades (3–)100–160 × 2–4 mm, flat, glabrous abaxially, scabrous and sparsely pilose adaxially. Panicles 5–18 × 2–8 cm, lax, open or contracted, golden-yellow, bright. Spikelets 5–7(–8.5) mm long, (1–)2–3(–4)-flowered; rachilla about 1.2 mm long, pilose, the hairs 1–1.5 mm long; glumes shorter than the spikelet, unequal, bright, scabrous on the keel; first glumes 2–4 × 0.1–0.2 mm, linear-lanceolate, subulate, usually about one half of the length of the adjacent floret, 1-nerved; second glumes 4–6.6 × 1 mm, oval-lanceolate, 3-nerved, covering about two thirds of the adjacent floret, rarely as long as the spikelet; lemmas 4–6 mm long, scabrous; apex 2-dentate and 2-awned, awned dorsally on the upper 1/3–1/4; dorsal awns 5–9 mm long, geniculate and twisted; callus with short hairs, the hairs about 0.5 mm long; palea shorter than the lemma, hyaline, 2-nerved, the nerves scabrous; apex 2-dentate or 2-setulate; ovary glabrous; anthers 2–3 mm long. Caryopses 2–3 mm long, compressed, glabrous; endosperm liquid.

Anatomy and micromorphology.—Ligule apices composed mostly of hairs, papillate cells only rarely present (Chaffey 1994); blades in transverse section flat, symmetric, without a well developed keel; adaxial side with wide, low ribs; furrows as wide as the adjacent ribs, less than one half of the leaf thickness; first order vascular bundles with adaxial and abaxial girders; smaller bundles with adaxial and abaxial sclerenchymatic strands; marginal sclerenchyma very small; bulliform cells in fan-shaped groups of 5–7 cells situated at the bases of the furrows; abaxial epidermis with the intercostal zone composed of rectangular to slightly fusiform long cells, with side walls slightly undulate; stomata in two rows in each intercostal zone; prickles present; macrohairs absent; costal zones with short cells in silico-suberose couples and long cells shorter and narrower than the long intercostal cells.

Distribution.—Canada and the United States. Native to Europe, *T. flavescens* was introduced in North and South America (Argentina, Chile). This species has been reported in California, Kansas, Massachusetts, Mississippi, Missouri, New Jersey, New York, Oklahoma, Vermont, and Washington (Kartesz 1998).

Specimens examined. **CANADA. Yukon:** Arctic Coast west of Mackenzie River Delta, 69°12'N, 138°30'W, 23–25 Jul 1938, *Porsild 7122* (S). **U.S.A. Wash. 41:160. 1928. *Trisetum spicatum* subsp. *montanum* (Vasey) W.A. Weber, Phytologia 33(2):106. 1976. TYPE: U.S.A. NEW MÉXICO: San Miguel Co.: Las Vegas, Jul 1881, *G.R. Vasey s.n.* (ISOTYPES: NY-232365!, NY-232368!, NY-232369!, US-81777!, US-156883!, US-868271!).

Trisetum argenteum Scribn., Bull. Div. Agrostol., U.S.D.A. 11:49-50, f. 8. 1898, nom. illeg. hom. *Trisetum shearii* Scribn., Cir. Div. Agrostol. U.S.D.A. 30:8. 1901. *Graphephorum shearii* (Scribn.) Rydb., Bull. Torrey Bot. Club 32(11):602. 1905. *Trisetum montanum* Vasey var. *shearii* (Scribn.) Louis-Marie, Rhodora 30: 213. 1928. TYPE: U.S.A. COLORADO: below Silverton, among rocks, Las Animas Canyon, 2700 m, 4 Aug 1897, *C.L. Shear 1214* (HOLOTYPE: US-747299!; ISOTYPES: US-747298!, US-747300!, US-868267!).

Trisetum montanum var. *pilosum* Louis-Marie, Rhodora 30:212. 1928. TYPE: U.S.A. New México. San Miguel Co.: near Cowels, 8200 ft, 26 Jul 1908, *Standley 4536* (HOLOTYPE: GH; ISOTYPES: US fragm. ex GH!, S!).

Perennials. Culms 50–70 cm. tall, glabrous. Leaf sheaths shorter than the internodes, glabrous or pilose; ligules about 3 mm long, truncate, dentate, glabrous dorsally; blades 100–150 × 3–10 mm, flat, glabrous or pilose. Panicles 10–24 cm long, lax, open to more or less contracted; rachis and pedicels scaberulous. Spikelets 4.5—6 mm long, 1–5 cm wide, 2–3(–4)-flowered; pedicels up to 2.5 mm long; rachilla about 0.8 mm, pilose, the hairs less than 0.5 mm long; glumes shorter than the spikelet, unequal, thin, hyaline; first glumes 3–3.5 × 0.4–0.5 mm, linear-lanceolate to lanceolate, about two thirds the length of the second glume, 1-nerved; second glumes 4–4.5 × 0.6–0.8 mm, oval to oval-lanceolate, 3-nerved; lower florets about 4 × 0.6 mm; lemmas glabrous; apex shortly two-awned, hyaline, awned on the upper third or fourth, approximately at 1–1.5 mm below the apex; awns 3.5–4 mm long, scabrous, diversely curved but not strongly twisted nor geniculate; callus with short hairs, the hairs about 0.1 mm long; paleas about 4 mm long, shorter than the lemma, 2-nerved, the nerves scabrous; apex shortly bisetulate; lodicules 0.5–0.8 mm long, apex bilobulate; anthers 0.8–1.2 mm long; ovary glabrous. Caryopses glabrous; endosperm semi-liquid.

Distribution.—Canada and United States. *Trisetum montanum* occurs in Arizona, California, Colorado, Idaho, Montana, New México, Utah, and Wyoming at 7500–11000 ft.

Comments.—This species is related to *T. cernuum*. Beal (1896) mentioned that *T. montanum* has been erroneously interpreted as an opened-panicle form of *T. spicatum*. Hitchcock (1928) considered this species as a variety of *T. canescens*, but later, (Hitchcock 1939, 1950) treated it as a valid species. Hitchcock (1950) distinguished it from *T. canescens* by its smaller culms with shorter and denser panicles, narrower blades, thinner glumes and lemmas, and more delicate awns. It also differs from *T. cernuum* var. *canescens* by having a glabrous ovary.

Specimens examined. **CANADA. Alberta**: Waterton Lakes National Park, 6000–7500 ft, 5 Aug 1950, *Breitung 14039* (S); 30 Jul 1950, *Breitung 13955* (S); crevices in argillite bluff, 5600 ft, Bertha Lake trail, W of Waterton Lake, 3 Aug 1956, *Hermann 13080* (US); Banff National Park, Johnson Valley Trail Head, 51°15'24.6"N, 115°51'26.3"W, 1443 m, 3 Jul 2004, *Peterson, Saarela & Smith 18397* (US). **Yukon**: 3600 ft, upper Rose River Valley, 17 Jul 1944, *Porsild & Breitung 10468* (S). **U.S.A. Range, 12 Jul 1940, *Swallen 6509* (US). **New Mexico:** 17-21 Aug. 1915, *Hitchcock 1445*(S); Mts of Las Vegas, 1881, *Vasey 21* (P); Las Vegas, Jul 1881, *Vasey s.n.* (P); Vicinity of Santa Fe, Sandia Mt., 3200 m, 19 Aug 1926, *Arsène & Benedict 16376* (P). **Taos Co.:** Rio Pueblo, 8500 ft, 11 Aug 1910, *Wooton s.n.* (US). **San Miguel Co.:** Indian Creek, Santa Fe Forest, 2400 m, 16 Aug 1923, *Eggleston 19051* (US); Cloudcroft, rich soil, open pine woods, 17-21 Aug 1915, *Hitchcock 13287* (US); Pecos River National Forest, Winsor Creek, 8500 ft, 28 Jul 1908, *Standley 4576* (US); Sandia Mountains, Las Apuestas Canyon, in woods, 7900 ft, in woods, *Ellis 40* (US). **Utah:** Wasatch Mt., 2700 m, 4 Sep 1907, *Tidestrom 482-a* (S); Abajo Mts., near Spring Creek, 2700–3000 m, 17–20 Aug 1911, *Rydberg & Garrett 9825* (US).

7. Trisetum orthochaetum Hitchc., Amer. J. Bot. 21:134, f.3. 1934. TYPE: U.S.A. MONTANA: Missoula Co.: Bitterroot Mts., near Lolo Hot Springs, collected in boggy meadow, 23-24 Jul 1908, *A. Chase 5129* (HOLOTYPE: US-1535753!).

Perennials. Culms up to 110 cm tall, glabrous, with 3 nodes, erect. Leaf sheaths glabrous; ligules 1.5–3.4 mm long, truncate, dentate to erose, sparsely ciliate; blades 80–200 × 3–7 mm, flat, scabrous. Panicles 17–19 × 2–3 cm, lax, the branches in distant whorls; rachis glabrous. Spikelets 6.5–9 mm long, 2- or 3-flowered; pedicels 2–4 mm long, scabrous; rachilla 1–1.5 mm long, hairy, the hairs up to 2 mm long; glumes shorter than the spikelet, 1/2–3/4 as long as the spikelet, unequal; first glumes 4–6 × 0.4–0.6 mm, lanceolate, 1-nerved; second glumes 5–6.5 × 1–1.2 mm, oval-lanceolate, 3-nerved; first floret 5–6 mm long, the upper ones 4.5–4.7 mm long; lemma glabrous to slightly scabrous, obscurely 5-nerved; apex bidentate, awned dorsally on the upper third or fourth, about 1.5 mm from the apex; awn 3.5—4 mm long, nearly straight, scabrous, purple; callus obtuse with short hairs, the hairs 0.3–0.4 mm long; paleas 4–5.5 mm long, as long as 3/4 the length of the lemma, hyaline, 2-nerved, the nerves scabrous; anthers 0.8–1 mm long; ovary densely hairy at the apex. Caryopses not seen.

Anatomy.—Leaf blades in transverse section expanded, flat or U-shaped, the keel not well developed; adaxial surface with low ribs, the furrows between them as wide as the ribs; median vascular bundle with sclerenchyma strongly developed towards the keel and adaxial girders I-shaped; first order bundles with adaxial and abaxial girders, alternating with second order bundles without sclerenchyma associated with strands in both epidermises; marginal sclerenchyma small; bulliform cells inconspicuous; abaxial epidermis with intercostal zones composed of fusiform long cells; stomata in two rows in each intercostal zone; costal zones with long cells narrower than intercostal long cells; short cells with sinuous walls; macrohairs absent.

Distribution.—Endemic to the United States, known only from northwestern Montana.

Comments.—*Trisetum orthochaetum* is easily recognized by its nearly straight awn. It is closely related to *T. cernuum*, in having a lax, open inflorescence with the glumes shorter than the spikelet and a hairy ovary.

Specimens examined. **U.S.A. Montana: Missoula Co.:** Bitterroot Mts., Granite Creek drainage, SW of Lolo Hot Springs, E of Granite Creek Rd., about 2 mi S of junction with road 4209, 4480 ft, 18 Jul 1986, *Shelley & King 1230* (US).

8. Trisetum projectum Louis-Marie, Rhodora 30(359):217–218. 1928. *Trisetum cernuum* Trin. var. *projectum* (Louis-Marie) Beetle, Leafl. W. Bot. 4:228. 1946. *Trisetum spicatum* (L.) K.Richt. var. *projectum* (Louis-Marie) J.T. Howell, Wasmann J. Biol. 37(12):22. 1979. TYPE: U.S.A. CALIFORNIA: Fresno Co.: Sierra Nevada, Dinkey Cr., 5300 ft, 25 Jun 1900, *H. M. Hall & H. P. Chandler 359* (HOLOTYPE: UC; ISOTYPES: GH, NY, US-390573!).

Perennials, caespitose. Culms 35–90 cm tall, glabrous; nodes 2. Leaf sheaths pilose; ligules 0.35–1.5 mm long, oval, dentate and ciliate at the apex, densely pilose dorsally; blades 80–130 × 2–3 mm, flat, soft, involute towards the apex, densely pilose on both surfaces, the hairs about 1.2 mm long. Panicles 9–23 × 2–3 cm, spiciform, interrupted, with short ascending branches, exserted, pale-yellow, shiny; rachis scabrous. Spikelets 6–6.5 mm long, 2-flowered, open at the apex; pedicels scabrous; rachilla about 1.5 mm long, pubescent, the hairs about 0.5 mm long; glumes acute, translucid; first glumes 5–5.5 × 0.5–0.7 mm, as long as or shorter than the spikelet, 1-nerved; second glumes 6.5–8 × 0.8–1 mm, longer than the spikelet, 3-nerved; first florets about 5 mm long; lemma glabrous, delicate and hyaline; apex ending in two setae about 1 mm long; awns about 5.5 mm long, borne on the upper third at 2 mm below the apex, not twisted nor geniculate, diversely curved; paleas about 3.5 mm long, shorter than the lemma, 2-nerved, the nerves scabrous; apex 2-dentate; lodicules 0.6–0.8 mm long; apex 2-lobulate; anthers 1–1.5 mm long; ovary glabrous. Caryopses not seen.

Anatomy and micromorphology.—Ligule apices with stiff hairs; ligule epidermis composed of long cells with straight walls, prickle hairs and macrohairs; short cells and stomata not observed; blades in transverse section expanded, flat, keeled; ribs present in both sides, rounded, low, separated by wide furrows; first order bundles with I-shaped girders; second order bundles alternating with the first order bundles, with or without sclerenchymatous strands; marginal sclerenchyma very small; bulliform cells inconspicuous; macrohairs present in both epidermises, abundant; abaxial epidermis composed of long cells somewhat fusiform, with straight lateral walls; intercostal short cells absent; stomata in four rows in each intercostal zone.

Distribution.—Endemic to the United States (California, Montana, and Nevada). This is the first report of *T. projectum* for Montana.

Comments.—*Trisetum projectum* has been treated as a variety of *T. canescens* (Hitchcock 1950), *T. cernuum* (Beetle 1946), and *T. spicatum* (Howell 1979). *Trisetum projectum* differs from *T. cernuum* subsp. *canescens* by having glabrous ovaries and spiciform panicles. Louis-Marie (1928-29) noted that *T. projectum* had been mistaken for *T. canescens*, from which it differs by its denser, interrupted, bright and pale-yellow panicles, glabrous lemmas, pilose blades, and glabrous ovaries. Hitchcock (1950) considered *T. projectum* to be a synonym of *T. canescens* because he thought there were intermediate forms, however, spiciform panicles and the glabrous ovaries are consistent characters of the former species. *Trisetum projectum* differs from *T. spicatum* by having less dense panicles, glabrous culms below the panicles (hairy in *T. spicatum*), and very unequal glumes, first glumes narrower than the second (glumes subequal in width in *T spicatum*), and second glumes usually longer than the spikelet (shorter than the spikelet in *T. spicatum*). Howell (1979) separated *T. projectum* from *T. spicatum* by its densely pubescent or velutinous foliage.

Specimens examined **U.S.A. California:** two mi NE of Mather, on trail to Cottonwood Meadow, dry woods of *Pinus ponderosa* and *Quercus kellogii*, 5500 ft, 9 Jul 1947, *Stebbins Jr. 3827* (US); Soda Springs, 9 Aug 1901, *Kennedy & Doten 264*, 265 (US); Sequoia National Forest, mountain meadow, 15 Jul 1927, *Swallen 790* (US), above Cahoon Meadow, 16 Jul 1927, *Swallen 797* (US); Lake Tahoe Region, 600 ft, 25 Jul 1907, *Pendleton & Reed 1247* (US); Near Donner Creek, vicinity of Truckee, 14–16 Jul 1913, *Hitchcock 10500* (US); Yosemite National Park, Upper Loyall Canyon, 9500 ft, 17–25 Aug 1908, *Hitchcock 3307* (US); Tahoe, open dry woods, 6225–7000 ft, 5 Aug 1908, *Hitchcock 3082* (US). (US); Southeastern California to Southern Utah, 9400 ft, 1987, *Purpus 5264* (US); Sierra Nevada, near Donner Lake, 1865, *Torrey 584* (US); Summit Lake, 6695 ft, 27 Aug 1948, *H & V. Bailey 2924b* (US); Yosemite Valley, 4060 ft, 5 Jul 1909, *Jepson 3136* (US); dry woods along Line Creek, Huntington Lake, 23 Jul 1923, *Swallen 853* (US). **Montana:** Spanish Creek Basin, moist woods, 16 Jul 1896, *Williams 2060* (US). **Nevada:** Glenbrook, Lake Tahoe, 6000–8000 ft, 8 Aug 1908, *Hitchcock 3184* (US).

9. Trisetum sibiricum Rupr., Beitr. Pflanzenk. Russ. Reiches 2:65. 1845. *Avena ruprechtii* Griseb., Fl. Ross. 4(13):418. 1852. *Trisetum ruprechtii* (Griseb.) Steud., Syn. Pl. Glumac. 1:226. 1854, *nom. superfl. Trisetum flavescens* var. *sibiricum* (Rupr.) Ohwi, Bot. Mag (Tokyo) 45 (532):192. 1931. *Trisetum bifidum* subsp. *sibiricum* (Rupr.) T. Koyama, Grass. Jap. Neighb. Reg. 533. 1987. TYPE: MALAYA. Zemlya tundra (LECTOTYPE: LE, designated by Tsvelev p. 384. 1983 as "Terra parva Samojedorum, fl. Belaja, leg. Ruprecht").

Trisetum sibiricum subsp. *litorale* Rupr. ex Roshev., Izv. Bot. Sada Akad. Nauk. SSSR 21:90. 1922. *Trisetum sibiricum* var. *litorale* (Rupr. ex Roshev.) Rupr. ex Roshev., Fl. URSS 2:254. 1934. *Trisetum litorale* (Rupr. ex Roshev.) Czer., Sosud. Rast. SSSR 390. 1981, hom. illeg. TYPE: RUSSIA. Litt. Oceani., glac. Kambalnitza, Peninsula Kanin, 13–14 Aug, *Ruprecht s.n* (LECTOTYPE: LE, designated by Tsvelev p.385. 1983; ISOLECTOTYPE: LE).

Perennials with small short rhizomes. Culms 16–40(–100) cm tall, erect, glabrous below the panicles, nodes 4, glabrous or subglabrous. Leaf sheaths glabrous, ciliate at the apex; ligules 1–1.5 mm long, truncate, dentate, ciliate, dorsally glabrous; blades 25–150 × 1.5–4 mm, flat, glabrous abaxially, scabrous to sparsely pilose adaxially, ciliate at the margin, with prominent adaxial ribs. Panicles 3–5.5(–20) × 1.5–2.5 cm, contracted, not spiciform, golden-yellow, not very dense, bright, somewhat lax and drooping; rachis glabrous. Spikelets 7–9 mm long, 2- or 3-flowered; pedicels scabrous; rachilla 1.2–1.4 mm long, densely hairy, the hairs 0.5–2 mm long; glumes shorter than the spikelet or the upper glumes equaling the florets, unequal both in length and width, hyaline towards the apex; first glumes (2.5–)4.5–5.5 × 0.3 mm, linear-lanceolate, 1-nerved; second glumes (4.5–)6.8–7 × 0.8–1 mm, oval-lanceolate, 3-nerved; first florets 5–8 mm long; lemma glabrous, keeled, dorsally scabrous only along the midnerve; apex ending in two setae; callus with hairs about 0.2 mm long; awns 6—8 mm long, borne dorsally on the upper third of the lemma, twisted, 1 or 2 times geniculate; paleas about 6 mm long, shorter than the lemma in the lower florets, longer than the lemma in the upper florets, almost smooth on the nerves; apex bisetulate; lodicules about 0.8 mm long, trilobulate at the apex; anthers 2–2.5 mm long; ovary glabrous. Caryopses not seen.

Chromosome number.—$2n = 14$ (Tateoka 1967, 1978; Frey 1992, 1993).

Anatomy and micromorphology.—Ligule apices composed of hairs and papillate cells; ligule epidermis composed of long cells with straight lateral walls; prickle hairs, macrohairs and stomata not observed; blades in transverse section expanded, V-shaped, with low and rounded ribs; furrows less than one half of the leaf thickness; abaxial surface without ribs; median bundle with a sclerenchymatic strand at the keel; first order vascular bundles with sclerenchymatic I-shaped girders; second order bundles free, alternating between the first order bundles; marginal sclerenchyma very small; bulliform cells not forming well defined fan-shaped groups; abaxial epidermis composed of fusiform long cells with straight side walls; short intercostal cells absent; stomata present; prickle hairs and macrohairs not observed.

Distribution.—*Trisetum sibiricum* is found in Alaska (U.S.A.) and Yukon (Canada) between 68° and 63° N and from the Bering Strait to Yukon. It is also widely distributed in Asia (Central Asia, Siberia, Mongolia, China), and Occidental Europe (Frey 1992).

Comments.—*Trisetum sibiricum* has been treated by some authors as a variety of *T. flavescens.* The characters that separate both species were clearly established by Frey (1992) who mentioned the lower sheaths pubescence, leaf blade width, prominent venation of the blades, awn geniculation, and color of the panicle to differentiate this species from *T. flavescens.* In addition, *T. sibiricum* has lemmas that are scabrous only along the midnerve in contrast to the uniformly scabrous lemmas of *T. flavescens.*

Specimens examined. **U.S.A. Vasey s.n.* (holotype: US-868199!; isotype: NY-431706!).

Caespitose perennials, sometimes with short rhizomes. Culms 9–60 cm tall, erect, tomentose to densely hairy below the panicle, with hairs antrorse below the panicle, then retrorse below; nodes 1 or 2. Leaf sheaths 1–3(–6) cm long, glabrous; ligules ca. 1 mm long, finely denticulate; blades 1–5 cm × 1–1.5 mm, flat or conduplicate towards the apex, glabrous or rarely hairy or scabrous, sometimes ciliate on margins. Panicles 2.5–7(–10) × 0.5–1.5(–2) cm, spiciform, gold-purplish to brown-purple, bright, usually interrupted at the base; rachis hairy. Spikelets 4.5–6 mm long, (1–)2-flowered; pedicels hairy; rachilla 0.8–1 mm long, hairy, the hairs 0.5–1 mm long; glumes shorter than the florets, as long as 3/4 to 4/5 of the spikelet, subequal or the first a little shorter and narrower than the second glume; sometimes, the second glumes equal or a little longer than the spikelet, scabrous or less frequently ciliate on the keel; first glumes 3.7–5 × 0.5–1 mm, lanceolate, 1–3-nerved; second glumes 4.5–6 × 0.5–1.3 mm, 3-nerved; florets 3.8–5 × 0.7–0.8 mm, the second floret 4–4.5 mm long; lemmas dorsally awned, glabrous, scabrous, purplish towards the base, stramineous towards the apex; margin hyaline; apex with two setae; awn 3.5–5 mm long, borne dorsally on the upper 1/3 or 1/4, geniculate or merely curved, sometimes twisted, scabrous, purple; callus obtuse, with hairs 0.3–0.5 mm long; paleas 3–4 mm long, shorter or a little longer than the lemma, hyaline, 2-nerved, the nerves scabrous; anthers 0.5–1 mm long; lodicules ca. 0.6 mm long, hyaline; apex 2-lobed; ovary glabrous. Caryopses 2–2.8 × ca. 0.6 mm, glabrous; endosperm liquid.

Chromosome number.—$2n = 14, 28, 42$ (Holmgren & Holmgren 1977).

Distribution.—A cosmopolitan species widely distributed in Asia, America (North, Central and South America), Europe, Australia, and New Zealand (Hultén 1959; Clebsch 1960; Nicora 1978; Tovar 1993; Pohl & Davidse 1994; Zuloaga et al. 1994; Edgar 1998; Barkworth 1999; Finot 2003a, 2004; Finot et al. 2004). In North America, *T. spicatum* is found in Canada, United States, and Greenland.

Comments.—*Trisetum spicatum* is an extremely variable species, and several subspecific taxa have been described. Louis-Marie (1928-29) recognized 14 varieties for the Americas and Hultén (1959), recognized 22 infraspecific taxa, including 14 subspecies and 8 varieties. Six of the fourteen subspecies recognized by Hultén (1959) are described for North America: subsp. *alaskanum* (Nash) Hultén, subsp. *pilosiglume* (Fernald) Hultén, subsp. *molle* (Michx.) Hultén, subsp. *majus* (Vasey) Hultén and subsp. *congdonii* (Scribn. & Merr.) Hultén. However, the lack of morphological discontinuities hinders the recognition of most of the infraspecific taxa (Randall & Hilu 1986).

Specimens examined. **CANADA. Alberta:** Jasper National Park, NE slope of Mount Edith Cavell, 5800 ft, 28 Aug 1956, *Hermann 13510* (US); Jasper National Park, 7000 ft, 17 Jul 1918, *Macoun s.n.* (US); Jasper National Perk, 9 mi NW of Bubbling Springs on Hwy 93 along Sunwapta River, 52°34'59.3"N, 117°44'18.1"W,1260 m, 5 Jul 2004, *Peterson, Saarela & Smith 18427* (US); Banff National Park, 11 mi NW of Mosquito Creek at Bow Summit, 51°43'16.9"N, 116°29'37.1"W, 2072 m, 4 Jul 2004, *Peterson, Saarela & Smith 18402* (US). **British Columbia:** SSW of Fort Nelson, 57°20'N, 123°56'W, 18 Jul 1960, *Calder & Kulckonen 27145* (SI); 13 mi NW of Pink Mountain on Hwy 97 towards ft. 10b. Trisetum spicatum var. **pilosiglume** Fernald, Rhodora 18:195. 1916. *Trisetum spicatum* subsp. *pilosiglume* (Fernald) Hultén, Svensk Bot. Tidskr. 53:215. 1959. TYPE: CANADA

NEWFOUNDLAND: Island off Pike's Arm, 19 Jul 1911, *M.L. Fernald, Wiegand & Bartram 4593* (HOLOTYPE: GH; ISOTYPES: CAN-33298, S-fragm. ex GH!, US-1024249!).

Perennials. Culms about 20 cm tall, densely hairy below the panicle, the hairs antrorse near the panicle, retrorse below. Leaf sheaths densely hairy; blades 40–60 × 2–3 mm, flat, densely hairy. Panicles 2.5–5 × 0.8–1.2 cm, spiciform, dense, tinged with green and purple; rachis densely hairy. Spikelets about 5 mm long, 2- or 3-flowered; pedicels hairy; rachilla about 0.8 mm long, the hairs about 0.5 mm long; glumes shorter than the spikelet, hairy, ciliate on the keel, acute, green on the back, the margins and apex purplish; first glumes 3.5–3.8 × 0.5 mm, 1-nerved; second glumes about 5 × 1 mm, longer and wider than the first glume, 3-nerved; lemma glabrous or shortly pilose towards the apex, dorsally awned on the upper third; apex with two setae; callus obtuse with hairs; paleas about 4 mm long, shorter or as long as the lemma; lodicules about 0.8 mm long; apex bilobulate, one of the lobes larger than the other; anthers about 0.8 mm long; ovary glabrous.

Chromosome number.—$2n = 14$ (Frey 1992).

Distribution.—This subspecies constitutes the boreal form of the species. It occupies the northeastern region of North America, south of Greenland, East of Canada (Newfoundland, Nova Scotia, Quebec, Manitoba, Ontario, and Saskatchewan), and northeastern United States (Maine, Michigan, Minnesota, New Hampshire, Vermont). Its northern limits are found at 61°N in southern Greenland (Neria), from where it extends to Newfoundland and Quebec, and northeast to the United States.

Specimens examined. **CANADA. Manitoba:** Hudson Bay, 14 Aug 1939, *E.C. Abbe & L.B. Abbe 3885* (S); Great Whale River, 8 Aug 1959, *E. Hultén s.n.* (S). **Nova Scotia: Victoria Co.:** rock crevices along river Salmon River, 5 Jul 1949, *Smith, Collins, Bruce & Sampson 2647* (US). **Ontario:** shore of Lake Superior at Heron Bay South, ca. 6 mi southeast of Marathon, 31 Jul 1961, *E.G. Voss 10448* (S). **Quebec:** Lac Mistassini, Ile Manitounouk (rive sud-est), 365–415 m, 12 Jul 1944, *Rousseau & Rouleau 99* (US) ; East Coast of Hudson Bay, sedimentary slopes near sea level at Boat Opening, Manitounuck Sound, 14 Aug 1939, *E.C. & L.B. Abbe 3863* (US); Lac Mistassini, Pointe Dutilly (Ile Manitounouk), 365–415 m, 23–25 Jul 1945, *Rousseau 1867* (US); Ile D'Anticosti, rivière La Loutre, eboulis argilo-calcaires, 6 Aug 1926, *F. Marie-Victorin & Rolland-Germain 25883* (US); calcareous cliffs and taus, Gros Morne, 7 Jul 1931, *Fernald & Weatherby 2424* (US); E coast of Hudson Bay, Great Whale River, 16 Aug. 1939, *E.C. & L.B. Abbe 4259* (US); Canadian Sub-Arctic Flora, Lac Mistassini et iles du centre, Quebec, 10–17 Aug 1943, *Dutilly & Lepage 11522*, 11483 (US); Ile d'Anticosti, Rivière Vaureal, 27 Jul 1925, *M. Victorin & R. Germain 20550* (P); Falaises de la Montagne St. Alban, pres du Cap-Rosier, 19 Jul 1923, *Marie-Victorin, Brunel, Rolland-Germain & Rousseau 17770* (US); rock crevices near Mt. St. Pierre, 27 Aug 1947, *Swallen 9778* (US); Bill of Portland Island, 13 Sep 1939, *Dutilly, O'Neill & Duman 87875* (US); Cape Jones Island, 54°27'N, 80°04'W, 17 Sep 1939, *Dutilly, O'Neill & Duman 97124* (US); Port Harrison, 58°24'N, 78°20'W, 7–8 Sep 1939, *Dutilly, O'Neill & Duman 87650* (US); Fort George, 53°50'N, 79°06'W, 21–27 Sep 1939, *Dutilly, O'Neill & Duman 97209* (US). **Newfoundland:** recuellis en 1816–1819, 1820, collector not indicated, no date (P); Northern shores of Notre Dame Bay, 20 Aug 1911, *Fernald & Wiegand 4495* (P); Labrador, 27 Jul 1923, *Sablou? 16* (US); Region of St. John Bay, 19 Jul 1929, *Fernald, Long & Fogg, Jr. 1289* (S); Roma Bay, 27 Jul 1930, *Janssan 248* (S); Labrador, 10 Jul 1937, *Potter 7867* (S); Labrador, Hopedale, 10 Jul 1937, *Potter 7865* (US); Western Newfoundland, St. John Bay, dry gravelly or shingly limestone barrens, Old Port Au Choix, 19 Jul 1929, *Fernald, Long & Fogg Jr. 1289* (US); Silurian area of Northwest coast, dry limestone barrens, Brig Bay, 6 Aug 1924, *Fernald, Long & Dunbar 26276* (US); Labrador, rocky hill, Battle Harbor, 13 Aug 1928, *Hitchcock 23871* (US); Labrador, Central Range of the Torngat, Scree slide from top of Precipice Ridge to Komaktorvil Lake, 59°12'N, 64°20'W, 29 Jul 1931, *Abbe 75* (US); Western Newfoundland, Lower Humber Valley, Hannah's Head, 12 Jul 1929, *Fernald, Long & Fogg, Jr. 1288* (US); Labrador, *Sornburger 240* (US); Labrador Peninsula, Battle Harbor, Aug 1912, *Birdseye s.n.* (US); Newfoundland, Western Newfoundland, St. John Bay, Doctor Brook, 24 Aug 1925, *Wiegand & Gilbert, Jr. 27454* (US); Newfoundland, Straits of Belle Isle, dry horizontal limestone, Rock Marsh, Flower Cove, 30 Jul 1924, *Fernald, Long, Dunbar 26275* (US); Western Newfoundland, Bonne Bay, limestone ledges and talus, Shag Cliff, 9 Aug 1929, *Fernald, Long & Fogg, Jr. 1291* (US); Labrador, Hopedale Region, Near the beach by the old Eskimo village, Hopedale, in *Salix-Empetrum* mat, 55°27'N, 60°10'W, *Abbe & Hogg 74* (US); Labrador, West Blanc Sables, 27 Jul 1893, *Waghorne 16* (US); Western Newfoundland, Bonne Bay, turfy limestone crest, 650 m, Killdevil, 23 Aug 1929, *Fernald, Long & Fogg, Jr. 1293* (US). **Saskatchewan**: Lake Athabaska, small island near base of Cornwall Bay, 59°27'N, 108°27'W, *Raup 6545* (US). **GREENLAND:** 62°30'N, 12 Jul 1878, *Kornerup 17* (S); Neria, 61°33'N, 24 Jul 1928, *Eugenius s.n.* (S). Neria 61°33'N, 24 Jul 1928, *Eugenius s.n.* (US); East Greenland, Grant Fjord (Clavering Fjord), Payer Land, 12 Aug 1939, *Bartlett 415* (US), Disko, ca. Neria 61°33'N, 19 Jul 1926, *Eugenius s.n.* (US); Angmagssalik, 65°N, 21 Aug 1939, *Bartlett 429* (US). **U.S.A. Maine:** Maine, Mt. Katahdin, North Basin, 13 Jul 1900, *Fernald s.n.* (US). **Michigan:** Isle Royal, 7 Aug 1901, *Stuntz & Allen 48* (US). **Minnesota: Lake Co.:** exposed rocks, Beaver Bay Is., 11 Jul 1938, *Fasset & Curtis 19562* (US). **New Hampshire:** Mt Washington, 1882, *Faxon s.n.* (US). **Vermont:** Smugglers Notch, Mt Mansfield, in turf of *Saxifraga*, etc., 24 Jun 1935, *Torrey et al. 2361* (US).

APPENDIX 1

Subgeneric treatment of *Trisetum* in North America.

Trisetum

Trisetum subgen. **Trisetum**

Trisetum subgen. **Trisetum** sect. **Trisetum**, Type: *Trisetum flavescens* (L.) P. Beauv.

Species included: *T. cernuum* var. *cernuum*, *T. cernuum* var. *canescens*, *T. montanum*, *T. orthochaetum*, *T. flavescens*, *T. sibiricum*.

Trisetum subgen. **Trisetum** sect. **Trisetaera** Asch. & Graebn., Type: *Trisetum spicatum* (L.) K. Richt.

Species included: *Trisetum projectum*, *T. spicatum* var. *spicatum*, *T. spicatum* var. *pilosiglume*.

APPENDIX 2

Numerical index of the species.

1. *Graphephorum melicoides*
2. *G. wolfii*
3. *Trisetum aureum*

4a. *Trisetum cernuum* var. *cernuum*,
4b. *T. cernuum* var. *canescens*

5. *T. flavescens*
6. *T. montanum*
7. *T. orthochaetum*
8. *T. projectum*
9. *T. sibiricum*

10a. *T. spicatum* var. *spicatum*,
10b. *T. spicatum* var. *pilosiglume*

APPENDIX 3

Index of exsiccatae.

APPENDIX 4

List of names and synonyms. **Accepted names** are present in bold, *synonyms* are italicized.

Acrospelion Besser ex Schult. & Schult.f. = **Trisetum**

Agrostis airoides (Poir.) Raspail= **Graphephorum melicoides**

Aira melicoides Michx. = **Graphephorum melicoides**

Aira spicata L = **Trisetum spicatum** var. **spicatum**

Aira subspicata L. = **Trisetum spicatum** var. **spicatum**

Arundo airoides Poir = **Graphephorum melicoides**

Avena airoides Koel. = **Trisetum spicatum** var. **spicatum**

Avena cernua (Trin.) Kunth = **Trisetum cernuum** subsp. **cernuum**

Avena distichophylla Vill. = **Trisetum distichophyllum**

Avena flavescens L. = **Trisetum flavescens**

Avena mollis Michx. = **Trisetum spicatum** var. **spicatum**

Avena nutkaensis J. Presl = **Trisetum cernuum** subsp. **cernuum**

Avena ruprechtii Griseb. = **Trisetum sibiricum**

Bromus berteroanus Colla

Calamagrostis airoides (Poir.) Steud. = **Graphephorum melicoides**

Calamagrostis sesquiflora (Trin.) Tzvelev
Danthonia intermedia Vasey
Deschampsia danthonioides (Trin.) Munro
Deyeuxia airoiodes (Poir.) P. Beauv. = **Graphephorum melicoides**
Dielsiochloa floribunda (Pilg.) Pilg.
Dupontia cooleyi A. Gray = **Graphephorum melicoides**
Graphephorum Desv.
Graphephorum altijugum E.Fourn.= **Peyritschia koelerioides**
Graphephorum cooleyi (A. Gray) Farw. = **Graphephorum melicoides**
Graphephorum melicoides (Michx.) Desv.
Graphephorum melicoides var. *cooleyi* (A. Gray) Scribn.= **Graphephorum melicoides**
Graphephorum melicoides var. *majus* A. Gray = **Graphephorum melicoides**
Graphephorum pringlei Scrib.ex Beal = **Trisetum pringlei**
Graphephorum shearii(Scribn.) Rydb. = **Trisetum montanum**
Graphephorum wolfii (Vasey) Vasey ex Coult.
Helictotrichon Besser ex Schult. & Schult. f.
Helictotrichon canescens (Buckley) Clayton = **Trisetum cernuum** subsp. **canescens**
Koeleria aurea Ten. = **Trisetum aureum**
Koeleria canescens Torr. ex Trin. = **Trisetum spicatum** var. **spicatum**
Koeleria spicata Reichb. ex Willk. & Lange = **Trisetum spicatum** var. **spicatum**
Koeleria subspicata (L.) Reichb. = **Trisetum spicatum** var. **spicatum**
Melica triflora Bigelow = **Trisetum spicatum** var. **spicatum**

ACKNOWLEDGMENTS

This paper is part of the doctoral thesis of VLF in the Dpto. Botánica, Universidad de Concepción, Concepción, Chile. We Thank the Directors and Curators of the following herbaria: BA, BAA, BAF, C, CR, CONC, F, LP, MERL, P, PR, QCA, SGO, S, SI, US. We thank John H. Rumely, an anonymous reviewer, and Barney Lipscomb for suggesting improvements to the manuscript. VLF gratefully acknowledges the Myndel Botanica Foundation for a fellowship to study types of *Trisetum* at Paris (P) and Stokholm (S); Project DIUC 204.121.009-1-0 at the University of Concepción for financial support; the MECESUP-Universidad de Concepción UCO 9906/01 for a fellowship to study the genus at Smithsonian Institution, Washington, DC and Instituto de Botánica Darwinion, Buenos Aires; and Oscar Matthei and Clodomiro Marticorena for directing VLF's PhD.

BOOK REVIEW

Tony Prato and Dan Fagre. 2005. **National Parks and Protected Areas: Approaches for Balancing Social, Economic, and Ecological Values.** (ISBN 0-8138-1248-8, hbk.). Blackwell Publishing Professional, 2121 State Avenue, Ames, IA, 50014, U.S.A. (**Orders:** 800-862-6657; 1-515-292-3348; www.blackwellprofessional.com). $124.99, 446 pp., b/w figures, graphs, tables, index, 7" × 10".

"This book is designed as a primary or supplemental text for upper division undergraduate courses and introductory graduate courses in conservation and management of national parks and protected areas, natural resource planning and management, natural resource economics, conservation biology, public land management, and related subjects."

Features of the book include (from the publisher's notes):

* a multidisciplinary, systems perspective;
* focus on science- and knowledge-based natural resource management; concentration on North American national parks and protected areas with information and examples from other parts of the world;
* clarification of methods for dealing with social, economic, and ecological uncertainty;
* explanations of biophysical and economic simulation models and information management technologies: GIS, remote sensing, decision support systems, computer animation, etc.;
* discussion of the role of local communities and joint decision making for designing and implementing management strategies;
* case studies that show multi-dimensional decision making for specific management problems and issues.

Chapters are these:

1. Contemporary issues in protected area management
2. Role and status of protected area
3. Cultural values
4. Social, economic, and ecological values
5. Institutional environment
6. Selection and delineation
7. Concepts for ecosystem management
8. Approaches to ecosystem management
9. Case studies in protected area management--I
10. Case studies in protected area management--II
11. Future planning and management
12. Synthesis

The brief and dry-sounding chapter titles belie the remarkable information and perspectives laid out in this book, hopefully to be read and absorbed by those who will help all of us preserve and maintain natural areas.—*Guy Nesom, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

NEW COMBINATIONS IN *FESTUCA CALIFORNICA* (POACEAE)

Stephen J. Darbyshire

Agriculture and Agri-Food Canada
Central Experimental Farm, Building #49
Ottawa, Ontario, K1A 0C6, CANADA

ABSTRACT

The *Festuca californica* Vasey complex is examined. Considerable morphological variation exists within and between populations which range from western Oregon to southern California. The characters of sheath pubescence, sclerenchyma distribution in the blades of vegetative shoots and ligule length are of use in distinguishing three taxa in the complex. Analysis of character variation and geographic distribution suggests that these taxa are best treated at the rank of subspecies; the new combinations *Festuca californica* subsp. *hitchcockiana* and *F. californica* subsp. *parishii* are provided.

RESUMEN

Se examina el complejo *Festuca californica* Vasey. Existe una variación morfológica considerable en y entre poblaciones que van desde el Oeste de Oregón hasta el Sur de California. Los caracteres pubescencia de la vaina, distribución de esclerénquima en las láminas de los tallos vegetativos y longitud de la lígula se usan para diferenciar los tres taxa del complejo. El análisis de la variación del carácter y distribución geográfica sugieren que estos taxa deben tratarse en el rango de subespecies; Se hacen las nuevas combinaciones *Festuca californica* subsp. *hitchcockiana* y *F. californica* subsp. *parishii*.

California fescue, *Festuca californica* Vasey, is the largest North American species of the genus and shows considerable variation in many morphological characters. It is usually readily distinguished from other North American species of *Festuca* by its large size and the presence of stiff hairs on the leaf collar region. These hairs may be absent over the back of the sheath apex and restricted to the margins (auricular region). Occasionally collar hairs are absent altogether on some sheaths, but examination of a number of leaves on the same plant will usually reveal hairs on the collar margins of at least some leaves.

Morphological variation was examined on 113 specimens of *Festuca californica* sensu lato, including three taxa that are sometimes recognized as separate species (e.g., Alexeev 1982; Aiken et al. 1997). Variation in characters used to distinguish taxa did not consistently correlate to allow the unambiguous recognition of separate species, although three infraspecific taxa may be recognized with some confidence. In addition to their morphological differences, they have largely separate distributions, hence are best treated as subspecies.

Unless otherwise stated, the descriptions of leaves refer to those of the sterile vegetative shoots or innovations which form a large proportion of the densely caespitose clumps of these bunch-grasses. The width of convolute, involute or conduplicate leaf blades is given as the widest diameter.

SIDA 21(3): 1455–1463. 2005

Festuca californica Vasey, Contr. U.S. Natl. Herb. 1(8):277. 1893. Type: U.S.A. California. Oakland hills, 1862, *H.N. Bolander 1505* (holotype: US-556212!).

Bromus kalmii var. *aristulatus* Torr., Pacific Railr. Rep. 4(5):157. 1857. *Festuca aristulata* (Torr.) Shear *ex* Piper, Contr. U.S. Natl. Herb. 10(1):32. 1906. *Festuca altaica* subsp. *eualtaica* var. *aristulata* (Torr.) St.-Yves, Candollea 2:273. 1925. Type: U.S.A. California. Mark West's Creek, 30 Apr 1854, *J.M. Bigelow s.n.* (lectotype, designated by Piper 1906:33: US-556211!; isolectotype: GH).

Plants densely caespitose, without rhizomes. **Culms** (30–)60–150(–275) cm tall; internodes glabrous to pubescent (often pubescent for up to 20 mm below the nodes). **Prophylls** 2–9 cm long, scabrous to pubescent (at least apically) and usually scabrous or ciliate on the veins. **Sheaths** open to the base, margins overlapping, glabrous or scabrous to pilose (sometimes only at the apex or on upper margins), persistent; **collars** usually densely pubescent, sometimes inconspicuously pubescent, with a few hairs at the margins, or glabrous; **ligules** (0.2–)0.8–1.5(–6) mm (ligules of the cauline leaves tend to be somewhat longer than those of the vegetative shoots), usually ciliate at apex, abaxial surface glabrous to pubescent; **blades** (0.5–)0.8–2(–2.5) mm wide (3–6.5 mm wide when flat), convolute, involute, conduplicate or flat, abaxial surface glabrous, scabrous or basally pubescent or pilose, adaxial surface puberulent to densely pubescent-pilose or more or less tomentose, 9–17(–19) veins, (3–)5–17(–19) adaxial ribs; **sclerenchyma** in a more or less continuous abaxial band or ring, usually with pillars or girders present at most veins, sometimes reduced to small strands at abaxial and adaxial surfaces (Fig. 1). **Inflorescences** (10–)15–25(–30) cm long, open; **branches** terete or angular, glabrous to scabrous-pubescent (especially on angles) and sometimes pubescent at the base in the axils of lower branches, spreading and lax, (1–)2(–3) per node, lower branches with a distinct pulvinus. **Spikelets** (8–)10–18(–20) mm long, borne toward the ends of the branches, usually green or sometimes reddish-purple, with (3–)4–6(–8) florets. **Glumes** lanceolate, glabrous or sparsely scabrous at apex. **Lower glumes** (3.5–)4.5–6.7(–8) mm long, 1 vein; **upper glumes** (4.5–)6–10 mm long, 3 veins; **lemma callus** indurate, wider than long, scabrous laterally; **lemmas** (5–)7.5–11(–11.5) mm long, lanceolate, scabrous, or puberulent (rarely pubescent), sometimes minutely bidentate, acute, usually with an awn (0.5–)1–3(–4) mm long; **paleas** slightly shorter than to slightly longer than lemma body, emarginate or bidentate, glabrous or pubescent on the margins, scabrous or pubescent between the veins apically or throughout, the veins scabrous to about the middle or sometimes right to the base; **rachillas** scabrous to pubescent (sometimes sparsely) at least on abaxial side (away from palea), usually glabrous on the adaxial side; **anthers** 3, (3–)4–7.5(–8.5) mm; **ovary apex** pubescent.

Distribution and habitat.—Dry open slopes and moist streambanks in chaparral, thickets, open forests and forest openings (coniferous, oak or mixed forests). Often on ultramafic substrates. Sea level to about 1500 m elevation. From

western Oregon to the Palomar Mountains in southern California (Fig. 2). It is reported as far north as Washington County, Oregon in the online specimen database of OSU (oregonstate.edu/dept/botany/herbarium/db.php).

KEY TO THE INFRASPECIFIC TAXA OF *FESTUCA CALIFORNICA*

1. Culms 30–80(–100) cm tall; internodes usually pubescent for 5–20 mm below the nodes; lower sheaths usually densely retrorse pubescent, sometimes sparsely pubescent or glabrous; blades 0.5–1.2(–1.5) mm wide, conduplicate (sometimes loosely), with (3–)5–9 shallow adaxial ribs (to about half as deep as blade thickness); sclerenchyma in small abaxial strands to a continuous band and adaxial strands present or absent, pillars rarely formed, girders absent; spikelets with 3–4 florets; plants of the San Gabriel and San Bernardino Mountains and southward ________ subsp. **parishii**

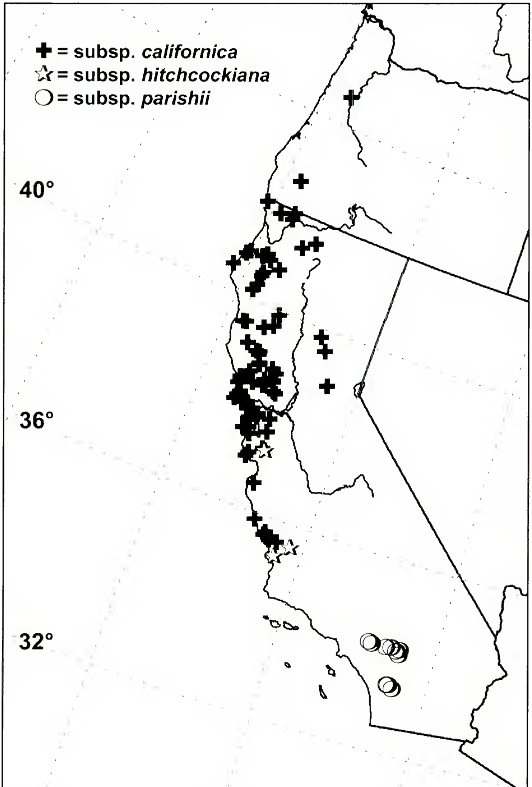

Fig. 2. Distribution of specimens of *Festuca californica* examined in this study. ✚ = subsp. *californica*. ☆ = subsp. *hitchcockiana*. ○= subsp. *parishii*.

1. Culms 60–180(–275) cm tall; internodes glabrous or pubescent for less than 5 mm below the nodes; lower sheaths usually glabrous or sometimes pubescent (the hairs spreading or sometimes retrorse); blades 0.8–2.5 mm wide (3–6.5 mm wide when flat), convolute, involute, conduplicate or often flat, with 7–15(–19) deep adaxial ribs (usually more than half as deep as blade thickness); sclerenchyma in a continuous abaxial band and with adaxial strands, forming pillars or girders at most of the veins; spikelets with (3–)4–6(–8) florets; plants more northerly in distribution.
   2. Ligules a short ciliate membrane 0.2–1(–1.2) mm long; spikelets (8–)12–18(–20) mm long; lemmas (5–)7.5–11 mm long ________________ subsp. **californica**
   2. Ligules a longer membrane (usually 1–6 mm long), ciliate or not; spikelets 8–12 (–17) mm long; lemmas 7–8(–8.5) mm long ________________ subsp. **hitchcockiana**

Festuca californica subsp. californica

Culms 60–180(–275) cm tall; internodes glabrous or often pubescent up to about 5 mm below the nodes. **Sheaths** glabrous to pubescent; **collars** usually densely pubescent (at least at the margins), sometimes inconspicuously pubescent or glabrous; **ligules** 0.2–1(–1.2) mm long, a ciliate membrane; **blades** 0.8–2 mm wide (3–5 mm wide when flat), convolute, involute, conduplicate or flat, with 7–15 (–19) deep ribs (usually more than half as deep as blade thickness); **sclerenchyma** a continuous abaxial band, with adaxial strands, usually forming girders at most veins (Fig. 1a, b). **Inflorescences** 15–25(–30) cm long. **Spikelets** (8–)12–18(–20) mm, with (3–)4–6(–8) florets. **Lemmas** (5–)7.5–11 mm long, usually entire, or sometimes minutely bidentate. Chromosome number: $2n = 56$ (Stebbins & Love 1941).

This is the most widespread subspecies, occurring from northwestern Oregon south to southwestern California. The leaf sheaths of the vegetative shoots are typically glabrous or scabrous, although plants with a few pubescent sheaths are not uncommon. The hairs are, however, usually not strongly retrorse and are often restricted toward the top of the sheaths. Plants with pubescent leaf sheaths differ from subsp. *parishii* in possessing sclerenchyma girders at the major veins in the leaf blades. Ligules are a ciliate membrane, usually about 0.5 mm long or less.

Selected specimens: **U.S.A. CALIFORNIA: Alameda Co.:** West Berkeley, 1916, *P.B. Kennedy*, (AHUC 5715); Berkeley, Shasta Road, N facing grassy slope, 1 Jun 1939, *G.L. Wilson & F. Camacho 7014* (DAO 786419). **Josephine Co.:** Galice Creek road 3.0 mi from junction with Rogue River road at Galice, steep serpentine hillside on N side of creek, common in partial shade at edge of oak-pine woods by the slope, elev. 1250 ft, 10 May 1974, *K.L. Chambers 3915* (DAO 540761).

Festuca californica subsp. **hitchcockiana** (E.B. Alexeev) S.J. Darbyshire, comb. et stat. nov. BASIONYM: *Festuca hitchcockiana* E.B. Alexeev, Byull. Moskovsk. Obshch. Isp. Prir., Otd. Biol., n.s., 87(2):111. 1982. TYPE: U.S.A. CALIFORNIA. Santa Clara Co.: 6 May 1921, *A.H. Wolley-Dod 207* (HOLOTYPE: K).

Culms 60–120 cm tall; internodes glabrous or pubescent for up to 5 mm below the nodes. **Sheaths** glabrous, scabrous or sometimes retrorse pubescent; **collars** densely to sparsely pubescent or sometimes glabrous; **ligules** (1–)1.5–6 mm long, with or without apical cilia; **blades** 0.8–2 mm wide (3–5 mm wide when flat), convolute, involute, conduplicate or flat, with 7–15(–17) deep adaxial ribs (usually more than half as deep as blade thickness); **sclerenchyma** as in subsp. *californica* (Fig. 1c). **Inflorescences** 15–25 cm long. **Spikelets** 8–12(–17) mm long, with (4–)5–6(–8) florets. **Lemmas** 7–8(–8.5) mm long, entire or minutely bidentate. Chromosome number unknown.

This subspecies is distinguished by its longer ligules which are usually not ciliate, but often lacerate. Ligules of leaves of the vegetative shoots are usually (1–)1.5–2 mm long while those of the culm leaves may be even longer. The collars may be glabrous or pubescent. Sclerenchyma in the leaf blades on the vegetative shoots is well developed with girders present at the major veins (Fig. 1c). The spikelets and lemmas tend to be somewhat smaller in this taxon than the other subspecies. Although the range overlaps with that of subsp. *californica*, it occurs only in central California (Santa Clara and San Luis Obispo counties) near the southern part of the range of the typical subspecies. It is less commonly collected than the other two subspecies and appears to have a more restricted distribution. The form of the ligule and somewhat smaller spikelets and floral bracts so clearly distinguish these populations that subspecific rank seems warranted.

Specimens seen: **U.S.A. CALIFORNIA: San Luis Obispo Co.:** See Canyon, 3 May 1948, *R.F. Hoover 7512* (DAO 635974); See Canyon, 14 May 1964, *R.F. Hoover 8864* (DAO 635612, 635951; RSA 201564); See Canyon, lower part of Perfumo Canyon, clay soil from serpentine, 14 May 1964, *R.F. Hoover 8878* (DAO 635956).

Festuca californica subsp. **parishii** (Piper) S.J. Darbyshire, comb. nov. BASIONYM: *Festuca aristulata* subsp. *parishii* Piper, Contr. U.S. Natl. Herb. 10(1):33. 1906. *Festuca parishii* (Piper) Hitchc. in Jepson, Fl. Calif. 1:169. 1912. *Festuca californica* var. *parishii* (Piper) Hitchc. in Abrams, Ill. fl. Pacific States 1:222. 1923. TYPE: U.S.A. CALIFORNIA: San Bernardino Mountains, Mill Creek Falls, alt. 5500 ft, 20 Jun 1901, *S.B. Parish 5036* (LECTOTYPE, designated by Hitchcock in Jepson 1912: 169: US-556210!).

Culms 30–80(–100) cm tall; internodes usually densely pubescent up to 20 mm below the nodes. **Sheaths** usually densely retrorse pubescent, rarely glabrous or sparsely pubescent; **collars** usually densely pubescent, at least at margins (rarely glabrous); **ligules** (0.2–)0.5–1.5(–2) mm, a ciliate membrane; **blades** 0.5–1.2(–1.5) mm wide, conduplicate (or loosely folded), with (3–)5–9 shallow adaxial ribs (up to about half as deep as blade thickness); **sclerenchyma** in small abaxial strands to a continuous band, with or without adaxial strands at the major veins, rarely forming pillars (girders absent) (Fig. 1d–f). **Inflorescences** 10–20 cm long. **Spikelets** 11–16 mm long, with 3–4 florets. **Lemmas** (8)9–11.5 mm long, usually minutely bidentate, sometimes entire. Chromosome number unknown.

This subspecies occurs in dry chaparral or open forests of southern California in the San Gabriel, San Bernardino and Palomar Mountains (Fig. 2). Although the lemmas tend to be somewhat larger than the other two subspecies, overall plants tend to be smaller. Leaf blades tend to be narrower and shorter (10–30 cm long, versus usually more than 30 cm long) and the sclerenchyma is less developed with the abaxial band often discontinuous or reduced to small fascicles opposite the veins, pillars only sometimes present and girders absent (Fig. 1d–f). Leaf sheaths of the vegetative shoots are usually densely retrorse pubescent, but are sometimes sparsely pubescent to glabrous.

Selected specimens: **U.S.A. CALIFORNIA: Los Angeles Co.:** San Dimas Expt. For., San Gabriel Mts., Wolfskill firebreak near Brown's Flat, 28 May 1942, *KHB (624) 631*, (RSA-POM 308944). **San Bernardino Co.:** San Bernardino Mts., 7 Oaks, Jul 1901, *A. BOOK REVIEWS

Tracy Irwin Storer, Robert L. Usinger, and David Lukas. 2004. **Sierra Nevada Natural History. Revised Edition.** (ISBN 0-520-23277-1, hbk.; ISBN 0-520-24096-0, pbk.). University of California Press, Berkeley, CA 94704, U.S.A (**Orders:** California Princeton Fulfillment Services, 1445 Lower Ferry Road, Ewing, NJ 08618, U.S.A., 609-883-1759, 609-883-7413 fax; www.ucpress.edu). $24.95 pbk., 439pp., color photos, b/w drawings, 5" × 8".

The original edition by Storer and Usinger was published in 1965. Lukas has extensively revised this popular guide to the topology, geography, fauna, and flora of the area, incorporating field and laboratory investigations and taxonomic changes. In the concise but thorough introduction he explains the region and its diversity. Very important is the relatively brief section, "The Changing Landscape," in which he discusses the effects of global warming, clear cutting of forests, the use of prescribed fire, introduced non-native species, and also human impact.

The book is not definitive in species of the area but rather those that are most likely to be encountered. Following each species description, distribution is noted, that is, the habitat, terrain, elevation. "Remarks" include interesting facts, such as, in the case of flowering plants, the use of them by man and other creatures. As in the earlier edition, drawings accompany many species in the text, and over 500 small but brilliant color photographs enhance the book, serving as both aid to identification and stimulus for the user.

The book is well bound and a comfortable-to-hold field-guide size.—*Joann Karges, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

Phyllis M. Faber (Ed.). 1997. **California's Wild Gardens: A Guide to Favorite Botanical Sites.** (ISBN 0-520-24031-6, pbk.). University of California Press, Berkeley, CA 94704, U.S.A (**Orders:** California Princeton Fulfillment Services, 1445 Lower Ferry Road, Ewing, NJ 08618, U.S.A., 609-883-1759, 609-883-7413 fax; www.ucpress.edu). $34.95 pbk., 236pp., color photos, 9" × 12".

This is a 2005 printing of a 1997 title, *California's Wild Gardens. A Living Legacy.* Quoting from the preface, "California is blessed with a wealth of plant life that reflects the diversity of its natural landscape. Showcasing some of the state's rare and unique plants and their distinctive habitats along with some of the more common treasures, this book attempts to provide an introduction to California's priceless botanical heritage." Both the California Native Plant Society and the California Department of Fish and Game are to be congratulated in producing this beautiful book.

EUGENIA INVERSA (MYRTACEAE), A NEW SPECIES FROM ESPÍRITO SANTO, BRAZIL

ABSTRACT

Eugenia inversa, a new species from coastal rainforests of the Brazilian state of Espírito Santo, is described and illustrated. The new species is apparently related to the central Brazilian *Eugenia mikanioides*, from which it is distinguished by pilose leaves and flowers, shorter pedicels and triangular, acute calyx lobes.

RESUMO

Eugenia inversa, uma nova espécie da floresta pluvial costeira do estado do Espírito Santo, Brasil, é descrita e ilustrada. Esta espécie é aparentemente próxima a *Eugenia mikanioides*, coletada no Brasil central, da qual se distingue pelas folhas e flores pilosas, pedicelos curtos e lobos do cálice triangulares.

Eugenia is one of the largest genera of the Myrtaceae in Brazil with about 350 native species (Landrum & Kawasaki 1997). The family as a whole comprises about 1000 species in Brazil (Landrum & Kawasaki 1997), and is especially well-represented in the southeastern Brazilian coastal forests, where it is frequently among the most sampled families in floristic inventories (e.g. Mori et al. 1983; Peixoto & Gentry 1990; Thomaz & Monteiro 1997). Among specimens examined from northern Espírito Santo, I have found an unidentified *Eugenia* that I consider as new and describe herein.

Eugenia inversa Sobral, sp. nov. (**Figs. 1, 2**). TYPE: BRAZIL. ESPÍRITO SANTO: mun. Conceição da Barra, Itaúnas, 15 Jan 2005, *M. Sobral 9666* (HOLOTYPE: BHCB; ISOTYPES: BRIT, CEPEC, M, MBM, K, MBML, RB, VIES).

Species haec a *Eugenia mikanioides* proxima, a qua foliis et floribus pilosis, pedicellis parvis et lobis calycinis exterioribus triangularibus quam interioribus valde majoribus recedit.

Small tree 3–4 m high. Bark reddish, peeling. Twigs, petioles and abaxial side of blades with indumentum of erect, brownish or grayish trichomes 0.4–0.8 mm long; pedicels and flowers with trichomes to 0.4 mm long. Petioles 1.5–2.5 × 1 mm long. Blades ovate, elliptic or oblong-elliptic, 60–100 × 30–50 mm, deflexed in living plants, discolored when dry, darker adaxially; glandular dots visible abaxially, to 0.1 mm in diameter and about 10 per square mm; apex acuminate to 20 mm; base cordiform, sometimes obtuse; midvein sulcate and occasionally

Fig. 1. *Eugenia inversa*. Scanned image of holotype (BHCB).

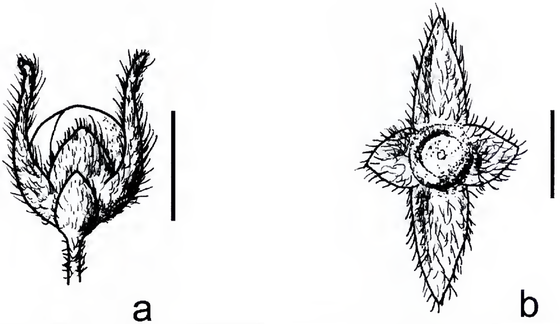

FIG. 2. *Eugenia inversa*. Schematic drawings of flowers: **a)** flower bud; **b)** calyx in an open flower viewed from above. Scales: 2 mm. Both from *Sobral 9666* (BHCB).

with trichomes to 0.3 mm long adaxially, salient abaxially; secondary veins 7–9 pairs, faintly visible adaxially, evident and sometimes weakly salient abaxially, leaving the midvein at angles about 70 degrees; paramarginal vein (sensu Carr et al. 1986) 3.5–5 mm from the revolute margin, sometimes a submarginal vein (sensu Carr et al. 1986) 0.8–1 mm from margin. Inflorescences glomeruliform to shortly racemiform (bracteate shoots sensu Landrum & Kawasaki 1997), axillary or terminal, sometimes ramiflorous, the axis 6–10 × 0.5–0.8 mm, with up to 6 flowers (or the flowers occasionally solitary), when axillary sometimes concealed by the leaves when observed from above; bracts triangular, 0.8–1.7 × 0.5–0.8 mm, persisting; pedicels 3–10 × 0.3–0.5 mm; bracteoles triangular, to 1 × 0.8–1 mm, densely covered with trichomes to 0.4 mm long and with 4–6 glandular setae to 0.2 mm long at the adaxial side, below the insertion of the flower; flower buds globose, to 3 × 2 mm, densely pilose; calyx lobes four, pilose on both sides, markedly unequal, the external ones lanceolate-triangular, 2–3 × 0.9–1.3 mm, visibly projected beyond the globe of the petals and sometimes slightly curved outwards in bud, the internal ones triangular, 0.7–1.3 × 1–1.8 mm; petals rounded, 1–1.3 × 1 mm, glabrous or with cilia to 0.1 mm long; stamens 30–40, 1–1.5 mm, the anthers globose, 0.2 × 0.2 mm, without evident glands; staminal ring 1 mm in diameter; style 1.8–2 mm, the stigma punctiform and finely papillose; ovary bilocular, with 1–4 central-basally attached ovules per locule. Fruits elliptic, vinose or black when ripe, sparsely pilose, 10–15 × 8–10 mm, 1-seeded; seed elliptic, with grayish testa; embryo with fused cotyledons and no evident hypocotyl.

Habitat, distribution and phenology.—*Eugenia inversa* is a small tree from restingas, that is, scrubby forests to 10 m high on sandy soils that exist along southeastern Brazilian coast line; presently it is known only for the municipality of Conceição da Barra, in northern Espírito Santo (about 18°30'S, 39°45'W); flowers were collected in January, February and June, and fruits in January, February, June and December.

Conservation status.—According to the criteria proposed by IUCN (2001) for evaluation of conservation status, this species could be considered as an endangered one (EN), since it fits criteria B1 ab(iii), that is, has an estimated range of less than 5000 km^2 (B1), grows in a severely fragmented habitat and is known from less than five localities (a), and its habitat presents a continuing decline in its extension (b(iii)), since restinga habitats in northern Espírito Santo have been suffering severe damage by anthropic activities such as urban expansion and extensive artificial *Eucalyptus* forestation.

Taxonomic affinities.—This species is apparently related to *Eugenia mikanioides* O. Berg (for description see Berg 1857–1859: 298), from which it can be set apart by the characters in the following key:

1. Leaves and flowers glabrous; pedicels more than 20 mm long; calyx lobes rounded, the internal ones larger than the external ones; plants from savanna formations of Goiás (central Brazil) ____ **Eugenia mikanioides**
1. Leaves and flowers evidently pilose; pedicels to 10 mm long; calyx lobes triangular, the external ones much larger than the internal ones; plants from coastal rainforests of Espírito Santo ____ **Eugenia inversa**

Etymology.—The epithet, derived from the Latin word for inverted, is allusive to the different sizes of the calyx lobes of the flowers; in most species of *Eugenia* with unequal calyx lobes, the external lobes are smaller than the internal ones. In *Eugenia inversa* the external lobes are markedly longer than the internal ones.

PARATYPES. **BRAZIL. Espírito Santo:** Conceição da Barra, 26 Feb 1992, *O. Pereira 2861* (RB, VIES); 9 Jun 1992, *O. Pereira 3461* (RB, VIES); 9 Dec 1992, *O. Pereira 4357* (RB, VIES); 15 Jan 2005, *M. Sobral 9670* (BHCB, MBM).

BOOK REVIEW

ELISEO TORRES and TIMOTHY L. SAWYER, JR. 2005. **Curandero: A Life in Mexican Folk Healing.** (ISBN 0 8263 3640 X, pbk.). University of New Mexico Press, 1601 Randolph Rd SE, Suite 200S, Albuquerque, NM 87106, U.S.A. (**Orders:** www.unmpress.com/Ordering.html, 1-800-249-7737). $14.95, 170 pp., b/w drawings, b/w photographs, 5 1/2" × 8".

In this hybrid between a memoir and an anthropological text, *Curandero: A Life in Mexican Folk Healing* recounts Eliseo "Cheo" Torres's experiences with curanderos, or traditional Mexican folk healers. The curandero tradition is strong in South Texas, where Dr. Torres was born and raised. This book covers the spiritual and historical aspects of the tradition, while making room to discuss the tradition as it is practiced today. Curanderos or curanderas heal their patients using herbs and techniques including massage and rituals. In this book, the reader is introduced to several famous curanderos including El Nino Fidencio and Don Pedrito Jaramillo, as well as fictional characters amalgamated from people Dr Torres knows. Herbal remedies used by curanderos, such as nopal cactus and the ubiquitous chamomile tea and "yerba Buena," or mint are discussed. The authors also lead the reader through magical remedies for spiritual illnesses including mal de ojo and susto. The text together with the black and white illustrations and photographs come together to provide an insider's view of a folk healing tradition that stretches across the Southwest and Mexico.—*Marissa Oppel, Museum Assistant, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A., moppel@brit.org*

ABSTRACT

Sericocarpus is a genus of five species of white-rayed asters native to North America. Three species are found in eastern North America (*S. asteroides, S. tortifolius, S. linifolius*) and two are found in western North America (*S. oregonensis, S. rigidus*). *Sericocarpus oregonensis* has been divided into two subspecies based on pubescence and geography (subsp. *californicus* and subsp. *oregonensis*). Over 2300 herbarium specimens were examined to determine the distribution and morphological ranges of variation in traits of each species. Multivariate morphometric analyses of 111 specimens were undertaken to determine which of the 44 vegetative and 19 floral characteristics examined were diagnostic for the species and which species were most similar. The results of cluster and discriminant analyses indicated that all five species were distinct. The species were distinguished on the basis of stem, leaf and floral traits and to a lesser degree on geographic distribution and habitat data. In order to explore the validity of the division of *S. oregonensis* into two infraspecific taxa, stem and leaf pubescence traits were examined on 125 specimens of *S. oregonensis*. The results indicated that *S. oregonensis* can be divided into two subspecies based on pubescence and geography. The statistical results and morphometric measurements were used to construct comprehensive descriptions and an identification key to all taxa of *Sericocarpus*. The pappus was found to be triple or rarely quadruple in all species.

RESUMEN

Sericocarpus es un género norteamericano con cinco especies que tienen los radios blancos. Tres especies se encuentran en el Este (*S. asteroides, S. tortifolius, S. linifolius*) y dos en el Oeste (*S. oregonensis, S. rigidus*). *Sericocarpus oregonensis* ha sido dividido en dos subespecies basadas en la pubescencia y la geografía (subsp. *californicus* y subsp. *oregonensis*). Se han examinado más de 2300 especímenes de herbario para determinar la distribución y los rangos morfológicos de variación en caracteres de todas las especies. Se realizó un análisis morfométrico multivariante de 111 especimenes para determinar cuales de los 44 caracteres vegetativos y 19 florales examinados eran diagnósticos para las especies y que especies eran las más semejantes. Los resultados de los análisis discriminantes y de agrupamiento indican que las cinco especies son diferentes. Las especies se diferencian por caracteres de tallos, hojas y flores, y en menor medida por su distribución geográfica y datos del hábitat. Para comprobar la validez de la división de *S. oregonensis* en dos taxa infraspecíficos, se examinó la pubescencia de tallos y hojas en 125 especimenes de *S. oregonensis*. Los resultados indican que *S. oregonensis* puede dividirse en dos subespecies basadas en la pubescencia y la geografía. Los resultados estadísticos y las medidas morfométricas se usaron para realizar descripciones

detalladas y una clave de identificación de todos los taxa de *Sericocarpus*. Se encontró que el vilano era triple o raramente cuádruple en todas las especies.

INTRODUCTION

The genus *Sericocarpus* Nees (Asteraceae: Astereae) includes five species found only in North America according to the most recent reviews of the genus (Nesom 1993, 1994, 2000; Semple & Leonard 2005). Three of the species occur in the eastern United States (*S. asteroides*, *S. tortifolius* and *S. linifolius*) and two occur in the Pacific States of the United States and on southern Vancouver Island in British Columbia, Canada (*S. oregonensis* and *S. rigidus*). The first of these two western species has been subdivided into two subspecies subsp. *oregonensis* and subsp. *californicus*. Nees (1832) first recognized *Sericocarpus* as a genus distinct from *Aster* L. Others such as Gray (1884), Small (1903), Fernald (1950), and Nesom (1993, 1994, 2000) also treated *Sericocarpus* as a distinct genus. However, in the last fifty years, most botanists have followed Cronquist (1955, 1968, 1980; Gleason & Cronquist 1991) in treating *Sericocarpus* as part of the genus *Aster* in the broad traditional sense, including Jones (1980) and Semple and Brouillet (1980a). Semple et al. (1996) retained *Sericocarpus* within *Aster* subg. *Aster* on the basis of similarities in phyllary traits and the results of a restriction fragment length polymophism analysis of chloroplast DNA (Xiang & Semple 1996), but Semple et al. (2002) treated it as a separate genus based on ITS sequence data, which they summarized and on morphological traits. *Sericocarpus* is more closely related to the goldenrod genus *Solidago* than to other North American species of asters, which themselves can no longer be placed in a large traditionally defined genus *Aster*. DNA studies have shown *Aster* in the new sense is restricted to Europe and Asia with one arctic-alpine exception (Noyes & Rieseberg 1999; Brouillet et al. 2001; Semple et al. 2002). Nesom (2000) included *Sericocarpus* in a narrowly defined subtribe Solidagininae O. Hoffmann; this is one branch of the "North American Clade" of the tribe Astereae (Semple at al. 2002).

Sericocarpus linifolius (L.) B.S.P. is the nomenclatural type of the genus. It has been treated as *Conyza linifolia* L., *Aster linifolius* L. and *Aster solidagineus* Michx., the latter name reflecting similarities to the grass-leaved goldenrods of the genus *Euthamia*, which at the time was erroneously included in *Solidago*. *Sericocarpus linifolius* lacks the prominent basal leaves and dentate leaf margins of *S. asteroides*. Its leaves are linear-oblong to linear-oblanceolate all along the length of the stem. *Sericocarpus linifolius* has the smallest heads in the genus.

Sericocarpus asteroides (L.) B.S.P. has been treated in the past as *Conyza asteroides* L., *Aster asteroides* (L.) MacMillan, *Aster conyzoides* Willd., and *Aster paternus* Cronq. Although other species may exhibit basal leaves, *S. asteroides* has distinctive, serrate, spatulate basal leaves and is the only species to have basal leaves usually present at the time of flowering. The lower stem leaves, also dentate, become progressively more narrowly ovate near the top of the stem.

Sericocarpus tortifolius (Michx.) Nees also has been known, at one time or another, as *Aster tortifolius* Michx., *Aster bifoliatus* (Walt.) Ahles, *Conyza bifoliatus* Walt., and *Sericocarpus bifoliatus* (Walt.) Porter. Its non-dentate leaves are smaller and more oblanceolate than the other four species. Its leaves and stem are the most densely pubescent in the genus. Of the three eastern species, *S. tortifolius* has the smallest range, which extends from southern Florida northeast to North Carolina and west to southern Mississippi.

Sericocarpus linifolius and *S. asteroides* have similar ranges. Both are found along most of the eastern seaboard from New Hampshire down to South Carolina, but they never extend down to southern Georgia or Florida. *Sericocarpus linifolius* occurs a little further west than *S. asteroides* generally does, occurring in western Tennessee and Kentucky. *Sericocarpus linifolius* can also be found in a small area in southeastern Indiana, while *S. asteroides* generally does not extend beyond central Ohio in the north except for a few isolated collections in southern Wisconsin, southwestern Michigan and northwestern Indiana. These latter may be chance adventives.

Sericocarpus oregonensis Nutt. has been treated in the past as *Aster oregonensis* (Nutt.) Cronq., *Sericocarpus californicus* Durand, and *Sericocarpus rigidus* Lindl. in Hook. var. *californicus* (Durand) Blake. The lower leaves of *S. oregonensis* are distinctly reticulate-veined and the heads are usually found in several to many separate clusters. Ferris (1958) divided *Sericocarpus oregonensis* into two taxa: subsp. *californicus* (Durand) Ferris and subsp. *oregonensis*. In the same year, Keck (1958) also recognized two subspecies but treated them in *Aster oregonensis*, as did Allen (1993). In contrast, Nesom (1993) recognized two varieties in the species: *Sericocarpus oregonensis* Nutt. var. *oregonensis* and *Sericocarpus oregonensis* Nutt. var. *californicus* (Durand) Nesom. Nesom (1993) described var. *oregonensis* as having scabrous-puberulent leaves, while var. *californicus* had densely hirsute or pilose leaves (Nesom 1993). *Sericocarpus oregonensis* subsp. *californicus* can be found in the Sierra Nevada range area of eastern California, while subsp. *oregonensis* extends from northern California to western Washington along the Coastal/Cascade ranges.

Sericocarpus rigidus Lindl.in Hook. has a number of nomenclatural synonyms, including *Aster curtus* Cronq. and *Sericocarpus rigidus* Lindley in Hook. var. *laevicaulis* Nutt. It is by far the rarest of the five species of genus. *Sericocarpus rigidus* is similar in appearance to *S. oregonensis* but is smaller in stature, being 1–3 dm tall as opposed to 4–12 dm tall. Furthermore, *S. rigidus* lacks the reticulate-veined lower leaf surfaces of *S. oregonensis*. The heads are usually found in a single cluster with typically 1–3 ray florets as compared to 4–7 in the case of *S. oregonensis*. *Sericocapus rigidus* is found in two isolated pockets, one in western Oregon and the second extending from western Washington at the south end of Puget Sound to the southern tip of Vancouver Island.

In 1990, *Sericocarpus rigidus* was included on the United States Fish and

Wildlife Service's "Endangered and Threatened Wildlife and Plants List" in the Federal Register (Clampitt 1993). In 1996, the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) assigned to *Aster curtus* (Cronq.) the status of "threatened" and revised the listing to *Sericocarpus rigidus* in 2000. COSEWIC describes threatened species as those "likely to become endangered if limiting factors are not reversed" (Douglas & Illingworth 1996). In the case of *S. rigidus*, the principal "limiting factor" is habitat destruction. Most populations are also threatened by competition from aggressive exotic species, such as *Cytisus scoparius*. Fire suppression has also favored the expansion of native species, such as *Symphoricarpos albus*. The proliferation of this shrub is crowding out *S. rigidus* from its natural habitat (Douglas & Illingworth 1996).

All chromosome number reports in *Sericocarpus* are diploid. In total, 44 chromosome count reports of $2n = 9_{II}$ or $2n = 18$ have been published: 14 for *S. asteroides*, five for *S. linifolius*, 14 for *S. oregonensis*, and 11 for *S. tortifolius*. (Huziwara 1965; Anderson et al. 1974; Pinkava & Keil 1977; Semple & Brouillet 1980b; Hill 1983; Semple et al. 1983; Jones & Smogor 1984; Semple 1985; Semple et al. 1989, 1992, 1993; 2001; Semple & Cook 2004). No count is known for *S. rigidus*. Polyploidy is unknown in the genus and thus is not a factor influencing morphology.

The goal of this study was twofold. First, a multivariate morphometric analysis of the genus had never been undertaken before. Second, detailed descriptions were needed to be prepare the treatment of the genus for Flora North America Project (Semple & Leonard 2005). The names of taxa used in this paper are those accepted at the conclusion of this study.

MATERIAL AND METHODS

Over 2300 herbarium specimens of *Sericocarpus* were examined; These were borrowed from or examined at BRIT, CAS, DAO, GH, LINN, MO, NY, ORE, OSC, UC, UVIC, WAT, WILLU and WTU (Holmgren et al. 1990). Of these, 111 specimens were selected for multivariate analyses based on their completeness and developmental stage. Forty-four vegetative and 19 floral characteristics were measured for each of the selected specimens. Some traits such as lower stem leaf features were not available for scoring on all specimens (Table 1). When possible, all traits were measured in replicates of five. Character measurements were then averaged and these averages were used in subsequent statistical analyses. Ray and disk achene pubescence was scored on a scale of 1–5 with 5 representing the highest degree of pubescence. Shape of the leaf apex and base were scored on a scale of 1–10 using a reference card developed in the laboratory.

Each specimen was assigned to an *a priori* group based on geography and morphological characteristics, which were determined through observations and a review of the literature (Nesom 1993). The exclusion of *a priori* traits from discriminant analyses avoided the introduction of circular logic and bias into the statistical analyses. When a pair of traits highly correlated with one another (Pearson's correlation coefficient (R = | 0.7 |) one of the pair was excluded from further analyses. Highly correlated traits were excluded because two traits showing high correlation could indicate that the phenotype of those two traits resulted from the regulation of a single gene, in which cases, including both traits would be redundant.

Analysis of pubescence variation in the two subspecies of *Sericocarpus oregonensis* (subsp. *oregonensis* and subsp. *californicus*) was assessed by measuring the number of hairs per mm^2 for each of the traits listed in Table 2.

All clustering and discriminant analyses were performed using either SYSTAT 10.0 (SPSS Inc. 2000) or SAS ver. 8.0 (SAS Institute Inc. 1999) software packages. UPGMA cluster analyses using average linkage on squared Euclidian distances were performed in order to determine the relative similarities among the 111 specimens. The cluster analysis used standardized data and all measured traits, with the exception of basal leaf traits, which were only present on *Sericocarpus asteroides* at the time of flowering.

For the canonical analyses, characters not used to define *a priori* group were selected based on the results of a stepwise discriminant analysis, which determines which traits best separate the *a priori* groups. Only nine traits with the highest F-values were then used in a classificatory discriminant analysis because only nine specimens of *Sericocarpus rigidus* were included.

A classificatory discriminant analysis assigns specimens *a posteriori* to groups using the set of characteristics chosen in the stepwise discriminant analysis. The classificatory analysis also includes a test for equality between group centroids (Wilk's lambda, Pillai's Trace and Lawley-Hotelling trace). Geisser assignment probabilities and correct classification rates were also determined. These assess the reliability of the *a posteriori* classification of the specimens relative to the *a priori* groupings and the strengths of alternative placements of the specimens.

Canonical discriminant analysis is a dimensional-reduction technique used to help visualize the results of the discriminant analyses. The number of canonical scores that can be used is one less then the number of *a priori* groups up to three. Canonical score plots were rotated to determine if a single perspective would suffice to illustrate group separation. Two dimensional plots of combinations of canonical scores were also plotted and those that best revealed group separation were selected.

Digital photomicrographs of cyselae were taken using a Nikon CoolPix 990 camera manually held against the ocular lens of either the dissecting or compound microscope. Pictures were taken of specimens under the compound light microscope with either below stage or above stage lighting. Final digital illustrations were made using CorelDraw 12® from digital images edited with Corel PhotoPaint12® (Corel Corp.). In some illustrations the contrast was manipulated

Table 1. Traits measured for the morphometric analysis of *Sericocarpus*.

STLNG	Stem length (mm)
STHRLO	Number of hairs on the lower stem per mm^2
STHRMD	Number of hairs on the mid stem per mm^2
STHRUP	Number of hairs on the upper stem per mm^2
BLHRSU	Number of hairs on the basal leaf surface per mm^2
BLHRMR	Number of hairs on the basal leaf margins per mm^2
BLHRVN	Number of hairs on the basal leaf vein per mm^2
BLLENG	Basal leaf length (mm)
BLWID	Basal leaf width (mm)
BLWTIP	Basal leaf measured from the widest point to the tip (mm)
BLAPX	Basal leaf shape at its apex (1–10)
BLBASE	Basal leaf shape at its base (1–10)
BLDENT	Basal leaf dentation—number of serration on the leaf margin
BLBEAD	Number of resin beads on the basal leaf per mm^2
LLHRSU	Number of hairs on the lower leaf surface per mm^2
LLHRMG	Number of hairs on the lower leaf margin per mm^2
LLHRVN	Number of hairs on the lower leaf vein per mm^2
LLLENG	Lower leaf length (mm)
LLWIDE	Lower leaf width (mm)
LLWTIP	Lower leaf measured from the widest point to the tip (mm)
LLAPX	Lower leaf shape at its apex (1–10)
LLBASE	Lower leaf shape at its base (1–10)
LLDENT	Lower leaf dentation—number of serration on the leaf margin
LLBEAD	Number of resin beads on the lower leaf per mm^2
MLHRSU	Number of hairs on the mid leaf surface per mm^2
MLHRMG	Number of hairs on the mid leaf margin per mm^2
MLHRVN	Number of hairs on the mid leaf vein per mm^2
MLLENG	Mid leaf length (mm)
MLWIDE	Mid leaf width (mm)
MLWTIP	Mid leaf measured from the widest point to the tip (mm)
MLAPX	Mid leaf shape at its apex (1–10)
MLBASE	Mid leaf shape at its base (1–10)
MLDENT	Mid leaf dentation—number of serrations on the leaf margin
MLBEAD	Number of resin beads on the mid leaf surface per mm^2
ULHRSU	Number of hairs on the upper leaf surface per mm^2
ULHRMG	Number of hairs on the upper leaf margin per mm^2
ULHRVN	Number of hairs on the upper leaf vein per mm^2
ULLENG	Upper leaf length (mm)
ULWIDE	Upper leaf width (mm)
ULWTIP	Upper leaf measured from the widest point to the tip (mm)
ULAPX	Upper leaf shape at its apex (1–10)
ULBASE	Upper leaf shape at its base (1–10)
ULDENT	Upper leaf dentation—number of serrations on the leaf margin
ULBEAD	Number of resin beads on the upper leaf surface per mm^2
NOINFL	Number of heads on lateral branch
HDHGT	Head height (mm)
HDWIDE	Head width (mm)
OUTPHY	Outer phyllary length (mm)
TWOPHY	Second layer phyllary length (mm)
THRPHY	Third layer phyllary length (mm)
INPHY	Inner phyllary length (mm)
RAYFLR	Number of ray florets per head
RSTRLNG	Ray strap length (mm)
RCORTB	Ray corolla tube length—measured from base to beginning of strap (mm)
RACHLNG	Ray cypsela body length (mm)
RPAPLNG	Ray cypsela pappus length (mm)
RPBSC	Ray cypsela pubescence (0–5)
DISFLOR	Number of disc florets per head
DCORTB	Disc corolla tube length (mm)
DACHLNG	Disc cypsela body length (mm)
DPAPLNG	Disc cypsela pappus length (mm)
DPBSC	Disc cypsela pubescence (0–5)
DCORLB	Disc corolla lobe length (mm)

TABLE 2. Traits measured for the pubescence analysis of *Sericocarpus oregonensis*; all counts are given in numbers of hairs/mm^2.

STHRLO	Number of hairs on lower stem.	MLHRSU	Number of hairs on mid leaf surface.
STHRMD	Number of hairs on mid stem.	MLHRVN	Number of hairs on mid leaf vein.
STHRUP	Number of hairs on upper stem.	MLHRMG	Number of hairs on mid margin.
LLHRSU	Number of hairs on lower leaf surface.	ULHRSU	Number of hairs on upper leaf surface.
LLHRVN	Number of hairs on lower leaf vein.	ULHRVN	Number of hairs on upper leaf vein.
LLHRMG	Number of hairs on lower leaf margin.	ULHRMG	Number of hairs on upper leaf margin.

to increase the difference between pappus bristles and background for illustrative purposes.

RESULTS

Cluster analyses

Standardized data for 53 characters (Table 1) were included in an UPGMA cluster analysis. Traits not included were those for which data was not available for all specimens, e.g. stem height and lower leaf traits. Results indicate separation into four main branches (Fig. 1; A–D) and two small basal clusters. The three eastern species clustered into three groups corresponding to the species with only three exceptions. Branch A included all the specimens of *Sericocarpus tortifolius* and no other taxa. Branch B included all but one of the *S. linifolius* specimens, with no inclusion of specimens of any other taxa. The single exception was a *S. linifolius* specimen (lin32), which occurred on a more basal branch along with one *S. asteroides* specimen (ast26). Branch C included all but two of the measured *S. asteroides* specimens, as well as two small *S. oregonensis* specimens (cal23 & cal19). Of the two *S. asteroides* specimens not clustered within Branch C, one specimen clustered with one *S. linifolius* specimen. The other *S. asteroides* specimen (ast92) occurred by itself on the basal branch of the dendrogram; it was a robust individual.

Branch D consisted of only members of the two western species *Sericocarpus oregonensis* and *S. rigidus*. The branch was subdivided into three clusters (a, b and c). Branch c included all nine *S. rigidus* specimens as well as two smaller *S. oregonensis* subsp. *oregonensis* specimens (oreg101 & oreg107). Branches a and b were composed entirely of *S. oregonensis* specimens with both clusters including specimens from the Sierras (subsp. *californicus*) and from the Coastal and Cascade Mts. (subsp. *oregonensis*). Six of the eight specimens in cluster a belonged to subsp. *californicus*. Four of the six specimens in cluster b belonged to subsp. *oregonensis*. The two specimens of subsp. *californicus* in cluster b had pubescence values at the lower end of the ranges of the traits for the subspecies.

A cluster analysis was performed on a matrix of 12 stem and leaf pubescence traits scored on 107 specimens of *S. oregonensis*. Specimens of the two subspecies were intermixed and did not form two distinct cluster groups corresponding to the geographically based subspecies.

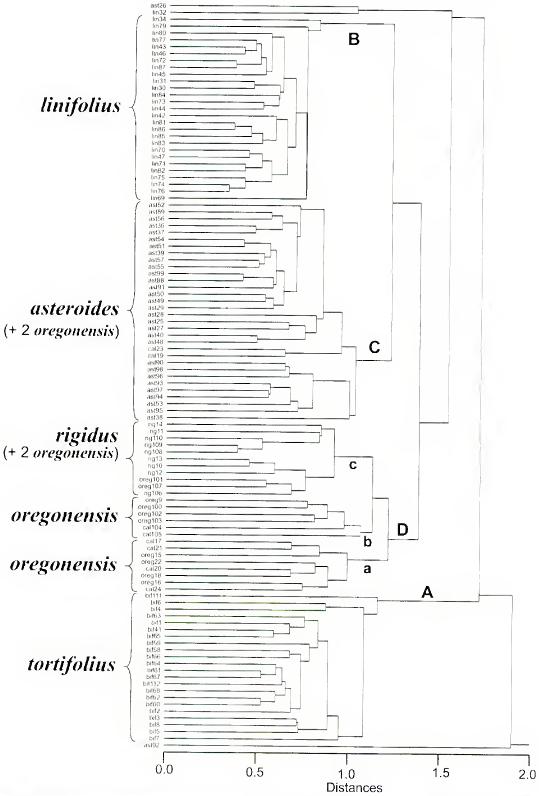

FIG. 1. UPGMA cluster analysis based on all characters. Branches indicated by letters are discussed in the text.

Discriminant Analyses

A canonical discriminant analysis was carried out on 107 specimens of *Sericocarpus*. *A priori* group membership was determined using the characteristics listed in Table 3. Leaf length, width and pubescence, as well as stem pubescence were diagnostic traits used in the assignment of all specimens into *a priori* groups. Specimens were assigned to groups in part on the basis of geographic distribution. In the literature, five species level groups have been widely accepted (e.g., Nesom 1993). Examination of more than 2300 specimens indicated that five species groups were recognizable using key characters from the literature. Three *a priori* groups included only specimens from the eastern United States. Specimens assigned *a priori* to the *S. tortifolius* group were the most pubescent, had obovate upper stem leaves and all came from the southeastern United States. Specimens assigned *a priori* to the *S. linifolius* group were glabrous for all traits listed in Table 3, had narrowly elliptic, lanceolate or linear leaves, and all came from the eastern United States. Specimens of the *S. linifolius* group also had the longest mid and upper stem leaves. Specimens assigned *a priori* to the *S. asteroides* group were from the eastern United States and had basal rosette and lower stem leaves that were petiolate and obovate to oblanceolate and usually serrate; upper stem leaves were reduced, becoming sessile and ovate to lanceolate. The widest lower and mid stem leaves were observed on specimens of *S. asteroides*.

Western North American specimens were assigned *a priori* to *S. oregonensis* and *S. rigidus*. Specimens with one or two ray florets with short straps were assigned *a priori* to the *S. rigidus* group; these came from the south end of Vancouver Island in British Columbia and western Washington and Oregon. Western specimens with at least three ray florets with longer, broader straps were assigned *a priori* to the *S. oregonensis* group, which was not subdivided into subspecies groups for the species level analysis. On average, *S. oregonensis* specimens tended to have the widest upper stem leaves.

A stepwise discriminant analysis was used to select traits to be included in the discriminant functions used in further analyses. The means, standard deviations, ranges, and minimum and maximum values of all characters analyzed are presented in Table 4. The nine characters selected and used in further analyses are indicated by asterisks. The stepwise discriminant analysis selected twelve traits as having some value in discriminating groups. Of these, the three with the lowest F-values (HDHGT, RCORTB, DISFLOR) were discarded in order that the number of traits used in the classificatory discriminant analysis not exceed the number of specimens in the smallest *a priori* group; nine suitable specimens of *S. rigidus* were included. Other traits scored were rejected from further analysis because they correlated highly with traits included in the stepwise discriminant analysis.

Table 3. Characteristics used to make *a priori* group assignments to five species level groups in *Sericocarpus*; means, ± standard deviations, (ranges) and minimum / maximum; all lengths and widths are given in mm and all pubescence counts are given in numbers of hairs/mm^2.

The Mahalanobis distances between group centroids and the associated F-statistics and their probabilities generated by the classificatory discriminant analysis (Table 5) indicated that all five *a priori* species level groups were strongly supported ($p<0.001$ in all cases). Other tests, i.e. the probabilities for the Wilk's lambda, Pillai's trace, and Lawley-Hotelling trace indicated there were significant differences between group centroids ($p < 0.0001$).

In the classificatory discriminant analysis, specimens was assigned *a posteriori* to five species level groups using the discriminant functions. In the *a posteriori* classification analysis (Table 6), 100% correct classification was made *a posteriori* for specimens assigned *a priori* to *Sericocarpus asteroides*, *S. tortifolius*, and *S. rigidus*. For *S. linifolius*, 96% of the specimens were correctly classified *a posteriori*; one of 28 specimens was assigned to *S. asteroides*. For *S. oregonensis*, 83% were correctly classified; three of 18 specimens were assigned to *S. asteroides*. Overall, 96% of specimens were correctly assigned *a posteriori* to their respective *a priori* groups. In the Jackknifed classification analysis (Table 7), the overall correct *a posteriori* assignment rate was 91%. Again, all specimens were assigned correctly to *S. tortifolius*. The correct classification rates for the other four groups were 90% for *S. asteroides*, 96% for *S. linifolius*, 72% for *S. oregonensis* and 89% for *S. rigidus*.

Plots of the canonical variate scores on the first and second and first and third canonical axes are shown in Fig. 2. Specimens of *S. linifolius* and *S. tortifolius* are separated from the other taxon on the first two axis, while the other three species separate on the first and third axes although with slight overlap toward the center of the distribution of symbols.

Univariate analyses of S. *oregonensis*: subsp. *oregonensis* and subsp. *californicus*
Pubescence traits of 107 specimens of *Sericocarpus oregonensis* were analyzed. The means, standard deviations, ranges (as well as, minimum and maximum values) for stem and leaf pubescence traits measured for subsp. *oregonensis* and subsp. *californicus* are presented in Table 8. Results indicate that subsp. *oregonensis*, which grows in the Coastal/Cascade Mountains region, was less pubescent than subsp. *californicus* found in the Sierra Nevada region of California. Two-sample t tests were run comparing each trait listed in Table 8 by subspecies. Even though the ranges of values of the subspecies overlapped, there

was a statistically significant difference (p=0.00, ± = 0.05) between the means for every trait.

DISCUSSION

Cluster and discriminant analyses support the division of *Sericocarpus* into five species. *Sericocarpus linifolius* and *S. tortifolius* are the two most distinct species within the genus. *Sericocarpus asteroides*, *S. oregonensis*, and *S. rigidus* are generally more similar to one another with the greatest similarity being between the latter two, which are the western North America species. The similarity between these three latter species is reflected in the inclusion of a few of the *S. oregonensis* specimens within the *S. asteroides* and *S. rigidus* branches in

TABLE 7. Results of an *a posteriori* jackknifed classificatory discriminant analysis of 107 specimens of *Sericocarpus* using a linear discriminant function.

Group	*a posterori* group					
a priori group	asteroides	tortifolius	linifolius	oregonensis	rigidus	N
asteroides	27 90%	0	0	3 10%	0	30
tortifolius	0	22 100%	0	0	0	22
linifolius	1 4%	0	27 96%	0	0	28
oregonensis	5 28%	0	0	13 72%	0	18
rigidus	1 11%	0	0	0	8 89%	9

the cluster analysis, even if such confusion of identity is unlikely due to very different general appearances and provenances. Regardless of the similarity on technical traits as seen in the cluster analysis between *S. asteroides* and the two western species, the 100% correct *a posteriori* classification rate for *S. asteroides* in the classificatory discriminant analysis establishes that it is indeed a distinct species, especially considering the obvious basal rosette trait was not included in the analyses. The technical similarities in traits scored is not reflected in the ease with which *S. asteroides* can be identified in the field.

All of the specimens placed *a posteriori* by the classificatory discriminant analysis into a different group than their *a priori* placements were examined and found to have been correctly placed *a priori* on the basis of the diagnostic traits not included in the analyses. While readily identified as belonging to one of the *a priori* groups, the specimens generally were either stunted or robust compared to other members of the group. Thus, either favorable or unfavorable growing conditions likely influenced others traits that were included in the analyses. The *S. linifolius* specimen not included in Branch B of the cluster diagram (Fig. 1) was also the one misclassified specimen in the classification matrix generated by the classificatory discriminant analysis. This specimen was found to be a very robust plant for the species, therefore explaining its *a posteriori* inclusion into the *S. asteroides* group. There is no doubt that it is specimen of *S. linifolius* based on the *a priori* characteristics excluded from the analyses.

The three misclassified *Sericocarpus oregonensis* specimens were examined, and though some did not always conform to the norm for one trait or another, the initial *a priori* assignments were correct. One of the misclassified *S. oregonensis* specimens (cal23), clustered, along with a second *S. oregonensis*

ULHRMG	8.00 ± 1.75 (6.24–9.75) 4.00 / 13.60	10.22 ± 1.79 (8.43–12.01) 6.60 / 14.20

specimen, within the *S. asteroides* group. Both of these were smaller, less robust plants. Two *S. oregonensis* specimens clustered within the *S. rigidus*. These specimens were dwarf plants with stem lengths corresponding to the lower end of the range for the species (STLNG = 24 cm and 46.5 cm, respectively, Mean = 62.4 mm). The remaining *S. oregonensis* specimens clustered into two groups. The branch b cluster in Fig. 1 is composed of four individuals of *S. oregonensis* subsp. *oregonensis* and two of *S. oregonensis* subsp. *californicus*. The latter two specimens have low hair counts for the subspecies (ULHRSU = 16.6 hairs/mm^2 and 18.8 hairs/mm^2, respectively; mean = 20.5 hairs/mm^2). The branch a cluster in Fig. 1 is composed of six *S. oregonensis* subsp. *californicus* and two *S. oregonensis* subsp. *oregonensis* specimens. Upon close re-examination of the two *S. oregonensis* subsp. *oregonensis* specimens, no obvious morphological traits which could account for its clustering within branch a were observed.

Of the five *Sericocarpus* species, *S. tortifolius* is the most distinct on scored technical traits. All cases clustered together with no inclusion of specimens from any other species. *Sericocarpus tortifolius* is also the only species to show 100% correct classification rates in both the Classification and Jacknifed matrices. The highest F-value (F = 122.457) and Mahalanobis distance (D = 97.071) occurred between the *S. linifolius* and the *S. tortifolius* group centroids. These results confirm the cluster analysis and canonical analysis results which indicate that of the five species, *S. linifolius* and *S. tortifolius* are the most distinct.

Of the one-hundred and seven specimens assigned *a posteriori* during a classificatory discriminant analysis, only four specimens were misclassified. The average Geiser assignment probabilities were: 0.94 for *S. asteroides*, 1.00 for *S. tortifolius*, 0.97 for *S. linifolius*, 0.82 for *S. oregonensis*, and 0.97 for *S. rigidus*. These high Geiser assignment probabilities indicate that the within-group variances are small in comparison to the between-group variances.

The strong F-values and low probabilities of the Wilk's lambda (F = 34.863, $p < 0.001$), Pillai's Trace (F = 22.640, $p < 0.001$) and Lawley-Hotelling trace (F = 48.065, $p < 0.001$) generated during the classificatory discriminant analysis, all indicate that the probability that all specimens tested are representative of one single group rather than five species groups is extremely small.

Scoring of canonical traits on the first and second axes show strong group separation by *S. tortifolius* and *S. linifolius*. The overlapping of the three remaining species on the first and second axes is resolved when the canonical scores are plotted on the second and third canonical axes. The separation visualized in the canonical analysis is supported by the aforementioned cluster and discriminant analyses.

The division of *S. oregonensis* into two subspecies, subsp. *oregonensis* and subsp. *californicus*, is based on both geographic and morphological traits. Those plants growing in the Coastal/Cascade Mountain ranges of Washington, Oregon and California (subsp. *oregonensis*) are more sparsely pubescent than those plants growing in the Sierra Nevada region of eastern California (subsp. *californicus*). The ranges for both subspecies overlap in far northern California; however, the means for all measured pubescence traits is consistently smaller in the case of *S. oregonensis* subsp. *oregonensis* specimens. Two-sample t test results indicate that the difference between the means of both subspecies is statistically significant (prob = 0.00, C.I. = 95%). *Sericocarpus oregonensis* is also found in an intermediate geographical region, namely Butte and Shasta counties in California, where both subspecies are found, but can easily be assigned to appropriate subspecies by examining pubescence traits.

In conclusion, based on the results of the multivariate morphometric analyses, and to a lesser extent on geographical data, the aster genus *Sericocarpus* should be divided into five species: *S. asteroides*, *S. tortifolius*, *S. linifolius*, *S. oregonensis*, and *S. rigidus*. Differences in the degree of pubescence and in geographical location within *S. oregonensis*, support the separation of this species into two infraspecific taxa: *Sericocarpus oregonensis* subsp. *oregonensis*, found in the coastal/cascade region of Washington, Oregon, and California is more sparsely pubescent than *S. oregonensis* subsp. *californicus*, which grows in the Sierra Nevada region of California. Subspecies ranks is adopted following Semple (1974) because the two infraspecific taxa have essentially allopatric distributions. For an alternative usage of infraspecific ranks see Turner and Nesom (2000) who presented the argument that subspecies rank should be used as a grouping category only like subgenus, subtribe, etc. We find it useful to continue to use two infraspecific ranks (subspecies and variety) to emphasize geographic features of the taxa.

TAXONOMIC TREATMENT[4]

Sericocarpus Nees, Gen. et sp. Aster. 10, 148. 1832. *Aster* subg. *Sericocarpus* (Nees) A.G. Jones. Brittonia 32: 238. 1980. *Aster* sect. *Sericocarpus* (Nees) Semple, Phytologia 58:429. 1985. LECTOTYPE [Britt. in Britt. & Brown 1913]: *Sericocarpus solidagineus* (Michx.) Nees = *Sericocarpus linifolius* (L.) B.S.P.

Aster sect. *Serratifolii* Loudon, Hort Brit. 347. 1830. "Leaves lanceolate and ovate, lower ones serrate" LECTOTYPE [Sundberg & Jones 1987]: *Aster conyzoides* Willd. = *Sericocarpus linifolius* (L.) B.S.P.

Perennial herbs from rhizomatous to stout, branching, woody caudex. Stem erect, glabrate to pubescent, (15–)32–48–62(–117) cm. Basal leaves usually absent at time of flowering, puberulent, (2–)4–8–11(–15) cm long, serrate near apex, spatulate to petiolate, reticulate veined. Stem leaves linear to (ob)ovate, sessile, acuminate to acute, sometime slightly cuspidate (1–)2–3–5(–11) cm long, (0.1–)0.4–0.8–1(–3) cm wide, reticulate veined, glabrate to moderately hispidulous or hispidulous-pilose, hairs 0.05–0.5 mm long, longest hairs sometimes twisted,

---

[4] All measurements in the taxonomic treatment are given in the following format: (minimum)–minus the standard deviation–**mean**–plus the standard deviation–(maximum).

usually sparsely to moderately finely glandular punctuate, the stipitate-glands recessed, sometimes resinous, margins ciliate, serrate becoming entire or entire, upper leaves decreasing in size upward. Capitulescence corymbiform to broadly corymbiform, sometimes compact; heads 2–5 per branch; bracts, ciliate, glabrate to pubescent, broadly lanceolate to narrowly ovate. Involucre (3.8–)5.0–6.0–7.0(–8.6) mm high at anthesis, (2.3–)3.8–4.8–5.9(–10.5) mm wide; phyllaries in 3–5 imbricate series, ciliate, glabrate to pubescent, base narrowly to widely oblong, tip narrowly to broadly acute, outer series (1.8–)2.5–3.3–4.1(–5.3) mm long, mid series (2.7–)3.5–4.4–5.2(–6.5) mm long, inner series more linear and less chlorophyllous, margins ciliate, dark green zone at the apex, thumb-nail shaped. Ray florets 1–6, strap (1.6–)2.9–4.3–5.8(–10.5) mm long, corolla tube (2.4–)3.0–3.2–3.3(–4.2) mm long, cypselae strigose to densely strigose, (0.7–)1.0–1.5–1.9(–3.3) mm long at anthesis, increasing twofold by maturity,pappus, triple or rarely quadruple: secondary outer series of very few linear scales, 0.1–1mm long; middle and inner series of barbellate bristles, secondary inner series of mid length tapering bristles, 35–70% the length of the primary inner series; primary outer series of tapering bristles 80–95% the length of the primary inner bristles; primary inner series bristles strongly clavate, (3.5–)4.3–5.2–6.1(–7.8) mm long. Disc florets, 5–19, corolla lobe (0.6–)0.89–1.2–1.4(–1.9) mm long, corolla tube (2.3–)3.4–4.3–5.1(–6.2) mm long; cypselae strigose to densely strigose, (0.8–)1.1–1.6–2.0(–3.3) mm long at anthesis, increasing 2–3 times by maturity, pappus, triple or rarely quadruple: secondary outer series of very few linear scales, 0.1–1mm long; middle and inner series of barbellate bristles, secondary inner series of mid length tapering bristles, 40–75% the length of the primary inner series; primary outer series of tapering bristles 80–95% the length of the primary inner bristles; primary inner series bristles strongly clavate, (3.3–)4.7–5.8–6.8(–8.3) mm long. Chromosomal base number: $x = 9$; all reports diploid ($2n = 18$). Flowering midsummer to early fall.

The pappus has been reported as double in the past (e.g., Cronquist 1980). Hood and Semple (2003) noted that the pappus was biseriate with the outer whorl slightly shorter than the strongly clavate inner whorl with some overlapping of the bases of the bristles. Semple and Hood (submitted) noted that a quadruple pappus was the likely plesiomorphic state in the North American clade; their labels for the four whorls are used here. Further examination of the pappus of *Sericocarpus* species revealed that it is usually triple (Fig. 3). What had been interpreted as a outer whorl of variable length non-clavate bristles is reinterpreted here to be two whorls that sometime grade from the few mid length secondary inner bristles into the primary outer bristles. The secondary inner series bristles tend to be slightly shorter, and thus more distinct, in ray fruit than disc fruit. The primary inner whorl bristles are very obviously clavate and are the longest. Very rarely, a few very short linear scales forming a secondary outer pappus series were present on some fruits; these were not easily

Sericocarpus conyzoides (L.) Nees _*plantaginifolius* Nees, Gen. et Sp. Aster. 150. 1832. TYPE: U.S.A. NEW JERSEY: *Nuttall s.n.* (HOLOTYPE: not seen).

Sericocarpus asteroides (L.) B.S.P. f. *albopapposus* Farwell, Pap. Michigan Acad. Sci. 1:100. 1923. TYPE: U.S.A. MICHIGAN: Galesburg, 31 Aug 1818, *Farwell 5097a* (HOLOTYPE: not seen).

Sericocarpus asteroides (L.) B.S.P. f. *roseus* H.K. Svenson, Rhodora 30:136. 1928. TYPE: U.S.A. MASSACHUSETTS: Falmouth, "in sandy soil," 1 Sep 1926, *Svenson s.n.* (HOLOTYPE: GH!)

Aster paternus Cronq., Bull. Torrey Bot. Club 74:149. 1947. Based on *Conyza asteroides* L.

Perennial herb from short-branching woody caudex. Stem very sparsely to moderately hispidulous-puberulent, erect, (14–)26–39–52(–65) cm. Basal leaves present at time of flowering, (2–)4–8–11(–15) cm long, serrate near apex, spatulate to petiolate, reticulate veined, puberulent. Stem leaves, narrowly to broadly ovate, sessile, (1–)2–4.0–6(–11) cm long, (0.4–)0.6–1–2(–3) cm wide, cuneate, acuminate to acute, reticulate veined, glabrate to sparsely hispidulous, sparsely to moderately glandular punctuate, margins ciliate, serrate, upper leaves decreasing in size upward, becoming entire. Capitulescence corymbiform; heads 2–5 per branch. Involucre (4.2–)5.0–5.7–6.4(–7.1) mm high at anthesis, (3.1–)3.8–4.4–5.1(–6.0) mm wide; phyllaries in 3–4 imbricate series, broadly lanceolate to narrowly ovate, outer series (2.4–)2.8–3.3–3.7(–4.2) mm long, mid series (3.3–)3.9–4.4–5.0(–5.4) mm long, inner more linear and less chlorophyllous, margins ciliate, dark chlorophyll zone at the apex, thumb-nail shaped. Ray florets, 3–7,

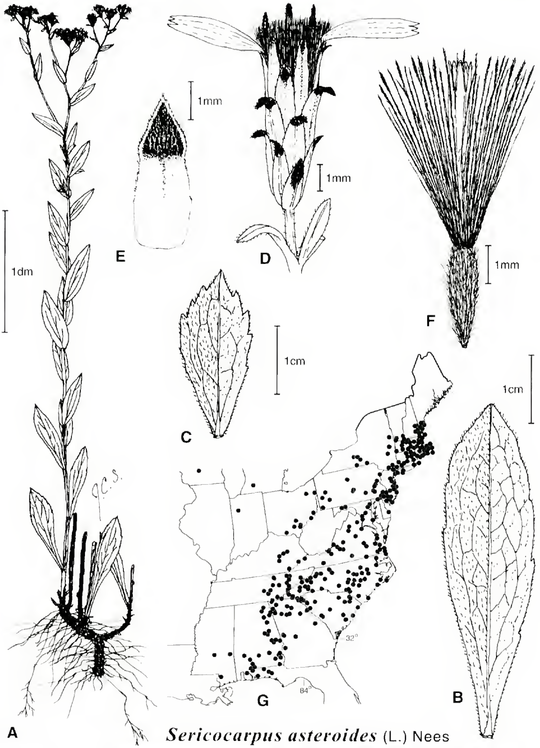

Fig. 5. Morphology and distribution of *Sericocarpus asteroides*. **A.** Habit. **B.** Lower mid stem leaf. **C.** Small serrate leaf. **D.** Head, on only some florets shown. **E.** Mid series phyllary with chlorophyllous zone dark. **F.** Mature disc floret achene with floret still attached. **G.** Distribution in the eastern United States based on all collections seen; the collections from Michigan is based on a literature report and was not seen.

strap (2.5–)3.5–4.3–5.2(–6.0) mm long, corolla tube (2.4–)2.6–3.1–3.5(–4.2) long, cypselae, densely strigose, (0.8–)1.0–1.2–1.4(–1.8) mm long at anthesis, increasing twofold by maturity, pappus triple or rarely quadruple: secondary outer linear scales 0–very few, 0.1–1mm long; secondary inner bristles few, 40–75% of primary inner series; primary outer bristles 70–90% of inner bristles; primary inner bristles moderately strongly clavate, (3.6–)4.0–4.4–4.8(–5.2) mm long. Disc florets, 9–20, corolla lobe (0.6–)0.8–0.9–1.1(–1.5) mm long, corolla tube (3.2–)3.4–3.7–4.0(–4.4) mm long; cypselae densely strigose, (0.8–)1.1–1.3–1.5(–1.7) mm long at anthesis, increasing twofold by maturity, pappus triple or rarely quadruple: secondary outer linear scales 0–very few, 0.1–1mm long; secondary inner bristles few, 50–70% of primary inner series; primary outer bristles 70–90% of inner bristles; primary inner bristles strongly clavate, (3.7–)4.3–4.7–5.0(–5.4) mm long. $2n = 18$.

Flowering mid summer to early fall. Dry sandy, clay, and shaly open soils in fields and open mixed and pine woods, road margins; 3–1550 m; extreme southern Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New Jersey, New York, Pennsylvania, Ohio, Maryland, Delaware, D.C., Virginia, West Virginia, eastern Kentucky, North Carolina, eastern Tennessee, South Carolina, northern and central Georgia, Alabama, and southern Mississippi (Fig. 5G). The species has not been reported from Louisiana (Gandhi and Thomas 1989; USDA, plants.usda.gov web site). Single collections of *S. asteroides* labeled as being from northwestern Indiana and south central Wisconsin are of questionable provenance or are likely chance introductions. A single collection reported from southwestern Michigan was not seen; this also is most likely an introduction or of "dubious status" (Voss 1996).

3. Sericocarpus tortifolius (Michx.) Nees, Gen. et Sp. Aster. 151. 1832. (**Figs. 3F–H, 6**) *Aster tortifolius* Michx., Fl. Bor. Amer. 2:109. 1803. non (Torr. & A. Gray) A. Gray (1868). TYPE: U.S.A. "Hab. in Carolina inferiore," *Michaux s.n.* (HOLOTYPE: P-MICHX!; ISOTYPE: P, several pieces on one sheet).

Conyza bifoliata Walt., Fl. Car. 204. 1788. non L. (1753), non Cham. & Less. (1831). *Sericocarpus bifoliatus* (Walt.) Porter, Mem. Torrey Bot. Club 5:322. 1894. *Aster bifoliatus* (Walt.) Ahles, J. Elisha Mitchell Sci. Soc. 80:173. 1964. TYPE: U.S.A. Carolinas? (HOLOTYPE/LECTOTYPE: BM?, not seen, not on p.36 of Schubert's photographs of Walter Herbarium)

Sericocarpus collinsii Nutt., Trans. Am. Phil. Soc. 2, 7:302. 1841. *Sericocarpus bifoliatus* (Walt.) Porter var. *collinsii* (Nutt.) Blake, Proc. Amer. Acad. Arts 51:515. 1916. TYPE: U.S.A. EAST FLORIDA: Mr. Ware (HOLOTYPE: BM, not seen; simple sketch seen);

Sericocarpus acutisquamus Small, Fl. S.E.U.S. 1206, 1339. 1903. TYPE: U.S.A. FLORIDA. Columbia Co.: Lake City, 29–31 Aug 1895, *G.V. Nash 2486* (HOLOTYPE: NY ex Columbia College!). Small lists *Sericocarpus bifoliatus* (Walt.) Porter var. *acutisquamus* Nash but this name does not appear to have been published.

Perennial herb from short-branching woody caudex. Stem erect, (33–)39–61–83(–117) cm, puberulent, hispidulous-pilose-villous hairs 0.1–0.5 mm long, sparsely stipitate-glandular. Basal leaves absent at time of flowering. Stem leaves sessile, obovate, acuminate to slightly cuspidate, (0.9–)1–2–3(–4) cm long, (0.3–)

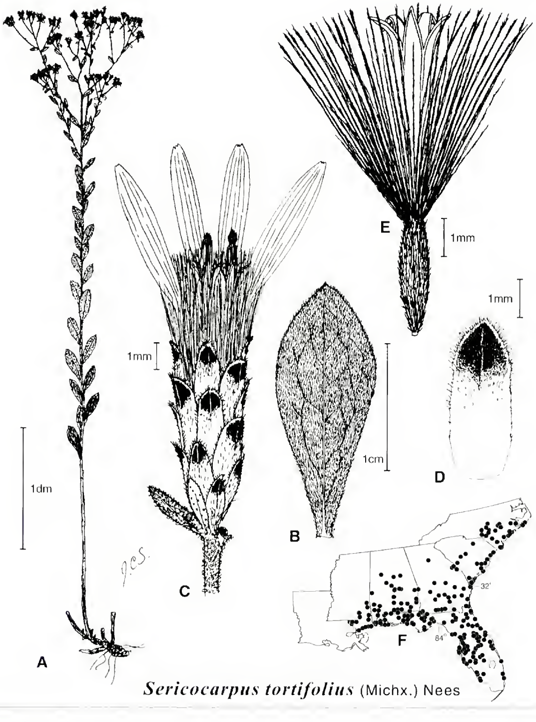

Fig. 6. Morphology and distribution of *Sericocarpus tortifolius*. A. Habit. **B.** Lower mid stem leaf. **C.** Head, only some florets shown. **D.** Mid series phyllary with chlorophyllous zone dark. **E.** Mature disc floret achene with floret still attached. **F.** Distribution in the eastern United States based on all collections seen.

0.6–0.8–1(–1) cm wide, reticulate veined, sparsely to moderately finely pilose-scabrous, hairs 0.05–0.1 mm long, finely glandular punctuate, the stipitate glands minute, margins ciliate, entire, upper leaves decreasing in size upward. Capitulescence corymbiform; heads 2–4 per branch; bracts, ciliate, pubescent, broadly lanceolate to narrowly ovate. Involucre (4.8–)5.2–6.0–6.7(–8.0) mm high at anthesis, (3.1–)3.8–4.4–5.1(–6.0) mm wide; phyllaries in 4–5 imbricate series, ciliate, puberulent base widely oblong, tip acute, outer series (1.8–)1.9–2.2–2.6(–3.1) mm long, first mid series (2.7–)2.8–3.2–3.7(–4.4) mm long, second mid series (3.6–)3.9–4.4–5.0(–6.1), inner series more linear and less chlorophyllous, margins ciliate, dark chlorophyll zone at the apex, thumb-nail shaped. Ray florets, 2–5, strap (3.4–)3.9–4.8–5.7(–6.4) mm long, corolla tube (2.7–)3.0–3.4–3.8(–4.2) long, cypselae densely strigose, (1.1–)1.2–1.5–1.8(–2.4) mm long at anthesis, increasing twofold by maturity, pappus triple or rarely quadruple: secondary outer linear scales 0–very few, 0.1–1mm long; secondary inner bristles few, 40–70% of primary inner series; primary outer bristles 80–90% of inner bristles; primary inner bristles moderately strongly clavate, (5.4–)5.9–6.5–7.1(–7.8) mm long. Disc florets, 6–11, corolla lobe (1.1–)1.2–1.4–1.6(–1.8) mm long, corolla tube (3.8–)4.19–4.82–5.5(–5.6) mm long; cypselae densely strigose, (1.2–)1.2–1.5–1.9(–2.6) mm long at anthesis, increasing twofold by maturity, pappus triple or rarely quadruple: secondary outer linear scales 0–very few, 0.1–1mm long; secondary inner bristles few, 50–70% of primary inner series; primary outer bristles 80–90% of inner bristles; primary inner bristles moderately strongly clavate, (5.7–)6.2–6.8–7.4(–8.3) mm long. $2n = 18$.

Flowering midsummer–early fall. Dry to moist clay, sandy and gravelly open soils in oak and pine barrens, oak scrub, pastures, roadsides, mostly coastal plain; ca. 5–200 m; eastern North Carolina, South Carolina, Georgia, Florida, Alabama, southeastern Mississippi and adjacent Louisiana.

4. Sericocarpus oregonensis Nutt., Trans. Amer. Phil. Soc. 2, 7:302. 1840. (**Fig. 7**)

Aster oregonensis (Nutt.) Cronq., Vasc. Fl. Pacif. Northw. 5:91. 1955. "Round Ft. Vancouver" [protologue]. "Margins of Wahlament & Wappatoo Island" [Nuttall's handwritten label], 1835?, *Nuttall s.n.* (HOLOTYPE: BM, photo!).

Perennial herb from stout, branching, woody caudex. Stem erect, (24–)40–62–85(–102) cm, glabrous to very sparsely hispidulous-scabrous, hairs 0.05 mm long, or moderately to densely hispidulous-pilose-villous, hairs 0.1–1.5 mm long, sometimes resinous-glandular. Basal leaves absent at time of flowering. Stem leaves broadly lanceolate to narrowly ovate, sessile, acuminate to acute, (1–)2–4–6(–10) cm long, (0.3–)0.6–0.9–1(–2) cm wide, reticulate veined, finely scabrous or hispidulous-scabrous, more densely so on the abaxial veins, the hairs 0.1–0.5(–2) mm long, glandular punctuate to very resinous, margins ciliate, entire, upper leaves decreasing in size upward. Capitulescence corymbiform; heads 2–4 per branch; bracts, ciliate, pubescent, broadly lanceolate to narrowly ovate. Involucre (4.7–)5.7–6.4–7.0(–7.2) mm high at anthesis, (4.4–)5.0–5.8–6.6(–7.2) mm wide; phyllaries in 3–4 imbricate series, ciliate, puberulent, base narrowly oblong, acuminate, outer series (2.8–)3.4–3.9–4.4(–4.6) mm long, mid series (3.8–)4.5–5.0–5.4(–5.6) mm long, inner series more linear and less chlorophyllous, margins ciliate, dark chlorophyll zone at the apex, thumb-nail shaped. Ray florets,

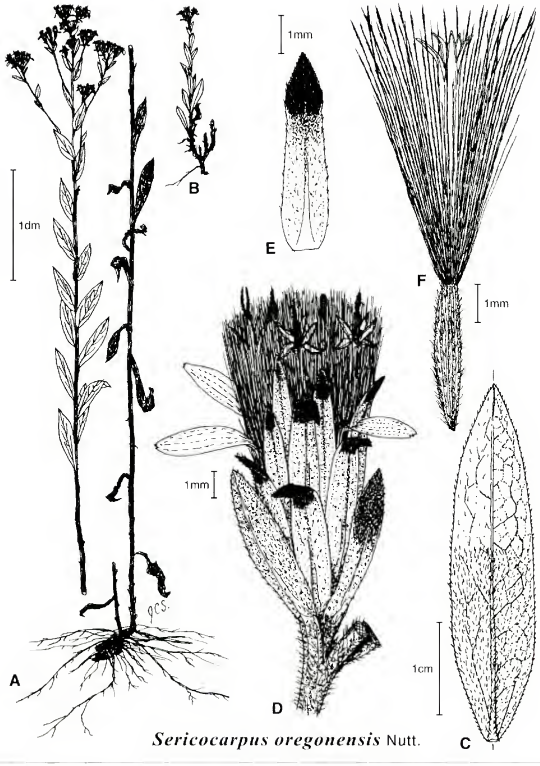

FIG. 7. Morphology of *Sericocarpus oregonensis*. **A–B.** Habits of large and small plants, respectively. **C.** Lower mid stem leaf; upper half subsp. *oregonensis,* lower half subsp. *californicus*. **D.** Head, on some florets shown; hatch marks indicated location of bract and second head (not shown). **E.** Mid series phyllary with chlorophyllous zone dark. **F.** Mature disc floret achene with floret still attached.

2–6, strap (3.1–)3.7–4.5–5.2(–5.6) mm long, corolla tube (2.6–)2.8–3.2–3.5(–3.8) mm long, cypselae strigose, (1.3–)1.5–2.1–2.6(–3.3) mm long at anthesis, increasing two-threefold by maturity, pappus triple or rarely quadruple: secondary outer linear scales 0–very few, 0.1–1mm long; secondary inner bristles few, 40–75% of primary inner series; primary outer bristles 80–95% of inner bristles; primary inner bristles moderately strongly clavate, (4.1–)4.7–5.3–5.9(–6.6) mm long. Disc florets, 9–20, corolla lobe (1.0–)1.1–1.2–1.4(–1.7) mm long, corolla tube (3.4–)4.1–4.6–5.1(–5.2) mm long; cypselae strigose, (1.4–)1.7–2.2–2.7(–3.3) mm long at anthesis, increasing twofold by maturity, pappus triple or rarely quadruple: secondary outer linear scales 0–very few, 0.1–1mm long; secondary inner bristles few, 40–75% of primary inner series; primary outer bristles 80–95% of inner bristles; primary inner bristles moderately strongly clavate, (4.8–)5.5–6.1–6.7(–7.2) mm long. $2n = 18$.

4a. Sericocarpus oregonensis subsp. **oregonensis (Figs. 7c, 8).** *Sericocarpus oregonensis* var. *oregonensis. Aster oregonensis* subsp. *oregonensis.*

Flowering midsummer to early fall. Stems glabrous-glabrate, the hairs minutely scabrous; leaves glabrous to very sparsely and minutely hispidulous-pilose, hairs 0.05 mm long, obviously resinous especially along the veins. Dry to moist sandy to rocky soils in open areas in oak and pine woods, brushlands, roadsides, disturbed habitats; 100–1800 m; Coast and Cascade ranges, Washington where it is rare, western Oregon, and northern California south to Mendocino County.

4b. Sericocarpus oregonensis Nutt. subsp. **californicus** (Durand) Ferris, Contr. Dudley Herb. 5:100. 1958. (**Figs. 7c, 8**). *Sericocarpus californicus* Durand, J. Acad. Nat. Sci. Phil. 2, 3:90. 1855. non *Aster californicus* Less. in Schldl. & Cham. (1831), nec Kuntze (1891). *Sericocarpus rigidus* Lindl. in Hook. var. *californicus* (Durand) Blake, Proc. Amer. Acad. Arts 51:515. 1916. *Aster oregonensis* (Nutt.) Cronq. subsp. *californicus* (Durand) Keck., Aliso 4:105. 1958. TYPE: U.S.A. CALIFORNIA. Nevada Co.: Nevada City, *Rattan s.n* (HOLOTYPE: P, fragment NY)

Flowering midsummer–early fall. Stems moderately to densely hispidulous-pilose, the longest hairs villous twisted, hairs 0.1–1.5 mm long; leaves moderately hispidulous-scabrous, more densely so along the abaxial veins, the hairs on the surface 0.1–0.5 mm long, those on the veins to 1–2 mm long, finely glandular punctate. Dry to moist sandy soils in open areas in oak and pine woods, along dry streams, granitic and serpentine barrens; 800–2200 m; Sierra Nevada Range of eastern California.

5. Sericocarpus rigidus Lindl. in Hook., Fl. Bor.-Amer. 2:14. 1834. (**Fig. 9**). SYNTYPES: U.S.A. OREGON or WASHINGTON: Columbia River, *Scouler s.n.* (LECTOTYPE [Cronquist 1955]: CGE?, not found in search of types; ISOLECTOTYPE: NY ex Torrey!).

Sericocarpus rigidus Lindl. in Hook. var. *laevicaulus* Nutt., Trans. Amer. Phil. Soc. 2, 7:302. 1840. TYPE: U.S.A. WASHINGTON: Fort Vancouver, *Nuttall s.n.* (HOLOTYPE: not seen)

Aster curtus Cronquist, Vasc. Fl. Pacif. Northw. 5:80. 1955. New name for *Sericocarpus rigidus* Lindl. in Hook. (1834).

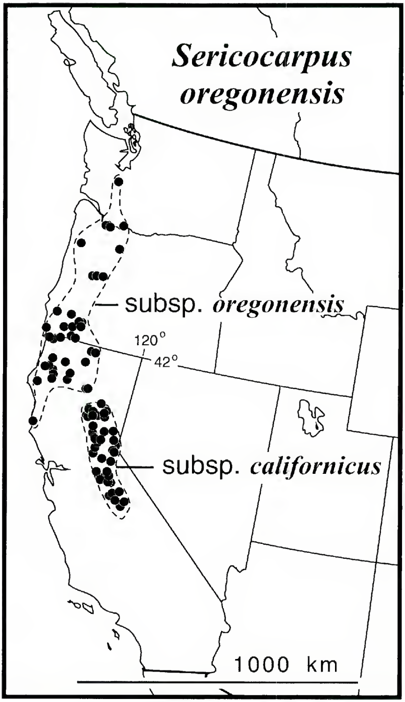

Fig. 8. Distribution of *Sericocarpus oregonensis* in the western United States based on all collections seen.

Perennial herb from short, branching, rhizomatous, woody caudex. Stem erect, puberulent, (19-)21-28-34(-37) cm. Basal leaves absent at time of flowering. Stem leaves, puberulent, obovate, sessile, acute, upper leaves becoming acuminate, (1-)2-3-4(-6) cm long, (0.3-)0.5-0.6-0.8(-0.9) cm wide, reticulate veined, margins ciliate, entire, upper leaves decreasing in size upward. Capitulescence broadly corymbiform, compact; heads 2-3 per branch; bracts ovate, ciliate,

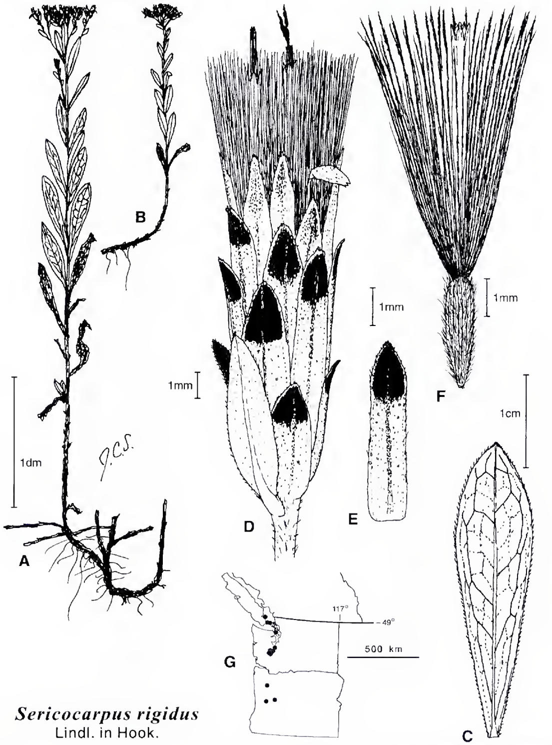

Fig. 9. Morphology and distribution of *Sericocarpus rigidus*. **A–B.** Habits or large and small plants, respectively. **C.** Mid stem leaf. **D.** Head, only some florets shown. **E.** Mid series phyllary with chlorophyllous zone dark. **F.** Mature disc floret achene with floret still attached. **G.** Distribution in the Oregon, Washington and British Columbia based on all collections seen.

puberulent. Involucre (6.1–)6.4–7.3–8.1(–8.6) mm high at anthesis, (4.1–)4.7–5.6–6.4(–6.5) mm wide; phyllaries in 3–4 imbricate series, slightly ciliate, puberulent, base narrowly oblong, tip acuminate to acute, outer series (3.1–)3.5–4.2–4.9(–5.3) mm long, mid series (4.6–)4.7–5.5–6.2(–6.5) mm long, inner series more linear and less chlorophyllous, margins ciliate, dark chlorophyll zone at the apex, thumb-nail shaped. Ray florets, 1–2, strap, ligulate, (1.6–)1.6–2.1–2.6(–3.0) mm long, corolla tube (2.5–)2.6–3.1–3.5(–3.9) mm long, cypselae strigose, (1.3–) 1.2–1.6–1.9(–2.2) mm long at anthesis, increasing twofold by maturity pappus triple or rarely quadruple: secondary outer linear scales 0–very few, 0.1–1mm long; secondary inner bristles few, 40–75% of primary inner series; primary outer bristles 80–95% of inner bristles; primary inner bristles moderately strongly clavate, (4.6–)5.1–5.7–6.2(–6.5) mm long. Disc florets, 9–17, corolla lobe (0.6–)0.7–0.8–0.9(–1.0) mm long, corolla tube (4.4–)4.6–5.1–5.6(–6.2) mm long; cypselae strigose, (1.4–)1.5–1.8–2.1(–2.3) mm long at anthesis, increasing twofold by maturity, pappus triple or rarely quadruple: secondary outer linear scales 0–very few, 0.1–1mm long; secondary inner bristles few, 40–75% of primary inner series; primary outer bristles 85–95% of inner bristles; primary inner bristles moderately strongly clavate, (5.7–)6.2–6.6–7.1(–7.4) mm long. $2n = 18$.

Flowering midsummer to early fall. Prairie habitats, dry pastures, dry grassy Garry oak forests with rocky outcrops; 10–120 m; extreme southern British Columbia, western Washington, and scattered disjunct locations in western Oregon (Fig. 6G). *Sericocarpus rigidus* grows on the southern part of Vancouver Island, B.C. and in scattered locations to the south end of the Puget Sound area in Washington. The species is rare throughout its range and is listed by COSEWIC in Canada as Threatened, by USFWS as Species of Concern, as Sensitive in Washington, and as Threatened in Oregon.

ACKNOWLEDGMENTS

This research was supported by Natural Sciences and Engineering Research Council of Canada Operating and Discovery Grants to J.C.S., a Natural Sciences and Engineering Research Council of Canada Post Graduate Scholarship and an Ontario Graduate Scholarship to R.E.C. This work was initiated as a Biol499 Senior Research Project at University of Waterloo by M.R.L. Gina Murrell (CGE) is thanked for assistance in attempts to locate type material of *S. rigidus* in 2004. Guy Nesom and David Keil are thanked for their helpful suggestions in their reviews of the manuscript.

BOOK REVIEW

Judith Sumner. 2004. **American Household Botany: a History of Useful Plants 1620-1900.** (ISBN 0-88192-652-3, hbk.). Timber Press Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (**Orders:** www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $27.95, 396 pp., b/w illus., 16 color plates, 6 1/2" × 9 1/4".

A history of plants in the domestic scene it is, but this book is much more, indeed an encyclopedic reference to the "useful" plants of North America from colonial times. It is also a compendium of the continent's cultural diversity and consequently its culinary as well as horticultural diversity. The author details what plants the early colonists brought from Europe both for comestible and medicinal purposes and how they adapted to the plants that native American tribes used for these and for other uses. Not least in importance was the knowledge of preparing food; for this the author quotes from the notable cookbooks dating from 1672, many of which listed the salutary effects of correct preparation. In order to have food through the long winters the colonists had to learn the best ways for preserving food by correct storage and through cooking methods such as pickling. Imported and native herbs and spices played a large role in both. The passages on the "botanical pantry," detailing the means of curbing growth of bacteria and fungi in fresh and preserved foods, the usages of spices for flavoring (how, for instance, sassafras became an important herb for Creole cuisine), the experiments using native plants as substitutes for oriental teas, are engrossing. One of the most important chapters, not surprisingly, as the author teaches medicinal botany in the Arnold Arboretum at Harvard University, is that on herbal medicines, in which she gives insights to the very chemicals that make the plants effective in healing—or dangerous in excess.

While food and medicine are the major portions of the book, the growing and use of plants through these two centuries is extremely valuable. The author tells us such facts as that cotton had become an economic crop by 1607 in Virginia and by the early 1700's was beginning to replace linen (homespun) as an affordable fabric, that American women were testing native plants for dyes and tannin from native plants, and a number of native plants were being used for inks, that public kitchens for the indigent were started in 1890.

Landscape plants are featured as well as the horticultural contributions of William Bartram and Thomas Jefferson. The author delves into the teaching of botany in schools beginning with the first textbook by Almira Phelps in 1829. Soon the discipline was not limited to the classroom but expanded into the garden and eventually to the wild. She also recounts Asa Gray's interest in teaching botany to youngsters, attested by his textbook of 1836 and his numerous contributions to botany, not least his influential *Manual of the Botany of the Northeastern United States* (1848).

This book is comprehensive—from the basic uses of plants for food to the ornamental uses of flowers in the parlor. It is well documented, authoritative, eminently readable, and a good resource for several disciplines.—*Joann Karges, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

NEOTYPIFICATION OF *CEROPEGIA PALUSTRIS* AND *LYONIA MARITIMA* (APOCYNACEAE: ASCLEPIADOIDEAE)

Alexander Krings

Herbarium, Department of Botany
North Carolina State University
Raleigh, NC 27695-7612, U.S.A.
Alexander_Krings@ncsu.edu

ABSTRACT

Ceropegia palustris Pursh and *Lyonia maritima* Elliott (Apocynaceae: Asclepiadoideae) are currently recognized as synonyms of *Funastrum angustifolium* (Pers.) Liede & Meve. The diminutive vine, one of the most readily recognizable taxa among a number of taxonomically difficult climbing milkweeds in the southeastern United States, occurs primarily in swamps, hammocks, and salt marshes. A neotype is proposed here for *C. palustris*, which will automatically also serve as the type of *L. maritima*, as Elliot was well-aware that the two were synonymous. Additional relevant historical specimens of interest housed at BM, CHARL, and PH are also discussed.

RESUMEN

Ceropegia palustris Pursh y *Lyonia maritima* Elliott (Apocynaceae: Asclepiadoideae) se reconocen usualmente como sinónimos de *Funastrum angustifolium* (Pers.) Liede & Meve. Esta pequeña trepadora, que es uno de los taxa más fácilmente reconocibles entre un grupo taxonómicamente difícil de trepadoras del Sureste de los Estados Unidos, aparece primariamente en pantanos y lagunas saladas. Se propone aquí un neotipo para *C. palustris*, que servirá también automáticamente como tipo de *L. maritima*, porque Elliot estaba muy convencido de que los dos eran sinónimos. Se discuten también especimenes adicionales de relevancia histórica que se encuentran en BM, CHARL, y PH.

Ceropegia palustris Pursh and *Lyonia maritima* Elliott (Apocynaceae: Asclepiadoideae) are currently recognized as synonyms of *Funastrum angustifolium* (Pers.) Liede & Meve (= *Cynanchum angustifolium* Pers.; Liede & Meve 2003). The diminutive vine, one of the most readily recognizable taxa among a number of taxonomically difficult climbing milkweeds in the southeastern United States (Drapalik 1969; Sundell 1981; Rosatti 1989; Liede 1997), is known from the Atlantic and Gulf Coasts of the United States, Mexico, and Belize, as well as the Bahamas and West Indies (Radford et al. 1968; Correll & Correll 1982; Balick et al. 1999). It occurs primarily in swamps, hammocks, and salt marshes, where it constitutes a quite inconspicuous component of the flora. The taxon was first described as *Cynanchum angustifolium* by Christiaan Persoon (Syn. Pl. 1:274. 1805). In 1814, Frederick Pursh independently described the species as *Ceropegia palustris* (Fl. Amer. Sept. 1:184). Pursh's name was the basionym for at least five combinations published over the next century (see below). In 1817, Stephen Elliott published the name *Lyonia maritima* for the

SIDA 21(3): 1507– 1513. 2005

taxon (Sketch Bot. S. Carolina 1:316), honoring John Lyon with a new genus, well-aware that Pursh had already described the taxon in *Ceropegia*. However, the conservation of *Lyonia* Nutt. (Ericaceae; 1818) against *Lyonia* Raf. (Polygonaceae; 1808) is automatically extended to *Lyonia* Elliott (ICBN, Art. 14.10; Greuter et al. 2000). Although the nomenclatural availability of *Lyonia* Elliott is moot, the issue of typification of Elliott's and Pursh's names remains of interest from an historical perspective as both men made important contributions to North American botany (Pursh 1814; Elliott 1817).

In his description of *Ceropegia palustris*, Pursh (1814) notes having seen a specimen in the Lyon herbarium. Liede and Meve (2003) list this specimen as the type, although without tracing it. Ewan & Ewan (1963) note that although John Lyon's journal has been saved, his herbarium, which apparently at one point had been left in Asheville, North Carolina (Gray 1842), has unfortunately been lost or destroyed. Additionally, no relevant specimen was found in BM, C, LIV, MANCH, PH, K, or OXF, herbaria known to house Pursh collections. In the absence of any specimens of *Funastrum angustifolium* known to have been seen by Pursh, a neotype must be designated. Unfortunately, the exact locality of Lyon's collection of the taxon cannot be ascertained. Lyon does not mention the taxon in his journal (Ewan & Ewan 1963). Further complicating matters is the fact that during Lyon's exploration of coastal Carolina, in 1803–1804 and later again in 1808, he collected from the southern border of South Carolina, northward to Wilmington, North Carolina (Ewan & Ewan 1963)—a rather expansive coastal strip of marshes. In the absence of a more narrowly definable locality, a neotype is thus chosen from the marshes of Charleston County (*S.W. Leonard 2715 with A.E. Radford*, NCU).

As indicated in the protologue of *Lyonia maritima*, Elliot was well-aware that *Ceropegia palustris* Pursh was a synonym (Elliott 1817). Thus, *L. maritima* Elliott is superfluous and illegitimate and the neotype chosen for *C. palustris* is automatically the type of *L. maritima*. However, from an historical perspective it remains of interest what specimens Elliott actually studied. His collections are known to be housed in the herbaria of CHARL and NY (Weatherby 1942; TLII). However, Weatherby (1942) makes no mention of a matching type for *Lyonia maritima* or its synonyms at CHARL. A search of the NY online type register has also proved unsuccessful. However, during a visit to CHARL to study Elliott's handwriting, an intriguing specimen was discovered—filed under *Asclepias* and mounted with material of *Asclepias pedicellata* (Fig. 1A). The specimen is clearly *Funastrum angustifolium* and is labelled "*Asclepias*" in Elliott's hand (Fig. 1B). Judging from the large script, CHARL curator Albert Sanders believes the specimen to stem from Elliott's early collecting days (pers. comm.). Apparently, Elliott's style of labelling, including the size of his script, changed noticeably over the years (Sanders, pers. comm.). Elliott was punctilious about

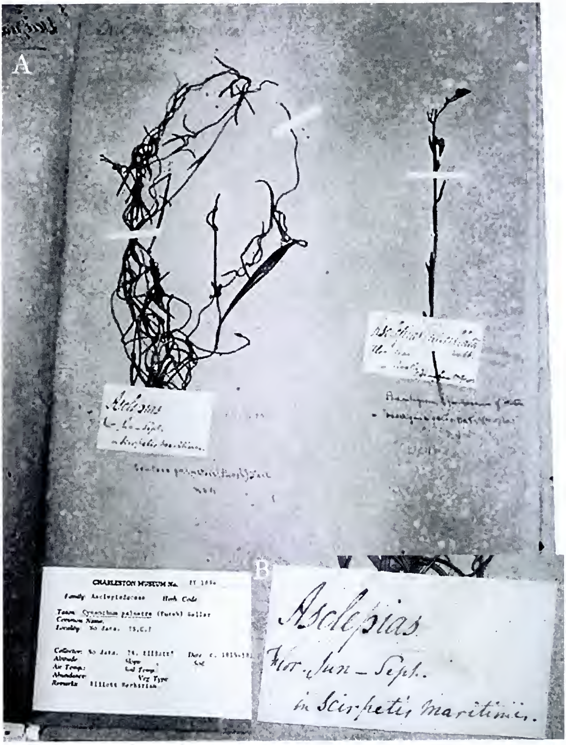

Fig. 1. **A.** Type of *Lyonia maritima* Elliott (specimen at left; CHARL). The specimen on the right is referred to *Asclepias pedicellata* Walter. **B.** (inset) Label detail of type of *Lyonia maritima* Elliott (CHARL).

noting the original collectors on labels associated with the plants given to him. No collector name appears on the label in question. Therefore, although no mention of *Lyonia* is made on the sheet, it is clear that this is a personal collection of the plant Elliott would later describe as *Lyonia maritima*. Weatherby (1942) and others likely missed the specimen as it would not be expected under *Asclepias*.

A search of PH by James Macklin resulted in an additional intriguing specimen. The specimen is clearly the taxon in question and bears (1) the name "*Vincetoxicum palustris* A. Gr." on the PH label, (2) a cut-out from an older sheet bearing Elliott's name ("S. Carol Elliott"), (3) another cut-out from an older sheet bearing the name "*Ceropegia palustris*," and "*Lyonia*," (4) a cut-out bearing the handwritten "Baldw Geo," and (5) a cut-out bearing the handwritten "pub. nom. Ceropegia pal. Bald. Geo." This latter annotation appears to be in the characteristic small, dense hand of Muhlenberg. Although only one taxon is present, the sheet appears to bear material of mixed origin. The abbreviations *Geo* and *S. Carol* likely refer to the states of origin: Georgia and South Carolina, respectively. The presence of Elliott's name, along with the geographical origin South Carolina, indicates the material to have been Elliott's that was at some point sent to PH. Elliott corresponded with numerous botanists, including Muhlenberg and Baldwin. The other labels on the sheet indicate origin of respective material from Baldwin, who was in Georgia 1812–1813. Unfortunately, it is difficult to date this specimen. The taxon is not mentioned in the correspondence between Baldwin and Muhlenberg, reproduced in *Reliquiae Baldwinianae* (Darlington 1843). The presence of an annotation bearing the name *Lyonia*, could indicate that the specimen was either received following publication of Elliott's *Sketch* or prior to and subsequently annotated. In either case, Elliott appears to have been the sender of some of the material.

Another interesting specimen is the Elliott sheet housed in deCandolle's *Prodromus* herbarium (G-DC). Decaisne (1844) notes seeing this specimen in his *Prodromus* treatment. Fortunately, the *Prodromus* herbarium is available on microfiche. The specimen in question can be found on IDC microfiche no. 1541. V.8: 588.41–595.32 [top row, 2nd specimen from right]. Two labels are found on the sheet. One label indicates the name used by Decaisne (i.e., *Seutera maritima*) and the other records the name as received by de Candolle from Elliott (i.e., *Lyonia maritima*).

As a final note, it appears that Thomas Walter collected this taxon in the course of his work on the *Flora Caroliniana* (Walter 1788)! Although the flowers (as well as the subtending sheet) have been eaten, it appears that the specimen found on Sheet 11 of his herbarium at BM and marked with a slashed 600 is indeed *Funastrum angustifolium* (Fig. 2). The glabrous specimen bears linear, sessile leaves and umbellate, 6–9-flowered inflorescences (based on the

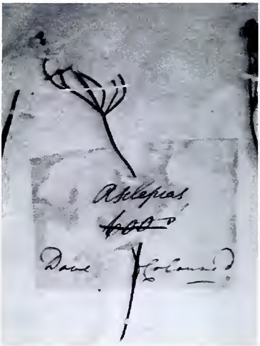

Fig. 2. Collection of *Funastrum angustifolium* on Sheet 11 of the Thomas Walter Herbarium (BM).

number of pedicel stubs). The stems are flexuous and 'caved in' in a manner consistent with recent collections of the vine versus erect asclepiads. Had he described the taxon in his flora, his name would have priority over Persoon's. As it is, Walter's collection will remain one of the earliest known collections of the taxon, if not the earliest.

ACKNOWLEDGMENTS

I thank the curators and staff of C, CHARL, BM, G-DC, K, LIV, MANCH, OXF, PH for their kind assistance in trying to locate specimens in their respective herbaria. Additionally, I thank James Macklin (PH) and Vicki Noble (BM) for supplying digital images and Albert Sanders (CHARL) for access to CHARL and thoughtful conversation. Also, I thank the Interlibrary Loan department of NC State University for timely assistance in obtaining works not held locally, Fred Barrie for a thoughtful review, and Wendy Worley for logistical support.

BOOK REVIEW

ALTON BOWMAN. 2004. **The Flower Mound, Flower Mound, Texas: A History and Field Guide to the Flowers and Grasses.** (ISBN 1-57864-290-6, pbk.). The Donning Company Publishers, 184 Business Park Drive, Suite 206, Virginia Beach, VA 23462, U.S.A. (**Orders/Availability:** Contact Alton Bowman, 817-430-1976). Price not given, 112 pp., color and b/w photos, b/w maps, bibliography, index, 8 1/2" × 11".

The book, *The Flower Mound, Flower Mound, Texas: A History and Field Guide to the Flowers and Grasses* is a wonderful resource for anyone interested in learning more about the history and flora of the Flower Mound, the namesake of the small town just north of Dallas. The opening chapters introduce readers to the location, geology and wildlife of the Flower mound, as well as a brief history of the mound including Native American archeology and first settlers. The author devotes a chapter to the history of ownership of the mound and how historic owners had the forethought to preserve the flora of the mound.

The majority of the book is written as a field guide. It is rich with color photographs of flora making identification easy for the user. The guide is arranged by which species blooms during specific seasons (~2 month periods), beginning with early bloomers such as ten-petal anemone to brown eyed Susan's in the early summer and ending with species of the later seasons such as gayfeather and saw-leaf daisies. At the end of each "season" is an incredibly handy quick-glance color guide to those species blooming during that period of time. Each plant description includes the plant's common name, Latin name, family name, expected blooming period, a description of the plant (height, fruits etc.), location on the mound, and seasonality. The description also includes other comments for each species, where the author has added interesting tidbits such as the history of the plant's name, historic uses, and other valuable information.

The Flower Mound, Flower Mound, Texas: A history and Field Guide to the Flowers and Grasses is a highly recommended book for any person with an interest in the Flower Mound—especially the flora of the Flower Mound. This is an incredibly easy to use guide; little to no previous botanical knowledge is needed to use it. The greatest thing about the book is the many historic images and color photos of the flowers and plants of the mound. All proceeds (100%) from the sale of this book are used for the perpetual care of the Flower Mound.—*Lee Luckeydoo, Herbarium, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

A NEW COMBINATION IN *MATELEA* (APOCYNACEAE: ASCLEPIADOIDEAE) FOR AN ENDEMIC JAMAICAN VINE

Alexander Krings

Herbarium, Department of Botany
North Carolina State University
Raleigh, North Carolina 27695-7612, U.S.A.
Alexander_Krings@ncsu.edu

ABSTRACT

A new combination in *Matelea* (Apocynaceae: Asclepiadoideae) for an endemic Jamaican vine is proposed.

RESUMEN

Se propone una combinación nueva en *Matelea* (Apocynaceae: Asclepiadoideae) para una trepadora endémica de Jamaica.

Critical study of West Indian specimens of subtribe Gonolobinae (Apocynaceae: Asclepiadoideae) has resulted in the need for a new combination for an endemic Jamaican vine:

Matelea rhamnifolia (Griseb.) Krings, comb. nov. *Gonolobus rhamnifolius* Griseb., Fl. Brit. W.I. 420. 1862. Protologue: 'Jamaica!, *Al.*, S. Anns, near Moneague.' TYPE: JAMAICA: *R.C. Alexander s.n.* (HOLOTYPE: GOET!)

The critical character defining placement in *Gonolobus* Michx.—dorsal anther appendages (Woodson 1941; Rosatti 1989; Stevens 2001)—is lacking, although mistakenly attributed to the species by Adams (1972). Other characters that have been used to refer taxa to *Gonolobus* include winged follicles and the absence of glandular hairs (see Woodson 1941). Follicles are unknown for *Matelea rhamnifolia*, although suspected to be winged, not muricate, based on its affinities to *M. correllii* Spellman. The follicle character is moot, however, as few fruit collections were apparently available to Woodson (1941) and more recent analysis has shown the character not to be useful in generic delimitation (Krings, unpubl.). Glandular hairs, although thought characteristic of *Matelea* Aubl. by Woodson (1941), are also without circumscriptional value in the *Gonolobus*-*Matelea* question, being present in both the type of *Gonolobus* Michx. (i.e., *G. suberosus* (L.) R. Br.) and numerous species lacking dorsal anther appendages (Rosatti 1989), including *M. rhamnifolia*.

The Jamaican endemic *Matelea rhamnifolia* appears most closely related to the Cuban endemic *M. nipensis* (Urb.) Woodson (at least among West Indian taxa); both likely belonging to a complex also including the Cuban endemics

SIDA 21(3): 1515–1517. 2005

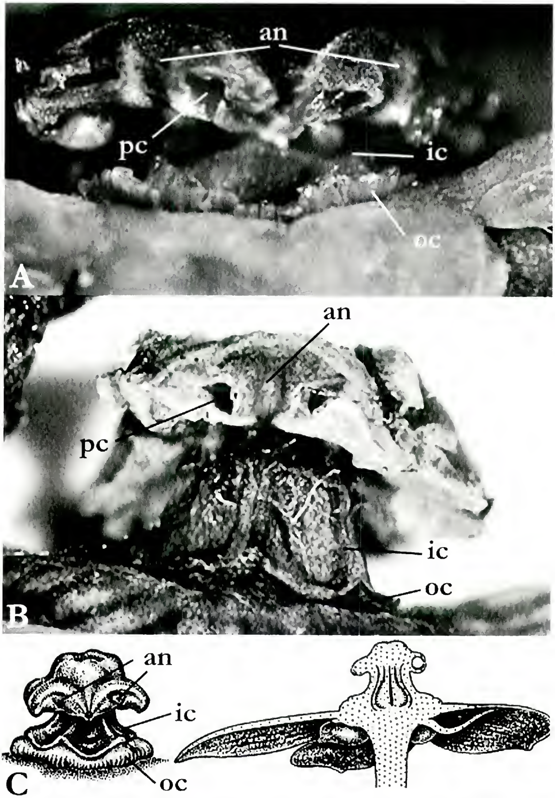

Fig. 1. Corona and gynostegium morphology of: **(A)** the Jamaican endemic *Matelea rhamnifolia* (from *Proctor 11825*, GH) and the related **(B)** Cuban endemic *M. nipensis* (from *Webster 3813*, GH) and *(C)* Bahaman endemic *M. correllii* (from Spellman 1978). Note absence of dorsal anther appendages in all three species. **an**=anther; **ic**=inner corona; **oc**=outer corona; **pe**=pollinium cavity.

M. bayatensis (Urb.) Woodson and *M. tigrina* (Griseb.) Woodson and the Bahaman endemic *M. correllii*. *Matelea rhamnifolia* and *M. nipensis* share oblong leaves that are basally truncate or rounded, reduced peduncles, short corolla lobes, and gynostegial coronas of similar morphology. Both species exhibit a low, somewhat undulating outer corona which subtends an inner corona and the associated staminal tube (Fig. 1A, B). The same morphology is present in *M. correllii* and was well-illustrated in the protologue of this latter species (Fig. 1C). The corolla lobes of both *M. rhamnfolia* and *M. nipensis* are also reticulate (at least when dry) and bear a white spot at each of the apices – both characters shared by the larger-flowered members of the complex mentioned above and the continental *M. pusilliflora* L.O. Williams. *Matelea rhamnifolia* is distinguished from *M. nipensis* by its larger leaves, a longer and more well-developed floral tube (ca. 1.3 mm vs. ≤ 0.5 mm), and a shorter filament tube (0.5 mm vs. 0.7 mm).

Representative specimens examined: *Matelea nipensis* (Urb.) Woodson: **CUBA:** *Ekman 9710* (ISOTYPES: NY, S); *Berazain & Alvarez 24357* (HAJB); *Clemente 4342* (NY); *Webster 3813* (GH).

Matelea rhamnifolia (Griseb.) Krings: **JAMAICA:** *Alexander s.n.* (HOLOTYPE: GOET); *Proctor 11825* (GH, IJ).

ACKNOWLEDGMENTS

I thank the curators and staff of the following herbaria for access to their collections or loans of specimens: BH, BM, BOLO, BREM, BRIT, C, CGE, DUKE, E, F, FI, FLAS, FR, FTG, G, GA, GH, GOET, H, HAC, HAJB, HBG, IJ, JE, K, KY, LL, M, MICH, MIN, MISS, MO, NCU, NO, NY, O, OK, OXF, P, PH, RSA, S, TENN, TEX, U, UC, UNA, US, USCH, USF, WILLI, WU, Z. I also thank the curators and staff of the following herbaria for searching their collections for West Indian Gonolobinae material, although finding no representation: BG, BKL, BR, BUF, COLO, CR, FLAS, IA, ISC, LD, MSU, NEU, NSW, UPS, TUR. Guy Nesom and an anonymous reviewer provided helpful comments on an earlier version of this paper.

Chuck R. Coffee and Russell L. Stevens. 2004. **Grasses of Southern Oklahoma and North Texas: A Pictorial Guide.** (ISBN 0-9754303-0-0, pbk.). Samuel Roberts Noble Foundation, Inc., Agricultural Division, 2510 Sam Noble Parkway, Ardmore, OK 73401, U.S.A. (**Orders:** Noble Foundation, Attn: Ag Publications Distribution, 2510 Sam Noble Pky., Ardmore, OK 73401; http://www.noble.org/Storefront/AgStore/Product.asp?ProductID=NF-FO-04-01). $25.00 + $4.00 shipping, 120 pp., color images, b/w drawings, glossary, index, 8 1/2" × 11".

Have you always wanted an easy to use pictorial reference for local north Texas or southern Oklahoma grasses? *The Grasses of Southern Oklahoma and North Texas: A Pictorial Guide* is that perfect reference. This guide includes color photographs of 116 common grasses of the north Texas and southern Oklahoma region. Each species is devoted one page with photographs showing the entire plant and up-close images of key features such as spikelets, inflorescence, and the sheath wrapping around the stem. Key features of the plant; including uses by wildlife and livestock, are included for each species. In small boxes that accompany the photographs, the authors have also included additional species information including family, tribe, synonymous names, longevity, seasonality, origin, height, and flowering period.

This book can easily be used by farmers, ranchers, students, gardeners, nature enthusiasts, and seasoned professionals alike. Familiarity with botanical terminology is not required; authors provide a figure with all key parts labeled, as well as a glossary of key terms. The plants included in the books are listed in multiple ways: by tribe, by indexes of common names, and by scientific names. Authors have also included a list of useful references for finding additional information.

This guide is highly recommended for anyone with an interest in learning about north Texas and southern Oklahoma grasses. Ranchers, land managers, and gardeners will find useful information regarding habitat, environmental value, and wildlife/livestock usage. The many color photographs are an asset for anyone wanting to identify these species in the field. It is often said that a picture is worth a thousand words, and this guide includes a number of carefully selected images showing the growth form and key features for each species. This guide will be a wonderful and useful addition to your library.—*Lee Luckeydoo, Herbarium, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

A NEW SPECIES OF *MATELEA* (APOCYNACEAE: ASCLEPIADOIDEAE) FROM HISPANIOLA

Alexander Krings

ABSTRACT

A new species of *Matelea* is described from Hispaniola, resulting from study of subtribe Gonolobinae (Apocynaceae: Asclepiadoideae) in the West Indies.

RESUMEN

Se describe una especie nueva de *Matelea* de la Española como resultado del estudio de la subtribu Gonolobinae (Apocynaceae: Asclepiaoideae) en las Indias Occidentales.

In the course of on-going systematic study of subtribe Gonolobinae (Apocynaceae: Asclepiadoideae) in the West Indies, a new species of *Matelea* Aubl. was discovered from Hispaniola:

Matelea pentactina Krings, sp. nov. (**Fig. 1, A–B, E**). TYPE: HAITI: Les Roseaux, Massif de la Hotte western group, rocky ledge, ca. 1300 m, 16 Sep 1928, *Ekman H 10685* (HOLOTYPE: S!).

Species nova distinguibili a *Matelea tamnifolia* (Griseb.) Woodson folio basi rotundata, non cordata vel auriculata, *a* Matelea constanzana*Jiménez corolla viridis vel flava, lobis utrinque reticulato-venosis, superne puberulis,* et a *Matelea ovatifolia* (Griseb.) Woodson corolla trichomata 0.11 mm longa, corona segmentis erectis ovatis, (1.5–)1.7–1.9 mm, via antheram 0.5–0.6 mm.

Twining vine; stems herbaceous when young, becoming woody with age, the bark cream-colored, somewhat corky; stems pubescent in lines, the trichomes white, multi-cellular, retrorsely curved or sometimes straight, to 0.2 mm long; leaves opposite, simple, the blades ovate to elliptic, (6.5–)12.7–21 mm × (2.6–)6.8–13.6 mm, both surfaces glabrous or glabrate, the apices obtuse to narrowly rounded, apiculate, the apiculum to 1.2 mm long, the bases rounded the margins entire, glabrous or ciliolate, the cilia ca. 0.08 mm long, colleters 2, yellow to orange, borne adaxially on the midvein at the base of the blade, to 0.2 mm long, petioles 2.9–9.4 mm long, grooved adaxially, glabrous except for the groove, trichomes mostly antrorse, to 0.18 mm long; inflorescence axillary, umbelliform, the peduncles severely reduced to obsolete, pedicels 5–12 mm long, puberulous with trichomes to 0.12 mm long or glabrate; sepals 5, ovate to lanceolate, ca. 1 mm long, the apices rounded to obtuse, both surfaces glabrous, the margins glabrous or very sparsely ciliolate; corolla rotate, pale green or yellow with dark green reticulations, 5-lobed, the lobes ovate, to 4.2 mm long, the adaxial surface

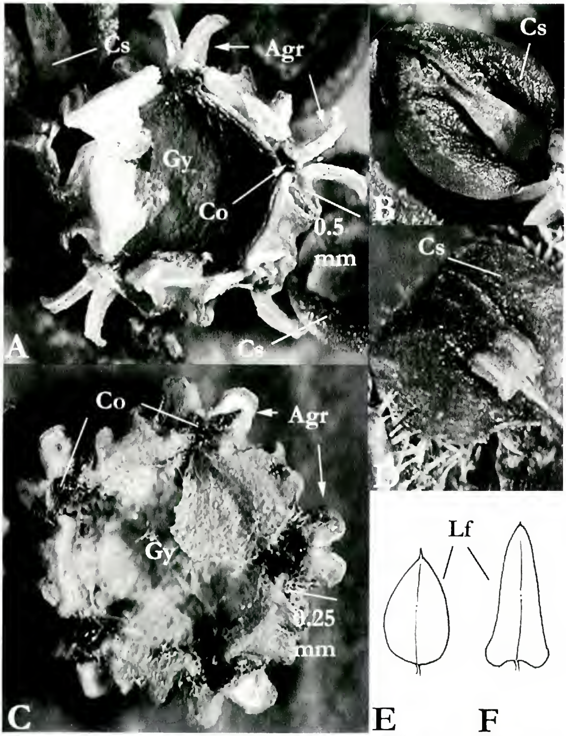

Fig. 1. *Matelea* subgenus *Poicilla*: **A–B & E,** *Matelea pentactina* Krings (*Ekman H 10685*, S); **C–E,** *Matelea ovatifolia* (Griseb.) Woodson (*Wright 2965*, GH); **F,** *Matelea tamnifolia* (Griseb.) Woodson (*Wright s.n.*, GH). **Agr** = Anther guide rail; **Co** = Corpusculum; **Cs** = erect staminal corona segment; **Gy** = Gynostegium; **Lf** = leaf.

pubescent near the base of the lobes, the trichomes whitish to 0.11 mm long, the abaxial surface glabrous; faucal annulus [Ca] pubescent; corona of fused staminal and interstaminal parts [C(is)], glabrous, the staminal segments [Cs] erect, foliate, ovate (1.5–)1.7–1.9 mm long, the apices obtuse, deeply notched, higher than the apex of the gynostegium; gynostegium stipitate, the stipe ca. 0.2 mm long; dorsal anther appendages [Cd] lacking; anther guide rails outwardly pronounced, 0.5–0.6 mm long; pollinaria descending; follicles unknown.

Etymology.—The epithet *pentactina* refers to the five, elongate, outwardly projecting anther guide rails, reminiscent of rays.

Additional specimens examined: **Haiti:** Massif de la Selle, gr. Crete-a-Piquants, Port-au-Prince, between Carrefour-Martin and Bois d'Orme, c. 800 m, limestone, 17 Dec 1926, *Ekman H 7402* (S!).

Matelea pentactina is most closely related to *Matelea ovatifolia* (Griseb.) Woodson (Fig. 1, C–E) and both its holotype and paratype have previously been referred to the latter (see Liogier 1981). Vegetatively the two species are exceedingly similar and may not be conclusively distinguished. However, a number of floral character states distinctly separate them (see Table 1 and key below). *Matelea ovatifolia* appears endemic to Cuba and *M. pentactina* to Hispaniola, although the single specimen seen from the Dominican Republic (*Fuertes 991*, GH) is sterile and thus cannot be conclusively referred to either based on morphology. A handwritten note with the holotype of *M. pentactina*, presumably by Ekman, indicates it was "seen occassionaly throughout southern Haiti (at least), although seldom with flrs!" A similar note on the paratype reads: "Rare, although I think I have seen it sterile before and taken it for some Metastelma [sic]." *Matelea pentactina* also appears closely related to the Hispaniolan *Matelea constanzana* Jiménez (nom. nov. for *Poicillopsis tuerckheimii* Schltr. as the epithet is not available in *Matelea*). This latter species was apparently known only from the type (Sto. Domingo prope Constanza, *Tuerckheim 3466*, Jul 1910; see also Liogier 1981) and appears to no longer be extant. The protologue indicated that *M. constanzana* also bears obtuse staminal corona segments, but exhibits glabrous white flowers. The striking reticulations evident in the pubescent, green or yellow-flowered *M. pentactina* were not described for *M. constanzana*.

According to the subgeneric classification erected by Woodson (1941), *Matelea pentactina* and *M. ovatifolia*, as well as *M. tamnifolia* (Griseb.) Woodson (endemic to Cuba; Fig. 1, F), belong to the entirely Antillean subgenus *Poicilla*. Woodson (1941) did not include the entity now known as *M. constanzana* in his treatment, but its affinities would seem to place it in his subg. *Poicilla* as well. Although many of Woodson's (1941) subgenera are likely ill-conceived (Stevens 1988), subgenus *Poicilla* is maintained here in the absence of a rigorous test of Woodson's (1941) concept. A key to the subgenus is provided below. On-going systematic study of West Indian Gonolobinae aims to improve generic and subgeneric circumscriptions.

TABLE 1. Floral morphological characters distinguishing *Matelea pentactina* from the related *M. ovatifolia* (Apocynaceae: Asclepiadoideae).

Character	Matelea pentactina	Matelea ovatifolia
Adaxial corolla surface trichomes	to 0.11 mm long	0.13–0.20 mm long
Erect staminal corona segments [C(s)]	(1.5–)1.7–1.9 mm long, ovate, the apices obtuse	0.99–1.28 mm long, obovate to suborbicular, the apices rounded to emarginated
Anther guide rails	0.5–0.6 mm long	to 0.26 mm long

KEY TO *MATELEA* SUBGENUS *POICILLA*

1. Leaf blades lanceolate, the bases cordate to auriculate ________ **Matelea tamnifolia**
1. Leaf blades ovate, the bases rounded to truncate (very rarely shallowly cordate).
   2. Vine exhibiting the combination of corolla lobes white, glabrous on both surfaces, not reticulate, and staminal corona segments rhombic, obtuse ________ **Matelea constanzana**
   2. Vine not exhibiting the above combination of characters (i.e., if corolla lobes white, then corona segments obovate to suborbicular, the apices rounded to emarginate OR if corona segments obtuse, then corollas green to yellow, reticulate)
      3. Adaxial corolla pubescence 0.13–0.2 mm long; erect staminal corona segments 0.99–1.28 mm long, obovate to suborbicular, the apices rounded to emarginate; anther guide rails to 0.26 mm long ________ **Matelea ovatifolia**
      3. Adaxial corolla pubescence to 0.11 mm long; erect staminal corona segments (1.5–)1.7–1.9 mm long, ovate, the apices obtuse; anther guide rails 0.5–0.6 mm long ________ **Matelea pentactina**

ACKNOWLEDGMENTS

I thank the curators and staff of the following herbaria for access to their collections or loans of specimens: BH, BM, BOLO, BREM, C, CGE, DUKE, E, F, FI, FR, FTG, G, GH, GOET, H, HAC, HAJB, HBG, IJ, JE, K, M, MICH, MIN, MO, NY, O, OXF, P, PH, RSA, S, U, UC, US, USF, WU, Z. I also thank the curators and staff of the following herbaria for searching their collections for West Indian Gonolobinae material, although finding no representation: BG, BKL, BR, BUF, COLO, CR, FLAS, IA, ISC, LD, MSU, NEU, NSW, UPS, TUR. The thoughtful review of a previous version of the manuscript by Mary E. Endress, Alain Liogier, and Paul Fantz is gratefully acknowledged.

BOOK REVIEW

Marianna Appel Kunow. 2003. **Maya Medicine: Traditional Healing in the Yucatan.** (ISBN 0-8263-2864-4, hbk.). University of New Mexico Press, 1601 Randolph Rd SE, Suite 200S, Albuquerque, NM 87106, U.S.A. (**Orders:** www.unmpress.com/Ordering.html, 1-800-249-7737). $29.95, 152 pp., tables, b/w figures, appendices, glossary, index, 6" × 9".

Marianna Appel Kunow wrote her new book, *Maya Medicine*, in a refreshingly conversational and easy to read style. It was the culmination of her graduate research into healing plants and the people of the Yucatan that use them. The text presents information about the author's field plant collection and also showcases the lives and practices of the healers with whom she worked.

Some of the studies into the Yucatan healers include discussions of how they became curers; some were trained through "dreams," while others learned from family members or extended education in addition to traditional western training. The author shares some information about the healer's family as well. Additional information includes the types of medicine practiced by the curers—medicinal plants, massage, ceremonial rituals and midwifery. Kunow also includes a chapter to discuss the common techniques used for treatment such as prayer, plant medicine, massage, plant magic, crystals, dream interpretation, and western medicine.

One of the more informative discussions is on the perceived causes of various diseases. Kunow introduces the concept of hot and cold types of conditions and various "magical" diseases such as the evil eye. Common ailments such as colds and skin complaints are also covered. Various plants used for these treatments are listed in table form

With respect to the actually layout of the book, approximately half of it focuses on Kunow's plant lists, illustrations and field notes. The author created multiple tables to relate both scientific and common names to two previous texts on ethno-botany: Roy's 1931 *Ethno-Botany of the Maya* and the *Book of Chilam Balam of Kaua* (Bricker). Common names in the various tables are given and compared in Spanish, Mayan and Kaua. The comparison tables are followed by black and white illustrations of thirty-six of the plants discussed as well as the valuable plant catalog of names and field notes for plant species collected. Other useful items such as a list of plant names by family, glossary of terms and index are also included.

In her book *Mayan Medicine*, author Marianna Appel Kunow shares her personal experience of working with various curers in the Yucatan during her graduate research. There are two foci for the content of this book: the healers and the plants they use. The author spends half of the book describing the healers' backgrounds, preferred practices, techniques and personalities. The remaining half is primarily tabular information about the names and uses of the plants collected and discussed during research activities by the author. The conversational style makes the text easy enough for most high school students and beyond to read and enjoy. Anyone with an interest in ethno-botany or traditional healing will likely enjoy reading *Mayan Medicine*.—*Lee Luckeydoo, Herbarium, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

NOTES ON THE *MATELEA BAYATENSIS-CORRELLII-TIGRINA* COMPLEX (APOCYNACEAE: ASCLEPIADOIDEAE: GONOLOBINAE) IN THE GREATER ANTILLES AND BAHAMAS

Alexander Krings

Herbarium, Department of Botany
North Carolina State University

Alexander_Krings@ncsu.edu

ABSTRACT

As a component of a larger study of the West Indian *Matelea* subgenus *Ptycanthera*, this study sought to critically examine patterns of morphological variation within the embedded *M. bayatensis-correllii-tigrina* complex. Resolution of species-level circumscriptions are necessary before larger issues of subgeneric and generic circumscription can be adequately addressed. Morphological characters were analyzed using parsimony analysis, neighbor-joining, and ANOVA. Results show that *Matelea bayatensis*, *M. correllii*, and *M. tigrina* are very closely related morphologically. The three species appear to differ only in pubescence and relatively minor floral character states, some of which overlap. At present, none of the observed variation appears important enough to warrant the continued recognition of three distinct species.

RESUMEN

Este estudio es un componente de otro más amplio de *Matelea* subgenus *Ptycanthera* delas Indias Occidentales, y está dedicado a examinar críticamente los patrones de variación morfológica en el complejo *M. bayatensis-correllii-tigrina*. Se necesita la resolución de las circunscripciones a nivel específico antes de abordar las circunscripciones de los géneros y subgéneros adecuadamente. Los caracteres morfológicos se analizaron usando análisis de parsimonia, del vecino más próximo, y ANOVA. Los resultados muestran que *Matelea bayatensis*, *M. correllii*, y *M. tigrina* están muy relacionados morfológicamente. Las tres especies parecen diferir sólo en la pubescencia y estados de carácter florales relativamente menores, algunos de los cuales se solapan. Actualmente, ninguna de las variaciones observadas parece lo suficiente importante como para justificar el reconocimiento de tres especies diferentes.

The Metastelmatinae-Oxypetalinae-Gonolobinae clade sensu Rapini et al. (2003) is the most morphologically diverse of the New World Asclepiadeae and most members have never been monographed. The circumscription of two Gonolobinae genera—*Gonolobus* Michx. and *Matelea* Aubl.—has been particularly complicated by the swelling of the latter by Woodson (1941). Unable to come to terms with the large variation in corona morphology, Woodson (1941) submerged numerous genera within *Matelea*, increasing its size from four to over 100 species. Estimates of species numbers of *Gonolobus* vary from 100 to 150 (Rosatti 1989; Mabberly 1997; Stevens 2001). The degree of variation is largely the result of differences regarding generic limits, as well as still poorly known tropical taxa. Woodson (1941) considered the entirely Antillean subgenus *Ptycanthera* to be "largely the deciding factor" for his inclusive treatment of *Matelea*, noting that "were it not for the Antillean species, one might compose a fairly respectable key to several genera upon the continent." As a component of a larger study of *M.* subg. *Ptycanthera*, that ultimately seeks to bear on issues of generic circumscription, this study sought to critically examine patterns of morphological variation within the embedded *M. bayatensis-correllii-tigrina* complex. Resolution of species-level circumscriptions are necessary before larger issues of subgeneric and generic circumscription can be adequately addressed.

METHODS

Based on study of available specimens (Table 1), a matrix of morphological character states (Tables 2 & 3) was developed for seven species and subjected to parsimony analysis using PAUP* (Swofford 2003). Besides *Matelea bayatensis* (Urb.) Woodson, *M. correllii* Spellman, and *M. tigrina* (Griseb.) Woodson (all members of subg. *Ptycanthera* sensu Woodson 1941), the matrix also included three additional West Indian taxa, representing other members of subg. *Ptycanthera*, as well as subg. *Poicilla* sensu Woodson (1941). Closely allied to *Matelea* (Rapini et al. 2003), the type for the genus *Gonolobus* Michx. (i.e., *Gonolobus suberosus* (L.) R.Br.) was chosen as the outgroup (see also Krings & Xiang 2004). The morphological data matrix (Table 2) was comprised of sixteen qualitative characters. Multistate characters were treated as polymorphisms. Bootstrap support values were determined using the branch-and-bound algorithm with 10,000 replicates. To examine phenetic similarity, the morphological character matrix was also subjected to Neighbor-joining (NJ) analysis using PAUP* (Swofford 2003). Continuous data represented by pedicel and corolla lobe length, both characters historically used by authors to delimit taxa in the complex (see Grisebach 1863; Urban 1925), were critically analyzed using ANOVA. In all, thirteen herbarium sheets of *Matelea bayatensis*, *M. correllii*, and *M. tigrina* were examined, although only four individual collections exhibited flowers (Table 1). These specimens essentially represent the sum total of available herbarium specimens of the group, as material was requested from eighty-three institutions known or likely to house material of subtribe Gonolobinae in the West Indies. Only the holotype of *M. correllii* (MO), the lectotype of *M. tigrina* (GOET fide Howard 1988), and a syntype of *M. tigrina* (MO), were not studied as they could not be obtained on loan.

RESULTS

Parsimony.—An exhaustive search using PAUP* (Swofford 2003) evaluated 945 trees and yielded two of shortest length (Length=29; CI=0.862; RI=0.692; Fig. 1). Nine of the sixteen morphological characters (56%) were parsimony informative. The two trees are identical except for resolution of the *Matelea bayatensis*-

TABLE 1. Specimens examined and chosen for analysis.

Subgenus of Matelea sensu Woodson (1941)	Species	Locality	Source
–	*Gonolobus suberosus* (L.) R.Br.	Southeastern U.S.A.	Krings & Xiang (2004)
Poicilla	*Matelea ovatifolia* (Griseb.) Woodson	Cuba, Oriente	*Wright 2965* (ST: G, GH, BREM, UC)
Ptycanthera	*Matelea bayatensis* (Urb.) Woodson	Cuba, Oriente	*Engström 3056* (ST: NY, S)
Ptycanthera	*Matelea correllii* Spellman	Bahamas, Long Island	Spellman (1978), *Correll 49112* (IT: F, FTG, GH, NY, US), *Correll 48157* (topotype: FTG, MO, NY); *Correll 44937* (FTG)
Ptycanthera	*Matelea oblongata* (Griseb.) Woodson	Cuba, Occidente	*Britton & Wilson 14867* (NY), *Britton et al. 7379* (NY), *Ekman 17625* (S), *Leon 17423* (NY), *Shafer 13508* (NY)
Ptycanthera	*Matelea pauciflora* (Spreng.) Woodson	Hispaniola	*Ekman H14296* (S), *Garcia & Pimentel 2531* (MO)
Ptycanthera	*Matelea tigrina* (Griseb.) Woodson	Cuba, Oriente	*Wright 1667* (ST: G, GH)

correllii-tigrina clade. The clade itself appears well-supported by bootstrap values, as is the *Matelea ovatifolia-oblongata* clade. The two Cuban taxa, *Matelea bayatensis* and *M. tigrina* emerged nearer one another than either to *M. correlli* in one of the trees, although with very weak bootstrap support.

NJ and ANOVA.—The neighbor-joining (NJ) analysis showed the Cuban taxa—*M. bayatensis* and *M. tigrina*—to be more similar to each other than either is to the Bahaman taxon *M. correllii* (Fig. 2). The NJ tree is identical to the second of the shortest trees identified by parsimony analysis (Fig. 1, B). *Matelea tigrina* bears sepals that are densely pubescent with both glandular and eglandular hairs and corolla lobes that are pubescent (though not densely so) on the abaxial surface. In contrast, *Matelea correllii* bears glabrous calyces and corollas. *Matelea bayatensis* is intermediate. Its sepals are scattered (not densely) pubescent, with glandular and eglandular hairs, and the abaxial corolla lobes are glabrous. Sepals are lanceolate in *Matelea bayatensis* and *M. tigrina*, and ovate in *M. correllii*. All three taxa in the complex show strong reticulations of their corolla lobes, white dots at the corolla lobe apices, and similar corona and gynostegial morphology. Although pedicel length and corolla lobe length have been used to delimit taxa in the complex (see Grisebach 1863; Urban 1925), an analysis of variance showed no statistically significant difference in mean

TABLE 2. Characters and states scored for the parsimony and neighbor-joining analyses.

Character	State
1. Adaxial leaf blade vestiture	0 = glabrous/glabrate; 1 = pubescent
2. Abaxial leaf blade vestiture	0 = glabrous/glabrate; 1 = pubescent
3. Leaf blade apex	0 = acuminate, 1 = acute or obtuse; 2 = rounded or emarginate
4. Leaf blade bases	0 = cordate; 1 = rounded/truncate; 2 = cuneate
5. Adaxial sepal vestiture	0 = glabrous; 1 = pubescent
6. Abaxial sepal vestiture	0 = glabrous; 1 = pubescent
7. Corolla coloration	0 = uniformly colored; 1 = reticulate; 2 = center differently colored
8. Corolla adornment	0 = absent; 1 = each lobe bearing a white spot apically
9. Corolla lobe shape	0 = broadly ovate to suborbicular; 1 = oblong, triangular-deltate, or lanceolate
10. Adaxial corolla lobe vestiture	0 = glabrous; 1 = pubescent
11. Abaxial corolla lobe vestiture	0 = glabrous; 1 = pubescent
12. Cs (staminal corona, see Kunze 1995)	0 = absent or shallow; 1 = well-developed, and/or foliate
13. Stylar head shape	0 = flat or depressed, 1 = conical
14. Stylar head appendage	0 = absent; 1 = present
15. Cd (dorsal anther appendages, see Kunze 1995)	0 = absent; 1 = present
16. Orientation of pollinium cavity in the gynostegial head	0 = +/- horizontal; 1 = descending

pedicel or corolla lobe length at the 95% confidence level between the three species (pedicel length: $F = 1.98 < F_{crit} = 3.49$; corolla lobe length: $F = 3.65 < F_{crit} = 3.86$). A graphical representation of these data shows evident overlap (Fig. 3).

DISCUSSION

The oldest name in the *Matelea bayatensis-correllii-tigrina* complex was provided by Grisebach (1863) for a Cuban taxon then referred to the genus *Gonolobus*: *G. tigrinus* Griseb. Urban (1925) later added *G. bayatensis* Urb. to the complex, distinguishing it from *G. tigrinus* by shorter pedicels, lanceolate sepals (vs. elliptic-oblong) which are scarcely pilose abaxially (vs. pilose), and longer corolla lobes, these ovate to ovate-rotund (vs. orbicular). A study of the types of both taxa quickly shows these characters to be problematic (*M. tigrina*: *Wright 1667*, G!, GH!; *M. bayatensis*: *Arth. Engström* in herb. Ekman 3056, NY!, S!). Urban's interpretation of sepal and corolla lobe shapes is subjective and these features appear to intergrade. Perhaps his pedicel measurements were not made on extant material, as pedicels on the remaining types are 2.71–3.96 mm long and thus well within the range of *G. tigrinus* (i.e., 2.6–3.69 mm). Furthermore, corollas of *G. tigrinus* were described in Grisebach's protologue as 5–6 mm long,

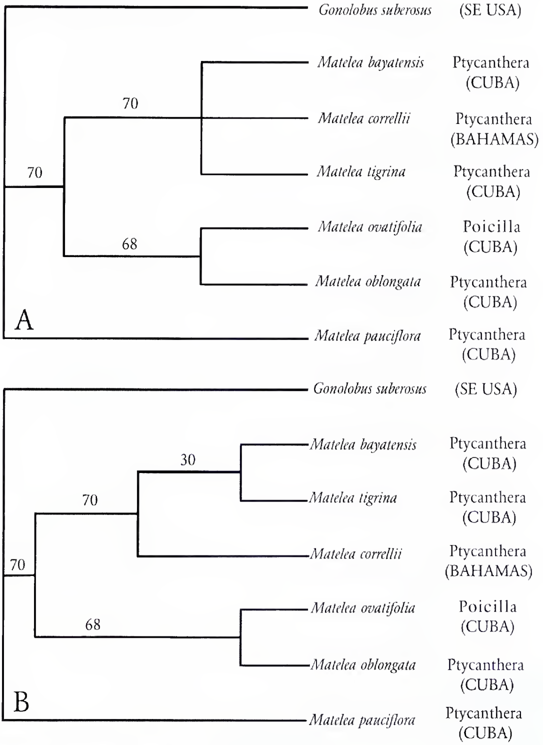

Fig. 1. The two shortest trees (A–B) resulting from a parsimony analysis of morphological characters (exhaustive search) in study of the Antillean *Matelea bayatensis-correllii-tigrina* complex (each tree: length = 29; CI = 0.862; RI = 0.692). Bootstrap support values appear above branches. Marginal annotations indicate subgenus of *Matelea* sensu Woodson (1941) (if applicable), followed by geographic distribution of the species.

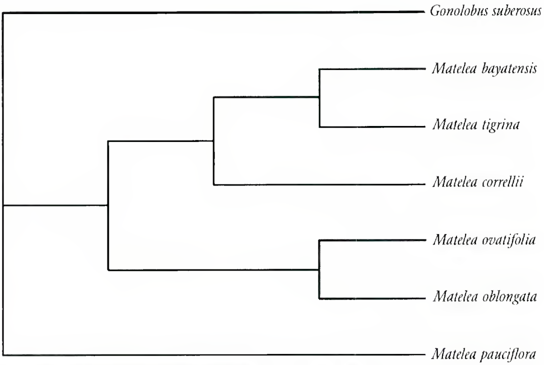

Fig. 2. Neighbor-joining tree showing phenetic similarity in the Antillean *Matelea bayatensis-correllii-tigrina* complex based on sixteen morphological character states.

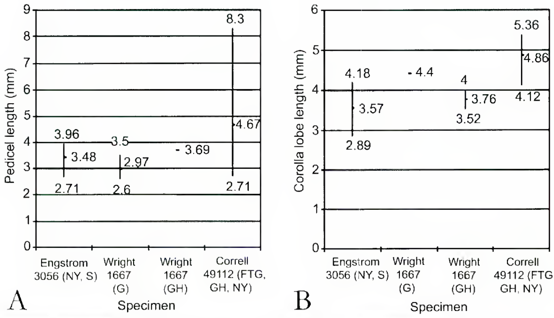

Fig. 3. Continuous floral characters historically used to delimit *Matelea bayatensis*, *M. correllii*, and *M. tigrina*: A, pedicel length; B, corolla lobe length. Measurements indicate maximum, mean, and minimum from top to bottom (in mm), unless only a single measurement was available. *Engström 3056* = *M. bayatensis*; *Wright 1667* = *M. tigrina*; *Correll 49112* = *M. correllii*. The two Wright specimens likely represent two different individuals collected at different times and localities (see Howard 1988).

Table 3. Morphological character matrix used in the parsimony and neighbor-joining analyses of the *Matelea bayatensis-correllii-tigrina* complex.

Taxon	**Character states**
Gonolobus suberosus	{01}10001{02}01{01}110010
Matelea bayatensis	001{01}011100001000
Matelea correllii	0011001100001000
Matelea oblongata	00{01}{12}000010021001
Matelea ovatifolia	001{01}000001020001
Matelea pauciflora	{01}1{12}1010010001100
Matelea tigrina	001{01}011100101000

just a millimeter shorter than *G. bayatensis*. When dried both taxa have similar corolla lobe lengths (to 4.18 mm in *G. bayatensis*; to 4.4 mm in *G. tigrinus*)—although differential shrinkage has been shown in other *Matelea* species (see Drapalik 1969). The sepal vestiture trait remains true. However, this seems insufficient basis for recognizing two separate species.

Without publishing a critical study of the complex, Woodson (1941) later provided new combinations for both taxa in *Matelea*, applying his concept that *Gonolobus* should be characterized primarily by dorsal anther appendages and smooth, winged follicles. Dorsal anther appendages appear to be lacking in both *M. tigrina* and *M. bayatensis*. Follicles of the two were unknown to Woodson (1941), as they are today, as both species are known only from the type specimens, none of which bear fruit. However, the interpretation of the presence of dorsal anther appendages can be difficult from herbarium specimens. At least six species transferred from *Gonolobus* to *Matelea* by Woodson (1941) were considered by Schlechter (1899) and Urban (1925) to bear dorsal anther appendages to some degree. The controversial taxa fall into two *Matelea* subgenera sensu Woodson (1941)—*Pachystelma* and the Antillean *Ptycanthera*—and include *M. bayatensis* and *M. tigrina*. The utility of the follicle character (primarily winged in *Gonolobus* vs. primarily muricate in *Matelea*) is also problematic. With greater collections since Woodson (1941), it has become clear that several taxa apparently lacking dorsal anther appendages bear winged instead of muricate follicles. These taxa include the more recently described *Matelea correllii* Spellman (1978) from the Bahamas, which bears extreme resemblance in habit, foliar, and floral characters to *M. bayatensis* and *M. tigrina*.

Matelea bayatensis, *M. correllii*, and *M. tigrina* are clearly closely related morphologically (Figs. 1–3). The three taxa appear to differ only in pubescence and relatively minor floral character states, some of which overlap (Fig. 3). This minor variation may be due to the very limited number of collections and might be completely indistinct if more collections were available. Flower sizes (including pedicel lengths) can likely be influenced by growing conditions, as can pubescence. At present, none of the observed variation appears important enough to warrant the continued recognition of three distinct species. At the least, based on current evidence (albeit limited), the two Cuban species—*Matelea bayatensis* and *Matelea tigrina*—can be considered synonymous. Considering geographic distribution, that the Cuban taxa appear more closely related to each other than each is to the Bahaman taxon, and that *Gonolobus tigrinus* is the oldest basionym, it also seems appropriate to treat the Bahaman taxon as a subspecies within *Matelea tigrina*. The question of whether the species should be referred to *Gonolobus* cannot yet be answered based on the material at hand. On-going work toward a robust phylogeny based on molecular data aims to address this question. Until then, new combinations are avoided to limit unnecessary names.

TAXONOMIC TREATMENT

Matelea tigrina (Griseb.) Woodson, Ann. Missouri Bot. Gard. 28:226. 1941. *Gonolobus tigrinus* Griseb., Mem. Amer. Acad. Arts ser. 2, 8:520. 1863. TYPE: CUBA: *Wright 1667*, 1860 (LECTOTYPE: GOET (fide Howard 1988); SYNTYPES: MO [image online!], G!, GH!).

Gonolobus bayatensis Urb., Symb. Antill. 9(3).420–421. 1925. [synon. nov.] *Matelea bayatensis* (Urb.) Woodson, Ann. Missouri Bot. Gard. 28:226. 1941. TYPE: CUBA: *Arth. Engström* in herb, *Ekman n. 3056* (SYNTYPES: NY!, S!).

Matelea correllii Spellman, Ann. Missouri Bot. Gard. 65:1255–1257. 1978. [synon. nov.] TYPE: BAHAMAS. LONG ISLAND: *D.S. Correll 49112* (HOLOTYPE: MO; ISOTYPES: F!, FTG!, GH!, NY!, US!)

Distribution.—The putative subspecific entity comprised by *M. tigrina* and *M. bayatensis* is apparently restricted to Cuba. The putative subspecific entity comprised by *M. correllii* is apparently endemic to the Bahamas.

Notes.—Spellman's (1978) note of a resemblance between *M. correllii* and *M. grisebachiana* (Schltr.) Alain is puzzling as the latter was described with leaves only to 0.7 cm wide (initially described as *Gonolobus tigrinus* var. *angustifolius* Griseb.) and oblong corolla lobes. Leaves of *M. correllii* average 1.5–2.5 cm diam. Schlechter (1899) also noted differences between *M. tigrina* and *M. grisebachiana* in the outer corona and in the presence of conspicuous dorsal anther appendages ('Cd' sensu Kunze 1995) in the latter. Unfortunately, the type of *M. grisebachiana* (Cuba, *Wright s.n.*) has not yet been located and may have been destroyed. Additional specimens of *M. grisebachiana* have also not been located and could thus not be analyzed.

ACKNOWLEDGMENTS

I thank the curators and staff of the following herbaria for access to their collections or loans of specimens: BH, BM, BOLO, BREM, C, CGE, DUKE, E, F, FI, FR, FTG, G, GH, GOET, H, HAC, HAJB, HBG, IJ, JE, K, M, MICH, MIN, MO, NY, O, OXF, P, PH, RSA, S, U, UC, US, USF, WU, Z. I also thank the curators and staff of the following herbaria for searching their collections for West Indian

Gonolobinae material, although finding no representation: BG, BKL, BR, BUF, COLO, CR, FLAS, IA, ISC, LD, MSU, NEU, NSW, UPS, TUR. The assistance of the North Carolina State University Libraries Inter-Library Loan Service is also gratefully acknowledged, as are the manuscript reviews by Bruce Hansen and Justin Williams.

BOOK REVIEW

Arturo Gómez-Pompa, Michael F. Allen, Scott L. Fedick, Juan J. Jiménez-Osornio (Eds.). 2003. **The Lowland Maya Area: Three Millennia at the Human-Wildland Interface**. (ISBN 1 56022 971 3, pbk.). Food Products Press, An Imprint of the Haworth Press, Inc, 10 Alice Street, Binghamton, NY 13904-1580, U.S.A. (**Orders:** www.haworthpress.com, 1-800-429-6784). $79.95, 659 pp., b/w illustrations, b/w photographs, 6" × 8".

The Lowland Maya have lived in the Yucatan Peninsula for over 3,000 years. This book takes an integrative approach in seeking to understand how the Lowland Maya have interacted with their environment so successfully without destroying its biodiversity. A total of 36 chapters, this book is a compendium of scientific and anthropological information from specialists in a wide range of fields including ethnobotany, ecology, geology, biodiversity, archaeology, horticulture, botany, anthropology, and history.

Areas of focus include the physical nature of the lowland environment, biodiversity, agriculture, interactions between plants and people, and a section on the future of the region. Included is a discussion of the impact of climate change on the area. The agriculture section includes an interesting chapter on the cultivation and distribution of the chocolate tree (*Theobroma cacao* L.), the possible use of periphyton as a fertilizer, and a chapter on bioprospecting plants and fungi in El Eden Ecological Reserve in Mexico.

The El Eden Ecological Reserve is discussed extensively with several chapters on its biodiversity including butterfly fauna, fungi, periphyton in wetlands, and ants. Chapters on the Maya view of fields and forests, traditional plant use, and anthropogenic plants document the Lowland Mayan concept of their environment, providing clues for their successful interaction with their world.

This is a "big picture" book filled with detailed chapters intended to help the reader understand that picture. The helpful "Summary of Recommendations" at the end of the book reviews this wealth of information and includes recommendations for the future.—*Marissa Oppel, Museum Assistant, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A., moppel@brit.org.*

RESUMEN

El estudio del tipo de *Mandevilla leptophylla* (A. DC.) K. Schum. ha revelado que el concepto de esa especie ha sido mal interpretado desde la última monografía del género. Por otro lado, el tipo de *Echites gracilis* Kunth, taxón incorrectamente tratado como un sinónimo de *M. subsagittata* (Ruiz & Pav.) Woodson, es coespecífico con el material referido hasta ahora como *M. leptophylla*. Por lo tanto, una nueva combinación, *M. gracilis* (Kunth) J.F. Morales es establecida, comentándose las relaciones entre este taxón y el verdadero concepto de *M. leptophylla*, incluyendose descripciones, ilustraciones y especímenes examinados de ambos taxones. *Mandevilla linearis* N.E. Br. es a su vez lectotipificado y reducido a la sinonimia de *M. gracilis*. Adicionalmente, dos nuevas especies de *Mandevilla* subgénero *Exothostemon*, *M. amazonica* y *M. colombiana*, ambas relacionadas con *M. gracilis*, son descritas e ilustradas, discutiendose sus afinidades taxonómicas

ABSTRACT

A study of the type collection of *Mandevilla leptophylla* (A. DC.) K. Schum. has revealed that the concept of this species has been misinterpreted since the last monograph of the genus. However, *Echites gracilis* Kunth, erroneously placed in synonymy of *M. subsagittata* (Ruiz & Pav.) Woodson, is conspecific with the material traditionally treated as *M. leptophylla*. Therefore, the new combination *M. gracilis* (Kunth) J.F. Morales is here proposed and the relationship with *M. leptophylla* is discussed. Clarifying descriptions, illustrations and specimen citations are included for both taxa. *Mandevilla linearis* N.E. Br. is lectotypified and relegated to the synonymy of *M. gracilis*. Two new species of *Mandevilla* subgenus *Exothostemon* (*M. amazonica* and *M. colombiana*) are also described and illustrated; their taxonomic affinities with *M. gracilis* are discussed.

El estudio de la colección tipo de *Mandevilla leptophylla* (A. DC.) K. Schum. ha permitido determinar que el concepto de esa especie manejado desde la última monografía del género (Woodson 1933) es incorrecto, dado que el tipo es totalmente discordante con la descripción y los especímenes examinados citados por Woodson (1933), perteneciendo incluso a un subgénero diferente. El tipo de *M. leptophylla*, el cual tiene corolas hipocrateriformes, proviene del estado de Bahia en Brasil y pertenece al subgénero *Mandevilla*, debido a sus láminas foliares con los coléteres agrupados en la base de la superficie adaxial del nervio central y tubo de la corola recto. Los especímenes citados por Woodson (1933), así como la descripción provista en su monografía, caracterizan a un taxón perteneciente al subgénero *Exothostemon*, debido a sus láminas foliares con coléteres distribuidos a lo largo de la superficie adaxial del nervio central y corolas infundibuliformes, con el tubo algo giboso basalmente. De esta manera, el concepto de *M. leptophylla* manejado desde la monografía de Woodson (1933), carece de un nombre disponible. Sin embargo, el estudio de especímenes tipo en el herbario de París (P), ha revelado que el tipo de *Echites gracilis* Kunth, incorrectamente reducido a la sinonimia de *Mandevilla subsagittata* (Ruiz & Pav.) Woodson por Woodson (1933), es concordante con el mal aplicado concepto de *M. leptophylla* manejado hasta ahora. Por lo tanto, la nueva combinación *M. gracilis* (Kunth) J. F. Morales es establecida, brindandose una descripción completa de ese taxón y de *M. leptophylla*, incluyendo ilustraciones, especímenes examinados y discusión de sus afinidades taxonómicas. Finalmente, se describen dos nuevas especies pertenecientes al subgénero *Exothostemon* (Woodson 1933), ambas relacionadas con *M. gracilis* y con hojas muy angostamente elípticas hasta casi lineares. A través de las descripciones, las partes de las corolas infundibuliformes siguen lo propuesto por Morales & Fuentes (2004).

Mandevilla amazonica J.F. Morales, sp. nov. (**Fig. 1**). Tipo. VENEZUELA. Amazonas: O de San Carlos de Rio Negro, 28 Nov 1977 (fl), *Liesner* 3968 (holotipo: INB; isotipo: MO).

A *Mandevilla colombiana* J.F Morales, cui similis, pedicellis minoribus 2–3 mm longis (vs. 8–12 mm), et corollae 1.8–2.2 mm diametro (vs. 3–3.5 mm), differt.

Liana; ramitas teretes a subteretes, sólidas, no huecas, muy diminuta y esparcidamente puberulentas cuando jóvenes, glabrescentes con la edad; coléteres interpeciolares inconspicuos, menos de 0.5 mm de largo. Hojas opuestas; pecíolos 1–2.5 mm de largo; láminas foliares 1.8–5.3 × 0.3–0.7 cm, angostamente linear-elípticas a angostamente linear-ovadas, el ápice agudo-mucronulado, la base auriculada y cordada, membranáceas, glabras a glabrescentes, con varios coléteres dispuestos en forma irregular a lo largo del nervio central adaxialmente, usualmente no revolutas marginalmente, la venación secundaria levemente impresa en ambas caras, la venación terciaria no evidente. Inflorescencia conspicuamente más larga que las hojas subyacentes, axilar, muy diminutamente y esparcidamente puberulenta, con 9 a 12 flores, pedúnculo 12–27 mm de largo, pedicelos 2–3 mm de largo, brácteas 1.5–2 × 0.5–1 mm, angostamente ovadas, escariosas; sépalos 2–2.2 × 0.9–1.2 mm, muy angostamente ovados, acuminados, el ápice usualmente no reflexo, algunas veces levemente reflexos distalmente, escariosos, glabrescentes, muy diminuta e inconspicuamente puberulentos, raramente inconspicua y esparcidamente puberulentos, el coléter solitario, entero, subentero a diminutamente lacerado;

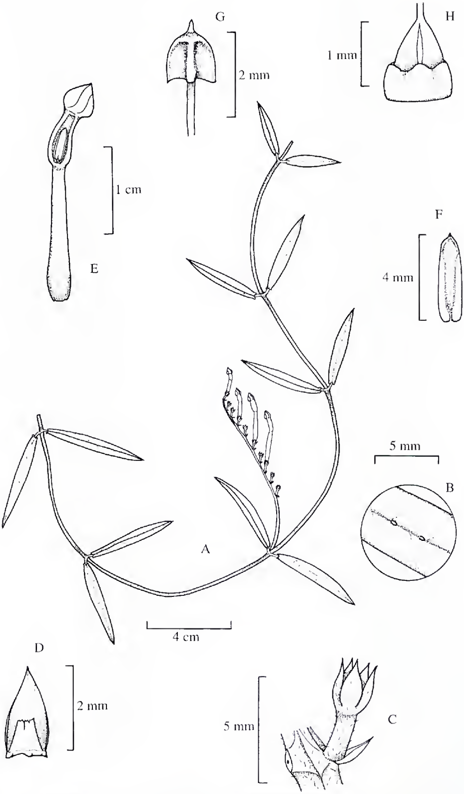

Fig. 1. *Mandevilla amazonica* (*Liesner 3968*, INB). **A.** Ramita con inflorescencias. **B.** Detalle de la superficie adaxial de la hoja, mostrando los coléteres a lo largo del nervio central. **C.** Cáliz, pedicelo y bráctea. **D.** Sépalo y coléter, vista adaxial. **E.** Tubo de un botón parcialmente abierto, mostrando la posición de las anteras y el tubo giboso. **F.** Antera, vista dorsal. **G.** Cabeza estigmática. **H.** Nectario y ovario.

corola hipocrateriforme, amarillo-anaranjada o amarillo-verdosa, la garganta rojiza interiormente, glabra externamente, el tubo 22–26 mm de largo, 1.8–2.2 mm de ancho, conspicuamente giboso, abultado en la posición de los estambres, el ápice del botón floral agudo; lóbulos 9–10 × 6–8 mm, obovados, extendidos, pero aparentemente crispados marginalmente; estambres insertos en la mitad distad del tubo de la corola, anteras 4–4.3 mm de largo, glabras dorsalmente, auriculadas basalmente, con las aurículas redondeadas, cabeza estigmática 1.4–1.6 mm de largo; ovario 1.2–1.5 mm de largo, glabro; nectario anular, ca. la mitad de la longitud del ovario, levemente pentalobulado. Folículos desconocidos.

Distribución, hábitad y ecología.—Endémica al estado de Amazonas en Venezuela, donde se encuentra creciendo en bosques alterados y áreas abiertas en elevaciones de 50–150 m. Especímenes con flores han sido recolectados en Noviembre y Diciembre.

Mandevilla amazonica es una especie bastante distintiva que se reconoce al instante por sus hojas muy angostas, 3–6 mm de ancho, con las láminas lineares o linear-elípticas, usualmente muy delgadas y frágiles al secar. Se encuentra cercanamente relacionada con *M. colombiana*, de la que se separa con facilidad por sus pedicelos más pequeños (2–3 mm vs. 8–12 mm), hojas con la venación secundaria impresa en ambas caras (vs. no impresa) y corola con el tubo mucho más angosto (1.8–2.2 mm vs. 3–3.5 mm). Adicionalmente y como consecuencia de sus láminas foliares angostamente linear-elípticas a angostamente linear-ovadas puede confundirse con *M. gracilis*, pero *M. amazonica* se separa al instante por su corola hipocrateriforme.

Especímenes examinados. **VENEZUELA. Amazonas:** S del aeropuerto de San Carlos de Río Negro, 3 Dic 1977 (fl), *Liesner 4153* (INB, MO).

Mandevilla colombiana J.F. Morales, sp. nov. (**Fig. 2**). Tipo: COLOMBIA. Caquetá: Solano, Paujil, río Caquetá, NO de Araracuara, 3 Dic 1993 (fl, fr), *Arbeláez & Sueroque 505* (holotipo: COL; isotipos: COAH, HUA, INB, U).

A *Mandevilla amazonica* J.F. Morales, cui affinis, pedicellis longiribus 8–12 mm longis (vs. 2–3 mm) et corollae 3–3.5 mm diametro (vs. 1.8–2.2 mm), differt.

Liana; ramitas teretes a subteretes, sólidas, no huecas, muy diminuta y esparcidamente papilado-puberulentas; coléteres intrapeciolares inconspicuos, menos de 0.5 mm de largo. Hojas opuestas; pecíolos 1–1.5 mm de largo; láminas foliares 4.5–5.5 cm × 2.5–4(–5) mm, lineares a linear-elípticas, agudas a agudo-mucronuladas apicalmente, la base cordado-auriculada, membranáceas, glabras, con los coléteres dispuestos en forma irregular a lo largo del nervio central adaxialmente, usualmente no revolutas marginalmente, raramente algunas hojas inconspicuamente revolutas, la venación secundaria y terciaria usualmente no impresa, algunas veces las venas secundarias inconspicuamente impresas abaxialmente. Inflorescencia más larga que las hojas subyacentes, axilar, glabra a glabrescente, usualmente con muchas flores, pedúnculo 16–18

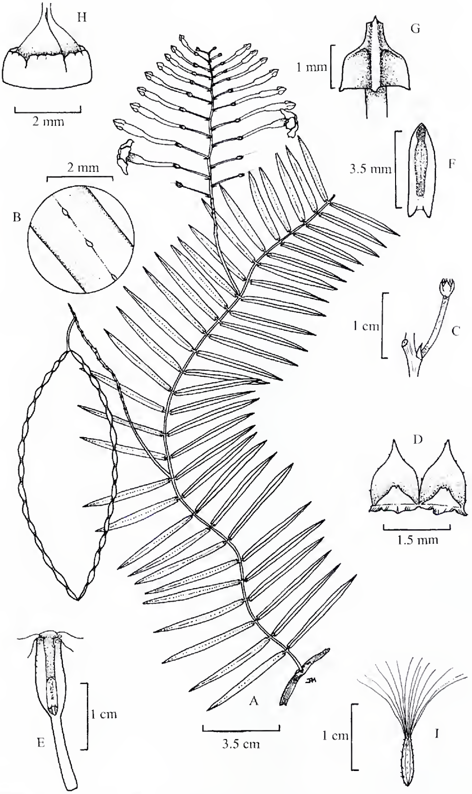

Fig. 2. *Mandevilla colombiana* (*Arbeláez & Sueraque 505*, HUA). **A.** Ramita con inflorescencia y frutos. **B.** Detalle de la superficie adaxial de la hoja, mostrando los coléteres a lo largo del nervio central. **C.** Cáliz, pedicelo y bráctea. **D.** Sépalos y coléteres, vista adaxial. **E.** Tubo de un botón parcialmente abierto, mostrando la posición de las anteras y el tubo basalmente giboso. **F.** Antera, vista dorsal. **G.** Cabeza estigmática. **H.** Nectario y ovario. **I.** Semilla.

mm de largo, pedicelos 8–14 mm de largo, brácteas 1.5–2 × 0.5–1 mm, ovadas, escariosas; sépalos 1.3–1.6 × 1–1.2 mm, muy angostamente ovados, acuminados, el ápice no reflexo, escariosos, glabros, glabrescentes o inconspicuamente puberulentos, inconspicuamente ciliolados marginalmente, coléter solitario subentero a variadamente lacerado apicalmente; corola hipocrateriforme, el tubo verde-rojizo, la garganta interiormente roja, los lóbulos amarillos, glabra externamente, el tubo 23–26 mm de largo, 3–3.5 mm de ancho, levemente giboso basalmente, el ápice del botón floral agudo; lóbulos 15–17 × 5–7 mm, obovados, extendidos y levemente reflexos y crispados marginalmente; estambres insertos en el extremo distal del tubo, anteras 4–4.5 mm de largo, glabras dorsalmente, auriculadas basalmente, con las aurículas obtusas, cabeza estigmática 1.7–2.1 mm de largo; ovario 1.5–2 mm de largo, glabro; nectario ca. la mitad de la longitud del ovario, levemente pentalobulado, el borde superior inconspicuamente eroso. Folículos 10.5–19 cm × 1.8–3 mm, muy esparcida e inconspicuamente puberulentos a glabrescentes, monilifomes; semillas 7–8 mm de largo, inconspicuamente puberulentas a glabrescentes, la coma 0.9–1.8 cm de largo, canela.

Distribución, hábitad y ecología.—Endémica al S de Colombia, en los departamentos de Amazonas y Caquetá, donde crece en vegetación asociada a afloramientos rocosos, así como vegetación secundaria en márgenes de quebradas y ríos, en elevaciones de 50–350 m. Especímenes con flores han sido recolectados en Noviembre, Diciembre y Marzo. Material con frutos ha sido recolectado a principios de Diciembre.

Mandevilla colombiana se encuentra relacionada con *M. amazonica*, otra especie de hojas lineares endémica al estado de Amazonas, en Venezuela. Aunque ambos taxones comparten algunos caracteres morfológicos, tales como la forma y el tamaño de las hojas, *M. colombiana* se reconoce por sus pedicelos más largos (8–14 mm vs. 2–3 mm) y flores con el tubo de la corola más angosto. Aunque también se puede confundir con *M. gracilis*, este último taxón tiene corolas infundibuliformes. *Mandevilla colombiana* también puede confundirse con *M. annulariifolia* Woodson y especies afines (e.g., *M. benthamii* (A. DC.) K. Schum.), pero este grupo de taxones se puede separar al instante por sus hojas verticiladas. El epiteto está dedicado a Colombia, país de belleza y diversidad florística incomparable, cuyo estudio de la flora me ha reportado una serie de novedades taxonómicas muy peculiares en los últimos años.

Especímenes examinados. **COLOMBIA. Amazonas:** Puerto Santander, trocha a La Chorrera, SO de Araracuara, 24 Nov 1993 (fl), *Cárdenas et al. 4206* (COAH, COL, INB); río Caquetá, Araracuara, Nov 1982 (fl), *Idrobo et al. 11265* (COL). **Caqueta:** Solano, Araracuara, río Caquetá, 3 Mar 1992 (fl), *Arbeláez & Restrepo 60* (COAH, HUA, INB, MO); Solano, Paujil, río Caquetá, NO de Araracuara, 27 Oct 1992 (fl), *Arbeláez et al. 273* (COAH); Solano, Araracuara, 25 Feb 1997 (fl, fr), *Arbeláez & Sueroque 743* (COAH), Araracuara, camino al Balcón del Diablo, 5 Mar 1986 (fl), *Palacios & Plazas 1204* (COAH); sierra de Chiribiquete, 24 Ago 1992 (fl), *Palacios et al. 2506* (COL).

Mandevilla gracilis (Kunth) J.F. Morales, comb. nov. (**Fig. 3**). Basiónimo. *Echites gracilis* Kunth, Nov. Gen. Sp. 3:219. 1818 [1819]. *Exothostemon gracile* (Kunth) G. Don, Gent. Syst. 4:82. 1838. Tipo: VENEZUELA. Amazonas: inter Cataractas Ature et Maypure, May (fl, fr), *Humboldt s.n.* (holotipo: P-HB; fotografías, INB).

Mandevilla linearis N.E. Br., Trans. Linn. Soc. London, Bot. 6:48. 1901, syn. nov. Tipo: GUYANA: Valle Kotinga, 1894 (fl), *McConnel & Quelch 194* (lectotipo: K, seleccionado aquí, fotografía en INB).

Lianas; ramitas teretes a subteretes, sólidas, no huecas, diminuta y esparcidamente puberulentas cuando jóvenes, glabrescentes con la edad; coléteres interpeciolares inconspicuos, hasta 0.3 mm de largo. Hojas opuestas; pecíolos 1-3 mm de largo; láminas foliares 2.5-7.5 × 0.2-0.8(-1.2) cm, lineares a linear-elípticas, angostamente agudas a angostamente acuminadas o mucronuladas apicalmente, la base levemente auriculado-cordada a angostamente cordada, firmemente membranáceas o subcoriáceas, glabras a glabrescentes adaxialmente, diminuta y densamente puberulentas a diminutamente tomentulosas abaxialmente, los coléteres irregularmente distribuidos a lo largo del nervio central adaxialmente, usualmente revolutas marginalmente, la venación secundaria y terciaria moderadamente impresa en ambas superficies, pero algunas veces las venas terciarias inconspicuas abaxialmente. Inflorescencia más corta o igualando las hojas subyacentes, axilar, diminutamente puberulenta a glabrescente, con 2 a 14 flores, pedúnculo 2-15(-20) mm de largo, pedicelos 1-2 mm de largo, brácteas 1.5-3.5(-5) × 0.5-1 mm, angostamente ovadas, escariosas; sépalos 1.7—2.3 × 1.1-1.6 mm, muy angostamente ovados, cortamente-acuminados apicalmente, el ápice no reflexo, escariosos, diminuta y esparcidamente puberulentos en la base a glabrescentes, el coléter solitario, subentero o irregularmente lacerado apicalmente; corola infundibuliforme, el tubo amarillo-anaranjado o matizado con rojizo, los lóbulos y la garganta amarilla, esparcida e inconspicuamente pilosulosa a glabra o glabrescente externamente, el tubo basalmente giboso, la parte inferior 23-29 mm de largo, 1.5-3 mm de diámetro, la parte superior 11-14 mm de largo, cónica, 10-16(-20) mm de diámetro en el orificio, el ápice del botón floral agudo-mucronulado o agudo-mucronado; lóbulos 8-20 × 6-18 mm, obovados, extendidos y algo reflexos marginalmente; estambres insertos en base de la parte superior del tubo; anteras 4.8-5.1 mm de largo, glabras dorsalmente, auriculadas basalmente, las aurículas obtusas a redondeadas, cabeza estigmática 1.2-1.4 mm de largo; ovario 1.5-1.9 mm de largo, glabro; nectario leve a moderadamente pentalobado, 1-1.3 mm de largo. Folículos 9-14 × 0.2-0.3 cm, glabros a glabrescentes, levemente moniliformes; semillas 6.3-8 mm de largo, glabras, coma 0.7-1.5 cm de largo, amarillo-café.

Distribución, hábitad y ecología.—Restringida al S de Venezuela (estados de Amazonas y Bolívar) y al O de Guyana, donde crece en sabanas y vegetación arbustiva asociada a afloramientos rocosas, así como en bosques de galería y

márgenes de bosques, en elevaciones de 750–1400 m. Especímenes con flores han sido recolectados de Marzo a Diciembre. Material con frutos se conoce en Marzo y de Septiembre a Diciembre.

Mandevilla gracilis pertenece al subgénero *Exothostemon*, donde se encuentra algo relacionada con *M. amazonica* y *M. colombiana*, pero se puede separar con facilidad por sus corolas infundibuliformes (vs. hipocrateriformes). Otras especies dentro del mismo subgénero con corolas infundibuliformes que ocasionalmente pueden presentar hojas con láminas lineares a linear-elípticas, incluyen a *M. lancifolia* Woodson y *M. nerioides* Woodson, pero estos dos taxones se distinguen de *M. gracilis* por sus hojas con los nervios secundarios dispuestos ca. en forma perpendicular en relación al nervio central (vs. arcuados), así como por sus ramitas jóvenes irregularmente acostilladas o aladas (vs. teretes a subteretes).

Echites gracilis fue incluido en la sinonimia de *Mandevilla subsagittata* (Ruiz & Pavon) Woodson por Woodson (1933, 1936), pero el tipo de *E. gracilis* tiene corolas claramente infundibuliformes, no hipocrateriformes como en *M. subsagittata*, por lo que debe ser removido de la sinonimia de este último taxón. Ahora bien, luego del análisis de los ejemplares tipo de *M. linearis* N. E. Brown y de *E. gracilis* es claro que ambos son coespecíficos. Ambos taxones comparten el mismo tipo de caracteres morfológicos en relación a la forma, dimensiones e indumento de las hojas, inflorescencias con brácteas escariosas, flores cortamente pediceladas, con los pedicelos usualmente inferiores a 5 mm de largo y corolas infundibuliformes, con la parte superior del tubo cónica. *Mandevilla linearis* fue considerado erróneamente como un sinónimo de *M. leptophylla* por Woodson (1933). Por lo tanto, debido a que *E. gracilis* tiene prioridad sobre *M. linearis* por ser un nombre más viejo, una nueva combinación se establece y el último taxón es relegado nuevamente a la sinonimia.

Mandevilla linearis es lectotipificado aquí. Dos sintipos fueron citados en la descripción original (Brown 1901), ambos colectados por McConnell y Quelch en las Guyanas. Estas dos colecciones se hayan montadas en una misma lámina y se encuentran depositadas en el herbario del Kew Botanical Garden (K). A pesar de que ambos sintipos se encuentran en buen estado de conservación, se designa la colección *McConnell & Quelch 194*, montada en la sección derecha, como el lectotipo, debido a que posee una inflorescencia completa, mientras que el otro sintipo (*McConnell & Quelch 132*) montado en la sección izquierda, carece de una inflorescencia completa.

BAHIA: Catingas entre Villa Novam y Rainha, fecha perdida (fl) *Martius 2271* (HOLOTIPO: M, foto F neg. 20147, dibujo en F).

Liana; ramitas teretes a subteretes, sólidas, no huecas, diminutamente hispídulas, glabrescentes cuando viejas, coléteres interpeciolares conspicuos, 1.5–3 mm de largo, usualmente muy desarrollados en tallos maduros. Hojas opuestas; pecíolos (1–)2–3 mm de largo; láminas foliares 3.5–8 3 0.5–1.6(–2.2) cm, muy angostamente elípticas, muy angostamente ovado-elípticas a linear-elípticas, el ápice agudo, algunas veces cortamente mucronulado, la base obtusa a redondeada, algunas veces dispuestos sobre la costa del pecíolo, membranáceas, muy esparcidamente hispídulas adaxialmente, densamente hispídulas abaxialmente, con 2 ó 3 coléteres agrupados en la base del nervio central adaxialmente, el margen algunas veces levemente revoluto y ondulado, la venación secundaria y terciaria levemente impresa abaxialmente, usualmente inconspicua adaxialmente. Inflorescencia usualmente más larga que las hojas subyacentes, axilar a terminal, diminutamente hispídula, con 1 a 5 flores, pedúnculo 14–42 mm de largo, pedicelos 6–13(–17) mm de largo, brácteas ca. 1 mm de largo, angostamente ovadas, escariosas; sépalos 4–7 3 1–2 mm, angostamente ovados, largamente acuminados, el ápice usualmente reflexo, escariosos, diminutamente hispídulos, coléteres usualmente en pares, ubicados cerca de los márgenes, enteros a subenteros; corola hipocrateriforme, el tubo verde, los lóbulos púrpura intenso o rojizo-púrpura, la garganta verdosa, glabra a glabrescente externamente, el tubo 22–29 mm, 2.5–3.5 mm de ancho, no giboso, el ápice del botón floral angostamente agudo; lóbulos 11–18 3 8–13 mm, obovados, extendidos y reflexos; estambres insertos en la mitad distal del tubo, cerca de la boca, anteras 5.3–6 mm de largo, dorsalmente glabras, la base auriculada, con las aurículas redondeadas, cabeza estigmática 1.9–2.1 mm de largo; ovario 1.3–1.5 mm de largo, glabro; nectario anular, 0.4–0.5 mm de largo, irregularmente lobulado. Folículos desconocidos.

Distribución, hábitad y ecología.—Esta especie está restringida al E de Brasil, en los estados de Bahia y Minas Gerais, donde crece en formaciones de Caatingas,

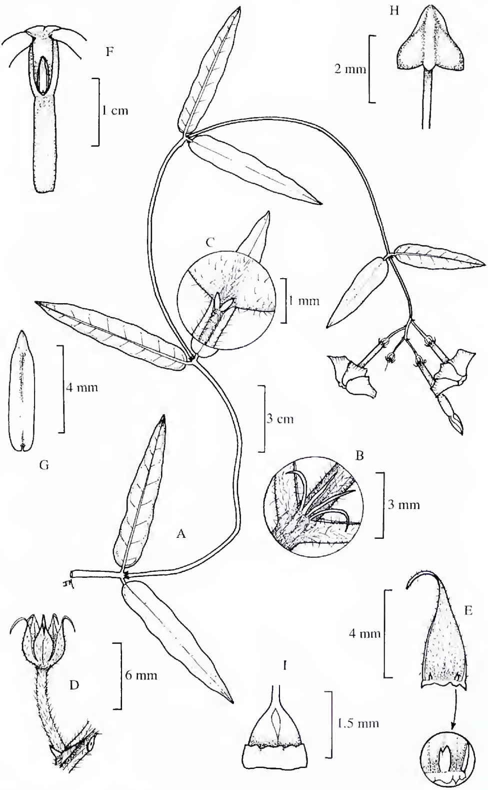

Fig. 4. *Mandevilla leptophylla* (*Taylor et al. 1481*, INB). **A.** Ramita con flores. **B.** Detalle de los coléteres interpeciolares. **C.** Detalle de la superficie adaxial de la hoja, mostrando los coléteres agrupados en la base del nervio central. **D.** Cáliz, pedicelo y bráctea. **E.** Sépalo y coléteres, vista adaxial, mostrando el detalle de un coléter. **F.** Tubo de la corola parcialmente abierto, mostrando la posición de las anteras y el tubo no giboso. **G.** Antera, vista dorsal. **H.** Cabeza estigmática. **I.** Nectario y ovario.

en suelos rocosos graníticos y de arenisca, en elevaciones 400–700 m. Especímenes con flores han sido recolectados de diciembre a marzo.

En la última monografía del género, Woodson (1933) citó cinco colecciones examinadas bajo su concepto de *Mandevilla leptophylla*, dos ellas sintipos de *Mandevilla linearis* (*McConnell 132* y *194*, ambas de Guyana) y las otras tres pertenecientes a colecciones hechas en las Guyanas (*Tate 228*, *Schomburgk 383*) y Brasil (*Ule 8450*). Tal y como se infiere de los especímenes examinados, él no examinó el tipo de *M. leptophylla*, colectado por Martius en el estado de Bahia, Brasil. De esta manera, a través del estudio de todas las colecciones tipos de los nombres sinonimizados por Woodson, así como de los especímenes anteriormente citados (excepto la colección de Schomburgk destruida en 1943 y de la cual no se encontraron duplicados en los herbarios BM y K ni en otros herbarios europeos), se ha logrado determinar que en realidad ninguno de estos especímenes corresponden en realidad a *M. leptophylla* y todos ellos deben ser tratados como *M. gracilis*.

Mandevilla leptophylla fue erróneamente incluida en el subgénero *Exothostemon* por Woodson (1933), basado principalmente en la incapacidad de examinar la colección tipo. Esta especie debe ser transferida al subgénero *Mandevilla* por sus flores con el tubo de la corola recto, no giboso basalmente, así como por sus láminas foliares con los coléteres agrupados en la base del nervio central adaxialmente y sépalos con los coléteres dispuestos en forma alterna de acuerdo al arreglo quincuncial del sépalo y no en forma epicéntrica. Dentro del subgénero *Mandevilla*, *M. leptophylla* se puede confundir con *M. angustifolia* (Malme) Woodson, otro taxón con hojas linear-elípticas, pero *M. leptophylla* se puede reconocer por sus láminas foliares densamente hispídulas abaxialmente (vs. glabras), corolas hipocrateriformes (vs. infundibuliformes), con los lóbulos púrpura intenso a rojizo-púrpura (vs. rosado intenso o púrpura-rosado) y anteras más pequeñas (5.3–6 mm vs. 6.5–7.5 mm).

Especímenes examinados. **BRASIL. Bahia:** Bahia, Machado Portella, 30 Dic 1912 (fl), *Lützelburg 5035* (M); Rio de Contas, cerca de Livramento do Brumado, 6 Mar 1994 (fl), *Souza et al. 5279* (ESA, INB, K, SP). **Minas Gerais:** Monte Azul, cerca de Vila Angical, 29 Ene 1991 (fl), *Taylor et al. 1481* (BHCB, INB, K, Z).

AGRADECIMIENTOS

Se agradece a los siguientes herbarios por el préstamo y uso de sus colecciones: BHCB, COAH, ESA, F, HUA, K, M, MO, NY, P, PORT, VEN, SP, US, Z. Quiero agradecer al Kew Botanical Garden (K) y a David Goyder por facilitar una fotografía del especimen tipo de *Mandevilla linearis*. También quiero agradecer a las siguientes personas por facilitar el acceso a diferentes herbarios o brindar facilidades logísticas para la visita de los mismos: Lucille Allorge (P), Julio Betancur (COL), Ricardo Callejas (HUA), Asunción Cano (USM), Dairon Cárdenas (COAH), Álvaro Cogollo (JAUM), Wilson Devia (TULV), José Luis Fernández-Alonso (COL), Ramiro Fonnegra (HUA), Paul e Hiltje Maas (U), Francisco Javier

Roldán (HUA), Philip Silverstone-Sopkin (CUVC), Bruno Wallnöfer (W) y Homero Vargas (QCNE).

BOOK REVIEW

JAMES L. CASTNER. 2004. **Photographic Atlas of Botany and Guide to Plant Identification.** (ISBN 0-9625150-0-0, spiral pbk.). Feline Press, P.O. Box 357219, Gainesville, FL 32635, U.S.A. (**Orders:** Feline Press, P.O. Box 357219, Gainesville, FL 32635, U.S.A.; jlcastner@aol.com). $40.00, 310 pp., color photographs, glossary, index, 8 1/2" × 11".

It has been said that a picture is worth a thousand words—this is very true for Castner's Photographic Atlas of Botany. Castner's book is a great resource for both beginners and professionals in the plant sciences field. The author presents the reader with plant anatomy and taxonomic traits in hundreds of precise color photographs. This is the book I wish I had had on my shelf when I started taking lab-based plant courses.

The author begins with an approximately 50 page pictorial guide to plant anatomy, roots, stems, leaves, flower structures, and fruit types. Castner includes photographs of live plants and microscopic anatomy of items such as roots stems and leaves. Included in the plant anatomy sections are images of leaf scars, specialized root/stem structures, leaf arrangement, leaf apices, leaf margins, flower structures, and flower anatomy as well as images of the different types of simple, multiple and aggregate fruits. The photographs presented include many cross and longitudinal sections among the various examples of each area of anatomy. For example, placentation types are shown in cross sections and multiple images of flower nectaries are provided. These perfectly composed photographs are unmistakable as to what they are depicting, thus providing a valuable resource to those learning plant anatomies or learning to use a flora key.

The majority of the book is devoted to plant taxonomy and shows photographs of the various plant families within the seedless vascular plants through the angiosperms. Each family section begins with traits given for each distinct family, as well as terminology that may be necessary to know while looking at the photographs associated with that family. The color photographs and labels within the photographs are crisp and clear, making traits easy to spot. Castner has collected a good diversity of photographs for the different families and subfamilies for the reader to view. The book finishes with a comprehensive glossary and helpful references.

James Castner's book *A Photographic Atlas of Botany and Guide to Plant Identification* is strongly recommended for those learning plant anatomy and taxonomy. This would make a wonderful reference text for botanical-based college courses. The book is organized by cladistic relationships between families which may frustrate some users, a "by family" index is included for those unfamiliar with such organization. This book is also a very reasonably priced, given the number and quality of the color photographs. These images make the task of learning plant anatomy and taxonomy easier because the photographs show the reader exactly what is being described. It can't be said enough that this photographic atlas is a fantastic resource for both beginners and professionals in the plant sciences. In fact, I recently purchased my own copy!—*Lee Luckeydoo, Herbarium, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

ESTUDIOS EN LAS APOCYNACEAE NEOTROPICALES XI: UNA NUEVA ESPECIE DE *MANDEVILLA* (APOCYNOIDEAE: MESECHITEAE) PARA SUR AMÉRICA, CON UN NUEVO REPORTE PARA LAS APOCYNACEAE DE PARAGUAY

J. Francisco Morales

Instituto Nacional de Biodiversidad
Apartado 22-3100
Santo Domingo, Heredia, COSTA RICA

RESUMEN

El estudio de los tipos de *Mandevilla lasiocarpa* y de los nombres asociados a este taxón como sinónimos, revela que todos son sinónimos de *M. hirsuta* y que el taxón para el que Woodson empleó este nombre en su monografía necesita un nombre nuevo. Por lo tanto, se propone *Mandevilla matogrossana*, se describe e ilustra detalladamente, discutiéndose su relación con *M. hirsuta*. Adicionalmente, se propone una nueva lectotipificación para *Echites hirsuta* var. *angustifolia* Stadelm. y se cita por primera vez la presencia de *M. hirsuta* en Paraguay.

ABSTRACT

The study of the types of *Mandevilla lasiocarpa* and related synonymy has revealed that all of them are synonyms of *M. hirsuta* and the concept of the species *M. lasiocarpa* used by Woodson in his monograph don't has a name. Therefore, a new name is proposed and this taxon is described and illustrated. The relations with *M. hirsuta* are discussed. *Echites hirsuta* var. *angustifolia* Stadelm. is lectotypified and *M. hirsuta* is reported for first time from Paraguay.

Durante la preparación de una nueva monografía de *Mandevilla* (Apocynoideae, Mesechiteae), casi la totalidad de colecciones originales de las especies descritas hasta el día de hoy han sido examinadas, con el fin de comprobar la correcta aplicación de nombres y sinónimos. Como resultado, se han producido tratamientos regionales que han propuesto la sinonimización de varios nombres (Morales 1998), así como la descripción de varios taxones (e.g., Morales & Fuentes 2004). En este proceso, he determinado que el concepto de *M. lasiocarpa* (A. DC.) Malme, utilizado desde la monografía de Woodson (1933), carece de un nombre, pues tanto la colección tipo, como el resto de nombres sinonimizados bajo esa especie, representan especímenes de la común *M. hirsuta* (Rich.) K. Schum. Por lo tanto, se procede a una discusión de los nombres involucrados en este complejo y a la descripción de una nueva especie.

Echites lasiocarpa A. DC. fue descrito por Alphonse de Candolle (1844), basado en un especimen colectado por Manso en Cuiabá, en el estado de Bahia, Brasil y en el concepto de *Echites hirsuta* Ruiz & Pav. var. *latifolia* Stadelm., cuyo tipo es una colección de Martius, hecha en el estado de Bahia, Brasil, y que corresponde a *M. hirsuta*. Ahora bien, el mismo De Candolle no estaba seguro de la identidad del especimen en Ginebra (G), pues dicha colección solo tiene frutos y él mismo indicó en su tratamiento "specim. fructif. non certo." Este especimen, a pesar de poseer solo frutos, es concordante en el resto de caracteres morfológicos con *M. hirsuta*. El estudio de un duplicado de la colección de Manso, en el herbario de la Universidad Martín Luther (HAL), en Halle, Alemania, ha demostrado que definitivamente se trata de un típico especimen de *Mandevilla hirsuta*, ya que este especimen tiene flores, de las que fácilmente, basado en la forma cónica de la parte superior de la corola, se infiere que pertenece a *M. hirsuta*.

Ahora bien, en forma posterior Woodson (1933) redujo *Echites hirsuta* var. *angustifolia* Stadelm. a la sinonimia de *Mandevilla lasiocarpa*, así como *E. lasiocarpa* var *lobbiana* A. DC. El material tipo de *E. hirsuta* var. *angustifolia*, fue colectado por Martius en Porto D'Estrella, en el estado de Rio de Janeiro, Brasil, mientras que *E. lasiocarpa* var *lobbiana* fue descrita a partir una colección hecha por Lobb en el mismo estado. El estudio de ambas colecciones ha demostrado que a la vez, ambos especímenes pertenecen a *M. hirsuta*, dado la forma de la corola entre ambas es idéntica (infundibuliforme, con la parte superior del tubo cónica). Basado en la lista de especímenes examinados por Woodson en su monografía, es fácil inferir que él no examinó las colecciones originales de ninguno de estos taxones, pues no fueron citados entre los materiales estudiados y que probablemente, basó su descripción en las colecciones citadas en dicho trabajo, que en su mayoría, correspondían a especímenes colectados por Malme en Mato Grosso, con una colección adicional hecha por Ducke en el estado de Pará, Brasil. Así, aunque su concepto de *Mandevilla lasiocarpa* es correcto y de hecho las colecciones de Malme pertenecen a un taxón distinto a *M. hirsuta*, los tipos de todos los nombres que él incluye cono sinónimos, pertenecen a *M. hirsuta*. En todo caso, la preparación de una nueva monografía de *Mandevilla* ha demostrado que *M. hirsuta* tiene corolas infundibuliformes, con la parte superior del tubo de la corola cónico, y se encuentra ampliamente distribuida desde México hasta Brasil, Bolivia, Paraguay y las Antillas, mientras que el concepto de *M. lasiocarpa* usado desde la monografía de Woodson (1933), representa un taxón raro conocido por pocas colecciones, caracterizado por sus corolas angostamente subinfundibuliformes, pero pareciendo hipocrateriformes, distribuido principalmente en el estado de Mato Grosso, en Brasil, con un par de colecciones disyuntas del estado de Bolivar, Venezuela y del departamento de Santa Cruz, Bolivia y que hasta el momento, no se ha examinado ningún especimen que demuestre su presencia en las estados costeros de Brasil. Por todos los datos expuestos, se hace necesario sinonimizar adecuadamente los nombres y proponer una nueva especie para el concepto de *M. lasiocarpa* utilizado por Woodson (1933). Las descripciones de las partes de la corola siguen el concepto usado por Morales & Fuentes (2004).

Mandevilla matogrossana J.F. Morales, sp. nov. (**Fig. 1**). TIPO. BRASIL. MATO GROSSO: Peixoto de Azevedo, cerca de Matupá, en camino a río Xingu, 24 Abr 1997 (fl, fr), *Souza et al. 15671* (HOLOTIPO: INB; ISOTIPOS: ESA, MT).

A *M. hirsuta* (Rich.) K. Schum., cui affinis, corollae augusta subinfudibuliformis, faucibus 9–11 mm longis (vs. 14–24 mm longis) et 4–7 mm diametro (vs. 12–20 mm) differt.

Liana; ramitas cilíndricas a subcilíndricas, usualmente sólidas, algunas veces huecas, esparcidamente híspidas, híspidulas, pilosas a pilosulosas; coléteres interpeciolares inconspicuos, 0.5 mm de largo o menos. Hojas opuestas; pecíolos 12–37 mm de largo; láminas foliares 5–12(–13.5) × 2–6.5 cm, elípticas, obovado-elípticas a angostamente obovadas, abruptamente caudado-acuminadas apicalmente, la base cordada, con los coléteres dispuestos en forma irregular a lo largo del nervio central adaxialmente, membranáceas, esparcida a moderadamente estrigillo-seríceas adaxialmente, densamente a moderadamente seríceas abaxialmente, no revolutas marginalmente, la venación secundaria conspicua en ambas caras, la venación terciaria usualmente inconspicua e impresa adaxialmente, levemente impresa abaxialmente. Inflorescencia usualmente más larga o al menos igualando las hojas subyacentes, axilar, densamente a moderadamente tomentulosa o seríceo-tomentulosa, con muchas flores pequeñas, pedúnculo 18–58 mm de largo, pedicelos 5–8 mm de largo, brácteas 4–11 × 1–1.5(–2) mm, angostamente ovado-elípticas a angostamente elípticas, escariosas a algo subfoliáceas; sépalos 4–7 × 1–1.5 mm, muy angostamente ovados a angostamente linear-ovados, acuminados, el ápice no reflexo, subfoliáceos, esparcidamente a densamente seríceos, el coléter solitario, entero, subentero a inconspicuamente eroso apicalmente; corola angostamente subinfundibuliforme, pero pareciendo hipocrateriforme, el tubo verde o crema-verdoso, los lóbulos crema, la garganta púrpura interiormente, velutino-híspida a densamente híspida externamente, el tubo giboso, abultado en la posición de los estambres, la parte inferior 11–20 mm de largo, 2–2.5 mm de ancho, la parte superior 9–11 mm de largo, angostamente cilíndrica, 4–7 mm de diámetro en el orificio, el ápice del botón floral acuminado; lóbulos 14–22 × 11–14 mm, obovados, extendidos y algo reflexos distalmente; estambres insertos en la base de la parte superior del tubo, anteras 4–4.5 mm de largo, glabras dorsalmente, la base auriculada, con las aurículas redondeadas, cabeza estigmática 1.1–1.3 mm de largo; ovario 1–1.3 mm de largo, glabro; nectario casi tan largo como el ovario, penta-lobulado, a veces casi totalmente dividido en cinco nectarios individuales. Folículos 10–14 × 0.2–0.3 cm, densa a moderademente villosos o hispidulosos, moniliformes; semillas 7–8.5 mm de largo, glabras, coma 1.5–2.3 cm de largo, café-canela.

Distribución, hábitat y ecología.—Conocida en el SE de Venezuela, Brasil (estado de Mato Grosso) y el NE de Bolivia, donde crece márgenes de carreteras y quebradas, así como en vegetación de sabanas y cerrados, en elevaciones de

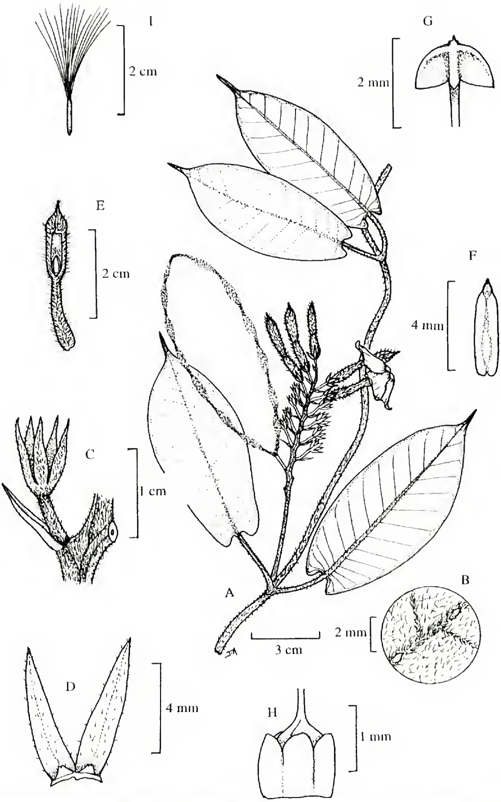

Fig. 1. *Mandevilla matogrossana* (*Souza et al. 15671*, INB). **A.** Ramita con inflorescencias y folículos. **B.** Detalle de la superficie adaxial de la hoja, mostrando los coléteres a lo largo del nervio central. **C.** Cáliz, pedicelo y bráctea. **D.** Sépalos y coléteres, vista adaxial. **E.** Botón floral parcialmente abierto, mostrando la posición de las anteras y el tubo basalmente giboso. **F.** Antera, vista dorsal. **G.** Cabeza estigmática. **H.** Nectario y ovario. **I.** Semilla.

50–350 m. Especímenes con flores y frutos han sido recolectados en febrero y de abril a julio.

En forma general, *Mandevilla matogrossana* ha sido tradicionalmente confundida con la común *M. hirsuta*, ya que en ausencia de flores, ambas especies son prácticamente idénticas, compartiendo forma y tamaño de hojas, inflorescencias, indumento y folículos similares. Sin embargo, la forma de la corola es determinante para separar ambas especies. De esta forma en *M. hirsuta* la parte superior de la corola es anchamente cónica (Fig. 2), mientras que en *M. matogrossana* en angostamente subinfundibuliforme y relativamente cilíndrica, dando la apariencia de una corola hipocrateriforme (Fig. 1 E). Asimismo, *M. matogrossana* puede ser confundida con *M. pavonii* (A. DC.) Woodson pero esta última especie tiene corolas hipocrateriformes (vs. angostamente subinfundibuliformes), sépalos más cortos (2.5–3 mm vs. 4–7 mm) y corolas con los tubos más largos.

El nombre de esta especie hace referencia al estado de Mato Grosso, Brasil, dado que la mayoría de colecciones conocidas provienen de esa zona geográfica.

BOOK REVIEW

Peter Loewer. 2005. **Seeds: The Definitive Guide to Growing, History & Lore.** (ISBN 0-88192-682-5, pbk.). Timber Press Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (**Orders:** www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $17.95, 229 pp., approx. 48 b/w illus., tables, index, 6 1/8" × 9 1/4".

Seeds: The Definitive Guide to Growing, History & Lore by Peter Loewer is an informative, easy to read, and entertaining book covering many topics relating to plant seeds. This book is especially useful because no botanical background is required to understand the text. Any necessary information on seed anatomy, ecological and botanical aspects is described by the author and often illustrated with black and white drawings. Mr. Loewer left no seed related topic out, including chapters on seed chemistry, plant families, flower pollination, seed longevity, dispersal, germination, the buying and selling of seeds, seed companies, seed collectors, collecting your own seed, seed diversity, and seed references galore. All topics are accompanied by a treasure trove of plant and interesting story examples.

The first few chapters cover the basics of plant families, flower pollination, seed chemistry, genetics, seed dispersal, and seed germination. The basic process of germination is described thoroughly with both text and pictures. Loewer goes into more detail in another chapter on specifics for germination such as storage, temperature, moisture, light, and a "paper towel" method of efficiently germinating seeds. A number of intriguing experiments on seed longevity are discussed including historical lore and storage recommendations for enthusiasts.

A number of chapters are devoted to the business of seeds because, after all, the business of seeds is big business. The chapter on buying and selling seed is truly eye-opening. The chapter includes a history of seed sales from Christopher Columbus and the Jamestown settlers buying staple crops to the first flower seed mail-order catalogs. In addition to the historical review of seed sales, a few seed company owners and their companies are profiled. The author also includes a chapter that introduces the reader to the many other businesses built on and around seeds; for instance businesses that make seed germinating equipment, special fungicidal seed coatings, and seed development companies.

There are a couple of chapters for the seed collector. They contain such useful information as how to collect, seed company contact information, and seed exchange information. To aid in your collection ventures, a variety of seed starting guides and informational handbooks are also recommended. A couple of extraordinary seed collectors are profiled in this chapter, Chris Chadwell of the Sino-Himalayan Plant Association for example.

The closing chapters offer guidance and suggestions to increase your success with starting seeds. The reader is taken through the process from choosing seed, seed starting medium, soil sterilization, labeling, propagation frames, seed starting conditions, seed sowing containers, lighting, emergence, hardening off and into the garden bed. The author stresses the importance of record keeping and proper labeling to help increase chances of success year after year. Also included are suggestions for starting ferns from spores.

Seeds: The Definitive Guide to Growing, History & Lore is a joy to read. This book is full of interesting stories, histories, examples, and useful information on learning about seeds and success with seed gardening. One of the most valuable reasons for buying this book is the large list of reference information including contact information for seed companies, exchange groups, literary resources, plant societies, and supplies. The book is recommended for anyone with an interest in seed history, lore, gardening, or how little things like seeds grow to become big business.—*Lee Luckeydoo, Herbarium, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

NEW SPECIES AND NEW COMBINATIONS IN *ERICAMERIA* (ASTERACEAE: ASTEREAE)

ABSTRACT

One new species of *Ericameria* is described and two new combinations are proposed. Using morphological and molecular evidence we describe ***Ericameria arizonica*** Roberts, Urbatsch, & Anderson, presently known only from the Grand Canyon, Arizona, and propose the elevation of *E. discoidea* var. *linearis* and *E. discoidea* var. *winwardii* to species rank as ***E. linearis*** (Rydb.) Roberts & Urbatsch and ***E. winwardii*** (Dorn & Delmatier) Roberts & Urbatsch, respectively.

RESUMEN

Se describe una nueva especie de *Ericameria* y se proponen dos nuevas combinaciones. Usando datos morfológicos y moleculares, describimos **Ericameria arizonica** Roberts, Urbatsch, y Anderson, conocida solamente de El Gran Cañón, Arizona, y proponemos la elevación de *E. discoidea* var. *linearis* y *E. discoidea* var. *winwardii* a nivel de especie como **E. linearis** y **E. winwardii**, respectivamente.

Sequence-based phylogenetic investigations and taxomomic studies of *Ericameria* done, in part, for preparing the treatment to appear in Flora North America (Asteraceae: Astereae) have revealed one previously undescribed species and indicate that two known varieties would be more appropriately treated at specific rank. *Ericameria arizonica* from Arizona is herein described as new and *E. discoidea* (Nutt.) G.L. Nesom var. *linearis* (Rydb.) G.L. Nesom and *E. discoidea* (Nutt.) G.L. Nesom var. *winwardii* Dorn & Delmat. are raised to the rank of species as *E. linearis* and *E. winwardii*. ETS/ITS sequence data (Roberts & Urbatsch 2003, 2004; Urbatsch et al. 2003) were invaluable in circumscribing the genus that in recent decades had been the subject of numerous investigations (Urbatsch 1978; Urbatsch & Wussow 1979; Nesom 1990; Nesom et al. 1990; Nesom & Baird 1993; Anderson 1995; Urbatsch & Roberts 2004). Although low levels of interspecific sequence variation disallowed an assessment of detailed

SIDA 21(3): 1557–1564. 2005

relationships among species, such data were not inconsequential either and offered some support for our present taxonomic decisions. *Ericameria*, in its most recent rendition, consists of 36 species that occupy arid habitats of western North America ranging from northern Mexico northward into Canada. Two species are restricted to Baja California, *E. juarezensis* (Moran) Urbatsch and *E. martirensis* Wiggins, while the other 34 grow in part or wholly north of Mexico.

NOMENCLATURAL TREATMENT

Ericameria arizonica R.P. Roberts, Urbatsch & J. Anderson, sp. nov. (**Fig. 1**). TYPE: U.S.A. ARIZONA. Coconino Co.: Grand Canyon National Park, South Rim, Mather Point, eastern edge of view point E of paved walkways, north-facing Kaibab Limestone cliff edges shaded by pinyon pine, 1 Oct 1998, *N. Brian 98-291* (HOLOTYPE: ASC!).

Frutices ad 0.5 m alti; caules ramosi resinosi glandibus stipitatis; folia ascendentia vel effusa elliptica vel anguste oblanceolata 10–35 mm longa 2–5 mm lata glandulosa typice resinosi-punctata; involucra obconica 5.5–7.5 mm longa 2.5–4 mm lata; phyllaria 4–5-seriata valde gradata lanceolata ad elliptica 2–7 mm longa 0.5–1.2 mm lata, apicibus acutis ad cuspidatis aliquando acuminatis; capitula radiata, flosculis 12–20; flosculi radii 1–8; flosculi disci 5–15, corollis 5–7 mm longis, ramis stylorum 2–2.7 mm longis, appendicibus stylorum 1.3–1.7 mm longis, cypselae 4–5.5 mm longae glabrae vel dense sericeae; pappi albidi 4–5.5 mm longi.

Shrubs to 0.5 m. Stems branched, bark reddish tan becoming darker when older, stipitate glandular, usually resin coated. Leaves ascending to spreading, elliptic to narrowly oblanceolate, 10–35 × 2–5 mm, flat to somewhat concave adaxially, margins entire, glandular, typically resin-dotted, apices acute, apiculate, midvein evident and 1–2 fainter collateral veins often present; axillary fascicles of leaves absent. Capitulescences of cymose clusters to 4 cm wide. Involucres obconic, 5.5–7.5 × 2.5–4 mm. Phyllaries in 4–5 series, strongly graduated, tan, lanceolate to elliptic, 2–7 × 0.5–1.2 mm, mostly chartaceous, margins abruptly constricted at base of appendage, apices acute to cuspidate, sometimes long acuminate, usually recurved, midvein faintly evident, often resin dotted. Capitula radiate, flowers 12–20. Ray flowers 1–8, laminae elliptic, 3–4 × 0.8–1.3 mm. Disc flowers 5–15, corollas 5–7 mm, tubes glabrous, lobes 0.5–1 mm. Style-branches 2–2.7 mm, appendages attenuate, 1.3–1.7. Cypselae 4–5.5 mm, glabrous to densely sericeous. Pappi whitish-tan, 4–5.5 mm.

Etymology.—*Ericameria arizonica* is named for Arizona, the only state from which this species is presently known.

Distribution, ecology, and phenology.—The species has been collected from several sites along the south rim of the Grand Canyon where it grows on steep limestone cliffs, ca. 2100–2300 m. Flowering occurs in September and October. Chromosome number unknown.

Discussion.—*Ericameria arizonica* is allied to *E. cervina* (S. Watson) Rydb., a species that typically occurs on granitic and other non calcareous substrates. *Ericameria arizonica* is distinguished from *E. cervina* by having stipitate glandular hairs especially on its inflorescence branches, much narrower, elliptic to

NATIONAL PARK SERVICE NPS FORM 10-512 (JUNE 1982)
Park Code
Technical Name Haplopappus cervinus Wats.

HERBARIUM COLLECTION

Fig. 1. Holotype for *Ericameria arizonica*, *N. Brian 98-291* (ASC). Size marker in lower left corner equals 1 cm.

narrowly obovate leaves, more acute phyllary apices, and its occurrence on limestone substrates (Figs. 1, 2). It is distinguished from *E. nana* Nutt., another species in this complex, by its taller stature, more widely spaced leaves, acute phyllaries, lack or reduction of axillary leaf fascicles, and the presence of stipitate glandular pubescence. Certain specimens, mostly from Nevada, such as *Train 2494* (WTU), 20 mi W of Panaca in Lincoln County, are similar to *E. arizonica* in leaf form but lack the stipitate glands and possess axillary fascicles of leaves. Relationships among such populations are not presently known.

Samples of all three taxa were included in the macromolecular-based investigations of *Ericameria* (Roberts & Urbatsch 2003), where less than 1% divergence was detected among their ETS/ITS sequences. Similar sequence differences for this region of DNA were observed among more distantly related species of *Ericameria*. *Ericameria arizonica* and *E. cervina* consistently occurred in a clade with *E. lignumviridis* (S.L. Welsh) G.L. Nesom, *E. nana*, *E. obovata* (Rydberg) G.L. Nesom, and *E. watsonii* (A. Gray) G.L. Nesom. Relationships of *E. arizonica*, designated "*E. cervina* 1" in our above cited molecular study, within this lineage were usually unresolved. The relationship of *E. cervina*, designated "*E. cervina* 2" in the molecular study, was sometimes weakly associated with *E. nana*. Despite the lack of sequence divergence among these species, they are clearly distinguished by morphological traits and substrate preferences.

PARATYPES. **U.S.A. Ericameria linearis (Rydberg) R.P. Roberts & Urbatsch, comb. nov. BASIONYM *Macronema lineare* Rydberg, Mem. New York Bot. Gard. 1:384. 1900. *Haplopappus macronema* A. Gray subsp. *linearis* (Rydberg) H.M. Hall, Carnegie Inst. Wash. Publ. 389:206. 1928. *Haplopappus macronema* var. *linearis* (Rydberg) R.D. Dorn. Vasc. Pl. Wyoming 295. 1988. *Ericameria discoidea* (Nutt.) G.L. Nesom var. *linearis* (Rydberg) G.L. Nesom. Phytologia 68:153. 1990. TYPE: U.S.A. WYOMING: Teton Forest Reserve, N.W. Wyoming, Gros Ventre River. *Tweedy 557* (HOLOTYPE: NY).

Distribution, ecology, and phenology.—*Ericameria linearis* grows on dry, stony slopes at elevations around 2300 m and flowers from late summer into fall. It has been documented for Beaverhead County in southwestern Montana and in Fremont, Park, Sublette, and Teton counties in northwestern Wyoming.

Discussion.—Leaves linear in shape, 1–2.5(3) mm wide, pubescence glandular or rarely glabrous, sometimes floccose-tomentose but still glandular; and involucres less than 11 mm tall characterize *Ericameria linearis*. Its probable sister taxon, *E. discoidea*, differs in having glandular but otherwise glabrous,

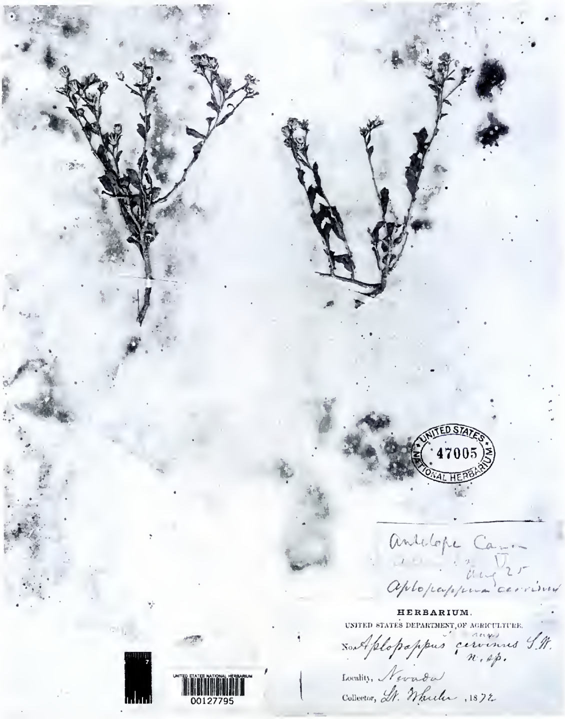

Fig. 2. Portion of probable isotype for *Ericameria cervina* based on *Haplopappus cervinus* Wats., Utah, Antelope Canyon, 1872, *Wheeler* (US). Size marker in lower left corner equals 1 cm.

oblong to oblanceolate leaves, mostly wider than 3 mm often with crisped margins and a darker green color, and involucres 10–13 mm tall. *Ericameria linearis* grows in southwestern Montana and northwestern Wyoming. Except for the possibility of its being sympatric with *E. discoidea* in southwestern Montana, the geographic ranges for the two species do not overlap. The latter is widespread in mountainous areas of southeastern Oregon, east-central California, Nevada, Utah, and Colorado; and it is not known from Wyoming. *Ericameria linearis* grows at lower altitudes than *E. discoidea* and for the most part at higher latitudes. Rydberg (1900) originally described *E. linearis* as a distinct species in the genus *Macronema* that, for the most part, is now included within the concept of *Ericameria*. Hall (1928) reduced the species to subspecific rank in *Haplopappus macronema* A. Gray, and others have likewise retained its infraspecific status. We restore the taxon to specific rank based on its morphological differences and its restricted, putatively allopatric distribution.

Ericameria winwardii (R.D. Dorn & C.H. Delmatier) R.P. Roberts & Urbatsch, stat. nov. *Ericameria discoidea* var. *winwardii* Dorn & Delmatier, Madroño 52:63. 2005. TYPE. U.S.A. WYOMING. Lincoln Co.: ca. 11 mi SW of Kemmerer, 41° 42 471' N, 110 43.381 W, 2135 m, 26 Jul 2002, *Dorn 9393* (HOLOTYPE: RM, ISOTYPES: BRY, COLO, IDS, MO, NY).

Distribution, ecology, and phenology.—*Ericameria winwardii* is known from Bear Lake County, Idaho, and Lincoln County, Wyoming. It grows on silty-clay and clay-shale slopes between 2050 and 2150 m (Dorn & Delmatier 2005). Flowering occurs late summer to fall.

Discussion.—Dorn and Delmatier (2005) observed a greater similarity of *Ericameria winwardii* to *E. linearis* than to *E. discoidea* on the basis of leaf form and pubescence. *Ericameria winwardii* is readily distinguished from *E. linearis* and *E. discoidea* by its smaller stature, floccose-tomentose pubescence throughout, absence of glandular hairs, and 10 or fewer florets per capitulum. Its stems lack the white, felt-like tomentum characteristic of *E. discoidea*. *Ericameria winwardii* appears to grow in finer, moister, less sloping soils than the other two species which are adapted to dry, well-drained, stony slopes and alpine fellfields (Hall 1928). We initially thought specimens of *E. winwardii* represented *E. linearis* but soon learned of their differences. Dorn and Delmatier (2005) independently concluded that *E. winwardii* represented an undescribed taxon, which they elected to treat as a variety within the *E. discoidea* complex. We conclude that it deserves specific rank due to its unique morphology, restricted, allopatric distribution, and adaptation to different edaphic conditions.

The sequence-based investigations of Roberts and Urbatsch (2003) included *Ericameria winwardii* (identified as *E. discoidea* var. *linearis* in that study) and typical *E. discoidea* (Nutt.) G.L. Nesom. In the combined analyses of the ETS/ITS data both taxa were placed in a lineage with *E. nauseosa* (Pall. ex Pursh) G.L. Nesom & G.I. Baird and *E. parryi* (A. Gray) G.L. Nesom & G.I. Baird. The former and latter pairs of taxa were sister in the Bayesian analysis of the ETS data, whereas, the combined ETS/ITS resulted in a trichotomy consisting of *E. discoidea* and *E. winwardii* with the third branch supporting *E. nauseosa* and *E. parryi*. Relationships among these taxa were unresolved within *Ericameria* when the ITS data were analyzed independently. As with *E. arizonica*, the percent sequence divergence among these taxa was comparable to that of other species in the genus (Roberts & Urbatsch 2003). Such low levels of divergence might indicate a relatively recent radiation of taxa or some measure of long generation time such that mutations in ETS and ITS regions accumulate slowly. Taxa in the *E. discoidea/nauseosa* lineage are characterized by a dense felty to floccose tomentum on some or all of their organs. Another measure of similarity among species in this clade is their ability to hybridize. Anderson and Reveal (1966) demonstrated the intermediacy of *E.* ×*bolanderi* (A. Gray) G.L. Nesom & G.I. Baird between *E. discoidea* and *E. nauseosa* in several morphological and anatomical characters providing abundant, circumstantial evidence for its hybrid origin. At the time of their study the putative parental taxa were regarded as belonging to different genera, *Halopappus* section *Macronema* and *Chrysothamnus*. Subsequently, Anderson (1984) provided evidence for hybrids forming between *E. nauseosa* and *E. parryi* resulting in a stabilized derivative taxon regarded by Nesom and Baird (1993) as *E.* × *uintahensis* (L.C. Anderson.) G.L. Nesom & G.I. Baird.

Despite the low level of resolution based on sequence data, *Ericameria discoidea*, *E. linearis*, and *E. winwardii* are morphologically distinct and apparently geographically allopatric. Observations of populations in nature suggest divergence in edaphic adaptations for *E. winwardii* compared to *E. discoidea* and *E. linearis* (Dorn & Delmatier 2005). Features of the leaves including shape, pubescence and margin characteristics can be used to distinguish among them. Distributional data indicate that the geographical ranges for the three taxa are distinct (Dorn & Delmatier 2005).

ACKNOWLEDGMENTS

The authors thank the curators and staff personnel of ASC, ASU, BRY, CAS, DH, RM, UNLV, US, UT, and WTU for specimen loans on which this and related research was based. We also thank Kurt Neubig for preparing the Latin diagnosis for *E. arizonica*, Yalma L. Vargas-Rodriguez, and reviewers (Guy Nesom) for their comments on this manuscript.

TAXONOMIC REVISION OF THE NEOTROPICAL GENUS: *ERITHALIS* (RUBIACEAE: CHIOCOCCEAE)

Vivian Negrón-Ortiz

Botany Department
Miami University
Oxford, Ohio 45056, U.S.A.

ABSTRACT

A taxonomic revision of *Erithalis*, genus of perennial trees and shrubs, is presented utilizing morphological data. Principal Component Analysis involving 14 vegetative and floral characters provided support for four morphologically distinct taxa (*E. angustifolia, E. harrisii, E. odorifera*, and *E. quadrangularis*) and a fifth poorly defined complex (*E. diffusa, E. fruticosa, E. salmeoides and E. vacciniifolia*). A few qualitative characters, as well as geographic distributions of the taxa, however, can distinguish the latter group. *Erithalis insularis* grouped within the fifth group, and is here placed in synonymy with *E. fruticosa*. Thus, in this study are recognized *E. angustifolia, E. diffusa, E. fruticosa, E. harrisii, E. odorifera, E. quadrangularis, E. salmeoides*, and *E. vacciniifolia* based on differences in inflorescence, flower, leaf, and growth habit characteristics. Phylogenetic relationships among the species, morphological description of their inflorescences and flowers, and the breeding system of *E. fruticosa* are presented. A key to the species, synonymies, typifications, descriptions, uses, and list of representative specimens is provided.

RESUMEN

Se presenta una revisión taxonómica de *Erithalis*, un género de árboles y arbustos de hoja perenne, utilizando análisis morfológicos. Análisis de Componentes Principales basados en 14 características vegetativas y florales confirman cuatro taxones (*E. angustifolia, E. harrisii, E. odorifera*, y *E. quadrangularis*) y un quinto complejo (*E. diffusa, E. fruticosa, E. salmeoides* y *E. vacciniifolia*). Este último grupo, sin embargo, puede distinguirse por varios caracteres cualitativos, además de la distribución geográfica de estos taxones. *Erithalis insularis* se agrupó con éste último grupo, y se coloca aquí como sinónimo de *E. fruticosa*. Por lo tanto, en este estudio son reconocidos *E. angustifolia, E. diffusa, E. fruticosa, E. harrisii, E. odorifera, E. quadrangularis, E. salmeoides*, y *E. vacciniifolia*, basándonos en diferencias de la inflorescencia, flor, hoja, y hábito de crecimiento. Se presentan las relaciones de filogenia entre las especies, descripción morfológica de sus inflorescencias y flores, y el sistema reproductor de *E. fruticosa*. Se provee una clave para las especies, sinónimos, tipificación, descripciones, usos y especímenes representativos.

INTRODUCTION TO *ERITHALIS*

Taxonomic History

Erithalis P. Browne (Rubiaceae: Chiococceae) is comprised of perennial trees or shrubs. It is distributed throughout the Caribbean Basin, Venezuela, and in the island of Fernando de Noronha, Brazil (Fig. 1). Twenty-six species, subspecies and varieties have been described in the genus (Andersson 1992; Candolle 1830; Correll & Correll 1982; Engler 1897; Lioger 1962, Lioger & Martorell 1982;

SIDA 21(3): 1565–1598. 2005

Grisebach 1864, 1866; Moore & Rendle 1936; Rafinesque 1838; Sauvalle 1869; Standley 1934; Steyermark 1974; Urban 1903, 1908; Zappi & Nunes 2000). In particular, the two widely distributed species—*E. fruticosa* L. and *E. odorifera* Jacq.—have been described under different names (Candolle 1830; Grisebach 1866; Rafinesque 1838; Urban 1903). For example, *E. odorifera* has been ranked as synonym, variety, or subspecies of *E. fruticosa* by many specialists on the Caribbean flora (Correll & Correll 1982; Grisebach 1864, 1866; Howard 1989; Lioger 1962) and on the neotropical Rubiaceae (Standley 1934; Steyermark 1974).

There has been little or no comprehensive examination of this genus across its entire range, and many species have been described on the basis of extremely limited material. Previous studies include the original species descriptions, which are mostly brief (Hooker 1873; Correll 1977; Candolle 1830; Engler 1897; Rafinesque 1838; Urban 1903, 1908; Zappi & Nunes 2000), taxonomic keys and/or species lists for particular regions (Adams 1972; Andersson 1992; Correll & Correll 1981; Lioger 1962; Lioger and Martorell 1982; Grisebach 1864, 1866; Moore and Rendle 1936; Sauvalle 1869; Steyermark 1974), and phylogenetic and biogeographical studies based on molecular data (Negrón-Ortiz & Watson 2002, 2003).

Among the regional floras, i.e., taxonomic keys and/or species lists for particular regions, the work done in Cuba (Grisebach 1866; Lioger 1962; Sauvalle 1869) is notable. In *Catalogus Plantarum Cubensium*, Grisebach (1866) lists for Cuba (without descriptions except when noted) four species of *Erithalis* and one variety: *E. angustifolia* DC., *E. fruticosa*, *E. fruticosa* var. *odorifera* Jacq., *E. parviflora* Griseb., and *E. rotundata* Griseb. He transferred *E. angustifolia* Rich. to *E. parviflora*, briefly describing it as follows: "corolla quam in ceteris minor, calycis limbo minutissime 5 dentato, antheris filamento brevioribus." Shortly thereafter, Sauvalle (1869) revised Grisebach's list, and reached similar conclusions. However, he treated *E. fruticosa* var. *odorifera* as a synonym of *E. rotundata*. In addition, he included *Chione* Griseb. in *E. vacciniifolia* (Griseb.) Wr., without any description except by listing the collection number, *2719*. By the mid-20th century, Liogier (1962) recognized only two species for this island, *E. fruticosa* and *E. vacciniifolia*, perhaps following Standley's treatment (see below for details).

The most complete treatment, but limited to species descriptions, is by Standley (1934), who recognized six species of *Erithalis*. He ranked *E. angustifolia* sensu Griseb. as synonym of *E. acuminata* Krug & Urb., and recognized the Puerto-Rican endemic *E. revoluta* Urb. as a distinct taxon. Liogier and Martorell (1982) then placed the latter species in synonymy with *E. fruticosa*. Standley (1934) was the first to proposed a broad delimitation for *E. fruticosa*: he considered *E. odorifera*, *E. inodora* Jacq., *E. elliptica* Raf., *E. odorata* Raf., *E. rotundata*, *E. parviflora*, *E. fruticosa* var. *inodora* DC. and *E. fruticosa* var. *odorifera* to be synonymous. In addition, Standley treated *E. angustifolia* DC., *E. pentagonia* DC., and *E. uniflora* Gaertn.f. as doubtful species. Subsequently, Liogier (1962) determined that *E. angustifolia* DC. is a synonym of *E. fruticosa*.

Moore and Rendle (1938) followed Standley's classification for their treatment in *Flora of Jamaica*, but with several modifications. In their classification, they maintained *E. fruticosa*, *E. harrisii* Urb. and *E. quadrangularis* Krug & Urb., which were also later sustained by Adams (1972). They ranked *E. odorifera* at the species level indicating that "this and *E. fruticosa* are very distinct," and that the leaves and calyx-tube are "much larger." They also added a new variety, *E. harrisii* var. *angusta* S. Moore ex Rendle. Adams (1972) placed the later two taxa in synonymy with *E. fruticosa*.

In his checklist of Neotropical Rubiaceae, Andersson (1992) listed 21 *Erithalis* taxa, including synonyms, varieties and subspecies. Of those, he tentatively accepted nine species, which represent merely Standley's six species with the addition of *E. salmeoides* Correll and *E. diffusa* Correll (Correll 1977), and *E. odorifera*, which he elevated to species rank separating it from *E. fruticosa* following Howard (1989). *Erithalis revoluta*, synonymized with *E. fruticosa* by Liogier and Martorell (1982), was maintained as a separate species by Andersson, who was perhaps not aware of Liogier and Martorell's work. Clearly, throughout these local floras and treatments, *E. fruticosa* ranked as a distinct species.

Species Concept

Various morphological characters have been used to delimit the species of *Erithalis*. I use the basic framework of Andersson who recognized nine species, and the recently transferred species, *E. insularis* (Ridl.) Zappi & T.S. Nunes (Zappi & Nunes 2000). Many of the morphological characters used historically display continuous variation among species, especially among taxa with overlapping distributions. *Erithalis fruticosa*, as traditionally recognized, exhibits considerable morphological diversity and a pan-Caribbean geographical distribution, and overlaps in distribution with many of the recognized taxa in the genus. *Erithalis odorifera* shares a similar distribution and habitat as *E. fruticosa*, occurring sympatrically on several islands, and intermediate forms between these two taxa appear to bridge the main differences between them (Moore & Rendle 1938; Negrón-Ortiz, pers. obs.; Steyermark 1974). Howard (1989) used characters such as size of the corolla tube, floral fragrance intensity, and leaf size to separate these two species.

Erithalis harrisii, *E. quadrangularis*, *E. revoluta*, and *E. vacciniifolia* are each considered endemic to one or several islands of the Greater Antilles (Fig. 1). Characters such as stipule length, the ratio of leaf length to width, petiole length and robustness, leaf apex, and calyx lobes shape have been used to separate these endemic species from *E. fruticosa* (Urban 1903). *Erithalis acuminata*, the only species reported endemic to the Lesser Antilles, is separated from *E. fruticosa* by the size of the corolla tube and height of the plant. *Erithalis diffusa* and *E. salmeoides*, currently considered endemic species to the Bahamian Archipelago (Correll & Correll 1982), differ from each other and *E. fruticosa* in growth habit, corolla, and anther length.

Erithalis insularis, a species collected from the island of Fernando de Noronha, Brazil, was recently transferred by Zappi and Nunes (2000) based on a type specimen originally described as *Palicourea insularis* Ridl. They claim it differs from the other *Erithalis* by "its poorly branched, few-flowered inflorescences, and leaves distributed along the new branches."

PHYLOGENY AND EVOLUTION

Morphometrics

Taxonomy of island genera is often regarded as difficult because of their complexity, including widespread and variable species that contain several more or less distinct forms, joined to one another by intermediates, and by the lack of discrete characters to separate these forms (Henderson & Ferreira 2002). Infra- and inter-specific variability of island species and other groups of taxa have frequently been examined by multivariate statistical techniques (e.g., Fritsch & Lucas 2000; Henderson & Ferreira 2002; Janovec & Harrison 2002; Negrón-Ortiz & Hickey 1996; Thompson & Lammers 1997), thus, I used multivariate techniques to investigate morphological variation within *Erithalis*. This was done as a precursor to determine the best characters for use in the phylogenetic analyses, and in the taxonomic treatment.

Morphological studies were based on specimens examined from herbaria BM, FTG, GH, LL, MO, MU, NY, Tex and US, and from field collections made in Jamaica, St. Vincent and the Grenadines (Lesser Antilles), Puerto Rico, Florida (USA), and Andros Island (Bahamas). Over 278 specimens were examined over the course of the study, representing the entire range of morphological and geographical variation within this genus. A total of 14 characters (leaf length, leaf width, corolla length, number of corolla lobes, style length, calyx length, anther length, filament length, inflorescence length, growth habit, petal type, stigma type, inflorescence type, position of anther relative to the stigma) were measured on 133 specimens. Specimens with complete data sets were selected for combined analyses of floral and vegetative data; these totaled 70 collections and represented ten species. The holotypes of *E. acuminata* (here after: *E. angustifolia*, see taxonomic treatment), *E. quadrangularis*, *E. salmeoides*, and *E. vacciniifolia*, isotypes of *E. angustifolia*, *E. diffusa*, *E. insularis*, *E. parviflora* and *E. salmeoides*, and syntypes of *E. angustifolia*, *E. harrisii* and *E. rotundata* were included in the study. The data matrix was subjected to standarized Principal Component Analyses (PCA) using JMP 3.1 (Statistical Discovery Software, SAS Institute Inc. 1995); scatter plots were generated using CA-Cricket Graph III 1.5.3 (Computer Assoc. International, Inc. 1992).

The results of the PCA indicate that the first three principal components for vegetative and floral characters accounted for 72% of the standardized variance. The first component explained 50% of the total variance, with the highest loading for the following characters: leaf length, leaf width, corolla length, style length, anther length, and filament length. The second component explained a further 12% of the variance, with the highest loading for calyx length and inflorescence type.

Five clusters were evident in the two dimensional PCA (Fig. 2). The type specimen of *E. angustifolia* is located in the upper part of the figure, separated from the other species by its narrow paniculate and racemose inflorescence-types, and larger acuminate leaf. *Erithalis harrisii* forms a single cluster, separated from the other clusters by its densely branched panicle inflorescence-type (sensu Delprete 1996) and recurved corolla lobes. A third cluster, separated from the rest by larger leaves, longer corolla and anthers, is comprised of *E. quadrangularis* and two specimens of *E. odorifera* from Dominica and St. Vincent, Lesser Antilles. In addition, these two *E. odorifera* specimens are small trees, similar in height and habit to *E. quadrangularis*. A fourth cluster grouped *E. odorifera* specimens, except for four individuals (Fig. 2), by characters of intermediate size between *E. quadrangularis* and *E. fruticosa* (Figs. 2, 3).

Erithalis diffusa, *E. fruticosa*, *E. salmeoides* and *E. vacciniifolia* formed a single cluster (Fig. 2), which also includes four individuals of *E. odorifera*. The

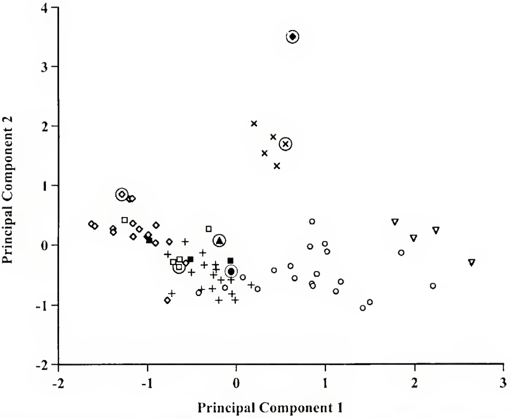

Fig. 2. Two dimensional PCA for floral and vegetative characters. The analyses involved 70 specimens. Symbols represent: ♦ = *E. angustifolia*, □ = *E. diffusa*, + = *E. fruticosa*, x = *E. harrisii*, ▲ = *E. insularis*, ❍ = *E. odorifera*, ∇ = *E. quadrangularis*, ● = *E. rotundata*, ◇ = *E. salmeoides*, ■ = *E. vacciniifolia*. Circled symbols represent holotypes, isotypes or syntypes.

types of *E. insularis* and *E. rotundata* group within this cluster. Although overlap between *E. diffusa*, *E. fruticosa*, *E. salmeoides* and *E. vacciniifolia* was evident in this cluster (Fig. 2), the geographic distributions of *E. diffusa*, *E. salmeoides* and *E. vacciniifolia* are not continuous. Typical *E. salmeoides* is found on Great Inagua, Bahamas, northern Dominican Republic, Jamaica and Cuba, *E. diffusa* is found in San Salvador & Crooked Island, Bahamas, and *E. vacciniifolia* is found in Cuba and southern Dominican Republic. In addition to their geographic distribution, they differ in growth habit and stigma type. *Erithalis vacciniifolia* and *E. diffusa* are prostrate or sprawling shrubs, whereas *E. salmeoides* is an erect shrub. *Erithalis diffusa* and *E. salmeoides* possess a bilobed stigma (Fig. 4 A, B, E), whereas the stigma of *E. vacciniifolia* consists of 5–8 minute lobes, with papillae spreading along the style (Fig. 4, C, D, F). Also, the placement of the anthers above the stigma is distinctive in *E. salmeoides*.

Erithalis fruticosa overlaps in distribution with many of the species, and in these areas of sympatry there are individuals with intermediate characters, masking species delimitations. For instance, *E. fruticosa* and *E. odorifera* co-occur in the SW coast of Puerto Rico intergrading continuously in vegetative and

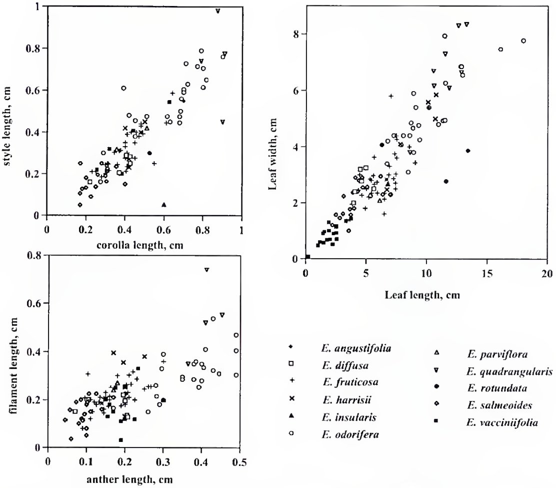

Fig. 3. Scattergrams of floral (A, B) and vegetative (C) characters. Symbols represent species, and each point represents an individual plant.

floral characters. Similarly, in Dominican Republic *E. vacciniifolia* and *E. fruticosa* occur together along the SE coast and intergrade continuously in stature and leaf size (McDowell, pers. obs.). In the Bahamas, *E. fruticosa* and *E. salmeoides* intergrade in their vegetative characters, but their floral traits are distinct. The presence of intermediates suggests hybridization. However, no experimental work has been done to investigate the potential for hybridization between the recognized species of *Erithalis*.

Most of the quantitative characters are not good discriminatory characters (Fig. 3). Nevertheless, it is obvious that specimens of *E. harrisii*, *E. quadrangularis*, and *E. odorifera* have distinctly larger flowers and leaves, compared to the other species of the genus (Fig. 3). *Erithalis vacciniifolia* has smaller and narrower leaves (Fig. 3C), whereas *E. salmeoides* has smaller flowers (Fig. 3A, B).

In summary, the PCA presented here provides support for recognition of four morphologically distinct groups, and a fifth poorly defined group. The distribution of individuals in the PCA ordination indicated the specimens of *E.*

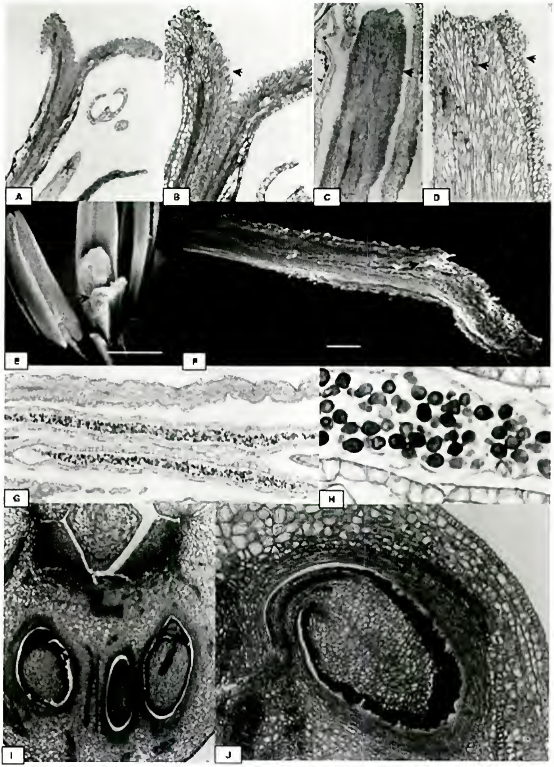

Fig. 4. Stigmas, anther, and ovules of *Erithalis*. **A–D, G–J.** Light micrographs of longitudinal sections. **E–F.** Scanning electron micrographs (SEM). A, B, E. Receptive bi-lobed stigma of *E. diffusa* (*Strittmatter s.n.*); Bar = 500µm. **C–D.** Stigma of *E. odorifera* (*Negrón-Ortiz 806*) from a flower bud showing the position of the stigmatic papillae (C), and detail of longitudinal slits of the middle lobes (D). F. angustifolia, *E. harrisii*, *E. quadrangularis*, and *E. odorifera* were readily distinguishable from each other and from specimens of the other species. The remaining taxa, *E. diffusa*, *E. fruticosa*, *E. salmeoides* and *E. vacciniifolia*, do not show clear-cut taxonomic distinctions based on the two dimensional PCA. Although characters such as stigma type, placement of the anthers relative to the stigma, growth habit, as well as their geographic distribution (to some extent) can distinguish these four species, the lack of distinct groupings in the PCA could be a consequence of introgression between *E. fruticosa* and any of the other species.

Phylogeny

Monophyly, phylogenetic relationships, and biogeography of *Erithalis* have been investigated by Negrón-Ortiz and Watson (2002, 2003) using DNA sequence data of the Internal and External Transcribed Spacers (ITS and ETS) of nuclear ribosomal DNA, and the chloroplast *trn*L-*trn*F intergenic spacer. These analyses involved seven species of *Erithalis*, including multiple populations of the widespread *E. fruticosa* and *E. odorifera*, but excluded *E. angustifolia* and *E. insularis*. I was unable to relocate *E. angustifolia*, and *E. insularis* is only known from the type specimen (Zappi & Nunes 2000). Negrón-Ortiz and Watson (2002) concluded that *Erithalis* is a well-supported monophyletic genus (Fig. 5); the evidence includes an eight base-pair indel in the *trn*L-*trn*F intergenic spacer, present in all species of this genus but in neither of the outgroup taxa. In addition, both molecular and morphological data support a close relationship of *Erithalis* to *Chiococca* P. Browne ex L. (Bremer & Jansen 1991; Delprete 1996; Negrón-Ortiz & Watson 2002). Biogeographic analyses suggest that a combination of vicariance and dispersal events appears to be involved in the historical and present distributions of *Erithalis*, and support a Greater Antillean origin for *Erithalis* (Negrón-Ortiz & Watson 2003).

To provide a more robust resolution of phylogenetic relationships within *Erithalis*, I carried out parsimony analyses of a combined data set of molecular characters (ITS, ETS & *trn*L-*trn*F sequences) and five morphological characters (corolla lobe: recurved, straight; growth habit: prostrate, erect; inflorescence type: corymbose, paniculate, racemose, others; position of anther relative to the stigma: above, below; stigma lobes: bi-lobed, 5–8) using PAUP* 4.0b8 (Swofford 2001), with gaps treated as missing data and polymorphic states as uncertain. The Branch and Bound Search Option was employed with MULTREES in effect and Furthest Addition Sequence. Bootstrap analysis was conducted for 500 replicates, with tree-bisection-reconnection (TBR) and STEEPEST DESCENT in effect (Felsenstein 1985), and branch support analyses (Bremer 1998) were performed using Autodecay 4.02 (Eriksson 1999). In addition, the molecular data set was analyzed using hierarchical likelihood ratio tests to estimate the best-fit model for the data set (MODELTEST v3.06; Posada & Crandall 1998). This procedure showed that the K80+G model best fit the data, then the heuristic

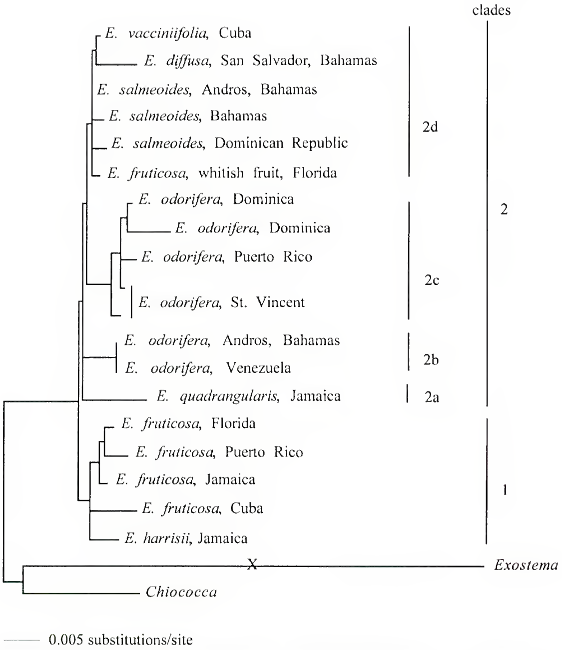

Fig. 5. The best maximum likelihood tree (–Ln = 4211.63789) inferred from analyses of molecular data. X = reduced 2.50 cm. Numbers represent clades.

ML analysis was done with random sequence addition for 100 replicates, MULTREES on and TBR branch swapping.

Analyses of the combined morphological and molecular data generated 13 most parsimonious trees of 101 steps (CI=0.561, RI=0.538, excluding constant and uninformative characters). Eight ML trees with a score of -Ln = 4211.63789 were recovered using the K80+G model of evolution (Fig. 5). The topology of the best ML tree is congruent with the 13 equally most parsimonious trees of combined morphological and molecular data set, and to those obtained via the analysis of ITS, ETS, and *trn*L-*trn*F spacer (Negrón-Ortiz & Watson 2000). Therefore, a cladogram with the results of heuristic ML analysis is shown in Fig. 5.

The phylogenetic analyses consistently identified two weakly supported major clades (Fig. 5). Clade 1 weakly supports a sister group relationship of *E. harrisii* to multiple populations of *E. fruticosa* that occur in the Greater Antilles and Florida. These two shrubby species share corolla size (mean = 4.4 vs. 4.0 mm, respectively), a stigma of 5–8 minute lobes, but differ in leaf length (mean = 9.21 vs. 6.12 cm, respectively; Fig. 3C) and leaf width (mean = 4.61 vs. 2.83 cm, respectively; Fig. 3C), inflorescence type, corolla lobe curvature, and leaf texture. In *E. harrisii* the inflorescence is a densely branched panicle, the corolla lobes are strongly recurved, and the leaves are thick, glossy above and scabrous below. In *E. fruticosa*, the inflorescence is commonly cymose [some individuals have a sparsely branched panicle (sensu Delprete 1996), others a corymb inflorescence type], corolla lobes vary from somewhat reflexed to straight, and the leaves are usually leathery. *Erithalis harrisii* occurs in mid- to high elevations (˜500–800 m) in the mountains of Jamaica, whereas *E. fruticosa* is mostly found at sea level throughout the Caribbean.

Clade 2 contains four subclades of five remaining species, but also includes one sample of the white-pinkish fruited *E. fruticosa* from Florida, suggesting that *E. fruticosa* is not monophyletic and/or that sample is of hybrid origin. Within clade 2, *E. odorifera* is largely monophyletic, with the exception of two samples from the Bahamas and Venezuela (subclade 2b), which fall outside the main *E. odorifera* subclade (2c). Perhaps, these populations lack sufficient molecular characters for supporting monophyly, or represent two cryptic lineages.

The Jamaican endemic *E. quadrangularis* is placed sister to the second major clade (2). *Erithalis odorifera* populations, morphologically resemble *E. quadrangularis,* sharing character states of floral morphology [linear anther shape and size (Fig. 3B), calyx length (mean = 0.13 cm), corolla length (Fig. 3A), stigma of 5–8 minute lobes (Fig. 4C, D, F), and upright growth habit]. *Erithalis quadrangularis* occurs at high elevations (600 - 800 m) in the mountains of Jamaica, at sea-level in the coast of St. Vincent (Lesser Antilles), and exhibits relatively larger (range = 8–21.7 vs. 6–13 cm in *E. odorifera*) and wider leaves (range = 3.5–10.1 vs. 3–7.7 cm in *E. odorifera*), axillary or terminal cymose-corymbose inflorescences (Fig. 6A), and recurved corolla lobes. *Erithalis odorifera* can be found from sea level to 300–500 m of elevation, exhibits axillary, cymose inflorescences (Fig. 6D), and straight corolla lobes.

The data weakly support a sister relationship of *E. odorifera* populations from the Lesser Antilles and Puerto Rico (subclade 2c) to subclade 2d which is composed of multiple species from the Bahamas, Florida, and the Greater Antilles. These two subclades exhibit more morphological differences than similarities. The *E. odorifera* subclade (2c) is comprised of shrubs or small trees with cymose

Fig. 6. Inflorescences of *Erithalis*. **A.** *E. quadrangularis* (*Harris* 12013). **B.** Solitary flower of *E. vacciniifalia* (*Pollard, Palmer & Palmer* 212). **C–D.** Axillary-cymose inflorescences of *E. fruticosa* (C, *Negrón-Ortiz* 795), and *E. odarifera* (D, *Negrón-Ortiz* 800). Bar = 1 cm.

inflorescences, larger corollas of 5–7 lobes, and long and wider leaves. The species of the Bahamas, Florida and Greater Antilles subclade (2d) are erect or prostrate shrubs, with corymbose inflorescences and/or solitary flowers or reduced cyme (sensu Delprete 1996), and small corollas (1.8–6.0 mm long; Figs. 3A, 6B).

The species of subclade 2d are morphologically distinct from each other, distinguished by differences in growth habit, leaf length and width, anther length, stigma type, and the placement of the anthers relative to the stigma. The taxa comprising this subclade vary from erect shrubs, such as *E. salmeoides*, to sprawling shrubs with prostrate branches, such as *E. diffusa* and *E. vacciniifolia*. *Erithalis vacciniifolia* displays smaller and narrower leaves, stigma of 5–8 minute lobes (Fig. 4F), and longer anthers (Fig. 3B). *Erithalis salmeoides* exhibits smaller anthers and styles (Fig. 3A, B), and the anthers extend above the stigma. *Erithalis salmeoides* and *E. diffusa* have a bi-lobed stigma (Fig. 4A, B, E).

In summary, the phylogenetic analyses presented here are in agreement with previous studies (Negrón-Ortiz & Watson 2002, 2003). The data confirm the monophyly of *Erithalis*, provide good resolution at the interspecific level, but do not support monophyly where more than one plant per species was sampled.

Geographic distribution and ecology

Erithalis is distributed from southern Florida throughout the West Indies, to Margarita and other Venezuelan islands, Quintana Roo (Mexico), the coast of Honduras, Colombia and the island of Fernando de Noronha, Brazil. The species occur in a wide variety of habitats, including coastal areas, open disturbed locales, rocky areas, montane areas, coppices, pinelands, sand dunes, limestone soils, and near coastal mangrove communities.

The species have bird-dispersed fruits (Bancroft & Bowman 1994; Negrón-Ortiz & Watson 2002, 2003), which helps explain the distribution of the genus across so many islands in the Caribbean, and the disjunct geographical distribution of *E. fruticosa* (Fig. 1).

FLORAL BIOLOGY

Inflorescence

The most common type of inflorescence is an axillary, many flowered compound cyme (Fig. 6); this varies greatly in length and number of flowers, and occurs either one or two per node. By various reductions or amplifications of development, these cymose inflorescences may appear paniculate, corymbose, or racemose. In other cases the inflorescence is reduced to a solitary, axillary flower (Fig. 6). In addition to these axillary inflorescence types, rarely terminal cymose-like inflorescences also occur in *Erithalis*.

The proximal portions of the inflorescences typically bear leaf-like bracts (pherophylls) of variable size and shape. In some cases the leaf-like bracts are similar in size and shape to leaves in the vegetative portion of the plant. The bracts decrease in size towards the distal parts, becoming small to minute.

Flowers

The flowers are bisexual, mainly white, but pinkish-white (Delprete, pers. obs.) and creamy-white corollas are also reported. The latter color, however, could be indicative of flower senescence (pers. obs.). Pentamerous corollas are typical in most species, but plants with 4–8-merous corollas do occur, and the number can vary even within a single inflorescence. Corolla lobes are mostly straight, but recurved corolla lobes are also present and characteristic of the Jamaican species *E. harrisii*. Rarely, both straight and recurved lobes occur within the same plant of certain species. Generally, the outside and inside of the corolla are entirely glabrous. In *E. harrisii* and some plants of *E. quadrangularis* an external indumentum is present, comprised of short hairs.

Stamens are present in the same number as the corolla lobes and alternate with the latter. The anthers are yellow, basifixed (Fig. 4E, G), and can be situated above, below or at the same level as the stigma. The latter character can be useful for species delineation, i.e., *E. salmeoides*. The pollen grains are binucleate (Fig. 4H). The bases of the filaments are either glabrous, with scattered hairs, or densely pubescent, and are connate forming a minute tube.

Erithalis exhibits two types of stigmas, which are of taxonomic importance (Fig. 4A-F). In almost all species the stigma consists of 5–8 minute lobes (usually 5), with papillae spreading along the style forming grooves (Fig. 4C, D, F). In only two species, *E. salmeoides* and *E. diffusa*, a bi-lobed stigma is present with papillae confined to the inside of the lobes (Fig. 4A, B, E). In the field, the papillae consisting of the first type of stigma change color from white to purple, indicative of loss of receptivity and senescence.

Erithalis displays two ripe fruit colors, dark-purple and whitish-pink. Whitish-pink fruit color has been reported in the Bahamas (Andros, Great Abaco, Great Inagua and Cat Islands), Florida (Miami), Virgin Islands (St. John), Cuba, and Mexico. Unique to *Erithalis* is the presence of a multi-locular ovary, whereas a single pendulous ovule per locule occurs in all genera of the Chiococceae (Fig. 4I, J).

Breeding systems

All species of *Erithalis* are monomorphic and homostylous. The flowers are fragrant, and produce abundant nectar. Neither secondary pollen presentation nor heterostyly occurs in any of the species. In addition, neither protandry nor protogyny was observed in the field (pers. obs.), so stigma receptivity appears simultaneous with anthesis.

The breeding system of dark-purple and whitish-pink fruited morphs *E. fruticosa* was examined at Fairchild Tropical Garden (FTG), Coral Gables, FL. The garden hosts small, wild populations of *Erithalis* where both fruit color morphs grow sympatrically. Eleven plants (7 dark-purple, and 3 whitish-pink fruited *E. fruticosa*) were marked, and five pollination treatments were designed to test the type of mating system (Negrón-Ortiz 1996). Emasculated and bagged flowers were tested for apomixis. Unpollinated and bagged flowers provided a test for autogamy, hand pollinated and bagged flowers tested for selfing, and emasculated, bagged and hand-pollinated flowers tested for outcrossing. Control flowers were neither bagged, emasculated, nor hand pollinated. Abscised corollas with their styles attached were examined for pollen tube growth (for details of methods see Negrón-Ortiz 1996), and at the end of field season, fruits from monitored flowers were collected and inspected for seeds.

A total of 350 flowers were monitored (subjected to pollination treatments and controls). Germinated pollen tubes were observed on the stigma of virtually every replicate for each pollination treatment, i.e., self, outcross, autogamy and control (Fig. 7A–C). Additionally, a greater number of pollen tubes reached the middle of the style than the base (Fig. 8A), suggesting intraspecific pollen tube competition. In 97% of outcrossed flowers (63 of 65 monitored flowers) the tubes successfully reached the base of the style (Fig. 7A), and seeds were produced (Fig. 8B). In the self- and unpollinated-bagged (autogamy) treatments, however, approximately 90% of the tubes were arrested in the stigma (Fig. 7B), and only a few reached the base of the style producing fruits (Fig. 8).

The results indicate that allogamy, i.e., outcrossing, is the main mating system occurring in *E. fruticosa*. However, self-sterility is incomplete because a few mature fruits were produced after self- (3%) and unpollinated-bagged (autogamy, 6%) treatments (Fig. 8B). There is no evidence for asexual seed production (Fig. 8B).

Fruit set was significantly greater for cross-pollinated flowers than for controls (97% vs. 26 %), suggesting that most fruits from the control treatment resulted from selfing and/or self-pollen deposition. In addition, comparisons between fruit set of manual cross-pollinated flowers and the control treatment of open-pollinated flowers reveals whether floral visitors are effective as pollinators. The results are consistent with an explanation of insufficient pollinator visits or limited pollination efficiency (e.g., if most visitors are acting as nectar robbers). Nectar was abundant at noon, and the only visitors observed at this site were bees and butterflies. Thus, it is possible that the study site at FTG lacks the natural pollinators.

USES

Erithalis, specifically *E. fruticosa*, has various economic and medicinal uses. The wood has been used for posts and torches (Kimber 1988; Little et al. 1974). The bark, fruits, and the resin have diuretic and astringent properties and are used to treat inflammation of the kidney and bladder, and blennorrhoea (any mucous discharge from the urethra or vagina; Liogier 1990). The leaves are used to treat skin sores (University of the Virgin Islands 2002). Other uses include treatment of hemorrhoids and measles, use as a styptic, drink ('spirit'), and as charms against spirits/witches.

The leaves and fruits of *E. fruticosa* are used as a source of food by the rock iguanas of British Virgin Islands, the Florida Key Deer and by the threatened white-crowned pigeon. The plant is used as a larval host by the coleoptera *Plocetes bahamensis* Casey (Anderson 1991).

SYSTEMATIC TREATMENT

Erithalis

Erithalis P. Browne, Civ. Nat. Hist. Jamaica. 165, t. 17, fig. 3. 1756. TYPE SPECIES: *Erithalis fruticosa* L.

Herrera Adanson, Fam. des plantes. 2:158. 1763. TYPE: based on P. Browne, Civ. Nat. Hist. Jamaica. 165, t. 17, fig. 3. 1756.

Fig. 7. Pollen grains and pollen tubes of ***Erithalis*.** **A–B.** Epifluorescent micrographs of *E. fruticosa* (*Negrón-Ortiz* 795). Pollen tubes following outcross (A) and self (B) pollinations. **C.** SEM pollen grain and tube of *E. vacciniifolia* (*Delprete* 7551), Bar = 10μm.

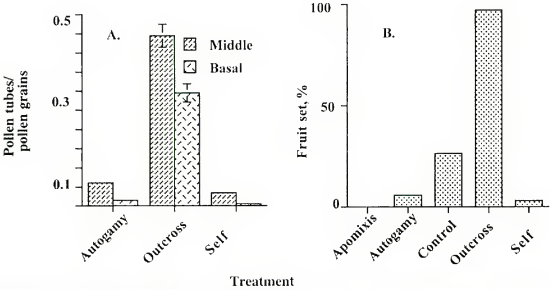

Fig. 8. Pollen tubes and fruit set per treatment. **A.** Ratio of pollen tubes in the style to pollen grains on the stigma; bars represent SE. **B.** Percent of fruit set per treatment.

Shrubs or **small trees**; raphides absent. Stipules interpetiolar, connate at base into cup-shaped sheath, truncate, deltoid to broadly triangular, apiculate, rarely acuminate, persistent. **Leaves** opposite, entire, long- to short-petiolate or sessile; blades acuminate, ovate, broadly ovate, broadly elliptic, narrowly obovate, obovate, oblong or oblanceolate, thinly to thickly coriaceous; domatia absent. **Inflorescence** axillary, paniculate and sparsely branched, corymbose, racemose, uniflorous, cymose-paniculate, cymose-corymbose, glabrous or puberulent; middle bracts long or minute. **Flowers** bisexual, fragrant, pedicellate. **Hypanthium** ovoid, obovoid or globose. **Calyx** cup-shaped, lobes small, 5 to 10, broadly triangular, broadly ovate or rounded, absent or minute, persistent. **Corolla** hypocrateriform or narrowly infundibuliform or rotate, actinomorphic, white to cream-white, rarely pinkish-white; tube internally glabrous, some with an external indumentum of short hairs; lobes 4–8, slightly imbricate, oblong or linear, margin entire, rounded at apex, recurved or somewhat straight. **Stamens** alternate to the corolla lobes, 4–8; **filaments** attached at base of the corolla tube, basally connate, filiform, smaller, equal or longer than corolla tube, puberulent or pubescent at basal portion (glabrous above) or with a tuft of hairs at base; **anthers** situated above, below or at the same level of the stigma; narrowly elliptic, narrowly oblong, or linear, round at base, round or acute at apex, dehiscing by longitudinal slits, basifixed. **Pollen** tricolpate, exine surface echinate-perforate, released as monads, binucleate. **Style** exserted just beyond the corolla, terete, glabrous. **Stigma** bilobed or 5–8 lobed, minute and agglutinated, ovate or oblong. **Ovary** inferior, 2–5 locules, 5–20 celled; placentation axile, placenta reduced, ovules pendulous. **Fruit** drupaceous, with woody pyrenes; pericarp fleshy, dark purple or whitish-pink. **Seeds** laterally compressed; **embryo** small.

KEY TO THE SPECIES

1. Prostrate or sprawling shrubs, with decumbent branches.
    2. Leaves sub-orbicular, rounded at the apex, 3.8–5.9 cm × 1.8–3.4 cm, pedunculate; stigma bi-lobed, anthers 1.9–2.1 mm long, longer than the filament; inflorescence a cyme, or cymose-paniculate (Bahamas) ______ **E. diffusa**
    2. Leaves ovate, elliptic, obovate, rounded to obtuse at the apex, 1.3–4.7 cm × 0.8–1.9 cm; sessile or short pedunculate; stigma with 5–8 small lobes; anthers approximately 1.2–2.8 mm long, shorter than the filament; inflorescence either a cyme, a solitary flower, a raceme, or found in any combination within the same plant (Cuba and Dominican Republic) ______ **E. vacciniifolia**
1. Erect shrubs or trees, with upright branches.
    3. Leaves narrowly elliptic with blade tip acuminate; inflorescence narrowly paniculate with long stalks and/or racemose (Martinique, St. Vincent and Trinidad) ______ **E. angustifolia**
    3. Leaf blades ovate, elliptic, or obovate.
        4. Leaf leathery, glossy above and scabrous beneath; inflorescence densely paniculate; corolla lobes recurved (Jamaica) ______ **E. harrisii**
        4. Leaves leathery or papery, glabrous above and predominantly smooth beneath; inflorescences primarily cymose, some racemose, narrowly paniculate, or found in any combination within the same plant; corolla lobes typically straight, or somewhat recurved.
            5. Anthers positioned above the style; stigma bi-lobed; inflorescence usually less than 4 cm long, rarely longer (Bahamas, Dominican Republic, Cuba and Jamaica) ______ **E. salmeoides**
            5. Anthers positioned below or equal to the style, rarely above the style or in any combination; stigma with 5–8 small lobes; inflorescences 5–9.7 cm long.

6. Anthers linear, 1.4–5.0 mm long; inflorescence 8 cm long or longer; middle bracts large; leaf papery or coriaceous, 7.7–21.6 cm long; corolla lobes straight or recurved.
    7. Inflorescences axillary or terminal, cymose-corymbose; middle bracts 3.4–10.4 cm long; corolla lobes recurved in anthesis; leaf coriaceous, 8–21.6 × 3.6–10.1 cm (mountains of Jamaica and St Vincent) **E. quadrangularis**
    7. Inflorescence axillary, mainly cymose; middle bracts minute to 2.4 cm long; corolla lobes straight in anthesis, rarely recurved; leaf papery or coriaceous, 6–12.9 × 3–7.7 cm (Bahamas, Greater and Lesser Antilles, Venezuelan islands) **E. odorifera**
6. Anthers ellipsoid, oblong, subglobose, in some cases somewhat linear, 0.7–3.5 mm long; inflorescence less than 8 cm long; middle bracts primarily minute; leaf coriaceous, 3.4–10.7 × 1.4–5.7 cm; corolla straight 4–6 lobes (throughout the Caribbean, Fernando de Noronha Island) **E. fruticosa**

Erithalis angustifolia DC., Prodr. 4:465. 1830. Type: CUBA: without locality, 1825, *de la Ossa* (holotype: G; IDC herbarium geneovense, microfiche!).

Erithalis acuminata Krug & Urb., Notizbl. Königl. Bot. Gart. Berlin. 1:319–320. 1897. Type: Lesser Antilles: Martinique, Guilding, 1877, *Duss 206* (holotype: B, destroyed; Lectotype: NY!, here designated).

Chiococca pulcherrima Wernh., J. Bot. 51:322. 1913. Type: Lesser Antilles: St Vincent, without date, *Anderson 308* (holotype: BM, isotype: K!).

Shrub 1–2 m high, the branches glabrous. **Leaves** coriaceaous; blades acuminate, gradually narrowed to the base, 6.2–13.8, 2.6–4.1; petioles 1.9–2.3 cm long. **Inflorescences** axillary, narrowly paniculate with long stalks and a few flowers, racemose, 9–10.5 cm long; glabrous; bracts minute. **Flower** pedicels 1–1.5 cm long. **Calyx** and hypanthium glabrate, calyx 0.9 mm long, denticulate. **Corolla** white, 1.7 cm long; **lobes** 5; **style** 5.5 mm long; stigmatic papillae 5 small lobes. **Stamens** 5; filaments white, 2 mm long, placed below the style; anther 3 mm long. **Fruit** a drupe, globose.

The name *E. angustifolia* is based on Candolle's description. The type is probably at G, while the photo is in the IDC microfiche, without number.

Distribution and ecology.—Found between 900–1100 m height in Montagne Pelée, Martinique, and St. Vincent and the Grenadines (Lesser Antilles). In addition, it was documented in the mountains of Trinidad.

Anderson collected *E. angustifolia* (as '*Chiococca pulcherrima*,' Fig. 9) in Trinidad, and described it as a scarce "beautiful shrub that grows on the summits of the highest mountains" (Wernham 1913). However, personal communication with Mr. Winston Johnson from the National Herbarium of Trinidad & Tobago indicates that *E. angustifolia* no longer occurs on the island.

Kimber (1988) listed this species (among others), and mentioned that all the species in the list were collected in 1962, 1963 and 1975. However, the species is not listed for the island in the document "Arbres de la Martinique–Les arbres

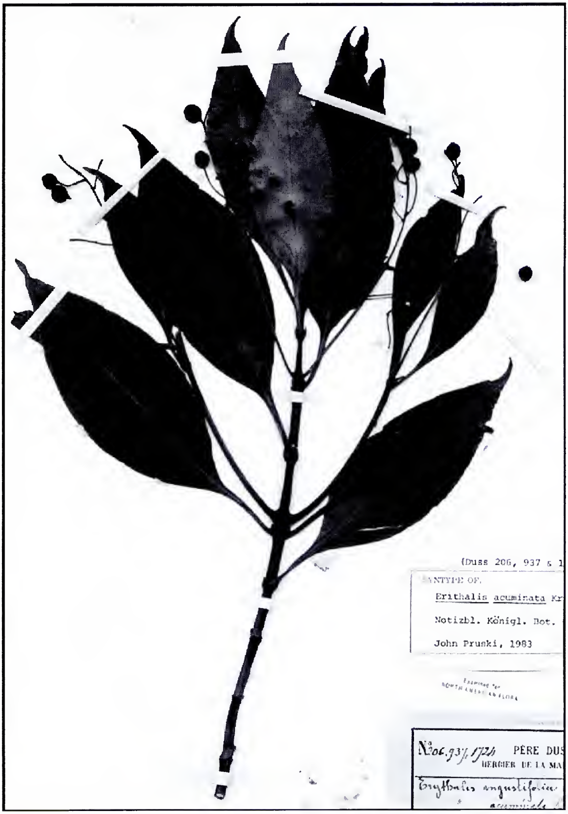

Fig. 9. *Erithalis angustifolia* (*Duss* 206) from Martinique, Lesser Antilles.

de la forêt martiniquaise-répertoire complet" written by F. Palli (www.palli.ch/~kapeskreyol/divers/arbres.html); only *E. odorifera* is documented.

Specimens examined. **TRINIDAD:** without locality, s.d., *Anderson 308* (Type of *Chiococca pulcherrima*, BM). **LESSER ANTILLES:** Martinique, Montagne Pelée, 1877, *Duss 206* (NY); Montagne Pelée, 1877, 1879, 1883, *Duss 206, 937, 1724* (SYNTYPE: NY; all numbers and dates on one label).

Common name.—Bois flambeau montagne.

Conservation status.—I was unable to locate *E. angustifolia* in St. Vincent and the Grenadines. According to Howard (1989), the Guilding collection cited by Urban may have been from St. Vincent Botanical Garden. However, I searched the collection at this institution, and found neither the plant nor records of its existence. I recommend searching for this species in Martinique and Trinidad to determine whether this taxon, is extinct. Certainly, it should be among the taxa in highly endangered of extinction.

Erithalis diffusa Correll., J. Arnold Arbor. 58:47. 1977. TYPE: BAHAMAS: San Salvador, N of airport, 21 Nov 1974, *Correll 43840* (HOLOTYPE: A!; ISOTYPES: FTG!, NY!)

Sprawling shrubs to 1 m high, the branches prostrate on ground to low-arching. **Leaves** glossy above; the blades leathery and thick, sub-orbicular to broadly oval, rounded at apex, 3.8–5.9, 1.8–3.4 cm; the petioles 0.8–1.0 mm long; young leaves slightly sticky. **Inflorescences** axillary, cymose, cymose-paniculate, 4.7–7 cm long; middle bracts minute; or solitary flowers. **Flowers** fragrant, pedicellate. Calyx and hypanthium glabrate, calyx 5-denticulate, 0.4–0.5 mm long; hypanthium about 1.5 mm long. **Corolla** white, 2.2–4.5 mm long; tube 1.5 mm long; lobes 4 or 5, somewhat straight. **Stamens** 5; filaments white, 1–2.5 mm long; **anther** yellow, linear, 0.19–0.21 cm long; situated below or at the same level with the stigma; longer or as long as the filaments. **Style** 1.6–3.3 mm long; stigma bilobed. **Fruit** a drupe, orbicular, about 5 mm in dm, dark purple when ripe.

Distribution and ecology.—*Erithalis diffusa* (Fig. 10) is endemic to the Bahamas: San Salvador and Crooked Islands. It grows in rocky shore locations; common in beach strand, scrub-land, coppices and coastal thickets. This species is a component of the coastal vegetation of San Salvador, which is defined as the sea strand/sea oats community, consisting of sea oats (*Uniola paniculata* L.), sea grapes (*Coccoloba uvifera* L.), and railroad vine (*Ipomea pes-caprae* (L.) R. Br.), all of which assist in stabilization of the dunes.

Specimens examined. **BAHAMAS. Crooked Island:** 20 Feb 1975, *Correll* (FTG); 18 Feb 1975, *Correll* 44380 (FTG). **SAN SALVADOR:** N of airport, 21 Nov 1974, *Correll* 43840 (Type FTG, NY); *Strittmatter* s.n. 2000 (MU); along Snow Bay, 2 May 2000, *Vincent et al* 8955 (MU); N of Polaris, 7 Feb 1973, *Van Eenwyk et al.* 4-2 (FTG); E of Field Station, 28 Dec 1980, *Thieret* 52532 (MU).

Erithalis fruticosa L., Syst. Nat., ed. 10, 930. 1759. TYPE: JAMAICA: without locality, s.d., (HOLOTYPE: P. Browne, Civ. Nat. Hist. Jamaica 1, t. 17, fig. 3. 1756).

Erithalis odorata Pers, Syn. Pl. 1:200. 1805, nom. Alt.

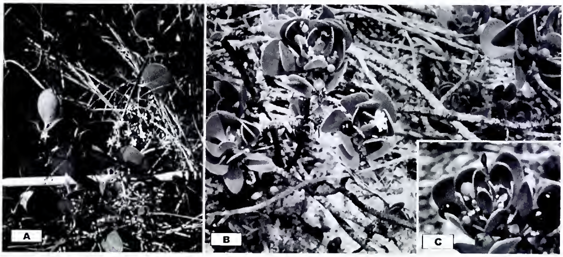

Fig. 10. ***Erithalis diffusa*** **from San Salvador, Bahamas. A. Growth habit. B. Detail of the globose, dark-purple drupaceous fruit (Photographs by Eric J. Tepe and Michael Vincent).**

Erithalis elliptica Raf., Sylva Tellur. 123. 1838. TYPE: JAMAICA: based on Swartz' description of *E. fruticosa*.

Erithalis harrisii Urb. var. *angusta* S. Moore ex Rendle, Fl. Jam. J. Bot. 73:279. 1935. TYPE: JAMAICA. Luana Point, Harris 9821 (HOLOTYPE: BM!).

Erithalis inodora Jacq., Select. Stirp. Amer. 73. 1763. *Erithalis fruticosa* var. *inodora* (Jacq.) Persoon, Syn. Pl. 1:200. 1805. TYPE: CURAÇAO: (no Jacq. specimen located).

Erithalis parviflora Griseb., Cat. Pl. Cub. 134. 1866. TYPE: CUBA: 1860–64, *Wright 2721* (HOLOTYPE: GOET!; ISOTYPES: K!, MO!, NY!, US!).

Erithalis revoluta Urb., Symb. Ant. 3:379. 1903. TYPE: PUERTO RICO: Guánica, Caña Gorda, *Sintenis 3796* (no type located). One set of Sintenis' West Indian collection was placed at B (now destroyed).

Erithalis insularis (Ridl.) Zappi & T.S. Nunes, Kew Bull. 55:655–656. 2000. Syn. nov. *Palicourea insularis* Ridl., J. Linn. Soc. Bot. 27:41. 1890. TYPE: BRAZIL: Pernambuco, Fernando de Noronha Island, 1887, *Ridley, Lea & Ramage 86* (HOLOTYPE: BM-n.v., not at BM per BM staff, LECTOTYPE: K!, here designated; ISOTYPE: B-destroyed, photo NY!).

Shrubs or **small trees** 0.6–8 m high, the branches mainly glabrous, some puberulent. **Leaves** glossy, leathery and thick; the blades dark-green above, obovate, oblong, elliptic-oblong, orbicular, oblanceolate, rounded or obtuse at the apex, 3.4–10.7, 1.4–5.7 cm; the petioles 0.4–5 mm long. **Inflorescences** cymose, cymose-paniculate, axillary or terminal, 5.8–6.8 cm long, the branches glabrous; bracts variable in length to minute. **Flowers** white, fragrant, pedicellate. Calyx and hypanthium glabrate, green, calyx 0.2–01.5 mm long. **Corolla** white, 2–6.5 mm long; **lobes** 4–6, straight. **Stamens** 4–6; **filaments** white, 0.8–3.8 mm long, the base with scattered hairs; **anther** yellow, 0.7–3.5 mm long, situated below or above the stigma. **Style** 1.1–6.0 mm long. **Stigma** with 5–8 minute lobes. **Fruit** a drupe, 3 to 5 mm in diameter, globose, dark-purple or whitish-pink; five to 14 celled.

Erithalis was established in 1756 (Browne 1756) based on *E. fruticosa* L. from Jamaica. In 1786, Forster, not aware of P. Browne's description, illegitimately used the name *Erithalis* for a description of an entirely different genus, *Timonius* DC. (= *Timonius* Rumph., originally described in 1743).

Erithalis fruticosa (Fig. 11) is morphologically a highly variable species (Long & Lakela 1976). It is a slow growing, evergreen shrub that typically is 1 to 2 m in height, and can occasionally reach 8 m in height. Commonly, the species has multiple stems arising near the ground. The branches root when they come in contact with the ground. The bark is gray, and smooth to warty. The resinous wood is brown, hard, fine-textured, and heavy. The foliage may be dense or sparse depending on whether the shrubs grow in full sun or partial shade (pers. obs.).

The species flowers and fruits throughout the year (Little et al. 1974; Nelson 1996) with peaks during the dry months of January, February and March. The fruits can be either dark- purple or whitish-pink, and both color fruits occur sympatrically in populations of Andros Island (Bahamas) and Coral Gables, Florida. Acevedo-Rodríguez (1996) observed the whitish-pink fruited form in St. John, U.S. Virgin Islands, Correll reported it in Cat Island (FTG # 46194) and Great Abaco (NY # 45561), and Shafer in Cuba (NY # 2803). The dark-purple fruits have a bittersweet flavor and are dispersed by birds (Bancroft & Bowman 1994; Howard 1989; Liogier 1997; Little et al. 1974; Nelson 1996). Fruits collected in Puerto Rico averaged 0.1087 + 0.0071 g/fruit, and air-dried seeds separated from them averaged 0.00092 g/seed or 1,080,000 seeds/kg (Francis, JK).

Distribution and ecology.—Erithalis fruticosa occurs in Florida, the Bahamas, the Greater and Lesser Antilles, Trinidad, Quintana Roo (Mexico), Belize (Howard 1989; Little et al. 1974), Parque Nacional Moroccoy and Venezuelan Caribbean islands (Liogier 1962), San Andrés, Providencia and Santa Catalina (Colombia; Jiménez-B. 2002), and the island of Fernando de Noronha (Brazil, Pernambuco). Although the species is reported for the Lesser Antilles, I did not see evidence of E. fruticosa during two recent collecting trips to St. Vincent and the Grenadines (Lesser Antilles).

Erithalis insularis is here placed as synonym of *E. fruticosa*, thus extending the range of *Erithalis*' distribution to the Atlantic Ocean. The fruits of *E. fruticosa* are dispersed by the threatened white-crowned pigeon in the Florida Keys and the Bahamas (Bancroft & Bowman 1994). Therefore, it is plausible that the disjunct geographical distribution exhibited by this species (Fig. 1) is a consequence of avian dispersal.

Erithalis fruticosa grows from near sea level to 120 m in elevation in Puerto Rico in areas that receive from 750 mm to about 1800 mm of annual precipitation (Little et al. 1974). The species is drought tolerant, and can grow in open areas and under the canopy of low-density forest. It is most common near beaches, on rock outcroppings and bluffs near the shoreline, especially in moist limestone areas, and on limestone hills in the interior. In Florida, it is found in beach strand vegetation, on sand dunes, and coastal hammocks (Nelson 1996).

Fig. 11. ***Erithalis fruticosa*. A.** Growth habit. **B.** Detail of the flower. **C–D.** White-pinkish (C; *Negrón-Ortiz* 794) and dark-purple (D; *Negrón-Ortiz* 795) fruits. (Photos A, B taken at Discovery Bay, Jamaica, and C, D at Fairchild Tropical Garden, Coral Gable, Florida).

In Martinique, it is reported as a component of the community of the littoral hedge, "a dense thicket at the seaward margin of the littoral woodland" (Kimber 1988).

Representative specimens examined. **U.S.A. FLORIDA. Common names and uses.—'Black torch' (Bahamas, Belize, Florida, Puerto Rico & Virgin Islands); 'Black candlewood' (Cayman Islands); 'Cubra prieta' or 'Rompe machete' or 'Víbona' or Jayajabico' or 'Yayajabico' (Cuba); 'Candlewood' (Lesser Antilles); 'Tea' or 'Manglillo' (Puerto Rico & Virgin Islands).

The wood is resistant to rot and has been used for posts and torches (Kimber 1988; Little et al. 1974; University of the Virgin Islands 2002). Native people from Martinique used boughs of *E. fruticosa* for torches during late 1600s, and by 1930s the natives were still using it, thus contributing to the species decline in that island (Kimber 1988). The bark, fruits, and the resin have diuretic and astringent properties and are used to treat inflammation of the kidney and bladder, and blennorrhoea (Liogier 1990). The leaves are parched and ground for treating skin sores (University of the Virgin Islands 2002). Other uses include treatment of hemorrhoids and measles, and use as a styptic.

The leaves and fruits of *E. fruticosa* are used as a source of food by a few animals. The leaves represent 3.5% of the rock iguanas' diet on Anegada, British Virgin Islands (Mitchell 1999). The fruits are consumed by the Florida Key Deer (Dooley 1975), a Federal Endangered mammal, and by the threatened white-crowned pigeon during nestling (Bancroft & Bowman 1994).

Conservation status.—Threatened in Florida (www.plantatlas.usf.edu/browse2.asp?family=RUBIACEAE).

Erithalis harrisii Urban, Symb. Ant. 5:514. 1908. TYPE. JAMAICA: near Troy, 30 June 1904 (fl), *Harris* 8743 (LECTOTYPE: NY 00115115, here designated).

Shrubs or **small tree** to 3–7.5 m tall, the branches puberulent. **Leaves** glossy above, scabrous below, thick; the blades obovate-oblong to elliptic-oblong, 4–10.9, 1.7–6 cm; the petioles 1–1.9 cm long. **Inflorescences** panicle, axillary or terminal, the branches puberulent; bracts 1–2, 0.9–2.8 mm. **Flowers** fragrant, pedicellate. **Hypanthium** globose. Calyx and hypanthium glabrate, calyx 5-denticulate, 0.5 mm long. **Corolla** white, 4–4.8 mm long; lobes 5, recurved. **Stamens** 5; filaments white, the base densely puberulent, 1.3–4 mm long, as long as or 3/4 as high as the style; **anther** yellow, linear, 1.5–2.5 mm long. **Style** 2.3 –4.5 mm long. **Stigma** of 5–8minute lobes. **Fruit** globose, green when immature, turning red to dark-red when mature or pink.

Distribution and ecology.—This species (Fig. 12) is endemic to the mountains of Jamaica. It is found in a few localities of woodland margins on rough limestone. It grows on rocky banks, at 500–800 m elevations.

Conservation status.—This taxon is listed under the 2003 IUCN Red List of Threatened Species and considered a low risk species, subcategory: nt (WCMC 1997).

Specimens examined. **JAMAICA:** near Troy, 30 Jun 1904 (fl), *Harris* 8743 (NY); syntypes: [NY (00115114), US]. **Trelawny Parish:** 1 Jan 1999 (fl), *Negrón-Ortiz* 789 (MU); 791 (MU); 14 Aug 1963, *Crosby & Anderson* 1196 (LL); Ramgoat cave, N of Albert Town, 29 Jul 1962, *Fosberg* 42935 (NY). **St. Ann Parish:** Mount Diablo, 12 Jul 1989, *Nesbeth & Scott* 078 (MO); road to Hollymount, 21 Sep 1962, *Adams* 11680 (MO). **Clarendon:** 30 Sep 1912, *Harris* 11227 (MO).

Erithalis odorifera Jacq., Select. Stirp. Amer. Hist. 72, pl. 173 (fig. 23: flower & fruit). 1763. *Erithalis fruticosa* L. var. *odorifera* (Jacq.) Grisebach, Fl. Brit. WI. 336. 1861. *Erithalis fruticosa* L. subsp. odorifera (Jacq) Steyermark, Fl. Venez. 9:869. 1974. *Erithalis odorata* Raf., Sylva Tellur. 123. 1838. (LECTOTYPE: Jacquin, Martinique. Plum. ic. 249, f.2., here selected).

Erithalis rotundata Griseb., Mem. Amer. Acad. Arts 2, 8:507. 1862. TYPE: CUBA: Monte Verde, Jan–Jul 1859, *Wright 1268* (LECTOTYPE: GOET!, here designated), ibid, *Wright 1267* (SYNTYPES: GOET!, MO!); ibid, *Wright 1268* [SYNTYPES: MO! (2 copies), NY! (2 copies)].

Large shrubs or **small trees** to 1–8 m tall, the branches glabrous. **Leaves** glossy, leathery and thick or papery; the blades obovate-oblong to elliptic-oblong, 6–13. 3–7.7 cm; the petioles 0.05–3.2 cm long. **Inflorescences** cymose, axillary, 9–9.7 cm long, the branches glabrous; bracts minute to 2.2 cm long. **Flowers** sweet fragrant, pedicellate. Calyx and hypanthium glabrate, calyx 0.5–1.1 mm long. **Corolla** white, 3.9–9 mm long; lobes 5–7, straight, rarely recurved. **Stamens** 5–7; filaments white, the base glabrous or with scattered hairs, 1.5–5 mm long; **anther** yellow, linear, 2–5 mm long. **Style** 1.2–8 mm long. **Stigma** of 5–8 minute lobes, rarely bi-lobed. **Fruit** a drupe, globose, dark-purple when mature.

Distribution and ecology.—The Bahamas, Greater and Lesser Antilles, and Caribbean coast of Venezuela.

Erithalis odorifera (Fig. 13) grows near the beach, on sandy coastal thickets, coppice, along the road, and from sea level to ~300 m in elevation; occurring solitary to abundant. This species is very distinctive in the Lesser Antilles, and according to Sandwith (1938), "it appears to replace *E. fruticosa*" in most of these

Fig. 12. *Erithalis harrisii*. **A.** Portion of a small tree with glossy leaves (arrows). **B.** SEM of the style and stamens. Common names and uses.—'Scented blacktorch' (Bahamas, Puerto Rico); 'Bwa flanbo' or 'Bwa chandèl' or 'Flambeau noir' or 'Bois chandelle' or 'Bois flambeau' (Dominica, Martinique); 'Parrot apple' (Tobago). In Dominica, the plant (part not specified) is used as a drink ('spirits'), and the twigs as charms against spirits/witches [label data, *Higgins* 102 (NY)].

Erithalis quadrangularis Krug & Urb., Notizbl. Königl. Bot. Gart. Berlin. 1:320. 1897. Type: JAMAICA: Manchester, 29 Apr 1896, *Harris 6318* (holotype: B-destroyed; lectotype: NY!, here designated).

Large shrub or **small tree** to 3.5–9 m tall, the branches glabrous. **Leaves** leathery and thick; the blades oval, ovate-elliptic, 8–21.6, 3.5–9.2 cm; the petioles 1–1.9 cm long. **Inflorescences** cymose-corymbose, axillary or terminal, 5.25–11.5 cm long; bracts 3.5–10.4 cm long. **Flowers** fragrant, pedicellate. Calyx and hypanthium glabrate or puberulent, calyx denticulate, 1–2.1 mm long. **Corolla** white, turning yellow, 6.8–12 mm long; lobes 6–8, recurved. **Stamens** 6–8; filaments white, 3–7.8 mm long, the base with scattered hairs; **anther** yellow, linear, 3.5–4.8 mm long. **Style** 4.5–10 mm long. **Stigma** of 5–8 minute lobes. **Fruit** subglobose.

Distribution and ecology.—*Erithalis quadrangularis* (Fig. 14) is endemic to Jamaica and to St. Vincent and the Grenadines. Known from a few Jamaican parishes: St. Ann, Clarendon, Manchester, and from Unity Valley district. It grows in woodlands on limestone, on rocky slopes, along roads, from sea level to 457 m elevation, and is not common. Although in many cases morphologically similar to *E. odorifera*, *E. quadrangularis* could be distinguished by longer, wider and thicker leaves, longer inflorescences, and recurved corolla lobes.

Conservation status.—This taxon is listed under the 2003 IUCN Red List of Threatened Species and represents a vulnerable species, criteria: B1, 2c (WCMC 1997).

Specimens examined. **JAMAICA. Unity Valley District:** between Moneague and Mt. Diablo, 2 Jul 1965, *Proctor* (I.L). **St. Ann Parish:** 23 May 1965, *Proctor* 26422 (I.L); Douglas Castle District, 11 Jun 1976, *Thorne & Proctor* 48167 (NY); Albion Pen, 12 May 1915, *Harris* 12013 (NY). **Clarendon Parish:** 22 May 1912, *Harris* (NY); Peckham Woods, May 1955, *Robertson* 2005 (NY)**: Manchester Parish:** Maudeville, 21–23 Sep 1908, *Britton* 3748 (NY); New Yveeu, 21–23 Sep 1908, *Britton* 3756 (NY); Marshall's Penn, 30 May 1959, *Proctor* 19678 (NY); vicinity of Marshall's Penn Est., 23 Apr 1961, *Kramer & Proctor* 1682 (NY); 25 Jul 1997, *Barcelona et al.* 1196 (MU). **Near Manchester:** New Greon, 29 Apr 1896, *Harris* 6318 (NY). **LESSER ANTILLES. St. Vincent and the Grenadines:** along the road, Jan 2000, *Negrón-Ortiz* 806 (MU).

Erithalis salmeoides Correll, J. Arnold Arbor. 58:49. 1977. TYPE: BAHAMAS. GREAT INAGUA: between Conch Shell Point and Lanter Head, 3 Aug 1975, *Correll* 45897 (HOLOTYPE: A!, ISOTYPE: FTG!).

Shrubs 3–7.5 m tall, the branches glabrous. **Leaves** leathery and thick; the blades obovate to broadly oval, rounded at the apex, 1.9–4.7, 1.2–3.8 cm; the petioles 0.4–0.9 cm long. **Inflorescences** cymose, cymose-paniculate, axillary, 4.5–5.4 cm long, glabrous; bracts variable to minute. **Flowers** fragrant, pedicellate. **Calyx** and hypanthium glabrate, calyx denticulate, 0.1–0.6 mm long. **Corolla** white, 1.7–4 mm long; lobes 4–5, straight. **Stamens** 4–5, longer than the style; filaments white, 0.3–2.5 mm long, the base with scattered hairs; **anthers** ellipsoid, 0.2–1.9 mm long. **Style** 0.5–2 mm long. **Stigma** bi-lobed. **Fruit** orbicular, dark-purple or whitish-pink.

Distribution and ecology.—Bahamas (Fig. 15): Great Inagua, Little Inagua, Mayaguana; Turks & Caicos; Dominican Republic, Jamaica, and Cuba.

This species is morphologically variable. In the southern Bahamian islands,

Fig. 14. *Erithalis quadrangularis* (*Proctor* 26422) from St. Ann Parish, Jamaica.

the species is reported as a low shrub, but in other areas it is taller in habit and morphologically (e.g., leaf size and shape, inflorescence length) indistinguishable from *E. fruticosa*, except for the position of the anthers with respect to the stigma height and the bi-lobed stigma (vs. stigma of 5–8 minute lobes, stamens positioned ≤ than the style, in *E. fruticosa*). In the molecular data phylogeny several specimens of *E. salmeoides* are placed in a polytomy with *E. fruticosa*, suggesting a close relationship or hybridization between these species.

Representative specimens examined. **BAHAMAS. Great Inagua:** Nov 1890, *Hitchcock s.n.* (MO), Salt Point Hill, 15 Dec 1997, *Freid* 97-093 (MU); 12 Oct 1904, *Nash & Taylor* 949 (NY); between Conch Shell Point and Lanter Head, 3 Aug 1975, *Correll* 45897 (Isotype FTG); near Smith's Thach Pond, between Conch Shell Point and Lanter Head, 23 Jul 1976, *Correll* 47475 (FTG, MO); near entrance to Flamigo Reserve, 27 Jul 1976, *Correll* 47565 (FTG). **Little Inagua:** Moujean Harbor, 17 Jul 1976, *Correll* 47351 (FTG). **Mayaguana:** S of Low Point Bay, 8 Feb 1973, *Proctor & Gillis* 33173 (MO). **Turks & Caicos:** Pine Cay, 24 Jan 1993, *Raven* 28205 (FTG, MO, NY); Salt Cay, Long Bay Point, 13 Jun 1979, *Buden* 23 (FTG); Providenciales, 16 Dec 1975, *Correll* 46406 (FTG, NY); 17 Dec 1975, *Correll* 46445 (FTG, NY). **Grand Turk:** Mount Wisdom, 20 Dec 1975, *Correll* 46558-A (FTG, NY). **CUBA. EXCLUDED TAXA

Illegitimate names include: *Erithalis obovata* Forst., *Erithalis timon* Spreng., and *Erithalis polygama* Forst. var. *timonius* Willd., all of which are synonyms of *Timonius timon* (Spreng.) Merr. var. *timon* (Darwin 1993). *Erithalis uniflora* Gaertn. is *Polyphragmon minus* A. Rich. ex DC., a description based upon a fruit of unknown origin (Standley 1934), and *Erithalis cymosa* Forst. is *Timonius forsteri* DC (Candolle 1830; Lioger 1962). *Erithalis pentagonia* DC is synonym of *Dendropanax arboreous* (L.) Dec. & Planch; Araliaceae), described from Cuba (Liogier 1962; Standley 1934).

ACKNOWLEDGMENTS

This research was made possible by grants from the National Science Foundation (DEB-9807089) and Willard Sherman Turrell Herbarium (#174) to V. Negrón-Ortiz. Special thanks go to the directors and curators of BM, FTG, GOET, GH, LL, MO, MU, NY, TEX and US for loaning specimens and/or sending images of type specimens; to David L. Gorchov for assistance in the field and constructive comments on earlier drafts; to Piero Delprete and Tim McDowell for helpful comments and greatly improving this manuscript; to Michael Vincent for providing assistance with nomenclature and constructive suggestions on previous drafts; to Piero Delprete, Ethan Freid, Tim McDowell and Lara I. Strittmatter provided leaf material used for molecular studies.

RESUMEN

Se describe e ilustra una nueva especie de Arecaceae (**Aiphanes stergiosii** M. Niño, Dorr, & F.W. Stauffer), y se presenta una clave para distinguir entre la nueva especie con especies relacionadas. Así mismo, se mencionan aspectos ecológicos y geográficos de su distribución.

ABSTRACT

A new species of palm (**Aiphanes stergiosii** M. Niño, Dorr, & F.W. Stauffer) is described and illustrated, and a key is given to distinguish this new species from related ones. In addition, information is provided on the ecology and geographical distribution of this new species.

INTRODUCCIÓN

El género *Aiphanes* Willd. (Arecaceae) tiene amplia distribución en el neotrópico con su centro principal de diversidad en el oeste de Colombia y Ecuador (Borchsenius y Bernal 1996). Hasta los momentos se conocen 23 especies de este género (Borchsenius y Bernal 1996; Bernal 2001). En la revisión de Borchsenius y Bernal (1996) solamente *A. aculeata* Willd. fue reportada en Venezuela y localizada en los estados Barinas, Delta Amacuro (localidad tipo del sinónimo *A. orinocensis* Burret), Miranda (localidad tipo de la especie) y Sucre. En el neotrópico, *A. aculeata* se distribuye desde Trinidad y Venezuela hasta Bolivia y Brasil (Henderson et al. 1995).

Recientes exploraciones botánicas por los Andes de Venezuela, llevadas a cabo por la Universidad de Los Llanos Occidentales "Ezequiel Zamora" (UNELLEZ) y el Smithsonian Institution de Washington, DC (U.S.A.) en el Parque Nacional Guaramacal, han dado como resultado el hallazgo de una nueva especie de *Aiphanes* para la ciencia, así como nuevos registros de distribución de palmas para la región andina venezolana (Dorr et al. 2000). El Parque Nacional Guaramacal está ubicado, entre los estados Portuguesa y Trujillo, coordenadas 9°21'-9°02' latitud Norte y 70° 00-70°15'30" longitud Oeste (Cuello y Romero 1999; Dorr et al. 2000).

Aiphanes stergiosii M. Niño, Dorr, & F.W. Stauffer, sp. nov. (**Fig. 1**). TIPO: VENEZUELA. PORTUGUESA. Municipio Sucre: Parque Nacional Guaramacal, "La Concepción" (Coord UTM 19-382.173 E y 1.033.526 N), 1700 m, Dic 2000, *M. Niño & B. Stergios 1431* (HOLOTIPO: PORT; ISOTIPOS: K, US, VEN, Z-ZT).

Differt a *A. lindeniana* habitu solitaro, foliis glabris, costa prominente in superficiebus ambabus folii, pedunculo magis angustiore (3-5 vs. 7-8 mm lato basi), sepalis floris pistillatae brevioribus (1-2.5 mm vs. 3.5-7 mm longis) et marginibus semper fimbriatis-adpressis.

Palma solitaria de hasta 6 m de altura. Tallo densamente espinoso, 2-4 m de altura, 3-4.5 cm de diámetro; espinas pardo-negruzcas, agrupadas en el centro del entrenudo, con espinas aplanadas, grandes y pequeñas de 1-9 cm de largo, base estrecha de 0.5-2 mm que se reduce a una acícula a partir de la parte media, generalmente descendentes. Hojas 4-8 por planta, ligeramente arqueadas; vaina foliar de 18-20 × 3-3.5 cm, con indumento blanquecino, espinas similares a las del tallo, 0.2-8 cm de longitud, la base ligeramente cubierta con indumento de la vaina o completamente lisa y brillante. Pecíolo de 20-30 cm de longitud, glabro, espinas largas en la base, hasta 9 cm de longitud, muy pocas y pequeñas en el ápice. Raquis de 85-95 cm de longitud, dorsalmente costado, de 4-6 mm de ancho en su parte media, cara adaxial con ninguna o muy pocas espinas, cara abaxial siempre con espinas, progresivamente de menor tamaño y cantidad hacia el ápice; espinas aceriformes, negras, dispersas, algunas con indumento blanquecino en la base, hasta 3.5 cm de longitud. Pinnas 18-24 por lado, insertas en grupos de 3-6. Pinnas mediales de 10-25 cm de largo y 5-8.5 de ancho, el ápice glabro por ambas caras, casi siempre con 0-4 espinas dispersas en el nervio central de la haz, bordes laterales lisos, glabros o con espinas dispersas de 1-5 mm de largo; ápice truncado, proyección distal sobresaliendo en una cauda de 5-25 mm de largo, con algunas espinas presentes muy delgadas de 1-4 mm de longitud; nervio medio amarillento y prominente en la haz y el envés, con 0-15 espinas en las nervaduras de la haz de 5-15 mm de largo, el envés sin espinas. Pinna apical casi siempre partida en dos (producto de la acción del viento fuerte) o entera, con borde apical praemorso, 15-25 cm de longitud y 15-24 cm de ancho, glabra, con 10-12 nervios prominentes por ambas caras, y 0-3 espinas de 5-15 mm de longitud. Inflorescencia interfoliar, péndula, 1-ramificada; prófilo inserto desde la base del pedúnculo, aplanado, glabro, hasta 45 cm de longitud y 1.4 cm de ancho; bráctea del pedúnculo ligeramente tomentosa, con algunas espinas negras dispersas, 90-120 cm de largo y 4-5 cm de ancho; pedúnculo terete, de 100-120 cm de largo y 3-5 mm de diámetro en la base, cubierto con espinas pardo-negruzcas pequeñas y cilíndricas de 5-20 mm de largo, con indumento

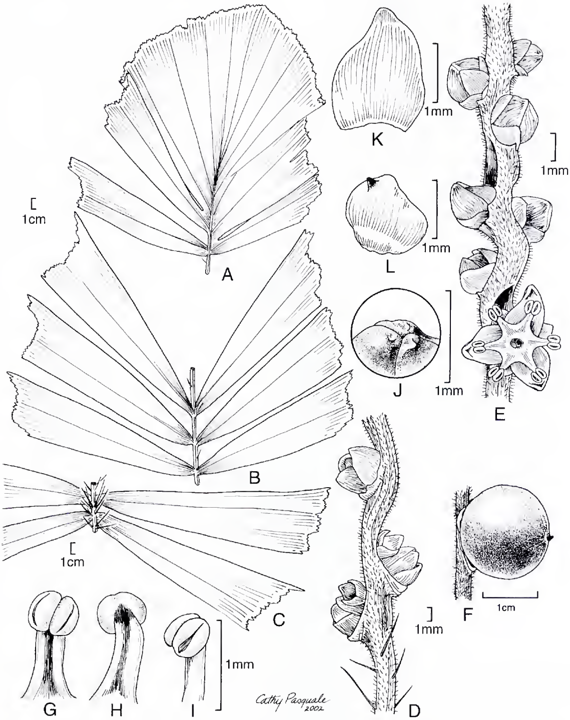

Fig. 1. *Aiphanes stergiosii* M. Niño et al. **A.** Apice de una hoja (la mayoría de los ápices eventualmente se presentan divididos, probablemente por factores ambientales). **B.** Parte media de una hoja. **C.** Base de una hoja. **D.** Flores estaminadas y pistiladas. **E.** Flores estaminadas. **F.** Fruto. **G–I.** Anteras. **J.** Pistilodio. **K–L.** Sépalos de una flor estaminada (todo basado en *Niño & Stergios 1431*, US).

ferrugíneo disperso; raquis hasta 35 cm de longitud, densamente ferrugineo-tomentoso, decreciendo en grosor desde 4 mm en la base a 1 mm en el ápice, con espinas de 5–12 mm de longitud decreciendo en tamaño y cantidad hacia el ápice del raquis; raquillas con espínulas pardo-negruzcas, densamente tomentosas, presenta una bráctea muy delicadas y caedizas en su base; raquillas basales de 20–45 cm de largo y 0.7–1 mm de grosor en su parte media, espinas en la base, con tríadas insertas cercanas a la base hasta 2/5 de la raquilla, luego flores estaminadas hacia el ápice; raquillas apicales de 5–12 cm de largo, sin espinas, con flores estaminadas en díadas, estrechamente cercanas o formando pares. Flores estaminadas blancas a violeta claro, superficiales, ligeramente sumergida dejando una pequeña concavidad; sépalos imbricados, 0.1–0.2 mm connados en la base, luego libres, 0.5–1 mm de largo; pétalos libres de 1.2–1.9 mm de largo; estambres 6, filamentos de 0.8–1.2 mm de longitud; anteras con 0.5–0.6 mm de longitud y 0.4–0.6 mm de ancho, dorsifijas, blancas, dehiscentes longitudinalmente y a los lados de cada teca, conectivo claro; pistilodio rugoso, piramidal, de 0.3–0.4 mm de altura; polen ovoideo, monosulcado. Flores pistiladas púrpura en la antesis; sépalos 1–2.5 mm de longitud, libres, imbricados, glabros, fimbriado-adpreso por los bordes; pétalos 3–4.5 mm de largo, connados ca. hasta la mitad de su longitud, o ligeramente más arriba, valvados, lóbulos triangulares; pistilo glabro, liso, piramidal, unicuspidado, de 2–3 mm de longitud; anillo estaminodial 2–3 mm de alto. Fruto globoso rojo o naranja, epicarpo liso y brillante, caedizos, con 10–15 mm de diámetro.

Distribución y ecología.—*Aiphanes stergiosii* es únicamente conocida del lugar tipo, en la vertiente sur del Parque Nacional Guaramacal entre 1600 y 2000 m. La comunidad de palmas posee mayor densidad a 2000 m, donde el suelo es poco profundo, arenoso y el bosque es más abierto por los fuertes vientos que dominan en la zona. El bosque donde habita es de montaña, húmedo, siempre verde, pluriestratificado, con abundantes epifitas y árboles de hasta 25 m de altura. La intervención humana es muy escasa dado lo inaccesible del sitio, solo hay evidencia de cazadores esporádicos.

El fruto de *Aiphanes stergiosii* es consumido por animales silvestres del bosque, seguramente por pequeños y medianos mamíferos, dadas las características de las mordidas en restos de frutos encontrados en el suelo, además de algunas huellas. Como es de suponer, la dispersión de las semillas la realizan estos animales y algunas aves de gran porte, como tucanes. Al observar el sitio donde deberían caer los frutos, se aprecia que incluso las semillas son consumidas totalmente y/o transportadas. Como indica Utrera (1999), la mastofauna del Parque Nacional Guaramacal, asociada a los bosques montanos, se caracteriza por el predominio de especies de hábitos alimentarios primordialmente frugívoros. Sin embargo se puede apreciar buena regeneración de la especie, dado que se observan pequeñas plantas dispersas en el área.

Nombre vulgar.—macanilla.

Relaciones taxonómicas.—Hasta los momentos la única especie reportada para el género en Venezuela es *Aiphanes aculeata*, la cual se puede distinguir de *A. stergiosii* por formar colonias en tierras bajas entre 100–500 m, además de poseer, hojas grandes con más de 2 m, foliolos tricuspidados y flores amarillentas. Las especies más relacionadas se encuentran en la región de los Andes Occidentales de Colombia, entre ellas están: *A. lindeniana* (H. Wendl.) H. Wendl., *A. hirsuta* Burret, y *A. erinacea* (H. Karst.) H. Wendl.

Aiphanes lindeniana es probablemente la especie que mayor afinidad tiene con *A. stergiosii*, además de compartir hábitats similares, poseen caracteres comunes como la inflorescencia 1-ramificada, espinulosa, con flores violeta o blancas y fruto globoso, naranja o rojizo. Se pueden distinguir principalmente por el aspecto que tiene *A. lindeniana* de ser más robusta y tener abundantes y densas espinas, con tendencia a formar colonias cespitosas, aunque se puede presentar solitaria. Las características más resaltantes que la separan de *A. stergiosii* son el indumento ferrugíneo en el pecíolo y raquis de la hoja; los foliolos con indumento y finamente espinuloso por el envés; las espinas pequeñas y abundantes en los bordes; los nervios principales espinosos, prominentes solo por la haz; y el envés pubescente a espinoso. El pedúnculo de la inflorescencia de *A. lindeniana* es grueso (7–10 mm de diámetro) y con gran densidad de espinas grandes (2–4.6 cm de largo); las flores pistiladas son evidentemente de mayor tamaño (hasta 7 mm de longitud), los sépalos en sus bordes son ligeramente fimbriado-adpresos (no muy evidente); el ovario ovoide a subgloboso; el polen es casi siempre globoso, con la exina finamente reticulada. No logramos ver el holotipo de *A. lindeniana*, pero si examinamos algunos especimenes referidos por Borschenius y Bernal (1996) (ver el Apéndice I).

Aiphanes stergiosii, en todas las colecciones realizadas en Venezuela, se le ha observado solitario; el raquis de la hoja sin indumento, liso con algunas espinas dispersas; los foliolos en sus bordes no tienen espinas o se presentan algunas dispersas, son glabros por ambas caras; los nervios principales son prominentes por ambas caras, los del envés no tienen espinas y algunas espinas están presentes en la haz; el pedúnculo de la inflorescencia es delicado hasta con 5 mm de diámetro, las espinas son ralas o escasas y pequeñas (0.3–1 cm de largo); las flores pistiladas son pequeñas, no mayores de 5 mm de longitud, los sépalos poseen una línea amarillenta, evidentemente fimbriado-adpresa de 1–2 mm de longitud; el ovario es piramidal; el polen es ovoide, ligeramente perforado y verrucoso (Fig. 2).

Otra especie similar es *Aiphanes erinacea*, hasta ahora sólo colectada en Colombia y Ecuador. Se puede diferenciar básicamente por poseer un hábito cespitoso, además de ser una planta de menor tamaño (hasta 5 m de tallo), conspicuamente prostrada, las hojas poseen espinas amarillas, y las pinnas están

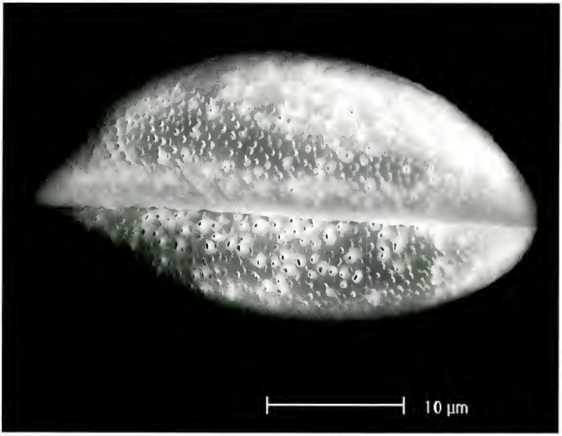

Fig. 2. Grano de polen de *Aiphanes stergiosii* M. Niño et al. en MEB (*Niño & Stergios 1431*, US).

en grupos de 2–3 (–4), el fruto es rojo oscuro, el polen es ovoideo con evidentes verrugas o espinas supratectales (Borchsenius y Bernal 1996).

Aiphanes hirsuta tiene un amplio rango de distribución geográfica y altitudinal (100–2200 m), aparece una forma en Centro América (Costa Rica y Panamá), así como en Colombia y Ecuador, con gran variabilidad. Sin embargo, difiere ampliamente de *A. stergiosii*, por ser cespitosa los foliolos en su cara abaxial poseen espínulas amarillentas, el pedúnculo de la inflorescencia es densamente armado con espinas de 3–5 cm de longitud, el fruto (casi siempre espinuloso) es rojo oscuro hasta púrpura, ocasionalmente blancuzco.

Existe una separación geográfica entre *Aiphanes stergiosii* y las especies relacionadas más cercanas, ca. 600 km con *A. lindeniana*, existiendo además barreras ambientales muy amplias, como el valle del Río Uribante (en Venezuela), que baja a tan solo 300 m, y los altos andes de la Sierra Nevada de Mérida, donde hasta ahora no se ha reportado otra especie de *Aiphanes*. Por este motivo también descartamos la posibilidad de una forma geográfica. La comparación entre especimenes colombianos nos evidencia la similitud entre ellos, pero también una notoria diferencia con la de Venezuela. Pensamos que se trata de una nueva especie que puede ayudar a dilucidar la especiación de este grupo de palmas en los andes.

CLAVE PARA DISTINGUIR LAS ESPECIES DE *AIPHANES* DE VENEZUELA DE ALGUNAS RELACIONADAS DE CENTRO AMÉRICA Y LA CORDILLERA NOROCCIDENTAL DE COLOMBIA

1. Tallos de 3–10 m × 6–10 cm; raquillas con indumento peltado, raramente espinoso; pistilodio de 0.5–1 mm de longitud (Venezuela, Colombia, Trinidad y Tobago, Brasil, Perú) ________ **A. aculeata** Willd.
1. Tallos de 3–6 m × 3–5 cm; raquillas pubescentes, glabras o espinosas; pistilodio diminuto hasta 0.5 mm de longitud (Costa Rica, Panamá, Venezuela, Colombia, Ecuador).
    2. Planta generalmente multicaule, alguna monocaule.
        3. Tallos y/o hojas armados con espinas amarillas.
            4. Inflorescencia sin ramificaciones; tallos hasta con 2 cm de diámetro (Oeste de Colombia) ________ **A. simplex** Burret
            4. Inflorescencia ramificada; tallos de 2.5–5 cm de diámetro (Colombia y Ecuador) ________ **A. erinacea** (H. Karst.) H. Wendl.
        3. Tallos y hojas armados con espinas negras o pardo oscuro.
            5. Ramas de la inflorescencia densamente cubierta de espínulas.
                6. Pinnas basales de 17–45 × 1–13 cm; fruto espinuloso, rojo oscuro a violeta (Costa Rica, Panamá, Colombia, Ecuador) ________ **A. hirsuta** Burret
                6. Pinnas basales de 7–20 × 0.5–1.5 cm; fruto completamente glabro, rojo claro a naranja (NO de Colombia) ________ **A. lindeniana** (H. Wendl.) H. Wendl.
            5. Ramas de la inflorescencia sin espínulas ________ **A. leiostachys** Burret
    2. Planta monocaule.
        7. Raquis de la hoja con indumento y finamente espinuloso; foliolos con borde densamente espinosos, envés con indumento y espinuloso, nervios principales del envés pubescentes a espinosos y la haz con hilera de espinas; base del pedúnculo de inflorescencia de 5–10 mm de diámetro (NO de Colombia) ________ **A. lindeniana** (H. Wendl.) H. Wendl.
        7. Raquis de la hoja casi siempre sin indumento, liso con algunas espinas dispersas; foliolos con bordes sin espinas o con algunas espinas dispersas, glabros por ambas caras; nervios principales del envés sin espinas, algunas espinas presentes en la haz pero sin formar una hilera continua; base del pedúnculo de inflorescencia de 3–5 mm de diámetro (Venezuela) ________ **A. stergiosii** M. Niño et al.

ABSTRACT

Three new species of *Vaccinium* (Ericaceae) are described from Costa Rica and Panama: ***Vaccinium almedae*** Wilbur & Luteyn, ***V. furfuraceum*** Wilbur & Luteyn , and ***V. luteynii*** Wilbur.

Key Words: Ericaceae, *Vaccinium*, Costa Rica, Panama

RESUMEN

Se describen tres nuevas especies de *Vaccinium* (Ericaceae) de Costa Rica y Panamá: ***Vaccinium almedae*** Wilbur & Luteyn, ***V. furfuraceum*** Wilbur & Luteyn, y ***V. luteynii*** Wilbur.

Palabras Claves: Ericaceae, *Vaccinium*, Costa Rica, Panama

INTRODUCTION

In order to validate the names of three new species of *Vaccinium* (Ericaceae) prior to their appearance in William Burger's *Flora Costaricensis*, which frowns on such distractions appearing therein, their descriptions are presented here. A discussion of the presumed relationships of each of these species will appear in a later paper treating systematically all the species of *Vaccinium* known from Mexico and Central America.

Vaccinium almedae Wilbur & Luteyn, sp. nov. (**Fig. 1**). Type: PANAMA. Chiriquí: Edwin Fabrega Dam and Reserve in Fortuna, along trail to hydrological station, along Río Hornito, below forestry house along the road in wet forest, 8°45'N, 82°05'W, 1200 m, 20 Jan 1989 (fl), *Almeda,de Nevers & McPherson* 6369 (holotype: PMA!; isotypes: CAS!, DUKE!, MO, NY!).

Frutex epiphyticus 1–2 m altus. Folia coriacea, integra, glabra; nervatioa camptrodroma. Petioli 7–15 × 2–3.5 mm, glabri. Inflorescentiae ramiflorae fasciculatae; pedicelli 5–10 mm longi, gracili; bracteolae 2, deltatae, 0.5–0.8 mm longi; margo fimbriato. Calyx pedicellis articulatus, 3–4 mm longus, glabrus; lobi calycis triangulari acuti, 0.2–0.4 mm alti. Corolla cylindrica glabra, 5–9 mm longa; lobi corollaei 5, ca. 2.5 mm longi. Stamina 10, filamenta 1–2.5 mm longa, glabra; thecae 1.4–2.2 mm longae, laevigatae, tubuli separati, gracili 3–4.8 mm longi, truncati.

Coarse, rigid, epiphytic **shrubs** 1–2 m tall; branchlets and branches ± terete, glabrous or nearly so but current season growth not present, thin, brownish or

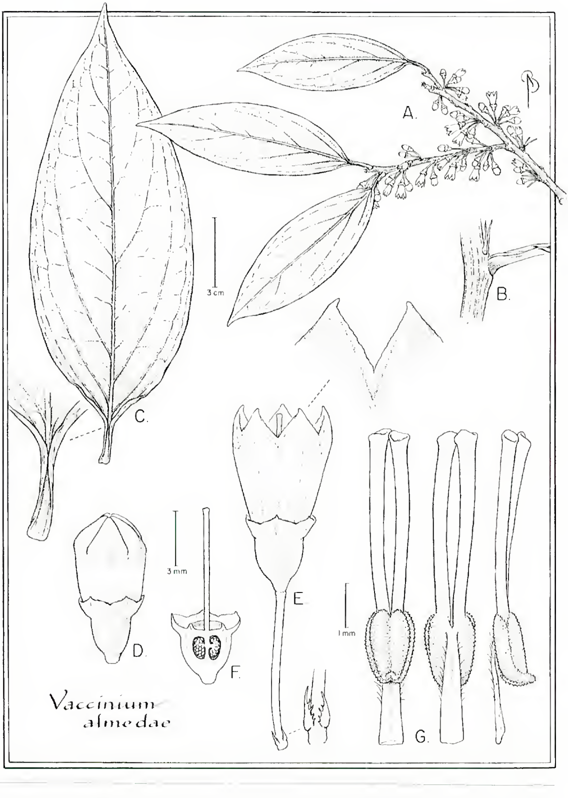

Fig. 1. *Vaccinium almedae*. **A.** Habit. **B.** Detail of leaf axil showing pseudostipular axillary bud scales. **C.** Leaf with detail of adaxial portion of blade-petiole junction. **D.** Flower in bud. **E.** Flower at anthesis with detail of basal pedicellary bracteoles and the thinner sinus tissue between the corolla lobes. **F.** Longitudinal section of gynoecium through calyx. **G.** Stamens showing ventral, dorsal, and lateral views (all drawn from the holotype, *Almeda et al. 6369)*.

grayish. **Leaf-blades** coriaceous, elliptic, mostly 6–18 cm long, 3–7.5(–9) cm broad, apically acute to acuminate, basally rounded to shortly tapering and sometimes curling or somewhat conduplicate around the petiole at the junction, marginally entire, glabrous on both surfaces, the venation 3-5-plinerved, the veins ± depressed above except the midrib elevated for the proximal third to half while elevated beneath through the 3–4 order and forming an indistinct reticulum; petioles mostly 7–15 mm long, 2–3.5 mm diam., somewhat flattened above and there rather broadly and shallowly grooved, glabrous. **Inflorescences** mostly ramiflorus, of several to numerous, sessile fascicles (2–10-flowered) emerging from small, depressed mounds 1–2 mm diam., 1–2 mm long; floral bracts ciliate, scale-like, 0.6–1.5 mm long; pedicels slender, glabrous, 5–10 mm long, 0.2–0.3 mm diam.; bracteoles 2, ciliate, deltoid, 0.5–0.8 mm long. **Flowers** 5-merous; calyx ca. 3–4 mm long, clearly articulate with the pedicels, the hypanthium cylindric-obconic, ca. 1.5–2.2 mm long, 1.6–2 mm diam., glabrous, the lobes broadly based, minute, varying from barely detectable to perhaps as much as 0.2–0.4 mm long, glabrous; corolla cylindric to more typically gradually funnelform, glabrous both externally and internally, greenish-white, 5–9 mm long, flaring to ca. 5–6 mm diam. from a 2–2.5 mm diam. base, the lobes narrowly triangular to deltoid, acute, ca. 2.5 mm long; stamens 10, included, 7–8 mm long, the filaments 1–2.5 mm long, united in the basal 0.5 mm, glabrous, flattened, the anthers attached medially, lacking spurs, 6–7 mm long, the thecae very finely pebbled, ca. 1.4–2.2 mm long, basally incurved and apiculate, the tubules ca. 3–4.8 mm long, dehiscing by truncate to slightly flaring, terminal pores; styles slightly exserted, glabrous. **Berry** immature, 3–4 mm diam., glabrous.

Distribution.—Presently known only from five collections; three made near the Fabrega Dam site at Fortuna (Chiriquí Province), one from Cerro Colorado (Bocas del Toro Province), Panama in wet forest, at 1150–1500 m, and one from Cerro Arizona near Santa Fe, Veraguas Province. Flowering: Jan.; immature fruits: Apr.

Additional collections examined: **PANAMA. Bocas del Toro:** region of Cerro Colorado 7 mi from Chami Camp, ca. 8°35'N, 81°45'W, ca. 1500 m, 12 Apr 1986, *McPherson 8825* (MO!). **Chiriquí:** Fortuna Dam region, along trail to hydrological station on Río Hornito, below forestry house on hwy, 8°45'N, 82°15'W, 1150–1200 m, 20 Jan 1989, *McPherson 13612* (DUKE!, MO!); Fortuna dam site, along stream on white sandy soil, 1200 m, 7 Feb 1985, *van der Werff & van Hardeveld 6609* (MO, photo NY neg. 13043). **Veraguas:** in forest below summit of Cerro Arizona, above Santa Fe, elev. 4400 ft, *Hammel & Kress 8568* (DUKE!)

ISOTYPE OF
Vaccinium furfuraceum Wilbur & Luteyn

Fig. 2. *Vaccinium furfuraceum*. Isotype (*Herrera 3286*, DUKE)

Much-branched, epiphytic, lianoid **shrubs** with branchlets brownish, ± terete, finely ridged and grooved, densely spreading hirsutulous, 1.5–4 mm diam. **Leaf-blades** somewhat coriaceous, ovate to ovate-elliptic, (2.5–)4–6 cm long, (1.2–)1.8–2.5 cm broad, basally rounded, apically acuminate and ± tapering abruptly to the narrowly rounded tip, marginally entire, glabrous above or nearly so except moderately pilose along the principal veins, moderately to densely spreading pilose beneath along the principal, secondary and even tertiary veins with hyaline trichomes up to 0.7 mm long and also densely beset especially when young with short, thick, glandular, scale-like trichomes ca. 0.1–0.2 mm long on both the veins and the surface, the venation weakly 5-plinerved, the secondary nerves joining together in a series of prominent arches, the lamina ± bullate, the midrib and secondary veins impressed above and elevated beneath and the tertiary veins slightly elevated on both surfaces; petioles 2–3(–4) mm long, densely spreading pilose. **Inflorescences** axillary, congregated distally, sometimes appearing terminal, racemes but with the rachis often contracted and the flowers hence appearing somewhat corymbose, 3–10(–12) flowered, 2.5–5 cm long overall; rachises (2–)4–8 mm long, densely glandular-strigillose with thickened trichomes 0.1–0.3 mm long and sparingly to moderately pilosulous with hyaline spreading trichomes, 0.3–0.6 mm long; floral bracts narrowly lanceolate to linear-lanceolate, marginally glandular ciliate, 2.5–2.6 mm long; pedicels (0.6–)1–2(–2.4) cm long, moderately to densely glandularly strigillose and also sparingly pilosulous with hyaline trichomes; bracteoles 2, appressed, linear-lanceolate, glandular-ciliate, located in about proximal third, ca. 2.8 mm long. **Flowers** 5-merous; calyx 3–4.5 mm long, strongly articulate with pedicels, the hypanthium shallowly obconic, ca. 1.5 mm long, ca. 5–6 mm diam. distally, prominently flaring from the approximately 3 mm diam. basal portion, densely and scurfily glandular-squamate throughout, the limb ca. 3 mm long including the lobes, the lobes deltoid-triangular to broadly oblongish with an abrupt distal tip, ca. 1–1.2 mm long, ca. 2.3 mm broad at base; corolla broadly cylindrical, relatively thin in texture, densely scurfily glandular-squamate externally, glabrous internally, the tube 8–12 mm long, ca. 8 mm in diam. distally, the lobes triangular, 2.5–3 mm long, ca. 3 mm broad basally, acute; stamens 10, included, ca. 7–9.5 mm long, the filaments conspicuously hyaline ciliate, flattened, 2–3 mm long, the anthers lacking spurs, ca. 7 mm long, the thecae granular, 2–2.2 mm long, basally incurved, the tubules ca. 3–5 mm long, dehiscing by latrorse, elongate clefts ca. 1–2 mm long; styles about as long as the corolla, straight, glabrous. **Berry** not seen.

Distribution.—Known only from the type collection made in Costa Rica in the Talamanca foothills of Limón Province at ca. 700 m.

Vaccinium luteynii Wilbur, sp. nov. (**Fig. 3**). TYPE: PANAMA. BOCAS DEL TORO: Fortuna Dam-Chiriquí Grande Road, 2–3 km N of the Continental Divide, ca. 8°48'N, 82°12'W, 700–

760 m, disturbed, steep roadside slopes, 15 Oct 1998 (fl), *Luteyn, Riggs,Guerra, and Sylva 15322* (HOLOTYPE: PMA!, ISOTYPES: AAU!, CAS!, DUKE!, E!, G!, K!, MO!, NY!, TEX!, US!).

Frutex epiphyticus; ramuli teretes glabri. Folia coriacea glabra, ovata vel ovato-elliptica vel oblongo-ovata, basi rotundata, apice acuta vel acuminata, lamina 5–15 × 3–6 cm; petioli glabri, 1–5 mm longi. Calyx pedicellis articulatus; hypanthium subglobosum, succulentum, glabratum, ca. 1 mm altum y 4–4.5 mm diam.; limbus calycis 3 mm longus, 10-lobata, lobi calycis 5, 0.6–1 mm longi acuti glabri; corolla succulenta, urceolata ad campanulata ca. 5–10 mm alta, ca. 6 mm diam.; extus glabra, intus pilosi, lobi corollae ca. 3 mm longi acuti.

Terrestrial or epiphytic **shrubs** to 4 m tall, with tan to dull reddish-brown, glabrous, terete branches. **Leaves** subopposite, the blades coriaceous, ovate to oblong-ovate or ovate-elliptic, ca. 5–15 cm long, 3–6 cm broad, apically acute to somewhat acuminate, basally rounded to almost subclasping, marginally entire and slightly thickened and revolute, glabrous or very nearly so on both surfaces, the venation 3–5(–7)-plinerved with lateral nerves arising from proximal 1/4–1/3 of midrib, midrib proximally much thickened and weakly elevated in basal 1/4 above, then thinner and weakly impressed becoming flush to slightly elevated near apex, lateral nerves weakly impressed to flush proximally above but soon slightly elevated distally, reticulate veinlets elevated above, all venation somewhat elevated beneath throughout; petioles stout, glabrous, 1–5 mm long. **Inflorescences** axillary (often appearing terminal), corymbose racemes mostly 5–8 cm long overall, 10–13-flowered, with glabrous to very sparingly and minutely puberulent peduncles; rachises 1.5–4.5 cm long; floral bracts persistent, triangular or lanceolate, scale-like, glabrous but often marginally, minutely ciliate, 2–2.5 mm long; pedicels glabrous, irregularly angulate or ridged, 20–40 mm long, ca. 0.6–1 mm in diam.; bracteoles 2, at or very near the base, subopposite, glabrous or minutely ciliate, lanceolate to narrowly triangular, persistent, 1.2–2 mm long. **Flowers** 5-merous; calyx 4–4.2 mm long, articulate with pedicels, the hypanthium subcylindric, deeply and bluntly rugose, glabrous, ca. 1 mm long, 4–4.5 mm in diam., the limb ca. 3 mm long, smooth above but broadly and saccately spurred opposite and below each lobe, the spurs solid (not hollow) and sometimes slightly and broadly bilobed, the lobes triangular, 0.6–1 mm long, acute, glabrous; corolla thick and somewhat fleshy, broadly urceolate to urceolate-campanulate, ca. 10 mm long, ca. 8 mm broadest diam. when fresh, but drying 5–8 mm long and ca. 6 mm in diam. just beneath the throat and 3.5–4 mm in diam. just above the calyx, green, externally glabrous and internally densely pilose with sordid, white trichomes especially in the throat and lobes, the lobes ca. 3 mm long, acute; stamens 10, included, ca. 6.5 mm long, the filaments 3.5–4 mm long, long-pilose in distal half, attached to the anther dorsally slightly above its middle, the anthers golden, lacking spurs, ca. 3.5 mm long, the thecae ca. 2–2.5 mm long, densely and finely papillate, the lower third strongly incurved, the tubules ca. 1 mm long, dehiscing by introrse, strikingly oblique pores. **Berry** not seen.

Distribution.—Montane rainforests in Panama, along the continental divide, between Bocas del Toro and Chiriquí, at 700–950 m.

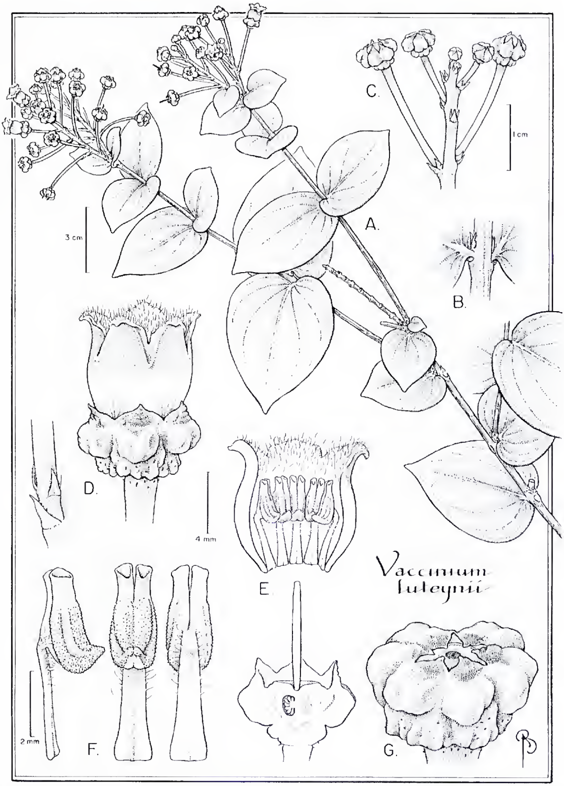

Fig. 3. *Vaccinium luteynii*. **A.** Habit showing subopposite leaves. **B.** Details of leaf insertion on stem. **C.** Details of inflorescence post-anthesis. **D.** flower showing saccate spurs below each calyx lobe and detail of pedicellary basal bracteoles and floral bract. **E.** Longitudinal section of corolla showing position of stamens and calyx (the sketch immediately beneath) **F.** Stamens showing lateral, ventral, and dorsal views. **G.** Calyx post-anthesis (all drawn from the holotype, *Luteyn et al. 15322*).

Additional collections examined: **PANAMA. Bocas del Toro:** along road between Florida and Chiriquí Grande, 1.2 mi N of Continental Divide, 5.3 mi N of bridge over Fortuna Dam, 8°44'N, 82°17'W, 910 m, 12 Mar 1985, *Croat & Grayum 60459* (DUKE!, MO!, NY!, WIS!); forest along the Gualaca-Chiriquí Grande road, 31.7 km S of Chiriquí Grande and 15.7 km N of Sitio de Presa, ca. 8°49'N, 82°12'W, 1070 m, *Luteyn 14831* (DUKE!, MO!, NY!, P!, PMA!, SCZ!, W!); Fortuna Dam-Chiriquí Grande road, 2–3 km N of the Continental Divide, ca. 8°48'N, 82°12'W, 700–760 m, 15 Oct 1998 (fl), *Luteyn, Riggs, Guerra & Sylva 15325* (DUKE!, MO!, NY!, PMA!, U!) **Chiriqui:** Fortuna Dam area, Km 63 N of dam along road to Chiriquí Grande, ca. 8°48'N, 82°12'W, 890 m, 16 Jan 2003 (bud), *Luteyn & Pedraza 15545* (NY!, PMA!); Campamento de Bijao-Fortuna, 19 Mar 1976, *Mendoza, Mendieta & Mayo 260* (DUKE); road from Fortuna Lake to Chiriquí Grande, 5 km along track just S of continental divide wet forest, 8°49'N, 82°12'W, 700 m, *Hampshire & Whiteford 441* (NY).

ACKNOWLEDGMENTS

We both thank Bobbi Angell for the clear and precise illustrations that surely make up for our failure in verbal descriptions. The NSF is to be thanked for financial support to JLL and others for fieldwork expenses without which these species and many others would not have been found before the forest in which they have flourished for centuries were leveled. We also are most appreciative for Guy Nesom (BRIT) checking the faulty Latin of one of us. And without Sherri Herndon's devoted attention to detail little would be accomplished. We also are most grateful for the two reviewers, Laurence J. Dorr and Lucia Kawasaki and the editor for their helpful criticisms, suggestions and agreeing to evaluate the manuscript on very short notice.

CUNICULOTINUS AND *LORANDERSONIA*, TWO NEW GENERA OF ASTERACEAE: ASTEREAE AND NEW COMBINATIONS IN *CHRYSOTHAMNUS*

ABSTRACT

Cuniculotinus is described as a new monotypic genus from California and Nevada to accommodate *Chrysothamnus gramineus*, resulting in the new combination ***Cuniculotinus gramineus***. Sequence-based phylogenetic investigations clearly demonstrate its remoteness from *Chrysothamnus* and place it nearer *Sericocarpus*. Four additional species regarded as *Chrysothamnus* are likewise shown to be phyletically distinct and are accomodated in the proposed new genus ***Lorandersonia***. *Lorandersonia* also includes one species previously recognized in *Hesperodoria*, *H. salicina*, and two species previously treated as *Tonestus*, *T. microcephalus* and *T. peirsonii*. New combinations in *Lorandersonia* are ***L. baileyi***, ***L. linifolia***, ***L. microcephala***, ***L. peirsonii***, ***L. pulchella***, ***L. salicina***, and ***L. spathulata***. *Chrysothamnus* is further modified by the inclusion of *Hesperodoria scopulorum* and *Vanclevea stylosa*, necessitating the new specific combinations ***C. scopulorum*** and ***C. stylosus*** and the varietal combination ***C. scopulorum*** var. ***canonis***.

RESUMEN

Se describe el género ***Cuniculotinus***, como un género nuevo monotípico de California y Nevada para ubicar a *Chrysothamnus gramineus* H.M. Hall. Por lo tanto se realiza una nueva combinación, ***C. gramineus***. Investigaciones filogenéticas basadas en secuenciación de ADN demuestran claramente su lejanía con *Chrysothamnus* y la ubica cerca de *Sericocarpus*. Del mismo modo, cuatro especies adicionales consideradas como *Chrysothamnus* muestran ser filogenéticamente distintas, por lo cual se propone el género nuevo ***Lorandersonia.*** Este nuevo género también incluye especies reconocidas previamente en *Hesperodoria*, *H. salicina*, y dos especies tratadas generalmente como *Tonestus*, *T. microcephalus* (Cronquist) G.L. Nesom & D.R. Morgan y *T. peirsonii* (D.D. Keck) G.L. Nesom & D.R. Morgan. Las combinaciones nuevas en *Lorandersonia* son: ***L. baileyi***, ***L. linifolia***, ***L. microcephala***, ***L. peirsonii***, ***L. pulchella***, ***L. salicina***, ***L. spathulata***. Además, se modifica *Chrysothamnus* con la inclusión de *Hesperodoria scopulorum* (M.E. Jones) Greene y *Vanclevea stylosa* (Eastwood) Greene lo cual hace necesarias las nuevas combinaciones específicas, ***C. scopulorum*** y ***C. stylosa,*** y la combinación de variedad *C. scopulorum* var. ***canonis.***

SIDA 21(3): 1615–1632. 2005

INTRODUCTION

Phylogenetic investigations based on sequence data of the nuclear ribosomal DNA spacer region, the ITS 1 and 2, plus the 5.8S, and a portion of 3' ETS, used to test decades-old hypotheses of relationships for species of *Chrysothamnus*, readily demonstrate its non-monophyly (Roberts & Urbatsch 2004). Hall and Clements (1923) comprehensively monographed *Chrysothamnus*, and Anderson (1986a) provided an updated and inclusive synopsis, nomenclatural information, keys, and distribution maps. During the intervening years, five species unknown to earlier monographers were published or elevated to specific rank; *Chrysothamnus pyramidatus* Hall & Clements was transferred to *Baccharis* (Rzedowski 1972) and subsequently placed in *Aztecaster* (Nesom 1993). The treatments by Hall and Clements and Anderson also differed in species alignments at infrageneric levels.

The sixteen species accounted for by Anderson (1986a) are placed in four distantly related clades in our sequence-based gene tree shown in Figure 1 (Roberts & Urbatsch 2004). Except for *Chrysothamnus* sect. *Punctati*, infrasectional gene tree relationships compared to the five sections recognized by Anderson (1986a) are largely incongruous. *Chrysothamnus albidus* (M.E. Jones ex A. Gray) Greene (sect. *Chrysothamnus*), *C. paniculatus* (A. Gray) H.M. Hall and *C. teretifolius* (Durand & Hilgard) H.M. Hall (sect. *Punctati*), and *C. nauseosus* Pallas ex Pursh) G.L. Nesom & G.I. Baird and *C. parryi* (A. Gray) G.L. Nesom & G.I. Baird (sect. *Nauseosi*) were resolved within *Ericameria*, supporting the conclusions of Nesom and Baird (1993), whose decisions were partially influenced by cpDNA restriction enzyme investigations of Suh (1989) and Morgan (1990). Thus, two independent molecular data sets, one chloroplast and one nuclear, corroborate the generic disposition of sect. *Punctati* and sect. *Nauseosi*. *Chrysothamnus gramineus* (sect. *Gramini*), the next most divergent taxon, is positioned outside of *Sericocarpus* and is here segregated as the monospecific genus *Cuniculotinus*.

Lorandersonia is proposed to accommodate four other species of *Chrysothamnus*, resulting in the following new combinations: *L. baileyi* and *L. pulchella* (*Chrysothamnus* sect. *Pulchelli* sensu Anderson 1986a) and *L. linifolia* and *L. spathulata* (sect. *Chrysothamnus*). Three additional species are robustly supported within the *Lorandersonia* clade and new combinations are made for these: *L. microcephala* and *L. peirsonii*, formerly regarded as *Tonestus*, and *L. salicina*, traditionally treated within *Hesperodoria*.

Chrysothamnus in the sense of Anderson (1986a) is left with seven species. Two additional taxa regarded as other genera are resolved within the *Chrysothamnus* clade and new combinations are proposed for them: *C. scopulorum* and *C. stylosus*, previously treated as *Hesperodoria scopulorum* and *Vanclevea stylosa*, respectively. *Chrysothamnus* as newly constituted comprises 9 species (Fig. 1).

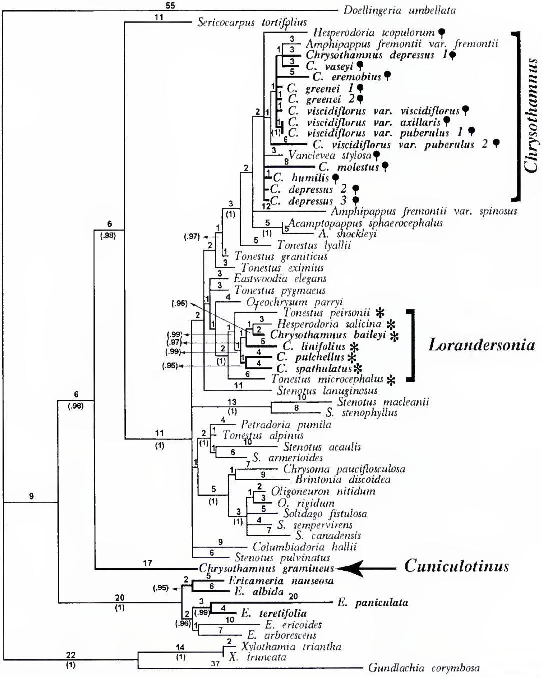

FIG. 1. Fifty percent majority rule consensus tree resulting from Bayesian analysis of combined ETS and ITS data sets is shown. This figure is modified from one published in Roberts & Urbatsch (2004). More details and a discussion of results from this and other analyses based on these sequence data are given. Bolded taxon names and wider branches highlight taxa treated as *Chrysothamnus* (Anderson 1986a). A large arrow indicates taxa treated herein as *Cuniculotinus*, the asterisk symbol * those considered *Lorondersonia*, and the 📍 symbol those taxa regarded as *Chrysothamnus*.

The primary purpose of the present paper is to provide formal nomenclatural changes reflecting the relationships discovered in our sequence-based phylogenetic studies. Taxa are also characterized and their relationships are discussed. A key to the taxa considered in this study is provided.

NOMENCLATURAL TREATMENT

Cuniculotinus Urbatsch, R.P. Roberts, & Neubig, gen. nov. TYPE: *Chrysothamnus gramineus* H.M. Hall, Muhlenbergia 2:342. 1916. *Cuniculotinus gramineus* (H.M. Hall) Urbatsch, R.P. Roberts, & Neubig, combination made herein. *Chrysothamnus* sect. *Gramini* L.C. Anderson, in part, Proc. Symp. Biol. *Artemisia* and *Chrysothamnus*, 29. 1986. *Ericameria* sect. *Gramini* L.C. Anderson, Great Basin Naturalist 55:87. 1995, in part.

E radice perenne multicaulis; caules erecti ca. 1 dm alti glabri striati, basi frutescentes usque ad apices foliosi; folia alterna sessilia lanceolata acuminata 30–85 mm longa 3–9 mm lata e basi 3–5-nervia glabria, marginibus integris scabris; capitula pauca, laxe racemosa 1–2 bracteata; bracteae angustae acutae quam involucro brevioribus; pedunculi 0.5–8 cm longi ad axillas foliorum oriundis; involucra cylindracea 11–15 mm longa 3–4 mm lata; phyllaria valde imbricata ca. 3-seriata oblonga obtusissima chartacea, exterioribus mucronatis ciliatis apice viridescentibus; flosculi disci 4–7 consimiles, corollis glabris tenuibus infundibuliformibus 9–12 mm longis, dentibus 5 ovatis acutis, antheris basi minute auriculatis apice attenuatis, ramis stylorum acutis longe exsertis; cypselae fere exacte cylindraceis 5–6-striatae glabrae; pappi setae argentei corollae aequilongi.

Subshrubs from a branching, woody caudex to 1 dm. Stems annual, several, to 6 dm, green with tan ridges descending from leaf bases, glabrous. Leaves cauline, alternate, ascending, sessile, linear to lanceolate or oblong-oblanceolate, 30–85 × 3–9 mm, coriaceous, margins entire or edged with conic trichomes, glabrous to sparsely pubescent, often resin dotted, midvein and 2–4 collateral veins prominent; basal leaves ± persistent; cauline leaves reduced in size distally and becoming bract-like in the capitulescence. Capitulescences solitary to cymose at branch tips, branches racemose. Involucres tubinate to cylindric, 11–15(–17.5) × 3–4 mm. Phyllaries in 4–6 series, graduated, silvery to pale yellow, generally marked with green to brownish distal patch, not keeled, ±imbricate, ovate or oblong to obovate, 2–14 × 0.7–3 mm, mostly chartaceous, midvein and 2 collaterals evident, apices truncate, mucronate to caudate tipped. Capitula discoid, receptacles flat, finely alveolate. Disk flowers 4–7, yellow, corollas 9–12 mm, lobes acute, 1–1.3 mm; anthers 3.1–4.1 mm, appendages attenuate, 0.5–1.1 mm. Style branches 3.5–4.2 mm, appendages linear, 1.4–1.7 mm, apices acute. Cypselae tan-brownish, oblong, 7–9 mm, glabrous, 5-6 nerved. Pappi silvery-tan, ±80 minutely-setose bristles, 8–10 mm. $x = 9$.

Etymology.—The generic name is based on the Latin word *cuniculus*, a rabbit, + "tinus" as applied to laurustinus (*Viburnum tinus* L.), a shrubby plant," thus "rabbit brush" a commonly used name for species of *Chrysothamnus* in the traditional sense.
